# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Doroła Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: Organizational Digital Transformations and the Importance of Assessing Theoretical Frameworks such as TAM, TTF, and UTAUT: A Review

*Authors: Bibhu Dash, Pawankumar Sharma, Swati Swayamsiddha*

**PAGE 1 – 6**

Paper 2: Adversarial Sampling for Fairness Testing in Deep Neural Network

*Authors: Tosin Ige, William Marfo, Justin Tonkinson, Sikiru Adewale, Bolanle Hafiz Matti*

**PAGE 7 – 13**

Paper 3: Text2Simulate: A Scientific Knowledge Visualization Technique for Generating Visual Simulations from Textual Knowledge

*Authors: Ifeoluwatayo A. Ige, Bolanle F. Oladejo*

**PAGE 14 – 22**

Paper 4: A Review on Artificial Intelligence in the Context of Industry 4.0

*Authors: Shadi Banitaan, Ghaith Al-refai, Sattam Almatarneh, Hebah Alquran*

**PAGE 23 – 30**

Paper 5: A Machine Learning Enabled Hall-Effect IoT-System for Monitoring Building Vibrations

*Authors: Emanuele Lattanzi, Paolo Capellacci, Valerio Freschi*

**PAGE 31 – 40**

Paper 6: Sequence Recommendation based on Deep Learning

*Authors: Gulsim Rysbayeva, Jingwei Zhang*

**PAGE 41 – 54**

Paper 7: Routing Overhead Aware Optimal Cluster based Routing Algorithm for IoT Network using Heuristic Technique

*Authors: Srinivasulu M, Shiva Murthy G*

**PAGE 55 – 64**

Paper 8: Supply Chain Network Model using Multi-Agent Reinforcement Learning for COVID-19

*Authors: Tomohito Okada, Hiroshi Sato, Masao Kubo*

**PAGE 65 – 69**

Paper 9: An Enhanced MCDM Model for Cloud Service Provider Selection

*Authors: Ayman S. Abdelaziz, Hany Harb, Alaa Zaghloul, Ahmed Salem*

**PAGE 70 – 77**

Paper 10: Dynamic Software Architecture Design for Virtual Rehabilitation System for Manual Motor Dexterity

*Authors: Edwin Enrique Saavedra Parisaca, Solansh Jaqueline Montoya Muñoz, Elizabeth Vidal Duarte, Eveling Gloria Castro Gutierrez, Angel Yvan Choquehuanca Peraltilla, Sergio Albiol Pérez*

**PAGE 78 – 85**

Paper 11: Insights into Search Engine Optimization using Natural Language Processing and Machine Learning

*Authors: Vinutha M S, M C Padma*

**PAGE 86 – 96**

Paper 12: Adaptive Rectified Linear Unit (Arelu) for Classification Problems to Solve Dying Problem in Deep Learning

*Authors: Ibrahim A. Atoum*

PAGE 97 – 102

Paper 13: Espousing AI to Enhance Cost-Efficient and Immersive Experience for Human Computer Interaction

*Authors: Deepak Chaturvedi, Ashima Arya, Mohammad Zubair Khan, Eman Aljohani, Liyakathunisa, Vaishali Arya, Namrata Sukhija, Prakash Srivastava*

PAGE 103 – 111

Paper 14: Implementation of Big Data Privacy Preservation Technique for Electronic Health Records in Multivendor Environment

*Authors: Ganesh Dagadu Puri, D. Haritha*

PAGE 112 – 118

Paper 15: Churn Customer Estimation Method based on LightGBM for Improving Sales

*Authors: Kohei Arai, Ikuya Fujikawa, Yusuke Nakagawa, Ryuya Momozaki, Sayuri Ogawa*

PAGE 119 – 125

Paper 16: Privacy Preservation Modelling for Securing Image Data using Novel Ethereum-based Ecosystem

*Authors: Chhaya S Dule, Roopashree H. R*

PAGE 126 – 135

Paper 17: Music Note Feature Recognition Method based on Hilbert Space Method Fused with Partial Differential Equations

*Authors: Liqin Liu*

PAGE 136 – 143

Paper 18: Hyperparameter Optimization of Support Vector Regression Algorithm using Metaheuristic Algorithm for Student Performance Prediction

*Authors: M. Riki Apriyadi, Ermatita, Dian Palupi Rini*

PAGE 144 – 150

Paper 19: Experimental Analysis and Monitoring of Photovoltaic Panel Parameters

*Authors: Zaidan Didi, Ikram El Azami*

PAGE 151 – 157

Paper 20: Hybrid Feature Selection Algorithm and Ensemble Stacking for Heart Disease Prediction

*Authors: Nureen Afiqah Mohd Zaini, Mohd Khalid Awang*

PAGE 158 – 165

Paper 21: Automatic Extraction of Indonesian Stopwords

*Authors: Harry Tursulistiyono Yani Achsan, Heru Suhartanto, Wahyu Catur Wibowo, Deshinta A. Dewi, Khairul Ismed*

PAGE 166 – 171

Paper 22: Software Effort Estimation through Ensembling of Base Models in Machine Learning using a Voting Estimator

*Authors: Beesetti Kiran Kumar, Saurabh Bilgaiyan, Bhabani Shankar Prasad Mishra*

PAGE 172 – 181

Paper 23: An Effective Heart Disease Prediction Framework based on Ensemble Techniques in Machine Learning

*Authors: Deepali Yewale, S. P. Vijayaragavan, V. K. Bairagi*

PAGE 182 – 190

**Paper 24: Explaining the Outputs of Convolutional Neural Network - Recurrent Neural Network (CNN-RNN) based Apparent Personality Detection Models using the Class Activation Maps**

*Authors: WMKS Ilmini, TGI Fernando*

**PAGE 191 – 197**

**Paper 25: Landmark Recognition Model for Smart Tourism using Lightweight Deep Learning and Linear Discriminant Analysis**

*Authors: Mohd Norhisham Razali, Enurt Owens Nixon Tony, Ag Asri Ag Ibrahim, Rozita Hanapi, Zamhar Iswandono*

**PAGE 198 – 213**

**Paper 26: Performance Comparison of the Kernels of Support Vector Machine Algorithm for Diabetes Mellitus Classification**

*Authors: Dimas Aryo Anggoro, Dian Permatasari*

**PAGE 214 – 219**

**Paper 27: Deep Study of CRF Models for Speech understanding in Limited Task**

*Authors: Marwa Graja*

**PAGE 220 – 226**

**Paper 28: Paw Search – A Searching Approach for Unsorted Data Combining with Binary Search and Merge Sort Algorithm**

*Authors: Md. Harun Or Rashid, Ahmed Imtiaz*

**PAGE 227 – 236**

**Paper 29: A Survey of Forensic Analysis and Information Visualization Approach for Instant Messaging Applications**

*Authors: Shahnaz Pirzada, Nurul Hidayah Ab Rahman, Niken Dwi Wahyu Cahyani, Muhammad Fakri Othman*

**PAGE 237 – 246**

**Paper 30: Driving Maneuvers Recognition and Classification Using A Hybrid Pattern Matching and Machine Learning**

*Authors: Munaf Salim Najim Al-Din*

**PAGE 247 – 256**

**Paper 31: An Approach to Automatic Garbage Detection Framework Designing using CNN**

*Authors: Akhilesh Kumar Sharma, Antima Jain, Deevesh Chaudhary, Shamik Tiwari, Hairulnizam Mahdin, Zirawani Baharum, Shazlyn Milleana Shaharudin, Ruhaila Maskat, Mohammad Syafwan Arshad*

**PAGE 257 – 262**

**Paper 32: Tamper Proof Air Quality Management System using Blockchain**

*Authors: Vaneeta M, Deepa S R, Sangeetha V, Kamalakshi Naganna, Kruthika S Vasisht, Ashwini J, Nikitha M, Srividya H. R*

**PAGE 263 – 271**

**Paper 33: Optimized Strategy for Inter-Service Communication in Microservices**

*Authors: Sidath Weerasinghe, Indika Perera*

**PAGE 272 – 279**

**Paper 34: Deep Learning based Analysis of MRI Images for Brain Tumor Diagnosis**

*Authors: Srinivasarao Gajula, V. Rajesh*

**PAGE 280 – 286**

**Paper 35: Classification of Psychological Disorders by Feature Ranking and Fusion using Gradient Boosting**

*Authors: Saba Tahseen, Ajit Danti*

**PAGE 287 – 294**

**Paper 36: Public Response to the Legalization of The Criminal Code Bill with Twitter Data Sentiment Analysis**

*Authors: Deny Irawan, Dana Indra Sensuse, Prasetyo Adi Wibowo Putro, Aji Prasetyo*

**PAGE 295 – 303**

**Paper 37: Evaluation of QoS over IEEE 802.11 Wireless Network in the Implementation of Internet Protocols Mobility Supporting**

*Authors: Narimane Elhilali, Mostapha Badri, Mouncef Filali Bouami*

**PAGE 304 – 310**

**Paper 38: Using Deep Learning Algorithms to Diagnose Coronavirus Disease (COVID-19)**

*Authors: Nfayel Alanazi, Yasser Kotb*

**PAGE 311 – 320**

**Paper 39: Enhanced Optimized Classification Model of Chronic Kidney Disease**

*Authors: Shahinda Elkholy, Amira Rezk, Ahmed Abo El Fetoh Saleh*

**PAGE 321 – 331**

**Paper 40: Automated Categorization of Research Papers with MONO Supervised Term Weighting in RECAApp**

*Authors: Ivic Jan A. Biol, Rhey Marc A. Depositario, Glenn Geo T. Noangay, Julian Michael F. Melchor, Christopher C. Abalorio, James Cloyd M. Bustillo*

**PAGE 332 – 339**

**Paper 41: R-Diffset vs. IR-Diffset: Comparison Analysis in Dense and Sparse Data**

*Authors: Julaily Aida Jusoh, Sharifah Zulaikha Tengku Hassan, Wan Aezwani Wan Abu Bakar, Syarilla Iryani Ahmad Saany, Mohd Khalid Awang, Norlina Udin @ Kamaruddin*

**PAGE 340 – 346**

**Paper 42: A Fully Immersive Virtual Reality Cycling Training (vProCycle) and its Findings**

*Authors: Imran Bin Mahalil, Azmi Bin Mohd Yusof, Nazrita Binti Ibrahim, Eze Manzura Binti Mohd Mahidin, Ng Hui Hwa*

**PAGE 347 – 353**

**Paper 43: First Responders Space Subdivision Framework for Indoor Navigation**

*Authors: Asep Id Hadiana, Safiza Suhana Kamal Baharin, Zahriah Othman*

**PAGE 354 – 363**

**Paper 44: Leaf Diseases Identification and Classification of Self-Collected Dataset on Groundnut Crop using Progressive Convolutional Neural Network (PGCNN)**

*Authors: Anna Anbumozhi, Shanthini A*

**PAGE 364 – 373**

**Paper 45: Enhancing Image for CNN-based Diagnostic of Pediatric Pneumonia through Chest Radiographs**

*Authors: Vaishali Arya, Tapas Kumar*

**PAGE 374 – 380**

**Paper 46: Long Short-Term Memory for Non-Factoid Answer Selection in Indonesian Question Answering System for Health Information**

*Authors: Retno Kusumaningrum, Alfi F. Hanifah, Khadijah Khadijah, Sukmawati N. Endah, Priyo S. Sasongko*

**PAGE 381 – 388**

**Paper 47: Assessment of the Healthcare Administration of Senior Citizens from Survey Data using Sentiment Analysis**

*Authors: Ramona Michelle M. Magtangob, Thelma D. Palaoag*

**PAGE 389 – 394**

**Paper 48: Hierarchical Pretrained Deep Learning Features for the Breast Cancer Classification**

*Authors: Abeer S. Alsheddi*

**PAGE 395 – 402**

**Paper 49: A Survey on Attention-Based Models for Image Captioning**

*Authors: Asmaa A. E. Osman, Mohamed A. Wahby Shalaby, Mona M. Soliman, Khaled M. Elsayed*

**PAGE 403 – 412**

**Paper 50: Towards an Automatic Speech-to-Text Transcription System: Amazigh Language**

*Authors: Ahmed Ouhnini, Brahim Aksasse, Mohammed Ouanan*

**PAGE 413 – 418**

**Paper 51: Graphical user Interfaces Generation from BPMN (Business Process Model and Notation) via IFML (Interaction Flow Modeling Language) up to PSM (Platform Specific Model) Level**

*Authors: Abir Sajji, Yassine Rhazali, Youssef Hadi*

**PAGE 419 – 431**

**Paper 52: A Fuzzy Logic based Solution for Network Traffic Problems in Migrating Parallel Crawlers**

*Authors: Mohammed Faizan Farooqui, Mohammad Muqem, Sultan Ahmad, Jabeen Nazeer, Hikmat A. M. Abdeljaber*

**PAGE 432 – 441**

**Paper 53: A Privacy-Centered Protocol for Enhancing Security and Authentication of Academic Certificates**

*Authors: Omar S. Saleh, Osman Ghazali, Norbik Bashah Idris*

**PAGE 442 – 452**

**Paper 54: A Systematic Literature Review on AI Algorithms and Techniques Adopted by e-Learning Platforms for Psychological and Emotional States**

*Authors: Lubna A. Alharbi*

**PAGE 453 – 464**

**Paper 55: Privacy and Integrity Verification Model with Decentralized ABE and Double Encryption Storage Scheme**

*Authors: Amrutha Muralidharan Nair, R Santhosh*

**PAGE 465 – 471**

**Paper 56: Design of a Hybrid Recommendation Algorithm based on Multi-objective Collaborative Filtering for Massive Cloud Data**

*Authors: Xiaoli Zhou*

**PAGE 472 – 481**

Paper 57: Equally Spread Current Execution Load Modelling with Optimize Response Time Brokerage Policy for Cloud Computing

*Authors: Anisah Hamimi Zamri, Nor Syazwani Mohd Pakhrudin, Shuria Saaidin, Murizah Kassim*

**PAGE 482 – 491**

Paper 58: Research on the Derivative Rule and Estimation Methods of Intelligent High-Speed Railway Investment Estimation

*Authors: Yang Meng, Chuncheng Meng, Xiaochen Duan*

**PAGE 492 – 501**

Paper 59: Early Warning for Sugarcane Growth using Phenology-Based Remote Sensing by Region

*Authors: Sudianto Sudianto, Yeni Herdiyeni, Lilik Budi Prasetyo*

**PAGE 502 – 510**

Paper 60: Fault Tolerance Smart Egg Incubation System with Computer Vision

*Authors: Emiliyan Petkov, Teodor Kalushkov, Donika Valcheva, Georgi Shipkovenski*

**PAGE 511 – 517**

Paper 61: A Novel Hybrid Deep Learning Framework for Detection and Categorization of Brain Tumor from Magnetic Resonance Images

*Authors: Yousef Methkal Abd Algani, B. Nageswara Rao, Chamandeep Kaur, B. Ashreetha, K. V. Daya Sagar, Yousef A. Baker El-Ebiary*

**PAGE 518 – 527**

Paper 62: Multi Feature DCR based Drug Compound Selection and Recommendation System for Efficient Decision-Making using Genetic Algorithm

*Authors: ST. Aarthy, J. L. Mazher Iqbal*

**PAGE 528 – 533**

Paper 63: The Predictors of Mobile Banking Usage: A Systematic Literature Review

*Authors: Mohammed Abd Al-Munaf Hashim, Zainuddin Bin Hassan*

**PAGE 534 – 540**

Paper 64: A Novel Approach: Tokenization Framework based on Sentence Structure in Indonesian Language

*Authors: Johannes Petrus, Ermatita, Sukemi, Erwin*

**PAGE 541 – 549**

Paper 65: An Efficient Real-Time Weed Detection Technique using YOLOv7

*Authors: Ch. Lakshmi Narayana, Kondapalli Venkata Ramana*

**PAGE 550 – 556**

Paper 66: Sobel Edge Detection Algorithm with Adaptive Threshold based on Improved Genetic Algorithm for Image Processing

*Authors: Weibin Kong, Jianzhao Chen, Yubin Song, Zhongqing Fang, Xiaofang Yang, Hongyan Zhang*

**PAGE 557 – 562**

Paper 67: Compiler Optimization Prediction with New Self-Improved Optimization Model

*Authors: Chaitali Shewale, Sagar B. Shinde, Yogesh B. Gurav, Rupesh J. Partil, Sandeep U. Kadam*

**PAGE 563 – 571**

Paper 68: Design of an English Web-based Teaching Resource Sharing Platform based on Mobile Web Technology

Authors: Yan Zhang

PAGE 572 – 580

Paper 69: A Study of Encryption for Multimedia Digital Audio Security

Authors: Xiaodong Zhou, Chao Wei, Xiaotang Shao

PAGE 581 – 586

Paper 70: Digital Twins for Smart Home Gadget Threat Prediction using Deep Convolution Neural Network

Authors: Valluri Padmapriya, Muktevi Srivenkatesh

PAGE 587 – 594

Paper 71: A New Privacy-Preserving Protocol for Academic Certificates on Hyperledger Fabric

Authors: Omar S. Saleh, Osman Ghazali, Norbik Bashah Idris

PAGE 595 – 609

Paper 72: Breast Cancer Prediction using Machine Learning Models

Authors: Orlando Iparraguirre-Villanueva, Andrés Epifanía-Huerta, Carmen Torres-Cecién, John Ruiz-Alvarado, Michael Cabanillas-Carbonell

PAGE 610 – 620

Paper 73: Placement of Edge Servers in Mobile Cloud Computing using Artificial Bee Colony Algorithm

Authors: Bing Zhou, Bei Lu, Zhigang Zhang

PAGE 621 – 637

Paper 74: Erythematous-Squamous Disease Detection using Best Optimized Estimators of ANN

Authors: Rajashekar Deva, G .Narsimha

PAGE 638 – 647

Paper 75: Realizing the Quantum Relative Entropy of Two Noisy States using the Hudson-Parthasarathy Equations

Authors: Bhaveshkumar B. Prajapati, Nirbhay Kumar Chaubey

Paper 97: An Autonomous Role and Consideration of Electronic Health Systems with Access Control in Developed Countries: A Review

*Authors: Mohd Rafiz Salji, Nur Izura Udzir*

PAGE 848 – 860

Paper 98: Semi-supervised Method to Detect Fraudulent Transactions and Identify Fraud Types while Minimizing Mounting Costs

*Authors: Chergui Hamza, Abrouk Lylia, Cullot Nadine, Cabioch Nicolas*

PAGE 861 – 870

Paper 99: Liver Disease Prediction and Classification using Machine Learning Techniques

*Authors: Srilatha Tokala, Koduru Hajarathaiah, Sai Ram Praneeth Gunda, Srinivasrao Botla, Lakshmikanth Nalluri, Pathipati Nagamanohar, Satish Anamalamudi, Murali Krishna Enduri*

PAGE 871 – 878

Paper 100: Image Super-Resolution using Generative Adversarial Networks with EfficientNetV2

*Authors: Saleh AlTakroui, Norliza Mohd Noor, Norulhusna Ahmad, Taghreed Justinia, Sahnus Usman*

PAGE 879 – 887

Paper 101: A Transformer Seq2Seq Model with Fast Fourier Transform Layers for Rephrasing and Simplifying Complex Arabic Text

*Authors: Abdullah Alshaqiti, Ahmad Alkhodre, Abdallah Namoun, Sami Albouq, Emad Nabil*

PAGE 888 – 898

Paper 102: Unsupervised Feature Learning Methodology for Tree based Classifier and SVM to Classify Encrypted Traffic

*Authors: RAMRAJ S, Usha G*

PAGE 899 – 904

**Paper 103: Indoor Pollutant Classification Modeling using Relevant Sensors under Thermodynamic Conditions with Multilayer Perceptron Hyperparameter Tuning**

*Authors: Percival J. Forcadilla*

**PAGE 905 – 916**

# Organizational Digital Transformations and the Importance of Assessing Theoretical Frameworks such as TAM, TTF, and UTAUT: A Review

Bibhu Dash<sup>1</sup>, Pawankumar Sharma<sup>2</sup>, Swati Swayamsiddha<sup>3</sup>

School of Computer and Information Sciences, University of the Cumberland, Williamsburg, KY USA<sup>1,2</sup>  
School of Electronics Engineering, KIIT University, Bhubaneswar, India<sup>3</sup>

**Abstract**—In this era of Industry 5.0, businesses worldwide are attempting to gain competitive advantages, increase profits, and improve consumer engagement. To achieve their goals, all businesses undergo extensive digital transformations (DT) by implementing cutting-edge technologies such as cloud computing, artificial intelligence (AI), the Internet of Things, and blockchain, among others. DT is a costly journey, including strategy, people, and technology. At the same time, many digitization efforts are failing miserably, resulting in project abandonment, loss of critical stakeholder trust, and the dismissal of important staff. Poor strategy, which may have pre-evaluated organizational flexibility and cultural misfits, is often criticized. As a result, it is critical to extensively investigate theoretical frameworks such as the Technology Acceptance Model (TAM), Task Technology Fit (TTF), and Unified Theory of Acceptance and Use of Technology (UTAUT), which were developed via significant research into various organizational kinds. All of these aspects are covered in this work by evaluating academic papers from the IEEE, Scopus, and Web of Science databases and reaching conclusions in future sections.

**Keywords**—Data growth; digital transformations; TAM; TTF; UTAUT; sustainability; FTM

## I. INTRODUCTION

With the increasing rise of social media, proper data storage and retrieval in a modern data-driven company model are important for long-term viability and competitive advantage. In the ever-expanding business sector, AI and machine learning are emerging as feasible digital domains for information storage and recovery, promising to improve access to knowledge and effective decision-making [1]. A recent Google analysis shows DT themes and trends rapidly rising, the most contested subjects worldwide [2]. Digitalization provides greater functional assistance to clients while also illuminating performance and producing more substantial revenue streams [3]. The following factors have been recognized as driving the growth of unstructured big data and digitalization worldwide.

### A. Data Growth

As data storage costs continue to decline due to the emergence of the cloud, organizations retain substantial volumes of transactional data for analysis and research [4]. Every industry type is seeing an increase in data due to the daily growth of e-transaction volumes in institutions. The dollar equivalent of electronic transactions will likely total

roughly \$118.3 billion globally in 2021, according to a recent Business Wire estimate [5], with developing markets increasing 15–20% faster than developed ones [6].

For a few decades, the objectives of businesses and the adoption of digitalization have changed due to the tremendous growth in data volume and quality. Because of these enormous data quantities, governance and regulatory organizations are under pressure to manage and preserve sensitive data. Data growth over the years depicts the price development for storing a gigabit of data from 1966 to 2020, as shown below. The cost of storing a gigabyte of data decreased drastically from \$1.05 million in 1966 to \$0.02 in 2017 [7]. Financial institutions are prompted by the cheaper storage costs to retain and process this enormous volume of data for important insight retrieval, organizational development, and decision-making [4].

### B. Swing in the Business Model

The convenience and cost of online transactions are made possible by digitalizing essential products and services. Because of the aforementioned considerations and the developing global market, global institutions operate differently than they did a few decades ago. Self-service analytics and unstructured data storage are helping modern digital enterprises hold onto market share in the face of escalating intra- and inter-domain competition. With the evolution of smartphones, Know Your Customer (KYC), and Know Your Product (KYP), the pressure on businesses mounted to promote speed, efficacy, and quality by going digitalization [7]. Thus, in contemporary customer-focused business models, data security, storage, and meaning extraction are gaining center stage.

## II. DIGITALIZATION AND ITS CHALLENGES

Data is the new gold as digitization approaches its zenith [8]. As data growth happens with constantly decreasing storage costs, organizations get the much-required push to be more data-driven than before in daily operations, as shown in Fig. 1. This study was significant because it expanded our understanding of the factors that push firms to adopt a data-driven approach to all facets of daily operations and works as catalyst for organizational sustainability. But making big data useful and facilitating faster information retrieval is now enterprises' key issue [9]. According to the study mentioned above by Chowdhary [9], firms can examine consumer insights and behavioral trends but cannot take particular data-driven

action because of decision management issues. This failure can result from issues with organizational implementation or poor C-suite execution. Some businesses are also aware of the value of data and digitization. However, the difficulty they have in filling the positions is the absence of human resources with the necessary degree of expertise and strategy. Below are some discussions of why an organization's digitalization journey fails and the cause of this.

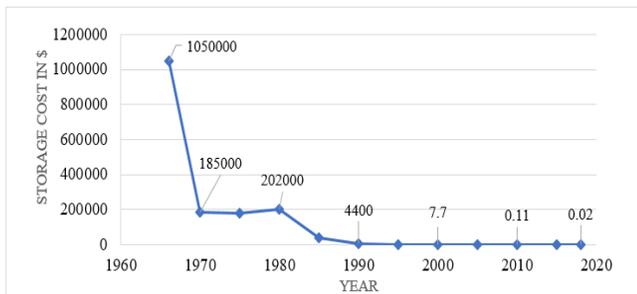

Fig. 1. Cost per gigabyte of data storage over time

#### A. Lack of Transformation Objectives

Without a solid leadership vision or goal, achieving digitalization objectives is very hard. The fact that digital transformation never had a chance to succeed is one of the key reasons it failed [6, 7]. It is generally viewed as a publicity stunt that will give a company an air of optimism, imagination, and the future. Therefore, no clear objectives have been set to guide digital transformation efforts, which are typically solutions looking for a problem to solve. This leads to a company releasing the latest technology to release emerging innovations without having performance indicators in place. When the project is closely examined, it dragged out, exceeded budget, and ultimately failed.

#### B. No Planning for Change Management

Agile operation and change management are essential in the modern digitalization journey. Businesses may decide how their daily operations will run while introducing new technology with the help of a change management strategy [10]. Whether it's a new ML model, Cloud adoption, ERP, or a different data pipeline build, a change management plan outlines how operations will run until the migration is successfully completed. If change management is properly outlined, the project is definitely going to lose its control, both concerning cost and time, and it is bound to fail.

#### C. Organizational Culture and Inner Endurance to Change

Recent research shows that 40–50% of Executives believe their teams never utilize the majority of the functionality offered by digitalized products because of internal resistance to change [10]. This problem affects more than just product development, sales, or finance; it also affects disciplines like marketing, business development, and architecture design. Professionals typically think that their own systems they've created are more dependable than other software. Similarly, they could not have the training required to properly use a new product and opt to put it on hold for the time being. It is majorly a cultural thing affecting many companies globally and ultimately leads to digital transformation failure.

#### D. Too Fast in Bringing Transformation through Technology

To be the first to market (FTM), many firms set an accelerated schedule for a digital transformation program shorter than their implementation partners and consultants advise. As a result, because the leadership needs to be made aware of the technical effort involved in transferring to alternative IT systems, some of the critical processes or Key Performance Indicators (KPIs) required to make the switch are skimmed on for enterprise adaptability and sustainability[10]. It leads to performance and quality compromise and ultimately leads to failure.

#### E. Poor Vision and Adoption of new Technology

Different corporate departments have various digitalization aspirations. For instance, marketing may desire to boost traffic regardless of whether it converts to customers, the engineering department may want to solve challenges that will improve performance, and the human resource team may want to meet hiring goals while not engaging with the rest of the company often [7, 10]. It could be challenging to get funding, get departmental buy-in, or commit to doing things to make a digital transformation program successful without a common organizational vision.

When only some people utilize the new IT solution as regularly as the leadership had planned, a company may effectively move to it just to run into a new challenge. When they are uncertain about the training they have received, employees understandably shy away from new technologies. Similarly, there is always a time when employees are reluctant to try out new tools in favor of tried-and-true methods. Organizations must create a strategy to enhance the digital adoption of new apps to achieve project Return on Investment (ROI). Sometimes it happens that junior staff members in an organization see the need for an improved alternative to the one they now use. They ask the leadership for a new response as a result. They are frequently declined, and even if they are grudgingly approved, the project does not obtain the required cash, help, and operational support to be effective throughout the whole organization. Sometimes these forced buy-ins adversely impact employee commitment and break the trust in the digitalization journey before it really starts [10].

#### F. Lack of Basics and Ignoring Customer Expectations

A digital transformation initiative should prioritize enhancing the company's capacity to serve its key customers. Any digital transformation effort will only succeed if it enables us to give value to our customers, regardless of how much better the design is, how quickly you put it out, or how good our implementation partners were. If we ignore our core loyal customers and design a new digital app or product that lacks our domain-specific information, then it's a waste of time and money, which will not meet business needs [8].

The biggest enterprises are leaders in technology, product, and innovation, but they also need a better history of losing millions to a failed digitalization journey [8, 9]. These businesses made unavoidable mistakes when using digitalization to empower their operations. The table below (see Table I) shows some of these world-famous brands and

the gaps in their journey to lose financially during their digital adoptions [10].

TABLE I. INFAMOUS DIGITALIZATION FAILURES AND THEIR REASONS

Organization	Targeted for	Reason for Failure
Hershey (1996)	Hershey was targeting more powerful ERP systems to replace their legacy IT systems.	1- No clear vision and trying to execute a pet project. 2-The transformation was rushed without proper testing.
HP (2003)	HP planned to stop legacy ERP systems and move to SAP for better customer and sales tracking.	1- Migration exceeded the target time frame. 2- Bad change management planning. 3- Didn't plan for a backup if this ERP implementation fails.
Miller Coors (2013)	MC planned digitalization through new app development and advanced ERP implementation to boost the supply chain.	The project went 3 years without any end with bad vendor selection and bad planning, ending with a lawsuit.
Revlon(2018)	Revlon was targeting to migrate its new ERP solutions to 22 countries where they operate	Due to bad planning, poor change management, and implementation issues, the company lost \$64 million, and the market cap dropped by 6.9%.

### III. THEORETICAL FRAMEWORKS AND THEIR ASSESSMENT

Academics develop theoretical frameworks through in-depth research, surveys, and testing. Theoretical frameworks aid in understanding the implicit theory in adopting, developing, or clarifying expressly stated norms before implementing new initiatives, strategies, and regulations. It aids in reducing biases that might skew our interpretations in a novel environment owing to cultural and technological incompatibilities in an organizational or public context. One theoretical framework may be used to analyze other theoretical frameworks, which can change our perspective and reduce the risks of theory selection and application [11]. Theoretical frameworks help us recognize the boundaries of our study's scope by helping us understand the nature of our research problem. Better and clearer theoretical framework analysis helps us improve our decisions, develop better strategies, and understand our objectives.

Digital transformations are expensive, people-focused, and strategy-driven. It is, therefore, quite challenging to select the ideal theoretical framework to analyze the benefits of a digitalization project. Quantitative program or project design and theoretical underpinnings are interrelated. The study's goals and a comprehensive literature review are used to select the research design. Quantitative project planning employs deductive reasoning, which starts with choosing the theoretical framework that will provide the project with a solid foundation and direction. The early sections of a quantitative research proposal include theoretical frameworks to provide the justification for the inquiry. To direct the methods we use, choosing the right theoretical framework is essential. Thus, the study of the right methodology will provide conclusions that

are compatible with the organization, its end goal, and its culture. The details about the theoretical framework needed to study before adopting digital transformations are discussed below in detail.

#### A. TAM

Decision-making about digital transformation and organizational sustainability can be enhanced using Davis' [11] Technological Acceptance Model. The study's guiding principle is usefulness and usability, which served as the foundation for the TAM model. TAM was first designed to provide a logical framework for evaluating the user acceptability of a certain information system or piece of information technology [12, 13]. TAM is developed and utilized regularly in fields other than IT, such as healthcare, retail, and finance. Perceived utility (PU) and perceived ease of use (PEU) are the two main components of TAM (see Fig. 2). (PEU). These criteria were all created to characterize the usability and effectiveness of new procedures or technologies. External factors impact both PU and PEU, favorably affecting users' feelings about using the target system. Additionally, the variables affect users' use behavior (UB) on the target system and process [13]. Fig. 2 shows how individuals and organizations feel about using the TAM model to analyze unstructured data and gain insights for better outcomes.

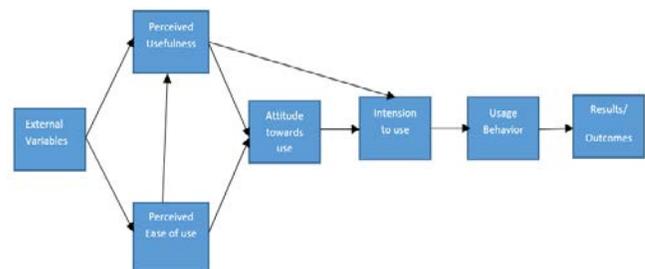

Fig. 2. Technology acceptance model and key attributes

According to contingency theory, the compatibility of an organization and its environment is a necessary condition for organizational performance. Verma et al. [14] investigated the adoption of self-serve analytics and digitalization by utilizing the TAM model to examine how system features affected managers' opinions. Despite the past effort, research has yet to employ a complete strategy to experimentally evaluate the technical fit, organizational fit, and environmental fit views. To evaluate the influence of technology fit, organization fit, and environment fit on applying data analysis, KPIs, and insights for data-driven performance outcomes, the TAM and TTF models were merged in this study.

#### B. TTF

More effectively than technical, environmental, and individual factors, Task Technology Fit (TTF) is a framework that encourages innovation and adaptability [14]. Adopting cutting-edge technology by a business is influenced by various elements, including financial competence, organizational growth, technical services, and external environmental factors [15]. The primary external factors influencing adoption were a relative advantage, competitive pressure, and government support. Individuals' behaviors in converting inputs into outputs were referred to as task characteristics [16]. This study

aimed to predict performance using a combination of organizational structure, technology utilization, and the application of information technology to strategy better to account for the unpredictability of the external environment. The task-technology fit hypothesis was developed in the adoption of information systems, and the use of the idea of fit to assess a technology's influence on business performance has increasingly increased [16]. Generally speaking, this idea contends that the effectiveness of an information system depends on how effectively a job and technology interlock (see Fig. 3).

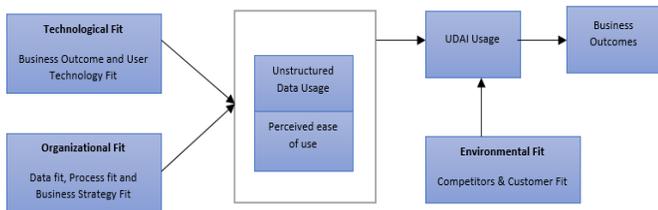

Fig. 3. TTF model for digital adoption

From the TTF perspective, novelty, output quality, and compatibility are crucial requirements for effective knowledge use and better outcomes. According to Wu and Chen [17], it still needs to be determined which elements, based on the TTF model, affect the performance of technology-driven companies. According to Wu and Chen, increasing TTF from the perspectives of technical, organizational, and environmental fit may impact technology-driven performance in any corporation to close the gaps. The Fintech mechanism is driven by business, and technological advancements are essential to any current Fintech perspective [18]. Excellent customer service and the development of distinctive products are essential for a firm to succeed in the Fintech industry.

### C. UTAUT

The TAM model is the foundation for the UTAUT, which is enhanced by "adding social influence and positive factors" [19]. A technological acceptance model using UTAUT was created by Venkatesh et al. [20] and describes users' intentions to adopt information technology, digital transformation, and subsequent user behavior. The theory strongly emphasizes four key concepts: (a) performance expectancy, (b) effort expectancy, (c) social characteristics, and (d) enabling conditions. This section's first three components cover usage behavior, while its final element emphasizes user behavior (see Fig. 4). UTAUT, sometimes referred to as child TAM, accounts for 50% of the variance in actual usage or user behavior (UB) and 70% of the variance in behavioral intention (BI) [21, 22].

A study of customer behavior is essential in this situation because it clarifies studies that show that customers' perceptions of performance improvement from technology are based on performance expectations [20]. TTF is used for utilities, UTAUT is used for companies, and the TAM framework is utilized for persons. The main focus of the new UTAUT model is on the economic or social effects of technology use. Fig. 4 shows how data-driven finance has changed from Fintech to TechFin [18-23] due to the major

changes in the worldwide regulatory environment in the finance industry following the 2008 financial crisis.

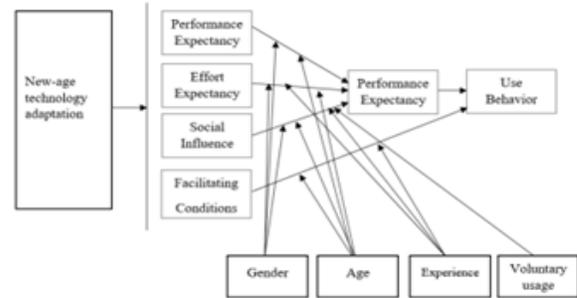

Fig. 4. Organizational technology adaptation applying the UTAUT model [18]

Decentralized norms and regulations provide AI, IoT, and modern technologies a platform to participate in money absorption, securities dealing, and illegal fund-raising that goes beyond what applies to it [20]. This study's concept and framework provide a new business and technical innovation paradigm. The study's findings provide theoretical underpinnings and practical advice for further education. Every corporation's technology and resources are its true assets [24], and business goals, procedures, and technical innovation determine the results.

### IV. KEY TAKEAWAYS FROM TAM, TTF, AND UTAUT

- Both internal and external elements are included in the TAM model. To ascertain if a new endeavor or computer project will be embraced by its potential users, TAM places a high value on "perceived utility" and "perceived ease of use." The TAM model examines exterior elements, including utility, content, pricing, and design, to examine their links with perceived usefulness and perceived usability [16]. Before we continue to investigate the idea of reasoned action, these external elements that impact organizational culture or commercial acceptance must be addressed (TRA) [25]. The TAM has a weakness, though, in that social influence is disregarded and has less of an impact in corporate settings today because it is based on individual ideas.
- In the current research, TTF is determined by evaluating how well the system function satisfies the demands of each specific activity [15]. Both corporate settings and specific workers can benefit from TTF. Every action we take inside the business must be assessed from both corporate and personal viewpoints to ensure that it meets the needs of all stakeholders. TTF is the connection between a task's needs, a person's aptitudes, and a digital device's and its software's capability. Additionally, TTF has been connected to the standard of personal performance, which may be applied in a wider framework of thinking about how information technology affects human performance [26]. The clear message here is that anything incompatible with people cannot be useful in an organizational setting.

- The UTAUT model is crucial because it compares the most popular technology acceptance theories and offers empirical insights into how people embrace new technologies. An important aspect of this paradigm that affects whether people or organizations should utilize the new system is the effect of social or competitive factors [15, 26]. A low or high social influence score may impact a company's journey toward digital transformation. This study describes how social impact influences executives' and workers' motivation, ultimately affecting organizational decision-making. Fig. 4 loudly highlights the impact of social influence and organizational cultural change as an output of that (see Fig. 5, which explains that the journey of necessity starts with a journey of influence).
- The veracity and viability of theoretical models for digitalization validation increase along with technological advancement. The interactivity, adaptability, and brilliance of digital systems are now considered prior elements in the UTAUT model. All three above models showed that attitude was fundamental to behavioral intentions and usage behaviors, partially mediated the effects of exogenous constructs on behavioral intentions, and directly affected organizational usage behaviors. This was shown to be true in both direct and indirect ways. Numerous implications for theory and practice are made using the study findings, and conclusions are formed.

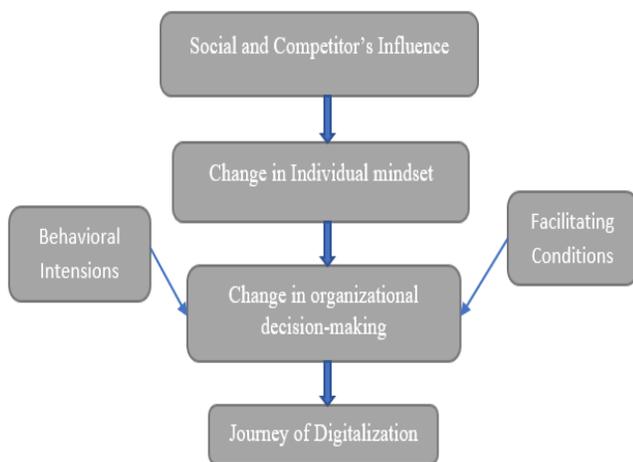

Fig. 5. UTAUT theory of social influence and digitization drive

## V. LIMITATIONS

The construction and analysis of theoretical frameworks aid in clarifying our implicit theory in a more specified manner. It is beneficial to evaluate other alternatives as well to avoid biases that may influence our understanding. However, it's different, and we need to realize that no one model that fits all. These frameworks are ancient and were created with a few scenarios in mind. However, contemporary organizations have complicated processes and needs. So, no single model can address all of their questions here. As a result, planners, project managers, and executives must investigate all three

frameworks and associated alternatives to prevent biases while attempting to match these models with some considerations and aspects to be avoided.

## VI. RECOMMENDATIONS

Because of the worldwide influences of 5G, smartphones, and shifting client sentiments, digital transformation is very necessary for modern enterprises [24]. Companies increasingly use people, technology, and procedure to their advantage in a multidimensional environment. But because it is expensive and cultural in character, affecting all aspects of the company domains, it is crucial to prepare it well. It is very much recommended to employ tested techniques and frameworks to analyze any positive and negative effects of any such major projects before beginning them. The existing organizational stance, its short- and long-term goals, and the cultural background may all be accessed using the theoretical frameworks TAM, TTF, and UTAUT [27, 28]. It is strongly advised that companies thoroughly research these works before selecting the right technology, vendor, and change management process to avoid misfiring in the future [29, 30]. Additionally, study results may affect behavior motivators and outside variables when analyzing executive-level intents and may serve as a basis for future analyses of the DT projects.

## VII. CONCLUSION

The practical assessment of theoretical frameworks, their drawbacks, the consequences for ongoing research, and sensible advice are highlighted in this study. This paper emphasizes the value of theoretical frameworks and explains why they are essential in post-pandemic organizations before beginning any new, expensive, and labor-intensive digitalization endeavor. Building software using these frameworks during pre-project strategy is crucial to achieving both qualitative and quantitative goals. As these models provide comprehensive perspectives of technology acceptability, technology use, and behavioral intents, future research is advised to improve data collecting from Fortune 500 businesses internationally and dialogues, including executives and stakeholders.

## ACKNOWLEDGMENT

Our chair and esteemed professor, Dr. Azad Ali, is acknowledged for his guidance and assessment of this work throughout our journey. Dr. Ali's inputs and suggestions are extremely beneficial in completing this systematic review.

# Adversarial Sampling for Fairness Testing in Deep Neural Network

Tosin Ige<sup>1</sup>, William Marfo<sup>2</sup>, Justin Tonkinson<sup>3</sup>, Sikiru Adewale<sup>4</sup>, Bolanle Hafiz Matti<sup>5</sup>

Department of Computer Science, University of Texas at El Paso, Texas, USA<sup>1,2,3</sup>

Department of Computer Science, Virginia Tech. SW Blacksburg, Virginia, USA<sup>4</sup>

Department of Mathematics and Statistics, Austin Peay State University, Tennessee, USA<sup>5</sup>

**Abstract**—In this research, we focus on the usage of adversarial sampling to test for the fairness in the prediction of deep neural network model across different classes of image in a given dataset. While several framework had been proposed to ensure robustness of machine learning model against adversarial attack, some of which includes adversarial training algorithm. There is still the pitfall that adversarial training algorithm tends to cause disparity in accuracy and robustness among different group. Our research is aimed at using adversarial sampling to test for fairness in the prediction of deep neural network model across different classes or categories of image in a given dataset. We successfully demonstrated a new method of ensuring fairness across various group of input in deep neural network classifier. We trained our neural network model on the original image, and without training our model on the perturbed or attacked image. When we feed the adversarial samplings to our model, it was able to predict the original category/ class of the image the adversarial sample belongs to. We also introduced and used the separation of concern concept from software engineering whereby there is an additional standalone filter layer that filters perturbed image by heavily removing the noise or attack before automatically passing it to the network for classification, we were able to have accuracy of 93.3%. Cifar-10 dataset have ten categories of dataset, and so, in order to account for fairness, we applied our hypothesis across each categories of dataset and were able to get a consistent result and accuracy.

**Keywords**—Adversarial machine learning, adversarial attack; adversarial defense; machine learning fairness; fairness testing; adversarial sampling; deep neural network

## I. INTRODUCTION

With some of the latest advances in artificial intelligence, deep learning (DL) can now be applied in areas as diverse as, face recognition system [19], fraud detection system [20], and natural language processing (NLP) [21]. As deep neural network model continues to be increasingly associated with important decision in our daily life, we cannot just view it as only a mathematical abstraction but also as a technical system for the modern society[22],[18][17]. Apart from looking at the various metrics to better understand and evaluate the logic behind the prediction of machine learning model, it is also imperative to look at the ethics in order not to infringe on people's privacy in which the ability to ensure fairness across all groups without bias in dnn model prediction is of serious concern to the community[23], while it is possible to have intentional or unintentional discriminatory pattern in dataset[24] which are being used to train a dnn model, it is imperative and to have some mechanism to identify such

discrimination in dataset before training model with it as such discrimination in dataset are eventually passed onto the trained model when the model is trained with discriminatory dataset especially when the discrimination is among the minority and the vulnerable in the society.

There are several forms in which discrimination can exist in dataset set, some of the forms includes group discrimination [25], [26] and individual discrimination [27], [28],[29]. Some of this discrimination can also be defined over a set of certain attributes such as gender, race age and so on., and when a machine learning model is trained with a discriminatory dataset, such discrimination in dataset is always passed to the trained model which make the model to make bias prediction over the same group being discriminated against in the dataset and this can be seen when ML model makes different decisions for different individuals (individual discrimination) or subgroups (group discrimination). Note that the set of protected attributes is often application-dependent and given in advance.

Our research work is focussed on the usage of adversarial sampling to test for the fairness in the prediction of deep neural network model across different classes of image in a given dataset. We are not dealing with the problem of individual discrimination or samples that differs only by some protected features. We aimed to use adversarial sampling to test for fairness in a dnn model, while also making an avenue for scaling the fairness through the misclassification rate across all group of image. Several adversarial samples were generated from the original image through several adversarial sampling techniques which includes Calini & Wagner, fast gradient sign method (FGSM), adversarial patch, gradient base evasion, and projected Gradient Descent (PGD). Although proposals and conceptual framework had been researched and formulated to address the issue of fairness in ML model [30], [31], [32]. One example is THEMIS randomly samples each attribute within its domain and identifies those discriminative samples [30], and also AEQUITAS which aims to improve the testing effectiveness with a two-phase (global and local) search [31] while SG [32] combines the local explanation of model [33] along with the symbolic execution [34] to cause an increment both in the discriminatory samples and diversity

## II. BACKGROUND

Adversarial machine learning deals with the study of attacks on machine learning algorithms, and of the defenses against such attacks.[1]. Many years ago, the focus of machine learning engineers and scientist was on obtaining high

accuracy for correct prediction, and while this had greatly been resolve in the past few years. The new challenge had focused on adversarial attack and defense against machine learning model there had been series of research survey which establish the need for protecting machine learning model against various forms of attach which make it to misclassify [2].

During the training of machine learning model, it is usually assumed that the training and test data are generated from the same statistical distribution. This assumption makes the final

model vulnerable to various forms of attack, majority of which includes evasion attacks, [3] data poisoning attacks, [4] Byzantine attacks [5] and model extraction [6].

#### A. Current Adversarial Techniques

1) *Gradient-based evasion attack*: In gradient base evasion attack, a perturbed image which seems like untampered to human eyes is made to be misclassified by neural network model (Fig. 1)[35].

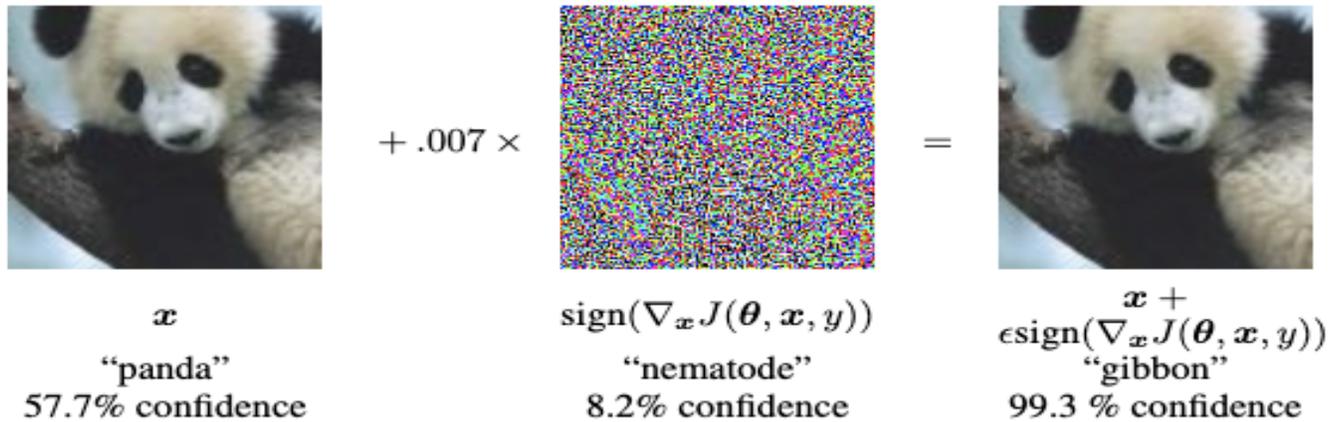

Fig. 1. Adversarial sampling based on addition of perturbation [35]

We can carry out this type of attack by trial and error method as we don't know in advance, the exact data manipulation that will break the model and make it to classify.

Let say we want to probe the boundaries of a machine learning model designed to filter out spam emails, it is possible for us to experiment by sending different emails to see what gets through. And so, a model has been trained for certain words like "momentum", and now we want to make an exceptions for emails that contains other words, if we want to attack, we can craft email with enough extraneous words which will eventually make the model to misclassify it.

#### B. Fast Gradient Sign Method (FGSM)

Let's assume we want to produce an adversarial sample  $x' = x + \eta$  such that  $x'$  is misclassified by the neural network. For us to make  $x'$  and  $x$  produce different outputs,  $\eta$  should be greater than the precision of the features. Let's represent pixel of an image by 8 bits, and we want any information below  $1/255$  of the dynamic range to be discarded. Here, the input is perturbed with the gradient of the loss with respect to the input which gradually increases magnitude of the loss until the input is eventually misclassified.

While  $\epsilon$  decides both the size and sign of each and every element of the perturbation vector which might be matrix or tensor which are being determined by the sign of the input gradient. Here, we just have to linearize the cost function and find the perturbation that maximizes the cost subject to an  $L_\infty$  constraint. This technique causes varieties of models to misclassify input and is also faster than other methods

1) *Projected gradient descent (PGD)*: PGD initializes the sample to a random point in the ball of interest which is being

decided by the  $L_\infty$  norm and does random restarts. This applies the same step as FGSM multiple times with a small step size while at the same time clipping the pixel values of intermediate results of each step to ensure that they are in an  $\epsilon$ -neighborhood of the original image the value of  $\alpha$  used is 1 which means that pixel values are changed only by 1 at each step while the number of iterations were heuristically chosen. This made it sufficient enough for the adversarial example to reach the edge of the  $\epsilon$  max-norm ball.

2) *Carlini and wagner (C&W) attack*: Berkeley, Nicholas Carlini and David Wagner in 2016 propose a faster and more robust method to generate adversarial examples [7]. The attack proposed by Carlini and Wagner begins with trying to solve a difficult non-linear optimization equation. However instead of directly the above equation, Carlini and Wagner propose using a different function and then propose the use of the below function in place of  $f$  using  $z$ , a function that determines class probabilities for given input  $x$ .

With the use of stochastically gradient descent, we can use the above equation to produce a very strong adversarial sample especially when we compare it to fast gradient sign method which can effectively bypass a defensive distillation technique which was previously proposed for adversarial defense [7], [8], [9], [10].

3) *Adversarial patch attack*: Adversarial patch can be devised to fool a machine learning models. They work by causing physical obstruction in an image or by randomizing images with algorithm. Since computer vision models are trained on images that are straight forward. It is inevitable that

any alteration to the input image can make the model to misclassify depending on the severity of the alteration.

We could define a patch function  $p$  corresponding to every transformation  $t \in T$  which applies the transformed patch onto the image and Hadamard product, and the final adversarial perturbed image  $\hat{x}$  which must satisfy  $\hat{x} = p_t(x; \check{z})$  in order to trained patch  $\check{z}$  and some  $t \in T$ .

For us in order to train patch  $\check{z}$ , we could use a variant of the Expectation over Transformations (EOT) framework of Athalye et al. [3]. Let's assume a family of transformations  $T$ , a distance metric  $d$  in the transformed space, and the objective is to find a perturbed image  $\hat{x}$

As the image is expected to be within  $\epsilon$ -ball in anticipation for transformations  $T$ . The attack could find some unconstrained optimization problem. The adversarial patch exploits the way machine learning model are trained for image classification by producing more salient inputs than real world objects. Such salient inputs are misclassified when fed to a machine learning model

### C. Current Defense Strategy and Limitation

1) *Adversarial training*: Adversarial training is a form of brute force supervised learning technique where several adversarial examples are fed into the model and are explicitly labeled as threatening. The approach is similar to a typical antivirus software, which is constantly being updated on a regular basis. As effective as adversarial training may be in defense against adversarial attack, it still requires continuous maintenance or update in order to be effective in combating new threats and it is still suffering from the fundamental problem of the fact that it can only successfully defend against threats or attack that has already happened and is already trained against.

2) *Randomization*: Several adversarial defense methods relied on randomization as a technique for mitigating the effects of adversarial Perturbations in the input and/or feature domain [11]. The idea behind this defense technique is the robustness of deep neural network model to random perturbation. The aim of randomization-based defense is to randomize the adversarial effects of the adversarial sampling into several random effects which is a very ok and normal thing for varieties of deep neural network models.

High success had been achieved by successful defense of Randomization-based defense technique against both black-box and gray-box based attacks, but it is still vulnerable white-box based attack, for example, the EoT method [12] can be easily attacked and compromised simply by considering the randomization process during attack.

3) *Denosing*: In denosing several research works had pointed to both input denosing and feature denosing as a technique for an effective adversarial defense. While input denosing is aimed at complete or partial removal of perturbation from the adversarial samplings or input, feature denosing is aimed at alleviating, reducing or mitigating

effects of adversarial perturbation on important features i.e features that are more impactful on the decision of deep neural network model.

Several methods had been proposed for denosing as a technique for adversarial defense such as conventional input denosing, GAN-based input denosing, auto encoder-based input denosing, feature denosing.

Each of these methods of denosing had been shown to be vulnerable to one form of adversarial attack or another. For instance, Sharma and Chen [13] had shown that input squeezing can bypass by EAD, While good performance was achieved on Testbed by APE-GAN techniques[14], it is easily defeated by white-box based attack[16], As for auto encode-based input denosing, Carlini and Wagner [15],[16] successfully demonstrated that it is vulnerable to the adversarial samples generated by attack, but with feature denosing, research had shown that it merely increase accuracy by 3% which makes it vulnerable to PGD attack.

## III. RESEARCH METHODOLOGY

Fairness when using adversarial sampling as input had shown to cause disparity in accuracy and robustness among different groups [16]. Our method of approach is such as to investigate the cause and offer a solution. The methodologies were in three(s) phases of activities;

### A. Phase-1: Development and Optimization of DNN Model from Scratch

We created a python project in jupyter notebook and created a deep neural network model (DNN) for image classification. We used cifar-10 dataset which consists of 60000 colored images with each image having 32x32 dimensions and categorized into 10 classes of image [Airplane, Automobile, Bird, Cat, Deer, Dog, Frog, Horse, Ship, Truck], with each category containing 6000 colored images. The whole 50000 images in the training dataset folder of cifar-10 was used for training our DNN model while the 10000 images in the test folder of cifar-10 dataset was used to validate our model.

With an initial accuracy of 72%, we needed a higher accuracy and hence, we did some hyper parameter turning by adjusting the learning rate, the number of convolutional layers, and adding some regularization until we are able to get a good accuracy that we can work with, after which we decide to compile and save our new model with KERAS being a high level neural network library that runs on tensorflow.

### B. Phase-2: Generation of Adversarial Sampling

Another python class was created in jupyter notebook in which we wrote algorithms for several adversarial attacks. We wrote adversarial algorithm for adding various kind of noise perturbation to all the images in the training folder (adversarial sampling) (Fig. 2). The algorithm automatically creates new folder and then puts all the adversarial sampling into the new folder. The adversarial folder which contains all the perturbed image or adversarial sampling is named **dogsa** (Fig. 3).

```
def noise_add(path,numb):  
    img = cv2.imread(path,0)  
    im = np.zeros(img.shape, np.uint8)  
    mean=40  
    sigma=50  
    cv2.randn(im,mean,sigma) # create the random distribution  
    noise_image = cv2.add(img, im) # add the noise to the original image  
    io.imwrite("dogsa\\"+str(numb)+".jpg", noise_image)  
    return noise_image
```

Fig. 2. Creation and addition of random gaussian noise distribution to image having image path and position as argument

Fig. 3. Generated adversarial sampling in the dogsa folder after iteration and noise attack

At this point, it was needful for us to test our model with the newly created adversarial sampling to see if it will misclassify those images, having satisfied the criteria of misclassification, it was needful for us to test for fairness across each of the 10 categories of images in the cifar-10 dataset. To actualize this, we separated each category of image in the cifar-10 dataset as separate entity and then observe the accuracy of misclassification across each entity to see if the accuracy of misclassification for each entity will be close, and indeed the accuracy of misclassification for each of the 10 categories of images were closely called which ensure fairness across each group.

### C. Phase-3: Evaluation and Removal of perturbation

This is a very tricky part, as several methods had been proposed with little or no effectiveness. Here, we write algorithm to remove the perturbation, considering the existence of several adversarial attack, we wrote an algorithm to remove all forms of perturbation while at the same trying to maintain the original property of the image. The algorithm iterate through all the images in the adversarial folder where we have our adversarial samplings and remove perturbation in each of them, and in the process creating a new folder name **dogsa-clean** where all the clean images from the adversarial folder are saved (Fig. 4).

Fig. 4. Images in the dogsa-clean folder after passing through the new separation of concern layer from software engineering concept

At this point, we wrote few lines of python code to load our model through keras, and iterating through each of the images in the **dogs-clean** folder where the cleaned images are saved and observe the result. After this, each categories of image were treated as separate entity to account for fairness across each group of images.

#### IV. RESULT AND DISCUSSION

On iterating through each category of adversarial samplings in our adversarial folder to see the rate of misclassification across each image, it was found that there is unfairness as some

of classes have high rate of positive misclassification than the others.

The rate of misclassification was not consistent as Airplane, Automobile, and truck (Fig. 5) has very low rate of misclassification compared with other groups, calini & wagner form of adversarial attack were added to them, while also updating the learning rate and regularization of our initial model and rebuild. The purpose of this is to ensure fairness and consistency across all the classes of image through consistence rate of misclassification (Fig. 6).

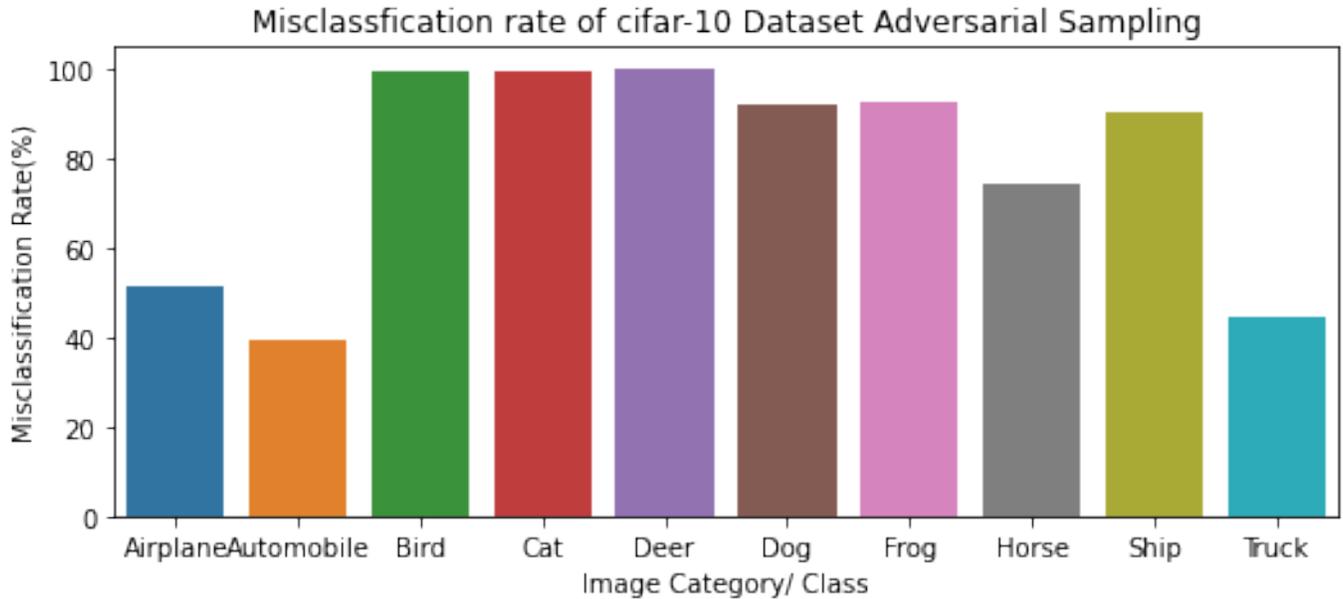

Fig. 5. Plotting of the misclassification rate of the generated adversarial sampling and visualization of fairness across each of the 10 category of images

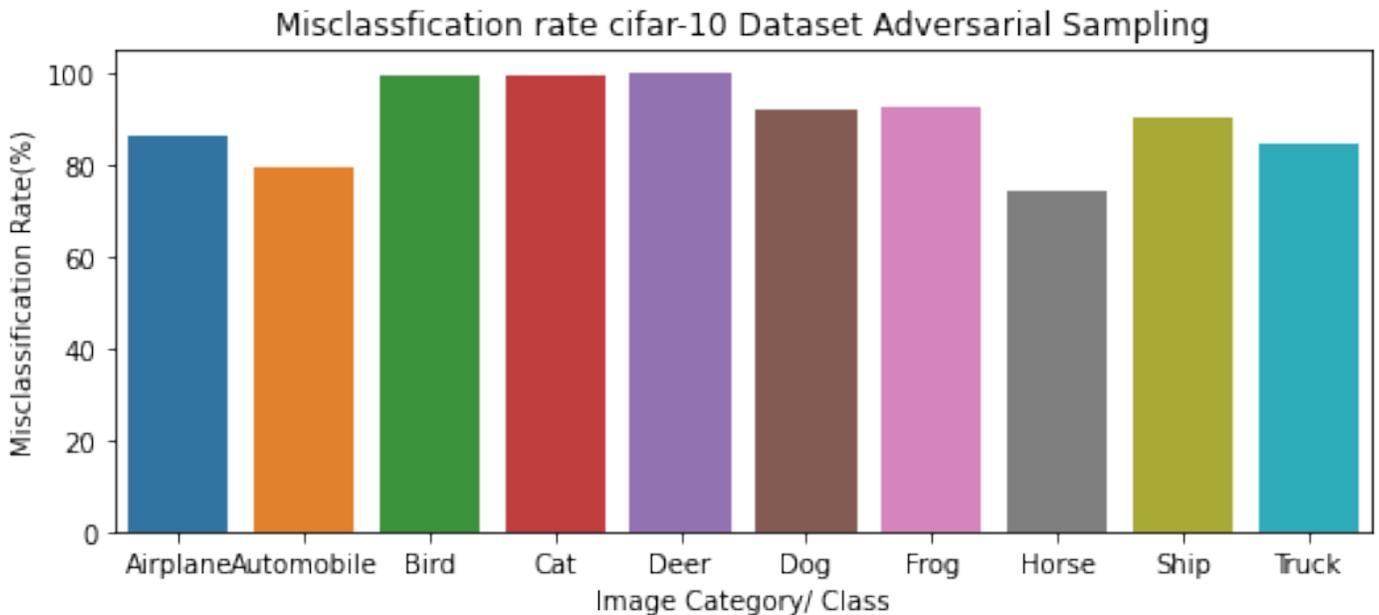

Fig. 6. Plotting of the misclassification rate of the generated adversarial sampling and visualization of fairness across each of the 10 category of images after Calini & wagner attack

With some consistencies in the rate of misclassification, series of algorithms were written to remove greater part of the noises and perturbation for better accuracy. Rather than labeling the attacked images as invalid input, we want the model to be able to predict the attacked images correctly and classify them to the category of images they belonged to.

We wrote an algorithm to iterate through all the images in our adversarial folder, remove as much perturbation and denoise as possible while creating a new folder **dogsa-clean** to store all the new images. Substantial lines of python codes were written to iterate through various classes of cleaned and denoised images in our dogsa-clean folder, and feeding them to the DNN model.

To our surprise and amazement, without making any further hyper-parameter tuning, we were able to have high rate of fairness and consistency across each of the classes of clean images while still maintaining a very good accuracy of prediction in our classifier.

## V. CONCLUSION

In this research, we successfully demonstrate a new method of ensuring fairness across various group of input in deep neural network classifier. Rather than the existing method of training the model on the adversarial sample and label them as invalid. We trained our neural network model on the original image, and without training our model on the perturbed or attacked image. When we feed the adversarial samplings to our model, it was able to predict the original category/ class of the image the adversarial sample belong to.

Through our method we were able to achieve fairness across all the categories of images in the cifar-10 dataset. We also introduce Separation of Concern (SOC) method from full stark software engineering which ensures that we can manage the filter layer as separate entity at any point in the development life cycle without re-training the model.

Surprisingly, we tried to compare the true rate and false rate of fairness for the adversarial sampling across each of the classes of image with that of the cleaned images. We found that the fairness rate was high, consistent and almost the same without any hyper parameter tuning or modification to the filter layer.

## VI. LIMITATION AND FUTURE RESEARCH

In this research, we use the existing forms of adversarial attack for the images. However, we envisage that there will be more sophisticated forms of attack in the future. It is for this reason that we adopt the model of separation of concern from software engineering for our filter layer. In the event of a more robust and sophisticated attack, rather than going back to development to retrain our model, we only need to improve the filter layer.

In addition, the filter layer can be made into a cloud based handy toolbox library. In that case, the filter layer can be managed in the cloud against any future robust attack and be automatically available to all existing deployed model.

## A. Material and Source

We use python 3.9 for this project, pip version 22.3.1, tensorflow, keras to save, load and consume our model and a host of other python libraries.

Our source code for the hypothesis and experiment on this research had been uploaded to github and is made available to the public, and can be accessed through the Uniform Resource Locator (URL) below:

# Text2Simulate: A Scientific Knowledge Visualization Technique for Generating Visual Simulations from Textual Knowledge

Ifeoluwatayo A. Ige<sup>1</sup>, Bolanle F. Oladejo<sup>2</sup>

Computer Science Department, Rochester Institute of Technology, Rochester, USA<sup>1</sup>  
Computer Science Department, University of Ibadan, Ibadan, Nigeria<sup>1,2</sup>

**Abstract**—Recent research has developed knowledge visualization techniques for generating interactive visualizations from textual knowledge. However, when applied, these techniques do not generate precise semantic visual representations, which is imperative for domains that require an accurate visual representation of spatial attributes and relationships between objects of discourse in explicit knowledge. Therefore, this work presents a Text-to-Simulation Knowledge Visualization (TSKV) technique for generating visual simulations from domain knowledge by developing a rule-based classifier to improve natural language processing, and a Spatial Ordering (SO) algorithm to solve the identified challenge. A system architecture was developed to structurally model the components of the TSKV technique and implemented using a Knowledge Visualization application called ‘Text2Simulate’. A quantitative evaluation of the application was carried out to test for accuracy using modified existing information visualization evaluation criteria. Object Inclusion (OI), Object-Attribute Visibility (OAV), Relative Positioning (RP), and Exact Visual Representation (EVR) criteria were modified to include Object’s Motion (OM) metric for quantitative evaluation of generated visual simulations. Evaluation for accuracy on generated simulation results were 90.1, 84.0, 90.1, 90.0, and 96.0% for OI, OAV, OM, RP, and EVR criteria respectively. User evaluation was conducted to measure system effectiveness and user satisfaction which showed that all the participants were satisfied well above average. These generated results showed an improved semantic quality of visualized knowledge due to the improved classification of spatial attributes and relationships from textual knowledge. This technique could be adopted during the development of electronic learning applications for improved understanding and desirable actions.

**Keywords**—Knowledge visualization; visual simulation; text-to-simulation knowledge visualization technique; natural language processing; electronic learning

## I. INTRODUCTION

Knowledge visualization is the application of visualization techniques to disseminate knowledge among individuals [1], [2]. The main purpose of knowledge visualization is to improve the communication of knowledge through visual means. Although most available knowledge sources are in either numeric or textual formats, it is highly necessary to provide a visual representation of such knowledge for easier assimilation and retention in human minds and for fostering required action [3]. Visual knowledge could be represented

with charts, maps, images, scenes, simulations, and videos. In this article, a textual knowledge visualization technique that visually simulates textual knowledge was developed. A visual simulation is a visual representation containing visual objects that dynamically move based on predefined spatial attributes or collisions. Although visual metaphors, scenes, and animations could be used for the visualization of textual knowledge, these techniques do not emphasize precision in the visual representation of spatial attributes. Such techniques may not be appropriate for related domains that require accuracy in visual object positioning and movement. Furthermore, expressing textual knowledge in visualizations is of utmost importance for effective assimilation to be achieved [4]. This paper, therefore, presents a Text-to-Simulation Knowledge Visualization (TSKV) technique for generating visual simulations from domain knowledge. A review of related works is described in the next section of this article which is followed by an implementation of the TSKV technique. A quantitative evaluation is finally presented to test for accuracy using modified existing information visualization evaluation criteria.

## II. REVIEW OF RELATED WORK

Knowledge visualization, according to [5] and [6] can be summarized into four major formats. Sketches, diagrams, images, and interactive visualizations. Fig. 1 show a word cloud of knowledge visualization techniques. A sketch is a visual representation that shows an abstract drawing or prototype of an idea or concept. Diagrams consist of boxes and circles that represent concepts and entities; and lines, and edges that depict the relationship between the entities. Diagrams are used to illustrate the classification and clustering of related concepts in a domain. Examples are Knowledge Graphs used for visualizing search histories [7]; concept maps used to illustrate concepts and relationships between them in specific domains such as medicine [8]; teaching and learning among others [9]. An image (visual metaphor) is a pictorial representation of humans and events. It is usually generated through rendering, photography, or paintings. Images are used to express emotions and give an idea about a concept such as comic images, icons, and emojis for storytelling [10]. Interactive visualization involves visually representing knowledge with animated objects and shapes. It allows users to interact and make decisions while viewing the visualization. Visualizations are usually shown in an ordered sequence of images. Examples are models such as archetypes [11];

semantic visualization tools [12]; virtual reality [13]; simulations, and animation [14].

Fig. 1. Knowledge visualization techniques

Existing literature research has shown that explicit knowledge could be visually represented with knowledge graphs, knowledge maps, and concept maps. Hao [15] used knowledge graphs to develop a surveying and remote-sensing application. Li [16] employed a concept map to develop adaptive learning systems. Visual metaphors replace key terms and concepts found in textual documents which visual characters. Huron [17] used data feeds to represent sediments. Chau [18] also used flowers to represent search results from the web. Hiniker [19] applied visual metaphors for clustering and viewing citations of literature from a large database. Keith [20] used visual metaphors to develop narrative maps for visualizing online narratives.

More recent KV techniques such as text-to-scenes, text-to-videos, and text-to-simulations generate more realistic visual presentations in form of images [21]; animations [22]; scenes [23], [24]; videos [25] and visual simulations [14]. A brief discussion of the major techniques related to our work is presented thus:

#### A. Text-to-Scene

Text-to-scene conversion generates static scenes from natural language text. Several authors have worked on this research area by applying different AI approaches. The first conversion system was WordEye [26]. Other authors applied machine learning techniques for text-to-scene conversion [27], [28]. Deep learning techniques such as Variational Auto Encoders (VAE) and Generative Adversarial Networks (GAN) are recently being applied for text-to-scene conversion [29], [30]. Our technique does not produce static scenes but dynamic simulations showing object-to-object collision behavior and movement.

#### B. Text-to-Simulation

Visual simulations are generated from textual inputs. Very limited research in this area exists in [14], [31], [32], and [33]. VoxSim architecture was presented in their work. They

applied a rule-based approach specifically predicate logic to set rules for each motion verb which was applied during conversion. However, precise geometric information of objects and their relative positions with other objects were not specified. Also, behavioral attributes of objects such as motion were not specified. The above issues were reported to have led to ambiguities in some simulation results. In our work, precise spatial grounding information of visual objects was included. Exact geometric information and their behavior attributes for all visual objects was also defined.

#### C. Text-to-Video

This involves converting natural language text to Videos that semantically depict the textual input. Recent research on text-to-video conversion exist [25], [34], [35]. A.I. techniques have been applied. Specifically, machine learning [36]; deep learning and neural networks such as convolutional neural networks [34]; recurrent neural networks [37], long short-term memory networks [38], and generative adversarial networks [25], [35] Although a rule-based approach was adopted, there is a slight resemblance between our work and most text-to-video conversion systems in that our prototype tool coupled with TTS and an existing screen capturing tool can generate a video of all simulations performed.

#### D. Natural Language Processing (NLP)

This involves NLP which involves several tasks such as sentence segmentation, tokenization, Part-of-Speech (POS), Named Entity Recognition Dependency parsing among others [39]. SpaCy [40], Natural Language Processing Tool Kit [41] and Stanford CoreNLP tool [42] are some NLP tools that perform NLP tasks. Although these tools perform these tasks, classification and extraction of domain-related keywords and attributes remain a research challenge due to the semantic interpretation of such words. A rule-based classifier was developed to classify and extract domain-related keywords, keyword attributes, and relations between keywords.

#### E. Spatial Relations and Arrangement

This involves defining the specific mapping of spatial keywords to predefined spatial information. Chang [28] and Ma [24] developed spatial relations for prepositions. Fisher [43] presented an arrangement model for determining the order of object placement and position. Our work also defines specific relation information for spatial keywords and prepositions by developing an algorithm for spatial positioning and rendering of objects.

#### F. CAD Models and Scenes

Computer-Aided Design is employed for creating models which are visual replicas of real-world objects. Most KV applications make use of existing CAD model datasets such as ShapeNet [23]; ScanNet [44] and Scene datasets such as SceneNet [45] for developing visual representations of textual knowledge. This work did not make use of existing datasets but developed new models. This is due to the scarce availability of models in the selected domain used for application validation.

### III. METHODOLOGY

We present a mathematical model for generating visual simulations from textual knowledge and a system architecture in the subsequent subsections.

#### A. Mathematical Model Formulation

We mathematically model the task of generating visual simulations from textual knowledge. This is carried out using linear functions given a set of textual inputs  $I_f (i = 1, 2, \dots, h, n)$ . The following definitions show each milestone required from textual input to visual simulation output.

**Definition 1:** Suppose there exist a Semantic Classifier  $C$ ;

$$C(I_f) = [\{E\}, \{A\}, \{e_f R e_h\}] \quad (1)$$

Where the set of entities is  $E_f (i = 1, 2, \dots, h, n)$ ,  $A$  is the attribute(s) set;  $R$  is the relationship between entities,  $e_f$  and  $e_h$  are entities.

**Definition 2:** Suppose there exist a model repository  $O$  and entity set  $E$ ;

$$o_f = f(e_f) \quad (2)$$

Where  $o$  and  $e$  are some models and entities in  $O$  and  $E$  and all entities in  $E$  have a one-to-one function in  $O$

**Definition 3:** Suppose there are a finite set of shapes  $O_f (i = 1, 2, \dots, h, n)$  with scaling factor  $s_f$ ; centroid coordinate  $p(b_f, c_f)$ , spatial attributes  $A_f$  and relation  $r$ . Let  $m$  be some numeric value;  $\alpha$  be the length of  $o_f$  and  $\alpha > A_i$ . Let there exist Scaling and relative positioning Transforms  $S$  and  $R$  respectively. Let there exist a rendering Engine  $K$ . The visual simulation is given by  $V$ .

1) For single object placement  $o_f$ ;

$$f(o_f) = S + p(b_f, c_f) \quad (3)$$

$$V = K(f(o_f)) \quad (4)$$

2) For two relatively positioned objects  $o_f$  and  $o_h$ ;

$$f(o_f) = S_i + p(b_f, c_f)$$

$$f(o_h) = S_h + p(b_h, c_h)$$

$$V = K(f(o_f \cap o_h)) \quad (6)$$

Where:

$$p(b_f, c_f) = p[(b_h), (m + c_h)] \quad \text{and}$$

$$f(o_f \cap o_h) = S_f + p(b_f, c_f) + S_h + p(b_h, c_h) + R(r)$$

3) For two relatively positioned objects  $o_f$  and  $o_h$  with spatial attribute  $A_i$ ;

$$f(o_f) = S_f + p(b_f, c_f); f(o_h) = S_h + p(b_h, c_h)$$

$$V = K(f(o_f \cap o_h)) \quad (7)$$

Where:

$$p(b_f, c_f) = p[(b_h - (\alpha/2 - A)), (m + c_h)] \quad \text{and}$$

$$f(o_f \cap o_h) = S_f + p(b_f, c_f) + S_h + p(b_h, c_h) + R(r)$$

Given textual input, the semantic classifier extracts all entities, attributes, and relationships between entities from textual input as described in Eq. (1). Next, a set of entities are extracted from the model repository (Eq. (2)). Each model has a unique centroid coordinate  $p(b_h, c_h)$  and a scaling vector. Eq. (3) and (4) describe how single models are rendered while taking into consideration its centroid coordinate and its scaling vector. To render two objects relative to each other (Eq. (6)) the centroid coordinate of an object is recalculated using the centroid coordinate of its relative object  $b_h$  and some numeric value which could be the height or thickness of the relative object added to  $c_h$  to get the  $c_h$ . For object relative positioned to each other with spatial attributes (Equation 7), the  $b_f$  value of an object is recalculated by; first subtracting the value of the spatial attribute from the mid-length value of its relative object. This result is further subtracted from the  $b_h$  value of its relative object. Some numeric value which could be the height or thickness of the relative object added to  $c_h$  to get the  $c_f$ .

#### B. System Architecture

Fig. 2 shows the Text-to-Simulation Knowledge Visualization architecture. It comprises four major modules: Natural Language Processing module, 2D Graphic Models Knowledge Base, Spatial Ordering module, and the user interface module.

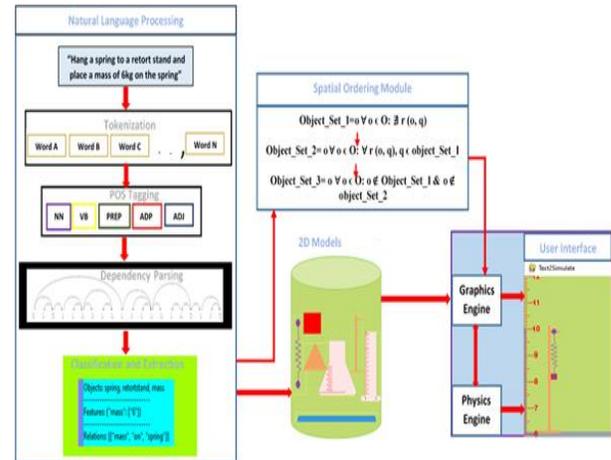

Fig. 2. Text-to-simulation knowledge visualization (TSKV) architecture

The Natural Language Processing module performs natural language processing tasks which are tokenization (breaking down the user's input sentence into words, numbers, punctuation marks, full stops, and discrete items); Part of Speech Tagging (allocating a POS tag per word); Dependency Parsing (assigning dependency labels to show relationship patterns between object and subject tokens); Classification and Extraction of domain-specific words, attributes, and relationships. 2D models can be found in the image repository. The Spatial Ordering Module determines the order of model rendering. The Graphic and Physics Engines are built into the application developed to cater for collision and interaction among models and also for rendering.

1) Natural language processing and dependency parsing:

We make use of SpaCy toolkit for natural language processing and dependency parsing. It is an existing industrial natural language processing library written in Python programming language [40]. SpaCy is known for a higher level of speed and accuracy in major NLP tasks such as POS tagging [46] and dependency parsing [47] when compared to other NLP applications. Tokenization of text, POS tagging, and parsing sub-libraries are used in our work. The NLP pipeline selected for this research supports English Language since it is the commonest medium of communication where this architecture was implemented and evaluated.

Each word in the user’s input is passed through a text corpus for relevance. If the sentence is not domain-related, the user is prompted to input domain-related sentences. Tokenization is done by converting each word in the sentence to tokens. Dependency parsing is done by assigning POS tags to each word, assigning dependency labels that show relationship patterns between object and subject tokens. Fig. 3 shows an example of a dependency graph given the sentence: *place a ruler*”

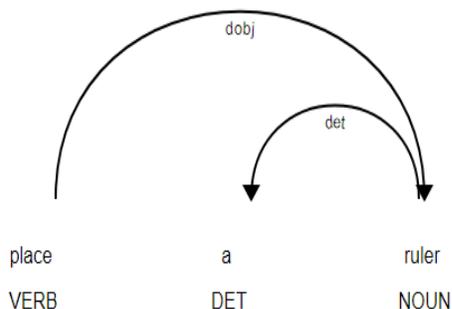

Fig. 3. Dependency graph for ‘place a ruler’

2) 2D models: A repository was created to store 2D models. Major apparatus objects used for performing High school experiments in Mechanics (a subtopic in Physics) are modeled in 2D for this research. The intended and purposely selected users for evaluation of the implemented architecture informed the choice of 2-Dimensional modelling. 2D graphic models provide necessary visual knowledge without much distraction and complexity.

The apparatus image library consists of 14 classes as shown in Fig. 4.

Each 2D apparatus model was created using modified existing objects from the Pymunk library. An apparatus model comprises of one or more objects. Fig. 4 is a class diagram showing each apparatus class, the attributes, and the methods. It also shows the relationship among the apparatus classes. The classes are CircularWeight(), BlockWeight(), RetortStand(), SpiralSpring(), KnifeEdge() and MetreRule(), Table(), Cup(), InclinedPlane(), TestTube(), Beaker(), GraduatedCylinder() and ErlenmeyerFlask().

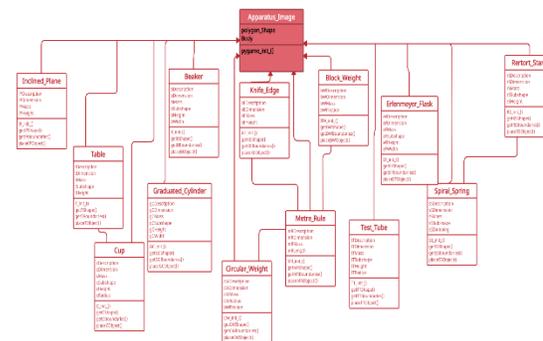

Fig. 4. Class diagram for apparatus model repository

Thirteen sub-classes inherit attributes ‘polygon\_shape’ and ‘body’ from the main class ‘Apparatus\_Image’ as shown in Fig. 4. Each object class contains the following methods:

- a) *\_init\_()*: This is a constructor which is called when a model is instantiated. It is used to initialize each class’s attributes.
- b) *getShape ()*: This method returns the model when called
- c) *getBoundaries ()*: This returns the dimensions of each model (left, right, top, bottom, centroidCordinate(x,y))
- d) *placeObject ()*: This places the model in space when called.

3) *Rule-based classification and extraction algorithm*: We present a novel rule-based classification algorithm that accepts a predefined objects-of-interest list and tokens (Fig. 5). Extracted noun tokens from the POS tagging must exist in the predefined list of objects of interest. The algorithm returns an object list, objects-attribute list, relations list, and object-rel-object list which shows the relationship between objects. In this work, the relationship between two objects is only considered.

Fig. 5. Rule-based classification and extraction algorithm

4) *Attributes and relations grounding*: We consider spatial attributes such as the weight, size, and unique position of objects which are extracted during NLP. The object's color and other characteristics are not emphasized as much work has been done on this area in literature [24], [28]. The spatial attributes are very essential for precision in visual simulation output. Three predefined sets of relations: *on*, *under*, and *inside* are considered. The bounding box approach was employed to determine close distance and positions appropriately. The (x, y) axis coordinates, the height, and the width of the bounding box of the model were used to determine relative positions.

5) *Spatial Ordering*: Spatial ordering is the task of sequentially rendering models and determining relative positioning for related models. Given a set of object list O, object-attribute list P, relations list Q, and object-rel-object list R, a visual simulation is sequentially rendered based on the following procedure:

$$\forall o \in O, p \in P, q \in Q, r \in R;$$

Render Object\_Set\_1 (s);

Render Object\_Set\_2 (s)

Render Object\_Set\_3 (s)

Where:

a) Object\_Set\_1\_list = o  $\forall o \in O: \nexists r(o, q) // o$  is independent of q

b) Object\_Set\_2\_List = o  $\forall o \in O: \forall r(o, q), q \in$  Object\_Set\_1

c) Object\_Set\_3\_List = o  $\forall o \in O: o \notin$  Object\_Set\_1 & o  $\notin$  Object\_Set\_2.

The next section presents an implementation of the methodology.

#### IV. "TEXT2SIMULATE" KNOWLEDGE VISUALIZATION SYSTEM

We develop a knowledge visualization system called *Text2Simulate* based on the architecture shown in Fig. 2.

##### A. Software Requirement Gathering and Elicitation

Domain experts (three teachers) who taught physics in High schools located in a remote area were interviewed to retrieve system requirements since the targeted users of the application are high school physics subject tutors and senior high school students from remote areas. It is expected that the users have an elementary level of proficiency in English language. The users should also be familiar with basic concepts and terms used in high school physics. The *Text2Simulate* Knowledge visualization system can be used by students with little or no supervision of teachers.

##### B. Dataset

The dataset used for this application is the models in the apparatus image library and physics-related sentences in natural language text. The apparatus object image library contains apparatus object images. Existing objects in the Pymunk library are modified and used to create apparatuses models for Ruler, knife-edge and other apparatuses shown in Fig. 2.

##### C. Graphic User Interface

The user interface is divided into three major sections as shown in Fig. 6. The visual simulation is viewed in the right section. On the upper left, the textbox is used for accepting textual input from users. Apparatus models can also be viewed by clicking on objects from the Toolbar. Selected models are then viewed on the right viewing pane. When the button 'analyze' is clicked, the extracted objects, object-attribute list, and the object-rel-object list are shown on the lower-left pane. The user then clicks the 'simulate' button to generate visual simulations which are shown on the right pane.

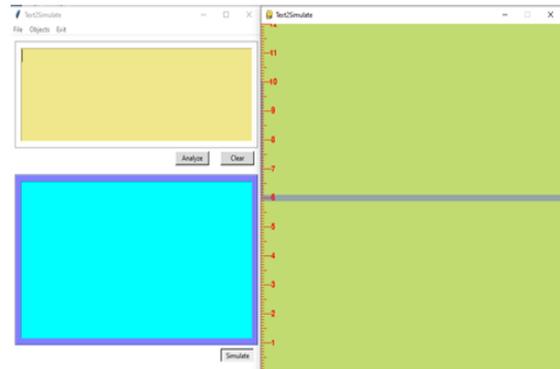

Fig. 6. Text2Simulate knowledge visualization system interface

##### D. Implementation Results

The models can be viewed by clicking each model as seen in Fig. 7. A table model is shown when clicked. Fig. 8 to 10 are screenshots of sentence inputs, classification results and visual simulation. The classification results show the objects, attributes and relations extracted from the sentence input. The figures show the screenshot of the visual simulation of the sentence. Fig. 8 shows a visual simulation result for 'Hang a spring to a retort stand and place a mass of 6kg on the spring'. During visual simulation, the motion can be viewed when the mass is attached to the spring. The spring continues to oscillate till it gets the equilibrium position. The screenshot was taken when the spring got to its equilibrium position.

Fig. 9 and 10 show visual simulation for sentence inputs describing principle of moments using a balanced ruler experiment [48].

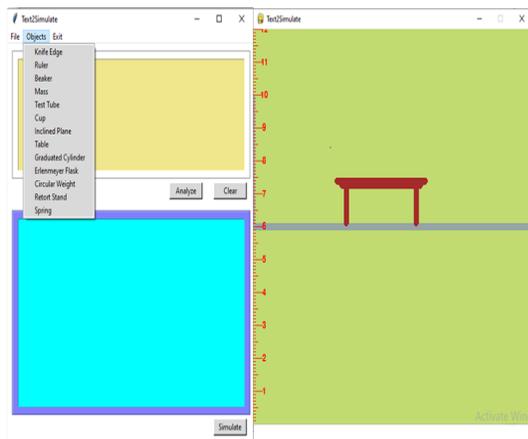

Fig. 7. A visual representation for 'Table' model

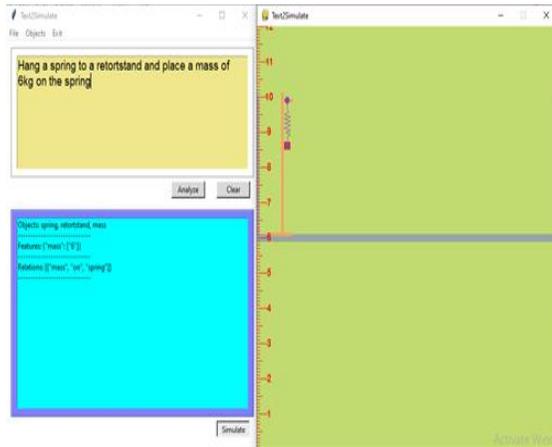

Fig. 8. Visual simulation screenshot of 'Hang a spring to a retort stand and place a mass of 6kg on the spring' sentence when spring is at equilibrium position

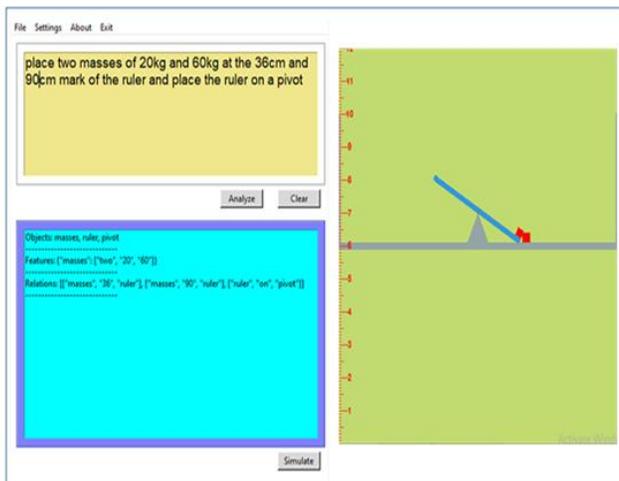

Fig. 9. Visual simulation screenshot of 'place two masses of 20kg and 60kg at the 36cm and 90cm mark of the ruler and place the ruler on a pivot'

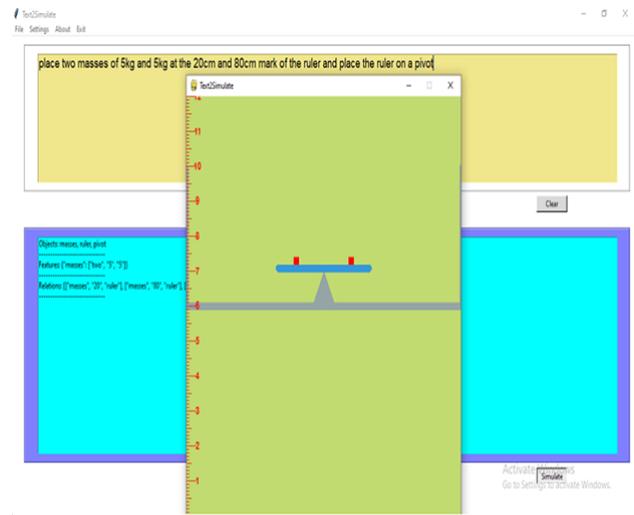

Fig. 10. Visual simulation screenshot of 'place two masses of 5kg and 5kg at the 20cm and 80cm mark of the ruler and place the ruler on a pivot'

## V. QUANTITATIVE EVALUATION

We first perform a quantitative evaluation on the rule-based semantic classifier. Then, the accuracy of converting textual knowledge to visual simulation representation is evaluated. Finally, a user evaluation on the knowledge visualization tool is conducted.

### A. Rule-Based Classification Evaluation

A total of 110 sentences were purposively selected and used for evaluation. A total of 60 sentences were extracted from the general domain; while the remaining 50 were domain-specific sentences. *Objects\_of\_Interest*, *Object\_Attribute* and *Object\_Relation\_Object* classification results are compared with human-generated classification. Standard performance evaluation metrics (recall, accuracy, precision, and F1 score) based on the confusion matrix are employed. Each outcome is assigned True Positive (TP) if it correlates with human-generated classification; assigned False Positive (FP) if it is extracted as a member of a list but false with human-generated classification and assigned False Negative (FN) if human-generated classification assigns it to a list but is not included in the extracted list. Eftimov [49] and Popovski [50] reported that the True Negative metric is not required for the evaluation of rule-based entity classification methods. Hence, True Negative values are not reported. Table I presents the three classification categories; Objects of Interest list; *Object-Attribute* list and *Object-Relation-object* list.

TABLE I. THE CONFUSION MATRIX FOR EVALUATION OF OBJECTS, ATTRIBUTE AND RELATIONS CLASSIFICATION

	LIST	TP	FP	FN
1	Objects of Interest	242	0	11
2	Object-Attribute	32	0	4
3	Object-Relation-Object	52	0	4

Fig. 11 displays the graph showing recall, accuracy, and F1 score values for *Objects\_of\_Interest*, *Object\_Attribute*, and *Object\_Relation\_Object* classification.

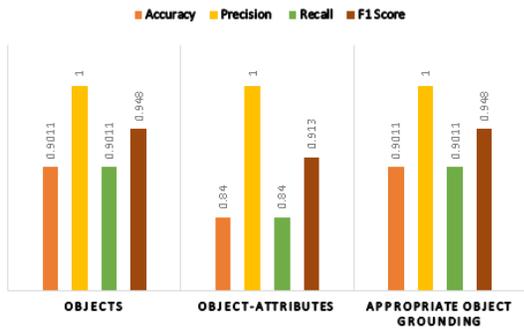

Fig. 11. A graph showing performance evaluation metrics for *Objects\_of\_Interest*, *Object\_Attribute* and *Object\_Relation\_Object* classification

The accuracy for *Objects\_of\_Interest* classification is 0.9565 as presented in Fig. 11; precision is 1; recall is 0.9565 and F1 score of 0.9777. For *object\_Attribute* classification and extraction, the accuracy is 0.8888; precision is 1; recall is 0.8888 and F1 score is 0.9411. Evaluation for the *Object\_Relation\_Object* classification produces; 0.9286 (recall); 1 (precision); 0.9286 (accuracy); and F1 score of 0.9630. The precision value of 1 for all the classifications is achieved because objects belonging to the list from the classifier actually belong according to human judgment. It can also be attributed to the advantage of employing a rule-based approach for the classifier modeling as reported in Al-Moslmi [51]. Accuracy and recall have the same value for all the categories. This shows that the classifier can correctly classify and extract all three categories to separate lists. This is also because True Negative outcome is not computed for this evaluation. Summarily, it can be concluded that evaluation results show that the classifier performed well above average. During error analysis of semantic classifier results, the dependency parser did not identify a few relations existing between objects as a preposition. They were identified as modifiers. However, human judgment categorized them as prepositions. Some attributes were also not identified since they did not have numeric values. The dependency parser did not identify a few compound words as nouns (objects). The words were split into modifier and noun ('inclined plane). However, human classification categorized them as Nouns.

### B. Evaluation of Knowledge Visualization System based on Visual Simulation Results

Existing evaluation criteria used for evaluating the visual representation of information visualization techniques in [52] and [53] were adopted and modified to include Object's Motion criteria. Two domain experts were selected to evaluate *Text2Simulate* Knowledge Visualization application based on visual representation results. The simulation generated from the *Text2Simulate* application were evaluated using 50 purposively selected domain-specific sentences and compared with human judgment based on the following modified criteria: Objects Inclusion (OI); Object-Attributes Visibility (OAV); Object's Motion (OM); Relative Positioning (RP) and

Exact Visual Representation of Text (EVR). Each criterion was evaluated using performance metrics based on a confusion matrix. Each result is Assigned True Positive (TP) if the visual simulation matches with human judgment; Assigned False Positive (FP) if the visual simulation is not semantically correct based on human judgment and Assigned False Negative (FN) if there is no visual simulation (object is static) but there should be simulation-based on human judgment. The confusion matrix for visual simulation tasks is presented in Table II.

TABLE II. CONFUSION MATRIX OUTCOMES FOR VISUAL SIMULATION

	CRITERIA	TP	FP	FN
1	Objects Inclusion (OI)	82	0	9
2	Object-Attributes Visibility (OAV)	21	0	4
3	Object's Motion (OM)	82	0	9
4	Relative Positioning (RP)	27	0	3
5	Exact Visual Representation of Text (EVR)	48	1	1

Fig. 12 shows the evaluation results for precision, accuracy, recall, and F1 score metrics of Objects Inclusion, Object-Attributes, Object's Motion, and Relative Positioning.

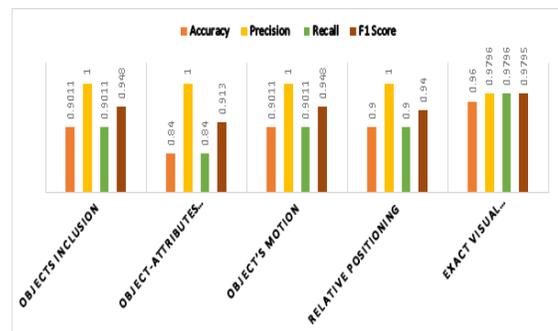

Fig. 12. A graph showing performance evaluation metrics for visual simulation

The visual presentation results showed almost a hundred percentage positivity for the knowledge presented as shown in Fig. 12. Spatial attributes were significantly visualized as well as the motion of objects which was dependent on their unique attributes, sizes, and intersection with other relative objects. During error analysis, a statement such as 'place two masses of 5kg and 20kg on a table' produced a visual representation showing only one mass and a table. Although the second mass was also rendered, it was hidden as both masses were placed at the same default location. Also, it was observed that some objects were not rendered even though the classifier identified them as objects as their models were not found in the image library.

### C. User Study Evaluation

A total of 10 physics teacher participants and 20 student participants who have little or no prior graphic knowledge and reside in developing areas were purposively selected for the user study. Both set of participants were trained on how to simulate physics experiments on the knowledge visualization tool. They were then asked to perform two experiments

namely: Principle of Moments Using a Balanced Ruler and Hooke's Law as shown in Fig. 8, 9 and 10. The participants were finally asked to fill a user feedback questionnaire which was based on a two-point Likert scale (Yes/No) after the performing both experiments. The questions in the survey was drafted to indicate the level of system effectiveness and their overall satisfaction with the application developed based on the following 10 purposively selected metrics: Graphic design (T1), User-Friendliness (T2), Meaningful Arrangement (T3), Meaningful Size (T4), Object-Attribute visible (T5), Semantic Correlation of Text and Simulation (T6), Ability to Understand (T7), Ease of Use (T8), Reading Robustness (T9), Reusability (T10). *Text2Simulate* knowledge Visualization application was chosen as the independent variable while T1 to T10 were the dependent variables. Results of the analysis of mean is in Fig. 13.

Fig. 13. Graph of mean for teachers and students evaluation of *Text2Simulate* based on T1-T10 metrics

Fig. 13 showed that the teachers were fully satisfied as T2, T3, T4, T5, T6, T8, T9, T10, and T11 metrics have an average value of 1. The metrics are User-Friendliness, Meaningful Arrangement, Meaningful Size, Object-Attribute visible, Semantic Correlation of Text and Simulation, Ease of Use, Reading Robustness, Reusability, and Knowledge Sharing. This can be attributed to the essential need for *Text2Simulate* application as a teaching aid and for electronic learning due to the recent pandemic occurrence as stated by one of the teachers. The high performance on these metrics is also due to the current non-availability of the laboratory apparatuses in schools of the participants and their preference for *Text2Simulate* application over conducting the experiment for students in their laboratories if available. The mean scores for student's overall satisfaction based on the metrics are well above 0.5. It is shown that the scores range from 0.7 to 0.95. This reflects that most of the students were satisfied with the application.

## VI. CONCLUSIONS AND FUTURE WORK

A Text-to-Simulation Knowledge Visualization (TSKV) technique for generating visual simulations from domain knowledge has been presented and implemented using a newly developed Knowledge Visualization application called '*Text2Simulate*'. The generated results have shown that precise semantic visual representations of spatial attributes and relationships between objects of discourse can be generated from natural language text using the above

technique. The developed rule-based semantic classifier can be used for domain-related classification of text which requires classification and extraction of objects, object properties, and the relationship between objects. The text-to-simulation technique for knowledge visualization produced a better visual representation of textual knowledge than existing knowledge visualization techniques due to its ability to visualize spatial object attributes retrieved from the text. This technique could be employed when developing electronic learning applications.

**Abstract**—Artificial Intelligence (AI) is seen as the most promising among Industry 4.0 advancements for businesses. Artificial intelligence, defined as computer models that mimic intelligent behavior, is poised to unleash the next wave of digital disruption and bring a competitive advantage to the industry. The value of AI lies not in its models, but in the ways in which we can harness them. It is becoming more common for industry objects to be converted into intelligent objects that can sense, act, adapt, and behave in a given environment. Leaders in the industry will need to make deliberate choices about how, when, and where to deploy these technologies. Our work highlights some of the primary AI emerging trends in Industry 4.0. We also discuss the advantages, challenges, and applications of AI in Industry 4.0.

**Keywords**—Artificial intelligence; Industry 4.0; intelligent manufacturing; industry analysis

## I. INTRODUCTION

Industry 4.0 is a term used to describe the Fourth Industrial Revolution. Manufacturing technologies are part of this revolution. Among the technologies included in this group are technologies like the Internet of Things (IoT), cyber-physical systems (CPS), and artificial intelligence (AI). A machine's ability to perform human functions, such as learning, reasoning, and solving problems, is commonly referred to as artificial intelligence. Using sensor technologies, machine intelligence agents can perceive and interact with their surroundings.

Artificial Intelligence allows computer systems to learn from experience, adjust to new input data, and make intelligent tasks. Fig. 1 illustrates the major areas and technologies associated with artificial intelligence.

- Machine learning is the process of developing computer systems that can detect patterns from raw data. There are two major types of machine learning: supervised and unsupervised.
- Supervised learning involves algorithms that generate a predictive model from a set of training data, which includes both training observation/examples and labels [3].
- Unsupervised learning refers to the creation of a model from observations/examples that do not have class labels [3].

- Deep Learning is concerned with algorithms inspired by the structure and function of the brain called artificial neural networks. These algorithms are used for a variety of tasks, such as image classification, by learning from large amounts of data and using multiple layers of artificial neural networks to produce intelligent decisions [4].
- Natural Language Processing (NLP) is a subfield of computer science and artificial intelligence concerned with the interactions between computers and human languages, with a focus on making it possible for machines to read, understand, and generate human language [5].
- Expert systems are designed to mimic the decision-making abilities of a human expert in a specific domain. They use a combination of knowledge representation, inference rules, and a database of facts to provide reasoning and advice to solve complex problems in fields such as medicine, finance, and engineering [6].
- Computer Vision is concerned with enabling computers to interpret and understand visual information from the world in the same way that humans do. It involves the development of models to perform tasks such as image and video recognition, object detection, and image segmentation [7].
- Speech Recognition, also known as Automatic Speech Recognition (ASR), is concerned with the ability of computers to recognize, understand, and transcribe human speech. The goal of speech recognition is to develop algorithms that can accurately transcribe or translate spoken language in real-time, enabling natural and convenient human-computer interaction [8].

AI is considered the next revolution in health care, manufacturing, and mobility. AI plays a vital role in Intelligent Manufacturing Systems (IMS) by introducing learning, acting, and reasoning. Manufacturing objects are transformed into intelligent objects that can self-correct without human intervention [11], [60]. Manufacturing will benefit from AI if it is able to harness new capabilities, many of which have seen

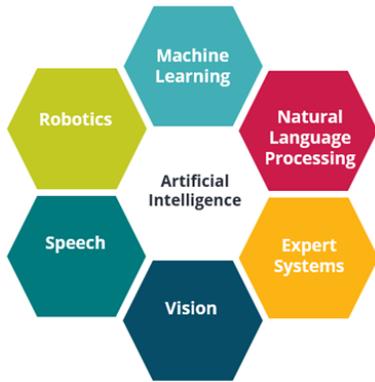

Fig. 1. Key AI areas and tech

dramatic increases in recent years [2].

AI combined with emerging technologies such as Big Data, Blockchain, and IoT can eliminate downtime, maximize throughput, and improve efficiencies. For example, FANUC and Cisco have optimized systems that enhance value for manufacturers [18], [47]. To reach the goal of autonomous machines in Industry 4.0, blockchain can be utilized by connecting the ERP, parts supplier, and the cyber-physical system in a factory, enabling the machines to order replacement parts securely and independently. Additionally, blockchain's ability to facilitate seamless and transparent financial transactions between smart devices is essential for the economic changes brought by Industry 4.0 [10].

The Reference Architecture Model Industry 4.0 defines the Industry 4.0 layers [16]. It consists of the following layers [16]:

- The business layer organizes business operations and connections between different processes, adhering to the legal and regulatory restrictions, to support the underlying business models.
- The functional layer describes an asset's role in Industry 4.0-based systems based on its logical functions.
- The information layer represents the assets' technical features, like services and data.
- The communication layer provides regular communication between the integration layer and the information layer about services and data.
- The integration layer represents the physical assets, and the digital capability provides computer-aided control and creates events based on the assets.
- The assets layer serves the physical world, such as physical objects, software, and actors in the physical world.

The service-oriented RAMI 4.0 goes deeper into representing digital manufacturing models [16].

LinkedIn reported in 2018 that six of the top 15 emerging jobs were related to AI, with positions requiring expertise in deep learning experiencing the highest growth, according to data from Monster.com [22]. Deep Learning is a branch of

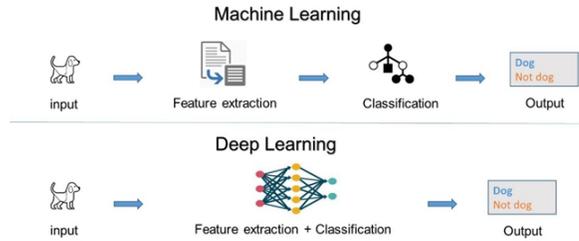

Fig. 2. Comparison between machine learning and deep learning

machine learning that utilizes multiple non-linear layers for feature extraction, transformation, and classification, either in a supervised or unsupervised manner [23].

Deep learning and classical machine learning are intended to model the relationship between inputs and outputs. Deep Learning distinguishes itself from traditional machine learning in its approach to feature learning, model building, and training. It combines these elements into one model, adjusting kernels or tuning parameters for optimal results [26]. Fig. 2 shows the main difference between traditional machine learning and deep learning.

Deep learning revolutionizes manufacturing by transforming facilities into highly efficient smart operations, leading to reduced operating costs, increased productivity, and decreased downtime [26]. Fig. 5 illustrates the main differences between machine learning and deep learning. Deep learning eliminates the need for expert involvement by incrementally learning high-level features from data, while traditional machine learning requires domain experts to identify features.

The remaining sections are organized as follows. Section II describes the methodology we followed in conducting the review. Section III presents the typical applications of AI in industry and shows some use cases. Section IV discusses the advantages and the challenges that are currently noticeable by using AI. Section V demonstrates the industry analysis. Section VI reviews some future trends. Section VII concludes the paper.

## II. METHODOLOGY

This study follows the two-stage approach developed by Webster and Watson[9] for reviewing relevant literature. As a first step, the following search phrases were used to search for papers published between 2016 and 2020 on Google Scholar and ScienceDirect:

- "Industry 4.0" & "Artificial Intelligence"
- "Industry 4.0" & "Trends"
- "Industry 4.0" & "Intelligent Manufacturing"

The search returned 176 results. In the second step, these papers were carefully reviewed, and unrelated papers were eliminated. We have compiled a final list of 39 relevant articles. Fig. 3 and 4 show the publication years and citation numbers of these papers. For example, 13 relevant articles have a total of 1400 citations in 2018. The selected papers are then grouped into four research categories, as shown in Table I. The

TABLE I. RESEARCH CATEGORIES OF THE SELECTED PUBLICATIONS

Research Category	No. of Publications
Applications of AI in Industry 4.0	24
AI technologies and approaches in the Industry 4.0	10
Advantages and Challenges	3
Emerging Trends	2

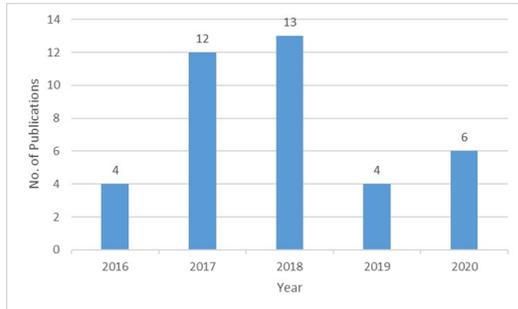

Fig. 3. The number of publications per year (2016–2020)

categories’ distribution shows that more attention has been paid to AI applications in Industry 4.0, followed by the primary approaches and methods of AI in Industry 4.0. Fig. 5 shows the paper organization’s block diagram and an overview of AI in Industry 4.0.

### III. AI APPLICATIONS AND USE CASES

This section represents applications of AI in major industries. Some case studies are then presented.

#### A. Applications

Today’s society uses artificial intelligence in a variety of ways. It has been used to develop and advance many fields and industries, including aerospace, automotive, electronics, finance, medical, education, retail, and more. Ahuett-Garza et al. provided a brief review of machine learning, IoT, and adaptive manufacturing in industry 4 [56]. Preuveneers et al. developed a study in AI and machine learning in intelligent manufacturing environments settings [57]

Intelligent manufacturing tools and models are explained in [58]. Lee et al. proposed that industrial AI’s main elements

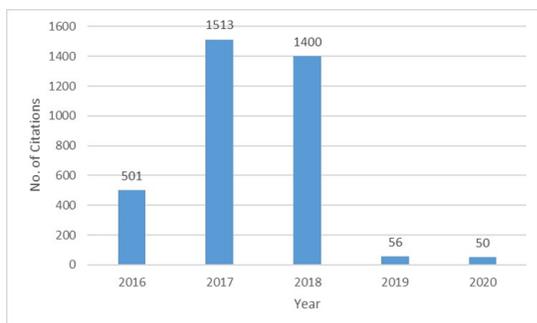

Fig. 4. The number of citations per year (2016–2020)

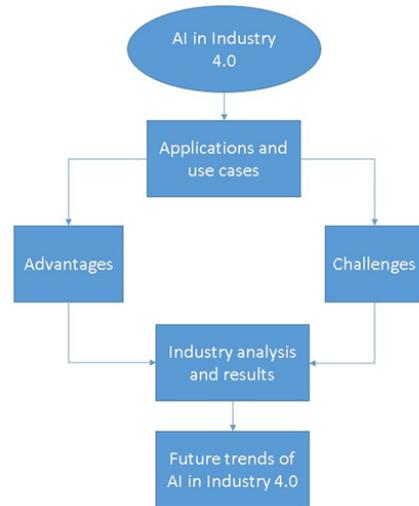

Fig. 5. The organization of the paper

include analytics technology, cyber technology, and big data technology [59]. Cheng et al. discussed the future development direction of Industry 4.0, which provides a reference for its intelligent manufacturing [61]. Liu et al. presented the manufacturing demonstration system based on IoT in Industry 4.0 [62]. Table II shows some main applications of AI in several industrial sectors.

#### B. Use Cases

This section includes several examples of the successful implementation of AI in Industry 4.0.

1) *Doxel robots use AI to improve accuracy and efficiency on large construction projects:* A new robot can check that building projects are going planned using AI and LIDAR. After a construction site shuts down for the day, robots created by Doxel can start working. Using LIDAR, it scans the construction sites and feeds that data into deep-learning algorithms.

The deep learning algorithms find anything that deviates from building plans so that the management team can fix the problems the next day. The main premise is that if errors have not been noticed directly on the worksite, they will create complex issues that take time and money to fix. Instant problem resolution leads to substantial cost savings. A recent test of the approach on an office building project improved labor productivity by around 38%.

2) *Anomaly detection of bearings at Altair engineering:* Bearings play a crucial role in the automotive sector. This example uses sensor data from four bearings, sampled at 20kHz, resulting in 1-second sampling every 10 minutes for 9 days. The dataset originates from NASA’s Prognostics Center of Excellence. The initial sampling, representing a new bearing, serves as a reference for detecting anomalies. The goal is to monitor the bearings’ health as they age and predict the beginning of degradation, which will be flagged as an anomaly to the user. Identifying anomalies enables the user to plan

TABLE II. APPLICATIONS OF AI IN INDUSTRY

Industry	Applications	Summary	Technology/Technique	Ref.
Aerospace	- Fuel consumption prediction	- A genetic algorithm-optimized neural network topology is designed to predict the fuel flow-rate of a transport aircraft	- Feed-forward backpropagation, Levenberg–Marquardt algorithms, and genetic algorithms	[25]
	- Aircraft failure times prediction	- Predict when the failure will happen by aircraft type and age	- Artificial neural networks and genetic algorithms	[15]
	- Aircraft design cycle time reduction	- AI is used to expedite the decision-making process in the early stages of the aircraft design process	- fuzzy logic and neural network	[14]
Automotive	- Driving Assistance and Autonomous Driving	- State-of-the-art deep learning technologies used in autonomous driving	- AI-based self-driving architectures, convolutional and recurrent neural networks, and reinforcement learning	[17], [37]
	- Driver monitoring	- Monitor drivers and identify driving tasks in vehicles	- Kinect, Random Forest, and Feedforward Neural Network	[13]
	- Vehicle manufacturing	- Human–collaborative robot assembly in cyber-physical production. Manufacturing system produces products from scratch without any human intervention during the process	- collaborative robots and additive manufacturing	[12, 53]
Electronics	- Diagnosis of electrical machines and drives	The AI methodologies are applied to an induction machine, utilizing as input signals the instantaneous voltages and currents	- Expert systems, artificial neural networks, and fuzzy logic systems	[50]
	- Smart refrigerators	- The intelligent refrigerator is capable of sensing and monitoring its contents and notifying the user about the type, quantity, and freshness of the food in the refrigerator	- Internet of Things, Mobile Internet, advanced control and sensing, and food preserving technology	[20], [30]
	- Intelligent video surveillance systems	- Intelligent video surveillance systems that control private and public places and detect dangerous situations	- Neural networks, classification, and clustering techniques	[24]
Medical	- Breast cancer detection	- Performance comparison between different machine learning algorithms on the Wisconsin Breast Cancer datasets	- Support Vector Machine, Decision Tree, Naive Bayes, and k Nearest Neighbors	[39]
	- Disease Diagnosis and symptoms checker	- Artificial intelligence platform for self-diagnosis and symptom checker	- Artificial Intelligence	[40]
	- Robot-assisted AI surgery	- deep learning approach for robotic machine segmentation	- Deep neural network	[43]
Retail	- Customer segmentation and clustering	- Systematic Approach to Customer Segmentation and Buyer Targeting for Profit Maximization	- K-mean clustering	[44]
	- Retail recommendation engines using machine learning	- Use of Deep Learning in Modern Recommendation System: A Summary of Recent Works	- Natural language processing, Deep Learning	[45]
	- RFID network planning	- Artificial intelligent paradigm is developed to model and optimize RFID networks	- Artificial neural networks and computational artificial intelligence algorithms	[46]
Telecom	- Smart traffic prediction and path optimization	- Optimizing space-air-ground integrated networks by artificial Intelligence	- Deep Learning	[49]
	- Security	- Articulating a comprehensive threat model for ML and categorize attacks and defenses within an adversarial framework	- Machine learning	[51]
	- Customer segmentation based on mobile usage	- Identifying prime customers based on mobile usage patterns	- Support vector machine and K-mean clustering	[52]

proper maintenance of the bearings, avoiding potential failures and irreversible issues.

Initially, Principal Component Analysis (PCA) is applied for dimension reduction. The samples are then compared to the healthy sample to assess the current health of the bearing, and the comparison is represented as a Health Index (HI). An anomaly is detected if there is a 95% decrease in correlation in 5 or more out of 10 consecutive samples. The entire machine learning model is located on an edge device and transmits the HI and anomaly status of each vibration pattern from the sensor in real-time to Altair’s SmartSight. The user can view the status graphically and, if an anomaly is detected, Altair’s SmartCore sends an email alert to the user.

3) *AI from the factory floor to the showroom at Mercedes-Benz:* The widespread use of AI in the automotive industry’s manufacturing process is well documented. OEMs are now incorporating AI into all areas of their business, including sales. With AI insights, companies can determine the best product segment to sell, to whom, and when. Mercedes-Benz, a large-scale truck and bus production plant in Brazil, uses Azure Machine Learning to transform its sales process. The tool combines internal and external data, such as registration numbers, macroeconomic indicators, local laws, sales info, and stats, to aid the brand’s sales reps in making tailored offers at the right time. The system improves with each monthly data report inputted by dealers, resulting in more accurate recommendations.

4) *AI from the ford motor company and Argo AI:* Ford Motor Company announced a partnership with Argo AI in 2017, investing \$1 billion in the virtual driver system for its SAE Level 4 autonomous vehicles [36]. The vehicles, equipped with Argo’s cutting-edge machine learning and computer vision technology, will be deployed for ride-hailing and delivery services in several cities in the US.

#### IV. ADVANTAGES AND CHALLENGES

This section highlights the significant advantages and challenges currently noticeable in using AI, especially in industrial environments.

##### A. Advantages

Significant savings in labor costs due to troubleshooting, maintenance, and repair: AI and machine learning allow machines and computers to replace human labor in many tasks, such as manufacturing, agriculture, and business services. Acemoglu et al. discussed the impact of AI in various industries and their economic impacts [28]. Business decision-makers realize that AI can help create new products, services, and business models [31], [35].

Improved reliability and efficiency through extended time between failures: AI enhances systems’ efficiency in various ways, including more accurate demand forecasting to better

Fig. 6. How companies are adopting AI

manage goods inventory and storage. AI's predictive maintenance helps prevent costly, unexpected machine shutdowns and maintenance in factories [55]. Many examples of AI's ability to improve systems efficiency have been discussed by Jimenez et al. [32].

Safer work environments through AI's ability to detect and respond to hazardous situations: Workplace injuries can be costly for businesses. AI can perform dangerous tasks, such as in construction, heavy machinery manufacturing, and oil and gas plants, reducing the risk of injury to workers. An example of AI enhancing workplace safety is provided in [33].

AI will generate new employment opportunities in various sectors, including cybersecurity, data analysis, machine learning, deep learning algorithms, and data science.

### B. Challenges

Implementing AI comes with its own set of challenges and problems. The issues to be aware of are outlined in Table III, along with recommended solutions.

## V. INDUSTRY ANALYSIS

The results of a survey conducted by Vanson Bourne in July 2017, with 260 respondents, showed that the main obstacles to the implementation of AI are a lack of IT infrastructure and a shortage of talent, as depicted in Fig. 6 [34]. The development of mature AI infrastructure is likely as the world moves towards IoT, smart cities, and cloud systems. The shortage of talent in the field of AI can be addressed through the creation of graduate certificates and programs focused on AI and machine learning offered by universities.

A survey by McKinsey Global Institute found that AI implementation outside of the tech sector is still in its early stages. Only 20% of 3,000 executives from ten countries and 14 industries reported using AI technology in a significant or central aspect of their business. Many companies are uncertain about the potential benefits and return on investment from AI. The study analyzed over 160 use cases and found that only 12% of these employed AI commercially [19]. Fig. 7 illustrates how companies are implementing AI.

A survey of Michigan-based small and medium-sized manufacturing executives conducted by Automation Alley in 2019 showed that only 22% of the companies were currently using AI, 37% were planning to implement it in the next year, and 4% had no plans to use AI (as shown in Fig. 7). The adoption of AI is expected to drive growth and improve revenue for companies that implement it, while those that don't adopt it risk falling behind.

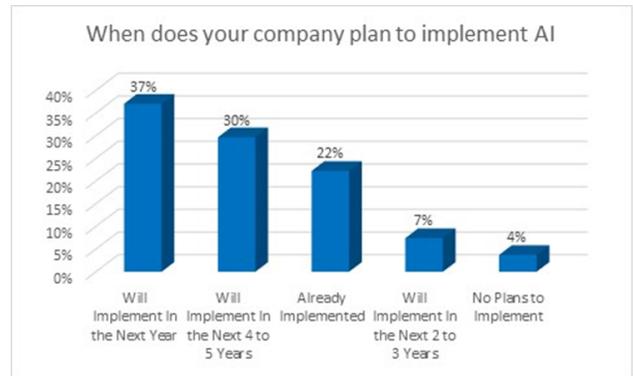

Fig. 7. When does your company plan to implement AI

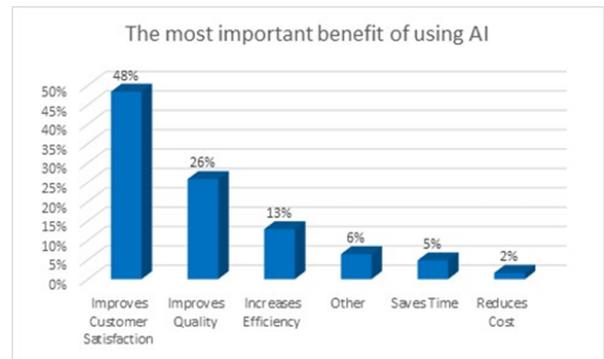

Fig. 8. The most important benefit of using AI

Fig. 8 shows what those Michigan executives surveyed believe to be the essential benefit of using AI, including 1) Improving customer satisfaction, 2) Improving quality, and 3) Increasing efficiency. Initial training and lack of understanding by senior management are the biggest challenges of using AI based on Automation Alley's survey results, as shown in Fig. 9. Many AI consultation companies can provide training and frameworks for AI systems in various business sectors. We believe that identifying AI barriers can lead to accelerating AI adoption.

AI implementation in a business requires the higher management to have the flexibility to change, openness and vision,

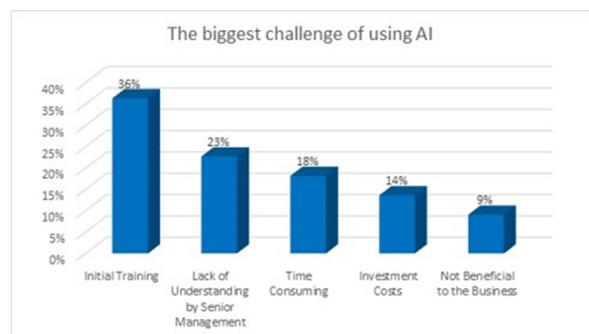

Fig. 9. The biggest challenge of using AI

TABLE III. AI CHALLENGES

Challenge	Description	Suggested Solution	Ref.
Quantity of data	One of the major challenges in manufacturing systems is handling and utilizing the large amounts of data generated, including understanding, cleaning, using, and storing it.	The suggested solution incorporates the latest cloud computing and high-performance cloud techniques to create a large-scale remote sensing data processing system that can handle on-demand real-time services	[38]
Privacy and ownership issues	The widespread collection of data by corporations raises privacy concerns, leading society to consider questions of data collection scope, accessibility, and ownership	Strong privacy guarantees, competitive advantages, and discriminatory policies	[29]
Difficulty collecting and labeling data	Collecting and labeling data is a costly, time consuming, and lengthy process	Transfer learning can be used to tackle this problem by creating high-performance learners that are trained with easily obtained data from different domains	[41]
Difficulty generalizing the results	It is hard to find one algorithm to be effective across a range of inputs and applications	The proposed learning theory analyzes individual problem instances using measure theory instead of sets of instances using statistics. It is not meant to compete with previous learning theories, but rather to complement them, due to differences in assumptions and objectives	[42]
Computation and run-time for AI algorithms	Machine learning and deep learning algorithms require heavy computation and large memory to perform in real-time applications	Algorithms optimization, virtual machines, and cloud computation	[54]

long-term objectives, and effective collaboration. However, there are also some specific challenges where executives may still need to learn more about AI and increase their knowledge on how to organize their business using AI [48].

## VI. EMERGING TRENDS

The major AI trends are discussed in the following subsections.

### A. Smart Devices

The manufacturing industry necessitates the use of sophisticated smart digital devices. Industry 4.0 utilizes AI and IoT to create intelligent objects. Future AI and IoT will possess features like self-configuration, self-defense, self-repair, and self-improvement [1].

### B. Manufacturing Systems

A predictive manufacturing system (PMS) is an intelligent manufacturing system that provides self-awareness, self-predictability, self-maintenance, and self-learning capabilities. In PMS, various technologies and techniques, such as statistics, data mining, models, and AI methods, are used to convert data into information, identify uncertainties, and make predictions about manufacturing systems [21].

The PMS conceptual framework includes a platform, predictive analytics, and visualization tools. Data is generated by the monitored assets. Platforms are chosen based on several factors, including computation speed and investment cost. The purpose of predictive analytics is to extract and predict future outcomes and trends. Among the benefits of PMS are cost reductions, improved operation efficiency, and improved product quality.

### C. Human-Machine Interaction and AI

The integration of AI with human-machine interaction is a crucial aspect in constructing Industry 4.0 enterprises. The goal is to optimize efficiency by seamlessly connecting human dynamics with hardware and software in machine-to-human and human-to-machine interfaces. One example is the AI-powered workspace where humans and machines work together to achieve outcomes not possible by either alone [27].

## VII. CONCLUSION

The meaning of AI and its subfields are continuously evolving. Industry 4.0's IoT, Big Data, cloud and cybersecurity pave the path for AI implementation and usage. Deep Learning revolutionizes manufacturing into highly efficient smart facilities. IT infrastructure investment and a talent pipeline for AI are crucial for unlocking its potential. The most common benefits of AI are improving customer value and quality. Adopters of AI should be aware of data privacy and ownership challenges, the cost of labeling data, and difficulties in generalizing results. AI adoption outside the technology sector is still in its early stages and manufacturers are aware of AI but its use is still limited. Future developments will involve further exploration of AI and its implementation in industrial settings.

# A Machine Learning Enabled Hall-Effect IoT-System for Monitoring Building Vibrations

Emanuele Lattanzi, Paolo Capellacci, Valerio Freschi  
Dep. of Pure and Applied Sciences, University of Urbino,  
Italy

**Abstract**—Vibration monitoring of civil infrastructures is a fundamental task to assess their structural health, which can be nowadays carried on at reduced costs thanks to new sensing devices and embedded hardware platforms. In this work, we present a system for monitoring vibrations in buildings based on a novel, cheap, Hall-effect vibration sensor that is interfaced with a commercially available embedded hardware platform, in order to support communication toward cloud based services by means of IoT communication protocols. Two deep learning neural networks have been implemented and tested to demonstrate the capability of performing nontrivial prediction tasks directly on board of the embedded platform, an important feature to conceive dynamical policies for deciding whether to perform a recognition task on the final (resource constrained) device, or delegate it to the cloud according to specific energy, latency, accuracy requirements. Experimental evaluation on two use cases, namely the detection of a seismic event and the count of steps made by people transiting in a public building highlight the potential of the adopted solution; for instance, recognition of walking-induced vibrations can be achieved with an accuracy of 96% in real-time within time windows of 500ms. Overall, the results of the empirical investigation show the flexibility of the proposed solution as a promising alternative for the design of vibration monitoring systems in built environments.

**Keywords**—Vibration sensor; machine learning; hall-effect

## I. INTRODUCTION

The growing attention toward the structural efficiency of civil structures and infrastructures prompts the need for the design of novel and effective systems capable of monitoring structural health at adequate time and space resolution, and providing effective evaluation and support for downstream decision-making in order to mitigate risks, increase safety, reduce maintenance costs [1], [2].

Structural Health Monitoring (SHM), i.e. the set of techniques, methodologies, and technologies that enable to obtain information regarding the state of a structure (for instance in terms of the functioning of structures or their response), is therefore becoming a crucial aspect of the lifetime cycle of the built environment.

The analysis of the vibrational response of a building, encoded into a time series of displacements and/or of accelerations is a commonly adopted approach for SHM, for instance for establishing potential damage states. This response is usually the result of the non-trivial interplay between several physical properties of the structure (e.g. mass distribution, stiffness, damage pattern, damping sources) and operating conditions [3].

Indeed, SHM methods make use of the vibration response of the structure to derive conclusions regarding its overall conditions (e.g. healthy or damaged). This is generally achieved by means of the acceleration signals gathered from a network of sensors positioned at specific points of the structure, and by subsequent processing to extract from acceleration signals information regarding the possible presence of damage (and also its localization and degree of severity).

In general, SHM can nowadays benefit from a suite of technologies from different fields that can be exploited by designers to develop effective systems at reduced costs. Indeed, recent advancements in the development of novel sensor devices, the advent of various communication and computation methodologies to support the so called Internet of Things (IoT), and the successful application of sophisticated machine learning tools represent three enabling factors for building successful SHM systems.

In the following, we provide a brief summary of the main contributions and key aspects regarding the progress of each of the analyzed technologies.

### A. Sensor Devices

Regarding the measurements of vibrations, accelerometers are commonly employed: they are in fact force-sensors coupled with a mass that applies a specific force proportional to the acceleration of the mass, according to the second Newton's law, when it is subject to vibration. Three types of transducers are mainly used to convert acceleration into proper electrical signals: piezoelectric, piezoresistive, and differential capacitive [1]. Piezoelectric accelerometers exploit the piezoelectric effect to measure changes occurring in specific materials undergoing mechanical stress. Piezoresistive sensors leverage the modifications induced in the electrical resistance of certain materials subject to mechanical deformation. Differential capacitive accelerometers measure changes in electrical capacitance to derive information about the displacement.

Regardless of the type of sensor, a common trend in many applications is the adoption of Micro-Electro-Mechanical-Systems (MEMS) as basic technology for SHM systems. Indeed, MEMS devices can be considered to be often on par with the performance of many macro-scale competitors, while they represent a lower cost and less invasive solution in many deployments.

### B. Processing and Communication Infrastructures

For what concerns communication infrastructures, SHM solutions have traditionally been based on wired networks.

However, the increased reliability of several wireless sensor networks (WSN) core technologies, integrated within a general Internet of Things communication protocols framework, have recently emerged as competitive alternatives thanks to their reduced installation costs and invasivity [2].

A standard IoT system usually consists of a three-tiered architecture with: *i*) a bottom layer, in charge of sensing and actuation through devices that collect data for transmission to upper layers and perform actuation according to specified policies/commands (potentially sent back from upper levels of the stack); *ii*) a middle layer, encompassing different types of communication networks (e.g. local area networks, cellular networks or, more generally, the internet) and devices (e.g. routers, gateways) enabled by different communication technologies, ranging from Bluetooth to WiFi, from LTE to 5G; *iii*) a top application layer devoted to data storage, processing and analysis usually hosted on cloud computing platforms.

### C. Machine Learning

Finally, once data is gathered from sensors (e.g. in the form of a time series) and is transmitted along the IoT communication pipeline, it is processed by means of machine learning techniques to perform inference and provide information (e.g. in the form of classification or regression) to downstream decision making. Deep learning represents the most recent forefront of this trend.

It should be remarked here the existence of an inherent tension between two different design strategies: on one hand, all data collected by a sensor can be transmitted remotely for its processing, on the other hand, it can be directly processed on board of sensor nodes. In the former case, data is sent for instance to edge devices, such as gateways, or to more powerful cloud computing hardware to which inference is delegated. In the latter case, machine learning models are used to perform predictions locally on peripheral devices. The above-mentioned tension is clearly the result of a trade-off among several variables, namely the energy spent for communication, the latency introduced by the processing/communication chain, and the accuracy achieved for solving a specific recognition task.

In this work, we introduce a vibration monitoring system purposed for SHM applications. The main goal of the proposed approach is to overcome the limitations of alternative solutions in terms of cost and flexibility (intended as ease of installation, maintenance, and operativity) through the design of a comprehensive system, which encompasses the following contributions:

- we design a novel Hall-effect based sensor to detect and measure vibrations; the resulting sensor is characterized by reduced costs and works at low frequency ranges (for instance it correctly detects peaks in the power spectrum of an earthquake waveform around 2.5Hz); the sensor is interfaced with off-the-shelf embedded platforms (i.e. a Raspberry PI) also characterized by reduced costs;
- we integrate the sensor node into an IoT framework that allows communicating readings to a cloud back-end system for visualization and processing purposes;

- we demonstrate the feasibility of performing complex machine learning inference directly on board of the adopted IoT hardware platform by implementing two different deep learning models (namely a convolutional and a recurrent neural network); non-trivial analysis of vibration signals by means of sophisticated deep learning models can be performed directly on board or offloaded to the cloud thanks to fully supported IoT functionalities;
- we provide an experimental assessment of the system under real-world working conditions in two use cases, namely the detection of a seismic event and an application for counting steps made by persons walking inside a public building; experimental results provide evidence of the versatility and flexibility of the proposed solution and its suitability as an alternative to other vibration monitoring systems.

The remainder of the article is organized as follows: in Section II we summarize the main state-of-the-art works in current scientific literature and frame their contributions with respect to our approach; in Section III we illustrate the proposed Hall-effect vibration sensor; in Section IV we describe the type and architecture of the two deep learning models used for performing inference; in Section V we introduce the setup adopted for the experimental validation of the proposed system and the related results obtained; in Section VI we conclude by recapitulating the main contributions and findings.

## II. RELATED WORK

The scientific literature about vibration monitoring in civil structures and infrastructures is particularly rich, being it a widely investigated subject of research.

A central assumption of SHM techniques is the possibility of monitoring the health status of a civil structure/infrastructure using vibration-based analysis. As a matter of fact, most SHM systems rely on the analysis of the so called-modal properties or vibration characteristics (i.e. natural frequencies, damping ratios, and mode shapes) which, in turn, depend on the physical features of the structure (i.e. mass, stiffness, and damping).

Since damaged structures change the physical properties of the structure, they result in modifications of the modal properties that can be used therefore as a proxy for damage detection [3]. Recent approaches have also introduced methods for detection and, at the same time, for the corresponding localization of possible damage within a structure, starting from the vibration data [4]. The main focus of our work is not the proposal of new methods for modal property analysis. Rather, we put forward a system-level design that could accommodate specific algorithmic approaches targeting vibration data analysis.

Importantly, many SHM methodologies nowadays make use of vibration data that can be extracted from MEMS sensors. These types of sensors, thanks to their increased precision, lower costs, and small size have progressively become a feasible alternative to traditional piezoelectric sensors [5], [2], [6]. In this article we describe a different approach for vibration sensing, based on a low-cost Hall-effect device which can be easily integrated into a wider IoT system.

Machine learning and, in particular, the deep learning paradigm, have increasingly gained popularity among scholars for vibration data processing [7]. For instance, in [8], the authors proposed a data-driven SHM method based on convolutional neural networks and fast Fourier transform to identify structural damage conditions from vibration data. An autoencoder architecture targeting nonlinear dimensionality reduction of input vibration signals has been recently introduced for the task of load identification in [9].

Another related line of research deals with the possibility of moving the execution of inference tasks (and also of learning tasks, in some cases) toward peripheral devices. Instead of relying on schemes entailing the transmission of whole data gathered from sensors to more powerful computing platforms (up to cloud systems), many works are currently investigating the opportunity to carry out specific machine learning tasks directly on board of sensor nodes or devices (such as gateways) located nearby in the network, according to *edge/fog computing* [10] or *tiny machine learning* paradigms [11], [12]. This potentially leads to benefits for security, privacy, and latency. The complex interplay between computation and communication also impacts energy consumption, which is a crucial factor to be taken into account in many IoT settings characterized by battery-operated devices[13].

Our contribution with respect to [8], [9] is represented by the implementation of two deep learning models on the embedded platform chosen as reference, hence showing the possibility of executing non-trivial machine learning tasks directly on the hardware platform in charge of collecting vibration data; given the integration with fully-fledged IoT protocols, the system can be reconfigured on the fly to also support cloud-enabled machine learning. We also benchmark the performances of the two implemented neural networks in a hypothetical smart building application (namely counting people's steps during walking).

Regarding the design of IoT systems for vibration monitoring, recently, Komarizadehal *et al.* have introduced a system based on an Arduino microcontroller equipped with five low-cost accelerometers [1]. The experimental assessment conducted by the authors with a comparison against two traditional piezoelectric sensors (as measured in terms of accuracy, resolution, and error) highlighted that the proposed platform can rival competitors, performing even better at low frequencies and low amplitude accelerations at a reduced (14x) cost [1]. In [14], an IoT sensing system for monitoring vibrations induced by construction sites is presented. The system, based on a Raspberry PI embedded platform and MEMS accelerometer is connected to the cloud via a USB dongle for 4G connectivity. Cloud-based frontend and backend complete the architecture implementing data storage and visualization (via MySQL database and web interface) and alarm detection based on predefined thresholds on the vibration signals.

Differently from our proposal, these works ([1], [14]) do not take into account any machine learning technique, while we also explore the implementation of machine learning models for vibration signal processing applications.

To conclude, the multifaceted field of SHM presents various challenges to be tackled by research toward the design of effective monitoring and diagnostics systems. Our proposal

attempts to bridge some gaps in the literature by contributing a low-cost solution based on a magnetic sensor device interfaced with a widely used commercially available hardware; the proposed solution supports machine learning inference on the device, as we demonstrate by embedding two deep learning models on it, while it also allows full integration with state-of-the-art IoT communication protocols to support cloud computing.

### III. THE PROPOSED HALL-EFFECT VIBRATION SENSOR

A Hall-effect sensor is a type of sensor in which the output voltage is directly proportional to the strength and direction of the magnetic field in which it is immersed. Its working principle is based on the Lorentz force induced by the presence of a magnetic field perpendicular to the direction of an electrical current applied to a thin strip of metal. As the result of the Lorentz force, a difference in electric potential (voltage) between the two sides of the strip can be measured which is proportional to the strength of the magnetic field [15]. As a special feature, a hall-effect sensor responds also to a static (non-changing) magnetic field differently from inductive sensors, which respond only to changes.

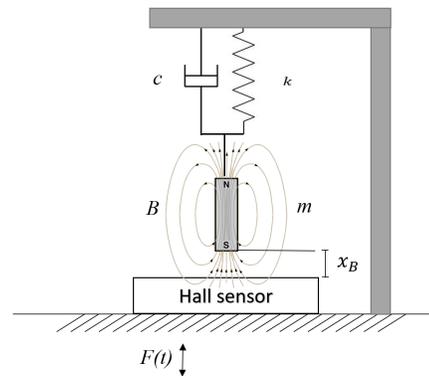

Fig. 1. The schematic representation of the proposed building vibration system consisting of a mass  $m$ , a spring  $k$ , a damping element  $c$ , and a magnetic field  $B$  positioned at a distance  $x_B$  from the hall-effect sensor

Hall sensors are traditionally used for proximity sensing, positioning, speed detection, and current sensing applications, or, combined with threshold detection, they act as a binary switch. In automotive, they are commonly used to time the speed of wheels and shafts, such as for internal combustion engine ignition timing, tachometers, and anti-lock braking systems.

In this work, we present a new low-cost IoT system, based on the Hall-effect, capable to measure building vibrations. In particular, we exploit the ability to produce an output proportional to the magnetic field of the Hall-sensor to dynamically monitor the displacement of an inertial static magnet with respect to the sensor which is rigidly anchored to the building.

Fig. 1 shows the main functioning principle of the proposed sensor. Notice that, for sake of simplicity the figure shows only the vertical axis but the same reasoning can be extended to other axes. The system can be led back to a classical damped harmonic oscillator consisting of a mass  $m$  suspended on a

spring characterized by a constant  $k$  together with a damping element with a viscous damping coefficient  $c$ . Moreover, in the proposed system, the suspended mass consists of a static magnet with a magnetic field  $B$  positioned at a distance  $x_B$  from a Hall-effect sensor. When the building is subject to vertical vibrations an external force  $F(t)$  is applied to the system which can be described, according to Newton's second law, by:

$$F(t) - kx - c \frac{dx}{dt} = m \frac{d^2x}{dt^2} \quad (1)$$

which can be rewritten into the form

$$\frac{d^2x}{dt^2} + 2\zeta\omega_0 \frac{dx}{dt} + \omega_0^2 x = \frac{F(t)}{m} \quad (2)$$

where  $\omega_0 = \sqrt{\frac{k}{m}}$  is called the undamped angular frequency of the oscillator and  $\zeta = \frac{c}{2\sqrt{mk}}$  is the damping ratio.

The value of the damping ratio  $\zeta$  critically determines the behavior of the system. A measuring system like the proposed one, must fall into the case called "underdamped" with  $\zeta < 1$ . Under this condition The system oscillates with the amplitude gradually decreasing to zero [16]. The angular frequency of the underdamped harmonic oscillator is given by

$$\omega_1 = \omega_0 \sqrt{1 - \zeta^2} \quad (3)$$

while the exponential decay of the harmonic oscillator is defined by

$$\lambda = \omega_0 \zeta \quad (4)$$

Considering a sinusoidal driving force defined as

$$F(t) = F_0 \sin(\omega t) \quad (5)$$

where  $F_0$  is the driving amplitude, and  $\omega$  is the driving frequency of the sinusoidal driving mechanism, equation 2 can be rewritten as:

$$\frac{d^2x}{dt^2} + 2\zeta\omega_0 \frac{dx}{dt} + \omega_0^2 x = \frac{1}{m} F_0 \sin \omega t \quad (6)$$

The general solution at the steady state that is independent of initial conditions and depends only on the driving amplitude  $F_0$ , driving frequency  $\omega$ , undamped angular frequency  $\omega_0$ , and the damping ratio  $\zeta$ . In particular, the steady-state solution is proportional to the driving force with an induced phase change  $\varphi$ :

$$x(t) = \frac{F_0}{mZ_m\omega} \sin \omega t + \varphi \quad (7)$$

where the value of the impedance of the system  $Z_m$  is defined as:

$$Z_m = \sqrt{(2\omega_0\zeta)^2 + \frac{1}{\omega^2}(\omega_0^2 - \omega^2)^2} \quad (8)$$

and the phase of the oscillation of the driving force  $\varphi$  is given by:

$$\varphi = \arctan\left(\frac{2\omega\omega_0\zeta}{\omega^2 - \omega_0^2}\right) + n\pi \quad (9)$$

Moreover, since the amplitude of the driving force  $F_0 = m\ddot{u}$  where  $\ddot{u}$  is the acceleration of the ground, the equation 7 can be rewritten as:

$$x(t) = \frac{\ddot{u}}{Z_m\omega} \sin \omega t + \varphi \quad (10)$$

From 10 results that the value of  $x(t)$  is proportional to the ground acceleration so measuring it entails measuring the ground acceleration. Furthermore, in the proposed system,  $x(t)$  describes  $x_B$  which is the distance between the hall sensor and the magnet and, since the measured voltage on the Hall sensor ( $V_{Hall}$ ) is proportional to the magnetic field  $B$ , which, in turn varies with the square of the distance, we can argue that measuring the voltage produced by the Hall sensor allows to measure the ground acceleration.

#### A. The Hardware Prototype

A prototype of the proposed system has been implemented by 3D printing a device capable of measuring building vibrations among the three orthogonal axes x, y, and z.

Fig. 2 shows the 3D solid model together with a picture of its realization. In particular, the central frame of the device sustains three orthogonal arms (yellow elements in the picture) that mount, at their ends, neodymium magnets. Each arm can only move along one degree of freedom as it is connected to the frame using a cylindrical bearing. The damping function is given by the bearing friction while the spring component has been implemented using magnetic repulsion with other neodymium magnets. Notice that, a calibrated mass has also been added to each arm since the very low mass of the magnets does not satisfy the design specifications. Finally, an analog linear Hall-effect sensor (Joy-it KY-024) has been placed perpendicularly and close to each suspended magnet to react at each displacement. The Hall-effect sensors are continuously sampled by means of a multichannel 16bit ADC (Az-Delivery ADS1115) which sends data to a Raspberry Pi model 3B+ through the I2C port.

Fig. 3 shows the circuit diagram together with a virtual representation of the electronic components. Since Hall-effect sensors produce an output also at a steady state (i.e. without any vibrations) the ADC has been connected in differential configuration so that it measures the difference between the sensor output and a reference value produced by means of the potentiometer R1. Tuning the potentiometer at a steady state allows calibrating the system to match the ADC specifications and to avoid ADC saturation.

#### B. The Management Software

The proposed hardware is managed by a python process installed as a daemon service in the Raspberry Pi which collects, elaborates, and sends data to a time series database.

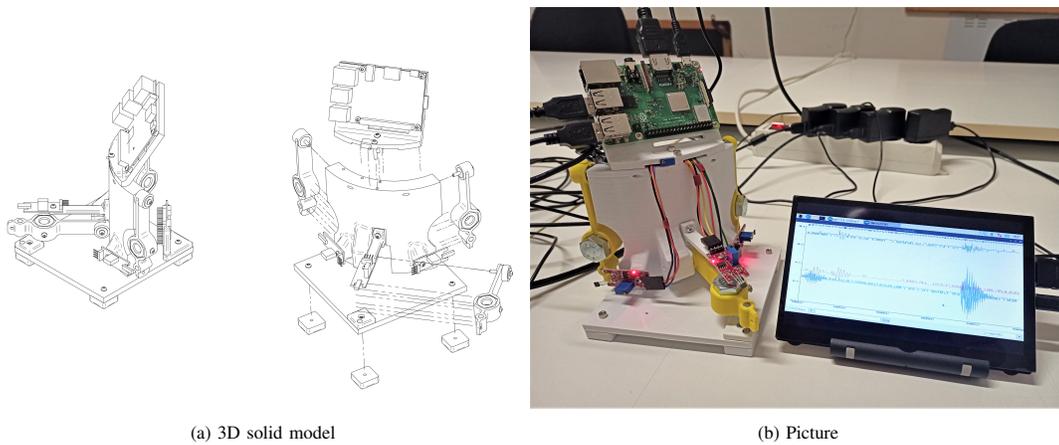

Fig. 2. A 3D solid model of the proposed system (a) together with a picture of its implementation (b)

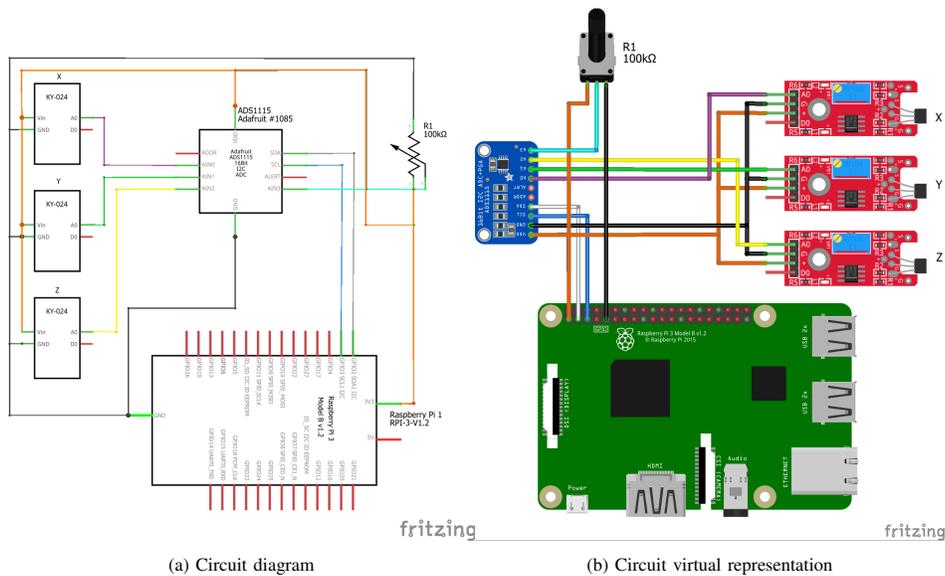

Fig. 3. A circuit diagram (a) and virtual representation (b) of the proposed sensor highlighting the single-board computer (raspberry Pi 3), the multichannel 16-bit ADC (ADS1115), and the three Hall-effect sensors (KY-024)

In particular, a first thread continuously samples the three ADC channels at a frequency of 50 Hz while a second thread elaborates and sends it to the remote server implementing a producer-consumer paradigm. In the current implementation, the consumer thread calculates the modulus of the three components of the signal and then computes the Root Mean Square (RMS) over a time window of 10 seconds. The RMS value is sent to the remote server while the entire buffer (10 seconds) containing the three signal components is stored only if the RMS exceeds a predefined threshold to avoid saving not significant data.

An autonomous monitoring system should guarantee the continuous collection of data avoiding as many as possible downtimes during which significant data could be lost. In a complex embedded system like the proposed one, several conditions can lead to the interruption of operation and the consequent loss of data such as, for example, a reboot of

the Raspberry Pi due to a glitch or a loss of the power supply, a crash on the python process, a problem on the I2C communication with the ADC module or a network down. To guarantee the best reliability of the monitor activity, the management software exploits several recovery strategies. First, installing the management process as a daemon service guarantees that the Linux OS automatically starts it at boot time or restarts the process in case of termination. Moreover, to recover the monitoring activity in case of a lack of data from the ADC, we activate a watchdog timer that reboots the platform if no data arrives for more than 10 seconds. Finally, the consumer thread has been designed to save data locally during network problems and, eventually, reestablish server communication when the network will work again.

#### IV. ADDING MACHINE LEARNING MODELS

To evaluate the suitability of the proposed system for the integration of machine learning algorithms, we tested two different supervised deep learning models, namely a Convolutional Neural Network (CNN) and a Long Short-Term Memory (LSTM) network aimed at recognizing a well-defined pattern, such as the vibrations induced by a walking person, within the time series collected by the system.

##### A. Deep-Learning Background

A CNN is typically composed of: *i*) a convolutional layer, *ii*) a pooling layer, *iii*) an activation function, *iv*) a fully connected layer, and *v*) a classification layer and it is traditionally used with very satisfying results in the field of image recognition and classification [17]. The convolutional layer takes as input a multi-channelled image, in  $n$ -dimensional format, and outputs a feature map. The pooling layer is in charge of keeping meaningful features while decreasing the size of the feature map. The activation layer allows us to learn other things, and its main role is to map the input to the output; the most well-known activation functions are: *Sigmoid*, *Tanh*, and *ReLU*, to cite a few. The fully connected layer acts as a classifier, and is normally placed at the end of the network, typically after the (last) pooling layer; the peculiarity of the fully connected layer is that each neuron is connected to all neurons of the predecessor layer. The final classification is however carried out by the classification layer, which is also responsible for error evaluation during training, i.e., for computing the difference between the predicted output and the actual one via the loss function. The most commonly adopted function is *Softmax*, which provides a prediction probability distribution.

It is worth noting that normally two-dimensional (2D) convolutional filters are used by CNN models to process 2D images; the opportunity to convert time series signal data to images is gaining a lot of momentum because it allows the application of computer vision techniques and performs classification tasks. In time series classification and pattern-recognition, this means that signals gathered from a triaxial sensor can be properly re-coded to images so that a “visual” analysis can be carried out to recognize, learn and classify patterns. Several re-coding techniques exist [18], [19], [20], and in this paper we leverage the deep learning approach proposed by [18], in which time series are converted to Gramian Angular Summation/Difference Fields (GASF/GADF) images. Such an approach envisages the representation of time series as a polar coordinate system that produce one image for the GASF and the other for the GADF. The main advantage of such an approach is that temporal and spatial relations are preserved.

Another deep learning approach used in time series classification is the LSTM model, which represents a recurrent neural network system. As detailed in [21], several versions of LSTM exist, but the most popular version is known as vanilla LSTM. A single LSTM unit is composed of a cell and three gates: input, output and forget gate. The cell is responsible for keeping track of values over time; the input gate is responsible for combining the current input, the output of the previous LSTM unit, and the value of the cell in the previous iteration

in order to decide whether to select the potential candidate values to be added. The forget gate considers current input, state on memory cells and output at previous time step in order to decide which information should be removed from previous cell states. The output gate computes the output (to be sent to the output block) by combining the output of that LSTM unit at previous time, the current input and cell value in the previous iteration. LSTM networks are able to capture temporal information from time series data; since CNN networks are able to automatically extract significant features, combining both networks to build a hybrid architecture can bring benefit in terms of performance and accuracy in time series pattern-recognition.

##### B. The Proposed Deep-Learning Models

Fig. 4 shows the architecture of the proposed LSTM (a) and CNN (b) models.

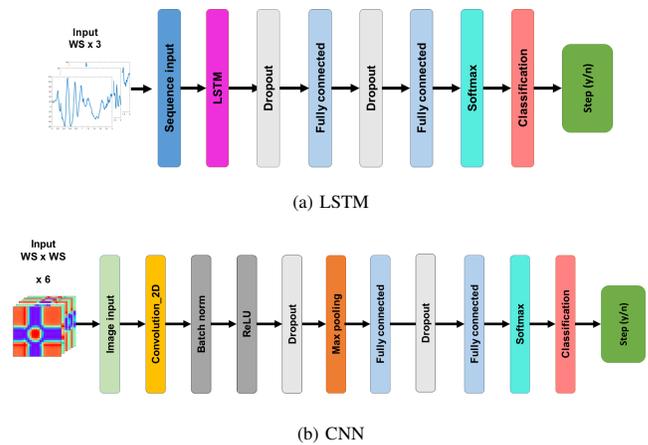

Fig. 4. The proposed deep learning models architecture i.e. (a) the LSTM network and (b) the CNN

Regarding the LSTM network, it takes in input the three signals gathered from the triaxial hall-sensor appropriately divided into windows of size equal to  $WS$ . These signals are arranged by a sequence input layer in a three-channel data chunk that is forwarded to an LSTM layer. The output of this layer is sent to two layers of fully connected neurons that act as a multi-layer Perceptron. Notice that, the two neurons layers are interspersed with two dropout layers, with a dropout probability 0.2, which helps prevent overfitting. The proposed network then terminates with a standard layer that computes the softmax function used by the classification layer to calculate the cross-entropy loss and to infer the presence or not of steps in the signal.

The proposed CNN model makes use of a the two-dimensional convolutional layer that acts on the six images obtained after encoding the three-time series into square images as described in Section IV-A. The images are then managed by an image input layer before going through the network structure. The convolutional layer is followed by a series of layers consisting of normalization, ReLU, dropout, and max-pooling layers. As in the previous network, the last part of the model is built by two neuron layers, a softmax, and a classification layer.

## V. EXPERIMENTAL SETUP AND RESULTS

In this section, we describe the experimental setup and we show the results obtained during two different sets of experiments, namely the building vibration monitoring and the machine learning-driven recognition of people's steps using the vibrations induced on the building floor.

### A. Experimental Setup

The Raspberry Pi model 3B+ was running the original Raspberry Pi OS (Raspbian) with an updated version of the Python3 interpreter. To manage the ADS115 16bit ADC we installed the *adafruit - circuitpython - ads1x15* library configured at the maximum data rate (860 samples per second). Thanks to the differential reading and the offset tuning circuit, the ADC gain was set to the maximum value which allows measuring in the  $\pm 0.256V$  range corresponding to a resolution of  $0.002V/bit$ .

In order to store, visualize, and process the collected data we built a time-series database by installing the InfluxDB open-source software on a desktop machine equipped with an Intel® Core i5 processor and 16GB of main memory running Ubuntu 22.04 LTS [22].

Concerning the machine learning experiments, the network models have been implemented, trained, and tested on the Matlab2022a® platform running on a Windows® desktop pc equipped with an Intel® Core i9 and 16GB of RAM. Moreover, once the models have been trained we converted them to C-language using the Matlab code-generation routine. The code was then compiled and executed on the Raspberry Pi to test its effectiveness and to measure the inference time. To provide a labeled dataset to the supervised classifier we manually annotated about 20 hours of collected traces with a binary label reporting the presence or not of vibrations induced by people's steps. Then the classification performances of the proposed classifiers have been measured using the following quantities:

$$Precision = \frac{TP}{TP + FP} \quad (11)$$

$$Recall = \frac{TP}{TP + FN} \quad (12)$$

$$F_1 score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \quad (13)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (14)$$

where  $TP$  are the true positives,  $TN$  the true negatives,  $FP$  the false positives, and  $FN$  the false negatives.

### B. Measuring Building Vibrations

The prototype of the proposed monitoring system has been installed on a building named Collegio Raffaello located in the center of Urbino city - Italy. This building covers an area of about 2,600 square meters and it was built at the beginning of the eighteenth century by the will of Pope Clement XI. The

building floors are mainly made of wooden beams covered by ceramic tiles. Nowadays, the ground floor of the Collegio Raffaello holds some craft stores and a bar while on the first floor takes place the Physics Museum of the University of Urbino. Lastly, the second floor, where the proposed system has been positioned, currently houses the degree program in Applied Computer Science and the degree program in Foreign languages and cultures of the University of Urbino so that, during the lesson period, it is frequented by many students and teachers.

Fig. 5(a) shows the data extracted from the InfluxDB database which represents the RMS calculated over a 10 seconds time window during a week on May 2022. Traditionally the University lessons are held only from Monday to Tuesday and are organized in units of two hours where the first one starts at 9.00 a.m. and ends at 11.00 a.m.. Then a second unit begins which ends with the lunch break at 1.00 p.m. Finally, in the afternoon, there may be one or more units starting at 2.00 p.m. The lesson activity exactly matches the peaks reported in the figure which shows high RMS values during the daytime hours of the five days of activity while, in the last two days of the week, the building vibrations are practically absent. Furthermore, the vibrations recorded are maximum in central days (Wednesday and Thursday) as happens for the occupation of the building.

Since the system also sends to the remote server the single waveforms relating to the x, y, and z axes during vibrational events that exceed the set threshold, it is possible to extract these traces for subsequent processing. Fig. 5(b) shows the raw signals from the Hall-effect sensors expressed in volts which have been collected when a single person was walking on the floor near the system. As expected, the greatest activity is recorded on the vertical axis (z) due to the transfer of the weight of the person on the floor, but it is nevertheless interesting to note that even in the x and y directions, which are parallel to the plane, it is possible to record non-negligible vibrations due to the walking activity.

During continuous monitoring of the prototype a strong earthquake (Mw 5.5) struck Bosnia and Herzegovina region, causing the death of one person, the injury of at least two others, and forcing hundreds of people fleeing from their homes. Despite the distance that separates Urbino from the epicenter (about 450Km), the proposed monitoring system was able to record the waveforms related to the event for a duration of over 100 seconds. The raw signals are reported in Fig. 6 together with the ground acceleration collected by the official seismic station of the Italian National Seismic Network located at Monte Paganuccio (the closest station to Urbino). Despite the visible differences, it is interesting to note how the trend of the waveforms has several common points. For example, in both cases, the magnitude of the signal appears to be greater in the x and y axes, which are parallel to the floor, rather than in the vertical one. Moreover, both systems measure a vibration activity that lasts about 60 seconds. Clearly, a punctual comparison between the two systems, in addition to being out of the scope of this paper, is not possible for the fact that the system we proposed was located on the second floor of a building while the seismic station is directly supported on the ground so that the vibrations recorded by our system are, in effect, those induced on the building by the motion of the

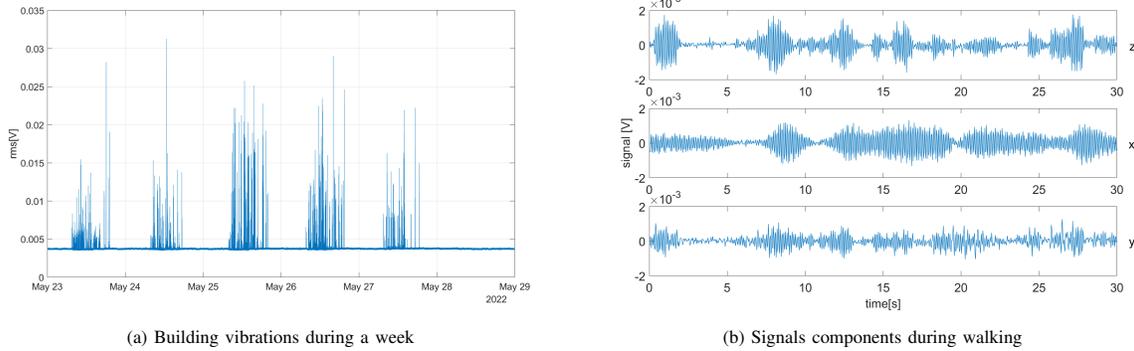

Fig. 5. Measured RMS of the building vibrations during an entire week (a) and triaxial components of the vibrations collected during single person walking

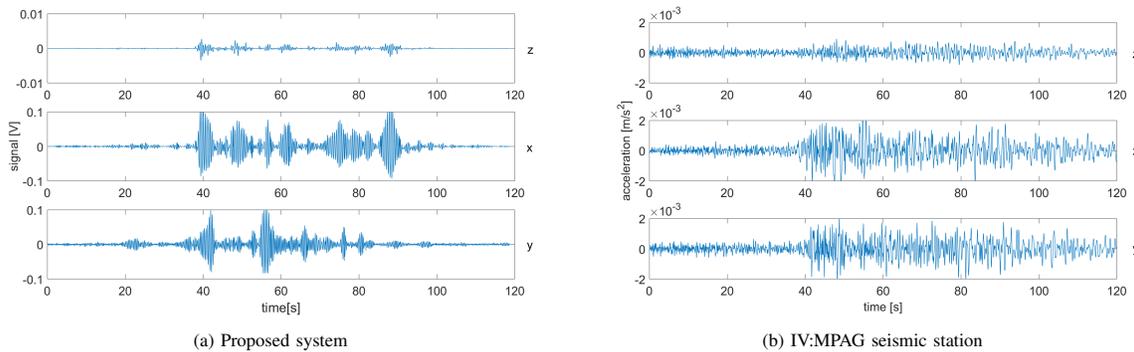

Fig. 6. Vibration waveforms measured during bosnia earthquake of April 22, 2022 (Mw 5.5) by the proposed system (a) and by the the IV:MPAG seismic station (b)

earthquake. Despite this, the comparison allows us to argue that the proposed system is sufficiently sensitive to low-intensity vibrations and therefore capable of monitoring the vibrations to which a building is subject.

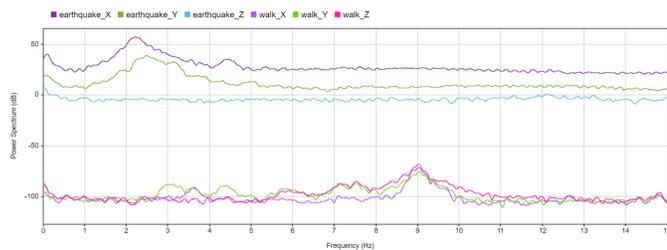

Fig. 7. Comparison of the spectral analysis of waveforms collected during an earthquake and single person walking

Finally, to evaluate the system response to the different patterns and kinds of vibrations, we report in Fig. 7 the power spectrum of the earthquake waveforms together with the spectrum of the vibration induced by a walking person. The first evident thing is that the two signals have very different predominant frequencies, for instance, the earthquake shows a main peak between 2 and 3 Hz (compatible with that detected by the seismic station) while the walking vibrations around 9 Hz.

### C. Detecting People's Steps

Starting from the labeled dataset, the two proposed models have been tested when varying the number of different components. The training set and test set have been split according to a holdout cross-validation methodology with 75% of the examples used for training and 25% kept for testing. Notice that, for a convolutional layer, this number represents the convolutional filters, for the LSTM layer the number of hidden units (i.e. the amount of information remembered between time steps), and for the fully connected layer the number of hidden neurons. Fig. 8 reports the performance measured after training and testing each configuration of the proposed models obtained when varying the number of internal components. As expected, both for LSTM and CNN, increasing the number of components increases the classification performances reaching a very high value (up to 96% of accuracy for LSTM). Each model was then ported on the Raspberry Pi to characterize it in terms of memory footprint and inference latency.

Table I reports the complete models characterization when varying the number of components. The increasing complexity of the models negatively reflects on the size and timing. Interestingly, the LSTM network outperforms the CNN both in terms of classification accuracy and memory and time requirements. For instance, the training time of CNN is 5× greater, the inference latency reaches about 3×, and the memory footprint is 7× greater with respect to the LSTM. Notice

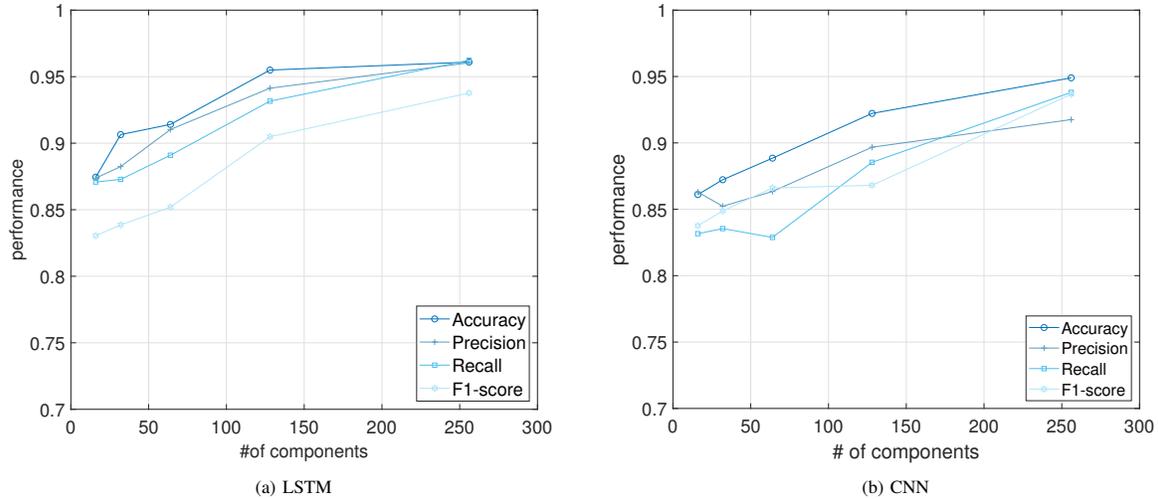

Fig. 8. Performance metrics of the LSTM (a) and CNN (b) networks when varying the network dimension

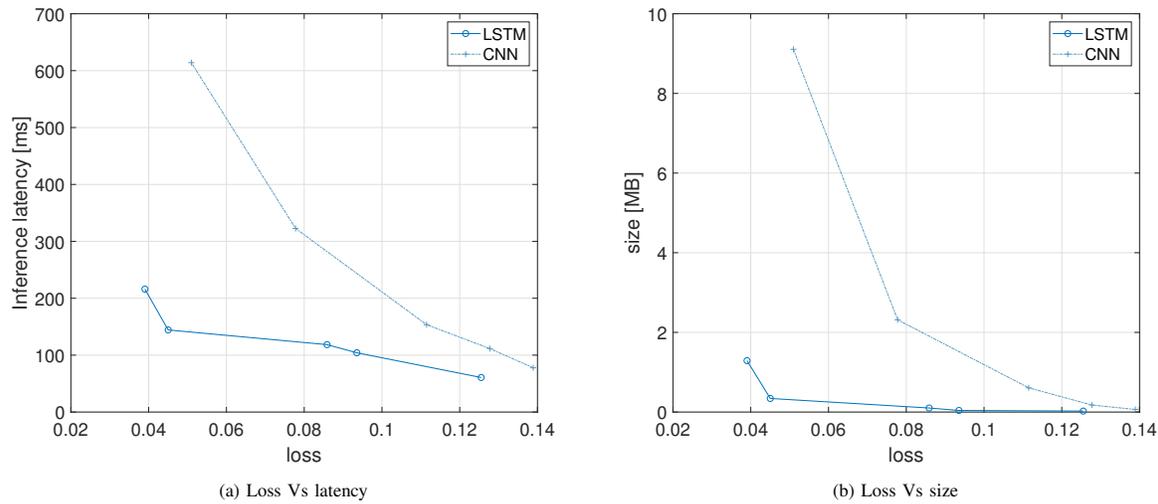

Fig. 9. Pareto curves of classification loss Vs inference latency (a) and model size (b)

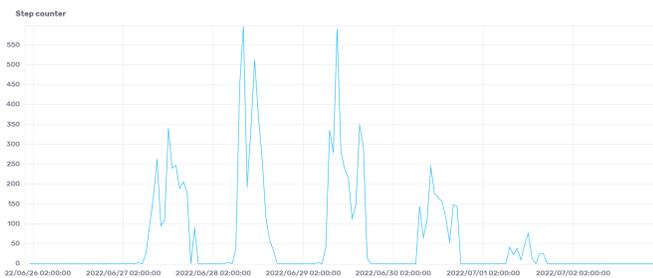

Fig. 10. The number of steps measured during a week on the collegio raffaello building

Pi as the inference latency would exceed the size of the monitoring window (500ms) thus making the consumer thread systematically slower than the producer with consequent data loss.

In Fig. 9, the Pareto curves obtained by plotting the classification loss Vs the inference latency (a) and model size (b) are reported. It is evident that the high classification performance combined with the low inference latency and the very low memory occupation make the LSTM network the best compromise for the detection of people's steps starting from the vibrations induced on the building using the proposed system.

that, for real-time requirements the last CNN configuration (i.e. # of components = 256) cannot be used on Raspberry

According to these results, we permanently installed the trained LSTM on our system prototype with the scope of measuring the walking activity on the building floor.

TABLE I. CNN AND LSTM ACCURACY, TRAINING TIME, LATENCY, AND MEMORY FOOTPRINT AS FUNCTION OF NUMBER OF COMPONENTS

# of components	Accuracy		Training T [s]		Latency T [ms]		Size [kb]	
	LSTM	CNN	LSTM	CNN	LSTM	CNN	LSTM	CNN
16	0.874	0.861	950	4534	60.7	77.6	25	68
32	0.906	0.872	818	4398	103.2	111.5	42	184
64	0.914	0.889	844	4449	114.8	153.4	106	638
128	0.955	0.922	868	4623	144.3	322.4	358	2429
256	0.961	0.949	921	5127	217.2	614.6	1353	9550

Fig. 10 shows the number of steps measured during the last week of June 2022. Notice that, this week there was no teaching activity so the building was frequented only by teachers. In particular, the plot has been obtained using the influxdb server querying language to sum the number of counted steps over a time window of one hour. The maximum value of about 550 steps/hour was found on Tuesday and Thursday which are the days of greatest attendance by teachers while the total amount of recorded steps was about 6,500 steps.

## VI. CONCLUSIONS

Vibration monitoring systems are traditionally used to assess the vibration impact of natural and human activities on buildings, to evaluate the health condition of structures. However, classical vibration monitoring systems are associated with limitations such as expensive devices, difficult installation, complex operation, etc. In this paper, we presented a low-cost Internet of Things monitoring system based on Hall-effect sensors encompassing integration with deep-learning machine models. The results obtained in real-life experiments (namely, the detection of seismic events and the count of steps made by people during walking in a public building) demonstrate that the proposed system can effectively gather vibration data in a built environment and operate in a standard fashion by transmitting all data remotely toward cloud-base backend or, conversely, perform intelligent pattern recognition tasks directly on the end device with accurate performance levels and reduced latency. We may therefore conclude that the proposed solution could represent a versatile and promising alternative to traditional vibration monitoring systems.

**Abstract**—Sequence recommendation systems have become increasingly popular in various fields such as movies and social media. These systems aim to predict a user's preferences and interests based on their past behavior and provide them with personalized recommendations. Deep learning, particularly Recurrent Neural Networks (RNNs), have emerged as a powerful tool for sequence recommendation. In this research, we explore the effectiveness of RNNs in movie and Instagram recommendation systems. We investigate and compare the performance of different types of RNNs, such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), in recommending movies and Instagram posts to users based on their browsing history. Additionally, we study the impact of incorporating additional information such as user's demographics and Instagram hashtags on the performance of the recommendation system. We also evaluate the performance of RNN-based movie and Instagram recommendation systems in comparison to traditional approaches, such as collaborative filtering and content-based filtering, in terms of accuracy and personalization. The findings of this research provide insights into the effectiveness of RNNs in movie and Instagram recommendation systems and contribute to the development of more accurate and personalized recommendations for users

**Keywords**—Long short-term memory (LSTM) and gated recurrent unit (GRU); RNN; deep learning; recommendation systems

## I. INTRODUCTION

Sequence recommendation systems have become increasingly popular in various fields, such as movies and social media. These systems aim to predict a user's preferences and interests based on their past behavior and provide them with personalized recommendations. One of the most promising approaches for sequence recommendation is deep learning, which has been shown to be effective in capturing the complex patterns and dependencies in sequential data.

Sequence recommendation systems have become an important area of research in recent years due to the growing amount of sequential data available in various fields such as music, videos, e-commerce, and social media. These systems aim to predict a user's preferences and interests based on their past behavior and provide them with personalized recommendations. Traditional approaches to sequence recommendation, such as collaborative filtering and content-based filtering, have been shown to be effective to some extent. However, they are limited in their ability to capture the complex patterns and dependencies in sequential data.

Deep learning, particularly Recurrent Neural Networks (RNNs), have emerged as a powerful tool for sequence recommendation. RNNs are particularly suitable for this task as they are able to model the temporal dependencies in the user's browsing history. Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) are two popular types of RNNs that have been widely used in sequence recommendation systems. LSTMs have been shown to be effective in capturing long-term dependencies in sequential data, while GRUs have been shown to be more computationally efficient.

Recent research has explored the application of RNNs in movie and Instagram recommendation systems. For example, researchers have used RNNs to model user's browsing history and predict their preferences for movies. Other researchers have used RNNs to model user's interactions on Instagram and recommend posts based on their interests. However, there is still a need to further investigate the effectiveness of RNNs in these systems and explore how incorporating additional information such as user's demographics, and Instagram hashtags can improve the performance of the recommendation system.

This research aims to fill this gap by exploring the effectiveness of RNNs in movie and Instagram recommendation systems and investigating the impact of incorporating additional information on the performance of the system. The findings of this research will contribute to the development of more accurate and personalized recommendations for users.

The vast amount of sequential data available in these domains, such as users browsing history, provides an opportunity for recommendation systems to offer personalized recommendations to users. However, despite the growing interest in using RNNs for sequence recommendation, there is still a lack of understanding of how well they perform in these specific domains and how to effectively incorporate additional information to improve the performance of the system. In particular, traditional approaches such as collaborative filtering and content-based filtering have been shown to be effective to some extent, but they are limited in their ability to capture the complex patterns and dependencies in sequential data, while RNNs, specifically LSTMs and GRUs, have shown to be promising in modeling temporal dependencies. This research aims to explore the effectiveness of RNNs in movie and Instagram recommendation systems by comparing the performance of different types of RNNs, and investigate the impact of incorporating additional information such as

user's demographics and Instagram hashtags on the performance of the recommendation system. Additionally, the research aims to compare the performance of RNNs-based movie and Instagram recommendation systems with traditional approaches in terms of accuracy and personalization.

In this research paper, we will focus on exploring the effectiveness of Recurrent Neural Networks (RNNs) in movie and Instagram recommendation systems. Movie recommendation is a challenging task because of the large number of movies available, the diversity of genres, and the dynamic nature of user preferences. Similarly, Instagram recommendation is a challenging task because of the large number of posts and users available, the diversity of content and the dynamic nature of user preferences. RNNs are particularly suitable for these tasks as they are able to model the temporal dependencies in the user's browsing history. We will investigate and compare the performance of different types of RNNs, such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), in recommending movies and Instagram posts to users. Additionally, we will also explore the impact of incorporating additional information such as user's demographics, and Instagram hashtags on the performance of the recommendation system.

The research in this paper will provide insights into the effectiveness of RNNs in movie and Instagram recommendation systems and contribute to the development of more accurate and personalized recommendations for users. The objectives of this research are as follows:

- To investigate and compare the performance of different types of Recurrent Neural Networks (RNNs), such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), in recommending movies and Instagram posts to users based on their browsing history.
- To study the impact of incorporating additional information such as user's demographics and Instagram hashtags on the performance of the recommendation system.
- To provide insights into the effectiveness of RNNs in movie and Instagram recommendation systems and contribute to the development of more accurate and personalized recommendations for users.
- To identify any limitation that the proposed RNN-based recommendation systems may have, and propose potential solutions to overcome them.

The paper is divided into five sections, which are organized as follows. The first section is the introduction, which provides an overview of the research topic and the research questions that the paper aims to address. In this section, the paper also provides background information on the topic and explains the significance of the research. The second section is the related work, which reviews the existing literature on the research topic. This section provides an overview of the key findings and ideas from previous research and explains how these findings relate to the research

questions addressed in the paper. The third section is the methodology, which explains the research design and methods used to collect and analyze the data. This section provides detailed information on the research participants, data collection procedures, and data analysis techniques. The fourth section is the results, which presents the findings of the research. This section provides an overview of the key findings, including any statistical analyses that were performed, and discusses the implications of the findings for the research questions. The fifth and final section is the conclusions, which summarizes the key findings of the research and draws conclusions about the research questions. This section also discusses the limitations of the research and suggests directions for future research.

## II. RELATED WORK

Algorithms help recommender systems make personalised suggestions. These systems now use artificial intelligence-based machine learning. The literature mentions various machine learning algorithms for recommender systems, making it hard to choose one. Recommender system researchers know nothing about algorithm usage. Developing recommender systems with machine learning algorithms often encounters issues. This paper [1] analysed machine learning research on recommender systems, identifying gaps and suggesting future research. This study aims to help new researchers appropriately situate their research by identifying trends in the use or study of machine learning algorithms in recommender systems and unresolved difficulties. Current categories of recommender systems are identified, selected machine learning techniques are characterised, big data technologies are discussed, different types of machine learning algorithms and their best domains are identified, and both major and alternative performance metrics are investigated.

Online stores increasingly use recommendation systems. Current recommendation algorithms are good at optimising a single task (such as click-through rate prediction) based on users' historical click sequences, but they don't model users' multiple behaviours or jointly optimise multiple objectives (such as both CTR and Conversion rate), which are crucial for e-commerce sites. This research suggested that multi-task learning and user interests based on a wide range of behaviours are needed to make meaningful progress towards multiple goals at once. This study [2] introduced Deep Multifaceted Transformers (DMT), a system that uses many Transformers to express multiple user behaviour sequences. "Multi-gate Mixture-of-Experts" does this.

Sequential recommendation research is growing. This study [3] recommends media and online products to customers based on their past behaviour and interests. Recent machine learning algorithms for sequential recommendation use deep learning and Transformers. In view of the surprising competitive performance of basic nearest-neighbor algorithms for session-based recommendation, the author examined nearest-neighbor techniques for sequential recommendation challenges. For two of four datasets, nearest-neighbor approaches outperformed the Transformer-based BERT4REC algorithm. Deep learning surpasses the simpler approaches for

the two bigger datasets, supporting the idea that neural methods improve with data.

A common recommendation situation made attainable by the internet has greatly enhanced user data collection. Authors can predict the user's next action by evaluating latent heterogeneous collaborative signals and sequential patterns. Sequential recommendation approaches and heterogeneous information network-based methods worsen the common data sparsity problem [4]. This innovative Sequence-aware Heterogeneous graph neural Collaborative Filtering (SHCF) model solves these problems by considering both high-order heterogeneous collaborative signals and sequential information.

Recent scholars have focused on sequential recommender systems, a nascent field (SRSs). SRSs model sequential user behaviours, user-thing interactions, and the temporal evolution of user preferences and item popularity, unlike collaborative filtering and content-based filtering. SRSs characterise user settings to provide more accurate, tailored, and dynamic recommendations. Researchers are becoming interested in sequential recommender systems (SRSs). SRSs represent and interpret sequential user behaviours, object-user interactions, and the time evolution of user preferences and item popularity, unlike collaborative filtering and content-based filtering. SRSs leverage the above attributes to better reflect user settings, interest and goals, and item consumption behaviour to deliver more accurate, tailored, and adaptable suggestions. This study [5] explained SRSs. Author defined SRSs, analysed and classified the most significant difficulties in this field, and reviewed SRS research progress, including present and past successes. Lastly, the author proposed intriguing study directions for this emerging discipline trend in such items consumption and your goals. This research introduces SRSs thoroughly. Author defined SRSs, evaluated and categorised the most urgent issues facing this area of study, and then examined SRS research progress, including the most recent and typical triumphs in this subject. Finally, the author suggests prospective research areas in this dynamic field.

DL-based sequential suggestion models have surpassed Markov chain-based and factorization-based methods in recent years. Yet, a reliable DL model for sequential recommendation has been shockingly neglected. This work [6] addresses deep learning-based sequential recommender systems for these difficulties. This study summarised the main factors that affect the performance of DL-based models and performed corresponding evaluations to showcase and demonstrate their effects. It also illustrated sequential recommendation, proposed a categorization of existing algorithms into three types of behavioural sequences, and demonstrated the effects of these factors. Finally, the author examined the sector's opportunities and challenges.

Sequential recommendation systems leverage user behaviour to anticipate preferences. Due to data paucity, this [7] strategy may not work as well in practise. This study introduced counterfactual data augmentation to help sequential recommendation algorithms overcome incomplete training data. The sampler and anchor models comprise this architecture. Anchor models train the final recommendation

list using both observed and produced sequences, whereas sampler models develop new user behaviour sequences based on the observed ones. This sampling method asks what a customer might buy if her recent purchases were different. Author used two learning-based methods to create the sampler model and increase output sequence quality while training the anchor model. To flesh out the image, the author theoretically evaluated how the generated sequences affected the anchor model, finding a balance between information and noise. This method was evaluated on nine real-world datasets, proving its usefulness and generalizability.

Recommender systems are increasingly used. Amazon and eBay offer millions of products for customers. Buyers can choose from a huge selection of products online. This increased level of personalization requires buyers to sift through a lot of company data. Recommendation systems can help manage this information overload. Conventional recommender systems use prior activities and profiles to provide recommendations. Deep learning methods have performed well in many situations. Yet, deep learning applications in recommendation systems have not been extensively studied. This tutorial's first segment introduced recommender systems and deep learning. In the following chapters, this study [8] reviewed and critiqued many state-of-the-art deep recommendation systems.

Due to the volume of products and consumers' changeable tastes, fashion-focused e-commerce businesses need recommendation engines. Since most users browse anonymously, historical preference data is rarely available, therefore suggestions can only be based on current session data. Dressipi rented 1.1 million fashion e-commerce sessions over 18 months for the 2022 ACM RecSys competition. Predicting a consumer's basket by session's conclusion was the goal [9]. All sessions are private and never save user data to replicate a real-world production setting. This article describes author's solution. Self-supervised learning inspired the Transformer design with dual learning goals to boost generalisation.

Online service domains are increasingly using sequential suggestion. It models consumer tastes based on past behaviour to predict spending. Real-world systems may capture massive amounts of user activity. This vast dataset can reveal consumer preferences. Hence, past programmes have largely recommended future behaviour based on observed patterns. Due to past experiences influencing current choices, sequential data may not be fully utilised. Real-world systems need speed, thus it's no longer practical to watch user behaviour before making conclusions. The Dynamic Memory-based Attention Network, a revolutionary long-sequence-based recommendation model, addresses this issue (DMAN). It breaks down the user's prior behaviour, trains the model, and saves memory blocks to preserve their preferences. DMAN dynamically splits each user's long-term interests into memory blocks to minimise auxiliary reconstruction loss and maximise memory integrity. Dynamic memory prepares the user's immediate and delayed preferences for a single set of suggestions. Empirical results reveal that this work [10] outperforms state-of-the-art sequential models on four benchmark datasets in capturing long-term dependencies.

User modelling using sequential suggestion reverses the user's interaction history to determine preferences. Such techniques require solid datasets with real sequential information for evaluation. This study [11] examines the timestamps of several major datasets and finds no meaningful sequential order. The datasets show that multiple user interactions occur at the same time. The dialogue between the parties is only semi-sequential. A leading sequential recommender performs similarly when encounters are randomly reordered. This page discusses Cinema Lens. Authors have noticed that sequential recommenders require new datasets with better sorting.

RNNs model sequences well. They can be enlarged, hold different types of information, and account for time. They're great at making sequential recommendations. This study [12] adds Recommender System considerations to Recurrent Neural Networks. The recommendation recipient's clear image is one such aspect. Author demonstrated how a novel Gated Recurrent Unit may efficiently represent consumers and their consumption habits to make personalised buy recommendations. These upgrades outperformed state-of-the-art recommender algorithms and a baseline Recurrent Neural Network in offline tests on two real-world datasets.

Sequential recommenders struggle to predict user behaviour as they move from recommendation to recommendation. "Cold-start" consumers with few real-world encounters are the problem. The difficulty of learning sequential patterns over consumers with few encounters will diminish the predictive power of sequential recommendation algorithms. MetaTL, a novel framework that models user transitions using meta-learning, improves sequential suggestion for novice users [13]. In particular, MetaTL 1 formulates sequential recommendation for cold-start users as a few-shot learning problem, extracts dynamic transition patterns among users with a translation-based architecture, and uses meta transitional learning to enable fast learning for cold-start users with limited interactions, resulting in accurate inference of sequential interactions.

In e-commerce, the ability to recommend products based on previous purchases can boost income. Most recommender systems ignore reviews, which include a wealth of information about the user's tastes. This study [14] compares 10 RNN architectures to make user-evaluated suggestions. We have explored and built multi-stacked bi-directional Gated Recurrent Units (GRUs), Long Short-Term Memory (LSTMs), and other RNN architectures.

Information overload necessitates recommendation systems. It may reduce research time by offering recommendations and forecasts based on user behaviour. More deep learning research uses deep neural networks. This study [15] introduced recommendation systems and deep learning algorithms. Each recommendation system is detailed and linked to its data sets. This paper's 2014–2017 citations provide a current overview.

Due to the sheer volume of online information, users may have trouble filtering, prioritising, and communicating pertinent material. Recommender systems employ real-time data to make customised recommendations. This study [16]

presents a smart clothing recommendation system to address the increased demand for customised outfits. Transfer learning extracts cosine similarity data from product photos to customise recommendations. In an online clothes store, the author exploited this. Displaying photos that are 80% or more like the user's product solves the personalised suggestion problem.

User modelling powers online recommendation systems. CF approaches are widely used to model customers' long-term preferences. Recurrent neural networks (RNN) have improved short-term customer choice prediction. Mixing long- and short-term models strengthens suggestions. Previous methods neglected dynamically merging these two user modelling paradigms. Traditional RNN structures like Long Short-Term Memory (LSTM) can handle linguistic and visual input, but they need to be improved to account for user behaviour. This study [17] proposes a time-aware and content-aware controller to improve RNN architecture by incorporating contextual information during state transitions.

Matching, or detecting if a document is relevant to a user's search query or interest level, is a major difficulty in search and recommendation. Machine learning, or "learning to match," has been applied to the issue using input representations and labelled data. Deep learning algorithms have been investigated to improve search and recommendation matching performance. Deep learning for matching has become the search and recommendation standard due to an unprecedented data influx, powerful computational resources, and cutting-edge deep learning techniques. Deep learning must learn representations and generalise data-matching patterns for this investigation [18].

Internet information overload? Recommendation systems support. With their extensive use in online applications and ability to mitigate over-choice issues, recommender systems are invaluable. Deep learning has performed well in recent years and can learn feature representations from scratch, attracting academics from many domains. Deep learning has been effectively used to information retrieval and recommender system studies, expanding its influence. Deep learning in recommender systems is growing. This work [19] aimed to review recent deep learning studies on recommender systems. The author assessed current methodologies and provided a taxonomy of deep learning-based recommendation models. Lastly, author added additional insights into this amazing development.

In recent years, deep learning has outperformed Markov chain and factorization-based sequential recommendation models. However, DL-based approaches have substantial limitations, such as inadequate user representation modelling and a failure to discriminate between user behaviour and object interactions. This research [20] addressed these concerns with sequential recommender systems built on DL. Examples of sequential recommendations, a categorization of existing algorithms based on three behavioural sequences, factors impacting DL-based model performance, and matching experiments are shown. Finally, author mapped out the future paths and problems of this discipline.

In this study [21], author describes five previously untested ways for strengthening deep learning-based top-n suggestions. A "Collaborative Memory Network" uses the latent component model and neighborhood-based algorithms to collaborative filter using implicit input, inspired by the Memory Network. Next, the author presented Neural Semantic Personalized Ranking, a probabilistic generative modelling approach that combines deep neural networks with paired rankings to solve this problem. Finally, author suggested adding a context-driven attention technique to Attentive Contextual Denoising Auto encoder for unstructured user and product data. The author created the context-aware Neural Citation Network using a flexible encoder-decoder architecture. This system uses an effective max time delay neural network encoder, attention mechanism, and author networks. To finish up, author proposed a general framework for natural language processing-based user preference inference utilising transfer learning for movie choices during conversation.

As internet data grows, recommender systems help manage information overload. Recommender systems are prevalent in online applications and can solve many difficulties caused by too many choices. Deep learning's amazing performance and the enticing property of learning feature representations from scratch have gained a lot of attention from a broad array of academics in disciplines including computer vision and natural language processing in recent years. Lately, deep learning has also had an effect on the research of recommendation and information retrieval systems, indicating its utility in this arena. The use of deep learning to recommender systems is a rapidly emerging subject at the moment. This study's [22] main purpose was to give readers with a comprehensive evaluation of the current findings from works on deep learning recommender systems. This publication provided an extensive overview of deep learning-based recommendation models and a taxonomy for grouping them.

As the number of individuals with Internet access grows, as does the need for personalised experiences and the speed at which people's online habits change, recommender systems have become a viable way to sort through massive volumes of data to find the most relevant results. Modern recommender systems produce useful recommendations but have accuracy, scalability, and cold-start concerns. Deep learning and other modern machine learning techniques, used for a wide range of complicated tasks, have been applied to recommender systems to improve their recommendations. For beginners, this study [23] analysed deep learning-based recommendation systems in detail. Author evaluated literature on deep learning models for recommender systems, obstacles, recommendation domain knowledge, and function. The author quantified all relevant studies and analysed these findings and ideas for additional investigation.

YouTube is a leading recommendation system. This study [24] provided a system overview and highlighted deep learning's efficiency gains. The research describes two unique deep candidates generating and ranking algorithms, and it does so in accordance with the standard two-stage paradigm for the retrieval of data. Author shared the expertise that

author earned via the process of planning, creating, and maintaining a big recommendation system that has a discernible impact on end users.

The area of machine learning had substantial success in several domains [25]–[27] and as a whole it has been dramatically changed by the emergence of deep learning. To be sure, its impact on the area of recommender systems wasn't immediately apparent. Yet, it was significant. This paper [28] discussed Netflix's issues employing deep learning for recommender systems and the lessons learned. Author first listed all Netflix suggestion-related occupations. Author found that different model designs work in different settings. Despite the fact that many deep-learning models may be considered as extensions of preexisting (basic) recommendation algorithms, author did not originally find large increases in performance over well-tuned alternatives that did not apply deep learning. Many deep-learning models are extensions of current approaches, although not all. Deep learning models were ineffective until the author added a significant number of characteristics from several heterogeneous data sources. Deep learning can worsen offline-online metrics misalignment, according to authors. Deep learning improved this recommendation by old and current metrics. This happened after author fixed deep learning issues.

### III. PROPOSED METHODOLOGY

The proposed model for this study is a Recurrent Neural Network (RNN) based movie and Instagram recommendation system. The model will consist of three main components:

- An encoder that processes the user's browsing history and extracts relevant features. This component will likely use a type of RNN, such as LSTM or GRU, to capture the temporal dependencies in the user's browsing history.
- An attention mechanism that assigns a weight to each feature based on its relevance to the user's preferences. This component will help the model to focus on the most important features of the user's browsing history.
- A decoder that generates recommendations based on the encoded features and attention weights. This component will likely use a type of RNN, such as LSTM or GRU, to generate the recommendations.

RNNs are powerful tools for processing sequential data such as time series, natural language, and user behavior. They can capture the temporal dependencies and patterns within the sequences and use that information to make predictions. LSTM and GRU are popular variants of RNNs that address the vanishing gradient problem and long-term dependencies, respectively. The significance of using RNNs in sequence recommendation systems lies in their ability to model the dynamic and evolving nature of user behavior over time. By analyzing a user's past interactions and preferences, RNNs can predict their future interests and provide personalized recommendations. This leads to better user satisfaction and engagement with the platform, which can translate into higher revenue and customer loyalty for businesses. Furthermore, RNNs can incorporate additional features such as user

demographics and context-specific information to improve the accuracy and personalization of recommendations. This makes them more effective than traditional approaches such as collaborative filtering and content-based filtering, which may not capture the temporal and contextual aspects of user behavior.

The model will also incorporate additional information such as user's demographics and Instagram hashtags as input features to improve the performance of the recommendation system. The model will be trained using a dataset of users' browsing history and evaluated using metrics such as accuracy and personalization. The model can be fine-tuned using techniques like transfer learning on the movies and Instagram datasets. Fig. 1 shows the proposed flowchart of current study:

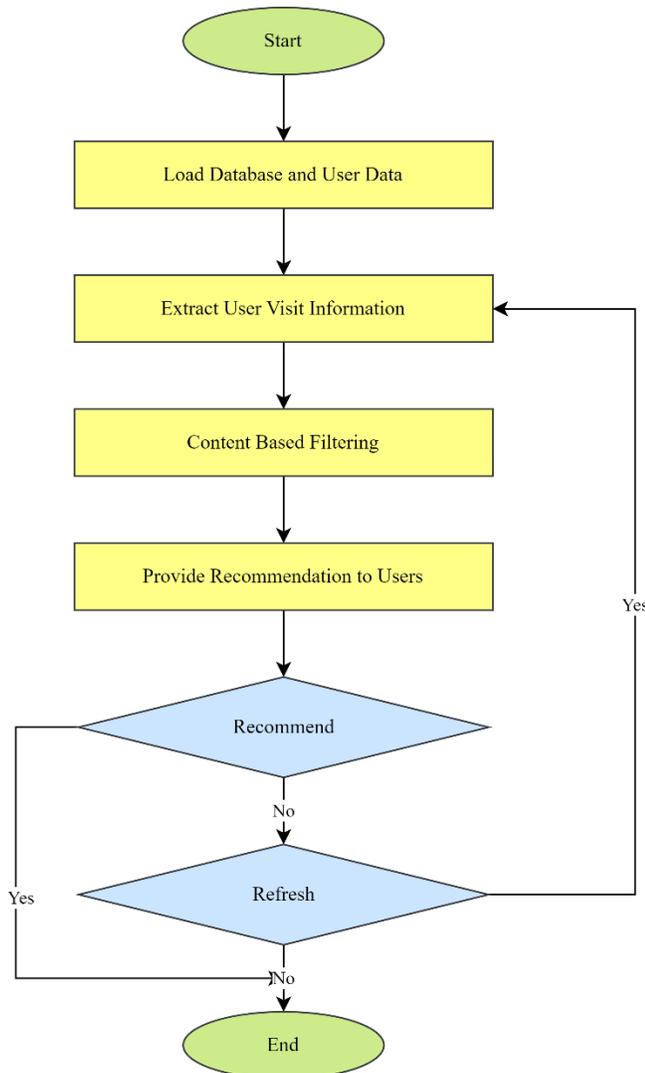

Fig. 1. Proposed flowchart of current study

#### A. Recurrent Neural Network (GRU, LSTM)

Recurrent Neural Networks (RNNs) are a type of neural network that are particularly well suited for processing sequential data. Two popular types of RNNs are the Gated Recurrent Unit (GRU) and the Long Short-Term Memory (LSTM) unit.

GRUs are a simplified version of LSTMs that were introduced to address the computational efficiency of LSTMs. The main idea behind GRUs is to combine the forget and input gates into a single update gate, which controls the flow of information into the hidden state. The hidden state in a GRU is updated using the following equations:

$$z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z)$$

$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r)$$

$$h'_t = \tanh(W_h x_t + U_h (r_t * h_{t-1}) + b_h)$$

$$h_t = (1 - z_t) * h_{t-1} + z_t * h'_t$$

Where  $x_t$  is the input at time step  $t$ ,  $h_t$  is the hidden state at time step  $t$ ,  $W_z, W_r, W_h, U_z, U_r, U_h$  are the weight matrices and  $b_z, b_r, b_h$  are the bias vectors,  $\sigma$  is the sigmoid function, and  $*$  denotes element-wise multiplication.

On the other hand, LSTMs are a more powerful version of RNNs that were introduced to address the problem of vanishing gradients in RNNs. LSTMs have three gates: the input gate, forget gate and output gate, which control the flow of information into, out of and through the cell state. The cell state in an LSTM is updated using the following equations:

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i)$$

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f)$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o)$$

$$c'_t = \tanh(W_c x_t + U_c h_{t-1} + b_c)$$

$$c_t = f_t * c_{t-1} + i_t *$$

$$c'_t h_t = o_t * \tanh(c_t)$$

Where  $x_t$  is the input at time step  $t$ ,  $h_t$  is the hidden state at time step  $t$ ,  $c_t$  is the cell state at time step  $t$ ,  $i_t, f_t, o_t$  are the input, forget and output gates,  $W_i, W_f, W_o, W_c, U_i, U_f, U_o, U_c$  are the weight matrices and  $b_i, b_f, b_o, b_c$  are the bias vectors,  $\sigma$  is the sigmoid function, and  $*$  denotes element-wise multiplication.

#### B. Convolutional Neural Network

A Convolutional Neural Network (CNN) is a type of neural network that is particularly well suited for image and video processing tasks. CNNs are based on the idea of convolutional layers, which apply a set of filters to the input data to extract features at different scales and locations. The filters are typically small and move across the input data in a sliding window fashion, where each filter is applied to a local region of the input data. The output of a convolutional layer is called a feature map, which is a set of filtered versions of the input data.

The basic equation for a convolutional layer is the following:

$$output(i, j, k) = bias(k) + \sum (input(i + p, j + q) * weight(p, q, k))$$

Where  $output(i, j, k)$  is the value of the output feature map at position  $(i, j)$  and channel  $k$ ,  $input(i, j)$  is the value of the input feature map at position  $(i, j)$ ,  $weight(p, q, k)$  is the weight of the filter at position  $(p, q)$  and channel  $k$ , and  $bias(k)$  is the bias for channel  $k$ . The summation is over the filter size  $(p, q)$ .

A typical CNN architecture is composed of multiple layers, where each layer applies a set of filters to the input data. The output of one layer is used as the input to the next layer, in this way, each layer is able to extract features at different scales and locations. Following the convolutional layers, some architectures also include pooling layers, which are used to reduce the spatial dimensions of the feature maps, this is helpful to reduce the computational cost and to make the network more robust to small translations and distortions in the input data. Commonly used pooling operation are max-pooling and average-pooling.

Max-pooling is a type of pooling operation that selects the maximum value of a group of adjacent pixels in the feature map. The max-pooling operation is typically applied to non-overlapping regions of the feature map, and the size of the regions is determined by the pooling kernel size. The equation for max-pooling is the following:

$$output(i, j, k) = \max(input(is:is + k, js:js + k, k))$$

Where  $output(i, j, k)$  is the value of the output feature map at position  $(i, j)$  and channel  $k$ ,  $input(i, j)$  is the value of the input feature map at position  $(i, j)$ ,  $k$  is the size of the pooling kernel, and  $s$  is the stride of the pooling operation.

Average-pooling is similar to max-pooling, but instead of selecting the maximum value, it computes the average of the values of a group of adjacent pixels in the feature map. The equation for average-pooling is the following:

$$Output(i, j, k) = \text{mean}(input(is:is + k, js:js + k, k))$$

Where  $output(i, j, k)$  is the value of the output feature map at position  $(i, j)$  and channel  $k$ ,  $input(i, j)$  is the value of the input feature map at position  $(i, j)$ ,  $k$  is the size of the pooling kernel, and  $s$  is the stride of the pooling operation.

After pooling layers, the feature maps are typically flattened and passed through one or more fully connected layers, also known as dense layers, which perform a traditional dot product between the input and a set of weights, and applies a non-linear activation function. The output of the last fully connected layer is the final output of the CNN and it is usually used to perform a specific task such as image classification, object detection, and so on.

The equation for a fully connected layer is the following:

$$output = \text{activation}(W * input + b)$$

Where  $output$  is the output of the fully connected layer,  $input$  is the input to the fully connected layer (which is the flattened feature map from the previous layer),  $W$  is the weight matrix,  $b$  is the bias vector and  $\text{activation}$  is the non-linear activation function applied to the output, examples of activation functions are ReLU, sigmoid, and Softmax.

### C. Transformer

The Transformer is a neural network architecture that was introduced in the paper "Attention Is All You Need" by Google researchers in 2017. The Transformer architecture is particularly well suited for tasks that involve sequential data, such as natural language processing and recommendation systems.

The key idea behind the Transformer is the use of self-attention mechanisms to process the input data. Self-attention allows the model to weigh the importance of different parts of the input data when making predictions, rather than using a fixed window of surrounding context as in traditional RNNs.

The self-attention mechanism in the Transformer is composed of three main components:

The query matrix (Q), which represents the input data.

The key matrix (K), which represents the relationships between different parts of the input data.

The value matrix (V), which represents the output data.

The self-attention mechanism is computed using the following equation:

$$Attention(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\text{sqrtd}_k}\right) * V$$

Where Q, K, and V are the query, key, and value matrices,  $d_k$  is the dimension of the key matrix, and  $\text{sqrtd}_k$  is used to scale the dot product between the query and key matrices. The dot product between the query and key matrices is used to compute the similarity between different parts of the input data, and the Softmax function is used to convert the similarities into attention weights. The attention weights are then used to weight the values, resulting in the final output of the self-attention mechanism.

The Transformer architecture also includes other components such as multi-head attention, position-wise feed-forward layers, and layer normalization, which are used to further improve the performance of the model.

### D. Significance of Sequence Recommendation

Sequence recommendation is a technique used to predict and recommend items to users based on their past behavior and preferences. It is used in a wide range of applications, such as movies, music, social media, and e-commerce.

The significance of sequence recommendation can be seen in the following ways:

1) *Personalization*: Sequence recommendation allows for the creation of personalized recommendations for each user based on their individual preferences and behavior. This can lead to higher engagement and satisfaction for the users.

2) *Increased sales and revenue*: By providing personalized recommendations, sequence recommendation systems can help increase sales and revenue for businesses by guiding users to products and services that they are more likely to be interested in.

3) *Improved user experience*: Sequence recommendation can improve the user experience by providing users with relevant and interesting content, reducing the time and effort required to find relevant items, and increasing the likelihood of users finding what they are looking for.

4) *Increased retention*: By providing personalized and relevant recommendations, sequence recommendation systems can help increase user retention, as users are more likely to keep coming back to the platform if they find it relevant and useful.

5) *Better understanding of user behavior*: By analyzing the data from sequence recommendation systems, businesses and organizations can gain a better understanding of user behavior and preferences, which can help inform future product development and marketing strategies.

#### E. Dataset (movielens)

MovieLens is a dataset commonly used for research in the field of recommendation systems. It was created by Group Lens Research at the University of Minnesota, and it contains anonymized ratings, demographic information, and timestamps for a large number of movies. The dataset is available in several different sizes, including a small dataset with 100,000 ratings and 1,300 tag applications applied to 9,000 movies by 700 users, a medium-sized dataset with 1 million ratings and 6,000 tag applications applied to 10,000 movies by 7,000 users, and a large-sized dataset with 20 million ratings and 46,000 tag applications applied to 27,000 movies by 138,000 users. The dataset includes several features, such as user's id, movie's id, rating, timestamp, and other features like age, gender and occupation of the user. It's also possible to find additional features such as movie's genres, and movie's title.

#### F. Dataset (Instagram)

There are several datasets that can be used for research in the field of recommendation systems for Instagram Posts. Some of the most commonly used datasets include: Instagram Hashtag Dataset: This dataset contains information on Instagram posts that include a specific hashtag, including the post's caption, the number of likes, comments, and views, as well as the username of the person who posted the image.

#### G. Content-Aware Hierarchical Point-of-Interest Embedding

Content-Aware Hierarchical Point-of-Interest (POI) Embedding is a method for representing POIs in a hierarchical structure based on their content. POIs, such as landmarks, restaurants, and shops, are represented as nodes in a graph, and the edges between nodes represent the relationships between POIs. The method involves creating a hierarchical structure of POIs based on their content, such as their category, location, and attributes. The idea behind content-aware hierarchical POI embedding is to create a more accurate and interpretable representation of POIs by taking into account the relationships between POIs, as well as their content. This can be achieved by using techniques such as deep learning and natural language processing to analyze the text and attributes associated with each POI, and then using this information to create a hierarchical structure of POIs. The main advantage of

content-aware hierarchical POI embedding is that it allows for more accurate and interpretable recommendations, as it takes into account the relationships between POIs, as well as their content. Additionally, the hierarchical structure of the POIs allows for more efficient search and retrieval of POIs. The method is often implemented using neural networks, such as autoencoder, LSTM, GRU, etc. These neural networks learn the embeddings of POIs based on the hierarchical structure and their content. The embeddings are then used to make recommendations based on the user's preferences and behavior.

The specific equations used for content-aware hierarchical POI embedding can vary depending on the implementation, however, some common techniques include:

**Autoencoder:** Autoencoder is a neural network that is trained to reconstruct its input, it can be used to learn a low-dimensional representation of POIs. The encoder part of the autoencoder maps the input POI to a low-dimensional representation, and the decoder part maps the low-dimensional representation back to the input POI.

The encoder equation is:

$$z = f(Wx + b)$$

Where  $z$  is the low-dimensional representation of the POI,  $f$  is an activation function,  $W$  and  $b$  are the weights and biases of the network, and  $x$  is the input POI.

The decoder equation is:

$$x' = g(W'z + b')$$

Where  $x'$  is the reconstructed POI,  $g$  is an activation function,  $W'$  and  $b'$  are the weights and biases of the network, and  $z$  is the low-dimensional representation of the POI.

**Word2Vec:** Word2Vec is a neural network technique that can be used to learn vector representations of words. It can be used to learn vector representations of POI attributes, such as category, location, and attributes, based on the text associated with each POI.

The main equation in the Word2Vec model is:

$$y' = W * x$$

Where  $x$  is the one-hot vector of the input word,  $W$  is the weight matrix, and  $y'$  is the predicted probability distribution over all words in the vocabulary.

**Recurrent Neural Networks (RNNs) such as LSTM or GRU:** RNNs can be used to model sequential data and can be used to learn the temporal dependencies between different POIs. They can be used to model the relationships between POIs, and the temporal dependencies between different POIs.

The main equation for LSTM is:

$$h_t = f(W_h * [h_{t-1}, x_t] + b_h)$$

Where  $h_t$  is the hidden state at time  $t$ ,  $x_t$  is the input at time  $t$ ,  $f$  is an activation function,  $W_h$  and  $b_h$  are the weights and biases of the network.

The main equation for GRU is:

$$r_t = \text{sigmoid}(W_r * [h_{t-1}, x_t] + b_r)$$

Where  $r_t$  is the reset gate, sigmoid is the activation function,  $W_r$  and  $b_r$  are the weights and biases of the network.

#### H. Model for Successive POI Recommendation

Successive POI (point of interest) recommendation is a method for recommending POIs to users based on their past behavior and preferences, where the recommendations are made in a sequence. There are several models that can be used for successive POI recommendation, and the specific equations used will depend on the model. Some popular models include:

Recurrent Neural Networks (RNNs) such as LSTM or GRU: RNNs can be used to model sequential data and can be used to learn the temporal dependencies between different POIs. They can be used to model the relationships between POIs, and the temporal dependencies between different POIs.

The main equation for LSTM is:

$$h_t = f(W_h * [h_{t-1}, x_t] + b_h)$$

Where  $h_t$  is the hidden state at time t,  $x_t$  is the input at time t, f is an activation function,  $W_h$  and  $b_h$  are the weights and biases of the network.

The main equation for GRU is:

$$r_t = \text{sigmoid}(W_r * [h_{t-1}, x_t] + b_r)$$

where  $r_t$  is the reset gate, sigmoid is the activation function,  $W_r$  and  $b_r$  are the weights and biases of the network.

Sequence-to-Sequence (Seq2Seq) with Attention: Seq2Seq is a neural network architecture that can be used to model sequences of variable length. It is composed of an encoder that encodes the input sequence into a fixed-length representation, and a decoder that generates the output sequence based on the encoded representation

The main equation for the encoder in Seq2Seq with Attention is:

$$h_t = f(W_h * [h_{t-1}, x_t] + b_h)$$

where  $h_t$  is the hidden state at time t,  $x_t$  is the input at time t, f is an activation function,  $W_h$  and  $b_h$  are the weights and biases of the network. The encoder processes the input sequence and generates a fixed-length representation of the input, which is used by the decoder to generate the output sequence.

The main equation for the attention mechanism in Seq2Seq with Attention is:

$$a_t = \text{softmax}(W_a * h_t)$$

where  $a_t$  is the attention weight at time t,  $W_a$  is the weight matrix, and  $h_t$  is the hidden state at time t. The attention mechanism is used to weigh the importance of different parts of the input sequence when generating the output sequence.

The main equation for the decoder in Seq2Seq with Attention is:

$$y_t = g(W_y * [s_{t-1}, c_t] + b_y)$$

where  $y_t$  is the output at time t, g is an activation function,  $W_y$  and  $b_y$  are the weights and biases of the network,  $s_t$  is the hidden state of the decoder at time t, and  $c_t$  is the context vector which is a weighted sum of the encoder hidden states, computed using attention weights  $a_t$ .

#### I. Content-Aware Successive Point-of-Interest Recommendation

Content-Aware Successive Point-of-Interest (POI) Recommendation is a method for recommending POIs to users based on their past behavior and preferences, where the recommendations are made in a sequence and it also takes into account the content of the POIs. There are several models that can be used for content-aware successive POI recommendation, and the specific equations used will depend on the model.

Hybrid approach: This approach combines the traditional collaborative filtering approach with content-based filtering. The main equation for this approach is:

$$R = \alpha * R_c + (1 - \alpha) * R_p$$

Where R is the final recommendation,  $R_c$  is the content-based recommendation,  $R_p$  is the collaborative-based recommendation, and  $\alpha$  is a weighting factor that determines the importance of each type of recommendation.

Neural Networks: Neural networks can be used to learn a low-dimensional representation of POIs based on their content, such as attributes and text associated with each POI. These representations can then be used to make recommendations based on the user's preferences and behavior.

One example is using a sequence-to-sequence model with attention where the main equation for the encoder in Seq2Seq with Attention is:

$$h_t = f(W_h * [h_{t-1}, x_t] + b_h)$$

Where  $h_t$  the hidden state at time t is,  $x_t$  is the input at time t, f is an activation function,  $W_h$  and  $b_h$  are the weights and biases of the network. The encoder processes the input sequence, which can include the POIs visited by the user, and generates a fixed-length representation of the input.

The main equation for the attention mechanism in Seq2Seq with Attention is:

$$a_t = \text{softmax}(W_a * h_t)$$

Where  $a_t$  the attention weight at time t is,  $W_a$  is the weight matrix, and  $h_t$  is the hidden state at time t. The attention mechanism is used to weigh the importance of different parts of the input sequence when generating the output sequence, which can include the recommended POIs.

The main equation for the decoder in Seq2Seq with Attention is:

$$y_t = g(W_y * [s_{t-1}, c_t] + b_y)$$

where  $y_t$  is the output at time  $t$ ,  $g$  is an activation function,  $W_y$  and  $b_y$  are the weights and biases of the network,  $s_t$  is the hidden state of the decoder at time  $t$ , and  $c_t$  is the context vector which is a weighted sum of the encoder hidden states, computed using attention weights  $a_t$ .

Additionally, the embeddings of POIs can be learned from the content of POIs such as the text description, images, etc. using neural networks such as CNN or autoencoder. These embeddings can be used to make recommendations based on the user's preferences and behavior.

### J. SM2M Model Structure

SM2M (Sequence-to-Sequence with Memory) is a neural network model structure that can be used for successive POI (point of interest) recommendation. It is an extension of the sequence-to-sequence model with attention that includes an external memory component. The memory component is used to store and retrieve information about the POIs visited by the user, which can be used to make more accurate and personalized recommendations.

The SM2M model structure consists of the following components:

1) *Encoder*: The encoder processes the input sequence, which can include the POIs visited by the user, and generates a fixed-length representation of the input.

2) *Memory*: The memory component is used to store and retrieve information about the POIs visited by the user. It can be implemented using a neural network such as a Long Short-Term Memory (LSTM) network or a Gated Recurrent Unit (GRU) network.

3) *Attention*: The attention mechanism is used to weigh the importance of different parts of the input sequence when generating the output sequence, which can include the recommended POIs.

4) *Decoder*: The decoder generates the output sequence based on the encoded representation and the information stored in the memory component.

The SM2M model is trained to predict the next POI in the sequence given the previously visited POIs and their attributes. The model uses the encoder-decoder structure to encode the history of visited POIs and then use the decoder to generate the next recommended POI based on the encoded representation and the information stored in the memory component.

Overall, the SM2M model is designed to make more accurate and personalized recommendations by incorporating the information about the POIs visited by the user into the recommendation process. Fig. 2 shows the SM2M Model architecture.

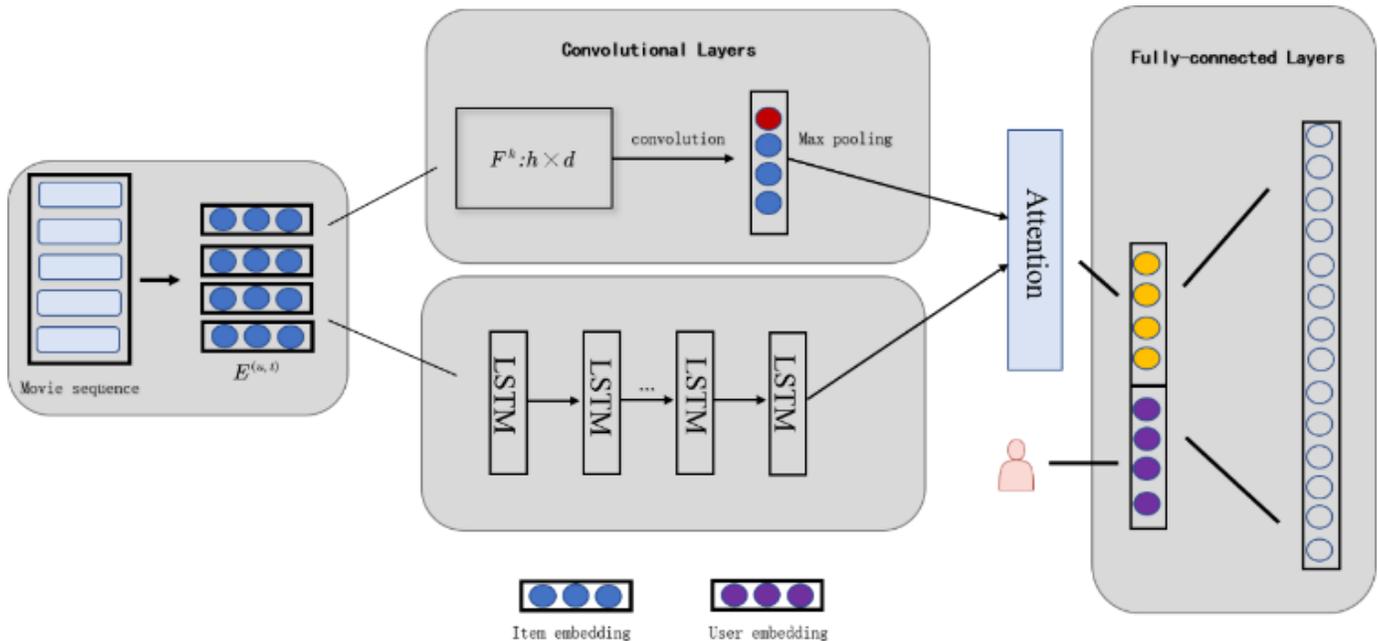

Fig. 2. SM2M model structure

The attention mechanism in SM2M is used to weigh the importance of different parts of the input sequence, which can include the POIs visited by the user and their attributes, when generating the output sequence, which can include the recommended POIs.

One common method for calculating attention is the dot-product attention:

$$a_t = \text{softmax}(h_t^T * W_a * h_m)$$

Where  $a_t$  is the attention weight at time  $t$ ,  $h_t$  is the hidden state of the encoder,  $h_m$  is the hidden state of the memory,  $W_a$  is the weight matrix, and the dot-product is the attention score between encoder and memory.

Another method is the multi-head self-attention:

$$q_i = W_q * h_i, k_i = W_k * h_i, v_i = W_v * h_i$$

$$a_i = \text{softmax}\left(q_i * \frac{k_i^T}{\text{sqrt}(d)}\right)$$

Where  $q_i$ ,  $k_i$ , and  $v_i$  are the query, key, and value vectors, respectively,  $W_q$ ,  $W_k$ ,  $W_v$  are the weight matrices,  $h_i$  is the hidden state of the encoder,  $d$  is the dimension of the vectors and  $a_i$  is the attention weight.

**Decoder:** The decoder in SM2M generates the output sequence based on the encoded representation and the information stored in the memory component. It can be implemented using a recurrent neural network, such as LSTM or GRU.

The main equation for LSTM decoder is:

$$h_d = f(W_d * [h_{d-1}, y_d, c_t] + b_d)$$

Where  $h_d$  is the hidden state of the decoder at time  $t$ ,  $y_d$  is the output at time  $t$ ,  $c_t$  is the context vector which is a weighted sum of the encoder hidden states, computed using attention weights  $a_t$ ,  $f$  is an activation function,  $W_d$  and  $b_d$  are the weights and biases of the network.

The main equation for GRU decoder is:

$$r_d = \text{sigmoid}(W_r * [h_{d-1}, y_d, c_t] + b_r)$$

Where  $r_d$  is the reset gate,  $\text{sigmoid}$  is the activation function,  $W_r$  and  $b_r$  are the weights and biases of the network.

### K. SP2P Model Structure

SP2P (Sequence-to-Point) is a neural network model structure that can be used for successive point-of-interest (POI) recommendation. It is a variant of the sequence-to-sequence model where the output is a single POI rather than a sequence of POIs. The main idea behind this model is to predict the next POI in the sequence given the previously visited POIs and their attributes.

The SP2P model structure consists of the following components:

**Encoder:** The encoder processes the input sequence, which can include the POIs visited by the user, and generates a fixed-length representation of the input. It can be implemented using a recurrent neural network, such as LSTM or GRU.

The main equation for LSTM encoder is:

$$h_t = f(W_h * [h_{t-1}, x_t] + b_h)$$

Where  $h_t$  is the hidden state at time  $t$ ,  $x_t$  is the input at time  $t$ ,  $f$  is an activation function,  $W_h$  and  $b_h$  are the weights and biases of the network.

The main equation for GRU encoder is:

$$r_t = \text{sigmoid}(W_r * [h_{t-1}, x_t] + b_r)$$

where  $r_t$  is the reset gate,  $\text{sigmoid}$  is the activation function,  $W_r$  and  $b_r$  are the weights and biases of the network.

**Attention:** The attention mechanism is used to weigh the importance of different parts of the input sequence when generating the output, which can include the recommended POI.

**Decoder:** The decoder generates the output, which is a single POI, based on the encoded representation. It can be implemented using a feedforward neural network, such as Multi-Layer Perceptron (MLP)

The main equation for the decoder is:

$$y = g(W_y * h_t + b_y)$$

Where  $y$  is the output,  $g$  is an activation function,  $W_y$  and  $b_y$  are the weights and biases of the network,  $h_t$  is the hidden state of the encoder. Fig. 3 shows SP2P model architecture.

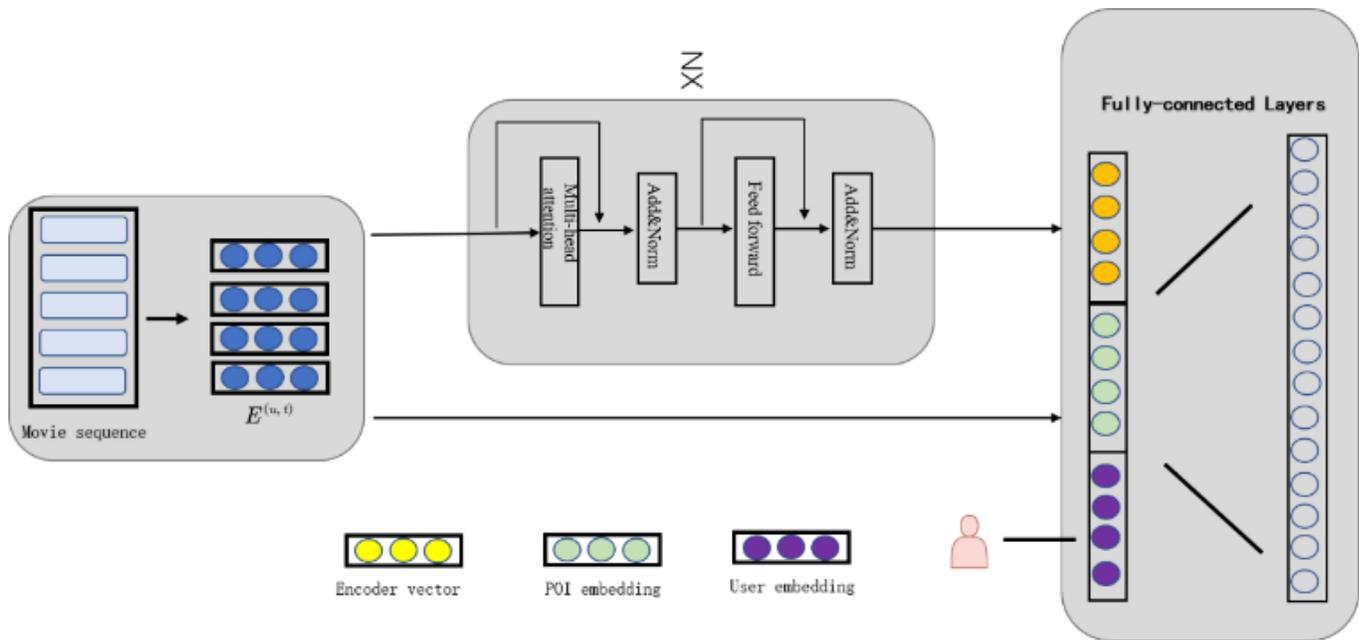

Fig. 3. SP2P model structure

#### IV. RESULTS AND DISCUSSIONS

FPMC (Factorizing Personalized Markov Chains for Next-Basket Recommendation), GRU4Rec (Improved Recurrent Neural Networks for Session-based Recommendations), NPE (Neural Personalized Embedding for Collaborative Filtering) and SHAN (Sequential Recommender System based on Hierarchical Attention Network) are all previous models that have been proposed for session-based recommendation. Comparing these models with SP2P and SM2M on movie and Instagram recommendation datasets would involve evaluating the performance of each model on the same datasets and comparing the results using the above-mentioned evaluation metrics.

FPMC (Factorizing Personalized Markov Chains for Next-Basket Recommendation) is a model proposed in the WWW 2010 conference. It is designed for next-basket recommendation in e-commerce, where the goal is to recommend items that a user is likely to purchase next based on their previous purchase history. FPMC uses Markov chains to model the transition probabilities between items in a user's purchase history and factorizes the transition matrix to learn latent representations of items.

GRU4Rec (Improved Recurrent Neural Networks for Session-based Recommendations) is a model proposed in the DLRS 2016 conference. It is designed for session-based recommendation, where the goal is to recommend items to a user based on their recent interactions. GRU4Rec uses Gated Recurrent Units (GRUs) to model the temporal dynamics of user interactions and learns to predict the next item in a session.

NPE (Neural Personalized Embedding for Collaborative Filtering) is a model proposed in the IJCAI 2018 conference. It is designed for collaborative filtering, where the goal is to recommend items to a user based on the preferences of similar

users. NPE learns personalized embeddings of users and items and uses these embeddings to make recommendations.

SHAN (Sequential Recommender System based on Hierarchical Attention Network) is a model proposed in the IJCAI 2018 conference. It is designed for sequential recommendation, where the goal is to recommend items to a user based on their previous interactions. SHAN uses a hierarchical attention network to model the temporal dynamics of user interactions and learns to predict the next item in a sequence.

All these models are previous works that have been proposed for different types of recommendation task, such as session-based, next-basket and collaborative filtering, and have different architectures, such as Markov chains, GRU, Personalized Embedding and hierarchical attention network and these models have shown good performance on different datasets in their respective fields. Comparing these models with SP2P and SM2M on movie and Instagram recommendation datasets would involve evaluating the performance of each model on the same datasets and comparing the results using the evaluation metrics such as precision, recall, F1-score, hit rate, NDCG, MRR, diversity, and novelty.

##### A. Performance of Models

Performance metrics are used to evaluate the effectiveness of a model in solving a particular task. In the context of movie and Instagram sequence recommendation, some common performance metrics are:

###### Recall:

$$\text{Recall} = \frac{(\text{Number of relevant items among top } n \text{ recommendations})}{(\text{Total number of relevant items})}$$

###### Normalized Discounted Cumulative Gain (NDCG):

$$NDCG = \frac{\left(\frac{\sum(z_i^{rel} - 1)}{\log_2(i + 1)}\right)}{(ideal_{DCG})}$$

where  $rel_i$  is the relevance of the  $i$ th item in the top- $n$  recommendations, and  $ideal_{DCG}$  is the ideal discounted cumulative gain computed by taking the maximum relevance for each position in the top- $n$  recommendations.

**Mean Reciprocal Rank (MRR):**

$$MRR = \frac{1}{n} * \left(\frac{1}{rank_1} + \frac{1}{rank_2} + \dots + \frac{1}{rank_n}\right)$$

Where  $rank_i$  is the rank of the first relevant item in the top- $n$  recommendations for the  $i$ th user.

Fig. 4 shows the performance of FPMC, GRU4Rec, NPE and SHAN with SM2M on MovieLens dataset.

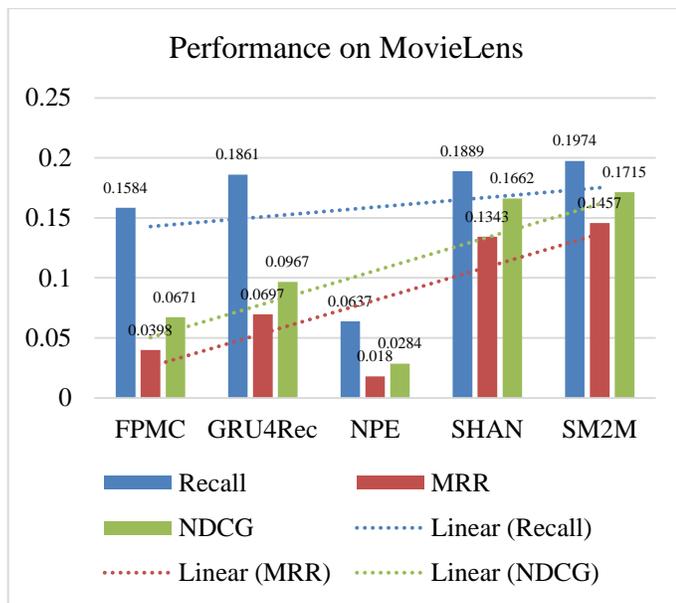

Fig. 4. Performance on movie lens

SM2M	0.1974	0.1457	0.1715	0.1341	0.0994	0.1160

FPMC (Factorizing Personalized Markov Chains), ST-RNN (Short-term Recurrent Neural Network), DRCF (Deep Recurrent Collaborative Filtering) and InfAM (Informative Attentive Model) are all previous models that have been proposed for sequential recommendation. Comparing these

models with SP2P (Sequence-to-Point) for movie and Instagram recommendation datasets would involve evaluating the performance of each model on the same datasets and comparing the results using the evaluation metrics such as recall, NDCG and MRR. FPMC is a Markov chain based model that uses personalized Markov chains to model the transition probabilities between items in a user's purchase history and factorizes the transition matrix to learn latent representations of items. ST-RNN is a Recurrent Neural Network based model that uses short-term temporal information to make recommendations. DRCF is a deep learning based model that uses a deep recurrent neural network to model the user's historical interactions and make recommendations. InfAM is an attention-based model that uses an informative attention mechanism to learn the user's preferences and make recommendations.

V. CONCLUSIONS

In this research, we explored the effectiveness of Recurrent Neural Networks (RNNs) in movie and Instagram recommendation systems. We investigated and compared the

performance of different types of RNNs, such as Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), in recommending movies and Instagram posts to users based on their browsing history. Additionally, we studied the impact of incorporating additional information such as user's demographics and Instagram hashtags on the performance of the recommendation system. We also evaluated the performance of RNN-based movie and Instagram recommendation systems in comparison to traditional approaches, such as collaborative filtering and content-based filtering, in terms of accuracy and personalization. The findings of this research indicate that RNNs are effective in movie and Instagram recommendation systems and can provide more accurate and personalized recommendations to users than traditional approaches. Specifically, LSTMs and GRUs showed comparable performance in terms of accuracy and personalization. Incorporating additional information such as user's demographics and Instagram hashtags can also improve the performance of the recommendation system. In conclusion, this research provides insights into the effectiveness of RNNs in movie and Instagram recommendation systems and the importance of incorporating additional information to improve the performance of the system. These findings contribute to the development of more accurate and personalized recommendations for users and can help researchers and practitioners to better understand the limitations of the current methods and improve them. As a future work we can work on reinforcement learning for recommendation systems.

**Abstract**—Globally, billion of devices in heterogeneous networks are interconnected by the Internet of Things (IoT). IoT applications require a centralized decision-making system due to the failure-prone connectivity and high latency of such a system. Low-latency communications are a primary characteristic of applications. Since IoT applications usually have small payload sizes, reducing communication overhead is crucial to improving energy efficiency. Researchers have proposed several methods to resolve the load balancing issue of IoT networks and reduce communication overhead. Although these techniques are not effective, in terms of high communication costs, end-to-end delay, packet loss ratio, throughput, and node lifetimes negatively impact network performance. In this paper, we propose a communication overhead aware optimal cluster-based (COOC) routing algorithm for IoT networks based on a hybrid heuristic technique. Using three benchmark algorithms, we form load-balanced clusters using k-means clustering, fuzzy logic, and genetic algorithm. In the next step, compute the rank of each node in a cluster using multiple design constraints, which are optimized by using the improved COOT bird optimum search algorithm (I-COOT). After that, we choose the cluster head (CH) according to the rank condition, thereby reducing the communication overhead in IoT networks. Additionally, we design chaotic golden search optimization algorithm (CGSO) for choosing the optimal best path between IoT nodes among multiple paths to ensure optimal data transfer from CHs. To conclude, we validate our proposed COOC routing algorithm against the different simulation scenarios and compare the results with existing state-of-the-art routing algorithms.

**Keywords**—Internet-of-things; communication overhead; cluster based routing; multipath routing; cluster head

## I. INTRODUCTION

The Internet of Things (IoT) in the modern world gives academics a platform to expand the communication paradigm to new and interesting heights [1]. IoT includes computing and sensor devices that offer services at anytime, anywhere. Computers, mobile phones, laptops, household appliances, consumer electronics, sensors, and actuators are just a few examples of the homogeneous and heterogeneous systems and components that make up this system [2]. Wireless sensor networks (WSN) are one of the IoT's components. The combination of a massive number of sensor nodes is what produces the data for the IoT network. Due of their extremely

low power consumption, these sensor nodes have a limited communication range. The data is generated by the wireless sensor network and is transmitted to the sink node by way of an intermediary sensor node. The sink node, which can also be referred to as a gateway node or Base Station (BS), gathers and aggregates the data before sending it to the cloud for additional processing and storage [3][4]. A separate routing protocol is used to send the data to the gateway node in an effort to use less energy. There have been a lot of studies done on data transmission schemes that balance IoT energy usage with data compression techniques that lower the energy needed for data transmission [5]. Data fusion is a complex issue, and there are still a number of issues that need to be researched. As a result, unlike the internet, the data from any terminal is crucial for IoTs. The loss of total control over a piece of equipment may result from the death of nodes from one location [6][7].

Distributed data routing and adaptable networking would therefore be more appropriate for IoT operation. Clustering is a crucial step in the process of making the IoT network more durable. These protocols address a number of concerns, including network longevity, scalability, dependability, and energy efficiency [8]. The IoT network's sensor nodes are dispersed throughout, and the clusters meet the following requirements. Each cluster's cluster head (CH) is chosen depending on a number of factors, such as queue size, link quality, and residual energy. One major limitation of IoT projects of this scale is in the name, the requirement of internet access. To overcome this problem, our design focuses on peer-to-peer communication [9]. With each unit not depending on an available network, this system can be deployed more quickly, with less overhead, and for a lower cost, meaning more of the world's cities can be supported. The network will have a single master device requires internet connectivity through an available access point, LTE connectivity, or direct connection to a local server to store and distribute the data produced. This device will handle storing the location and index of each new device on the network so that the data it receives can be easily analyzed and passed along through the proper channels [10].

Recently, several routing algorithms [11]-[20] have been proposed to solve security issues in IoT-WSN. A security-

aware routing algorithm, or security-aware probability of success (SA-PoS), addresses proactive jamming attacks that target IoT-based multi-hop WSNs [11].

Confidential cluster-based routing (SNCR) protocol [12] in WSN uses a secure network coding-enabled method that resists eavesdropping attempts and reduces energy dissipation within a clustered network. For NDN-IoT networks, lightweight authentication and secured routing (LAsER) [13] was developed. That network allows for scalability with minimum computational or cryptographic overhead. SCOTRES is a trust-based solution for secure routing in adhoc networks that uses design metrics to increase the intelligence of network components [14]. In order to improve the performance of energy efficiency with the multi-hop data security against malicious assaults, an energy-aware and secure multi-hop routing (ESMR) protocol [15] is created. For mobile IoT devices with its connection to WSN, an intrusion prevention framework is employed to ensure data security with increased network delivery ratio [16]. A game theoretic approach is used in an energy-conscious trust derivation system [17] to reduce overhead while ensuring IoT-WSN security. For multi-gateway IoT-WSN, an effective authentication and key agreement mechanism [18] is employed to increase security. IoT is used in the context of several services, including business analytics, cancer care, emergency and operational services, in a smart Saskatchewan healthcare system [19]. To reduce the total energy consumption needed by sensor nodes to meet quality of service requirements, an energy-efficient secure routing algorithm [20] is implemented (QoS). In order to maximize dependability and decrease the path failure rate in IoT-WSN, communication overhead cognizant solutions are also implemented.

In order to further improve, a hybrid heuristic technique-based Communication Overhead aware Optimal Cluster based routing algorithm (COOC) is created for IoT networks algorithm is designed for IoT networks based on hybrid heuristic technique. The main contributions of our proposed COOC routing algorithm are given as follows:

- We utilize three benchmark algorithms for optimal cluster formation, k-means clustering, fuzzy logic, and genetic algorithm.
- To compute the rank of each node in a cluster using multiple design constraints, which are optimized by using the Improved COOT bird optimum search algorithm (I-COOT).
- To select CH according to trust degree condition, thereby reducing the communication overhead in IoT networks.
- A chaotic golden search optimization algorithm (CGSO) is used for choosing the optimal best path between IoT nodes among multiple paths to ensure optimal data transfer from CHs.
- We validate our COOC routing algorithm against the different simulation scenarios and compare the results with existing routing algorithms.

The paper's remaining section is organized as follows: Section II describe the recent works related to secure aware routing protocols for IoT. In Section III, we deliberate the problem statement and network's model of suggested COOC routing algorithm. Section IV discusses the proposed methodology of COOC routing algorithm. Section V illustrates the simulation results and comparative analysis. Section VI concludes the paper.

## II. LITERATURE REVIEW

The existing related works of routing protocols for IoT networks are discussed in this section. Table I summarizes the research gaps we gathered from the previous studies.

For WSN, an enhanced energy-efficient CH selection technique [21] is suggested, which is used to increase network throughput and lifetime while reducing energy usage. They took into account the LEACH method's cluster head selection, and they presented data fusion strategies based on the clustering of dual cluster heads. The two clusters were chosen to gather, consolidate, and send the data, and in this two CH selection approach, the cost of communication between the two clusters is reduced.

To calculate the spread of jamming assaults, experiments based on the IEEE 802.15.4 standard's MPH, AODV, and DSR protocols are utilized to generate an epidemic model [22]. The routing path in IoT networks as well as the impact of the jammer attack in terms of attack intensity and attack persistence is validated using the Susceptible-Infected-Recovered (SIR) model.

TABLE I. SUMMARY OF RESEARCH GAPS FOR ROUTING PROTOCOLS FOR IOT NETWORK

Ref.	Protocol	Cluster, CH	Application	Enhancement	Research gap
[21]	IEECHS	☑	Smart city	Consumption of Energy	Suffer from excessive energy drain
[22]	SIR	☑	Industrial	Security	Lack of reliability
[23]	MQTT	☒	Smart city	Consumption of Energy	Not ensures real-time packet transmission
[24]	CMMA	☑	Healthcare	Consumption of Energy	Not suitable for high density nodes
[25]	SIoMT	☑	Healthcare	F-measure	High network latency
[26]	ATAR	☑	Healthcare	Consumption of Energy	Vulnerable to dictionary attacks

For quick and timely data communication between M2M, which improves QoS with the minimum degree of reliability standard, MQTT protocol [23] is employed. In order to provide efficient communication for IoMT-based applications, Clustering Model Medical Application (CMMA) [24] is utilized for CH selection. For edge-computing based IoT, the CMMA protocol outperforms the performance in terms of

sustainability and energy efficiency. With the goal of network optimization, swarm intelligence optimization is applied in IoT. The bee colony optimization (BCO) technique, which aims to build distributed groups of nodes with common properties without any initialization knowledge pertinent to the output or utilizing complex parameters, is modified to change the key parameters in order to automatically organize the clusters [25]. IoMT-WSN uses the thermal aware routing protocol (ATAR) [26] to enhance latency and energy economy. Each node modifies its power level during transmission by observing its surrounding nodes. The received signal strength indicator value yields the value of the neighbor node. It is necessary to have a neighbor with high throughput values, which ultimately leads to energy efficiency and low heat generation.

### III. PROBLEM STATEMENT AND SYSTEM MODEL

#### A. Problem Statement

A clustering technique has been proposed by Yarinezhad et al. [27] to balance the traffic strain placed on the CHs in IoT-WSNs. The 1.2-approximation approach is used in the clustering process. Data packets were sent from the CHs to their final destination using an energy-conscious routing mechanism. By properly segmenting the area, this routing technique spreads the communication load of the data packets among many nodes close to the destination. In order to prevent the creation of a hot spot close to the sink, the data from the cluster heads is transported to it along the best possible paths. The Fixed-Parameter Traceable Approximation Clustering (FPTAC) approach used grouping techniques to cut down on the number of individual sensor nodes, which also decreased the algorithm's temporal complexity. IoT devices with energy constraints use more energy since nodes are mobile, which reduces the network lifetime. Due to each node's finite energy supply, optimization of energy consumption is thought to be the main goal in the study of WSN system architecture. By using the energy more effectively and extending the lifespan of the network, clustering of nodes helps lower the energy consumption of the network in WSNs.

As the number of sensor-enabled physical devices connected to the internet has dramatically increased, it is crucial for data to be transferred from source to destination as quickly as possible. So, routing is important in the Internet of Things. However, IoT is mobile by its very nature. Mobility is a good contender for effectively addressing hand-off time concerns, data transmission delays, overhead, and low packet delivery rates. The requirements for IoT routing protocols change constantly depending on the application. IoT have risen to the forefront of medical media technologies due to their small size and capacity for wireless data transport. High energy efficiency, transmission reliability, and extended battery life of sensor devices are necessary for a dependable network. The effectiveness of healthcare delivery is increased by taking protocol layers, data routing, and energy optimization measures into account. The need for steady, dependable, and real-time transmission due to the sizeable volume of data makes it imperative to find a solution. Numerous heterogeneous devices, a high bit error rate,

frequent network failures, and QoS assurance are the main problems with routing protocols. The quick and broad use of the Internet of Things (IoT) around the world has boosted the significant performance attained in terms of applications, technology, and security. Finally, we address the issues in IoT network, communication overhead, energy consumption and congestion issues for an optimal reliable solution. To overcome those problems in previous studies, COOC routing algorithm is proposed for IoT networks. The main objectives of COOC routing algorithm is describes as follows:

- Optimize clustering and multipath routing is used to formulate communication overhead aware optimal cluster-based (COOC) routing.
- By using COOC routing, we were able to increase network throughput and reduce computation and communication costs.
- Furthermore, COOC routing reduces the battery-power consumption of the network, increasing its overall lifetime.
- NS-2 simulator is used to evaluate our COOC routing.

#### B. Network Model of our COOC Routing Algorithm

Fig. 1 shows the typical structure of IoT network with our proposed COOC routing algorithm using optimal clustering and efficient multipath routing. The routing protocol is then used to send the data gathered from IoT sensors to the base station (BS). Almost all of the IoT network's gadgets run on limited, non-rechargeable energy sources like batteries. IoT applications typically operate in crowded, harsh locations, making it difficult to add or swap out the sensors' power sources.

The k-means clustering, fuzzy logic and genetic algorithm is used for the cluster formation using the basic information of IoT nodes location and distance between nodes to BS. Then, the rank of the nodes is compute by the individual position of nodes with respect to other nodes using multiple design constraints. The rank decreases in the up direction and increases in the down direction. Next, we develop an I-COOT algorithm for design constraints optimization which used to select CH among multiple nodes. Finally, we find the optimal best path between IoT nodes among multiple paths by using CGSO algorithm.

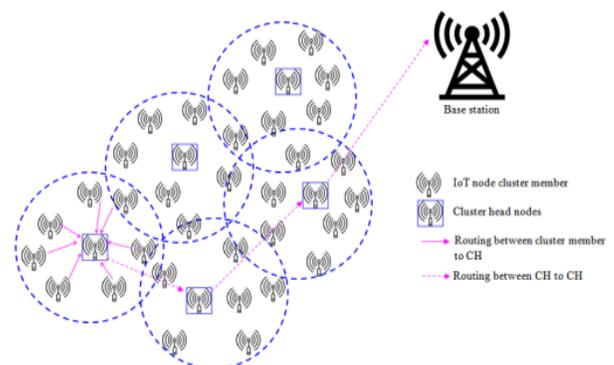

Fig. 1. Typical structure of IoT network with our COOC routing algorithm

#### IV. PROPOSED METHODOLOGY

We describe working function of our COOC routing algorithm which consists following set of process are clustering, design constraints for rank computation, optimization of design constraints and optimal path selection.

##### A. Clustering using Benchmark Algorithms

The creation of energy-efficient solutions becomes crucial since IoT nodes are energy-constrained and run on a small internal battery. In order to prepare for impending demand, energy conscious IoT networks must simultaneously forecast their energy use. A collection of sensor nodes that can sense, calculate, and transmit make up the network. Energy conservation in IoT becomes a major concern to increase network lifetime. Since clustering is regarded as an efficient and suitable way for transmitting the data without any issues, multiple efforts have been made to improve the routing protocols in the network to date. In this study, we used the k-means clustering, fuzzy logic, and genetic algorithms as three benchmark load-balanced clustering methods. It is necessary for this particular application to illustrate the chromosomal distribution to utilize the k-means clustering technique to partition unsatisfactory groupings. Our supposition is that the population is divided into clusters.

$$cq^{i,*} = \frac{1}{m_i} \sum_{c \in c_i} cq_N, \quad i=1,2,\dots,k \quad (1)$$

Where the number of cluster-related elements is  $m_i$ . The  $f$  symbol represents the altered feature space with a greater or even infinite dimension, and  $Y$  stands for the data space. The following objective function is minimized by KFCM.

$$I_{kfcM}(u, v) = \sum_{K=1}^C \sum_{j=1}^N \mu_{Kj}^M |\Phi(y_K) - \Phi(v_j)|^2 \quad (2)$$

The difference between the sizes of the largest cluster and the smallest cluster normalizes the size of the cluster and the size of the cluster.

$$\hat{H}_A = \frac{H_A - H_{\min}}{H_{\max} - H_{\min}} \quad (3)$$

$$\hat{H}_w = \frac{H_w - H_{\min}}{H_{\max} - H_{\min}} \quad (4)$$

Where  $H_{\max}$  and  $H_{\min}$  represent the normalized values, which range from zero to one, respectively. By explicitly detecting its presence in the algorithm, this circumstance can be avoided. Fuzzy logic provides the ability to make defensible conclusions in a world of uncertainty, imprecision, and missing data. It is therefore the optimal strategy to use in scenarios with real, continuous-valued elements because it uses data acquired in surroundings that include such qualities. The aforementioned context is appropriate for the information gathered about computer network traffic, which supports its use in anomaly detection. The membership degree of an element is obtained using a fuzzy membership function, which accepts a variety of arguments. The Gaussian membership function is an illustration of such a function.

$$\xi = E^{-\frac{(y-\hat{y})^2}{2\theta^2}} \quad (5)$$

Where  $\theta$  is a parameter that defines the standard deviation,  $\hat{y}$  is the center,  $y$  is the value to calculate its membership. In this paper, the function is derived from the Gaussian membership function as

$$\xi_k = 1 - E^{-\frac{(y_k - \hat{y}_k)^2}{2\theta_k^2}} \quad (6)$$

Using fuzzy logic, it is possible to determine whether an abnormality is happening right now. A fuzzy method is used to reduce this issue without impairing the system's capacity to detect anomalies.

##### B. Genetic Algorithm

Genetic Algorithm (GA) is a worldwide, parallel, stochastic search approach that exhibits significant robustness in problem domains where formal, strict, classical analysis is not feasible. The roulette wheel and a competition are two of these selection techniques. The odds of winning in roulette are determined by the fitness values of the chromosomes, which dictate

$$q_j = \frac{F_j}{\sum_{i=1}^N F_i} \quad (7)$$

Based on the results of the trials, it can be concluded that fuzzy logic and k-means clustering are not as exact as the best option for categorization. The precision and recall are both greatly enhanced by the GA algorithm. The definitions of recall and precision

$$precision = \frac{tp}{tp + fp} \quad (8)$$

$$recall = \frac{tp}{tp + fn} \quad (9)$$

The superiority of the GA algorithm becomes more apparent and we can get the meaningful findings more quickly when it is applied to a few additional data sets.

$$precision = \frac{|relevant \cap retrieved|}{|retrieved|} \quad (10)$$

$$recall = \frac{|relevant \cap retrieved|}{|testing|} \quad (11)$$

When the user is aware of the nonlinearities in the problem, the GA method can perform pretty well. However, the GAKFCM is more accurate and can overcome problems for the GA algorithm. And take a different look at the GA algorithm. The workings of cluster construction employing k-means clustering, fuzzy logic, and genetic algorithm are described in algorithm 4.1.

**Algorithm 4.1** Benchmark algorithm for cluster formation

Input: location, distance between nodes and BS

Output: Formation of cluster

1. Initiate the random population
2. Minimize the KFCM by objective function
 
$$I_{kfcM}(u, v) = \sum_{K=1}^C \sum_{j=1}^N \mu_{Kj}^M |\Phi(y_K) - \Phi(v_j)|^2$$
3. The condition is avoided by specifically checking for it within the algorithm
4.  $j=0$  and  $i=1$
5. Define Gaussian membership function
 
$$\xi = E \frac{-(y-\hat{y})^2}{2\theta^2}$$
6. Find fitness values of the chromo  $q_j = \frac{F_j}{\sum_{i=1}^N F_i}$
7. Get the useful results faster
 
$$precision = \frac{|relevant \cap retrieved|}{|retrieved|}$$

$$recall = \frac{|relevant \cap retrieved|}{|testing|}$$
8. Update the final values
9. End

C. Design Constraints Optimization

The practice of minimizing the amount of input constraints when creating a predictive model is known as design constraint optimization. In some circumstances, less input constraints might increase model performance while also lowering the computing cost of simulations. Using the Improved COOT bird optimal search method (I-COOT), this work chooses the cluster head (CH) based on the rank of each node. Coots are little waterfowl that belong to the Rallidae family of rails. They belong to the Fulica genus, which is named after the Latin word for "coot." This bird's actions on the water's surface can be used as an optimization technique. Coots appear to be well within what is, for surf scoters, a zone of repulsion as they travel at an angle to their direction of motion. There is no assurance that a solution will be found in one run when using population-based optimization approaches to discover the ideal number of optimization issues. However, if there are enough random solutions and optimization processes, the likelihood of discovering the overall best improves. Using the formula, the population is produced at random in the small area.

$$cootpos(j) = rand(1, D) * (ua - la) + la \quad (12)$$

where  $cootpos(j)$  is the coot position,  $d$  the number of variables or problem dimensions,  $la$  is the lower bound of the search space and ' $ua$ ' is the upper bound of the search space. Each variable may have a different lower bound and upper bound problem.

where  $D$  is the number of variables or problem dimensions, and  $lb$  and ' $ua$ ' represent the lower and upper bounds of the search space, respectively. Coot position is

$cootpos(j)$ , there could be many lower bound and upper bound issues for each variable.

$$la = [la_1, la_2, \dots, la_D], ua = [ua_1, ua_2, \dots, ua_D] \quad (13)$$

In order to carry out this movement, we take into account a random place within the search space and move the coot in that direction.

$$P = rand(1, D) * (ua - la) + la \quad (14)$$

The search space is explored by this coot movement in many areas. This movement will let the algorithm escape the local optimal if it becomes stuck in the local optimal. The new position of the coot is calculated as follows:

$$cootpos(j) = cootpos(j) + B * r2 * (P - cootpos(j)) \quad (15)$$

we compute  $B$  using the random movement of the coot in various directions, where " $r2$ " is a random value in the range  $[0, 1]$ .

$$B = 1 - l * \left( \frac{1}{Iter} \right) \quad (16)$$

Where,  $Iter$  is the maximum iteration and  $l$  is the current iteration. The typical alignments of two coots are used for implementing chain movement. We may also move the coot toward the other coot by roughly halving the distance between them after first calculating the distance vector between them. We employed the first technique, and a formula was applied to determine the coot's new position.

$$cootpos(j) = 0.5 * (cootpos(j - 1) + cootpos(j)) \quad (17)$$

The group is often led by a few coots in the front, and the remainder of the coots must move closer and alter their posture in accordance with the group's leaders. One possible query is if each coot will change its position according to which leader. The coots can adjust their position based on the average position of the leaders, which can be taken into consideration. Premature convergence results from taking the average position into account. We employ a system in accordance with the leader-selection process to carry out this movement.

$$k = 1 + (j \bmod nl) \quad (18)$$

where  $K$  is the leader's index number,  $NL$  is the total number of leaders, and  $I$  is the index number of the current coot. Based on the leader's  $k$ , the coot ( $j$ ) must update its location to determine the coot's subsequent position based on the chosen leader.

$$cootpos(j) = leaderpos(K) + 2 * r1 * \cos(2r\pi) * (leaderpos(K) - cootpos(j)) \quad (19)$$

Where, the coot's current position is  $cootpos(j)$ ,  $leaderpos(K)$  has been chosen as the leader position.  $R1$  is a random number between 0 and 1,  $\pi$  is the same as pi, or 3.14, and ' $r$ ' is a random number between 0 and 1. Around this current ideal location, this formula seeks out better positions. Leaders may need to shift away from the present best position in order to find better positions. This formula offers a useful method for moving away from and toward the ideal place.

$$leaderpos(j) = \begin{cases} A \times r3 \times \cos(2r\pi) \times & r4 < 0.5 \\ (gbest - leaderpos(j)) + gbest & \\ A \times r3 \times \cos(2r\pi) \times & r4 \geq 0.5 \\ (gbest - leaderpos(j)) - gbest & \end{cases} \quad (20)$$

Where the best position ever discovered is  $gbest$ , R3 and R4 are random numbers in the range [0, 1], is equal to 3.14 pi, R is a random number in the range [1, 1], and B is determined using the formula.

$$A = 2 - l \times \left( \frac{1}{Iter} \right) \quad (21)$$

Where 'Iter' for the most iterations and 'l' stands for the current iteration. 2 x r3 greater random movements are made to prevent the algorithm from becoming stuck at the local optimum. This indicates that while we are in the exploitation phase, we are simultaneously undertaking exploration. Cos(2rπ) looks for a better position near the best search agent by searching in various radii about it. Algorithm 4.2 describes the working process of CH selection using I-COOT.

**Algorithm 4.2** CH selection using I-COOT

Input : Energy efficiency, Link quality, Path loss, Distance and Delay  
Output : design constraints optimization and CH

- 1 Initialize the random population
- 2 The population is randomly generated  
 $cootpos(j) = rand(1, D) \cdot (ua - la) + la$
- 3 J=0, and i=1
- 4 Define coot towards this random position  
 $P = rand(1, D) \cdot (ua - la) + la$
- 5 Selection of leader  $k = 1 + (j \bmod nl)$
- 6 Selection of coot based on selected leader  
 $cootpos(j) = leaderpos(K) + 2 \times r1 \times \cos(2r\pi) \times (leaderpos(K) - cootpos(j))$
- 7 Compute B  $A = 2 - l \times \left( \frac{1}{Iter} \right)$
- 8 Update the final values
- 9 End

**D. Optimal Path Selection**

A well-known trade-off in the architecture of IoT is minimizing power consumption at the expense of the performance of the network. Traditional sensor network platforms were created with a focus on low power consumption at the expense of communication throughput. To collect auditory and visual data, which has a high need for transmission throughput, new apps are being used. According to the investigation, conventional ways fail to deliver improved security and quality of service (QoS), as well as to balance the temperature and load of WSN-IoT devices. They also fail to extend the network lifetime and reduce energy depletion. In order to ensure optimal data transfer from CHs, we have created the chaotic golden search optimization algorithm (CGSO), which selects the best path among numerous paths connecting IoT nodes. Kiefer introduced the golden section search (GSO) in 1953. (Kiefer, 1953). When an

object function is uni-modal, this approach can be used. The approach performs admirably when solving object functions that are either impossible to discriminate or difficult to differentiate. 2-D GSS for object tracking is a newly introduced variation of the golden section search. It also appears in straightforward maps like the logistic map. Typically, a one-dimensional chaotic map looks like this:

$$y(N + 1) = F(\mu_1, \mu_2, \dots, \mu_M, y(N)), N = 0, 1, 2, 3 \dots \quad (22)$$

A chaotic map is fused with GSO algorithm to optimize path selection constraints. The chosen control parameters  $\mu_j, j = 1, \dots, M$  are quite modest, yet even a little shift in the chaotic variable's starting value, x, will have a significant impact on subsequent values of the chaotic variable, y. To define one-dimensional chaotic maps as follows:

$$y(N + 1) = by(N)(1 - y(N)) y(0) \in (0, 1), \quad (23)$$

$$y(0) \notin \{0, 0.25, 0.5, 0.75, 1\}$$

$$y(N + 1) = \cos(K \cos^{-1}(y(N))) y \in (-1, 1) \quad (24)$$

Chaos with b=4 is generated by the logistic map. le=0.6932 is the Lyapunov exponent of the Chebyshev map with k=2. The scout bee uses abandoned food sources as new ones.

$$Y_{ji} = y_{min,i} + f(y_{max,i} - y_{min,i}) \quad (25)$$

Depending on the scale factor  $f_1$  &  $f_2$  the creation of new food sources is viewed as a black box procedure. The primary concept is that, in order to ensure a high-quality solution that will play a crucial part in succeeding generations, the updating of the scale factor and, consequently, the creation of the food sources, are, with a given probability, controlled. The procedure introduces the Chaotic Golden Search Optimization Technique (CGSO), a traditional local search algorithm for non-differentiable fitness functions. In order to produce high-quality food sources, the scale factor golden section search uses the golden section search to scale factor. This procedure produces two intermediate points in the range [a = 1, b = -1]:

$$f_1 = a - \frac{a-b}{\delta}, \quad (26)$$

$$f_2 = b + \frac{a-b}{\delta} \quad (27)$$

The scaling factor's upper and lower bound values are calculated as follows. In the GSS algorithm, the first two points  $y_1, y_2 \in [l, u]$  are calculated as follows.

$$C = \frac{-1 + \sqrt{5}}{2} \quad (28)$$

$$y_1 = Cl + (1 - C)u \quad (29)$$

$$y_2 = (1 - C)l + Cu \quad (30)$$

The search is carried out until the stop criteria are met. As a result, just one of these portions is chosen for the subsequent iteration. As a result, it is essential that the two parts are of equal width. In certain circumstances, the bigger portion is

therefore taken more repeatedly, and the convergence speed is slowed.

$$Q + P = P + R \quad (31)$$

$$\frac{Q}{P} = \frac{Q}{P} = \frac{(P+Q)}{Q} = \frac{1}{C} = \varphi \quad (32)$$

From above equations, we follow that  $\varphi=161803398\dots$  and  $C=1.61803398\dots$ . Thus, if  $n$  is the number of iterations then,  $\varphi^n$  is the convergence rate of CGSO algorithm. The search interval shrunk to less than 1.0% of the original interval for  $n=15$ . The algorithm 4.3 describes the working function of optimal path selection using CGSO. We follow from the aforementioned equations that  $\varphi=161803398\dots$  and  $C=1.61803398\dots$ . As a result, if  $n$  is the number of iterations, then the CGSO algorithm's rate of convergence is  $\varphi^n$ . Less than 1% of the initial search interval for  $n=15$  remained after the search interval shrank. The operation of the CGSO-based optimal path selection algorithm is described in algorithm 4.3.

**Algorithm 4.3** Chaotic Golden Search Optimization algorithm (CGSO)

Input: CH, congestion rate, aggregation delay

Output: optimal paths

- 1 Initialize the random population
- 2 Define one-dimensional chaotic map  
 $y(N+1) = F(\mu_1, \mu_2, \dots, \mu_M, y(N)), N = 0, 1, 2, 3, \dots$
- 3 The interval values are  $a = 1, b = -1$
- 4 Define the initial food sources  
 $Y_{ji} = y_{\min,i} + f(y_{\max,i} - y_{\min,i})$
- 5 Calculate two points in GSS algorithm:  
 $y_1, y_2 \in [l, u] \quad C = \frac{-1 + \sqrt{5}}{2}$
- 6 The convergence speed is reduced  $Q + P = P + R$
- 7 Update the final values
- 8 End

V. RESULTS AND DISCUSSION

We describe simulation results and comparative analysis of suggested COOC and existing routing algorithms with the different simulation scenarios. COOC routing algorithm is simulate and analyze using Network simulator (NS-2). The simulation results are done for performance evaluation of the COOC routing algorithm against existing state-of-art algorithms' performance, based on clustering FPT (CFPT) [28], routing FPT-approximation (RFPT) [29], energy-efficient and EB-CRP (energy-balanced cluster-based routing protocol) [30] and fixed-parameter tractable approximation clustering (FPTAC) [27].

A. Simulation Setup

The sink is situated in the centre of a terrain measuring 1000 m by 1000 m, where the nodes are situated. A grid of 100 nodes is created, and the remaining 900 are distributed at random. The sensor node's transmission and reception power consumption are 24.92 and 19.72 mJ per byte, respectively,

according to the simulation requirements. IoT sensors come in a variety of numbers, ranging from 200 to 1000. Each sensor node and each gateway are assumed to have a starting energy of 2J. Each node communicates with the others via the CSMA/CA MAC layer protocol. To send the data packets to the gateways, the sensor nodes employ the TDMA that the BSs choose. The IoT sensor nodes' transmission range is 100 metres, and the data packet size is 4000 bits. The simulations are run 30 times, and the accompanying graph shows the typical outcome of the runs. The precise configuration of our simulation is described in Table II.

TABLE II. SIMULATION SETUP

Simulation Area	1000m×1000m
Number of IoT sensors	200-1000
Data size	4000 bits
Control packet size	200 bits
Senor sensing range	80 m
Initial energy of sensor nodes	2J
MAC protocol	CSMA/CA
Bandwidth	250 Kb/s
Payload size	30 bytes
Transmission range	100 m
Avg. energy consumption of transmitting node	24.92mJ per byte
Avg. energy consumption of receiving node	19.72mJ per 1 byte
Simulation time	30 times

B. Comparative Analysis on Routing Algorithms

1) *Impact of node density:* Using 200, 400, 600, 800, and 1000 nodes as well as a fixed network size of 1000m×1000m, we analyze the performance of our proposed and existing routing algorithms. A simulation analysis of existing and proposed routing algorithms, energy consumption, throughput, network lifetime, routing overhead, reception ratio, and average link lifetime is presented. Energy consumption of our proposed and existing routing algorithms is compared in Table III and Fig. 2. By utilizing node density as an indicator of energy consumption performance, the proposed COOC routing algorithm ensures better solution. The energy consumption of our proposed COOC routing algorithm is 21.685%, 17.196%, 12.161% and 6.474% efficient than the existing CFPT [28], RFPT [29], EB-CRP [30], and FPTAC [27] routing algorithms respectively. The throughput of our proposed and existing routing algorithms is compared in Table IV and Fig. 3. It appears that the COOC scheme has the most throughput compared to the other routing schemes, with a value of 80300Mbps for 200 nodes and 66000Mbps for 1000 nodes. The CFPT scheme has the lowest throughput, with a value of 25000Mbps for 200 nodes and 8000Mbps for 1000 nodes. Overall, the results suggest that the COOC scheme provides the best performance in terms of throughput, followed by FPTAC, EB-CRP, RFPT and CFPT.

TABLE III. ENERGY COMPARISON (J) WITH NODE DENSITY

Routing scheme	Number of nodes				
	200	400	600	800	1000
CFPT	173.48	274.4	558.76	958.34	1229.3
RFPT	137.56	236.41	522.22	919.08	1195.3
EB-CRP	97.28	197.20	485.73	887.08	1139.3
FPTAC	51.79	159.52	449.71	850.52	1106.5
COOC	12.53	121.51	412.5	812.54	1070.5

FPTAC	69000	65000	60000	57000	51000
COOC	80300	79900	73123	68500	66000

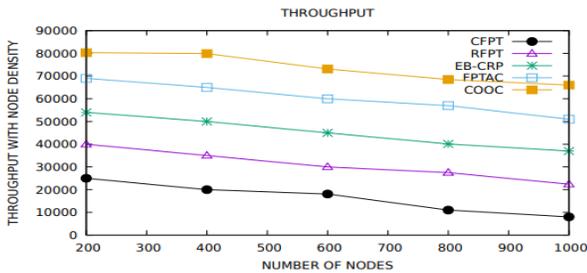

Fig. 3. Throughput with node density

The network lifetime of our proposed and existing routing algorithms is compared in Table V and Fig. 4. By utilizing node density as an indicator of network lifetime performance, the proposed COOC routing algorithm ensures better solution. The network lifetime of our proposed COOC routing algorithm is 26.147%, 19.09%, 13.073% and 6.537% efficient than the existing CFPT [28], RFPT [29], EB-CRP [30], and FPTAC [27] routing algorithms respectively. The routing overhead of our proposed and existing routing algorithms is compared in Table VI and Fig. 5. By utilizing node density as an indicator of routing overhead performance, the proposed COOC routing algorithm ensures better solution.

TABLE V. NETWORK LIFETIME WITH NODE DENSITY

Routing scheme	Number of nodes				
	200	400	600	800	1000
CFPT	28.02	27.05	26.16	24.27	23.89
RFPT	33.07	30.12	28.46	27.49	26.04

FPTAC	57.86	62.62	65.13	68.71	73.34
COOC	55.12	59.21	63.89	67.29	70.10

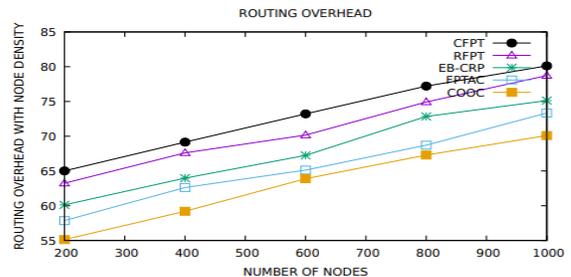

Fig. 5. Routing overhead with node density

TABLE VII. RECEPTION RATIO WITH NODE DENSITY

Routing scheme	Number of nodes				
	200	400	600	800	1000
CFPT	64.02	63.12	61.42	60.12	59.29
RFPT	72.12	70.44	68.12	65.69	64.90
EB-CRP	82.24	80.15	78.60	76.75	75.50
FPTAC	90.21	89.21	88.12	87.30	86.21
COOC	98.13	97.41	96.3	95.20	94.12

The routing overhead of COOC routing algorithm is 13.465%, 10.451%, 7.219%, and 3.744% efficient than the existing CFPT [28], RFPT [29], EB-CRP [30], and FPTAC [27] routing algorithms respectively.

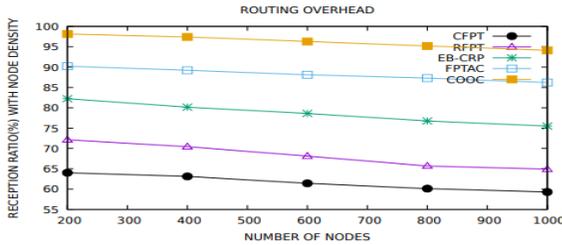

Fig. 6. Reception ratio with node density

TABLE VIII. AVERAGE LINK LIFETIME WITH NODE DENSITY

Routing scheme	Number of nodes				
	200	400	600	800	1000
CFPT	12.51	11.25	10.14	8.75	7.51
RFPT	15.21	13.75	12.52	11.25	10.54
EB-CRP	17.25	16.16	14.57	13.48	11.75
FPTAC	19.53	18.25	17.54	15.75	14.51
COOC	22.01	20.75	19.51	18.25	17.48

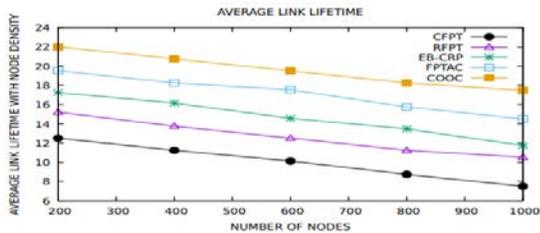

Fig. 7. Average link lifetime with node density

The reception ratio of proposed and existing routing algorithms is compared in Table VII and Fig. 6. By utilizing node density as an indicator of reception ratio performance, the proposed COOC routing algorithm ensures better solution. The reception ratio of COOC routing algorithm is 32.119%, 21.94%, 16.059% and 8.03% efficient than the existing CFPT [28], RFPT [29], EB-CRP [30], and FPTAC [27] routing algorithms respectively. The average link lifetime of proposed and existing routing algorithms is compared in Table VIII and Fig. 7. It appears that the COOC scheme has the most average link lifetime compared to the other routing schemes, with a value of 22.01 seconds for 200 nodes and 17.48 seconds for 1000 nodes. The CFPT scheme has the lowest average link lifetime, with a value of 12.51 seconds for 200 nodes and 7.51 seconds for 1000 nodes. Overall, the results suggest that the COOC scheme provides the best performance in terms of average link lifetime, followed by FPTAC, EB-CRP, RFPT and CFPT.

## VI. CONCLUSION

In this work, based on hybrid heuristic, we propose communication overhead aware optimal cluster-based (COOC) routing algorithm for IoT networks. With the use of

k-means clustering, fuzzy logic, and genetic algorithms, we form load-balanced clusters. I-COOT is used to optimize multiple design constraints to compute the rank of each node in a cluster. In IoT networks, we reduce communication overhead by select CH according to the rank condition. A chaotic golden search optimization algorithm (CGSO) is designed for optimizing data transfer from the CHs by identifying the best path among multiple paths among IoT nodes. In conclusion, we validate our proposed COOC routing algorithm against different simulation scenarios. From the simulation results, we observed that the effectiveness of our proposed COOC routing algorithm perform very effective manner in terms of consumption, throughput, network lifetime, routing overhead, reception ratio, and average link lifetime compared to existing routing algorithms.

**Abstract**—The COVID-19 vaccination management in Japan has revealed many problems. The number of vaccines available was clearly less than the number of people who wanted to be vaccinated. Initially, the system was managed by making reservations with age group utilizing vaccination coupons. After the second round of vaccinations, only appointments for vaccination dates were coordinated and vaccination sites were set up in Shibuya Ward where the vaccine could be taken freely. Under a shortage of vaccine supply, the inability to make appointments arose from a failure to properly estimate demand. In addition, the vaccine expired due to inadequate inventory management, resulting in the vaccine being discarded. This is considered to be a supply chain problem in which appropriate supply could not be provided in response to demand. In response to this problem, this paper examines whether it is possible to avoid shortage and stock discards by a decentralized management system for easy on-site inventory control instead of a centralized management system in real world. Based on a multi-agent model, a model was created to redistribute inventory to clients by predicting future shortage based on demand fluctuations and past inventory levels. The model was constructed by adopting the Kanto region. The validation results of the model showed that the number of discards was reduced by about 70% and out-of-stocks by about 12% as a result of learning the dispersion management and out-of-stock forecasting.

**Keywords**—Supply chain management; agent based model; multi-agent reinforcement learning; COVID-19 vaccination

## I. INTRODUCTION

The vaccination with the COVID-19 virus vaccine for the pandemic is managed through a vaccination ticket and vaccination reservation system, and priority vaccination is given based on the risk of serious illness and the security of the medical care system, because the amount of vaccine that can be secured is limited and its supply is expected to be sequential. The ministry of health, labour and welfare also prioritizes vaccinations based on the risk of severe cases of the disease and the availability of healthcare [1]. In July 2021, the amount of vaccine supplied by the national government to local governments became significantly insufficient. This caused some local governments to temporarily suspend vaccination appointments and medical institutions that have been forced to reduce their supply of vaccine are forced to coordinate with applicants who have made reservations to postpone their vaccinations [2]. However, about 2.2 million doses of vaccine have been discarded due to expiration [3]. In light of the above, some areas disposed vaccines due to inadequate inventory management while some areas are

experiencing shortages. The essence of these problems is that inventory management and demand forecasting were not properly carried out. The only centralized control by the government or relevant ministries is not sufficient to manage the situation.

Thus, when the issue of vaccine shortage and disposal was widely recognized in the press, etc., the measures to be taken focused on the storage method from the pharmaceutical knowledge of vaccines and the proposed solution regarding the vaccination system, and the Ministry of Health, Labor and Welfare provided an explanation on how to ensure the vaccination system [4]. However, very few have addressed issues related to supply chain management regarding the increased demand for vaccines related to the growing number of COVID-19 virus cases and inventory management related to this demand.

This paper creates two model of inventory management and shipping plan. These are the centralized management model and the decentralized management model. The centralized management model ships vaccines based on demand from each municipality. The decentralized management model is a model in which each municipality uses reinforcement learning to manage inventory and forecast demand [5]. In this model, a vaccination site with sufficient inventory provides inventory to a vaccination site with insufficient inventory. The model is designed to verify how effectively vaccines can be utilized when each municipality takes the initiative in inventory management and shipping.

## II. PRIOR RESEARCH

Supply chain research has been conducted using various approaches to achieve various objectives, such as avoiding shortage, reducing excess inventory, and reducing costs including design and model proposals based on engineering knowledge [6], mathematical optimization of risk management methods [7], and realistic simulation models focusing on lead time [8]. These approaches have achieved some goals.

In recent years, machine learning, especially AI, has been widely utilized as a problem-solving method. For example, it is researched to assign various planning tasks to machine learning in the design (long-term strategy), planning (medium-term and short-term strategy), and execution (operational level) stages for proactive supply chain problem-solving approaches [9]; and it is researched to seek to make strategic decisions based on machine learning forecasts of

environmental changes such as demand fluctuations for passive factors [10].

This paper examines the effectiveness of vaccine inventory exchanges from a supply chain management perspective by reinforcement learning about changes in vaccine demand at vaccination sites.

### III. COMPOSITION OF THE SIMULATION MODEL

#### A. Building the SCM Model in MAS

There are so many players to study for the Supply Chain Management (SCM). These players generally include from producers to retailers etc. Each player collects information for the sales strategies to be made by management of service, inventory and cost. They which are under the control of upper headquarter office, make their own decisions within their responsibility [11] [12].

Multi-Agent Simulation (MAS) discusses the coordination of behavior in a set of autonomous intelligent agents [13]. This simulation can lead to the whole optimum of the collection in which each player decide to act on its own.

The characteristics of the vaccine supply chain are close to those of the Multi-Agent Simulation. Supply chain model using multi-agent system makes it possible to analyze what kind of supply chain management is appropriate.

The agent based model of supply chain management in this study is built by artisoc3.0. This software is based on java and is specialized for multi-agent simulation [14].

By using Multi-agent Simulation to study supply chain management, we can analyze the linkages between each agent [15], [16], [17], between clusters [18], resilience [19], [20], dynamic network model [21], [22] and etc.

#### B. The Way to Apply Reinforcement Learning

In this study, the concept of Q-learning was applied to COVID-19 vaccine inventory management in each agent. There are some studies that using Q-Learning to manage inventory with expiration dates [23][24][25]. The agents in a competitive supply chain take their decisions individually in a distributed environment and independent of one another. At the same time, they must coordinate their actions [26][27]. In this time, supply chain management is needed to the balance the decision between centralized management and decentralized management.

The state as Q-learning is to avoid out of stock. In supply chain management, there is a value called safety stock quantity, which is the minimum amount of inventory that should be maintained to avoid out of stock. The state is defined in which the inventory quantity always exceeds the safety stock quantity.

The action as Q-learning is the selection of suppliers and the amount of order. Each agent has two way to select supplier. One is the order to an upper supplier with regular and limited quantities. The other is the request surrounding vaccination sites to provide vaccine inventory if they have a surplus. Acquiring vaccine inventory from upper supplier takes time, but the agent will certainly have amount of vaccine inventory.

The orders between same agents are not sure if they are in vaccine inventory, but if they have a surplus, they can get inventory immediately.

The reward as Q-learning is the amount of inventory in excess of the safety stock quantity. If the agent collects more inventory, some vaccine inventory might expire and be discarded. It would also unnecessarily increase transportation requirements by shipping to other agents. For these reasons, it is important to maintain an appropriate amount of inventory

#### C. Basic Structure of the Agent Model

There are three types of supply chain agents to be constructed in this study: government agents, local government agents, and vaccination site agents. Each of these agents behaves autonomously and has the ability to collect information, process information, make decisions, and act on its own.

The government agent can ensure the stock of vaccines on a regular basis. Based on the amount of vaccines demanded by the local government agents, the government agent ships vaccines to the local government agents. In this case, priority is given to the areas with large demand.

The local government agent ships vaccine stocks based on the quantity requested by the vaccination site agents. In this case, priority is given to the locations with the largest demand.

The vaccination sites agents consume vaccine inventory by administering vaccinations. The number of vaccinations (demand) over the past 100 days is recorded, and the amount of vaccine requested from the municipal agents is calculated based on consumption fluctuations.

As for the deadline for vaccine consumption, it is assumed to be 40 days after the government agent secures the vaccine.

This simulation is performed as one step per day, and the simulation is performed for five-year periods.

The relationship between each agent is shown in the Fig. 1

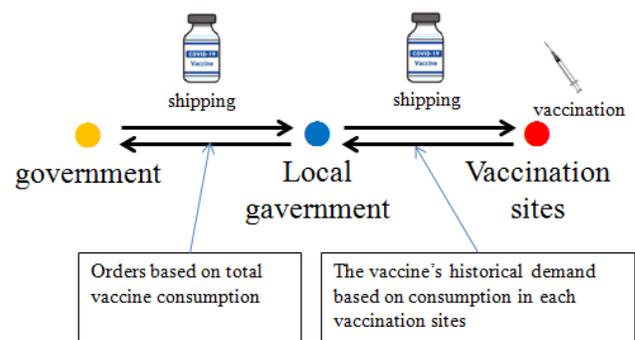

Fig. 1. The relationship between each agent

#### D. Centralized Management Model

1) Demand and supply: Each vaccination site should randomly vaccinate 0-50 persons per day. The reason for having variation due to randomness is that there are cases where the number of people who wish to be vaccinated continues to reach the daily limit in cases where vaccinations are given by appointment through the reservation system. In

addition, some vaccination sites that did not implement the reservation system had far more applicants than initially expected, resulting in shortage [28]. Conversely, there are days when the number of applicants for vaccination does not reach the allowable daily dose. Not only do such fluctuations in demand exist, but also there is always a steady-state shortage of vaccine throughout the country. To account for these fluctuations in demand and shortage conditions, the total number of vaccine stocks per 30 days was set in the simulation to 100,000 per 30 days, while the total demand is set to exceed this number. Since the total number of vaccination sites is 203, the average number of vaccine demand over the 30-day period is 100. The average number of vaccines in demand over a 30-day period is  $203 \times 30 \text{ days} \times 2.5 \text{ doses} = 152250 \text{ doses}$ .

2) *Vaccine supply method*: Local governments distribute vaccines based on demand at vaccination sites. In this case, the number of vaccines to be distributed is stated by the following formula. The lead time is 1 day.

$$\text{amount of shipping to vaccination sites} = \frac{\text{stock in local government} \times \text{one vaccination sites}}{\text{sum of demand in all vaccination sites}} \quad (1)$$

The amount of vaccine shipped by the government to local governments is based on the number of vaccination sites under the local government. This is stated by the following formula.

$$\text{amount of shipping to each local government} = \frac{\text{government stock} \times \text{number of vaccination sites in local government}}{\text{all vaccination sites}} \quad (2)$$

Suppose a country can obtain 100,000 doses of vaccine every 30 days.

**E. Decentralized Management Model**

1) *Differences from the centralized management model*: This model is used for the same model, as the centralized model of the demand specification and vaccine supply methods. The difference is that each vaccination sites has ability to receive the vaccine from other sites. When a vaccination center estimated the possibility of shortage of vaccine, it would inquire at other vaccination sites in the order of near to itself to see if there was any sufficient stock. If the other vaccination sites determine that they afford to tolerate sharing the vaccine stock, the vaccine can be shipped to other vaccination sites. In this case, the vaccination sites themselves calculate and set their own order time and order quantity based on the results of the reinforcement learning of fluctuations in vaccination demand and stock expiration dates.

2) *Reinforcement learning model*: The demand for vaccines and vaccine expiration dates for the past 100 days are recorded. This data is used to estimate future inventory status to prevent vaccine shortage through regression analysis. The objective variable was the amount of orders placed to other vaccination sites, and the explanatory variables were own demand and the number of days remaining before the

expiration date of the vaccine in their possession. An order quantity formula and conditions for order time are as follows.

$$\text{amount of order} = \text{average in demand} \times (\text{number of days left until the vaccine use deadline} + \text{lead time}) \quad (3)$$

$$\text{condition for order: stock} < (\text{number of days left until the vaccine use deadline} \times \text{average of demand}) \quad (4)$$

**IV. APPLICATION OF REAL DATA TO THE SIMULATION MODEL**

This simulation model is modeled after cities in the Kanto region. The government agent is a single agent modeled as the Ministry of Health, Labor and Welfare, which manages the importation of vaccines. The local government agents are seven agents modeled as Tokyo, Kanagawa, Saitama, Chiba, Gunma, Ibaraki, and Tochigi prefectures, which distribute vaccines to each vaccination site. A total of 203 vaccination site agents, modeled to designated cities, cities, and special wards, administer vaccines. The basic relationship between agents is shown in Fig. 2

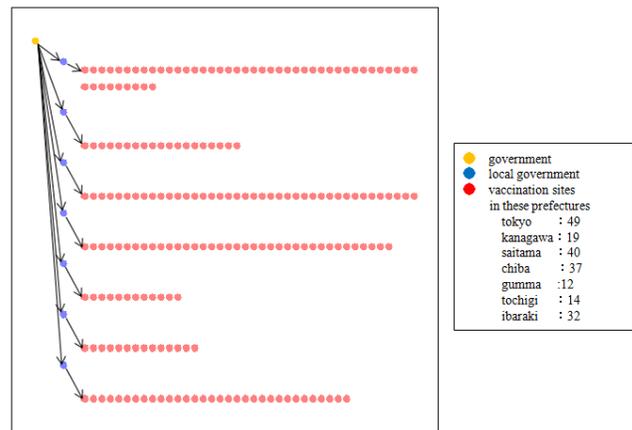

Fig. 2. Relationship diagram of each agent

**V. RESULTS**

**A. Results**

The results of the modeling and simulation according to the above are given in Table I.

TABLE I. SIMULATION RESULTS

Simulation No.	Centralized management model		Decentralized management model	
	Discarded number	Vaccine shortage	Discarded number	Vaccine shortage
1	82	28878	41	5456
2	64	28338	57	5206
3	72	27263	62	5389
4	73	28198	49	5402
5	84	27947	87	5411
average	75	28125	59	5373

Each simulation number is a five-year simulation, and "average in Simulation No." is the average of each experiment. Discarded number is the number of discarded vaccine. Vaccine shortage is the total number of vaccine demand in the absence of vaccine when there was a demand for vaccination.

### B. Considerations

Regarding the number of vaccine discards, the decentralized management model has reduced the number of discards to about 70% of the centralized management model. Shortage were also reduced to about 12% of the centralized management model. These indicate that more effective vaccination is possible when there is an exchange of vaccines among vaccination sites.

As for the reason for the number of discards, it was observed that when periods of extremely low demand occur consecutively, even vaccination sites with stock shortages are fully stocked, resulting in sufficient discarded vaccine. It was also observed that when demand increased during the above-mentioned period of reduced demand and small inventory, there was an overall shortage of vaccine to meet the demand, resulting in shortage.

## VI. CONCLUSION

In this paper, vaccine inventory management and shipping plan were simulated using a centralized management model and a decentralized management model to reveal the management of the vaccine demand and to avoid shortage. Compared to the model with centralized management, which caused problems in reality, the decentralized management model verified in the model reduced shortage of expired vaccines by approximately 70% and vaccine shortage by approximately 12%. It is estimated that the ability to exchange vaccines in the vicinity of vaccination sites where vaccines are consumed will greatly reduce the number of discards and the possibility of non-vaccination due to vaccine shortages.

## VII. FUTURE RESEARCH ISSUES

The next challenge is to consider supply chain management that considers multiple product elements and can streamline those that include more variables.

In Japan today, prices for food and many other things are rising. And it is said that security is needed for many things such as rare metals, semiconductors, oil, wheat, etc. But these problems are treated as vertical issues such as price increases for raw materials, processing cost, and so on. Many factors must be considered across the board to solve essential problems that affect the final product.

## ACKNOWLEDGMENT

The author appreciates Associate Professor Hiroshi Sato and Associate Professor Masao Kubo in National Defense Academy in Japan for providing help and instructions for this study.

**Abstract**—Multi-Criteria Decision-Making (MCDM) techniques are often used to aid decision-makers in selecting the best alternative among several options. However, these systems have issues, including the Rank Reversal Problem (RRP) and decision-making ambiguity. This study aimed to propose a selection model for a Cloud Service Provider (CSP) that addresses these issues. This research used the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) to rank the alternatives. The entropy technique is utilized to determine the weight of the criteria, and Single Valued Neutrosophic (SVN) is employed to address uncertainty. To select the best cloud provider based on Quality of Service (QoS) criteria, we used a dataset from Cloud Harmony for this study. The results indicated that the suggested model could effectively resolve the RRP under conditions of uncertainty. This research is novel and is the first to address both the problem of uncertainty in decision-making and RRP in MCDM.

**Keywords**—MCDM; TOPSIS; neutrosophic set; single valued neutrosophic; cloud services provider; quality of service

## I. INTRODUCTION

Cloud computing, an emerging paradigm, offers users pay-per-use or on-demand services. It provides users with three primary categories of service models: infrastructure as a service (IaaS), platform as a service (PaaS), and software as a service (SaaS). IaaS offers computational assistance to cloud clients. PaaS provides a framework for application development. SaaS gives users access to pre-made apps. Due to the vast number of software products and flexibility in utilizing cloud services, many large firms, such as Microsoft and Google, are investing significant amounts of money in offering various cloud services. However, finding and identifying a CSP has become a challenging task for cloud users due to the growing number of cloud providers.

Cloud benchmarking service providers, such as Cloud Harmony and Cloud Spectator [1, 2], analyze the performance of multiple CSPs and publish their findings online, serving as the foundation of the simple method cloud customers use to select the optimal CSP. However, the execution environment used by cloud customers may differ from the performance assessed by a third party in a given context. As a result, professionals or cloud users must evaluate multiple CSPs based on their experience to choose the optimal CSP.

The above issue has motivated researchers to design a mechanism for selecting the optimal CSP, which requires a set of QoS criteria to assess cloud services and a methodology for rating them according to these criteria [3].

MCDM is a structured and formal decision-making approach used to deal with complex problems and conflicting criteria.

There are several MCDM approaches used in related works, such as TOPSIS, Decision-Making Trial and Evaluation Laboratory (DEMATEL), Simple Additive Weightage (SAW), VIseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR), Analytic Hierarchy Process (AHP), Elimination Et Choice Translating Reality (ELECTRE), Preference Ranking Organization Method for Enrichment Evaluations (PROMETHEE), Complex Proportion Assessment Method (COPRAS), Analytic Network Process (ANP), Multi-objective Optimization on the Basis of Ratio Analysis Method (MOORA), Stepwise Weight Assessment Ration Analysis (SWARA), and others [4], [5], [6], [7] and [8].

Generally, TOPSIS is the most popular technique for handling MCDM problems [9]. It depends on synthesizing the criteria and dividing the alternatives into two subsets: positive and negative solutions. The optimal solution has the shortest distance from the positive set of solutions and the longest distance from the negative set of solutions [10].

Due to its advantages over other fuzzy extensions, SVN Set has been taken into consideration for handling vagueness. The membership function, used in fuzzy set theory developed by Zadeh et al. [11], translates linguistic terms into membership values. However, the value of membership for a term may vary among experts. For example, one expert may give a value of two to express the linguistic term "low," while another may give a value of three.

To address this issue, a Neutrosophic Set (NS) is employed. With the condition that the three membership values must be less than or equal to three, NS allows decision-makers to judge in three degrees: truth, indeterminacy, and falsity. As a generalization of all fuzzy set versions, NS has been combined with several MCDM techniques and aids decision-makers in resolving ambiguity in their judgment [12].

The main contributions of this research can be summarized as follows:

- A comprehensive analysis of the robustness of MCDM models against the RRP.
- An evaluation of the suggested model's resistance to RRP.
- The integration of SVN theory with a modified Entropy-based TOPSIS method.
- A comparative analysis between the proposed model and other MCDM models.

The rest of the paper is organized as follows: Section II discusses related work. Section III presents the methodology used in the proposed model. In Section IV, we present the results and validation of our model. Section V summarizes the conclusions of our research, and Section VI outlines future work.

## II. RELATED WORK

The increasing number of CSPs has attracted the interest of researchers in evaluating their performance in different applications. The primary objective of this research is to assess CSP performance and develop techniques for finding the most effective and optimal CSP. MCDM techniques have been extensively utilized in previous publications to handle decision-making problems in various industries, such as supplier and employee selection. Since the current proposed methodology combines TOPSIS with NS to identify the optimal CSP, we first explored MCDM-based techniques. Then we reviewed numerous publications that used NS in conjunction with MCDM to tackle different decision-making problems. After that, we highlighted the drawbacks of the MCDM-based TOPSIS technique.

Zulqarnain et al. [13] applied neutrosophic TOPSIS to select the most suitable supplier and found that neutrosophic can handle uncertainty in decision-making. However, they did not consider the RRP in TOPSIS.

Garcia et al. [14] discovered that the TOPSIS technique suffers from RRP due to changing the normalized value of the judgment matrix when an alternative is added. They proposed two hypothetical values representing the minimum and maximum values for each criterion, and the modified technique can handle some cases of RRP.

Abdel-Basset et al. [15] developed a hybrid technique combining neutrosophic set theory and AHP to evaluate cloud services. They implemented a function to convert linguistic terms into crisp values. The hybrid technique is effective when classical AHP fails due to an inconsistent pairwise decision matrix; however, it does not address RRP.

Kumar et al. [16] developed a hybrid technique by combining AHP and TOPSIS. AHP is used to obtain each criterion's weight, and TOPSIS is used to rate CSPs based on cloud benchmarking reports. A significant limitation of this research is that it cannot handle the uncertainty problem, or RRP, in MCDM.

Jatoth et al. [17] developed an integrated model that consists of AHP and grey TOPSIS. The grey set is used to handle uncertainty in decision-making. The proposed model considers both functional and non-functional requirements of cloud services but does not consider the RRP.

Aires et al. [18] proposed R-TOPSIS, a modified version of TOPSIS. This model requires a judgment matrix, criteria weights, and domains for each criterion. It uses the domain of each criterion with a max or max-min normalization approach to normalize the judgment matrix. The Positive Ideal Solution (PIS) and Negative Ideal Solution (NIS) are computed using a novel method. The results showed that the model fails to handle RRP when removing a non-distinct criterion.

Goswami et al. [19] proposed a technique for choosing the optimal steel grades and their corresponding heat treatment procedures using a hybrid technique based on entropy and TOPSIS. The limitation of this model is that it cannot handle uncertainty or RRP.

Tiwari et al. [12] developed a framework based on neutrosophic TOPSIS to handle uncertainty in decision-making. The framework is validated against only two types of RRP: the insertion and deletion of alternatives from the decision matrix.

Hezam et al. [20] developed an MCDM model based on neutrosophic AHP and TOPSIS to identify the priority groups for the COVID-19 vaccine. The model was able to handle uncertainty, but it has not been validated against the RRP.

Trabay et al. [21] built a mathematical model based on MCDM to rate the trustworthiness of cloud services based on various opinions. The results showed that fuzzy TOPSIS provides more accurate results than TOPSIS, fuzzy AHP, and AHP.

Saha et al. [22] proposed a hybrid MCDM model consisting of ANP and VIKOR, where ANP is used to obtain the local rank of CSP, and VIKOR is used to obtain the global rank. The major disadvantage of this model is that it cannot handle uncertainty or RRP.

Dani et al. [23] developed a technique to assess the efficiency of educational boards. They used a linear weighted model and TOPSIS. The results showed that the ranks obtained by both models were very similar.

Dhand et al. [24] developed a network selection model consisting of fuzzy AHP and ELECTRE, where fuzzy AHP is utilized to obtain the weight of each criterion, and ELECTRE is utilized to rate networks. Results showed that the model could effectively select the optimal network, but it has not been validated against the RRP.

According to previous research, we can consider CSPs ranking as a decision problem. The majority of researchers employed MCDM to select the optimal CSP. Some techniques are extended to fuzzy or NS theories to handle uncertainty. The previously discussed related works addressed either the RRP or uncertainty, but none tried to address both rank reversal and uncertainty simultaneously.

NS has become essential in solving decision problems because it can more efficiently handle uncertainty problems in decision-making. Therefore, we used a neutrosophic set with an integrated Entropy-TOPSIS technique to choose the optimal CSP. The novel model is effective and robustly selects CSPs in the neutrosophic state. Our research is the first to apply the integrated Entropy-TOPSIS technique to CSP ranking.

### III. METHODOLOGY

#### A. Basic Concepts

This section introduces Entropy, TOPSIS and some basic definitions of NS and SVN.

1) *Neutrosophic set theory*: This theory considers every idea  $\langle X \rangle$  along with its negation  $\langle \text{Anti-}X \rangle$  and a group of "neutralities,"  $\langle \text{Neut-}X \rangle$ , which lies between the two boundaries and supports neither  $\langle X \rangle$  nor  $\langle \text{Anti-}X \rangle$  [11].

a) *Single valued neutrosophic set*: Let  $X$  be a space of objects,  $x \in X$ . A neutrosophic set  $N$  on  $X$  is defined by a truth membership  $T_N$ , an indeterminacy membership  $I_N$ , and a falsity membership  $F_N$ .  $T_N(x)$ ,  $I_N(x)$  and  $F_N(x)$  are subsets of  $[0, 1]^+$ , and the sum of their values is between  $0$  and  $3^+$  [12].

b) *Score function*: Junaid et al. [25] proposed the following score functions  $S(x_{i,j})$  to transform the neutrosophic numbers into crisp numeric value.

$$S(x_{i,j}) = \frac{Lx_{i,j} + Mx_{i,j} + Ux_{i,j}}{3} + (T_{x_{i,j}} - I_{x_{i,j}} - F_{x_{i,j}}) \quad (1)$$

$$S(x_{i,j}) = \frac{1}{s(x_{i,j})} = \frac{1}{\frac{Lx_{i,j} + Mx_{i,j} + Ux_{i,j}}{3} + (T_{x_{i,j}} - I_{x_{i,j}} - F_{x_{i,j}})} \quad (2)$$

Where  $L$ ,  $M$ , and  $U$  are the lower, medium, and upper values of the neutrosophic numbers, and  $T$ ,  $I$ , and  $F$  are the degrees of truthiness, indeterminacy, and falsity. If there is more than one decision expert, then the average of all experts' scores should be calculated to obtain the aggregated matrix [25].

2) *Entropy*: Entropy is an objective weighting method developed by Shannon [26]. It is used to calculate the weight of criteria for a multi-objective decision problem without considering the decision-makers' opinions. Weights are identified using the entropy method, which automatically computes the weight of criteria based on the judgment matrix, i.e., the significance of the parameter in relation to the other parameters. The steps of entropy are listed in [19].

3) *TOPSIS*: TOPSIS is the most widely used MCDM method, which ranks alternative solutions based on increasing the distance from the negative ideal point and reducing the distance from the positive ideal point. The steps involved in the TOPSIS method are listed in [19].

#### B. Proposed Model

Aires et al. [18] determined that an effective solution for the RRP in TOPSIS technique should take the following factors into account at the same time:

- Selecting a normalization method that reduces the consequences of alternative dependence.
- Using fixed NIS and PIS even if the set of alternatives is modified.

In addition to that, a lot of related works used the neutrosophic set to eliminate uncertainty in decision-making [25]. Therefore, we proposed a model based on SVN numbers to handle uncertainty problems, and we modified the normalization procedure in the Original TOPSIS technique. Moreover, a normal Gaussian distribution for normalization [27] and fixed PIS and NIS were used to calculate the rank of alternatives.

The steps of the proposed model are given in Algorithm 1, and a schematic diagram of the proposed model is presented in Fig. 1.

---

#### Algorithm 1: Proposed Model

---

##### A. Phase I: Modified Entropy

**Input:** The decision matrix  $D$  ( $m \times n$ ) which contains the performance values and is represented in linguistic terms. 'm' denotes the number of alternatives, and 'n' denotes the number of criteria.

**Output:** The weight of each criterion.

*Step 1:* Create a Decision Matrix  $D$ .

$$D = \begin{bmatrix} x_{1,1} & \dots & x_{1,n} \\ \vdots & \ddots & \vdots \\ x_{m,1} & \dots & x_{m,n} \end{bmatrix} \quad (3)$$

*Step 2:* Map each linguistic term to its equivalent SVN value using Table I.

TABLE I. MAPPING BETWEEN LINGUISTIC TERM AND SVNS

Linguistic terms	SVNs
Extremely Low (EL)	$\langle (1, 2, 3); (0.3, 0.75, 0.7) \rangle$
Very Low (VL)	$\langle (2, 3, 4); (0.4, 0.6, 0.65) \rangle$
Low (L)	$\langle (3, 4, 5); (0.6, 0.35, 0.4) \rangle$
Medium Low (ML)	$\langle (4, 5, 6); (0.7, 0.3, 0.35) \rangle$
Medium/Fair (M/F)	$\langle (1, 1, 1); (0.5, 0.5, 0.5) \rangle$
Medium High (MH)	$\langle (5, 6, 7); (0.8, 0.25, 0.3) \rangle$
High (H)	$\langle (6, 7, 8); (0.85, 0.2, 0.25) \rangle$
Very High (VH)	$\langle (7, 8, 9); (0.9, 0.15, 0.2) \rangle$

Step 3: Convert the SVN into crisp numbers using score function given in Equation 1.

Step 4: Compute normalized decision matrix ‘ $r_{i,j}$ ’.

$$r_{i,j} = \frac{x_{i,j}}{\sum_{i=1}^m x_{i,j}} \quad (4)$$

Step 5: Calculate the entropy value ‘ $e_j$ ’ for each criterion.

$$e_j = -h \sum_{i=1}^m r_{i,j} \ln(r_{i,j}) \quad (5)$$

where  $h=1/\ln(m)$  and  $m$  is the number of alternatives.

Step 6: Compute the degree of divergence ‘ $G_j$ ’ for each criterion.

$$G_j = |1 - e_j| \quad (6)$$

Step 7: Compute the weight of each criterion ‘ $w_j$ ’.

$$w_j = \frac{G_j}{\sum_{j=1}^n G_j} \quad (7)$$

### B. Phase II: Modified TOPSIS

**Input:** The same decision matrix in (phase I) and the criterion weightages ‘ $w_j$ ’ from (phase. I).

**Output:** The rank of each alternative.

Step 1: Calculate the normalized decision matrix ‘ $M$ ’ using the normal Gaussian distribution function  $F(x_{i,j})$ .

$$m_{i,j} = F(x_{i,j}) = \int_{-\infty}^{x_{i,j}} e^{-(x-\mu)^2/2\sigma^2} dx \quad (8)$$

Step 2: Calculate the weighted normalized decision matrix.

$$W_{i,j} = w_j * m_{i,j} \quad (9)$$

Step 3: Calculate the PIS and NIS using the following equations.

$$v_j^+ = \{v_1^+ \dots v_m^+\} = \begin{cases} v_j^+ = w_j & \text{if } j \in \text{Benefit Criteria} \\ v_j^+ = 0 & \text{if } j \in \text{Cost Criteria} \end{cases} \quad (10)$$

$$v_j^- = \{v_1^- \dots v_m^-\} = \begin{cases} v_j^- = 0 & \text{if } j \in \text{Benefit Criteria} \\ v_j^- = w_j & \text{if } j \in \text{Cost Criteria} \end{cases} \quad (11)$$

Step 4: Compute the Euclidean distance  $S_i^+$  and  $S_i^-$  of each alternative from the PIS and NIS.

$$S_i^+ = \left[ \sum_{j=1}^m (v_{i,j} - v_j^+)^2 \right]^{1/2} \quad (12)$$

$$S_i^- = \left[ \sum_{j=1}^m (v_{i,j} - v_j^-)^2 \right]^{1/2} \quad (13)$$

Step 5: Calculate the closeness index ( $P_i$ ) for each alternative.

$$P_i = \frac{S_i^-}{S_i^+ + S_i^-} \quad (14)$$

Step 6: Rank each alternative based on its relative closeness index ( $P_i$ ) in descending order.

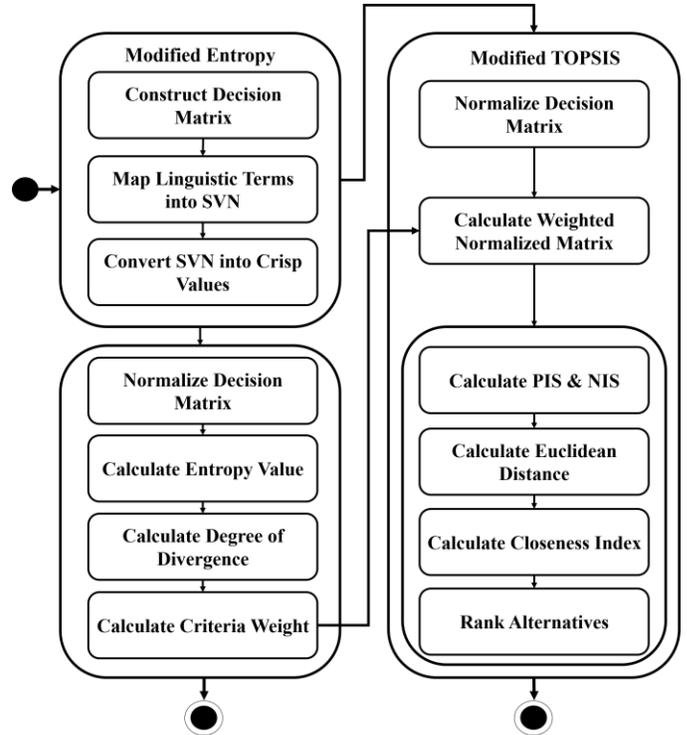

Fig. 1. Schematic diagram of the proposed model

## IV. CASE STUDY

The proposed CSP selection methodology assists cloud users in choosing the appropriate cloud service for their needs. A case study was carried out to validate its reliability, where we applied the proposed model using a real dataset obtained from Tiwari et al. [12]. This dataset was obtained from reports issued by Cloud Harmony [1], a cloud benchmarking service provider. In addition to applying our proposed model in the case study, we conducted sensitivity and performance studies on the proposed model. Furthermore, the model was compared and validated with other studies.

### A. Data Set

The dataset contains ten QoS parameters from six real-world CSPs. The QoS parameters used are Cost (C), Latency of Network (NL), Sequential Disk RW Performance Consistency (SDRWPC), Random Disk RW Performance Consistency (RDRWPC), CPU Integer Performance (CPUIP), CPU Floating Point Performance (CPUFPP), Memory Performance on Scale (MPS), Memory Performance on Triad (MPT), Sequential RW Disk Performance (SRWDP) & Random RW Disk Performance (RRWDP). The first four criteria are costly, while the others are benefit criteria. Table II shows the dataset, where all values are represented in linguistic terms [12].

TABLE II. DATA SET [12]

CSP	C	NL	SDRWPC	RDRWPC	CPUIP	CPUFPP	MPS	MPT	SRWDP	RRWDP
Soft Layer	L	VL	L	F	L	L	H	H	F	F
Rack Space	F	F	F	F	L	L	H	H	H	L
Ms. Azure	L	F	L	L	VL	VL	F	F	L	L
Google	L	H	L	L	L	L	H	H	VL	VL
Digital Ocean	L	F	VL	VL	L	L	H	H	L	L
Amazon EC2	L	VL	L	L	L	L	H	H	L	L

### B. Cloud Service Ranking

The proposed model was used to calculate the rank of CSPs. Table II presents the judgment matrix for the dataset used in this study, which was formed based on 10 QoS measures and 6 CSPs. After applying the proposed model shown in (Algorithm 1), the rank of each CSP was calculated using the closeness index. Rack space was ranked as the optimal CSP, while Amazon EC2 was the worst CSP.

### C. Sensitivity Analysis

The analysis was conducted to evaluate the proposed model's reliability and consistency in different RRP scenarios. This analysis had two objectives: the first was to determine the RRP when changing the number of alternatives, and the second was to test the proposed model's reliability. This was achieved by performing a complete test to observe a variation in each case. The ranking model is considered to be reliable if it consistently ranked CSPs.

The Five types of RRP are discussed as follows:

1) *The first type: Deletion of an alternative from the dataset:* This rank reversal analysis was carried out by deleting only one CSP. Six experiments were performed on the Cloud Harmony dataset (Table. 2). In each experiment, a single CSP was deleted. No changes were observed in the closeness index and rank of alternatives, demonstrating that the proposed model is resistant to the RRP found in the first type.

2) *The second type: Addition of an alternative to the dataset:* This rank reversal analysis was carried out by adding a CSP alternative. Four experiments were performed, and the closeness index and rank were calculated each time. The rank of alternatives was not affected by adding any alternatives, demonstrating that the proposed model is resistant to the RRP found in the second type.

3) *The third type: Addition of an irrelevant alternative:* The third type of RRP is carried out by adding an irrelevant alternative to the dataset to assess the reliability of the proposed model. We added an irrelevant  $(CSP)_x$  with the same criteria as Rack Space alternative which exists in the data set (Table II). The Closeness index and rank were computed, and

we observed that rank was the same before adding an irrelevant alternative  $(CSP)_x$ .

4) *The fourth type: Testing the property of transitivity by dividing the existing matrix into two sub-decision matrices:* In the Fourth type, the decision matrix was divided into two subsets, then the rank was calculated in each sub set and compared to the rank of the original decision matrix. After performing this test, we found out that the rank obtained from the two subsets was the same as the rank obtained from the original matrix.

5) *The fifth type: The deletion of a non-distinct criterion:* The Fifth type was carried out by deleting a non-distinct criterion from the existing dataset. A non-distinct criterion is a criterion with the lowest standard deviation. In our experiment the third criterion named SDRWPC was removed since it had the lowest standard deviation, then we observed that rank obtained after removing the non-distinct criterion was the same as the rank obtained before removing this criterion, which demonstrates that the proposed model is resistant to RRP found in type five.

The above rank reversal sensitivity analysis for all test cases showed that the proposed model is resistant to the RRP.

### D. Results Validation

A validation was conducted to verify the accuracy of the rank calculated by the proposed model as follows:

1) *Firstly,* comparative analysis was performed to validate the proposed model. Fig. 2 demonstrates the ranking of each CSP obtained using the model and related work. Rack space was ranked first in all techniques, Google second, Digital Ocean third, Ms. Azure fourth, and soft layer and Amazon EC2 sixth and fifth, respectively, in all techniques except the technique proposed by Kumar et al. [16]. In addition, the model ranked the alternatives almost identically to those developed by Goswami et al. [19] and Aires et al. [18]. In contrast, it slightly differed from the model developed by Kumar et al. [16]. Therefore, it could be concluded that the proposed model accurately ranks CSPs.

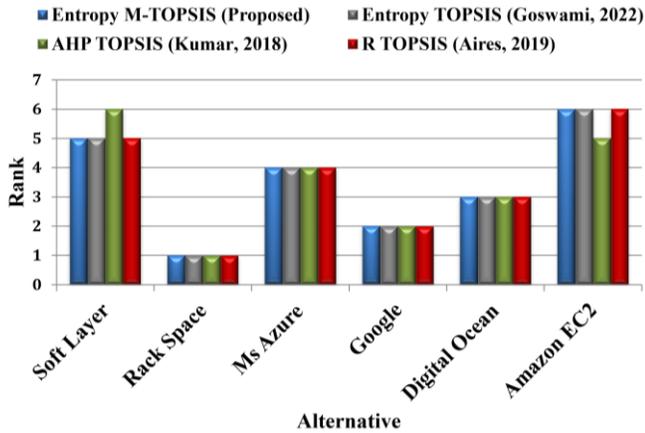

Fig. 2. The rank of CSP for the proposed model & related work

2) *Secondly*, the suggested model and other related work were compared [18], [19], and [16]. Table III shows the resistance to the RRP for the proposed model and related work. The proposed model could handle all five types of RRP, while the original TOPSIS, Entropy-TOPSIS, and AHP-TOPSIS techniques could not handle all kinds of RRP. R-TOPSIS, developed by Aires et al. [18], could handle all types of RRP except type five.

TABLE III. THE RRP ANALYSIS FOR THE PROPOSED MODEL AND RELATED WORK

Method	Type 1	Type 2	Type 3	Type 4	Type 5
Proposed Model	√	√	√	√	√
Entropy-TOPSIS	X	X	X	X	X
AHP-TOPSIS	X	X	X	X	X
R-TOPSIS	√	√	√	√	X
TOPSIS	X	X	X	X	X

3) *Thirdly*, statistics of dispersion and similarity were used to compare the techniques in related work with the proposed model. The following statistical methods were applied in validation phase [18], [28] and [29]:

- *Similarity*: Mean Absolute Error of Rank (MAER) and Spearman’s Rank Correlation (SRC).
- *Dispersion*: The Standard Deviation of the closeness coefficient for each rank (SD), the difference between the closeness coefficient of the best alternative and the worst (BWD), and the difference between closeness coefficient of the 1<sup>st</sup> and 2<sup>nd</sup> alternative (FSD).

The simulation was implemented in MATLAB. Table IV compares the proposed model and its other variants, considering similarity (SRC and MAER) statistics and dispersion (SD, BWD and FSD) statistics. An average of four simulation cycles was used for 4,000 simulated cases.

Comparing the dispersion measures for each technique, the proposed model generally had smaller values for (SD, BWD and FSD) than the other models. Furthermore, based on the statistical methods used to compute the similarity degree between the ranks obtained by the four techniques, it was observed that there is a very high degree of similarity between the rankings, indicating that the suggested model corresponds to the other methods. Fig. 3 and Fig. 5 show that the MAER value between the proposed model (M1) and method (M2) is the lowest. In contrast, Fig. 4 and Fig. 6 show that the SRC value between (M1) and (M2) is the highest. Moreover, method (M4) deviated from the proposed model more than the other methods. Therefore, it can be concluded that the proposed model is more similar to the method (M2) according to all similarity measures.

TABLE IV. DISPERSION AND SIMILARITY STATISTICS

Method	SD	BWD	FSD	SRC	MAER
Entropy M-TOPSIS (M1)	0.0582	0.1106	0.0569	0.8120	0.0823
Entropy TOPSIS (M2)	0.1959	0.3740	0.1946		
Entropy M-TOPSIS (M1)	0.0582	0.1106	0.0569	0.2295	0.3420
AHP-TOPSIS (M3)	0.2109	0.3989	0.1946		
Entropy M-TOPSIS (M1)	0.0582	0.1106	0.0569	0.1080	0.3963
R TOPSIS (M4)	0.1504	0.2858	0.1674		

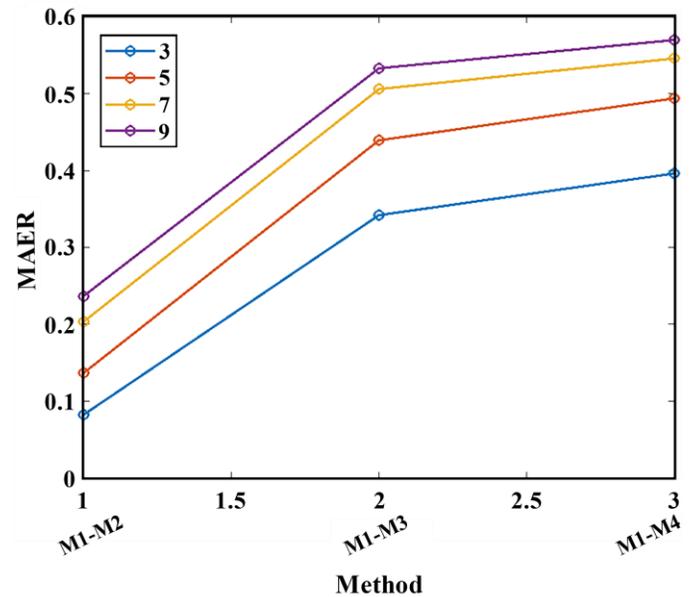

Fig. 3. MAER by number of alternatives

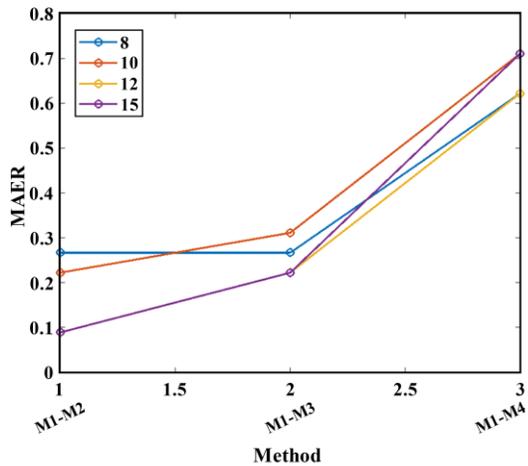

Fig. 4. MAER by number of criteria

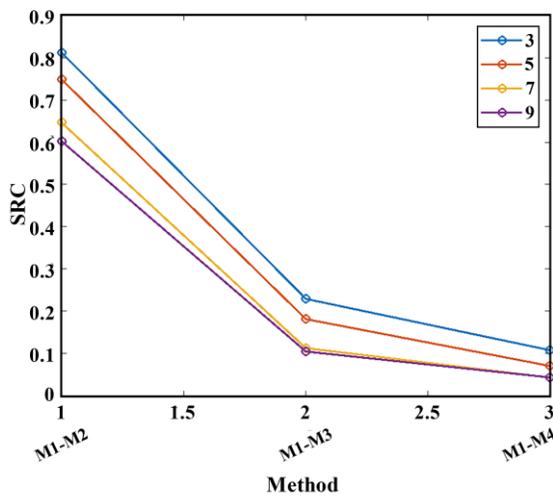

Fig. 5. SRC by number of alternatives

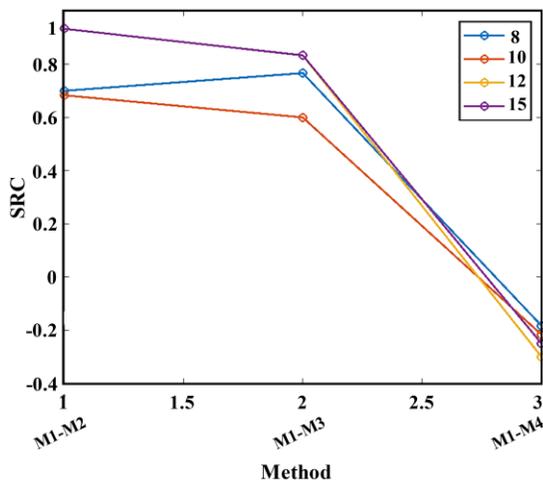

Fig. 6. SRC by number of criteria

4) *Fourthly*, the execution time of the proposed model and related work was measured with increasing the number of alternatives. The analysis was carried out using a Core i5 (8<sup>th</sup> Gen.) PC, with WIN 10 (64-bit) OS, and 8 G.B RAM. Linguistic terms for about 1,500 alternatives and ten criteria were randomly generated. Fig. 7 shows the execution time of the proposed model and other related work. It can be noted The proposed model took less time to execute than Entropy-TOPSIS and AHP-TOPSIS and only slightly more time than R-TOPSIS, by just a few milliseconds.

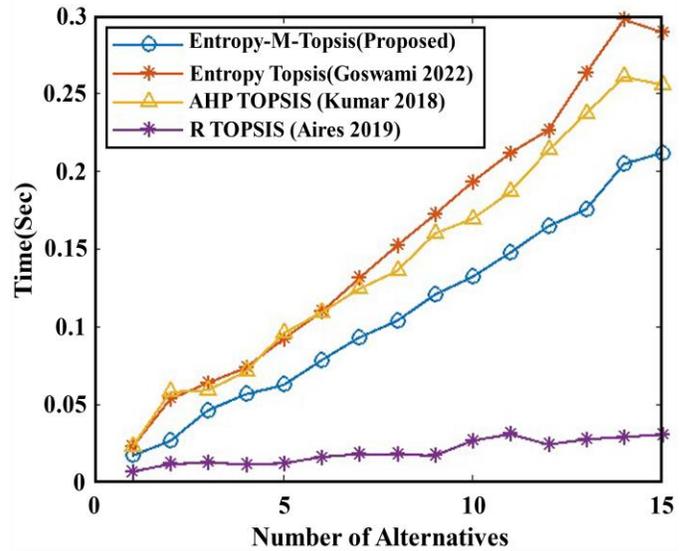

Fig. 7. Analysis of the execution time

## V. CONCLUSION

The analysis of RRP in TOPSIS presented in this study is comprehensive. We have identified that the normalization process and the selection of PIS and NIS are the leading causes of RRP in TOPSIS. To address these issues, we utilized the normal Gaussian distribution function for normalization and introduced a new approach for calculating PIS and NIS. Moreover, we proposed a novel extension to handle insufficient information, including degrees of truth, indeterminacy, and falsity, by integrating SVN with the suggested model. The proposed model was validated through sensitivity analysis, comparative analysis, and statistical measures of similarity and dispersion. The results indicated that the proposed model could improve the decision-making process under uncertainty with high accuracy and robustness against RRP, making it applicable to any multi-criteria decision problem. One limitation of this research is that it did not consider subjective weighting-based approaches that determine criteria weights based on the judgments of decision-makers. Table V summarizes the overall results of this research work.

TABLE V. SUMMARY OF THE OVERALL RESULTS

Model	Evaluation Criteria	
	Handling Uncertainty	Handling All Types of RRP
Proposed model	√	√
Entropy-TOPSIS	x	x
R-TOPSIS	x	x
AHP-TOPSIS	x	x

## VI. FUTURE WORK

New extensions of neutrosophic sets can be utilized to solve the uncertainty problem and provide more accurate results to support the decision-making process. In addition, the output from various MCDM techniques, such as COPRAS, PROMETHEE, and others, can be compared to the results of the current research. Finally, other subjective and objective weighting-based approaches can be utilized, and the difference in rank can be assessed.

## ACKNOWLEDGMENT

We would like to thank Prof. F. Smarandache and Dr. Mohamed Abdel-Basset, for their support.

**Abstract**—The architectural design is fundamental in the construction process of a virtual rehabilitation system since it allows to understand the components and their interaction, and it is a guide to develop the software. This article proposes a dynamic architecture design that could be used independently of software and hardware in a virtual rehabilitation system for motor dexterity. This proposal contributes to the software engineering area since it provides a starting point for the development of virtual rehabilitation systems. The system implementation was done with two tracking devices (hardware) and two rehabilitation games (software). It was validated with the User Experience Questionnaire (UEQ). Results show that the use of a dynamic architecture allowed to use different devices efficiently and quickly, regardless of the game, preventing the user from feeling a change or difficulty in carrying out the tasks.

**Keywords**—Software architecture; dynamic architecture; virtual rehabilitation systems; motor dexterity

## I. INTRODUCTION

Software architecture as a subfield in engineering defines the structure, operation, properties and relationship between software elements [1, 2].

Today the changing nature of technology has driven the customization and application of modern design techniques to meet the software requirements of emerging systems [2], one of them is Virtual Rehabilitation Systems (RhV) [3]. These types of systems have simplified the need for physical environments and have shown good results in the area of rehabilitation through repetition, sensory feedback, multisensory stimulation, and motivation [4].

Based on the literature review [5-11] it was seen that existing designs based on proposed software architectures for RhV systems are poorly described or difficult to maintain and evolve over time.

Even seeing that the recurring variation between the different proposals [5-11] is that its components, despite maintaining the same functional purpose, are continually added, eliminated, and replaced due to the characteristics of the patients, budgetary limitations, or the variety of options available that allow the development of these systems, such as Tech-MCS for remote control of therapy [12], CyberTouch or SaebOGlove applied to the rehabilitation of upper extremities [13, 14], Leap motion, among others.

Giving a system the ability to adapt to these aspects that are already structural is a case of application of a Dynamic Architecture. A type of architecture where there is variation between the number of nodes and links that compose them topologically [15].

It is essential to encourage this type of architecture so that the systems evolve and adapt since there are various diseases that cause problems in motor dexterity such as epileptic encephalopathy, which presents abnormalities associated with progressive brain dysfunction and causes motor impairment due to epileptic activity generated by seizures [16]. Another example is Acquired Brain Injury (ACD) which produces physical, neurocognitive, and/or psychological deficiencies [17]. Its fundamental consequence is the loss of previously developed brain functions that involve the motor and sensory systems [18].

Other examples are autism, cerebral palsy, and stroke, among others. All these conditions cause motor difficulties in the daily life of those who suffer from them, becoming severely disabling on many occasions and requiring rehabilitation tasks. According to the World Health Organization (WHO) [19] 16% of the world's population – experiences significant disability today.

The objective of the work was the design of a dynamic software architecture for virtual rehabilitation systems to improve manual motor dexterity. The implementation was validated with the development of a system that, based on the architecture, can dynamically exchange tracking devices. In this case, this validation was used with two low-cost tracking devices: Leap Motion and a prototype of a haptic glove.

This work emphasizes the use of low-cost devices to demonstrate their applicability from a budgetary point of view, considering that most of the explored systems use expensive and high-priced materials, causing them not to be accessible to the public, for this reason, it proposes the use of Leap Motion and which according to a previous study [20, 21] has shown acceptance, accuracy, and effectiveness to capture specific movements for physical therapies.

The rest of the paper is organized as follows: Section II describes the background Section III presents the dynamic architecture proposal and the dynamic architecture applied in

the virtual rehabilitation system, Section IV shows the results and discussion and, Section V describes the conclusions.

## II. BACKGROUND

### A. Related Works

The design of the architecture in virtual rehabilitation systems is a fundamental part of their creation, however, the literature does not show many related works that focus on this point. In Avola's work [11], a framework for the rapid prototyping of virtual rehabilitation systems is proposed. This proposal also includes a description of libraries to be used as well as information on software development such as avatars and stage design. Another proposal by Avola [22] shows a framework to develop low-cost serious 3D games, this system allows physiotherapists to create personalized rehabilitation exercises without special programming knowledge.

Regarding the design of dynamic software architectures, the work of Cuesta [23] informally elaborates a reflexive model of software architectural description with the scope to dynamic systems but does not go into depth in a practical aspect. Other works such as the ones done by León [5] and Ortiza [6] do not focus their proposal on architecture and show proposals for systems with isolated architectures in their case of application.

### B. Software Architecture

The software architecture of a computer program or system is the structure or structures of the system, comprising software components, the externally visible properties of those components, and the relationships between them [24].

Software architecture is important for a wide variety of technical and non-technical reasons. Some of the reasons are: 1) An architecture will inhibit or enable quality attributes, 2) Decisions that are made in an architecture allow reasoning and managing changes as the system evolves, 3) The analysis of an architecture allows an early prediction of the qualities of a system 4) A documented architecture improves communication between interested parts. 5) Architecture defines a set of constraints on the subsequent implementation. 6) Architecture is the key artifact that allows the architect and project manager to reason about cost and schedule. 7) Architecture-based development focuses attention on component assembly, rather than simply creating it [24].

Architecturally significant requirements (ASR) are those requirements that have a significant impact on the architecture of a software system. They are a subcategory of general software requirements.

### C. Dynamic Architecture

The objective of Software Architecture is to describe the structure of systems, and this should include both its static and changing –dynamic– parts. In fact, in many systems, the differential feature, which distinguishes it from other similar systems, is the dynamic behavior of its architecture; often, it can be even more important than the static schema of departure [15].

Systems have grown in diversity and complexity, which is why the need for dynamic architectures now arises. A dynamic

architecture has as its main characteristic the addition, elimination, or replacement of components, sometimes even as part of normal operation, so structurally they must be taken into account during the design [23]. When the evolution of architecture is continuous, and the changes inside it follow a predefined pattern, then it must be considered that this pattern is an intrinsic part of the structure.

## III. METHOD

### A. Dynamic Architecture Proposal

For the dynamic architecture proposal, the steps shown in Table I have been carried out.

TABLE I. DEVELOPMENT METHODOLOGY

Description Methodology
Step 1: Identification of system quality attribute requirements.
Step 2: Identification of architecturally significant requirements.
Step 3: Identification of architecture components.
Step 4: Classification of components: Identification of static and/or dynamic components.
Step 5: Design of architecture components.
Step 6: Documentation of architecture and validation of design decisions.
Step 7: Analysis and evaluation of software architecture.

### B. Dynamic Software Architecture for Virtual Rehabilitation Systems

For architecture design, the steps described in Table I were considered.

1) *Identification of system quality attribute requirements:* Virtual Reality (VR) technology applied to rehabilitation finds its foundation in the field of motor learning [25]. Virtual Reality attributes that align with the motor learning variables (VAM) defined by Levac & Svestrup [26] are practice: enriched environment and motivation (Table II). These variables are related to software quality attributes for systems.

2) *Identification of architecturally significant requirements:* The functional requirements that have been considered to develop the architecture are shown in Table III.

3) *Identification of architecture components:* The approach is presented in four components that are described below

a) *Component a - data capture:* This component seeks to integrate tracking devices to achieve the detection of rehabilitation movements. A sub-component to consider will be a calibration section, to alleviate lighting, latency, and proximity range issues.

b) *Component b - controller:* This component is the one that receives and stores information as established in the configurations of the rehabilitation sessions or movements. A subcomponent to consider will be a data reporter along with its respective connection to the database.

TABLE II. ATTRIBUTES

VAM	Attributes	Software quality attributes
Practice: quantity, task specificity, and meaning	Potential for abundant repetition of practice tests. Ecologically valid VE improves task specificity. Train movements that are identical to those required in real-life tasks. Options to individualize at different challenge levels. Enriched environment. Goal-oriented tasks. Familiarity with commercially available virtual reality gaming systems.	Reliability Usage facility
Enriched environment	Accurate and consistent. Auditory, visual, or tactile. Performance knowledge. Results knowledge. Positive motivational feedback. Motor learning variable.	Efficiency
Motivation	Novelty of VR technology. Game features. Feedback. Goal-oriented tasks. Ability to individualize treatment options. Users can select tasks. Competition with other players. The coincidence between cognitive and physical effort.	Performance

TABLE III. FUNCTIONAL REQUIREMENT

Functional requirements	Architecture module
Hand-object interaction for better presentation.	System: Game for motor manual rehabilitation
Data capture through hardware for visualization and/or necessary calculations for the software	Hardware device: - Optical tracking device - Haptic tracking device
Information saving from hardware (loose data) and/or final results based on the information given by the hardware.	Relational Database

c) *Component c - movement classifier*: This component goes along with movement and gesture recognition functions. It is used to identify the precision with which a patient performs an action.

d) *Component d - virtual scene*: This component offers an interactive and playful rehabilitation environment developed or accepted by medical specialists. Some specific subcomponents will have to manage the duration of the sessions, the number of elements, and control parameters (right or left hand).

4) *Classification of component - Identification of static and/or dynamic components*: Given that there are a variety of options for tracking devices on the market, as well as games or virtual environments, components A and D (Fig. 1) are proposed as dynamic so that, depending on the demographic, budgetary or patient conditions, they can be replaced. or complemented (added). On the other hand, components B and C (Fig. 1) are considered static since they must be the control axis of the system.

5) *Design of architecture components*: Fig. 1 shows the generic design of the architecture proposed together with the four identified components. An application instance of the proposed architecture for each of the components is detailed below.

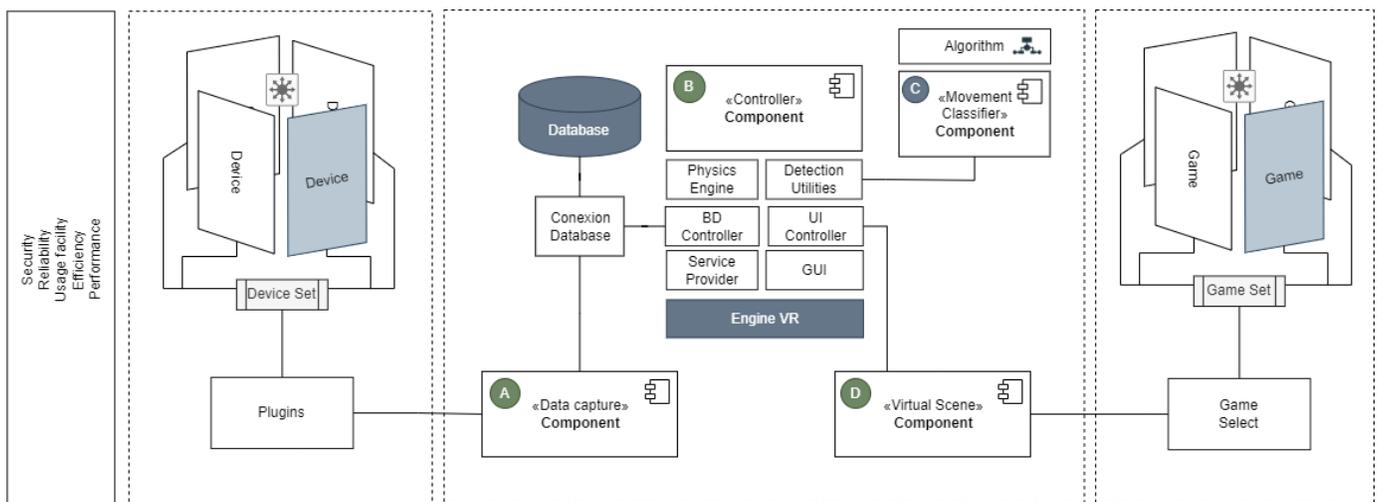

Fig. 1. Generic design of a dynamic software architecture for virtual rehabilitation systems

a) *Component a - data capture*: In this step, two devices have been selected to capture data from the detection of rehabilitation movements: Leap Motion Controller and a Haptic Glove. A calibration section was also considered in this module, to alleviate lighting, latency, and proximity range issues.

Leap Motion Controller (LMC): It is an optical device without markers oriented to control gestural movement. It detects hand movements, fingers, and even objects around its range of vision. LCM can control different interfaces on any computer simply by executing hand movements without touching screens [21]. This device is small and cheap compared to others on the market. LMC dimensions are: 75 mm long, 25 mm wide, and 11 mm high. Its structure consists of two cameras that contain monochrome sensors sensitive to infrared light, whose function is to capture all images [27]. The coverage area (Fig. 2) of the Leap Motion device: it is a hemisphere with a radius of 61 cm, which depends on the viewing angle of the lenses of the two cameras, as well as the maximum intensity provided by the USB connection to the LEDs.

Haptic Glove: The device allows to perform movements in order to control an avatar. This glove uses a sensor that detects supination and pronation movements of the hand, as well as abduction and adduction movements of the wrist.

b) *Component b - controller*: This component must maintain a direct relationship with the data generated in the tracking device and its representation in virtual environments. For this purpose UNITY was selected (Fig. 3)

c) *Component c - movement classifier*: In this work the Dynamic Time Warping (DTW) algorithm is used for sequence recognition [28] to evaluate the degree of similarity of the movements with other previously recorded, given its compatibility with Leap Motion SDK.

d) *Component d - virtual scenario*: Finally, in Component D, a rehabilitation environment was designed through a 2D game. Which focuses on controlling the execution of movements in the hands. This design was based on the International Classification of Functioning, Disability, and Health (ICF) [29] of the WHO and focused on exercises that make it possible to enhance the component of mobility-oriented activities to improve motor dexterity.

The specific activities to be implemented, according to the ICF classification, refer to subclassification d4453: "Turn or twist hands or arms" and subclassification d4400: Pick up:

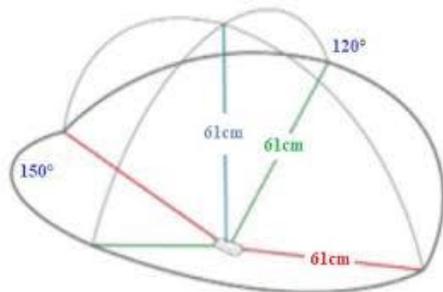

Fig. 2. Leap motion coverage area

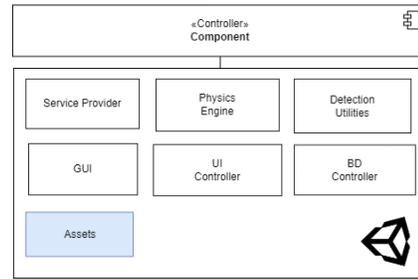

Fig. 3. Controller subcomponents

"lift or take a small object with hands and fingers, as when picking up a pencil. These exercises were proposed by two physical therapy specialists and a pediatric neurologist. The implemented gestures were extension, flexion, supination, and pronation, and the combination of them to achieve displacement and jumps. The tracking device (Leap Motion or Haptic Glove) allows to control the game avatar.

The objective of the game is to mobilize an avatar through a road which must avoid a certain number of obstacles through jumps until reaching a destination. Every time it avoids an obstacle it will receive points and/or prizes depending on the difficulty, and every time it misses it loses one point.

The game has three difficulty levels which refer to the proximity of the obstacles and the reaction time of the patient to jump. Fig. 4 shows avatar control using Leap Motion and Fig. 5 shows avatar control with the haptic glove.

Fig. 6 shows the running game environment. Since many types of patients can be trained in motor rehabilitation sessions, the system must be adapted to the different needs of each patient.

Fig. 4. Game in execution, controlled with leap motion

Fig. 5. Game in execution, controlled with the haptic glove

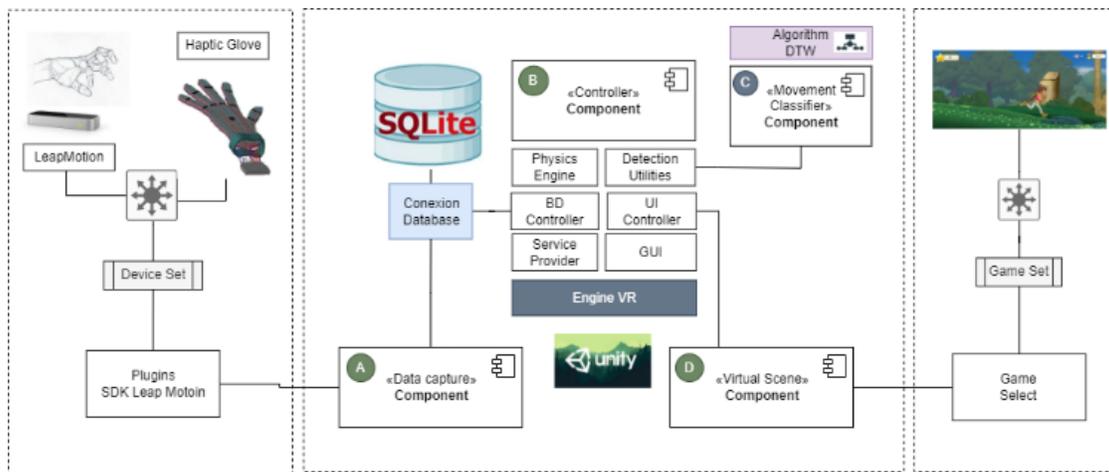

Fig. 6. Dynamic software architecture for a virtual rehabilitation system for the improvement of manual motor dexterity

The game allows different configurations according to the characteristics of the patient: Sex (Male or Female), Age (allows to use a different avatar). The game allows to set the time for the exercises, the number of obstacles, and which hand to use (left or right hand). These features are a clear example of the need for dynamic architecture.

6) *Documentation of architecture and validation of design decisions:* As a result of the application of the architecture, the specific implementation of the architecture is shown in Fig. 7. The validation of design decisions is very complex and generally depends on the context. For validation, there are qualitative techniques such as scenarios, questionnaires, or checklists and quantitative techniques with metrics, simulations, mathematical models, prototypes, or experiments [30].

It was determined to validate the design by a quantitative technique performing a simulation of rehabilitation, experimentation, and a specific analysis because of the changing nature of the system. This point is described in detail in step 7.

7) *Analysis and evaluation of software architecture:* For the evaluation, a comparative analysis of the user experience (UX) was used, considering the implementation with the LeapMotion optical tracking device and the implementation with the haptic glove. The instrument was the validated User Experience Questionnaire (UEQ) [31].

Fig. 7. Game in execution, shows the control of time to achieve the goal by avoiding the obstacles. points and reward system is managed

UEQ comprehensively measures six dimensions: (a) Attractive: the product must look attractive, pleasant, and friendly; (b) Efficiency: the user must perform tasks with the product quickly, efficiently, and pragmatically; (c) Perspicuity: the product must be easy to understand, clear, simple and easy to use; (d) Reliability: the interaction with the product must be predictable, safe and meet the expectations; (e) Stimulation: the use of the product must be interesting, exciting and motivating; (f) Novelty: the product must be innovative, inventive and creatively designed [32].

UEQ consists of 26 questions and applies a seven-point Likert scale. The questionnaire is shown in Fig. 8.

The population size was university students from a public university. The sample was non-probabilistic for convenience. There were participants from schools of Medicine, Psychology, Engineering, and Natural Sciences of Education and Accounting. The age range was between 18 and 22 years old, there were 50 men and 56 women with a total of 106 participants.

	1	2	3	4	5	6	7		
desagradable	<input type="radio"/>	agradable	1						
no entendible	<input type="radio"/>	entendible	2						
creativo	<input type="radio"/>	sin imaginación	3

Fig. 8. UEQ questionnaire

During the evaluation, each participant receives an explanation of the use of the system. Then each participant used the system with their dominant hand. Each participant had a 20-minute interaction with the system, 10 minutes with the Leap Motion device, and 10 minutes with the haptic glove.

IV. RESULTS AND DISCUSSION

A. Results

Table IV shows the results for the use of the Leap Motion Controller device. Values between -0.8 and 0.8 represent a more or less neutral evaluation of the corresponding scale, values > 0.8 represent a positive evaluation, and values < -0.8 represent a negative evaluation. The range of the scales is between -3 (terribly bad) and +3 (extremely good) [33].

As shown in Table IV and Fig. 9, all the values are positive for the use of Leap Motion, with Perspicuity being the highest value, followed by the attractiveness value. For our study and the evaluation of the architecture, the most relevant values are related to the efficiency and reliability scales. These values are positive according to the scale but could be improved.

As shown in Table V and Fig. 10, the evaluation of the use of the system with the Haptic Glove, positive values have also been obtained within the Evaluation Scale, but a little lower ones compared to the use of Leap Motion. Focusing on the Efficiency and Reliability values, both are very similar to the values obtained with Leap Motion.

TABLE IV. RESULTS OF LEAP MOTION EVALUATION

UEQ OF LEAP MOTION EVALUATION		
Attractiveness	1.987	0.96
Perspicuity	2.068	1.31
Efficiency	1.517	1.15
Dependability	1.649	0.95
Stimulation	1.703	1.16
Novelty	1.401	1.33

TABLE V. RESULTS OF HAPTIC GLOVE EVALUATION

UEQ OF LEAP MOTION EVALUATION		
Attractiveness	1.930	0.90
Perspicuity	1.988	1.17
Efficiency	1.517	1.15
Dependability	1.623	0.93
Stimulation	1.696	1.18
Novelty	1.380	1.29

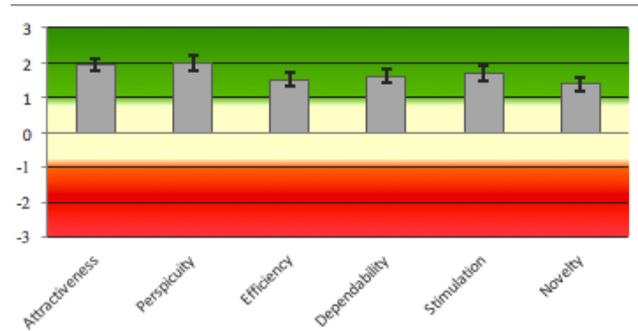

Fig. 10. Results of haptic glove

B. Discussion

According to our User Experience results, the proposed software architecture gave the system through the non-functional requirements of efficiency and reliability enough dynamism so that users not only use different tracking devices for virtual rehabilitation but also in regarding the ease of use, the preliminary users did not feel a change in terms of performing the tasks with the device. Added to this is the fact of performance, since none of the participants reported discomfort and all described the system as a tool support for active participation during the rehabilitation process.

This work provides a contribution by focusing on the architectural aspect of this type of system, since unlike other works where solutions to mobility and rehabilitation problems are proposed, this area is not deepened, leaving said design proposals in isolated environments, traditional and poorly approaches documented.

In works such as [6-8], architectures such as session management and feedback modules are proposed to provide information to therapists or doctors and patients respectively. It is considered that the administrative aspect is not the focus of this proposal but it can be implemented through the integration of the UI and database controller subcomponents. In addition, it will be up to the developer to decide how to complement each exposed component according to its context and rehabilitation tools.

This work does not cover the communication complexities as it works [7] that are usually manifested in customized constructions of tracking devices, where serial or wireless bridge models are used, this prototype uses one of these devices, however, these problems are solved by moment of implementation with the use of external libraries with support for Unity.

It is emphasized that in all cases it is mentioned that the interfaces must be designed with the aim of guiding a high usability which is an aspect that is dealt with in this work.

The architecture prototype was validated with low-cost devices, which demonstrates its versatility so that it can be implemented for systems that have been shown and seek effectiveness [34] to function in any clinical or home environment. This aspect is also reinforced by showing that the devices can be selected from a broader universe that can provide a variety of alternatives regarding costs or patient comfort to treat much less invasive or intrusive devices [35] and adapt to their needs.

This work also proposes to make the rehabilitation environment or game dynamic, in the prototype it was implemented with a single option to make it similar to traditional systems and guide user tests in a single line, however it is recommended to expand the application in groups separated from users, of more varied ages and longer usage times, since such dynamism is easier to achieve once the tracking device is integrated. For future lines of research, it may also be advisable to increase the sample size and include a control group to check the effectiveness of the system with users with manual motor problems. Our results provide evidence of the application of the architecture in previous environments with healthy users.

## V. CONCLUSION

This work showed the design of a dynamic software architecture for low-cost virtual rehabilitation systems for the improvement of manual motor dexterity. The development had the constant advice of medical specialists in physical therapy who identified the exercises to be performed: pronation/supination and flexion/extension for the application instance. The proposed architecture has two static components for the administrative control of the system and two dynamic components to integrate gaming environments and tracking devices. This type of architecture is proposed to delve into this type of system and adapt to the various diseases that cause problems in motor dexterity.

The proposed architecture shows the feasibility through its application instance of reusing and integrating the various tracking devices as well as the different game interfaces that have been proposed in the literature in this gap.

The development considered the required attributes of virtual rehabilitation systems for therapies. With respect to other immersive-type systems, Leap Motion has the advantage that it does not cause discomfort in terms of dizziness and/or nausea, in addition to its characteristics that there is no physical contact with the skin, which is an advantage when patients are children.

The limitations of the study are given by the time of use of each device. As future work, it is intended to implement the suggestions received by the participants, and to carry out the validation of the architecture with other data capture devices and games.

## ACKNOWLEDGMENT

This contribution was financed by the “Universidad Nacional de San Agustín de Arequipa” under contract IB-42-2020-UNSA project “Virtual Rehabilitation System (VR) for motor and cognitive improvement in children with Epileptic Encephalopathy. CEPIVIRT”.

**Abstract**—Among the potential tools in digital marketing, Search Engine Optimization (SEO) facilitates the use of appropriate data by providing appropriate results according to the search priority of the user. Various research-based approaches have been developed to improve the optimization performance of search engines over the past decade; however, it is still unclear what the strengths and weaknesses of these methods are. As a result of the increased proliferation of Machine Learning (ML) and Natural Language Processing (NLP) in complex content management, there is potential to achieve successful SEO results. Therefore, the purpose of this paper is to contribute towards performing an exhaustive study on the respective NLP and ML methodologies to explore their strengths and weaknesses. Additionally, the paper highlights distinct learning outcomes and a specific research gap intended to assist future research work with a guideline necessary for optimizing search engine performance.

**Keywords**—Search engine optimization; google search; natural language processing; machine learning; recommendation

## I. INTRODUCTION

In the present era of the competitive market, every organization and individual intends to ensure that their information reaches the right clients in minimal effort. Stakeholders also need to have a clear insight into their upcoming business demands. From all these perspectives, business products and services are usually maintained via websites. This target is met by using Search Engine Optimization (SEO), which facilitates carrying out the operation to assist the client webpage or its contents to offer higher ranks on the standard platform of Google [1]. The prime distinction between paid advertisement and SEO is that SEO uses an organic methodology to generate ranking scores [2][3]. It will eventually mean that a user will not be required to pay to be in that environment of using SEO [4]. In simplified form, the user of SEO tools identifies and extracts suitable content from a target webpage and optimizes it so that the webpage always appears at the top of google searches [5]. SEO tools, therefore, assist in making higher visibility of the webpage and offers a higher probability of reaching the maximum number of customers. There standard operational taxonomy of SEO is of two types, i.e., on-page and off-page process SEO [6][7]. Basically, the ranking associated with the webpage can be improved by appropriately building the web content using an on-page process of SEO. This process essentially includes constructing higher-quality content, generating appropriate keywords, managing meta-tags, and enhancing the different

objects to ensure that it is well-chosen by the target customer in the on-page SEO process. On the other hand, the backlinks' optimization process is carried out at the backend of the webpage in the off-page process of SEO. This form of SEO mainly focuses on establishing relationships among the content to reach its appropriate customer. Currently, a specific set of programs called bots are used to perform crawling within the webpage using existing search engines, viz. Bing/Google [8]. This operation aggregates information associated with the target web contents, placing them in the form of an index. The web contents are analyzed within the index by such algorithms considering a massive number of signals or ranking values. This is done to ensure the availability of the page at the top of query hits. The prime target of such a form of the search algorithm is to evolve up with a highly authoritative page to offer a superior experience of searching by the user. Irrespective of all the efforts towards improving the performance of SEO tools, there are still serious concerns that have posed as an impediment, viz. i) inaccurate formulation of webpage index, ii) identifying and constructing a precise keyword, iii) structuring the wrong webpage/contents not in line with the target topic, iv) internal linking to be highly incoherent, v) slower /fluctuating uploading performance of the web page in different computing device [9][10]. Therefore, this paper identifies the potential of using Natural Language Processing (NLP) and Machine Learning (ML) approaches to improve the performance of SEO. The paper contributes to potential learning outcomes from existing literature. Further, it also contributes towards identifying significant research gaps extracted from existing techniques to improve SEO performance.

The paper's organization is as follows: Section II discusses the fundamental information about SEO, followed by reviewing existing research practices of SEO with NLP in Section III. Section IV discusses ML practices used in SEO while Section V discusses existing SEO tools. A discussion of existing research trends of SEO is carried out in Section VI, while the research gap is highlighted in Section VII. Section VIII makes discussion about the results and research implications. Section IX finally concludes the paper with significant learning outcomes followed by a briefing of future work to be carried out.

## II. INSIGHTS ON SEO

This section presents insights into SEO or Website positioning. Firstly, a brief description of SEO followed by a

working principle of a search engine is discussed to understand the intrinsic mechanism of SEO. Further, factors affecting website posting are briefly discussed, and finally, this section discusses challenges in SEO.

### A. Search Engine Optimization

SEO is an act that includes a series of professional activities. These activities include the practice of improving the structure of content, thereby increasing visibility in search engines and gaining a large amount of traffic to the website [11]. Common SEO practices include rich content creation, keyword optimization, and link building. Thus, SEO is a powerful mechanism for advancing search engine algorithms to come up with the most relevant and appropriate web content and improve the website's ranking (in an organic way) in search results, ultimately boosting marketability and increasing sales.

### B. Work Principle of the Search Engine

Search engines are obviously fundamental to the SEO process, but many practitioners are unaware of how they work. Therefore, one must first comprehend the basics of search engines to learn SEO. A search engine is a service that enables web search by performing three important tasks such as crawling, indexing, ranking, and recognizing items in the system record or database corresponding to keywords specified by the user [12-13]. Crawling enables search engines to discover content, and indexing is a mechanism for obtaining web documents and maintaining replicas of the content they have visited. The ranking is mainly subject to search engines mainly concerned with SEO operations. Fig. 1 depicts the schematic architecture of the web content indexing process.

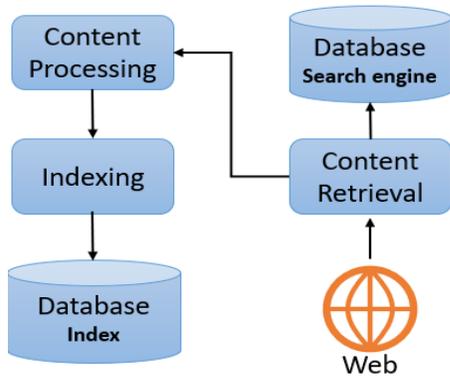

Fig. 1. Procedure of web content indexing

Web content is retrieved using a WebCrawler (bot) that stores the web content in a database of search engines. In addition, web content is subject to data processing operations such as stemming, HTML tag, and stop-word removal. Later, indexing is done by search engines by generating direct and replicating content, such as single words and their positional information on the search page. Furthermore, the search engine keeps the indexes in its index database. Fig. 2, depicts the schematic architecture of the content querying and retrieval procedure.

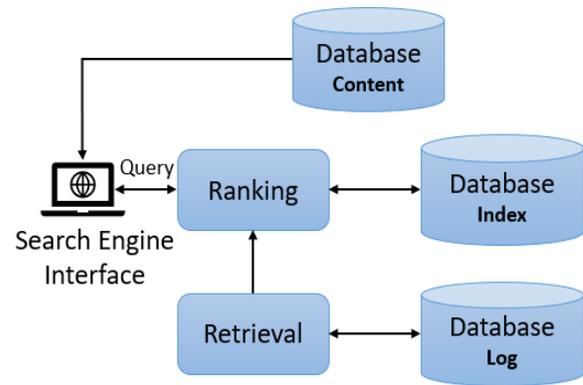

Fig. 2. Content querying and retrieval

Through the search engine interface, the user provides a search query. The search engine algorithm creates a URL ranking list that matches the user's query to the index database based on contextual information. The search engine then displays a snippet subjected to the ranked URL to the user, who can browse and select to retrieve the corresponding content in its original form from the content database.

### C. Factors Affecting Ranking and SEO Challenges

The ranking of web content is influenced by many factors, including page relevance, temporal factors, and link weights [14]. A webpage's relevance is determined by its tags, density distribution, and identical keywords. Temporal aspects are concerned with the oldness of websites, web contents and webpages, the oldness of links, and the duration of domain registration. There are both internal and external links in the contents. However, the external link is given more weight as it is associated with significant factors such as quality, quantity, relevancy, and repetition. A basic mechanism of SEO includes almost all the core attributes of the above-discussed factors, which can be numerically simplified and expressed as follows:

$$Seo = \int C + L + K + O \quad (1)$$

Where,  $C$  is the web content,  $L$  denotes link,  $K$  refers to user keyword,  $O$  represents other factors such as oldness of website, or blog, server, web-design, URL, domain name, and many more. All these factors have priority and should follow priority order as mentioned in the above expression 1. Apart from this, a few challenges associated with search engines significantly affect the quality of the SEO process [15-16]. The first major issue is content spamming, a common method used by unethical users to get their web pages in top results. The next issue is the article spinning, similar to scraping data using specialized software that takes the copied original and reproduces it as a new, original article for future use. The third issue is keyword stuffing, in which users reuse keywords like name, meta, head, etc., in different HTML tags and URL spammers. Furthermore, masquerading is an SEO technique used to mislead users by redirecting them to a page that is different from the page crawled by search engines. Similarly, a URL redirection is also a significant issue where the file is redirected to a specific URL as soon as the user loads the site.

### III. REVIEW OF SEO APPROACHES USING NLP

NLP is an area of ML that reveals the precise structure and meaning of content. Modern websites are driven by algorithms, which determine what they display in search results for specific keywords. Using NLP in optimizing web content, it can be expected that the content would reach the top of the search rankings. NLP can be used to analyze website content and optimize it for specific keywords or phrases. It can be used to identify and correct grammar and spelling errors, as well as to generate content that is optimized for search engines. NLP techniques can also be used to analyze user queries and optimize website content to better match those queries

Many research works are using the mechanism of NLP to achieve optimization in the search ranking. This section provides a brief highlight of the existing literature in the context of SEO. A research article presented by Killoran et al. [17] has examined the influential factors that have a high impact on search ranking. It is reported that search ranking is formed on the basis of participants' category, SEO experts, search engine companies, and users. During the choice of keywords, the authors stated that the website's target audience and competitors have to be taken into account. The study concludes that a combination of appropriate keyword placement and link-building may yield the desired solution. The study of Hajeer et al. [18], applied the NLP mechanism to overcome the limitations associated with the Porter algorithm used for term normalization and index time reduction in the content retrieval systems. The authors have presented a different stemming technique to enhance content searching in an information retrieval system. The results claim improvement over existing technologies. Tsuei et al. [19] devised a customized decision model based on the interview and survey for SEO in internet marketing to boost the hit rate of websites on the search page that satisfy users' requirements. The finding of this study suggests that meta tags are the most influential factor that has a significant impact on the search ranking.

The work of Luh et al. [20] aimed to examine the ranking mechanism of the Google search engines from an SEO viewpoint. The study suggested an estimation function for determining the score of query matching from a limited set of ranking factors. Further, re-ranking is carried out on the basis of obtained scores. The scope of the presented scheme is evaluated based on the comparison of newly obtained ranks with the original ranks. Jenkins et al. [21] developed a model for constructing text annotations for SEO. This model employs the Extreme Gradient Boosting algorithm for precise labeling phrases. Also, logistic regression is considered in this model to generalize the rank of aggregated annotations for clusters of content. The study findings demonstrate that the presented model increases the traffic to the web content by 1-2%. A semantic architecture using web and data mining techniques is presented by Sharma et al. [22] for personalizing the eCommerce search engine. The design and development of the architecture consist of a series of implementation phases were, firstly, a query expansion is performed to transform the input user query using NLP operations to understand the user

requirement. Afterward, ontology classification is carried out to filter out the relevant subjects of the web content. Further topic modeling is carried out using clustering, and statistical computation is then carried to perform a re-ranking operation. Semantic annotation for semi-structured data on a web page using header identification and object classification is presented by Zhang et al. [23]. The authors have designed a description framework for annotating the data domain, and header identification is carried for annotating data objects on the webpage. In addition, a feature vector is constructed for data objects which are left by header identification, and a neural network is then applied to perform semantic annotation.

Adoption of the latent semantic analysis for SEO is carried out by Horasan [24]. In this study, the keyword extraction process from textual data with latent semantic analysis is performed to draw a relationship between documents/sentences and terms in the text using linear algebra. Uzun [25] suggested a model-based string technique and DOM tree for content extraction. The string technique extracts information with the HTML tags followed by the crawling process. The study of Barrett et al. [26] presented an approach for searching large video corpora for clips depicting human language queries expressed as sentences. In this study, a compositional semantics scheme is applied to encode refined meaning to extract the differences between two phrases with the same words under a different context. Sal et al. [27] used a disseminated cooperative cache based on evolutive summary counters to store approximate records of data accesses in a search engine. Ghanbarpour and Naderi [28] examined the ranking technique for keyword search according to the relevancy of the query over graph-structured data. Soltani et al. [29] employed an approach of semantic search engines to develop a different model for software signature search engines. The authors have used the document-to-vector model to compute the signature and user query vectors.

The work of Dai et al. [30] suggested an efficient and adaptive semantic-based keyword ranked search technique using Doc2Vec for secured cloud data. Chen [31] focuses on adopting a user interaction approach to control linguistic ambiguity to improve search engine outcomes. Zhang et al. [32] have suggested a scheme to recognize the identifiers that are associated with semantic text queries. In order to enhance text queries, the authors have looked for keywords within class names from APIs with semantically related APIs. However, if the corpus projects do not have sufficient vocabulary, this technique may not work as well. Calvillo et al. [33] presented an automated mechanism to classify and locate research information based on NLP. The implementation of this scheme focuses on cleaning data by removing aspects such as images and words that are not significant. The digital library was used to extract a percentage of the content from different articles such as abstract, introduction, keywords, and other segments of the article, which help to perform the tests. Hamzei and Hakimpour [34] introduced a method for analyzing queries for spatial search engines. This method employs iterative query segmentation identification of location-names and spatial relationships. Table I highlights the summary of the work being discussed in this section.

TABLE I. SUMMARY OF SEO USING NLP TECHNIQUES

Authors	Problems	Techniques	Advantage	Limitation
Killoran et al. [17]	Search ranking	Analytical study	Highlights influential factors, and important suggestion	Only theoretical and analytical discussion
Hajeer et al. [18],	Indexing time	Stemming	Outperforms Porter algorithm	Related to Over-stemming and only 2.3% of improvement
Tsuei et al. [19]	Identification of factor affecting SEO driver	Decision making system	Highlighted significant website SEO factors	subjective opinions of decision-makers
Luh et al. [20],	Examine ranking of the Google search engines	Rank estimation function and re-ranking scheme	Achieved the best SEO effectiveness	Considered limited set of ranking factors
Jenkins et al. [21]	Understanding content to attract new user	XGBoost and Linear regression	Increases traffic by 1-2 %	Higher dependency on more keystrokes.
Sharma et al. [22]	SEO for ecommerce	Ontology and Semantic Approach	Provides context-aware results and recommendations	Lacks statistical outcome analysis to justify its usability
Zhang et al. [23]	Identification for highlights of multimedia file system	Annotation, Header recognition, Neural network	Semantic annotation of semi-structured information	Only applicable for Chinese language
Horasan [24]	Adoption of knowledge contents	Latent semantic analysis and linear algebra	Complies with the SEO criteria, helpful for who do not know SEO	No effective benchmarking
Uzun [25]	Time efficiency in Web scrapping	String technique and DOM tree	Achieves time efficiency in web scrapping	Dependency on various manual process
Barrett et al. [26]	searching large video corpora from text query	searching large video corpora	Does not require any prior video annotation	Computationally in-efficient
Sal et al. [27]	understanding the underlying content of multimedia	Cooperative cache scheme	Flexible to support large data for analysis	Domain-dependent implementation
Ghanbarpour and Naderi [28]	ranking search problem	Model-based ranking function	Improves the accuracy of the ranking	Only support single keyword search
Soltani et al. [29]	Digital security	Paragraph Vector Model	Achieves higher recall rate	Computationally expensive
Dai et al. [30]	multi-keyword ranking search	Doc2Vec model	Simplified structural model	documents may be lost in the encrypted forms
Chen [31]	misinterprets the user query	Personalized topic search system	Quick response to user search needs	Limited to English language and used small dataset
Zhang et al. [32]	Recognition of the identifiers that are associated with semantic text query	Neural network model (CBOW)	Provides a good scope	If the corpus projects do not have sufficient vocabulary, this technique may not work as well.
Calvillo et al. [33]	locating research paper	NLP based SEO	Better performance in the classification of research article	does not capture position in text,
Hakimpour [34]	analyzing queries for spatial search engines	Iterative query segmentation and spatial relationships.	Better interaction between the users and the search application	Induces to spatial complexity

#### IV. REVIEW OF SEO APPROACHES USING ML

The prime objective of any SEO approach is to find the targeted content which could meet the expectation of the user and thereby make the web content available to them with least effort. This operation demands a better for of optimization, where Machine Learning (ML) approach plays a significant contributory role. ML can help SEO professionals by analyzing the vast amounts of data required to optimize a website's ranking. For instance, it can be utilized to search ranking factors to get insight into website age, bounce rate, and content length. These were significant indicators of high-ranking websites. ML can also help predict future search engine

algorithm changes, enabling SEO professionals to make proactive adjustments. Overall, the use of ML in SEO offers numerous benefits, including increased accuracy in predicting search engine algorithms, automation of SEO tasks, and the ability to analyze large amounts of data. This section briefs about some of the literatures where ML approaches has contributed towards this optimization process considering various forms of use-cases.

The most recent work carried out by Boppana and Sandhya [35] have used Recurrent Neural Network (RNN) in order to facilitate a better form of recommendation system to be used in SEO operation with perspective to web crawling practices. The

core target of this work is mainly to reduce the error while recommending the popularity of extracted information. A clustering approach based on extracted features from contextual information is implemented in this process. The work carried out by Burgess et al. [36] address the problems associated with security of web-contents, which is another essential concern in SEO process. The authors have used Long Short-Term Memory (LSTM) for identifying the possible threat in traffic associated with web-content while making redirection in HTTP. The study claims of successful control of such malicious redirection. Similar aspect of security consideration was also witnessed in investigation carried out by Liu and Fu et al. [37] where an SEO tool is required to confirm the vulnerability in the web-contents. The solution is provided by the author by considering phishing attack on web contents where feature learning is used. The study has used an unsupervised learning methodology in order to identify the insecure web-contents. Further, the model has also used a random walk of biased nature considering fusion of information over URL and structural information.

Soliman et al. [38] have implemented a model using random forest for addressing the need of semantics and linked data of the web-contents. The implementation has used Resource Description Framework (RDF) where random forest is used for retrieving the current state of RDF for assisting in further classification process. Study in the direction of the recommendation system in SEO is also reported in work of Ismail et al. [39], where the focus is mainly towards customizing the recommendation system over web-contents. The study model has used fuzzy logic concept integrated with structural analysis for achieving adaptive recommendation system. Label propagation is another essential target to be achieved in SEO and it becomes quite challenging in presence of heterogenous information. Study in such problem is addressed by Hisano et al. [40] by storing a voluminous information in the form of a network followed by applying Jacobian iteration for learning weights. This technique also contributes towards performing better analysis. It should be noted that web-contents consideration in SEO will also be inclusive of presence of multi-media file systems too. It is found that identification of highlights of such files is completely dependent on trained data curated by human. This hinders scalability as well as is expensive in nature of deployment. This problem is addressed in work of Kim et al. [41] by introducing a ranking mechanism using deep learning technique in presence of noise. The technique is completely free from any category as well as harnesses such web-contents that are weakly supervised.

A unique work carried out by Lister [42] has considered a use-case of improving knowledge transfer using machine learning approach. The idea of this model is to make use of all the essential geo-spatial information associated with educational system and use them for constructing content, searching relevant contents, and exploring essential knowledge contents. This process exponentially facilitates for SEO implementation over educational system. Adoption of SEO towards education system is also investigated by Peralta et al. [43] where a problem associated with tedious search process by teacher in finding appropriate content is addressed. The study has used a probability-based computational framework followed by resource classification in the form of clusters to make the search easier. Studies towards educational system further continues in the work of Rahman and Abdullah [44] which deals with more about customization of recommendation system.

Credibility is another essential attribute to be considered during SEO operation in order to assess the source of information. Such motive is seen to be implemented in work of Mahmood et al. [45] where reputation computation is carried out by eliminating the negative referrals. The study has used feedback-based Bayesian network in order to compute the level of expertise. Further, the work of Massaro et al. [46] have used neural network along with LSTM in order to assess the influence of web-content over an experience of user. Social network plays a dominant role in its interactive web-content where SEO plays a significant challenge to promote information on such platform in presence of complicated connected nodes in social network. Such problem is addressed in Abu-Salih et al. [47] where it targets to find the social influencer on the basis of domain considering both machine learning and semantic analysis. Further study towards social network is also seen in work of Tey et al. [48] and Xu et al. [49] where a recommendation system is built. The work carried out by Serrano [50] has investigated the impact of deep learning for computing the learning relevance towards searching voluminous web-content. It is to be noted that a structured corpora is required for building effective SEO as noted in work of Tahir et al. [51]. The work carried out by Yuan et al. [52] have used a supervised learning approach for feature normalization in order to improvise the interaction process of web contents. Further work is also carried out by Zhou et al. [53] towards user preference and recommendation of video tags is carried out by Zhou et al. [54]. Table II highlights the summary of the work being discussed in this section.

TABLE II. SUMMARY OF SEO USING ML TECHNIQUES

Authors	Problems	Techniques	Advantage	Limitation
Boppana and Sandhya [35]	Error minimization during recommendation	RNN, clustering	Achieves 99.6% of accuracy	Domain specific implementation
Burgess et al. [36]	Malicious redirection	LSTM	Achieves 98.78% of accuracy	Induces to spatial complexity
Liu and Fu et al. [37]	Identification of insecure web-contents	Unsupervised feature learning	Achieves more than 95% of precision	Induces complexity associated with feature matching during validation
Soliman et al. [38]	Effective search of web-contents	Random forest	Achieves 92% of accuracy	Doesn't address prediction performance of retrieval of data
Ismail et al. [39]	Unstructured web-contents	Fuzzy Logic	Achieves 94% of accuracy	Higher dependency towards ruleset
Hisano et al. [40]	Prediction (use-case based)	Building network with heterogeneous data, weight learning	Improved accuracy	Case specific prediction of web-contents
Kim et al. [41]	Identification for highlights of multimedia file system	Deep learning using ranking	Category independent	Iterative process, not applicable for active SEO tool
Lister [42]	Adoption of knowledge contents	Pedagogy-based learning	Helpful for knowledge delivery system	The model lacks adoption of constraints
Peralta et al. [43]	Complex search process of educational content	Recommendation system using Probability, annotation of learning resources	Better performance for hybrid recommendation	No benchmarking computationally
Rahman and Abdullah [44]	Customization of educational contents	Profile-based learning system, decision tree	Effective learning outcomes on real-test	No benchmarking
Mahmood et al. [45]	Credibility analysis	Bayesian network (Feedback)	Good convergence performance	Applicable for smaller network of web.
Massaro et al. [46]	Intelligent score allocation of webpage	LSTM, Neural network	Simplified modelling	Restricted to smaller number of webpages
Abu-Salih et al. [47]	Extracting contextual contents of social network	Sentiment analysis, machine learning, retrieval of influencer, graphical approach	Capable of processing larger data	Domain-dependent implementation
Tey et al. [48]	Recommendation issue in social network	Personalized recommender	Simplified structural model	Not applicable for complex network
Xu et al. [49]	Personalized search and recommendation	Ontological similarity	Disambiguation in recommendation design	Model dependent on human intervention towards input feature
Serrano [50]	Investigational study towards neural network	Review study towards ranking and relevance of learning models	Random neural network to have higher scope	Doesn't specifically considered internal processing of SEO
Tahir et al. [51]	Reliable corpora building	Generation of corpora	Mean yield of crawling improves significantly	Specific to language
Yuan et al. [52]	Optimizing interaction of web contents	Supervised learning	Energy reduction	Assessed on one type of client application
Zhou [53]	Evaluation of ranking performance	Gain attribute learning	Minimize dependencies on labelling	Highly iterative scheme
Zhou [54]	Recommendation (video tag)	Deep learning	Scalable model	For smaller data

## V. EXISTING SEO TOOLS

At present, there are various commercially available SEO tools which are meant to productively use time and effort towards performing data analysis and research. Some of the existing SEO tools commercially used are as follows:

### A. Commercial SEO Tools

- *Ubersuggest*: This is a free SEO tool that is meant to determine the best suited keywords followed by concluding the intention behind it. It does so by exhibiting both the long and short phrases of top ranked webpage. An exclusive report is generated on the basis of trend analysis, degree of competition, and quantity of keywords [55].
- *Moz Pro*: This SEO tool is considered as one of the best products by experts owing to its up-to-date services even compared to Google services with search algorithm. Various beneficial response are facilitated to the user via its recommendation system. Apart from this, it also offers recommendation of various keywords that contribute towards increasing page ranking. Various web-metrics are retrieved from client application in order to assess its performance via this SEO tools [56].
- *KWFinder*: The prime motive of this SEO tool is to assist in evaluating all the keywords with long trail that has minimal competitive level. It can perform evaluation of ranking as well as enhancement of specific key metric in order to upgrade popularity of webpage [57].
- *SEMRush*: This is one of the most frequently used digital marketing tool which facilitates the user to verify the ranking of their webpage. It also performs feasibility analysis for new ranking as well as analysis among different domain. Therefore, it offers significant privilege to assess their services with that of competitors on the basis of analytical report [58].
- *Google Search Console*: This tool is freely available for all users facilitated by Google. This tool can be used for indexing the sitemap of the webpage by adding their code or via using Google Analytics. This SEO tool also let the user control about the indexing policies as well as it also controls the representation structure of the website. Apart from this, the complete visualization and usage aspect of the user can be controlled by this SEO tools [59].
- *Ahrefs*: This SEO tool is mainly used for online crawling of the websites. The core purpose of its usage resides in finding out the backlinks used by the competitor. Further, it is also used for exploring the contents with highest links as well as it can also repair the broken links to find out popular web-contents [60].
- *Serpstat*: This tool is used as a hacking platform for achieving goals of content marketing and SEO. It carries out all the task that is required for managing team to analyze the competitors. It also has an enriched

availability of competitor analyzed data as well as all the aggregated keywords [61].

- There are also various other commercially available SEO tools e.g., *Screaming Frog* [62], *Keywords Everywhere* [63], *Fat Rank* [64], *Siteliner* [65], *SEOquake* [66], *Google Trends* [67], *Majestic* [68], *Woorank* [69], *SpyFu* [70], etc. Further, information about the beneficial and limiting attributes of all the discussed commercially used SEO tools are as follows:

### B. Beneficial Attributes Existing SEO Tools

The first advantage of majority of these SEO tools are that they are free of cost. The paid tools are based on usage patterns. Majority of them are reported to use local SEO tools in order to optimize the localized traffic. They are also mobile friendly as well as customer friendly while the recommendation services are based on experts.

### C. Limiting Attributes Existing SEO Tools

A robust usage of SEO will yield a page with higher rank and this will also attract the attention of competitors. Hence, this is a continuous effort to be at top of rank, which is extremely challenging. There are fair feasibility of SEO to change which often causes uncertainty of consistency of ranks in upcoming times. The process of generation of response in SEO is quite a slower process. Even after frequent webpage updating, there is no assurance of timely results within a tentative duration of time.

## VI. EXISTING RESEARCH TREND

At present, there are different categories of studies being undertaken for improving the performance of SEO. Table III highlights the research trends of using different standard approaches in SEO.

TABLE III. SUMMARY RESEARCH TRENDS ON SEP (2017-2022)

Items	Conference	Journal	Early Access Article	Books	Magazine
Total manuscript	298	70	12	3	3
NLP-based approach	2	10	0	0	0
ML-based approach	29	12	1	0	0
Miscellaneous	267	48	11	3	3

From Table III, it can be seen that there are very a smaller number of journal publications associated with both standard NLP and ML based approach in SEO as compared to miscellaneous approaches, which are normally application specific. The trend of minimal journal publication eventually means that both NLP and ML approach has just very a smaller number of research implementation in IEEE Xplore digital library. Similar trend of publication towards NLP and ML is also observed for other reputed publication of Elsevier, Springer, Wiley, etc. This concludes that there should be more attempts towards wholesome utilization of NLP and ML

approach for addressing the open-end research problems as illustrated in next section.

## VII. RESEARCH GAP

After reviewing the existing approaches towards addressing the challenges in SEO, following research gap has been identified.

### A. *More Focus on Local Problems*

A closer look into the existing approaches towards SEO shows that there are different variants of techniques in order to address specific set of problems or to cater up certain application demands. However, there is no existing framework, which can develop a solution towards addressing combined local problems over webpages e.g., duplicated contents, difference in performance in different computing device (e.g., PC, tablet, Smartphone), poor link building, inaccurate navigation system, not search friendly, inaccurate redirection, cluttered URLs, loading of page to be consuming high time, ignoring local search or not considering markup data. Although, all the above-mentioned problems have been individually found to be investigated, but they have not been combinedly addressed. Solving some of the local problems and ignoring the remaining of problems will eventually lead to impractical solution towards improving SEO.

### B. *Few Emphases Towards Content Generation*

One of the targets of the SEO approach is to generate a precise content in order to meet the business objectives by reaching to maximum targeted customer. However, this is highly computationally challenging task. Existing approaches has evolved up with various techniques to ensure content quality, meta-data generation, and accuracy in its predictive approach. Such problems are mainly found to be solved using different variants of artificial intelligence and ML approaches. However, all such ML techniques suffer from serious drawbacks either of computational complexities or towards dependencies toward massive trained data. Existing ML approaches are also highly iterative and is mainly meant for passive mode of predictive operation. Therefore, they are less likely to be used for practical world application of SEO.

### C. *Few Studies Towards Smart Content Management*

There is no doubt that ranking plays a significant role in SEO building process. However, such forms of ranking mechanism suffer from lower scale of adoption of objective function. Moreover, usage of existing deep learning scheme makes the process so much complicated and resource dependent that there is less scope of performing updating procedure. Without proper updating procedure, it is impossible to revise the solution being built for addressing local problems in SEO. At the same time, implementation of existing frameworks using NLP or ML will require serious re-engineering process, which is definitely not a cost-effective deployment scheme.

Hence, all the above-mentioned research gap are required to be bridged, without which a better form of SEO tool is impractical to be designed.

## VIII. DISCUSSION AND RESEARCH IMPLICATIONS

In this survey work, the study explored the use of NLP and ML techniques in SEO. Through the literature review, it has been found that NLP techniques are particularly useful in improving the readability and quality of web content, while ML techniques are effective in analyzing various factors that influence search rankings. However, a combination of both techniques is often most effective, and there is a growing body of research on the integration of NLP and ML in SEO. This section delves deeper into the specific implications of these findings. The entire section includes discussing the practical implications of these findings for SEO practitioners and web content creators. Additionally, this section addresses challenges in the current research on NLP and ML for SEO, and suggests potential avenues for future research to address these issues.

### A. *Findings and Discussion*

One of the most significant challenges in SEO is predicting and analyzing search engine algorithms. Based on the above-mentioned discussion it has been explored that, both NLP and ML techniques have been increasingly used in SEO to help search engines better understand the intent and meaning of web content, and to improve search rankings. One of the most common applications is the use of NLP to better understand search queries and match them with relevant content. It can be adopted to identify the underlying meaning and intent of search queries, and then match them with the most relevant content on the web. Another way that NLP techniques can be used in SEO is to improve the readability and quality of web content. Researchers have developed tools that use NLP to analyze the readability, grammar, and spelling of web content, and provide suggestions for improvement. On the other hand, ML techniques have been also be used to improve SEO in a number of ways. One of the most common applications is the use of ML to predict search rankings. Researchers have developed algorithms that use ML to analyze various factors that influence search rankings, such as keyword density, backlinks, and user engagement, and then make predictions on which websites are most likely to rank highly.

Irrespective of various number of research-based models being evolved, there are still an open-end problems associated with the performance of SEO. From commercial application viewpoint, existing studies don't promote towards potential links exploration while developing the model which will present the client webpage towards maximized rankings of search engine. The existing models do offer some solution to promote the popular content based on domain specific frameworks; however, there is lack of consistency towards the link building process. Irrespective of various study implementation using NLP, existing research work also doesn't seem to consider much of content management programs along with considering complexities of data within it. One such issue is presence of iterative tags of title, which still existing NLP is not able to address properly. The content management using NLP is required to be consistently updated, without which dynamic crawling could lead to ineffective convergence of search operation of web contents. Although, existing contribution of ML are quite notable; but they are also scattered as well as highly specific to use-cases. Hence, adoption of such models will be quite expensive and will require time-to-time

update and amendment based on business structure. At present, there is no generalized architecture or framework to address global problems all together. There is an increased proliferation in using different variants of ML approach towards optimizing various essential operation in building an effective SEO. However, existing ML approaches are mainly iterative, demands voluminous set of data, and doesn't have much consideration of multi-objective function along with adoption of practical constraints. This further reduces the scope of predictive approach and hence, existing SEO has not yet harnessed the full capabilities of ML approaches in order to gain a better result.

### B. Remarks and Implications

It's difficult to determine which method is better, as both NLP and ML have their own strengths and weaknesses, and the choice of method will depend on the specific application and context.

NLP techniques are particularly useful in understanding the natural language used in search queries and web content. They can help search engines better understand the intent and meaning behind search queries, and can also improve the readability and quality of web content. However, NLP techniques may not be as effective in analyzing more quantitative factors, such as keyword density and backlinks, which are important for search rankings. On the other hand, ML techniques are particularly useful in analyzing large amounts of data and identifying patterns that are difficult for humans to detect. They can be used to analyze various factors that influence search rankings, such as keyword density, backlinks, and user engagement, and can make predictions on which websites are most likely to rank highly. However, ML techniques may not be as effective in analyzing the natural language used in search queries and web content.

While NLP and ML techniques are often used separately in SEO, there is also a growing body of research on the integration of these techniques. In many cases, a combination of both NLP and ML techniques may be most effective. For example, using NLP to better understand search queries and match them with relevant content, and using ML to predict search rankings based on a range of factors. Additionally, the effectiveness of either technique will depend on the quality of the data used and the specific algorithms and models used. Another area of research is the use of NLP and ML to identify and address black hat SEO techniques, such as keyword stuffing and link farming. An algorithm can be developed using NLP and ML to detect web content that has been artificially optimized for search engines and prevent websites from using them to manipulate search rankings.

Although, the use of NLP and ML in SEO offers numerous benefits, but it also has limitations, including the accuracy of the algorithms used and the cost of implementing technology. As ML and NLP technology continues to advance, it is likely that it will become increasingly essential in optimizing website ranking and visibility.

## IX. CONCLUSION

This paper has investigated towards the performance improvement approaches from research viewpoint towards

developing a strong ecosystem of a holistic marketing. In this perspective, there are evolution of massive number of searches by the customers and digital marketers annually with an intention of fulfilling certain commercial targets. The prime outcome is to end up their search towards more relevant conclusive services or products. For this purpose, the webpage is required to be optimized for maximized ranking and higher visibility. Based on above learning outcomes, potential research gap is explored and the future work will be carried out towards addressing all the pitfalls of existing system as well as adopt all the beneficial points of the existing literatures. The first research gap is possible to be solved by developing a unique architecture integrating both NLP and ML approach, which will be capable to address majority of the local problems in building SEO using predictive page ranking approach. The second research gap can be solved by further improving the similar architecture and add novel functionalities towards efficient content generation process in SEO. A new variant of deep learning approach can be used with feedback connection over a tree-based network system. This will offer a capability to processes complete sequence of data available in web page. Focus will be also towards achieving better predictive generated data with lesser epoch values for confirming lower computational complexities. The third research gap can be addressed by further improving the same model using improved version of machine learning algorithm. In order to meet an optimization objective, a multi-objective function can be designed using three parameters i.e., state, reward, and actions in order to get more updated contents.

# Adaptive Rectified Linear Unit (AReLU) for Classification Problems to Solve Dying Problem in Deep Learning

Ibrahim A. Atoum

Department of Computer Science and Information Systems  
College of Applied Sciences, Al Maarefa University  
Riyadh, Saudi Arabia

**Abstract**—A convolutional neural network (CNN) is a subset of machine learning as well as one of the different types of artificial neural networks that are used for different applications and data types. Activation functions (AFs) are used in this type of network to determine whether or not its neurons are activated. One non-linear AF named as Rectified Linear Units (ReLU) which involves a simple mathematical operations and it gives better performance. It avoids rectifying vanishing gradient problem that inherents older AFs like tanh and sigmoid. Additionally, it has less computational cost. Despite these advantages, it suffers from a problem called Dying problem. Several modifications have been appeared to address this problem, for example; Leaky ReLU (LReLU). The main concept of our algorithm is to improve the current LReLU activation functions in mitigating the dying problem on deep learning by using the readjustment of values (changing and decreasing value) of the loss function or cost function while number of epochs are increased. The model was trained on the MNIST dataset with 20 epochs and achieved lowest misclassification rate by 1.2%. While optimizing our proposed methods, we received comparatively better results in terms of simplicity, low computational cost, and with no hyperparameters.

**Keywords**—Rectified Linear Unit (ReLU); Convolutional Neural Network; activation function; deep learning; MNIST dataset; machine learning

## I. INTRODUCTION

The concept of Artificial Intelligence (AI) revolves around creating intelligent machines that are able to simulate human thinking while Machine Learning (ML) is a branch of this concept that allows these intelligent machines to learn the hidden patterns from the input data [1]. Neural networks (NNs) as a subset of ML simulate the human brain using a set of algorithms. These networks consist of input, hidden, and output layers. These layers consist of neurons that mimic the structure of a biological neuron, where each neuron has inputs that are processed to give outputs, which in turn will be input to another neuron. When neural networks consist of more than three layers then they can be called Deep Learning Networks (DLNs) [2].

AFs play a critical role in DLNs to extract the results from the input values and thus determine whether the underline neuron is activated or not [3]. DLNs can be considered as just a linear regression without AFs, so appropriate AFs must be used to model a nonlinear DLNs. AFs classified as binary step, linear activation and nonlinear activation functions.

Binary step function is a basic threshold classifier where some threshold value is decided to choose which output neurons should be activated or deactivated. Linear activation function is a simple straight line activation function that converts linear input signals into non-linear output signals. Nonlinear AFs are what make it easier for the DLNs model to adapt to a variety of data and to distinguish between outcomes; examples are: ReLU, Leaky ReLU, Sigmoid, Tanh and Softmax [4]. Some of these are suited to be used in hidden layers and others in output layers.

There are two terms used in training the model, the first is the term feedforward, which is used in NNs to refer to the transition with specified weights from input to output, while the term backpropagation, as the name suggests, moves from output to input with readjustment of weights depending on loss values and then propagation processes straight ahead. This approach allows the use of gradient methods, such as gradient descent or stochastic gradient descent, to train multi-layer networks and update weights to reduce loss [5] [6]. ReLU as a nonlinear AF has gained a lot of interest in research due to its simplicity, low computation cost and it avoids the vanishing gradient problem that inherent to the earliest AFs like tanh and sigmoid [7]. Despite all the previous advantages of this function, it has a problem called the Dying ReLU problem, which indicates that the neuron becomes inactive and outputs zero only for any input. This problem has been attributed to a high learning rate and a high negative bias [8].

ReLU was initially introduced by [9]; the researchers designed an electronic circuit to simulate a hybrid slug in which the latent cortex combines the digital selection of an active cluster of neurons with an analog response, and this behavior is achieved by dynamically changing the positive feedback inherent in recurrent cortical connections, this behavior, according to the researchers, created computational capabilities creates the process of stimulus selection, conferring the ability to modify and generate a spatio-temporal pattern in this cortex.

ReLU was later used in object recognition by [10], and researchers summarized the three stages used to extract object features such as filter bank, nonlinear transformation and a kind of feature pooling layer emphasizing that most systems use one or two of these stages, assuming that the use of two stages gives more accurate results. The study demonstrated the

accuracy of this hypothesis by using nonlinear layers and pooling layers on different object data sets through either supervised optimization or unsupervised pre-training.

ReLU was also popularized by [11] in the context of Restricted Boltzmann Machines. The study demonstrated how to create a more powerful type of hidden units for Restricted Boltzmann Machines (RBM) in object recognition and face comparison by combining weights and biases for an infinite set of binary units with approximating these stepped sigmoid units with noisy corrected linear units.

Leaky ReLU [12] has added a slight slope in the negative range; this modification on ReLU ends the presence of dead neurons in the negative region by using a hyperparameter. Thereafter many leaky ReLU variants have been appeared like Parametric Rectified Linear Unit (PReLU) [13] which introduces a new learnable parameter as a slope for the negative part and Exponential linear unit (ELU) has used an exponential function to transition from the positive to small negative values [14].

The value of the loss function is related to the results of the model. If the value of the loss function is low, this means that the model will give good results [16]. Loss functions are divided into two types, classification and regression. Classification functions also divided into binary entropy loss/log loss and hinge loss. During the execution of AReLU the first function was used [15]. AReLU is applied on MNIST dataset that contains 70000 images of black and white handwritten digits divided into 60000 images for training and 10000 images for Testing [17].

In this study, the decreasing value of the used loss function was exploited as an adaptive parameter to keep the network active. The study is presented into four sections: section two introduces the idea of ReLU, section three identifies the ReLU dying problem, and section four introduces the AReLU. Section five presents the results and finally section six is the conclusion.

## II. RECTIFIED LINEAR UNIT (RELU) ACTIVATION FUNCTION

Artificial neurons are mathematical model that mimic human biological neurons and they are the basic building blocks of neural networks as shown in Fig. 1.

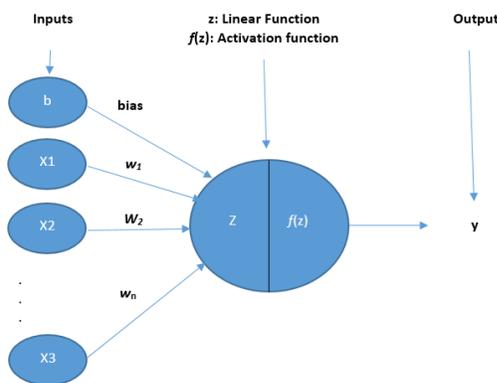

Fig. 1. Artificial neurons representation

Where  $z = ((w_1 \times x_1) + (w_2 \times x_2) + \dots \dots \dots + (w_n \times x_n)) + b$  states the linear function, accordingly the activation function  $y = f(z)$ .  $x_1$  to  $x_n$  represents the inputs,  $w_1$  to  $w_n$  illustrates the weights that connect inputs with perceptions and they measure the significance level of each input. The bias value ( $b$ ) is added to the weighted sum of the inputs to prevent the activation function from getting a zero value. This linear results in linear modeling come from the linear mapping of the input function to output in hidden layers. The role of activation function is to convert these linear outputs into non-linear outputs for further computation as in

$y = \alpha * (((w_1 \times x_1) + (w_2 \times x_2) + \dots \dots \dots + (w_n \times x_n)) + b)$ ; where  $\alpha$  is the activation function. The literature has introduced many activation functions such as Sigmoid, binary step, Tanh, ReLU, Leaky ReLU, identity and Softmax.

ReLU activation function can be described mathematically as in Eq. (1) and graphically as in Fig. 2, where  $x$  is the input to the neuron. The function  $f(x)$  equal zero for all negative input values and equal original input value for all positive input values as in Eq. (1).

$$f(x) = \max(0,x) \quad (1)$$

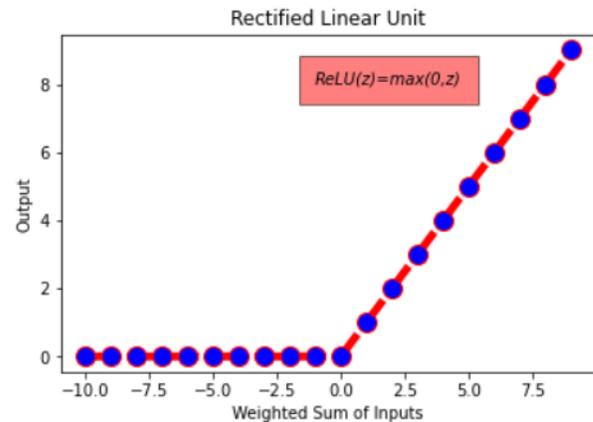

Fig. 2. ReLU representation

ReLU avoids vanishing gradient problem occurred with other activation functions by preserving the gradient [18]. This problem is formed when the gradients of deep neurons vanish or becomes zero, this means that the deep layers of the network may not learn or learn very slowly [19]. Derivative Activation function is fundamental to optimizing neural network, the ReLU ( $x$ ) can be expressed as:

$$f(x) = \max(0, x)$$

It can be simplified as follows:

$$\max(0, x) = \begin{cases} 0, & x < 0 \\ x, & x \geq 0 \end{cases}$$

The first order derivative of this function is:

$$\frac{d}{dx} f(x) = \frac{d}{dx} \max(0, x) = \frac{d}{dx} \begin{cases} 0, & x < 0 \\ x, & x \geq 0 \end{cases}$$

And can be illustrated as:

$$\frac{d}{dx}f(x) = \frac{d}{dx} \begin{cases} \frac{d}{dx}(0), x < 0 \\ \frac{d}{dx}(x), x \geq 0 \end{cases}$$

The final derivative is:

$$\frac{d}{dx}f(x) = \frac{d}{dx} \begin{cases} 0, x < 0 \\ x, x \geq 0 \end{cases}$$

### III. RELU DYING PROBLEM

Dying ReLU problem is one limitation for ReLU where its neurons output is zero as illustrated by the red outline in Fig. 3.

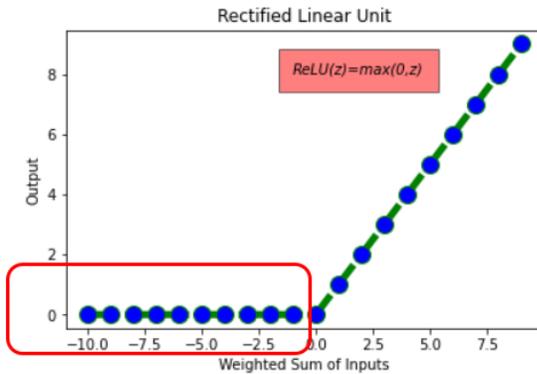

Fig. 3. Red outline where ReLU outputs 0

The normal situation for ReLU neurons is to stay active, update weights, and keep learning. Although this feature provides the power to ReLU through the sparsity of the network, it poses a problem when most of the inputs of these ReLU neurons are in the negative range, and the issue becomes more complicated when the output of most Neurons is zero, making their task so abnormal that they become inactive and unlearning. This inevitably causes gradients to fail to flow during backpropagation.

The cause of this problem is due to two main factors: High Learning Rate and a Large Negative Bias. The former one allows faster learning with the possibility of a numerical overflow, while its very small value may never converge or stumble on a suboptimal solution. So choosing an average rate that is neither too large nor too small ensures an optimal approximation of the mapping problem as represented by the training data set. The best way to discover the value of the learning rate is through trial and error, not analytically for a particular model on a particular data set. This can be illustrated by the update process in backpropagation as shown in Eq. (2).

$$newW_{ij} = oldW_{ij} - LR \left( \frac{\partial Error}{\partial oldW_{ij}} \right) (2)$$

where  $\frac{\partial Error}{\partial oldW_{ij}}$  is the derivative of error with respect to weight. We can see from Eq. (2) that giving a high value of the learning rate (LR) will cause a high value for the last part of Eq. (2)  $LR * \left( \frac{\partial Error}{\partial oldW_{ij}} \right)$ , so subtracting large number from

$oldW_{ij}$  will end up with highly negative  $newW_{ij}$ . These negative results cause negative inputs for ReLU, therefore generating the dying ReLU problem.

Biases are extra inputs that ensure neurons are activated regardless of the input. Changing the value of the weights in the neuron changes the steepness of the curve without the ability to change it to the right or left, to change the curve to the left or right the value is changed. Giving a high negative bias value makes the ReLU activation input negative. To mitigate Dying ReLU problem, several techniques have emerged, all trying to keep the network active when the input is negative or zero.

Leaky ReLU [12] demolished dead neurons in the negative part by adding a slight slop in the negative range using a hyperparameter ( $\alpha=0.1$  or more) as shown in Eq. (3) and illustrated in Fig. 4.

$$f(x) = \max(ax, x), \text{ where } a > 0 \quad (3)$$

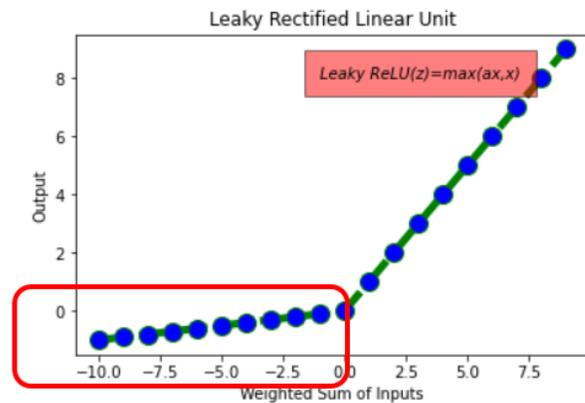

Fig. 4. Red outline where leaky ReLU outputs less than zero

Parametric Rectified Linear Unit (PReLU) [13] thereafter presented a new learnable parameter as a slope for the negative part as in Eq. (4):

$$f(x) = \max(ax, x), \text{ where } a \text{ is a Learnable Parameter} \quad (4)$$

And Exponential linear unit (ELU) used an exponential function  $\propto (e^x - 1)$  to transition from the positive to small negative values [14] as shown in Eq. (5).

$$f(x) = \begin{cases} x, x > 0 \\ \alpha (e^x - 1), x \leq 0 \end{cases} \quad (5)$$

### IV. ADAPTIVE RECTIFIER LINEAR UNIT (ARELU) ON MNIST DATASET

The study used the MNIST dataset of handwritten greyscale images, these images were size-normalized and centered in a fixed-size image available from NIST [20] as shown in Fig. 5 which shows the first 25 images of MNIST.

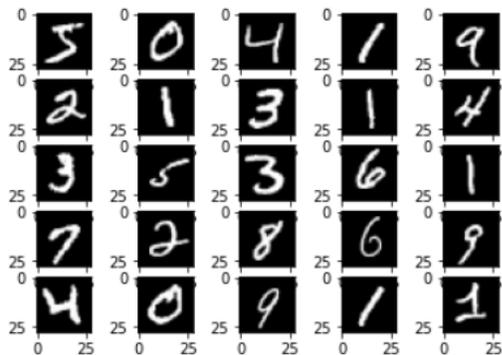

Fig. 5. Subset of MNIST dataset

This dataset composed of approximately 70,000 handwritten monochrome images of 0 to 9 (10 digits), each of which is 784 pixels in size, so that the input data is in pairs (70,000,784) and output (70,000, 10) as shown in Fig. 6.

To form the network, the AReLU activation function were used in the hidden layer and softmax in the output layer. The used loss function is categorical\_crossentropy and the optimizer is Adamax. The batch size is adopted to 128 and the number of epochs to 20.

Once the output is generated from the final neural net layer, loss function (input vs output) is calculated and backpropagation process is performed where the weights are adjusted to get the minimum loss. Neural Networks are trained using the gradient descent process. This process consists of the backward propagation step which is basically chain rule to get the change in weights in order to reduce the loss after every epoch.

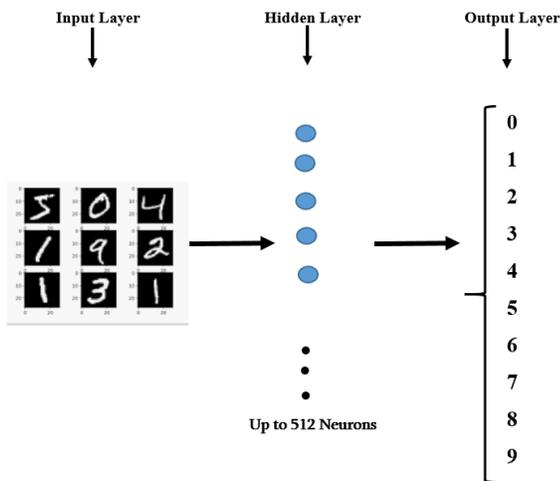

Fig. 6. MNIST neural network

The primary goal of AReLU is to mitigate Dying ReLU problem by improving the previous methods by using the adaptive Loss Function ( $l$ ) parameter instead of hyperparameter one.  $l$  is multiplied by the input value as shown in Eq. (6) to transit from the positive to small negative values.

$$f(x) = \begin{cases} x, & x > 0 \\ l * x, & x \leq 0 \end{cases} \quad (6)$$

The AReLU has implemented by using Python programming language according to the algorithm shown in Fig. 7 and more illustrated in Fig. 8. It is noticed from the equation that there is no change in the case of the positive values, but only the change in the negative inputs, as we notice this in Fig. 9(a).

- Step1: START AReLU
- Step2: Import the required libraries.  
*keras, matplotlib, mnist, etc...*
- Step3: Loading the built-in MNIST Dataset.  
*mnist.load\_data()*
- Step4: Creating the model and add the layers: Input, Hidden and Output using dense layer from keras
- Step5: Compile the model by using the defined Loss Function, Optimizer and the metrics
- Step6: for i in range of epochs
  - 6.1 Fitting the Model by using the training set.
  - 6.2 Update AReLU parameter=new Loss value
- Step7: Evaluate the model on the testing set.
- Step8: STOP

Fig. 7. AReLU algorithm

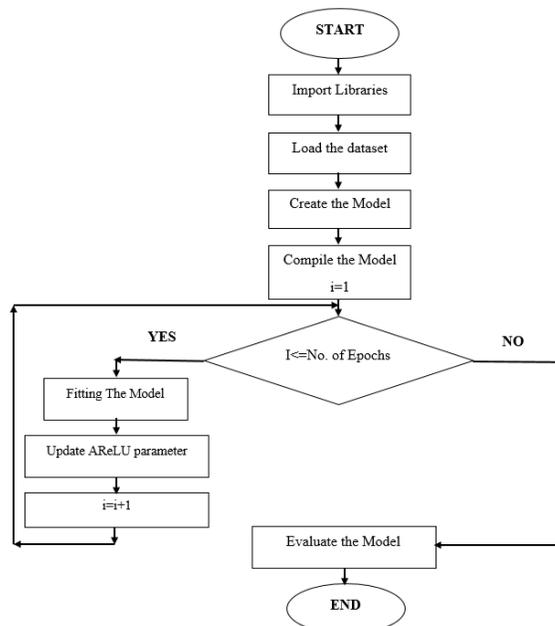

Fig. 8. AReLU flowchart

The used structure of the deep neural network is shown in Fig. 9 that composed of four layers, one input layer represents the input shape as 784 image pixels, two hidden layers each composed of 512 neurons and the final 10 neurons layer that characterize the output layer.

Binary Cross-Entropy Loss/Log Loss has been used as loss function in the model compilation process; where in this phase the loss function, the optimizer and the metrics are defined. This function is defined in Eq. (7); where N is the number of rows and M the number of classes.  $p_{ij}$  are the corrected probabilities, a negative average is used to compensate for negative values resulted from calculating log value of

corrected probabilities because their values range between 0 and 1. It is one of the most common loss functions used in multiclass classification problems. The value of this function decreases as the predicted probability converges to the actual label.

$$Loss = -\frac{1}{N} \sum_i^N \sum_j^M y_{ij} \log(p_{ij}) \quad (7)$$

Backpropagation in a network aims to make a change in the error value with respect to weights and this process is called derivative because its goal is to make a change in one value with respect to another. The first derivative of this function is:

$$\frac{d}{dx} f(x) = \frac{d}{dx} \begin{cases} \frac{d}{dx}(x), x > 0 \\ \frac{d}{dx}(l * x), x \leq 0 \end{cases}$$

$$\frac{d}{dx} f(x) = \frac{d}{dx} \begin{cases} 1, x > 0 \\ x, x \leq 0 \end{cases}$$

The function starts with any initial  $l$  value; say 0.1 and then it is automatically adapted according to the initial loss function value. Fig. 9(b) shows the Graphical Representation of AReLU Derivative. It is evident that the values of the derivative are close to zero but are not zero in the case of negative values.

The most effected activation function used in the output layer in the case of multi-layer classification problems is Softmax, which converts the raw outputs of a neural network into a vector of probability scores between 0 and 1. Its equations is defined in:

$$Softmax(o)_i = \frac{e^{o_i}}{\sum_{j=1}^N e^{o_j}}$$

Where  $\mathbf{o}$  is the input vector,  $e^{o_i}$  is the standard exponential function for  $o_i$ ,  $N$  is the number of classes in the multiclass classifier and  $e^{o_j}$  is the standard exponential function for output vector and  $e$  is the exponential which is equal nearly 2.718.

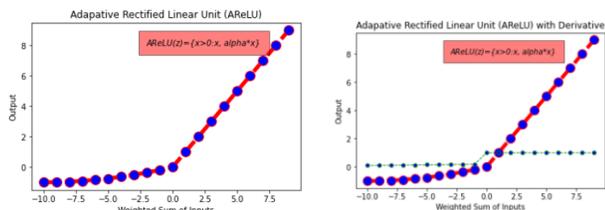

Fig. 9. AReLU graphical representation and its derivative

V. RESULTS

Fig. 10 illustrates the relationship between the training and validation accuracy over 20 epochs, the accuracy escalations are noticed in the first three epochs, indicating that the network is learning fast, thereafter the curve flattens, indicating that there is no need for more epochs to further training the model. The model accuracy was 98.8% (meaning

9880 of the 10000 images were predicted correctly!) and 120 images were wrongly tagged (1.2%).

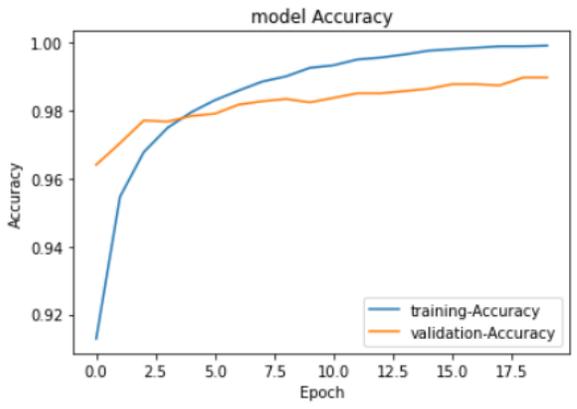

Fig. 10. AReLU model accuracy

AReLU gives better results based on the Misclassification Rate (MR) which is a measure of the percentage of observations that were incorrectly predicted by some classification model [21] and it's calculated as in

$$MR = \frac{Incorrect\ Predictions}{Total\ Predictions}$$

The MR for our model was 1.2% where for PReLU is 1.62 according to [22] as shown in Table I. This study measured the MR for different adaptive ReLUs including Sigmoid, tanh, MSAF, MSAF\_Symmetrical, ReLU, LReLU, ELU and adaptive tanh.

TABLE I. MR MEASUREMENTS FOR ACTIVATION FUNCTIONS ON MNIST DATASET

AF	MR
Sigmoid	7.01
Hyperbolic Tangent	1.86
MSAF	12.59
MSAF_Symmetrical	11.28
ReLU	2.08
LReLU	1.68
PReLU	1.6
ELU	1.88
Adaptive tanh	2.93

Reading Fig. 11 which illustrates the relationship between training and validation loss, we can see the rapid loss in the training set at the first two epochs while validation loss remained almost constant for several epochs, in contrast to the loss level of the training set, which means that the model can be generalized to unseen data.

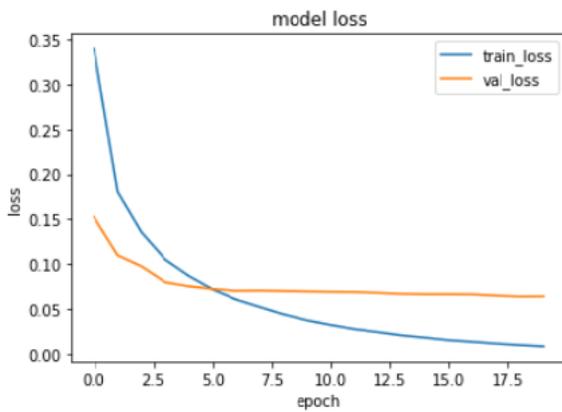

Fig. 11. AReLU model loss

## VI. CONCLUSION

This article produced automatic and adaptive activation function in which it retained inherent characteristics of ReLU with simplicity, high accuracy, speed and low loss ratio. Expected diminishing characteristic of Loss function value has exploited in implementing the AReLU, this function is used to measure the difference between the current output and the expected output. Cross-entropy type is used in developing the ReLU as one of the most widely used loss functions in machine learning due to its role in better generalization and faster model training. This function is used in binary and multi-class classification cases. AReLU is implemented by using Python programming language on MNIST dataset of handwritten digits to get 1.2% classification Rate. The model maintained the gains that the previous methods indicated, such as simplicity, low computational cost, no fixed coefficients, and adaptation in nature. In the future, AReLU will be applied to different data sets and work to reduce the rate of misclassification while maintaining the characteristics of simplicity, low computational cost, and no hyperparameters.

## ACKNOWLEDGMENT

The Author would like to express his gratitude to AlMaarefa University, Riyadh, Saudi Arabia, for providing funding to do this research.

**Abstract**—Because of recent technological and interface advancements in the field, the virtual reality (VR) movement has entered a new era. Mobility is one of the most crucial behaviours in virtual reality. In this research, popular virtual reality mobility systems are compared, and it is shown that gesture control is a key technology for allowing distinctive virtual world communication paradigms. Gesture based movements are very beneficial when there are a lot of spatial restrictions. With a focus on cost-effectiveness, the current study introduces a gesture-based virtual movement (GVM) system that eradicates the obligation for expensive hardware/controllers for virtual world mobility (i.e., walk/ jump/ hold for this research) using artificial intelligence (AI). Additionally, the GVM aims to prevent users from becoming dizzy by allowing them to change the trajectory by simply turning their head in the intended direction. The GVM was assessed on its interpreted realism, presence, and spatial drift in the actual environment in comparison to the state-of-the-art techniques. The results demonstrated how the GVM outperformed the prevailing methodologies in a number of common interaction components. Additionally, the empirical analysis showed that GVM offers customers a real-time experience with a latency of ~65 milliseconds.

## I. INTRODUCTION

Virtual reality (VR) has been around for years, but it has only lately piqued the attention of customers and professionals as the technology grows increasingly economically viable. VR economies are exploding, with the overall global demand estimated to approach four billion revenues by 2025, involving 45 million VR headset deployed and a global population coverage of 3% [1]. Human-computer interaction approaches in the earlier years compelled human behaviour to conform to the computer's capabilities; however, VR perspective is unique in that the computer now must mirror the actual environment to deliver the most authentic view feasible. To provide individuals an immersive experience, VR develops a variety of participation activities relating to visual, auditory, and tactile sensitivities. Widely available methodologies for

VR mobility are heavily reliant on a controller to explore and move, or actual relocating in a constrained geographic space, disregarding proliferating necessities on the strategy for travelling an unregulated virtual space by physically strolling the user's legs, which causes fatigue [2]. The most extensively used VR movement methods are listed below.

1) *Gadgets*: A frequent strategy for navigation in the VR world is to use gadgets such as joysticks and head orientation tracking with Gyro in VR head mounted displays. For consumers focused on control movement in VR, these gadgets are intuitive and comfortable, straightforward to use, and productive. However, because of a perceptual mismatch [3] between visual and vestibular inputs [4], joysticks frequently influence the vision to act swiftly [5] and erratically, creating dizziness [6].

2) *Teleportation*: Another typical strategy for reducing dizziness is to provide many gateway locations allowing players to swiftly move from one location to the next. Unfortunately, due to the discontinuous movement that negatively impacts the user's experience and may induce vertigo, these tactics are not organic enough to boost the interactive experience in the virtual environment [7].

3) *Walking-in-place (WIP)*: The WIP approach allows users to travel in a specific location while controlling the character's motion and orientation using real body gesture detection sensors such as Microsoft Kinect [8]. This technique enhances the matching among mechanoreceptors of data from a person's body movements and tactile senses through machine screens, rendering it more natural and potentially lowering operator dizziness. Nevertheless, this technique requires the user to remain in one place and use their entire body, as well as a large amount of underlying hardware, that are costly and not available to all. A good travel experience, on the other hand, must cause less fatigue in a walk-through arrangement [9].

4) *Hand gestures*: In virtual reality, a gesture is a stance or motion of the user's body which is employed as input. The

\*Corresponding Author

WIP approaches tend to depend on the same gesture for triggering forward perspective motion: leg gestures like those used while climbing a stairway [10]. This motion emerges to be more exhausting than actual walking. Hand gestures, on the other contrary, can be an organic and efficient technique for controlling motions in virtual reality. Furthermore, movement based on hand gestures has the benefit of requiring less exertion and decreasing dizziness as it can be performed while sitting or standing [11]. For VR engagement, there are a range of gesture communication devices that facilitate communication more authentically with items in the virtual environment. These gesture communication devices are classified on the mode of input as wearable sensor, touch, and computer vision [10].

The authors in current research introduce a gesture-based virtual movement (GVM) system to facilitate an inexpensive solution for supporting individuals with walk-through activities in virtual worlds, which allows customers to unwind while sitting or standing in a place as if they're in reality

#### A. Key Contributions

The authors' goal in this study is to enrich the user's immersive experience. The following are the major findings of this research.

1) *Cost efficiency*: GVM is a low-cost solution that eliminates the requirement for any additional costly gesture recognition gear.

2) *Purging dizziness*: GVM reduces dizziness by letting users modify their trajectory by merely tilting their head in the desired direction and hand movements for gesture recognition to move in VR.

3) *Handling strain*: GVM relieves the user of physical strain.

4) *Usability*: The usefulness of the suggested approach is demonstrated by user input on several factors such as interpreted realism, presence, and spatial drift in the real world.

5) *Real-time experience*: With a latency of ~65 milliseconds, the suggested system offers consumers a real-time experience.

#### B. Paper Organization

The manuscript is further divided into sections. Section II presents a brief literature survey of the various VR techniques. Section III introduces the proposed model, GVM. Section IV explains the experimentation done and the results achieved that highlights the suitability of GVM. Section V concludes this research. Finally, Section VI highlights the future work.

## II. LITERATURE SURVEY

Table I shows a comparison of various widely used VR movement methods based on the dimensions of motion sickness and physical strain. Hand gestures have been shown to be a remedy for motion sickness and physical strain; however, using a hand gesture detection system necessitates the acquisition of expensive gears. Thus, the authors introduce a GVM system to facilitate an inexpensive solution for

supporting individuals with walk-through activities in virtual worlds, which allows customers to unwind while sitting or standing in a place as if they're in reality.

TABLE I. COMPARISON OF MOST EXTENSIVELY USED VR MOVEMENT METHODS

#	Methodology	Motion Sickness	Physically Straining
1	Gadgets	Yes	Yes
2	Teleportation	Yes	No
3	Walking-in-place	No	Yes
4	Hand Gestures	No	No

Mine [12] proposes using hand-based communication to manage mobility and walk-through in a simulated world. An elevated hand-gesture tracer gadget, such as Leap Motion, is a unique technology which delivers input via hand gesture mapping, allowing for bare-hand interactivity [13] in a three-dimensional world. Ni et al. [14] investigates menu selection employing freehand signals, whereas Kulshreshth et al. [15] provides the findings of the first thorough research on finger-count panels to assess their suitability for 3D menu choice applications. Beattie et al. [16] demonstrates a CAD Engagement Facility that allows users to deconstruct a kinematic model in virtual reality and operate and analyse constituent parts. Lee et al. [17] offer TranSection, a hand-based communication strategy for executing a strategy game in virtual reality. Salomoni et al. [18] describes research in which recreational virtual world interfaces are reconsidered in view of the rise of head-mounted displays. These concepts, unfortunately, do not yet include how to handle walk-through activity in a simulated world.

Numerous studies have investigated ways to execute a natural and pleasant interaction approach in VR employing Leap Motion to solve this research gap. Codd-Downey et al. [19], for instance, offers a finger tracking movement approach that uses a 2DOF driving paradigm like typical mouse and keyboard control in 3D computer gaming. Khundam [20] presents a novel engaging single-hand-gesture control drive system with palm norm. The results reveal that controlling tour activity with hand gestures is more natural than to use a joystick. There are several aspects of VR controller hardware for diverse approaches, and some studies have developed a system that gathers multiple devices for a certain objective. The Oculus Rift and Leap Motion have lately been employed in several studies, particularly in virtual reality. Programmers are particularly interested in studying usage patterns and determining what the most productive utility for them in the future is through VR engagement.

Prior studies on in-air controllers and hand monitoring intended to develop and deploy VR applications. The precision of hand monitoring is critical for a reliable system. Sato et al. [21] provide a technique for monitoring a user's hand in three dimensions and identifying hand gestures in real time even without any intrusive sensors connected to the hand. Several cams are used to assess the location and direction of a user's hand floating in 3D environment. A neural network that is adequately trained recognises specified motions in a rapid and reliable fashion. 3D item processing for a desktop machine and

3D movement for a big holistic projection system are two typical applications. Many studies have been done on hand gestures and their uses. Chastine et al. [22] describe research comparing single hand gestures to typical keyboard, mouse, and controller input of first-person gameplay. The purpose of this study is to enable game analysts, architects, and builders to better understand how to include gesture control in current applications. The findings demonstrate that in FPS games, human rehearsals are crucial for gestural-based gaming system performance. As people continued through the activities, users were increasingly skilled at using the gadget, indicating that gesture-based handling can be used by users with no prior knowledge. This feedback helps programmers to employ Leap Motion as a device in virtual reality and ensures that there is a compelling incentive for them to do so in the long term.

Many people use virtual reality headsets to interact with 3D models. Stefan Greuter and David J. Robert [23] present the SpaceWalk technology. This system, which consists of two hardware devices: a motion sensing unit and a cordless VR gear, allows for low-weight full-body VR experience while wandering around the living area. The preponderance of the equipment in this system are made up of an Oculus Rift (DK1) HMD and a backpack tablet which operates standard VR program (Unity3D) alongside their extension script that connects all the elements. Participants may move and engage with things in the virtual world in this research's living area, however this framework is not designed for huge VR environments. Weibel et al. [24] describe how to build a moderate, fully interactive, stochastic virtual world setup that allows users to naturally perceive intangible cultural assets. They look at new technology including the Oculus Rift virtual reality headset, Microsoft Kinect, and the Leap Motion controllers. When it comes to constructing HMD VR situations, modern technologies such as the Oculus Rift HMD, Microsoft Kinect, and Leap Motion provide excellent results.

The usage of the Kinect or Leap Motion in conjunction with organic conversational inputs lets users engage directly with the virtualized world. However, because of the user's movement control, this VR system is generally limited to the comparatively small region in front of the sensing element. As a result, adopting engaging hand gestures for motion in VR will increase the VR system's admin tools via rigorous positioning and replacing previous techniques.

Users can employ an expanding number of input gadgets to engage with systems and apps. When building applications for technological innovations, though, there are no defined interface guidelines or benchmarks, and the customer satisfaction suffers the consequences. Jake Araullo and Leigh Ellen Potter [25] give a study that investigates the perspectives of a set of people who used the Oculus Rift and the Leap Motion device to play. The incorporation of blended conventional and non-traditional input methods, as well as depending on existing interface paradigms when leveraging innovative methods, were found to have a detrimental impact on system adoption in this study.

The present research proposes a gesture-based virtual movement (GVM) system that eliminates the need for pricey equipment for immersive virtual movement (i.e., walk/jump/hold for this research) with a focus on affordability. By enabling users to alter the trajectory by merely rotating their head in the desired direction, the GVM also seeks to prevent users from feeling dizzy.

### III. PROPOSED MODEL

The goal of authors is to employ user hand gestures to create movement in the virtual environment. The suggested GVM's overall process flow is shown in Fig. 1. The overall procedure is segmented into the following:

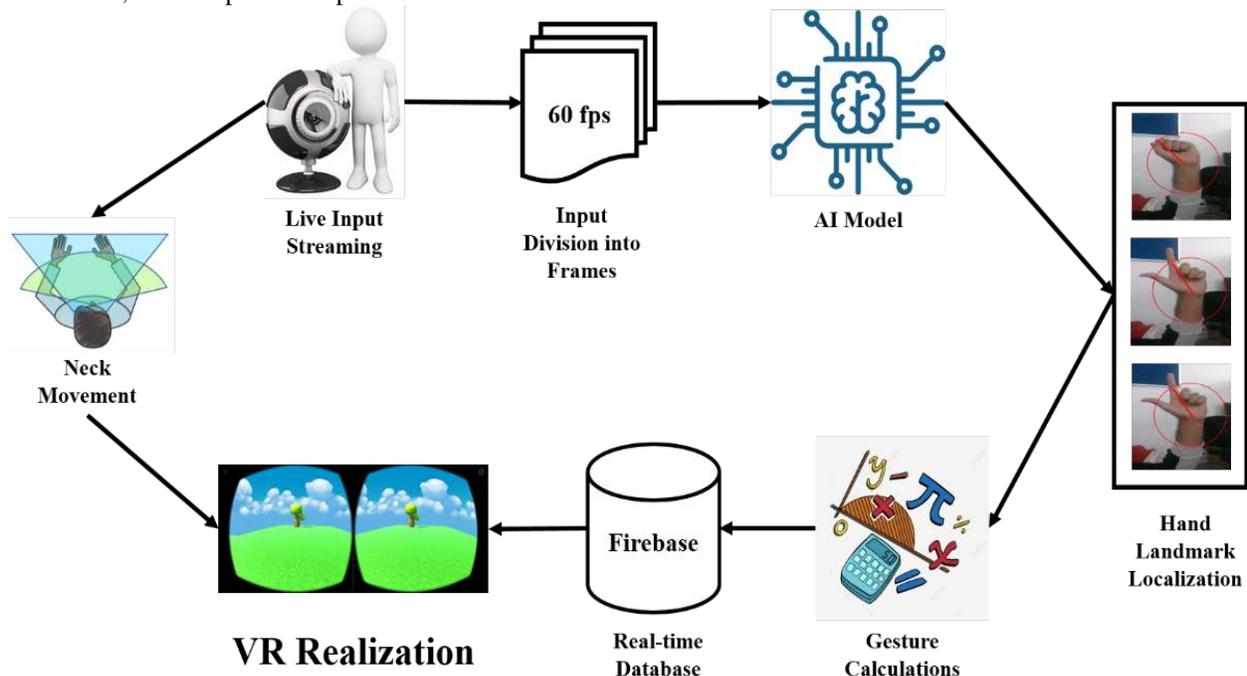

Fig. 1. Process flow of the proposed model

- Input Processing
- Gesture Identification
- Database Interaction
- VR Realization

### A. Input Processing

The suggested approach uses streamed live video as an input. The footage is divided into frames at a 60 frames per second rate rather than being supplied directly to the model. Webcam data is used to provide each frame to the model that are further fed to an AI model for recognizing the hand landmarks.

### B. Gesture Identification

An artificial intelligence (AI) model built on top of MediaPipe's [26] recognises the hand motions. A platform for creating pipelines that do interpretation over any type of sensory input is entitled MediaPipe. The AI model works in two phases i.e., palm detection and hand land-marking achieved through a palm detector and hand landmark model, respectively.

- Using an aligned hand bounding box, a palm detector identifies palms on a whole input picture. A single-shot detector model tailored for cellular real-time is utilised to find the first hand placements.
- A hand landmark model which generates high-definition 2.5D landmarks based on the palm detector's clipped hand bounding box. After detecting the palm across the entire picture, a second hand landmark model uses regression, or direct location projection, to carry out exact feature point placement of 21, 3D hand-knuckle positions inside the identified hand areas. Only six of them were used for the suggested gestures model, as seen in Fig. 2. The model acquires a reliable inherent hand posture depiction and is unaffected by self-occlusions or semi-transparent hands. In every instance, the landmarks are almost perfectly spotted.

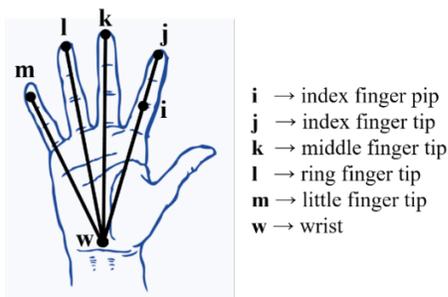

Fig. 2. 3D hand-knuckle coordinates used in proposed model

Rather than employing hard computing, authors have opted to soft computing to identify gestures more precisely. The proportionate placements of various landmarks serve as the basis for codes. Utilizing relative locations, authors programmed three distinct gestures: hold, move, and jump.

- Hold: In this gesture, the radius is formed by the line connecting the wrist and the tip of the index finger, as shown in Fig. 3(a).
- Jump: In this gesture, the radius of the circle is established by the line connecting the wrist and the pip of the index finger, and the tips of the remaining fingers are contained within the circle, as seen in Fig. 3(b).
- Move: In this motion, all finger tips are located outside the circle, with the radius being the line between the wrist and the tip of the index finger (see Fig. 3(c)).

Every live streamed hand gesture is labelled as either one of three (hold/jump/move) and further the gesture calculations are used to classify the gestures accurately. The gestures calculation starts with the identification of Euclidian distance,  $\delta$  between the coordinates of wrist ( $x_w, y_w$ ) and index finger pip ( $x_i, y_i$ ) as per equation (1)

$$\delta = \sqrt{(x_w - x_i)^2 + (y_w - y_i)^2} \quad (1)$$

After the  $\delta$  is calculated, the behavior of index (j), middle (k), ring (l) and pinky (m) fingers are identified using equation (2) and (3)

$$a = \Psi_{finger \in j}(x_{finger}^2 + y_{finger}^2 - \delta^2) \quad (2)$$

$$b = \Psi_{finger \in k,l,m}(x_{finger}^2 + y_{finger}^2 - \delta^2) \quad (3)$$

The gesture,  $\Omega$  is the calculated based on equation (4)

$$\Omega = \begin{cases} \text{hold, if } a < 0 \text{ and } b < 0 \\ \text{jump, if } a < 0 \text{ and } b > 0 \\ \text{move, if } a > 0 \text{ and } b > 0 \end{cases} \quad (4)$$

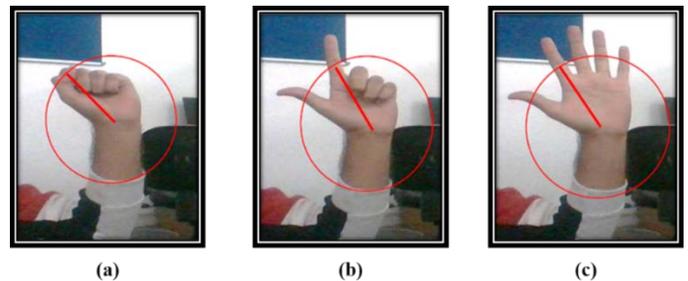

Fig. 3. Gestures for (a) Hold; (b) Jump; and (c) Move

### C. Database Interaction

The AI Model [27, 28] subsequently sends the gesture to the real-time database (Firebase in current research), which updates the motion parameter with the potential movement gestures (isMove, isHold or isJump). The Firebase database gives the system the most recent value of the information as well as modifications to that information by using a single API. The clients are able to retrieve their data from any platform, including the web and mobile devices, owing to real-time synchronization.

On the other side, the Unity3D Engine [29] is coupled to the real-time database. The Unity3D engine serves as the base layer for the present VR experience. Additionally, C# scripting is used to fetch data from the real-time database each time a database update is triggered.

#### D. VR Realization

The user has complete freedom to roam around the area and may utilise gestures to commence any movement. In the virtual environment, neck movement provides the directional input. Users of Virtual Reality (VR) may freely spin their heads 160° while viewing the surroundings owing to rotational tracking (as presented in Fig. 4).

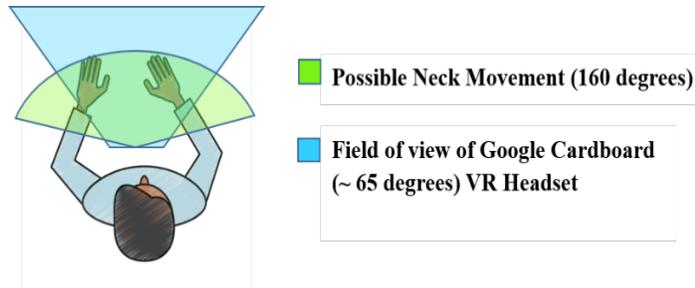

Fig. 4. Neck movement for VR environment

The user's head movement determines how the player rotates. The trajectory of the avatar's movement is controlled by the Head Mounted Display (HMD) spin. The field of view (FOV) of cell phone based VR headsets like Google Cardboard is only approximately 65 degrees (as presented in Fig. 4). The avatar travels both in translation and rotation inside the VR environment based on the data received.

### IV. EXPERIMENTS AND RESULTS

Current research's objective is to assess the system behavior, empirical characteristics, and experience aspects that are most important for VR locomotion [30]. To evaluate the efficacy of GVM, a comparison research using four approaches i.e., walking-in-place, controller/joystick, teleportation, and GVM (the proposed approach) is conducted. Current research investigates the propose model on two aspects i.e., 1) Latency and 2) User Experience.

#### A. Environmental Setup

The HTC Vive headgear and Epic Games' Steam VR SDK for Unreal Engine 4 were used in the development of the experimented-with VR locomotion methods. With a display resolution of 1080 x 1200 (2160 x 1200 combined pixels), 90 Hz refresh rate, 110 field-of-view, and complete 360 room-scale human monitoring, the HTC Vive headgear allows high-fidelity visuals. It is well known in the commercial VR industry and is made to use room-scale equipment, which uses sensors to transform a place into a 3D world. The HTC Vive monitoring system, an extra sensor that can be utilized to monitor tangible goods and translate them into activities or items in the simulated space, is supported by the system. Using a pristine HD 720p/30 fps camera with a diagonal field of view of 55 degrees and automatic light adjustment, the Hand Gesture Detection feature of Logitech C270 Digital HD webcam is employed.

1) *Walking in place*: The participant's limb motions during walking in place must be converted into virtual reality activity. The participants' right foot-mounted HTC Vive tracker and HTC Vive controllers were used to record and, respectively, manage the VR movement velocity and

direction. The VR movement velocity is closely correlated with the users' actual walking speed; that is, the quicker the participants moved around in actual situations, the quicker their avatars moved in the simulated space. Right footstep speed is used to imitate left footstep speed. The HTC Vive controllers' orientation affected the motion direction. Users have to manually turn themselves in the intended way in order to adjust the movement's trajectory.

2) *Controller/joystick*: In this approach, the type of controller can be anything from a straightforward joystick to a gaming remote or a keyboard. To enable controller-based VR movement, the HTC Vive controllers have been used as a touchpad. Motion is initiated by tapping the touchpad, and the velocity of motion is controlled by where the thumb is placed on the touchpad. The HMD system displayed a directional line to indicate the direction of motion, which has been governed by the orientation of the HTC Vive controllers.

3) *Teleportation*: With this method, you may point or use a controller to indicate where you want to teleport to. The HTC Vive Controllers' grip trigger is used. Whenever the trigger is pulled, a graphical signal that showed the movement's location, a ray accompanied by a marking on the simulated ecosystem's ground appeared. The trigger is pushed to initiate movement. The teleportation's orientation has been decided by the participant's body orientation.

4) *GVM*: GVM is a low-cost solution that eliminates the requirement for any additional costly gesture recognition gear. It reduces dizziness by letting users to modify their trajectory by merely tilting their head in the desired direction and hand movements for gesture recognition to move in VR. GVM relieves the participant from the physical strain. The usefulness of the suggested approach is demonstrated by user input on several factors such as interpreted realism, presence, and spatial drift in the real world. With a latency of approximately 65 milliseconds, the suggested system offers consumers with a real-time experience.

The virtual 3D environment is build using Unity 3D Engine, version 2019.4.40f1 (LTS) and deployed for Android and IOS platform. A simple Unity3D scene as presented in Fig. 5 is setup for the survey having 3D assets and paths to explore.

Participants can perform various movement actions like Jump/Hold/Move within the environment and move freely. This investigation gathers information to create an assessment of the strategies' efficacy in real-world settings. It moreover gathers information through semi-structured questionnaires to create a "rich description" of the perspectives of the participants.

#### B. Latency

The duration that it takes for information which is fed at an end of the connection to appear at the opposite end is referred to as latency. Typically, authors gauge how long it takes for information to go from one end to the other. In this setup we actually measure the round trip time (RTT), the "latency" (time of event from real-time database to Unity3D Engine) can easily be estimated as  $\Delta_i = 0.5 * RTT$ , where  $\Delta_i$  represents the latency.

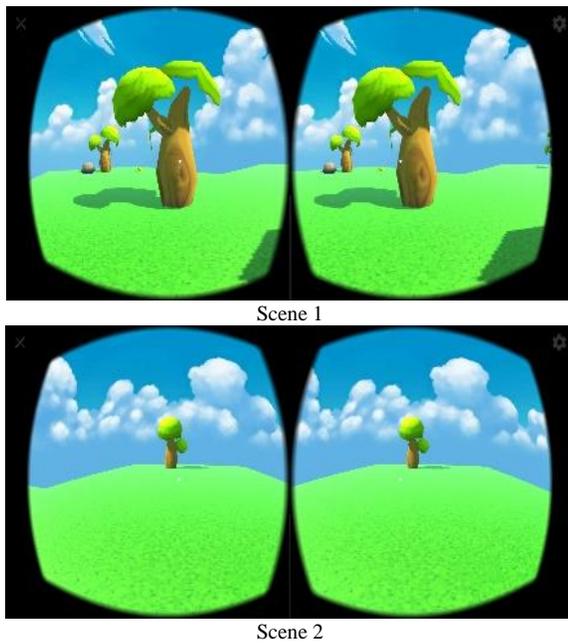

Fig. 5. Virtual environment created for experimentation

The tests were run with both/all clients on the same machine, located behind a 100mbits connection. For the Firebase Real-time Database, the location [us-central1] was selected. The average latency for three hundred observations is used to summarize the time offset between the data flow and RTT is calculated as approximately 65 milliseconds.

### C. User Experience

Utilizing the Game Experience Questionnaire (GEQ) [31], the user experience is assessed. Due to its capacity to address a broad variety of experiential aspects with strong reliability, the GEQ is a customer experience questionnaire which has been utilised in numerous areas (including gaming, virtual reality, and location-based services) [32, 33]. In numerous research on subjects including VR education [34], haptic engagement in VR [35], virtual reality orientation and mobility [36, 37] and virtual reality entertainment [38], the usage of GEQ has also been validated in the VR arena. The GEQ's Competence, Sensory and Imaginative Immersion, Flow, Tension, Challenge, Negative Affect, Positive Affect, and Tiredness categories are deemed pertinent and helpful for current investigation of the underlying strategies. According to a sequence of phrases in the GEQ questionnaire, the participant has been prompted to describe how he or she experienced throughout the encounter. It had 16 assertions that have been scored on a five-point severity scale from 0 ('not really') to 4 ('strongly') and included phrases like "I forgot everything around me". At the beginning of the research, demographic information was gathered, including age, gender, regularity of VR exposure ('never, seldom, often, and every day'), and familiarity with VR technology.

1) *Analysis of participants:* Within our institution zone, the participants have been sought for between October 2022 and December 2022. Participants needed to be physically capable of using VR technology, although prior VR

experience wasn't really necessary. Participants have been informed of the possibility for dizziness as well as their right to withdraw from the research at any moment. To be a part of the study, every participant provided their informed permission.

The four VR locomotion strategies were tested on thirty people (N = 30, mean age: 22.7, male/female: 18/12). Twelve individuals had only sometimes used virtual reality (VR), whereas eight people had used it regularly. Ten participants had never utilized VR. Twenty participants had earlier used VR; six had done so with HMDs and portable VR headsets, eleven had done so solely with HMDs, and three had done so only with portable VR headsets. Each participant finished the episode satisfactorily.

2) *Methodology:* After providing the informed consent, the participants responded to demographic and VR encounter forms within approximately ten minutes' duration. Then, the participants had additional trial opportunities to discover at their leisure and witness a "clean" rendition of the VR world, that is, one that had no time restrictions and did not use the VR locomotion approach for an average five minutes). The exercise was then completed by the participants within a duration of ten minutes on average. The participants may provide vocal comments while traversing using the GVM approach, and the investigators have been taking notes in order to tackle these issues in the discussion. The GEQ questions have been completed once the work has been finished within a duration of five minutes on average.

3) *Results & discussions:* There have been thirty tasks in total, one for each participant. The typical assignment took thirty-seven minutes to complete. The GVM technique stood out magnificently outstanding in the majority of the GEQ constituents (i.e., Competence, Sensory and Imaginative Immersion, Flow, Tension, Challenge, Negative Affect, Positive Affect, Tiredness) after the couple mean leader board analysis (depicted in Table II).

TABLE II. GEQ RANKING FOR VR LOCOMOTION TECHNIQUES

S.No.	VR Locomotion Techniques	Benchmark GEQ Rating
1	WIP	Ok
2	Controller	Borderline excellent
3	Teleportation	Good
4	GVM	Excellent

The participants felt that WIP offered excellent degrees of immersion because of its authentic and organic movement. However, most participants indicated the approach to be exhausting due to the difficulty of translating actual body action to virtual reality motion. Others said this function added a certain amount of amusement, enjoyment, and exercise. Eventually, amidst the investigators attempting to take all necessary precautions, such as setting up a virtual boundary structure and an open area, participants still reported experiencing a pause in their exploration in the simulated space due to their fear of running into actual physical items in the real

world. It was discovered that the controller/joystick VR movement was simple to use and has been described as "pleasant," "simple," and "pleasant." However, a few users mentioned experiencing brief motion nausea at the beginning of the questionnaire job.

Owing to its visible 'jumps' and irregular mobility, teleportation was deemed the weakest engaging of the four modalities. On the contrary, the participants judged GVM to be more engaging and competent than the majority of the GEQ aspects. In addition to reducing fatigue compared to WIP, it also eliminated motion sickness brought on by hand gestures. The user had fewer difficulties using GVM because of the predetermined hand movements. The majority of participants praised GVM and rated it as the easiest and perhaps most enjoyable approach. Fig. 6 and Table III shows a normalized mean value (NMV) between 0 - 10 of each technique for every GEQ Component.

- **Competence:** The tests revealed that the Competence scores for the various strategies differed statistically significantly. On analyzing the Competence grade of GVM with all other techniques, the NMV showed substantial variances, favouring GVM with a NMV of 8.87.
- **Sensory and Imaginative Immersion:** The findings indicated statistically significant contrasts among the four strategies for the Sensory and Imaginative Immersion aspect favouring GVM in close vicinity to WIP.

- **Flow:** Following the test, there have been no appreciable variations in the Flow component amongst the four strategies; nonetheless, participants gave the Teleportation approach a higher rating.
- **Tension:** GVM obtained the lowest mean value (3.64) in the assessment, followed by WIP, Teleportation, and Controller, in that order.
- **Challenge:** The challenge score between GVM and Teleportation differed significantly according to the MSR, showing that GVM (mean value: 5.02) is a less difficult approach than teleportation and others.
- **Negative effect:** The testing activity for Negative effect demonstrated significant differences throughout all technique analyses. In the mean assessment of GVM, WIP, Controller, and Teleportation, the GVM showed minimal negative effect. Teleportation on the other hand put extra strain on the participants due to continuous transition in the virtual world.
- **Positive effect:** The GVM and teleportation had greater value, but the assessment did not reveal any changes in the Positive Affect component amongst the four approaches.
- **Tiredness:** The Tiredness aspect exhibited substantial variations according to the assessment. In each instance, GVM, Teleportation, and Controller all scored much lower on Tiredness compared to WIP

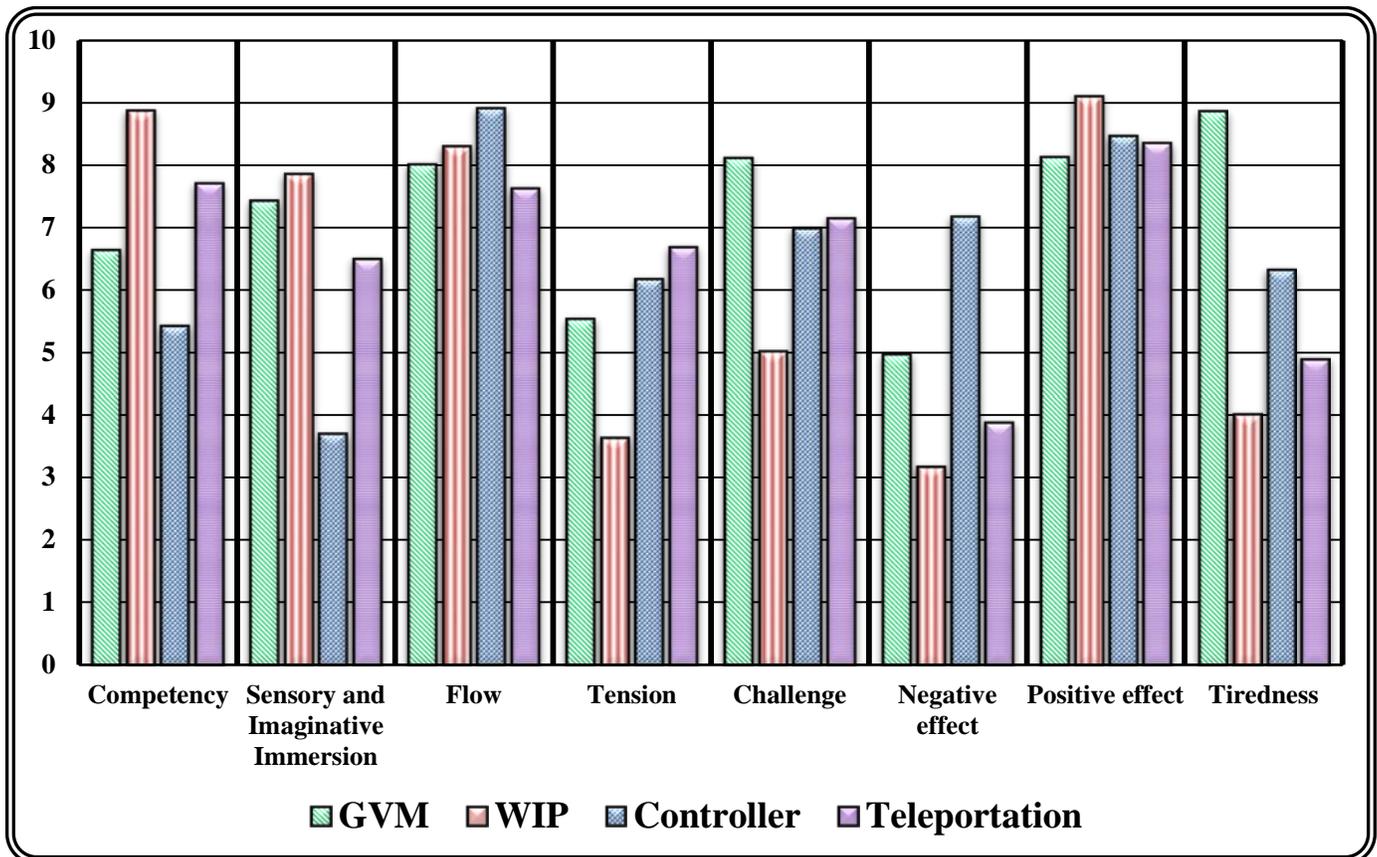

Fig. 6. Normalized mean value for various GEQ components

TABLE III. GEQ COMPONENTS NORMALIZED MEAN VALUE FOR EXISTING TECHNOLOGIES

Evaluation Parameter	Proposed Method (GVM)	WI P	Controll er	Teleportat ion
Competency	6.63	8.87	5.42	7.71
Sensory and Imaginative Immersion	7.42	7.86	3.7	6.5
Flow	8	8.3	8.9	7.63
Tension	5.53	3.64	6.17	6.69
Challenge	8.1	5.02	6.98	7.15
Negative effect	4.96	3.18	7.17	3.89
Positive effect	8.12	9.1	8.46	8.35
Tiredness	8.85	4.02	6.32	4.9

Fig. 7 shows overall positive components mean values for each techniques, positive GEQ components include Competence, Sensory and Imaginative Immersion, Flow, Positive Effect. In this the mean value of GVM is highest. Further, Fig. 8 shows overall negative components mean values for each technique, negative GEQ components include Tension, Challenge, Negative Effect, Tiredness. In this the mean value of GVM is lowest.

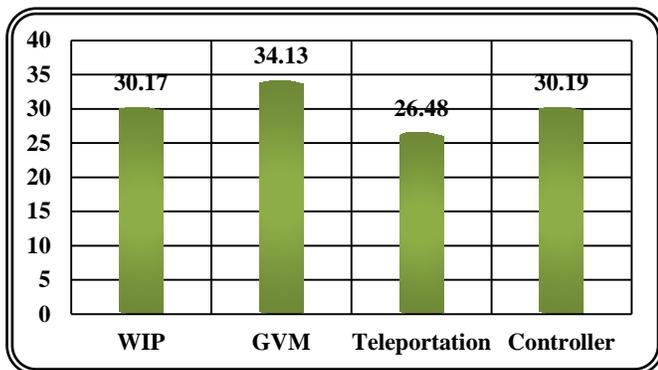

Fig. 7. Mean value for various positive GEQ components

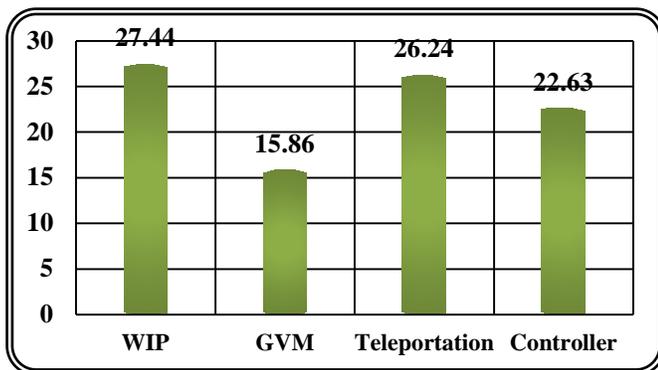

Fig. 8. Mean value for various negative GEQ components

### V. CONCLUSIONS

A range of hand gestures must be recognised and reliably classified by gesture recognizers in order to provide improved

user interfaces for Virtual or Augmented Reality goods. This study compares the most common virtual reality mobility systems and finds that gesture control is a crucial technology for enabling unique virtual world communication paradigms. The present research proposes a gesture-based virtual movement (GVM) system using artificial intelligence (AI) that eliminates the need for pricey equipment for immersive virtual movement (i.e., walk/jump/hold for this research) with a focus on affordability. By enabling users to alter the trajectory by merely rotating their head in the desired direction, the GVM also seeks to prevent users from feeling dizzy. In comparison to cutting-edge methods, the GVM's interpreted realism, presence, and spatial drift in the real world were evaluated. According to the empirical analysis, GVM offers customers a real-time experience with a latency of ~65 milliseconds. Additionally, the results demonstrated how the GVM outperforms the existing techniques in many standard interaction elements.

### VI. FUTURE WORK

A proof-of-concept for using hand motions identified by computer vision to enable movement in a virtual world is provided by the work discussed in this paper. However, there remains lots of opportunities for enhancement and more research.

- *Enhancement of Gesture Lexical Items:* Authors aim to increase the number of hand gestures available for use in directing the movement of the virtual world. This can entail introducing fresh motions that let users navigate across the area or control items.
- *User Interface Layout:* It will be crucial to create a user interface that is simple to understand and use as the system grows increasingly complicated and feature-rich. We will investigate several methods for creating a user interface that permits individuals to swiftly and simply manipulate the virtual world in upcoming work.
- *User Experience:* In order to enhance the user experience, we will research several ways to let users know when their gestures have been effectively identified. This can entail adding haptic or visual feedback features to let users know when they have performed a motion correctly.
- *Reduce delay:* Making the virtual reality environment feel more realistic by lowering system delay may significantly enhance user experience. Optimizing data communication between the AI model and the Unity3D engine is one method for lowering latency. This can entail transferring data using more effective methods or requiring less data to be transferred in real-time.

In conclusion, there are a wide range of prospective directions for further research in this field, including increasing the gesture lexicon, improving gesture detection, enhancing user interface, offering users input, and lowering latency. Future research in these areas has the potential to dramatically improve user engagement and increase the effectiveness and efficiency of the gesture-based movement mechanism.

# Implementation of Big Data Privacy Preservation Technique for Electronic Health Records in Multivendor Environment

Ganesh Dagadu Puri, D. Haritha

Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation,  
Vaddeswaram, AP, India

**Abstract**—Various diagnostic health data formats and standards include both structured and unstructured data. Sensitive information contained in such metadata requires the development of specific approaches that can combine methods and techniques that can extract and reconcile the information hidden in such data. However, when this data needs to be processed and used for other reasons, there are still many obstacles and concerns to overcome. Modern approaches based on machine learning including big data analytics, assist in the information refinement process for later use of clinical evidence. These strategies consist of transforming various data into standard formats in specific scenarios. In fact, in order to conform to these rules, only de-identified diagnostic and personal data may be handled for secondary analysis, especially when information is distributed or transferred across institutions. This paper proposes big data privacy preservation techniques using various privacy functions. This research focused on secure data distribution as well as security access control to revoke the malicious activity or similarity attacks from end-user. The various privacy preservation techniques such as data anonymization, generalization, random permutation, k-anonymity, bucketization, l-diversity with slicing approach have been proposed during the data distribution. The efficiency of system has been evaluated in Hadoop distributed file system (HDFS) with numerous experiments. The results obtained from different experiments show that the computation should be changed when changing k-anonymity and l-diversity. As a result, the proposed system offers greater efficiency in Hadoop environments by reducing execution time by 15% to 18% and provides a higher level of access control security than other security algorithms.

**Keywords**—Privacy preservation; data privacy; data distribution; anonymization; slicing; privacy attacks; HDFS

## I. INTRODUCTION

The widespread access to virtual health documents and assets controlled through Health Information Systems (HISs) enables to strengthen scientific studies, support care centers through medical education. It also assists various groups for fitness methods through management and governance (e.g., scientific audits for high-satisfactory development and care coordination) [1], [2]. Furthermore, health data is often processed and linked with different data sources, along with facts from scientific trials, having allowed for the harvesting of extra insights which might be beneficial. It is now no longer most effective for scientific practices, however additionally for

designing and improving facts fitness structures and contributing to greater efficient policymaking [3]. While the benefits of secondary use of studies and nursing data makes vital for boosting the high-satisfactory of treatment. There are nevertheless several uncertainties regarding how this data is accessible, through whom, and under what conditions. Data sharing (in particular while it includes private and sensitive attributes and is made accessible to the third party enterprise or geographical region in which it's miles engendered) can bring about a lack of privacy for individuals, along with users and health professionals, further to the requirement to gain earlier than taking part in research [4]. As a result, data safety and affected person privacy are vital demanding situations to address.

Another problem in processing health data for secondary applications is informational discrepancies and diversity in clinical records and data. This is related to the lack of uniform data representation. Hospital Information System (HIS) handles both structured and unstructured documents. Although there are still many unresolved issues that may hinder the use of hybrid materials, especially disjointed health data, they are made possible by leveraging and efficiently integrating structured and semi-structured health information. There is a distinct position arising from their complementary use. In a single, structured way while considering data responsiveness, privacy can hamper, and ethical concerns raise [5]. Digital evidence should be transformed into a unified, standardized, and codified representation using modern methods such as big data analysis [6]. Proper use of this data requires the use of appropriate anonymization procedures. This paper presents a novel integrated architecture for collecting clinical data from heterogeneous sources and transforming them into formats useful for clinical secondary use while adhering to the above requirements. Proper distribution of attribute weightage is also important [7].

The main contributions of this paper are:

- Protect the distribution of large heterogeneous datasets with a novel approach to maintaining privacy in Hadoop environments.
- Defeat various network and database attacks such as SQL injection, collusion attacks and similarity attacks.

The rest of Section II describes state-of-the-art systems that demonstrate previous work by various authors. The Section III

describes the research methods used for the proposed system, including a detailed description of the proposed architecture and execution flow. Section IV provides a description of the algorithm and determines how to handle large data distribution tasks. This section describes data protection against internal attacks and data security algorithms against external attacks. Section V focuses on the results and detailed discussion. Extensive experimental analysis and obtained results are defined in tabular and graphical formats. Finally, Section VI describes the conclusions of the proposed system and future issues.

## II. LITERATURE SURVEY

This section describes various state-of-the-art systems used by previous researchers. According to [8], the newly proposed Secured Map Reduce (SMR) layer introduces a security and privacy layer between HDFS and the MR (Map Reduce) layer, and this approach is known as SMR model. A major value in this work is to facilitate data exchange for knowledge mining. This architecture ensures privacy and security for data consumers, addresses privacy scaling issues, and maintains a trade-off between privacy and utility. SMR models significantly reduce runtime and information loss compared to traditional techniques, and minimizes CPU and memory consumption. According to the work proposed in [9][10], current PPDM strategies have been exhaustively investigated and classified based on data modification methods. This is the researcher's main contribution and will help researchers in the field to fully understand the PPDM. In addition, they compared and considered the advantages and limitations of various PPDM approaches. The vast increase in customer data retention has spawned a new field of research known as privacy-preserving data mining (PPDM). The fundamental challenge of PPDM is to modify data using specific techniques and create powerful data mining models of the modified data while meeting specified privacy requirements and ensuring that information is available for intended data analysis activities. Current review studies aim to leverage data mining jobs without compromising the security of people's sensitive information, especially at the record level.

In the research work proposed in [11], the authors provide a well-designed taxonomy that allows systematic and rigorous classification of this difficult research subject. Recently, the term "big data" has become popular. The proliferation of social networks, the Internet of Things (IoT), and the outsourcing of cloud computing have created an incredible amount, velocity, and variety of data. According to [12], authors proposed Mondrian-based k-anonymity method. A deep neural network (DNN)-based architecture is presented to protect the privacy of high-dimensional data. Experimental results show that the proposed method reduces data information loss while preserving privacy. Many companies actively or passively collect data from consumers. It also collects personal data from various databases.

This data includes personally identifiable information (PII) that can be used to identify an individual. Data analysts and researchers have paid much attention to protecting privacy in the explosion of data for big data and cloud computing.

Numerous data anonymization strategies and DNN privacy models have been thoroughly researched.

In research activities [13], data analysts and academics have paid much attention to privacy-aware data distribution for big data and cloud computing. Various data anonymization approaches and DNN models have been thoroughly researched to protect privacy. A public identity-based PDP protocol for secure data storage helps to protect the privacy of many users. This approach allows TPA to correctly assess the integrity of group-shared data. According to [14], it is a privacy-preserving cloud-based mobile multimedia data exchange system with attribute names and values for each attribute, and only attribute names are visible in access policies. However, the attribute values are included in the cipher text. Encryption has two phases online and offline. Data owners can prepare the intermediate cipher text components in an offline step. After receiving a specific access policy and multimedia data encryption request, the data owner can quickly create the final legal cryptogram in an online phase. Most of the processing costs for verification testing and decryption are offloaded to cloud servers using a decryption outsourcing approach. According to the safety case, PPCMM is adaptively safe in the standard model.

In research work [15], three strategies are used to ensure data confidentiality and integrity. It describes homomorphic encryption, order-preserving encryption schemes, and attribute-based encryption. These strategies are best used in the cloud to ensure privacy. It is also ideal for big data to maintain efficiency and scalability for huge datasets for decision making. Big data is a vast accumulation of enormous data sets that cannot be analyzed by ordinary computing techniques. Big data is therefore a vast amount of rapidly changing data with mixed data types. According to [16], IoT deployments in many industries meet the privacy challenges faced by IoT in resource-constrained devices. It provides an opportunity to address some of the uses of blockchain in various fields and IoT privacy concerns. Based on the utilization of blockchain in IoT, authors proposed various research studies. This study aims to review current research on blockchain applications in IoT for privacy protection. After reviewing current solutions, it was determined that blockchain is the most effective way to avoid identity disclosure, surveillance, and tracking in IoT.

According to [17], a new privacy utility approach uses lightweight elliptic curve cryptography (ECC) to protect privacy and particle swarm optimization (PSO) clustering to maintain utility. PSO is used to cluster datasets and ECC is used to ensure confidentiality of clustered datasets. The proposed method is tested on medical datasets and compared to other methods based on various performance criteria such as clustering accuracy, F-measure, data usefulness, and privacy metrics. According to [18], the various impacts of privacy laws on forensic investigations of embedded devices, the role of anti-forensics, and proposals for embedded forensic investigation guidelines and initiatives to address privacy concerns.

They also proposed a SMART system that enables built-in digital forensic investigations to protect privacy at every level of traditional forensic frameworks. This protects cooperation

with unincorporated owners of embedded computers in cybercrime investigations. According to Slawomir Goryczka et al. [19], it is considered an insider attack against a number of data providers that insert records and attempts to take closure through covert attacks against records inserted by other providers. In this work, the authors proposed a secure multiparty computing protocol for ensuring privacy across multiple data providers. A research paper proposed in [20] identifies privacy issues related to big data and its use. It has been suggested that processing different types of data through different channels poses different threats to user privacy. The authors of [21] emphasized a no-delay framework for the release of medical records to protect privacy. The usefulness of published data is enhanced by a late validation approach. Similarity and skewness attacks could be possible when forming sensitive value groups for publishing records. In a research paper [22], [23], the authors proposed a framework for processing streaming data and measuring term similarity within groups using standard means and addressed the similarity attack issue.

### III. PROPOSED SYSTEM DESIGN

Fig. 1 below shows the multivendor environment and different constraints for data collection. First, it collects synthetic and real-time data from a variety of sources, including medical systems, historical data, and runtime data collection from various web applications. This data may include sensitive user information. Also, records collected; need to create a privacy view when sending data. Malicious user can predict the data of provider by using background knowledge. There is need of the study that defines some security policies on the pre-trained model for secure data distribution. The problem of database attacks and privacy violations on privacy view works like a data hiding technique should be eliminated.

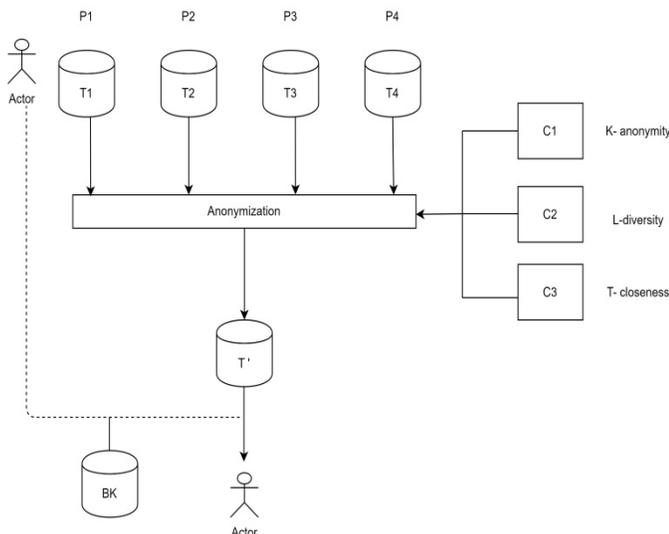

Fig. 1. Multivendor environment and different constraints for data collection

Fig. 2 shows the proposed system architecture with strategic execution. In data providers block, data collected from a variety of sources. It includes various systems such as medical systems, historical data, and runtime data collection

from various web applications. As data collected is very large and considered as big data, nodes are added to process such large data. Using HDFS name nodes are added for processing of data as shown in Fig. 2. Data nodes will provide information for processing to generate privacy view and at the same time detect attack and attacker. Name nodes are keeping directory view of all files in HDFS. Data nodes are sending information to these name nodes and respond to name node in all file operation of privacy view and attack prevention system. This data may include sensitive user information. This study defines some security policies on the pre-trained model for secure data distribution. Privacy view works like a data hiding technique that eliminates the problem of database attacks and privacy violations.

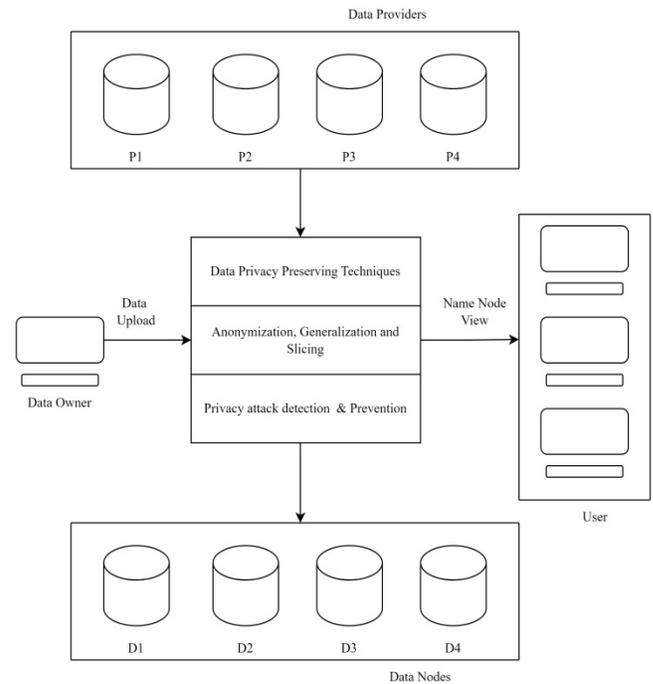

Fig. 2. System architecture for privacy preservation and privacy attack detection in distributed environment

#### A. Techniques for Maintaining Privacy

Anonymization, generalization and slicing are the main methods used in the proposed model. In the anonymization, L-diversity and K-anonymity methods are used. To increase the anonymization level, top-down and bottom-up generalization is used. Slicing basically relies on splitting attributes and tuples. For attribute split (vertical split), split data as {name},{age-zip},{gender} and for tuple split (horizontal split), split as {t1,t2,t3,t4,t5,t6}. In attribute partitioning, age and zip code are quasi-identifiers (QIs), so they are highly correlated and thus partitioned together. These QIs may be known to the attacker. A tuple partitioning system should check the sensitive attribute (SA) column for L-diversity. Equivalence groups are created using K values of quasi identifiers in such a way that they are indistinguishable from each other. In that equivalence class L different sensitive values will be added to make it impossible to identify value of individual from anonymized data.

## B. Privacy Attack Detection and Prevention

Another important feature of this system is the detection of privacy attacks and the prevention of the use of defined algorithms. End users can perform insider, collusion, sql injection and similarity attacks by making minor changes to update the actual value and making it available to another user. Using privacy protection and fingerprint generation technology, such attacks can be easily detected and prevented efficiently

## IV. ALGORITHM DESIGN

### A. Privacy View Generation

It is similar to one-way hash functions to generate the privacy view. The goal of the algorithm presented is to keep sensitive data secure and avoid privacy intrusions. As a result, anonymous views on miniature buckets are generated. In algorithm step 1 to step 6 are used to read the input record wise and apply generalization on quasi-identifiers of the records. While performing anonymization on entire set of quasi-identifiers, validation of that is done using K-anonymity. The records which do not satisfy the criteria of anonymization are added in bucket. Permutation is applied on records so that more records get anonymized. Step 7 to step 12 are applied for the pruning and creating final bucket after anonymization. Bucketization is used to avoid leakage of the records in case of privacy preserved view. It stores records which do not satisfy constraints after pruning and permutation methods.

---

#### Algorithm 1: Algorithm for privacy view generation

---

**Input:** Input dataset DSet, total number of data providers Dp, Constraint policy C {K\_Anonymity, L\_Diversity}

**Output:** Privacy view (NT\*) with selective provider

**Step 1:** foreach (DSet till null)

**Step 2:** foreach (col in table)

    foreach (row in table)

**Step 3:** Select quasi identifier (QiF) and set of sensitive attributes (S\_Att)

**Step 4:** Executes generalization to classify the tuples in QiF with multiple groups

**Step 5:** Perform anonymization on entire set of attributes

**Step 6:** While (validate data privacy(DSet, Dp, C) = 0) do

    if (DSet[i] ← DSet) validated with QiF then

        add D[i] till K-anonymity

    else break;

    Bucket\_List(i1) → DSet;

**Step 7:** Apply permutation on dataset (DSet[i]=I( null-1))

**Step 8:** Apply Pruning on(DSet)

**Step 9:** Execute step 1,2,3 on Bucket\_List (i1)

**Step 10:** if (C != (DSet) && (Dp # 1))

    Bucket(i2) → Bucket\_List (i1(j))

**Step 11:** Show (Bucket\_List (i2)!=null)

**Step 12:** end while

**Step 13:** end for

---

### B. Algorithm 2

The top-down and bottom-up Algorithm 2 is similar to the base-up method. The main difference is in how coalition checks are performed, starting with 0-foe and working up.

---

#### Algorithm 2: Algorithm Top down and Bottom up generalization view

---

**Input:** Input dataset DSet, total number of data providers Dp, Constraint policy C {K\_Anonymity, L\_Diversity}

**Output:** Privacy view (NT\*) with selective provider

**Step 1 :** Read data from dataset from bottom set or top set

$$data[ ] = \sum_{n=1}^m (\text{Row } [n])$$

**Step 2:** Check data count with K-anonymity and L-diversity for each block

**Step 3:** calculate the fitness score F\_Score(DataSet[])

**Step 4 :** if (F\_Score >= Th)

    Generate best generalized view as T\*

**Step 5 :** end loop

**Step 6:** return T\*;

---

When an infringement by any foe is detected (early stop) or all m-policies are examined, the algorithm comes to a cessation. The algorithm represents the basic idea of a bottom-up speculating approach. Using K-anonymity and L-diversity for each block in the dataset, fitness score is checked to generate the best generalized view of privacy preservation. This score is checked against the threshold value for the anonymization.

## V. RESULTS AND DISCUSSIONS

The proposed system is implemented using Java 1.8 and NetBeans 8.0 in an open source Hadoop 2.0 environment. The Intel 2.7 GHz hardware setup is done with 12 GB of RAM. The Hadoop setup is done with a name node and two data nodes using a MapReduce process. According to the problem description, the results obtained are demonstrated using a standalone machine and a Hadoop system. The input dataset size is 101850 instances for both experiments, with and without Hadoop environment. Anonymized views are generated using a definition of C constraints, including K-anonymity and L-diversity. Execution time is measured in milliseconds. Publishing the records using constraints is tedious task if the input data is large. In many cases data need to be preprocessed before giving to the privacy preservation system. This increased data with the need of preprocessing and formatting cannot be executed timely by existing infrastructure and framework.

TABLE I. EXECUTION TIME FOR TRADITIONAL MACHINE WITH VARIOUS L AND K VALUES

Measures	Slicing	Bucket	Final Bucket
L=8 and K=10	11586	1109	184
L=9 and K=12	11776	1316	187
L=10 and K=15	13330	1541	182
L=11 and K=13	11891	1257	188
L=12 and K=15	12950	1550	388

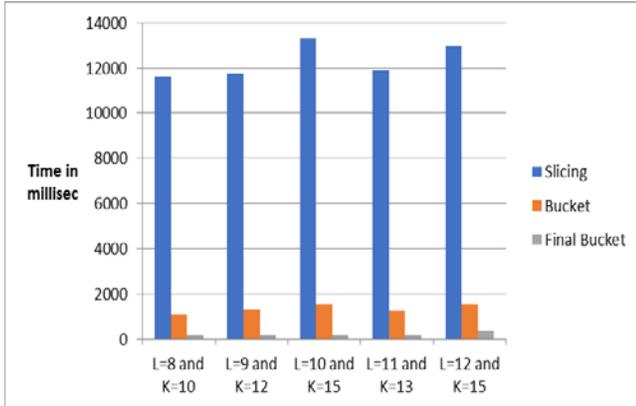

Fig. 3. Execution time for traditional machine with various L and K values

Table 1 and Fig. 3 show the time required to generate T\* views as slicing, bucket generation and final bucket generation. This experiment was conducted on a typical configuration of a single machine. As a result, the execution time of all three processes increased even as the values of L and K increased.

TABLE II. EXECUTION TIME FOR HDFS WITH VARIOUS L AND K VALUES

Measures	Slicing	Bucket	Final Bucket
L=8 and K=10	9827	225	222
L=9 and K=12	7178	262	220
L=10 and K=15	8773	271	186
L=11 and K=13	9354	244	223

After the privacy view generation, few records do not satisfy the constraints set by L-diversity and K-anonymity. If these records are dropped in the system, there is significant loss of information. In this proposed system, these records are stored in the bucket. Bucket is storage area where we can apply the privacy view generation constraints again. Few records may not satisfy the constraints in this stage also. Again dropped records are stored in the final bucket and applied with L-diversity and K-anonymity criteria. For different values of K and L execution time is varying. This execution time is measured in milliseconds.

Fig. 4 shows the time required to generate T\* views using different K and L values mentioned in Table 2. Graph shows the execution time in the Hadoop environment.

Execution time on Hadoop is about 15-18% faster than on a standalone machine with a similar dataset. Increasing the L and K value will increase the execution time subsequently on traditional machine. On HDFS also there is increase in execution time with the increase in these values. Time for privacy view generation, bucket formation and final bucket formation is considered in the execution time.

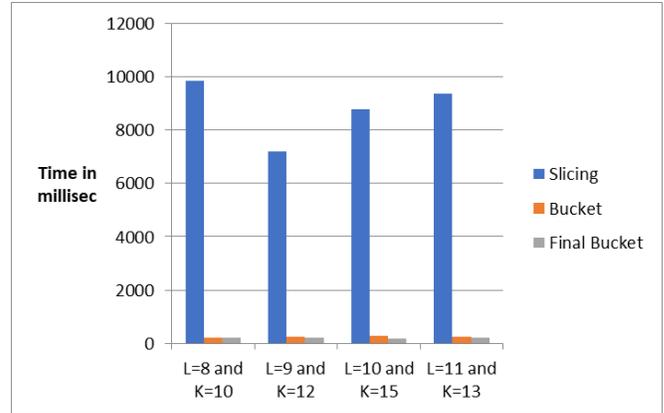

Fig. 4. Execution time for HDFS with various L and K values

TABLE III. EXECUTION TIME FOR TRADITIONAL MACHINE WITH CONSTANT (L=8)

Measures	Slicing	Bucket	Final Bucket
L=8 and K=10	11586	1109	184
L=8 and K=11	12994	299	174
L=8 and K=12	13110	1180	180
L=8 and K=13	11123	1229	196

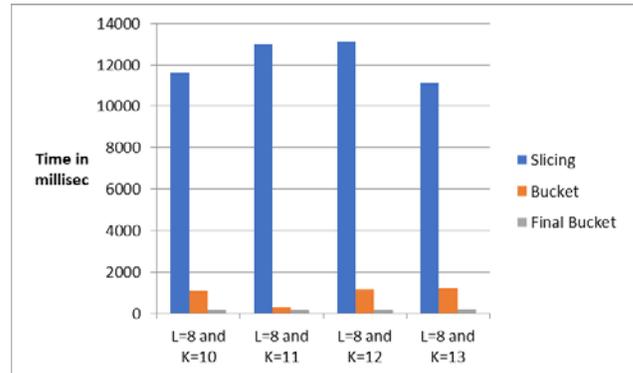

Fig. 5. Execution time for traditional machine with constant (L=8)

Table 3 and Table 4 are enlisting the values for constant L value. Experiment is carried out using constant value 8. In this experiment, value of L-diversity is kept constant and varying k-anonymity values to illustrate the time required generating anonymized views. In this experiment, there is some variation in run time when both values are changed. As only K value is changed, more number of records will appear and available for creation of L-diverse sensitive group. So with increase in k values execution time is reduced.

TABLE IV. EXECUTION TIME FOR HDFS WITH CONSTANT (L=8)

Measures	Slicing	Bucket	Final Bucket
L=8 and K=10	8735	263	208
L=8 and K=11	10362	325	214
L=8 and K=12	9861	281	227
L=8 and K=13	7675	238	213

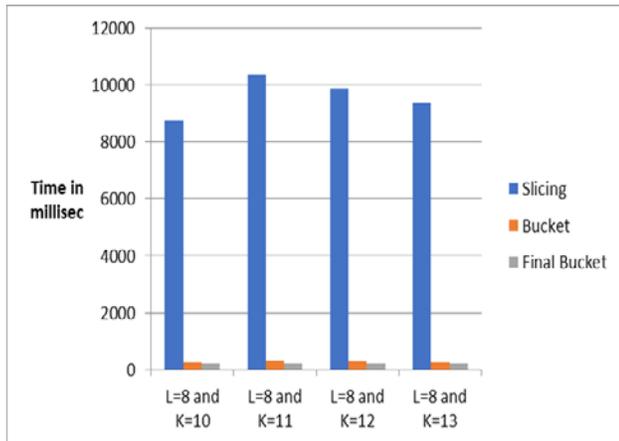

Fig. 6. Execution time for HDFS with constant L-diversity

The Fig. 6 describes the similar execution according to Fig. 5 in Hadoop environment. Almost 24% execution time is reduced using HDFS based a parallel execution.

TABLE V. EXECUTION TIME FOR TRADITIONAL MACHINE WITH CONSTANT (K=15)

Measures	Slicing	Bucket	Final Bucket
L=10 and K=15	13330	1541	182
L=11 and K=15	9500	1534	174
L=12 and K=15	8184	1540	188
L=13 and K=15	10424	1601	192

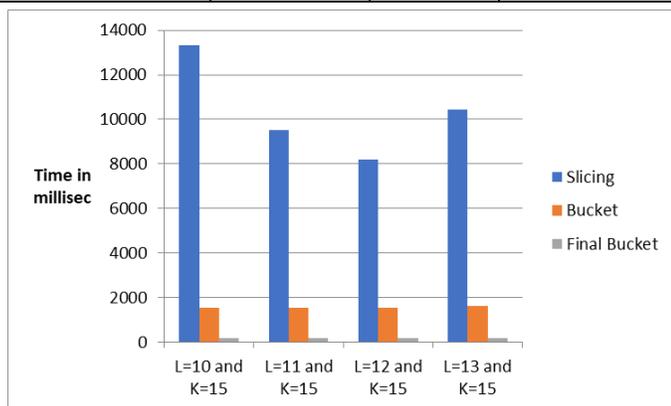

Fig. 7. Execution time for traditional machine with constant k-anonymity

Execution time for traditional machine with constant (K=15) is listed out in Table 5. Fig. 7 shows the generation of T\* views with constant K-anonymity and different L-diversity using a standalone machine. The time required to create the

final anonymized view of slices and buckets is reduced, even if the K and L values change. As multiple providers are providing electronic health records with disease as sensitive attribute, insider attack is possible. M-privacy algorithm takes care of collusion attack which takes place in multivendor environment [19]. But M-privacy algorithm cannot work on large scale data. In this research slicing and bucketization techniques are applied on big data using hadoop distributed file system.

TABLE VI. EXECUTION TIME FOR HDFS WITH CONSTANT K AND DIFFERENT L VALUES

Measures	Slicing	Bucket	Final Bucket
L=10 and K=15	9109	260	461
L=11 and K=15	6555	269	232
L=12 and K=15	7947	272	225
L=13 and K=15	7755	242	219

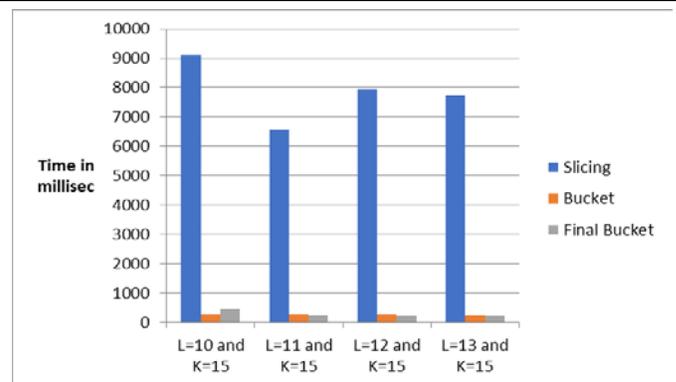

Fig. 8. Execution time for HDFS with constant k and different L values

Table 6 and Fig. 8 above show the generation of privacy views with different values of L-diversity and constant K-anonymity in the Hadoop framework. Slightly changing L-diversity by the k constant does not make much difference. In many cases, the input data cannot satisfy the constraints of C, which can lead to longer times.

## VI. CONCLUSION

In this paper, various privacy-preserving techniques for large-scale health datasets in distributed environments are implemented. Various privacy techniques such as data anonymization, generalization, random permutation, slicing and fingerprinting are used to protect and eliminate privacy attacks. This system provides maximum security in HDFS-based distributed environments and standalone systems. This approach is effective when dealing with real-time data containing sensitive information. Experiments are evaluated on the entire execution using synthetic and real-time healthcare datasets. The system provides 100% privacy with privacy-preserving technology while maintaining the highest accuracy in privacy-based data delivery. Implementation of various machine learning techniques for distributed dynamic data security is a future challenge for the system.

**Abstract**—Churn customer estimation method is proposed for improving sales. By analyzing the differences between customers who churn and customers who do not churn (returning), we will conduct a customer churn analysis to reduce customer churn and take steps to reduce the number of unique customers. By predicting customers who are likely to defect using decision tree models such as LightGBM, which is a machine learning method, and logistic regression, we will discover important feature values in prediction and utilize the knowledge obtained through Exploratory Data Analysis (EDA). As results for experiments, it is found that the proposed method allows estimation and prediction of churn customers as well as characteristics and behavior of churn customers. Also, it is found that the proposed method is superior to the conventional method, GradientBoostingClassifier (GBC) by around 10%.

**Keywords**—LightGBM (light gradient boosting machine); EDA (exploratory data analysis); churn prediction; linear regression; gradient boosting method; GradientBoostingClassifier: GBC

## I. INTRODUCTION

Churn customer estimation method is very important for improving sales. By analyzing the differences between customers who churn and customers and who do not churn (returning), a customer churn analysis to reduce customer churn is conducted through taking steps to reduce the number of unique customers. By predicting customers who are likely to defect using decision tree models such as LightGBM, which is one of a machine learning method, and logistic regression, for discovering important feature values in prediction and utilize the knowledge obtained through Exploratory Data Analysis (EDA).

In order to predict churn customers, the method based on LightGBM and EDA is proposed here. LightGBM is decision tree gradient boosting frameworks just as of XGBoost method and is convenient and fast machine learning method. Although there are differences in the details of the implementation method, there is no problem in thinking that they are almost the same framework in general. LightGBM is much faster than XGBoost method because it handles continuous values as histograms. XGBoost did not originally have this implementation, but now it is also possible to adopt a histogram-based algorithm with the parameter `tree_method = hist`.

The comparison between XGBoost and LightGBM is also a research topic because gradient boosting is highly practical.

There is "Benchmarking and Optimization of Gradient Boosting Decision Tree Algorithms" published in September 2018 [1]. After testing XGBoost, LightGBM, and Catboost<sup>1</sup>, it is concluded that no method is clearly superior in all situations.

The specific features and advantages of XGBoost and LightGBM is as follows,

- No need to impute missing values
- There is no problem even if there are redundant feature values (even if there are explanatory variables with high correlation, they can be used as they are)
- The difference from random forest is that trees are made in series.

On the other hand, approaches to data analysis can be broadly divided into a "hypothesis verification type" that verifies hypotheses with data and an "exploration type (EDA)" that generates hypotheses from data. Methods of data analysis are roughly divided into CDA: Confirmatory Data Analysis and EDA [2]-[6]. CDA is a general term for analytical methods aimed at hypothesis verification, while EDA is an analytical method aimed at obtaining hypotheses and knowledge from large-scale, multi-general data. EDA does not select explanatory variables in advance and performs exploratory analysis by seeking knowledge from a wide range of subjects. When we actually analyze data, we go back and forth between the hypothesis testing type and the search type to find out what we know.

Data analysis requires setting hypotheses to be verified, and there is nothing to be gained from analysis without hypotheses. However, there are times when a hypothesis cannot be obtained. Therefore, in order to create a hypothesis, it is necessary to look at the data from various angles and explore trends. Therefore, an exploratory data analysis is performed.

EDA can help by making sure stakeholders are asking the right questions. EDA helps answer questions about standard deviations, categorical variables, and confidence intervals. Once EDA is complete and insights are obtained, the features can be used for more sophisticated data analysis and modeling, including machine learning.

The cost of acquiring a new customer is higher than the cost of retaining an existing customer, up to five times as

<sup>1</sup> <https://catboost.ai/en/docs/concepts/python-quickstart>

much. Therefore, lowering the churn rate has a large positive impact on profits. Churn prediction is especially important for subscription-based services. By predicting churn, you can estimate CLTV (customer lifetime value)<sup>2</sup> and measure the growth potential of your business [7]-[19]. Also, customer churn is when customers cancel services such as subscriptions, and revenue churn is, for example, the loss of Monthly Recurring Revenue: MRR at the beginning of the month.

Customer profiling method with Big Data based on Binary Decision Tree: BDT and clustering for sales prediction is proposed and tested with POS: Point of Sales data [20]. Furthermore, a modified Prophet+Optuna prediction method for sales estimations is also proposed [21]. In this study, churn customer estimation method is proposed and examined with POS data for improving further sales.

In the next section, some of previous works are introduced. Then the proposed method for customer churn prediction is described followed by the experiment. Then conclusion and some discussions are described.

## II. PREVIOUS WORKS

The 5:25 rule states that if you reduce customer churn by 5%, your profit margin will improve by 25%. From a medium-to long-term strategy perspective, it is important to implement planned measures after fully considering the balance between the customer retention rate, the defection rate, and the acquisition of new customers. Selling products to new customers requires five times the cost of selling products to existing customers (1:5 rule). Reducing the probability of customer defection and increasing sales of existing customers are important for increasing corporate profits.

It is important to maintain sales to reduce the withdrawal rate related to the top 20% of the treatment menu from the Partley's law<sup>3</sup>. A good way to identify the top 20% is to use a point card. With a point card, it is relatively easy to identify whether a customer is a regular customer or not.

If the new customer development cost is 100, the existing customer retention cost will be 17 to 20. The top 20% of customers account for 60-80% of total sales. Furthermore, in the bottom 30%, the degree of contribution to sales is less than 4%. The top 5% of customers with the highest loyalty often purchase related products. Reducing the defection rate (=increasing the rate of continuous purchases) has a large impact.

If the defection rate drops from 30% to 20%, the company's expected total sales now and in the future will increase by 1.5 times. A 10% increase or decrease in the attrition rate leads to a 50% increase or decrease in sales.

$$CAV = \frac{OD \cdot CNS \cdot CS}{1 - CPR} \quad (1)$$

where CAV: Customer Asset Value, OD: Overall Demand, CNS: Customer Number Share, CS: Customer Share, CPR: Continuous Purchasing Rate.

where, the share of the number of customers is the ratio of customers who purchase the company's products among all customers in the relevant market, and the intra-customer share is the ratio of the company's products to all purchases of the product group by one customer. In addition, 1-continuous purchase rate: customer defection rate = the ratio of customers who purchased the company's products to no longer purchase the company's products.

For existing customers, the largest defection (=low repeat rate) occurs from the first purchase (F1, Frequency = 1) to the second purchase (F2, Frequency = 2). Also, if the purchase at F1 is not a regular purchase, the repeat rate from F1 to F2 is often about 20 to 40%. Furthermore, the repeat rate rises from F2 to F3, F3 to F4, etc., and when it exceeds F3, it rises to about 70 to 90%, and stable repeat earnings can be obtained.

Possible reasons for separation are as follows.

- 1) I did not get the results I wanted or could not get them.
- 2) I felt that the price of the treatment was higher than the benefits obtained (e.g., I was dissatisfied with the cost performance).
- 3) I felt dissatisfaction and anxiety about the company's response, not the treatment.

Therefore, customer defection analysis is necessary. It is necessary to calculate the "customer defection rate", the percentage of customers who did not use the service for the second time or more during a certain period of time, from Customer Relation Management (CRM) data, and to analyze the trend of "what kind of customers are defected". In particular, if the customer abandons the service after using it multiple times, it is necessary to take a customer's purchase history, frequency, and questionnaire.

For example, conducting questionnaires using Google Form, etc., and the "Frequently Asked Questions (FAQ)" page posted on the company's website have a great impact on customer satisfaction. , it is possible to avoid the risk of customers feeling dissatisfied and leaving. In addition, customer information in CRM is not just for approaching repeat customers, but it is necessary to collect and analyze data to grasp the tendency of customers who have already left, and to find out the reasons for leaving.

## III. PROPOSED METHOD

First, customer churn is defined and then features of the customer churn are extracted from the customer data derived from the POS: Point of Sales data.

Customer churn prediction is performed by the following method.

- *Theme setting*: Define business problem and goals to be achieved → Define Before → After with monitorable metrics
- *Analytics design*: Define the built model and necessary data → In many cases, data such as transaction history and CRM (customer relationship management) system

<sup>2</sup> <https://www.cccmk.co.jp/columns/hint3>

<sup>3</sup> <https://magazinn55.exblog.jp/5554516/>

- *Dataset generation:* Preparing data and performing EDA, performing necessary preprocessing to create datasets suitable for machine learning algorithms.
- *Predictive model training and testing:* Train a churn prediction (departure prediction) model using various machine learning algorithms for classification problems → test the learned prediction model

After that customer churn is characterized and estimated based on LightGBM. Meantime, ROC (Receiver Operatorating Characteristic) curve evaluation method<sup>4</sup> is applied to the estimated churn ratio followed by feature importance is analyzed.

Some of the countermeasures are proposed for mitigation of customer churn.

#### IV. EXPERIMENT

##### A. Data Used

We used POS customer data from 1 September 2009 to December 31, 2021. The outline of the data is as follows:

- 1) Total number of customers (persons) 878,181 Number of unique customer IDs
- 2) Total number of cases (cases) 8,857,257 Number of sales item IDs (cut and color are counted as 2 cases, discounts are also counted as 1 case)
- 3) Cancellation of sales (number of cases) 350,017 Number of sales cancellation details

##### B. Definition of Customer Churn

A customer who visited the store in the previous three months did not return to the store in the next three months, and a customer who did not visit the store was defined as a churn. To give an easy-to-understand example, it was defined as "out of the customers who visited the store between January and March, the customers who visited between April and June returned, and the customers who did not visit the store were rejected."

The format of the final churn prediction output is as follows. It is a specification that predicts the probability that each customer will defect in the next three months. In other words, the customer ID and the likelihood of churn are represented as paired data as shown in Table I.

TABLE I. FORMAT FOR OF THE FINAL CHURN PREDICTION OUTPUT

Customer_ID:	Chance_of_Customer_Churn
1	5%
2	50%
3	30%

About 65,000 customers visited all stores from January to March 2021, and customers who visited between April and June returned to the store, and those who did not return to the store.

“0” in Fig. 1 represents recurrence and “1” as customer churn. The overall churn rate was about 42%.

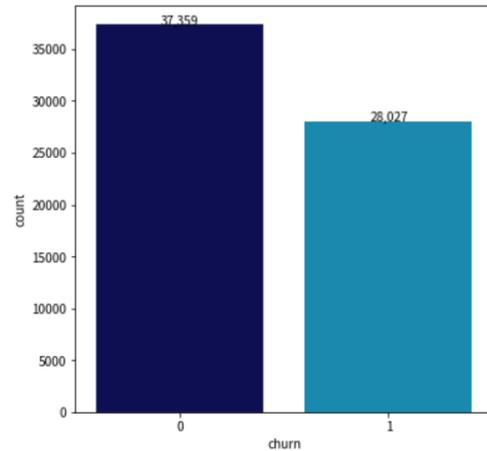

Fig. 1. Overall customer churn

The features used are shown in Table II.

TABLE II. FEATURES USED IN THE POS DATA ANALYSIS

Schema_name	description
customer_id	Customer ID
visits_count	Number of visits
unit_price_ave	Average unit price per store
first_visit_date	Customer's first visit date
last_visit_date	Customer's last visit date
gender	Gender
age	Age(customers_who_do_not_enter_are_0)
distance	Distance_to_the_store_calculated_from_the_zip_code
menu	Categorization_by_menu
unit_price_per_visits_co unt	Average_unit_price_per_visit/number_of_visits

##### C. Preliminary Results

1) *The difference between churn customers and non-churn customers:* The difference between churn customers and non-churn customers was evaluated from the number of visits. The results are shown in Fig. 2. In the figure, orange indicates churn and blue indicates return. The lower the number of visits to the store, the higher the attrition rate, and the higher the number, the lower the attrition rate. There is a marked difference.

<sup>4</sup> <https://zero2one.jp/ai-word/roc-curve-and-auc/>

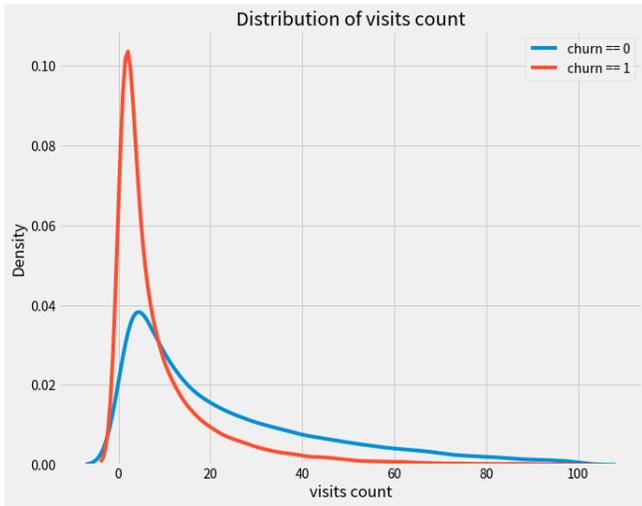

Fig. 2. The difference between churn customers and non-churn customer

2) *Average cost per visit:* Customers with low unit prices have a high churn rate, and customers with high unit prices have a low churn rate. However, there is no big difference depending on the unit price as shown in Fig. 3.

Fig. 3. Average cost per visit dependency against churn rate

3) *Customer's first visit date:* The horizontal axis in Fig. 4 indicates how many days before the first visit to the store from the analysis point. This time, we analyzed customers who visited the store from January to March, so March 31st was the day before. From this, we can see that the churn rate is higher for people who first visited the store recently, and the churn rate is lower for people who first visited the store a long time ago. These differences are significant.

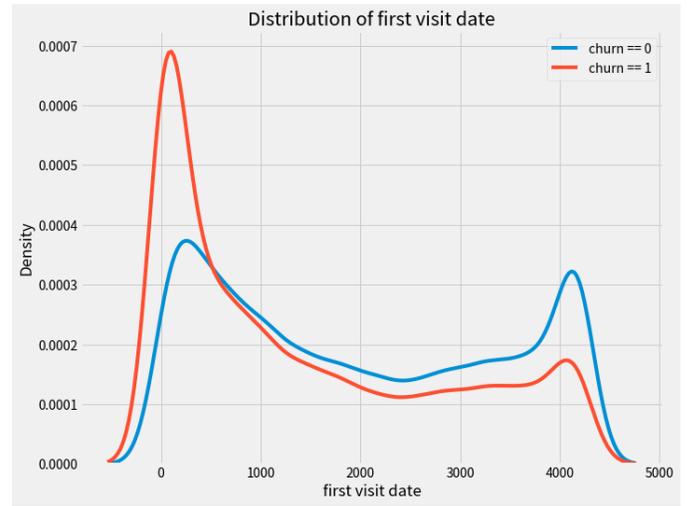

Fig. 4. Customer's first visit date dependency against churn rate

4) *Customer's last visit date:* The horizontal axis in Fig. 5 shows the number of days before the last visit from the point of analysis, just like the date of the first visit. This time, we analyzed customers who visited the store from January to March, so March 31<sup>st</sup> was the day before. From this result, we can see that the withdrawal rate is lower for those who last visited the store more recently, and the withdrawal rate is higher for those who last visited the store more than 50 days ago.

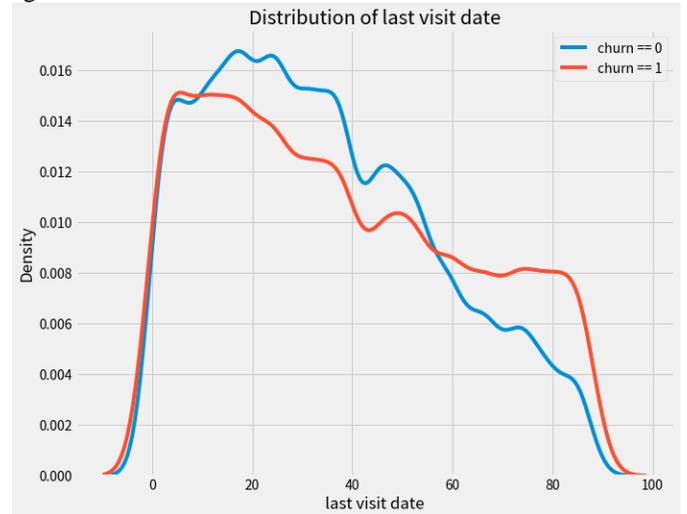

Fig. 5. Customer's last visit date dependency against churn rate

5) *Gender:* The churn rate is lower for men than for women (the churn rate for those entered as women exceeds 60%, but for men it is a little over 50%) as shown in Fig. 6. Customers whose gender is unknown (not entered) have a very low churn rate. The reason for that is unclear.

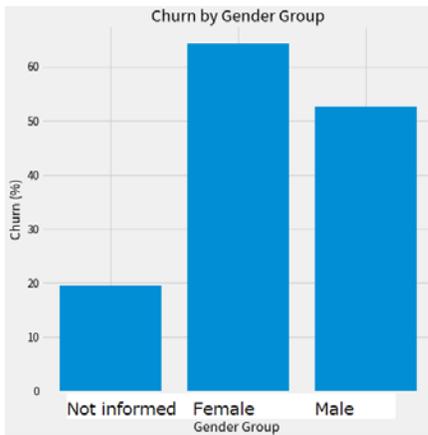

Fig. 6. Gender dependency against churn rate

6) *Age*: The churn rate is high for those in their 20s and 30s and decreases for those in their 50s as shown in Fig. 7.

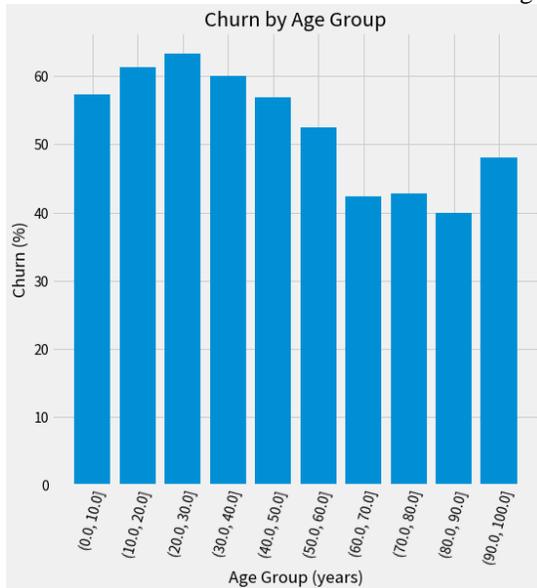

Fig. 7. Age dependency against churn rate

7) *Service menu*: We categorized customers according to the menu they ordered the most and investigated the churn rate. As a result, it was found that the rejection rate for dyeing white hair is very low at around 30%, while the rejection rate for child cuts and school cuts is high as shown in Fig. 8.

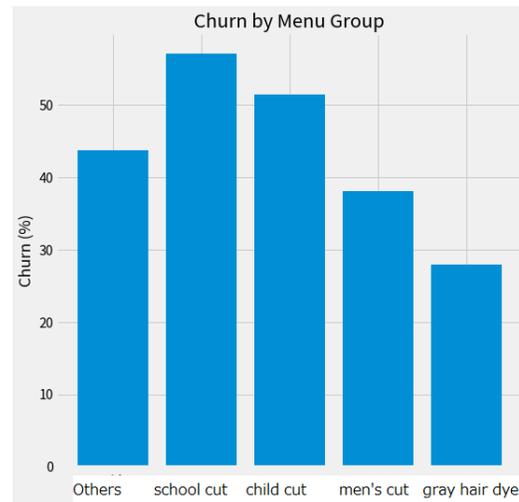

Fig. 8. Service menu dependency against churn rate

8) *Average cost per visit / number of visits*: Fig. 9 shows only those customers whose average unit price per visit/ number of visits is more than 2000 Yen in KDE<sup>5</sup> (Kernel Density Estimation). Customers with this value of 6,000 Yen or more seem to have a slightly higher churn rate. In other words, it seems that the churn rate is high for people who order expensive menus despite the fact that they visit the store less frequently.

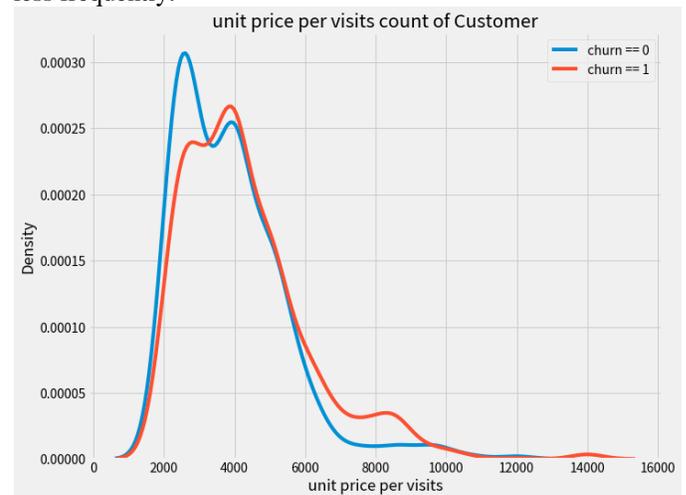

Fig. 9. Characteristics of the average cost per visit / number of visits

<sup>5</sup> <https://cran.r-project.org/web/packages/spNetwork/vignettes/NKDE.html>

D. Customer Churn Prediction

1) *LightGBM based prediction of customer churn*: The results of predicting customer churn using the above feature values (excluding distance to the store) are shown below. Fig. 10 shows the feature value order of customer churn prediction using LightGBM. It can be seen that the number of visits to the store on the day of the first visit has a large effect and is greatly affected to the churn.

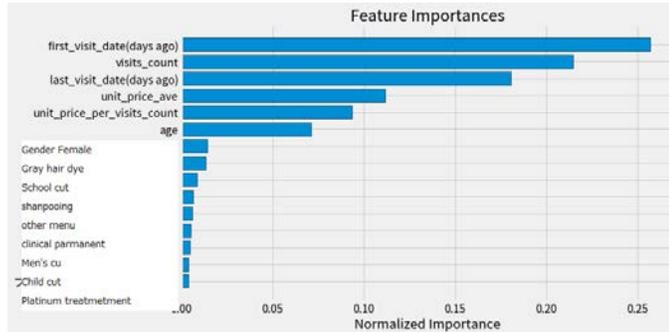

Fig. 10. Feature value order of customer churn prediction using LightGBM

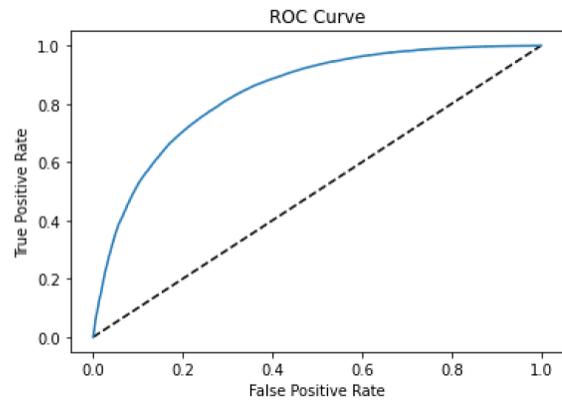

2) *ROC curve evaluation*: ROC curve and Churn pct are evaluated. Each axis represents TPR (True Positive Rate) and FPR (False Positive Rate) and plots the TPR and FPR values when changing the threshold for classifying into Positive and Negative. As shown in Fig. 11, ROC curve and Churn pct (histogram) are seemed reasonable (not perfectly satisfied but marginal). Also, AUC (Area Under the Curve) and logarithmic function of loss are evaluated. As shown in Table III, both show reasonably satisfied values.

TABLE III. AUC AND LOGARITHMIC FUNCTION OF LOSS

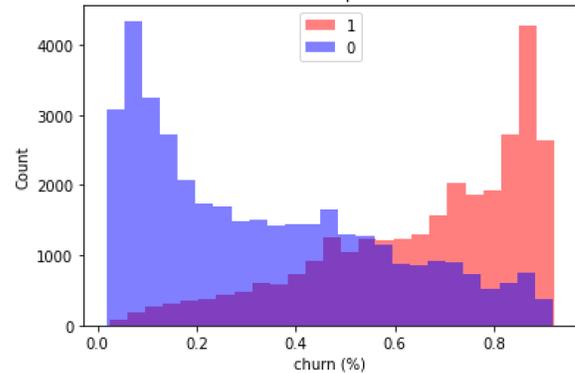

AUC	0.837
Log_loss	0.496

3) *Customer churn characteristics*: Customer churn characteristics are summarized as follows:

- a) *Age*: Younger customers have a higher attrition rate, and those in their 60s to 80s have a lower attrition rate.
- b) *Gender*: Female divorce rate is high.
- c) *Number of visits*: The lower the number, the higher the churn rate.
- d) *Unit price (1 store visit)*: The lower the rate, the higher the withdrawal rate.
- e) *Date of first visit*: Most recent customers (customers who have recently visited for the first time) have a high churn rate.
- f) *Date of last visit*: The withdrawal rate is lower for the most recent visit.
- g) *Menu*: Low withdrawal rate for gray hair dyeing, high withdrawal rate for school and child cuts.
- h) *Distance to stores*: This hardly contributes to the churn rate and seems to depend on the availability of parking lots.

(a) ROC curve

(b) Churn pct (histogram)

Fig. 11. ROC curve and churn pct of the churn rate prediction based on LightGBM

V. CONCLUSION

Churn customer estimation method is proposed for improving sales. By analyzing the differences between customers who churn and customers who do not churn (returning), we conduct a customer churn analysis to reduce customer churn and take steps to reduce the number of unique customers. By predicting customers who are likely to defect using decision tree models such as LightGBM, which is a machine learning method, and logistic regression, we discover important feature values in prediction and utilize the knowledge obtained through EDA.

As results for experiments, it is found that the proposed method allows estimation and prediction of churn customers as well as characteristics and behavior of churn customers. Also, it is found that the proposed method is superior to the conventional method, GradientBoostingClassifier: GBC by around 10%.

FUTURE RESEARCH WORKS

Further investigations are required for improvement of prediction accuracy. We could be able to take measures such as sending DMs and coupons to customers with a 90% chance of churn. In order to increase the accuracy of churn prediction, not only LightGBM but also ensemble models such as Random Forest and logistic regression will be learned, and the accuracy will increase a little more. In addition, this time, we had the customers of all stores who visited the store during a specific

period learn, but if we try to learn for each store without narrowing down the period, a different result may appear.

#### ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

**Abstract**—The broad usage of images in real-time applications demands a cloud infrastructure due to its advantages. Many use cases are built where the image data is shared, sharing becomes the core function, and the medical domain takes its broad advantage. The cloud is a centralized infrastructure for its all-operation usages; it depends mainly on the trusted third party to handle security concerns. Therefore, the privacy preservation of the image data or any data becomes an issue of concern. The distrusted system advantages are achieved using blockchain technology for image data security and privacy concerns. The traditional approaches of the security and privacy models raise many apprehensions as these are designed on the centralized systems of the data sharing mechanisms. It is also observed that large data files are not wisely handled, which demands building a framework model that takes image data and any other data of any size to ensure a dependable optimal security system. This paper presents a framework model to achieve optimal time complexity for securing the privacy aspects of the image data or any other data that uses space optimal file system using distributed security mechanism for both the storage and sharing of the data. The proposed framework model for optimal time complexity and security uses a duplication algorithm using stakeholder agreement to ensure efficient access control to the resources using the cryptographic approach to the Ethereum ecosystem. The performance metric used in the model evaluation includes the degree of availability and efficiency. On benchmarks, it performs well compared to the traditional cloud-built distributed systems. The quantified outcome of the proposed scheme exhibits a 42.5% of reduction in time for data repositioning, a 41.1% of reduction in time for data retrieval, a 34.8% of reduction in operational cost, a 73.9% of reduction in delay, and a 61% faster algorithm execution time in contrast to conventional blockchain method.

**Keywords**—Blockchain; data security; Ethereum; image data; privacy; security

## I. INTRODUCTION

In the real world, many applications may include the Map image, medical images, or any other real-time images to be stored and shared to meet their respective objectives of map-based driving assistants, diagnostic systems for medical professionals, and smart transport systems [1-3]. These applications extract intrinsic information for the functional operation and computation of the applications, including general and private information. Vulnerability to private

information is considered a loophole to the system's robustness [4-5]. Though the digital systems built for real-time applications boot the connivance of operation by suitable ecosystems, the cumulative data storage raises concerns about the considerable data handling challenges [6]. Application engineers and domain experts for an application built on the data storage and sharing required to analyze the data features of interest to meet the application goals. However, the data generator or uploader stakeholder may not be able to keep track of the data that might be useful to them. Digital data sharing provides ease of data analytics that ensures application efficiency and, as a result, yields an automatic and intelligent decision-making scheme for specific applications [7]. Though there exist many advantages of end-to-end systems for data or image data storing and sharing yet, significant challenges exist that require attention by the researchers, and those significant challenges include: 1) storage aspect of the extensive data in terms of time complexity of retrieval and 2) the vital security concerns. The research statistics reveal that data exist in heterogeneous formats, but the images are large in percentages [8]. The images are multi-dimension data and require larger storage space than other data formats. Its processing takes more and more computing storage to process and analyzes, limiting exploiting its usage for the application goals and efficiency. At the same time, vulnerability due to various system loopholes concerns data security and privacy information leakage. It lacks efficient interoperability requirements due to the inefficient trade-off handler capacity of the security models [9]. Most data possess critical and delicate material; therefore, preserving privacy is essential to maintain the stakeholder losses or damages, either financial or reputational.

It is also essential that only the authenticated data be utilized to perform any analytical process, as the tampered image data or other data minimizes the accuracy and reliability of the results of the decision-making systems that may deceive the correctness of the system. The secure and fast system ensures better data interoperability, so sharing the data securely makes the system more robust and effective. The cloud ecosystem is today's most popular choice for flexible data storage and optimal sharing. However, towards the security of the data, the cloud ecosystem adopts practical cryptography and privacy preservation, and access control followed by the appropriate authentication schemes [10]. Irrespective of the various security schemes available for data security and privacy leakage protection, there are no full-proof adaptive

systems. The assumption lacks the reality that storage and data distribution do not have threats if it is through the cloud. This unreliability is because cloud security models largely depend upon a Trusted Third Party (TTP), and TTP suffers many collusion attacks without suitable non-repudiation schemes [11]. Regrettably, there is no typical confirmation instrument for prevailing systems, and there is no operative countermeasure to punish a malicious process in the cloud ecosystem. The most promising distributed technology platform Ethereum is gaining popularity. Recently, it has been used to build many security models or schemes to provide reliable and robust data-sharing systems using distributed databases [12]. The Ethereum-based platform facilitates distributed technology like blockchain. This open-source distributed database mechanism can be exploited to build effective authentication, access control, secure storage, and sharing schemes for an image or other data [13].

Though there are many significant advantages of the Ethereum-based distributed systems, many traditional approaches based on this technology limit their potential effect due to many of the issues that may include: Though there are many significant advantages of the Ethereum-based distributed systems. Still, many of the traditional approaches based on this technology limit their potential effect due to many of the issues that may include: 1) It lacks non-repudiation in the distributed databases as well as does not handle the large data effectively due to non-scalability factor as these distributed data is accessible to all the participating databases as a ledger. 2) Another associated problem is that it lacks control over the data access by the authenticated stakeholder. 3) And last but not least, to design an optimal system to minimize the time complexity and yet be robust enough to ensure system reliability and availability most securely. Literature reveals the fact that these problems are not handled well. Therefore, this paper deals with the two primary objectives: a framework component that balances the time complexity overhead for data security and privacy preservation of images or any other data over a distributed database storage and sharing ecosystem. This concept's prime agenda is also to balance privacy preservation with reduced time complexity associated with the data-sharing process on the distributed scale over cloud networks. To sum up, the contribution of the paper is as follows:

1) The framework model is deployed on the open-source Ethereum distributed database system over the cloud to validate the agreements among the stakeholders of the file storage and sharing process and authenticated access control mechanism.

2) The framework model exploits a unique type of file system, namely Space Optimal File System (SOFS), in the form of a node-to-node collaborative approach that can store the image or any other data to overcome the limitations of the centralized storing and sharing systems.

3) The framework is flexible to work not only on image data. Instead, it can work on any other data of regular or large files to overcome the limitations of the non-scalability in traditional systems built on distributed systems.

4) The cryptographic key mechanism is used for every chunk of the data so that data is not accessible to the SOFS ledgers

5) Finally, it provides a novelty of handling optimal time complexity and data security to ensure real-time feasible data storage and sharing mechanisms.

The paper is presented in six sections. The literature review is described in Section II, followed by a discussion of identified research gap in Section III. Section IV elaborates on the design and deployment aspects of the proposed framework model, an algorithm discussion is carried out in Section V, the performance analysis is described in Section VI, a discussion of the accomplished outcome is carried out in Section VII, and finally, Section VIII concludes the paper

## II. LITERATURE REVIEW

Jiang et al. [14] choose a blockchain for the data store and search on the Ethereum platform by designing a price model using two distinguished stakeholders, namely the data owner, who is awarded for providing the data. Another stakeholder is the miner, who is granted the search operation. This model minimizes the keyword duplication cost to gain a cost advantage. Thus, Debe et al. [15] offer a distributed scheme using an Ethereum-based blockchain system to handle these issues. The system validation against the attack models shows resilience to it. In the work of Hasan et al. [16], a blockchain-based model deals with images and other data to handle the storage and the sharing contract among the stakeholders. A joint study on scalability and Adhoc usage of accountability is considered a research problem by Podgorelec et al. [17] and proposes a concept of state channel as a service (SaaS) that ensures secure distributed connections for off-site chain issues in the payment system. Another significant work in the healthcare domain is Madine et al. [18], which securely uses a specific file system, cryptography, and blockchain-based authorization architecture to share patient records' consent. In the work of Abou-Nassar et al. [19], an interoperable distributed trust model is proposed using blockchain using C# on Ethereum. A practical approach towards the design of "privacy-preserving permissioned blockchain architecture" has been presented by Lin et al. [20] by modifying the Ethereum and customized cryptographic intrinsic elements. The authors, Kumar et al. [21], highlight that along with health care, another domain like cryptosecurity, distributed data collaboration, and immutability take advantage of blockchain technologies. The work of Ullah et al. [22] highlights that though the current cloud ecosystem-based data store system provides many advantages but still lacks data leakage and risk to private information due to the centralized operations and dependency on the TTP, a single point of failure may collapse the system. In Yan et al. [23], a dynamic data upload process and search verification through a fuzzy keyword are proposed. Using E-blockchain and Rivest-Shamir Algorithm (RSA) ensures fairness between the user and the cloud data store. Xiang et al. [24] have presented a data trading mode using blockchain and machine learning by building a contract among the stakeholder by eliminating the TTP. The E-Blockchain is used to meet this requirement in the model proposed by Debe et al. [25], enables a decentralized agreement to establish trust-based sharing among the IoT devices and the fog, and performs well

compared to the existing trust model, which is centralized for its operation. Yet another recent and significant work by Hasan et al. [26] proposes the data chunk transfer process decentralized using blockchain that ensures privacy and confidentiality using a proxy cryptographic approach using a specific file system. Yang et al. [27] presented a layer-based trust approach using the Hyperledger architecture to handle this problem. It has been validated against the attack, namely distributed denial service (DDoS). However, one interesting fact about Ethereum, blockchain, and Smart Contracts is discussed in the work of Chen et al. [28], where the users encounter the threats of resource abuse. Saini et al. [29] presented a framework using Smart Contracts (SC) and blockchain (BC) for access control to secure healthcare-related data. Debe et al. [30] present a scheme that uses BC and SC for a decentralized Bidding process and a reputation system that cost-effectively ensures security. The use of BC and Ethereum with SC is also found in Kaynak et al. [31]. Table I highlights the summary of the above-related studies on security.

TABLE I. SUMMARY OF RELATED WORK

Approaches	Advantage	Limitation
Blockchain-based [14]-[19]	can secure different forms of data	No benchmarking
Blockchain with Cryptography [33]-[37], [39], [40]	Ensure privacy preservation, better access control, secure sharing	Computationally complex process
Homomorphic encryption [42]	Secure, ubiquitous data	Slow execution time
Traditional Public Key Encryption [32][41][38]	Simpler architecture, the supportability of wide varieties of application	Not resistive to dynamic attackers

Thus, this paper aims to fill this gap by designing a generalized framework model that supports image and non-image data using the Ethereum platform and cryptography for privacy preservation in an optimal time complexity way. The next section outlines problems derived from existing approaches.

### III. IDENTIFIED RESEARCH CHALLENGE

After reviewing the existing schemes, specific research challenges have surfaced, which are as follows:

- A centralized server stores the information in most of the existing blockchain-based schemes. Such storage often invites identity theft, privacy leakage, and other associated security issues.
- Adopting complex security architectures requires proper knowledge to handle them in case of unidentified attacks on data. Mishandling of security features by data owners eventually leads to intrusion. At the same time, they also have to depend on adopting trusted third parties, which are equally vulnerable from a data ownership viewpoint.
- Conventional blockchain-based operations cannot manage large-scale data and very often lead to scalability issues that degrade the performance of repositioning and querying the data from miners.

- The majority of existing studies suffer from loosely coupled ownership of data. Once the blockchain stores the data, the availability and reachability of data are far more to other users using malicious access policies.

Hence, the above mentioned research problems have been identified and are subjected to proposed solutions emphasizing data privacy preservation. Apart from this, the storing the image in conventional blockchain is usually centralized and there is higher possibility of intrusion, whereas Ethereum-based approach are decentralized and its control of validation is carried out by multiple nodes with higher accountability. Hence proposed study considers Ethereum-based ecosystem for this purpose. The following section discusses the adopted research methodology.

### IV. RESEARCH METHODOLOGY

This paper proposes a customized framework model that supports image data security for its privacy preservation in the optimal time complexity by exploiting the Ethereum-based distributed data store system characteristics like blockchain.

The summary of the adopted method is as follows: The overall structure of the implementation is classified into four stages. The *first stage* of development is associated with constructing the Ethereum module, which maintains various associated repositories of data identity, timestamp, Secured Hash Algorithm (SHA), and auditor identity. The *second stage* of development is primarily responsible for request assessment and management of metadata. This module further contributes towards applying asymmetric encryption over the split data in adherence to the bandwidth capacity. The idea is to secure the storage units. The *third stage* of development performs authorization to the data requestor while Ethereum records are validated. Finally, the *fourth stage* of the proposed method introduces the smart agreement process, where the transactions are assessed and duplicate records are identified. The module finally performs a key updating process.

The framework aims to support or work on image data or other small to large-size and multi-dimension data to ensure the system's scalability. The core idea of the proposed scheme is to introduce an authorization mechanism for image data from various perspectives of the application using images; it could be for multi-disciplinary applications. It will also eventually mean that considered image data could easily take the shape of high-dimensional data, progressively increasing its challenge during the computational process. In the proposed scheme, the user is facilitated with the privilege to construct a tailored policy towards accessing their intellectual property (image) using an intelligent agreement system when applied with Ethereum blockchain. Further, a specific administrative use is responsible for uploading the comprehensive image data over the proposed storage network. The complete operation of uploading and accessibility to the file system calls for the usage of the exclusively designed request control message. The blockchain users initiate the uploading process upon receiving the request control message from the comprehensive storage network. Similarly, the retrieval process also demands the usage of different variants of request control messages by the blockchain user.

This operation further facilitates accessing and storing the data on the user's device. This data could also be accessed (after authorization) by other legitimate users and administrators to obtain prior and new information. The proposed scheme constructs the entire network in a peer-to-peer method where the role of the secure storage service provider can be played by the user, who is further required to get registered to play the role of blockchain user. Upon accomplishment of this initial step, such a user can facilitate all the computing nodes and accessibility towards storage services. To eliminate the constraints associated with storage and channel capacity, the proposed system adopts using distributed cloud server as the primary point of storage instead of opting for multiple local storage units. Once the request control message is obtained for prompting towards file storage task, the proposed scheme applies asymmetric encryption for its data to be stored in the blockchain network. Therefore, adopting encryption over securing the primary data acts as a security shield against any attempt of a security breach.

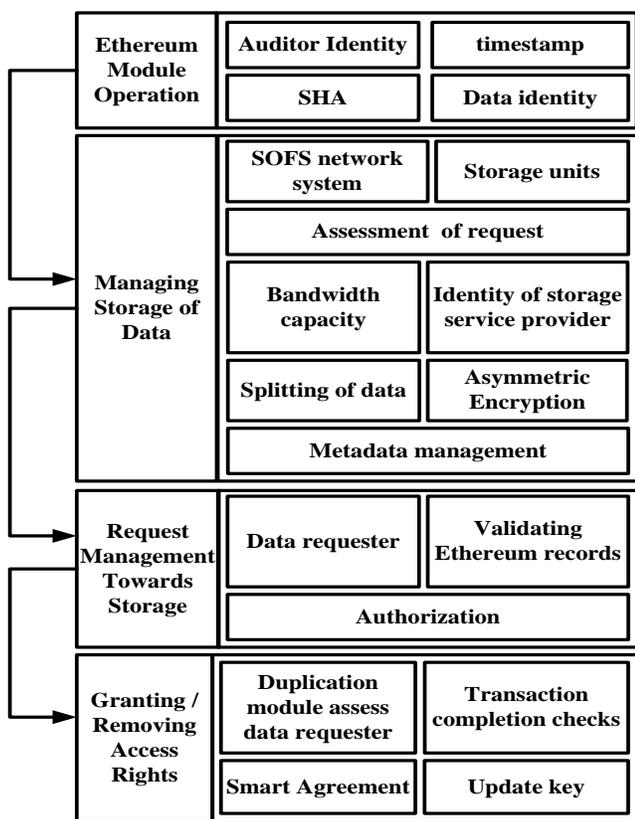

Fig. 1. Proposed architecture

Further the blockchain network is introduced with the recently encrypted data that also carry out sharing of information (related to secret key) in the blockchain network. This process also transforms private and public keys, which facilitates the blockchain user to gain potential control over the user's data either by revoking the request or permitting access. It should be noted that the proposed blockchain network performs interaction with the service provider of data using web 3.0. The usage of the Ethereum blockchain assists in managing multiple transactions records more effectively and securely. High-level planning of the functional framework

model is shown in Fig. 1 with the inclusion of the stakeholders in general, which can be easily customized to any functional domain along with the intrinsic technologies used for the security and privacy-preserving way data is stored and shared. According to Fig. 1, four essential blocks of operation are carried out towards achieving the target of privacy preservation, mainly emphasizing balancing the security demands and optimal computational efficiency. Each modular block carries a discrete set of interconnected operations where the core image file is subjected to security processing over the Ethereum distributed data system.

The complete operation stated in Fig. 1 is highly sequential from top to bottom. Initially, the Ethereum module is constructed with hash-based encryption followed by asymmetric encryption over the split data. A scheme also maintains a better indexing process using metadata management based on every request. The module also assists in performing validation of the Ethereum records followed by final management of removing or accessing rights permission. A unique and smart agreement is designed, followed by updating key. The core logic of the architecture mentioned above is to ensure faster and safer data repositioning over a cloud environment in a distributed manner. The consecutive section further illustrates all the blocks discussed earlier regarding algorithm design.

## V. ALGORITHM IMPLEMENTATION

From the discussion carried out in prior section, it is noted that proposed Ethereum-based ecosystem introduces a novel mechanism of image splitting which supports an extensive decentralization scheme followed by efficient request management for controlling image sharing. This section discusses the design of an algorithm implementation towards the methodology briefed in the prior section.

### A. Strategies for Algorithm Implementation

The algorithm's execution begins with a user who forwards its data to the interface, delivering the data to the request's handler. This request is sent to the Ethereum module, further interacting with the SOFS and duplication modules. In parallel with this process, the encrypted data from the storage is also forwarded to the Ethereum client. A decentralized datastore system using hashing is used to arrange this data. This hashed data is then sent to the transaction pool and authenticator module, further updated towards the Ethereum client. The data from the duplication module is now forwarded to the intelligent agreement management module controlled by the data owner. It is also delivered to the request handler for the next Ethereum client module. Updating operations of these transactions are simultaneously carried out in this process. Apart from this, the complete blocks of the data considered for the proposed implementation are the access scheme, duplication module, and pairing of keys. All these three blocks consist of essential information associated with the identity of the auditor for the Ethereum client, innovative agreement, the signature of the user, identity of the client, identity of data, value of hashed data, and time stamp. These are also the seven essential components of the Ethereum module. It should be noted that proposed scheme of privacy preservation adopted are hybridized form of both transactional and smart contract-based

privacy in Ethereum in order to keep a balance in storage and security at same time.

### B. Algorithm Design

The core algorithm of the proposed scheme consists of the following operations, i.e., Ethereum module operation, managing storage of data, request management towards storage, and granting/removing access rights. The core steps of the proposed algorithm are as follows:

Algorithm for Securing image using Ethereum
<b>Input:</b> $m$ (Components of Ethereum)
<b>Output:</b> $d_{val}$ (validated data)
<b>Start</b>
1. <b>For</b> $c=1:m$
2. $R_{req} \rightarrow E_c$
3. $E_c \rightarrow S_{net} \rightarrow$
4. $S_{net} \rightarrow val(avail(S_c))$
5. $S_{net} \rightarrow confirm(S_c)$
6. $data_1 \leftarrow f_1(Data)^n$
7. $data_2 \leftarrow f_2(data_1)$
8. $data_3 \rightarrow f_3(data_2)$
9.     obtain $d_{val}$
10. <b>End</b>
<b>End</b>

The discussion of prime operations toward each algorithmic step is as follows:

- *Ethereum Module Operation:* This is the initial module of implementation, which models the proposed Ethereum module focusing on privacy preservation towards image data. The proposed study considers the auditors' identity based on their computing devices. The study also uses a conventional Secured Hash Algorithm of a crucial size of 256 bits to hash the data for each image data chunk. A unique identifier is used for allocating the identity of stakeholders. There must be trust established between the SOFS network and the requestor node. The proposed system considers an innovative agreement, similar to smart contract, a well-structured program executed over the Ethereum module. Its primary responsibility is to validate all incoming data access requests for storage that are accessible to all the users of the Ethereum module. All the transactions of any form are carried out by the Ethereum module, which is highly distributed to offer better and faster access to files. The algorithm considers  $m$  number of components of the  $E_c$  Ethereum module (Line-1), where the data provider performs initiation of its reposition request  $R_{req}$  via its interface (Line-2).
- *Managing Storage of Data:* This module is responsible for managing all forms of incoming requests, encryption, and storage simultaneously. The Ethereum client  $E_c$  forwards its information to the  $S_{net}$  SOFS network (Line-3). It should be noted that all form of file request for storage is initially accepted by the storage units, which are regular users and part of the Ethereum client system interconnected via the cloud ecosystem.

The confirmation of the storage space  $S_c$  must be done by the Ethereum client (Line-5) by priorly validating them using the *val* method concerning their availability (Line-4). The  $S_c$  module carries out the request verification by constructing an array that retains all transactions of accepted files to be stored (Line-5). This operation significantly reduces time complexity from both storage and query processing. The  $S_c$  module carries out the identity of the storage unit offered by any cloud service provider concerning channel capacity and storage space availability with a duplication module.

- *Request Management Towards Storage:* This module carries out specific operation steps before managing all forms of requests. The complete input of an image data is split into the equivalent size of blocks of  $n$  number using an explicit function  $f_1(x)$  to generate split data  $data_1$  (Line-6). This operation offers a beneficial solution for dealing with more extensive or high-dimensional datasets. It is to be noted that the process carried out by SOFS is entirely decentralized, and hence there is no event of failures in storing split data over multiple storage units over the cloud. Further, an explicit function  $f_2(x)$  is used for performing the RSA, which is stored in the form of tree-based networks over the storage units (Line-7). This operation results in multiple encrypted data  $data_2$  (Line-7). The time complexity problem further reduces as the complete encryption is carried out in parallel to all the chunks of the data.
- Apart from this, storing the stakeholder's metadata on the  $E_c$  module's block is essential, although they are stored in the SOFS network system for their original data input. The proposed scheme also audited this data at a specific periodic interval, forwarding the signature to the following consecutive data blocks. The  $E_c$  will synchronize all the generated encrypted blocks of data. An interesting point from a security perspective is that a tiny amendment being carried out on any one block will change the whole setup of blocks of data due to any malicious activity. Hence, even if one block of data is stolen or compromised, it will be useless for an attacker. An additional layer of security is further implemented by storing the hashed value of these data to mitigate the problem of data leakage over cloud servers. The complete management of the data blocks is carried out so that the proposed algorithm evaluates the legitimacy of the data requester as a mandatory step. Suppose the requestor's identity is legitimate (from the metadata). In that case, it is added to the Ethereum distributed data system record, which is finally forwarded to the data storage unit. This operation potential assists in retaining maximum accountability of image data on SOFS network. Moreover, this accountability is carried out at period interval of time to keep the blocks updated thereby maintaining higher transparency. All the accessing of data can be carried out from this module. However, if the data requestor is found illegitimate (not a data owner), the proposed algorithm checks the access policy by updating the

records maintained by the Ethereum-distributed data system. In short, the Ethereum client maintains all the forms of the legitimate and illegitimate list of requestor nodes, resisting any attacker from accessing the file maliciously.

- *Granting / Removing Access Rights:* Using the verification process managed by the Ethereum client system, the valid data requestor can initiate the transactions, followed by regular updating towards the Ethereum client. However, for optimal security, the algorithm further steps towards updating its public or private key by generating a new version of it. The SOFS network system carries out this operation to control crucial sharing by granting or removing access rights. The beneficial aspect of this operation is that it can offer a higher degree of data privacy, eliminating the probability of key-based attacks. In this process, an explicit function  $f_3(x)$  is designed to manage the intelligent agreement system which is primarily response for handling data access request along with permission to be granted for access/deny (Line-8). For this purpose, the proposed scheme develops a duplication module for testifying its evidence based on four types of keys, i.e., keys to be used for preliminary instance, keys that are eliminated for the first time, and second and third time considering public and private keys. This operation generates  $data_3$ , which ultimately yields validated data  $d_{val}$  (Line-9). The proposed algorithm also maintains a record of all the access  $Rec$ . The process carried out by function  $f_3(x)$  can now be further extended: The algorithm assesses the event of successful completion of the accessing by the stakeholder, followed by eliminating the keys for all the identified instances. The intelligent agreement module reviews the complete record of access  $Rec$ , which finally generates a new record  $Rec$ . The algorithm enforces the stakeholder to request access if their old access record is not found in this  $Rec$ . The unique access is generated by yielding new key pairs, then applying asymmetric encryption to all the split data blocks and generating a key for encryption. The generation of the unique access is the contribution towards deploying a unique security measure to resist unauthorized data access. The storage system of the SOFS network receives this encoded file as well as the private key of the stakeholder. The file is further encrypted when it arrives within the SOFS network system while the user's private key is shared. All the keys are eliminated once the system records access completion, which makes the scheme high-level secured from intrusive activity on stored data.

## VI. RESULT ANALYSIS

The implementation of the proposed study is carried out on a conventional windows machine with 16 GB RAM and Core-i7 processor. An open-source server environment has been adopted for Java scripting the proposed algorithm. The proposed scheme also uses a high-level object-oriented language to deploy innovative agreements over an Ethereum environment. A standard benchmark test environment of

Mocha 6.2.0 is used, while Ganache is considered for the Ethereum platform. The complete assessment is carried out over a standard Kovan testnet. The standard nodes from Amazon Web Services, i.e., AWS nano, are considered for the storage nodes that perform their data transmission over 100mps with NVIDIA GEFORCE GTX as GPU. The performance parameters considered for assessing the proposed system with the existing system (conventional blockchain) are as follows:

- *Time for Data Reposition:* This is the time required to store the data in the distributed cloud servers after being subjected to block operations.
- *Time for Data Retrieval:* This is the time required for the stakeholder to access their stored data from distributed location to their local system.
- *Operational Cost:* This is the cumulative number of resources (in memory and bandwidth) used for overall repositioning and retrieval processing.
- *Delay:* This is latency associated with data transmission from one point to another. The study considers cumulative delay for both repositioning and retrieval.

The proposed system is evaluated based on 100 GB of sample data programmatically generated traffic in IoT. Assessed over 1200 simulation rounds, the sample data is allocated and increased arbitrarily to map with a practical world environment.

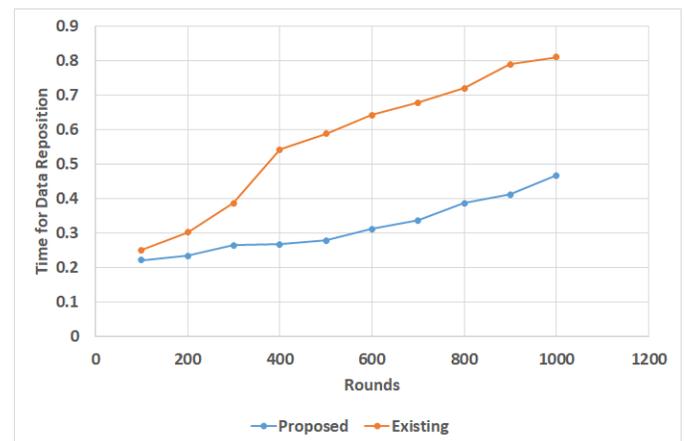

Fig. 2. Analysis of time for data reposition

Fig. 2 highlights the time required to store the data, stating the proposed system offers very little time consumption compared to conventional blockchain technology. The prime reason behind this is the higher dependency on adopting consensus-based mechanisms by traditional blockchain technology, which also induces scalability issues. On the other hand, the proposed scheme doesn't have any such dependencies that result in faster processing. Apart from this, conventional blockchain technology is inherently characterized by a slower process if the size of the network increases. A closer look into the proposed scheme shows that the tree-based structuring of hashed data makes the flow of the encoded blocks of spitted data much faster than the existing scheme.

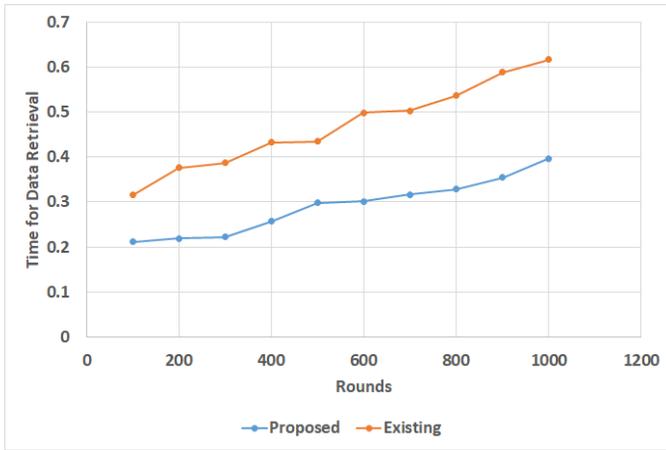

Fig. 3. Analysis of time for data retrieval

Fig. 3 highlights that the proposed system offers much-reduced consumption of time for retrieval of data in comparison to the conventional blockchain. A similar reason for time for repositioning can be stated as its cause. Apart from this, the process of metadata management by the SOFS network system makes the faster process of requestor legitimacy. Although it depends upon the synchronization time of updating, it still offers speedier query processing. Conventional blockchain has a higher dependency on node operation. In contrast, the proposed scheme outsources this dependency towards the Ethereum distributed database system using the SOFS network system, making the retrieval system relatively faster with a speedy auditing process for the information request.

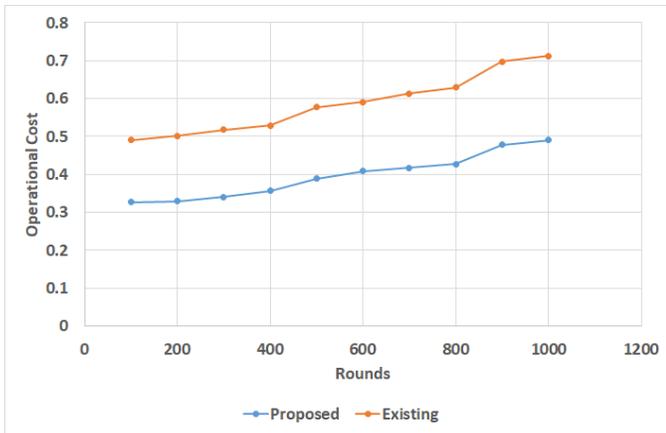

Fig. 4. Analysis of operational cost

Fig. 4 showcases that the proposed system offers reduced operational costs compared to conventional blockchain technology. Operational cost is one of the prime performance parameters to ascertain the applicability of the blockchain process toward data security in a realistic environment. The prime rationale behind this outcome is that traditional blockchain enforces the miners to solve problems with updates of new transactions by the ledger, which consistently increases resource dependencies. On the contrary, the proposed scheme controls its resource inclusion as a preemptive method of computing the entire path of data forwarding to the distributed

storage unit, considering all the constraints from a security perspective. This offers a reduced consumption of resources leading to reduced operational costs.

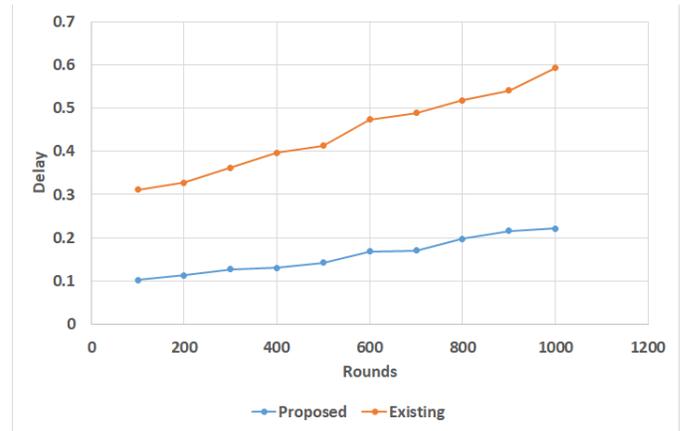

Fig. 5. Analysis of delay

Fig. 5 showcases that the proposed system offers a significantly reduced delay trend compared to conventional blockchain. It is to be noted that traditional blockchain forces the individual to have their key to make it completely decentralized. This process offers a sophisticated key management scheme and increases the information stored and retrieved. This eventually leads to a potential lag in time. However, the proposed system provides innovative agreement management, supporting faster auditing tasks over split encrypted data. Hence, irrespective of the usage of the RSA scheme, there are no complications towards key management both during storing and retrieval. The proposed system offers reduced delay trends to support various online applications over distributed cloud applications and services. Hence, the proposed method provides evidence to show its complete control over reducing time complexity.

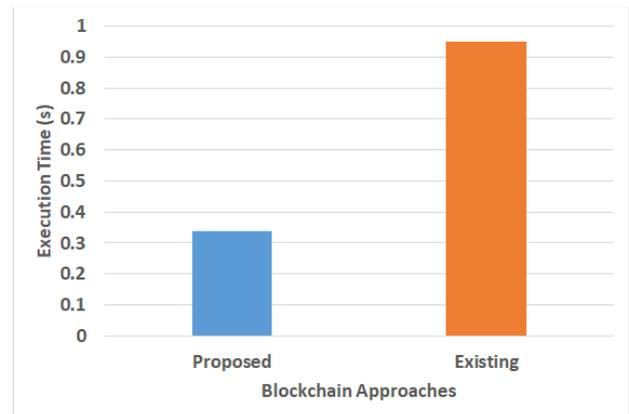

Fig. 6. Analysis of execution time

From the point of benchmarking, the proposed evaluation process considers assessing execution time. It should be noted that an indirect evaluation of memory is analyzed in the operational cost metric exhibited in Fig. 4. The outcome exhibited in Fig. 6 showcases that the proposed blockchain approach offers approximately 61% faster execution time compared to the existing blockchain scheme. A similar reason

stated for preliminary analysis is also to be attributed for this outcome. Hence, it is found that the proposed system can perform cost-effective computational operations in IoT.

## VII. DISCUSSION

The graphical outcome highlighted in the prior section shows that the proposed blockchain-based operation offers better performance than conventional blockchain architecture in various respects. One of the prime reasons for the betterment in performance is its non-dependency from any entities associated with a trusted third party as witnessed in existing system [11]. This process is enabled using the proposed smart agreement system incorporated in the system design connected to processing the data over the network. This fact also contributes towards a lesser operational cost score for the proposed system, as noted in Fig. 4. The outcome will also contribute towards an effective large-scale data-sharing process among multiple enterprises. Apart from this, it can be noted that the proposed scheme offers reduced delay (Fig. 5) and time of retrieval (Fig. 3); owing to faster computational speed, the proposed scheme significantly controls the scalability problem in conventional blockchain design. This process is implemented by using the sharding mechanism.

From the perspective of the privacy preservation viewpoint, there is a potential difference between conventional and proposed Ethereum design methodology. The conventional Ethereum experience low processing speed whereas processing speed is much lower for proposed scheme. Apart from this, proposed scheme maintains a novel blockchain network topology with higher control of data and transaction where the compliance is monitored using smart agreement with updates. This offers higher privacy conservation in contrast to existing Ethereum.

Unlike the existing mechanism of secure data sharing [7][8][12][13][16][25], as illustrated in Section II, the proposed system enables the direct accessibility of the data to its owner. The data owner can carry out the associated process of its access policy and its need for amendment or customization. Hence, complete control of data ownership is retained in the proposed scheme in adherence with the smart agreement of laws towards privacy protection. From the perspective of legal authority of General Data Protection Regulation (GDPR), it is known that blockchain system is always considered to possess a data controller (where at least one legal person resides) in order to ensure the correct implementation of law of data protection in EU. Such forms of data controllers are mandatory require to adhere to the protocols of GDPR. Hence, the proposed scheme of Ethereum, in spite of its decentralized scheme, always offers its architecture to be controlled by multiple authorities in order to ensure data privacy as per the algorithm implementation.

## VIII. CONCLUSION

The proposed concept presents a discussion about a novel computational framework that harnesses the potential of the Ethereum distributed database system for facilitating a secure validation of the data or any participating nodes towards storing and retrieving the data from distributed cloud servers. The novelty of the proposed scheme is as follows:

1. The model presents a duplication module for evidence to offer an assurance of the legitimacy of each transaction being carried out by the Ethereum-based distributed database system
2. The proposed scheme introduces a novel image data-sharing process and associated access policy management using a unique intelligent agreement system.
3. The complete assessment is carried out over Amazon Web Service nano nodes for standardizing its outcome using the SOFS network system and Ethereum client
4. The proposed scheme can control all the problems that impede decentralization using distributed storage units organized by the SOFS network system. At the same time, the complexity associated with data security and scalability is addressed using the presented splitting of data followed by encryption on every split data.
5. The proposed system offers approximately i) 42.5% of reduction in time for data repositioning, ii) 41.1% of reduction in time for data retrieval, iii) 34.8% of reduction in operational cost, and iv) 73.9% of reduction in delay trend in comparison to conventional blockchain method.

The possible shortcoming of the paper is that it is further required to be evaluated on real ground and find a similar consistency in its outcome. More test environments are further required to ensure this. From the above outcomes assessed on a standard benchmarked testbed, it can be stated that the proposed scheme offers better control over time complexity and high-end data privacy. Future work will further extend the present model toward more optimization-based processing. For this purpose, various bio-inspired approaches will be investigated to improve the blockchain operation further. The major emphasis will also be given to the impact of the massive peak and concurrent bottleneck conditions on the performance of blockchain operations. Further in order to offer higher privacy preservation over proposed scheme, the future work direction will be to extract the stochastic trends of dynamic attacker considering the network attributes to develop a novel attack map. This distributed attack map can be used for sandboxing any form of illegitimate or suspicious data request to further confirm the legitimacy of the request. Improving upon encryption protocol over such distributed attack map is anticipated to offer higher degree of privacy preservation.

# Music Note Feature Recognition Method based on Hilbert Space Method Fused with Partial Differential Equations

Liqin Liu

Music School, Hubei Engineering University, Hubei, 432000, China

**Abstract**—Hilbert space method is an old mathematical theoretical model developed based on linear algebra and has a high theoretical value and practical application. The basic idea of the Hilbert space method is to use the existence of some stable relationship between variables and to use the dynamic dependence between variables to construct the solution of differential equations, thus transforming mathematical problems into algebraic problems. This paper firstly studies the denoising model in the process of music note feature recognition based on partial differential equations, then analyzes the denoising method based on partial differential equations and gives an algorithm for fused music note feature recognition in Hilbert space; secondly, this paper studies the commonly used music note feature recognition methods, including linear predictive cepstral coefficients, Mel frequency cepstral coefficients, wavelet transform-based feature extraction methods and Hilbert space-based feature extraction methods. Their corresponding feature extraction processes are given.

**Keywords**—Partial differential equation; Hilbert space method; musical note feature recognition method; cepstral coefficients; empirical modal

## I. INTRODUCTION

With the continuous progress of science and technology, the development of high and new technologies such as computer technology, information technology, and microelectronics, and the continuous improvement of computer computing power, people are paying more and more attention to how to find the objective function in complex problems that can be solved by lower-order variables [1]. The traditional method can no longer meet the higher precision requirements in researching mathematical problems, and it is increasingly challenging to meet practical application requirements. Traditional methods are generally studied by analyzing variables and constructing a step response function [2]. Usually, each parameter in the differential equation needs to be derived, and the corresponding equation is obtained by using the variation relationship of partial derivatives of each variable at different orders. The Hilbert space is composed of many independent variables, and these independent variables have their corresponding equation expressions at different orders [3].

The traditional denoising method of music noise is a point-by-point iterative method with good timeliness. However, many iterative calculations and numerical analyses are often required to establish partial differential equations, which are computationally intensive, time-consuming, and challenging to

obtain accurate results [4]. This paper establishes a numerical music noise model based on partial differential equations, and the initial value problem of partial differential equations is transformed into numerical and iterative noise. The model is simple, convenient, easy to implement, and accurate. In this method, the continuous function in the time domain is first transformed into a higher-order system state equation, then converted into a discrete form through a series of inverse transformations, and then processed with partial derivatives, thereby realizing the numerical analysis of partial differential equations [5]. This method can effectively solve many nonlinear problems, and the calculation accuracy is improved to a certain extent compared with other algorithms.

The traditional signal analysis techniques commonly used at present are based on linear predictive analysis or Fourier analysis, or Wavelet analysis techniques. The principle of these techniques is based on processing raw data, decomposing it into a linear model, and then describing it with Fourier transform [6]. Therefore, these techniques are mainly aimed at analyzing linear and stationary signals, but for nonlinear signals, the linear model is often difficult to describe effectively, and the Hilbert space method can make good use of these theories [7]. The Hilbert space method is a new nonlinear signal feature recognition method proposed by Academician Huang E et al. The principle of this method is based on the decomposition of the Hilbert space method. The SCV or FFTM technique synthesizes a linear stationary non-second-order derivative sequence signal to represent its characteristics. The Hilbert space method can be used to identify nonlinear signals and effectively applied to identify linear signals, which has high practical application value.

## II. RELATED WORK

In this case, we use the partial differential equation learning model to solve the challenging facial recognition problem. There is a proposal for a unique feature selection method that uses a learning model based on partial differential equations. Because of this, the extracted features are more resistant to shifts in lighting conditions and can be rotated and translated without losing their integrity. This article by Xia Miao (2021) employs the face detection algorithm in face recognition technology to first detect the face and intercept the expression data, then calculates the increase rate, all in gauging students' focus in class. The expression is then scored based on the revised model of concentration analysis and evaluation of a college Chinese class, which is utilized to identify the

expression. In the end, the concentration score is the expression score multiplied by the head-up rate. Experiments are conducted in real classrooms, and findings are analyzed to draw appropriate conclusions and instructional recommendations [8]. The sparse representation of sample points in the neighborhood is created after the k-nearest neighbor approach selects a large neighborhood set for each face, thus combining the locality of the k-nearest neighbor with the robustness of sparse representation. Utilizing sparse reconstruction coefficients to characterize neighborhood geometry and weighted distance to characterize class dissimilarity, the sparse preserving nonnegative block alignment approach builds a discriminant partial optimization model. The two algorithms are successful and robust, as evidenced by their ability to produce accurate clustering and recognition results across a wide range of conditions, including both real and simulated occlusion. This study validated the model through in-class practice assessments, teachers' inquiries, and interviews with students and teachers to ensure its accuracy. The outcomes demonstrate the validity and trustworthiness of the proposed combined evaluation approach based on expression and head-up rate.

As a preprocessing step in a wide variety of applications, such as sound separation and musical note transcription, musical pitch estimation is used to identify the pitch of a musical note or the fundamental frequency (F0) of an audio stream. Based on the categorization framework, Tamboli (2019) creates a neural network optimized for musical note recognition (OBNN). The strategies for identifying musical notes were identified after reviewing a variety of surveys and studies. Here, an OBNN is utilized to identify musical pitches. Similarly, by utilizing various approaches, we can improve the efficiency of musical note recognition [9]. The most recent studies on musical note identification are successfully summarized here, along with the characteristics and categorizations gleaned from those studies.

Automatic speech/music classification employs various signal processing methods to sort audio/visual files into predefined categories. In order to categorize incoming audio signals into speech/music signals, Arvind Kumar's (2022) suggested work investigates Hilbert Spectrum (HS) obtained from various AM-FM components of an audio signal, also known as Intrinsic Mode Functions (IMFs). Hilbert Transform of the IMFs yields a two-dimensional representation of the HS, a map of instantaneous energy (IE) and frequencies (IF). Via creating unique IF and Instantaneous Amplitude (IA) based cepstral features, we subject this HS to a Mel-filter bank and Discrete Cosine Transform (DCT). Three datasets (Slaney Database, GTZAN Database, and MUSAN Database) were used to validate the results. Extensive experiments were undertaken on various combinations of audio files from the S&S, GTZAN, and MUSAN databases to evaluate the broad applicability of the proposed characteristics, and positive results were attained. Finally, the system's performance is compared to previously implemented cepstral features and other related efforts [10].

Integrating AI with deep music for recommendations has been a growing area of study in recent years. Deep learning is a complicated machine learning technique that may infer value

laws from features observed in training samples. The proliferation of deep learning networks is key to the future of AI and offers a fresh perspective on music score identification. Qin Lin's (2022) paper utilizes the enhanced deep learning algorithm to study music score recognition. To achieve feature extraction and intelligent recognition of music scores, we build on the foundation of the classic neural network by introducing the attention weight value improved convolutional neural network (CNN) and the high execution efficiency deep belief network (DBN). A CNN&DBN-based feature learning method was developed for music score extraction using the feature vector set extracted by CNN&DBN as input [11]. Experimental results show that the proposed model effectively recognizes a wide range of polyphony music types, with improved recognition and performance; the improved algorithm applied to soundtrack identification achieves a recognition rate of up to 98.4%, which is significantly higher than those of other classic algorithms. It demonstrates the massive potential for study in the field of music retrieval using deep learning and provides data support for building a knowledge graph in the music field.

It is a common goal in engineering and computer science to give machines sensing abilities on par with those of humans. Much work has been done to give computers the ability to collect, process, evaluate, and understand their environment in the same ways humans do. Explicitly referring to the auditory system, machine hearing is the capacity of computers to perceive their acoustic surroundings in the same way humans do. A proper audio signal representation is crucial to accomplishing this lofty goal. This study by Alas F et al. (2016) provides a comprehensive overview of the most recent advances in audio feature extraction methods for analyzing standard audio signals like voice, music, and environmental noise [12]. For the sake of thoroughness, the writers revisited old methods and included the most recent developments based on new fields of research and unique bio-inspired recommendations. These methods are classified in a taxonomy that groups them by their physical or perceptual underpinnings and then further subdivided by the type of computing they do (time, frequency, wavelet, image-based, cepstral, or other domains). The methods are described, and recent applications to issues with machine hearing are provided as illustrative instances.

Since its introduction, the Hilbert-Huang transform method has been widely used thanks to its superiority in several different contexts. The Hilbert spectrum accurately reflects the signal energy's dispersion over multiple scales. Using the Hilbert energy spectrum, which characterizes the distribution of instantaneous energy, Li X (2011) proposes a novel characteristic dubbed ECC. Compared to the conventional short-term average energy, the experimental findings clearly show that ECC performs better [13]. Combining the ECC and mel frequency cepstral coefficients (MFCC) provides a more detailed picture of the energy distribution over both the temporal and frequency domains, and the features of this set outperform those of the short-term average energy, pitch, and MFCC in terms of recognition accuracy. Then, after that, new and improved ECC variants are created. Combine ECC with the teager energy operator to get TECC, and add the

instantaneous frequency to the energy to get EFCC. Seven different emotional states are tested, with boredom having the highest detection rate (83.57%) and the highest categorization accuracy (100%). The proposed characteristics ECC, TECC, and EFCC were shown to enhance speech emotion recognition performance in numerical tests significantly.

Film video noise is commonly understood as digital signal system errors manifested as artifacts in the video image. Videos captured with different cameras will always have some degree of this distortion. The primary purpose of noise reduction is to lessen the amount of distracting background noise in a video while allowing the image's edges and textures to come through clearly. Pingli Sun et al. (2021) provide a comprehensive explanation of the space-time noise reduction filter's workings, along with the development of a 3D-filter algorithm for Gaussian noise, an enhanced 3D-filter algorithm for mixed noise based on the 3D-BDP (bloom-deep-split) filter, and a filter algorithm for luminance and color noise in dimly lit scenes [14]. They build a novel iterative denoising algorithm by deconstructing the PDE denoising process. Partial differential equations can be thought of as an iterative denoising of the filter. The new algorithm's initial stage employs a wavelet-domain adaptive Wiener filter as its filtering foundation, with promising results achieved by careful tuning of the filter's parameters. Analysis findings demonstrate that the model proposed in this section can efficiently eliminate multiplicative noise compared to the existing denoising model. The experimental report demonstrates that, compared to the partial differential equation method for denoising, the algorithm's parameters have some stability and can obtain satisfactory processing outcomes for many images. Using the proper partial differential equation approach, the pseudo-Gibbs are eliminated in the second step of the algorithm, greatly enhancing its performance. After applying the new algorithm to a Gaussian-noise-filled image, the pseudo-Gibbs effect, which frequently occurs in wavelet denoising, and the step effect, which occurs in partial differential equation denoising, are both eliminated, details are better preserved, the peak signal-to-noise ratio is improved, and numerous experiments demonstrate the algorithm's efficacy as a denoising method.

### III. DENOISING MODEL OF MUSICAL NOTE FEATURES BASED ON PARTIAL DIFFERENTIAL EQUATIONS

The music note feature denoising method based on a partial differential equation mainly uses the variational denoising method (TV) to identify the noise feature. The principle of this method is to transform the denoising problem into an extreme problem of finding the energy functional expression established under two constraints. The basic idea of this method is to transform an extreme value problem with a time window constraint function into an unconstrained next-dimensional signal and solve it in the time domain, and then obtain the actual non-stationary random process through iterative transformation, and finally realize the estimation of the noise spectrum [15].

Before studying the de-algorithm, the noise reduction model needs to be studied first. The noise reduction model is expressed as formula (1):

$$u_o(x, y) = u(x, y) + n(x, y) \quad (1)$$

Based on the noise reduction model, related personnel proposed a global variational model based on a bounded variation space, and its definition is shown in formula (2):

$$TV(u) = \int_{\Omega} |\nabla u(x, y)| d\Omega \quad (2)$$

Formula (2) satisfies constraints (3), (4):

$$\int_{\Omega} u(x, y) dx dy = \int_{\Omega} u_o(x, y) dx dy \quad (3)$$

$$\int_{\Omega} \frac{1}{2} |u(x, y) - u_o(x, y)|^2 dx dy = \sigma^2 \quad (4)$$

Usually, the noise will make the overall variational energy of the acquired musical note features large, and it is difficult to identify accurately. The noise reduction model can optimize the overall variational model of musical note features, that is, to minimize the overall variational energy, and it can accurately identify the temporal and spatial dimensions of music. Therefore, the denoising of musical note features is mainly to minimize the energy functional, which can be expressed as formula (5) by using the Lagrange multiplier method:

$$\hat{u} = \arg \min_u \{ E(u) \} = \frac{\lambda}{2} \int_{\Omega} (u - u_o)^2 dx dy + \int_{\Omega} \sqrt{u_x^2 + u_y^2} dx dy \quad (5)$$

The Euler-Lagrange equation corresponding to formula (5) can be deduced by the variational method, as shown in formula (6):

$$\lambda(u - u_o) - \frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) - \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) = 0 \quad (6)$$

The gradient descent flow equation corresponding to the variational problem Equation (6) is shown in Equation (7):

$$\begin{aligned} \frac{\partial u}{\partial t} &= \frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) - \lambda(u - u_o) \\ &= \text{div} \left[ \frac{\nabla u}{|\nabla u|} \right] - \lambda(u - u_o) \end{aligned} \quad (7)$$

TV flow is stable and has a globally optimal solution. It is a diffusion function between forward diffusion and progressive diffusion. This function can obtain a better diffusion process and feature information effect of musical note features [16]. The numerical implementation of the TV model is as follows:

The numerical realization of the TV model usually has three differential schemes: explicit, implicit, and semi-implicit. The implicit and semi-implicit schemes have higher secrecy than the explicit scheme. However, for the semi-implicit and implicit numerical implementation methods, the secrecy makes the whole calculation process more complicated in the iterative process of removing noise. Complex and the convergence rate is relatively slow. Compared with the other two numerical iterative implementations, the numerical implementation using

clear difference has a much faster convergence rate [17]. Therefore, the display scheme is commonly used by people, and the implementation of the display scheme is as follows:

The first display scheme is available as shown in formula (8):

$$u^{n+1} = u^n + \frac{\nabla t}{2\lambda} \operatorname{div} \left( \frac{\nabla u^n}{|\nabla u^n|} \right) - \nabla t \frac{(u_0 - u^n)(\mu u_0 - \mu + 1)}{(\mu u^n - \mu + 1)^3} \quad (8)$$

Substituting the difference quotient for the partial derivative, the formula (9) can be obtained:

$$\begin{aligned} \nabla_{\pm}^x u_{i,j} &= \pm(u_{i\pm 1,j} - u_{i,j}), \nabla_{\pm}^y u_{i,j} = \pm(u_{i,j\pm 1} - u_{i,j}) \\ \nabla_0^x u_{i,j} &= (u_{i+1,j} - u_{i-1,j})/2, \nabla_0^y u_{i,j} = (u_{i,j+1} - u_{i,j-1})/2 \\ u_{i,j}^{n+1} &= u_{i,j}^n + \frac{\Delta t}{2\lambda} \left[ \Delta_+^x \frac{\Delta_+^x u_{ij}^n}{\sqrt{(\Delta_+^x u_{i,j}^n)^2 + (\Delta_0^y u_{i,j}^n)^2 + \tau^2}} \right. \\ &\quad \left. + \Delta_-^y \frac{\Delta_+^y u_{ij}^n}{\sqrt{(\Delta_0^x u_{i,j}^n)^2 + (\Delta_+^y u_{i,j}^n)^2 + \tau^2}} \right] - \\ &\quad \Delta t \frac{(u_0 - u^n)(\mu u_0 - \mu + 1)}{(\mu u^n - \mu + 1)^3} \end{aligned} \quad (9)$$

Among them:  $u^n$  is the musical note feature after the  $n$ th diffusion, CCC is the time interval or time step, and is a first-order, second-order recursive relationship, which is characterized in that the continuous wave signals in the upper and lower columns are both continuous. Based on this feature, good results are obtained after analyzing the fusion of partial differential equations by establishing simple equations, differential equations, and related methods.

In denoising music note features, to improve processing efficiency, it is necessary to add regularization parameters in the iterative process. Of course, in continuous iteration, the regularization parameters need to be continuously updated to achieve better results.

#### IV. MUSIC NOTE FEATURE RECOGNITION BASED ON THE HILBERT SPACE METHOD

The relational expression between each order in Hilbert space is linear, and each inter-order variable function is described and defined by itself to form a set of vector groups. Under this method, many problems can be used as time series models for solution analysis and forecasting. However, combining time series with variables in practical applications is often necessary, which is also a significant feature of the Hilbert space method [18].

Hilbert spectrum has the following characteristics:

- It can describe random processes that are linearly independent and independent of each other between two variables and have high-order convergence and stability. Therefore, the Hilbert space method can be

used to study the linear correlation between variables in a multi-period non-stationary single system.

- It can be used for analysis when the non-deterministic and unstable states are in the Hilbert space equation. The combination of non-deterministic and unstable states can be combined to build a new model to solve. Hilbert space can be used in practical observation for analysis under uncertainty and steady state instead of simply solving by differential equations.

The principle of music note feature recognition is to analyze and compare the feature vectors corresponding to different note definition domains and consecutive states. It can analyze the position relationship of different notes by calculating the matrix of words corresponding between functions and feature vectors to analyze different notes and then get different feature vectors, also known as the Hilbert space method. Based on its recognition principle, its implementation model can be obtained, as shown in Fig. 1.

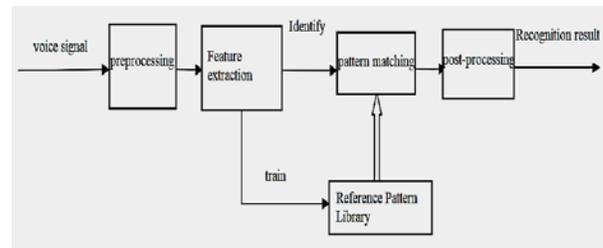

Fig. 1. Identification model

#### A. Hilbert Space Method

The Hilbert space method is a new method applicable to nonlinear and non-stationary signal processing, which can be used to study the decomposition and fitting of nonlinear problems and is of great importance in many practical applications. The Hilbert space method consists of two steps: firstly, the signal is decomposed by EMD, through which a single set of components IMF can be obtained. The IMF can effectively reflect the internal vibration pattern of the signal. Then the decomposed obtained IMF is subjected to Hilbert transform and Hilbert spectrum analysis. The results of Hilbert spectrum analysis are transformed into the corresponding state curves, and then the Hilbert space method with instantaneous time series is obtained [19].

#### B. Empirical Modal Decomposition

One of the essential concepts in the Hilbert space equation is the decomposition of modalities. In a broad sense, any new definition can be achieved using elements of different types or properties. However, for most mathematical problems, if we want to study more complex functions usually use both descriptive and approximation-type methods, but in Hilbert space equations, a special type of decomposition modality is used. The form of a continuous function is discrete into several and then a series of combinations to make it a new set of definitions [20]. EMD is the key step of the Hilbert space method, which can be regarded as the screening process to obtain IMF. The rationality and effectiveness of the EMD process are based on the following two points:

- Any complex signal  $s(t)$  can be represented as  $n$  instantaneous frequencies with actual physical meaning. In Hilbert space, each independent period can be expressed as  $n$  different frequencies, so the complex signal  $s(t)$  is represented as shown in formula (10).

$$s(t) = \sum_{k=1}^n imf_k(t) + r_n(t) \quad (10)$$

- The termination condition of the screening: Definition of IMF.

Based on the above, IMF is a signal (function) that is symmetric concerning the local zero means (Local Zero Mean). It has the same number of extreme value points (Extrema) and zero crossing points (Zero Crossings). Moreover, the graphical representation of IMF is shown in Fig. 2.

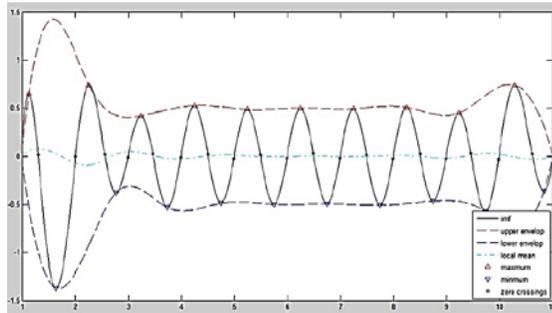

Fig. 2. IMF's diagram

### C. EMD Filtering

The Hilbert transform is superior in IMF components, and its superiority in different problems is unmatched by other modeling methods. IMF with a "single component" is integral to the Hilbert analysis process. However, most musical note signals are not IMF and do not represent Hilbert space, so it is not easy to analyze and process them when model identification is performed. Therefore, it is required that a straightforward Hilbert transform of such a signal cannot give a complete description of its frequency content. The signal has to be decomposed into IMFs so that a signal containing IMFs can be obtained [21]. The decomposition method that can effectively decompose a group of IMFs is EMD, and the essence of this decomposition method is to determine the intrinsic vibration mode of a signal based on its characteristic time scale and to define its characteristic frequency by this intrinsic vibration mode, to realize the classification of its mode. Therefore, the Hilbert transform can decompose the signal into two low-order high-order dynamic states with different Eigen frequencies and position functions. For the high-dimensional discrete spectral estimation problem, it is required to have enough time windows to ensure that the computational results converge to a suitable size range and to obtain a more accurate data set and its modal parameters (e.g., step length, step width, etc.), which is where the DMD method can have advantages in dealing with complex nonlinear models.

Based on the definition of IMF, the filtering process can be performed using the envelope formed by the signal's local maxima and local minima, respectively. Local maxima of a

signal mean decomposing a stochastic process containing all non-zero elements into a series of a small number of components and performing an exact calculation in each component to obtain an estimate of the objective function [22]. However, a definition is given for the Hilbert space: "Based on the characteristic equation (FME) algorithm proposed is a new method-Rython." The FME algorithm is an essential branch of Hilbert space, which can be used to solve signals and parameters. It has a wide range of applications in analyzing, estimating, and predicting time variation. The mean value of the upper and lower envelope of the original signal  $s(t)$  is denoted as  $m_1(t)$ . Then the difference between  $s(t)$  and  $m_1(t)$  is the first component, denoted as  $h_1(t)$ , as shown in formula (11).

$$s(t) - m_1(t) = h_1(t) \quad (11)$$

In the second screening, considering  $h_1(t)$  as the original signal and applying the same method, formula (12) is obtained.

$$h_1(t) - m_{1,1}(t) = h_{1,1}(t) \quad (12)$$

Then the screening process is similarly repeated  $k$  times until  $h_{1,k}(t)$  satisfies the conditions of IMF for the first IMF component. This process is expressed as shown in formula (13).

$$\begin{cases} h_{1,1}(t) - m_{1,2}(t) = h_{1,2}(t) \\ \vdots \\ h_{1,k-1}(t) - m_{1,k}(t) = h_{1,k}(t) \end{cases} \quad (13)$$

Let  $IMF_1(t) = h_{1,k}(t)$  so that  $IMF_1(t)$  is the first IMF component screened from the original signal  $s(t)$ , and we refer to this level of screening as inner-level screening. The inner-level screening process requires the determination of a screening termination criterion, which is an essential inner-level condition that determines whether the inner-level sequence can be extrapolated. This criterion can be bounded by the standard deviation SD (Standard Deviation) between two successive screening results. SD is defined by formula (14):

$$SD = \sum_{t=0}^T \left[ \frac{|h_{1,k-1}(t) - h_{1,k}(t)|^2}{h_{1,k-1}^2(t)} \right] \quad (14)$$

In summary, the standard EMD decomposition flow chart is shown in Fig. 3.

The Hilbert space method is a novel method applicable to nonlinear and non-smooth signal processing, which can be used to study the decomposition and fitting of nonlinear problems and is of great importance in many practical applications. The Hilbert space method consists of two steps: firstly, the signal is decomposed by EMD, through which a single component IMF can be obtained, which can effectively reflect the internal vibration pattern of the signal, and then the decomposed IMF is analyzed by Hilbert transform and Hilbert spectrum, and the result of Hilbert spectrum analysis is transformed into the corresponding state curve, and then the Hilbert space method with instantaneous time sequence [23].

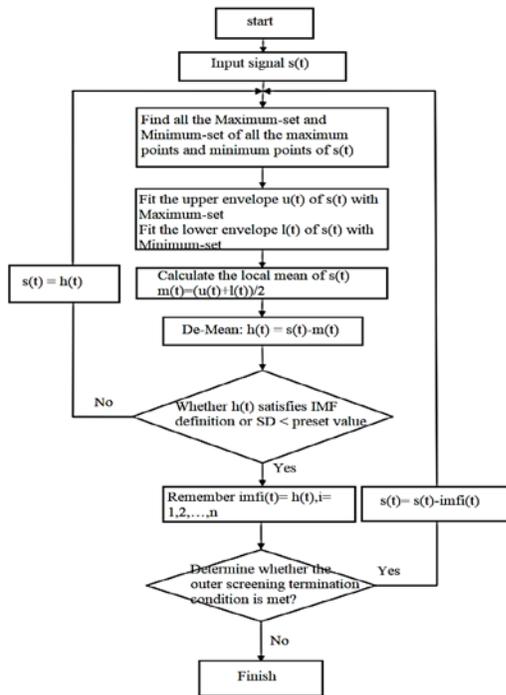

Fig. 3. EMD decomposition flow chart

After the original signal  $s(t)$  is decomposed into a set of IMFs by EMD, it can be expressed as shown in formula (15):

$$s(t) = \sum_{i=1}^n imf_i(t) + r_n(t) \quad (15)$$

This provides validity guarantees for the convenience of the Hilbert transform and the calculation of the instantaneous frequency.

The combined form of the Hilbert Marginal Spectrum (the HMS) and the instantaneous energy density level equation is the most commonly used and represent the instantaneous energy density function in the Hilbert space. The algorithm can be used to obtain the model parameters by selecting the model parameters and then transforming the complex problem into a simple mathematical one. The Hilbert marginal spectrum is a nonlinear multi-model with high prediction accuracy, and the algorithm can transform a complex problem into a linear solution. It can accurately estimate its approximate solution, as shown in formula (16). The equation of energy density level is the most commonly used and representative model parameter in Hilbert space, which can be not only directly obtained but also used for solving. It is widely used in various complex problems, and its representation is shown in the formula (17).

$$h(\omega) = \int_0^T H(\omega, t) dt \quad (16)$$

$$IE(t) = \int_{\omega} H^2(\omega, t) d\omega \quad (17)$$

The commonly used feature extraction methods are linear predictive cepstral coefficients, Mel frequency cepstral coefficients, wavelet transform-based feature extraction methods, and Hilbert space method-based feature extraction methods.

Feature extraction based on linear prediction cepstral coefficients

The feature extraction of linear predictive cepstral coefficients is the most critical and core problem in the whole multivariate statistical analysis process. We usually use single-factor models to perform dimensionality reduction in traditional regression methods. However, as the application range becomes wider and wider, the computational conditions keep improving, and the complexity of data processing becomes more and more complicated, it is challenging to meet the actual accuracy requirements, and it is impossible to directly use the variance estimation method to do multiple linear prediction verification on experimental samples. Therefore, a new linear predictive cepstral coefficient model is proposed, which can reduce the complexity of data processing by extracting feature space information with more implied parameters and higher dimensionality [24]. The feature extraction process of linear predictive cepstral coefficients is shown in Fig. 4.

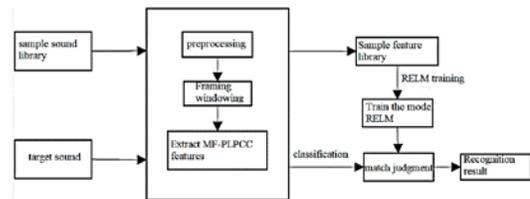

Fig. 4. Feature extraction of linear predictive cepstral coefficients

1) Feature extraction based on Mel frequency cepstrum coefficients: Mel frequency cepstrum coefficient is a nonlinear feature, and its parameters change with time. Therefore, its characteristics must be processed in some way before linear regression analysis is performed. However, the above method has some problems: firstly, it needs to calculate a large number of offline fitted curve weights and use one of them as the standard deviation, so it is computationally intensive, and the rate of change of the offline fitted curve weights will change over time. Thus it cannot accurately describe the distribution of linear feature points on a straight line. Secondly, a series of complex processes, such as obtaining new parameters, may be required before this can be used to achieve the goal of maximizing the effective extraction rate, so these are essential elements to be studied based on Mel coefficients and the feature extraction of Mel frequency cepstrum coefficients is shown in Fig. 5.

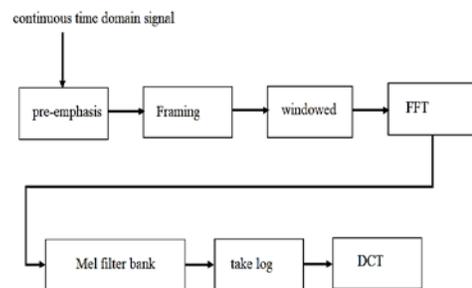

Fig. 5. Feature extraction of Mel frequency cepstral coefficients

2) *Study of wavelet transform-based feature extraction method:* As an extension of time-frequency local features in time and space, wavelet transform is a newly developed time-scale analysis method, which decomposes the image with each sub-band coefficient (i.e., distance resolution) to deal with the noise component, and the signal contains some high-frequency components. At the same time, it can effectively eliminate the low-frequency part. Moreover, wavelet transform is also a time-frequency local feature analysis method. It can extract the high-frequency components in time, space, and scale to more accurately analyze the local signal information. The feature extraction process of wavelet transform is shown in Fig. 6 [25].

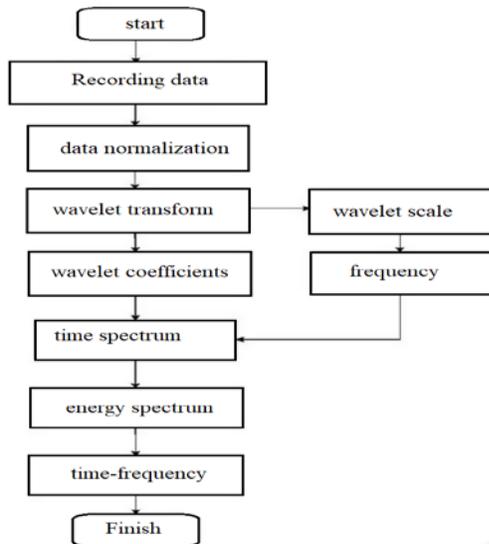

Fig. 6. Feature extraction process of wavelet transform

3) *Feature extraction method based on Hilbert space method:* The Hilbert space classification algorithm is based on the linear discriminant method of feature extraction, which is based on the traditional minimum distance classification method combined with a variety of statistical decision theories to achieve the recognition of different dimensions in the sample. The method predicts the target region by training sample data, however, due to a large amount of data and noise interference. Therefore, further improvements are needed: firstly, the original sample point information is multiplied and fitted with other discrete cosine matrices; secondly, the corresponding coordinate transformation coefficients are maximized or minimized according to the feature vectors of the classified objects, and finally, the linear discriminant method is used for parameter estimation, and the final output is combined with the Hilbert space classification method to realize the efficiency of feature extraction.

## V. CONCLUSION

To sum up, with the development of computer technology, artificial intelligence has become the trend brought by the technological progress in the new era background. With the introduction of modern new technology, the traditional method

of extracting music note features can no longer meet the needs of modern technological development. With the introduction of new technology, the traditional method of extracting musical features can no longer meet the needs of modern technology. The feature recognition method integrating partial differential equation and Hilbert space method has become the inevitable development of technology in the new era. In this paper, we propose a TV denoising model using partial differential equations, i.e., establishing its energy generalization, obtaining its Euler-Lagrange equation by variational method, and finding its numerical solution by gradient descent flow method, which can effectively protect the detailed information of music note features. In addition, when using the Hilbert space method for feature extraction and identification, the nonlinear and non-smooth feature signals can be effectively identified. It is easier and faster to use the Hilbert space method for feature identification, and the information of the feature signal can be studied accurately.

Faculty of Computer Science, Universitas Sriwijaya, Palembang, Indonesia<sup>2,3</sup>

**Abstract**—Improving student learning performance requires proper preparation and strategy so that it has an impact on improving the quality of education. One of the preparatory steps is to make a prediction modeling of student performance. Accurate student performance prediction models are needed to help teachers develop the potential of diverse students. This research aims to create a predictive model of student performance with hyperparameter optimization in the Support Vector Regression Algorithm. The hyperparameter optimization method used is the Metaheuristic Algorithm. The Metaheuristic Algorithms used in this study are Particle Swarm Optimization (PSO) and Genetic Algorithm (GA). After obtaining the best SVR hyperparameter, the next step is to model student performance predictions, which in this study produced two models, namely PSVR Modeling and GSVR Modeling. The resulting predictive modeling will also be compared with previous researchers' prediction modeling of student performance using five models: Support Vector Regression, Naïve Bayes, Neural Network, Decision Tree, and Random Forest. The regression performance metric parameter, Root Mean Square Error (RMSE), evaluates modeling results. The test results show that predictive student performance using PSVR Modeling produces the smallest RMSE value of 1.608 compared to predictions of student performance by previous researchers so that the proposed prediction model can be used to predict student performance in the future.

**Keywords**—Student performance; feature selection; particle swarm optimization; genetic algorithm; support vector regression

## I. INTRODUCTION

Educators need a prediction of student performance to improve student achievement. Predicting student performance is used as material for evaluating student learning so that it can facilitate the diversity of potential students, both those who excel academically [1][2] and detect students who have the potential to experience failure [3]. Accurate prediction of student performance can also be the right policy decision in educational institutions [4].

The implementation of the Machine Learning Algorithm to predict student performance is to compare the accuracy of both classification and regression [5]. The Machine Learning Algorithms used include Neural Networks, Decision Trees, Naïve Bayes, SVM, KNN, and Logistic Regression [2][5][6]. Support Vector Machine (SVM) is a Machine Learning Algorithm that can be used to predict student performance

[5][7][8][9]. As for solving regression problems, SVM is better known as Support Vector Regression (SVR) [10]. SVR has good generalization ability, can be implemented for non-linear data with high dimensions, and has low computational complexity [11]. In addition, other advantages of SVR are overcoming overfitting and making predictions with data that is not too large [12]. From these advantages, SVR can be implemented in this study to predict student performance [11]. Problems often experienced by SVR occur in large-scale data, thus making significant computational processes challenging to determine optimal hyperparameter values [11][13].

Optimal selection of hyperparameters in Machine Learning Algorithms has been carried out using various Metaheuristic Algorithm approaches, namely Particle Swarm Optimization (PSO)[14], Artificial Bee Colony (ABC) [15], and Genetic Algorithm (GA) [16]. The SVR Algorithm is a Machine Learning Algorithm; optimizing hyperparameters in SVR modeling will increase the value of modeling accuracy [16][17].

## II. RELATED WORK

Many researchers have researched student performance prediction using Machine Learning Algorithms. Tomasevic et al. [6] predict student performance by comparing Machine Learning Algorithm modeling, namely KNN, SVM, ANN, Decision tree, Naïve Bayes, and Logistic Regression with classification and regression models. This study used data on students' past learning achievements, learning engagement, search activities, discussion participation, and demographics. The results of this study show that ANN outperforms other Machine Learning Algorithms with the best accuracy.

In the study of student performance prediction conducted by Xu et al. [18], using student activity data, as many as 4,000 students on the online duration, traffic volume, and connection frequency. The resulting classification prediction modeling is in the form of passed and failed. The Machine Learning Algorithms used include Decision Trees, ANN, and SVM. This study showed that the ANN and SVM Algorithms for predicting student achievement were the most accurate.

Cortez et al. [5] compared the accuracy of predicting student performance with classification and regression modeling using Neural Network, Decision Tree, Naïve Bayes, Random Forest, and SVM Algorithms to predict student

\*Corresponding Author.

performance in mathematics and Portuguese. The experimental results show that in the classification case, the Naïve Bayes Algorithm produces the best accuracy for predicting student performance in mathematics and the Decision Tree Algorithm produces the best accuracy for predicting student performance in Portuguese. In the regression case, the Random Forest Algorithm has the best accuracy for predicting student performance in mathematics. In contrast, the Naïve Bayes and Random Forest Algorithms produce the best accuracy for predicting student performance in Portuguese.

This study will use previous research datasets, namely the performance of high school students in Portugal in mathematics [5], with the development of the SVR Algorithm. The choice of the SVR algorithm is because the algorithm can overcome overfitting and make predictions with data that is not too large [12]. The development of the SVR Algorithm is to find optimal hyperparameters in the SVR Algorithm using the Metaheuristic Algorithm, namely PSO and GA [14][16]. By using optimal hyperparameters, the application of the SVR Algorithm can increase the accuracy of predictive modeling [16][17]. So the proposed contribution of this research is developing a model predicting student performance on the SVR Algorithm with hyperparameter optimization using the Metaheuristic Algorithm, which previous researchers have not done.

### III. MATERIAL AND METHOD

In this study, there are several stages needed to predict student performance. In the early stages, the collection of the student performance dataset, Split dataset to data training and data testing, Optimization of hyperparameters on SVR using the Metaheuristic Algorithm, and Modeling of Student Performance Prediction.

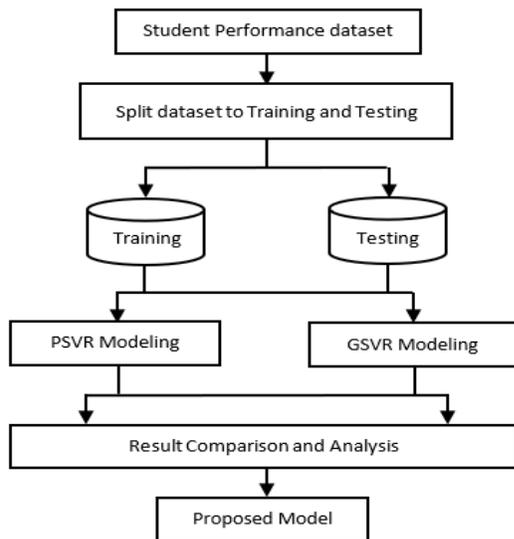

Fig. 1. The proposed method

In Fig. 1, it can be seen the stages carried out in this study. The first step was collecting the dataset. Dataset collection can be done by downloading from the UCI Machine Learning Website<sup>1</sup>. After processing the dataset, the dataset will be split into training and testing data, with 90% of the training data and

10% of the testing data. Training data is used when training Algorithms and looking for suitable models, while data testing is used as test data to determine the performance of the model that has been produced. The next step in this study is to model student performance predictions using the SVR Algorithm with hyperparameter optimization. This study used two models: GSVR Modeling and PSVR Modeling. After predictive modeling is generated, the next step is to evaluate the performance of the regression performance metrics using RMSE and compare it with Machine Learning Algorithm modeling done by previous researchers using the same dataset [5].

#### A. Data for Student Performance Prediction

This study uses a dataset of student performance at secondary schools in Portugal from the UCI Machine Learning Repository Website. This collection of student performance data comes from two secondary schools, namely the Gabriel Pereira School and the Mousinho da Silveira School mathematics. It consists of 395 instances and 33 demographic, social, financial, and academic data attributes [5]. Of the 33 attributes in this dataset, one attribute is the result of students' mathematics final exam scores, namely G3, which will be used as the target for modeling student performance predictions, so 32 attributes in the dataset affect student performance. The description of the student performance dataset used can be seen in Table I.

TABLE I. FEATURES AND DESCRIPTION OF THE DATASET

Feature	Description
school	student's school
sex	student's sex
age	student's age
address	student's home address type
famsize	family size
Pstatus	parent's cohabitation status
Medu	mother's education
Fedu	father's education
Mjob	mother's job

### B. Machine Learning Algorithms

This research will focus on developing the SVR Algorithm by optimizing hyperparameters using the Metaheuristic Algorithm. At the end of the development, we will compare with other Machine Learning Algorithms used by previous researchers to predict student performance, namely Support Vector Regression (SVR), Naïve Bayes, Neural Networks, Decision Trees, and Random Forests [5].

1) *Support vector regression (SVR)*: SVR is a development of the SVM Algorithm introduced by Vladimir Naumovich Vapnik in 1995 [19]. SVR shows good performance in solving regression problems [11]. SVR applies the Structural Risk Minimization (SRM) method, which is a method with a focus on finding the optimal hyperplane and minimizing errors from the training data and incentive loss function, resulting in a continuous and real-value data output [20]. In this study, the hyperparameters used are C, gamma, and epsilon.

2) *Naïve Bayes*: Naïve Bayes is a simple probabilistic classifier that calculates a set of probabilities by summing the frequencies and combinations of values from the given dataset [21]. This Algorithm uses Bayes theorem and assumes that all attributes are independent or not interdependent, given the value of the class variable [22]. Naive Bayes is based on the simplifying assumption that attribute values are conditionally independent when given output values [23]. In other words, given the output values, the probabilities of observing together are the product of the individual probabilities [24].

3) *Neural networks*: Neural networks are information processing Algorithms inspired by the workings of the biological nervous system, especially in human brain cells, in processing information [25]. Neural networks consist of many information-processing elements that are connected and work together to solve a particular problem, which is generally a classification or prediction problem [26].

4) *Decision tree*: A Decision tree is a predictive model technique used for task classification and prediction [27]. A

Decision tree divides the problem search space into problems [28]. The process in the decision tree is to change the form of table data into a tree model. The model tree will generate rules and be simplified [29].

5) *Random forest*: Random Forest Random Forest is a supervised learning Algorithm released by Breiman [30]. Random Forest is commonly used to solve problems related to classification, regression, etc. This Algorithm is a combination of several tree predictors, or it can be called a decision tree, where each tree depends on a random vector value sampled freely and evenly on all trees in the forest [31]. The prediction results from the Random Forest get the most results from each decision tree [32].

### C. Metaheuristic Algorithm for Optimizing Hyperparameters in the SVR Algorithm

A Metaheuristic can be defined as an iterative generation process that guides subordinate heuristics by intelligently combining different concepts to exploit the search space used to organize information in efficiently finding a near-optimal solution [33]. A Metaheuristic Algorithm is used to help optimally find hyperparameters to produce the best accuracy value in predictive modeling [12][17]. Determining hyperparameters in a Machine Learning Algorithm is a significant step in modeling [16]. The optimal hyperparameter is determined based on the fitness function. The fitness function is as follows.

$$\text{Fitness function} = \sqrt{\sum_{i=1}^n (\hat{y}_i - y_i)^2} \quad (1)$$

Where  $\hat{y}_i$  is the predicted value,  $y_i$  is the original value of the sample dataset, and  $n$  is the total number of samples. In this study, The Metaheuristic Algorithms used to find optimal Hyperparameters in SVR are PSO and GA, which will be discussed as follows.

1) *Particle swarm optimization (PSO)*: PSO has been developed by Kennedy and Eberhart as an optimization Algorithm [34]. The way PSO works is based on the results of observing the social behavior of a group of birds and fish moving to a specific position to get food, which is then referred to as the best position in the multidimensional search space [35][36]. The term particle denotes a bird in a flock that collectively influences its intelligence or that of the group [37]. According to the search area, particle movement with velocity will save it as the best position as Pbest and Gbest [38]. PSO aims to get the optimal solution by minimizing the fitness function [39].

In this study, we will apply PSO as an optimizer for SVR hyperparameters, with the name PSVR Modeling. The steps taken are the initialization of the initial parameters of the PSO in the form of particle velocity, initial particle position, and iteration. Particles will update the position and velocity memory to obtain the Pbest and Gbest values [11]. The best fitness value of the iteration limit will produce the best SVR hyperparameter combination in the form of C, gamma, and epsilon in PSVR Modeling.

2) *Genetic algorithm (GA)*: GA is an evolutionary Algorithm inspired by the mechanism of natural selection based on Charles Darwin's theory [40]. GA was introduced in 1975 at the University of Michigan by John Holland [41]. GA is widely used to solve optimization problems [42]. GA works to find the optimum solution simultaneously at several points in one generation, and then GA manipulates the population structure symbolically as the best solution [43]. In GA, a solution is a chromosome, and a group of chromosomes is called a population. Chromosomes from one population form a new population based on the objective function or the best fitness value [44].

This study will also apply GA as an optimizer for SVR hyperparameters, with the name GSVR Modeling. The steps are to initialize the initial GA parameters in the form of the initial population and iteration limits. The initial population in the state of individuals will be selected based on the order of the best fitness function with the selection stages [16]. After that, the cross-over stage is carried out, namely the exchange of genes between one chromosome and another based on the parameter of the crossover rate. The next stage is a mutation, in which the resulting chromosome will replace one or more genes with other genes at random [45]. In the final stage, a new individual will be generated to determine the best fitness value obtained from the iteration limit to produce the best SVR hyperparameter combination in the form of C, gamma, and epsilon in GSVR Modeling.

#### D. Evaluation Method

The developed model will be evaluated using regression performance metric parameters in the final stage. The function of the regression performance metric parameter is to measure the accuracy of modeling predictions of student performance. This study's regression performance metric parameter is the Root Mean Square Error (RMSE). RMSE can be defined as the square root of the average value of squared errors between the actual value and the forecast value [36].

$$RMSE = \sqrt{\frac{1}{n} \sum_{j=1}^n (y_j - \hat{y}_j)^2} \quad (2)$$

Where  $\hat{y}_j$  is the predicted value of student performance,  $y_j$  is the original value of the student performance sample dataset, and  $n$  is the total number of samples.

#### IV. RESULT AND DISCUSSION

This study uses the student performance dataset by Cortez [5], focusing on students' final exam scores in Mathematics. This student performance dataset from two secondary schools consists of 395 instances and 33 attributes. This dataset is a file with the Comma Separated Values (CSV) format in excel. After checking each row and column of data, no empty data is found in this dataset, so it can be stated that this dataset has been filled in completely. The next step is to model student performance predictions by optimizing hyperparameters in SVR Algorithm using the Metaheuristic Algorithm, which is then compared with modeling student performance predictions that have been carried out by previous researchers using Machine Learning Algorithms.

#### A. Results of Previous Research Results using Machine Learning Algorithms

Cortez et al. [5] have researched predicting student performance modeling using Machine Learning Algorithms, including SVR, Naïve Bayes, Neural Networks, Decision Trees, and Random Forests. The modeling results that have been produced are in Table II below.

TABLE II. RESULT OF PREVIOUS RESEARCH [5]

Algorithm	RMSE
SVR	2.09
Naïve Bayes	2.01
Neural Networks	2.05
Decision Tree	1.94
Random Forest	1.75

In Table II, the modeling results show that the best predictive modeling of student performance is obtained in modeling predictive student performance in the Random Forest Algorithm with an RMSE value of 1.75, while the worst student performance in the SVR Algorithm with an RMSE value of 2.09. In previous studies, only making comparisons of the accuracy of modeling predictions of student performance using Machine Learning Algorithms and hyperparameter optimization has not been carried out on Machine Learning Algorithms. So that in this study will improve the accuracy of modeling student performance predictions with the SVR Algorithm by optimizing hyperparameters using the Metaheuristic Algorithm.

#### B. Results of Optimization Hyperparameter SVR using Metaheuristic Algorithm and Modeling

This stage is the initial stage for developing the SVR Algorithm to predict student performance. Hyperparameter optimization is performed to determine the best hyperparameter composition of the SVR Algorithm as a predictive model to be developed. The settings for the hyperparameter values to be optimized are C, gamma, and epsilon by determining the range of upper and lower limit values, with hyperparameter values C = [100 - 1000], gamma = [0.001 - 0.009], and epsilon = [0.001 - 0.009]. The predictive modeling of student performance resulting from hyperparameter optimization using the Metaheuristic Algorithm is as follows.

1) *Optimization hyperparameter SVR using particle swarm optimization (PSVR modeling)*: In this study, PSO will be applied as an optimizer for SVR hyperparameters. The SVR hyperparameters are C, gamma, and epsilon. Meanwhile, as an optimization Algorithm, the PSO parameters will be determined by initialization, also carried out on the initial PSO parameters. The PSO parameter will be set with a total of 50 particles, while the value of C1 is 1.0 and C2 is 2.0, with a weight value of W is 0.5. The number of iterations in this research will be varied by the number of iterations of 50, 100, 250, and 500.

TABLE III. RESULT OF PSVR MODELING

Iteration	Optimal Hyperparameter			RMSE
	C	gamma	epsilon	
50	380	0.001	0.006	1.681
100	103	0.002	0.001	1.608
250	358	0.001	0.008	1.683
500	450	0.001	0.005	1.675

Based on the PSVR Modeling results in Table III, the optimal SVR hyperparameter combination was obtained at C, gamma, epsilon = [103, 0.002, 0.001] at the 100th iteration is the best RMSE value of 1.608. The selection of optimal hyperparameters generated in PSVR Modeling results from searching for a combination of hyperparameter limits on SVR that has been determined using the PSO method search stages. In the PSO method, the resulting hyperparameter combination will be evaluated for its fitness value based on the Pbest and Gbest values of the iterations and predetermined PSO parameters so that the best hyperparameter combination with the smallest RMSE value is obtained.

2) Optimization hyperparameter SVR using genetic algorithm (GSVR modeling): GA will be applied as an optimizer for SVR hyperparameters in this study. The SVR hyperparameters are C, gamma, and epsilon. Meanwhile, as an optimization Algorithm, the GA parameters will be determined by initialization, also carried out on the initial GA parameters. The GA parameter will be determined by a total of 50 individuals, while the mutation coefficient value is 0.01, with a cross-over coefficient value of 0.5. The number of iterations in this research will be varied by the number of iterations of 50, 100, 250, and 500.

TABLE IV. RESULT OF GSVR MODELING

Iteration	Optimal Hyperparameter			RMSE
	C	gamma	epsilon	
50	102	0.001	0.006	1.831
100	101	0.001	0.008	1.831
250	100	0.001	0.008	1.830
500	101	0.001	0.007	1.831

Based on the GSVR Modeling results in Table IV, the best RMSE value was 1.830 at the 250th iteration with the optimal SVR hyperparameter combination at C, gamma, epsilon = [100, 0.001, 0.008]. In GSVR Modeling, selecting optimal hyperparameters is also the result of searching for a combination of hyperparameter limits on a predetermined SVR using the GA method search stages. In the GA method, the resulting hyperparameter combination will be evaluated for its fitness value based on the GA stages to get the best individual based on the iteration results and GA cycle stages in the form of selection, cross-over, and mutation so that the best hyperparameter combination with the smallest RMSE value is obtained.

From the experimental results, obtained modeling of student performance with PSVR Modeling and GSVR Modeling, which will then be used to be compared with student performance modeling in previous studies.

### C. Comparing and Analysis Results

In this study, modeling of student performance predictions has been carried out using the SVR Algorithm, which is optimized for hyperparameters with the Metaheuristic Algorithm, by producing a proposed model in the form of PSVR Modeling in Table III and GSVR Modeling in Table IV. In the PSVR Modeling experiment with the optimal SVR hyperparameter, the RMSE value was 1.608, and GSVR Modeling with optimal SVR hyperparameters produced an RMSE value of 1.830, so when compared to modeling student performance predictions using the Machine Learning Algorithm obtained from previous research in Table II, which will produce a comparison like in Fig. 2.

Fig. 2 shows that modeling predictive student performance with PSVR Modeling gets the best results with the smallest RMSE value of 1.608 compared to the RMSE value on GSVR modeling and performance prediction modeling students conducted in previous studies. It can also be seen that the SVR algorithm gets the highest RMSE value of 2.09 compared to the Machine Learning algorithm used in previous studies for modeling student performance predictions. With this research, it can be seen that optimizing the hyperparameters in the SVR algorithm can reduce the error value or increase the accuracy of modeling student performance predictions.

Fig. 3 shows the graph of increasing accuracy using hyperparameter optimization using the Metaheuristic Algorithm for the SVR Algorithm. The experimental results show an increase in the accuracy of the SVR algorithm with the proposed model. GSVR Modeling shows an increase in accuracy of 12.44% with a decrease in the error value with RMSE from 2.09 to 1.830 compared to the SVR Algorithm. As a comparison, the best improvement is PSVR Modeling which shows an increase in accuracy of 23.06% with a decrease in the error value with RMSE from 2.09 to 1.608 compared to the SVR Algorithm.

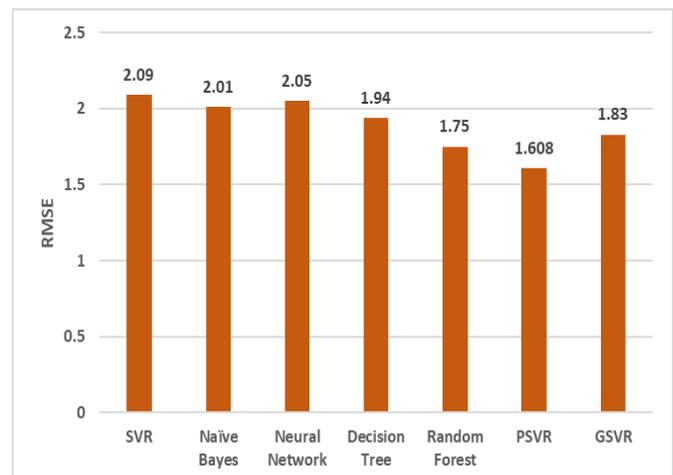

Fig. 2. Comparison of the results modeling student performance prediction

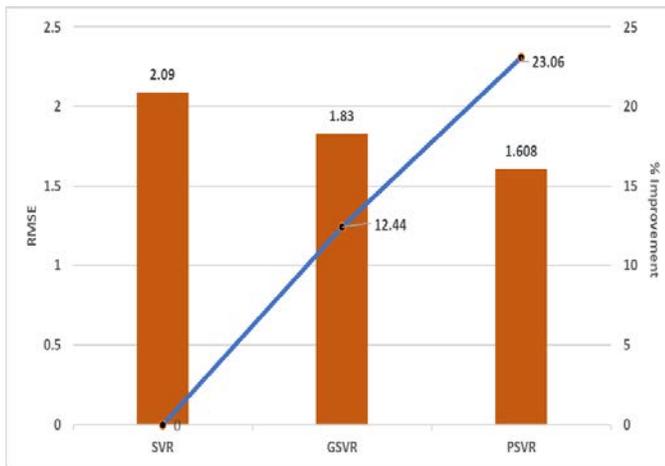

Fig. 3. Percentage Improvement of SVR with hyperparameter optimization using metaheuristic algorithm

## V. CONCLUSION

Modeling student performance predictions using an accurate Machine Learning Algorithm can predict student performance so that appropriate strategies can be determined to improve student learning outcomes. In previous research [5], modeling predictions of student performance were compared using several machine learning algorithms. This study has developed a predictive model for student performance by optimizing the hyperparameters in SVR using the Metaheuristic Algorithm, namely PSO and GA, to produce a proposed model with two models, PSVR Modeling and GSVR Modeling. In predicting student performance predictions using PSVR Modeling, the prediction accuracy is the best compared to predicting student performance using other Machine Learning Algorithms with an RMSE value of 1.608. The increase in the accuracy of the RMSE value was also generated by modeling predictions of student performance with PSVR Modeling of 23.06% compared to predictions by modeling student performance using the SVR Algorithm. This experiment shows that the student performance prediction model with the proposed model can be used to predict student performance in the future. In this study, the selection of optimal hyperparameters in the SVR Algorithm has been proven to increase accuracy in predicting student performance. Future research is expected to be able to conduct experiments by setting hyperparameters on C, gamma, and epsilon with a more varied range of values so that it is possible to obtain even better predictive modeling accuracy results.

## VI. FUTURE WORK

In future research, further the development will be carried out on predicting student performance modeling using the Feature Selection Method with Metaheuristic Algorithms. So modeling student performance predictions using the feature selection method will produce features that influence student performance predictions and increase the accuracy of the resulting model.

## ACKNOWLEDGMENT

The first author is a doctoral student at the Faculty of Engineering, Universitas Sriwijaya. The authors would like to

thank Universitas Sriwijaya for their support in carrying out this research.

# Experimental Analysis and Monitoring of Photovoltaic Panel Parameters

Zaidan Didi, Ikram El Azami

Computer Science Research Laboratory (LaRI)-Faculty of Sciences,  
Ibn Tofail University, Kenitra, Morocco

**Abstract**—In this article, we establish a technique based on the internet of things to simultaneously monitor the main values that characterize a photovoltaic solar panel. This technique allows to discover the problems and the monstrosities during the operation. This study also allows to collect the parameters and quantities measured for analysis. This method is based on exploiting the advantages of IoT technology. For this it will be a good choice to use and exploit the Esp32 microcontroller, because the two WIFI and Bluetooth modules are integrated. The design process began by creating a system to measure the intensity of the electric current delivered by the photovoltaic panel. A current sensor was implemented for this purpose. To prevent damage to the microcontroller, a voltage divider was proposed to decrease the voltage at the pin level of the Esp32 for measurement. Next, the power and energy values were calculated to estimate the production capacity. In the final stage, a low-power Bluetooth link was created to transmit the four quantities to a smartphone or other compatible device. Real-time values were presented as graphs on the free ThingSpeak platform and displayed on both, an LCD screen and the serial monitor of the Esp32 microcontroller. The system was tested without any problems or errors.

**Keywords**—Current sensor; bluetooth low consumption; photovoltaic panel; Esp32 microcontroller

## I. INTRODUCTION

Currently, the exploitation of renewable energies is experiencing an intense and remarkable increase, to reduce and minimize costs and expenses in the energy field [1]. In this realization we strongly noted this last report between the electric energy and the energy generated by the photons coming from the sun, this report exceeds 25% [2], [3].

The proper functioning of solar panels is sensitive to being affected by climatic problems. As a result, the distortion negatively influences and can reduce the performance of photovoltaic panels [4], [5], [6], [7], [8]. To regularly detect the operating problems of photovoltaic systems, proactive management is necessary to ensure real-time monitoring of the values of the main parameters of this system. In this article, a design has been processed to measure and supervise the values of the quantities that characterize a photovoltaic panel, which will then be transmitted through low-consumption Bluetooth connectivity. Our document is ordered as follows. In the first section we have elaborated a summary. In Section II, similar studies have been presented which have dealt with the same objectives. Section III is reserved for the hardware part in which the essential characteristics of the Esp32 microcontroller and the ACS712-30A current sensor have been exposed. In the

same section, we have exposed a detailed conception of our realization. Section IV brings together the results and the discussion via diagrams and curves which represent the results obtained experimentally. Noted here that the values of the parameters are collected and stored on the ThingSpeak platform which is reserved for connected objects while we exploit the HTTP protocol. Finally, in the last section a conclusion closes this study.

## II. RELATED WORK

### A. Transfers Data with Bluetooth Modules, HC-06 and HC-05

In recent years and thanks to the technological revolution in the field of the Internet of Things, several scientific studies have integrated the Arduino microcontroller with the two external Bluetooth modules HC-05 and HC-06 [9], [10], [11], [12], [13]. These Bluetooth modules are greedy because they consume a large amount of energy, and we have noticed the non-compatibility with the Arduino card, which in many cases complicates the proper functioning of these modules to achieve connectivity via Bluetooth.

### B. Use of the F031-06 Voltage Sensor for the Measurements

In the same design, other delicate researches have used the F031-06 voltage sensor as the main element to measure the potential difference that characterizes the photovoltaic panel [14], [15], [16], [17], [18], thus, the operating principle of this sensor is essentially based on the structure of a resistive divider, therefore, we quickly concluded that this sensor is characterized by the non-stability of the measurements, moreover, over a given measurement range the output of this sensor is always a linear function, in the research we have done, we have noticed a wide sensitivity to noise and the values measured with this sensor are slightly different to the real values.

### C. Transfers Data with WIFI Module

In the same context, other research has integrated the WIFI module to transmit the different measured quantities of photovoltaic panels such as current, voltage and energy [19], [20], [21], [22], [23]. Noted here that in the studies used by the integrated WIFI module of the Esp32 microcontroller, the IP address is assigned dynamically by a DHCP server, so this address changes its value at each restart, this becomes a major problem and complicates the situation in the case where a web server is installed on the Esp32 microcontroller. In most cases, this inconvenience is overcome by integrating the Wifi.config function to set the IP address, this function accepts the

following attributes, Ip, gateway, dns, and subnet. In general, these studies are very successful, while the Wi-Fi network coverage space remains a challenge.

#### D. Arduino Mega as Main Processing Element

In other scientific research, the hardware design consists of an Arduino Mega board, therefore an ATmega2560 microprocessor [24], [25], [26], [27], [28]. These studies profusely reduce the hardware complexity and make the model clearer, We noted here that the Arduino Mega2560 board is characterized by several advantages such as the number of input / output (54 pins), a large number of analog pins (16 pins), serial ports (3 ports), an I2C port and an SPI port, compared to the ordinary Arduino board, the Mega2560 is characterized mainly by a large memory predisposition, let's also add compatibility with the majority of Arduino modules. the IoT.

### III. MATERIALS AND METHODS

In this section, the material design used in this realization is presented, it is based mainly on the following elements:

#### A. Microcontrôleur Esp32

In this study, the Esp32 Microcontroller plays a key role, because it is created to promote and ensure the learning and development of connected objects, and embedded applications [29], it is characterized by a large computing capacity in comparison to the Arduino, this microcontroller wakes up regularly when a specific condition is verified, In practice, experiments show that the Esp32 microcontroller greatly minimizes the amount of energy consumed thanks to the reduced duty cycle, The ESP32 microcontroller integrates the WROOM-32 microprocessor (Tensilica Xtensa LX6) which particularly works under a clock frequency of 240 MHz. Also noted that the Bluetooth (Bluetooth Low Energy) and WIFI modules (WIFI: 802.11 n width 2.4 GHz) are integrated.

#### B. ACS712 30a Current Sensor

The ACS712 current sensor is essentially based on the ascending Hall effect. Whatever the nature of the electric current (direct (DC) or alternating (AC)), the ACS712 sensor is connected in practical embodiments in series with the load, with a sensitivity of around 66mV per ampere, see Fig. 1, [30][31].

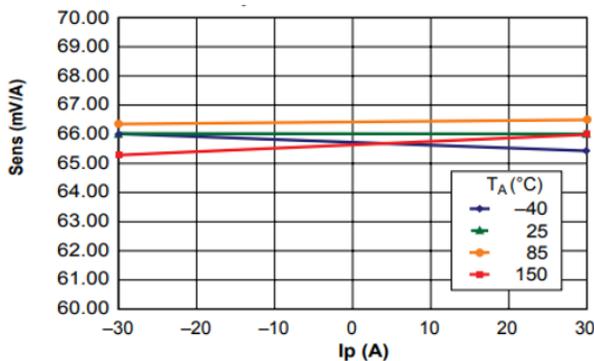

Fig. 1. Sensitivity of the ACS71230-a sensor

Among the advantages of the ACS712 sensor, the authors have noted that this sensor accepts the passage of electric current in both directions, this makes it possible to measure a positive or negative electric current in specific situations. The current inside this sensor generates a magnetic field; at the output, a DC voltage proportional to the current will be obtained. It is equally important to note that a calibration with a blank reading is strongly recommended. Note also that an external magnetic field (like for example) can negatively influence the measurements made. In practical implementations, the ACS712 Hall effect current sensor (10nF) is distinguished by intense noise corresponds to 130mA, the authors have greatly limited this noise by adding a 470nF capacitor, also have profusely limited this noise by adding a 470nF capacitor. The pins of the ACS712 are denoted in Fig. 2, the technical characteristics are given as follows: Dimensions: 31x13x15mm, Chip: ACS712ELEC-30A, Measured current range: -30A to +30A, Vref at 0A: Vcc/2 i.e. 2.5V, Sensitivity: 66mV/A, Insulation: 2.1KV, Consumption: 10mA, Error: 1.5 % at 25°C, Power supply: 5VDC (4.5-5.5VDC).

#### C. Autres Elements

Since the photovoltaic panels in our realization generate a maximum voltage equal to 42V, and since the voltage at the terminals of the ESP32 microcontroller must not go above 5v, next, we installed a voltage divider to lower the voltage to avoid unbuttoning the ESP32 microcontroller. The value of resistors R1 and R2 are calculated to identify the two conditions (the maximum voltage at the microcontroller terminals must not exceed 5V and the maximum voltage of the PVs equal to 42V) ie R1=1kΩ, R2=12KΩ. The voltage value at pin R2 is measured by ESP32 pin number 34 see Fig. 4. Other hardware elements are used, an LCD display to display the measured quantities like the current intensity value, voltage, power, energy. Finally, we have a rectangular photovoltaic panel with an area equal to 1.6 m<sup>2</sup>.

#### D. Comparison of Wireless Techniques

Table I, summarizes a comparison between five standard wireless technology, Bluetooth, RF 433MHz, ZigBee, and WIFI, therefore, the association standards, power consumption, bandwidth and throughput are represented in table1[32].

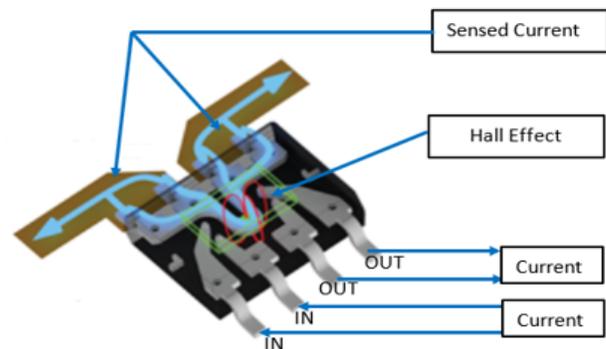

Fig. 2. Designation of the pins of the ACS712 sensor

TABLE I. COMPARISON BETWEEN STANDARD WIRELESS TECHNOLOGIES

Technologies	RF	WI-Fi	BlueTooth	ZigBee
Standards Association	IEEE 802.15.4	Low	433 MHz	4-9 Kb/s
Energy consumption	IEEE 802.11	High	2.4GHz	---
Frequency	IEEE 802.15.1	Low-High	2.4GHz	<24 Mbps
Debit	IEEE 802.15.4	High	2.4GHz	<1Mb/s

E. Formula Evaluation

To carry out this study, we chose an open area characterized by the absence of obstacles which can negatively influence the propagation of UHF waves, this place is also characterized by the absence of radio emissions on the 2.4 GHz frequency so no interference phenomenon, the weather conditions are very favorable with a very clear sky and a temperature of 29C. At first, we studied the aspect of propagation of UHF radio waves which constitutes a principle of bidirectional exchange for Bluetooth technology on a frequency band of 2.4 GHz, therefore, we studied the attenuation of these UHF waves to reduce obstacles and unwanted effects that can negatively influence the UHF signal coverage area. Note here that the undesirable epiphenomena of Ultra High Frequency wave attenuation are defined by Eq. (1) in [33], [34].

$$PL_{dB} = 10 \log_{10} \left( \frac{p_t}{p_r} \right) \quad (1)$$

- PLdB : Wave attenuation in dB,
- pt : Transmitted power
- pr : received power

Note that the distances related to attenuation are well determined, Fig. 3 presents this attenuation corresponding to ultra-high frequency waves (UHF)

In practice, in the UHF signal damping equation in dB, a coefficient is added to determine a true ratio between the acquired power P and the separation distance d, this coefficient is denoted by n and equation (2) in [36] represents this mutation (n: path factor , n=2 free space, X<sub>δ</sub>: Gaussian random variable, δ: standard deviation).

$$PL(d) = x_{\delta} + PL(d_0) + 10n \log_{10} \left( \frac{d}{d_0} \right) \quad (2)$$

In the field of telecommunications and signal transmission, the Friis Eq. (3) explains an interesting relationship between the distance d between the transmitter and the receiver in a free space, as well as the power and the antenna gain [37].

$$\frac{p_r}{p_t} = G_t G_r \frac{\lambda^2}{(4\pi d)^2} \quad (3)$$

- P<sub>t</sub>: Power delivered by the transmitter (W)
- P<sub>r</sub>: Power delivered by the receiver (W)
- G<sub>r</sub>: Receiver Gai

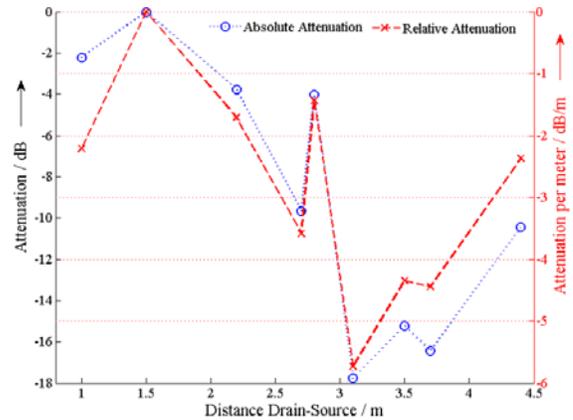

Fig. 3. Attenuation of UHF wave determined in time domain [35]

- G<sub>t</sub>: Transmitter Gain
- λ: Signal Wavelength
- d: Distance between (transmitter, receiver).

Scientifically, an important interpretation allows to exchange enormously to believe that the free space attenuation is proportional to the square of the frequency. Therefore, these expressions appear only in formulas where the antenna gain expression is represented. On the other hand, this help has totally disappeared the condition where we have antennas with a fixed surface. [38]. It is therefore concluded that the antennas are the cause of a loss of gain due to non-compliance. Equation (4) represents this effect.

$$\frac{p_r}{p_t} = G_t G_r (1 - |s_{11}|^2)(1 - |s_{22}|^2) \left( \frac{\lambda^2}{(4\pi d)^2} \right) \quad (4)$$

- s<sub>11</sub>/s<sub>22</sub>: reflection coefficients on the transmit/receive antenna.
- Gr/Gt: Receiver/Transmitter Gain
- λ: Signal Wavelength
- d: Distance between (transmitter, receiver).

F. The Main Design Proposal

In this section, we will develop the main diagram of our realization, as well as the advantages which draw the strong point of this monitoring system.

- The design and implementation are very easy.
- The use of data transfer via a low-consumption Bluetooth link and very useful in places far from communication networks (absence of GSM and Internet for example).
- Wireless monitoring – secure and reassured data exchange.

We have proposed the following general scheme for measuring current and voltage, in order to calculate power and energy, see Fig. 4. These four values will be sent via a low-power Bluetooth link that we must create in the next section.

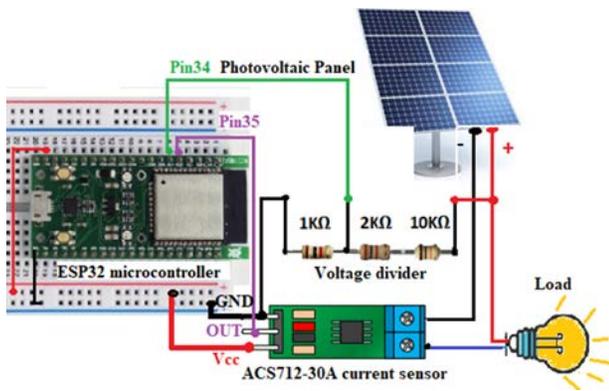

Fig. 4. Main design diagram

In this section, the main diagram of this study is proposed. It was started by measuring the current intensity with the ACS712-30A sensor at the level of pin35 of the Esp32 microcontroller, see Fig. 4. After an aid to lower the potential difference was developed, thanks to a voltage divider so as not to exceed the 5v threshold which represents the maximum voltage that the Esp32 microcontroller can support. The measurement is therefore carried out at the resistance level R2, therefore, the pin34. Note that to know the voltage between the terminals of the photovoltaic panel, the mesh law and Ohm's law was used. And finally, the values of the voltage (V) and the current (I) we used to calculate in an exact way the two other parameters: the instantaneous power (P) and the energy (E).

#### G. Creation of the Bluetooth Link

The classic HC-05 and HC-06 external modules are outdated despite the simplicity of integration in IoT projects, these two modules have major drawbacks, such as large power consumption, another thing is that these two modules use the old Bluetooth V2.0, this is a heavily outdated version. To remedy this problem linked to high energy consumption, the Esp32 was used because the Bluetooth module is integrated into the body of this microcontroller by the manufacturer. The choice to use an Esp32 is highly difficult because it is characterized by a flow rate of around 1Mb/s and the consumption will be reduced 10 times thanks to the new cell construction technology [39]. In the main code, to establish and ensure a connection via Bluetooth Low Energy, first the BluetoothSerial.h library was declared; this library comprises all the functionality necessary to guarantee the serial connection via Bluetooth technology. Subsequently, the declaration of a BluetoothSerial class object is mandatory, this object is called SerialBT.

To initialize the Bluetooth module, it is must to interact with this SerialBT object. To listen to the client connection event, in the second step the callback function and the void setup() function should be configured. Still in the code, started the serial communication with a rate equal to 115200 baud, naming the begin() method on the BluetoothSerial object allows us to initialize the Bluetooth interface. It receives the name of the Esp32 microcontroller as input, in our realization "ESP32\_iosm". Finally in the void loop() function, a verification of the reception of data via the Bluetooth module. The working process of our study is shown in Fig. 5.

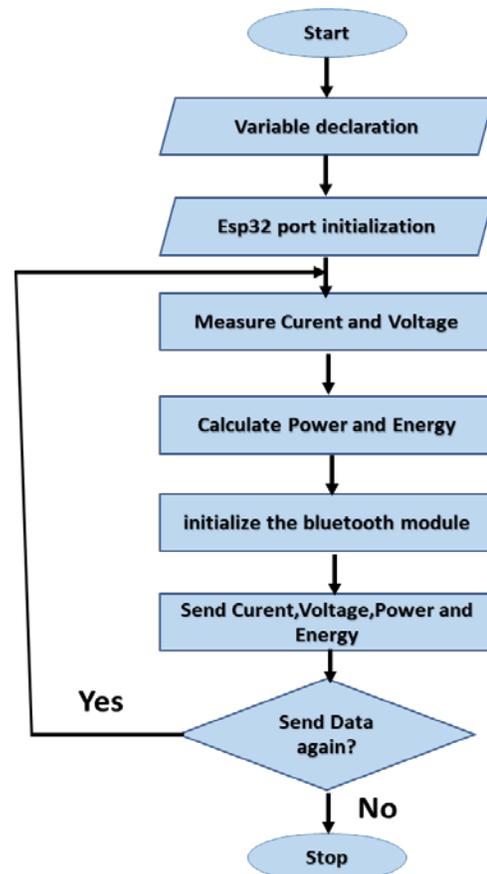

Fig. 5. Operation process flowchart

#### IV. RESULTS AND DISCUSSION

This achievement has been implemented correctly, see Fig. 6 , the transfer of data via this Bluetooth link is a good affirmation of this success, the screenshots in Fig. 8 and Fig. 9 express and describe in real time the quantities transmitted ( Energy, Power, Voltage and Current).

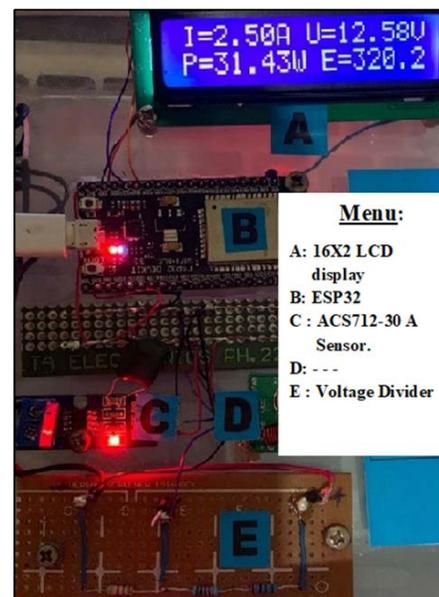

Fig. 6. Practical realization of the study[29]

A. Experimental Results

The Arduino Integrated Development Environment (IDE) was used to compile and upload the code, our Esp32 microcontroller will be immediately recognized and detected by other Bluetooth devices under the name we assigned in the previous section “ESP32\_iosm”, see Fig. 7.

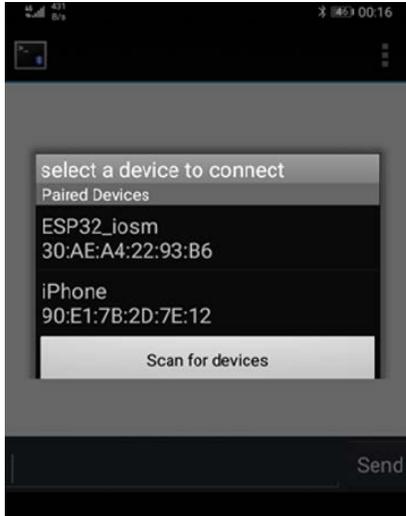

Fig. 7. Detection of the Esp32 microcontroller on smartphone

A new COM port will be available to perform the pairing when the pairing action is completed. After a discovery operation, Fig. 8 exposes on a smartphone the data received as a result of a low-power Bluetooth communication.

Fig. 8. Receiving data on a smartphone

The different experimental results are grouped in Table II, these results imprint the first five loops of this achievement, these values are displayed in real time on the serial monitor of our microcontroller, see Fig. 9.

TABLE II. MEASUREMENT- EXTRACT

Loop number	Current (A)	Voltage (V)	Power (W)	Energy (Ws)
1	1.53	14.59	22.33	102.70
2	2.68	14.63	39.29	141.99
3	1.53	14.62	22.49	164.42
4	1.46	14.60	21.37	185.79
5	1.52	14.60	22.17	207.96

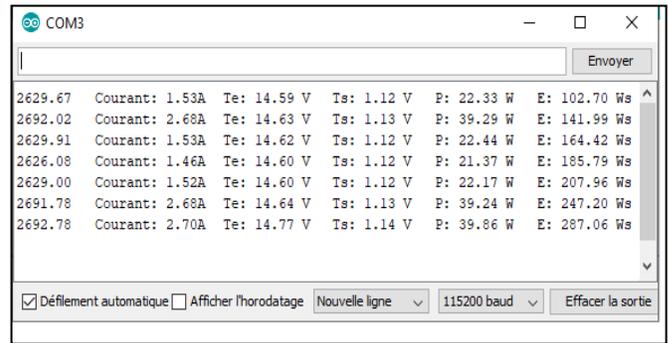

Fig. 9. Preview of the result on the serial monitor

Finally, to facilitate the comparison and make the data clearer in the form of representative graphs, we made use of a free "open source" web application, the TingSpeak platform, which is reserved for the realization of the Internet of Things and the embedded electronics projects, Fig. 10, we used the http protocol to collect the data to transfer the connected objects. In the Fig. 11, we have presented the variations of energy / second and Fig. 12 displays a representation of the total energy of our photovoltaic panel.

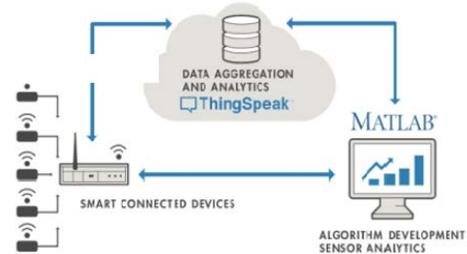

Fig. 10. TingSpeak plateforme

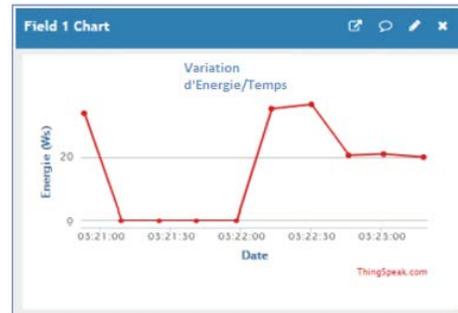

Fig. 11. Energy variations/second

Fig. 12. Energy total variation

## V. CONCLUSION

The experimental results of this study show that monitoring the main parameters of photovoltaic panels with low-power Bluetooth modules is still a good choice in isolated places, or when GSM or Internet network coverage is absent. Note that the implementation of these projects is simple, easy and not expensive. The monitoring of these parameters in real time and in distinct intervals allows us to discover and see operating strangeness. This greatly increases the credibility of the system and guarantees its proper functioning.

# Hybrid Feature Selection Algorithm and Ensemble Stacking for Heart Disease Prediction

Nureen Afiqah Mohd Zaini<sup>1</sup>, Mohd Khalid Awang<sup>2</sup>

Faculty of Informatics and Computing, Universiti Sultan Zainal Abidin,  
22000 Tembil, Terengganu, Malaysia

**Abstract**—In cardiology, as in other medical specialties, early and accurate diagnosis of heart disease is crucial as it has been the leading cause of death over the past few decades. Early prediction of heart disease is now more crucial than ever. However, the state-of-the-art heart disease prediction strategy put more emphasis on classifier selection in enhancing the accuracy and performance of heart disease prediction, and seldom considers feature reduction techniques. Furthermore, there are several factors that lead to heart disease, and it is critical to identify the most significant characteristics in order to achieve the best prediction accuracy and increase prediction performance. Feature reduction reduces the dimensionality of the information, which may allow learning algorithms to work quicker and more efficiently, producing predictive models with the best rate of accuracy. In this study, we explored and suggested a hybrid of two distinct feature reduction techniques, chi-squared and analysis of variance (ANOVA). In addition, using the ensemble stacking method, classification is performed on selected features to classify the data. Using the optimal features based on hybrid features combination, the performance of a stacking ensemble based on logistic regression yields the best result with 93.44%. This can be summarized as the feature selection method can take into account as an effective method for the prediction of heart disease.

**Keywords**—Heart disease prediction; feature selection; stacking; accuracy

## I. INTRODUCTION

The process of learning a function that maps an input to an output based on examples of input-output pairs is referred to as supervised learning in the field of machine learning. This task involves learning a function that maps an input to an output. It accomplishes this by drawing conclusions about a function based on a collection of samples from training that have been labelled [1]. In a variety of fields, including marketing, commercial applications, pattern recognition, image processing, classification, and prediction, feature selection has been utilized. It is common to encounter a sizable data collection and a high number of features while working with actual applications. Most of the time, just a few of the features are important and pertinent to the objective. Since the remaining features are viewed as unimportant and unnecessary, doing without them would not only affect performance but also classification accuracy. As a result, choosing a suitable and compact feature subset from the original features is crucial to improving classification performance and accuracy as well as overcoming the curse of dimensionality. To determine the importance of attributes, feature selection techniques are employed, and the aim is to

minimize the number of input variables to those demands most relevant to the model. Aside from minimizing the number of attributes, feature selection also reduces processing time as well.

According to [2], medical records from the National Heart Institute Malaysia (IJN) discovered between January 1, 2009, and December 31, 2018, were used in a non-interventional study that looked back 10 years. From the IJN database, there were 3923 out of 4739 eligible and used in the analysis. Another study by [3] in 2019, conducted by the Department of Statistics of Malaysia, found that heart disease was the leading cause of death in Malaysia. Representing 15% of all fatalities requiring rapid medical attention. However, heart disease can be prevented by avoiding dangerous factors. In machine learning, varieties of algorithms such as supervised, unsupervised, semi-supervised, reinforcement, and transduction, are frequently employed. Supervised learning is the ability of an algorithm to synthesize knowledge from previously labelled data in order to predict future unlabelled cases [4].

In this study, 13 attributes from the UCI dataset are used for the experiment to determine the cause of heart disease. Nevertheless, not all attributes are useful, and a feature selection method is needed to prove the only important cause of heart disease. The choice of attributes based on the feature selection method might vary depending on the feature selection method used. The prediction of heart disease can be detected based on symptom from patients which make the specialist's task easier. When we talk about predicting heart disease, we should note that prediction is one of the applications of machine learning that is utilized frequently. With the assistance of machine learning, data mining is quickly becoming an essential part of the healthcare industry by employing classification and prediction techniques which are used to generate models that describe necessary classes [5].

It is commonly held risk factors such as age, sex, chest pain type, trestbps, chol, fasting blood sugar, restecg, thalach, exang, oldpeak, slope, number of major vessels, and thalassemia are the major risk factors for heart disease according to the dataset used. In light of these considerations, this research employed a feature selection method to build a heart disease risk assessment model that could aid specialists in making accurate early predictions [6].

Even though several feature selection strategies have been used in decision support systems for medical datasets, there is

always the opportunity for improvement. The combination of feature selection algorithms and classifiers has to be tuned for heart disease datasets with a lot of feature space in order to deliver high performance. The proposed framework is based on a well-balanced mix of two different types of feature selection algorithms that work well together.

This study aims to propose a hybrid feature selection that combines both chi-squared and ANOVA techniques. Chi-squared is utilized for the selection of categorical features, whereas ANOVA is applied to numerical features. The research proposes to combine the highest rank from both techniques, and the five most influential features are derived from a total of 13 features. The five most influential features are then evaluated using an ensemble stacking approach to improve the accuracy of heart disease prediction.

This paper is organized as follows: Section II discovered related works consisting of accuracy achieved by the author using feature selection technique for the prediction of heart disease. Section III discusses the dataset to use for the experiment along with the feature selection technique and framework that visualize the whole process for the experiment. Lastly, section IV discussed the result obtained based on the experiment made, and in Section V, the conclusion is presented.

## II. LITERATURE REVIEW

There are several elements that lead to heart disease, however the present approaches for heart disease prediction are inadequate and need to be improved. By using reduction approaches to remove some of the redundant features, the prediction accuracy might be improved. Feature selection is a process of selecting important attributes of the dataset. Pre-processing is the main step for selecting important attributes for a certain dataset. In this research, ten base classification algorithms and three subsets of meta-models are tested for the prediction of accuracy.

### A. Filter Method

The filter method is one of the feature selection methods that independently evaluates the importance of each feature. The selected features are subsequently used as input for a model-building process.

Before induction can take place, the filter method is used to remove unwanted attributes using one paradigm which independently act[7]. Karl Pearson pioneered the use of chi-squared statistics for categorical data, but it will take some time before the asymptotic distribution of these statistics was thoroughly understood [8].

However, the valid conclusion from chi-squared depends on several assumptions such as [9]:

- 1) A cross-tabulation can be used to figure out actual frequencies. The chi-squared test should not be used for percentages or other derived statistics.
- 2) The two variables are nominal which is the categories have no natural ordering.
- 3) Independent observations.

- 4) More than 75%-80% of contingency table columns have an expected count of  $\geq 5$ , and none have an expected count of 0.

Aside from chi-squared, [10] ANOVA test is another filter-based feature selection technique used in this research. By utilizing the SelectKBest class, the `f_classif()` function is called upon to determine the most important features. SelectKBest class may be found in the scikit-learn library which employs a scoring function to assign the features with the highest score.

According to [11], Classification and Regression Trees (CART), Gradient Boosting Machine (GBM), Adaboost, K-Nearest Neighbor (KNN), Multilayer Perceptron (MLP), Stochastic Gradient Descent (SGD), Support Vector Classifier (SVC) and Naïve Bayes are tested through feature selection to find the best accuracy algorithm. CART was found to have the best accuracy with 87.65%. Four important attributes from eleven features are selected based on the feature selection. The author uses the majority voting technique to find out the best attributes and the result proved that `st_slope_flat` and `st_depression` are the best and second highest results go to `max_heart_rate_achieved`, `exercise_induced_angina`, and `cholesterol`. The authors claimed these attributes are the leading cause of heart disease.

In 2019 [12], the author uses a rapid miner as a tool to test the accuracy of each algorithm. Six algorithms such as Decision Tree, Logistic Regression, Logistic Regression SVM, Naïve Bayes, and Random Forest are tested and the result found out Logistic Regression SVM is the highest with 84.85%. However, the author did not reveal the attributes of the leading cause.

On the other hand, [13] investigated the use of principal component analysis (PCA) in clinical aspect. To measure the effectiveness of reducing infection risk among university student, a pilot study of 200 volunteers was carried out. Essential clinical parameters were identified and confirmed by medical experts. From the clinical history variables with 49 parameters, the disease was identified through the use of PCA. PCA method was utilized to confirm the weightage of risk level towards the disease in order to ensure the system possesses the highest possible level of accuracy, reliability, and efficacy. Cumulative achieved with the use of PCA is 58.288% and the author proof optimal accuracy, reliability, and efficiency to conduct mass-screening of students.

The author in [14], found the most accurate algorithm achieved 85.00% using chi-squared feature selection with the BayesNet classifier. The dataset of heart disease is tested using principal component analysis (PCA), chi-squared testing, ReliefF, and symmetrical uncertainty. The author agreed to use PCA feature extraction with IBK and the result is highest for recall at 87.22% but the accuracy is low compared to the chi-squared result. Based on the results, `cp` is categorized as the most influential feature for heart disease prediction followed by `exang`, `chol`, and `thal`. Different features are ranked differently based on which feature selection is used.

Based on the dataset, this research [15] compares several machine learning techniques and determines the most efficient classification technique. KNN, NB, decision tree (J48), and RF are four different classification algorithms and other techniques, such as SVM were used to compare with affinity degree (AD) classification. All these algorithms are then tested on three different UCI dataset. As a result, J48 demonstrates the highest level of performance when compared to the other four classifiers as the purpose of this research is to investigate the compatibility of affinity to use for classification method.

The study by [16] affirms the use of the backward feature selection technique resulted in the highest accuracy of 88.52% using the decision tree algorithm. Algorithms such as random forest, support vector machine, decision tree, k-nearest neighbor, logistic regression, and gaussian naïve bayes are tested and the decision tree outperformed the other five algorithms. They also experimented with the accuracy using ten different feature selection techniques which are ANOVA, chi-squared, mutual information, ReliefF, forward feature selection, backward feature selection, exhaustive feature selection, recursive feature elimination, lasso regression, and ridge regression. As a result, backward feature selection is the most influential feature selection technique which leads to a better result.

Research done by [17], suggested dataset of 70000 patients and 11 features are tested with the chi-squared feature selection method. Features involved in this research consist of age, gender, height, weight, systolic blood pressure, diastolic blood pressure, cholesterol, glucose, smoking, alcohol intake, and physical activity. Seven algorithms and the chi-squared method were used to filter the most influential features. The author adjusted some features of the dataset to discover the factors that have the greatest impact on cardiovascular disease which resulted in weight and height as the most influential cardiovascular disease. As a result, Multi-Layer Perceptron achieved the highest accuracy with 87.23%.

The authors of the research [18], proposed two different datasets and use a feature selection technique to find the best features. The author also tested the ensemble classifier with a sampling technique to find the best accuracy. ANOVA is one of the feature selection techniques used by the author to find the best features for improved accuracy. The study [19] suggested a model predict numerous diseases as there are very few suggestions made about the detection of numerous diseases. The author takes into consideration conditions such as heart disease, diabetes, and kidney disease. There are only a few features in the dataset that will not affect how well the prediction system works and only important features will be taken into consideration for the decision-making. Chi-squared and ANOVA are applied to trace out the best features from the dataset. Exang, cp, ca, oldpeak and thalach are chosen as the most influential features.

A study conducted by [20], shows the size of the dataset increase as the complexity of the model increases. Classification and regression fields are tested respectively in this research for comparison purposes as they might be a potential resource for the researcher to decide on appropriate

algorithms. Chi-squared as one of the feature selection methods is used for categorical, ordered with missing values, and ordered without missing values. The major benefit of chi-squared is, it decreases computing complexity through the merging procedure by decreasing the number of categories for each predictor.

Recently, [21] developed a heart failure survival prediction model with the help of an ensemble tree machine learning approach. Extreme Gradient Boosting (XGBoost) was demonstrated as the most accurate classifier with 83.00%. During the pre-processing stage, the unimportant feature will be removed to obtain better accuracy. The author uses ANOVA and chi-squared to analyze numerical and binary features, respectively. The most influential features consist of anemia, time, ejection\_fraction, and serum\_creatinine but 'time' features are counted as the highest contribution for the improvement of accuracy.

A comparison of the result obtained shows that different authors came out with different results. The highest accuracy achieved based on past work is 88.52% from the decision tree. Thal features can be categorized as the most influential features seems all the experiments conducted with feature selection show that thal ranked the most among other features. As will be shown in succeeding sections, we analyze and present a comparison with our feature selection technique together with the result of accuracy for heart disease prediction.

### III. METHODOLOGY

This study is based on the UCI dataset of heart disease which consists of 303 datasets and 13 attributes. The original attributes consist of age, sex, cp, trestbps, chol, fbs, restecg, thalach, exang, oldpeak, slope, ca, thal, and target. Data dictionary in Table I will explain further the attributes involved.

TABLE I. DATA DICTIONARY FOR INVOLVED FEATURES

Feature Name	Data Description
X <sub>1</sub> = Age	age
X <sub>2</sub> = Sex	1=male, 0=Female
X <sub>3</sub> = Cp	chest pain type: Value 0=typical angina, Value 1=atypical angina, Value 2=non-anginal pain, Value 3=asymptomatic
X <sub>4</sub> = Trestbps	resting blood pressure
X <sub>5</sub> = Chol	serum cholesterol in mg/dl
X <sub>6</sub> = Fbs	(fasting blood sugar > 120) 1=True, 0=False
X <sub>7</sub> = Restecg	resting electrocardiographic results: Value 0=normal, Value 1=having ST-T wave abnormality, Value 2=showing probable or definite left ventricular
X <sub>8</sub> = thalach	max heart rate achieved
X <sub>9</sub> = Exang	exercise induced angine: 1=yes, 0=no
X <sub>10</sub> =Oldpeak	ST depression
X <sub>11</sub> = Slope	slope of peak exercise:Value 0=upsloping, Value 1=flat, Value 2= downsloping

$X_{12}$ = Ca	number of major vessel(flourosopy)
$X_{13}$ =Thal(Thalassemia)	0 = error (in the original dataset 0 maps to NaN's),1 = fixed defect,2 = normal,3 = reversable defect
Y= Target	0 = no disease,1 = disease

Cases of heart disease and non-heart disease are extracted from the dataset and displayed visually.

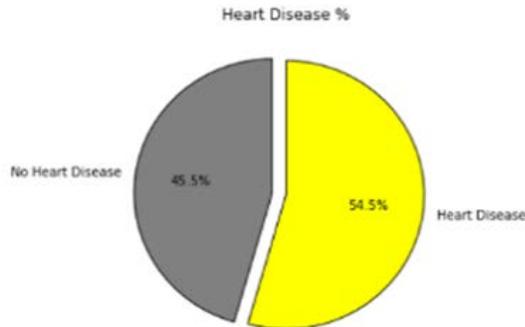

Fig. 1. Data visualization of heart disease and non-heart disease patients

According to Fig. 1, 54.50% of patients suffer from heart disease and the remaining 45.50% are free from heart disease.

The execution is accomplished using the following procedures:

- 1) UCI Cleveland dataset is obtained
- 2) Data visualization is performed
- 3) Dataset is divided into testing and training data
- 4) Applying algorithms method for training
- 5) Train the model
- 6) Heart disease prediction based on accuracy obtain

From the UCI dataset, 80% of the dataset has been assumed as training input for machine learning methods, and the model has been fitted accordingly. The remaining 20% is test data for predicting heart disease [22].

### B. Pre-Processing

Dimensionality reduction is a pre-processing procedure that can eliminate irrelevant data, noise, and redundant features to improve the accuracy of learning features and save training time [23]. Data pre-processing often encompasses the following task [24]:

**Data cleansing:** The first stage in data cleansing is identifying mistakes and inconsistencies in the database by evaluating the data. In other words, this phase is known as data audits and will identify all forms of database irregularities [25].

**Normalization:** Initially, pre-processing is not only a method for transforming raw data into a clean dataset but it also improves the performance of machine learning. By way of explanation, if data is acquired from various sources, it is collected in a raw format which is incompatible with analysis and machine learning [26].

**Feature discovery:** Feature discovery is one of the pre-processing methods which is the data filtered from the pre-

processing section. The advantage of feature discovery is extracting meaningful data from identified correlations of patterns [27].

**Management of imbalance data:** An example of an issue known as imbalance data classification is when the proportional class size of a dataset differs significantly by a significant margin from one another. From this, a group of a small number is represented as a minority class and the remaining belong to the other group represented majority class [28].

### C. Feature Selection

Attribute or feature selection is a data reduction method that is applied to the dataset. This method decreases the size of the data by eliminating unnecessary or duplicate attributes. Methods for selecting features subset can be broken into four distinct categories which are the embedded method, wrapper method, filter method, and hybrid method [29]. In our research, the features are divided into numerical and categorical which is the filter method applied. As it operates independently from the induction algorithm, this method is faster than the wrapper approach and produces a better generalization. However, the chi-squared method favours selecting a subset with a large number of features, necessitating a threshold to select a subset [30].

According to [31], it is found that the filter approaches are effective, scalable, computationally straightforward, and independent of the classifier. In this research, categorical features consist of sex, fb, restecg, exang, slope, ca, thal and target while age, trestbps, chol, thalach, and oldpeak are numerical features. Chi-squared is used to generate categorical features and ANOVA is tested for numerical features. Both methods generate the features according to rank based on the importance of each feature. The Table II below shows the selected features for categorical and numerical features.

TABLE II. SELECTED FEATURES FOR CATEGORICAL AND NUMERICAL

Feature Selection	Selected Features
Categorical	$X_{12}, X_3, X_9$
Numerical	$X_8, X_{10}$

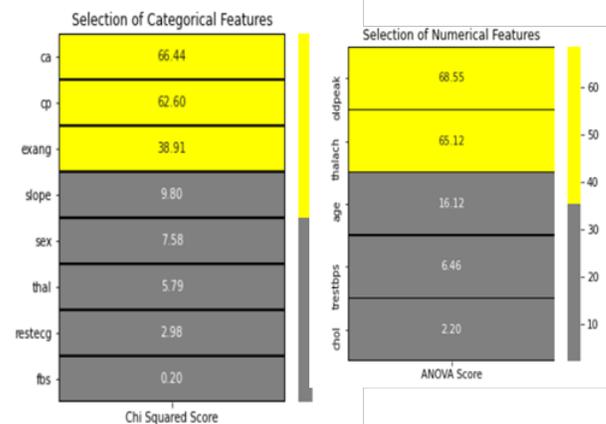

Fig. 2. Ranked each feature selection method for categorical and numerical features

Fig. 2 depicts the ranking of the involved features based on their importance. Ca, cp, and exang counted as the highest rank tested with chi-squared for categorical features while oldpeak and thalach counted as the most influential features for the numerical group using the ANOVA score.

#### D. Chi-Squared

Chi-squared is one of the techniques for categorical types of data. The chi-squared test determines if two categorical variables are significantly associated. Two-sided chi feature selection is tested between each categorical and binary outcome with a p-value. The features are retained with two-sided  $p < 0.05$  [32].

Several steps involved in the chi-square process are explained as follows [33]:

Step 1: All features from the original dataset are selected.

Step 2: Utilize the chi-squared () function from the scikit-learn to figure out whether the two features are independent or not. Use (1) to find the chi-squared score for each of the following features.

$$X^2 = \sum \frac{(f_o - f_E)^2}{f_E} \quad (1)$$

Step 3: The value with the highest chi-squared value probably relies on the target feature and is therefore selected for model creation. SelectKBest() was utilized to choose the five features with the highest chi-squared value.

Step 4: The next step is to determine a threshold to construct a subset for the number of features represented by n. The optimal number of features with the highest Chi test score is utilized based on the top five ranking features. In this research, five features with the highest Chi test score are tested to create the original feature subset.

According to [34], the strategy for the chi-squared method is incrementally adding important characteristics to the feature subset. At each level, this method will determine the significance threshold and discards features that fall below it. As a result, the chi-squared strategy is more efficient than similar step-wise selection methods. Most of the studies prove the use of the chi-squared method among other feature selection methods improves most of the classifiers' performance and accomplishes outstanding results [35].

Based on [36], up to 1900, the evolution of the chi-squared test process can be divided into six stages. Six related stages included:

- 1) From the multivariate error law to the multivariate normal distribution.
- 2) Exponent distribution in multivariate normal density.
- 3) Multinomial distribution approximation by multivariate normal density.
- 4) Evaluation of the exponent when the moment is multinomial.
- 5) The definition to which probability refers.
- 6) Provision for the effect of estimating an undetermined parameter.

#### E. ANOVA

Analysis of Variance (ANOVA) is another technique used for the classification method. ANOVA is tested for numerical feature from the dataset and the ratio between variances from two different samples are formulated [33]. For completion of the ANOVA technique, the below step is applied [33]:

Step 1: All features are selected from the original dataset

Step 2: The target feature function from scikit-learn is calculated using ANOVA F-score for each feature. Below (2), (3), (4) are the following formula to calculate ANOVA.

$$F = \frac{\text{variance between groups}}{\text{variance within groups}} \quad (2)$$

$$\text{Variance between groups} = \frac{\sum_{i=1}^n n_i (\bar{Y}_i - \bar{Y})^2}{(k-1)} \quad (3)$$

$$\text{Variance within groups} = \frac{\sum_{i=1}^k \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2}{(n-k)} \quad (4)$$

Step 3: The result from the test is used to perform feature selection which enables the removal of features that are unrelated to the target variable. The most influential features with the lowest variance are chosen in the experiment and tested with SelectKBest(); K represents the number of features for the final dataset.

Step 4: The number of features(n) with the highest ranking is used to create various feature subsets.

Research conducted by [37], shows the use of ANOVA can enhance the accuracy which is a 9.1% increase from 72.70%.

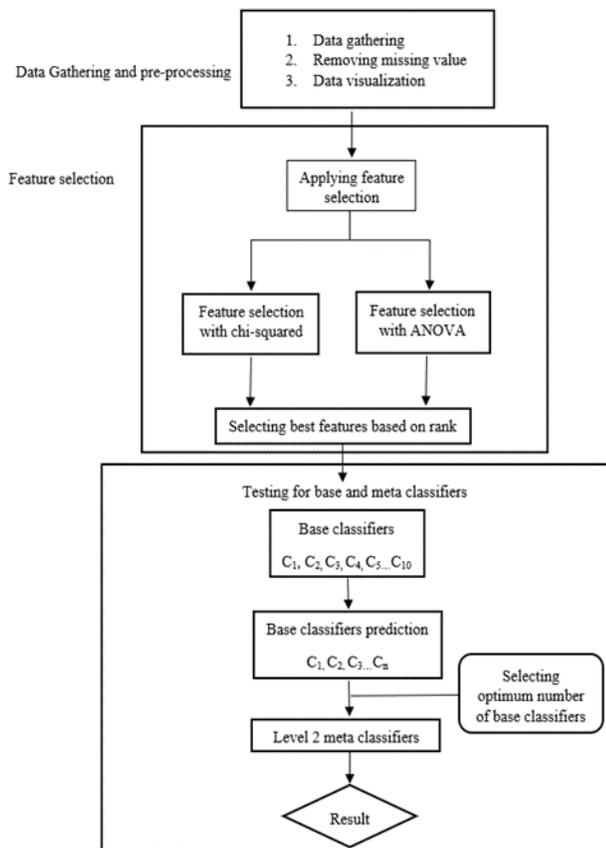

Fig. 3. Proposed framework for feature selection method

About Fig. 3, several steps are applied including data gathering and pre-processing before feature selection is applied. 13 attributes from the dataset are extracted to remove the missing value and visualize the data accordingly. Before we go deeper for base and meta classifiers, the feature selection method is applied to the data. Feature selection with the chi-squared technique is applied for categorical features while the ANOVA technique is applied for numerical features. Accuracy is tested for each feature selection method and the best accuracy is selected before we filter the important features. From the experiment made, five important features have been sorted out.

The data are then tested for base and meta-classifier methods. Ten base algorithms consisting of logistic regression (LR), support vector classifier (SVC), random forest (RF), extra tree classifier (ETC), naïve bayes (NB), extra gradient boosting (XGB), decision tree (DT), k-nearest neighbor (KNN), multilayer perceptron (MLP), and stochastic gradient descent (SGD) is tested and result obtained is used to find the optimum number of base classifiers. Then, meta-classifiers are applied for MLP, LR, NB, and SVC algorithms.

#### IV. RESULTS AND DISCUSSION

The proposed work is using the chi-squared method for categorical features and ANOVA for the numerical feature. 13 features from the UCI dataset are reduced to five features and tested accordingly. Highly rank of features are tested using the required method and there is an improvement in terms of accuracy for each algorithm.

Table III will further explain the involvement of five attributes for chi-squared and ANOVA and the achieved accuracy for each feature selection method.

TABLE III. FIVE CHOSEN ATTRIBUTES FROM CHI-SQUARED AND ANOVA

Selected attributes	Data Dictionary
$X_{12} = ca$	Number of major vessels
$X_3 = cp$	Chest pain type: Value 0= typical angina, Value 1=atypical angina, Value 2=non-anginal
$X_9 = exang$	exercise induced angine: 1=yes, 0=no
$X_{10} = oldpeak$	ST depression
$X_8 = thalach$	max heart rate achieved

Chi-squared and ANOVA technique feature selection was the focus of the subsequent testing phase. Ca, cp, exang, oldpeak, and thalach was chosen as the first five attributes selection which is superior to those of another feature selection algorithm.

Accuracy tests for both the base and meta classifiers using these five features and the result show an improvement from the accuracy of base classifiers. Results for both techniques of feature selection which are chi-squared and ANOVA are contracted in the following table.

TABLE IV. ACCURACY OF CLASSIFIERS BEFORE AND AFTER FEATURE SELECTION IS APPLIED

Algorithms	Feature selection					
	Base Classifier	Base classifier (after FS applied)	Meta classifier	Meta-classifiers (after FS applied)		
LR	85.24	91.80	90.16	93.44		
RF	83.60	86.89				
KNN	81.96	86.89				
DT	72.13	81.97				
NB	85.24	88.52				
SVC	86.88	91.80			83.60	91.80
XGB	85.24	81.97				
MLP	88.52	90.16			88.52	91.80
SGD	83.60	86.89				
ETC	86.88	83.61				

From Table IV, logistic regression obtains the highest accuracy compared to the other nine algorithms. For the level 1 base classifier, 85.24% is achieved before feature selection is applied and increases to 6.56% after feature selection is applied. Level 2 meta-classifier, increase from 90.16% to 93.44%.

For SVC, the accuracy increases by 4.92% from 86.88% for base classifiers and meta-classifiers, the accuracy achieved is 91.80% from 83.60%. MLP achieved 90.16% accuracy from 88.52% for base classifiers while the accuracy spike from 88.52% to 91.80% for meta-classifiers.

Classification and regression trees (CART) have an acquired accuracy of 87.65%, according to the literature [11]. The author makes an effort to boost precision by employing feature selection and an ensemble technique. There has been some improvement, but the accuracy is still low. In the current research, we suggested the same process but with a new set of features and an alternative method of feature selection. Logistic regression was able to provide a success rate of 93.44 percent, which is an increase over earlier efforts.

## V. CONCLUSION

The main goal of this work is to develop hybrid feature selection method for heart disease prediction that combines chi-squared and ANOVA approaches. ANOVA is used to choose numerical data, whereas Chi-squared is used to pick categorical features. The involved algorithms are logistic regression, k-nearest neighbor, decision tree, random forest, gaussian naive bayes, extra gradient boosting, support vector classifier, multilayer perceptron, stochastic gradient descent, and additional tree classifier. Various algorithms are tested for base classifiers. The meta-classifier is evaluated using the logistic regression, support vector classifier, and multilayer perceptron methods. Then, feature selection techniques are used to evaluate the base and meta-classifiers.

We decided to assess the efficacy of two distinct feature-selection algorithms in this study. Chi-squared tests and analysis of variance are utilized as feature selection methods. The experimental results show that the accuracy of heart disease prediction may be improved by employing the hybrid feature selection technique.

In addition to the utilization of feature selection techniques, the selected features from the dataset are also something that have to be emphasized. The chi-squared test and the analysis of variance (ANOVA) are used to evaluate the results of the experiment regarding five characteristics, namely ca, cp, exang, oldpeak, and thalach. The logistic regression method had a performance that was 93.44% better than the other ensemble stacking techniques. Because the accuracy of the approach might change depending on the dataset that is being used, it will be possible in the future to evaluate the technique of feature selection using a variety of different datasets.

**Abstract**—The rapid growth of the Indonesian language content on the Internet has drawn researchers' attention. By using natural language processing, they can extract high-value information from such content and documents. However, processing large and numerous documents is very time-consuming and computationally expensive. Reducing these computational costs requires attribute reduction by removing some common words or stopwords. This research aims to extract stopwords automatically from a large corpus, about seven million words, in the Indonesian language downloaded from the web. The problem is that Indonesian is a low-resource language, making it challenging to develop an automatic stopword extractor. The method used is Term Frequency – Inverse Document Frequency (TF-IDF) and presents a methodology for ranking stopwords using TFs and IDF, which is applicable to even a small corpus (as low as one document). It is an automatic method that can be applied to many different languages with no prior linguistic knowledge required. There are two novelties or contributions in this method: it can show all words found in all documents, and it has an automatic cut-off technique for selecting the top rank of stopwords candidates in the Indonesian language, overcoming one of the most challenging aspects of stopwords extraction.

**Keywords**—Stopwords extraction; attributes reduction; TF-IDF; large corpus; Indonesian stopwords; NLP

## I. INTRODUCTION

Stopwords are any common words that carry low information content [1]. Despite their high occurrence, they only add a little semantic data to the document [2]. They are also referred to as negative dictionary or noise words. They cause a small retrieval degree and prediction outcomes. Since they make up a considerable portion of the documents, text-mining tasks will be very computationally intensive. This high computational cost is caused by the dimensionality curse and requires larger computer memory and computational time. Furthermore, in information retrieval experiments, it has been shown that removing stopwords improves precision significantly when compared with when they are not removed [3, 4]. Stopwords also play a significant role in feature extraction [5, 6], topic modeling [7], classification [8], ontology construction [9], and keyword extraction [10].

There are two categories of stopwords: domain-specific and general. Domain-specific stopwords are a set of words that make no discriminant value inside a specific context or domain. They differ from one domain to another domain. For example, the word “learning” could be a stopword in the education domain, or the word “machine” could be a stopword

in the machinery domain, but neither of those words is a stopword in the computer science domain. On the other hand, general stopwords are a list of stopwords or stoplists that are not specific to one domain and are usually available to download as a public domain object.

General stopwords are the most used in Natural Language Processing (NLP) because of their availability, and it takes a considerable effort to develop a domain-specific stoplist. It is easier to create a domain-specific stoplist based on a general stoplist by adding and/or removing some terms. General stoplists, however, need to be updated frequently. In addition, over time, the use of some ordinary words has altered subjects on social aspects such as industrial revolution changes, new media, cultural shifts, and education. For these reasons, reviewing, updating, and adjusting existing stoplists is essential [5]. Updating a general stoplist can be done manually, but it takes time and may omit the latest stopwords. This problem can be solved automatically by developing a general stoplist.

Researchers have developed many methods for automatically creating stoplists, especially in English, since decades ago. Since then, many methods have been developed to create English stoplists. In contrast, there are relatively few studies to develop a stoplist for non-English languages like Indonesian. The problem is that Indonesian is a low-resource language, making it challenging to develop an automatic stopword extractor.

There were only two research documents about general stopwords extraction in Indonesian [11, 12]. Those documents show 394 and 330 general stopwords extracted from Kompas daily newspaper. Both of stopwords lists extracted using Term Frequency (TF) method, it is a rare method to use in extracting stopwords. Most researchers use a combination of Term Frequency and Inverse Document Frequency (TF-IDF) in NLP. Unfortunately, TF cannot detect words that occur in all documents and cannot implement threshold to limit the number of generated stopwords.

This research paper aims to solve the problem above and develop an up-to-date general stoplist in the Indonesian language. The method used is crawling recent news from an Indonesian online newspaper's website to gather data and make the required dataset. The stopwords extraction method uses TF-IDF.

This document is organized in this way; the following section comprises a brief coverage of the present literature in the areas of automatic stopwords extraction, the methods used for stopwords extraction, and the experiments. Then we

describe the results of this research. We conclude this research document by presenting the advancement of our methods compared to previous works.

## II. RELATED WORKS

Many methods have been used to develop stoplists. Some of them are frequency-based approach [13], Bidirectional Long Short term memory (BiLSTM) [14], Word Embedding [15], Finite Automata [16], and utilizing characteristic and discriminant analysis [17]. The dataset or corpus used to extract or identify stopwords vary. Some researchers used corpus from an online newspaper [18], social network [19], or patent [20]. As the purpose of this research is to develop an Indonesian general stoplist, only relevant research papers are discussed.

There are three research papers discussing the development of the Indonesian stoplist. One of them only involves developing a cuisine-specific stoplist for the Indonesian language [12]. However, since this research aims to develop a general Indonesian stoplist, only the other two papers are reviewed further here based on their proposed method.

Fadillah Z Tala, in his master thesis [11], proposed an Indonesian stoplist because there was no Indonesian stoplist that could be used in his experiment in information retrieval. In his work, he created the dataset based on articles from the “Kompas daily” newspaper. He downloaded the articles every day for one year long, starting from the beginning of January 2001 until the end of December 2001. The total number of articles was 3160. The result of his experiment was 394 stopwords in Bahasa Indonesia.

Yudi Wibisono has created a stoplist in his coursework [12]. As the source of his dataset, he also used articles from the “Kompas daily” newspaper. He used several hundred articles to create 330 stopwords. The method used was Term Frequency, like Tala’s work, but he removed some words manually.

Tala and Wibisono used the Term Frequency (TF) method to extract stopwords in their work. These days, Term Frequency-Inverse Document Frequency (TF-IDF) is another method that is generally used in information retrieval systems. TF-IDF is one of the traditional methods based on statistics [21]. It has been used in many different applications, such as document clustering [22], text classification [23], detection of domain name generation algorithms [24], and comparing research trends [25]. Term frequency or word frequency is a rarer method used in information retrieval systems compared to TF-IDF.

## III. METHODS

Different methods were used in each stage of this research. As shown in Fig. 1, the steps for this study were differentiated into three stages: data gathering, pre-processing or data cleaning, and stopwords extraction.

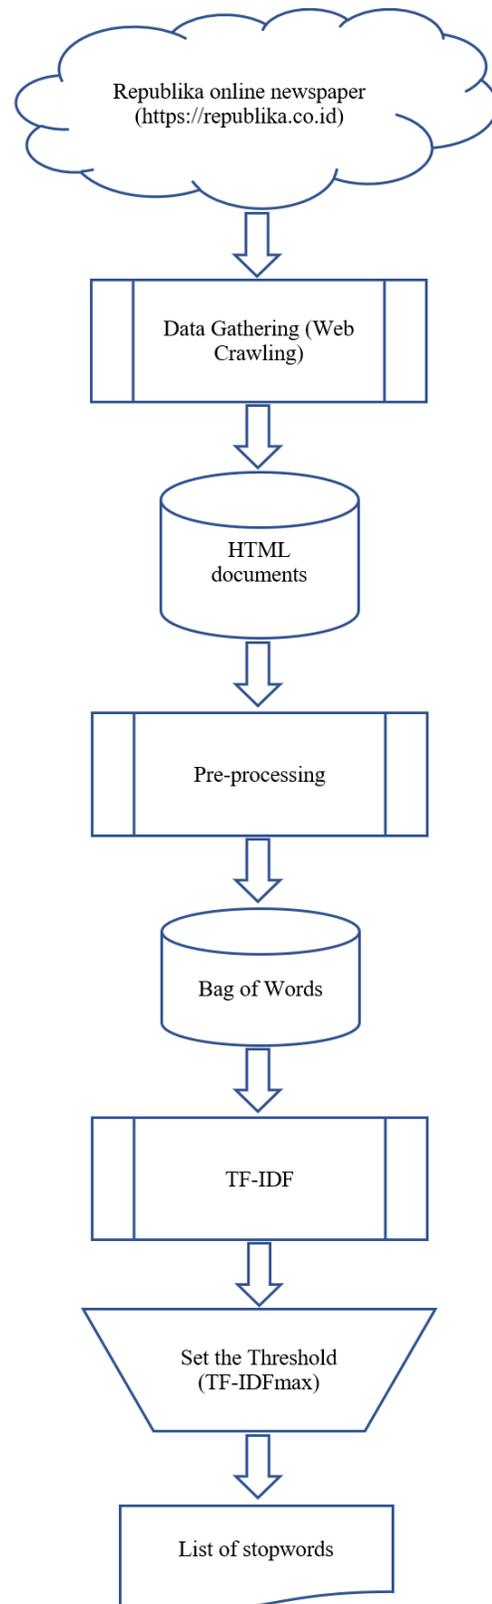

Fig. 1. Steps for this study

This work is different from the previous studies in some stages. First, the data source in the data gathering stage of this research is crawled from the “Republika daily” newspaper, whereas the previous studies used data from the “Kompas daily” newspaper. Moreover, in their studies, they used Term Frequently (TF), but in this work, we used the TF-IDF method, a combination of the Term Frequently and Inverse Document Frequency methods.

#### A. Data Gathering

The dataset or corpus for this research was gathered from Republika, an Indonesian online newspaper. The method used to gather the data was “Focused Web Crawling” [26, 27]. “Focused Web Crawling” is a method to download or harvest particular data from websites, commonly from one website. The crawler was developed using Python programming language to crawl web addresses from the Republika website. There were 6111 articles downloaded, containing 6,947,178 words, 87,998 of which were unique.

#### B. Pre-Processing

Pre-processing is a required process to clean the dataset. Some steps in pre-processing are case folding, HTML tags removal, special characters removal, tokenizing, dealing with missing data, dealing with data error, and stemming. These stopwords extractions implement pre-processes are as follows:

- Case folding: Converting characters from uppercase to lowercase. The fastest and simplest way is entirely changing words to lowercase, including words occurring in a sub-title or title and words at the beginning of a sentence. Since some papers used uppercase for *Term Frequency* and others used lowercase *term frequency*, so in our research, we converted all words into lowercase, which means that we treat those two phrases as the same phrase.
- HTML tags removal: Removing all HTML tags, scripts, and other metadata from HTML documents is mandatory. It returns clean texts from documents in HTML format.
- Special characters removal: It includes removing punctuations, numbers, and other non-text characters. Examples of the special characters that removed from the text are @%&+?,:;-'()[]{}|`~"0123456789.
- Tokenizing: It separates each word from documents into an array of items or a bag of words.

#### C. Stopwords Extraction

Extracting stopwords from Indonesian documents is the primary purpose of this study. The stopwords extraction from the dataset used the TF-IDF method after the pre-processing steps. Eq. (1)-(5) present this TF-IDF:

$$TF - IDF(\omega_i) = tf(\omega_i) \times idf(\omega_i) \quad (1)$$

$$tf(\omega_i) = \frac{n_{ij}}{\sum_{k=1}^m n_{kj}} \quad (2)$$

$$idf(\omega_i) = \log\left(\frac{N}{df(\omega_i)}\right) \quad (3)$$

$$df(\omega_i) = |\{j: \omega_i \in d_j\}| \quad (4)$$

where  $f(\omega_i)$  is frequency of occurrence of term or word  $\omega_i$  in document  $j$ , and  $N$  is total number of all documents in document collection  $\{d_j\}$ .  $df(\omega_i)$  indicates the number of documents contain term  $\omega_i$  in the document collection.  $n_{ij}$  is the number of occurrences of  $i$ th term appearing in  $j$ th document.  $n_{kj}$  is occurrence frequency of  $k$ th term appearing in  $j$ th document.  $|\{j: \omega_i \in d_j\}|$  is number of document consisting  $i$ th term. Getting the value of each term in every document is done by examining every term in the document collection or corpus.

For the whole document collection, corpus or dataset, the average of TF,  $tf(\omega_i)$ , is divided by the number of documents consisting of term  $\omega_i$ . Thus, the TF-IDF formula of term  $\omega_i$  for the whole document collection is:

$$TF - IDF(\omega_i) = \frac{\sum_j^N tf(\omega_{ij})}{df(\omega_i)} \times idf(\omega_i) \quad (5)$$

## IV. EXPERIMENTS

Several experiments have been done to find the methods. For example, the data gathering method should be tried many times before we can harvest the data automatically. It is because the articles or documents are spread into tens of categories or sub-categories in the data source (<https://www.republika.co.id/>), such as News, Playing Games, Economics, Football, Islam Digest, or International. Since the structure of these web pages was not crawler friendly, we used Focused Web Crawling strategy to handle them. The data is then processed using the discussed pre-processing methods.

The pre-processing methods used were standard methods for Natural Language Processing. Our experiments regarding pre-processing proceeded smoothly. All pre-processes were done automatically by using applications developed in Python languages. The Python language was chosen because of its many machine learning libraries, especially for NLP. Later, a bag of words or an array of terms resulted from pre-processes fed into the TF-IDF method.

We used the TF-IDF formula shown in (5) to extract stopwords. Since there is no need for a training dataset, this NLP approach is categorized as an unsupervised machine learning method. It contains  $idf(\omega_i)$  that comes from equation (3). It normalizes equation (5), limiting results of  $TF - IDF(\omega_i)$  between zero and one.

If  $TF - IDF(\omega_i)$  is equal to 0, it means that the  $i$ -th word ( $\omega_i$ ) exists in all documents. Table I shows three words contained in all documents that are *republikacoid* (republika.co.id), *wib* (west Indonesian time zone), and *lainnya* (others). The greater value of  $TF - IDF(\omega_i)$  denote that the word is less significant to be a stopwords. Fig. 2 shows the correlation between  $TF - IDF_{\max}$  and the number of stopwords extracted in the logarithmic scale. This figure shows that those words are stopwords if maximum of  $TF - IDF(\omega_i)$  is equal to 1.

TABLE I. SAMPLE OF EXTRACTED STOPWORDS USING TWO DIFFERENT METHODS

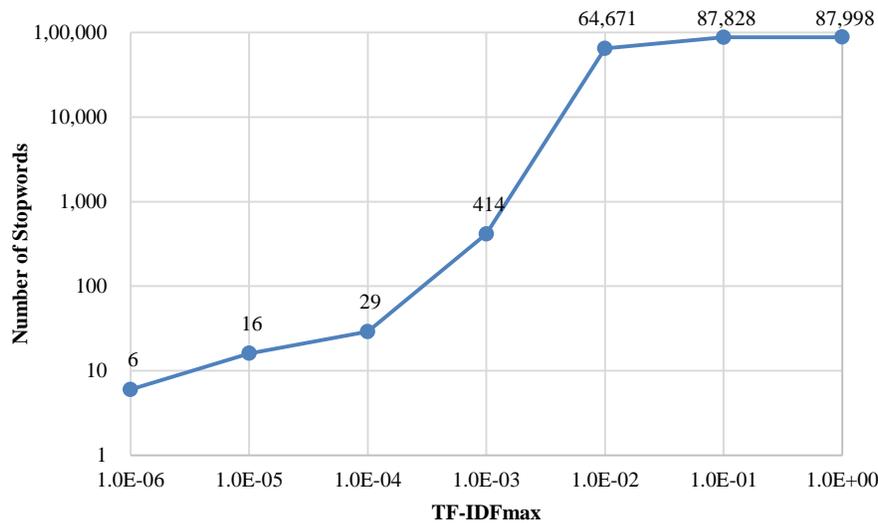

Fig. 2. The correlation of the threshold (TF-IDFmax) and the number of stopwords extracted in the logarithmic scale

## VI. RESULTS

The number of extracted stopwords using the proposed method depends on the defined TF-IDF threshold. For example, the system extracted only six stopwords for the maximum of TF-IDF  $10^{-6}$ , and 414 stopwords if the maximum of TF-IDF increased to  $10^{-3}$ . However, for TF-IDF<sub>max</sub> equal to 0.01, the number of stopwords is blown up to 64,571. The cut-off of the number of stopwords can be done by setting the value of TF-IDF<sub>max</sub>. Since the range of TF-IDF is 0 to 1, the threshold can be maintained constantly. For example, if the threshold is set to 0.001 and the number of documents doubled the number of stopwords generated by TF-IDF does not change significantly. If we only use TF to extract stopwords and set the threshold to 8,000 and double the number of documents, then the frequency of stopwords generated might be doubled, resulting in the number of stopwords changing significantly as shown in Table I under Tala's and Wibisono's method.

The extracted stoplist contains some words specific to the dataset. For example, since the dataset or document collection source is *Republika* online daily newspaper, then there are some words with TF-IDF equal to zero. It means that those words occur in all documents. Table I shows the sample of extracted keywords from the same document collection using two different methods. Results in the left column are based on the previous researcher's method, and the right column is based on the method proposed in this work. As shown in this table, other methods can not reveal words that occurred in all documents.

Analyzing the top 100 extracted stopwords shows that the method used in this research, TF-IDF, is better than the previous methods. First, this research output can reveal the words that occur in all documents and place it in the top ranks, while the old method can reveal only two words and place them in ranks 17 and 26. Second, TF-IDF method can expose all words in the sentence "copyright ... all right reserved" that occur in most of the documents, where the old method cannot reveal any of those words.

## VII. CONCLUSIONS AND FUTURE WORKS

Stopwords extraction using TF-IDF has three advances compared to TF. First, it can detect words that occur in all documents with TF-IDF equal to zero. Second, it can implement threshold to limit the number of generated stopwords. Third, it can expose all words that occur in most of the documents and place it in the top ranks.

This research can be improved for future works in two ways. First, the documents in the corpus should be classified by its domain because stopwords for one domain are different from other domains. Secondly, develop a recommender system, a web-based application for the stopwords extraction that can be accessed by public.

**Abstract**—For a long time, researchers have been working to predict the effort of software development with the help of various machine learning algorithms. These algorithms are known for better understanding the underlying facts inside the data and improving the prediction rate than conventional approaches such as line of code and functional point approaches. According to no free lunch theory, there is no single algorithm which gives better predictions on all the datasets. To remove this bias our work aims to provide a better model for software effort estimation and thereby reduce the distance between the actual and predicted effort for future projects. The authors proposed an ensembling of regressor models using voting estimator for better predictions to reduce the error rate to over the biasness provide by single machine learning algorithm. The results obtained show that the ensemble models were better than those from the single models used on different datasets.

**Keywords**—Machine learning; software effort estimation; voting; regression; evolutionary algorithms

## I. INTRODUCTION

For a given project, the effort estimation of software is always a burdensome task. For an extended period, team and finance managers strive to precisely calculate the effort, cost, and time while helping evaluate the project's schedule and budget parameters [1]. It is very tough to predict those specifications during the early stages of the project, where the scope of every module has yet to be marked, and when we still have no conclusive evidence for the ultimate functional requirements of the product [2]. Most frequently, insufficient knowledge of the affecting factors and the possible risks that can happen, or the work deadline fears, and conventional effort estimation methods [3], which are widely accepted by the opinions of various software domain experts, may sometimes lead to erroneous estimates. Because of these, the software product may not be delivered in time with the expected non-functional requirements. Though there are frequent improvements in the up-gradation of software development standards, surveys [4] show that only a quarter of the total number of beginnings is successful. These issues, which result in going beyond the budget or schedule, may lead to its termination [5]. Though the usage of agile methodology [6] reduced some concerns, project omissions are still occurring because of not having access to all the country's projects. For a country that just has a limit to its country's

projects, obtaining success in the projects is still a problem. All the managers of the project are claiming otherwise. The causes are the poor skillsets of the teams on the project and less bonding with stakeholders. There are high chances of more project success if the effort is well predicted from the beginning. But once the project's parameters are set, it's not a good idea to increase either the budget or the schedule because that could lead to risks that are hard to predict.

The client's approval for that scenario must be independent of the chosen process model for project development, time, and cost determination. For this case, some simple and easy conventional techniques that experts accept, such as PERT, CPM, etc., are primarily deployed [7]. Researchers started working on methods depending on software lines of code, and functional points as the previously mentioned techniques are vulnerable [8]. In various ways, the software parameters try to be up to date with the improved technologies. However, those techniques struggle to keep pace in the fastest-growing world, specifically with the reusability components and software dependencies that have already gone so far in their enhancement.

After considering all these drawbacks, researchers dug deep for efficient predictive techniques for effort, especially in data science areas [9]. This area is highly trusted, proving its potential with uncertain and unstructured data. Hence, it is believed that they can find the effort and duration way better than existing models. In other methods, they consider patterns in the previous data and do not rely on human influences, making them unique in their work. The factors behind this are systematic research that builds the best model for prediction to reduce the error rate for data. Biased models have been generated for some time. Their work is limited to a particular dataset, repeatedly underfitting or overfitting using varied ensemble techniques. The critical role is preparing data that has a crucial impact on the model, but divergent methods are to be used. Even the individual algorithms may not give an improved score, which is evident from various journals. The same can be repeated with effort and cost prediction when working with data and building models with those algorithms [10].

Though using all project parameters produced better results in the literature, some works included proper feature

selection strategies, eliminating irrelevant features for less computation usage and creating a unique effect with fewer features than the others. Some of them are the Genetic Algorithm [11], PSO [12], and WCO [13].

This work aims to improve the existing models on reliable machine learning algorithms for the best effort prediction. An averaging ensemble of various regressors proposes a hybrid model for this aim. Also, the proposed work conducted experiments on various datasets such as cocomo81, china, Desharnais, Maxwell, Kemerer, and Albrecht etc. to evaluate the behavior of the model with varying datasets.

## II. RELATED WORK

Amini et al. [14], in their paper combined two techniques, namely embedded and wrapper methods. The main motto of their writing is to integrate GA into regularized learning to improve prediction accuracy in regression problems. The outcome of their study reduced the dimension feature space by over 80% without affecting the accuracy. De Carvalho et al. [15] proposed an Extreme learning machine for forecasting software efforts. For selecting the best features, the Pearson correlation coefficient is used for feature selection. Extreme Learning Machines (ELM) are used with different numbers of hidden layers in their work. The ELM model values are compared with the models mentioned in the literature, namely LR, SVM, KNN, and MLP. The metric evaluated for comparison is MAE.

Ghosh et al. [16] proposed the binary variant of SFO for selecting features. This work compared ten state-of-the-art techniques and declared that BSFO based on adaptive hill climbing had shown better reliability. Carbonera et al. [17] surveyed over 120 studies and indicated that this study encouraged the researchers to minimize the space in the effort estimation. Chhabra et al. [18] worked in soft computing Fuzzy model along with PSO. This Fuzzy logic improved the existing COCOMO technique. The metric followed is MRE for result comparison. Ghatasheh et al. [19] proposed a firefly algorithm to optimize software effort. The results were better than the conventional models used earlier.

Wani et al. [20] worked on ANN and PSO. The limitation in their work is that the combination is giving better results for only the cocomo81 dataset. The ANN showed fast training speed than MLP. This method ended with lesser MdmRE and MRE than other models. Ali et al. [21] used all bio-inspired feature selection strategies with Support Vector and Random Forest regressors. The evaluation metrics considered are Correlation Coefficient (CC), Mean Absolute Error (MAE), Root Mean Square Error (RMSE), Relative Absolute Error (RAE), and Root Relative Squared Error (RRSP).

Kodmelwar et al. [22] modified a neural network for effort prediction. The proposed method uses java for the front-end tool. The metrics used for comparison are PRED, MRE, MAE, MMRE, and RE. Desai et al. [23] combined ANN with cuckoo optimization, and experiments were performed on various datasets. This hybrid combination worked well then

all other literature models except for the ACO technique. Langsari et al. [24] optimized the parameters of the COCOMO II model using particle swarm optimization. PSO is a valuable strategy for resolving dataset uncertainty and optimizing the values. The author worked on the Turkish software industry dataset.

Hosni et al. [25] concentrated on parameter tuning ensemble using grid search optimization. The authors evaluated results over seven datasets to compare statistical measures, namely mean, median, and inverse ranked weighted mean. Used three algorithms, GS, PSO, and UC-Weka, and concluded that PSO gained over other approaches. Goyal et al. [26] proposed an SG5 neural network model trained on the Cocomo dataset and tested in the Kemerer dataset. It excelled over the traditional models. Padhy et al. [27] developed an Aging and survivability-related reusability optimization model, and the software metric estimation is done with the help of UML or Class diagrams. To overcome the limitations of ANN, some different Evolutionary Computing (EC) algorithms like Genetic Algorithms, Differential Evolution, and Particle Swarm Optimization (PSO) have been proposed. By implementing the above algorithms, the regression outputs are improved so that the results are significantly accurate and most effective.

Pospieszny et al. [28] proposed ensemble averaging with a 3-fold validation, namely SVM, MLP, and GLM, to predict both effort and duration. Here used the standard ISBSG dataset and considered the MMRE and PRED metrics. In their paper, Shekhar et al. [29] discussed various software cost estimation techniques and models. The authors classified these techniques into algorithmic and non-algorithmic, which helps the software team rule out the weaker methods and provides specific areas for considering an approach.

Venkatesh et al. [30] calculated the workforce to determine the cost and effort of the project, which outperformed other models, like regression models and neural networks. This work applied to several PROMISE datasets by considering RMSE as the root metric. Nassif et al. [31] worked on four different neural networks, the oldest projects used for training and the newest projects used for testing. Here ten-fold cross-validation is achieved. The author concluded that in 60% of datasets, CCNN performed better than other models, and on 40% of datasets, RBFNN performed better than others. Miandoab et al. [32] proposed a hybrid Algorithm using a particle swarm optimization algorithm and fuzzy logic.

Dizaji et al. [33] combined Ant Colony Optimization (ACO) and Lorentz transformation as Chaos Optimization Algorithm (COA). The meta-heuristic algorithms like ACO and COA are used to estimate the cost of the software. Mean Absolute Relative Error (MARE) is taken into consideration. Here the dataset is classified and distributed among the ACO and hybrid ACO and COA algorithms according to their functionalities. The results show that the performance is improved and efficient when the ACO algorithm is combined with COA.

### III. METHOD

The proposed approach introduces a novel method of using ensemble techniques with voting for software development effort estimation. This approach combines the strengths of multiple models and leverages the diversity of their predictions to improve accuracy. By investigating the impact of different factors on the accuracy of the ensemble with voting, this approach can provide insights into how to optimize the performance of the ensemble for different datasets and problems. The proposed approach can also have practical applications for software development organizations, as it can help them to make more accurate and informed decisions about project planning and resource allocation. The proposed architecture is illustrated in Fig. 1.

- Collect historical project data: Gather historical project data including information on the size of the project, the number of developers involved, the complexity of the software, and the amount of time and resources required to complete the project.
- Preprocess the data: Preprocess the data to remove any outliers or errors, and to convert the data into a format that can be used by the ensemble models.
- Train multiple estimation models: Train multiple estimation models on the preprocessed data, such as linear regression, decision trees, neural networks, and support vector machines.
- Implement the voting algorithm: Implement the voting algorithm to combine the predictions from the multiple models. There are different types of voting algorithms such as majority voting, weighted voting, and threshold voting.
- Evaluate the ensemble with voting: Evaluate the accuracy of the ensemble with voting using a validation set of historical data that was not used during training. Compare the performance of the ensemble with voting against individual models and other ensemble techniques.
- Investigate the impact of different factors: Investigate the impact of different factors on the accuracy of the ensemble with voting, such as the number of models, the type of models, the voting algorithm, and the size and quality of the historical data.
- Apply the ensemble with voting to new data: Apply the ensemble with voting to new software development projects to assess its accuracy and reliability in real-world scenarios.

#### A. Data Preprocessing

Preprocessing of data involves data cleansing approaches. It has a clear positive impact on training the machine learning models. It reduces the dataset's noise by filling in missing values, removing duplicate records, dropping unnecessary columns, etc. Finally, it produces the data in its best representation to be used for model building. Without preprocessing, models might learn the noise as an underlying pattern, leading to overfitting or underfitting the data. Here,

we dropped some attributes in our work, such as project ids, dates of projects, other categorical details, etc. We ignored the missing data records.

#### B. Normalization

Normalization is done as a second step, and it is essential to scale the features within a range for the model's performance. This normalization sets the feature scale from 0 to 1 and is implemented using the MinMax scalar in Python. In our datasets, we normalized all the input and output features.

$$x_{new} = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

#### C. 5 - Cross Fold Validation

Cross-fold validation is an interesting technique, which makes our model more reliable. Instead of considering a particular subset for training and the remaining part for testing, it uses the entire dataset for training and testing purposes. A five-fold validation usually splits the entire dataset into five equal sets or folds, where for every time, four sets are used for training, and one set is used for testing. This process is repeated for four (k-1) iterations, i.e., all possible combinations, and it will give the average score of all iterations.

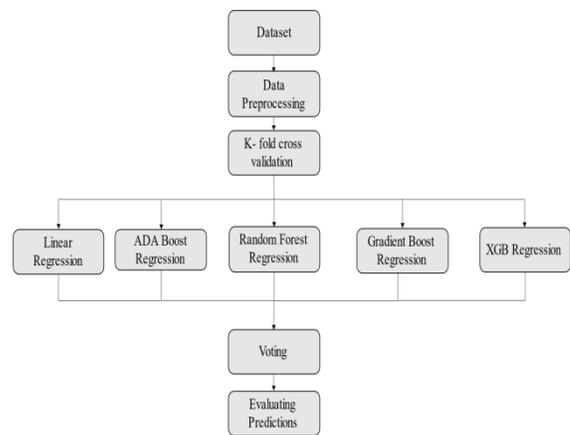

Fig. 1. Proposed architecture

#### D. Algorithms

In our work, we build a hybrid model with the help of five machine learning Regression algorithms. Each algorithm has a different structure in its implementation.

1) *Linear regression*: Linear Regression frames an equation for the given attributes to fetch the target variable. It assumes a linear relationship between the characteristics of a dataset. The equation is  $y = f(x)$ , where  $y$  represents the output variable and  $x$  is the set of input attributes. This algorithm performs better than complex models when the dataset is linear.

2) *Random forest*: Random Forest is a bagging model. It constructs several trees for prediction. Every tree is constructed from a subset of the training data. Every tree will give some effort for a test set. All predictions are averaged to

get the final estimate of how much work needs to be done, lowering the result's error rate.

3) *Boosting techniques*: Every boosting algorithm has a base model. After each iteration, a new weak learner is added to the sequence of learners; every iteration model reduces the residual effort. We implemented three boosting models in our work: Ada Boost, Gradient Boost (GB), and Extreme Gradient Boost. AdaBoost handles missing data well and undergoes no overfitting. It has fewer parameters to tune when needed and is sensitive to outliers. Gradient Boosting is a sequence of tree learners robust to outliers, depending on residuals. XGB has been showing better results than GB as it includes the calculation of similarity weights.

#### E. Voting

Every algorithm is unique in its background processing of data. Hence, all algorithms can find their patterns of data. Here comes the idea of ensembling [34]. Ensembling is obtained by combining various models. Bagging, boosting, voting, etc., are some of the ensemble approaches [35]. Here we aggregated predictions of various models, i.e., averaged the output predictions of all models and produced one model closer to the actual effort than any individual model. We took the Linear Regression, Decision Tree Regression, Random Forest Regression, Support Vector Regression, and Neural Network Regression outputs, calculated the average of all the values, and compared them with the actual effort in the test dataset. The results are given for evaluation metrics.

#### F. Pseudo Code

```
# Step 1: Collect historical project data
data = load_data()
# Step 2: Preprocess the data
data = preprocess_data(data)
# Step 3: Train multiple estimation
models
models = []
for i in range(num_models):
    model = train_model(data)
    models.append(model)
# Step 4: Implement the voting algorithm
def ensemble_predict(models, input):
    predictions = [model.predict(input)
for model in models]
    return voting_algorithm(predictions)
# Step 5: Evaluate the ensemble with
voting
validation_set = load_validation_set()
ensemble_accuracy = 0
for input, target in validation_set:
    ensemble_prediction =
ensemble_predict(models, input)
    ensemble_accuracy +=
evaluate_prediction(ensemble_prediction,
target)
ensemble_accuracy /= len(validation_set)
# Step 6: Investigate the impact of
different factors
```

```
# For example, vary the number of models,
the type of models, the voting algorithm,
and the size and quality of the
historical data.
```

```
# Step 7: Apply the ensemble with voting
to new data
new_data = load_new_data()
for input in new_data:
    ensemble_prediction =
ensemble_predict(models, input)
process_prediction(ensemble_prediction)
```

#### IV. EVALUATION CRITERIA

In problems like predicting continuous values, we calculate the error rate given as the difference between the actual and predicted values. For our problem statement, we looked at the MAE (Mean Absolute Error), MSE (Mean Squared Error), and RMSE (Root Mean Square Error) metrics, which are used to compare models.

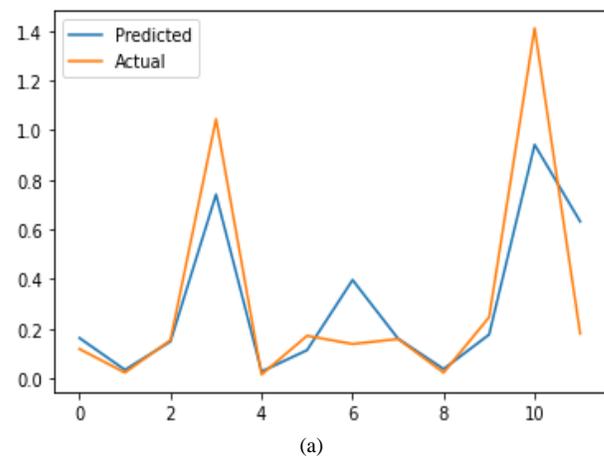

$$MAE = \frac{\sum abs(y_{actual} - y_{predicted})}{n} \quad (2)$$

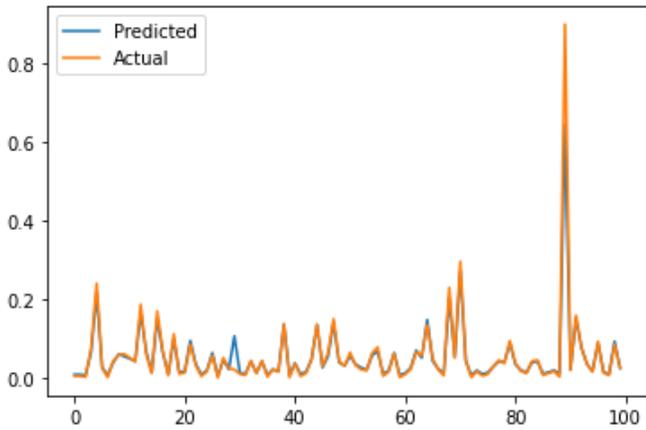

$$MSE = \frac{\sum (y_{actual} - y_{predicted})^2}{n} \quad (3)$$

$$RMSE = \sqrt{\frac{\sum (y_{actual} - y_{predicted})^2}{n}} \quad (4)$$

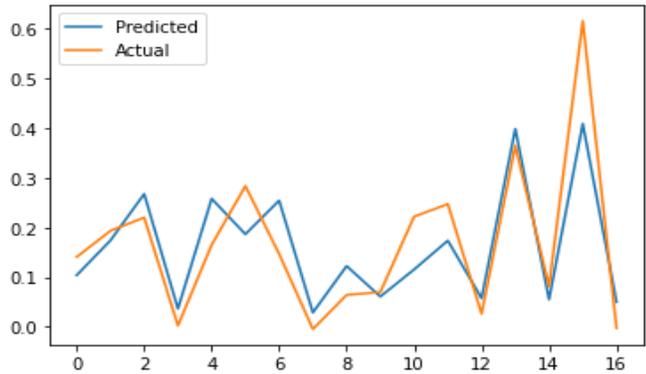

#### V. RESULTS AND DISCUSSION

Below, Fig. 2 represents the deviation between actual and predicted effort values on all datasets, where the X-axis represents the record number. The Y-axis represents the effort of the record. Fig. 2(a), 2(d) on Cocomo81 and Maxwell show a notifiable difference in peak effort values. The values are closer to the China dataset in Fig. 2(b). Fig. 2(c) and 2(f) show a constant gap between actual and predicted values. Fig. 2(e) on Albrecht shows a considerable difference.

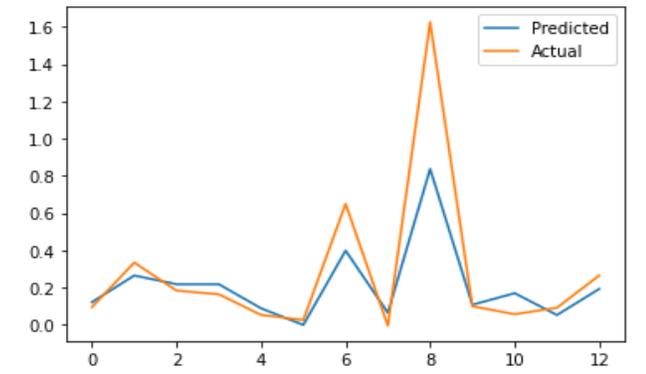

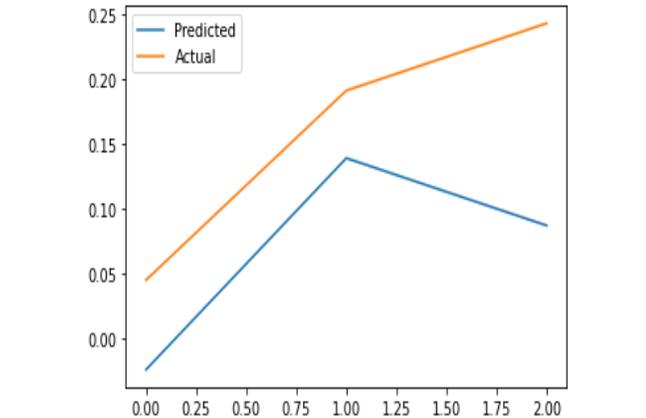

(b)

Fig. 2. (a) Cocomo81 actual vs. predicted effort (b) China's actual vs. predicted effort (c) Desharnais actual vs. predicted effort (d) Maxwell actual vs. predicted effort (e) Kemerer actual vs. predicted effort (f) Albrecht actual vs. predicted effort

Fig. 2(a) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the COCOMO81 dataset. This graph shows a noticeable difference at the peak points.

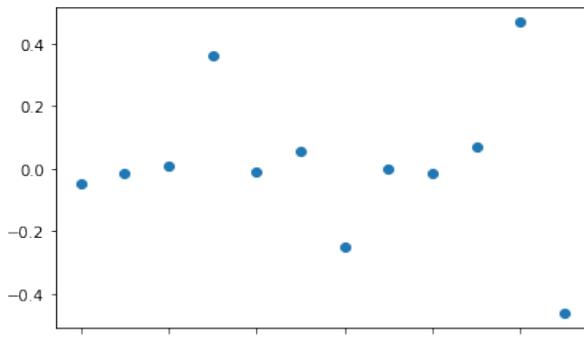

Fig. 2(b) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the China dataset. We can see that the predicted line has come close to the actual line in many places.

Fig. 2(c) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the Desharnais dataset. In this graph, records 10 and 11 have a significant deviation, whereas records 12 to 14 have the least deviation.

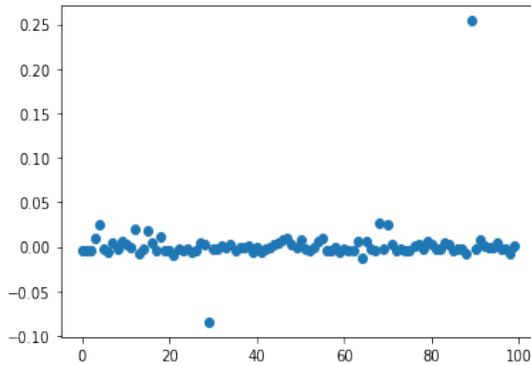

Fig. 2(d) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the Maxwell dataset. This graph shows a noticeable difference at the peak points.

Fig. 2(e) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the Kemerer dataset. As the test set records are meager, they show a significant deviation, but the deviation range is 0.05.

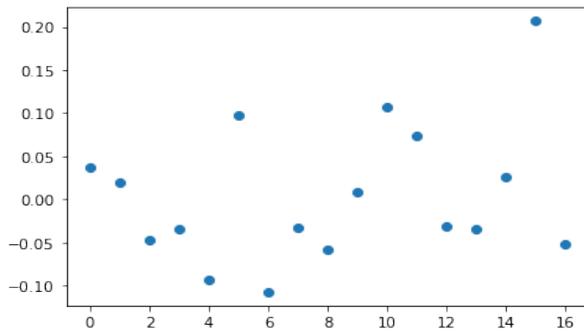

Fig. 2(f) represents a line graph drawn to show the deviations between actual effort and the predicted effort by our proposed model in the Albrecht dataset, where the X-axis represents the record number and the Y-axis represents the effort of the record. Fig. 3 represents the residuals graphs between actual and predicted effort values on all datasets. Fig. 3(a) and 3(d) on Cocomo81 and Maxwell shows a notifiable difference in peak effort values. Fig. 3(b) of the China dataset shows values closer to 0 ("zero"). Fig. 3(c) and 3(f) show a constant gap between actual and predicted values. There is a significant difference in Albrecht's Fig. 3(e).

(d)

(e)

(f)

Fig. 3. (a) Cocomo81 prediction residuals (b) China prediction residuals (c) Desharnais prediction residuals (d) Maxwell prediction residuals (e) Kemerer prediction residuals (f) Albrecht prediction residuals

The above Fig. 3(a) represents a graph that shows the residuals between actual effort and the predicted effort of the data records of the COCOMO81 dataset ranging from -0.4 to +0.4, and most of the data points are present in the range of -0.2 to +0.2.

The above Fig. 3(b) represents a graph that shows the residuals between actual effort and the prediction effort of the data records of the China dataset ranging from -0.10 to +0.25. In the presented graph, most data points are nearer to 0, indicating that the proposed model is working much more efficiently in the China dataset.

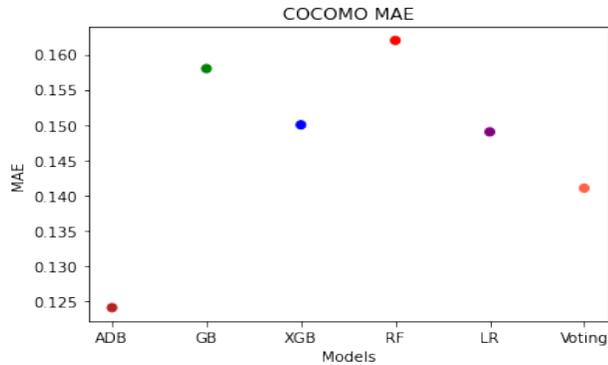

The above Fig. 3(c) represents a graph that shows the residuals between actual effort and the predicted effort of the data records of the Desharnais dataset, ranging from -0.10 to +0.20. In this graph, most of the data points are below point 0. That means the proposed model predicted values are less than the actual values.

Fig. 3(d) shows a graph of the residuals between actual effort and predicted effort of the Maxwell dataset data records, ranging from -0.2 to +0.8. According to this graph, the proposed model prediction is much closer to the actual values based on working on this dataset.

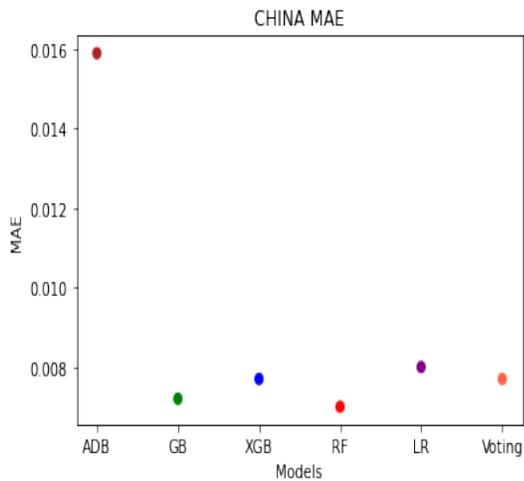

Fig. 3(e) depicts a graph displaying the residuals between actual effort and predicted effort of the Kemerer dataset data records, ranging from 0.05 to +0.16.

The above Fig. 3(f) represents a graph that shows the residuals between actual effort and the predicted effort of the data records of the Albrecht dataset ranging from -0.15 to +0.20.

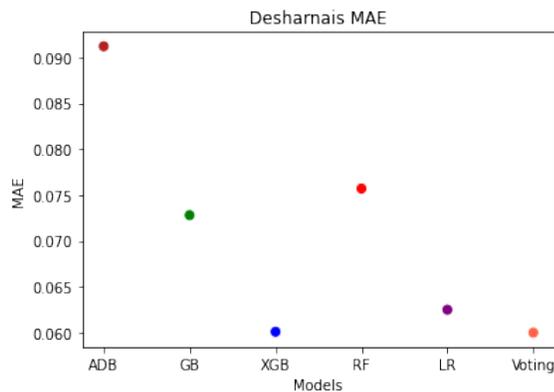

Below, Fig. 4 shows the bar plots of all the implemented models, representing the mean absolute error on all six datasets. Fig. 4(a) the voting model outperformed GB, XGB, RF, and LR except for ADB. Fig. 4(b) shows that, except for RF, voting showed less residual than all others. Fig. 4(c), (d), and (f) voting models are reliable. From all the above comparisons, we concluded that voting is a constant performer. On all datasets, the models behave randomly, whereas voting shows an upvote constantly.

(f)

Fig. 4. (a) COCOMO81 mean absolute error (b) CHINA mean absolute error (c) DESHARNAIS mean absolute error (d) MAXWELL mean absolute error (e) KEMERER mean absolute error (f) ALBRECHT mean absolute error

The graphical representation of Mean Absolute Error for various models that are worked on the COCOMO dataset is shown in Fig. 4(a), with the ADB model giving the slightest error followed by voting and the Random Forest giving the highest error among the models presented.

Fig. 4(b) shows a graphical representation of the Mean Absolute Error for various models tested on the CHINA

dataset. The RF model produces the lowest error, and the ADB produces the highest error.

Fig. 4(c) shows a graphical representation of the Mean Absolute Error for various models tested on the Desharnais dataset, with the Voting and XGB models producing the lowest error and the ADB having the highest error.

The graphical representation of Mean Absolute Error for various models that are worked on the MAXWELL dataset is shown in Fig. 4(d), with the XGB model giving a minor error and the LR model giving the highest error among the models presented.

Fig. 4(e) shows a graphical representation of the Mean Absolute Error for various models tested on the Kemerer dataset. The XGB model produces the lowest error, and the LR model produces the highest error.

Fig. 4(f) shows a graphical representation of the Mean Absolute Error for various models tested on the Albrecht dataset. The RF model produces the lowest error, and the LR model produces the highest error.

We normalized the literature results and compared them with the obtained model's results (see Tables I-VI)

Our work includes testing the voting regressor on six datasets. From the above tables, observations in all datasets voted on, showed excellent performance in minimizing the actual and predicted effort error. On the COMO81 dataset, absolute error is the minimum for voting, and squared errors are minor for linear regression. On COCOMO81, China, Desharnais, Kemerer, Maxwell, and Albrecht had excellent performances. Finally, we concluded that all dataset implementations support voting, which makes voting more reliable and robust. Voting followed by linear regression shows that the datasets have a linear relationship between the attributes of the projects.

## VI. CONCLUSION

We studied various existing research papers on software effort estimation in this work. In the early days, we relied on many conventional approaches, considering the line of codes, functional points, CPM and PERT, etc., or merely relying on the people's judgment that has ample experience in software project effort determination. Because extensive developments in project building consider multiple parameters in every project, these techniques might not be feasible anymore with rapid results in software projects. And at the same time, machine learning has gained momentum in recent decades in various domains. And there is some work taking place in software engineering through machine learning. Therefore, our work aims to provide a robust machine learning model for effort calculation. We successfully used the machine learning ensembling concept to predict software development efforts. We considered every parameter for the effort estimation. Based on our research, the ensembling of models outperformed other single models. We recorded a lower error rate from the ensemble model comparatively. The average of different predictors positively impacted the output, which shows the vital role played in optimizing software effort estimation in the machine learning area. The input dataset dramatically affects how well the machine learning algorithm works, and in our work, models performed very well with our datasets.

**Abstract**—To design a framework for effective prediction of heart disease based on ensemble techniques, without the need of feature selection, incorporating data balancing, outlier detection and removal techniques, with results that are still at par with cutting-edge research. In this study, the Cleveland dataset, which has 303 occurrences, is used from the UCI repository. The dataset comprises 76 raw attributes, however only 14 of them are listed by the UCI repository as significant risk factors for heart disease when the dataset is uploaded as an open source dataset. Data balancing strategies, such as random over sampling, are used to address the issue of unbalanced data. Additionally, an isolation forest is used to find outliers in multivariate data, which has not been explored in previous research. After eliminating anomalies from the data, ensemble techniques such as bagging, boosting, voting, stacking are employed to create the prediction model. The potential of the proposed model is assessed for accuracy, sensitivity, and specificity, positive prediction value (PPV), negative prediction value (NPV), F1 score, ROC-AUC and model training time. For the Cleveland dataset, the performance of the suggested methodology is superior, with 98.73% accuracy, 98% sensitivity, 100% specificity, 100% PPV, 97% NPV, 1 as F score, and AUC as 1 with comparatively very less training time. The results of this study demonstrate that our proposed approach significantly outperforms the existing scholarly work in terms of accuracy and all the stated performance metrics. No earlier research has focused on these many performance parameters.

**Keywords**—Machine learning; heart disease; ensemble techniques; random over sampling, isolation forest

## I. INTRODUCTION

Cardiovascular disease (CVD) is considered to be the foremost reason of death in the world. It is estimated that half of all CVD cases occur in Asia. Besides, near about three-quarters of all the global mortality are anticipated to happen because of persistent diseases by 2021, with 75% of deaths due to heart disease. These circumstances create an imperative need to design decision support system (DSS) for early prediction of heart disease. About 80 % of CVD are preventable if predicted at an early stage.

Traditional method of heart disease diagnosis includes extensive examination of patient. In this case the diagnosis of disease totally depends upon domain experts' knowledge and exactness of collected clinical data. This invasive method of diagnosis is not reliable and efficient. So there is need for cost effective and highly accurate Non-invasive approach such as Machine Learning (ML) to design prediction model.

ML is able to filter out pertinent connection between tremendous measures of data. Advancement in Artificial intelligence has played very significant role in the new era of computing. Various researchers have tried and tested data mining techniques in the healthcare domain and found it to be outperforming. The limitation of the prevailing analysis was the utilization of tedious task of feature engineering within the classification process. The principal inspiration of this research is to makeover data to usable form so that researchers can use it to design DSS to enhance safety of the patients.

In this work, proposed a model with data pre-processing, data balancing and outlier detecting followed by ensemble classifier. Standard scalar is used in the data pre-processing stage where each attributes with standard deviation of one is achieved. Imbalanced data is explored and oversampling technique was proposed to improve the reliability of the model. Anomalies or outliers are considered as noise in the data and may lead to misclassification. Furthermore proposed anomalies detection and removal using Isolation forest algorithm. Besides, Ensemble techniques bagging, boosting, Voting and stacking are applied to measure the effectiveness of the proposed methodology. This article focuses on the prediction of cardiac disease employing ensemble techniques of ML without feature engineering.

The main contributions of the proposed work include:

- A novel combination of data standardization, data balancing, and outlier detection to transform the data into usable form.
- The study involves the isolation forest for outlier detection of multivariate data, which has not been extensively explored in the previous research.
- The study assesses the performance of heart disease prediction system using ensemble techniques without feature selection designed, which have not been studied in depth in previous research.

The rest of the paper is structured as follows: In Section II literature analysis is provided, research gap is highlighted in Section III; Methodology is projected in Section IV. The detailed results of the proposed approach are presented in Section V followed by comparative study with existing research work in Section VI, and finally conclusion and future scope in Section VII.

## II. LITERATURE ANALYSIS

According to WHO, heart disease represent predominant reason of death in developing countries. One of the reasons to fail in the treatment of heart disease is unidentified pattern with cardiac data. Machine learning has been proved the remedy for that, as it is able to extract the pattern in cardiac data to predict the heart disease.

Researchers have explored and evaluated several methodologies, including single-base classifiers, ensemble approaches, and hybrid techniques as the prediction model. Furthermore, data pre-processing techniques, feature selection techniques, and optimization approaches were employed to improve the performance of the prediction system.

Many researchers implemented basic ML classifiers on a cardiac dataset and achieved good results. Authors suggested a modified random forest [1] to boost the prediction ability of the classifier. The proposed work achieved the highest accuracy of 86.84% with the UCI Cleveland dataset. Author [2] implemented Logistic regression (LR), K nearest neighbour (KNN) and Random Forest (RF) classifiers on a medical dataset from the UCI repository. The highest accuracy achieved with KNN is 87.5%, when implemented on the Python platform.

The above mentioned, state of the art research used conventional algorithms to design decision support system for heart disease prediction and it has been observed that the average accuracy is below 90%.

Instead of relying on a conventional model to provide an exceptional solution, the ensemble method leverages the strengths of numerous models to mitigate the limitations of a single model. In [3], proposed homogeneous ensemble learning using an accuracy-based weighted ageing classifier. The proposed model achieved an accuracy of 93% on the Cleveland dataset. Instead of utilizing conventional single model, majority vote Ensemble model can be used [4] in the prediction system of heart disease. This approach has produced 90% accuracy for Cleveland dataset. According to this literature survey, an ensemble method has shown to be more successful than a single model strategy.

Many feature selection methods have been proposed by researchers for obtaining more relevant features from a given dataset. Javeed et al. [5] proposed a randomized search algorithm (RSA) to get the optimal subset of features, and grid search optimized RF was used as a classifier. The experimental results have achieved 93.33% accuracy while improving the training accuracy as well. Muhammad et al. [6] proposed a model where four feature selection methods, namely fast correlation-based feature selection (FCBF), minimum redundancy, maximal relevance (mRMR), least absolute and selection operator (LASSO), and Relief, were tested on 10 different machine learning classifiers. It was found that, for the features chosen by FCBF, ETC's accuracy increased from 92.09 % to 94.41 % compared to complete features. Dissanayake et al. [7] performed research where filter, wrapper, and embedded feature selection approaches were

implemented. The test findings show that DT with backward elimination wrapper feature selection outperforms with an accuracy of 88.52 %.

## III. RESEARCH GAP

The majority of the scholarly work is focused on improving accuracy via feature selection techniques. However, to eliminate the data cleaning operations while yielding high disease prediction accuracy, a computationally effective feature selection approach is required [8]. There is need to investigate a new intelligent technique to generate a meaningful concise set of features. Noise and outliers present in the data make it difficult to select exact features [9]. As feature selection is a tiresome activity and only some of the existing work discussed in the literature is able to predict heart disease with good accuracy, there is a dire need to test machine learning framework without feature selection for the effective prediction of cardiovascular disease [10].

The dataset discussed in the existing work is imbalanced with an uneven contribution of the majority and minority classes. Class imbalance has not been amply focused in the previous research. The problem of class imbalance must be taken care of before implementing any classification mechanism. On the other hand; only a few researchers have worked on outlier removal from dataset. There is a need for an outlier detection method that can differentiate between normal data and outliers [11]. Only few Researchers have experimented unsupervised outlier detection techniques such as DBSCAN, isolation forest, K-means clustering. There is need to experiment and analyse Isolation forest for outlier detection. The utilization of ensemble based algorithms needs to be experimented rigorously and analysed for effective prediction of heart disease.

The unique aspect of the proposed research work is to design a framework for heart disease prediction that can handle the problems of imbalanced class, outlier detection and still conveys comparable performance index without any feature engineering.

## IV. MATERIALS AND METHODS

In this research, we present a new paradigm for predicting cardiac disease, which can predict the presence and absence of heart disease reliably, as shown in Fig. 1.

### A. Dataset Description

The Cleveland dataset used for this proposed work has 303 instances with 76 clinical and physical parameters. Most of the research work has chosen just 14 features in their scholarly work as these attributes are the most significant in the prediction of heart disease. Other attributes such as exercise protocol and time when ST measure depression was performed, had minor effects on heart disease and so 62 attributes are omitted by researchers.

As seen in Table I, the UCI repository specifically mentions these 14 attributes when uploading the dataset for open access.

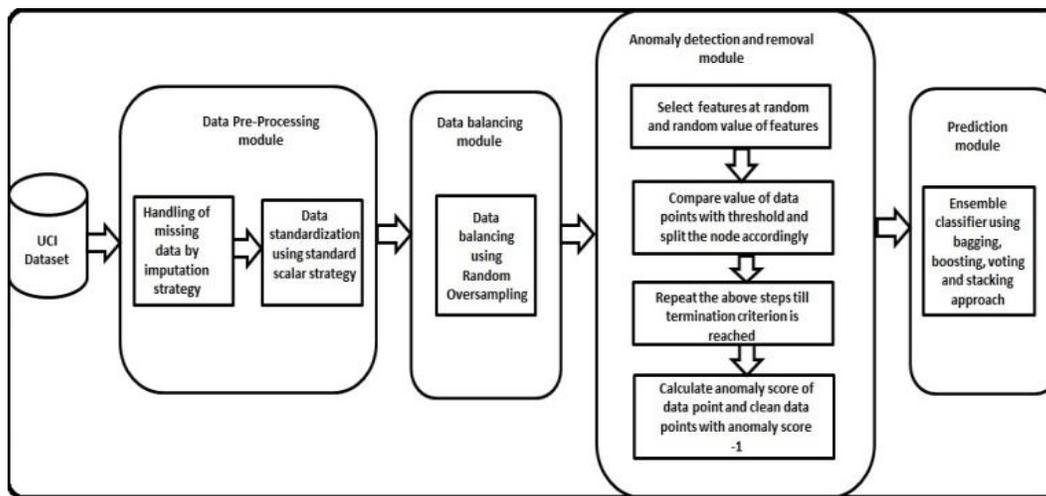

Fig. 1. Proposed heart disease prediction system using random oversampling, isolation forest and ensemble prediction model.

TABLE I. IMPORTANT 14 ATTRIBUTES FROM 76 ATTRIBUTES OF UCI DATASET

Sr. No.	Name of Attribute	Position in the dataset	% of the data Complete
1	Age in years	3	100
2	Sex	4	100
3	Chest pain type	9	100
4	Resting Blood Pressure	10	100
5	Serum Cholesterol	12	100
6	Fasting blood sugar	16	100
7	Resting ECG	19	100
8	Maximum Heart Rate	32	100
9	Exercise-induced angina	38	100
10	ST depression	40	100
11	The slope of the ST segment	41	100
12	Number of containers colored by fluoroscopy	44	98.67
13	Thalassemia	51	99.33
14	Diagnosis value	58	100

Among these, 13 are independent variables and 1 is a dependent target variable for the diagnosis of heart disease, where 0 represents the absence of heart disease and 1 represents the presence of heart disease.

### B. Data Preprocessing

Before catering data into the machine learning classifier, it is important to analyse and pre-process the data to improve its quality. A few attributes, as shown in Table I, have missing values. Missing values are replaced by the mean value of those attributes [12].

Creating a data-analysis-based decision support system necessitates standard data, which frequently necessitates pre-processing activities such as data cleansing, pruning, and scaling. Data standardisation is performed to scale each feature

to unit variance. Attributes assessed at different scales do not contribute equally to the model fitting and may result in bias. To address this possible issue, feature-wise standardisation is utilised prior to model fitting [13]. The feature in each column of  $x$  is normalized independently, so that each feature has a mean  $\mu = 0$  and a standard deviation  $\sigma = 1$ .

A value is standardized as (1).

$$z = \frac{x - \mu}{\sigma} \quad (1)$$

Where mean  $\mu$  is defined in (2).

$$\mu = \frac{1}{N} \sum_{i=1}^N X_i \quad (2)$$

And standard deviation  $\sigma$  is as in (3).

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (3)$$

Where  $N$  is the number of instances in each column ( $N=303$ ).

### C. Data Balancing

As per the exploratory data analysis of the target variable, the given Cleveland dataset has 138 instances of healthy people and 165 instances of people with heart disease. The dataset has unequal distribution of negative (0) and positive (1) instances.

Because of this unequal number of positive and negative classes, it will be difficult for machine learning models to learn the pattern of the dataset and it may hamper the performance of the model [14]. To address the problem of imbalanced data, the random oversampling technique is proposed. It randomly duplicates examples from the minority class with substitution and adds them into the training dataset. The superiority of random oversampling is that all individuals from the minority and majority classes are maintained; therefore, no information from the original training set is lost. Synthetic Minority Oversampling Technique (SMOTE) is another method of data for oversampling where samples are created synthetically but it may create noise with high dimensional data. Data augmentation using SMOTE may provide diverse results and may not always be beneficial for medical data [15].

### D. Anomaly Detection

Anomaly detection is the technique of identifying outliers in data. Researchers have preferred to use unsupervised anomaly detection models. Isolation forest is a unique method based on this isolation property of outliers and is fundamentally different from other density-based and cluster-based outlier detection methods [16]. In this research paper, it is proposed to use an isolation forest (iForest) to isolate the anomalies from the data samples.

Here is the algorithm to compute an isolation tree:

- 1) Choose a feature at random from data and refer it as  $f$ .
- 2) Choose a value at random from the feature  $f$  and utilize as threshold ' $t$ '.
- 3) Data points with  $f < t$  are saved in Node 1 whereas the data points with  $f \geq t$  kept in Node 2.
- 4) Steps 1–3 repeated for Node 1 and Node 2.
- 5) Stop the process when the tree has reached full maturity or when a termination requirement is fulfilled.

An isolation tree can be extended to an isolation forest—an ensemble of multiple isolation trees.

The isolation forest in sklearn has 2 important inputs:

$n\_estimators$ : Number of Isolation trees to be trained

$Contamination$ : Fraction of anomalous data points.

In our case we suspect 5% of the data to be anomalous and set contamination to 0.05.

Steps in building an Isolation forests:

- 1) Construct an Isolation Tree either from the entire feature set or a randomly chosen subset of the feature set.
- 2) Construct  $n$  such Isolation trees.
- 3) Calculate an Anomaly score for each data point using formula in (4).

$$s(x, n) = 2^{-E(\hat{h}(x)/c(n))} \quad (4)$$

$s$  = score (closer to 1: outlier, closer to 0: normal data point),

$E(\hat{h}(x))$  = Average path length taken by data point  $x$ ,

$c(n)$  = Average path length of every terminal nodes.

Isolation forest can be used for univariate as well as multivariate dataset. Let us consider our case of the multivariate dataset as shown in Fig. 2.

Isolation tree divides the data into “boxes”. It has the property that it segregates the region containing anomalies earlier than the boxes containing normal data points. If the feature has an anomaly, the anomalous point will be far away from the normal points in the data. It helps isolation forests to isolate out anomalies relatively early in the splitting process.

As shown in the figure, the anomaly can be detected at split 2 only. If we go on splitting the data, few normal points got isolated much later as shown in split 4. Isolation Forest can detect the outliers faster and require less memory as compared to other algorithms.

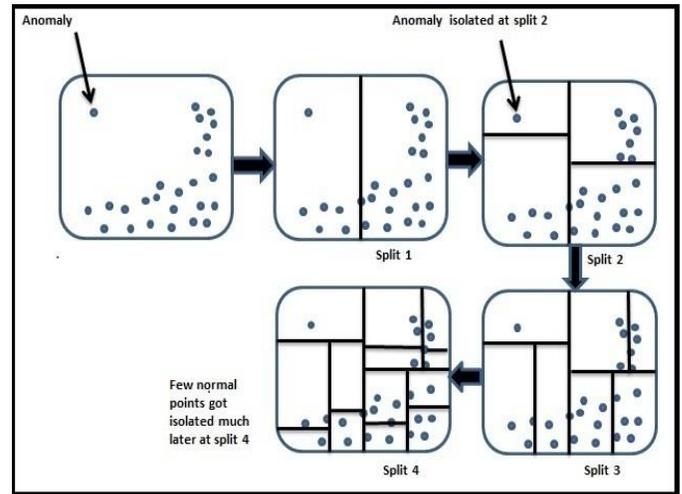

Fig. 2. Splitting process in isolation forest where anomalies are isolated early in split 2 as compared to normal data point isolated in split 4.

### E. Prediction Module: Ensemble ML Techniques

Ensemble learning is a machine learning model in which numerous models (commonly referred to as weak learners or base models) are trained to handle the same issue and then integrated to provide improved results. We tested our model using bagging (RF, ETC), boosting (XGBoost, AdaBoost), voting (hard, soft voting), and staking (RF+SVM) ensemble techniques.

Here we discussed the ensemble techniques, implemented in our proposed work.

**Bagging:** In this kind of approach, several instances of the same base model are trained in parallel (independently from each other) on separate bootstrap samples and then aggregated in some form of "averaging" process.

We have implemented Random Forest and Extra Tree classifier as bagging techniques.

**Random Forest:** This classifier belongs to the ensemble classifier family. It employs decision tree models to improve prediction outcomes. It generates numerous trees from the training data set, and a bootstrap approach is used to each tree. The random forest technique is a bagging method in which deep trees fitted on bootstrap samples are blended to create an output with lower variance.

**Extra Tree classifier:** Extra Trees classifier is a type of ensemble technique that delivers classification result by accumulating the results of multiple uncorrelated decision trees grouped together in a "forest." It differs as compared to Random forest in a way the decision tree is built in the forest. It separates nodes by selecting cut-points completely at random, and it also grows the trees using the whole training sample.

**Boosting:** Boosting is an ensemble modeling strategy that seeks to construct a strong classifier from a collection of weak classifiers to reduce training errors. A random sample of data is chosen, fitted with a model, and then trained sequentially—that is, each model attempts to compensate for the shortcomings of its predecessor. In this work, proposed to use XGBoost and AdaBoost boosting techniques.

**XGBoost:** XGBoost is the state of the art gradient boosted tree algorithm that boosts the performance of weak learners. It uses greedy algorithm to calculate the best split. To begin, a weak classifier is fitted to the data. It adds another weak classifier to upgrade the present model's performance, without losing the prior classifier's performance. The same process is continued and it employs a gradient descent approach to reduce the loss when adding new models. Each new classifier must take into account where the prior classifiers failed to perform well. To generate a new model, the method constantly reduces the errors of prior models in the gradient direction.

**AdaBoost:** AdaBoost is a boosting machine learning algorithm that use weighted linear combination to cascade numerous weak learners into a particular classifier. AdaBoost uses a learning technique to re-weight samples of the original training data in a sequential manner. It is an iterative approach, with each iteration giving more weight to the misclassified occurrences from the preceding iteration. Each instance is initially allocated an identical weight, and iteratively, the weights of all wrongly classified instances are increased while the weights of successfully classified examples are decreased. The algorithm recursively applies the base classifier with fresh weights to the training data. The final classification model produced is a linear combination of all the models developed over the rounds. AdaBoost completely considers each classifier's weight; nonetheless, it is vulnerable to outliers and noisy data.

**Voting Classifier:** Voting classifier aggregates the output of each classifier provided to it and produces the final prediction of the class label of a new instance based on voting. The voting can be of two types, hard or soft. Simple majority voting is utilized in the situation of hard voting. In this situation, the class with the highest number of votes is projected. A forecast is created for soft voting by averaging the class-probabilities of each classifier. The projected class is the one with the highest average probability. In the proposed work, model is checked for both hard and soft voting. In the proposed model LR, NB, DT, SVM, KNN has been ensemble as base models in hard voting and LR, NB, DT, KNN are used in soft voting.

**Stacking:** The stacking approach is a two-layered ensemble technique. The top layer comprises of all the baseline models used to predict the outcomes on the test dataset. The second layer consists of a Meta-Classifier, which accepts all of the baseline model outcomes as input and generates new prediction. The second layer combines the output of the first layer. Here, RF is used as baseline model and SVM as Meta Classifier.

## V. RESULTS AND ANALYSIS

The experiment has been conducted on Python platform using different libraries on an Intel Core i5 processor 9300H CPU with 2.40GHz, 4GB NVIDIA GTX 1650 graphical processing unit Lenovo machine equipped with 8GB RAM. Exploratory data analysis and data pre-processing have been performed. The dataset is divided into 75% of training data and 25% of testing data. Stratified k fold has been introduced in

the dataset's training phase to avoid sampling bias. The accuracy, precision, recall, sensitivity, specificity, PPV, NPV, F1 score, ROC\_AUC score, and computing time of the model are used to validate the performance of the suggested technique.

The experiment focused on the evaluation of the model by implementing random oversampling and isolation forest for various ensemble classifiers. The number of instances after implementing Random oversampling to Cleveland dataset is as shown in Table II.

Before implementation of random oversampling the total number of instances in the dataset are 303 with 138 instances indicating absence of heart disease and 165 instances for presence of heart disease. After processing data for random oversampling, the total number of samples is 330 since the positive and negative class instances are evenly distributed and equal to 165.

TABLE II. UCI CLEVELAND DATASET OVER SAMPLING RESULTS

Class	Absence of HD	Presence of HD
Before Random Oversampling	138	165
After Random Oversampling	165	165

The isolation forest is used to identify and clear outliers from the dataset. After removing outliers, the dataset has 313 samples. The performance assessment of the ensemble classifier model using the proposed methodology is shown in Table III.

It demonstrates that the implementation of random oversampling and an isolation forest has given excellent performance for all the ensemble classifiers. Many existing research papers put emphasis on feature engineering, but our proposed approach works on the whole featured dataset and demonstrates the significance of data balancing and outlier removal in the prediction of heart disease. The suggested approach outperformed numerous existing studies in the literature without requiring high computational time. The accuracy of the proposed model for ensemble classifiers is in the range of 97.47 % to 98.73 % for the Cleveland dataset. The highlighted column demonstrates that soft voting provides excellent result among all the implemented ensemble methods.

Confusion matrix for implemented ensemble classifiers is as shown in Fig. 3.

From the confusion matrix, it has been observed that, RF, ETC and AdaBoost Ensemble Techniques provide False Negative (FN) value of 2, that means two patients with actual heart disease are incorrectly predicted as non-heart disease persons. For XGBoost, Voting and hybrid ensemble techniques, FN value is 1 indicating only one heart disease patient incorrectly predicted as non-heart disease patient by the model.

Fig. 4 explores the graphical presentation of all the performance parameters of the proposed methodology with all the ensemble techniques implemented.

TABLE III. PERFORMANCE EVALUATION OF PROPOSED METHODOLOGY FOR CLEVELAND DATASET

Metric	RF	ETC	XGBoost	AdaBoost	Hard Voting	Soft Voting	Stacking
Accuracy	97.47	97.47	98.73	97.47	98.73	98.73	98.73
Sensitivity	95	95	98	95	98	98	98
Specificity	100	100	100	100	100	100	100
PPV	100	100	100	100	100	100	100
NPV	95	95	97	95	97	97	97
F1-Score	0.97	0.97	0.99	0.97	0.99	0.99	0.99
AUC	0.998	0.982	0.995	0.995	--	1	0.980
Computational Time in sec.	0.054	0.062	0.144	0.114	0.016	0.011	0.631

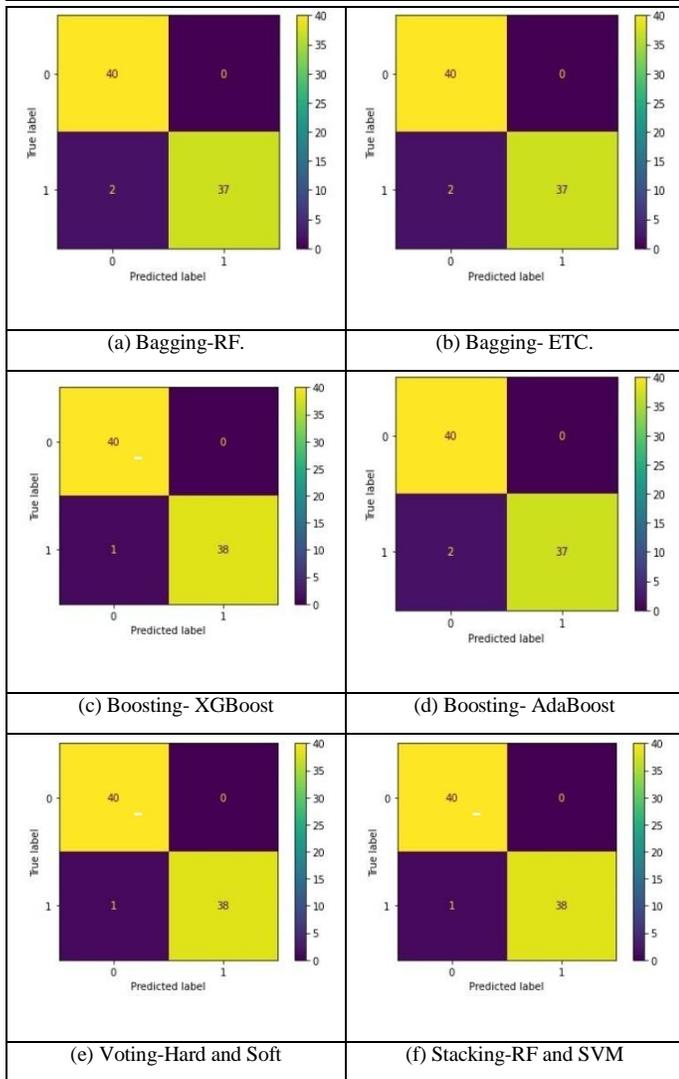

Fig. 3. Confusion matrix of implemented ensemble classifiers.

It reveals that all the ensemble techniques provide excellent performance when applied to random over sampling to cater with imbalance data and isolation forest for anomaly detection to the Cleveland dataset with 303 instances without any feature selection.

Proposed work is additionally assessed for ROC\_AUC analysis. The ROC curve is a depiction of the True positive

rate vs the False positive rate. In other words, it is trade-off between sensitivity and specificity. The area the ROC curve (AUC) is said to be excellent for values between 0.9-1. Fig. 5 shows ROC-AUC curves for various ensemble techniques applied in the experimentation. Accuracy and AUC are two important metrics for the binary classification problem. The values of AUC for all the techniques are found to be excellent as per the observation in the ROC curve.

Fig. 6 demonstrates the two cases of the heart disease prediction system as heart disease positive and heart disease negative on a GUI application created using tkinter in Python.

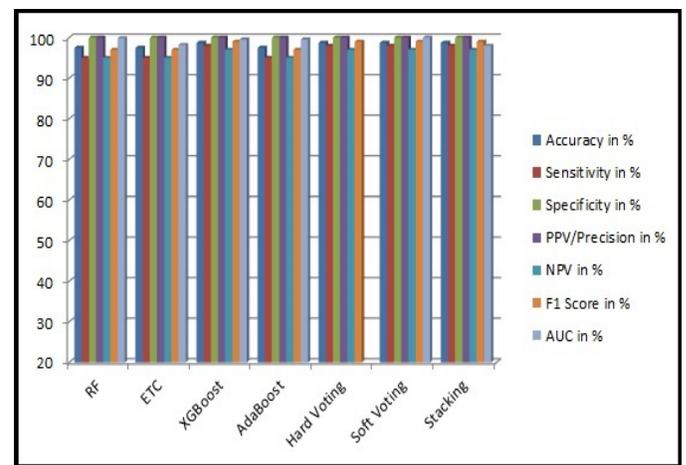

Fig. 4. Performance parameters of proposed ensemble technique for Cleveland dataset.

The proposed work's credibility is demonstrated by comparing its findings for the same dataset with three approaches listed below.

Approach 1: Without Random Over sampling and Isolation Forest for Ensemble Techniques.

Approach 2: Without Isolation Forest with Random Over sampling for Ensemble Techniques.

Approach 3: Without Random Over sampling with Isolation Forest for Ensemble Techniques.

In the first approach, Cleveland dataset is processed without random over sampling and no isolation forest. The results of this implemented methodology are tabulated as shown in Table IV.

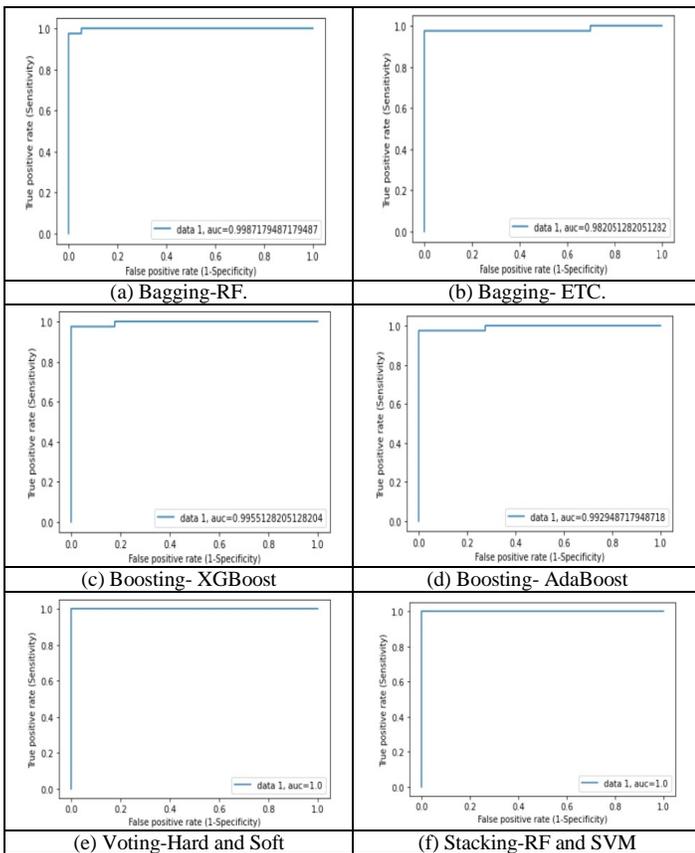

Fig. 5. ROC curve of various ensemble Techniques used in the experiment, displaying corresponding AUC values.

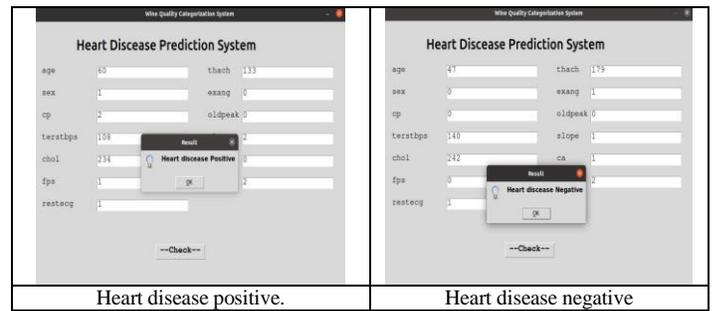

Fig. 6. GUI for Heart disease positive and negative cases using tkinter in python.

The highlighted column in Table IV demonstrates that, soft voting is the best performing ensemble model with 96.05% accuracy for approach 1. But the performance of the proposed research is far better as compared to the implemented methodology in approach 1.

Similarly, in the second approach, Cleveland dataset is processed with random over sampling, no isolation forest and in the third approach Cleveland dataset is processed sampling with isolation Forest, no random over sampling.

The results of these implemented methodologies are tabulated as shown in Table V and Table VI respectively and the best results are highlighted.

The projected results in Tables IV, V and VI reveal that our proposed research work of implementation of Ensemble Techniques with random oversampling and isolation forest give excellent performance in terms of all performance matrices as compared to implementation strategy of all the three approaches.

## VI. COMPARISON AND DISCUSSION

The reliability of the proposed work is demonstrated by comparing its findings to those of other state-of-the-art current systems conducting imbalanced data processing and outlier detection for the Cleveland dataset as shown in Table VII. Researcher [17] implemented imputation of missing values and outlier removing processes in order to provide quality data to ML model. Mahalanobis distance metric is used to drop the outliers in the data. Further, NB optimized with grid search found to provide accuracy of 84.8%. Instead of conventional model, an ensemble based majority voting scheme is proposed by researchers [18]. Outliers in the dataset are identified and removed using filter based techniques. From different combinations of ensemble, SVM +NB+ MLP ensemble provided highest accuracy of 84%. Researchers [19] proposed machine learning framework using data imbalance technique SMOTE and feature selection technique on ensemble (LR+KNN) classifier for heart disease prediction. Box plot technique is used to identify the outliers. The suggested architecture was assessed on the Framingham, heart disease, and Cleveland dataset and found to outperform them all. SMOTE based ANN [20] is proposed to Cleveland UCI dataset. The imbalance nature of the presented dataset is analyzed, and SMOTE oversampling strategy is proposed to improve the performance of the ANN classifier. Deep learning has been effectively used in heart disease prediction. Researchers experimented isolation forest for outlier detection

for multivariate data using selected features from 13 features of Cleveland dataset [21]. Accuracy is found to be improved but sensitivity and specificity is very poor. Researchers used filter based feature selection and isolation forest for anomalies detection. The proposed approach found to be performing effectively for KNN with eight neighbours on UCI Cleveland dataset [22]. Researchers investigated anomaly detection using K-means clustering algorithm [23]. After removing anomalies, five classification techniques KNN, RF, SVM, NB and LR are used to build the prediction model. It is found that without anomalies RF and NB are performing better as compared to with anomalies in the dataset. DBSCAN is implemented to identify and remove the outliers, a hybrid SMOTE-Edited Nearest Neighbor (SMOTE-ENN) to balance the training data distribution and XGBoost as a classification model for heart disease prediction [24]. Most of the existing research work, proposed to use feature selection extensively. The state of the art research rarely used combination of data balancing and outlier detection in data pre-processing.

The suggested methodology outperforms prior research work utilizing data balancing techniques and outlier identification techniques. The performance of the data balancing solution using Random Oversampling and outlier detection using Isolation Forest on Ensemble Classifier is excellent in all performance metrics. The proposed model in our research outperformed previous models and research findings, with an accuracy of 98.73 % for Cleveland dataset.

TABLE VII. COMPARISON OF PROPOSED METHODOLOGY WITH STATE-OF-THE-ART RESEARCH FOR UCI CLEVELAND DATASET

Author Name, Year, Reference	Methodology	Accuracy	Sensitivity	Specificity	PPV	NPV	F Score	AUC Score
Sivaraman et al. (2021) [17]	Mahalanobis distance+ Grid search optimization +NB	84.8	82.7	86.4	83.2	--	82.8	91
Bashir et al. (2021) [18]	Filter based outlier removing + Majority voting	84	84.80	83.22	--	--	84	--
Rahim et al. (2021) [19]	SMOTE+ Box plot +Feature importance (5 features)+ LR-KNN	98.0	--	--	--	--	--	--
Waqar et al. (2021) [20]	SMOTE+ ANN	96	95.7	--	96.1	--	95.7	100
Bharti et al. (2021) [21]	Isolation Forest+ Lasso FS+DL	94.2	82.3	83.1	--	--	--	--
Ramesh et al. (2022) [22]	Isolation Forest+Filter FS (7 features) +KNN	94.1	94.8	--	91.7	--	90.8	79.9
Ripen et al. (2021) [23]	K means clustering +RF	88	--	87	87	--	--	--
Fitriyani et al. (2020) [24]	DBSCAN+ SMOTE ENN+ XGBoost	98.4	98.3	98.3	98.5	--	98.3	--
Proposed Methodology	Random Oversampling+ Isolation Forest+ Ensemble Techniques	98.73	98	100	100	97	99	100

For binary classification problem of presence and absence of heart disease, accuracy and AUC are the most important metrics. The highlighted row in the Table VII demonstrates that the proposed methodology has highest accuracy and AUC as compared to state of the art research.

## VII. CONCLUSION AND FUTURE RESEARCH

In this paper, we propose ensemble techniques that are supported by Random Oversampling and Isolation Forest for efficiently predicting heart disease. All the ensemble models are found to be performing excellently in all evaluation results. The accuracy range for the Cleveland dataset, for all models is 97.43% to 98.73%, sensitivity 95% to 98%, specificity 100%, precision 100%, NPV 95% to 97 %, F score 0.97 to 0.99, AUC score 0.98 to 1 with less computational overhead.

Most of the previous researchers implemented feature selection techniques to improve the accuracy of ML and DL models. Here we propose a model without any feature selection and achieve remarkably improved performance metrics. Experimental results prove that the ensemble approach with data pre-processing techniques resolves the issue of computational intricacy. Random oversampling and isolation forest significantly improve the performance of ensemble classifiers.

Data balancing with oversampling helps to make data more reliable by avoiding over fitting or under fitting the model. Noisy data removal with an isolation forest improves the quality of the data. The validity of the suggested framework on the UCI Cleveland dataset demonstrates that our framework is both trustworthy and efficient. It incorporates novel pre-processing techniques while also employing an inventive ensemble. Furthermore, the computational time is remarkably reduced with highly reliable results.

In the future, optimization techniques can be implemented for hyper parameter tuning to deploy the model. Because of the NP-hardness of feature selection approaches, a meta-heuristic feature selection method can be devised. There is a strong need for real-world clinical factors that are easily approachable and computed in real-time for the future of clinical cardiac disease detection via ML-centered systems.

University of Sri Jayewardenepura, Nugegoda, Sri Lanka<sup>2</sup>

**Abstract**—This study aims to use the Class Activation Map (CAM) visualisation technique to understand the outputs of apparent personality detection models based on a combination of Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN). The ChaLearn Looking at People First Impression (CVPR'17) dataset is used for experimentation in this study. The dataset consists of short video clips labelled with the Big Five personality traits. Two deep learning models were designed to predict apparent personality with VGG19 and ResNet152 as base models. Then the models were trained using the raw frames extracted from the videos. The highest accurate models from each architecture were chosen for feature visualisation. The test dataset of the CVPR'17 dataset is used for feature visualisation. To identify the feature's contribution to the network's output, the CAM XAI technique was applied to the test dataset and calculated the heatmap. Next, the bitwise intersection between the heatmap and background removed frames was measured to identify how much features from the human body (including facial and non-facial data) affected the network output. The findings revealed that nearly 35%-40% of human data contributed to the output of both models. Additionally, after analysing the heatmap with high-intensity pixels, the ResNet152 model was found to identify more human-related data than the VGG19 model, achieving scores of 46%-51%. The two models have different behaviour in identifying the key features which influence the output of the models based on the input.

**Keywords**—Apparent personality detection (APD); convolutional neural network based recurrent neural network (CNN-RNN); class activation map (CAM); explainable AI (XAI)

## I. INTRODUCTION

Explainable AI (XAI) has gained attention in machine learning as it is crucial to comprehend the behaviour of these models, that is, how these models generate their outputs. These techniques can be used to gain a deeper understanding of the inner workings of a model and can help improve the trust and adoption of AI systems in various applications. Artificial neural networks and deep learning methods are often considered as black boxes, as the inner workings of these techniques and how they produce output based on input are not fully understood. Therefore, researchers tend to explore

techniques to make these into glass boxes, that is, to understand how input features contribute to the output. According to the literature [1], these techniques are divided into different categories.

### • Local Vs Global

- **Local:** Explain how a model makes a single prediction and evaluates its performance on a given set of examples.
- **Global:** Global techniques for explaining a model do not require a specific set of example data and instead provide an overall understanding of how the model works. These techniques can include analysing the model's architecture and studying the relationships between the model's parameters.

### • Model Specific Vs Model Agnostic

- **Model Specific:** These techniques only apply to a single model or a group of specific models.
- **Model Agnostic:** These techniques can be applied to any model to explain the model's predictions.

XAI techniques are grouped into different clusters based on the type of data, the purpose of interpretability, and the flow of interpretation signals, in addition to the two primary categories mentioned above.

The Saliency map is the oldest and most commonly used technique to explain convolutional neural network (CNN) predictions. The saliency map specifies the pixels that activate a particular layer in the network. The literature discloses three main approaches: Deconvolutional Network [2], Backpropagation [3], and Guided Backpropagation [4]. Table I summarises the most popular XAI techniques.

Researchers discovered various XAI methods to understand the deep learning model predictions in addition to the methods mentioned in Table I.

Apparent Personality Detection (APD) based on a person's appearance is a trending research topic in affective computing because apparent personality is helpful in various applications. A few of those applications are listed below:

- **Job Screening:** From the past [10] to the present [11], [12], psychological researchers have tended to find a relationship between personality and job performance. Barrick et al. [11] identified a relationship between Extraversion and Conscientiousness personality traits in the ratings of sales representatives. Inceoglu and Warr [13] conducted a study to reveal the relationships between job engagement and personality. They concluded that there is a relationship between Extraversion, Conscientiousness and Emotional Stability. Hence, the different personality traits contribute to job roles, performance, and satisfaction. Such as, a team leader should have a high level of Extraversion and Conscientiousness and a low level of Neuroticism.
- **Recommendation Systems:** Dhelim et al. [14] discuss the need for personality-aware recommendation systems. Hence, people with the same characteristics act in the same way. It is easy to recommend products or solutions if the customer's personality is known. The authors also mentioned that personality-aware recommendation systems are better when dealing with cold start and data sparsity issues than traditional recommendation techniques.
- **Social Robotics:** A study by Lee et al. [15] found that if the robot's personality is similar to the user's personality, users enjoyed dealing with the robot. Kirby et al. [16] highlight the importance of affective-social robots with emotions and apparent personalities. The robot can identify the user's state and act accordingly. It is essential to consider this when designing social robotics.
- **Personal Assistants:** There are many personal assistants available nowadays, including Apple Siri, Microsoft Cortana, Google Assistant, and Huawei Celia. These personal assistants can be enhanced by adding the automatic personality detection feature, which leads to higher user interaction with personal assistants.
- **Animation Movies:** Designing an animation-movie character is challenging since it should reflect the character's qualities, including personality [17]. Identification of the facial features which contribute to the different personality traits will be beneficial in this field to improve the outcomes.
- **Health Care and Counselling:** In psychology, researchers are researching the relationship between personality and mental health, personality and physical

health and personality and illness. Smith and MacKenzie [18] discuss how personality traits (such as neuroticism) affect a human's health. Hence psychology research proved that our mental and physical health is affected by personality. It will be beneficial to identify personality for early treatment processes and personalised counselling plans based on the personality.

- **Criminology:** Reid [19] explained the connection between personality and crime. Hence, with better personality prediction solutions, authorities can identify and prevent criminal activities.
- **Education and Personalised Learning:** Salazar et al. [20] highlight the importance of having an affective recommendations system in the education field. Moreover, they mentioned that it is vital to change the content based on the learning style, emotions and personality.

According to the review study conducted by [21], psychological studies, political forecasting, forensic, and word polarity detection can also be enhanced by automatic personality detection.

Thus, an individual's apparent personality can be used in different domains to improve performance and effectiveness. Researchers introduced deep learning solutions, including convolutional neural networks and recurrent neural network architectures, to measure apparent personality. After achieving higher accurate predictions by APD deep learning models, researchers tend to find how these models produce the output for given input features using XAI techniques. The other purpose of applying XAI in APD models is to identify prominent facial and non-facial features that affect the personality, which is more important to improve the trust and adoption of AI systems in the above mentioned applications. All works performed in this area used ChaLearn Looking At People First Impression V2 (CVPR'17) dataset [22]. This is the only dataset publicly available with labelled Big Five Personality traits [23].

Zhang and co-workers [24] applied a heatmap feature visualisation technique to visualise the features affecting the APD. They have used different deep learning architectures such as ResNet, DAN, and DAN+. Their study results convey that different models focused on different features of the face, including facial and non-facial data, including background data. Ventura and co-workers [25] conducted a quantitative study to identify prominent facial features and emotions that influence APD.

TABLE I. MOST POPULAR XAI TECHNIQUES APPLIED IN THE FIELD OF CNN

Technique	Year	Local/ Global	Model Specific/ Agnostic	Description
Deconvolutional Network [2]	2013	Local	Specific	Deconvolutional networks work as the inverse of convolution, pooling (unpooling), and inverse of ReLU. This technique recognises the features activated by the immediate layer for the given input. It reconstructs the input from the activations of the layer.
Backpropagation [3]	2014	Local	Specific	For a given input, calculate the gradients concerning the network parameters. This technique highlights the pixel space based on the gradients they receive, which implies the contribution of these pixels to the final output.
Guided Backpropagation [4]	2015	Local	Specific	Guided Backpropagation is a combination of a deconvolutional network and the backpropagation technique. This technique identifies the essential features based on the reconstruction signal's negative values (deconvolutional) and negative values of the input in the forward pass (backpropagation).
CAM [5]	2015	Local	Specific	Class Activation Map (CAM) detects different regions contributing to a given class score. The last fully connected layers are replaced by a global average pooling (GAP) layer, which averages the activations of feature maps. The GAP layer produces a vector, then calculate the weighted sum of the vector's components and sends it to the SoftMax layer. The calculated weighted values help identify the essential features that activate each convolutional feature map by projecting them back.
Deep LIFT [6]	2019	Local	Specific	This technique calculates the activation feature map by multiplying the input with the measured gradients for the given input with a class of interest.
Grad-CAM [7]	2020	Local	Specific	This is a more flexible version than CAM because this produces feature activation with fully connected layers. When the class of interest and input is produced to the network, the network calculates the gradient flow into the final convolutional layer.
Guided Grad-CAM [7]	2020	Local	Specific	Since the Grad-CAM cannot highlight fine-grained regions, the same authors suggest combining the Grad-CAM and Guided Backpropagation techniques to obtain the Guided Grad-CAM.
LIME [8]	2016	Local	Agnostic	Local Interpretable Model-Agnostic Explanations (LIME) manipulate the input data by creating a set of artificial data. These artificial data consist of part of the original input data. The artificial data is then introduced to the model and classified into different categories. Hence, the presence or absence of certain input parts can decide the contribution to the model's output.
SHAP [9]	2017	Local and Global	Agnostic	Shapley Additive Explanations (SHAP) is based on the Shapley values used in game theory. Shapley values are vastly applied in the cooperative game theory to find each player's contribution/ importance. The same theory is applied in the XAI to identify feature importance for the final output.

They applied CAM and Action Unit (AU) [26]. CAM is applied to find the discriminative regions in the scene data. CAM results convey that the facial regions, such as the eye, nose, and mouth areas, contribute to the final prediction. From the Action Coding System, 17 AU was applied to find the influence of emotions in APD. The results indicate that few AUs affected personality detection. They concluded these results with 50 images extracted with the highest personality scores.

Wei et al. [27] applied feature map visualisation to the models they trained to predict the apparent personality. Results show that ResNet identified the facial region as the primary contributor, while DAN and DAN+ activate background data rather than facial data. However, with plain background data, DAN and DAN+ identify facial data, while ResNet fails to identify facial data as primary contributing features. They summarised the model interpretability techniques results with 12 randomly selected images.

Yang and Glaser [28] used saliency map model interpretability techniques to interpret the APD models' outputs. They also concluded that ResNet pre-trained model-based APD architecture could identify facial features as primary contributors. Li et al. [29] calculated heatmap on scene data to identify the most contributing features using the Seaborn Python library [30]. Their findings revealed that critical facial features such as the eye, nose, and mouth

contribute to APD. However, non-facial features such as clothing and furnishing affect the APD model's output. They conducted a quantitative study by considering the face area and heatmap of contributing features and concluded that 73.96% of the highlighted points are face key points (eye, nose, and mouth). They used 32 frames for the experiment from each video from the test dataset of CVPR'17 [22].

A summary of the works conducted in this area used heatmap visualisation techniques such as saliency map techniques to interpret the prediction of APD models. Most of these works concluded that facial regions and non-facial data contribute to the output. A majority of these techniques tend to interpret the CNN architectures' output. These researchers used different pre-trained models in the development and various XAI techniques and concluded that different architectures tend to highlight different areas. Less attention has been paid to work focusing on describing the outputs of Convolutional Neural Networks based Recurrent Neural Network (CNN-RNN) architecture and work on conducting a quantitative study to prove the findings.

#### A. Contribution

Contributions of the work to the APD area are as follows:

- 1) Prior works mainly focused on explaining the CNN-based APD models. This work focused on CNN-RNN models.

2) A quantitative study is conducted to identify primary contributing features for the CNN-RNN-based APD model's output.

The primary aim of this work is to explain the CNN-RNN-based APD models using the CAM technique.

The rest of the paper is organised as follows: Section two discusses the Methodology, Section three contains the Results and Discussion, and Section four contains the Conclusion.

## II. METHODOLOGY

This section includes the methodology followed in this study to explain the predictions of the APD models. Fig. 1 shows the overall methodology followed to identify how the human data (facial and non-facial data excluding background) affected apparent personality.

According to Fig. 1, first, the dataset is pre-processed by dividing it into raw frames. Then the extracted frames were used to train, validate, and test the model. After completing the model development, the CAM visualisation technique was applied to the test dataset. The bitwise intersection between the heatmap and the background removed raw frames was calculated to clarify the facial and non-facial (non-background) features that contributed to the network's output.

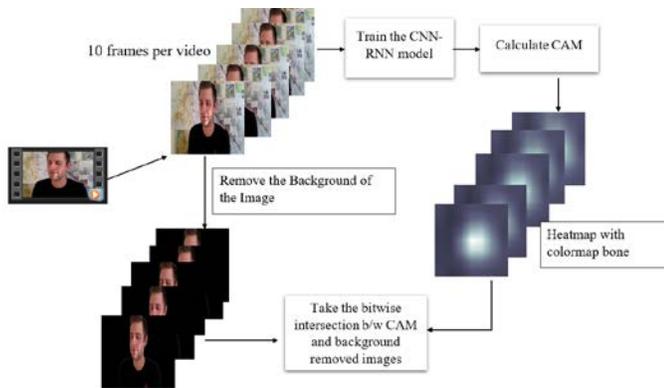

Fig. 1. Overall methodology

### A. Preparation of Data

The experiment used the CVPR'17 [22] dataset, which consists of videos of people facing the camera. These participants are from different nations, ages, and ethnicities. The dataset initially consisted of 3,000 videos which were again processed in 10,000 clips. The training, validation, and test datasets include 6,000, 2,000, and 2,000 video clips. Each video clip is labelled with Big-Five traits ranging from 0 to 1. For model development, ten frames were extracted from each video.

### B. Network Architecture

In CNN-RNN architecture development, the CNN part was developed using pre-trained deep learning models, trained initially on the ImageNet Classification problem (ILSVRC). Two deep learning architectures were designed, developed, and tested to compare the XAI technique findings. VGG19 [31] model is used for the first model, and the second, the

ResNet152 [31] model, is used for the CNN branch. These two models were selected because these are the most common pre-trained models used in several previous works [24], [27], [29]. RNN branch consists of one Gated Recurrent Units (GRU) layer to capture the temporal information, and Fig. 2 illustrates the network's architecture.

### C. Network Parameters

Following are the network parameters used in the current study, finalised after a few experiments conducted with the dataset.

- Batch size = 4
- Early Stop counter: 20
- Maximum number of epochs = 200
- Optimiser: Adam
- Learning rate =  $1 \times e^{-5}$
- Loss: Mean Absolute Error

All experiments were conducted on a precision server with Nvidia RTX 3090 24 GB.

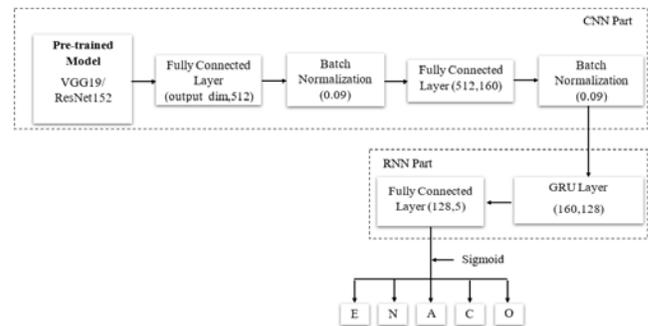

Fig. 2. Deep CNN-RNN network architecture

### D. Visualisation

This study followed the following steps to determine which features (human or background) mainly affected personality prediction in the CNN-RNN deep learning models.

**Step 1:** Removed background data from the raw frames extracted from the video clips (10 frames for each video). Python library Rembg [32] was used to detect human beings from the raw frames. This library uses U2-Net [33] deep learning architecture to detect an object.

$P_{human}$  = Pixels that correspond to the human detected from the raw frames

**Step 2:** Calculated the bitwise intersection between heatmaps and the output of step 1.

Instead of using COLORMAP\_JET [34], the most popular colour map for feature importance visualisation, we used COLORMAP\_BONE [34]. COLORMAP\_BONE, as seen in Fig. 3, uses black and white to represent low and high intensities in pixels. Moderate intensities receive grey colour (in between black and white). Thus, it is more convenient to

identify which features affect more to the output with different intensities.

$$I_1 = P_{human} \cap P_{heatmap_1} \quad (1)$$

$P_{heatmap_1}$  = Pixels which were highlighted by the CAM visualisation technique

$$I_2 = P_{human} \cap P_{heatmap_2} \quad (2)$$

$P_{heatmap_2}$  =  $P_{heatmap}$  pixel values (R, G, B) greater than or equal to 100 (higher intensities)

**Step 3:** Calculated fractions  $f_1$  and  $f_2$ :

$f_1$ : Pixels highlighted by CAM and belongs to the area where the human being exists in the frame / the pixels highlighted by CAM

$f_2$ : Pixels highlighted by CAM with high intensity and belongs to the area where the human being exists in the frame / the pixels highlighted by CAM with high intensity

$$f_1 = \frac{I_1}{P_{heatmap_1}} \times 100 \% \quad (3)$$

$$f_2 = \frac{I_2}{P_{heatmap_2}} \times 100 \% \quad (4)$$

**Step 4:** Followed the above steps for all video files in the test dataset; Measured the average of  $f_1$  and  $f_2$ .

$$F_1 = \frac{\sum_{i=0}^n f_1}{n} \quad (5)$$

$$F_2 = \frac{\sum_{i=0}^n f_2}{n} \quad (6)$$

where  $n = 2000$  (size of the test dataset)

**Step 5:** Repeated the same process for all personality traits.

Fig. 3. Opencv colormaps

### III. RESULTS AND DISCUSSION

The models were trained ten times, and the highest accurate model was selected for feature visualisation. Table II summarises the highest accuracy of each model (VGG19-based CNN-RNN model) and Table III (ResNet152-based CNN-RNN model). The accuracy of the model is calculated using the following equation:

$$\text{Accuracy} = 1 - \frac{1}{N} \sum_{i=1}^N |\text{target}_{ij} - \text{output}_{ij}| \quad (7)$$

$N$ = number of videos, the target is the respective ground-truth value, and output is the predicted value from the model for a given video.

TABLE II. VGG19-BASED MODEL ACCURACY

Big Five Personality Trait	Accuracy
E	90.23%
N	89.95%
A	90.52%
C	90.04%
O	90.16%
Mean Accuracy	90.18%

TABLE III. RESNET152-BASED MODEL ACCURACY

Big Five Personality Trait	Accuracy
E	90.53%
N	90.20%
A	90.21%
C	91.15%
O	90.42%
Mean Accuracy	90.50%

The ResNet152-based model outperforms the VGG19-based model by achieving approximately 90% accuracy for all the traits. While VGG19 based model achieved more than 90% accuracy for all the traits except for neuroticism.

#### A. Visualisation Techniques Results

As mentioned in the methodology section, we calculated the  $F_1$  and  $F_2$  values for all five personality traits with two architectures.

TABLE IV. VGG-19 BASED MODEL F SCORES

Big Five Personality Trait	$F_1$ score	$F_2$ score
E	35.36%	35.76%
N	36.19%	35.40%
A	36.19%	35.40%
C	36.19%	35.40%
O	36.19%	54.00%

Table IV conveys that human data (excluding background) affect personality prediction by 35% - 36%, with  $F_1$  score and  $F_2$  score, except for the Openness trait, which is 54% for  $F_2$ . Hence, with VGG19 openness trait is more influenced by human data with high intensity.

Table V conveys that nearly 35% - 38% ( $F_1$ ) of the facial and non-facial data (excluding background) affected the personality prediction. Furthermore, with  $F_2$  scores, it is 36% to 51%. Since the  $F_2$  scores were calculated using pixels with high intensities in the heatmap, and we can conclude that ResNet152 identified more human data than VGG19 for Extraversion, Openness, Neuroticism, and Conscientiousness traits. In both architectures, the Agreeableness trait is more

affected by background data than other traits (Tables IV and V). In the ResNet152-based model, Extraversion and Openness traits were less affected by background information than other traits (Table V).

TABLE V. RESNET152-BASED MODEL F SCORE VALUE

Big Five Personality Trait	F score	F2 score
E	38.19%	51.44%
N	36.25%	46.95%
A	32.52%	36.08%
C	35.58%	44.14%
O	37.37%	47.68%

Tables IV and V express that the human data (facial and non-background data) affected the personality prediction by nearly 40%, implying that the image's background affected the apparent personality by almost 60%, with  $F_1$  scores. Nevertheless,  $F_2$  scores confirm that high intensities (heatmap) were allocated to human data with ResNet152. The previous works to explain the outputs of the CNN-based APD models also concluded that facial, non-facial, and background data affected the prediction. Zhang and co-workers [24] concluded that different features affect different CNN models designed to predict the apparent personality. As per their demonstration, background data are highlighted as features contributing more to the model prediction. Wei and co-workers [27] also concluded that different models highlighted different features. The models they designed using ResNet and VGGFace-based architectures highlighted different image regions of the input image. Also, they concluded that VGGFace-based architecture is more prone to background data. The current work's quantitative results also convey that models identified different features from the input. Furthermore, ResNet152 is more towards human data rather than the background.

#### IV. CONCLUSION

The primary goal of the current study is to explain the output of the CNN-RNN-based APD models using the CAM as the XAI technique. The results convinced that the models' output is based on the background rather than non-background data (human data, including facial and non-facial data). Usually, the human data (facial and non-facial data excluding background) affects the personality prediction more than the background. However, the findings imply a different conclusion. Even past researchers highlighted this fact with various XAI techniques for CNN-based APD. Hence, the current study with the CNN-RNN APD model also concludes that the background is more influential for APD than human data with the CAM visualisation technique. Also, the models acted differently in the current study because they produced different  $F_1$  and  $F_2$  scores. Furthermore, for Extraversion, Openness, Neuroticism, and Conscientiousness ResNet152 based CNN-RNN models recorded higher  $F_2$  values than  $F_1$ , which implies that more contributing features are from human data. The study's conclusions are derived from an assessment of the deep learning architectures employed and the efficacy of the background removal procedure.

#### ACKNOWLEDGMENT

Our special thanks to the Faculty of Computing of General Sir John Kotelawala Defence University for providing access to servers to experiment.

**Abstract**—Scene recognition algorithm is crucial for landmark recognition model development. Landmark recognition model is one of the main modules in the intelligent tour guide system architecture for the use of smart tourism industry. However, recognizing the tourist landmarks in the public places are challenging due to the common structure and the complexity of scene objects such as building, monuments and parks. Hence, this study proposes a super lightweight and robust landmark recognition model by using the combination of Convolutional Neural Network (CNN) and Linear Discriminant Analysis (LDA) approaches. The landmark recognition model was evaluated by using several pretrained CNN architectures for feature extraction. Then, several feature selections and machine learning algorithms were also evaluated to produce a super lightweight and robust landmark recognition model. The evaluations were performed on UMS landmark dataset and Scene-15 dataset. The results from the experiments have found that the Efficient Net (EFFNET) with CNN classifier are the best feature extraction and classifier. EFFNET-CNN achieved 100% and 94.26% classification accuracy on UMS-Scene and Scene-15 dataset respectively. Moreover, the feature dimensions created by EFFNet are more compact compared to the other features and even have significantly reduced for more than 90% by using Linear Discriminant Analysis (LDA) without jeopardizing classification performance but yet improved its performance.

**Keywords**—Scene recognition; convolutional neural network; smart tourism; feature selections

## I. INTRODUCTION

Scene recognition is a crucial aspect for the development of many software applications such as in the area of intelligent robotics, autonomous driving and intelligent video surveillance. Moreover, scene recognition is the basis component in accomplishing the tasks for any object detection tasks [1]. The basic goal of scene recognition is to label all photos of scenes, whether they are outdoor or indoor, semantically and properly.

The magnificent scenery as well as the beautiful and historical landmarks of certain places has become one of the attraction factors for the tourist to come and visit these places. In this context, a software application that equipped with an intelligent landmark detection based on scene recognition algorithm can be developed to serve certain useful tasks. For instance, a tourist may get useful information and

recommendation based on the detected landmark such as the nearby food attractions, and transportation and accommodation information. Besides, the application may assist the tourist agent while guiding the tourist visiting the attraction places. However, the scene recognition is a challenging task due to the difficulty to distinguish the common structure of the public scene objects such building, monuments, parks, beaches and so on [2]. Scene images also might be captured from different angles which triggered the high intra-class difference problems [3].

Deep learning and transfer learning based classification is the emergence approach in any machine learning tasks [4]–[6]. In scene recognition, the pretrained CNN models by using ResNet50 architecture were adopted [4], [5]. Although the classification accuracy obtained was good (92.17% and 94.4%), ResNet50 produced larger features dimensionality. Therefore, there are lot of studies in the other domain have various of Efficient Net (EFFNET) CNN architectures such as masked face recognition [7], smoke detection [8], chest X-ray scanning [9]–[11] and fake face video detection [12] due to its exceptional classification performance as well as to generate lightweight features.

The key contributions of this paper are the proposed super lightweight Landmark recognition model trained by using Convolutional Neural Network (CNN) to address the challenges of distinguishing the common public structure of landmark scenes. The features extracted by using the pretrained CNN model of EfficientNet (EFFNET) which produced the lightest features as compared to the other CNN models. Afterwards, Linear Discriminant Analysis (LDA) feature selection algorithm has been adopted that has significantly reduced the dimensionality of features without sacrificing classification performance at all and even have improved the classification performance. The recognition model training by using CNN was also very efficient as it required very minimal number epoch to complete and yield the best classification performance.

The remainder of the paper is organized in the following way: Section II provide the previous studies conducted in scene recognition. In Section III, the Methodology is described in more detail. Sections IV presents the experimental results. The conclusions and directions for the future studies are presented in Section V.

## II. RELATED WORKS

Scene recognition is a subset of object recognition and can be treated as classification problem to serve certain purposes. It is a problem to describe the content or the objects that exist in the outdoor or indoor scene images. Scene recognition algorithms have adopted in many areas in computing field such as human computer interaction, robotics, smart surveillance system and autonomous driving [1]. Besides, scene recognition was also studied for tourism industry in assisting tourist or tourist guide to recognize the tourism attractive places or landmarks. There are Monulens [13], a real-time mobile-based landmark recognition, Smart Travelling [14] that used to recognize tourist attraction, nearby events, police stations and hospitals, Augmented Reality (AR) based landmark detection [15] and a system to distinguish large number of landmarks. All the aforementioned applications used the handcrafted features such as Histogram of Oriented Gradients (HOG), Scale Invariant Feature Transform (SIFT) and Bag of Features (BoF), and traditional machine learning approach such as Support Vector Machine (SVM). The recent works of scene recognition have shifted to deep learning-based approaches as tabulated in Table I.

TABLE I. RELATED WORKS OF SCENE RECOGNITION

Authors	Dataset	Techniques	Results
[16]	Places image	ImageNet-Linear SVM	Accuracy - 91.9%
[2]	Landmark database	DEep Local Features (DELf)	Specificity-0.99
[4]	Tourist Attraction Images	ResNet50	Accuracy - 92.17%
[5]	Scene images	ResNet-CNN	Accuracy - 94.4%

The study conducted in [16] established Places dataset to benchmark the performance of scene recognition algorithm which was denser in term of density and diversity of scene images in comparisons to the other scene recognition benchmark datasets such as SUN, Scene-15 and MIT Indoor67. The scene recognition algorithm trained by using Places dataset outperformed the accuracy performance of scene recognition algorithm trained by using ImageNet dataset for all scene recognition benchmark datasets. The evaluations were carried out by using CNN based features and linear SVM as classifier. The problem of high density and diversity of scene images as well as to determine whether the scene images contained landmark objects have been also addressed in [2] study. A metric learning-based approach was proposed in which the CNN is trained by curriculum learning technique and updated version of Center loss to overcome large variations of scene images. On the other hand, the existence of landmark objects in scene images determined by calculating distance between the image embedding vector and one or more centroids per class. Other than landmarks diversity issue, the scene recognition algorithm is also facing the high inter-class similarities where numerous landmarks have very similar building or architecture design. To overcome this problem, the CNN model based on ResNet50 was adopted in [4] to classify tourist attraction places in Jakarta, Indonesia such as Cathedral Church, Jakarta Old Town, Istiqlal Mosque and Maritime

Museum. The ResNet based model also demonstrated exceptional performance in [5] via its proposed method namely Scene-RecNet to classify the aerial scene views such as airports, forests and rivers. The Scene-RecNet was more versatile and stable as the features are adjusted and modified in the convolutional and fully-connected layers that eventually improved the processing speed, small storage space and good recognition accuracy.

Table II shows the summary of previous studies that have adopted deep learning approaches, specifically transfer models.

TABLE II. RELATED WORKS OF DEEP LEARNING

Authors	Dataset	Techniques	Results
[17]	Land images	LeNet+Bagging based CNN	Recall-0.784

The study conducted in [17] addressed the problem of land-use classification at the hilly and mountainous area by using ensemble learning approaches to improve the overall classification accuracy performance and classes number optimization to solve classification accuracy problem for coniferous forest. The bagging-based CNN using Bagging (Bootstrap AGGregatING) ensemble classifier is capable to overcome the problem of unstable procedures which means the great impact on classification due to minor differences of the data. Whereby the optimization of the classes' number was carried out by utilizing spectral clustering (SC) that divides data into subsets based on its similarity. The pre-trained LeNet CNN architecture have used for feature extraction. The pre-trained CNN architecture was also proposed in [18] for automatic screening of COVID-19. Specifically, two pre-trained CNN architecture ResNet50 and VGG16 were fused with the combination of Moment Invariant methods that improved the performance of previous COVID-19 classification models. It is also worth to note that many previous studies were adopted variant of EfficientNet (EFFNET) CNN architectures for extracting the features from the X-ray to detect lung related diseases. A variant of EFFNET namely EFFNETB0 with Bi-LSTM was proposed by [9] detect Covid-19 faster and with high accuracy low cost on chest X-ray images. Along with that, the features from EFFNETB0 were fused with DenseNet121 and LAB and CIE color space. The model training was performed by using Bi-LSTM classifier that yield the best classification accuracy as compared to the other ensemble classifiers. Similar techniques

were also used in [11] to detect COVID-19 from lung X-ray. The other variant of EFFNET so called EFFNET B2 was found to be most effective as compared to the other variants in [10] to reduce the class imbalance problem for diagnosing pneumonia from chest X-RAY. The fine tuning on EFFNET architecture provides desirable impacts which reduce computational effort and the use of batteries. The evaluation of several EFFNET variants were also carried out in [12] to detect fake face video in social media website. Based on the evaluation, the optimal performance of detection is by using EFFNET B4 and B5 and the classification accuracy performance drops when using EFFNET B6 and B7. Next, The EFFNET with Linear SVM were used to address the issues images complexity to recognize the face mask wearing in [7]. In this study, the classification accuracy EFFNET has outperformed the other CNN models using DENSENET201, NASNETLARGE and INCEPTIONRESNETV2 with very light size of features. The lightness of features produced by EFFNET have been utilized by [8] through the proposed novel lightweight smoke detection for detecting fire in its early stages. A module for smoke region segmentation was also proposed in this study where the encoder-decoder approach with atrous separable convolutions were investigated.

According to the comprehensive survey conducted by [1], the top three performance recognition approaches fall under Patch Feature Encoding, Discriminative Region Detection and Hybrid Deep Models. Specifically, the CNN based feature extraction using ResNet-152, AlexNet and SE-ResNeXt-101 were recorded the significant performance on Scene-15, Sports-8, Indoor-67 and SUN-397.

Based on the discussions of the previous studies, it can be summarized that the pretrained CNN architecture is flexible and capable to provide robust recognition performance in various fields and domains. The CNN architecture is flexible as the layers and its parameters can be easily fine tuned to fit the requirement of data and optimum performance could be achieved. In particular, the EFFNET based CNN architecture has proven quite decent performance so far in terms of classification performance as well as to produce lightweight features. Therefore, the use EFFNET also might be extended in the domain of scene recognition to overcome the issue of high inter-class similarity in scene images.

### III. METHODOLOGY

This section describes the methodology undertaken to carry out this research, as depicted in Fig. 2. The methodology consists of four parts which are data acquisition, feature extraction, feature selection and model training.

#### A. Experimental Setup

The experiment in this study was performed by using Python libraries based on Spyder 4.2.2 and PyCharm 2020.3.3

(Community Edition) software tools. Specifically, the feature extractions and classifications were performed by using Scikit-learn and Keras libraries.

#### B. Scene Recognition Model Training

The landmark recognition model training consists of four main steps which are data acquisition, feature extraction, feature selection and classification model training.

1) *Data acquisition:* The images for UMS Landmark Dataset were captured with a Nikon D7100 camera with a resolution of  $6000 \times 4000$  pixels between 10.00 am. and 11.00 am. Fig. 1 shows the image samples of the popular landmarks in UMS [20]. This dataset has been made public and is available for download on the Kaggle website [21].

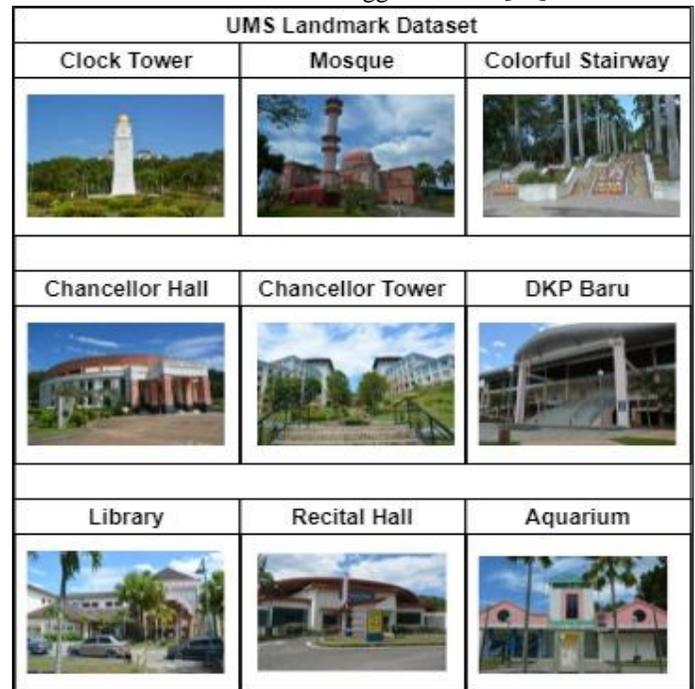

Fig. 1. Samples of UMS landmark dataset

Based on Fig. 1, there are nine categories of landmark consisting around 100 images with different camera angles. These landmarks are the popular tourist attractions for sightseeing and photography. Aside from this dataset, the public Scene-15 dataset [22] for scene recognition benchmarking was also evaluated in order to test the efficacy of the landmark recognition algorithm. This dataset contained 15 scene categories, comprising outdoor and indoor sceneries. There were 200 to 400 images in each category with an average resolution of  $300 \times 250$  pixels.

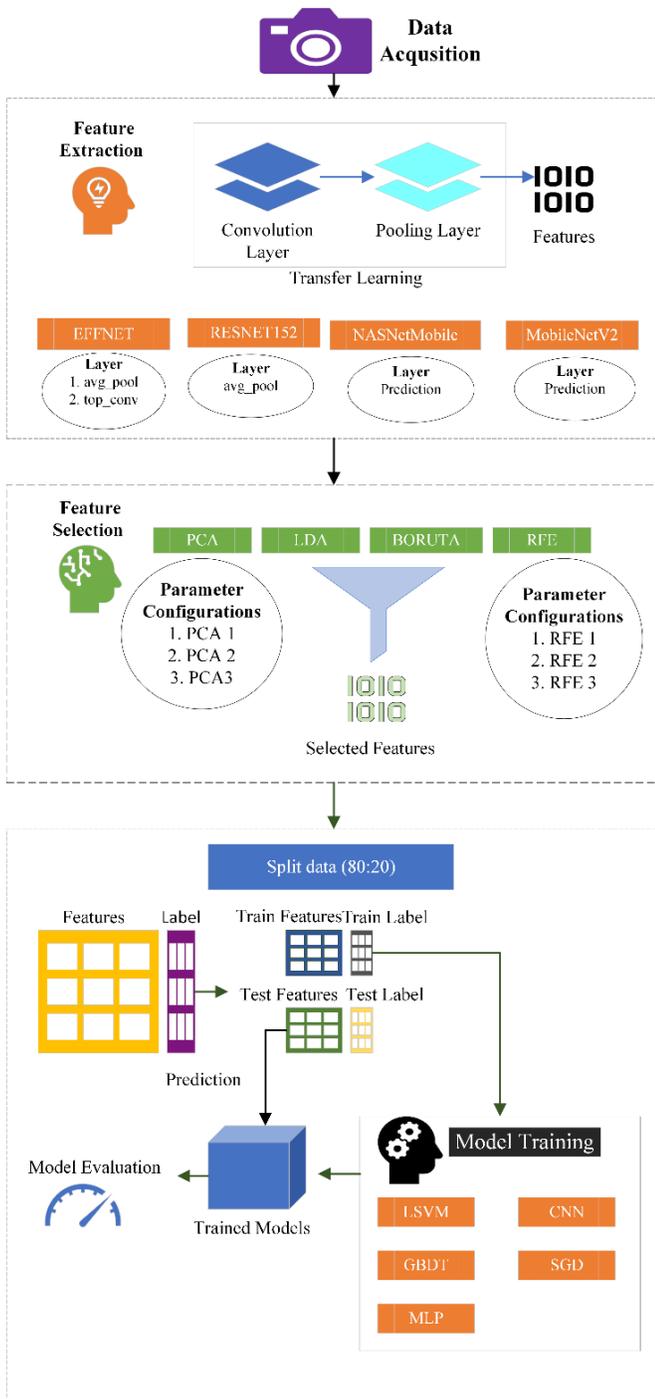

Fig. 2. Methodology

2) *Feature extraction:* Feature extraction is a process to transform the representation of the data into meaningful semantics for determining the category of the data in classification. In this work, the feature extraction was carried out by using transfer learning approach. The features of the images were extracted by re-using the model weights on the pre-trained Convolutional Neural Network (CNN) model. Transfer learning reduces the time it takes to train a neural

network model and lead in decreasing generalization error. The extracted features of an image had created a vector of values that the model would use to characterize the image features. These characteristics were used in designing a new model.

In particular, four pre-trained CNN model were evaluated for feature extraction, which are Efficient Net (EFFNET) [23], RESNET152 [24], NASNetMobile [25] and MobileNetV2 [26]. EFFNET has been adopted and demonstrated to have an outstanding performance in recent studies such as in the Covid-19 detection based on chest X-Ray [9], [27], smoke detection [8], fake video detection [12], pneumonia classification [10], masked face detection [7] and food recognition [28]. Meanwhile, the RESNET152 was also reported to have a good performance for scene recognition [1].

Many previous studies have shown that the NASNetMobile model performs well, such as the classification of rice diseases with an accuracy of 85.9% [29], ECG signal classification for cardiac examination [30] with an accuracy of 97.1 %, lung nodule classification from CT lung images with an accuracy of 88.28% [31] and skin lesion classification from dermoscopic images with an accuracy of 88.28% [32]. For on-device and embedded applications, the proposed MobileNetV2 has a low-latency, low-computation architecture. For instance, MobileNetV2 was used as an embedded food recognizer [33].

The pretrained CNN models were built with various layer types. In this work, two layer types of EFFNET layer were chosen to generate the feature matrices, namely *top\_cov* and *avg\_pool*. The model weights used in the EFFNET were ImageNet and both layers produced 62,720 and 1,280 feature dimensions. On the other hand, the *avg\_pool* was the selected layer to generate 2048 features dimensions for RESNET152 model. Then, both NASNetMobile and MobileNetV2 produced 1000 feature dimensions.

The extracted features consist of one dimensional (1D) features matrix which will be fed into the traditional machine learning classifiers and the 1D CNN classifier (Conv1D). To work with 2D CNN classifier (Conv2D), the 1D features matrix was reshaped into 2D features matrix. The *top\_cov* and *avg\_pool* layers in EFFNET produced (16, 16, 5) and (16,16,245) output shape after being reshaped. Meanwhile, the *avg\_pool* layer of RESNET152 produced (32, 32, 2) feature shape after being reshaped. Meanwhile the *prediction* layer of NASNetMobile and MobileNetV2 generated a (2, 2, 250) feature shape. The feature shape represents the height, width and depth of the images which make the edge and colors of the spatial features to be detected.

3) *Classification model:* The extracted Conv1D or 1D features as described in (2) were fed to Linear Support Vector Machine (LSVM), CNN (1D), Gradient-Boosting Decision Tree (GBDT), Stochastic Gradient Descent (SGD) and Multilayer Perceptron (MLP). Linear kernel is applied and one-versus all (OVA) training strategy is used in LSVM. The parameters used for the classifiers during the experiment are shown in Tables III, IV, V and VI.

TABLE III. LSVM PARAMETERS

Parameters	Value	Description
Penalty	l2	Specifies the norm used in the penalization. The 'l1' leads to coef_ vectors that are sparse.
Loss	square_hinge	Specifies the loss function. 'hinge' is the standard SVM loss (used e.g. by the SVC class) while 'squared_hinge' is the square of the hinge loss.
Dual	1e-4	Tolerance for stopping criteria.
C	1.0	Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.
Multi-class	ovr	Determines the multi-class strategy if y contains more than two classes. "ovr" trains n_classes one-vs-rest classifiers, while "crammer_singer" optimizes a joint objective over all classes

TABLE IV. GBDT PARAMETERS

Parameters	Value	Description
Loss	deviance	The loss function to be optimized. 'deviance' refers to deviance (= logistic regression) for classification with probabilistic outputs
learning_rate	0.1	Learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.
n_estimators	100	The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.
subsample	1.0	The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.
criterion	friedman_mse	The function to measure the quality of a split

TABLE V. SGD PARAMETERS

Parameters	Value	Description
Loss	hinge	Defaults to 'hinge', which gives a linear SVM
penalty	l2	Defaults to 'l2' which is the standard regularizer for linear SVM models
alpha	0.0001	Constant that multiplies the regularization term
fit_intercept	True	Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.
max_iter	1000	The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

TABLE VI. MLP PARAMETERS

Parameters	Value	Description
hidden_layer_sizes	(100,)	The ith element represents the number of neurons in the ith hidden layer.
activation	relu	Activation function for the hidden layer.
solver	adam	The solver for weight optimization.
alpha	0.0001	0.0001
batch_size	auto	Size of minibatches for stochastic optimizers
learning_rate	constant	Learning rate schedule for weight updates.

On the other hand, the Conv2D training features produced by EFFNET were fed into 2D Convolutional Neural Network classifier which is a fully connected layer. Table VII shows all the layers, the output shapes and the total parameters for EFFNET (*avg\_pool*), EFFNET (*top\_conv*) and RESNET152.

TABLE VII. 2D CONVOLUTIONAL NEURAL NETWORK ARCHITECTURE

Layer (type)	Output Shape			Parameters		
	EFFNET (AvgPool)	EFFNET (TopConv)	RESNET152	EFFNET (AvgPool)	EFFNET (TopConv)	RESNET152
conv2d (Conv2D)	(None, 16, 16, 32)	(None, 16, 16, 32)	(None, 32, 32, 32)	1472	70592	608
dropout (Dropout)	(None, 16, 16, 32)	(None, 16, 16, 32)	(None, 32, 32, 32)	0	0	0
conv2d_1 (Conv2D)	(None, 14, 14, 32)	(None, 14, 14, 32)	(None, 30, 30, 32)	9248	9248	9248
max_pooling_2d (MaxPooling2D)	(None, 7, 7, 32)	(None, 7, 7, 32)	(None, 15, 15, 32)	0	0	0

dropout_1 (Dropout)	(None, 512)	(None, 512)	(None, 512)	0	0	0
dense_1 (Dense)	(None, 12)	(None, 12)	(None, 12)	6156	6156	6156
Total params	820,204	883,168	3,702,924			
Trainable params	820,204	883,168	3,702,924			
Non-trainable params	0	0	0			

CNN possesses convolution layer that has several filters to perform the convolution operation, which are RELU, pooling layer, and fully connected layer. The RELU layer produces the rectified feature map by performing the operation on the elements. The rectified feature map next feeds into a pooling layer. Pooling is a down-sampling operation that reduces the dimensions of the feature map. The rectified feature map is fed into a pooling layer. Pooling is a down-sampling operation that decreases the feature map's dimensionality. By flattening the

two-dimensional arrays from the pooled feature map, the pooling layer turns them into a single, long, continuous, linear vector. When the flattened matrix from the pooling layer is given as an input, a fully connected layer forms classifiers the images.

The dataset will undergo training and testing phase in creating the classification model. In CNN, the epoch refers to the number of times the model trains all datasets. Whereby, batch size is a small amount of data used for training. A suitable number of epochs needs to be adjusted until a small gap between test and training error can be observed. When the appropriate number of epochs is not chosen, underfitting and overfitting problems occur.

The learning rate determines how frequently the weight in the optimization method is updated. Fixed learning rate is used and the Adam is chosen as optimizer.

Dropout is a better regularization strategy for deep neural networks to avoid overfitting. The method essentially removes units from a neural network based on the probability desired. A default value of 0.5 is set in this experiment. Loss function measure the successfulness of classification and in this experiment by defining the distance between two data points. In this experiment, the categorical cross-entropy loss function was used.

4) *Feature selection*: Feature selection plays important roles to improve the performance of recognition model by reducing the features dimensionality and transforming the feature into meaningful features [34], [35]. The meaningful features are characterized by the features that are more salient, less overfit and reduced the training execution time which eventually improve the accuracy performance [36]. In this work, Principal Component Analysis (PCA) [37], Linear Discriminant Analysis (LDA) [38], Boruta [39] and Recursive Feature Elimination (RFE)[40] were evaluated.

Table VIII shows the number of features selected after performing the feature selection algorithms. Unlike PCA, LDA and RFE, Boruta provided automatic mechanism in determining the number of features. Therefore, manual parameter configurations to determine the number of features selected were not required. Meanwhile, the number of features selected for LDA need to be set to less or equal to the total class in the dataset. For PCA and RFE, experiments were conducted to test three configurations with different percentages of features selected, which are 70%, 40% and 10%.

TABLE VIII. NUMBER OF FEATURES SELECTED

Feature Selection	Configurations	Features	UMS Dataset	Scene-15 Dataset
PCA	PCA1 (70%)	EFFNET	896	
		RESNET152	819	
		NASNETMobile	700	
		MobileNetV2	700	
	PCA2 (40%)	EFFNET	512	
		RESNET152	205	
		NASNETMobile	400	
		MobileNetV2	400	
	PCA3 (10%)	EFFNET	128	
		NASNETMobile	100	
		MobileNetV2	100	
		LDA	EFFNET	8

RFE	RFE1 (70%)	EFFNET	896	
		RESNET152	1434	
		NASNETMobile	700	
		MobileNetV2	700	
	RFE2 (40%)	EFFNET	512	
		RESNET152	819	
		NASNETMobile	400	
		MobileNetV2	400	
	RFE2 (10%)	EFFNET	128	
		RESNET152	205	
		NASNETMobile	100	
		MobileNetV2	100	

5) *Classification model performance metrics*: The model's overall performance on the testing set was measured using the accuracy metric as the performance metric. Assume that CM is a n by n confusion matrix, with n equaling the total number of various scene categories. Next, the actual category is indicated by the row of CM, while the anticipated category is indicated by the column of CM. Then, let C (i,j) denote the value of the CM cell in index row I and column j, with i,j=1,2,...,n. The following equation defined the accuracy metrics:

$$accuracy = \frac{\sum_{i,j=1}^n C_{i,j}}{\sum_{i=1}^n \sum_{j=1}^n C_{i,j}} \quad (1)$$

#### IV. FINDINGS

This section presents the analysis from the experiment results comprising feature extraction, classification and feature selection performance. The first part of this section presents the discussion of classification performance evaluation, the second part discusses about the feature dimensions size, shape and the number of epoch used in CNN training, followed by the performance analysis for feature selection.

##### A. Classification Performance

Table IX shows the recognition accuracy of feature extraction based on EFFNET, RESNET152, NASNetMobile and MobileNetV2 and classification by using Linear SVM (LSVM), CNN (2D), CNN (1D), Gradient-Boosting Decision Tree (GBDT), Stochastic Gradient Descent (SGD) and Multilayer Perceptron (MLP) on UMS-Scene and Scene-15 dataset.

In comparison to the Scene-15 dataset, most of the algorithms performed well on the UMS landmark dataset, as shown in Table IX. As the UMS landmark dataset had a higher image resolution, the quality of the collected images was more likely to have influenced the result. The bar charts in Fig. 3, Fig. 4, Fig. 5, and Fig. 6 show how the features and classifiers employed in the UMS landmark and Scene-15 datasets compare in terms of performance. The classification accuracy of various features on various classifiers is shown in Fig.3. EFFNET with avg\_pool layer is the best feature due to its perfect achievement on all classifiers except MLP. To demonstrate its efficacy, Fig. 4 shows the classification accuracy of various classifiers on various features. Except for NASNetMobile, CNN 1D and GBDT had been found to be resilient to a variety of features, including the ability to attain 100% classification accuracy on all features. In contrary, CNN 2D performed poorly with NASNetMobile and MobileNetV2. This was most likely because the 2D shape features generated by the CNN 2D classifier were incompatible.

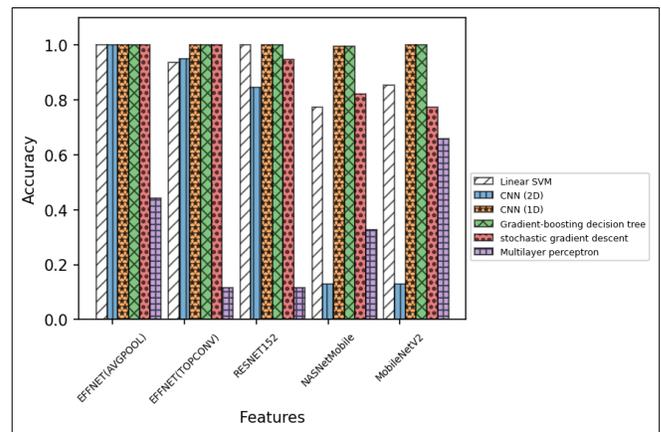

Fig. 3. Performance of features on UMS landmark dataset

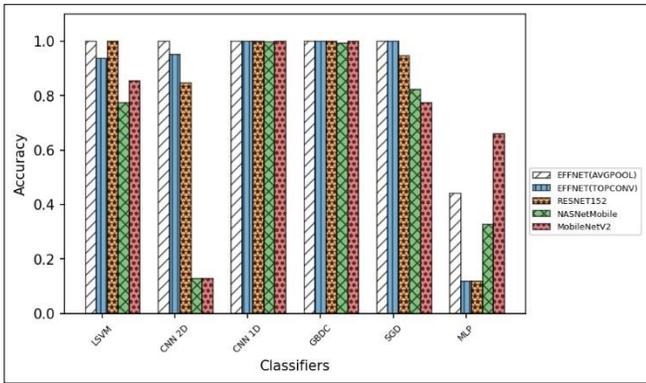

Fig. 4. Performance of classifiers on UMS-landmark dataset

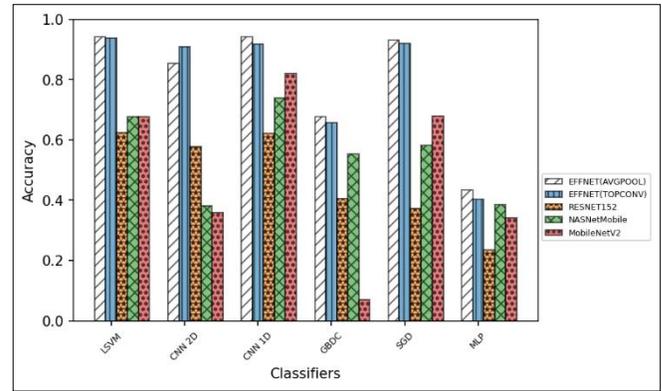

Fig. 6. Performance of classifiers on scene-15 dataset

EFFNET based features performed well across many classifiers in the Scene-15 dataset, apart from GBDC and MLP, as shown in Fig. 5. RESNet152, NASNetMobile, and MobileNetV2, on the other hand, produced less discriminative features. Fig. 6 shows that LSVM and CNN 1D perform consistently across all features and worked exceptionally well with EFFNET features. GBDC and MLP, on the other hand, only achieved 67.61% and 43.39% accuracy, respectively. Moreover, the CNN 2D and SGD only worked well with EFFNET features. Overall, the best classification accuracy on the Scene-15 dataset was 94.26% using CNN 1D classifier and EFFNET (AVGPOOL) features. Based on the study conducted in [1], the RESNet152 indeed yielded the best performance on Scene-15, Sports-8, Indoor-67 and SUN-397. However, based on the result of the experiment in this paper revealed that the EFFNET have better performance on Scene-15 dataset. Next, the confusion matrix of classification accuracy is illustrated in Fig. 7.

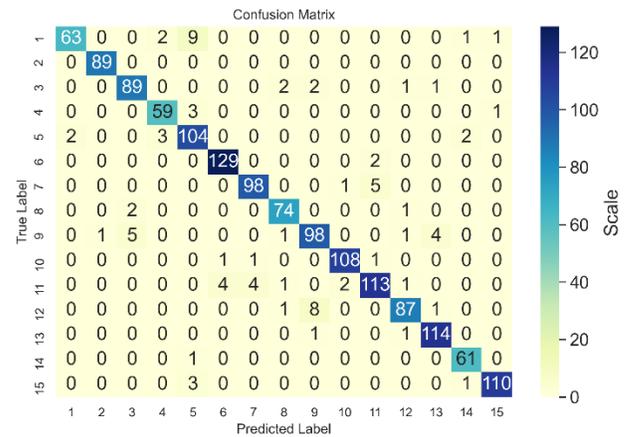

Fig. 7. Confusion matrix of classification using CNN 1D-EFFNET (AVGPOOL) on Scene-15 dataset

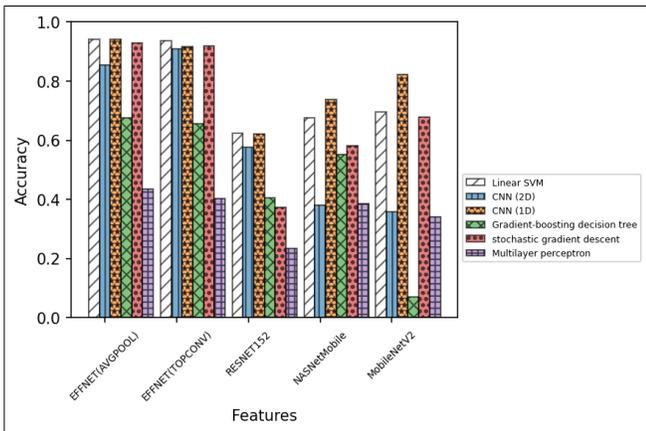

Fig. 5. Performance on features on scene-15 dataset

As plotted in Fig. 7, there are few scene images had been miscategorized. For instance, category 1 (office) was classified as category 5 (store), category 7 (tall building) was classified as category 11 (coast), category 9 (street) was classified as category 3 (living room), category 13 (mountain) was classified as category 9 (open country), and category 12 (open country) could be classified as category 9 (open country) (street). This shows that the high inter-class similarity classification problem still exists due to the appearance diversity of scene photos.

Table X and Table XI shows the precision, recall, F1-score and sup. (support) performance of the algorithms on UMS landmark dataset and Scene-15 dataset. Precision is the capability of a classifier to avoid classifying a negative instance as positive. It is described for each class as the proportion of true positives to the total of true positives and

false positives. Recall is the capacity of a classifier to find all instances that are positive. It is described as the ratio of true positives to the total of true positives and false negatives for each class. A weighted harmonic mean of recall and precision is used to get the F1 score, with the best result being 1.0 and the lowest being 0.0. Due to the inclusion of precision and recall in their computation, F1 scores are lower than accuracy measurements. Support is the number of instances of the class that occur in the particular dataset. The requirement for stratified sampling or rebalancing may be indicated by unbalanced support in the training data, which may point to structural flaws in the classifier's reported scores. Imbalanced support in the training data may indicate structural weaknesses in the reported scores of the classifier and could indicate the need for stratified sampling or rebalancing.

TABLE X. CLASSIFICATION PERFORMANCE ON UMS LANDMARK DATASET

### B. Features Shape and Number of Epoch

The extracted features were reshaped into 1D and 2D representations, as can be referred in Table XIII. The 1D feature shape was being fed to LSVM, CNN 1D, GBDT, SGD, and MLP, whereby the 2D feature shape was being fed to CNN 2D classifier. For both datasets, Table XII and Table XIII show the

features' form as well as the best number of epoch for training the CNN. As seen in Table XII, the EFFNET generated the largest 1D features (62720) by using the average pool layer. NASNetMobile and MobileNetV2, on the other hand, generated the smallest number of features (1000). The best classification accuracy can be obtained by using only 30 epochs via CNN 1D for all the features. Whereby, the number of epochs was higher for training the CNN 2D are except for MobileNetV2.

TABLE XII. FEATURES' DIMENSION SIZE AND EPOCH FOR UMS LANDMARK DATASET

Feature Extraction	Layer Name	Features Shape (1D)	Features Shape (2D)	No.Epoch (CNN 1D)	No.Epoch (CNN 2D)
EFFNet	avg_pool	(1, 1280)	(16,16,5)	30	120
	top_conv	(1, 62720)	(16,16,245)	30	120
RESNet152	avg_pool	(1,2048)	(32,32,2)	30	150
NASNetMobile	Prediction	(1,1000)	(2,2,250)	30	60
MobileNetV2	Prediction	(1,1000)	(2,2,250)	30	30

TABLE XIII. FEATURES DIMENSIONS SIZE AND EPOCH DOR SCENE-15 DATASET

Feature Extraction	Layer Name	Features Length (1D)	Features Length (2D)	No.Epoch (CNN 1D)	No.Epoch (CNN 2D)
EFFNET	avg_pool	(1, 1280)	(16,16,5)	120	150
	top_conv	(1, 62720)	(16,16,245)	30	150
RESNET 152	avg_pool	(1,2048)	(32,32,2)	60	150
NASNetMobile	Prediction	(1,1000)	(2,2,250)	60	150
MobileNetV2	Prediction	(1,1000)	(2,2,250)	30	150

Based on Table XIII, the number of epoch required for training the CNN classifiers for Scene-15 dataset was larger than UMS landmark dataset. It was found that the CNN 2D required up to 150 epochs for CNN training.

Fig. 8, Fig. 9, Fig. 10, and Fig. 11 present the graph of model accuracy and model loss over number of epochs for EFFNET and MobilenetV2 by using CNN 2D and CNN 1D classifiers. To determine the appropriate number of epochs for each CNN architecture, the evaluation was made on 30, 60, 90, 120, and 150 epochs. By using 120 number of epoch, the EFFNET with avg\_pool layer managed to obtain the best classification performance with very minimal gap between training and test model lost, as can be seen in Fig. 9. On the

other hand, a slightly larger gap size can be observed between training and testing in model loss in EFFNET using top\_conv layer with stagnant performance in model accuracy despite of larger number of epochs being used as shown in Fig. 11.

In summary, the feature extraction by using EFFNET by using avg\_pool and top\_conv layers with both CNN and SVM classifiers can be considered as the best option in this context and with their own merits. For instance, the EFFNET with avg\_pool layer produced a light feature size which definitely use less computational effort for storage and classification. Meanwhile, the EFFNET with top\_conv layer, even though it produced a larger size of features, but required a very minimum number of epochs to run the CNN classifier with a high classification accuracy. Thus, the trained model, by using EFFNET-avg\_pool with CNN 1D classifier could be deployed in the development of Landmark Recognition System.

C. Effect of Feature Selection

The performance of feature selection methods such as PCA, LDA, Boruta, and RFE on the UMS and Scene-15 datasets, is discussed in this section. The feature selections were applied to EFFNET, RESNET152, NASNETMobile, and MobileNetV2 features, in particular.

1) UMS dataset: The three PCA variations, as shown in Table XIV, mirrored the varying proportions of features selected, as seen in Table IX. As shown in Table XIV, the baseline referred to the findings achieved in the prior trial without any treatment employing feature selection.

TABLE XIV. EFFECT OF PCA ON ACCURACY FOR UMS DATASET

Feature Extraction	Classification	Baseline	PCA 1	PCA 2	PCA 3	Spark-line
EFFNET	LSVM	1.00	1.00	1.00	<b>1.00</b>	
	CNN (1D)	1.00	1.00	1.00	<b>1.00</b>	
	GBDT	1.00	0.99	0.99	0.99	
	SGD	1.00	1.00	1.00	<b>1.00</b>	
	MLP	0.44	0.68	0.59	0.57	
RESNET 152	LSVM	1.00	1.00	1.00	1.00	
	CNN (1D)	1.00	1.00	1.00	1.00	
	GBDT	1.00	0.98	0.96	0.95	
	SGD	0.95	1.00	1.00	1.00	
	MLP	0.12	0.66	0.64	0.64	
NASNet Mobile	LSVM	0.77	0.77	0.77	0.77	
	CNN (1D)	1.00	1.00	1.00	<b>1.00</b>	
	GBDT	0.99	0.91	0.92	0.98	
	SGD	0.82	0.88	0.80	0.91	
	MLP	0.33	0.12	0.12	0.61	
MobileNetV 2	LSVM	0.85	0.85	0.85	0.85	
	CNN (1D)	1.00	1.00	1.00	<b>1.00</b>	
	GBDT	1.00	0.88	0.87	0.89	
	SGD	0.77	0.82	0.77	0.85	
	MLP	0.56	0.72	0.12	0.12	

Based on the overall result in Table XIV, the treatment of PCA had a positive effect on majority of the features as it has retained accuracy performance and even more, slight improvement on the accuracy can be observed on all the features especially the MLP classifiers. In a flipside, the accuracy performance using GBDT has slightly affected regardless any features used.

Table XV shows the classification performance after the LDA and Boruta were performed on all the features. The LDA had a positive effect on the accuracy performance for almost all the features except the classification using MLP. Despite pruning more than 90% of features by using LDA, the accuracy performance improvement can be observed on RESNET152, NASNETMobile and MobileNetV2 along sustaining the best accuracy performance on EFFNET. On the other hand, the BORUTA only demonstrated positive effect on EFFNET and RESNET152. The other highlight was the classification using MLP on EFFNET features has dramatically improved the accuracy performance from 0.44 to 0.83.

TABLE XV. EFFECTS OF LDA AND BORUTA ON ACCURACY FOR UMS DATASET

Feature Extraction	Classification	Baseline	LD A	BORUT A	Trendline
EFFNET	LSVM	1.00	<b>1.00</b>	1.00

	GBDT	1.00	<b>1.00</b>	1.00	
	SGD	0.77	<b>1.00</b>	0.77	
	MLP	0.56	0.19	0.12	

Table XVI presents the analysis of feature selection performance using RFE.

TABLE XVI. EFFECTS OF RFE ON ACCURACY FOR UMS DATASET

Feature Extraction	Classification	Baseline	RFE 1	RFE 2	RFE 3	Spark-line
EFFNet	LSVM	1.00	1.00	1.00	<b>1.00</b>	
	CNN (1D)	1.00	1.00	1.00	<b>1.00</b>	
	GBDT	1.00	1.00	1.00	<b>1.00</b>	
	SGD	1.00	1.00	1.00	<b>1.00</b>	
	MLP	0.44	0.46	0.48	0.55	
RESNet152	LSVM	1.00	1.00	1.00	1.00	
	CNN (1D)	1.00	1.00	1.00	1.00	
	GBDT	1.00	1.00	1.00	0.96	
	SGD	0.95	0.93	1.00	1.00	
	MLP	0.12	0.39	0.12	0.64	
NASNet Mobile	LSVM	0.77	0.14	0.16	0.20	
	CNN (1D)	1.00	0.82	0.34	0.12	
	GBDT	0.99	0.96	0.98	0.99	
	SGD	0.82	0.44	0.39	0.10	
	MLP	0.33	0.12	0.12	0.12	
MobileNet V2	LSVM	0.85	0.13	0.23	0.22	
	CNN (1D)	1.00	1.00	0.77	0.17	
	GBDT	1.00	0.99	0.99	0.98	
	SGD	0.77	0.13	0.13	0.12	
	MLP	0.56	0.12	0.12	0.12	

RFE worked well on EFFNET and RESNET152, as shown in Table XVII. Moreover, the performance of MLP on RESNET152 had substantially improved from 0.12 to 0.64. On the other hand, RFE absolutely failed to perform on NASNetMobile and MobileNetV2, resulting in a significant fall in the accuracy of all classifiers used.

Next, the detailed analysis of feature selection performance on each feature and machine learning classifier are shown in Fig. 12, Fig. 13, Fig.14 and Fig.15.

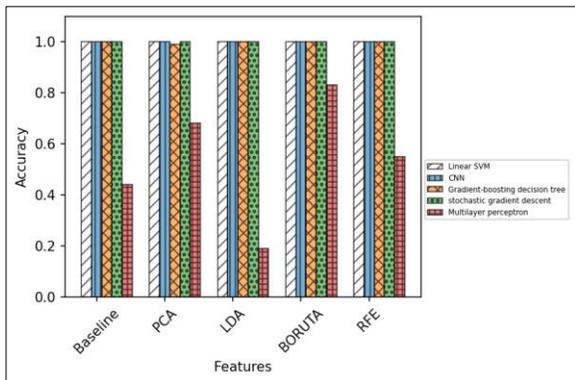

Fig. 12. Effects of feature selection on machine learning classifiers for EFFNET (UMS dataset)

As shown in Fig. 12, except for MLP, all classifiers in EFFNET performed remarkably well on all feature selections. Whereby, the EFFNET features would be more compatible with MLP if PCA and BORUTA is applied as the accuracies were increased by 55% and 89% respectively. On RESNET152 with EFFNET, a similar pattern of feature selection performance can be observed, as shown in Fig. 13. In fact, regardless of which feature selection is employed, the accuracy of SGD can be improved. When PCA and RFE were used with MLP, a positive effect on accuracy was noticed.

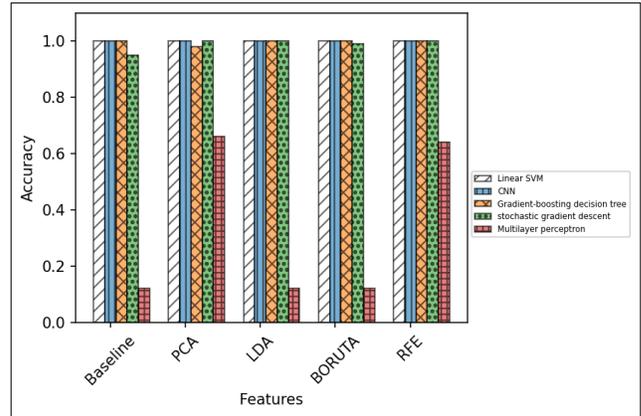

Fig. 13. Effects of feature selection on machine learning classifiers for RESNET152 (UMS dataset)

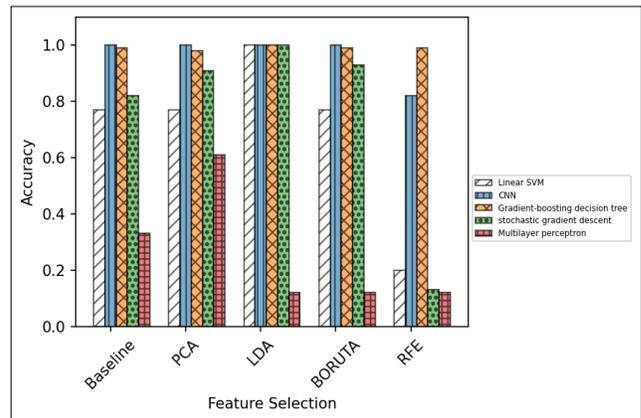

Fig. 14. Effects of feature selection on machine learning classifiers for NASNETMOBILE (UMS dataset)

According to the graph in Fig. 14, GBDT's performance appeared to be consistent across all feature selections, but the performance of the other classifiers dropped when RFE was applied. The best performance of LSVM and SGD could be seen when LDA was used. On MobileNetV2, CNN performed very well with all the feature selections and GBDT was slightly incompatible with PCA. Similar with NASNetMobile, LDA had also improved the accuracy of LSVM and SGD.

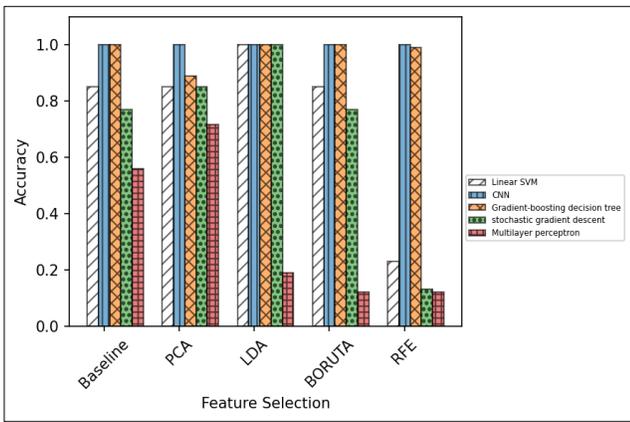

Fig. 15. Effects of feature selection on machine learning classifiers for MOBILENETV2 (UMS dataset)

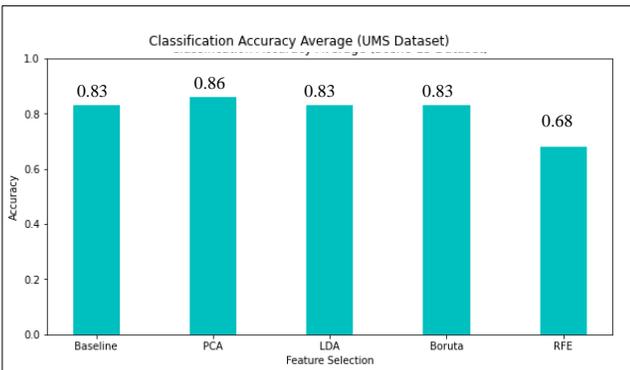

Fig. 16. The average performance comparisons of feature selection for UMS dataset

The summary of feature selection performance across features and classifiers for the UMS dataset is shown in Fig. 16. The PCA was found to be the most robust feature selection method since its performance was consistent across various features and classifiers. However, when accuracy and feature size were taken into account, LDA's performance was the most significant. Meanwhile, if execution time was not a major concern and automatic feature selection is one of the criteria for selecting features, the BORUTA could be considered. Aside from that, the results of Tables XII, XIII, and XIV implied that EFFNET is the best and stable features. The best classifiers were GBDT and CNN, which consistently excelled across a variety of feature selections.

2) *Scene-15 dataset*: Table XVII shows the performance analysis of PCA on Scene-15 dataset.

TABLE XVII. EFFECTS OF PCA ON ACCURACY FOR SCENE-15 DATASET

Feature Extraction	Classification	Baseline	PCA 1	PCA 2	PCA 3	Spark line
EFFNET	LSVM	0.94	0.94	0.93	0.91	
	CNN (1D)	0.94	0.93	0.92	0.93	
	GBDT	0.68	0.06	0.01	0.05	
	SGD	0.68	0.93	0.93	0.93	
	MLP	0.43	0.56	0.32	0.33	
RESNET15 2	LSVM	0.62	0.61	0.59	0.55	
	CNN (1D)	0.62	0.66	0.66	0.66	
	GBDT	0.41	0.33	0.44	0.49	
	SGD	0.37	0.54	0.52	0.52	
	MLP	0.23	0.40	0.44	0.44	
NASNet Mobile	LSVM	0.68	0.70	0.68	0.67	
	CNN (1D)	0.74	0.77	0.73	0.71	
	GBDT	0.55	0.52	0.51	0.54	
	SGD	0.58	0.68	0.61	0.64	
	MLP	0.39	0.63	0.08	0.08

	GBDT	0.07	0.42	0.42	0.56	
	SGD	0.68	0.65	0.68	0.65	
	MLP	0.34	0.60	0.08	0.08	
<b>AVERAGE</b>		<b>0.57</b>	<b>0.62</b>	<b>0.55</b>	<b>0.57</b>	

Overall, PCA did not enhance classification accuracy considerably. SGD and MLP are the only two classifiers that performed better with PCA. For instance, EFFNET-SGD accuracy increased from 0.68 to 0.94, whereas NASNETMobile's classification accuracy increased from 0.39 to 0.63.

The accuracy performance of LDA and BORUTA treatment as compared to without feature selection treatment (Baseline) can be referred in Table XVIII. As depicted in Table XVIII, LDA performed excellently on many features and classifiers, except EFFNET-GBDT, NASNETMobile-GBDT and MOBILENetV2-GBDT. In contrast, BORUTA did not increase the accuracy of nearly all features, and there was even a slight drop in accuracy.

TABLE XVIII. EFFECTS OF LDA AND BORUTA ON ACCURACY FOR SCENE-15 DATASET

Feature Extraction	Classification	Baseline	LDA	BORUTA	Spark line
EFFNet	LSVM	0.94	0.99	0.93	
	CNN (1D)	0.94	0.99	0.93	
	GBDT	0.68	0.05	0.70

	MLP	0.34	0.75	0.23	
<b>AVERAGE</b>		<b>0.57</b>	<b>0.73</b>	<b>0.55</b>	

The analysis of RFE accuracy performance is shown in Table XIX. The pattern of data presented in Table XIX obviously indicates that RFE has brought less impact on improving almost all feature representation. However, the positive effects of RFE can be seen on EFFNET-SGD, EFFNET-MLP and MobileNetV2-MLP.

TABLE XIX. EFFECTS OF RFE ON ACCURACY FOR SCENE-15 DATASET

Feature Extraction	Classification	Baseline	RFE 1	RFE 2	RFE 3	Spark line

	SGD	0.68	0.67	0.69	0.23	
	MLP	0.34	0.59	0.08	0.08	
<b>AVERAGE</b>		<b>0.57</b>	<b>0.56</b>	<b>0.47</b>	<b>0.28</b>	

Fig. 17 to 20 show a detailed analysis of feature selection performance for each feature and machine learning classifier. Based on the graph shown in Fig. 17, the transformation of EFFNET feature by using LDA had improved the classification accuracy of LSVM, CNN, SGD and MLP. In addition to that, the PCA, BORUTA and RFE brought significant effects on the accuracies for MLP and SGD.

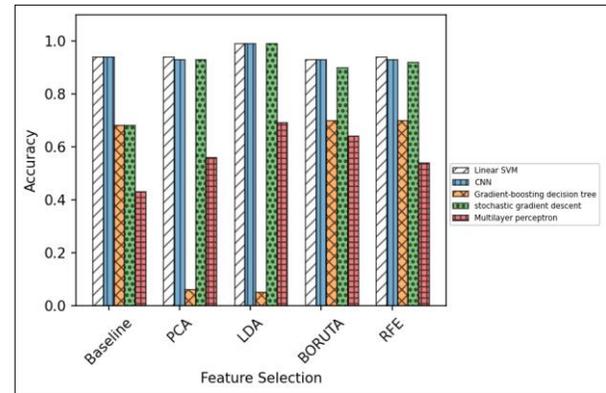

Fig. 17. Effects of feature selection on machine learning classifiers for EFFNET (scene-15 dataset)

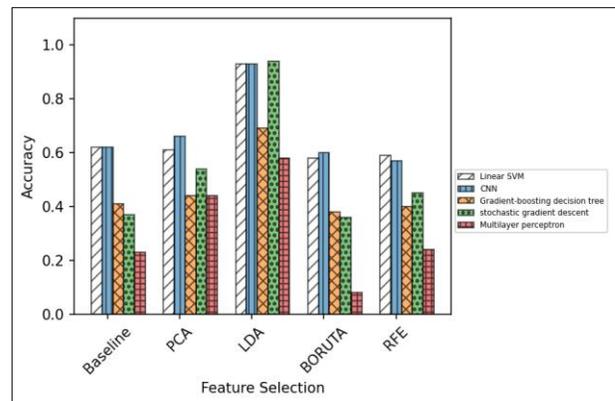

Fig. 18. Effects of feature selection on machine learning classifiers for RESNET152 (scene-15 dataset)

As for RESNET152, as shown in Fig. 18, there was a tremendous increase on the accuracy when LDA was being used to transform the features for CNN, LSVM and SGD. The rest of the feature selection techniques by using PCA, BORUTA and RFE seemed to have less positive impacts on the accuracies. Similarly in Fig. 19 and Fig. 20, LDA still outperformed the accuracy of PCA, BORUTA and RFE on all classifiers except GBDT. For NASNETMobile, PCA demonstrated a bit of an improvement on the accuracies for CNN, SGD and MLP. There were no positive effects on the LSVM, CNN, SGD, and MLP accuracies for BORUTA and RFE.

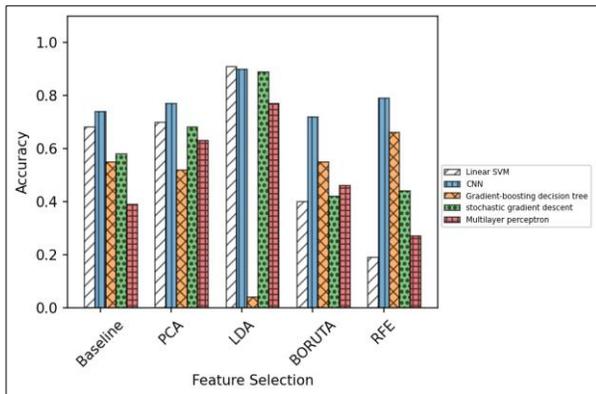

Fig. 19. Effect of feature selection on machine learning classifiers for NASNETMOBILE (scene-15 dataset)

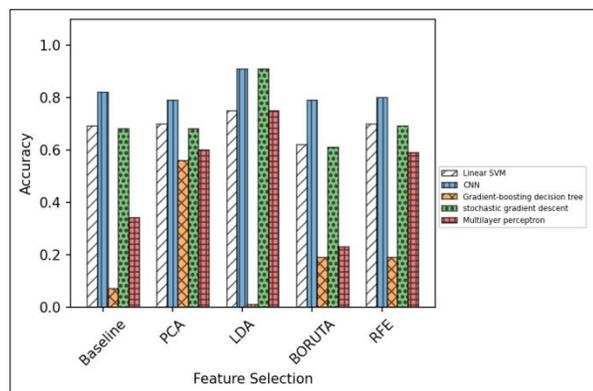

Fig. 20. Effect of feature selection on machine learning classifiers for MOBILENETV2 (scene-15 dataset)

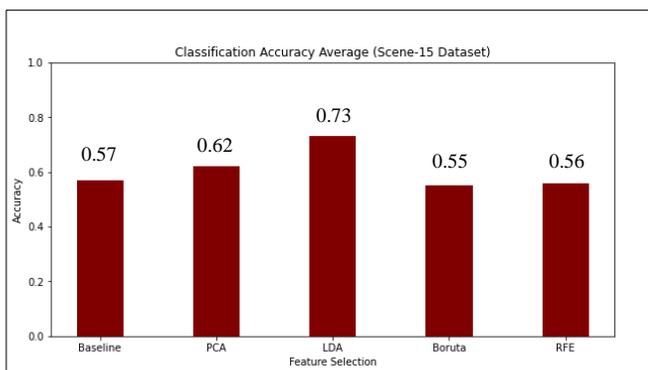

Fig. 21. The average performance comparisons of feature selection for scene-15 dataset

Fig. 21 shows the summary of feature selection performance on the Scene-15 dataset. LDA was the best feature selection technique for the Scene-15 dataset since it not only worked with a wide range of features and classifiers, but it also improved classification accuracy significantly. BORUTA and RFE, on the other hand, have no substantial impact on classification performance. Due to the constant performance across numerous feature selections, it can also be inferred that EFFNET is the best features and, LSVM is the best classifier.

## V. CONCLUSION AND FUTURE WORKS

This paper evaluated several transfer learning approaches and feature selections for effective and super lightweight landmark recognition model. A landmark recognition model was trained through the features extraction by using the pre-trained CNN architectures and machine learning classifiers. The new UMS landmark datasets were created, and the landmark recognition model was also evaluated with the Scene-15 dataset. The findings showed that the EFFNET CNN architecture with CNN classifier is the best feature extraction and classifier in this study. EFFNET-CNN achieved 100% and 94.26% accuracies on UMS landmark and Scene-15 dataset, respectively. Moreover, the features created by EFFNET were more compact compared to the other features. Furthermore, based on the evaluation of several feature selection algorithms, LDA was determined to be the best feature selection technique for vastly reducing feature dimensionality by 99.69% for UMS landmark dataset and 98.90% for Scene-15 dataset while maintaining good accuracies. However, although a super lightweight landmark recognition model was produced, it must undergo extra pre-processing step to reduce the dimensionality of features which will impose excessive computational costs of processing. Therefore, future works that can be suggested are to evaluate the effect of the proposed dimensionality reduction technique on the computational cost of the algorithms as well as to test it on various benchmark datasets.

# Performance Comparison of the Kernels of Support Vector Machine Algorithm for Diabetes Mellitus Classification

Dimas Aryo Anggoro, Dian Permatasari

Informatics Department, Universitas Muhammadiyah Surakarta  
Surakarta, Indonesia

**Abstract**—Diabetes Mellitus is a disease where the body cannot use insulin properly, so this disease is one of the health problems in various countries. Diabetes Mellitus can be fatal, cause other diseases, and even lead to death. Based on this, it is essential to have prediction activities to find out a disease. The SVM algorithm is used in classifying Diabetes Mellitus diseases. This study aimed to compare the accuracy, precision, recall, and F1-Score values of the SVM algorithm with various kernels and data preprocessing. Data preprocessing included data splitting, normalization, and data oversampling. This research has the benefit of solving health problems based on the percentage of Diabetes Mellitus and can be used as material for accurate information. The results of this study are that the highest accuracy was obtained by 80% (obtained from the polynomial kernel), the highest precision was obtained by 65%, which was also obtained from the polynomial kernel, and the highest recall was obtained by 79% (obtained from the RBF kernel) and the highest F1-score was obtained by 70% (which was also obtained from the RBF kernel).

**Keywords**—Diabetes mellitus; kernel; normalization; oversampling; SVM

## I. INTRODUCTION

Diabetes Mellitus is a disease where blood sugar levels are overly high because the body cannot use insulin properly. Diabetes Mellitus has become a severe health problem in various countries, including Indonesia [1]. The International Diabetes Federation (IDF) explained that in 2021 the number of people with Diabetes Mellitus in Indonesia reached 19.5 million, while in 2019 the figure was 10.7 million. This means there has been an increase of nearly 9 million cases in just two years, during the COVID-19 pandemic. With almost two times the addition, Indonesia ranks fifth in the world. Not only in Indonesia, but this upward trend in cases also occurs worldwide. According to IDF data, at least 1 in 10 people or as many as 537 million people live with Diabetes Mellitus. If not appropriately treated immediately, Diabetes Mellitus can be fatal, cause other diseases, and even lead to death. Based on this, it is essential to have prediction activities to find out a disease. This activity is carried out so a disease can be detected quickly and treated immediately.

Activities in predicting various diseases have been carried out in various scientific fields, one of which is computer science. Along with the development of information and communication technology, it can be used to improve the

ability of the system to help detect Diabetes Mellitus disease [2]. Data mining is part of the Knowledge Discovery in Database (KDD) process that can classify, predict, and get a lot of information from large data sets [3]. Classification is an important stage in data mining, classification is carried out by looking at variables from existing data groups and aims to predict the class of an object that was not previously known [4].

## II. LITERATURE REVIEW

Previous research regarding applying the K-Nearest Neighbour classification model to the diabetes patient dataset explained that the study had the highest accuracy of 39% [5]. Another study is the implementation of the Decision Tree C4.5 algorithm for diabetes prediction resulted in a prediction model with the highest accuracy of 70.32% [6]. The previous study's shortcoming is that the prediction model's accuracy is still below 80%, so there is a need to improve accuracy performance. In research [7] that compared the accuracy, recall, and precision classification of the C4.5 algorithm, Random Forest, Support Vector Machine (SVM), and Naïve Bayes resulted in the C4.5 algorithm obtaining accuracy of 86.67%, the Random Forest algorithm obtained an accuracy of 83.33%, the SVM algorithm obtained accuracy by 95%, and the Naive Bayes algorithm obtained an accuracy of 86.67%. The highest accuracy algorithm is the SVM algorithm. Therefore in this study applying the SVM algorithm for the classification of Diabetes Mellitus disease.

The SVM algorithm was chosen because it is reliable in processing large amounts of data by optimizing hyperplanes in high-dimensional space that maximizes margins between data [8]. The kernel in SVM is used to determine kernel parameters and produce the best accuracy in the classification process. Linear kernels are used when a hyperplane can easily separate classified data. At the same time, non-linear kernels are used when the data is separated using curved lines or a plane in space with high dimensions [9].

This study aims to compare the performance metrics e.g., accuracy, precision, recall, and F1-Score values of the SVM algorithm with various kernels and preprocessing data in the classification of Diabetes Mellitus disease. The SVM algorithm is evaluated to determine which kernel can produce the best performance metric.

It has the benefit of solving health problems based on the percentage of Diabetes Mellitus and can be an accurate information material. The output of this study is to imply that the SVM algorithm is expected to show better performance values than previous studies.

### III. METHODOLOGY

#### A. Data Collection

The first stage in this study is the collection of Diabetes Mellitus datasets. The dataset used is the Pima Indian diabetes dataset obtained from the UCI Machine Learning Repository. Several variables and attributes can facilitate the research process in data mining. The Pima Indian diabetes dataset consists of 768 data and 9 features. The variables and features used are shown in Table I.

TABLE I. VARIABLES AND ATTRIBUTES OF PEOPLE WITH DIABETES MELLITUS

Variable	Attribute
X1	Pregnancies, the number of pregnancies during life in the range of 0-17 times.
X2	Glucose, glucose/blood sugar levels. Normal blood sugar levels are below 120 mg/dL, while the sugar levels of diabetics are more than 120 mg/dL. The data range in the dataset is 0-199 mg/dL.
X3	Blood Pressure, blood pressure with mmHg units, the data range in the dataset is 0-112 mmHg.
X4	Skin Thickness, skin fold thickness with a data range of 0-99 mm. The norm is about 12.5 mm.
X5	Insulin, insulin levels in the blood with a data range of 0-846 U / ml.
X6	BMI, body mass weight with a data range of 0-67.1 BMI
X7	Diabetes Pedigree Function, History of diabetes Mellitus disease in the family with a data range of 1.001-2.42.
X8	Age, age of the patient (years) with a data range of 21-81 years.
Y	Outcome, negative and positive class variables (0 and 1). 0 are indicators of non-diabetics while 1 is an indicator of diagnosed diabetics.

#### B. Data Preprocessing

1) *Data splitting*: The next stage is the data splitting stage, which separates training data and testing data. Training data is used to create models that are applied to testing data [10] and testing data cannot be used for the training process, so the model learns from the new data [11]. Training and testing data are determined randomly, so the proportion between categories remains balanced [12]. In this study, splitting data was divided into 80% training data and 20% testing data.

2) *Data normalization*: Normalization of data in datasets aims to create data in the same range of values [13]. This study used the min-max and z-score normalization methods.

a) *Min-Max normalization*: Normalization of min-max can overcome non-uniform data forms with a range of values greater than 0-1 [14]. Min-max normalization was chosen because it has the advantage that the data is balanced between before and after normalization [15]. The normalization of min-max is presented in (1).

$$x_{new} = \frac{x_{old} - x_{min}}{x_{max} - x_{min}} \quad (1)$$

$x_{new}$  represents the min-max value,  $x_{old}$  is the value to be normalized,  $x_{min}$  is the lowest value of the overall data and  $x_{max}$  is the highest value of the entire data.

b) *Z-Score normalization*: Z-Score normalization is used to compare the performance or quality of data goals with the average distribution of data across groups based on standard deviation values [16]. Z-score normalization was chosen because it is a suitable method for balancing the data scale [17]. (2) is a formula for knowing the z-score.

$$x_{new} = \frac{x_{old} - \mu}{\sigma} \quad (2)$$

$x_{new}$  is the z-score value,  $x_{old}$  is the value to be normalized,  $\mu$  is the average value of the whole data and  $\sigma$  is the standard deviation value.

3) *SMOTE (Synthetic Minority Over-sampling Technique)*: The SMOTE method can handle dataset class imbalances by making data replication of minor classes equivalent to major classes [18]. The diabetes dataset used in this study had a total of 268 positive classes and 500 negative classes, so there was an imbalance between the positive and negative classes. Therefore, the SMOTE method was used in this study to balance between positive classes and negative classes. (3) is the formula for SMOTE.

$$x_{syn} = x_i + (x_{knn} - x_i)\gamma \quad (3)$$

$x_{syn}$  is the resulting new class data,  $x_i$  is the approach to i,  $x_{knn}$  is the x closest to  $x_i$  and  $\gamma$  is a random number between 0-1.

#### C. Data Processing

1) *Support Vector Machine (SVM)*: SVM is a good algorithm for data classification [19] with the principle of finding the best hyperplane that serves as a separator of two data classes [20]. The best hyperplane is determined by measuring the hyperplane margin and finding its maximum point, margin is the distance between the hyperplane and the nearest point of each class and this closest point is called the support vector [21]. The following is a description of SVM, there is data  $\vec{x}i \in (\vec{x}1, \vec{x}2 \vec{x}3... \vec{x}n)$   $x_i$  is data consisting of n attributes and two classes  $y_i \in +1, -1$ . Suppose that the two classes can be perfectly separated by a d-dimensional hyperplane defined by (4).

$$\vec{w} \cdot \vec{x}i + b = 0 \quad (4)$$

Data  $\vec{x}i$  which belonging to the positive class (+1) are shown in (5).

$$\vec{w} \cdot \vec{x}i + b \geq -1 \quad (5)$$

Meanwhile, data  $\vec{x}i$  belonging to the negative class (-1) are shown in (6).

$$\vec{w} \cdot \vec{x}i + b \leq +1 \quad (6)$$

The maximum margin can be obtained by maximizing the value of the distance between the hyperplane and its closest point or support vector which  $\frac{1}{\|\vec{w}\|}$  [22]. It is formulated as Quadratic Programming (QP) by looking for a minimum point based on (7).

$$\min \tau(w) = \frac{1}{2} \|\vec{w}\|^2 \quad (7)$$

By paying attention to the constraints on (8).

$$y_i(\vec{x}_i, \vec{w} + b) - 1 \geq 0 \quad (8)$$

$y_i$  is the target class to  $i$ ,  $\vec{x}_i$  is the input data to  $i$ ,  $\vec{w}$  is the weight, and  $b$  is the relative field position.

2) *Kernel SVM*: To work around high-dimensional data, a kernel can transform the input space into a feature space [23]. Kernel functions commonly used in SVM are Linear [24], Radial Basic Function (RBF) and Polynomial [25]. The parameters possessed by kernel functions are used in the testing process [26]. There is no definite conclusion about the best kernel, therefore this study will compare 4 kernel functions, namely linear, RBF, polynomial and sigmoid.

a) *Kernel linear*: The Linear kernel was chosen because it is the simplest kernel and is used when the data is linearly overstretched.

$$K(x, y) = x \cdot y \quad (9)$$

b) *Kernel polynomial*: The Polynomial kernel was chosen because it can be used when the data is not linearly separated and is suitable for use in solving classification problems in all training data that has been normalized.

$$K(x, y) = (\gamma(x \cdot y) + C)^d \quad (10)$$

c) *Kernel Radial Basic Function (RBF)*: The RBF kernel is used when the data is not linearly separated, it is chosen because it performs well with specific parameters, and the result of the training has a small error value.

$$K(x, y) = \exp(-\gamma|x - y|^2) \quad (11)$$

d) *Kernel sigmoid*: This sigmoid kernel was chosen because it is similar to the two-layer perceptron model of the neural network, which works as an activation function for neurons.

$$K(x, y) = \tanh(\gamma(x \cdot y) + C) \quad (12)$$

3) *Evaluation*: In evaluating the performance of each SVM kernel, we implement several performance metrics, including Accuracy, Performance, Recall and F1-score. Before computing the performance metric score, we build a confusion matrix defined as an evaluation method that provides information comparing the classification of prediction results with the actual classification [27]. In a confusion matrix, there are four terms of value, namely True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). Based on these values, accuracy, precision, recall, and F1-Score values can be generated.

Accuracy is the ratio of predicted correct values of all data [28].

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (13)$$

Precision indicates a correctly classified prediction of positive values divided across positive classified data [28].

$$Precision = \frac{TP}{TP + FP} \quad (14)$$

Recall compares the positive correct predicted value with the entire positive correct value [29].

$$Recall = \frac{TP}{TP + FN} \quad (15)$$

The F1-Score shows the average comparison of precision and recall values [29].

$$F1 - Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (16)$$

#### IV. RESULTS AND DISCUSSIONS

This stage is a decipherment of the research obtained and its explanation.

##### A. Data Preprocessing

The dataset used is the Pima Indian diabetes dataset which consists of 768 data and nine attributes. The initial stage carried out in this study is the process of collecting and processing datasets. In this study, data preprocessing was divided into three steps. The first step is the data splitting process, where the Diabetes Mellitus dataset will be divided into training data and testing data. The second step is the data normalization process to create data in the same range. The third step is an oversampling process to balance the dataset class using the SMOTE method. Data processing in the study uses the Python programming language in the google colab application.

1) *Data splitting results*: After getting the dataset, the next step is to divide the dataset into training data and testing data. The Diabetes Mellitus dataset totaled 768 data consisting of eight variables and one target/class. Then the dataset is divided into 80% training data, totaling 614 data and 20% testing data, totaling 154 data. The diagnosis of Diabetes Mellitus is divided into two, namely non-diabetics who are denoted by 0 and diabetics who are denoted by 1. Obtained diabetics totaled 268 data and non-diabetics amounted to 500 data.

2) *Data normalization results*: The normalization methods used are min-max and z-score.

Fig. 1 shows a comparison of the variables in the dataset, there are two variables being compared namely pregnancies and insulin, the data has a fairly high range of values. For example, on the insulin variable, where the value range is from 0 to over 200, this is considered unbalanced. The min-max normalization method is used to process values into the range 0-1. Fig. 2 shows the results after normalizing the min-max,

where the range of values for the insulin variable becomes smaller, ranging from 0 to 1.

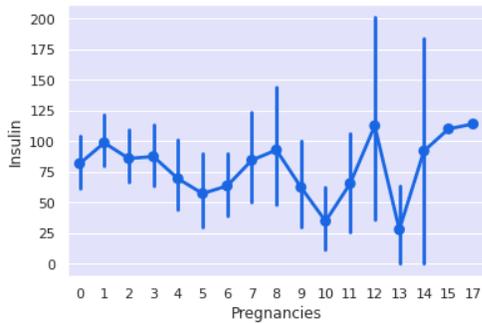

Fig. 1. Before normalization.

Fig. 2. After min-max normalization.

In addition to using the min-max method, data normalization is also carried out using the z-score method. Z-score is performed by processing the mean and standard deviation from the values of its attributes. Fig. 3 shows the results after normalizing the z-score.

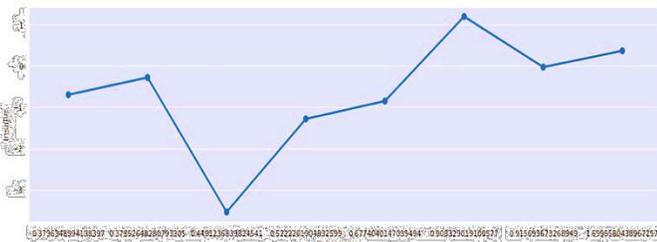

Fig. 3. After Z-score normalization.

3) *Oversampling results:* In the dataset there is a difference between the number of positive and negative classes, therefore there is a need for class balancing. Class balancing is done by oversampling using the SMOTE method and is carried out on training data only. Oversampling is carried out after splitting data so that data replication does not appear in data training and data testing [30]. It can be seen in Fig. 4, before oversampling the number of positive classes was 221 and the number of negative classes was 393. Meanwhile, after oversampling, the number between the positive and negative classes becomes the same, which is 393 so that it becomes balanced.

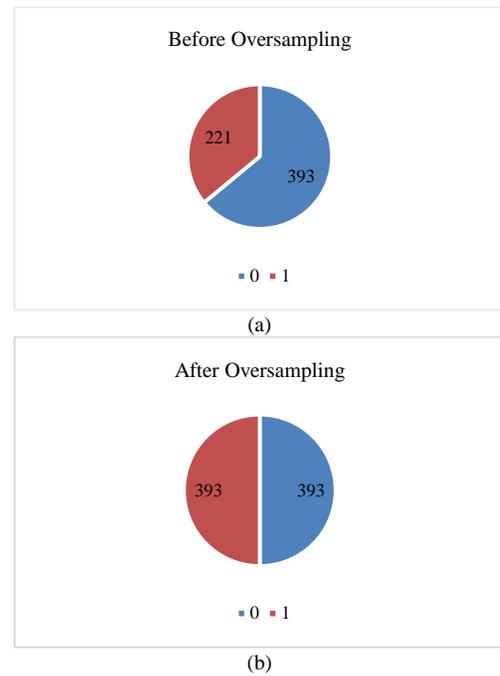

Fig. 4. (a) Data before oversampling, (b) Data after oversampling.

### B. Data Preprocessing and Evaluation

This study compared the performance of the SVM algorithm kernels for the classification of Diabetes Mellitus diseases. SVM kernels include linear, polynomial, RBF, and sigmoid kernels. Evaluation is carried out using the confusion matrix method to calculate the accuracy, precision, recall, and F1-score by optimizing the best parameters for each kernel. Each kernel on SVM has a specific parameter, the cost parameter (C) being the most commonly used value for all kernels. The gamma ( $\gamma$ ) parameter is used to determine the degree of proximity between two points to make it easier to find  $\gamma$  hyperplanes consistent with the data. The gamma parameter is used by polynomial, RBF, and sigmoid kernels. Next is the degree (d) parameter used to map data from the input space to the higher dimension space in the feature space, only the polynomial kernel uses this parameter [31]. The best parameters on the kernel are determined by trial and error. Table II evaluates the classification models of various SVM kernels before different data preprocessing is carried out.

TABLE II. RESULTS OF EVALUATION OF VARIOUS SVM KERNELS BEFORE DATA PREPROCESSING

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	76%	77%	77%	51%
Precision	66%	68%	69%	12%
Recall	57%	55%	53%	8%
F1-Score	61%	61%	60%	10%

For this experiment in Table II, all parameter values in each kernel use auto parameters from python. The highest accuracy is obtained from the polynomial and RBF kernels, which is 77%. The highest precision was obtained from the RBF kernel, which was 69%, the highest recall was obtained from the linear kernel, which was 57% and the highest F1-score was obtained from linear and polynomial kernels, which was 61%. Table III evaluates the classification models of various SVM kernels after preprocessing data with min-max normalization and SMOTE oversampling. Meanwhile, Table IV evaluates the classification models of different SVM kernels after preprocessing data with normalization of z-score and oversampling SMOTE.

Table III and IV show that the highest accuracy is obtained by applying z-score normalization and SMOTE oversampling, which is obtained by 80% using a polynomial kernel. The polynomial kernel using the parameter value  $C=1 \gamma=0.1 d=1.5$  is obtained through trial and error to produce margin optimization values that maximize the hyperplane by mapping the data into higher dimensions. The highest precision is also obtained from the polynomial kernel, which is 65%. This shows that the higher the accuracy value, the higher the precision value. The highest recall was obtained at 79% from the RBF kernel shown in Table III. The RBF kernel uses the parameter value  $C=2.5 \gamma=1.5$ . The highest F1-score is obtained from the RBF kernel shown in Table III, which is 70%. The values in the parameters  $C, \gamma$ , and  $d$  are the most optimal values to get the maximum accuracy value. If the value is increased or decreased, the accuracy value will decrease.

TABLE III. RESULTS OF EVALUATION WITH MIN-MAX AND SMOTE

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	77%	79%	79%	76%
Precision	61%	64%	63%	59%
Recall	72%	72%	79%	68%
F1-Score	66%	68%	70%	63%

TABLE IV. RESULTS OF VALUATION WITH Z-SCORE AND SMOTE

	Kernel			
	Linear	Polynomial	RBF	Sigmoid
Accuracy	79%	80%	77%	78%
Precision	62%	65%	61%	62%
Recall	74%	74%	72%	72%
F1-Score	68%	69%	66%	67%

## V. CONCLUSION AND FUTURE WORKS

This research produces the highest accuracy of up to 80%, obtained from polynomial kernels. So the shortcomings of previous research have been resolved in this study. By optimizing the use of the kernel on the SVM algorithm, it is proven to be able to maximize performance. Hence, it can be concluded that the SVM algorithm performs better in classifying Diabetes Mellitus.

This study found that the performance of the SVM algorithm kernel to produce the highest accuracy was obtained from the polynomial kernel. The accuracy results produced in this study can be used as an accurate and beneficial recommendation for overcoming health problems related to Diabetes Mellitus.

For further research, we can also implement other datasets that contain more data. Also, we can create different novel kernels which may gain better accuracy results. In addition, the results of this study can also be used in making applications to detect Diabetes Mellitus which can be web-based or mobile.

# Deep Study of CRF Models for Speech understanding in Limited Task

Marwa Graja

College of Computer and Information Sciences  
Jouf University, KSA

**Abstract**—In this paper, we propose to evaluate in depth CRF models (Conditional Random Fields) for speech-understanding in limited task. To evaluate these models, we design several models that differ according to the level of integration of local dependencies in the same turn. As we propose to evaluate these models on different types of processed data. We perform our study on a corpus where turns are not segmented into utterances. In fact, we propose to use the whole turn as one unit during training and testing of CRF models. This represents the natural way of conversation. The language used in this work is the Tunisian Arabic dialect. The obtained results prove the robustness of CRF models when dealing with raw data. They are able to detect the semantic dependency between words in the same speech turn. Results are important when CRF models are designed to take into account the words with deep dependencies in the same turn and with advanced preprocessed data.

**Keywords**—Speech understanding; Arabic dialect; CRF models

## I. INTRODUCTION AND RELATED WORKS

Spoken Language Understanding is an important component in spoken dialogue systems. It aims to extract concepts from an utterance to clarify speech meaning. Therefore, the key link in an automatic understanding process revolves around the correspondence between the set of words in the utterance and the set of semantic concepts. In order to resolve this correspondence, the first research works in this field exploited linguistic formalisms such as regular grammars and context-free grammars. Recent works have rather oriented towards the exploitation of machine learning models for concept detection, these models are widely used for the semantic annotation of speech utterances.

Our overview of the literature showed that learning models constitute the dominant context for speech understanding due to the performances recorded particularly in restricted domains. These models enjoy several advantages reported by [1] [2] [3]. Indeed, the intervention of a human expert is limited to the labeling of data, which represents an easier task than the modeling of grammars or patterns. Moreover, these models offer better portability since they are domain and language independent. However, the effectiveness of these models is sensitive to the used corpus, which must be representative and large, in order to determine their parameters [4].

Machine learning models are classified into generative and discriminative models [2] and they are widely applied to speech understanding. HMM (Hidden Markov Models) is an example of generative models and they are used by [5] for speech understanding of Spanish language, using the DIHANA

corpus. The DIHANA corpus task deals with requests of information about railway services. This work uses HMM in the most realistic situations where dialogues are not segmented into utterances. The results of their work are very important. They obtained 92% as F-measure. This good result is due to the large size of the corpus used for training models.

In the literature, several studies show that discriminant models perform better than generative [6] [2] [7]. CRF models (Conditional Random Fields), as an example of discriminant models, have been widely exploited in many tasks in natural language processing such as semantic annotation and syntactic analysis [8], [9] [10]. A particular distinction is reported for CRF models whose performance exceeded that of other models, [11] [2] [12]. It is so important to notice that the CRF models have the capacity to integrate correlated characteristics that make it possible to take into account the local context of an utterance. All of these observations encouraged us to exploit these models in the context of the speech understanding of the Arabic dialect.

Several works have shown the robustness of Conditional Random Fields (CRF) models for request information in the French language using the MEDIA corpus [12]. The MEDIA corpus is manually annotated with semantic concepts of touristic information. Turns in this corpus are segmented into utterances, which simplifies the speech understanding. Raymond et al. [12] have used CRF models and domain knowledge through a set of rules made manually. This has reduced the conceptual error rate (from 11.2% to 10.9% as CER), and has increased the performance of the system to 92% as F-measure. This justifies the advantage of segmenting turns into utterances and the important size of the training corpus.

In addition, CRF models offer two major advantages. On the one hand, they allow segmentation and conceptual annotation taking into account the local context of the utterance. On the other hand, they make it possible to guarantee convergence towards the most probable concepts by taking into account all the previous and following observations in the statement [13]. Indeed, these models have the ability to use all the observations of a sequence to predict a conceptual label. This represents an interesting distinction compared to HMM (Hidden Markov Models).

In this paper, we propose to evaluate the performance of CRF models. We designed several models that differ according to the level of integration of local dependencies in the same turn. We also propose to use several processing levels on the corpus. In addition, almost all learning-based understanding

methods have been interested in modeling speech turns segmented into utterances, we suggest to use turn as a whole unit (not segmented into utterances) to test the performance of CRF models, which represents the natural way of conversation.

This paper is organized as follows. In Section II, we present CRF models for speech understanding. Section III presents Spoken Dialogue Corpus for Tunisian Dialect. Section IV deals with evaluation metrics. In Section V, we present experiments and discussion. A conclusion is drawn in Section VI.

## II. CRF MODELS FOR SPEECH ANNOTATION

Conditional Random Fields (CRFs), initiated by Lafferty, are discriminant models that define the conditional probability of observation sequences according to label sequences [14]. Lafferty defines the conditional sequence labeling probability  $Y=y_1...y_n$  given an observation sequence  $X=x_1...x_n$  as follows:

$$P(Y|X) = \frac{1}{z(X)} \exp(\sum_j \lambda_j t_j(y_{i-1}, y_i, X, i) + \sum_k \mu_k s_k(y_i, X, i)) \quad (1)$$

With

$$z(X) = \sum_y \exp(\sum_j \lambda_j t_j(y_{i-1}, y_i, X, i) + \sum_k \mu_k s_k(y_i, X, i)) \quad (2)$$

- $z(X)$  is a factor that normalizes the probabilities.
- $t_j(y_{i-1}, y_i, X, i)$  represents the transition characteristic function for an observation sequence between the labels at position  $i$  and  $i-1$ .
- $s_k(y_i, X, i)$  represents the characteristic function of the state of the label for a sequence of observations .
- $\lambda_j$  et  $\mu_k$  are real values which make it possible to attribute a weight to each characteristic function to specify its importance. These values therefore make it possible to characterize the discriminating power of the model. These parameters are fixed during the learning phase and make it possible to maximize the likelihood on a set of already annotated data.

Referring to the model defined in Eq. (1), the most likely sequence of concepts for labeling a sequence of input words is:

$$Y^* = \arg \max_y P(Y|X) \quad (3)$$

CRF is modeled by undirected graph models (see Fig. 1) to define a probability distribution over a process of label  $Y$  given an observation  $X$ , by maximizing a conditional probability [14].

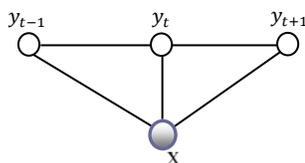

Fig. 1. Graphical design for CRF models

In this graph, the set of vertical nodes are two random fields  $X$  and  $Y$ , respectively describing the set of observations and the set of annotations. Two variables linked in the graph

express that one depends on the other. Based on this, each node  $y_t$  depends on the preceding node  $y_{t-1}$  and the following node  $y_{t+1}$ , and implicitly on the variable  $x$ . Therefore, each variable  $y_t$  must be linked to a variable  $x$  to guarantee the dependence between the labels on the one hand and the sequences of observations on the other.

Learning CRF models consists in determining from the learning corpus, the vector  $\theta = \{\lambda_1, \lambda_1, \dots, \lambda_{k1}, \mu_1, \mu, \dots, \mu_{k2}\}$  that represents the weight vector of the characteristic functions  $t$  and  $s$ . After the learning step, the exploitation of CRF models on new data consists in finding the most probable sequence of states given a new sequence of observations, which are not encountered in the training corpus. We perform this by applying the Viterbi algorithm, as it is the case with HMM models.

## III. SPOKEN DIALOGUE CORPUS FOR TUNISIAN DIALECT – TUDICOI

### A. Corpus Description

The TUDICOI corpus, used in this work, consists of spontaneous oral dialogues of railway request information, in Tunisian Dialect (TD). The purpose of these requests is to consult the timetables of the train, the type of train, the destination of the train, the route taken by the train, the price and types of tickets and the reservation of tickets. We should notify that several requests can be combined during a dialogue between tellers and customers [15].

The transcribed part of the TuDiCoI corpus consists of 1825 dialogues representing 12182 turns. These turns consists of 6533 customer turns and 5649 agent turns. We list the features of the TuDiCoI corpus in Table I.

TABLE I. SPECIFICATION OF THE TUDICOI CORPUS

# dialogues	1 825
# customer turns	6 533
# agent turns	5 649
# customer word	21 551
# customer vocabulary	1 437

Note that on average, each dialogue consists of three turns for the customer and three turns for the agent. Additionally, each customer turn is comprised of an average of 3.3 words. It is important to note that this average is low due to the agglutinative aspect of words in the dialect and the frequent use of keywords to request for information.

TABLE II. CHARACTERISTICS OF SOME DIALOGUE CORPORA IN LIMITED TASKS

Corpus	#D	#T	#V	#W	A	L	Task
Trains 93	98	5 900	860	55 000	H-H	Ang	Manufacture and shipment of goods on the railways.
DIHANA	900	15 413	823	48 243	H-M	Esp	Railway information.
SARF	350	9 763	827	117 156	H-M	Ar	Railway information.

TuDiCoI	1 825	12 182	1 437	21 551	H-H	TD	Railway information.
TARIC	4 662	18 657	--	71 684	H-H	TD	Railway information.
MEDIA	1 257	38 434	2 715	156 048	H-M	Fr	Hotels reservation.

Table II shows the characteristics of different dialogue corpora used in other projects in different languages. It should be noted that #D designates the number of dialogues, #T the number of speaking turns, #V the size of the vocabulary, #W the number of words. A designates the type of corpus (H-H for Human-Human and H-M for Human-Machine). Finally, L provides information on the language used (Eng. for English, Esp. for Spanish, Ar. for Arabic, TD for the Tunisian dialect and Fr. for French). These corpora vary in size from a few tens to thousands of dialogues.

### B. Annotation Schema

We proposed in this work an annotation scheme to perform the manual concept annotation step. Table III summarizes the annotation scheme defined for dialogue acts and semantic concepts [16].

TABLE III. SEMANTIC CONCEPTS

Domain concepts		Requests concepts	
Train	Ticket_Numbers	Path_Req	Existence_Req
Train_Type	Ticket	Hour_Req	Trip_timeReq
Departure_hour	Hour_Cpt	Price_Req	Clarification_Req
Arrival_hour	Departure_Cpt	Dialogue concepts	
Day	Arrival_Cpt	Rejection	Salutation_Begin
Origin	Price_Cpt	Acceptance	Salutation_End
Destination	Class_Cpt	Politeness	
Fare	Trip_time	Out of vocabulary	
Class	Ticket_type	Out	
Link concepts			
Choice			
Coordination			

Due to the complexity of the annotation task, effort, and manual verification, we have annotated only 1476 dialogues which represents 5047 customer turns. The characteristics of the annotated corpus are summarized in Table IV.

TABLE IV. CHARACTERISTICS OF THE ANNOTATED PART OF THE TUDICOI CORPUS

# Annotated dialogues	1 476 / 1 825
# Customer annotated turns	5 047 / 6 533
# Annotated Customer words	16 772 / 21 551

In order to define the parts of the TuDiCoI corpus used for our evaluations, we have divided the annotated corpus into two parts. The first part of the corpus is used for learning and it represents about 80% of the total size, while the second part constitutes 20% of the corpus used for the test. Table V provides information on the characteristics of these two different parts in terms of number of dialogues, speaking turns and words.

TABLE V. CHARACTERISTICS OF TRAINING AND TEST CORPUS

	Training	Test
Dialogues	1202	267
Turns	4131	906
Words	13555	3217

Since we are interested in literal understanding, which does not depend on dialogical context, we have classified all the speaking turns of the test part into three types, according to the recommendation proposed by the ARPA community [17], namely sets A, D and X. Table VI presents the characteristics of these different sets. This classification makes it possible to give an overview of the types of turns contained in the test part.

TABLE VI. CHARACTERISTICS OF THE TEST CORPUS DIVIDED INTO THREE SETS A, D AND X

# Client turns			
A	D	X	Total
379	482	45	906
41.83%	53.21%	4.96%	100%

The first set corresponds to the context-independent customer turns (Set A). This set contains the turns that have no connection with the history of the dialogue. While the second set corresponds to the context-dependent ones (Set D). This set contains the turns that have a relationship with the dialogical context. The third set corresponds to out-of-context turns of the dialogue (Set X). This set includes marginal turns that are not related to the domain. Table VII shows an example for each series.

TABLE VII. EXAMPLE FOR EACH SET A, D AND X

Set	Transcription ◀ / ▶ Transliteration / Translation
A	تكية لتونس برميير كلاس / tikiyh ltuwnis brumiyir klaAs / A first class ticket to Tunis
D	بقداش هي ؟ / b.qad~Aš hiya ? / How much does it cost ?
X	دخلت عالانترنت وشفت / dxalt ʕalAantirnaAt wuʕuft / I am connected to the Internet and I saw

We utilize these different sets of the TuDiCoI corpus for the evaluation of CRF-based speech understanding method for the TD.

Almost all speech-understanding methods are interested in modeling speech turns segmented into utterances. The alternative we have proposed is to use the turn as a whole unit for training and testing the performance of CRF models [16]. This represents the natural way of conversation.

### C. Pretreatments

To evaluate CRF-based speech understanding, we prepared three versions of the TuDiCoI corpus:

- The first version (version I) is a raw version which is not pre-processed, thus increasing the complexity of the structure of the dialect turns. In this version, the words do not respect the spelling transcription guide. Therefore, a word can be written in different spellings. Likewise, this version has morphological problems

such as the agglutination of a particle with the word, which follows it. The evaluations carried out on this version of the corpus is used to test the performance of the CRF models on data not processed in advance.

- The second version of the annotated corpus (version II), is partially preprocessed. This version has undergone spelling correction, morphological analysis of verbs and nouns, as well as synonymy analysis processing.
- The third version of the annotated corpus (version III) presents an improvement compared to the second version and which consists in processing the agglutinations of the names of cities, which makes it possible to dissociate the particle, if it exists, from the name that is attached to it.

#### D. Tabular Corpus

After the manual labeling step into concepts, we converted each version of the annotated corpus into a standard representation adopted by CRF models. This representation uses a set of labels called the BIO notation (Begin Inside Outside) [18], in which:

- The label starting with "B-???" indicates the beginning of the conceptual segment.
- The label "I-???" denotes any meaningful word that is part of the conceptual segment.
- The label "O" is assigned for words that do not refer to any conceptual label.

سلام	B- Salutation_Begin
عليكم	I- Salutation_Begin
تذكرة	B-Ticket
لتونس	B-Destination
بقداه	B-Price_Req
زوز	B-Ticket_Numbers
زوز	B-Ticket_Numbers
لتونس	B-Destination
وقتاش	B-Dep_Hour_Req
يخرج	B-Departure_Cpt
هو	O
تسكرة	B-Ticket
لتونس	B-Destination
ماضي	B-Dep_hour
ساعة	I-Dep_hour

Fig. 2. Example of BIO notation from the TUDICOI corpus

The advantage of using BIO notation is that it is able to segment a set of words into several conceptual segments and display them one after the other [19] [7]. An example from TUDICOI corpus in BIO notation is shown in Fig. 2.

The tabular corpus is used for training and testing CRF models. Conceptual labeling using CRF models consists in finding the best sequence of states, given a sequence of input observations. This problem is solved using the Viterbi algorithm due to the linear topology of CRF models [20]. This algorithm makes it possible to give the list of n best results.

#### IV. EVALUATION METRICS

The evaluation makes it possible to evaluate the conceptual correspondence, which consists in seeking the pairing between a set of words of a turn and a set of semantic concepts. For this, we use the Concept Error Rate (CER). The CER makes it possible to compare the list of reference semantic concepts with the list of concepts emitted by the system according to the following equation:

$$CER = \frac{\# \text{ incorrect predicted concepts}}{\# \text{ reference concepts}} \quad (4)$$

We use other measures to evaluate conceptual labelling such as Precision, Recall, and F-measure. The Precision represents the number of correct concepts found compared to the number of concepts found by the system.

$$Precision = \frac{\# \text{ correct concepts found}}{\# \text{ concepts found}} \quad (5)$$

The Recall represents the number of correct concepts found by the system with regard to the reference concepts.

$$Recal = \frac{\# \text{ correct concepts found}}{\# \text{ reference concepts}} \quad (6)$$

The F-measure combines Precision and Recall according to the following equation:

$$F - \text{measure} = \frac{2 \times \text{Recal} \times \text{Precision}}{\text{Recal} + \text{Precision}} \quad (7)$$

We used in our experiments, the free tool CRF++ for the training and testing steps. It should be noted that the CRF++ tool implements learning by Newtonian method and uses decoding using the Viterbi algorithm.

#### V. RESULTS AND DISCUSSION

In order to evaluate the performance of CRF models, we used several models that differ according to the level of integration of local dependencies in the same turn. These dependencies vary according to the unigram (one word) or bigram (two words) interval of the word to label.

After an initial test phase, we limited the number of models tested to four.

- The first (Model 0) is a model that does not take into account any dependence between the words of the same turn. In this case, CRF models play the role of a simple semantic tagger.
- The second (Model 1) is a model that uses a two-word window taking into account the previous word and the next word in the same turn.
- The third (Model 2) is a model that uses a window involving two words before and two words after the current word.
- The fourth model (Model 3) consists of improving the third model by adding two local dependencies. This dependency uses two bigrams taking into account the current word with the precedent word (respectively with the next word).

Then, we use these models for learning the CRF parameters based on different versions of the annotated corpus (version I,

II and III). The Table VIII, Table IX and Table X illustrate the results of the evaluation of the concept labeling in terms of Precision, Recall, F-measure and Concept Error Rate (CER).

TABLE VIII. RESULTS OF THE CONCEPTUAL LABELING OF VERSION I OF THE CORPUS

		Model 0	Model 1	Model 2	Model 3
<b>CER</b>	(%)	20.05	10.44	8.98	8.47
<b>Precision</b>	(%)	79.19	88.50	89.86	90.33
<b>Recall</b>	(%)	76.36	80.45	79.68	79.21
<b>F-measure</b>	(%)	77.75	84.28	84.46	84.40

TABLE IX. RESULTS OF THE CONCEPTUAL LABELING OF VERSION II OF THE CORPUS

		Model 0	Model 1	Model 2	Model 3
<b>CER</b>	(%)	18.65	9.05	8.39	7.70
<b>Precision</b>	(%)	80.72	90.22	90.75	91.45
<b>Recall</b>	(%)	78.13	83.57	82.47	82.47
<b>F-measure</b>	(%)	79.40	86.77	86.41	86.73

TABLE X. RESULTS OF THE CONCEPTUAL LABELING OF VERSION III OF THE CORPUS

		Model 0	Model 1	Model 2	Model 3
<b>CER</b>	(%)	20.05	9.19	8.51	7.86
<b>Precision</b>	(%)	79.28	90.12	90.66	91.26
<b>Recall</b>	(%)	76.75	83.93	82.68	82.24
<b>F-measure</b>	(%)	77.99	86.92	86.48	86.52

Based on these experiments, we notice that the CER decreases with the improvement of the quality of data used for learning. This clearly shows that the pre-processing carried out makes it possible to improve the speech understanding. We noticed also that the models that take into account the dependence between the different words of the same turn (Model 2 and Model 3) make it possible to improve the speech understanding. This is justified by the decrease in the CER and the increase in the F-measure.

Besides these results, we justify the robustness of CRF models with not processed data. Table VIII shows that the F-measure is 77.75% for the "Model 0" which does not take into account underlying dependencies, and reaches 84.40% for the "Model 3" by introducing the bi-model gram.

The examination of the errors made by the CRF models, directed us to carry out other experiments by exploiting the same test corpus, but with considering the dependence of the turn according to the dialogical level and exploiting the sets A, D and X (Table VI). Based on this classification, we tested the CRF models using these different sets on the different versions of preprocessing corpus.

Indeed, we obtained three different versions according to the processing performed for each set A, D and X, starting from the raw version to the fully processed version for each series. The conceptual labeling of the different series is based

on the same CRF models based on the different models (Model 0, Model 1, Model 2 and Model 3) presented previously.

Table XI summarizes the results obtained in terms of CER, Precision, Recall and F-measure. From these results, we notice that the CER obtained on the type A speech turns (speech context-independent set) is the lowest rate, comparing it with the results of sets D and X. Therefore, we can conclude that a large part of the errors is due to the presence of out-of-context statements of the dialogue (Set X) and of context-dependent statements (Set D). These results are expected since we are interested in this work in the literal understanding, which does not depend on the dialogical context, so, the turns depending on the context increase the error.

There are other sources contribute to the increase CER. It is mainly about the appearance of terms that are not processed in the training corpus. This is due to the presence of certain phenomena linked to spontaneous speech such as hesitation allowing the addition of out-of-vocabulary words.

TABLE XI. RESULTS OF THE CONCEPTUAL LABELING OF SETS A, D AND X WITH DIFFERENT TYPES OF PROCESSED DATA (VERSION I, II AND III)

		Version I		
		A	D	X
<b>Model 0</b>	CER (%)	16.93	23.21	38.59
	Precision (%)	82.58	75.68	59.25
	Recall (%)	80.32	72.24	56.14
	F-measure (%)	81.43	73.92	57.65

<b>Model 1</b>	CER (%)	8.83	12.53	12.28
	Precision (%)	90.45	85.99	84.09
	Recall (%)	83.73	76.95	64.91
	F-measure (%)	86.96	81.22	73.26

<b>Model 2</b>	CER (%)	8.03	10.26	10.52
	Precision (%)	91.17	88.15	85.00
	Recall (%)	82.99	76.36	59.64
	F-measure (%)	86.89	81.83	70.10

<b>Model 3</b>	CER (%)	7.29	9.92	10.51
	Precision (%)	91.87	88.44	86.36
	Recall (%)	82.46	75.94	66.66
	F-measure (%)	86.91	81.71	75.24

		Version II		
		A	D	X
<b>Model 0</b>	CER (%)	15.38	21.76	42.10
	Precision (%)	84.20	77.36	55.55
	Recall (%)	82.00	74.37	52.63

	F-measure (%)	83.09	75.83	54.05
--	---------------	-------	-------	-------

<b>Model 1</b>	CER (%)	7.02	11.34	17.54
	Precision (%)	92.55	87.53	78.26
	Recall (%)	87.35	79.66	63.15
	F-measure (%)	89.88	83.41	69.90

<b>Model 2</b>	CER (%)	6.95	10.25	14.03
	Precision (%)	92.49	88.55	81.39
	Recall (%)	85.75	79.23	61.40
	F-measure (%)	88.99	83.68	70.00

<b>Model 3</b>	CER (%)	6.15	9.66	8.77
	Precision (%)	93.30	89.13	87.17
	Recall (%)	85.81	79.24	59.64
	F-measure (%)	89.40	83.89	70.83

		<b>Version III</b>		
		<b>A</b>	<b>D</b>	<b>X</b>
<b>Model 0</b>	CER (%)	17.61	22.23	42.10
	Precision (%)	81.92	76.76	55.55
	Recall (%)	79.84	73.74	52.63
	F-measure (%)	80.87	75.22	54.05

<b>Model 1</b>	CER (%)	6.84	11.95	17.54
	Precision (%)	92.75	86.97	78.26
	Recall (%)	87.73	73.74	63.15
	F-measure (%)	90.17	75.22	69.90

<b>Model 2</b>	CER (%)	6.65	10.95	10.52
	Precision (%)	92.83	87.82	85.00
	Recall (%)	86.23	79.01	59.64
	F-measure (%)	89.41	83.18	70.10

<b>Model 3</b>	CER (%)	5.74	10.61	8.77
	Precision (%)	93.76	88.10	87.17
	Recall (%)	86.30	78.67	59.64
	F-measure (%)	89.87	83.12	70.83

In conclusion, CRF models perform well even with not processed turns. On the other hand, conceptual labeling based on CRF models failed when dealing with new terms that are not in the training corpus. These terms can be non-vocabulary

words or domain words. This last case is mainly due to the reduced size of the corpus used to learn the CRF models.

## VI. CONCLUSION

In this work, we proposed to evaluate in depth the performance of CRF models in the context of speech understanding in dialogue systems. We tested CRF in different models and in different types of processed data. We proved that these models show robustness against noisy data. They recorded good results for conceptual labeling (F-measure of 86.52%). Thus, we found that CRF models have the ability to detect task-specific compound words and label them correctly. These interpretations confirm the performance of these models even for under-resourced languages. As future work, we planify to compare these results with deep learning models for the same task to compare performance between machine learning using CRF models and deep learning models such as CNN (Convolutional Neural Network).

# Paw Search-A Searching Approach for Unsorted Data Combining with Binary Search and Merge Sort Algorithm

## Paw Search Algorithm

Md. Harun Or Rashid<sup>1</sup>, Ahmed Imtiaz<sup>2</sup>

Department of Computer Science and Engineering, Rangamati Science and Technology University, Jhagrabil, Rangamati, 4500,  
Chattogram, Bangladesh<sup>1,2</sup>

**Abstract**—Searching is one of the oldest core mechanism of nature. Nature is changing gradually along with searching approaches too. Data Mining is one of the most important industrials topic now-a-days. Under this area all social networks, governmental or non-governmental institutions and ecommerce industries produce a huge number of unsorted data and they are to utilize it. For utilizing this huge number of unsorted data there needs some specific features based unsorted data structure tools like searching algorithm. At present there are several sorted data based searching algorithms like Binary Search, Linear Search, Jump Search and Interpolation Search and so on. In this paper of Paw Search Algorithm, it is fully focused to develop a new approach of searching that can work on unsorted data merging several searching techniques and sorting techniques. This algorithm starts its operation by breaking down the given unsorted array into several blocks by making the square root of the length of the given array. Then these blocks will be searched within its specific formula till the target data is found or not, and in the inner side of each block there will be performed Merge Sort and Binary Search approach gradually. Time and Space Complexity of this Paw Search algorithm is comparatively optimal.

**Keywords**—Paw; search; unsorted; data; blocks; square root

### I. INTRODUCTION

In this present world, technology is the heart of all activities, operations and so on, and the large amount of unsorted data sets generated from different sites of the world as well as different institutions are the largest and best resources of the present technology. Managing this large amount of data with proper data structure techniques is the best tool for leading this IT world now-a-days. In this paper, we will go through a new technique of searching of data from the given unsorted array of data. There are several techniques raised now-a-days, but here we will go through a new dimension of searching and merging several built in techniques along with some new approaches to generate an optimal output.

In present world there are tons of unsorted data produced within a minimal time randomly. There are several searching algorithms like Linear Search [1, 2, 3], Binary Search [1, 2], Jump Search [1, 4], Hybrid Search [1, 5] and Interpolation Search [1, 6] now-a-days which work only on sorted data. But till now there are less approaches that work on randomly

generated unsorted data. Several optimal data structures tools are badly required to operate this very large number of unsorted data which are producing day by day. Data Mining is one of the most important industrials topic now-a-days. Under this area of data mining for all social networks, governmental or non-governmental institutions and ecommerce industries produce tons of unsorted data and they are to utilize it. For utilizing this tons of unsorted data there is a need of some specific feature based unsorted data structures tools like searching algorithm [6] based on unsorted data array. So, a data structure tool [7] that will work on directly unsorted data is the prime concern for developing another searching approach.

Data scientists are trying to develop several data structures tools to utilize the tons of unsorted data randomly around the globe continuously. With a view to helping the data scientists here I am trying to develop data structures tools for finding out of any data from any given array of unsorted data. We know that sorting of data consumes a large number of time; so, from this concept of time utilization there needs some specific approach that can perform searching operation on unsorted data which minimize the uses of time. As the technology and technology related models/industries appreciate the approaches that minimize time consuming, so this is the demand of time to have high performer approach consuming less time without sorting the large data set at a single time.

Through this whole paper we will go through the approaches to develop a specific feature based searching algorithm entitled paw search algorithm that will be capable to perform searching operations on unsorted data, and here we may also go through the help of some existing searching approaches and sorting approaches at the inner phase of searching operation to ensure the high performance of searching.

The main principle of this Paw Search Algorithm is to work on (i) unsorted data segmenting the given array of data into several (ii) blocks.

Initially it starts working with  $x$  blocks of unsorted data by making the square root of the length  $n$  of the given array of data i.e.,  $x = \text{ceiling}[\sqrt{n}]$  where  $n$  is length of the given array of unsorted data.

This algorithm will never check all of the blocks of unsorted data linearly, rather than it will go the blocks of unsorted data all but as like as binary approach but not fully follow the binary approaches. And for the inner block operation we will also call here the merge sort approach for the better performance of this paw search algorithm.

## II. LITERATURE REVIEW

In this section we will go through the several existing searching algorithms, and most of them here work only on sorted data:

### A. Classification of Searching Techniques

There are several searching techniques present now-a-days. Depending on external and internal issue there are two types of searching techniques as (i) external search and (ii) internal search, and based on sequential and interval issue there are two types of searching techniques as (i) sequential search and (ii) interval search.

### B. Present Searching Algorithms

There are several searching algorithms based on sorted data. Some of them are listed below-

1) *Linear search algorithm*: Linear search algorithm [3] could be an easy search algorithmic program. It's a sequent search that performed on sequences of numbers that are ascending or down or unordered. And it checks every component of the whole list to look a specific information from the list. If the comparison is equal, then the search is stopped and declared productive. For a listing with  $n$  things, the most effective case is once the worth of item to be searched is adequate to the primary component of the list, during this case only one comparison is required. Worst case is once the worth isn't within the list or happens one time at the top of the list, during this case  $n$  comparisons are required.

2) *Binary search algorithm*: It is a quick search formula because the run-time quality is  $O(\log n)$ . Divide and conquer Principle is used here as its' search formula. This formula performs higher for sorted knowledge assortment. In binary search [8], we tend to 1st compare the key with the item within the middle position of the info assortment. If there's a match, we are able to come forthwith. If the secret's but middle key, then the item should lie the lower  $1/2$  the info collection; if it's bigger, then the item should lie the higher  $1/2$  the info assortment.

3) *Hybrid search algorithm*: Hybrid Search algorithmic [3, 9] rule combines properties of each linear search and binary search and provides a far better and economical algorithmic rule. This algorithmic rule may be accustomed search in associate degree unsorted array whereas taking less time as compared to the linear search algorithmic rule. As mentioned this algorithmic rule is combines 2 looking algorithms, viz. Linear Search and Binary Search. Like Hybrid Search algorithmic rule, the array is split into 2 sections so searched in every of the sections. The algorithmic rule starts with examination the key component to be searched with the 2 extreme components of the array, the primary and therefore

the last, further because the middle component. If a match is found, the index worth comes back. However, if it's not, the array is split into two sections, from the center index. Currently the search is meted out within the section on the left in a very similar method. The acute components and therefore the middle component of the left division are compared with the key worth for a match, that if found, returns the index worth. If not, the left section is once more divided into two components and this method goes on until a match is found within the left section. If no match is found within the left division, then the algorithmic rule moves on to the proper division, and therefore the same procedure is meted out to search out a match for the key worth. Now, if no worth is found that matches the key worth even when ransacking through all sections, then it's more divided and therefore the method repeats iteratively till it reaches the atomic state. If the worth isn't gift within the array, as a result of that the algorithmic rule returns -1.

4) *Interpolation search algorithm*: Interpolation search [2, 10] rule is improvement over Binary search. The binary search checks the part at middle index. However, interpolation search could search at completely different locations supported price of the search key. The weather should be in sorted order so as to implement interpolation search. As mentioned the Interpolation Search is Associate in Nursing improvement over Binary explore for instances, wherever the values in a very sorted array are uniformly distributed. Binary Search continuously goes to the center part to ascertain. On the opposite hand, interpolation search could head to completely different locations in line with the worth of the key being searched. For example, if the worth of the secret's nearer to the last part, interpolation search is probably going to start out search toward the tip facet.

5) *Jump search algorithm*: Jump search algorithmic [11, 12] rule, additionally known as block search algorithmic rule. Solely sorted list of array or table will use the Jump search algorithmic rule. In jump search algorithmic rule, it's not in any respect necessary to scan each component within the list as we have a tendency to liquidate linear search algorithmic rule. We have a tendency to simply check the  $m$  component and if it's but the key component, then we have a tendency to move to the  $m + m$  component, wherever all the components between the  $m$  and  $m + m$  component square measure skipped. This method is sustained till  $m$  component becomes adequate to or larger than key component known as boundary price. The worth of  $m$  is given by  $m = \sqrt{n}$ , wherever  $n$  is that the total range of components in associate array. Once the  $m$  components attain the boundary price, a linear search is finished to seek out the key price and its position within the array. And also the numbers of comparisons square measure adequate to  $(n/m + m - 1)$ . It should be noted that in Jump search algorithmic rule, a linear search is finished in reverse manner that's from boundary price to previous price of  $m$ .

Though there is a large number of searching approaches [13] on different aspects like strings [14], numeric values and

so on there is still a concern of optimizing [15, 16] these approaches.

Now-a-days industry requires specific feature based searching tools like audio, video and/or image based searching [17, 18], and as the industry is changing day by day with the help of upgraded technology, searching approaches are also gradually being changed as needed [19, 20].

And, still there needs of most powerful, high performer, fast searching unsorted data based searching approaches; keeping this conscious in mind, this paw search approach for unsorted data is demand of time now.

### III. METHODOLOGY

In this Methodology section, we will go through several sections like Planning, Design, Paw Search Algorithm etc. for the development of the proposed approach of search precisely and clearly:

#### A. Planning

Define To develop this algorithm I have planned several data structure approaches, arrays, sub-arrays or blocking, sorting approaches and so on.

- First plan is to manage several unsorted data sets that may be generated from different environment like weather data, space data and son.
- Second plan is to find out the length of the array with filling this array with that unsorted raw data.
- Third plan is to divide the unsorted array into several sub-arrays which are termed as data blocks in the later chapters of this paper.
- Fourth plan is to find out an optimal way to have operations on these blocks by traversing them.
- Fifth plan is to operate a searching approach on the blocks for finding out the optimal outputs.
- Sixth plan is to calculate the time and space complexity of this algorithm.
- Seventh plan is to compare these time and space complexity with different present searching algorithms properly.

The designation process of this algorithm is briefly described in part B of this section.

#### B. Design

To design this algorithm we are to go through a list of unsorted data set firstly as the main principle of this Paw Search - A Searching Approach for Unsorted Data Combining with Binary Search and Merge Sort Algorithm is to work on (i) unsorted data segmenting the given array of data into several (ii) blocks.

Initially it starts working with x blocks of unsorted data by making the square root of the length n of the given array of data i.e.,  $x = \text{ceiling}[\sqrt{n}]$  where n is length of the given array of unsorted data. but when the length of this array isn't a perfect square root number then the block number becomes a

fraction number, but the block number can't be a number as a fraction number in real, so we are to operate here the ceiling operator to get the integer number of blocks. But in this situation there needs some dummy data as like zero to make the block size perfect i.e., same length of each block.

For example let assume an unsorted array arr1[ ] of data of the length of 16 which is a perfect square root number that is shown in Table I.

TABLE I. UNSORTED ARRAY ARR[ ] OF 16 LENGTH

5	0	6	3	7	1	9	2	4	17	10	8	11	16	13	15
---	---	---	---	---	---	---	---	---	----	----	---	----	----	----	----

Here n=16; Since 16 is a perfect square root number

So the block numbers,  $x = \text{int}[\sqrt{16}] = 4$

TABLE II. X BLOCKS FROM ARR1[ ]

5	0	6	3	7	1	9	2	4	17	10	8	11	16	13	15
Block 1				Block 2				Block 3				Block 4			

Here the Block1, Block2, Block3 and Block4 are the four blocks of the segmented arr1 [ ] shown in Table II

Now let assume another unsorted array arr2 [ ] of data of the length of 8 which is not a perfect square root number that is shown in Table III

TABLE III. UNSORTED ARRAY ARR2[ ] OF 8 LENGTH

7	5	10	3	21	1	6	9
---	---	----	---	----	---	---	---

Here n=8; Since 8 is not a perfect square root number

So the block numbers,  $x = \text{int}[\sqrt{8}]$   
 $= \text{int}[2.828427125]$   
 $= 3$  [By applying ceiling operation]

TABLE IV. X BLOCKS FROM ARR2[ ]

7	5	10	3	21	1	6	9	0
Block 1			Block 2			Block 3		

Here the Block1, Block2 and Block3 are the three blocks of the segmented arr2[ ] shown in Table IV. In Block4 there is putted an extra zero as a dummy data for remaining the blocks size same.

However, this paw search algorithm will never visit all of the blocks of unsorted data linearly, rather than it will go through the blocks of unsorted data all but as like as binary approach. But it won't fully follow the binary approach.

The designing resources and working procedures list of this algorithm is listed here-

- Unsorted Data Set
- Square Root Generating Function
- Ceiling Operator

- Generating Blocks
- Block Visiting Loop
- Inner Block Searching Approach
- Exit

### C. Paw Search Algorithm

Assume that there is an array with the length of  $n$  of the nodes value of any given graph or other randomly generated unsorted data, now let's demonstrate our desired Paw Search Algorithm for finding out the target data from this given array of unsorted data. Here, we will go through the procedural steps of this Paw Search Algorithm. The procedures of this Paw Search Algorithm are shown below-

#### PAW (SEARCH ALGORITHM)

```

Divide the given array into x blocks where  $x = \text{ceiling}[\sqrt{n}]$ 
Loop for Block
//For Block1:
Block[ ] = x1[ ] = [ ]
    mergesort (Block[ ], L, U)
If(Block[last_element]  $\geq$  Target)
{
    If(x[last_element] == target)
        {Print "TARGET FOUND"}
        Exit
    Else
    {
        BinarySearch ( Block(x)[ ], 1,U)
            If (x[mid] == target)
                {Print "TARGET FOUND"}
                Exit
            Else
                {Jump to the next Block}
    }
Else
    {Jump Block[ ] = x[last]}
Update Loop
Loop Exit
If (target == not found)
    {Print "Unsuccessful"}
Exit
    
```

#### //Merge Sort Function

```

mergesort (Block[ ], l, U)
If U > 1
Find the middle point to divide the array into two halves:
middle m = 1+ (U-1)/2

    Call mergeSort for first half:
    Call mergeSort(arr, l, m)
    Call mergeSort for second half:
    Call mergeSort(arr, m+1, U)

Merge the two halves sorted in step 2 and 3:
Call merge(arr, l, m, U)
    
```

#### //Binary Search Function

```

Binary Search (Block[ ], 1,U)
Input the Block[ ] array of x elements I sorted form
LB = 0,UB = n; mid = int((LB+UB))/2
Repeat step 4 and 5 while(LB <= UB and (A[mid] != item)
If (item < A[mid]) UB = mid-1
Else
    LB = mid+1
    mid = int((LB+UB)/2)
    If (A[mid] == item)
        Print "Item is found"
    Else
        Print "Item is not found"
    Exit
    
```

The above mentioned procedures are the proposals of the Paw Search Algorithm, which also includes the Binary Search and Merge Sort Algorithm for completing its operation more efficiently. The further explanation of this algorithm is discussed later sections with proper examples.

### D. Explanation and Implementation

Let's understand the block visiting procedures now, a graphical view is illustrated in Fig. 1 to show the working flow of the  $x$  blocks generated from the length of the array by making square root on it, and the length of each block is also  $x$  i.e., the block size and the block numbers are same.

Here  $x$  is the block number and  $l, k, m, p, y$  are also the sub number of  $x$  and they are the right mid, right-right mid, ..... , left mid, left-right mid, ..... , and gradually so on.

For implementing this algorithm let assume an array  $A[]$  with the length of  $n$  as shown in the following Table V.

TABLE V. GIVEN ARRAY WITH N ELEMENTS

ARRAY ELEMENTS										----					
INDEX NUMBER	0	1	2	3	4	5	6	7	8	----	n-4	n-3	n-2	n-1	n

So the initial step of this algorithm is to calculate the square root value  $x$  of the length of the given array  $A[]$ .

$$x = \text{sqrt}(n) = \text{ceiling}(\sqrt{n})$$

It generates  $x$  number of blocks as Block(1), Block(2), Block(3), Block(4), ....., Block(x-3), Block(x-2), Block(x-1), Block(x) which are shown in Fig. 2.

The operational steps of these  $x$  number of blocks are also shown in Fig. 2. This algorithm follows the Left to Right approach. According to this Fig. 2, the first Block[1] is to go under the algorithmic operation firstly, secondly the last Block[x], then Block [mid], then Block [Right-mid], then Block [Right-mid], ....., ....., ....., Block [Left-mid], Block [Left-Right-mid], ....., Block [Left-Left-mid], ....., ....., ....., etc.

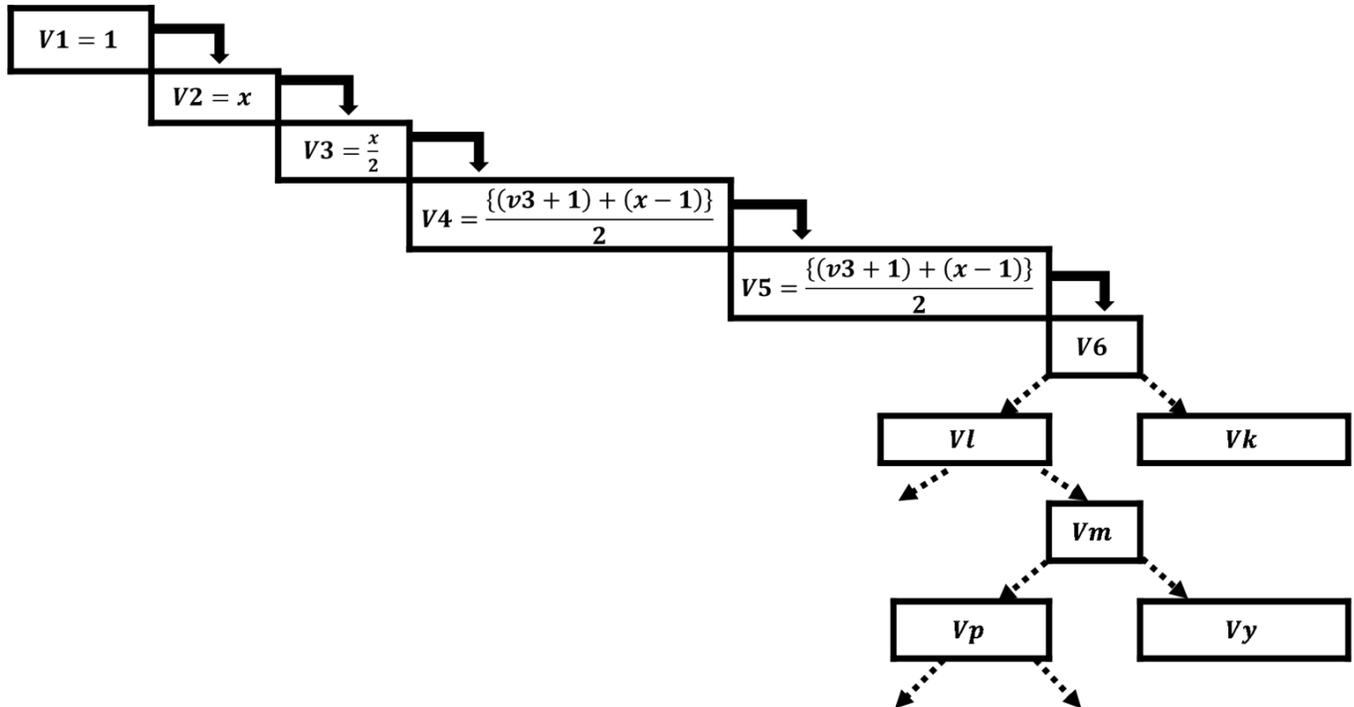

Fig. 1. Traversing procedure tree of the  $x$  blocks

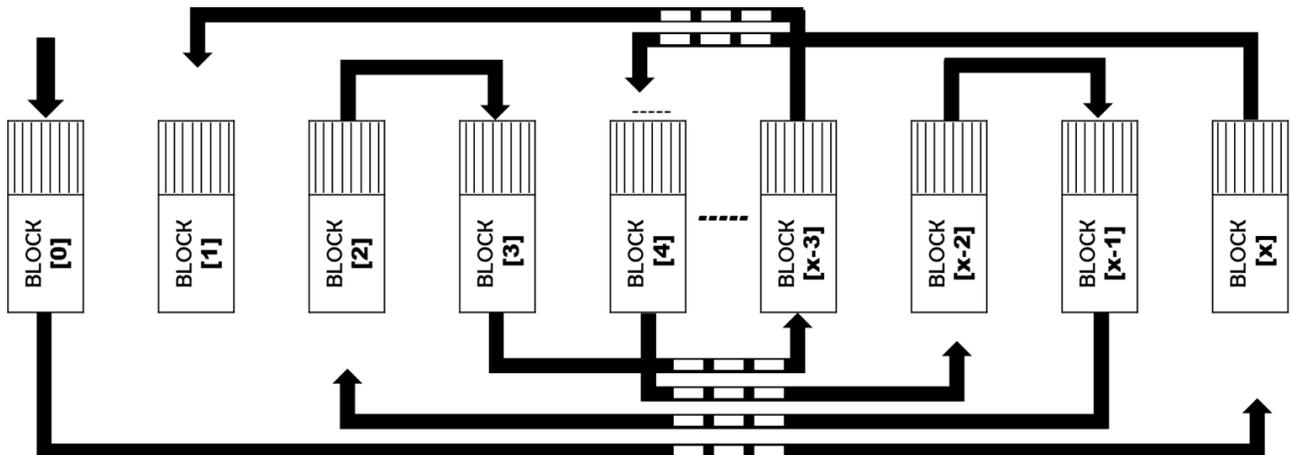

Fig. 2. Graphical view with paw search algorithm of the given array (table 5) with elements

For better understanding the implementation of this Paw Search Algorithm we will go through an example with proper explanation. Lets' assume another array B[] with the length of n, where n=9 as shown in Table VI. And let the SEARCH ITEM = Target = 5.

TABLE VI. ARRAY B[] WITH 9 ELEMENTS

4	6	1	9	3	5	8	7	2
---	---	---	---	---	---	---	---	---

Firstly, Lets' find out the number of Blocks:

$$x = \text{ceiling}[\sqrt{n}] = \text{ceiling}[\sqrt{9}] = 3$$

So, the blocks are shown in Table VII follows:

TABLE VII. BLOCKS OF ARRAY B[] WITH 9 ELEMENTS

4	6	1	9	3	5	8	7	2
Block 1			Block 2			Block 3		

For Block1:

```
//Sort the block using merge sort approach
mergesort (Block1[ ], 0, 2) //input
{
Block(x)[]={3, 5, 9} //sorted
}
If((Block1(last)==6) >= (Target==5))
{
Print "TARGET FOUND"
}
Else
{
//Binary Search
beg = lower_bound = 0
end = upper_bound = 2
mid =(beg + end)/2=(0 + 2)/2= 1
Block1[mid]= x[1]= 4
if (x[1]== target)
{
Print "TARGET FOUND"
Exit
}
Else
{
```

Jump to the next Block

```
}
}
Else
{
Jump x(last)
}
x++
Exit
```

For Block2:

```
//Sort the block using merge sort approach
mergesort (Block2[ ], 3, 5) //input
{
Block(x)[]={3, 5, 9} //sorted
}
If((Block1(last)==9) >= (Target==5))
{
If(x(last)==target)
{
Print "TARGET FOUND"
}
Else
{
//Binary Search
beg = lower_bound = 3
end = upper_bound = upper_bound+2=5
mid =(beg + end)/2=(3 + 2)/2= 4
Block1[mid]= x[4]= 5
if (x[4]== target)
{
Print "TARGET FOUND"
Exit
}
Else
{
Jump to the next Block
}
}
}
```

```

Else
{
Jump x(last)
}
x++
Exit
    
```

So, here the target is found in Block2.

#### IV. PERFORMANCE ANALYSIS

Some fundamental key terms related to performance measurement of this proposed searching approach of paw search algorithm will be discussed through this section briefly. Basically, here we will cover the time and space complexity of this proposed searching approach and also cover a brief comparison of different existing searching approaches with this proposed searching approach:

##### A. Space Complexity

The Now lets' go through the time complexity phase of this Paw Search Algorithm. For calculating Time complexity of this algorithm we are to go through the divide and conquer approach of recursive method through traversing the x blocks generated by squaring root the length n of the given array of data.

Let the block1 of the length of x elements generated by squaring root the length n of the given array of data i.e.,  
 $Block1(x) = \{E(1), E(2), E(3), E(4), \dots, E(x-3), E(x-2), E(x-1), E(x)\}.$

First of all we are to calculate the space complexity of merge sort approach for sorting this sub array i.e., Block1 of x length. And we already know that the space complexity of this merge sort approach is  $O(x)$  that means that it needs of space for sorting this sub array data is as equal as the length of the sub array, here which is x. As the size of each and every block is same and at a time only one block will be sorted, so here the space complexity is  $O(x)$ .

Now, let's calculate the space complexity of this paw search algorithm to find out the target value for this sub array x i.e., Block1

```

For Block1:
//Space Complexity Calculation
If(x(last)>=target)
{
If(x(last)==target)
{
Print "TARGET FOUND"
}
Else
{
    
```

```

Binary Search Algorithm
if (x[i]== target)
{
Print "TARGET FOUND"
i++
Exit
}
Else
{
Jump to the next Block
}
}
}
Else
{
Jump x(last)
}
Exit
    
```

So, there needs space as same as the length of the array x for performing this operation successfully. We can also see the graphical view (push and pop operation of stack method) of the recursive method of this Block1 x as below in Fig. 3.

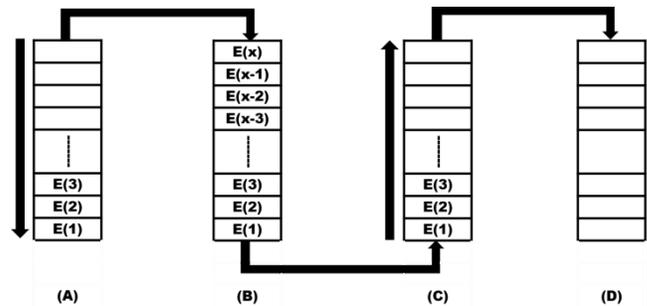

Fig. 3. Space complexity calculation

Where Fig. 3(A) shows the PUSHING of Block1's data into the STACK, Fig. 3(B) shows Block1 fully PUSHED into the STACK, Fig. 3(C) shows the POPPING of Block1's data from the STACK and Fig. 3(D) shows the Block1 which is fully popped from the STACK.

So, this Block1 needs same space as the length of this Block1 i.e., x. Similarly, all rest of the blocks need same space as their block size. So, here the space complexity is  $\log(x)$ .

Now, for finding out the target element from each block we will operate here the Binary Search approach. And we already know that the space complexity of the Binary Search approach is  $\log(x)$ .

So, the space complexity under the categories of worst case, average case and best case of this Paw Search Algorithm as below:

Paw\_(Space\_complexity)  $S(n) = O(\{\text{Space Complexity of the Block of given array} + \text{Space Complexity of Merge Sort Algorithm} + \text{Space Complexity of Binary Search Algorithm}\})$

$$\begin{aligned} \Rightarrow \text{Paw}_-(\text{Space\_complexity}) S(n) &= O(\log n + n + \log n) \\ &= O(n + 2 \log n) \\ &= O(2 \log n) \end{aligned}$$

$\therefore$  Paw\_(Space\_complexity)  $S(n) = O(\log n)$  [ $\because 2$  is the constant]

Hence the space complexity of this paw search algorithm is  $\log n$

### B. Time Complexity

Now let's go through the time complexity phase of this Paw Search Algorithm. For calculating Time complexity of this algorithm we are to go through the divide and conquer approach of recursive method through traversing the  $x$  blocks generated by squaring root the length  $n$  of the given array of data.

Let the Block1 of the length of  $x$  elements generated by squaring root the length  $n$  of the given array of data i.e.,  $\text{Block1}(x) = \{E(1), E(2), E(3), E(4), \dots, E(x-3), E(x-2), E(x-1), E(x)\}$ .

Firstly, we are to calculate an extra time for generating this  $x$  blocks by making square root of the given data array of the length of  $n$ .

Secondly, we are to consider the time complexity of merge sort approach for sorting this sub array i.e., Block1 of  $x$  length. And we already know that the time complexity of this merge sort approach is  $x \log(x)$ .

Now, let's calculate the space complexity of this paw search algorithm to find out the target value for this sub array  $x$  i.e., Block1

```
//For Block1:
If(x(last)>=target)
    If(x(last)==target)
        Print "TARGET FOUND"
    Exit
Else
    BinarySearch( Block[ ], L, U)
        if (x[i] == target)
            Print "TARGET FOUND"
        Exit
    Else
        Jump: Update Block
```

```
Else
    Jump: Update Block
Exit Block
Exit Loop
```

Thirdly, we are to find out the time complexity for the Binary Search approach for this Block1 i.e.,  $x$ . And we already know that the time complexity of the Binary Search approach is  $\log(x)$ .

So, the time complexity under the best case category is  $\sqrt{n}$

And the time complexity under the category of worst case and average case of this Paw Search Algorithm as bellow:

Paw\_(Time\_Complexity)  $T(n) = O(\{\text{Time for making Square Root of the given array} + \text{Time Complexity of Merge Sort Algorithm} + \text{Time Complexity of Binary Search Algorithm}\} * \text{Number of Blocks})$

$$\begin{aligned} \Rightarrow \text{Paw}_-(\text{Time\_Complexity}) T(n) &= O\{(1+n \log n + \log n) * \sqrt{n}\} \\ &= O\{\sqrt{n}(1+(n+1) \log n)\} \\ &= O\{\sqrt{n}(n \log n)\} \\ &= O\{n * \sqrt{n}(\log n)\} \\ &= O\{\sqrt{n^3}(\log n)\} \end{aligned}$$

$\therefore$  Paw\_(Time\_Complexity)  $T(n) = O(\sqrt{n^3} \log n)$

Hence the time complexity under the categories of worst case and average case of this paw search algorithm is  $\sqrt{n^3} \log n$

### C. Difference between Binary Search and Paw Search

The Paw Search Algorithm and the Binary Search Algorithm aren't same. There are several distinct difference between this two approaches. A difference chart between these two algorithms is shown in Table VIII follows:

TABLE VIII. DIFFERENCE BETWEEN PAW SEARCH AND BINARY SEARCH ALGORITHM

Paw Search Algorithm	Binary Search Algorithm
It begins its operation with the unsorted array of data.	It begins its operation with the sorted array of data.
It divides the given array of unsorted array of data of $n$ length into $x$ blocks by squaring root the length i.e., $x = \sqrt{n}$	It doesn't divide the array into blocks.
The input data is either unsorted or unsorted doesn't fact here.	The input data must be sorted here.
Time Complexity here in Worst Case is $\sqrt{n^3} \log n$	Time Complexity here in Worst Case is $\log n$
Time Complexity here in Average Case is $\sqrt{n^3} \log n$	Time Complexity here in Average Case is $\log n$
Time Complexity here in Best Case is $\sqrt{n}$	Time Complexity here in Best Case is $\log n$
Space Complexity here in Worst Case is $\log n$	Space Complexity here in Worst Case is $\log n$
Space Complexity here in Average Case is $\log n$	Space Complexity here in Average Case is $\log n$

Time Complexity here in Best Case is $\log n$	Time Complexity here in Best Case is $\log n$
It is a combined searching system.	It is a unique searching system.

So, the Paw and Binary Searching technique isn't similar at all rather than it is quite different and comparatively more efficient than Binary Searching technique. It also should be mentioned that the Paw Search Algorithm solves the limitation of taking fully sorted array as an input of Binary Search Algorithm.

**D. Difference between Jump Search and Paw Search**

The Paw Search Algorithm and the Jump Search Algorithm aren't same. There are several distinct difference between this two approaches. A difference chart between these two algorithms is shown in Table IX follows:

TABLE IX. DIFFERENCE BETWEEN PAW SEARCH AND JUMP SEARCH ALGORITHM

Paw Search Algorithm	Jump Search Algorithm
It begins its operation with the unsorted array of data.	It begins its operation with the sorted array of data.
It divides the given array of unsorted array of data of n length into x blocks by squaring root the length i.e., $x = \sqrt{rt}(n)$	It also divides the given array of sorted array of data of n length into x blocks by squaring root the length i.e., $x = \sqrt{rt}(n)$
It doesn't follow the linear approach for traversing its blocks.	It follows the linear approach for traversing its blocks.
It is faster.	It is comparatively slower.
It doesn't travel the blocks sequentially.	It travels the blocks sequentially.
Under the block operation it operates here binary search approach as an inner approach.	Under the block operation it operates here linear search approach as an inner approach.
The input data is either unsorted or unsorted doesn't fact here.	The input data must be sorted here.
It is a combined searching system.	It is a unique searching system.

So, the Paw and Jump Searching technique isn't similar at all rather than it is quite different and comparatively more efficient than Jump Searching technique. It also should be mentioned that the Paw Search Algorithm solves the limitation of taking fully sorted array as an input of Jump Search Algorithm.

**E. Time Complexity Comparisons with others Algorithms**

A comparison list of time complexity of different search algorithms like linear search, binary search, hybrid search, interpolation search and paw search in different cases like worst case, average case and best case is shown in Table X as follows:

TABLE X. TIME COMPLEXITY COMPARISONS

	Best Case	Average Case	Worst Case
Linear Search	$O(1)$	$O(n)$	$O(n)$
Binary Search	$O(1)$	$O(\log n)$	$O(\log n)$
Hybrid Search	$O(1)$	$O(\log 2n)$	$O(n)$

Interpolation Search	$O(1)$	$O(\log(\log N))$	$O(n)$

**F. Space Complexity Comparisons with Others Algorithms**

A comparison list of space complexity of different search algorithms like linear search, binary search, hybrid search, interpolation search and paw search in different cases like worst case, average case and best case is shown in Table XI as follows:

TABLE XI. SPACE COMPLEXITY COMPARISONS

	Best Case	Average Case	Worst Case
Linear Search	$O(1)$	$O(n)$	$O(n)$
Binary Search	$O(1)$	$O(\log n)$	$O(\log n)$
Hybrid Search	$O(1)$	$O(\log 2n)$	$O(n)$
Interpolation Search	$O(1)$	$O(\log(\log N))$	$O(n)$
Paw Search	$O(\log n)$	$O(\log n)$	$O(\log n)$

**V. CONCLUSION WITH FUTURE WORK**

By developing this long discussion of this research paper, I come to know that research is the fundamental weapon of this globalizing world i.e., IT world, and the large number of unsorted data is the heart of each and every research now-a-days. And managing this large number of unsorted data properly with proper searching technique is the core point of this paw search algorithm. The prime attraction of this research work is to develop a specific as well as more optimal formula of searching purposes from the unsorted list or array of data with the help of other searching and sorting techniques like merge sort and binary search. This Paw Search Algorithm shows the optimal way to generate a proper searching output taking an unsorted data list or array of data along with optimal time and space complexity, several comparisons of different searching approaches with this paw search algorithm are shown in Table VIII, IX, X and XI consecutively.

However, research is a continuous process. It will be upgraded with the demand of time day by day. There are also available a lot of future works here, some of them are listed below:

- Developing a more optimal logic/formula to optimize this algorithm
- Developing a Machine Learning Model to predict the desired block containing the desired data with Machine Learning Approach

**ACKNOWLEDGMENT**

It is a great pleasure for me to present this thesis paper titled as "Paw Search - A Searching Approach for Unsorted Data Combining with Binary Search and Merge Sort Algorithm".

I express heartiest thanks to friends and my well-wisher for their continuous inspiration and support, which led me to complete this research work.

Finally, I express my appreciation to my parents and other family members for their unconditional support as without their support and inspiration, it would be impossible for me to complete this research successfully.

Application & Research on Multimedia, Universiti Tun Hussein Onn Malaysia, Parit Raja, Malaysia<sup>4</sup>

**Abstract**—Instant messaging applications, including WhatsApp, Viber, and WeChat, are moving beyond text messages to videos and voice calls, which are proportioned to current media, files, and locations. In this study, we surveyed existing forensic visualization and forensic analysis techniques for instant messaging applications, with the aim of contributing to the knowledge in the discussion of these research issues. A total of 61 publications were reviewed after searching various academic databases, including the IEEE, ACM Digital Library, Google Scholar, and Science Direct during the last five years. Our observation from research trends indicates that both forensic analysis and information visualization are relatively mature research areas. However, there is a growing interest in forensic visualization and automated IM forensic analysis. We also identified the lack of discussion on forensic selection criteria in existing forensic visualization works and the needs of benchmarking the evaluation method of automate forensic analysis tools.

**Keywords**—Forensic analysis; forensic visualization; instant messaging apps; mobile forensics; and mobile communication apps

## I. INTRODUCTION

Mobile Instant Messaging (IM) applications (apps) are becoming essential for smartphone users in their daily communication activities. As reported by Statista [1], the number of smartphone subscriptions worldwide in 2021 surpassed more than seven billion. Some of the most widely used IM apps include LINE, WhatsApp, WeChat, and Facebook Messenger [2]. As an example, WhatsApp has been upgraded beyond a basic messaging app to support more sophisticated features such as end-to-end encryption, deleting sent messages, and enable disappearing messages. These features, however, could be exploited by cybercriminals targeting IM apps for criminal activities.

According to a Norton report, malware, keylogging, and social engineering are the top three potential cybersecurity risks related to IM apps [1]. This is consistent with a report by Kaspersky, which showed that 341,954 attempts to follow phishing links were blocked in 2021, with 90% links coming from WhatsApp [2]. Furthermore, phishing statistics reported by PurpleSec identified that WhatsApp is one of the top three most impersonated brands in phishing attacks [3], [4].

In the context of smartphones, the acquisition of digital evidence involves mobile forensic techniques [7]. The acquired

artifacts can be valuable, as these include various significant metadata, such as application data, communication data, location data, and browsing history data. These data are, however, produced in unstructured data - raw data that are not in the organized data model form. The unstructured data could be challenging for forensic examination activities, for instance time-consuming and increase investigation cost [8], [9].

Therefore, there has been significant interest in examining appropriate approaches to expedite digital forensic analysis activities. One of the potential approaches is the use of forensic visualization. It is a common practice for digital forensic investigators to perform cross-analysis using various forensic software, but there is a lack of advanced visualization approaches to facilitate evidence analysis [5]. It also has been pointed out that the application of multimedia technology in presenting digital evidence could increase judicial understanding [6], [7], [8].

In this study, we explored the literature on forensic analysis of mobile applications, information visualization, and forensic visualization. The contributions of this work are twofold: (1) to provide insights into digital forensic analysis and the development of its automated tools, forensic analysis of IM apps, and forensic visualization to assist forensic analysis, and (2) to discuss the research trends and future research directions for these areas, including the potential of incorporating forensic visualization in IM forensic analysis. The knowledge gaps are identified from this study such as the needs of evaluation benchmarking and the lack of forensic selection criteria in the existing studies.

The remaining sections of this survey paper are organized as follows: Section II presents the review methodology while in Section III, associated works addressing forensic analysis and the techniques of visualization and mobile forensic analysis are discussed. Section IV reviews existing work in forensic analysis of IM apps. Section V discusses the role of forensic visualization in forensic analysis. Section VI presents the discussion on the research trends of forensics visualization and mobile forensic analysis techniques for future works. Section VII concludes this study.

## II. REVIEW METHODOLOGY AND PROCESS

A literature survey in forensic analysis, forensic visualization, and information visualization was performed by adopting the method used in [9] and [10] (see Fig. 1).

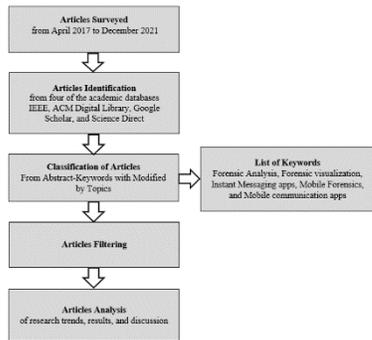

Fig. 1. Data collection method

To obtain a fair overview of the literature on forensic analysis and information visualization, we surveyed materials published in the English language over the past five years (i.e., April 2017 to June 2022). A total of 61 publications were located after searching various academic databases, including the IEEE, ACM Digital Library, Google Scholar, and Science Direct.

The search words used were different in each case, such as “digital forensics”, “forensic analysis”, “intelligent visual analytics digital evidence”, “mobile forensics”, and “information visualization”. For the search in Title, Abstract, and Keywords, quotation marks were entered and modified by topic, such as “forensics visualization”, “information visualization in digital forensics”, “forensic analysis in visualization”, and “forensic analysis in mobile application”. We filtered the articles from the search results to include “digital forensics”, “forensic analysis”, and “visual analytics”. We utilized the term “Web of Science” in title, abstract, and keyword searches in Advanced Search, and searched within Topics. Furthermore, we defined the document type as “articles” with no restrictions for all search results, and we only looked at journal publications.

## III. DIGITAL FORENSICS ANALYSIS

Forensic analysis is one of the phases in digital forensics, which is undertaken after evidence collection and examination. It involves “analyzing the results of the examination, using legally justifiable methods and techniques, to derive useful information that addresses the questions that were the impetus for performing the collection and examination.” [11]. More importantly, forensic analysis encompasses the gathering of evidentiary materials, evidence interpretation, results validation, and evidence presentation in an intelligible manner [12].

As discussed in [13], event reconstruction includes the combination of temporal, functional, and relational analyses of available evidence artifacts. Temporal analysis includes searching for other events that occurred around similar timestamps as those of one or more events already identified as related to the case being investigated. Functional analysis

involves understanding what actions were possible within the environment of the offense and how the offender’s toolkit works. Relational analysis involves studying how the various systems involved in a compromise relate to each other and how they interact.

String and keyword search, file filtering, and timeline analysis are examples of commonly used techniques in forensic analysis. String and keyword searching techniques can be used to filter out words, phrases, strings, and keywords that provide clues when searching for evidence. It is one of the primary features used in both commercial and non-commercial forensic tools, (e.g. Magnet Axiom, Autopsy). It has also been widely validated in academic forensic investigation studies, such as those analyzing web URL information [14]. Nowadays, the conventional keyword searching technique might be limited in a large volume of data, as it could lead to false negative or false positive and requires background knowledge about the case [15]. Therefore, studies such as [16] and [17], have examined the use of the semantic-based approach for text clustering with the aim of improving the performance and accuracy of forensic analysis.

Another technique, known as file filtering, can be applied as digital sieving of important files from irrelevant files by utilizing cryptographic hashes to screen the hash values of target files. For example, when using the MD5 Hash (and/or SHA-1 Hash) and Known File Filter options to process evidence, a hash value for each item is generated. The hash value of each file item inside the evidence is computed, and known files are filtered for the freshly computed hash value data [18]. The file filtering technique is significant in forensically examining file systems, for example, examining file similarities, as in [19], and examining file types, as in [20]. A limitation of this technique, however, is that it cannot be applied to corrupted files.

The timeline analysis technique is a chronological analysis of incidents to display all occurrences in a chronological sequence. However, emerging computing pose various factors that must be considered to generate a unified timeline, such as different time zone settings, timestamp interpretations, clock skew, and syntax [21]. Therefore, manual timestamp inspections may no longer be adequate to support investigations. Some recent studies have applied other scientific methods to enhance temporal analysis such as visualization approach, such as using graph-based and ontology-based approaches [22], [23] and highlighting patterns in the timeline analysis [24], [25], [26].

It is unlikely that a single method of data analysis is applied when examining digital evidence, as the evidence could have multiple interactions. The applied methods of data analysis can be mixed, depending on the complexity of a system’s architecture. For example, Carrier [27] presented data analysis based on layers, in which physical storage media analysis was the bottom layer. The next layers comprised volume analysis, memory analysis, file system analysis, and database analysis, while application analysis was the top layer. In a work by [28], the authors demonstrated system analysis, operating system analysis, application analysis, network analysis, device analysis, and Shim cache analysis to present Windows registry

forensics. Analyzing cloud apps on Android mobile devices, [29] demonstrated the analysis of app files in private storage, external storage, app database, and app account data and analyzed apps using the static and dynamic analysis approach. X. Zhang et al. [30] performed IoT botnet forensics by applying network traffic analysis, servers' disk analysis, servers' memory analysis, and database analysis. As described in these works, the configurations and deployments of systems architectures can vary. Undertaking the tasks manually may result in advertent or inadvertent mistakes and biases. The advancement of computing infrastructures and the interconnection of devices have made the tasks more complex and time-consuming. Hence, the automation of the tasks is essential to improve the efficiency of forensic analysis.

**B. Metrics of Automated Forensic Analysis Tools**

The development of automated forensic analysis tools is a developing field with a wide range of scientific techniques applied in many cyber forensics areas to keep pace with evolving computer generations [31]. Ayers [32] proposed seven metrics for computer forensic tools that are absolute speed, relative speed, reliability, accuracy, completeness, auditability, and repeatability.

Absolute speed, which refers to the elapsed time required to complete analysis tasks. Relative speed, which involves the average rate at which the tool can process evidence compared with the rate at which data can be read from the original evidential media. Reliability, which includes the proportion of tests that the tool executes successfully, as in performing without crashes and providing outputs in the intended format. Accuracy, which refers to the proportion of analysis results that are correct. Completeness, which concerns the proportion of evidence artifacts present in a forensic image that are identified and reported by the tool. Auditability, which includes the proportion of results that are fully auditable back to the original evidence data. Repeatability, which involves the proportion of tests that ran as stipulated in every aspect. Table I summarizes the applied forensic tools metrics in existing works related to forensic analysis tools.

TABLE I. A SUMMARY OF FORENSIC TOOL METRICS USED

Metric	A. Singh et al. [28]	Lin et al. [33]	Kumar et al. [34]	Subedi et al. [35]	Anglano et al. [36]
Absolute speed	√	√ (efficiency)	-	-	-
Relative speed	-	-	-	-	-
Reliability	√	-	-	-	-
Accuracy	-	√	√	√	√
Completeness	√	√	-	-	√
Auditability	-	-	-	-	-
Repeatability	√	-	-	-	√ (fidelity)
Other metrics	-	effective	-		effectiveness, generality, repeatability

In practice, it is unlikely for a study to include all the specified metrics in a tool due to the limited scope, time, and tool functionality. It has been observed that completeness and accuracy are the most applied metrics. The metrics are consistent with digital evidence principles by the RFC 3227 [37].

There are also other studies that proposed new or additional metrics to evaluate forensic tools. For example, Lin et al. [33] used the effective metric to evaluate their tool's efficacy in locating the source of the evidence artifact. Additional metrics proposed by Anglano et al. [36] are (1) effectiveness, which is the ability to correlate users' actions with the generated data, and (2) generality, which is the ability to analyze any mobile application on as many different Android devices as possible. It is observed that this work defined the repeatability metric as the ability to provide to a third party the possibility of replicating the same set of experiments. Considering the repeatability definition by Anglano et al. [36], we argue that all works shown in Table I are repeatable because detailed methodologies were provided. Furthermore, it is essential for academic work to provide a repeatable methodology for comparison with other similar research works. Other notable observations are that: (1) aforementioned studies used the same term to discuss different evaluations, such as Anglano et al. [36] using the "effective" term to discuss correlation ability, while Lin et al. [33] used the term to discuss the ability to locate data, and (2) the studies used different terms to describe the same evaluation, for example, Anglano et al. [36] using "fidelity" as a term to discuss repeatability.

**IV. FORENSIC ANALYSIS IN MOBILE COMMUNICATION APPS**

Examining IM apps is one of the continuous research works in mobile forensics. In addition, new updates of apps' features pose challenges for mobile forensics practices [38]. In this section, we describe the basic concepts of mobile forensics, and recent works involving the forensic analysis of mobile IM apps are reviewed.

**A. Forensic Analysis of Mobile Instant Messaging Apps**

Forensic analysis of mobile IM apps has received considerable attention and is rapidly emerging in recent years. For example, Anglano et al. [39] performed an in-depth analysis on how to decode, interpret, and correlate the data generated by users, using Telegram Messenger as a case study. The experiments involved user account information, contacts, chats, message exchanges, phone calls, and deleted information. The proposed methodology of this work was evaluated based on completeness, repeatability, and generality. It should be noted that analysis tasks were conducted manually and involved the evaluation of sources. The study's event reconstruction includes temporal and relational analyses. In a similar vent, Akinbi and Ojie [40] demonstrated forensic analysis of Conversation and Xabber apps on Android smartphones. The study discussed the results obtained from the completeness of recovered data, the sources of data, and timeline analysis to present the chronology of chat logs, message contents, and deleted files.

Riadi and Firdonsyah [41] compared mobile forensics tools' effectiveness on four IM apps, which were Short Message Service, Blackberry Messenger (BBM), LINE, and WhatsApp. The applied tools in this study were Andriller, Oxygen Forensic Suite, WhatsApp DB/Key Extractor, and Metasploit. The experiments were conducted on Android smartphones and an Android smartwatch. Tool effectiveness was evaluated using the success rate percentage of artifact extraction, in which Oxygen Forensic Suite showed the highest success rate at 57.14% on BBM and WhatsApp, while Smartwatch achieved 42.85% success rate on SMS and LINE. Additionally, the completeness of the recovered artifacts was evaluated using the percentage of artifact extraction.

Due to concerns over privacy, the features of encrypted chat and end-to-end encryption have been updated in some IM apps. These pose another dimension in forensic analysis of investigating possible ways to recover data from encrypted databases. For example, [42] examined the encryption status of WhatsApp, Facebook Messenger, LINE, and Hangouts on Android smartphones. The study compared encrypted and unencrypted databases between rooted and unrooted smartphones. The results of the recovered data from unencrypted databases were presented in terms of the point of origin of data, database structures, and data completeness. Rathi et al. [43] performed forensic analysis tasks on four encrypted Android IM applications, which were WeChat, Telegram, Viber, and WhatsApp. It was demonstrated that encrypted WeChat and Viber databases can be acquired from rooted devices, WeChat database can be decrypted using the IMEI number and the phone identifier encryption key, WhatsApp messages can be acquired from unrooted devices, WeChat data can possibly be retrieved from unrooted devices by downgrading the app version, and Telegram data were irretrievable from unrooted devices. However, with the current version of the WeChat application, the approaches used in their study are no longer valid [44]. Although this study did not directly specify the evaluation method, it has been observed that the forensic analysis result was presented based on the completeness criterion. The analysis tasks were undertaken manually and involved the evaluation of evidence sources.

Also focusing on the decryption methodology for forensic analysis, [45] investigated Wickr and Private Text Messaging apps on both rooted and unrooted Android smartphones, as well as jailbroken and non-jailbroken iOS smartphones. The results of this study showed that the proposed method was able to decrypt the databases of both apps and examine the encrypted databases' structure. The verification method of recovered user-entered password was used to decrypt the entire data. The method was evaluated based on the efficiency of estimated password recovery time. It is observed that this work focused on cryptographic contribution, as there was no discussion on data completeness and sources of evidence.

There are studies that attempted to compare recovered data from volatile and non-volatile memories. Focusing on Android LINE Messenger, [46] examined data remnant through the simulation of user activities, such as installation, uninstallation, logins, conversations, file transfer, and other LINE activities. The findings of the study showed that evidence artifacts from the LINE app can be recovered from both volatile and non-

volatile memories. Similarly, their study attempted to analyze the artifacts using the evaluation metrics of evidence sources and completeness. Agrawal and Tapaswi [47] conducted the forensic analysis of the Android Google Allo messaging app. The study demonstrated manual analysis tasks on device images. An interesting observation is that this study applied inferential statistics to evaluate the completeness metric. The recovered files were evaluated based on the point estimation value, while margin of error was used to calculate confidence limits. Another study that applied the inferential statistics concept was conducted in [48]. The study demonstrated the residual data of Android Kik Messenger on the NAND flash memory and the heap memory. The results of this study were presented by comparing the count and the average number of recovered messages between the NAND memory and the RAM memory.

Considering the extensive manual tasks of forensic analysis, some studies have proposed the development of automated tools. Barradas et al. [49] demonstrated forensic analysis tasks on eight messaging apps, which were Facebook Messenger, WhatsApp, Viber, Signal, Twitter, Telegram, Hangouts, and Trillian. The proposed tool, called RAM Analysis System (RAMAS), was designed based on the file-carving approach to extract potential evidence artifacts from physical memory. This study simulated common user activities on messaging apps. The performance of RAMAS was measured using the analysis time metric by varying the memory image size and the number of modules. The results indicated that reducing the set of strings improved the elapsed time, while running several modules in parallel resulted in a sub-linear time for analysis completion. The tool also supported event reconstruction tasks by applying the timeline analysis technique.

Nizam et al. [50] presented a tool to automate keyword indexing to assist the forensic analysis of WhatsApp. The main module of the tool involved loading a list of keywords from selected crime categories and uploading WhatsApp chat text files. Subsequently, a text-matching algorithm was executed, and a keyword count that showed the number of found keywords in the chat files was generated. The tool was tested using software engineering properties, which were application functionality testing and user acceptance testing. No event reconstruction feature was observed in this tool.

Using WhatsApp and LINE as case studies, [51] proposed a tool that applied the information visualization approach to support forensic analysis activities. Using visualization techniques, the tool was able to visualize key information, such as total number of messages, number of contacts, top-most frequent contact, top-most frequent words, and location map. Event reconstruction was supported by this tool using the timeline analysis approach. As in [50], this tool was evaluated through functionality testing and user acceptance testing.

A notable observation found from these works is that the simulation of user activities on the studied apps was used to elicit the generation of artifacts. The recovered artifacts from IM apps were mainly associated with user account information, contact information, chat histories, message exchanges, media exchanges, phone calls, app database, and deleted information.

Furthermore, analysis results from rooted and unrooted Android devices or jailbroken and non-jailbroken iOS devices presented significant differences involving encrypted data. Most of the studies examined recovered artifacts on device images manually, except for a few studies that used proposed automated tools. We also note that results from the metrics of origin of artifact and completeness of recovered artifact were the two predominantly reported forensic analysis results. Evaluation metrics, however, varied in these studies, and several studies did not directly specify their metrics. We discuss our further observation of the trends of studies on forensic analysis of IM apps in Section V.

## V. AN OVERVIEW OF INFORMATION VISUALIZATION

Information visualization is the process of displaying data as graphical markings on a computer screen or other media, to enhance people's ability to recognize visual patterns, such as watching, browsing, discriminating, and comprehending data [33]. Information visualization (InfoVis) is considered as a mature area, as evidenced in a study by Rees and Laramee [52], which surveyed over 23,000 pages of information visualization books. The study also highlighted that InfoVis research papers were cited in many areas, including networks, finance, healthcare, and security.

Data types in InfoVis can be classified into multi/high-dimensional, relational, sequential/temporal, geospatial, and textual [53]. Multi-dimensional and high-dimensional data are presented in a table-like form, where the rows denote data objects, while the columns denote data dimensions, attributes, features, or descriptors. Relational data refers to the common case of binary relations and are represented as graphs. Sequential and temporal data concern the serial order of data points in a sequence, for instance, the time series data. Geospatial data involves creating maps of the real world to visualize spatial and non-spatial relationships among the data. Textual data are inherently multivariate data sources, for example, text corpora as a semi-structured source of information integrated with approaches (e.g., semantic, text-mining) to transform raw texts into structured data sources.

Sorapure [54] discussed four key elements in InfoVis for improving data interpretation, which are text, image, data, and interaction. Text is often included as titles, labels, annotations, explanations, and other commentaries. Significant functions of text are guiding interpretation, providing explanation, establishing context, and facilitating navigation. The image element concerns generating and maintaining users' interest by selecting the most effective ways to convey information. Data literacy is important in enabling users to formulate questions and make decisions informed by the data. It involves creating arguments based on the data, effectively using tools to manipulate and represent the data, and being able to communicate with the data. Interactions include activities from users, such as selecting, exploring, reconfiguring, encoding, abstracting, filtering, and connecting, to establish interactions with InfoVis.

The application of InfoVis in many different fields further indicates that it is a reliable approach to support data interpretation and decision-making tasks. In the context of digital forensic analysis, interpreting gathered evidence is the

key to establishing connections in crime investigations. With the use of intelligent computing and decision-support frameworks, InfoVis has a significant role in assisting forensic analysts in digital evidence analysis activities [55].

### A. Role of Visualization for Forensic Analysis

The use of information visualization techniques in digital forensics has received considerable interest in the digital forensics' community. Existing works applied information visualization to visualize forensic data using various case studies, such as mobile phones, network data, IoT data, and Windows system files.

A study in [56] demonstrated how visual representation could support faster and more accurate decision-making during real-time digital forensics investigations. The Nested Blocks and Guidelines Model (NGBM) was adopted to design the visualization interactions in this study. Using fileless malware as a case study, the usability of the proposed tool was evaluated through the tool's components, such as investigation timeline, network activity, read/write entropy, and system performance. Examples of the used data were "time series", "IP Address", "Windows Event Logs", "PowerShell Events", and "Syslog", while the involved visualization methods were line charts, ellipses, area charts, and time series.

Tassone et al. [5] proposed a proof of concept to visualize digital forensics datasets that consisted of three stages of visualization lifecycle, which were decode, store, and visualize. Three visualization techniques were used, namely treemap, geographic map plot, and word cloud. This study used three case studies to represent the XRY mobile forensics dataset to evaluate tool utility. The treemap technique was used to visualize SMS messages, the geographic map technique was used to map locations from a coupon app, and the word cloud technique was applied to visualize data from a text-based communication app. The three case studies were able to demonstrate the utility of the tool.

Kotenko et al. [57] proposed a visual analytics approach for network forensics to analyze network traffic. The proposed approach consisted of two stages, which are data slice classification and the selection of an information visualization model. The visualization model can be determined from data types, such as numerical (e.g., pie chart, bar chart), tree (e.g., TreeMaps), planar (e.g., Voronoi Maps), semi-structured (e.g., Chord diagram), unstructured (e.g., graph), and a combination of data types and models. The usability of the proposed tool was evaluated using a case study of an SSL-strip attack that involved 200584 network packets in the files. The model was demonstrated in a three-hour training lab session, in which the result showed that 8 out of 10 students were able to solve the use-case within the lab session using the proposed visual analysis tool.

Also investigating network traffic data, [58] applied a 3D model and the use of time-based information as a display third axis, combined with a computer network topology in a single interactive data. The proposed tool, Scanmap3D, was evaluated based on its effectiveness to solve questions from network forensics challenges. The results were compared with other

tools that applied traditional statistical and 2D graphical analysis approaches.

Implementing Windows Jump List, [59] presented a graphical digital forensics tool, known as Jump List Analyzer. The study applied statistical charts (e.g., histogram) to visualize attributes, such as AppID, time, zoom, CustDest file, recorded file, and GUI interface. The tool was demonstrated to support forensic investigations of users' background and behavior analysis. Compatibility, friendliness, and functionality were the three applied metrics to evaluate the Jump List Analyzer. A comparison with other tools suggested that the proposed tool can effectively visualize large volumes of data.

Analyzing an online social network, [60] proposed a forensic analysis model that included evidence acquisition, evidence solidification, evidence analysis, and evidence visualization. Evidence analysis used semantic analysis method in natural language processing, and it involved text analysis, hot word frequency analysis, and physical locations. Sina Microblog was used to demonstrate the proposed tool's feasibility. Web page files, such as HTML text data, CSS files, JavaScript files, and images, were the involved metadata. However, there was no detailed information on InfoVis.

Applying the use of 3D and 2D models, [61] proposed a drone forensic framework to investigate the post-flight investigation of drone activities. The authors applied 3D visualization models to visualize three specific parameters, which were roll, pitch, and yaw along the flight path, while other parameters, which were drone-controller communication, signal type, battery, altitude, number of satellites used, and speed at each point of time, were visualized using 2D models. Each parameter value was logged based on the timestamp. Graphs and charts, such as line charts, were utilized for the 2D models. This study measured forensic visualization aspects based on performance and responsiveness. The study indicated that the tool could manage the visualizations of sensor data without interruptions.

Focusing on cloud computing's containers and Virtual Machines (VMs), [62] applied InfoVis to visualize the bytes contained in a virtual machine file for rapid incident response. The extracted data were visualized using two-dimensional colored visualization. The proposed visualization method was evaluated based on relative speed and accuracy using a series of *t*-tests for significant difference. A total of 42 participants were involved in the test, in which they were divided into test and control groups. Results showed that members of the test group did not have to wait to access the test data, and accuracy rates were relatively equivalent between the groups.

X. Zhang et al. [63] proposed an automated knowledge-sharing forensic platform by applying the ontology-based approach. The proposed method involved five layers: collection, extraction, analysis, visualization, and abstraction. A timeline-based visualization panel was used to display the investigated metadata. The platform would allow forensic investigators to create schemas based on the results of their forensic investigation. However, the authors did not further discuss the applied visualization model, which might be due to the study focusing on the knowledge-sharing approach.

Chow and Ab Rahman [64] demonstrated a mobile forensic visualization tool that visualized metadata from the Android data partitions of different models. Examples of data visualization were frequent message texts, top contacts, call duration, and location maps. Tool usability was evaluated through application functionality testing and user testing. In a similar study, [51] presented a tool to visualize WhatsApp and WeChat metadata. Examples of data visualization were chat history, timeline of chats, frequent contacts, and location maps. It was observed that the visualization models and evaluation methods used in this study were similar to those of [64]. Both studies highlighted the use of forensic visualization to enhance forensic analysis tasks for mobile forensics.

Shidek et al. [65] demonstrated timeline graph visualization to display data from WhatsApp chat conversations. The utility of the tool was evaluated through questions derived from forensic analysis goals: what cyber incident occurred, who was involved in the incident, and where, when, and how the incident occurred. Also applying timeline graph visualization, [66] presented a visualization-based approach to support malware investigations on the Internet of Things environment. This study applied the data mining method to preprocess DLL files and assign weights to represent malicious and benign files. It was evaluated using a questionnaire survey for academicians and industry practitioners. The respondents were asked about visualization evaluation, user experience, and time performance. A *t*-test was used to examine the significant difference for performance evaluation.

Fig. 2 and Fig. 3 summarize the results from the literature survey of forensic analysis of IM apps. Further discussion of the findings is in the next section.

## VI. RESULTS AND DISCUSSION

In this section, we present the results of, and insight on, forensic analysis of Instant Messaging (IM) apps and forensic visualization for forensic analysis.

### A. Forensic Analysis of Instant Messaging Apps

The findings are summarized into methods of forensic analysis tasks, evaluation metrics, evaluation methodologies, and event reconstruction methods.

Fig. 2 and Fig. 3 present most of the studies manually analyzed forensic artifacts of IM apps, while three studies demonstrated the use of automated tools to perform forensic analysis tasks. A closer inspection of the table shows that the evaluation metrics for manual forensic analysis were different from those for automated forensic analysis. Origin of data and completeness were the most applied metrics to evaluate manual forensic analysis. For automated forensic analysis, tool performance and tool functionality were the two applied metrics.

Our examination of evaluation methodologies shows that the qualitative methodology was more predominant to be applied in manual forensic analysis studies. This is likely related to the most applied evaluation metrics. For example, the evaluation metric of origin of data is more meaningful in a qualitative way rather than quantitative. Mixed methodologies, on the other hand, are observed as the major selection of research designs evaluating automated forensic analysis tools.

It is identified that very few studies used manual analysis method and generate event reconstruction. This is an unexpected finding, since event reconstruction is the outcome of forensic analysis. A likely explanation is that extensive manual tasks might demotivate the research works from including event reconstruction in their research questions. This was echoed by Kang et al. [67], who highlighted that event reconstruction in manual analysis is limited to personal knowledge, prone to human errors, and time-consuming. In contrast, two out of the three studies that used automated forensic analysis included event reconstruction. This further supports the benefit of automating forensic analysis tasks, which is expediting event reconstruction.

As evidenced by the number of publications from 2017 until 2021, it can thus be suggested that IM forensic analysis has received significant interest from the forensics community, and the research on automated IM forensic analysis is growing. Therefore, we argue that automating IM forensic analysis to facilitate forensic analysis tasks is a promising research area. This is supported by a previous study by Anglano et al. [36], which indicated that the automated forensic analysis of mobile apps has recently received interest and that their proposed tool was able to achieve greater artifact coverage than did previous studies.

### B. Research Trends of Forensic Visualization for Forensic Analysis

The research trends were summarized based on InfoVis data types, visualization techniques, case studies, and the number of publications (see Table II). The InfoVis data types

were adopted from [53], while the list of visualization techniques was adopted from a survey conducted in [68].

TABLE II. TRENDS OF FORENSIC VISUALIZATION APPLICATIONS TO SUPPORT FORENSIC ANALYSIS

InfoVis Data Types	Forensic Visualization Techniques	Case Studies	References
Relational	Bar Chart	Network Traffic, Windows OS, Intelligent Transport System	[62], [63], [69]
	Pie Chart	Network Traffic, Electronic Mail System	[57], [60]
	Histogram	Windows OS, Electronic Mail System	[59], [60]
	Treemap / Graph	Mobile Apps (SMS), Network Traffic, Windows Diagnostic Log	[5], [57], [70]
Multi-dimensional and high-dimensional	Colorization table, RGB Binary	Container and Virtual Machine, Malware detection	[62], [71]
Text	Word cloud	Mobile Apps (text-based communication apps), Android Operating System, Instant Messaging Apps	[5], [64], [51]
Geo-spatial	Geographic maps	Mobile Apps, Android Operating System, Instant Messaging Apps	[5], [64], [51]
Sequential and temporal	Time-based/timeline	Windows OS, Cloud Computing, Internet of Things (IoT), Electronic Mail System, WhatsApp Artifact, Android Operating System, Instant Messaging Apps, Container and Virtual Machine	[64], [72], [51], [59], [60], [65], [62]

From Table II, we can see that forensic visualization was applied in various case studies, including recent computing trends, such as the Internet of Things. This finding accords with an earlier observation in [52], which showed various applications of InfoVis. Similarly, it indicates the generality of forensic visualization for incorporation into investigations of various digital infrastructures.

It is observed that each study incorporated more than one forensic visualization technique. Furthermore, most of the related studies demonstrated the selection of techniques based on data types, for example in [64], [57], [61], and [66]. This further indicates that different data types may require different visualization techniques. Therefore, we argue that the feature of the selection of visualization techniques must be incorporated in forensic visualization tools to ensure effective evidence interpretation.

Charts and graphs are the major visualization techniques applied, and relational is the most studied data type. This might be related to the usage flexibility of charts and graphs to visualize the relational data type. It can be argued that various types of charts and graphs are significant in providing evidence interaction, as well as interpretation, to users. For instance, [61] demonstrated that various parameters of drone flight data and sensor data can be visualized using various types of charts.

This is also consistent with the list of visualization techniques from a previous survey conducted in [68].

Time-based visualization is the second-most applied visualization technique. This is an unsurprising finding since timeline analysis is a major aspect of forensic investigations. The importance of timeline and its connection with digital forensics investigations were also echoed in the studies by [25] and [23]. Timeline analysis is not limited to examining the time of an incident, but it is also applicable to many other purposes, for instance, event correlation and time zone determination.

Word cloud and geographic maps were also applied as case studies involving mobile forensics data. This is, therefore, not surprising because most smartphone apps comprise textual and geo-spatial data. For example, the three case studies of [5], [64], and [51] used the word cloud to visualize textual data from communication and IM apps. This indicates that the metadata from smartphones involved enormous text-based data. Therefore, applying a word cloud can help analysts quickly understand the patterns of text-based data in relation to forensic investigations. Furthermore, incorporating geographic maps into the tool would expedite investigators in assessing geospatial data without manually examining the data using external map applications.

Another important finding is the evaluation methods of the proposed approaches. Table III summarizes the evaluation methods observed in the surveyed studies. The most applied method is performing technical simulations to evaluate tool usability, followed by conducting user testing to evaluate the tool, and using a focus group to solve forensic challenges. This shows that evaluation methods for visual analysis tools are relatively not mutually exclusive. Therefore, there is a need for benchmarking evaluation methods in this research area.

TABLE III. EVALUATION METHODS OF FORENSIC VISUALIZATION

Evaluation method	References
Technical simulations (e.g., case studies) to evaluate tool usability	[56], [59], [60], [61], [63]
User testing to evaluate tool functionality and performance	[64], [51], [62], [66]
Focus group to solve forensic challenges	[57], [58], [65]

In relation to the automated forensic tools metrics proposed by Ayers [32], speed (absolute and relative), reliability, accuracy, and completeness are the evaluation metrics used in existing studies. This is in line with our finding from automated IM forensic analysis tools, which show that performance and functionality are the most applied metrics. It should be noted that these studies might use different terms to describe the metrics. The result suggests that the existing tools were validated based on widely recognized metrics of computer forensics.

Despite the benefits of forensic visualization, most of the previous studies provided limited discussion on the selection criteria of forensic visualization techniques in relation to forensic analysis. This reflects the finding in [68] that most existing applications do not meet all forensic selection criteria. Forensic selection criteria include the following [68]: meaning, where the interpretation of evidence remains unaltered by the

visualization technique used; errors, which is the ability to identify and account for errors to prevent evidence from being questioned; transparency, which is the ability to examine and verify all the data; and timeline, which shows users the events that occurred within a specific timeframe. These criteria are important to ensure the analysis results are valid and admissible in court of law. This observation suggests a knowledge gap(s) that needs to be addressed to highlight the significance of forensic visualization.

## VII. CONCLUSION AND FUTURE WORKS

In this study, a literature survey was conducted to examine state-of-the-art IM forensic analysis and forensic visualization techniques. It appears from our literature survey that both forensic analysis and InfoVis are relatively mature research areas. However, there is a growing interest in forensic visualization and automated IM forensic analysis. This brings various research opportunities to fill up the knowledge gaps. For instance, there is a need to benchmark evaluation methods and metrics in both areas. Furthermore, there is a lack of discussion on forensic selection criteria in existing forensic visualization works.

Therefore, our next research work will be conducted on the automated forensic analysis of IM applications by integrating the forensic visualization approach. Statistical analysis and machine learning algorithms would be incorporated to utilize the forensic selection criteria in forensic visualization. It is expected that the outcomes of this study will significantly aid digital forensics practitioners in analyzing and interpreting evidence data and aid judicial authorities in understanding the presentation of evidence.

## ACKNOWLEDGMENT

The first author is currently a PhD student at Universiti Tun Hussein Onn Malaysia. This research was supported by the Ministry of Higher Education (MOHE) through Fundamental Research Grant Scheme (FRGS/1/2020/ICT07/UTHM/03/1). The authors would like to thank the anonymous reviewers for their constructive and generous feedback.

# Driving Maneuvers Recognition and Classification Using A Hybrid Pattern Matching and Machine Learning

Munaf Salim Najim Al-Din

Department of Electrical and Computer Engineering, University of Nizwa, Birkat Al-Mouz, Nizwa, P.C. 616, Oman

**Abstract**—Since most of the road and traffic accidents are related to human errors or distraction, the study of irregular driving behaviors is considered one of the most important research topics in this field. To prevent road accidents and assess driving competencies, there is an urgent need to evaluate driving behavior through the design of a driving maneuvers assessment system. In this study, the recognition and classification of highway driving maneuvers using smartphones' built-in sensors are presented. The paper examines the performance of three classical machine learning techniques and a novel hybrid system. The proposed hybrid system combines the pattern matching Dynamic Time Warping (DTW) technique for recognizing driving maneuvers and the machine learning techniques for classification. Results obtained from both approaches show that the performance of the hybrid system is superior to that obtained by using classical machine learning techniques. This enhancement in the performance of the hybrid system is due to the elimination of the overlapping in the target classes due to the separation, the recognition and the classification processes.

**Keywords**—Driving behavior classification; driving maneuvers; pattern matching; machine learning

## I. INTRODUCTION

According to previous studies in the field of traffic safety and road accidents, abnormal or irregular driving behaviors have been considered to be one of the main factors that greatly contribute to road accidents [1]. With the increase of vehicles all over the world, abnormal driving patterns detection and monitoring will most defiantly contribute to the reduction of road accidents. In addition to the above benefits, studies of driving patterns and behaviors have been instrumental in the development of advanced driver assistance systems (ADAS) and autonomous vehicles (AVs) [2, 3]. Driving behaviors can be assessed from two different perspectives namely; drivers' actions or the vehicle's dynamic state. In the first approach the driver is considered as the focal element where a set of parameters that affect the driver's vigilance and attention are continuously observed to predict his/her competence to achieve the driving course in a robust and safe manner [4]. Drivers' state monitoring systems may contain different modules, such as facial recognition systems, physiological signals monitoring and drivers' interaction and control. For example, drivers' interaction and control, combined with facial recognition, have been shown to be effective in detecting driver fatigue, drowsiness, and distraction [4].

In the second approach, the dynamic state of the vehicle, such as longitudinal and lateral accelerations, braking, is monitored to detect and classify abnormal driving patterns or maneuvers. In general, signals captured through the vehicle's built-in sensors captured through the CAN-BUS [5, 6], or external sensors such as accelerometers and gyroscopes, and GPS [7, 8], or a combination of in-vehicle and external sensors [9], can be used for the aforesaid purposes. In the past ten years, smartphones have emerged as an efficient and very reliable tool in this field, since they have powerful computational capabilities, richness and variety of built-in sensing devices and ability to have multiple ways of communication with external devices connected to the OBD-II port. Furthermore, smartphones especially with the emergence of 5G technology have been enabled to play cooperative coordinator between vehicles through vehicle-to-everything networks. With all the above listed features provided by smartphones, attention has been immensely focused on the utilization of smartphones in monitoring and analyzing driving behaviors.

The analysis of driving behavior is dependent on the maneuvers to be analyzed as well as the collected data or estimated parameters used to describe them. Various methods were proposed in the literature to perform this task. The simplest approach considers the driving process as a rule-based or fuzzy classification problem. A set of thresholds are defined or extracted, based on experience or trial-and-error, to assess the driving parameters and then classify driving maneuvers [7, 10-18]. In general, these methods are not reliably accurate because the thresholds, fuzzy sets and rules, as well as the classification results, are all based on presuppositions. The second approach is based on pattern matching and recognition techniques, such as Dynamic Time Warping (DTW) [19]. This approach is based on measuring the level of similarity between captured signals and standard patterns. The disadvantage of using classical DTW is the heavy computational burden especially when dealing with multivariate time series.

Recent research has demonstrated that machine learning techniques are capable of identifying and classifying irregular driving patterns using models and rules that evaluate driving maneuvers and then driving behavior. Machine learning approaches are generally classified into supervised learning approaches and unsupervised learning approaches. Various supervised learning approaches, such as K-Nearest Neighbor (KNN), Naive Bayes, Decision Trees, and Random Forest (RF)

[20], linear regression [21], Support Vector Machines (SVM) [22, 23], and Neural Networks [24] require the extraction of features, such as statistical values, time domain parameters, and frequency domain parameters, for training. On the other hand, unsupervised learning approaches, such as K-means clustering [25] and Principal Component Analysis algorithms [21] can infer and generate rules and threshold-based discriminators for clustering purposes. During the past decade, different methodologies and techniques have been proposed and implemented successfully in the field of driving behavior classification [4, 8].

In this paper, three classical machine learning techniques namely Random Forest (RF), Support Vector Machine (SVM) and K-Nearest Neighbor (KNN) were used to recognize and classify six highway driving maneuvers. The data required for training and testing the machine learning models were collected through smartphones' accelerometers and gyroscope sensors. Furthermore, a novel hybrid approach based on the integration of pattern matching DTW and machine learning approaches has also been proposed and investigated in this study. The basic idea of this hybrid approach is to separate the recognition process from the classification process. The DTW developed in this study is used to provide signal similarity measures for the input signals, while the three above-mentioned machine learning techniques were utilized for classification.

The rest of the paper is organized as follows: Section II introduces briefly three machine learning techniques, the RF, the SVM and the KNN. Section III provides a brief description of the structure and workflow of the system. In Section IV, the maneuver detection unit is described with emphasis on the implementation of an adaptive sliding window. In section V, the structure and implementation of the driving maneuvers identification unit is presented. Evaluation of the performance of the two approaches is presented and compared in Section VI. The conclusions are drawn in Section VII.

## II. CLASSICAL MACHINE LEARNING

A wide range of techniques have been developed to recognize and classify driving maneuvers in the literature. In recent years, driving maneuver classification using machine learning techniques has received increasing attention for the evaluation of driving patterns and drivers' profiling [4]. Three machine learning techniques have been used in this study, namely RF, SVM, and KNN, for recognizing and classifying driving maneuvers. These three techniques will be discussed briefly:

### A. Random Forest Technique

A random forest classifier is an ensemble classifier that is made up of a set of decision trees trained on different sub-sets of the training data and then their predictions are aggregated to improve prediction accuracy and control over-fitting. An RF classifier usually uses bootstrap aggregation and boosting, in which random samples of the training dataset are selected with replacement and trained independently. The use of bagging and feature randomness to generate a set of decision tree classifiers typically results in high variance and low correlation. As a solution to this problem, these decision trees are usually

connected in parallel and by using majority voting the variance is minimized and thus the prediction is improved. The implementation of RF classifier is summarized as follows: [26]:

- 1) Select M random samples from the labeled training set using the bootstrapping technique.
- 2) Construct a RF with N parallel decision trees.
- 3) Form N samples to train the N parallel decision tree models as follows:
  - a) For each feature x in a given feature set  $N_i$  calculate the Information gain from the entropy of the classes and the entropy of the feature x.
  - b) Find the node with the maximum information gain and split it into sub-nodes.
  - c) Iterate through a and b to form the tree until reaching the lowest amount of samples needed to split.
- 4) Repeat steps (1) and (2) to get N tree classifiers.
- 5) For testing data, find the prediction of each decision tree, and allocate the new data to the category that wins the majority votes using the following formula:

$$P^*(x) = \max_y \sum_{t=1}^N I(N_t(x) = P(x)) \quad (1)$$

In the formula,  $P^*(x)$  is the classification result of random forest,  $N_t(x)$  is the classification result of each classification tree,  $P(x)$  is a classification target, and  $I(\cdot)$  is an indicator function which returns 1 if the condition in the argument is true, 0 otherwise.

### B. Support Vector Machine

The main function of the SVM algorithm is to find the finest hyperplane in an N-dimensional space that separates the data and clusters them based on classes by using a kernel function. The SVM is in fact a binary classifier but can be extended to handle multi-class classification by training a series of binary SVMs or by solving a single optimization problem. A high classification rate can be achieved if the optimal selected hyperplane has the largest functional margin. This margin is represented by the distance of the hyperplane to the nearest training data points of any class. For the learning process of the SVM algorithm, constrained nonlinear optimization is used to obtain an optimal hyperplane. In general, a SVM classifier uses a nonlinear mapping function that maps the data into a high-dimensional feature space to distinctly classify the data points as follows:

$$P(x) = \sum_i \lambda_i K_i \langle x \cdot x_i \rangle + b \quad (2)$$

Where,  $\lambda_i$  is support vector,  $x_i$  is data sample,  $i = 1, 2, \dots, C$ ; C number of classes and  $K_i \langle x \cdot x_i \rangle$  are a set of kernel functions defined by:

$$K_i \langle x \cdot x_i \rangle = \begin{cases} e^{-z_1 h(x)^2} & \text{if } x \in X^1 \\ \vdots & \vdots \\ e^{-z_c h(x)^2} & \text{if } x \in X^C \end{cases} \quad (3)$$

In the above equation  $h(x)$  is a binary decision function expressed as:

$$h(x) = \sum_j \lambda_j y_j \langle x \cdot x_j \rangle + b \quad (4)$$

While  $x_i$  is the  $i^{\text{th}}$  sample of the training dataset, which includes the  $N$  number of samples with  $C$  categories and the value of the parameter  $z_j$  can be computed from the chi-square test [27]. The final classification decision is made according to a rule of the form:

$$P^*(x) = \arg \max_c (w_c K_i \langle x \cdot x_i \rangle + b) \quad (5)$$

The weighting factor appearing in Eqn. 8 is defined as:

$$w_i = \frac{N/n_i}{\sum_{i=1}^C N/n_i} \quad (6)$$

Where,  $N$  and  $C$  denote the training sample size and category size, respectively.  $n_i$  indicates the sample size of every category with  $i = 1, 2, \dots, C$ .

The implementation of the SVM classifier is summarized as follows:

- 1) Select  $M$  random samples from the labeled training set using the 5-fold technique and initialize the kernel matrix  $K_i$ .
- 2) For each sample  $x$  calculate:
  - a) Calculate the distance  $h_j(x)$ ,  $\{j = 1, 2, \dots, C\}$ ;  $C$  number of classes.
  - b) Calculate the value of the weighting factor  $w_j$  and parameter  $z_j$  for every support vector.
- 3) Find  $P(x)$  from Eqn.(2).
- 4) Find the new Kernel matrix from  $P(x)$  and from the previous Kernel matrix.
- 5) Repeat steps (2) to (4) until finding the optimal hyperplane, i.e  $h_j(x)$  with optimal functional margin.
- 6) For testing data, find the prediction from equation (4).

### C. K-Nearest-Neighbors Technique

The KNN is a supervised machine learning algorithm for classifying classes based on their feature similarity to other classes. In the KNN the classification of a certain testing sample depends on its distance with respect to other samples in the training dataset. The distance between two samples is employed to measure their similarity [28]. The distance is calculated using different measures such as the Chebyshev distance, the Euclidean distance, and more generally the Minkowski distance. In this paper the Minkowski distance between two feature vectors is used. Where the Minkowski distance is a distance measured between two points in  $N$ -dimensional feature space by the following formula:

$$d(x_i - x_j) = \left( \sum_{i=1}^C |x_i - x_j|^p \right)^{\frac{1}{p}} \quad (7)$$

Where  $x_i$  and  $x_j$  are two features vectors and  $p$  is an integer value.

The implementation of the KNN classifier is summarized as follows:

- 1) Select  $M$  random samples from the labeled training set using the 5-fold technique.
- 2) Set the value of the nearest data points  $K$  which can be any integer preferably to be odd integer.
- 3) For every point in the testing data do the following:

- a) Compute the distance between the test data and each sample in the training data as in Eqn(7).
- b) Sort the distances obtained in (a) in an ascending order.
- c) Select the first  $K$  rows from the sorted distances array.
- d) Assign a class to the test point depending on most frequent class of these rows.

### III. SYSTEM STRUCTURE

Fig. 1, shows the general workflow of the proposed system. The system consists of four main interrelated units namely, data collection unit, data processing unit, maneuver recognition unit, and finally, maneuver classification unit. In this section, the functions of the first two units are briefly introduced. A detailed description of the operation of these units can be found in [29].

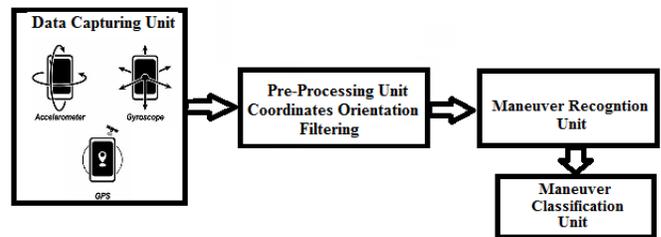

Fig. 1. The proposed system workflow.

Using calibrated Android smartphones with built-in accelerometers and gyroscopes, raw vehicle data was collected at a rate of 50 samples/second. The calibration method for the smartphones' IMUs sensors are adopted from [30]. As well as the data captured by the IMUs, the smartphones' GPS data was used for referencing the location of the vehicle.

The pre-processing unit is intended to achieve two main functions namely, signal filtering, and transformation of sensors data to the vehicle's coordinate system. The first problem is typically attributed to the fact that the IMUs in Smartphones are based on MEMS technology, thus they suffer from white Gaussian noise. Furthermore, the sensors are very sensitive hence they capture in addition to the variation of the dynamic parameters of the vehicle's vibration [30]. Fig. 2 shows instantaneous captured data for a sample maneuver. A locally weighted running line smoother (LOSS) filtering technique is used for removing this noise and smoothing the recorded signals. The use of this type of filter was investigated and its performance was compared with two other filters; the one-dimensional Kalman filter and the simple moving average filter. The LOSS filter was found to be the best effective filtering approach when compared with others, and Fig. 3 shows a sample of a smoothed signal [29-30].

A coordinate reorientation module is integrated with the pre-processing to correct the collected sensors' data by aligning the smartphone's coordinate system with the vehicle coordinate system. By presuming that the vehicle is driven on a horizontal road, during the initial calibration, the vehicle roll and pitch angles relative to a tangent frame both can be considered to be zero. Furthermore, if the vehicle does not experience any

acceleration, the smartphone's roll and pitch angles can be estimated from accelerometer measurements of the gravity vector. This can be done using a set of geometrical rotations using Euler angles. The determination of Euler angles is fully explained in [31].

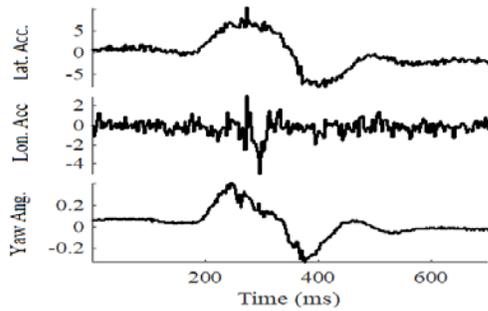

Fig. 2. Raw signals captured by the smartphone's IMUs.

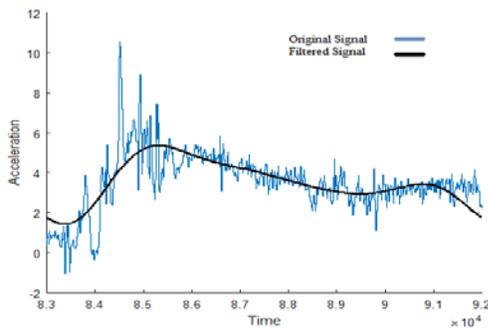

Fig. 3. Raw and filtered accelerometer signal.

#### IV. MANEUVERS DETECTION

Table I, presents the list of maneuvers that can be detected by the proposed system. These maneuvers have been detected by an adaptive sliding window with a short-term energy endpoint detection algorithm.

TABLE I. MANEUVERS CLASSES

1-	Acceleration straight road segment	2-	Braking straight road segment
3-	Left lane change straight road segment	4-	Right lane change straight road segment
5-	Merging into highway	6-	Exit from highway

Maneuvers are detected in three iterative stages. In the first stage a window of 100ms width is used to compute the short-term energy of the signal. Based on the fact that for an infinite sequence of a discrete signal the energy is defined by:

$$\hat{y}[n] = y[n]W[m - n], m - M + 1 \leq n \leq M \quad (8)$$

Where  $W$  is a window function given by:

$$W[m - n] = \begin{cases} 1 & 0 \leq m \leq M - 1 \\ 0 & \text{Otherwise} \end{cases} \quad (9)$$

The energy contained in this short interval then can be computed by:

$$E_w = \sum_{n=m-M+1}^m (y[m]W[n - m])^2 \quad (10)$$

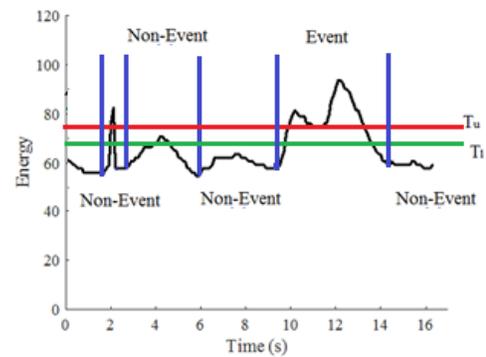

Fig. 4. Maneuver detection using short-term energy.

Once the short-energy is computed it will be compared with a set of pre-defined thresholds, as shown in Fig. 4. If this energy is less than a specific threshold  $T_l$  for the whole 100msec window, then this frame will be ignored and will be considered a non-event. Otherwise, if the energy is greater than  $T_l$ , then the starting time of the event detected is recorded and the short-term energy is computed for a sliding window as in Eq. (10). The width of the window will increase by 20msec and the short-term energy will be calculated over the whole interval of the extended window. For each step in this stage the following conditions will be checked:

- If the computed short-term energy remains less than the upper threshold  $T_u$  for 1 second or drops below  $T_l$  in a short time, then this segment will be considered a false event and the system will start with a new 100msec window as in the first stage.
- When the short-term energy for the extendable sliding window is computed to be higher than the upper threshold  $T_u$  for more than one second, then the system will consider this signal as a result of an event. If the system records the starting time of the event, it will continue to compute the short-term energy for the extendable sliding window and compare it with  $T_u$ . If the short-term energy drops below  $T_l$  for more than 100ms, the system will record the ending time of the event.

#### V. MANEUVERS IDENTIFICATION

Generally, supervised machine learning techniques such as decision trees, support vector machines, neural networks, and many others are used to identify and classify types of driving maneuvers in a single process. All these techniques require a set of features to represent the input signals such as time, frequency or statistical features, for training and testing. In this study, sixteen time and statistical features listed in Table II were used to train and test the recognition and classification performance of the first approach. It should be noted that classical machine learning techniques, when trained with time and statistical features, cannot provide a clear description of how patterns of signals behave. In this regard, it is difficult to draw any conclusions from the parameters of the systems. Additionally, errors resulting from recognition and classification will accumulate and affect the performance of these techniques.

TABLE II. SELECTED STATISTICAL FEATURES

1	Mean	9	Peak to peak value
2	Median	10	Peak to RMS value
3	Maximum value	11	Root-sum-of-squares
4	Minimum value	12	Skewness
5	Standard of deviation	13	Kurtosis
6	Mode	14	Range of values
7	Variance	15	Interquartile range values
8	RMS value	16	The mean absolute deviation

Due to the fact that time-varying signals are required to recognize the types of driving maneuvers, it has been shown that pattern recognition or matching techniques, such as the DTW technique, are superior in this regard. DTW identifies the types of maneuvers by comparing input patterns against standard templates and calculating the similarity level between them. As a result of using the DTW method, incoming signals can be compared with a predefined standard template regardless of any differences in their amplitudes or durations. Therefore, it would be likely to have a set of standard templates to measure the similarity of maneuvers for different drivers [32-35]. It should be noted that the main disadvantage of the DTW approach is its extreme computational requirements, since it computes the similarity level between all the possible patterns in the input signals. In the case that multi-signal identification is required, this problem will become more complex. Furthermore, a considerable amount of work is required to select and compute the reference templates because it is very difficult to collect all possible templates that would cover all driving styles and behaviors of drivers [19].

Fig. 5 shows the basic structure of the DWT unit. The DTW technique utilizes discrete dynamic programming to determine the similarity between two signals, regardless of any difference in time, frequency, or deformation related effects to dynamic spatiotemporal differences. In a previous study [29], the recognition unit was implemented using  $(n \times m)$  DTW units, where  $(n)$  represents the number of signals and  $(m)$  represents the number of standard patterns for each signal. As a consequence, for every detected event, i.e. driving maneuver, a  $(n \times m)$  matrix containing warping cost is derived by comparing all the signals with all the stranded templates. This study has reduced the amount of computation required by the classical DTW technique by reducing the number of signals used to recognize driving maneuvers, as well as by utilizing energy activation units. In this study, the implementation of the DWT technique is based on two facts, which have been demonstrated in previous studies. The first is that there are only three signals, longitudinal acceleration, lateral acceleration, and yaw angle. The second fact is that the signals vary according to certain patterns, so their energy depends on these variations, see Table III.

When using the DWT technique to identify the type of any signal, a set of standard signals, or templates, are required to compare the unknown input signal with them and measure the similarity level. The selection of these reference signals for each specific class is not a straight forward task since the set of the collected signals, for each maneuver class, have different

time durations and amplitudes. There are three different approaches in electing a suitable reference signal from a set of measurements namely; the longest common sequence approach, the medoid sequence approach, and the average sequence approach. In this paper, for a specific DWT unit, the signal that has the minimum average of distances with all the signals in that set is extracted and elected to be the reference signal or template. The details of this novel methodology are given in [35].

## VI. EXPERIMENTS AND RESULTS

In this work two different approaches were used to recognize and classify highway driving maneuvers. The first approach utilizes the classical machine techniques described in Section II, while in the second approach the DTW and the aforementioned techniques were integrated to create a hybrid system. With this system, the DTW method will be used for the

recognition process while classical machine learning techniques will be applied for the classification process.

### A. Experimental Data

Before exploring the analysis and results, it is worth mentioning that the development of the system progressed through two levels, the development level and the naturalistic driving testing level.

At the development level ten drivers with different types of vehicles and experience were volunteered to drive through a 16km highway road segment that has different configurations and conditions as shown in Fig. 6. Each driver was asked to execute the driving maneuvers listed in Table I with different categories; i.e. Light, Normal and Hard. All of the vehicles were equipped with smartphones that were programmed to collect sensor data at a rate of 50Hz and four cameras that recorded the surrounding vehicles. Every class of driving maneuver was performed by each driver at least five times, so the total number of driving maneuvers gathered in this phase was 900 samples. This part of the dataset was then presented to experts to obtain their judgment and to build the knowledge base that is required for labeling the maneuvers. This initial dataset was used to train and test the two suggested systems.

Fig. 6. The route used to collect initial dataset.

The 5-fold cross-validation technique was used from which 60% of the initial dataset were utilized to generate and extract the data and the features that are required in the computation of the DTW reference templates, define the lower and upper limits that define the range of values of each cluster, i.e. class and statistical features vectors for training the systems.

### B. Models Evaluation

To assess the validation of the two approaches the remaining 40% of the initial dataset has been used to validate their performance.

The first assessment of the system was to test its capability to detect driving maneuvers, i.e. recording the starting and ending time. Fig. 7 shows a portion of a short trip conducted to cover some of the basic maneuvers. As shown in Fig. 7, these are the raw data that were captured directly from the calibrated smartphone's sensors. Fig. 8 illustrates the pre-processed signals, i.e. after smoothing the signals of Fig. 7. As shown in the figure, the red rectangles represent the output of the maneuver detection unit. As it can be seen, the unit effectively detects the beginning and the end of any variation in the input signals. According to the testing of maneuver detection unit with manually registered maneuvers, the detection rate was more than 96%.

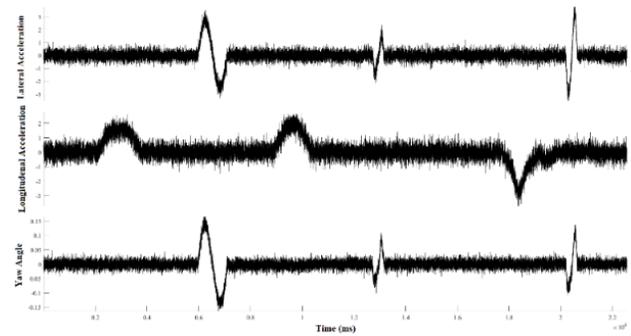

Fig. 7. Raw data captured from the smartphone's sensors.

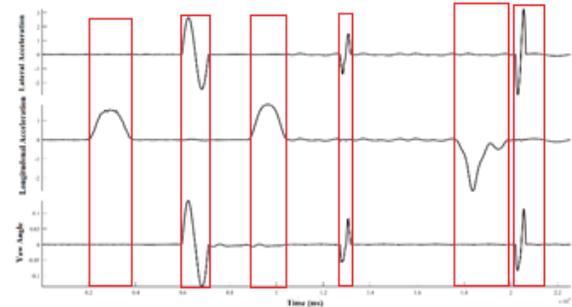

Fig. 8. Signals after filtration and maneuver detection.

Three evaluation metrics namely Precision (PR), Recall (RC), and F1-score (F1) have been used for evaluating the performance of each system in addition to the confusion matrix. Precision is generally defined as the probability that a certain class of maneuvers is correctly classified in either recognition or classification results. In contrast, recall is the probability that all maneuvers in a particular maneuver class are correctly identified. Finally, the F1-score is determined based on both precision and recall, as shown in Eq. (11), where a high F1-score indicates the system's overall performance quality.

$$F1 = \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} = \frac{2TP}{2TP + FP + FN} \quad (11)$$

Where TP is true positive, FP is false positive and FN is false negative. All these three values can be found using the confusion matrix.

In the first approach, namely the three classical machine learning models, all the statistical features listed in Table III were obtained for each segmented maneuver. It should be noted that the models are performing both the recognition and classification processes. The confusion matrix for the RF model is shown in Fig. 9, and Table IV presents a comparison for each maneuver of the three models in terms of PR, RC and F1.

As it can be seen from Table IV, the performance of the RF model is the highest, where the average precision of the model is 0.84, the recall is 0.833 and the F1 score is 0.835. For the SVM the parameters are (PR = 0.783, RC = 0.772, F1 = 0.775) and for the KNN they are (PR = 0.749, RC = 0.736, F1 = 0.74). It is not an easy task to dig for the actual factors behind the low performance of the models when compared with the RF.

However, both SVM and KNN are not efficient algorithms when they deal with large data sets, and they do not function well when the target classes are overlapped. The RF model is able to handle large datasets because it is based on the bagging algorithm which generates as many trees as possible based on the testing data and generates an output combining the tree outputs. Therefore, the RF techniques can be considered as an ensemble learning approach, hence it would reduce the overfitting problem in decision trees, reduces the variance and improves the accuracy.

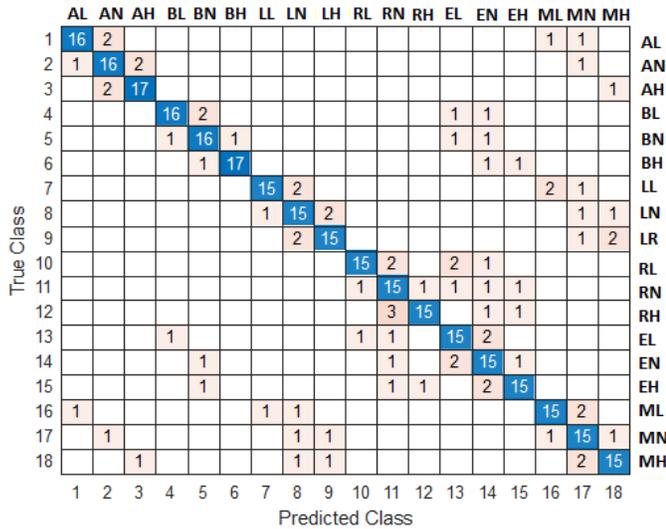

Fig. 9. Confusion matrix for the classical RF implementation.

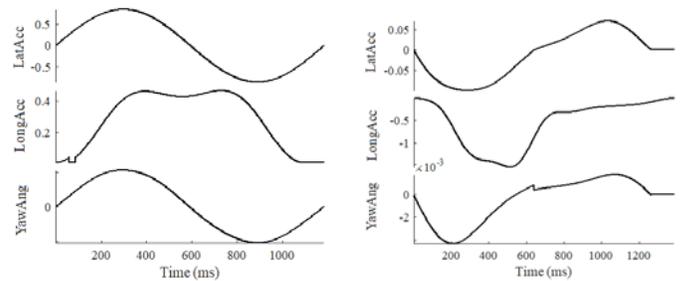

TABLE IV. COMPARISON OF THE MODELS FIRST APPROACH

Class	RF			SVM			KNN		
	PR	RC	FI	PR	RC	FI	PR	RC	FI

RH	0.89	0.80	0.84	0.88	0.75	0.81	0.82	0.70	0.76
EL	0.81	0.85	0.83	0.68	0.75	0.71	0.70	0.70	0.70
EN	0.67	0.80	0.73	0.60	0.75	0.67	0.54	0.75	0.63
EH	0.89	0.80	0.84	0.79	0.75	0.77	0.70	0.70	0.70
ML	0.85	0.85	0.85	0.79	0.75	0.77	0.79	0.75	0.77
MN	0.70	0.80	0.74	0.63	0.75	0.68	0.56	0.70	0.62
MH	0.81	0.85	0.83	0.75	0.75	0.75	0.71	0.75	0.73

It should be mentioned here that a thorough analysis has been conducted in this study to identify the overlap in the target classes. It was found that there are two groups of maneuvers which could have a high similarity rate between their classes. The first group contains the Acceleration, Left-Lane change and the Merging maneuvers and the second group contains the other three maneuver classes. Fig. 10(a) illustrates a signal that was manually recorded as a left-lane change, while the system recognized it as a merging maneuver. On the other hand, Fig. 10(b) shows a break maneuver but has been recognized by the system as an exit maneuver. From the point of view of the author, this noise in the dataset needs careful analysis, hence it will be left to a future investigation.

In the second approach the same 5-fold cross-validation method was used to extract the DTW reference templates and again to train and validate the same models but for a specific maneuver type. As mentioned previously in this approach the DTW unit is acting as a recognition unit while the three classical machine learning models are acting as classifiers.

The performance of the DTW was first tested and it was found that the structure of the unit needs some modification to overcome the problem of overlapping classes. A simple two-hidden layers neural network was integrated into the unit, where the three measured distances obtained from each DTW are fed as an input to this neural network. Fig. 11 shows the confusion matrix for the predicted maneuvers. All the performance measures, precision, recall and F1-score were calculated for the recognition unit and they are equal to 0.95, which indicates an excellent validity of the recognition unit.

(a): LLC recognized merge. (b): Break recognized exit.

Fig. 10. Examples for misrecognized classes.

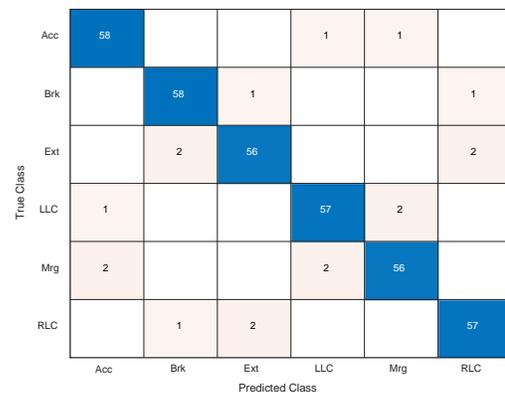

Fig. 11. Confusion matrix for the recognition unit.

Table V presents a comparison between the three models that perform a classification process for each maneuver separately. Fig. 12 shows samples of the confusion matrix for different cases. Again the performance of the RF model is the highest when compared with the others and still the KNN model has the lowest performance. The average precision of the RF model is 0.908, the recall is 0.905 and the F1 score is 0.91. These newly obtained results indicate an enhancement of 9% is achieved when using the second approach. Similar improvements were also noticed in the other models, where for the SVM the performance indicators are PR = 0.875, RC = 0.871, F1 = 0.87 and an average enhancement of 12.25%, while the performance indicators for the KNN model are PR = 0.838, RC=0.835, F1 = 0.84 and an average enhancement of 13.5%.

### C. Naturalistic Driving Testing

In the second stage of this study, a comprehensive dataset was collected by installing only the data collection app onto the smartphones of 25 drivers who drove frequently to and from various locations and the University of Nizwa, as shown in Fig. 13. Data collected in this phase is real naturalistic driving data based on different routes that are very dynamic and include many different types of roads.

Fig. 13. The routes used for collecting the naturalistic dataset.

After performing the necessary preprocessing for the data of each driver, the captured signals were analyzed by an off-line Matlab code to detect and extract driving actions by using the adaptive sliding window described in Section V. Table VI provides a list of the number of driving events obtained in this phase.

TABLE VI. COMPARISON OF THE MODELS SECOND APPROACH

Type of Maneuver	#	Type of Maneuver	#
Acceleration	680	Right-Lane Change	495
Braking	595	Exit	256
Left-Lane Change	508	Merge	255

As a result of the high number of maneuvers obtained from smartphone sensors, a separate module was developed to label the maneuvers in addition to the suggested system. The module uses a semi-supervised labeling system based on the DTW technique. The module is similar to the DTW recognition unit with the exception that it was specifically designed to identify maneuver classes. The only difference between the two systems is that there are nine DTW units and each one is devoted to a single class of a certain maneuver. A detailed explanation of the implementation of this technique can be found in [36]. The distance between two time series signals is given by:

$$Distance(A, B) = \frac{DTW(A, B)}{ED(A, B) + \delta} \quad (12)$$

Where A is a standard reference signal, or template used by the DTW and Euclidian distance calculation, B is the signal that needs to be classified, DTW(A, B) is the distance measured by the classical constrained DTW algorithm, ED(A, B) is the classical Euclidian distance and d is an extremely small positive quantity used to avoid divide-by-zero error.

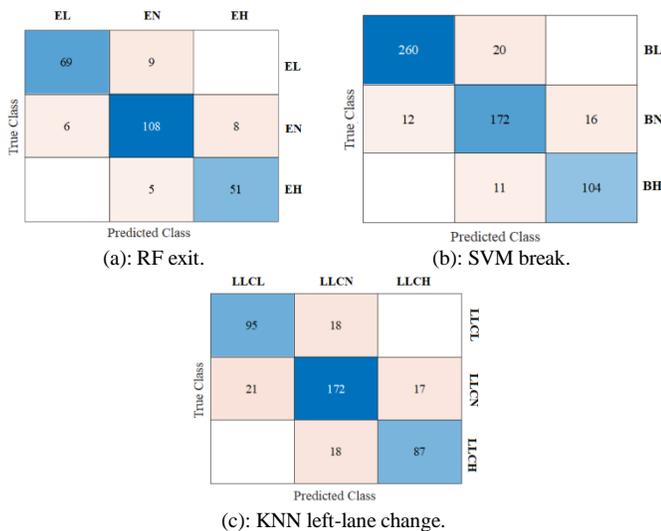

Fig. 14. Confusion matrices samples for hybrid system naturalistic dataset.

Fig. 14 shows the confusion matrix for different cases. As it has been expected the RF model has the highest performance with respect to the SVM and KNN, while the KNN model is still showing the lowest performance. The average precision, recall and F1-score are all approximately 0.9, those for the SVM are 0.87 and finally those for the KNN are 0.834. As it can be seen, the results are almost the same for both datasets and this gives a positive indication that the suggested approach is stable and reliable.

## VII. CONCLUSIONS

Two different approaches are presented in this paper for the recognition and classification of highway driving maneuvers using smartphone sensors. Raw data captured through smartphone's IMUs sensors are first pre-processed by transforming sensors' data from the smartphone's coordinates system to the actual vehicle coordinates system, then these data were smoothed by using the LOSS filter and finally, the longitudinal and lateral acceleration and the yaw angle are deduced from these data. Three parameters were found to be sufficient to recognize and classify driving maneuvers.

The first approach investigated in this paper utilizes three different classical machine learning techniques, namely RF, SVM and KNN techniques. Results obtained from this approach showed that RF had the highest performance when compared to SVM and KNN. This superiority of the RF model can be attributed to the fact that the RF model can handle large datasets efficiently. It's based on the bagging algorithm and uses the Ensemble Learning technique. Nevertheless, it was found that the classical implementation of machine learning techniques suffers from a serious problem in dealing with noisy data, i.e. overlapping in the target classes. It was found that there are two groups of maneuvers which could have a high similarity rate between their classes. The first group contains the Acceleration, Left-Lane change and the Merging maneuvers and the second group contains the other three maneuver classes.

In this paper, a hybrid technique is used to overcome the overlapping between the classes. The recognition unit of this

approach utilizes a novel DTW unit that demonstrates an excellent recognition rate with F1-Score of 0.95. The maneuver classifications are then obtained by machine learning techniques. When compared to the classical approach, the performance of the novel approach was significantly improved.

A large dataset was collected from naturalistic driving for 25 drivers on different highways. About 2800 maneuvers were obtained from this dataset. With such a high number of maneuvers a semi-supervised labeling system based on the DTW technique was used. The module is similar to the DTW recognition unit but was trained solely for labeling maneuver classes. The second approach was tested on the second dataset. Results obtained show a high rate of recognition and classification, nearly the same as that obtained with the first dataset.

**Abstract**—This paper proposes a system for automatic detection of litter and garbage dumps in CCTV feeds with the help of deep learning implementations. The designed system named Greenlock scans and identifies entities that resemble an accumulation of garbage or a garbage dump in real time and alerts the respective authorities to deal with the issue by locating the point of origin. The entity is labelled as garbage if it passes a certain similarity threshold. ResNet-50 has been used for the training purpose alongside TensorFlow for mathematical operations for the neural network. Combined with a pre-existing CCTV surveillance system, this system has the capability to hugely minimize garbage management costs via the prevention of formation of big dumps. The automatic detection also saves the manpower required in manual surveillance and contributes towards healthy neighborhoods and cleaner cities. This article is also showing the comparison between applied various algorithms such as standard TensorFlow, inception algo and faster-r CNN and Resnet-50, and it has been observed that Resnet-50 performed with better accuracy. The study performed here proved to be a stress reliever in terms of the garbage identification and dumping for any country. At the end of the article the comparison chart has been shown.

**Keywords**—Garbage detection; Resnet; TensorFlow; CNN

## I. INTRODUCTION

India generates 62 million tons of waste every year, of which less than 60% is collected i.e. around 25 million tons of waste remains in the open and forever stagnating. The country is moving towards a technological revolution, work on smart cities and sanitation have moved in to the limelight. Still, the method of collection of waste products is ancient and inefficient. Due to mismanagement of waste in urban and rural areas, garbage dumps tend to pile up around corners of vicinities creating a source of bad odor and a breeding ground for pests and diseases. Often, it is very difficult to find these accumulations of waste and eliminate them before they cause harm to a colony, neighborhood, locality or a city. The

efficiency and effectiveness of pre-existing waste control measures needs to be improved to save on monetary resources utilized in these procedures and preserve the aesthetic value of cities. An even more pressing concern is the deterioration of healthy living conditions due to these accumulations. The idea was to create a product that uses the live feed of CCTV cameras on the streets to identify the areas where garbage has begun to accumulate. This will assist the garbage collection and waste control authorities like the Nagar Nigam in cleaning the city in a less time consuming and focused fashion.

Urban garbage monitoring, currently, is done entirely with the help of human resources. In present times all major cities have CCTV cameras in place nowadays which have been put in for ensuring security, detecting and catching traffic violators and perpetrators of criminal activity. Progress has already started to be seen in the direction of automating the processing of these video feeds with computer vision instead of manual monitoring. In better developed cities in the country, automatic vehicular number plate capturing and image capturing have been devised to catch traffic offenders exceeding the speed limit without the efforts of an on-field traffic police officer. Similarly, this proposition is to viably use these camera feeds for detecting garbage dumps with the help of machine learning techniques based in computer vision. This idea is very feasible as it does not require changes in the existing infrastructure, only nominal additions to deal with the processing needs of the software to analyze the video feed, making it not only easier to implement but economically viable as well.

Large advancements have already been made in the field of using machine learning techniques using computer vision with the concepts of deep learning and neural networks (CNN) [1][2]. Frameworks based on these technologies are making automation easier as they make the need for human intervention redundant in day-to-day tasks. Neural networks are used to mimic the human mind to act in place of

individuals and focus human resources on much more important tasks. Convolutional Neural Networks are used to classify images or parts of images into differentiable categories by detecting various features of the image like edges, colors and backgrounds to classify an object present in it. Our objective is to provide a smart solution for garbage collection that analyses live video feeds and highlights garbage present in frames.

This paper is organized as follows, section one is on introduction, section two focused on literature review, section three is on the methodology which will introduce the algorithm; the experiment that will be conducted is introduced in section four and lastly section five is a conclusion.

## II. LITERATURE REVIEW

As per Huang, Kevin Murphy & Wu et al. [3], their work provided a model to select a detection architecture that obtains right speed/memory/accuracy balance for a given application and platform. Various ways were investigated to trade accuracy for speed and memory usage in modern convolutional object detection systems

As per Anitya, Kumar & Wu et al. [4], their paper introduces a Quick Locale based Convolutional System strategy (Quick R-CNN) [13][14] for question recognition. Quick R-CNN expands on past work to effectively characterize object recommendations utilizing profound convolutional systems. Quick R-CNN trains the VGG16 arrange nine times more efficiently than R-CNN, is 213 times faster at test-time, and accomplishes a higher Guide on PASCAL VOC 2012.

As per Nurminen, Jukka & Wu et al. [5] in their research work modern machine learning based approaches are used, in particular, the Yolo neural network system, to detect high-level objects, e.g. pumps or valves, in diagrams which can be scanned from paper archives or stored in vector or pixel form. In this concept, a simulator is used to automatically generate labeled training material to the system. A previously trained network is retrained to detect the components of interest.

As per Chen, Chunlin & Wu et al. [6], their research works to solve the problem of detecting objects, especially small objects, in complex scenes, the authors of this paper have proposed a novel module named as Adaptive Convolution Block (ACB), which adjusts the parameters of convolutional filters corresponding to the current feature maps and then filter these feature maps with the obtained convolutional filters to generate boosted features. Due to such adaptive convolution, the boosted features can pay more emphasis on the exercised objects, suppressing the background information caused by irrelevant surroundings and improve the detection accuracy.

As per Huang, Lili & Wu et al. [7], their research focuses on instruction-guided object detection, i.e., predicting the objects associated with the implementation of a specific instruction for intelligent robots. An amendment to the current detection paradigm is proposed by incorporating semantic instruction description effectively. To address the challenges related to picking out instruction-related objects from the detection results of a general object detector, a flexible dataset is introduced that can well adapt to the variation of the instruction set and only annotates instruction-related object

samples. An amendment to the current detection paradigm is proposed by incorporating semantic instruction description effectively.

As per Kharinov, Mikhail & Wu et al. [8], their paper focuses on the problem of automatized object detection in color images. The explication basing on the classic pixel clustering methods is discussed and advanced. The parameter for the heterogeneity of image areas is introduced. New methods for improving the quality of an image with automatically produced object names are suggested.

As per Liu, Ying & Wu et al. [9], their paper proposes a garbage detection system based on deep learning and narrowband IOT[16][17][18] concepts. The system automatically identifies garbage directly in embedded monitoring module, and manages thousands of monitoring front-ends via background server [12][25][26][27]and narrow-band Internet of Things. The improved YOLOv2 network model[28] is adopted to do garbage detection and recognition, in the front-end embedded module of the system

As per Hu, et al. [10], their research proposes a method for object detection by receiving a user input that specifies one or more first regions and one or more second regions in a template image. The other regions include furthermore objects of interest [19][20][21]. The method further constitutes each of the one or more first regions recognizing a third region in an image under detection comparable to the first region in the template image by matching the image from the point of espial with the template image [22][23][24]. The method further constitutes computing a transformation function based on the similarities from each of the one or more first regions to its comparable third region. The method further constitutes the computed transformation function to the one or more second regions to localize one or more fourth regions in the image for the object detection.

## III. METHODOLOGY

Table I shows the comparisons between CNN Algorithms which were implemented until ResNet50 was finalized as the final framework. Fig. 1 shows the general progression of the research methodology discussed in this paper.

TABLE I. CNN ALGORITHMS COMPARISON TABLE

CNN Algorithms	Confidence %
Standard Tensorflow Algo	75
Inception v1.0	85
Faster r-CNN	90
ResNet50	95

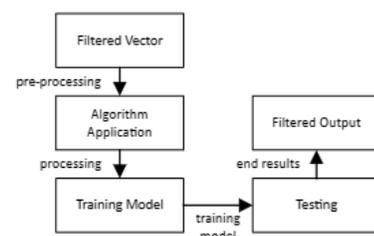

Fig. 1. Flowchart depicting the methodology

A. Algorithm Used

Learning algorithm – Learning algorithm of ResNet is main back-propagation algorithm furthermore, continuous and online learning algorithm response is applied.

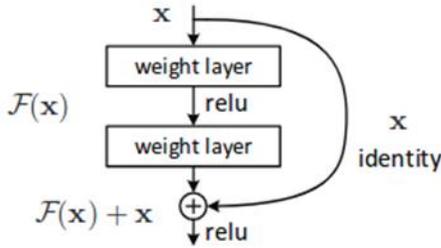

Fig. 2. Residual learning

- The identity shortcuts (x) [29] can be directly used when the input and output are of the same dimensions as shown in Fig. 2.

$$Y = F(X, \{W_i\}) + X \quad (1)$$

- When the dimensions change, A) The shortcut still performs identity mapping, with extra zero entries padded with the increased dimension. B) The projection shortcut is used to match the dimension (done by 1\*1 conv) using the following formula [29]:

$$Y = F(X, \{W_i\}) + W_s X \quad (2)$$

- The first case adds no extra parameters, the second one adds in the form of  $W\{s\}$  [29].
- ResNet50 is 3 layers deep as shown in Fig. 3.

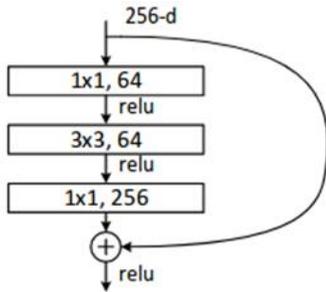

Fig. 3. ResNet50 layer architecture [29]

1) Evaluation Method

$$Recall = \frac{TP}{(TP+FN)} \quad (3)$$

$$Precision = \frac{TP}{(TP+FP)} \quad (4)$$

In this formula, TP, FP, and FN are the number of true cases, false positive cases, and false negative cases respectively.

B. Detection Model

The solution proposed in this research work boasts a minimalistic architecture thus does not have many technical requirements. Anyone can run the software to its maximum efficiency as it requires a live video source as its primary and only external component.

The research work began with intensive research into the necessary fields with the help of different research papers dealing with detection for custom objects, and several blogs detailing similar projects ideas to find the most efficient technology stack to be used. Initially work started with Tensorflow to run our basic object detection code with its library of trained objects, but the confidence threshold of the resultant matched objects was never above 50%. To circumvent this issue a private python code was used which allowed for the use of ResNet50 [29] (A convolutional neural network) model increasing the confidence percentage for more pixelated images. Running the code on these packages gave positive results. Residual learning provides the advantages like potentially deeper, thus this study uses this approach.

Next moving forward, the primary focus was on creating and training the main detection model with a custom dataset. The dataset is formed of 20000 images of various forms of garbage heaps and dumps found all over the world with plans to update the source code to implement a self-learning agent which learns from the outside environment and makes better predictions over time. A Nvidia graphics card along with tensorflow-gpu library were used for training. The trained dataset was then tested for image files. The threshold in the start was 85% but the restrains made the threshold percentage to go up to 95%. Finally, custom designed python modules derived from the raccon dataset by Datitran were used for running the webcam live feed from video source devices, using the OpenCV package of python [11]. Multiple webcams feed can work in cohesion to create a community network to prevent illicit garbage collection throughout a whole smart community. Via the output feed, the target location will automatically get pinged on the software’s hub portal and all active organizations can be informed. The whole process was done in an Anaconda environment running Python 3.5 and Tensorflow 1.12.0.

C. Technology

ResNet-50 is a convolutional neural network that is trained on more than a hundred million images from the ImageNet database. This network is 50 layers deep and can classify images into 1000 object categories. As a result, ResNet-50 has learned rich feature representations for a wide range of images and has an image input size of 224-by-224.

TensorFlow is a free and open-source software library for dataflow and differentiable programming across a range of task and a symbolic math library. It is used for machine learning applications such as neural networks. Experience in TensorFlow is a standard expectation of the machine learning industry. Several python packages are being used here, such as SciPy, NumPy, OpenCV3, Pillow, Matplotlib and Keras.

D. Modules

Identification of correct Technology/Tools – The project started with a search for the correct tools required to materialize the project’s vision. Tensorflow was the first library to be selected for the training models followed by several Python packages like OpenCV, Keras, Pillow.

Testing Models-Several models like Inceptionv3 and R-CNN were tried before settling for ResNet50 framework for

the training of the module. ResNet50, as shown in Fig. 4, when used with Tensorflow was able to provide faster training speed as well as better accuracy.

Collection of Garbage Datasets-Initially the project requirement included a large dataset consisting mainly of Indian/local street garbage and open dumps. The final dataset consists of images taken from SpotGarbage Dataset, some public datasets from Kaggle as well as a large number of personal inclusions. The dataset contains over 15000 training images and over 5000 testing images.

Training the Dataset-To train a robust detection classifier the images in the dataset were individually labelled. The image .xml data, containing information such as borders and dimensions of objects in the images, was used to create .csv files containing all the data for the train and test images in tabular structures for labelling. With the images labeled, the TFRecords were generated that served as input data to the TensorFlow training model. Xml\_to\_csv.py and generate\_tfrecord.py scripts from Dat Tran's Raccoon Detector dataset were used with slight modifications to the original work to include our custom directory structure. Then a label map was created and editing of the training configuration file was done. Then the training code was executed and it took about eight hours and two million steps for the model to be successfully trained.

Coding image/video modules and module for live feeds – The coding of the different modules was done in python programming language mainly utilizing the OpenCV package and the trained dataset in an anaconda environment running via a command line prompt.

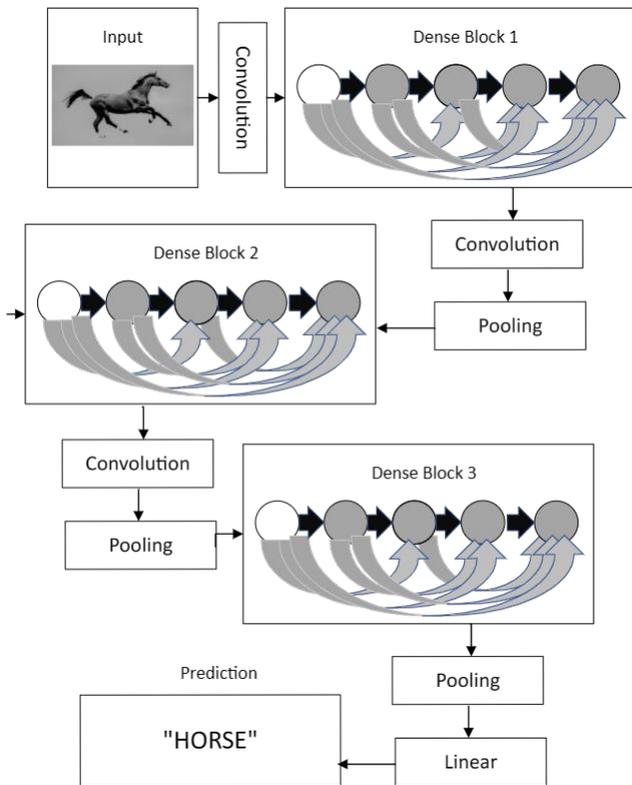

Fig. 4. A standard ResNet50 network

Testing of the Dataset- The trained module can be utilized to detect garbage in an image, video or a live webcam feed. Table II shows the summary of the test results.

TABLE II. SUMMARY OF TEST RESULTS

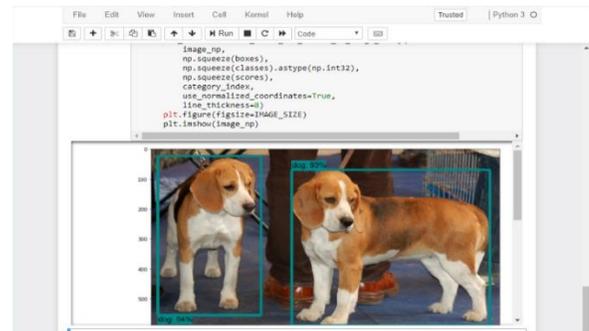

Number of test pictures	5000
Test Speed	0.71
Average Detection Accuracy	85.07
Detection Accuracy Variance	0.089

#### IV. RESULTS

Fig. 5 shows the prototype used in the experiments. The first prototype worked with object detection for all preexisting libraries of Tensorflow only on images. It can be seen in Fig. 5(a) that both the objects are being detected as dogs along with a confidence percentage. The second prototype worked with the designed custom garbage database running classifier on images, videos. It can be seen in Fig 5(b) that separate dumps of garbage are also shown as separate labels rather than just one. The third prototype worked with the designed custom garbage database running classifier on live feed. This is the finalized product, as it can be seen below in Fig. 5(b), the garbage dump present in the frame running on a live footage can be segmented very precisely and is detected with a very high certainty level. The comparative algorithmic confidence percentage is shown in Table III below.

TABLE III. COMPARATIVE ALGORITHMIC % CONFIDENCE

CNN Algorithms	Confidence %
Standard Tensorflow Algo	75
Inception v1.0	85
Faster r-CNN	90
ResNet50	95

(a)

(b)

Fig. 5. Prototype (a) 1, (b) 2 and (c) 3

In Fig. 6, it has been observed that the total loss during training and the chart shows the decrement of the loss with respect to the time.

As per Fig. 7 which shows the comparison chart between various CNN algorithms such as Standard tensorflow algo and inception as well as faster r-CNN and ResNet, and it can be observed very clearly that Resnet 50 worked absolutely fine and with increased level accuracy.

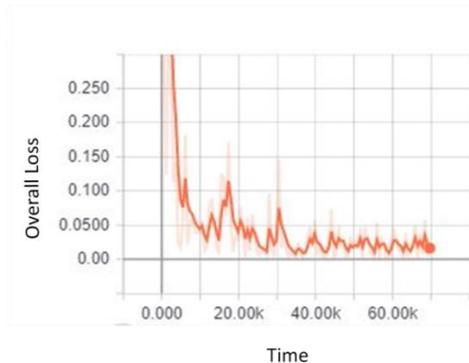

Fig. 6. Total loss during training

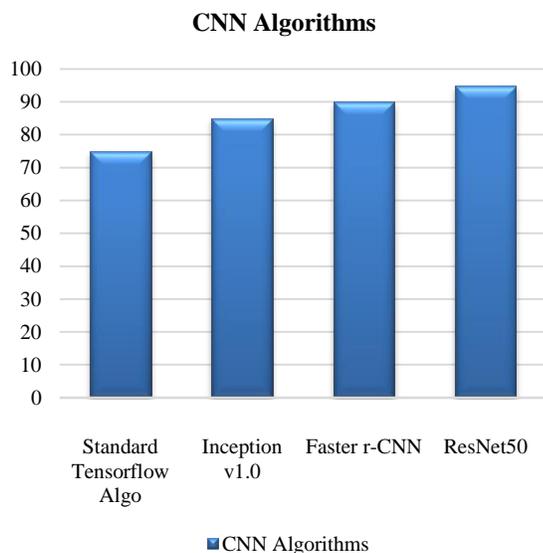

Fig. 7. CNN algorithms comparison chart

This paper proposes a live garbage detection product which can be used by private as well as public authorities alike. It can be developed further to provide a wide array of services like distinguishing between biodegradable, non-biodegradable and toxic wastes, classification of waste like glass, paper, polythene etc., even determining the best and most economical process for different types of waste segregated from the dumps.

## V. CONCLUSION

This research work proposes a solution to the garbage collection problem, faced by many in the modern communities. It is an automated garbage detection solution which can be used by garbage collection authorities as well societies alike. It entails live video analysis (like CCTVs) for identification of open garbage dumps and unofficial land dumps in streets, societies etc. For garbage detection several frameworks were utilized like the ResNet50 model and the Tensorflow technology to custom train a model. OpenCV3 along with other packages of python were implemented to run the live video feed. The implementation still needs to map every frame faster which can be done using better models and a larger dataset for training, so as to decrease the lag suffered during video testing. The dataset can also be implemented in a improved manner by specifying the dataset towards a state or city for better accuracy.

In the future versions of the project there are plans to implement-

- Classification of garbage into various categories like Biodegradable, Non-Biodegradable, Hazardous and Recyclable wastes.
- Train the model for a large dataset and differentiate waste into different classes like cardboard, glass, paper, plastic, tin/metals etc.
- Suggest the best methods to treat the various types of garbage identified by the software.
- Integrate the machine learning model and deploy it on mobile and various IOT devices.
- Shift the model on a cloud-based system for an even faster detection and better accuracy [15].

This venture can help in cleaning the streets of the country also increase public awareness over the subject as well. Some quality of life improvements are still needed in the project, but with the lack of other similar service in the market it's a step forward in the right direction.

This article mainly contribute towards identification and predict the garbage and dumps with the help of CCTV and video segments. The performance of the model is also at par from the other algorithms and comparatively satisfactory.

## ACKNOWLEDGMENT

This research was supported by Universiti Tun Hussein Onn Malaysia (UTHM) through Matching Grant (vot H995).

**Abstract**—One of the most important concerns facing urban regions across the world is air pollution. As a result, it's critical to monitor pollution levels and notify the public on the state of the air. An indicator called the Air Quality Index (AQI) does this by mapping the concentration of different contaminants into a single number. Because the examination of pollutant data is frequently opaque to outsiders, poor environmental control judgments may result. This has led to a need for a tamper-proof pollution management system for use by authorities, like the state and central pollution boards. To address these challenges, a model using machine learning algorithms to predict the air quality and store that information in the blockchain is proposed. Machine learning algorithms are used to categorize the air quality, and blockchain technology guarantees a permanent, tamper-proof record of all air quality data. Such a system might address the persistent issues with data dependability, immutability and trust in pollution control. The execution time of two main operations on blockchain are measured. The execution time of the put block is measured as 10 ms and the get block gets executed in 1 ms that fetches data from the blockchain ledger.

**Keywords**—Air pollution; air quality index; machine learning; blockchain technology

## I. INTRODUCTION

Air quality refers to how well the air is suited for breathing by people, animals, and plants. An average healthy person breathes approximately 14,000 liters of air each day. As a result, poor air quality may have an effect on the quality of life for both the present and future generations by hurting human well-being, the environment, the economy, and urban sustainability.

AQI Category (Range)	PM <sub>10</sub> (24hr)	PM <sub>2.5</sub> (24hr)	NO <sub>2</sub> (8hr)	O <sub>3</sub> (8hr)	CO (8hr)	SO <sub>2</sub> (24hr)	NH <sub>3</sub> (24hr)
Good (0-50)	0-50	0-30	0-40	0-50	0-1.0	0-40	0-200
Satisfactory (51-100)	51-100	31-60	41-80	51-100	1.1-2.0	41-80	201-400
Moderately polluted (101-200)	101-250	61-90	81-180	101-168	2.1-10	81-380	401-800
Poor (201-300)	251-350	91-120	181-280	169-208	10-17	381-800	801-1200
Very poor (301-400)	351-430	121-250	281-400	209-748	17-34	801-1600	1200-1800
Severe (401-500)	430+	250+	400+	748+	34+	1600+	1800+

Fig. 1. Air quality index (AQI) category range

The government keeps an eye on the air quality in various locations to determine the pollution level and to ensure that pollutant levels are within acceptable limits for human health. Air quality agencies can better plan how and when they will take action to safeguard the public's health by identifying how much pollution is present in a given location. Fig. 1 shows the AQI category range of the major pollutants.

The current technique for tracking industrial pollution is centralized, with a lack of openness and the possibility of data falsification. As a result, a consistent and tamper-proof mechanism must be utilized, such as secure software with data encryption and simultaneous data transfer directly to the regulator. Blockchain delivers Distributed ledger technology (DLT), which possesses the potential to solve many of the present system's open issues. Blockchain nodes are a network of multiple storage and computing devices that replicate data over a highly available and fault-tolerant infrastructure. Thus, blockchain facilitates the operation of a distributed database that is transparent and tamper-resistant. There is a need to design and develop an application using machine learning to predict Air quality category and store it on the blockchain that ensures it is tamper-proof and secure. The proposed system has three modules namely machine learning model, Blockchain network and Client application

The machine learning model is trained using industrial air pollution data. Supervised learning algorithms such as random forest classifier, decision tree classifier and Naive Bayes are used to predict the air quality index and the quality range of the given input data. The design of the ML model has these phases. The dataset comprises pollutant concentration information from over 15 industrial areas across India. This data set has around 37-40 pollutants, but the seven most appropriate pollutants are considered. The dataset is cleaned and partitioned into training and testing data. On comparing the results, best results were obtained from decision tree classifier with an accuracy of 99.6%.

The next module is the Blockchain network. The chaincode contains the ML model deployed in it. Once the client supplies the data to the blockchain, the chaincode that has the ML

model will start executing. Once the air quality category has been predicted, it is sent as a transaction to the users of blockchain for endorsement according to the endorsement policy decided prior. The users of this system are the members of state and central pollution control boards. The transaction is then ordered and validated by the respective chain code. If the transaction is validated, it is stored on the ledger.

S. Benedict [1] proposed a blockchain enabled IoT cloud implementation to tackle the existing issues of security hazards and performance inefficiencies in smart cities. It particularly highlights the implementation of chaincodes for air quality monitoring systems in Smart Cities. The proposed architecture named as IoT enabled Blockchain for Air Quality Monitoring System (IB-AQMS) is illustrated using experiments.

Abu Buker [2] proposed an indoor AQI monitoring system to predict the AQI through the Neural Network Algorithm and Block-chain. The Indoor Air Quality system consists of sensors such as temperature, humidity, Carbon Di Oxide, Particulate Matter, Carbon Mono Oxide, and LPG. The Neural Network decision-making model is used to predict the AQI. The suggested IoT-based smart block-chain technology plays a vital role by imparting scalability, privacy, and reliability.

The significant objectives of proposed work are:

- To design and experiment with Random Forest classifier, Decision tree classifier and Linear regression algorithms to predict air quality category and consider the one with best accuracy.
- To implement blockchain-based solutions to resolve the ongoing issues with data dependability in pollution monitoring.
- To ensure a permanent, immutable record of all air quality data of industries.
- To develop GUI for the user to maintain an immutable record of all air quality information.

The organization of the paper is as follows: Section II discusses about the background literatures used for modelling AQI index and use of blockchain based technology for storing data. Section III elaborates the proposed solution and discusses about detailed implementation followed by discussion of result in Section IV. Finally, the conclusive remarks are provided in Section V and future scope is presented in Section VI.

## II. BACKGROUND

The work [3] by S. Mahanta investigates the efficacy of different existing prediction models in forecasting AQI values based on input values. According to Dyuthi Sanjeev's article [4], the AQI is calculated based on pollutants or attributes that have the greatest impact on air pollution. The Random Forest model is the most efficient, according to the research, with a score of 99.4 percent accuracy. Timothy M's research [5] proposes a method for evaluating air quality by building prediction models that link sensor data to an air quality score. Aditya C R [6] uses logistic regression to determine if a data sample is contaminated, as well as auto regression to predict future PM2.5 values based on present PM2.5 data. The study's

purpose [7] is to examine a range of existing prediction models to see how effective they are at predicting data from the study area.

Yue-Shan Changa [8] offers an ALSTM (Aggregated Long Short-Term Memory Model) that combines regional air-quality monitoring stations, industrial zone stations, and external emission source stations. Mahmoud Reza Delavar's [9] study provides a novel method for predicting air pollution in urban regions based on both stationary and non-stationary sources, using machine learning and statistical approaches.

This study [10] will be using Data Mining and Machine Learning models in this research project, to forecast the AQI and classify the AQI into buckets labeled as Good, Satisfactory, Moderate, Poor, Very Poor and Severe. Regression models are used to predict AQI. In order to predict AQI bucket, KNN (K Nearest Neighbors) algorithm with repeat CV classification is used. Station-level data from Indian cities was used to accurately classify and forecast AQI Labels. KNN and repeat CV classification performed best in terms of accuracy. M. Lücking et al. [11] offer a software design for a pollution monitoring system (PMS) based on distributed ledger technology and the long-range protocol, which is described in this paper. It provides adaptable, traceable, and energy-efficient monitoring. Multiple unresolved issues in the functioning of pollution monitoring systems, such as storing data that is invalid or susceptible to tampering, are addressed by distributed ledger technology in a Hyperledger Fabric blockchain.

One of the prime components of blockchain is cryptography for providing confidentiality and authentication using efficient keys. In regard to this author Vaneeta in paper [12] proposes multi-tier framework by including a superior authentication scheme using enhanced public key encryption and digital signature. Sina Rafati Niya's paper [13] proposes an automated approach for measuring, monitoring, and storing air and water quality in factories, lakes, and other sites, based on an IoT and Blockchain-based system.

The proposed system in paper [14] collects real-time air pollution data from industrial locations using 5G wireless IoT sensors and transmits encrypted blockchain data to the index measurement service and cloud via a periodic blockchain transaction. This device enables real-time pollution monitoring in industrial settings and also protects data from tampering. The distributed messaging protocol and blockchain's encryption technologies increase the efficiency of data processing and exchange, while maintaining data integrity. The main objective of this research study [15] is to give an overview of technologies such as Artificial Intelligence, Blockchain and Internet of Things (IoT) and their current applications in the fields of public healthcare and the environment.

Air pollution has been a source of great concern for a long time, but it has come to the attention of stakeholders only recently. The Air Act of 1981 was the piece of legislation that established the requirement for air quality monitoring and opened the door to the monitoring techniques employed in India under the CPCB's oversight. This study [16] suggests that we adopt a thorough approach to manage air pollution. In this

paper [17] development of less expensive, simple-to-use, portable air pollution monitoring sensors, which deliver high-time resolution data in almost real-time and makes access to environmental data convenient is discussed. A variety of air contaminants can already be monitored by sensor devices, and new technologies are constantly being developed.

Regulating and monitoring pollution emissions becomes increasingly essential for battling the illness. This research [18] proposes an Internet of Things (IoT) based system that uses low sensors to monitor pollutants. It is developing a hardware layer of device that is capable of measuring concentrations of pollutants by means of three sensors, respectively, MQ-131, PMSA003 and MICS-6814. The given research study [19] proposes use of Internet of Things (IoT) sensors to periodically collect air quality information such as pollutant concentration and transmit the same over Low power wide area (LPWA) network. IoT cloud is used to process and analyze the data. The participatory urban sensing architecture for PM<sub>2.5</sub> monitoring described in this research [20] has more than 2500 devices operating in Taiwan and 29 other nations. The framework's open system design, which is built on the ideas of open hardware, open source software, and open data, is its defining feature.

The paper [21] introduces CNN-ILSTM, an Air Quality Index prediction model based on Convolution Neural Networks (CNN) and Improved Long Short-Term Memory (ILSTM). The experimental data set includes air quality data from 00:00 on April 4, 2019 to 23:00 on June 30, 2021 in Shijiazhuang, Hebei Province, China. Air pollution is affecting public health and causing a slew of health-related issues, resulting in a significant medical bill each year. Taking air quality information into account, the study [22] offers a safe path when the air quality index is poor to reduce the impact on human health. Dijkstra's method is used to discover the safest path between source and destination. This study also points out research gaps in various studies on similar grounds. The first completely expandable blockchain architecture for supporting distributed applications is called Hyperledger Fabric. Additionally, Fabric is the first blockchain platform to support distributed applications created in common, all-purpose programming languages, independent of a native coin as a system backend.

As indicated in the study [23], Fabric proposes a revolutionary architecture that is evocative of middleware-replicated databases and isolates transaction execution from consensus while enabling policy-based endorsement. Author Sangeetha in paper [24] proposed that Security issues are one of the core problems in mobile adhoc networks owing to the decentralized architecture. The proposed system introduces a new scheme that acts as multi-layer security under two different stages and enhances security in MANET's by modelling the different interactions among a malicious node and with a number of legitimate nodes.

Based on two publicly accessible datasets, this paper [25] regression models using support vector regression (SVR) and random forest regression (RFR) to predict the Air Quality Index (AQI) in Beijing and the nitrogen oxides (NOX) content in an Italian city. The performance of the regression models was assessed using the root-mean-square error (RMSE), correlation coefficient (r), and coefficient of determination (R<sup>2</sup>). SVR based model predicts AQI better whereas RFR based model predicts NOX concentration better. According to study in this paper [26], most of the research on Air quality uses Machine learning techniques and Big data analytics on data collected by IoT sensors. Aim of this study is to evaluate such techniques on air quality forecasting. Based on the observations made, study suggests the need for more research and development in real time air quality monitoring. To suffice the needs of future cities, an integrated air quality monitor with hybrid machine learning models can be developed that address impacts of dynamic quality on various atmospheric levels.

Research paper [27] proposes a real-time IoT based system for air quality monitoring. Study uses models such as CNN-LSTM-BOA (Convolution Neural Networks-Long Short Term Memory-Bayesian Optimization Algorithm) and other baseline models such as SVM (Support Vector Machine), ANN (Artificial Neural Network), Ensemble model. The LSTM model proved to be good for prediction. Results suggest that the proposed models perform better than baseline models. As part of further research, this study also suggests using statistical criteria, AI algorithms can evaluate performance and compare the results to publicly available data sets. Proposed technique in paper [28] used IoT sensors and Artificial Intelligence techniques that are said to reduce implementation costs to ⅓ since before. The proposed model includes wireless sensor nodes to measure gas concentrations (MQ series) which are connected by IEEE 802.11 Wireless LAN AP to an IoT cloud that stores and maintains data in turn connected to a machine learning model responsible for predicting air quality levels. Model uses ARIMA prediction technology which stands for differential autoregressive moving normal model.

Research [29] proposes a predictive model using a multilayer perceptron, support vector regression and linear regression to predict future condition of air quality in a vehicle, based on data collected from sensors. Performance of these models can be evaluated using Root mean square error, coefficient of determination (R<sup>2</sup>), Mean Squared Error and Mean Absolute Error. For data collected, the support vector regression model had the highest performance in terms of R<sup>2</sup> and had a lower error rate.

### III. PROPOSED SOLUTION

The suggested system's mechanism is depicted in Fig. 2. It demonstrates how the entire technique is broken down into five system implementation components.

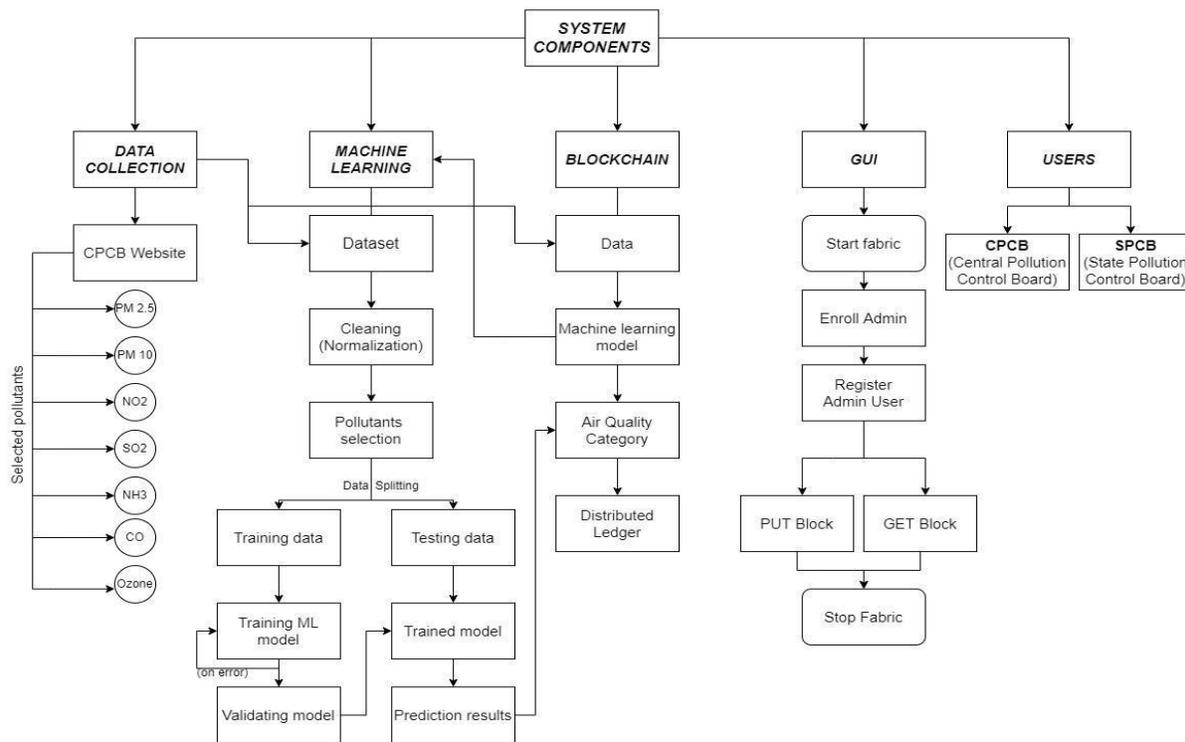

Fig. 2. System components

#### A. Data Collection

- Web scraping is used to collect data for the seven pollutants directly from the official CPCB website. This scraped data is given as input into the machine learning model deployed as the chaincode on the blockchain network. Chaincode then gives the AQI category as Good, Satisfactory, Moderately polluted, Poor, Very Poor and severe. The values of all seven pollutants and AQI categories are then stored on the distributed ledger.
- The web scraping process is divided into three steps. The first step is to set up to and from dates. For these consecutive dates 24hr-data is received. Second, is to pull the data for the setup dates in JSON format and finally, to parse this data and store this in a table form. The data is collected from an industrial area named Peenya in the city of Bangalore in Karnataka, India which is one of the biggest industrial areas in Asia.
- The data set is obtained from the Central Pollution Control Board's official website (CPCB). The website has around 15 stations in industrial areas all over India. The data is from Jan 1st 2020 till April 23rd 2022 for seven pollutants. Data is being considered on a 24-hour basis for five pollutants (PM2.5, PM10, NO2, SO2, NH3) and eight hourly basis for two pollutants (CO and ozone). The dataset has around 12600 rows.

#### B. Machine Learning Model

- The above air pollution data set is divided 80 percent for the machine learning model's training and 20 percent for its testing. Supervised learning methods-Linear regression, Random Forest classifier, and

Decision Tree classifier were the three machine learning techniques used to predict the air quality category of the given input data. The core nodes of the decision tree classifier represent dataset properties, the branches represent decision rules, and each leaf node represents the classification outcome. A 99.56 percent accuracy rate was generated by the decision tree classifier.

- Random forest algorithm is considered as an ensemble learning algorithm. The algorithm's core concept is to construct short and weak decision-trees with few attributes, in parallel, and then merge the trees to generate a single, powerful learning model by taking the majority vote or by just taking the average. An accuracy score of 99.06 % was observed for this model.
- Linear regression, a supervised learning algorithm, is the most common regression model which is used to determine how the independent variable(s) and the dependent variable are related. It is employed to ascertain how the value of the independent variable affects the value of the dependent variable. Finding the best fit line is essential when using linear regression since it reduces the error between the actual and projected values. A sloping straight line is used to represent the connection between the variables. The line that fits the data the best is the one with the least error or inaccuracy. An accuracy score of 91.79 % was observed for this model. Comparing the three learning algorithms. Decision tree classifier produced the most accurate results, with a 99.56 percent accuracy.

### C. Blockchain Network

A blockchain is a type of distributed ledger or database that securely and impenetrably keeps a chain of data in the form of blocks in chronological order. The chain of blocks, also known as a ledger, is continuously expanding, thus new blocks are added to the end of the ledger. Each new block retains a reference to the content of the preceding block using a hash value. The distributed ledger material is secured using the public key encryption process, which also ensures consistency, irreversibility, and non-reputability. The block's immutability, anonymity, and compactness are guaranteed by the use of a cryptographic one-way hash function, such as SHA256. In a peer-to-peer (P2P) network, the ledger and its contents are copied and synced among several peers, forming a distributed ledger. There are three basic categories of blockchains: consortium blockchains, private permissioned blockchains, and public permissionless blockchains. All blockchain data is open to and visible to the general public since the permissionless blockchain type stresses the public component. The Bitcoin and Ethereum blockchains are two examples of such a blockchain. A private blockchain, on the other hand, permits only selected nodes to join the network, making it appear to be a type of distributed but nonetheless centralized network. Combining the two, the consortium blockchain only allows a predetermined set of nodes to take part in the distributed consensus process.

The proposed work implements private blockchain using Hyperledger Fabric. Hyperledger Fabric is a distributed ledger platform that is open-source and enterprise-ready. It features extensive privacy controls that ensure that only the information you want shared with "permissioned" (known) network participants is shared.

The operation of fault-tolerant distributed ledgers is principally due to distributed ledger technology (DLT). Each distributed ledger node keeps a local copy of the data, and new data is added to the ledger in the form of transactions. New transactions are validated using digital signatures and saved in node memory, which is then passed on to other DLT nodes in the network. Eventually, approved transactions are either directly put to the ledger or recorded in a block and then added to the ledger. Most DLT consensus systems (like Kafka or Raft) or even Byzantine fault-tolerant ones are crash-tolerant (e.g., Nakamoto consensus). Crash fault tolerance is the capacity of a consensus mechanism to reach consensus across all validating nodes notwithstanding the (temporary) unavailability of nodes.

Comparing private-permissioned distributed ledgers versus public-permissionless distributed ledgers, the former frequently provides greater flexibility (maintainability), faster speed (rapid transaction confirmation and maximum throughput), and a high level of transparency.

The users of our blockchain network are the State Pollution Control Boards (SPCB), Central Pollution Control Board organization (CPCB) and an orderer organization. All the three organizations form a private "subnet" of communication called channel as shown in Fig. 3.

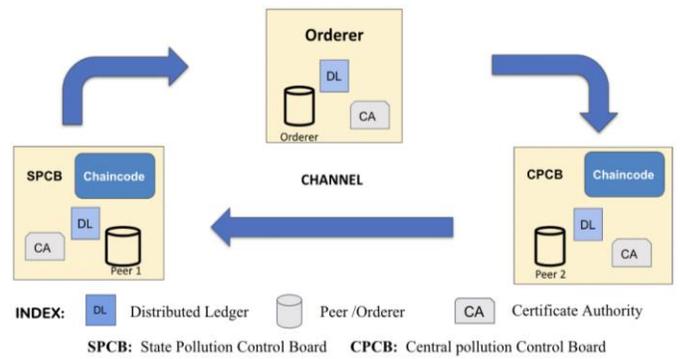

Fig. 3. Blockchain architecture

Chaincode (smart contracts) in Hyperledger Fabric are small programs written in Go, JavaScript/TypeScript or Java that contain the business logic to be executed as transactions on the blockchain. The chaincode has methods to store data received from machine learning models and query the ledger.

To digitally sign the response and endorse the transaction, the endorsement system chaincode is employed. After the transaction is ordered, a validation system chaincode compares the endorsements in the transaction to the endorsement policy defined for the chaincode. If the policy on endorsement isn't followed, then that transaction is marked invalid. Once the transaction has been endorsed, it is ordered and validated by respective peers and chaincode. If the transaction is validated successfully, it is stored on the ledger and every peer will maintain a copy of the same. Otherwise it is rendered unsuccessful.

Every transaction should be endorsed by either peers of SPCB or CPCB organizations, which is mentioned in the endorsement policy. Orderer nodes sequence groups of approved transactions into blocks and bundle them. These blocks are added to the blockchain. The Orderer then distributes blocks to all peers associated with it. Every peer validates the distributed block separately, maintaining consistency, to ensure the block is endorsed by the peers of the right organization and follows the endorsement policy. To prevent altering the ledger's state, all invalidated blocks are appended to an immutable block that was produced by the orderer and was designated invalid by the peer.

For a transaction to occur between the client application and the blockchain network, the client application primarily needs to have a certificate saying it can interact with the blockchain network and should have the necessary information of the network. The steps in transaction are as shown in Fig. 4.

1) The client application enrolls a user in order to get a valid certificate required to communicate with the Hyperledger Fabric blockchain network. Next the client application calls one or more peers to discover the network and since Hyperledger fabric is a private permission blockchain, users get to access only a part of the network. This step is not to be performed before every transaction. Once the required certificate along with topology of the required part of the blockchain network is obtained by the client application, the actual transaction process can be started.

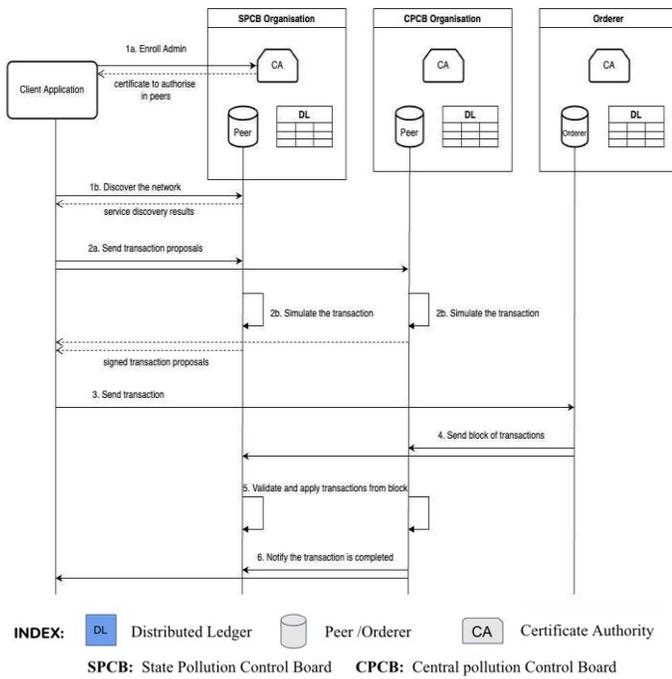

Fig. 4. Transaction proposal

2) Transaction proposals are sent to peers by the client application. These transactions should satisfy the endorsement policy, hence peers simulate the transaction by calling the smart contract which determines what has to be read and what has to be written to the world state based on their copy of the ledger if the transaction succeeds. This information along with the digital signatures from the peers is returned to the client application.

3) The client application next sends the transaction (which contains the simulation results and peer signatures) to the ordering service.

4) The ordering service creates a block once it has collected, validated, and ordered the appropriate number of transactions. The block is then transmitted to the channel's lead peers, who pass it along to the other peers.

5) The transactions are validated and applied by each peer that receives the block. The world state databases are updated with the transaction read/write sets as well as the blockchain copies on the peers are appended with new transactions.

6) The client application is expected to wait until relevant peers notify them that the transaction has been successfully completed. This notification indicates that it actually was appended to the blockchain network on a given peer.

Fig. 5 presents the flowchart of GUI system. The user application is for SPCB and CPCB. Once they access the website they can click on "START NETWORK" to start the network setup. Once the network is up and running, one can enroll the admin by clicking "ENROLL ADMIN" and once this is done, the admin user can be registered through "REGISTER USER".

#### D. GUI

The major functionality of the client is to collect values of pollutants on a 24 hr basis and transfer these to the blockchain along with the details of the concerned industrial area. The user inputs the "to" and "from" date after clicking the "PUT BLOCK" button as shown in Fig. 5 for which the required data is to be extracted. Once the date is entered, the concentration values of each pollutant for that particular "to"-date is fetched and displayed with the help of an API designed by us. The pollution data is then sent to the ML model with the help of another API. The model then calculates the AQI and determines the AQI category. This predicted category is then stored in the blockchain ledger along with the prefetched pollution data. Further, the ledger can be accessed through the GUI by clicking on the "GET BLOCK" button and the contents are displayed as shown in Fig. 5.

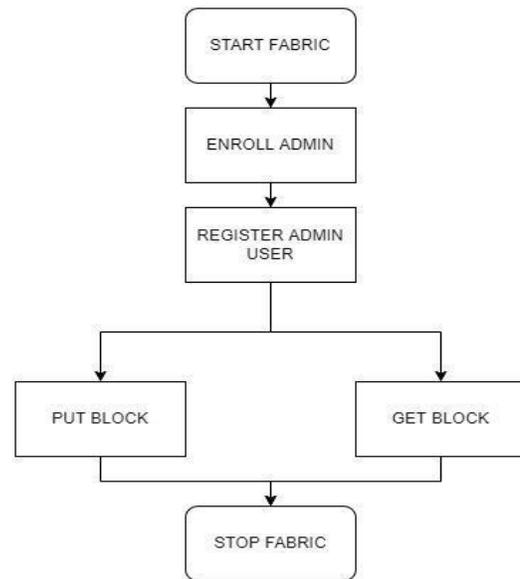

Fig. 5. GUI of the system

#### E. Users

The users of our system are the State pollution control board (SPCB) and the Central pollution control board (CPCB).

The SPCB is a council that analyzes, supervises, and partakes in an inquiry. The Board has a team of experts and a testing facility to evaluate the quality of various samples taken from industrial areas' soil, water, and air samples. It operates in accordance with the guidelines that the government occasionally sets. The CPCB advises the government and SPCB on issues pertaining to the implementation and enforcement of the Air, Water, and Environmental Acts.

#### IV. SYSTEM IMPLEMENTATION

Steps in setting up blockchain Network:

1) *Generate certificates using cryptogen tool:* All entities must be first recognized and granted permission before entering a consortium network under a permissioned blockchain. With the help of a bin/cryptogen tool provided by Hyperledger Fabric, crypto material is created. The

cryptographic components of the Test Network are created using a configuration file, and the finished product is stored in the directory structure. Along with these and docker compose files consortium network can be started.

2) *Generating orderer genesis block*: A "genesis block" is the initial block of a freshly established channel and first block of the "orderer system channel".

3) *Generating channel configuration transaction 'channel.tx'*: The shared configuration for a Hyperledger Fabric blockchain network is stored in a set of configuration transactions, one per channel.

4) *Generating anchor peer update for Org1MSP and Org2MSP*: Peers that are present outside of the organization are known as anchor peers. Any communication between organizations needs anchor peers.

Build your first network (BYFN) end-to-end test

Channel name: mychannel

Creating a channel...

Channel 'mychannel' created

This will launch all of the containers, and then drive a complete end-to-end application scenario.

5) *Having all peers join the channel...*

- a) peer1.org1 joined channel 'mychannel'
- b) peer0.org2 joined channel 'mychannel'
- c) peer1.org2 joined channel 'mychannel'

Administrators can conduct channel-related actions on a peer, such as joining the peer to a channel, using the peer channel command.

6) *Updating anchor peers for org1...*

a) Anchor peers updated for org 'Org1MSP' on channel 'mychannel'

Updating anchor peers for org2...

b) Anchor peers updated for org 'Org2MSP' on channel 'mychannel'

7) *All GOOD, BYFN execution completed*

- Installing smart contract on peer0.org1.example.com
- Installing smart contract on peer0.org2.example.com
- Instantiating smart contract on mychannel
- Waiting for instantiation request to be committed ...
- Submitting initLedger transaction to smart contract on mychannel
- The transaction is sent to the two peers with the chaincode installed (peer0.org1.example.com and peer0.org2.example.com) so that chaincode is built before receiving the following requests

8) *Total setup execution time: 181 secs ...*

## V. RESULTS AND DISCUSSION

The below Fig. 6 shows the User Interface with start network, Enroll admin and register user button options. Once the start network option is selected the blockchain network is established between two organizations of CPCB and SPCB. During start network steps 1 to 8 get executed. After the network is up the admin is enrolled by entering user name and password. Once the admin is logged the user can register by entering username and password.

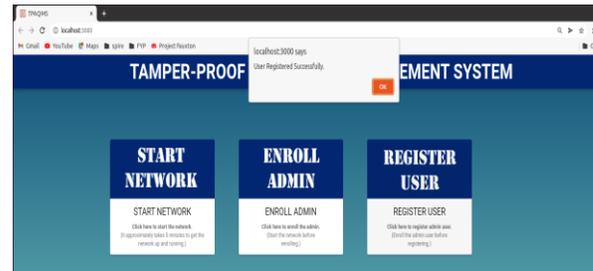

Fig. 6. User Interface

The Fig. 6 shows the User Interface for inserting the from and to dates for which the data must be fetched from the CPCB website. After fetching data of pollutants from CPCB website the Machine Learning model for calculation of AQI index is executed and its air quality category is identified. Put Block option places the transaction consisting of pollutant values along with AQI category on the blockchain ledger. Get block option retrieves block from ledger. The blockchain network can be stopped by selecting Stop Network option (see Fig. 7).

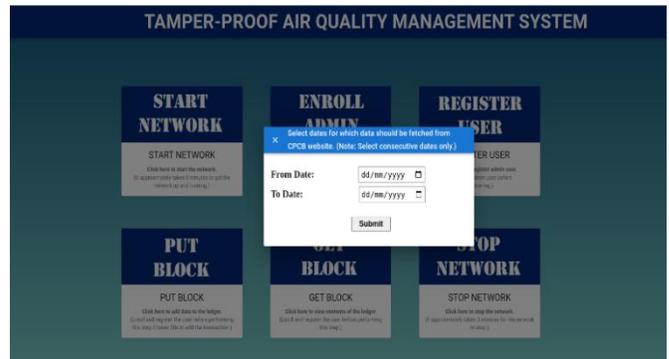

Fig. 7. Input dates to get pollutants

Fig. 8 shows the ledger data maintained by blockchain network accessible only to two organizations. It stores date with pollutant values and AQI category.

Date	PM2.5	PM10	NO2	SO2	NO	CO	Count	AQI Category
10 Jun 2022	37.51	93.24	8.99	16.93	36.86	0.57	2812	Moderately Polluted
15 Jun 2022	31.44	67.55	10.2	17.17	33.31	0.52	2937	Moderately Polluted
19 Jun 2022	27.9	72.35	13.97	9.05	24.59	0.5	414	Satisfactory

Fig. 8. Ledger data

The performance parameter considered is time required for setting the blockchain network. The graph in Fig. 9 represents the average execution time of certain transactions in blockchain network.

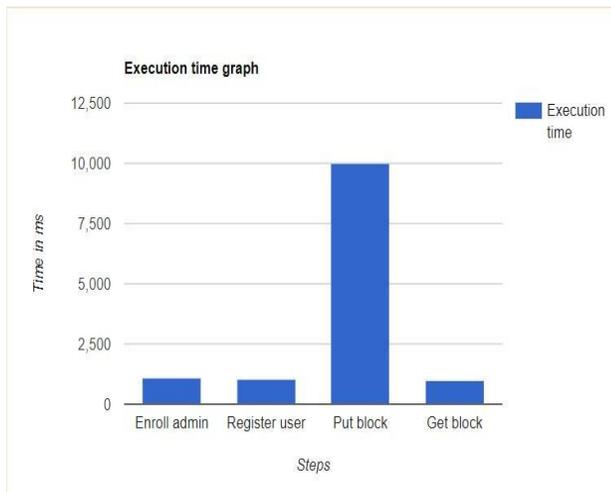

Fig. 9. Execution time

The configuration of a computer system considered is 64bit OS, 12 GB RAM, i7 core processor, 1.99 GHz. For a transaction to occur in a private blockchain network such as Hyperledger fabric, the client application needs to enroll and register the user whose execution times are 1000ms. The execution time of the put block is 10,000ms which includes fetching pollution data blockchain ledger. Lastly, the get block gets executed in 1000ms that fetches data from the blockchain ledger from the CPCB website that is sent to the ML model which determines the AQI category that is to be stored in the blockchain ledger.

The proposed system uses Hyperledger Fabric blockchain network. It is a private network. Hyperledger Fabric is private, permissioned network and does not use currencies. Proposed system is a simple attempt to store transaction securely on ledger. Ethereum blockchain network used in [30] is private or public without any permissions for users and even uses currency called as ether. As a solution for verifying the accuracy of sensitive pollution data, offers a blockchain management system. Data provided by an air quality monitoring network with high geographical and temporal resolution could be traced back in time. Ethereum blockchain supports preserving data on the average densities of zones regarded to be the city's key areas.

## VI. CONCLUSION

The present system for tracking pollutants emitted in industrial areas is centralized, lacks complete transparency and is highly susceptible to data tampering. Proposed tamper-proof air quality management platform combines a machine learning model to predict the AQI category which is then stored on Blockchain. Prediction accuracy has improved using the Decision tree algorithm which is a machine learning algorithm that gives us an accuracy of 99.56%.

It is discovered that a blockchain-based solution can address data dependability issues in pollution monitoring while

also providing a permanent, tamper-proof record of industrial air quality data. As a result, industrial area-specific air quality data may be provided in a credible and transparent manner, allowing industries and the government to take the required steps to minimize pollution.

## VI. FUTURE SCOPE

The proposed tamper proof air quality management system is limited to collecting pollutant data from CPCB website calculating AQI category and storing on blockchain ledger of two organizations. The system can be enhanced by incorporating Internet of Things for collection for pollutant values. IoT device with sensors for different pollutants can be installed and real time data can be collected, calculate the AQI category and store the transaction on blockchain ledger.

# Optimized Strategy for Inter-Service Communication in Microservices

Sidath Weerasinghe, Indika Perera

Department of Computer Science & Engineering, University of Moratuwa, Sri Lanka

**Abstract**—In the last decade, many enterprises have moved their software deployments to the cloud. As a result of this transmission, the cloud providers stepped ahead and introduced various new technologies for their offerings. People cannot gain the expected advantages from cloud-based solutions merely by transferring monolithic architecture-based software to the cloud since the cloud is natively designed for lightweight artifacts. Nowadays, the end user requirements rapidly change. Hence, the software should accommodate those accordingly. On the contrary, with Monolithic architecture, meeting that requirement change based on extensibility, scalability, and modern software quality attributes is quite challenging. The software industry introduced microservice architecture to overcome such challenges. Therefore, most backend systems are designed using this architectural pattern. Microservices are designed as small services, and those services are deployed in the distributed environment. The main drawback of this architecture is introducing additional latency when communicating with the inter-services in the distributed environment. In this research, we have developed a solution to reduce the interservice communication latency and enhance the overall application performance in terms of throughput and response time. The developed solution uses an asynchronous communication pattern using the Redis Stream data structure to enable pub-sub communication between the services. This solution proved that the most straightforward implementation could enhance the overall application performance.

**Keywords**—Microservices; software architecture; inter-service communication; performance; streams

## I. INTRODUCTION

Recently, cloud computing has become considerably popular in the software industry, ultimately making businesses consider migrating their workloads to the cloud environment from their on-premise servers, as managing on-premise server farms is more costly and requires extra effort and maintenance. Based on the particular requirement, the consumers can choose the cloud services such as Infrastructure as a Service (IaaS), Platform as a Service (PaaS), software as a Service (SaaS), and Function as a service (FaaS). The main advantages of using the cloud are that consumers can gain whatever service they require according to their budget. The cloud provider fully manages the environment, and consumers no longer have the hassle of worrying about maintenance. Higher availability and easy vertical and horizontal scalability are some of the advantages of using cloud resources.

In the early days, requirements were very bounded, less volatile, and limited. Therefore, maintaining monolithic architecture software was easy. However, in modern society,

user requirements are complex and subject to constant change, making it cumbersome to make adequate changes to monolithic systems. In the monolithic architecture, all the data access layers, data store layer, logic layer, and user interface layer are tightly coupled into one single package. As a result, changing the code, adapting to the new technology, and testing the product have become problematic. Therefore, people invented Service Oriented Architecture (SOA) to design loosely coupled services. In modern SOA implementations, all the services are orchestrated by the Enterprise Service Bus (ESB). The main disadvantage of this architecture is that all the service calls are routed through this ESB, which is a single point of failure. The performance also tends to get impacted because of that [1].

Cloud services are designed for the light weighted small-scale artifacts like microservices. Hence, people cannot get the complete advantage of migrating their monolithic system into the cloud. Due to this cause, people are trying to reengineer their existing products into microservices architecture by separating the services and making them individual microservices [2]. There are many strategies to decompose the monolithic service into services, such as decomposing by the domains and subdomains, decomposing by the business capabilities, decomposing by the system responsibilities, and decomposing by the resources [3]. After converting monolithic applications into microservices architecture, people can gain many advantages such as improving code maintainability, adapting to new technologies, efficiently scaling only the required service, improving resilience, gaining more business agility, being easy to understand, etc. [4].

Some systems still have not moved their software to the microservice architecture because of certain performance issues related to response time and the application's throughput. Microservice design is an independent service; such services need to communicate with each other to provide the user requirements. Those services deployed in the distributed environment and for the communication services must send and receive the data packets through the network, adding extra latency compared to the monolithic architecture software. Synchronous and Asynchronous communication styles are the two communication styles that are used for microservices interservice communication [5]. Synchronous type still mainly uses the request/response-based behavior, and the request waits until the response reaches. Most people use HTTP or gRPC communication protocols due to inter-service communication in the microservices. Asynchronous communication styles use message brokers to exchange messages to the relevant microservices. They are mainly using the Pub/Sub mechanism,

which means that requests are not waiting for a response, and there are blocking threads associated with the communication. Researchers invert the broker less asynchronous methods, but there is no guarantee of the exact message delivery [6]. Most programming languages support microservice development, and they also develop the framework in conformance to that. Java language based Spring boot [7] and VertX [8], Node.js programming language based Molecular [9], and Golang programming language based GoMicro are fine examples of such instances [10].

This research focuses on the main performance issue of the microservice architecture, which is caused by the inter-service communication in the microservice architecture. As a result of the research, the solution was proposed to reduce the communication latency when communicating on microservice. The researcher has brought REST-based behavior to the top of the Redis Streams data structure for distributed communications. The network layer used the TCP-based socket connection and the serialized data packets to reduce the network latency while transferring the data. The rest of the paper discusses the implementation and the evaluation of this research outcome.

## II. LITERATURE REVIEW

### A. *Microservices*

Previous research publications showed that microservices research contributions started around the 2000 decade. After 15 years, Microservice research is drastically getting published in various academic journals and conferences [11]. Before the emergence of Microservice architecture, most engineers used Service Oriented Architecture (SOA) to build enterprise software. But, researchers have proven that they are faced with capacity issues and scaling issues with the SOA applications [12]. AI-Debagy and Martinek conducted a comparative review regarding the monolithic and microservice architecture. The experimental results of that research showed that monolithic applications perform 6% more on the throughput when compared to microservice-based applications [13]. Nevertheless, researchers have failed to elaborate on the underlying reason for the performance issue. The National Polytechnic School researched the challenges and problems faced during the system migration from monolithic to microservices architecture [14]. Finding suitable tools for migration, reorganizing the engineering team to work with the microservices, identifying the correct microservice design, guaranteeing consistency, and learning about the new framework are the challenges/problem they have highlighted in their research article. Lithuanian researchers reviewed the monolithic to microservice architecture, microservices methods and techniques [4]. One of the methods is to identify all subsystems associated with the monolithic architecture and create a dependency graph. Then architects can determine the services that need to be created as a microservice from the monolithic system. Another method is to identify the business logic from the dataflow diagram and decide what microservices can be created based on the independent business logic. As a best practice of the migration process, it is better to identify the minor steps and execute them one by one. With that, they have a guarantee on the path of restoration. The

software engineering department of Tashkent University published the mechanism to decompose the monolithic architecture system to microservice-based architecture with less development effort [15]. The process started with analyzing the monolithic system, then extracting micro functions, refactoring the service catalog, and finally, orchestrating the services. However, the researchers have not shown the proposed mechanism's real-world application. Florian Auer and team conducted the assignment to find out the facts that companies consider when migrating their system to microservice architecture [16]. Scalability, maintainability, complexity, reusability, modularity, deploy-ability, reliability and testability quality attributes of the Microservice are considered in their study. They have also figured out that most of the companies do not measure the process, product and the quality attribute in depth before the migration. Only after the migration that the companies realize the implications it has. This is caused because there is no standard framework and tech stack that engineer can use when developing the microservices.

### B. *Inter-Service Communication*

Presently, a lot of programming languages and microservice frameworks have emerged to develop microservices. When developing the Microservice, engineers use a tech stack solely based on their area of expertise. In most scenarios, they do not consider the application's nature. There are ample ways to perform service-to-service communication, which is the most crucial part of the microservice architecture. But, there is no clear-cut approach to identifying the most suitable and efficient method. Christy Pachikkal researched the microservices communication styles as synchronous communication and asynchronous messaging [5]. According to that research, developers need to intensely go through the system's functional / non-functional requirements and choose the correct communication style. Most developers use the REST protocol because of the ubiquity of the protocol, which makes them architecturally understand how this protocol works [17]. REST protocol mainly uses JSON format. But in certain instances, it uses the XML-based format for message passing. Those message formats take massive amounts of time to message parsing because of the weight of the message. As a solution, REST is supported for the binary JSON (BSON), which also has overhead with the field names within the data structure [18]. Google invented the Remote Procedure Call(RPC) framework-based protocol to get more performance than the REST over HTTP [19]. Abram Perdanaputra conducted research related to the microservice, which is deployed on the Kubernetes environment. In addition to that, all the communication is done by the gRPC protocol. They have decoded the request and the responses for transparent tracing, but that can be achieved in the passive mode. HTTP/2 was introduced in 2015. It is considered a binary protocol, which gives more efficient bandwidth usage and header compression [20]. Researchers have enabled the multiplexing for HTTP/2 protocol so that the clients can send multiple requests via the same TCP connection before the response is received by the client. This implies that if people can use the same TCP connection to send and receive messages, then they can reduce the latency in message passing. Google has invented a new protocol named Quick UDP Internet Connection (QUIC), which uses the User Datagram Protocol

(UDP) instead of the TCP connections, and behaves as a transport protocol for HTTP/2 [21]. Norwegian University researchers argue in other works that QUIC protocol performance degrades when the messages payload size gets larger than the HTTP/1.1 [22]. Gaetano Carlucci et al. conducted research on the QUIC and showed how QUIC and TCP protocols behave when the network is congested. Their experimental results have proven that TCP is able to provide better response time when compared to the QUIC protocol when a network packet loses.

A group of researchers in Indonesia has implemented asynchronous communication for the microservice architecture with the help of RabbitMQ message broker [23]. Seven Microservices were developed and deployed in an environment that could easily scale down. Communication between the services is done in an asynchronous event-driven manner which led to speed up the application because there was no waiting as request/response architecture. They proposed durable topics which can send the events to the subscriber, i.e., microservices when available. With this concept, they guarantee the message delivery to the client. Sanjana et al. researched the highly resilient inter-process communication service for the microservice architecture [24]. In their implementation, they have used the Kafka message broker and have enabled the pub/sub messaging style to do the inter-service communication. Researchers have used the Camel routes, which are capable of message transformations and validation when doing message routing. With that function, they have proven that inter-service communication can be done without changing the existing architecture of the microservice implementations. Therefore, they argue that provided solution is highly resilient and lightweight for inter-service communication. This non-functional requirement is brought up because they have implemented the solution over the existing framework.

### III. METHODOLOGY

This research focuses on implementing a solution for the inter-service communication method to improve the overall performance in a microservice architecture. When implementing the solution, the researcher has considered asynchronous communication as a communication style according to the facts found in the literature review part. The proposed system uses the Redis with Streams data structure, combined with Pub/Sub communication pattern for message passing in the underlying implementation.

#### A. Redis

Redis is an open-source solution that people can use as an in-memory data structure store. The advantage of the Redis is that it gives high read/write speed with high concurrency [25]. Redis is, by default, a support for easy scaling with the cluster concept. It also brings high availability and fault tolerance with the concept of virtual hash slots. Redis uses its own communication protocol to engage with clients as RESP (Redis Serialization Protocol), and it is also a binary safe protocol [26]. Since it is a Serialization communication protocol with binary safety, transporting the payloads will take less bandwidth. All the clients are connected to the Redis using the

TCP connection. In this proposed method, the stream-oriented connection, which is similar to Unix sockets is used.

#### B. Redis Streams

Redis streams are introduced from Redis 5.0, which can publish the message to the stream, and consumers who subscribe to that stream can receive them. Redis streams differ from Kafka because the stream is an append-only data structure that helps with real-time messaging. The main advantage over the pub/sub model is that Redis streams persist the messages. Hence, it can guarantee the exact message delivery. Message reliability is the most important part of microservice inter-service communication, and can be achieved from this model.

#### C. Component Architecture

Fig. 1 depicts the system architecture of the proposed solution. Microservice A, B, and C are independent microservices that are deployed in the distributed environment. In order to produce the functional requirements in the software, each microservice needs to communicate with one another. In the proposed solution, communication is enabled through the Redis Streams as Pub/Sub communication style. Every microservices creates a Unix-based socket connection from the microservice to the Redis server via TCP 6379 port. All the messages are passed through that TCP connection over the RESP protocol. Every time the microservice does not create and close the connection, when the microservice starts, the TCP connection creates and will live until it shuts down. Thus, network creation and closing time can be reduced with this approach. Using this mechanism developed, the Java-based library enables efficient communication between the microservices and brings all attributes of the HTTP protocol to the developed library. Programmers can use this without changing the existing architecture of their system.

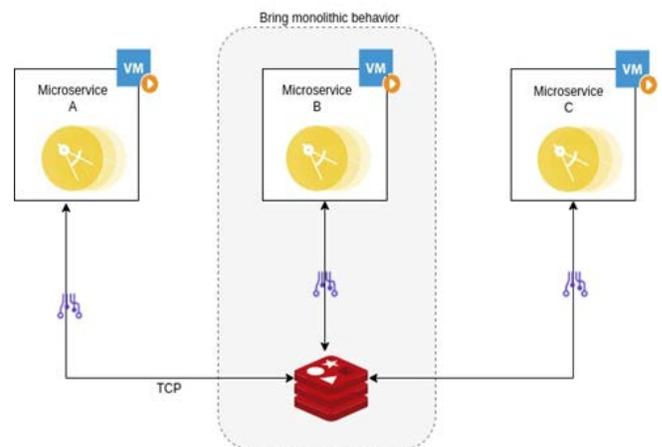

Fig. 1. High-level system architecture

### IV. IMPLEMENTATION

This section briefly describes the implementation of the proposed solution. Java programming language and Spring boot microservice framework have been used to implement the proposed solution according to the literature review the researcher has conducted. The researcher has implemented the request/response-based stateless client like HTTP Client, but beneath, it works on the pub/sub communication style. As a

communication medium, the researcher has used the Redis Streams. Spring Boot provides a spring-boot-starter-data-redis library, which can be used to build the solution [27]. That gives high-level and low-level abstractions for integrating with the Redis server.

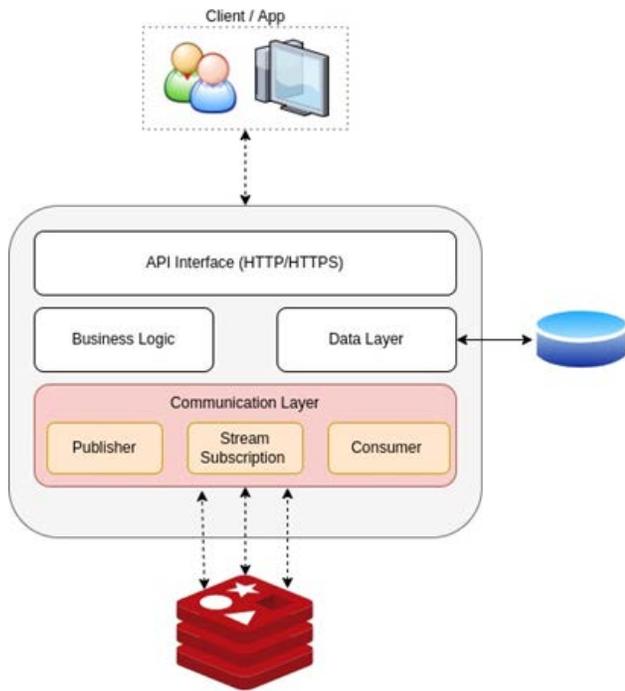

Fig. 2. High-level component architecture

The researcher has segregated one microservice into four main categories (see Fig. 2). The main category is the API interface, the programming component that the microservice communicates with external parties. In this implementation, the interface is neither touched nor changed because the external parties use that and cannot adhere to the implementations by changing their applications. Other categories are the business logic part and the data access layer. Business logic is the main part that contains the functionalities of the microservices. Most of the microservices are segregated from these business functions. Another category is the data layer, the part that communicates with the data sources, such as the database. We have developed the communication layer with three sub-programming components: publisher, stream subscription, and consumer.

- 1) *Publisher*: Responsible for sending the message to the correct microservice.
- 2) *Stream subscription*: Decides the destinations of the messages.
- 3) *Consumer*: Responsible for receiving messages.

#### A. Request Handling in Microservices

3<sup>rd</sup> party client sends the HTTP request by invoking the API exposed from the microservice A, as per Fig. 3. The researcher has used Spring Boot REST Controller to expose the API, which gives the developer the to enable restful web services. When the microservice starts, it establishes the Unix socket-based connection to the Redis server using the TCP port

with the configured IP and the port. After that, create the subscription using the stream keys, which are also configured in the properties file. Stream keys belong to the other microservices that microservice A needs to send the messages. After receiving the request from the 3<sup>rd</sup> party client, microservice A starts processing that request and makes the EventStructure object using the request details and processed details. EventStructure is the object sent as a message to microservice B to get more details. That object contains all the HTTP message details such as HTTP method, parameters, headers, body, client details, publisher details, etc. After processing the HTTP request, the microservice decides which microservice needs to be called to provide the client's correct response. Based on that, microservice A chooses the correct stream key and publishes the message. When publishing the EventStructure object, it is serialized and passed as a byte buffer record. Because of this mechanism, network consumption can be vastly reduced when transferring data. Each published event has a unique event ID. Afterward, that ID and EventStructure object will be stored as a callback reference in a HashMap to process the response.

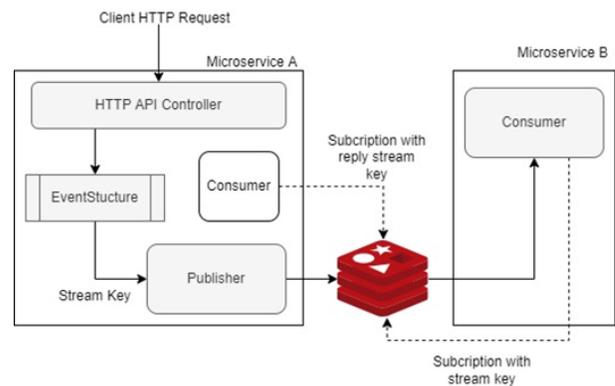

Fig. 3. How request serve

#### B. Response Handling in Microservices

After processing, the business logic response can be set to the EventStructure object. Publisher and reply stream key data can be retrieved from the EventStructure object and can publish the response using those data. Consumers placed in the microservice A can identify the client data by receiving the stream event and mapping the response data with the HashMap data, which is stored earlier. After processing, the response API controller can send the response back to the client using the HTTP protocol as per Fig. 4.

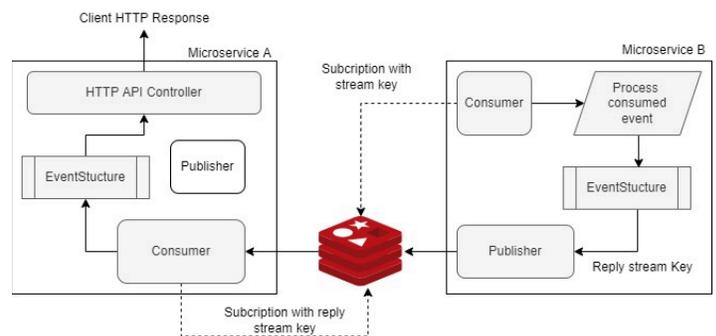

Fig. 4. How response serve

### C. Quality Attributes

Quality attributes are the most vital in Microservice architecture. Most people transition to microservice architecture considering scalability, performance, maintainability, traceability, and availability [28]. When implementing the new solution, the quality attributes are preserved and improved.

1) *Scalability*: Proposed solution can be horizontally (scaling out) and vertically (scaling up) scalable. If this solution is deployed in the cloud-based VM, the VM specification can be increased at any given time and ultimately support vertical scaling. Thus, JVM has more resources to execute computations, and there is no barrier to the implantation. By performing horizontal scaling, people can add more microservice instances based on business needs. When adding the new application, it creates the subscription using the stream key. Redis server is responsible for delivering the messages solely to one subscriber, which means that the request is received only by one microservice. The Redis service covers service discovery and load balancing. Therefore, the developer does not need to ponder on it when scaling the applications. Hence, message duplication is not happening with this implementation, guaranteeing the exact message's delivery.

2) *Maintainability*: There is no impact on the overall maintainability of this implementation. Developers can use this implementation for internal communication instead of HTTP Clients. There's no requirement for maintenance in the internal load balancer for inter-service communication.

3) *Traceability*: This is the most important quality attribute in relation to technical support, as the troubleshooting support engineers need to know what has happened to the request and the response. The developed implementation supports end-to-end request/response tracing via the Redis server. If there's a need to trace the request and the response, the Redis GUI client can be installed after connecting to the Redis server of that client.

4) *Availability*: With this implementation, exact message delivery is guaranteed from the Redis Streams. Hence, availability can be achieved through this.

## V. RESULTS AND DISCUSSION

By critically reviewing the microservice architecture, the researcher analyzed that the impact of inter-service communication on performance is very high as a result of all the microservices deployed in the distrusted environment, making it mandatory to call each other over the network to produce the results. In this research, the researcher has proposed and implemented a solution that can be used to improve inter-service communication, ultimately bringing in overall application performance in terms of response time and throughput. HTTP inter-service communication and implemented solution have been deployed in a cloud VM-based environment to test and evaluate the application response time and throughput.

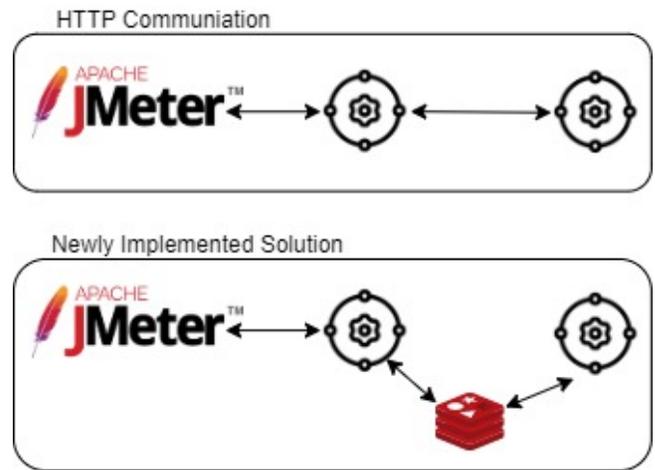

Fig. 5. Testing architecture

The Fig. 5 depicts the high-level system architecture of the load-testing environment. To generate the load, the researcher has used Apache JMeter, which is the most famous and vastly used tool in the industry, as well as in academic research [29]. Well-known cloud provider AWS (Amazon Web Services) has been used to deploy the systems [30]. Most enterprise software companies and enterprise-grade software are developed in the AWS cloud. Numerous scientific types of research are also conducted recently from the AWS cloud. Hence, the AWS platform is chosen in this instance as well to evaluate the system [31]. AWS EC2 is a virtual machine infrastructure as a service that contains the Intel Xeon processors with burstable for high frequency and a balanced memory/network and IO resources.

The T2 instance type has been chosen as it is a low-cost general-purpose instance category that provides better CPU performance for microservices and low-latency interactive applications [32]. T2.Medium EC2 instance type has been used to deploy the two microservices and JMeter, which has two virtual CPUs and 4GB memory on each. T2. A small instance type is used to deploy the Redis server, which contains one virtual CPU and 2GB of memory. All the VMs are provisioned in one virtual private network (VPN) and the same subnet under one security group. This network architecture can minimize network latency by calling the application through the same subnet and improves security by using the same security group.

In Fig. 6, straight arrows are the path that conducts the test for the common standard HTTP communication. The dotted arrows depict the newly implemented solution load test path.

The test is executed in two different methodologies,

1) *Scenario A*: Controlled the application's overall throughput and the request/response size and then measured the inter-service communication turnaround time.

2) *Scenario B*: Controlled only the request/response size and measured the throughput, overall application response time, and inter-service communication turnaround time.

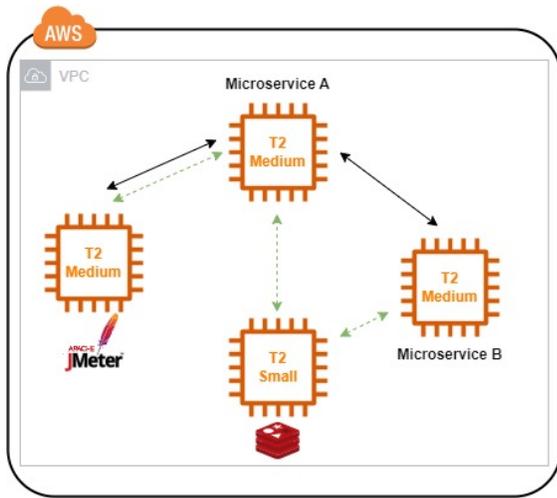

Fig. 6. Deployment architecture

A. Scenario A

Based on the studies conducted, the researcher has chosen different testing scopes to evaluate the system with existing systems. The researcher started with different throughput values and payload sizes. For each constant throughput value, the payload size has been changed as below, and traffic has been generated from the JMeter.

- Call the HTTP GET method from the microservice, and the backend microservice returns the 200 OK HTTP response code with the empty body.

Call the HTTP POST method with a 1KB size JSON payload, and the backend microservice returns the 200 OK HTTP response with a 1KB JSON format response.

Using the above test scenarios (Table I), the researcher has evaluated the HTTP communication method, inter-service communication turnaround time, and the newly implemented solution for inter-service communication turnaround time. Each test scenario was run for a time period of 1 hour and repeated three times, generating an average value of the inter-service communication.

Fig. 7 reflects the difference between the turnaround time on the proposed solution and the HTTP protocol implementations. When the throughput gets high, both the proposed solution and the HTTP protocol solution's turnaround time increase; when considering the payload size, it can be comprehended that both perform the same behavior. But in the all-test scenarios, the proposed solution's turnaround time is getting much lower than HTTP protocol implementation. In the HTTP protocol, a socket connection needs to be created for each connection to close the connection once the response is received. Furthermore, the network packets are neither in a binary method nor fully serialized. Therefore, when transferring the data packet through the network consumes considerable time. In the new implementation, Microservices has established a TCP socket-based connection with the Redis server. Hence, when Microservices starts, it acts as part of the particular Microservice. When sending data to other Microservices, it needs to be serialized and passed as a byte buffer record to reduce the usage of network resources. Due to

that, the implemented solution turnaround time is less than the standard HTTP communication method.

B. Scenario B

In this scenario, only the payload sizes have been controlled and evaluated for the application's overall response time and the Microservice's inter-service communication turnaround time. The researcher has conducted this test scenario in the same cloud environment, and for the payload size, only 1KB sized JSON payload, 5KB sized JSON payload, and URL were chosen. To capture the overall application response time, JMeter listeners are being added. The inter-service communication turnaround time has been calculated by processing the logs. Each test scenario was run for 1h and continued three times to get the average value of the inter-service communication turnaround time, overall application response time, and application throughput.

TABLE I. TEST SCENARIOS

Number	Test Case Scenario
1	Controlled the throughput to 10TPS and send HTTP GET request
2	Controlled the throughput to 10TPS and send HTTP POST request
3	Controlled the throughput to 100TPS and send HTTP GET request
4	Controlled the throughput to 100TPS and send HTTP POST request

Turnaround Time Comparison

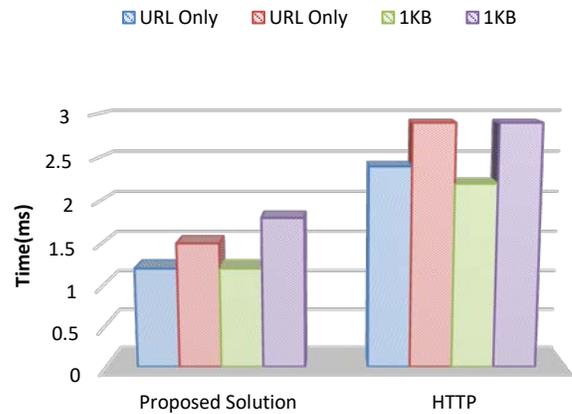

Fig. 7. Turnaround time comparison chart

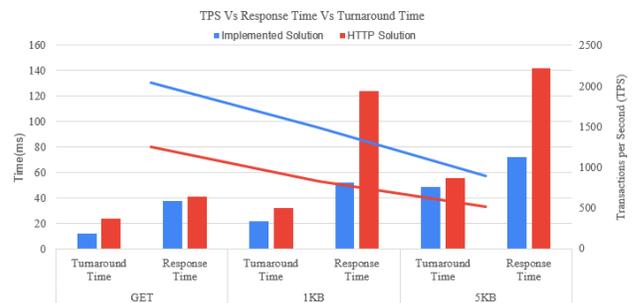

Fig. 8. TPS / response time / turnaround time comparison chart

As in Fig. 8 it can be observed that with the increase of the payload size, throughput is getting decreased. It is a typical network behavior that, when packets get heavy, will decrease the overall network performance. Hence, the response time also increases when the payload size increases. By comparing the implemented solution and the generic HTTP interservice communication method, it can be seen that in all the cases, response time gets better in implemented solution compared to the HTTP communication method.

Critically evaluating the above diagram, it can be concluded that;

Inter – service communication turnaround time  
 $\propto$  Application response time

Inter-service communication turnaround directly impacting to the whole application response time. This means that if some systems took more time to communicate between services, then overall response time will become high on that system due to inter-service communication.

Payload size  $\propto$  1/Throughput

Request and response payload size impacting to the system throughput because transferring large network packets will take some considerable time between services. Hence response time will be getting increased. With the results of that, overall system throughput will be getting decreased.

## VI. CONCLUSION AND FUTURE WORK

In Microservice architecture, all the services are deployed as independent services in a distributed environment. However, unlike in monolithic software, the data must be derived through the network call to share the data between services. As a result of that, additional latency will be added to the overall application response time. Most software companies are faced with issues related to performance in terms of response time and throughput when migrating their monolithic architecture to microservice-based architecture. However, there is a capacity-wise and cost-wise advantage by scaling required services when necessary.

This research focuses on finding a solution to reduce the inter-service communication time between services. The initial studies found that most of the existing protocols take time for connection establishment and connection closure when sending and receiving the response. Besides, sending massive payloads will cause additional latencies. We have implemented the solution by addressing the above-mentioned problems and reducing latency when communicating between the services. We have used the Redis Stream data structure and built the request/response-based message-passing solution for inter-service communication. A TCP-based socket connection is created when the microservice starts. When sending the payload, it will be serialized and sent as a protocol buffer. Redis server is responsible for the exact message delivery based on the subscription and the stream key. The test scenarios are conducted by deploying the implemented solution in the AWS cloud-based VMs, and the system is evaluated against the Spring Boot standard implementation. Test results depict that the implemented solution performs well in terms of application response time and throughput. This research will

continue to find a cloud-native solution to gain more performance and maintainability.

# Deep Learning based Analysis of MRI Images for Brain Tumor Diagnosis

Srinivasarao Gajula<sup>1</sup>, V. Rajesh<sup>2</sup>

Research Scholar<sup>1</sup>, Professor<sup>2</sup>

Department of ECE, Koneru Lakshmaiah Education Foundation  
Guntur, AP, India-522302<sup>1,2</sup>

**Abstract**—This Identification and examination of brain tumour are critical components of any indication system, as evidenced by extensive research and methodological advancement over the years. As part of this approach, an efficient automated system must be put in place to enhance the rate of tumor identification. Today, manually examining thousands of MRI images to locate a brain tumor is arduous and imprecise. It may impair patient care. Since it incorporates several picture datasets, it might be time-consuming. Tumor cells present in the brain look a lot like healthy tissue, making it hard to distinguish between the two while doing segmentation. In this study, we present an approach for classification and prediction of MRI images of the brain using a convolutional neural network, conventional classifiers, and deep learning. Here we have proposed a new method for the automatic and exact categorization of brain tumour utilizing a two-stage feature composition of deep convolutional neural networks (CNNs). We used a deep learning approach to categorize MRI scans into several pathologies, including gliomas, meningiomas, benign lesions, and pituitary tumour, after first extracting characteristics from the scans. Additionally, the most accurate classifier is selected from a pool of five possible classifiers. The principal components analysis (PCA) is used to identify the most important characteristics from the retrieved features, which are then used to train the classifier. We develop our proposed model in Python, utilizing TensorFlow and Keras since it is an effective language for programming and performing work quickly. In our work, CNN got a 98.6% accuracy rate, which is better than what has been done so far.

**Keywords**—Convolutional neural networks (CNN); magnetic resonance imaging (MRI); principal components analysis (PCA)

## I. INTRODUCTION

In the field of medicine, images need to be segmented to be broken down into their constituent pieces. To better analyze a picture, it is helpful to "spit out" the representation of the image. This is because the picture is segmented into several individual parts. Recently, deep learning models have begun to make their presence known in the world of biomedical applications. The network that is used for deep learning has many layers that are hidden from view.

Brain tumour is one of the most debilitating diseases. Brain tumours are frequently found in several locations in the brain. The diagnosis of brain tumour at an earlier stage is essential for more effective treatment. After a clinical suspicion of a brain tumour, imaging studies are necessary to pinpoint the exact location of the tumour, measure its size, and assess its potential

for spreading to other parts of the brain and skull. Based on these findings, doctors select the most effective course of treatment from among surgery, radiation, and chemotherapy. The survival rate of a patient afflicted with a tumour can obviously be raised with precise early detection. Therefore, the radiology department has placed a greater emphasis on the research of brain malignancies through imaging modalities.

Brain tumours are malignant growths that start in the brain or the protective membranes that surround the brain and skull. Finding malignant tumours anywhere on the body and treating them early is challenging. According to a current study, the incidence of brain tumours has grown significantly. Problems with hearing or speech, persistent headaches, memory decline, vision loss, and behavioral shifts are all indicators of a more serious brain disorder. The performance of image processing steps depends heavily on the results of image segmentation [1]. In this situation, we have been particularly concerned with extracting the tumour from the MRI scans of the brain. Medical professionals can pinpoint the exact site of the brain tumour with greater precision. Radiologists, engineers, and physicians all use medical image processing to gain a deeper understanding of patients. Considering the difficulties in segmenting brain tumours and the importance of this task in clinical practice, a wide range of segmentation, automation, and semi-automation mechanisms have been developed. Deep learning techniques rule medical image processing techniques and research [2]. The CNN is a classification method that uses deep learning to determine different types of brain tumors.

The different analyses were performed using deep learning techniques to segment and detect brain tumors. For brain tumour segmentation, Yanming Sun et al. [3] proposed a robust and efficient CNN technique. John Schmeelk [4] worked with two-dimensional images by employing a two-dimensional wavelet transform. To complete the procedure of segmenting MRI brain images, Parra et al. [5] utilised an artificial neural network (ANN) method. In this study, a learning vector quantization (LVQ) network was constructed using an ANN method. Papageorgiou et al. [6] used fuzzy cognitive maps (FCMs) to describe design specialists. Incorporating a computationally clever training strategy known as the activation Hebbian algorithm enhanced the FCM ranking model's classification accuracy. El-Sayed et al. recently introduced decision support systems in medicine that use normal and abnormal categories. MRI scans were classified using a hybrid framework [7]. There are three main phases to the hybrid architecture that is proposed. In the first step, MRI

scans are extracted using discrete wavelet transformations (DWT). In the second step to minimize the number of MR image features, we used principal component analysis (PCA). In the end, two different classifiers were utilized to differentiate normal MR images from those that were aberrant. Othman et al. used a probabilistic neural network (PNN) and image processing to classify brain tumours automatically [8]. The suggested PNN classifier went through the decision-making process in two stages. The first stage involved the extraction of features via the use of principle component analysis (PCA), and the second stage involved classification through PNN. Pei et al. suggested a method that improves texture-based tumour segmentation in longitudinal MRI by utilizing tumour growth patterns as novel characteristics. This method makes use of tumour growth patterns [9]. A new convolutional neural network (CNN) model for brain tumour classification was proposed by Muhammad Sajjad et al [10].

The MR images were segmented to determine where the tumour was located. The next step was to enrich the existing data set. Next, they used the proposed CNN to carry out the categorization procedure. They have a 94.58% success rate when classifying data. The MR dataset was split into two categories, normal and aberrant, by Kanmani et al. [11]. To improve classification efficiency, they applied the threshold-based region optimization (TBRO) technique. They used this technique to carry out segmentation. The proposed method was experimentally validated with a success percentage of 96.57 percent. Seetha J. et al. [13] proposed an approach to speed up computations while maintaining high precision. The ImageNet database is utilised for categorization purposes. To obtain high accuracy, a loss function that is based on gradient descent is implemented. Fuzzy C-Means clustering was used for tumour segmentation by Tonmoy Hossain et al. [14], and it accurately predicted tumour cells. After performing segmentation, they applied traditional classifiers and a convolutional neural network to choose features for classification. In the traditional classifier section, they applied and compared the outcomes of various traditional classifiers such as K-Nearest Neighbor, Logistic Regression, Multilayer Perceptron, Nave Bayes, Random Forest, and Support Vector Machine. A comprehensive overview of existing techniques for segmenting and identifying MRI brain images was provided by Srinivasarao Gajula et al. [15]. You may learn in this article how many people are diagnosed with brain tumours annually. General advice about how to stay healthy while dealing with the sickness is included [16]. The modality-paired learning approach, which employs a 3D U-Net as its backbone network, was proposed by Yixin Wang et al. [17]. This method employs paralleled branches to independently extract features from multiple modalities before combining them via efficient layer connections. Gajula, S., et al. [18] proposed that the machine-learning technique of logistic regression may be used to do automatic brain abnormality identification. Disorders including Alzheimer's, transient ischemic attacks (TIAs), and brain tumours are all identifiable by this TSLR model. The most frequently accessed data sources were reported by Wenyin Zhang et al. [19]. The authors then provide a brief overview of the three types of multi-modal brain tumour MRI image segmentation techniques: traditional segmentation techniques, segmentation techniques based on classical machine learning

techniques, and segmentation techniques based on deep learning techniques. Typical algorithmic structures, principles, and benefits and drawbacks are outlined for each approach. At last, they discuss the difficulties and offer a possible perspective for future patterns of development. Gupta, Gaurav, and colleagues [20] proposed data mining techniques for MRI image classification. This research proposes a novel hybrid approach to brain tumour classification using support vector machines (SVM) and fuzzy c-means. Image-enhancing methods including contrast enhancement and mid-range stretching are implemented in this algorithm. Skull stripping uses a combination of double-thresholding and morphological processes. To find the suspicious area in a brain MRI, fuzzy c-means (FCM) clustering is applied to the segmented image. Brain MRI images are classified using support vector machines (SVMs) after features are extracted using a grey-level run-length matrix (GLRLM). A modified KNN-based clustering and segmentation method is proposed by Xie et al. [21] that uses Minkowski distance as the primary parameter. Using transfer learning, Srinivasarao Gajula et al. [22] presented the super pixel method for detecting and segmenting brain tumours. Data sets were pre-processed initially before being fed into a VGG-19 transfer learning network, which was then used to detect brain tumours. The next step is for a UNet model to locate malignant growths. In this study, we offer an effective and skilled technique based on both conventional classifiers and convolutional neural networks for automatically segmenting and detecting brain tumours.

The focus of this research is on the use of magnetic resonance imaging (MRI) of the brain to detect tumors. Finding brain tumours early is important because it helps medical professionals make a correct clinical diagnosis. The purpose of this work is to develop an algorithm for detecting tumours in MR brain images that is both accurate and reliable. Neurosurgeons and other medical professionals can use the system. The technology, which makes use of image processing, pattern analysis, and computer vision, is designed to boost the sensitivity, specificity, and efficiency of screening for brain tumours.

This paper is organized as follows: Section II of this study presents the proposed methodology that will be discussed in detail. Section III presents the results and discussion, and Section IV presents the conclusion and future work.

## II. PROPOSED METHODOLOGY

Using a convolutional neural network, which we show here, we provide a method for the categorization and prediction of MRI images of the brain. Our initial prospective model classified and identified brain tumours using machine learning methods. The suggested approach aims to improve human health and longevity by classifying brain cancers. The suggested effort attempts to simplify the classification of brain tumours while simultaneously increasing their accuracy compared to existing methods. This technique was selected because, in comparison to conventional CNN, it possesses greater capabilities in terms of both accuracy and speed when it comes to classification.

### A. Data Acquisition

The dataset that was gathered is separated into two categories: training brain images and testing brain images. Among these training datasets contains 2870 images of 4 different classes like pituitary, meningioma, glioma, and no tumor, and the testing dataset contains 394 images of 4 different classes. These images are analyzed, and then the algorithms get processed once they've been pre-processed.

### B. Pre-Processing

During the pre-processing step, the primary objective is to precisely eliminate the redundancy that was present in the image that was collected while maintaining the details that are an important part of the entire method. This is done to improve not just the quality of an image but also its entire appearance. Removing unwanted noise from an image is a key part of any pre-processing method used to fix a degraded image [12]. Adaptive filtering is one kind of denoising in which the process is carried out in accordance with the noise data already present in an image on a regional level. Possible image de-noising methods are as follows:

$$I(x, y) = \frac{\sigma_y^2}{\sigma_{local}^2} (I(x, y) - \mu_{local}) \quad (1)$$

Where  $I(x, y)$  is the reduced image,

$\sigma_y^2$  =variance

$\mu_{local}$  = mean around window pixel

$\sigma_{local}^2$  = local variance of window.

### C. Segmentation

The process of segmentation is used with several medical imaging modalities to identify contaminated tumour tissue. Image analysis must begin with the stage of segmentation because it is essential to the process. Segmentation is the process of dividing an image into distinct sections or blocks that have similar and identical characteristics. The procedure of segmenting a brain tumour involves separating the normal brain tissues and solid tumours from the tumour tissues, such as hydrocephalus and dead cells, which are found within the tumour. Image segmentation has several methods. The choice of segmentation techniques, on the other hand, is determined by the kinds of features that are going to be processed and extracted.

### D. Global Threshold Segmentation:

A threshold image can be given as  $g(x, y)$

$$\text{Here } g(x, y) = \begin{cases} 1, & \text{if } f(x, y) > T \\ 0, & \text{if } f(x, y) < T \end{cases} \quad (2)$$

here 1 is object and 0 is background and  $f(x, y)$  is input image. In case of global thresholding T is constant applicable over whole image. Algorithm for automatic estimation of threshold T is as follows.

*Step 1:* Select an initial estimate for T.

*Step 2:* Segment image using T as two groups with group1 (G1) values as greater than T and group 2 (G2) values as less than or equal to T

*Step 3:* Compute average intensity values for G1 as m1 and for G2 as m2

*Step 4:* Compute a new threshold value  $T_{new} = 1/2 (m1+m2)$

*Step 5:* Repeat (2) through (4) until the difference in  $T_{new}$  in successive iterations is smaller than  $\Delta T$ .

In the past, the most prevalent segmentation methods were pre-processing and thresholding, or a mixture of the two. The thresholding method is the simplest, and it incurs the least amount of calculation cost. The histogram of the image is an essential factor in determining the global threshold. Utilizing the values of the local attributes allows for not only the enhancement of the histogram but also the computation of the global threshold to be performed. At the beginning of this procedure, we will select the MRI image of the brain. In the following stage, we will be calculating the value of the threshold. After that, we will have two distinct groupings of pixel values. We are computing the arithmetic mean by utilizing these two groups. The new threshold is determined by arithmetically averaging the two means. This technique is repeated until the desired number of iterations has been reached.

### E. Feature Extraction

The term "feature extraction" is used to describe the procedure of reducing unstructured data to a set of quantifiable characteristics that may then be processed without losing any of the original data's context. To better characterize a large dataset with fewer resources, feature extraction is employed. To classify the data, two different kinds of features were extracted: texture-based features and statistically based features. During the process of feature extraction, we will obtain several characteristics of the images, such as their mean, skewness, entropy, standard deviation, centroid, energy, dissimilarity, homogeneity, and correlation features.

### F. Proposed Methodology using CNN

To detect tumours, a five-layer convolutional neural network has been developed and is currently being used. In our 5-layer CNN model, there are seventeen stages, as well as the hidden layers, which provide us with the best possible outcome in terms of tumour detection. In the domain of medical image processing, convolutional neural networks have found widespread application. Throughout the years, several researchers have attempted to construct a model that can detect the tumour in a more effective manner. We attempted to develop a model that is capable of accurately classifying the tumour based on images taken from a 2D MRI of the brain. Although a fully connected neural network is capable of tumour detection, we elected to employ a convolutional neural network (CNN) for our model due to parameter sharing and sparsity of connection.

The process by which the suggested work will be carried out on the chosen data sets is depicted for us in Fig. 1. Fig. 2 displays a variety of MRI images, some of which contain tumours while others do not.

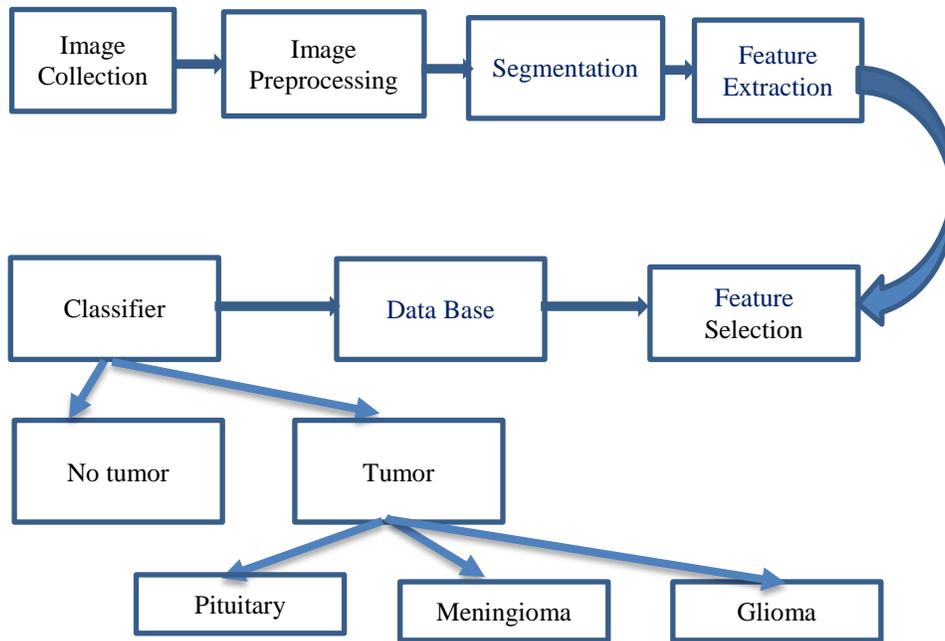

Fig. 1. Basic block diagram of proposed work

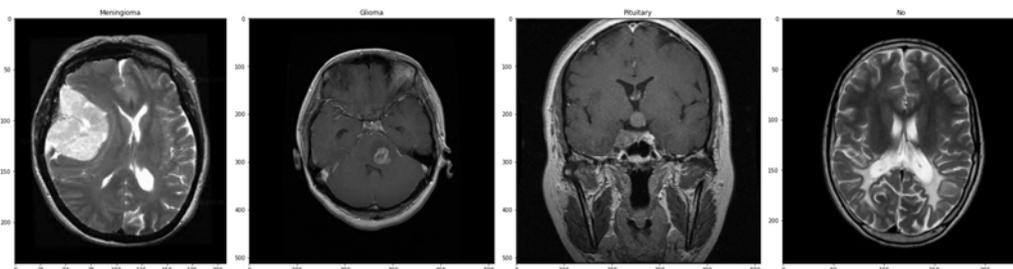

Fig. 2. (a) Meningioma (b) Glioma (c) Pituitary (d) No tumor

Our suggested method takes an exhaustive set of images as input and scales them all to the same dimensions as  $256*256*3$ . The input layer is typically administered by sixty-four convolutional filters of size  $2*2$ , and we use this to design a convolutional kernel that is both complex and efficient. Here we are using the ReLU activation function. If the input is positive, ReLU may be a piecewise linear operation that returns that value directly; otherwise, it returns zero. The pooling process involves summing the features that fall inside a 2D filter's coverage zone, as if the filter were dragged over each channel of the feature map. In a typical CNN model design, numerous convolutional and pooling layers are stacked on top of one another. Pooling layers is used to reduce dimensionality when working with large feature maps. As a result, the number of parameters that need to be learned to determine the level of computation carried out in the network is reduced. The pooling layer is responsible for summing up the features that are available in a certain portion of the feature map that was produced by a convolutional layer. Because of this, subsequent operations are carried out on summarized data

rather than correctly positioned features that were generated by the convolutional layer. Because of this, the model is more capable of distinguishing between distinct positions held by features in the input image.

Pooled feature maps are created after pooling. After merging many images into one, we need to flatten the resulting matrix into a column vector for further processing. After that, the data is sent to a neural network for evaluation. The use of two stacked, interconnected layers, the dense layer, was exemplified by Dense-1 and Dense-2. Keras processes the neural network using the dense function, and the resultant vector feeds the network's layer.

The RMS optimizer was utilised in the construction of the model, and binary cross-entropy was chosen to serve as the loss function. Because of this, we were able to evaluate the accuracy of the tumour detection. A suggested method for locating tumours is depicted in Fig. 3, and it makes use of a convolutional neural network (CNN).

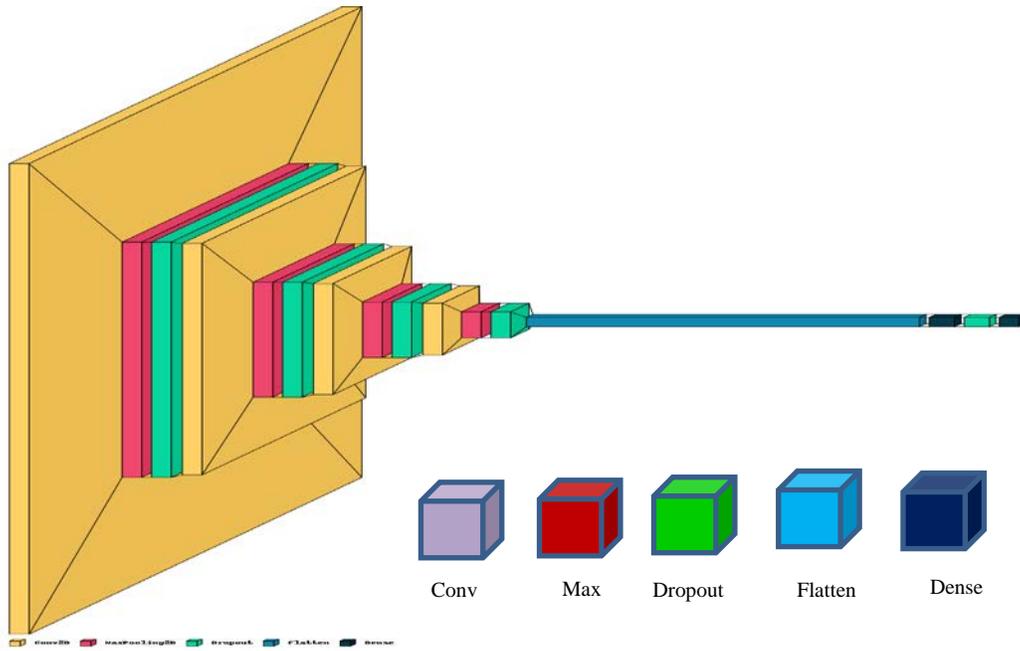

Fig. 3. Proposed methodology for tumor detection convolutional neural network

### III. RESULTS AND DISCUSSION

The effectiveness of the proposed network will be assessed based on the following quality metrics.

$$Sensitivity = \frac{TP}{TP+FN} * 100\% \quad (3)$$

$$Specificity = \frac{TN}{TN+FP} * 100\% \quad (4)$$

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} * 100\% \quad (5)$$

$$Precision = \frac{TP}{TP+FP} * 100\% \quad (6)$$

TABLE I. PERFORMANCE OF EXISTING AND PROPOSED ALGORITHMS

CNN Architecture	Sensitivity	Specificity	Precision	Accuracy
AlexNet	84.3	92.3	93.1	87.9
GoogleNet	84.8	95	95.5	88.6
VGG-16	81.2	87.3	88.1	83.4
Seetha et al. [13]	85	85.3	88.5	97.5
Tonmoy Hossain et al. [14]	86.2	91.5	93.5	97.87
Proposed Method	90	92	94.1	98.6

The comparison of several quality metrics with both existing and suggested methods is presented in Table I.

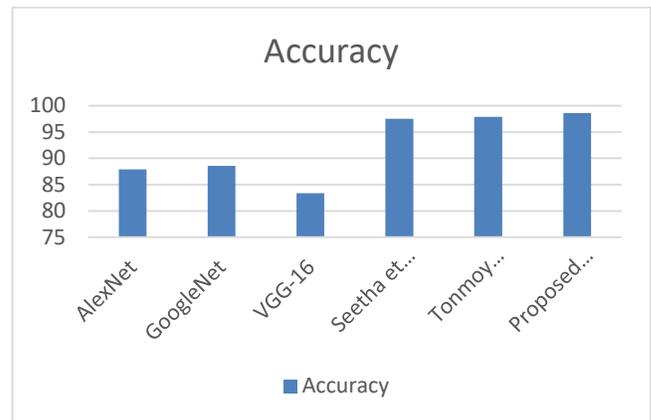

Fig. 4. Accuracy comparison

Fig. 4 shows the results of a comparison of different quality metrics using both existing and recommended methods. Fig. 5 depicts the model structure and various layers of the proposed model. Fig. 6 shows different MRI images- Prediction of brain tumours by the proposed model. Fig. 7 shows the accuracy and loss curves of the proposed model.

#### IV. CONCLUSION

Image segmentation is an essential part of medical image processing because of the extensive variety of medical images. The primary objective of this study is to develop a low-complexity, high-accuracy, automatic brain tumour categorization system. Images obtained from MRI and CT scans were analyzed and employed in the segmentation of the brain tumour. The proposed research was divided into four stages: data collection and pre-processing, data segmentation, MR image feature extraction, and data classification. In our research, we applied a method called global threshold segmentation for tumour segmentation, which accurately predicted the presence of tumour cells. The procedure of segmentation was then followed by classification using both conventional classifiers and a convolutional neural network. Following that, we put a variety of conventional classifiers to use and analyzed the results of each. The proposed method successfully distinguished between healthy and diseased tissues in MR images with an accuracy of 98.6%. The same method can also be utilised to detect and study a variety of disorders that are present in other areas of the body. Future research can improve accuracy by combining more effective segmentation and extraction methods with real-time images and clinical settings, as well as a large data set covering a wide range of conditions and classifiers with optimization methodology.

#### FUNDING DETAILS

No private, government, or non-profit organization provided direct money for his study.

#### INFORMED CONSENT

According to the author's declaration, there was no informed consent given.

#### DECLARATION OF COMPETING INTEREST

The authors have no conflicts of interest.

#### ETHICAL APPROVAL

This article does not contain any data or other information derived from experiments or research in which human or animal participants participated.

# Classification of Psychological Disorders by Feature Ranking and Fusion using Gradient Boosting

## Classification of Psychological Disorders

**Abstract**—Negative emotional regulation is a defining element of psychological disorders. Our goal was to create a machine-learning model to classify psychological disorders based on negative emotions. EEG brainwave dataset displaying positive, negative, and neutral emotions. However, negative emotions are responsible for psychological health. In this paper, research focused solely on negative emotional state characteristics for which the divide-and-conquer approach has been applied to the feature extraction process. Features are grouped into four equal subsets and feature selection has been done for each subset by feature ranking approach based on their feature importance determined by the Random Forest-Recursive Feature Elimination with Cross-validation (RF-RFECV) method. After feature ranking, the fusion of the feature subset is employed to obtain a new potential dataset. 10-fold cross-validation is performed with a grid search created using a set of predetermined model parameters that are important to achieving the greatest possible accuracy. Experimental results demonstrated that the proposed model has achieved 97.71% accuracy in predicting psychological disorders.

**Keywords**—Electroencephalograph (EEG); psychological disorders; negative state emotions; gridSearchCV; gradient boosting classifier

### I. INTRODUCTION

A clinically severe issue with the capacity of an individual to think straight or rule out their emotions or behavior characterizes a psychological disorder. It is typically accompanied by anxiety or impairment in critical areas of functioning. There are many different sorts of mental diseases. Psychological problems are another term for mental problems. The latter is a larger phrase that includes mental disorders, psychological disabilities, and (additional) states of mind that cause severe distress, functional impairment, or the risk of self-harm. This preliminary report is about psychiatric illnesses. The 11th Revised Version of the Disease Classification System (ICD-11) estimates that 960 million people, or one out of every eight people, will live on the planet in 2019 and suffer from a mental disorder, with anxiety and depression being the most common. Depression disorders harmed 280 million people in 2019, including 23 million children and adolescents. Anxiety disorders afflict 301 million people, with 58 million of them being children and adolescents. Schizophrenia affects roughly 24 billion people worldwide or one in every 300. In 2019, 40 million people

were impacted by bipolar disorder [1]. As a result of the COVID-19 disease outbreak, the number of individuals living with anxiety and depression increased significantly in 2020. Estimations reveal a 26% spike in anxiety disorders and a 28% spike in serious depression disorders in only one year [2]. Many patients with psychiatric problems don't have access to suitable treatment or preventative options. Many people face stereotypes, marginalization, and infractions of their human rights. EEG is inexpensive and useful for assessing resting-state activity in the brain in natural environments, allowing for large amounts of data to be collected quickly. Furthermore, as the acquisition of technology improves and calculations improve, EEG is gathering steam as a foundational technology for brain-computer interfaces [3]. Relatively low cost, ease of use, and adaptable territory setup Echocardiography has been widely used in uncovering the aetiologies of various mental illnesses (e.g., depression [4], Alzheimer's [5], epilepsy [6], schizophrenia [7], autism spectrum disorder [8], anxiety [9], and so on). Typical brain activity and emotional swings are always present in depression, a mental disorder with clinical signs like severe depression and impaired thinking. EEG can therefore identify these aberrant events as a technique for monitoring brain activity.

Metadata and computational scientific research advances are being made in transforming mental healthcare. The scope of evidence that can be measured in terms of neural mechanisms and objective markers has expanded. Furthermore, the use of machine learning, also known as artificial intelligence, has grown. Machine learning can evaluate the effectiveness of forecasts on previously unseen (test) data that wasn't used prior, fitting the model for training data, utilizing out-of-sample forecasts, and providing individualized, and possibly high levels of therapeutic applications [10]. Machine learning is expected to aid or even replace physician judgments such as diagnostic testing, prognosis, and patient experience [11]. Individually, Cross-validation learning and psychological disorders had previously been investigated. Collaborations between these two fields have recently been combined, and machine learning has been used by researchers to identify psychological disorders using EEG data. Negative emotions like anxiety and depression encourage a series of psychological and physiological changes that put one's long-term health at risk. So for this, we sought to develop a new classification model for considering negative emotional features from EEG brainwave emotion features

(positive, negative, or neutral) in patients with severe psychological disorders. The contributions to this study are as follows:

- It is difficult but also necessary to accurately extract EEG features since the success of the classifying depends on this extraction. We extract negative state features from EEG brainwave data from emotional features (positive, negative, neutral) for psychological disorders.
- For negative state features we have applied the “Divide and Conquer” approach to four equal parts for finding more optimal results from each feature subset.
- We present the K-Means cluster technique to obtain labeled EEG signal features for each feature subset.
- Ensemble methods (RF-RFECV) techniques for feature selection have been employed to build and determine the highest-ranking features from each feature subset and merge them into an appropriate feature set for classifying psychological disorders.
- To obtain an optimal hyperparameter of the Gradient boosting, the tree classifier GridSearchCV has been used.
- Performance of hyperparameters of gradient boosting trees such as the number of trees, tree depth, several learning rates, and the number of subsamples are utilized.

This article is broken up into five sections. Beginning with the introduction. Most related works were described in Section II. Additionally, Section III provides materials and methods, and resources. In Section IV, Experimental Results are discussed. Finally, the conclusions are given in Section V.

## II. RELATED WORK

Most of the recent imaging research (i.e., employing magnetic resonance) has relied on supervised machine learning. To differentiate patients from health controls (HCs). Studies have primarily concentrated on Alzheimer's disease, schizophrenia, and depression, but have rapidly been expanded to include other diagnosing topics [12]. Literary work suggests that certain machine learning in EEG might predict significant psychological disorders and serve as an unbiased index of psychological disorders, according to the findings. The comprehension of the support vector machine, elastic net, and random forest machine learning methods was highlighted. The elastic net model with intelligence quotient adjustment performed the best with different bands of the EEG dataset [13]. According to various cross-validation experiments, the probability of diagnosis achieved employing the provided approach in a training dataset among 207 entities, such as 64 patients with severe depression, 40 patients with severe schizophrenia, 12 bipolar depression patients, and 91 healthy or normal subjects, is over 85% with some further advances [14]. The proposed methodology has the possibility of being a beneficial adjunct treatment tool for healthcare practitioners. EEG acquisition and pre-processing were adequate, discovered that numerous of them lacked thorough

clinical characteristic identification. Moreover, numerous studies employed parameters of the model or testing techniques that were flawed. Indeed, it's suggested that future researchers of psychological disorders using Deep Learning enhance the accuracy of clinical evidence and use cutting-edge model choice and test procedures to improve research standards and progress toward diagnostic value[15]. Using techniques for extracting multivariate EEG features and algorithms, the goal of this research is to provide an analytical framework for robotic GAD identification. Resting-state EEG data were collected from 45 GAD patients and 36 health control (HC) with 97.83 percent accuracy aberrated features helped classification performance [16]. This study classifies the EEGs of 43 VHS and 53 MDD patients using data mining techniques. This includes cleaning and normalizing the data beforehand, using Linear Discriminant Analysis (LDA) to map information into a brand-new feature space, and Genetic Algorithm (GA) to determine the much more features [17]. Methods are used in mental health to predict the likelihood of mental diseases and, thus, to execute prospective treatment outcomes. This review article lists many machine-learning techniques for identifying and diagnosing depression. The three classes of ML-based depression detection methods include deep learning, classification, and ensemble. The authors describe a generic paradigm for diagnosing depression that includes raw data, which was before, ML training; exposure, detection classifications, and performance assessment are all part of the process [18].

In [19], six channels (FT7, FT8, T7, T8, TP7, and TP8) are used to extract features from the frontal area of the brain. The following band powers—delta, theta, alpha, beta, gamma1, and gamma2—along with their related asymmetry and paired asymmetry—are employed as linear characteristics. The classifiers used are bagging and three different kernel functions of the Support Vector Machine (SVM) (polynomial, gaussian, and sigmoidal). Relief is the creation of predictive models utilizing the Decision Tree (DT) technique to find rules and relevant features; the feature selection method is applied. The feature selection methods SVM (Gaussian Kernel Function) and Relief were employed to achieve the best classification accuracy of 96.02% and 79.19% for the identification and severity rating of depression, respectively [19]. A widespread EEG system with three electrodes in the prefrontal lobe was used to record all electroencephalogram (EEG) signals from subjects during the sound stimulus and resting state at just the Fp1, Fp2, and Fpz electrolytic positions. A maximum of 270 linear and nonlinear features were recovered after denoising with the Finite Moment Generating Filter, which incorporates the Kalman derivation method, Discrete Wavelet Transformation, and an Adaptive Predictor Filter. The dimensionality of the feature space was then decreased using the minimal-redundancy-maximum-relevance feature extraction strategy. The depressed individuals were separated from the healthy controls using four classification techniques (SVM, KNN, Classification Trees, and ANN) [20].

The spatial frequency data of a few chosen EEG channels is used to extract features. Theta and beta bands were chosen as EEG frequency bands for this investigation using a

technique called "choosing a frequency range". The characteristics of the chosen frequency ranges of EEG are subject to feature selection. As for limitations of existing methods, it may be that they struggle with handling large datasets, lack effective feature selection algorithms, or have difficulty generalizing to new data. The proposed method may be designed to address these limitations and provide a more effective solution to the problem at hand. Finally, a variety of machine learning methods were used to categorize the chosen subset of characteristics from the statistically relevant EEG networks' proper frequencies. A random forest classification model with either nine or ten attributes is used. It is possible to classify anxiety on two or four levels with an accuracy of 94.90% and 92.74%, respectively [21]. The carefully chosen main studies were used in comprehensive mapping research. The objectives were to present a comprehensive picture of the most important research areas in the diagnosis and forecast of mental diseases by combining EEG with DL. [22]. SVM was used to categorize the stress levels using the labeled data from the k-means clustering method. Using only the beta-band ultimate power feature in the right (Fp2) prefrontal region, the achievement of the classification model was endorsed using the 10-fold cross-validation method. This result confirmed the excellent efficiency of 98% accuracy because of the significant adjustments in beta activity all through pre- and post-stimuli latent patterns using localized and reduced features and evaluating model accuracy and false positive findings on EEG data from people with MDD and HV. The motivation to write this research to solve the following issue came from considering the above kinds of literature and using abilities in this field [23]. Most of the research for psychological disorders has been done with resting states, eye open and closed states of EEG dataset.

- To find the best solution for a problem, it is important to consider all possible options and evaluate them based on relevant criteria. This involves a systematic and analytical approach to identifying the optimal solution.
- How can unsupervised learning data be effectively handled or processed, given the lack of labeled information, to improve the quality of the resulting models or insights?
- How to solve the overfitting issue in machine learning refers to identifying and implementing techniques that can prevent a model from becoming too complex and fitting too closely to the training data, which can result in poor performance on new, unseen data.
- Which parameter is used to develop the best model?
- Lack of standardization: Many studies in this field use different EEG acquisition protocols, pre-processing methods, feature extraction techniques, and machine learning algorithms, which make it challenging to compare results and generalize findings.

- Limited diagnostic focus: While some studies have investigated a range of mental health conditions, others have primarily focused on a few specific disorders, such as depression, anxiety, schizophrenia, or Alzheimer's disease. Further research is needed to evaluate the usefulness of machine learning with EEG for diagnosing other psychological disorders.

### III. PROPOSED METHODOLOGY

Psychological disorders are complex and can manifest in many ways, making diagnosis challenging for healthcare professionals. Machine learning algorithms have the potential to improve the accuracy and efficiency of diagnosis by identifying patterns in large datasets that may be difficult for humans to detect. The use of feature ranking and fusion in combination with gradient boosting is a promising approach for improving the performance of machine learning algorithms in the context of psychological disorder classification. Feature ranking techniques can help identify the most relevant features for classification, while feature fusion can combine different sources of information to improve the overall accuracy of the algorithm. Therefore, the motivation behind this research is to explore how these techniques can be applied to improve the accuracy and efficiency of psychological disorder classification using machine learning. The goal is to develop a more effective diagnostic tool that can assist healthcare professionals in accurately identifying and treating psychological disorders.

In this work, we have comprehensively analyzed the positive, negative, and neutral states of the publicly accessible EEG brainwave Dataset. In this research, for the recognition of psychological disorders, we extract the negative state of this dataset. The proposed method for the classification of psychological disorders using feature ranking and fusion with gradient boosting is an appropriate solution for the problem due to its ability to handle large datasets, and improve generalization, and flexibility. The method uses a feature selection algorithm to select the most important features for classification, which can enhance the accuracy and efficiency of the model. The proposed method also employs techniques to prevent overfitting, such as grid search for hyperparameter tuning, which can enable the model to generalize better to new and unseen data. This section outlines the configuration for the classification procedure, as well as the methodology used to conduct the research, and discusses a potential strategy for minimizing features in an EEG analysis by establishing the RF-RFECV method. The proposed architecture diagram shows the steps of this research in Fig. 1.

#### A. Data Preprocessing

Divide and Conquer strategy has been applied to the negative state features of the EEG brainwave dataset to find an optimal solution to a problem. Four distinct feature sets were compared to see how changing the measurements would affect the results and which feature set performed better [25].

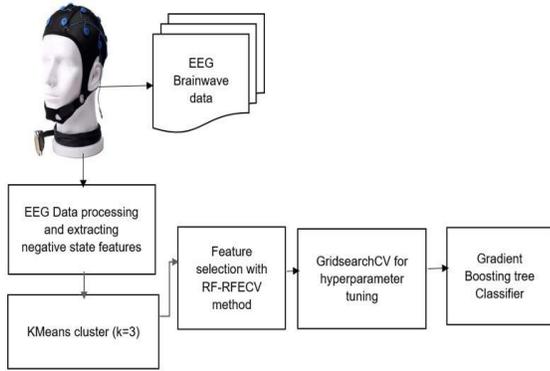

Fig. 1. Proposed architecture of psychological disorder classification

Steps of divide and conquer approach:

1) *Divide*: Divide the dataset  $D$  into 4 Feature subsets (FS)

$$D = \frac{(f_0, f_1, f_2, \dots, f_n)}{4} \quad (1)$$

$$= FS_1, FS_2, FS_3, FS_4$$

2) *Conquer*: Applied feature selection technique for each FS.

3) *Combine*: Selected features from each FS have been fusion into the final features set (FFS).

Further, the K-Means clustering technique [26] is applied to label unlabeled datasets to group the features into 3 similarity clusters.

The steps of K-Means are as follows:

- Initially, we generate random  $k$  points, referred to as means or cluster centroids.
- Every feature is categorized according to the nearest mean, and the precise location of that mean, which represents the average values of the features categorized in that cluster so far.
- Clusters are the result of repeating the process for a predetermined number of iterations.

The algorithm's final goal is to minimize the squared error function, which is represented by:

$$J(v) = \sum_{i=1}^c \sum_{j=1}^{c_i} (\|x_i - v_j\|)^2 \quad (2)$$

Where,

“ $\|x_i - v_j\|$ ” is a measure of how far the  $n$  data points are from each cluster's center [27]. In this research, the three clusters are chosen as 0, 1, and 2 for labeling EEG negative data as shown in Fig. 2

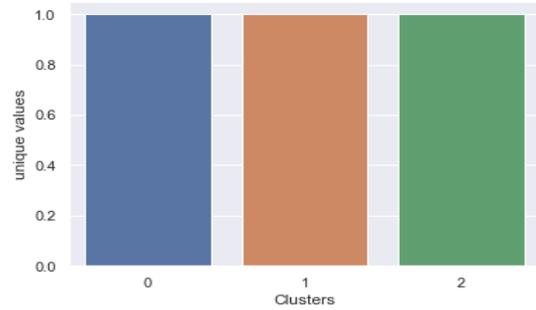

Fig. 2. Negative state features with 3 clusters i.e., 0, 1, 2

### B. Feature Selection

Selecting features from thousands of features is the most challenging research problem. RF-RFECV is used for feature selection. The algorithm is trained by Random Forest (RF) to generate the importance of features. The importance of each feature is calculated by equation 3.

$$fi_i = \frac{\sum_{j: \text{node } j \text{ split on feature } i} ni_j}{\sum_{k \in \text{all nodes}} ni_k} \quad (3)$$

RF classifier can be trained to produce feature importance values [28] that represent the relative importance of each feature. Following that, features are ranked in order of importance value. The component with the lowest importance value is eliminated. The classifier is then retrained using the remaining features until it runs out of features to train with. Finally, the complete ranking of the features can be obtained using the feature-importance-based RFE method i.e., (RF-RFECV). It has been demonstrated that, an embedded feature selection method performs well and makes up for the drawbacks of the filter and wrapper methods. The following pseudocode represents the proposed feature selection algorithm.

---

#### Algorithm 1: Feature Selection with RF-RFECV

---

Input: Feature Subset FS:  $\{f_0, f_1, f_2, \dots, f_n\}$   
 Output: Rank features according to smallest feature importance value,  $R$   
 Step 1: set  $R = \{\}$   
 Step 2: Repeat steps 3-9 until  $FS$  is not empty  
 Step 3: Train the RF using  $FS$ .  
 Step 4: Compute the importance of the feature with an equation (3).  
 Step 5: Determine the ranking method,  $\text{Rank} = fi^2$   
 Step 6: Rank the features in sorted orders.  
 $N_{rank} = \text{sort}(\text{Rank})$   
 Step 7: modification of the feature rank list  
 $\text{modify } R = R + FS(N_{rank})$   
 Step 8: Delete the features with the lowest rank  
 $\text{modify } FS = FS - FS(N_{rank})$   
 Step 9: Fusion the highest-rank features of  $FS_1, FS_2, FS_3, FS_4$  into the final dataset.  
 Return final dataset Fusion feature subset (FFS)

---

### C. Machine Learning Model

Gradient-boosting tree classifier is applied to predict the test results of psychological disorders. Gradient boosting is a sequenced method based on the ensemble principle. It integrates a group of weak learners and generates higher prediction accuracy. The model results are weighted based on the results of the initial instant  $t-1$  at any instant  $t$ . The working procedure gradient boosting is as follows.

Step 1: Create a fundamental model to predict the dataset. Take the total of the cluster column and presume that represents the expected value. The simple mathematical calculation behind these first steps.

$$F_0(x) = \arg \min_y \sum_{i=1}^n L(y_i, y) \quad (4)$$

Step 2: Determine the Residuals

$$e = (Y - \hat{Y}) \quad (5)$$

Step 3: Determine the decision tree's leaf output values

$$Y_m = \arg \min_Y \sum_{i=1}^n L(y_i, F_{m-1}(x_i) + Y h_m(x_i)) \quad (6)$$

Step 4: Update the prediction

$$F_m(x) = F_{m-1}(x) + V_m h_m(x) \quad (7)$$

### D. Hyperparameter Optimization by GridSearchCV

A method for identifying the best hyperparameters in a grid out of a set of parameters is called GridSearchCV. Gradient boosting trees could be a challenge to set up as an algorithm [29]. Grid search common ranges are produced because of the gradient boosting technique's key hyperparameters, which serve as the starting point for one's work. This might be done by assigning a dictionary for links, the names of the model hyperparameters, to the values to search for in the GridSearchCV [30]. The following is the procedure for finding the best hyperparameters with GridSeachCV.

#### Algorithm 2: GridSearchCV for hyperparameter optimization

**Input:** Dataset  $FFS = \{f_0, f_1, f_2, \dots, f_n\}$

**Output:** Best parameter with the highest accuracy

Step 1: Create the gradient boosting tree model and parameter

Step 2: Create a dictionary using the model's parameters.

- Develop an *estimator* of gradient boosting tree classifier
- Develop a *Param\_grid* with key hyperparameters  
The efficiency of model evaluation metrics.  
 $Score=f(Key Parameter)$
- Develop the *CV* for iterations

Step 3: Repeat the process step 2, going through each possible set of the grid's values one at a time.

Step 4: Fit the data set in the object function

Step 5: Run the objective functions multiple times per each possible pair of hyperparameter values.

**Return** the most accurate hyper-parameters available with the highest accuracy.

The GridSearchCV key hyperparameter for gradient-boosting trees is shown below in Table I.

TABLE I. KEY HYPERPARAMETERS FOR GRADIENT BOOSTING TREE WITH GRIDSEARCHCV

Model	n_estimators	Learning rate	subsample	Max depth
Gradient Boos tree	[10,50, 500,1000]	[0.0001, 0.001,0.01, 1.0]	[0.5, 0.7,1.0]	[0.5, 0.7,

### E. Performance Evaluations

Before the prediction model is constructed, a model must be assessed using several evaluation criteria [31]. To date, we have evaluated our prediction models using means and accuracy scores. However, the accuracy score and mean alone aren't always sufficient to assess a model adequately because it doesn't specify whether a class (positive or our models incorrectly forecast a negative) in the event of a poor accuracy rating this is clarified by precision score.

$$\text{Mean } \bar{x} = \left( \frac{\sum x}{n} \right) \quad (8)$$

$$\text{Std deviation SD} = \sqrt{\sum \left( \frac{x-\bar{x}}{n-1} \right)} \quad (9)$$

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (11)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (12)$$

$$\text{score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (13)$$

$$\text{Confidence Score} = CI = \bar{x} \pm z \frac{s}{\sqrt{n}} \quad (14)$$

## IV. EXPERIMENTAL RESULTS

The study is significant in that it demonstrates the usefulness of an affordable and straightforward approach to diagnosing several psychological disorders using EEG. The proposed method employs a feature selection algorithm to select the most important features for classification, which can improve the accuracy and efficiency of the model. Additionally, the gradient boosting algorithm used in the method can handle large and complex datasets, making it well-suited for problems that involve many features and samples. The EEG brainwave dataset has been used, which has three states of emotion: positive, negative, and neutral. From these, three emotional states negative emotional states features were extracted for the recognition of psychological disorders for this work. 708 rows and 2548 columns of unlabeled data were used in the negative state. Applied the "Divide and Conquer" approach into 4 equal parts  $FS_1, FS_2, FS_3, FS_4$  to find more accurate results from each feature subset. The ensemble approach has been used for feature selection, followed by random forest feature importance with recursive feature elimination with cross-validation technique. Based on this procedure, selected the rank features for each subset, and fusion these new features into a new feature subset or new dataset.

An applied new dataset for the classification process used a gradient-boosting tree with GridSearchCV hyperparameter tuning. The best parameter combination is kept after the GridSearchCV evaluates all potential parameter value

combinations. This research primarily focuses on four parameters. GridSearchCV uses *max\_depth* for denoting the number of depths of a tree, *n\_estimators* for several sequential trees *learning\_rate* is used to determine how each tree will affect the predictions and, the *sub\_sample* for several analyses that will be chosen for every tree for the strongest impact on prediction accuracy. Several performance metrics are used for choosing the best parameter such as mean score, standard deviation score as well as accuracy.

The configuration that showed the best performance, achieving a means score of approximately 94.6 %, had a *learning\_rate* of 0.1, a *max\_depth* of 9 levels, 1000 *n\_estimators*, and a *sub\_sample* of 50% has presented in Table II.

Table II also presents the performance of parameters with different combinations of parameter values like *learning\_rate* of 1.0, 1000 of *n\_estimators*, *Subsample* of 40%, and *max\_depth* of 7 achieved means score is 92%.

*learning\_rate* of 0.2, 500 of *n\_estimators*, *Subsample* of 90% and *max\_depth* of 6 achieved means score is 91%.

*learning\_rate* of 1.0, 1000 of *n\_estimators*, *Subsample* of 90% and *max\_depth* of 7 achieved means score is 89%.

Accuracy of each parameter combination 91%, 89%, 92%, 92%, 96.71%.

TABLE II. BEST PARAMETERS FROM THE GRIDSEARCHCV METHOD

Sl.no	Best parameter	Means Score	Std score	Accuracy
1	n_estimators=1000, Subsample=0.4, learning_rate=1.0, max_depth=7	92.00%	0.028	91.00%
2	n_estimators=500, Subsample=0.9, learning_rate=0.2, max_depth=6	91.00%	0.26	89.00%
3	n_estimators=1000, Subsample=0.9, learning_rate=1.0, max_depth=7	92.00%	0.028	92.00%
4	n_estimators=1000, Subsample=0.9, learning_rate=1.0, max_depth=7	89.00%	0.24	92.00%
5	n_estimators=1000, subsample=0.5, learning_rate=0.1, max_depth=9	94.93%	0.27	96.71%

Additionally, the accuracy of each cluster is 0, 1, 2, and has achieved 95.5%, 96.8%, and 100% accuracy. The classification results in representation in Table III for clusters of 0, 1 a, and 2, Precision, Recall, and f1-Score achieved the highest accuracy in cluster 2 compared to other clusters for the proposed gradient boosting Classifier with GridSearchCV for a new dataset.

TABLE III. CLASSIFICATION REPORT OF EACH CLUSTER

Clusters	precision	recall	F1 score
0	94%	96%	95%
1	98%	97%	97%
2	100%	100%	100%

Fig. 3 represents the accuracy analysis of four algorithms with the x-axis being proposed and existing algorithms and the y-axis being proposed as the accuracy value. The accuracy of the proposed classifier without ranked features is 94% and with ranked features is 96.71%.

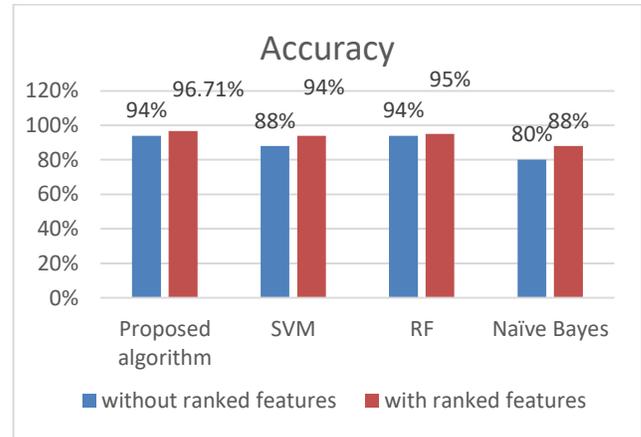

Fig. 3. Comparative analysis with another existing algorithm

The accuracy of SVM without ranked features is 92% and with ranked features is 94%. The accuracy of RF with ranked features is 95% and without ranked features is 94%. The accuracy of Naïve Bayes classifier achieved 80% accuracy without ranked features and 88% accuracy with ranked features. It can be concluded that the proposed algorithm with ranked features (new dataset) produces effective results as compared to existing algorithms.

Table IV displays the Confidence score of various psychological disorders (stress, depression, bipolar disorder, anxiety, autism, schizophrenia, mood disorder, and personality disorder) in an EEG negative emotional state with clusters 0, 1, and 2, which is represented. Schizophrenia disorders achieved an 85% confidence score as compared to other disorders.

TABLE IV. THE CONFIDENCE SCORE OF PSYCHOLOGICAL DISORDER

Psychological disorder	Accuracy	Negative Emotional State (0,1,2)
Depression	65.00	Cluster-0
Anxiety	35.00	Cluster -0
Stress	77.00	Cluster -0
Bipolar Disorder	50.50	Cluster -1
Personality	58.00	Cluster -1
Schizophrenia	85.00	Cluster -2
Autism	50.00	Cluster-2

Table V compares the state-of-the-art methods of other machine learning methods with the same dataset our proposed algorithm achieved the highest accuracy.

TABLE V. COMPARATIVE ANALYSIS OF PROPOSED WORK WITH OTHER WORK

Study	Classifiers	Datasets	Accuracy
The proposed method	Gradient Boosting Tree with GridSearchCV	EEG brainwave dataset	96.71%
[24]	Adaptive Boosted LSTM and DevoMLP	EEG brainwave dataset	85%
[31]	RNN	EEG brainwave dataset	95%
[32]	XGBoost	EEG brainwave Dataset	95%

## V. CONCLUSION

The study has demonstrated the usefulness of an affordable and straightforward approach to the brain utilizing EEG for the diagnosis of several psychological disorders, including stress, bipolar disorder, autism, mood, personality, anxiety, and depression. One significant advantage of the proposed method is its ability to handle large and complex datasets using gradient boosting, which is a powerful algorithm for handling such data. In addition, the techniques used to prevent overfitting, such as grid search for hyperparameter tuning, can help the model generalize better to new and unseen data. This is an important consideration when dealing with medical data where the model's ability to generalize to new data is crucial for accurate diagnosis. This study presents a unique method of feature selection with different feature subsets and makes a new dataset with 1300 features with the RF-RFECV algorithm with labeling using the K-Means Cluster technique. To address overfitting and optimize the parameters of the gradient boosting classifier, we employed the GridSearchCV algorithm to find the optimal hyperparameters for predicting psychological disorders from the EEG brainwave dataset, which has achieved 96.71% accuracy in classifying psychological disorders using negative states of emotion. The future will be, to calculate the severity of the psychological disorder and develop a web application for clinical diagnostics.

## ACKNOWLEDGMENT

None of the funding sources for this study were public, private, or nonprofit. We sincerely thank the professors of Christ University's department of computer science and engineering, Bangalore, India.

## CONFLICT OF INTEREST

The authors declare no conflict of interest.

# Public Response to the Legalization of The Criminal Code Bill with Twitter Data Sentiment Analysis

Deny Irawan<sup>1</sup>, Dana Indra Sensuse<sup>2</sup>, Prasetyo Adi Wibowo Putro<sup>3</sup>, Aji Prasetyo<sup>4</sup>  
Faculty of Computer Science, Universitas Indonesia, Jakarta, Indonesia<sup>1, 2, 3, 4</sup>

**Abstract**—The Criminal Code Bill, also known as Rancangan Kitab Undang-undang Hukum Pidana (RKUHP), passed in the House of Representatives (DPR) on December 6, 2022, is being debated because several issues need to be fixed. Therefore, research was conducted to determine the public's reaction to the ratification of the Criminal Code Bill by analyzing Twitter data. This study aims to obtain a general response to the legalized RKUHP. We use sentiment analysis, a text-processing method, to get data from the public. To do this, we used N-grams (unigrams, bigrams, and trigrams) along with three algorithms: Naïve Bayes, Classification and Regression Tree (CART), and Support Vector Machine (SVM). The result of sentiment analysis found that 51% of tweets were positive about the ratification of the RKUHP, and 49% were negative. In addition, it was also found that SVM has the best accuracy compared to other algorithms, with an accuracy value of 0.81 on the unigram combination.

**Keywords**—Sentiment analysis; RKUHP; support vector Machine (SVM); Naïve Bayes; classification and regression tree (CART)

## I. INTRODUCTION

The Criminal Code Bill, also known as RKUHP, was signed into law on December 6, 2022. This is a momentous occasion, as this law would replace the existing Criminal Code (KUHP) [1]. Because the current Criminal Code is a legacy of Dutch colonialism, it is a version of the *Wetboek van Strafrecht voor Nederlandsch-Indie*. Changes are needed because the old Criminal Code is not keeping up with the times [2]. In addition, the revision of the previous RKUHP was carried out in partly making new laws related to the KUHP, which made regulations run wild, had no system or pattern, was inconsistent, made problematic laws, and even damaged the basic building system old KUHP [3]. RKUHP will be valid for three years from the date of promulgation [4]. However, the RKUHP is considered to have problematic articles still. Nurina S. (2022), in an interview with The Guardian, stated that at least 88 reports contain broad provisions that can be exploited and misconstrued by both the government and the general public to punish anyone and suppress the freedom of expression [5].

The response to ratifying RKUHP still has pros and cons. Because responses are essential determinants of every human action, interesting to see the public's response to RKUHP; when deciding, we need others' opinions. Companies or governments must know how the public feels about their products and services. The public sometimes utilizes Facebook and Twitter to engage socially online. Web-based social networks gradually engage the public [6]. This is consistent with research conducted in the United States about the public's

reaction to the Chicago Department of Public Health's laws on electronic cigarettes, which examined the public's response on Twitter. The data can help organizations predict, recognize, and respond to how the community will react by finding patterns in how people have responded to this policy [7]. In addition, according to research conducted in Mexico, governments frequently use Twitter to interact with their citizens. As a result, it has emerged as a valuable source of information for studying how governments interact with their constituents and how those citizens respond to those communications. These insights about how people interact with the government can be used to help make public policies and understand how the public sees those policies [8].

The ratification of RKUHP has the same context. It will be fascinating to watch how Twitter data is utilized to gauge public opinion toward the ratification of RUU KUHP because these messages on Twitter are openly accessible. Consequently, it can be viewed as raw data primarily for the extraction of opinions and for the analysis of policy by analyzing the sentiment [9]. This will aid the government's ability to forecast, detect, and respond to the public's reaction to the dissemination of information before it is completely implemented. Sentiment analysis is another term for "opinion mining" or "emotion Artificial Intelligence". It refers to applying natural language processing (NLP), Using text mining, computational linguistics, and biometrics to carefully identify, extract, assess, and look into people's emotions and personal data [6].

This research aims to identify the sentiments surrounding the ratification of the RKUHP. The analysis results are reprocessed to determine what aspects of RKUHP concern the public. The use of public sentiment will assist the government in gauging the public's reaction to the ratification of the RKUHP and can be utilized as input for the planned socialization. In addition, by using multiple algorithm models, this research will identify the optimal categorization model that might be used by the government when trying to determine public responses with data from twitter.

This research consists of five sections. The introduction, which contains the research's context and objectives, is the first section. The second section is a review of previous research and the theoretical framework. The study's research methodology is described in the third section. The fourth section is the results and discussion, which includes the findings from the research. The conclusion is the concluding section of the study.

## II. LITERATURE REVIEW

### A. Previous Research

This section contains considerable research that employs various methods for sentiment analysis. The first research authors use one methodology for measurement sentiment analysis, shown in Table I. Authors in [10] have investigated the Naïve Bayes algorithm's capacity to classify public mood under COVID-19's new normal. From the 2807 tweets that have been processed, the test results show that Naïve Bayes has done an excellent job, with an accuracy of 83% and an F1-score of 84%. The author in [11] researched sentiment analysis using the Support Vector Machine (SVM) with Weka (Waikato Environment for Knowledge Analysis) method and tested it on three different data sets with various labels. Because of this, the data set with the highest f1-score is the third one, which only has two titles: positive and negative.

Further research uses two methodologies for measurement sentiment analysis. In a study [12], sentiment analysis tests on comments on YouTube using Naïve Bayes and Support Vector Machines (SVM). Results when using a data scale of 7:3, with 70% of the data used for training and 30% for testing, show that the combination of Naïve Bayes and SVM results in higher accuracy and superior performance. In a study [13], researchers compare Naïve Bayes and SVM to evaluate the classification results that each method produces. Twitter data is used in this study for Tokopedia services. The outcomes demonstrated that, with an accuracy of 83.34%, the SVM linear kernel technique surpassed the Naïve Bayes technique. In a study [14] Using Twitter data, researchers assess the sentiment analysis of the COVID-19 virus infection on Indonesian public transportation. In this study, the authors used two comparison methods: Naïve Bayes and decision trees. The result is that Naïve Bayes outperforms the Decision Tree with an accuracy of 73.59%.

The third research uses more than two methodologies for measurement sentiment analysis. In a study [15], Researchers researched the sentiment analysis of tourists in Thailand during the COVID-19 pandemic. This study used three methods: SVM, Classification and Regression Tree (CART), and random forest. Consequently, SVM could identify the attitudes and intentions of the English-language tweets that included Phuket and Chiang Mai the best. Still, for tweets mentioning Bangkok, CART is the most accurate, with accuracies of 94.3%. Bangkok has more data tweets than others. Subsequent research, customer reviews of Amazon products. Researchers in this study [16] used four sentiment analysis methods: Naïve Bayes, SVM, Decision Tree, and K-Nearest Neighbor. In addition, this research also added TF-IDF and N-gram to its processing. The results of the TF-IDF method with N-grams show unigrams with SVM were the maximum accuracy results for Amazon product customer reviews. This study also found that comments on Amazon products influence potential consumers' purchasing decisions. The two studies [15][16] were conducted to determine the differences and accuracy of the sentiment analysis method.

TABLE I. PREVIOUS RESEARCH

No	Ref	Algorithm and Method	Sentiment Analysis and Objective	Result
1	[10]	Naïve Bayes	Provides a sentiment analysis of how well society is accepting the new normal with data from Twitter and investigates the Naïve Bayes algorithm's capacity to classify public mood under COVID-19's new normal.	During the COVID-19 pandemic, the majority of people were able to adjust to their new everyday normal. The test results show that Naïve Bayes has done an excellent job.
2	[11]	SVM with Weka (Waikato Environment for Knowledge Analysis)	This study didn't specifically look at sentiment analysis. Instead, it used three different data sets, two from Twitter and one from the Internet Movie Database, to test how well the SVM algorithm worked (IMDB).	The highest-scoring data set is the third (IMDB data), with only two titles: positive and negative.
3	[12]	Naïve Bayes and SVM	Provides a sentiment analysis of positive and negative YouTube comments and evaluates the combination of two algorithms, naïve Bayes and SVM.	The combination of Naïve Bayes and SVM results in higher accuracy and superior performance for seeing sentiment in YouTube comments.
4	[13]	SVM and Naïve Bayes	Sentiment analysis for Tokopedia service with data from Twitter and evaluation of the performance of Naïve Bayes and SVM.	The data do not specify the sentiment analysis results for the Tokopedia service; they evaluate that SVM is more accurate than Naïve Bayes.
5	[14]	SVM and Decision Tree	Sentiment analysis to determine what commuter line riders think about how the Covid-19 pandemic could spread on public transportation—and Comparison Accuracy from algorithm naïve Bayes and decision tree.	Most people in the community have a positive outlook that includes a plea and a call to stop the COVID-19 outbreak and get it under control. With an accuracy of 73.59%, Naive Bayes is better than the Decision Tree.
6	[15]	decision tree, random forest, and SVM with TF-IDF and combination ngram (unigram, bigram, and trigram)	Sentiment analysis to find out the expression of tourists about tourist attractions, events, festivals, and experiences from July to December 2020 whit data from Twitter.	The results showed the top 10 words for each type of feeling, which can be looked at to learn more and give the right advice.
7	[16]	SVM with a combination of term weighting and ngram	This study aims to assess the impact of sentiment (positive, negative, and neutral) and Amazon product reviews on sales performance. Also, to	The Result found that comments on Amazon products influence potential consumers' purchasing decisions. In

			identify the optimal combination of SVM, TF-IDF, and ngram.	addition, the TF-IDF method with N-grams shows unigrams with SVM were the maximum accuracy results for Amazon product customer reviews.
--	--	--	---	---

Based on previous research, researchers will use the Naïve Bayes [10][13][14], SVM [11][12] [13][15][16], and CART [15] in evaluating sentiment analysis. In addition, the N-gram and TF-IDF methods will be used because they are proven to increase accuracy [16]. The study used positive and negative labels because it was established in research [11] that they have the highest accuracy compared to data using more than two labels.

### B. Sentiment Analysis

According to Pang et al. (2002), opinion mining and sentiment analysis are two terms that refer to the same process. Sentiment analysis automatically analyzes, extracts, and textually processes material to derive the sentiment information in a single opinion sentence. An individual's perspective, or their predisposition to have a positive or negative view or opinion about a particular issue or object, can be determined using a technique known as "sentiment analysis" [17] [12].

### C. Data Preprocessing

Data Preprocessing involves converting raw data into a format the user may understand. Frequently, the data must be more structured and consistent, lack specific behaviors or patterns, and contain missing values, all of which contribute to many errors. Consequently, it needs to be cleaned, integrated, altered and decreased. The noise is eliminated, and missing values are filled in when cleaning is performed [18][19].

### D. N-Gram

The word n-gram feature counts sets of sequential N words in each tweet, where N can range from 1 to N. [20]. N-grams can be more informative. There could be  $t^2$  bigrams containing t different words. In practice, only some characteristics are generated because terms can't follow each other. Usually, n-grams are more distinct than words. A more extensive, less common feature space is an n-gram. A larger n increases information and computational expense [21]. In this research, we combine the unigram, the bigram, and the trigram forms of the n-gram.

### E. Term Frequency - Inverse Document Frequency (TF-IDF)

According to Jones (1972), Inverse Document Frequency (IDF) is a technique that can be combined with term frequency to lessen the influence of implicitly famous words in the corpus. This is how IDF is meant to be used. IDF gives greater weight to terms that appear more frequently in the document,

regardless of whether those words are used often or infrequently [22][23]. TF-IDF is now the most popular text classification and document categorization scheme [24][21].

### F. Naïve Bayes Algorithm

This categorization method is based on Bayes' Theorem and makes strong (naive) assumptions about feature independence. A Naïve Bayes classifier makes the following assumptions: that the proximity of one feature (element) within a class is unrelated to the proximity of other items. The Naïve Bayes algorithm is often used to divide texts into different groups, and it was recently used to separate data from sentiment analysis into groups [6].

The algorithm relies on Bayes' theorem and presumes that the class variable's value provides information for all variables independently. It is simple to program the Naïve Bayes classification algorithm to perform exceptionally well in supervised learning, and it can also be used in difficult real-world situations. The Naïve Bayes method is simple to grasp, needs an education dataset to figure out how to calculate its variables, doesn't care about things that have nothing to do with the problem, and works well with correct data from a single source [25][10].

### G. Support Vector Machine (SVM) Algorithm

According to Han et al. (2012), the Support Vector Machine (SVM) algorithm's goal is to locate the Maximum Marginal Hyperplane (MMH) by utilizing margins and support vectors. The MMH hyperplane is the best one available since it has the most significant margin distance and can be used to accurately and maximally segregate data for each class. Suppose both margins are in a position that is parallel to the hyperplane. In that case, the margin is defined as the point at which the shortest distance from a hyperplane to one side equals the distance from the hyperplane to the other side of the margin [26][24].

### H. Classification and Regression Tree (CART)

The classification and regression trees (CART) method is a systematic technique that was developed by Breiman et al. (1984) [27][28]. For the construction of decision trees, CART employs historical data. The dependent variable decides whether a classification tree (for categorical categories) or a regression tree (for variables with continuous categories) will be formed. The newly discovered observations can then be predicted (using a regression tree) and classified (using a classification tree) using the constructed tree. Contrary to classification trees, regression trees do not have any pre-determined classes. On the other hand, classification trees allow the user to select or calculate dependent variable types based on an external criterion. [27][29][30][28]. The CART approach consists of three steps: (1) the creation of the entire tree; (2) the selection of the ideal tree size; and (3) the evaluation of the results. (3) using a built tree to organize data or generate new information[28].

### III. METHODOLOGY

The research consisted of several stages, including the collection of data, the creation of data sets, the labeling of data, the processing of data, the grouping of words using n-grams and term weighting (TF-IDF), classification modeling, the evaluation of classification modeling, and, finally, the output of sentiment results and recommendations. This is shown in **Error! Reference source not found.**

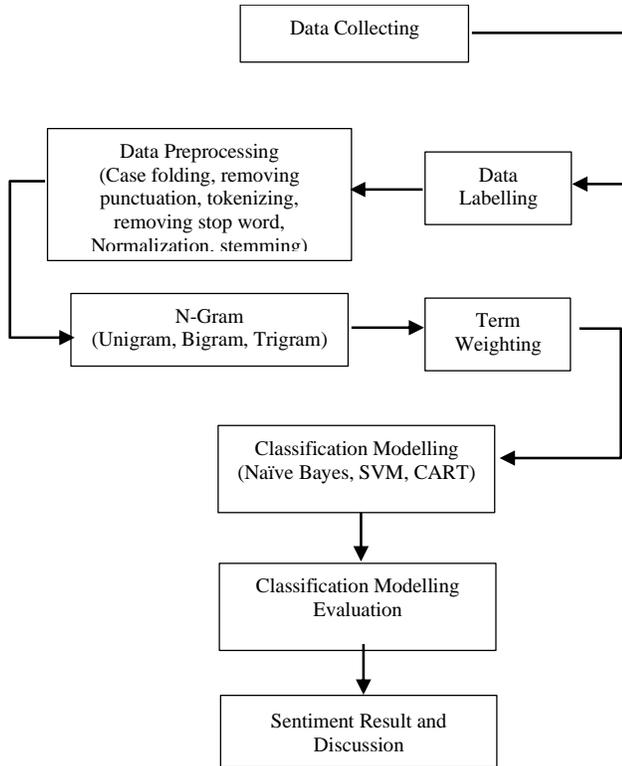

Fig. 1. Methodology for research

#### A. Data Collecting

Python and the twitter-snsrcape library package are used to harvest Twitter tweet data at this step. Data was gathered using a search for the phrase "RKUHP" tweeted between December 6, 2022, and December 31, 2022. Tweets taken are in Indonesian, and identical tweets will be deleted. Related Tweets that only use the RKHUP hashtag and only contain ads will also be disqualified. Tweets are not converted into English due to possible differences in meaning in processing. All words resulting from sentiment will use the Indonesian language.

#### B. Data Labelling

In this phase, the training data is labeled manually whether tweets are positive (pro) or negative (con) with the ratification of the RKUHP. In this phase, irrelevant tweets are also deleted.

#### C. Data Preprocessing

In the preprocessing of tweet data, a series of operations are performed so that machine learning algorithms can read the tweet's standards and patterns in Table II. The method is as follows:

- 1) Case Folding turns all capital characters in tweets into lowercase letters.
- 2) Remove Punctuation and eliminates punctuation, URL links, numbers, hashtags, and emoticons from tweets.
- 3) Tokenization is the process of breaking sentences into separate words.
- 4) Stop Word is the process of removing words that don't add any meaning.
- 5) Normalization is the process of uniforming words with the same meaning but different spellings.
- 6) Stemming is changing words that have affixes into essential words.

TABLE II. PREPROCESSING PROCESS

Process	Tweet
User Tweet	Dukung pengesahan RKUHP untuk supremasi hukum https://t.co/MLmR6BHBIS #DukungPengesahanKUHP
Case folding	dukung pengesahan rkuhp untuk supremasi hukum https://t.co/mlmr6bhbis #dukungpengesahankuhp
Remove Punctuation	dukung pengesahan rkuhp untuk supremasi hukum
Tokenizing	['dukung', 'pengesahan', 'rkuhp', 'untuk', 'supremasi', 'hukum']
Stop Word	['dukung', 'pengesahan', 'rkuhp', 'supremasi', 'hukum']
Normalization	['dukung', 'pengesahan', 'rkuhp', 'supremasi', 'hukum']
Stemming	['dukung', 'kesah', 'rkuhp', 'supremasi', 'hukum']

#### D. N-Gram

In this phase, word separation is carried out; we combine the unigram, the bigram, and the trigram forms of the n-gram. Words are created using unigrams (one word), bigrams (two words), and trigrams (three words). Tweets that have at most three words will be deleted.

#### E. Term Weighting

The next step was word feature extraction using the term frequency-inverse document frequency (TF-IDF). The word weight in a given document is typically calculated using the TF-IDF technique. The term frequency describes the often appearing; that often appears in a manuscript (TF). Frequently occurring terms will obstruct the search for uncommon words. The inverse document frequency (IDF), which lessens the weight of often-appearing words, can gauge how significant a word's meaning is in a document [31].

#### F. Classification Modelling

In this step, classification modeling is applied to the test data using three machine learning algorithms: Nave Bayes, SVM, and CART. Modeling is done separately to produce accurate results. Each algorithm tests the words formed in the ngram process, and the term weighting process has been carried out. This classifier uses the sklearn library in Python. This study used 80% training data and 20% testing data. This is so that machine learning algorithms can perform better, according to research by Pham et al. in Nguyen et al. research, when training data is raised from 30% to 80%. However, when it is increased from 80% to 90%, the opposite occurs[32] [33].

G. Classification Modelling Evaluation

In this phase, the performance of each machine learning algorithm in the previous step will be evaluated. Evaluation is conducted using a confusion matrix by looking at the value of the accuracy of each algorithm. Accuracy, precision, and recall are the evaluative test parameters whose computations are derived from the confusion matrix table [13].

H. Sentiment Result and Discussion

This is the final stage in producing sentiment words for the word cloud. Which, according to the N-gram phase, consists of one word, two words, and three terms and is derived from the sentiment with the maximum accuracy. Then, the discussion will be made in light of these findings.

IV. RESULT AND DISCUSSION

A. Results of Classification Modeling Evaluation

The number of tweets extracted using the snsrape library is 17,107. After cleaning the same tweets, the number of tweets increases to 10,763. Then, label each tweet manually. Then, preprocessing process the tweet and generate it again to yield 9,079 tweets. The tweet then executed the classification algorithms and the n-gram combination method. After preprocessing, the dataset is split into training and test sets. 80% of the dataset is used for training, and the remaining 20% is used for testing. The dataset's features are produced using an n-gram mix of unigrams, bigrams, and trigrams. The created words will then be weighted using term analysis. Different data are made when n-grams and term weighting are combined. The results are presented in Tables III, IV, and V.

Using the confusion metrics, we have calculated the performance of each algorithm here. The confusion matrix, which measures the classification overlap, is an effective tool for performance evaluation. The multi-label classification task must establish the confusion matrix because each instance may be assigned to multiple classes [34]. The performance evaluation of the multi-label classifier is based on computing performance averages, including precision, recall, and F1-score [34]. Precision measures how accurate a class's predictions are relative to all the predictions included in the course. Recall is the percentage of a class's total number of categorized facts that can be predicted accurately. The f1 score calculation was then utilized to mix the precision and recall [35] [12].

For each n-gram combination used, precision, recall, and f1-scores for the CART algorithm are displayed in table III. The findings of CART do not differ much when unigrams, bigrams, or trigrams are used. In the bigram findings, for example, the precision value is 0.73 for negative and 0.75 for positive, and the recall value is 0.70 for negative and 0.75 for positive. The f1 values for positive and negative are then 0.72 and 0.74, respectively. As shown in Fig. 2, out of the 852 negatively judged tweets, 624 were true negatives (TN), and 228 were false negatives. In contrast, out of 964 positive tweets, 263 were false positives (FP), and 701 were true positives (TP).

TABLE III. PRECISION, RECALL, AND F1-SCORE CART

	N-Gram	Precision	Recall	F1-score
Negative	Unigram	0.74	0.70	0.72
	Bigram	0.73	0.70	0.72
	Trigram	<b>0.75</b>	0.69	0.72
Positive	Unigram	0.72	0.76	0.74
	Bigram	0.73	0.75	0.74
	Trigram	<b>0.71</b>	<b>0.77</b>	0.74

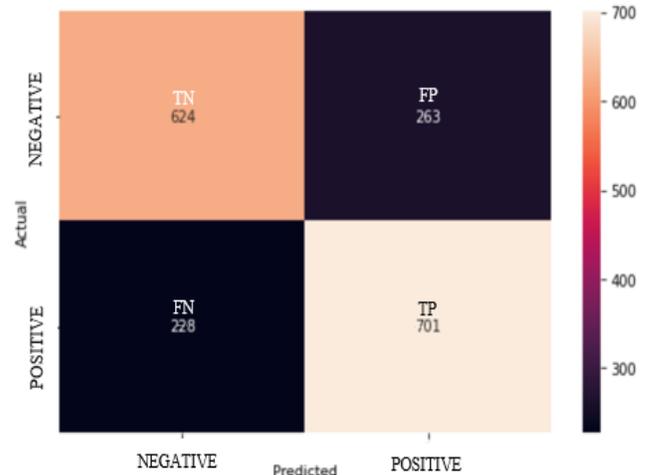

Fig. 2. The confusion matrix bigram CART

Table IV shows the SVM algorithm's precision, recall, and f1-score for each n-gram combination. The unigram test had the best average outcomes, with precision values of 0.81 for negative and 0.80 for positive groups and recalled values of 0.76 for negative and 0.82 for positive. The f1-score is 0.78 for the negative and 0.81 for the positive. As shown in **Error! Reference source not found.**, 711 of the 877 tweets that received a negative evaluation were true negatives, and 166 were false negatives. Comparatively, out of 939 positive tweets, 186 were false positives, and 753 were true positives.

TABLE IV. PRECISION, RECALL, AND F1-SCORE SVM

	N-Gram	precision	recall	f1-score
Negative	Unigram	<b>0.81</b>	0.79	<b>0.80</b>
	Bigram	0.79	<b>0.78</b>	0.79
	Trigram	0.81	0.76	0.78
Positive	Unigram	<b>0.80</b>	<b>0.82</b>	<b>0.81</b>
	Bigram	0.79	0.81	0.80
	Trigram	0.78	0.82	0.80

Fig. 3. The confusion matrix unigram SVM

The Naïve Bayes algorithm is presented in Table V for each possible combination of n-grams. The trigram test had the most outstanding results overall, with accuracy scores of 0.78 for negative responses and 0.79 for positive ones, recall scores of 0.79 for negative answers and 0.77 for positive reactions, and an f1-score of 0.78 for negative and positive responses. As shown in **Error! Reference source not found.**, of the 926 tweets that received a negative rating, 718 were true negatives, and the remaining 208 were false negatives. The 890 positive tweets, in contrast, contained 186 false positives and 704 true positives.

TABLE V. PRECISION, RECALL AND F1-SCORE NAÏVE BAYES

	N-Gram	precision	recall	f1-score
Negative	Unigram	0.75	0.77	0.76
	Bigram	0.75	0.79	0.77
	Trigram	0.78	0.79	0.78
Positive	Unigram	0.77	0.75	0.76
	Bigram	0.79	0.75	0.77
	Trigram	0.79	0.77	0.78

Fig. 4. The confusion matrix trigram naïve bayes

Calculating the accuracy of each method is another function of the confusion matrix, which can be seen in Table VI. It has been demonstrated that the SVM constructed using the unigram has the maximum accuracy, equal to 0.81. In addition, bigram and trigram SVM continues to have the highest accuracy compared to other algorithms, with respective values of 0.79 and 0.78. When utilizing trigram combinations, Naïve Bayes on 0.78 achieves a higher level of accuracy. CART has the same accuracy in all ngram combinations.

TABLE VI. ACCURACY CART, SVM AND NAÏVE BAYES

Algorithm	NGRAM Accuracy		
	Unigram	Bigram	Trigram
CART	0.73	0.73	0.73
SVM	0.81	0.79	0.79
Naïve Bayes	0.76	0.77	0.78

The analysis results in Table VI are consistent with research in [13] and [15] that shows that SVM has higher accuracy when compared to Naïve Bayes and CART. The SVM study achieved an accuracy of 83.34% and a Naïve Bayes of 75%. According to research [15], the amount of data used by the random forest and CART algorithms determines the soundness of multiple decision trees, the complexity of the trees, and thus the algorithm's accuracy. This explains why CART has the same accuracy because it has the same number of data sets.

In line with the results of this investigation, a study in [16] discovered that SVM with the unigram combination had the highest accuracy when compared to the other ngram combinations. This is likely due to the ease with which SVM can map words weighted with TF-IDF rather than utilizing multiple words to infer sentiment. This compares favorably with naïve Bayes, where the more word combinations in ngrams, the higher the accuracy. Many ngram combinations raise the level of accuracy in Naïve Bayes. Therefore, based on this, it was found that the combination would affect the accuracy of each algorithm. SVM is preferred over algorithms, Naïve Bayes, and CART because of its high accuracy. For Naïve Bayes, a higher gram would be preferable. Because CART is affected by a large amount of data, vast amounts of data will affect its accuracy.

B. Content Sentiment Analysis

Nine thousand seventy-nine tweets were included in the data obtained after being processed using Python and Microsoft Excel programming languages. Several duplicate and irrelevant tweets have been removed from the message. The result is that 51% of tweets, or 4.623 of them, favor the ratification of the RKUHP, while 49% of tweets, or as many as 4.455 of them, are in opposition to it, as can say be seen in **Error! Reference source not found.**

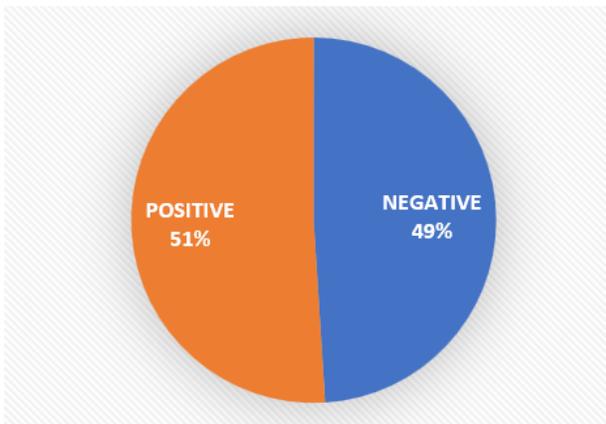

Fig. 5. Result of the sentiment of the ratification of RKUHP

The word cloud for a negative sentiment is displayed in **Error! Reference source not found.** Negative sentiment is associated with a wide variety of topics and concepts, including 'tolak', 'kontroversi', 'kritik', 'hina', 'koruptor', 'penting kuasa'. The most common words are 'sah', 'tolak,' 'rakyat,' and 'negara' in that order. The RKUHP received a negative response because it was thought to contain several articles that could be construed as contentious. Based on word cloud sentiments such as the words 'kritik,' 'hina' and 'demokrasi', some articles are considered to silence criticism, specifically regarding insulting the president. Then the words 'koruptor' and 'korupsi' articles regarding corruption, with a minimum reduction in prison for corruption. Then there's the phrase 'penting kuasa' and 'rakyat', because some people believe that a lot of the new RKUHP articles were written more for the authorities' interests than for the people's interests themselves.

Fig. 6. Word cloud of negative sentiment

Besides having negative sentiments, there are also words representing positive sentiments in the word cloud. Word like 'sah', 'baru', 'hukum pidana', 'baru' dan 'tujuan' support the approval of the ratification of this RKUHP. The RKUHP is significant because it strengthens Indonesia's current criminal code. In Indonesia, criminal law that has undergone patchwork is no longer regarded as complying with legal criteria. The positive word Cloud is shown in **Error! Reference source not found.**

Fig. 7. Word cloud of positive sentiment

We may deduce what words are at the center of people's conversations based on the outcomes of positive and negative sentiments in **Error! Reference source not found.** and **Error! Reference source not found.** The words that arise may serve as a first reflection for the organization of positive and negative things that are the community's response. This can be used as a resource for organizations to improve their understanding of the policies they issue. This is in line with the findings of a study [8] on how the Mexican government uses Twitter to connect with the people.

As a result, the outcomes of these attitudes can be employed by the government as a foundation for socialization. Because there is still the problem of the pessimism of RKUHP, there are still drawbacks to the ratification of the RKUHP, which is still relatively high and reaches 49% of the population. To find a solution to this problem, the government needs to engage in more social activities and listen to people's perspectives on matters that are regarded as contentious. This is done to ensure that both the adoption of the RKUHP in 2025 and its passage into the Criminal Code happen smoothly. Words that elicit negative responses might be utilized as the primary focus of socialization. This will help in mitigating the public's adverse reaction. Mitigation of this rejection will be better if there is a grouping of tweets based on topic, as in Research [36]. In this study, we used BERTopic to classify the tweets. BERTopic will help categorize tweets and make it easier for the government to bring up specific RKUHP-related topics. Throughout the processing, it was discovered that the steaming method had limitations since particular terms, such as "pengesahan", were mistakenly converted into the root word "kesah". Hence the potential limits of the world cloud's word interpretation.

## V. CONCLUSION

Examining Twitter sentiment, this study identifies responses to the ratification of the RKUHP. The RKUHP ratification drew 51% positive and 49% negative comments on Twitter. This demonstrates that, even though the positive is superior, the value is just 2%. According to the negative comments, the problem of controversial articles is related to the article about insulting the president, the post about cutting punishments for corrupt officials, and the piece about not representing the people. This must be the emphasis of the government's efforts to socialize the RKUHP.

The evaluation of the three tested algorithms—CART, SVM, and Naïve Bayes—found that SVM had the highest accuracy and was the most reliable even when the n-gram combination was used. SVM produces an accuracy value of 0.81 on the unigram, 0.79 on the bigram, and 0.79 on the trigram.

This research is limited to grouping tweets that have yet to be grouped into specific topics and imperfections in the steaming process. It is hoped that future research can categorize recent tweets based on grouping relevant issues related to the RKUHP so that they are not only the results of grouping terms from the Word Cloud. It can also add more data which makes the topic even better. In addition, it can improve the algorithm steaming process to make it better.

#### ACKNOWLEDGMENT

Thanks to the Indonesian Ministry of Communication and Information for supporting, assisting, and funding this research. As well as support from the Faculty of Computer Science, University of Indonesia.

# Evaluation of QoS over IEEE 802.11 Wireless Network in the Implementation of Internet Protocols Mobility Supporting

Narimane Elhilali<sup>1</sup>, Mostapha Badri<sup>2</sup>, Mouncef Filali Bouami<sup>3</sup>

Applied Mathematics and Information Systems Laboratory-Multidisciplinary Faculty of Nador,  
University Mohammed Premier Oujda, Morocco<sup>1,2,3</sup>

**Abstract**—Now-a-days, the internet is an essential part of our digital lives. With the growing number of users, the ultimate goal is to enable all users to stay connected to the internet at anytime and anywhere, regardless of their mobility. Any delay or jitter in the system can cause a deterioration in the performance of multimedia services, such as video streaming, or cause websites to partially load. The current Internet Protocol version 4 (IPv4) cannot handle all the IP addressing requirements, while the next generation Internet Protocol version 6 (IPv6) has been developed to solve some of these problems by improving the quality of service and providing many other features. The primary contribution of this paper is to investigate the evaluation of Quality of Service (QoS) functionality, including end-to-end delay, throughput, jitter, and packet loss, in WLAN mobility environments for MIPv4 to MIPv6 using the OMNeT++ simulator.

**Keywords**—QoS; MIPv4; MIPv6; handover; mobility; priority

## I. INTRODUCTION

In recent years, communication networks have become the main engine of the world, especially mobile communications, which have spread everywhere. Wireless networks that provide access to the internet are the solution for users who need to move around while exchanging multimedia services such as video, voice, or data. The IEEE 802.11 standard [1], which includes the medium access control (MAC) and physical layer (PHY), has been improved since its initial approval by the IEEE in 1997. The improvements are defined as amendments to the initial standard, such as IEEE 802.11e and IEEE 802.11r, which mainly concern the MAC layer. IEEE 802.11e added QoS mechanics, while IEEE 802.11r improved mobility between the cells of wireless networks (handover) [2] and allowed nodes to switch more quickly between access points (APs).

The Mobile Internet Protocol (MIP) [3] is an IETF communication protocol that allows users to stay connected when moving from one cellular network to another without interrupting the connection. The two versions of MIP, Mobile IPv4 (RFC 3344) and Mobile IPv6 (RFC 3775) [4], are designed to facilitate node mobility and maintain connections when changing locations. MIPv4 is a popular mobile internet protocol based on the IPv4 protocol, which has the responsibility of traffic routing on the internet. However, it cannot handle the IP addressing margin for all users and also has some limitations in terms of quality of service, MIPv6 has

been developed to provide mobility support for IPv6, and improves some of this limitations. In order to ensure node mobility, applications and flows, quality of service is particularly important for traffic, and it can give priority to different flow services (such as video, voice, data, etc.) based on a certain level of performance. QoS metrics [5] measure performance in four different aspects: throughput, delay, jitter, and packet loss.

The main objective of this article is to assess the impact of internet protocol mobility support, from Mobile IPv4 to Mobile IPv6, on QoS performance in mobility environments based on 802.11g wireless networks using the OMNeT++ simulator [6]. The QoS functionalities are analyzed and compared, the packets are classified into four traffic classes (background, best effort, video, and voice) with different priority levels of the EDCA mechanism according to the nominal bit rate.

The rest of this paper is organized as follows. Section (2) describes related works on QoS performance on mobile internet protocols. Section (3) introduces QoS in IEEE802.11. Section (4) provides the different QoS Parameters. The simulation results include Simulation Environment, Simulation Scenario, results, analysis, and simulation comparison are talked in section (5), finally we conclude in section (6) and future work in section (7).

## II. RELATED WORKS

Several studies have been conducted to evaluate the quality of service (QoS) performance of different network protocols, including Internet Protocol version 6 (IPv6) and Mobile Internet Protocol version 6 (MIPv6). In this paragraph, we discuss three studies that evaluate the QoS performance of video and audio applications in IPv6 and MIPv6 using simulation tools such as OPNET. The studies analyze various QoS metrics such as delay variation, end-to-end delay, packet loss, and handover latency to investigate the effectiveness of different network standards and protocols. The results of these studies provide valuable insights into the strengths and weaknesses of different protocols in terms of QoS performance.

E.S. Ikeremo and M.C. Kelly T. Pepple [7] discuss the evaluation of QoS performance metrics of video streaming in IPv6, including delay variation, end-to-end delay, and packet loss. The simulation analyzes the effect of frame rates, type of

service, and bandwidth parameters on the QoS metrics using the OPNET environment.

In [8], the authors study the evaluation of QoS in Mobile Internet Protocol v6 using IEEE 802.11e and IEEE 802.11b standards by OPNET simulator. The paper based on the Route Optimization to investigate the QoS metrics such as packet delay variation, HA binding delay, and latency in the MIPv6 handover with video conference applications in real time. The results indicate that the IEEE 802.11e amendment is more effective than IEEE 802.11b during the handover process.

Zakari et al. [9] present a comparative performance study of IPv4 and IPv6 protocols based on the results of QoS metrics of video and audio applications. The study shows that IPv6 performs better than IPv4 in both scenarios.

### III. QoS IN IEEE 802.11

IEEE 802.11e is an amendment to the IEEE 802.11 standard that was approved in 2005. It introduces Quality of Service (QoS) enhancements to the Medium Access Control (MAC) protocol sub-layer of the data link layer of the OSI model. 802.11e improves WLANs by enabling the transport of voice and video with QoS. The packets can belong to different traffic classes that have different transmission priorities. Packets with high priority are more likely to be transmitted before lower priority packets, which reduces delay and jitter for responsive applications.

When QoS is implemented in 802.11, the MAC uses different technical functions [10]. One of these techniques is Enhanced Distributed Channel Access (EDCA), which provides different processing for different classes of packets and channel capacities. EDCA is part of the Hybrid Coordination Function (HCF) and defines four categories of channel access (or priorities), as shown in the table below, from the lowest to the highest priority categories. The Table I represent the different Access categories priority for EDCA function:

TABLE I. ACCESS CATEGORIES PRIORITY IN EDCA FUNCTION

Level	Priority	Access Category
Lowest	1	Background
	2	
to	0	Best Effort
	3	
	4	Video
	5	
Highest	6	Voice
	7	

### IV. QoS PARAMETERS

IPv6 is the most recent version of Internet Protocol [11], this new IP address was involved to fulfill the need for more Internet addresses, and to treat some requirements and limits of IPv4. The quality of service is the important requirement in this new version of the protocol, it has been supported and improved. The evaluation of QoS performance can be measured based on different parameters [12], such as:

#### A. Network Throughput

Throughput is the maximum transmission capacity of a volume of data between two points on a communication line in a given time. QoS optimizes the network by managing network bandwidth and prioritizing applications according to the resources they need. The mathematical formula for throughput is:

$$\text{Throughput} = \frac{\text{Packets Received of data}}{\text{delivery time}} \quad (1)$$

#### B. End-to-End Delay

End-to-end delay is the time it takes for a packet to travel from the source to the destination. It should ideally be as close to zero as possible. It can also be defined as the time difference between the instance of sending and receiving of the packet between two nodes. The mathematical formula for end-to-end delay is:

$$\text{Delay} = \frac{\sum \text{link packet delays}}{\sum \text{packets received}} \quad (2)$$

Where the sum of link packets delays is:

$$d_{\text{transmission}} + d_{\text{propagation}} + d_{\text{queueing}} + d_{\text{processing}} \quad (3)$$

$$d_{\text{trans}} = \frac{\text{packet length}}{\text{transmission rate}} \quad (4)$$

$$d_{\text{prop}} = \frac{\text{distance btw nodes}}{\text{propagation rate}} \quad (5)$$

$d_{\text{queue}}$  depends on congestion and  $d_{\text{proces}}$  is a few microseconds.

#### C. Network Jitters

Jitter, also known as Packet Delay Variation (PDV), is a phenomenon that occurs due to network congestion or queuing, or when data packets are delayed or lost. If jitter is too high, it can lead to a deterioration in the quality of voice or audio communication. In OMNeT++, packet jitter is measured as the difference between the packet delays of successive packets, which is called the Instantaneous Packet Delay Variation. The mathematical formula for jitter is:

$$\text{Jitter} = \frac{\sum_i^n D_i}{\sum \text{packets received}} \quad (6)$$

Where, the sum of delay variation D is:

$$(D_2 - D_1) + \dots + (D_n - D_{n-1}) \quad (7)$$

D. Packets Loss

Packet loss is defined as the number of data packets that are dropped between two nodes during network traffic. The mathematical formula for packet loss is:

$$\text{PacketLoss} = \frac{\text{Packets Sent} - \text{Packets Dropped}}{\text{Packets Sent}} \times 100\% \quad (8)$$

V. SIMULATION RESULTS

This part, describe the simulation paradigm that was studied in OMNeT++, the simulation scenarios that were chosen, and the results obtained from the experiments.

A. Simulation Environment

In this section, we describe the environment for our simulation experiments, which was implemented using the OMNeT++ 5.6.4 simulator. Our simulation represents a wireless network based on the IEEE 802.11e, IEEE 802.11g, and IEEE 802.11r standards. It includes wireless hosts moving throughout the network area, separated to trigger handover and communicate via access points. The wireless host equipment used in the simulation is a compatible node with support for the IPv6 protocol, as well as handover mechanisms and the Mobile IPv6 protocol. The access points used support multiple wireless radios and multiple Ethernet ports. Table II outlines the simulation parameters, and Table III lists the applications used during the simulation.

TABLE II. NETWORK SIMULATION PARAMETERS

Parameters	Value
Network Simulator	OMNeT++ (V 5.6.2)
Framework	INET
Simulation Area	600x400
Simulation Time	10 s
Channel	Wireless (IEEE802.11)
Standard	IEEE802.11 e/g/r
Speed of node	10 mps
Mobility Model	Linear Mobility
Application layer	TCP, UDP
Network interface model	PHY/WIFI's MAC
Internet Protocol	IPv4, IPv6
Frequency	2.412 GHz
Bandwidth	20 MHz
Data Rate	54Mbit/s
AP Beacon Interval	100 ms
Performance streams	End-to-end delay, packet delay variation, throughput, Packet Loss

TABLE III. NETWORK SIMULATION APPLICATION PARAMETERS

Access Category	Packet Length	Packets Access Priority	Nominal Bitrate
Background	900 B	1	24 Mbps
Best Effort	900 B	0	28 Mbps
Video	600 B	5	5 Mbps
Audio	125 B	6	100 kbps

B. Simulation Scenario

The simulation in Fig. 1 demonstrates handover between two access points (APs) in an 802.11g wireless LAN. A wireless node (sender) moves linearly through the network at a speed of 10 m/s, while the wireless node (receiver) remains stationary. Both nodes are configured to use a PHY rate of 54 Mbit/s. The two access points are separated by a distance of 400 meters. When the host moves within the network area, it uses an active scanning method to attach to the nearest AP, choosing the one with the highest signal strength before exchanging data. Two simulation scenarios were created, one with the wireless node implemented with IPv4 protocol mobility support, and the other with the node implemented to support mobility in IPv6. In both simulation scenarios, the source node sends UDP data to the destination node in wireless mode via four UDP streams, each corresponding to a different access category (background, best effort, video, and audio). QoS functionality is enabled, and parameters such as end-to-end delay, jitter, throughput, and packet loss are measured and analyzed to examine how mobile protocols affect the performance of each other for different access categories during horizontal handover. Packets with the highest priority must have lower delay times and higher throughput. The figures below show the network design implemented in the OMNeT++ simulator and the flow chart of the simulation scenario.

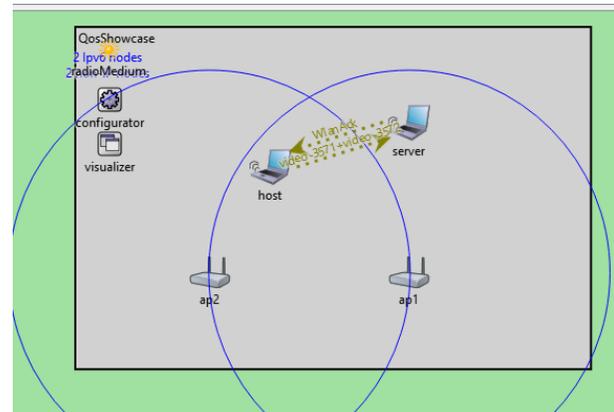

Fig. 1. Network topology design in OMNeT++

The overall flow chart of our proposed scenario is shown as Fig. 2.

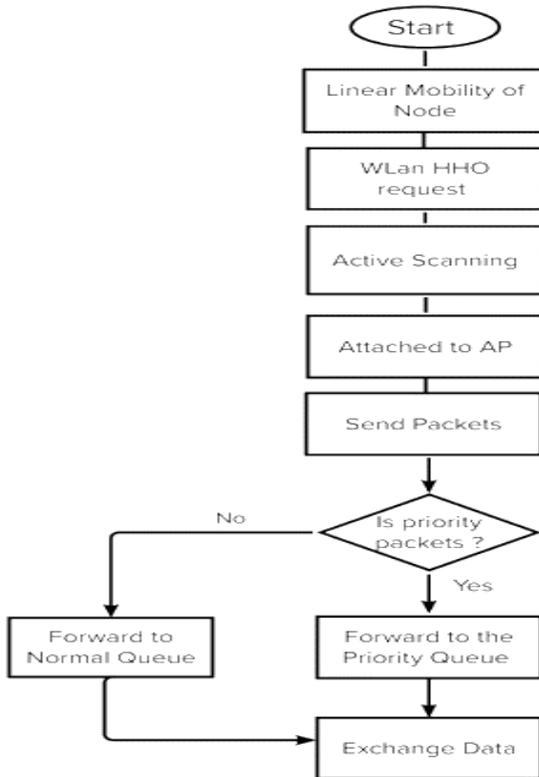

Fig. 2. Flow chart of simulation scenario proposed

C. Results and Analysis

1) Scenario 1: It was implemented with IPv4 mobility support to evaluate the QoS functionality between the two nodes during handover of the two access points in a wireless network.

In Fig. 3, we observed that the throughput values matched their nominal bitrate for high priority traffic (video and audio), 5Mbps for video and 100kbps for audio, in contrast to the lower priority traffic (background and best effort), which had lower throughput values. This explains the instability in the graphs.

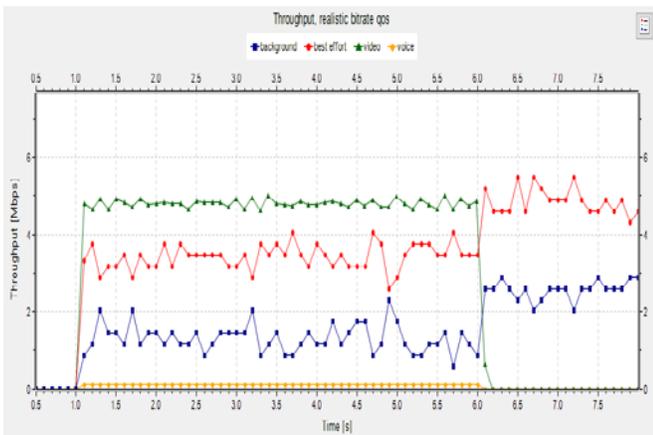

Fig. 3. Throughput variations in scenario 1

The Fig. 4 presents the jitter values for the video and audio access categories remained relatively low (especially for video) compared to the more dispersed scatter points observed for the background and best effort categories, which can reach up to 0.06s. Jitter values began to decrease when the video and audio traffic stopped.

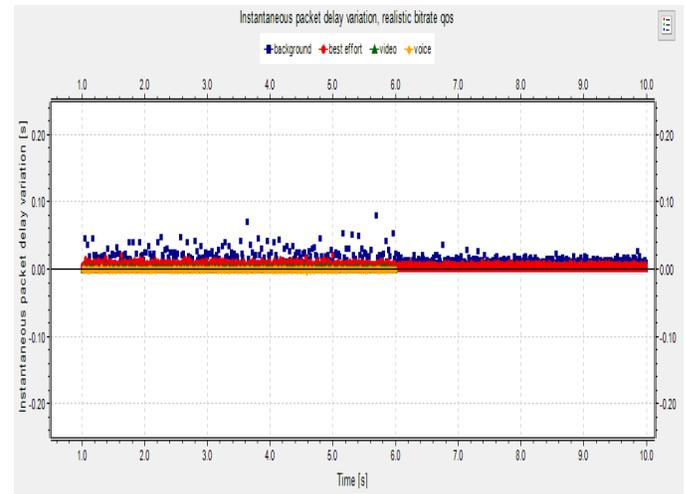

Fig. 4. Jitter variations in scenario 1

This scatter plot in Fig. 5 analyzes the delay of each of the four access categories studied. The video and audio categories were more likely to be sent first, which explains the lower values of packet delay observed in these categories. The best effort category was prioritized over background because its packets were sent periodically, which takes more time.

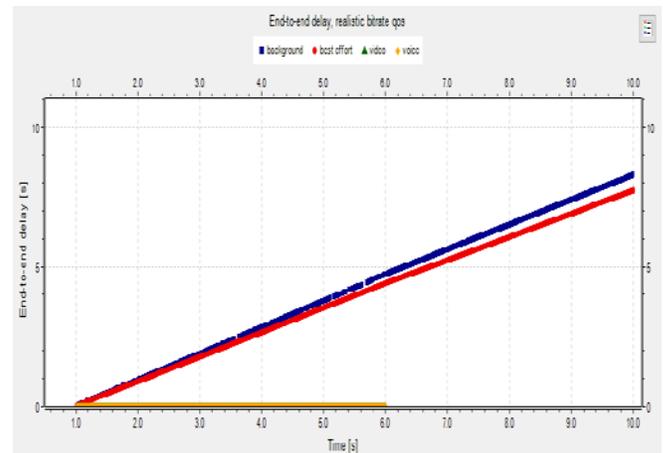

Fig. 5. End-to-end delay variations in scenario 1

In Scenario 1, the QoS parameters were measured for various access categories. The results were summarized in Table IV that provides values for parameters such as end-to-end delay, jitter, throughput, and packet loss, and allows us to compare the performance of different categories in terms of QoS. Overall, the results suggest that high-priority traffic, such as video and audio, had a lower jitter and delay compared to low-priority traffic, such as background and best effort.

TABLE IV. SIMULATION RESULTS OF QoS IN IPV4 MOBILITY SUPPORT

Access Category	Throughput (Mbps)	End-to-End Delay (s)	Jitter (ms)	Packet Loss (%)
Background	1.68	5	440	14
Best Effort	3.63	4.26	73	25
Video	2.38	0.0012	1.1	0
Audio	0.05	0.0008	0.6	0

2) Scenario 2: The objective of this scenario 2 was to evaluate the QoS performance in handover during the implementation of ipv6 mobility support in wireless network. Based to the graph obtained in Fig. 6, the throughput of video reaches a maximum bitrate of 16 Mbps, then it settles stable at 5 Mbps during the last simulation. On the other hand, the throughput of audio takes a maximum value of 6 Mbps. The priority is given to the packets of these two access categories; this explains the straightness of the curve. The line charts of the other lower access categories (background and best effort) show an improvement and a stability in the values of productivity. As long as a high priority packet continues to send, the throughput for the background and best effort categories is lower. It increases just when the traffic for the high priority categories stops.

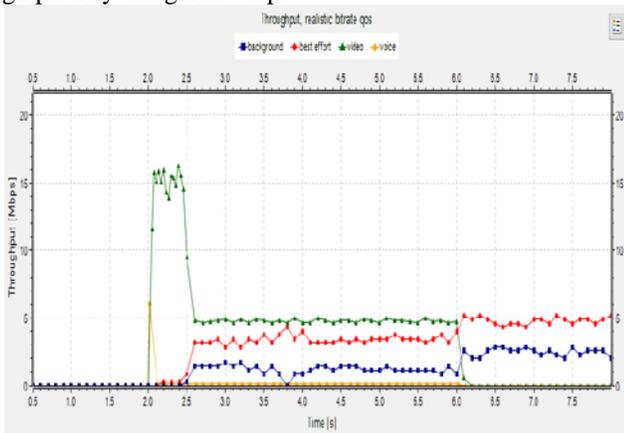

Fig. 6. Throughput variations in scenario 2

The scatter plot in Fig. 7 represents the jitter results for Scenario 2. The jitter starts at two seconds from the beginning of node mobility. The scatter graph for video and audio show horizontal data points, with values almost at zero. In contrast, the best effort and background categories showed more dispersion because the priority of these access categories is low and the packets are not sent consecutively.

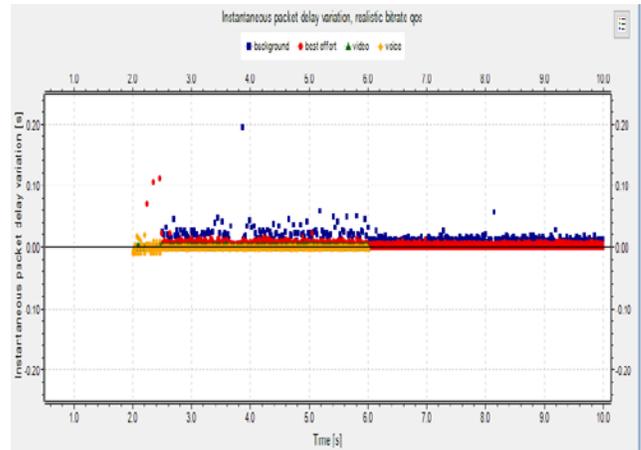

Fig. 7. Jitter variations in scenario 2

In the end-to-end delay graph shown in Fig. 8, the higher priority access categories such as video and voice are characterized by low or almost zero expected delay because they are sent before the lower priority categories like background and best effort.

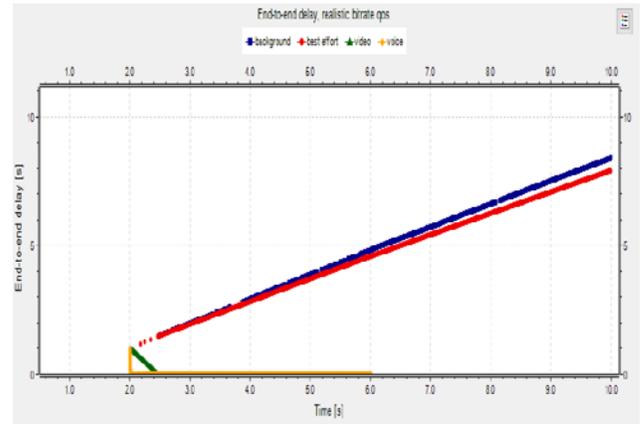

Fig. 8. End-to-end delay variations in scenario 2

Table V provides a summary of the QoS parameter values obtained for the various access categories in Scenario 2, including throughput, end-to-end delay, jitter, and packet loss:

TABLE V. SIMULATION RESULTS OF QoS IN IPV6 MOBILITY SUPPORT

Access category	Throughput (Mbps)	End-to-end delay (s)	Jitter (ms)	Packet Loss (%)
Background	1.43	5.57	380	11
Best Effort	3.12	5	67	21
Video	3.5	0.14	1.1	0
Audio	0.995	0.1	0.5	0

#### D. Simulation Comparison

Based on the results obtained, IPv6 mobility support shows relatively better performance than IPv4 mobility in terms of QoS. In particular, it produces higher average throughput values of 3.5 Mbps in video and 0.995 Mbps in audio applications, which are better than the throughput values of Mobile IPv4 as is evident from Fig. 9. The packet delay values were very low in video and audio, which distinguishes the highest priority queue with low packet delay, the background with a high value of delay because the queue priority is low, and the best effort with high throughput and medium packet delay (see Fig. 10). Regarding jitter, as seen in Fig. 11, the study shows that it is close to zero in video and audio in both Mobility IPv4 and Mobility IPv6, but more dispersed in background and best effort. Packet loss was high in background and best effort for both protocols, which explains the high level of jitter in those categories (refer Fig. 12). However, in Mobility IPv6, the packet loss values show better results compared to Mobility IPv4.

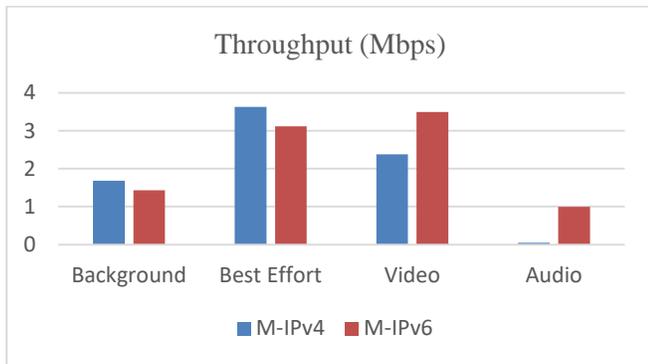

Fig. 9. Throughput comparison

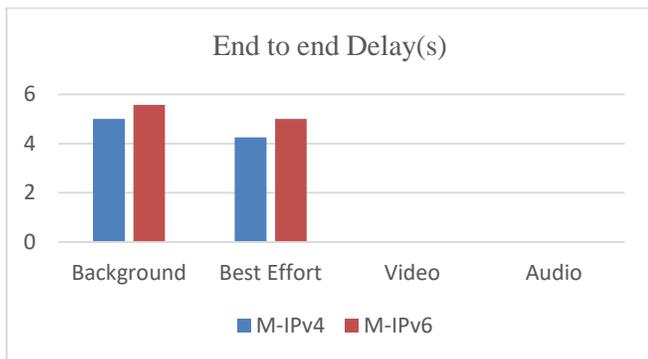

Fig. 10. End to end delay comparison

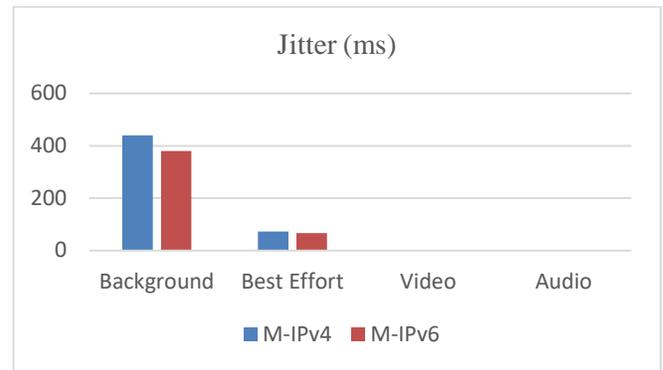

Fig. 11. Jitter comparison

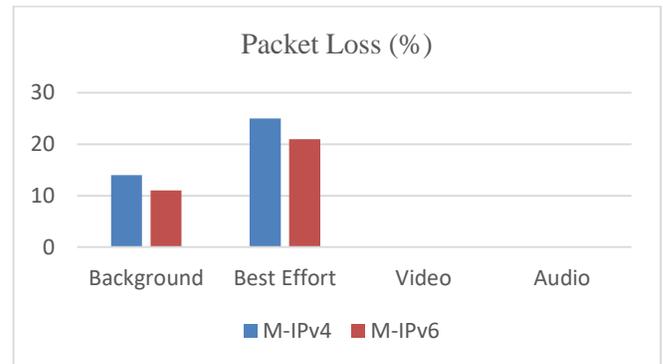

Fig. 12. Packet loss comparison

#### VI. CONCLUSION

This paper provides a detailed comparison of the QoS performance between different access categories, which is crucial for evaluating the effectiveness of the network protocols and identifying areas for improvement. By analyzing the values presented in the Table IV and V, one can gain a deeper understanding of the strengths and weaknesses of each access category in terms of QoS, allowing for more informed decision making and optimization of network performance. The study concludes IPv6 mobility support facilitates node movement in a wireless network and contributes to the improvement of quality-of-service performance. With QoS, IPv6 has a built-in mechanism for ensuring the quality of services, which makes it possible to prioritize urgent packets and to manage the processing of data packets more efficiently. In the simulation, priority is given to video and audio applications. Based on the results obtained, MIPv6 provides better QoS, with an improvement in throughput, fewer lost packets, and slight delay compared to Mobile IPv4 throughput, which was not stable in the four types of services.

## VII. FUTURE WORK

The future work could explore the potential benefits of using QoS mechanisms in MIPv4 and MIPv6 such as Differentiated Services (DiffServ) and Resource Reservation Protocol (RSVP). The results of the study could provide useful insights for the design of mobile networks that aim to provide high QoS levels for multimedia traffic.

# Using Deep Learning Algorithms to Diagnose Coronavirus Disease (COVID-19)

Nfayel Alanazi<sup>1</sup> and Yasser Kotb<sup>2</sup>

Information Systems Department-College of Computer and Information Sciences, Imam Mohammad Ibn  
Saud Islamic University (IMSIU), Riyadh, Saudi Arabia<sup>1,2</sup>  
Computer Science Division-Department of Mathematics-Faculty of Science, Ain Shams University, Cairo,  
Egypt<sup>2</sup>

**Abstract**—With the rapid development in the area of Machine Learning (ML) and Deep learning, it is important to exploit these tools to contribute to mitigating the effects of the coronavirus pandemic. Early diagnosis of the presence of this virus in the human body can be crucially helpful to healthcare professionals. In this paper, three well-known Convolutional Neural Network deep learning algorithms (VGGNet 16, GoogleNet and ResNet50) are applied to measure their ability to distinguish COVID-19 patients from other patients and to evaluate the best performance among these algorithms with a large dataset. Two stages are conducted, the first stage with 14994 x-ray images and the second one with 33178. Each model has been applied with different batch sizes 16, 32 and 64 in each stage to measure the impact of data size and batch size factors on the accuracy results. The second stage achieved accuracy better than the first one and the 64 batch size gain best results than the 16 and 32. ResNet50 achieves a high rate of 99.31, GoogleNet model achieves 95.55, while VGG16 achieves 96.5. Ultimately, the results affect the process of expediting the diagnosis and referral of these treatable conditions, thereby facilitating earlier treatment, and resulting in improved clinical outcomes.

## I. INTRODUCTION

In November 2019, the unique COVID-19 was reportedly discovered for the first time in Wuhan, located in Hubei Province in China. A month later, the World Health Organization (WHO) announced that the virus is capable of causing a respiratory illness that manifests clinically as coughing, fever, and inflammation of the lungs. COVID-19 was first discovered in China, but it has now been found in a significant number of different places across the globe [1, 2]. This is not only owing to the quick transmission of the virus but also the high incidence of death that has been seen as a result. Consequently, WHO declared the emergence of the new COVID-19 virus to form a pandemic [3]. WHO declared a public health emergency due to the pandemic on January 30, 2020. According to the recommendations made by the Chinese National Health Commission, radiographic evidence of pneumonia is needed as part of the clinical diagnostic criteria in Hubei Province [4], where it emphasizes the significance of different CT scan pictures for determining the degree of COVID-19 lung inflammation.

In order to a recent increase in the number of COVID-19 patients, waiting times at hospitals for CT scan image

evaluation have increased significantly. This effect causes a significant danger by spreading illness to other patients. The healthcare system becomes overburdened due to the lack of radiologists, which is generally much lower than the number of patients. In return, this causes a delay in the discovery and quarantine of infected persons in addition to the low effective treatment of patients [4]. Researchers create more intelligent, highly responsive, and efficient diagnosis approaches due to the rapid spread of COVID-19 and the enormous demand for diagnosis. In the past several years, artificial intelligence in the medical field has received widespread attention as a potentially helpful tool for guiding clinical choices and the diagnosis of diseases [5, 6]. It is noteworthy that artificial intelligence is being emphasized to work effectively in the current epidemic for the prediction of outbreaks.

A Canadian company (Blue Dot) successfully reported this outbreak's location in late December. Artificial intelligence is being emphasized to work effectively in the current epidemic to predict outbreaks. Consequently, there is an urgent need to create a clever system that can detect occurrences of COVID-19 correctly and mechanically. The research community needs to develop a dataset that is comprehensive and ready for testing as soon as possible.

CNN is the most popular machine learning algorithm which is used for image processing and training. In environment of Convolutional Neural Networks had validated very successful achievements, for example, classification of image processing, and text based, sign identification, object identifier, faces recognition. A CNN can also detect COVID traces.

This study aims to automatically identify and quantitatively evaluate the pneumonia lesions that are visible in individuals with COVID-19 who have chest CT scans. We will apply three well-known CNN models ResNet50, VGG16, and GoogleNet due to their classification efficiency in recognizing and classifying the images. The models will be compared to select the best model that can achieve high accuracy. Each model will introduce into two stages each stage has a different large dataset and different batch sizes to measure the impact and the effect of data size and batch size factors on the accuracy of the models. Each model will be trained and tested in 100 epochs. The outline of the paper is divided into the following sections. Section II illustrates the literature search. Section III discusses the proposed method in which the datasets and materials are included, where deep transfer learning models are also

explained. Section IV presents the analytical results, and finally, the paper's conclusion is drawn in Section V.

## II. RELATED WORK

There is rising interest in alternate ways of identifying coronavirus infection when using medical imaging due to the rapid spread of COVID-19. Processing and analysis of X-rays, including Computed Tomography (CT), have been performed using different deep learning methods, which have assisted physicians in predicting COVID-19 infection [7]. Several approaches that rely on identifying coronaviruses when using deep learning applications were presented. Wang and Wong [8] propose the COVID-Net approach, which represents an artificially intelligent system based on convolutional neural networks that are designed to differentiate COVID-19 instances from other types of cases by assessing lung abnormalities from X-ray pictures. A variant form of the Inception model is presented where it has an accuracy of 89.5% when extracting the features of COVID-19. This extraction uses different CT images [9]. A 3D deep learning system that is based on the location-attention mechanism is constructed, and CT scans are used in its construction. The objective of this system is to locate sick regions associated with COVID-19 patients. This method is able to differentiate COVID-19 pneumonia from influenza-related illnesses. One caused by viruses has an accuracy of 86.7% [10]. In order to identify the cases of coronavirus, a powerful type of neural network called a deep neural network is trained by using different CT scans. This network is able to differentiate among the infected areas and those affected by other lung diseases [11]. Song et al. [12] built a ResNet architecture to extract complex features from the CT data, and for the classification of COVID-19, a feature pyramid network is integrated with an attention module. In order to differentiate between instances of COVID-19 and those caused by the coronavirus, a diagnostic technique that relies on CT scans has been developed [13]. Islam et al. [14] investigate whether those who have the coronavirus can be identified by the use of chest X-rays as having the infection. The Convolutional Neural Network (CNN) and the Short-Term Long Memory (LSTM) have both been included into a new design that many researchers have constructed. The applications of machine learning, including deep learning, are conducted in COVID-19's imaging-based medical research. The primary objective of the researchers in [1] is to design a model that could make a diagnosis of COVID-19 in a manner that is analogous to the way that radiologists do it, but in a shorter period. They are able to attain performance levels that are equivalent to those of expert radiologists while reducing the amount of time spent diagnosing patients by 65% when compared to the amount of time spent by in-clinic radiologists. Despite this, there are still areas of development that can be made in order to more efficiently enhance both their suggested model and the overall system so that people may have personal access through to it. Deconstruct, transfer, and compose is the name of the deep convolutional neural network that was created and validated to recognize COVID-19 patients from the chest X-ray photos of such patients. This network is referred to by its acronym, "DeTraC" [15]. They recommended a decomposition approach to check for anomalies in the dataset by studying the class

boundary conditions. This is performed to achieve a high degree of accuracy (93.1%) and sensitivity (100%). In [16], a deep learning technique is founded on the ResNet-101 CNN model. In their suggested technique, the pre-training step consists of using thousands of photographs to distinguish significant items, and the re-training phase consists of the same images for detecting abnormalities in chest X-ray images. This approach has just a 71.9% success rate in terms of accuracy. The hospital layer, the patient layer, and the cloud layer are the proposed layers for the proposed structure, which includes three levels [17]. For the goal of collecting information from the patient layer of the data model, wearable sensors and a mobile application are utilized. An identification model based on deep learning and neural networks is used to the X-ray images of the patients in order to locate COVID-19. These images are used in conjunction with the diagnosis.

The proposed model achieves an accuracy of 97.9% and a specificity of 98.85% in its predictions. In [18], previously trained deep learning models are used, such as ResNet50, VGG16, VGG19, and DensNet121. A unique architecture is developed for the diagnosis of X-ray images as either COVID-19 or normal. The VGG16 and VGG19 models have the highest accuracy levels among those considered here. The model that is proposed consists of two phases, the first of which is preprocessing, the second of which is data augmentation, and the third of which is transfer learning. At the end, it demonstrates an accuracy of 99.3%. In the proposed model [19], three different types of deep transfer models, including AlexNet, Google Net, and ResNet18, are applied to a set of 307 photographs that include four various sorts of classes, which comprise: COVID-19, normal, pneumonia bacterial, and pneumonia viral. The models are used to classify the images. The study is broken up into three different situations to cut down on the amount of time spent when executing them and the amount of memory that is used. When it comes to the most recent deep transfer model, Google Net achieves a testing accuracy of 100% and a validation accuracy of 99.9%. In [20], a deep learning-based system is developed for identifying COVID-19 from chest X-ray images by utilizing four tuning models such as ResNet18, ResNet50, Squeeze Net, and DensNet-121. The system is able to do this by using the images as training data. The solution that is recommended involves the addition of additional data in order to generate an updated version of the COVID-19 photographs. As a direct consequence of this, the total number of samples increases. Ultimately, the obtained results achieve a sensitivity of 98% and a specificity of 90%. In [21], a model that makes use of deep learning, as well as machine learning classifiers, is developed. This model is used in a total of 38 trials to accurately identify COVID-19 through the use of chest X-ray images. Ten of these tests are carried out with a wide range of machine learning strategies, and fourteen of these experiments are carried out by utilizing a pre-trained network that is outfitted with the most recent advances in transferring learning technology. The accuracy of the system is 98.50%, while its specificity is 99.18%, and its sensitivity is 93.84%. They conclude that the CNN system can recognize COVID-19 from a limited number of photographs without the need for any preprocessing and with a decreased number of layers. This

result was obtained after they got to the opinion that the CNN system was able to.

In this research, a convolutional neural network models are presented to classify" COVID-19 images from other images, and the proposed methods are determined based on the most effective architectures, which are chosen by ILSVRC competitors as the top 5 CNN architectures. The GoogLeNet architecture won in the 2014 ILSVRC where it reduces the error rate in comparison to AlexNet and ZF-Net, and also reduces the number of parameters to 4 million in comparison to 60 million as it appears in AlexNet [22, 23]. In contrast, the VGG outperforms the other model due to the existence of the multilayer model [24] that involves nineteen more layers than the ZefNet and AlexNet. The reason behind this is to show the relations of the network representational capacity in depth. The VGG uses  $3 \times 3$  filters that are smaller than the  $11 \times 11$  and  $5 \times 5$  filters in the ZefNet. Small-size filters can produce the same impact and efficiency as large-size ones. Additionally, the small-size filter can reduce the computational complication and decrease the number of parameters. The ResNet (Residual Network) is developed in [25] and the winner of the ILSVRC in 2015, where the goal was to create an ultra-deep network to avoid the vanishing gradient issue and use the shortcut connections to enhance the deep network convergence. When compared with the VGG, the computational complexity is lower in terms of the ResNet also the enlarged depth.

In addition, many factors will affect the models leading to poor or accurate results. The study [35] aimed to point up the importance of choosing the appropriate batch size to gain the best accuracy on expected time. Different batch sizes were used to measure the best accuracy such as 16, 32, 64, and 128 they notice whenever use a small batch size that will improve the performance of the models. [36] were used 6 batch size and gained 97.78% accuracy while [39] achieved 75.51% with the same model GoogleNet, although the data size of positive COVID-19 in [36] was near to [39] but in general the number of non-COVID-19 was greater than in [36] than [39]. In the same way, the [37] and [38] use 32 batch size and [37] acquired high accuracy of 99.8% while the [38] get 76.38% with the same model ResNet50.

Consequently, some previous studies produced that the small batch size is an essential factor and has a major impact on the accuracy of the model while another study [40] gained the best accuracy by using 64 batch size. Thus, in this study, we will measure the impact of batch size and dataset size on the accuracy.

### III. PROPOSED METHOD

The proposed method is introduced to utilize three transfer learning CNN models, which comprise VGG16, ResNet50 and GoogleNet, with larger datasets from that is used in the previous studies. Different batch sizes and different images sizes are used to evaluate the performance in order to improve the results and gain the best accuracy and lower loss rate. Anaconda open-source platform is used to install and manage the Python packages which contains from 1,500+ open-source packages and that simplify the deployment and management for packages which made our experience faster and easier.

From Anaconda we create the TensorFlow environment, and we able to install all required packages on that environment.

#### A. Datasets

In this study, a publicly available accessible dataset of chest X-rays is used and taken from COVID-19 patients. These individuals either have pneumonia, normal chest X-rays or are suspected of catching COVID-19. The information for the dataset comes not just from publicly available sources, but also from hospitals and medical professionals through indirect means. The Kaggle dataset repository contains all of the photographs and data that have been made public. X-ray pictures are included in the first dataset that is collected. For the sake of this application, a COVID-19 detection model is constructed by using X-ray pictures. To create a training dataset that is divided in 70% and another scans that are divided in 30%, two datasets are used where the first of which contains 14994 images and the second which contains 33178 images are either pneumonia, normal or COVID-19 X-ray scans. The study [26] contains 2843 covid-19 images; the study [27] includes images of three categories train, test and validation. Similarly, [28] contains 2313 images of covid-19 while [29] represents many categories COVID, Lung\_Opacity, Normal and Viral Pneumonia. Both datasets are divided into 70% for the training dataset. After being rescaled, the X-ray scan pictures are shown in Fig. 2 with a size of 160.

This dataset is one that can be accessed by the general public. It presently has the most data and is labeled as of the time this article was written. In the near future, there will be a rise in the number of datasets as well as the number of samples that each one contains. Labeling is a different topic to be considered. The illness is depicted on X-ray scan pictures that are included in this collection.

#### B. Image Preprocessing

Applying the algorithms to unclear data will not give accurate and correct outcomes as it will fail to recognize the patterns effectively. Thus, data preprocessing is essential before undergoing to computations methods to enhance data accuracy.

Preprocessing is applied to the best picture of the CT Scan COVID-19 to achieve greater consistency in classification results and improved feature extraction. In the current study, assigned image resize is performed on each image to draw attention to COVID-19 in the Region of Interest (ROI), eliminate irrelevant details, and lessen the amount of work to be conducted. The CNN method requires a significant amount of iterative training. To accomplish this, a large-scale image dataset is necessary. A large-scale dataset is required to eliminate the chance of overfitting. The flow chart of the proposed approach is shown in Fig. 1 which illustrate the basic processes of our proposed study.

#### C. Data Augmentation

Several distinct data augmentation procedures are applied to the training set by utilizing the image data generator function of the Keras library, which is part of the Python programming language. This is performed to minimize overfitting and to boost the variety of the dataset. The values are by scaling, by bringing them into the same range. As a result, the rescaling

factor of 1./255 is the proposed model is applied to convert each pixel value from [0,255] to the values 0 and 1. When performing a shear transformation, one axis of the image is kept in its original position while the other axis is stretched to a predetermined angle known as the shear angle. In this example, the shear angle is set to 0.2. When performing the random zoom transformation, the zoom range argument is used; a value of less than 1.0 means that the images will be magnified. On the other hand, in order to zoom out of the image, a value that is greater than 1.0 is utilized; consequently, a zoom range of 0.2 is applied, which results in the image being magnified. The image can be flipped vertically by using the Flip function. Increase in this type of data collection.

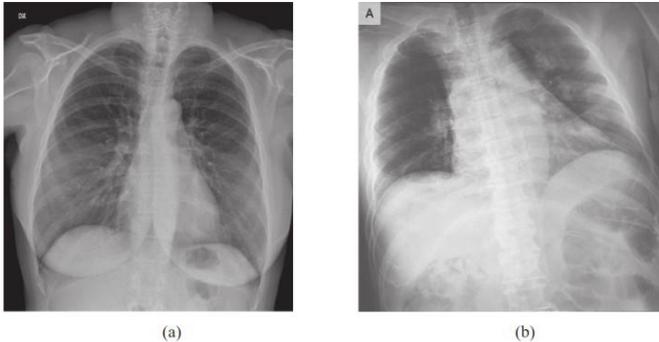

Fig. 1. Example of x-ray image taken from dataset 1

#### D. Convolutional Neural Network

In this section, we will consider the various methods of transfer learning as well as deep neural network analyses. In deep learning, the CNN neural network offers solutions in particular for the recognition, classification, and analysis of images and videos. An architecture for CNN is developed, with the visual cortex of the organization serving as a source of inspiration. Where this design is comparable to the connection model in which neurons in the brains of humans [17], CNN's recent success can be credited, at least in part, to the network's capacity to learn from large-scale datasets such as the Image Net effectively. The fundamental components of the CNN may be separated into three different levels. The neural network comprises three layers: the convolution layer, the pooling layer, and the fully connected layer. The fully connected layer is the last layer.

In conclusion, the convolutional and pooling layers are in charge of the learning that the model produces, whilst the fully connected layer is in charge of the classification [18]. The primary component of the CNN architecture is referred to as the convolutional layer. At this layer, the opportunity to acquire knowledge regarding the characteristics of the inputs is obtained. In order to produce the feature map, high-level and low-level filters are first applied to the input image. In general, the sigmoid and the ReLU function can be found in this layer.

### E. Visual Geometry Group Network (VGG)

Simonyan et al. [30] developed the VGG-Net model, which includes minimal convolution within the network. Because of its more complex structure, which is followed by layers of related double or triple convolution layers, it is frequently used in CNN models. This is due to its structure [30]. This is the most significant difference between this model and the models that came before it, despite the fact that this model is relatively straightforward. In older models, the layers of convolution and sharing follow each other within the same order. Within this model, approximately 138 million parameters are calculated [31]. The VGG database offers an accurate representation of features for more than one million pictures (the Image Net dataset), which spans one thousand different categories. The model is able to function as an effective feature extractor for newly acquired photos that meet the requirements. The Image Net dataset has the capability to extract related features from different related photos, including entirely new ones that either does not currently exist in the dataset or that may be found in an entirely different category from those that are already existing. As a result, employing pre-trained models as an effective feature remover gives a distinct competitive edge [30]. Fig. 3 identifies the framework in which the VGG16 is built on.

Each convolution layer in the VGG16 is preceded by a ReLU layer and incorporates the maximum pooling layers for sampling. The architecture of the VGG16 employs three convolution filters and a total of 13 convolution layers to extract features. It contains three layers that are completely connected for classification, two of which a function represents hidden layers, and the final classification layer consists of one thousand units representing different picture categories that are stored in the ImageNet database [30]. Each of these layers has a different purpose. This structure provides the appearance of a larger filter while retaining the advantages of employing smaller filter sizes. It has been demonstrated that the VGGNet can function more effectively with a reduced number of parameters, particularly when compared to earlier models. Additionally, a single ReLU layer is replaced with two separate ReLU layers for the two convolution layers rather than a single ReLU layer. As a result of the convolution and partnering layers, the spatial size of the input volumes in each layer is shrunk, which leads to an increase in the volume's depth. This increment of using this depth In fact, this increment is due to the fact that the number of filters also increases. More effective when applied to object classification problems and edge detection [31].

1) *ResNet50*: ResNet50 is an architecture that is designed to have a more in-depth structure than any of the other architectures that have come before it. It is made up of 152 layers in total. In 2015, the development of the ResNet was witnessed [32]. It achieved the highest- ranking possibility in the ImageNet competition that was held in 2015, coming in first place with an error rate of 3.6% [32]. The architecture of the model's residual mapping is displayed in Fig. 4 for viewing pleasure. The blocks that feed the data to the following levels are added to the model, which is the most significant aspect that separates it from other designs. This

feature distinguishes it from other architectures. Fig. 4 illustrates the residual mapping structures where other architectures do not have this feature. The system value is altered in a manner that is described by adding this value at intervals of every two layers in the space that is occupied by the Linear and ReLU activation codes. The value of the integral from the below layer is added to the value of  $a = [Integral + 2]32$ . Increasing the number of layers in a model typically results in improved performance, but in actual practice, the situation is shifting in a different direction. In light of this, if the new theory is correct and  $w = [I + 2] = 0$ , then  $a = [I + 2] = b[I + 2]$ .

Because of this issue, the derivative will produce a value of 0 in the problem such that it is not desired [32]. However, the value feed may optimize the learning error even if the value  $a = [I]$  from the below two layers is 0. This results in the network being trained into an efficient deal more rapidly. The architecture is made up of the residual blocks that is displayed in Figure 4. The convolution of the input value  $x$  in the residual block produces  $a = F(x)$ . Fig. 4 represents the residual mapping structure.

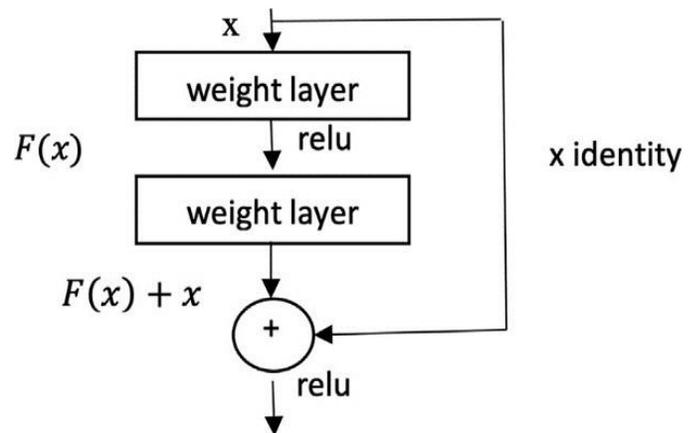

Fig. 4. Residual mapping structure

The result is applied after the ReLU convolution series. The final result is then added to the initial  $x$  entry, and the equation for  $H(x) = F(x) + x$ . Learning residuals from images rather than features is what allows the ResNet50 model to provide a simple training, including a significant advantage in its application [32].

2) *GoogleNet*: In contrast, the Google Net architecture has a total of 22 layers, making it significantly more extensive in depth and breadth than the Alex Net's architecture is, despite having a significantly lower total number of parameters in the network (five million parameters) than AlexNet has. This is due to the fact that GoogleNet has significantly fewer parameters than AlexNet has (60 million parameters). An implementation of the "network in network" design is among the most essential components of the Google Net architecture. Lin et al. [8] use a model called "inception modules." Inception makes use of parallel 1, 1, 3, 3, and 5 5 convolutions, including a parallel max-pooling layer in order to simultaneously collect a wide range of information. The

reason behind this is that it is able to record characteristics simultaneously. To satisfy the requirements of the practical application of the implementation, dimensionality reduction is accomplished by adding 1 x 1 convolutions prior to the previously mentioned 3 x 3, 5 x 5 convolutions (and also after the max-pooling layer). This is conducted in order to fulfil the expectations of the practical application. This is required because there is a requirement to maintain some level of control on the quantity of related computation. The very last layer is referred to the filter concatenation layer, and all it does is to aggregate the results of all of the layers that are running in parallel. Although this contributes to the formation of a single inception module, the version of the Google Net architecture that is utilized in the experiments that we carry out makes use of a total of nine inception modules. This is the status although the fact that this contributes to the formation of a single inception module. You can use as a reference in order to obtain a more comprehensive summary of the structure pertaining to this architecture [32].

**F. Evaluation Measures**

1) *Accuracy (ACC)*: Accuracy is the proportion of accurately predicted authentic and forged images. Accuracy is computed as:

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} * 100\% \quad (1)$$

Where True Positive (TP) refers to photos that have been accurately categorized as tampered, and False Negative (FN) refers to images that have been incorrectly labelled as tampered. True Negative (TN) denotes the photos that are initially categorized appropriately, whereas False Positive (FP) refers to the images that are first classed incorrectly. Table I presents the fundamental of evaluation metrics.

TABLE I. EVOLUTION MATRIX

		Predicted Class	
		Yes	No
Actual Class	Yes	True Positive	False Negative
	No	False Positive	True Negative

A manipulated picture is considered to have been improperly classified if it is recognized as the authentic version of the image, while an authentic image is considered to have been improperly classed if it is recognized as having been tampered with.

Here,

FN=False Negative

FP=False Positive

TN=True Negative

TP=True Positive

2) *Error*: The collective term for a model’s inaccurate predictions are known as errors. This is used to learn about all of the incorrect predictions that are produced.

$$Error = \frac{(FP + FN)}{(TP + TN + FN + FP)} * 100\% \quad (2)$$

3) *True positive rate (TPR)*: The number of fake images that are correctly discovered is known as the TPR, which is calculated as follows:

$$TPR = \frac{TP}{TP+FN} * 100\% \quad (3)$$

4) *True negative rate (TNR)*: TNR refers to the proportion of real photos that have been correctly categorized.

The following formula represents the calculation of the TNR:

$$TNR = \frac{TN}{TN+FP} * 100\% \quad (4)$$

5) *False positive rate (FPR)*: The FPR, or false positive rate, is the fraction of original photos that are incorrectly categorized. It may be computed as follows:

$$FPR = (1 - TNR) * 100\% \quad (5)$$

6) *Precision*: The total of positive predictions that are accurate is calculated as follows:

$$TPR = \frac{TP}{(TP+FN)} * 100\% \quad (6)$$

7) *Recall*: Recall is the ratio of the positive sample that is taken by model And is calculated as follows:

$$Recall = \frac{TP}{(TP+FN)} * 100\% \quad (7)$$

8) *F1-score*: The F1 score is calculated by averaging the recall of the model with the accuracy of the model. One is maximal and zero is minimal value. If the value is at its highest possible, the model is said to be of high quality.

$$F1 - score = \frac{2 * (Precision * Recall)}{(Precision + Recall)} * 100\% \quad (8)$$

9) *F-Measure*

$$F = \frac{2TP}{(2TP+FP+FN)} \quad (9)$$

IV. RESULTS AND DISCUSSION

TABLE II. EXPERIMENT RESULT

Model Name	Batch Size	Epoch Size	Testing Accuracy	Dataset Size
GoogleNet	16	30	94	14994
	32	21	94.46	
	64	34	93.64	
ResNet50	16	91	94.84	
	32	88	96.11	
	64	84	93.3	
VGG16	16	61	93.55	
	32	89	94	
	64	41	93.3	
GoogleNet	64	84	95.62	33178
ResNet50	128	86	96.07	
	64	77	96.07	
VGG16	64	89	95.81	

A. Feature Extraction Performance

The trained CNN is in its system on extracted characteristics before using it to categorize the data. To assess the effectiveness of the CNN models, test features are extracted from the test pictures and are analyzed with a variety of pre-trained models. Currently, the CNN models extract features from both the training and testing datasets using various pre-trained models, such as Google Net, ResNet50, VGG-16, and ResNet50. In the current study, a comparison of the performance of several CNN models is carried out. Even though the ResNet50 does not demonstrate the highest performance in terms of greater accuracy, it is clear that the ResNet50, which is suggested in this study, obtains a superior accuracy and specificity than the other pre-trained models. However, when compared to CNN models, the performance of the scratch model is not considered to be sufficient. The results of the produced ResNet50 model are much superior to those obtained by the VGG16 and GoogleNet models presented in Table II.

B. Comparative Analysis

It is a time-consuming process to use the appropriate datasets of chest X-ray pictures for the COVID-19 detection process. The researchers made use of a variety of preprocessing methods, feature extraction strategies, and classification approaches [24, 33].

However, it is difficult to identify a prospective strategy or combination of techniques that are more supportive in diagnosing COVID-19 from the chest X-ray picture. The reason behind this is that there are so many different possible approaches. In the vast majority of instances, a level of accuracy that is found greater than 90% is observed from a statistical perspective, this constitutes a very high degree of accuracy. However, the objective would be to improve the degree of accuracy to be as near as possible to 100%, where it is given that incorrect diagnosis, even in a very small number of instances, is not quite acceptable. It is very obvious that the approach that is proposed creates a greater classification accuracy when it comes to identifying COVID-19 in comparison to the other strategies that are proposed in the literature. However, the study by Loye et al. [19] shows a more accurate result of 100% than what is found in this study. This might be because the dataset that they use to assess the performance of the system only have a very small number of photos (69 COVID-19 and 79 normal images, respectively) [34]. The accuracy of the suggested technique, which utilizes the feature fusion that is derived from Googlenet, ResNet50, and CNN (VGG16), is demonstrated to be higher when utilizing the CNN as the classifier. On the other hand, when using a binary classifier on the chest X-ray dataset, the ResNet50 achieves a satisfactory level of performance.

In Table II, a different experiment is illustrated when using different batch sizes and epochs when also using the 14994 images dataset. The first set of experiments with GoogleNet employs three different batch sizes (16, 32, and 64) and epochs (30, 21, and 34), and the results show that the testing accuracy reaches 94%, 94.46%, and 93.64% as shown in graph in Fig. 5.

The second ResNet50 model is utilized for experimental purposes, and it achieves a testing accuracy of 94.84%, 96.11%, and 94.53% by utilizing the same batch sizes 16, 32, 64 and epochs used in 91, 88, and 83, correspondingly as shown in graph Fig. 6. The final experiment in the 14994-image dataset is performed by using the VGG16 model, which achieves 93.55%, 93.75%, and 94% as shown in graph Fig. 7, respectively, when using the same batch size 16, 32, 64 and epochs used in 61,89,41. Following that, an experiment is performed with X-ray images by using an increased dataset of 33178 images. When using the same model three times, the batch size and time period each time are changed. The very first GoogleNet model includes a testing accuracy of 95.64% and uses batch sizes of 64 and 84, respectively. The second ResNet50 model should then be run with two different batch sizes of 64 and 128, while maintaining the same level of testing accuracy, which should be 96.07%. The final VGG16 model that is utilized for the experiment, which includes a batch size of 64, and its epoch's size reaches 89. It is able to reach an accuracy of 95.81%. Both the VGG16 and GoogleNet models almost achieve the same level of performance when it comes to the COVID-19 classification. The ResNet50 model, which provides the maximum classification performance with a testing accuracy of 95%, is used for both datasets in order to conduct the evaluation. 32, 64, and 128 batch sizes are applied in order to measure the accuracy in each batch and select the best batch size.

Regardless of the fact that the picture size is decreased by more than half of the original sizes in this experiment, the system is still exhibiting its resilience by accurately detecting COVID-19 instances. This is the case although the fact that the image size is lowered. One possible explanation for this is because the state-of-the-art algorithms have been able to identify a greater variety of unique characteristics and extract those characteristics.

Fig. 8 demonstrates confusion matrix of ResNet50 in first stage, Fig. 9 represents confusion matrix of VGG16 also in first stage while Fig. 10 shows the confusion matrix of VGG16 and ResNet50 in second stage.

## V. CONCLUSION

The rationale behind utilizing X-ray pictures in the COVID-19 detection process is initially discussed in this paper. After that, a few similar papers on pre-trained CNN systems utilizing X-ray pictures are highlighted. In order to create a COVID-19 detection, a large public dataset consisting of chest X-rays is used because there is insufficient public COVID-19 datasets. The first dataset contains 14994 COVID-19 X-ray pictures, while the second dataset contains 33174 COVID-19 X-ray. These are used for training and testing stages, respectively. The photographs are scaled to be 160 by 160 pixels. The dataset is made more comprehensive by including different picture enhancement techniques.

Transfer learning models GoogleNet, ResNet50, and VGG16 were used by utilizing the X-ray images of COVID-19 patients and other patients. The pre-trained ResNet50 model produced the highest classification performance of automated COVID-19 classification with an accuracy of 96%. This was compared to the other two suggested models, which both had a classification accuracy of 94%. By presenting our work's results in graphs and tables, we were able to draw attention to the performance of the categorization. It is recommended that the number of examples that are included in the dataset to be raised so that the model can achieve a more accurate performance. In addition, we hope in the future to use pre-processing techniques that can affect positively on the results and that will increase the intelligence of the models and will lead to predicting the accurate result that can be generalized.

# Enhanced Optimized Classification Model of Chronic Kidney Disease

Shahinda Elkholy<sup>1</sup>, Amira Rezk<sup>2</sup>, Ahmed Abo El Fetoh Saleh<sup>3</sup>

Information Systems Dept.-Faculty of Computers and Information, Mansoura University,  
Mansoura, Egypt

**Abstract**—Chronic kidney disease (CKD) is one of the leading causes of death across the globe, affecting about 10% of the world's adult population. Kidney disease affects the proper function of the kidneys. As the number of people with chronic kidney disease (CKD) rises, it is becoming increasingly important to have accurate methods for detecting CKD at an early stage. Developing a mechanism for detecting chronic kidney disease is the study's main contribution to knowledge. In this study, preventive interventions for CKD can be explored using machine learning techniques (ML). The Optimized deep belief network (DBN) based on Grasshopper's Optimization Algorithm (GOA) classifier with prior Density-based Feature Selection (DFS) algorithm for chronic kidney disease is described in this study, which is called "DFS-ODBN." Prior to the DBN classifier, whose parameters are optimized using GOA, the proposed method eliminates redundant or irrelevant dimensions using DFS. The proposed DFS-ODBN framework consists of three phases, preprocessing, feature selection, and classification phases. Using CKD datasets, the suggested approach is also tested, and the performance is evaluated using several assessment metrics. Optimized-DBN achieves its maximum performance in terms of sensitivity, accuracy, and specificity, the proposed DFS-ODBN demonstrated accuracy of 99.75 percent using fewer features comparing with other techniques.

**Keywords**—Machine learning (ML); feature selection (FS); chronic kidney disease (CKD); deep belief network (DBN); grasshopper's optimization algorithm (GOA)

## I. INTRODUCTION

Chronic renal disease, or chronic kidney disease (CKD), worsens over time, eventually causing kidney failure. Most of the time, it can go undetected for up to 25% of its usefulness before being discovered. For people who are unaware of kidney failure's symptoms, this might make it difficult to diagnose and treat the condition. Treatment for kidney failure aims to manage the causes and slow the progression of renal failure. Patients in the last stages of renal failure will require dialysis or a kidney transplant if treatment fails [1]. Renal failure affects four out of every 1000 people in the UK, while dialysis keeps more than 300,000 Americans with kidney failure alive [2]. More people in South Asia, Africa, and the rest of the world have renal illness, according to the National Health Service (NHS). Because chronic renal failure cannot be detected until it has progressed to an advanced state, recognizing kidney failure at an early stage is critical. By detecting renal disease at an early stage, the likelihood of permanent damage to the kidneys is reduced. As a result, patients should have regular checkups and early diagnosis to avoid serious risks of renal failure and related disorders [1].

Doctors can make therapy decisions that slow the rate of progression. Measuring parameters allow for differentiation, and patients' medical records can be used to classify and predict disease using data mining techniques [3].

Data mining techniques allow for the extraction of meaningful information from large and hidden databases. As a method of gaining knowledge from unstructured information, data mining techniques can be applied even when the information is not directly related to medicine [4]. Data mining has three stages: data processing, data modeling, and data post processing. Data mining jobs in data modeling include classification/predictive algorithms and regression algorithms that are learned through a supervised learning process. As a result of missing and unneeded data being stored in the hospital database, it is difficult to mine the patient data. As a result, prior to implementing data mining techniques, it is necessary to improve data processing and data reduction methodologies [5]. Accurate and reliable data makes the identification of CKD easier and faster. Data classification can be used to identify CKD from a patient's medical records but an important part of the classification process is the establishment of a link between the feature values and the class labels for the data being processed. Hence, classification is a supervised procedure. An algorithm for classification and prediction uses training data to build a model, which is then used to predict test data [6]. Using artificial intelligence (AI) approaches, categorization models have recently been improved. Multiple issues arose as a result of the high-dimensional nature of the medical data, including high processing complexity, overfitting, and low finishing model interoperability. Feature selection (FS) is the quickest and most effective way to address the issue. This method aims to reduce the number of features to a manageable subset by removing redundant or irrelevant ones. In order to save calculation time, it makes use of a small number of characteristics to extract the maximum amount of data from a dataset [7]. The selected feature subset is useful in modeling these functions. To improve prediction results, FS approaches are used in a wide range of applications such as machine learning (ML), data mining, and pattern recognition [8]. Wrapper, embedded, and filter-based methods are all examples of FS validation methods. To validate the feature subset in a filter technique, one uses fixed measurements rather than learners and a predetermined set of features. However, the wrapper method uses the learning strategy as a sub-process of evaluation to determine whether or not a feature set is better than it was previously. This method, which is widely used, has certain drawbacks, such as a high computational cost, difficulty in recognizing user-defined parameters of the learner, and

built-in constraints on the learners [9]. Embedded techniques are simpler than wrapper approaches in terms of complexity. But the selection of features is based on the learning technique [10]. The filter and wrapper methods are both integrated into the embedding method, which removes their respective drawbacks. Despite the cheap computational complexity of the filter approaches, the feature subset used for classification was shown to be unreliable. The wrapper approaches, on the other hand, achieve better classification results while using a lot more time. All three techniques have improved the classification of the features. In addition, the FS procedure has improved features rather than the classifier. High classification performance was achieved with high computing complexity using wrapper and hybrid approaches.

This paper aims to enhance the accuracy of CKD classification using the DFS-ODBN method which an innovative wrapper strategy for CKD detection that incorporates density-based feature selection (DFS) with optimized DBN based on GOA to tackle these difficulties. Used techniques are capable of solving the problem of class imbalance in the dataset which may affect classification performance in addition to this heuristic way that determine whether or not a feature is worthwhile. To improve the final classifier outputs of the DFS-ODBN algorithm, the addition of optimization algorithm called GOA as parameter adaptation to increase the performance of the classifier helps to enhance the accuracy of the optimized DBN classifier. From the UCI repository, a benchmark CKD dataset is used to test the efficiency of the DFS-ODBN method. The model was evaluated using metrics like accuracy, sensitivity, and F-measure. The results showed that the provided DFS-ODBN strategy outperforms the evaluated approaches in terms of classification performance.

The following is the article's flow: Other diagnostic approaches are reviewed in Section II; Section III presents a review of related methods and technologies; Section IV provides a discussion of applied methodology, and Section V includes simulation test results for the proposed method, comparing the results with other related studies. Section VI provides the future work with the concluded presented work.

## II. RELATED WORK

Much research has used data mining algorithms to accurately predict CKD in patients based on their medical records. From the original set of features, there has been a focus on a subset of relevant features that play a significant role in the medical diagnosis sectors because of the high dimension of required multidimensional medical multimedia data for CKD prediction. All of the studies used performance indicators including specificity, accuracy, and sensitivity to support their CKD prediction approach. We'll go through some current research on predicting kidney disease later on.

The UBFST (Union Based Feature Selection Technique) was developed for the rapid and accurate classification and diagnosis of chronic kidney disease (CKD). This method uses SVM, regression tree, and random forest to classify CKD [11]. Using a Las Vegas Wrapper Feature Selection approach (LVW-FS) and an ensemble learning-based model, hemodialysis treatment time can be predicted with acceptable

accuracy. Using the LVW selection methodology, they have developed a new way of extracting crucial vital indicators. As a method of classification, a group of learners was used in this study to give numerous classifiers. Through a variety of trials with different learners, the suggested model based on LVW and the ensemble learning method was shown to have the greatest influence in decreasing hyperthyroidism characteristics and excluding noise [12]. Their technology can forecast the health of the kidney based on factors such as age, albumin and glucose levels, and more.

An evolutionary algorithm (GA) based on neural networks optimize weight vectors to train a neural network. For CKD diagnosis, the system outperforms existing neural networks in terms of accuracy [13]. For the dataset of CKD, using multilayer perceptrons (MLPs), probabilistic neural networks (PNNs), radial basis functions (RBFs), and SVM. The PNN algorithm surpassed the SVM, MLP, and RBF algorithms in terms of performance [14]. In Colombian population neural networks were used to predict the likelihood of CKD in people [15].

The study [16] proposed a method for diagnosing chronic renal illness based on grey wolf optimization (GWO) and hybrid kernel support vector machines (HKSVM). The UCI ML repository's chronic kidney dataset yielded a 97.26% accuracy rate. CKD can be identified using two fuzzy classifiers known as FuRES and FOAM, which are both fuzzy rule-building expert systems (FuRES). FuRES provides a minimum NN-based classification tree. The weight vector with the least fuzzy entropy is determined by the categorization criteria. The 386 CKD patients were identified using two fuzzy classifiers. FuRES, on the other hand, performs better than FOAM in cases where the training and prediction processes are both noisy. In the detection of CKD, both FOAM and FuRES performed better, although FuRES outperformed FOAM.

PCA and SVM were used to diagnose cervical cancer. A total of 32 potential risk factors as well as four specific outcomes were examined in this study: Hinselmann, Schiller, cytology, and biopsies. SVM with recursive feature removal and SVM with PCA were used to classify the target objects (PCA-SVM). PCA-SVM came out on top over the other two methods [17].

Using three classification algorithms Olex-GA, Ant Colony Optimization ACO and PSO compared them to developed system for diagnosing CKD. The ACO method with Density Based Feature Selection to select the important features showed superior performance and the highest accuracy [18].

Seven ML techniques are comprised to predict the CKD, J48, SVM, NBTree, LR, MLP, Naïve Bayes and Composite Hypercube on Iterated Random Projection (CHIRP) are utilized. The results of experiments show better performance for CHIRP [19].

C5.0, Artificial neural network, CHAID, logistic regression, random tree, K-Nearest neighbors and linear support vector machine were the seven classifier algorithms used to predict CKD. Results were calculated using all features from the classifier, features chosen by CFS, features chosen by Wrapper, LASSO regression, SMOTE, and chosen features

SMOTE with all the features, LASSO with selected features. The LSVM was found to have the highest accuracy in SMOTE with all features [20].

The research [21], has an additional strategy based on Recursive Feature Elimination (RFE). The most strongly representative features of CKD were chosen using the RFE algorithm. SVM, KNN, decision tree, and random forest were used to classify the features. All classifier parameters were fine-tuned to provide the best classification results, and all methods produced promising results. For all measures, the random forest approach surpassed all other algorithms. Multiclass statistical analysis was used to investigate and evaluate the system, and the empirical results of SVM, KNN, and decision tree algorithms revealed significant values of 96.67 percent, 98.33 percent, and 99.17 percent in terms of accuracy metric.

To properly pick the features subset, several feature optimization techniques were described to see the effect of them on the performance of the ML model which was tested on five influential classification models Logistic regression, Random forest (RF), SVM, K-nearest neighbors and Xtreme gradient boosting (XGB), experiments have shown that the accuracy of the model can be enhanced by using Linear discriminant analysis (LDA) feature optimizer that performs the highest outstanding result [22].

### III. RELATED METHODOLOGIES

#### A. Feature Selection

Pattern recognition, knowledge discovery, and statistical research all rely heavily on feature selection. It is the goal of feature selection to eliminate unneeded inputs. No predictive class information is required to determine which features are relevant. Reducing the dimensionality of features and omitting features that are not relevant to classification can result in a comprehensive model. As the name implies, the fundamental issue in feature reduction lies in identifying the optimal collection of features to maximize classification performance [23]. Simplifying the data collection, reducing the problem of over fitting, and reducing the amount of data stored are all benefits of feature selection [24].

Three types of feature selection approaches exist. A variety of methods, including filtering, embedding, and wrapping methods. The filter method chooses the highest-ranking features, and the resulting subset can then be used in any classification algorithm that is needed to be used. Various classification methods could be tested after feature selection using the filter approach as shown in Fig. 1 [25]. The classifier's performance can be improved by reducing processing time and making better use of the dataset's optimized data while making a suitable feature selection [26]. Fastness and scalability are two more advantages of the filter approach in feature selection [27].

The classifier algorithm is used as a black box to determine scores for feature sets based on estimated power [28]. Testing and training on a given dataset are used to evaluate a subset. All features of subsets can be searched for in a wrapper approach that uses the wrapper algorithm around the classifier shown in Fig. 2 [25]. In spite of the advantages of working with correlated data and identifying the relevant correlations, over-fitting difficulties may arise. Feature selection is included in the construction of the classifier in the embedded method illustrated in Fig. 3.

When using an embedded technique, you don't have to deal with costly computations and can instead interact directly with your classification model. Table I displays the benefits and drawbacks of various feature selection approaches.

TABLE I. BENEFITS AND DRAWBACKS OF VARIOUS FEATURE SELECTION APPROACHES

approach	Benefits	Drawbacks
<b>Filter</b>	Scalable and quick without being dependent on any classifier,	Interaction with classifiers is not considered.
<b>Wrapper</b>	- A higher degree of computational efficiency, Simple, Classification accuracy models with dependencies are the best kind. - The classifier interacts with it. - Wrapper approaches have a high computational complexity. Models include a hierarchy of dependencies	Over fitting is a possibility, and the process is computationally intensive.

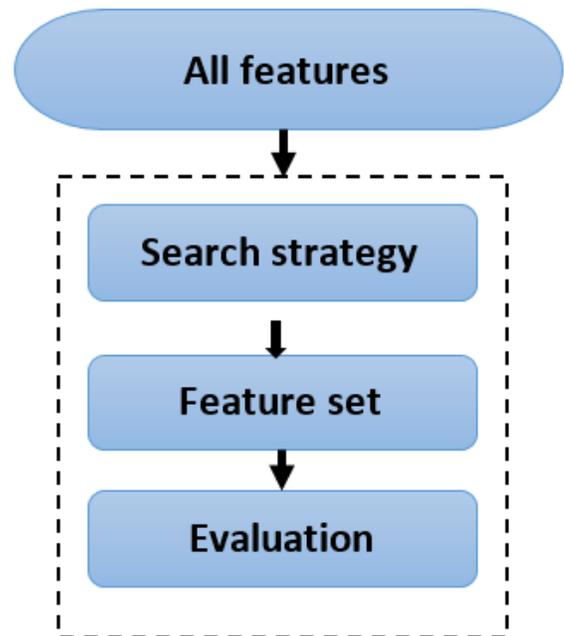

Fig. 1. Filter approach of feature selection

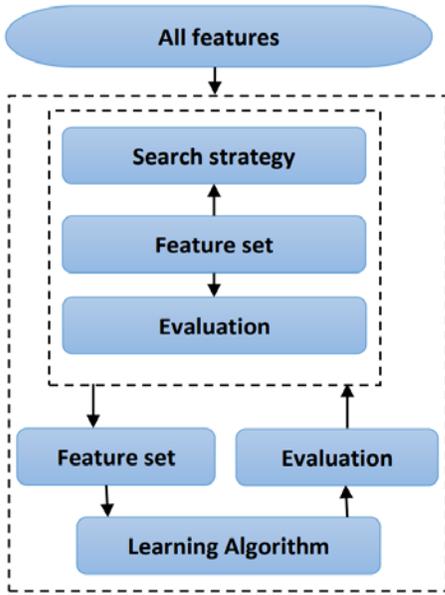

Fig. 2. Wrapper approach of feature selection

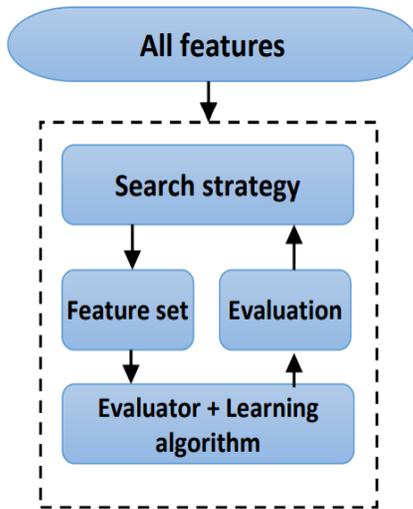

Fig. 3. Embedded approach for feature selection

### B. DBN

Using an unsupervised machine learning paradigm, deep belief networks are a more advanced kind of generative neural network. A DBN can be created by stacking and training individual Restricted Boltzmann Machines (RBM) in a layered configuration. The pre-training stage is a step of unsupervised learning. Stacking sub networks, each with two processing levels, divides the network into groups. These weights are provided to the network as a way to avoid the issues that can arise from using random numbers to initialize the connection weights. Unsupervised learning is used to steer the learning phase of an energy-based stochastic neural network (RBM), which includes two layers of neurons, hidden and visible nodes. Unsupervised training may be used for this function by using the Greedy Layer Wise unsupervised training algorithm. RBM has a hidden layer including nodes and a visible layer including nodes, respectively.

Using an unsupervised learning technique, one can learn an RBM, a generative stochastic neural network. There are two processing tiers in the RBM's network, as depicted in Fig. 4. Construction and reconstruction operations can be carried out independently of one another because these layers are linked together [29].

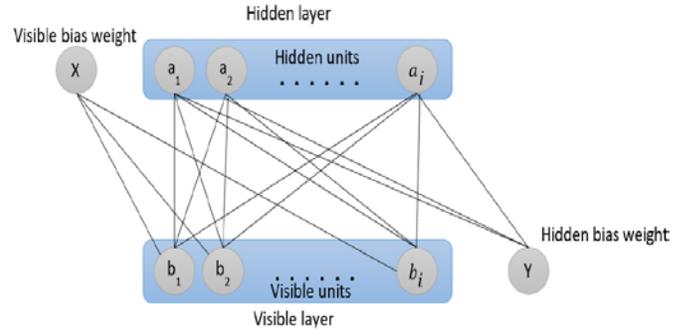

Fig. 4. The RBM architecture

In the visible layer (b), there are visible units  $(b_1, b_2, b_3, \dots, b_i)$  that represent the features of the pattern, while in the hidden layer (a), there are hidden units  $(a_1, a_2, a_3, \dots, a_j)$  that accept their data from the visible units and are able to reconstruct the pattern's characteristics from them. The visible node  $B_i$  and the hidden node  $H_j$  have a weight of  $U_{ij}$  in the  $k \times l$  matrix  $U$ , which represents the weights between visible and hidden levels. Let's assume that the binary and hidden units are  $B$  and  $A$ . In this case,  $A \in \{0,1\}^l$  and  $B \in \{0,1\}^k$ . As shown below in (1), the RBM energy function is a quadratic function of the square of:

$$\text{Ene}(B, A) = -\sum_{i=1}^k R_i B_i - \sum_{j=1}^l Z_j A_j - \sum_{i=1}^k \sum_{j=1}^l B_i A_j U_{ij} \quad (1)$$

where  $Z$  and  $R$  are the basis vectors of the hidden and visible layers, respectively. Also, the likelihood of the  $(B, A)$  configuration is shown in the following equation.

$$\text{pr}(B, A) = \frac{e^{-\text{Ene}(B, A)}}{\sum_{B, A} e^{-\text{Ene}(B, A)}} \quad (2)$$

Normalization is reflected in the denominator of the aforesaid equation. Stochastic gradient descent (SGD) is used to optimize RBM parameters  $Z, R$ , and  $U$  based on the training data's log likelihood. In order to calculate the probability of a given sample over all potential hidden vectors, one can use the following formula:

$$\text{pr}(B) = \frac{\sum_B e^{-\text{Ene}(B, A)}}{\sum_{B, A} e^{-\text{Ene}(B, A)}} \quad (3)$$

$Z, R$ , and  $U$  are used to generate stochastic gradient ascent derivatives of  $\text{pr}(B)$ , which lead to the following equations:

$$U^{n+1} = U^n + \xi(\text{pr}(A/B)B^T - \text{pr}(\tilde{A}/\tilde{B})\tilde{B}^T) - \eta U^T + \alpha \Delta U^{n-1} \quad (4)$$

$$Z^{n+1} = Z^n + \xi(B - \tilde{B}) + \alpha \Delta Z^{n-1} \quad (5)$$

$$R^{n+1} = R^n + \xi(\text{prob}(A/B) - \text{prob}(\tilde{A}/\tilde{B})) + \alpha \Delta R^{n-1} \quad (6)$$

With

$$\text{pr}(A_j = 1/B) = \text{sigma}(\sum_{i=1}^k U_{ij}B_i + R_j) \quad (7)$$

And,

$$\text{pr}(B_j = 1/A) = \text{sigma}(\sum_{i=1}^l U_{ij}A_i + Z_j) \quad (8)$$

where  $\eta$ ,  $n$ ,  $\xi$ , and  $\alpha$  denote the weight decays, number of hidden nodes, learning rate, and momentum weights, in that order. The Softmax function is symbolised by the symbol  $\text{sigma}$  in the logistic model. For the visible and hidden nodes, two different learning methods are used to figure out their weights and biases. Both CD and persistent contrastive divergence (PCD) fall under this category (PCD).

DBN uses an error propagation method and fine-tuned optimal performance to identify the starting weights, which are obtained by undertaking unsupervised pre-training. RBM pre-training is still lacking in the optimal number of layers and nodes. The outcomes are affected by the number of layers and also the number of nodes, but the ideal value relies on the type of dataset and the attributes to be learned. Therefore obtaining the global optimum value has certain downsides. GOA is used to solve the problem of DBN in our job. GOA is a technique for determining the DBN's ideal value and, as a result, reducing error.

#### IV. PROPOSED MODEL

The proposed DFS-ODBN model consists of three phases namely: preprocessing phase, feature selection phase and classification phase. The first phase, preprocessing, involve dealing with the dataset nature which include many missing data due to the archive of data in hospitals. Preprocessing also include normalization of scale of data to make all attribute in a specified range. The second phase involves selecting a subset of attributes to reduce the complexity and time of classification phase. Feature selection phase involve selecting the most appropriate features among all available features using DFS feature selection algorithm in wrapper approach which repeatedly apply DFS method. In last phase, classification, the DBN classifier is used to predict the case of data which ckd or NOT ckd. The classifier parameters are estimated and tuned using an optimization algorithm called GOA. The use of optimization algorithm helps in parameter adaptation to increase the performance of the classifier. The last step is model evaluation which assesses the performance of the proposed system according to many metrics such as: accuracy, sensitivity, f-measure, and precision. The evaluation proved that the proposed system is better than many other related methods. The proposed system is shown in Fig. 5.

##### A. Description of Dataset

UCI's Machine Learning Repository now has the CKD dataset used in this study which was collected and uploaded by the Apollo Hospital in India in 2015. There are 400 data points total, with 25 different properties, 11 of which are numeric and 14 of which are nominal [30]. 250 of the dataset's 400 instances have been assigned to the ckd class, while the remaining 150 have been assigned to the NOTckd class. Table II shows the CSD dataset's attribute breakdown.

##### B. Preprocessing

The quality of the data used in data mining operations must be high in order to achieve a high level of performance at a cheap cost. Anomaly type characteristics will be converted to numeric in the preprocessing step. A total of 14 nominal attributes will be transformed into numerical attributes.

TABLE II. CHRONIC KIDNEY DISEASE DATASET INFORMATION

Features	Type
Red blood cell count (Rc)	Numeric
Sugar (Su)	Nominal
Hypertension (Htn)	Nominal
Sodium (Sod)	Numeric
Red blood cells (Rbc)	Nominal
Packed cell volume (Pcv)	Numeric
Pus cell (Pc)	Nominal
Age (Age)	Numeric
Appetite (appet)	Nominal
White blood cell (Wbcc)	Numeric
Bacteria (Ba)	Nominal
Diabetes mellitus (Dm)	Nominal
Specific gravity (Sg)	Nominal
Serum creatinine (Sc)	Numeric
Anemia (Ane)	Nominal
Pus cell clumps (Pcc)	Nominal
Blood glucoses (Bgr)	Numeric
Coronary artery disease (Cad)	Nominal
Pedal edema (Pe)	Nominal
Blood pressure (Bp)	Numeric
Blood urea (Bu)	Numeric
Albumin (Al)	Nominal
Haemoglobin (Hemo)	Numeric
Potassium (Pot)	Numeric
Class (class)	Nominal

1) *Missing values*: More than half of the variables in the CKD dataset are missing, necessitating the handling of missing values in order to improve accuracy. The mode method is used to replace the empty value with the attribute's maximum frequency when a value is lacking. Attributes can be univariate, monotonous in their missing values, or arbitrary. Only one characteristic has all of the missing values in univariate analysis (feature). If at least three attributes are missing values, the model is said to be monotonous. If the missing values are of random characteristics, then it is arbitrary [31].

2) *Data normalization*: There are numerous approaches to data normalization. Keep the data in a range for each input feature in order to reduce the neural network's preference for one feature over another. Training time can be reduced by normalizing data such that all features are trained at once. It is particularly beneficial for modelling applications when the

inputs are often on a wide range of scales. The features or outputs are rescaled using the Min-Max normalizing method from one range of values to another. Most of the time, the features are rescaled to fall between 0 and 1 or -1 and 1. It is common to perform the rescaling by applying a linear interpretation formula like:

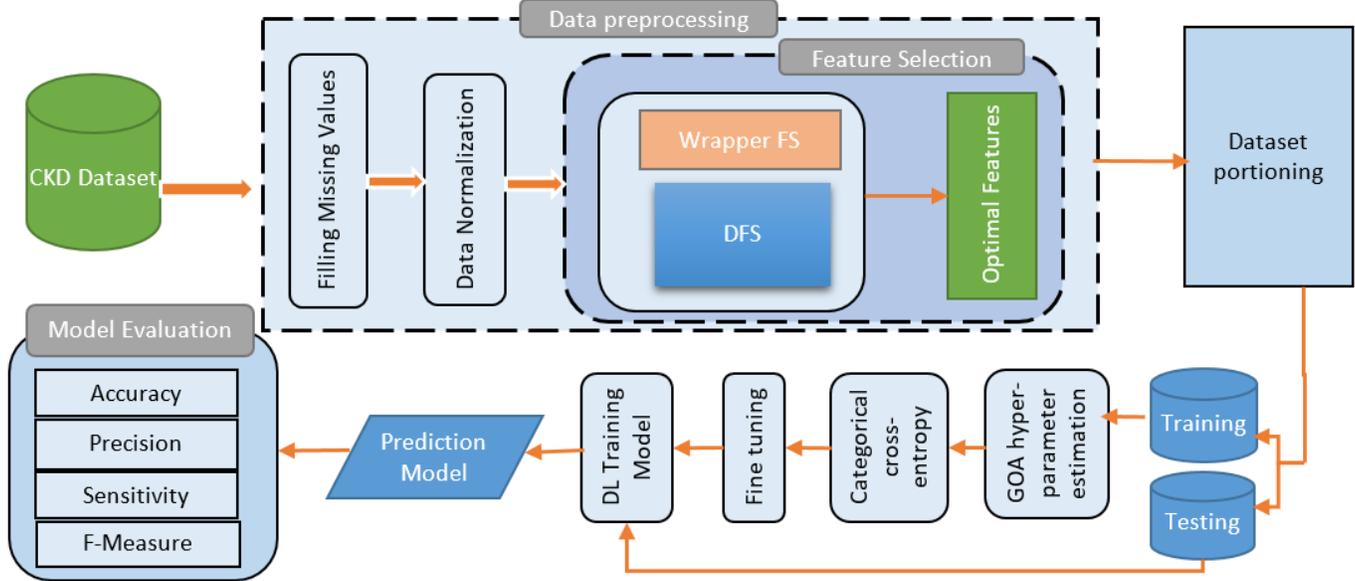

Fig. 5. Proposed framework

$$x'_i = ((\max_{\text{target}} - \min_{\text{target}})x \frac{(x_i - \min_{\text{value}})}{(\max_{\text{value}} - \min_{\text{value}})} + \min_{\text{target}}) \quad (9)$$

where  $(\max_{\text{value}} - \min_{\text{value}}) = 0$  . when  $(\max_{\text{value}} - \min_{\text{value}}) = 0$  for a feature, it shows that that feature in the data has a constant value. Feature values having a constant value should be deleted from the data set because they do not contribute any useful information to the neural network. Min-max normalization maintains the same range of values for each feature when it is applied. The advantage of using min-max normalization is that it keeps all of the data's relationships intact.

### C. DFS for Feature Selection

In order to select the best features, the proposed algorithm employs the following procedures. It is necessary to organize the CKD dataset into groups once the preprocessing is complete. Selecting a collection of features in each iteration is done using DFS. The most important feature in the classification process is a subset of the best features in the raw dataset.

Features can be evaluated using the DFS method, a heuristic approach. A feature is considered good if it has less overlap with other classes than other features. The DFS method takes into account the distribution of features across all classes and their associations for determining rankings. As a first stage in DFS, every feature in every class is given a probability density function (PDF). The next step is to rank the features depending on the overlap area, and this is done next. Parametric and non-parametric methods of computing PDF are

the most frequent approaches [32]. The first method assumes that data has a Gaussian distribution, so the work of estimating density simply entails choosing appropriate values for the distribution's mean and variance. Instead of making assumptions about the shape of the density function, non-parametric techniques simply calculate the density from the observed data. Many pattern recognition applications lack a standard format for estimating the density of raw data. When using random distributions and non-parametric approaches, it is unnecessary to know the fundamental density forms before using these methods [32]. Because of this, the proposed solution is described as using the following parametric approach:

$$p(x) \cong \frac{k}{MVo}$$

Here, the value of the derived PDF for instance  $x$  is represented by the expression  $p(x)$ , whereas  $M$  the total number of examples,  $Vo$  is the volume surrounding  $x$ , and  $k$  the number of instances within  $V$  are all given. To get a more accurate PDF, try increasing  $M$  and decreasing  $Vo$ . After estimating PDFs for each class, the next step is to compare the value of each feature based on the calculated PDFs for each class. As previously stated, a feature is considered good if it has less class overlap than the rest. The estimation of PDF for each class label and feature is used to estimate the amount of overlap between occurrences of a certain feature class. The significance of a feature for class label prediction decreases as the overlapping region grows larger, and this leads to a decline in classification performance. The overlapping value of a feature  $r$  in class  $\omega$  can be calculated using the formula 2.

$$Ov(r, \omega) = \int \text{Minimum}(\text{Maximum}(\text{PDF}(\omega_i)), \text{PDF}(\omega))$$

such that  $i$  is not equal to  $\omega$  and  $1 \leq i \leq \#$  of classes

#### D. Optimized DBN based on GOA

"Reference [33] proposed the GOA algorithm. It was inspired by the swarming activity of grasshoppers in nature. A grasshopper's flight path in a swarm is affected by the following three factors: Those three factors are: human social connection, gravitational pull, and wind advective forces. The GOA algorithm is used for minimizing the value of error in order to get the ideal DBN value. The GOA has a series of steps, as outlined below:

1) *Step 1: initial step:* It is necessary to initialize the RBM parameters in GOA, as well as the number of candidate solutions,  $MIN_{CA}, MAX_{CA}$ , and maximum number of evaluations, before performing any analysis. A decrease in the repulsion area, comfort area, and attraction area is represented here by the parameter  $CA$ . The starting population is then generated at random, and using the objective function, each solution in the population is assessed.

2) *Step 2: assessment of fitness:* For each search agent, the fitness function is calculated and computed after initialization. For the sake of this study, we define fitness as the minimization of DBN's mean square error:

$$\text{Fitness} = \text{Min}_{\text{error}} = \frac{1}{E} \sum_{i=1}^E \left( \frac{P(x,y) - T_y}{T_y} \right)^2 \quad (10)$$

The mean square error denotes the average distance between the predicted and observed values.  $T_y$  and  $P(x, y)$  represent the target value for the appropriate data  $y$  and the estimated probability of the appropriate data  $x$ , respectively.

The RBM parameter is tuned using this algorithm to reduce the amount of error that occurs. Using a DBN for unsupervised pertaining and supervised fine tuning was the basis for the proposed method. GOA is used throughout the entire process of relating and fine tuning. The range of hyper-parameters in our model was identified by conducting random search experiments and then selecting their values at random until we achieved the best performance. It takes less time and effort to train a network using random search. Because not all hyper-parameters are equally important for tuning, random experimentation based on hyper-parameter values is more efficient.

3) *Step 3: updating:* Update the best target's position in each evaluation and factor  $C$  in this phase. In actuality, there is no goal because we don't know what the global optimum is or what the precise goal is. The target must be identified at each stage of the optimization process. During optimization in GOA, it is assumed that the fittest grasshopper is the target. Grasshopper must advance toward the good target in order for GOA to save it in search space during this iteration. Position and  $C$  updates are calculated as follows:

$$x_m^d = C \left( \sum_{n=1, n \neq m}^Z C \frac{d_{ub} - d_{lb}}{S} S(|X_n^d - X_m^d|) \frac{X_n - X_m}{d_{mn}} \right) + d_T \quad (11)$$

In the  $d$ -dimension,  $d_{lb}$  and  $d_{ub}$  denote the lower and upper bounds, respectively. The  $d$ -dimensional goal is  $d_T$ . The following formula can be used to determine the strength of social forces represented by the function  $S$ :

$$S(f) = g e^{-\frac{f}{r}} - e^{-f} \quad (12)$$

where  $g$  and  $r$  stand for the intensity of attraction and the length scale of attraction, respectively.  $C$  represents a decreasing coefficient that reduces the repulsion zone, comfort zone, and attraction zone. The GOA algorithm's primary governing parameter is  $C$ , which is kept current using the eq. 13 below.

$$C = \text{Max}_C - y \frac{\text{Max}_C - \text{Min}_C}{Y} \quad (13)$$

where  $Y$  denotes the most iterations possible and the current iteration is referred by  $y$ ,  $\text{Max}_C = 1$  and  $\text{Min}_C = 0.00001$ .

4) *Step 4: termination:* When the maximum number of iterations is achieved, the position is updated iteratively. Finally, the best objective was returned, with the global optimum being a combination of position and fitness. The GOA algorithm is used to figure out what the ideal value of DBN should be. Once DBN has classified the ckd or NOTckd, the process is complete. This means that the result from the classifier is either positive or negative. Below, the GOA algorithm 1 is illustrated and the steps are shown in "Fig. 6".

Line #	Algorithm 1: DBN optimized based on GOA algorithm
1	<b>Input:</b> candidate solution, $RBM$ parameters, $MAX_C$ , maximum # of iters, $MIN_C$ ,
2	<b>Output:</b> Optimal parameter combination
3	Set initialization of the candidate solution and random population of parameters of RBM
4	Set initialization of $MAX_C$ , maximum # of iters, $MIN_C$
5	Compute the fitness value $fit(i)$ for each individual agent using mean square error as fitness function
6	Set best individual search agent = $W$
7	<b>While loop</b> ( $Q < \text{max \# of iters}$ )
8	modify $C$ using eq. 3
9	<b>foreach</b> individual:
10	The current individual position is modified using eq. 2
11	reset the individuals above and below the bounds
12	<b>for end</b>
13	Updating $W$ to a better solution
14	$Q = Q + 1$
15	<b>while end</b>
16	Return $W$ as optimal

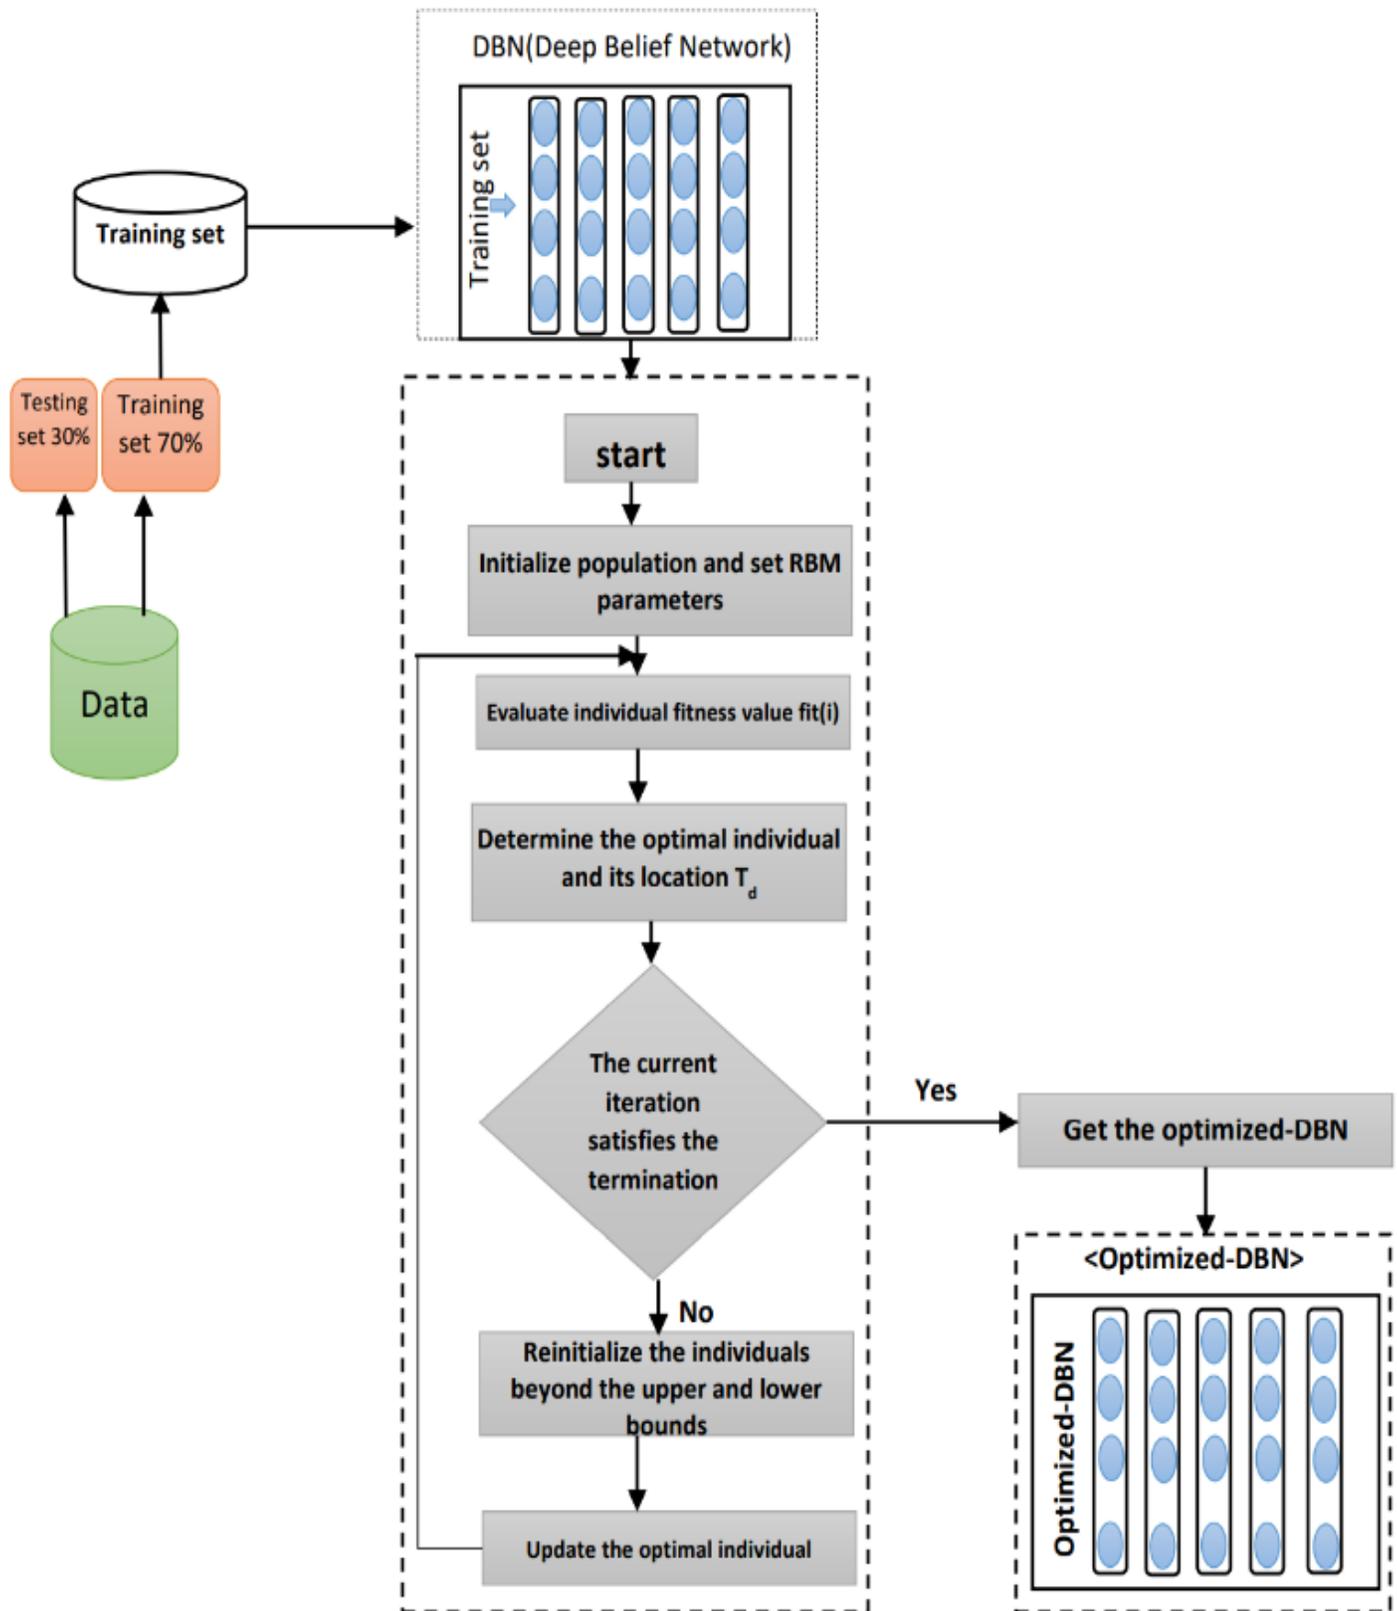

Fig. 6. DBN optimized based on GOA algorithm

## V. EXPERIMENTAL RESULTS

### A. Environmental Setup

The proposed model was developed in MATLAB 2016a, with some preprocessing done in Weka. MATLAB is a powerful data mining tool. Models and applications are built based on data analysis. A Core i7 machine with an NVIDIA graphics card is utilized for testing and assessments.

### B. Performance Metrics

In order to train the model, the data set is randomly divided into two parts, with the first portion containing 70% of all the total collection of data. The data from the second section is used for testing (30% of the time). The suggested model is evaluated and validated using six performance measures. Accuracy, precision, sensitivity, and F-Measure [34] are some examples of these parameters. By measuring performance measures, the confusion matrix describes the performance of categorization algorithms. The following measures were utilized in this study to evaluate the performance of the methodologies in use.

1) *True positive (TP)*: This indicates occurrences of positive outputs that have been appropriately classified.

2) *False negatives (FN)*: These are false negatives that are not actually false negatives.

When unfavorable outcomes are mistakenly labeled as positive ones, the term "False Positive" (FP) is used.

3) *False negative (FN)*: good events that were mistakenly labeled as negative in the report.

- **Accuracy**: An image's accuracy in a database is determined by how closely the image's coordinates match the database's real value. Accuracy measures are quite close to the genuine value, and they are processed as a true proportion of the outcomes:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (14)$$

- **Sensitivity (Recall)**: Sensitivity is a term used to describe the state of being sensitive. A test's sensitivity or recall refers to its capacity to correctly identify people who suffer from a certain illness (True Positive Rate). In this way, it can be stated:

$$\text{Sensitivity} = \frac{TP}{TP+FN} \quad (15)$$

- **Specificity**: When a test has high specificity, it can accurately identify people who do not have the condition (True Negative Rate). According to the definition, it is:

$$\text{Specificity} = \frac{TN}{TN+FP} \quad (16)$$

- **Precision**: Predictive Value (PPV) or Precision is a measure of the accuracy of a categorization result. The following is the formula used to arrive at this result:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (17)$$

- **F-measure**: According to this method, the harmonic mean of precision and recall is calculated as follow:

$$F - \text{Measure} = 2 \times \frac{\text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \quad (18)$$

### C. Performance Comparison

As a result of using a variety of feature selection methods, including filtering and wrapping, CKD diagnosis was improved. In all of the methods used, the original dataset can be reduced in dimension to produce a new dataset. Twenty-five different variables were included in the dataset that was used. The dataset was condensed down to 11 attributes using the DFS wrapper approach. On a smaller dataset, the optimized-DBN classifier was able to identify 2 FPs and 3 FNs. The value of FN in the Optimized-DBN classifier method is lower than the values of FN in the other methods. When compared to the current system, the proposed combination of Optimized-DBN and unsupervised training has better accuracy than other research work. Layers (visible layer, hidden layer, and output layer), nodes, and weights and biases for the layers were used to develop the final architecture of Optimized-DBN. Our competitors' quantitative measures are compared to ours in this section. Table III represents the different performance evaluation metrics, i.e., accuracy, f-measure, precision, and sensitivity for the proposed system DFS-ODBN and other different related methods.

A sensitivity and accuracy analysis of the proposed DFS-ODBN technique is shown in Fig. 7. As shown in the figure, the FDS-ODBN technique has improved in both sensitivity and precision.

TABLE III. PERFORMANCE METRICS FOR PROPOSED SYSTEM AND OTHER SYSTEMS

Methods	Results(%)			
	Sensitivity	Precision	F-measure	Accuracy
Shrivastava, Sahu and Hota [11]	94.00	95.14	94.57	93.25
Rady and Anwar [14]	95.61	95.98	95.79	94.75
Rubini and Perumal [16]	91.61	92.33	91.97	95.00
Elhoseny et al [18]	96.00	96.46	96.00	95.00
Chittora et al [20]	98.00	96.67	98.31	98.86
M.M. Hossain [22]	99.43	99.82	99.60	99.50
Proposed model	99.63	98.81	99.63	99.70

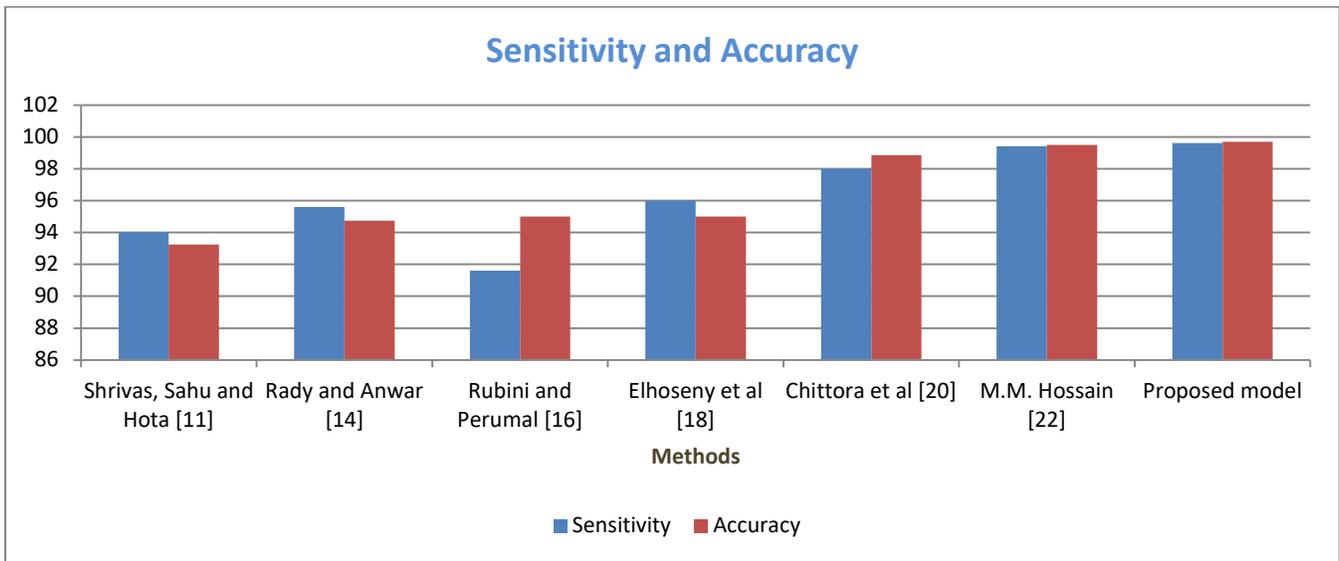

Fig. 7. Evaluation metrics (sensitivity and accuracy) Vs. classifiers

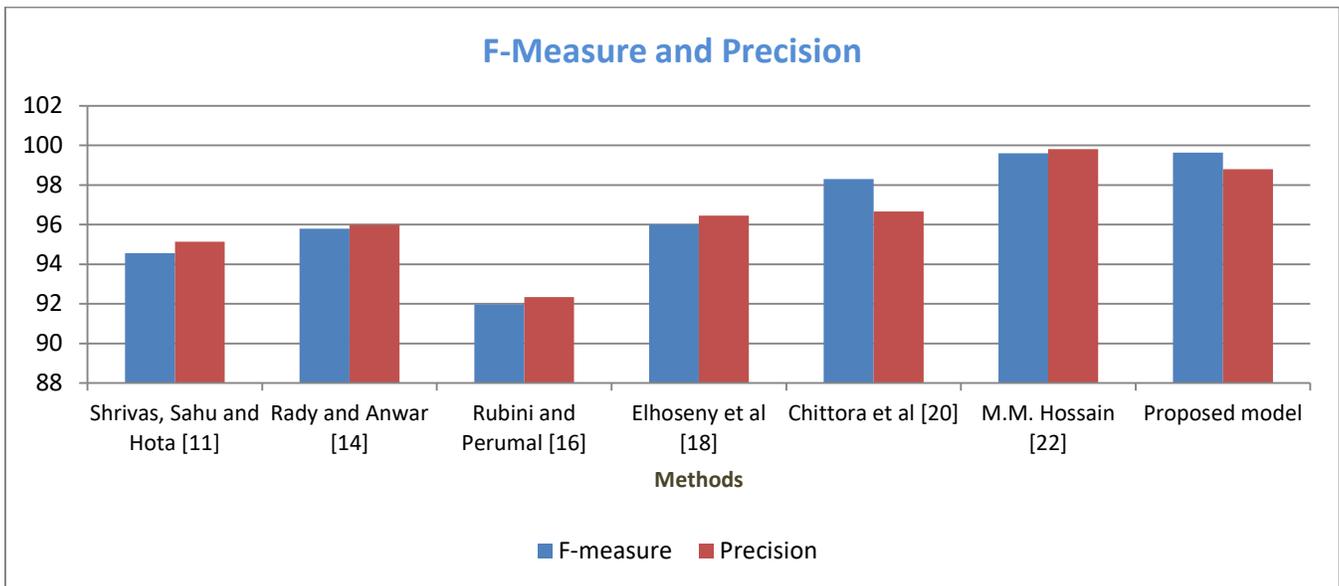

Fig. 8. Evaluation metrics (F-measure and precision) Vs. classifiers

This method is, 4.7 percent more accurate than [16]. 6.52 percent more accurate than [11]. percent more accurate than [14]. 4.7 percent higher [18] and 1.1 percent higher [20].

F-measure and precision analysis are shown in Fig. 8 in terms of the feature selected for the proposed technique DFS-ODBN. According to the graph, the FDS-ODBN technique now has higher precision and precision values. In terms of precision, this method is 3.66308 percent higher than [11], and 2.82084 percent higher than [14]. The proposed method is 6.46607 percent higher [16] and 3.364 percent higher [18] in terms of the F-measure.

## VI. CONCLUSION AND FUTURE WORK

The study looked at the classification of medical data in order to identify the patient's disease at an early stage of development. The most difficult part of classifying medical

data is selecting the best subset of attributes from the dataset under consideration. A DFS feature selection algorithm was used to select the best features from a preprocessing stage in which the missing values were eliminated. Based on the presence or absence of CKD, the dataset was divided into two classes: the ckd class and the NOT ckd class. The Deep Belief Network algorithm was used for this classification because it is the best method for data classification. It was necessary to use the GOA algorithm in order to obtain the DBN network hyperparameters. GOA has strong capabilities to explore the search space and it benefits from high exploration and exploitation.

Furthermore, the classification issues can be overcome with an average computational cost. Using CKD datasets, Optimized-DBN was able to achieve its maximum performance in terms of sensitivity, accuracy, and specificity. When compared to other techniques, the proposed DFS-ODBN

demonstrated accuracy of 99.75 percent. In the future, with algorithms designed or prediction techniques, the data classification can be enlarged and missing values can be removed by new imputation approaches, classification, and prediction. The development of hybrid and novel optimization algorithms for the classification of medical data and feature selection is recommended as a focus for future contributions

**Abstract**—Natural Language Processing, specifically text classification or text categorization, has become a trend in computer science. Commonly, text classification is used to categorize large amounts of data to allocate less time to retrieve information. Students, as well as research advisers and panelists, take extra effort and time in classifying research documents. To solve this problem, the researchers used state-of-the-art supervised term weighting schemes, namely: TF-MONO and SQRTF-MONO and its application to machine learning algorithms: K-Nearest Neighbor, Linear Support Vector, Naive Bayes Classifiers, creating a total of six classifier models to ascertain which of them performs optimally in classifying research documents while utilizing Optical Character Recognition for text extraction. The results showed that among all classification models trained, SQRTF-MONO and Linear SVC outperformed all other models with an F1 score of 0.94 both in the abstract and the background of the study datasets. In conclusion, the developed classification model and application prototype can be a tool to help researchers, advisers, and panelists to lessen the time spent in classifying research documents.

**Keywords**—Text classification; supervised term weighting schemes; optical character recognition; machine learning algorithms

## I. INTRODUCTION

Writing and publishing have taken popularity on the internet using online services where text classification plays an important role [1]. An example where text classification can be applied is in the increasing amount of published research documents online or offline due to the advancement of computer and information technologies [2]. Documents, in this case, refer to textual records, and each copy contains a group of words that ranges from sentence to paragraph long. It is through the use of text classification, the prediction and classification of documents can be made possible by categorizing them into which class they belong based on their inherent properties [3].

While there are many ways to classify research papers online, there is also a need to categorize those with only physical copies. Approved research papers refer to peer-reviewed and panel-evaluated complete research in local school libraries. Additionally, research papers still in the proposal period are subject to revisions and need to be more

easily distinguishable whether they are suitable for the course. Moreover, classifying large documents is time and energy-consuming [4]. For such reasons, it is necessary to make a tool that efficiently organizes approved and work-in-progress research papers individually or in bulk.

In this study, to classify research documents, first, OCR will be used. Optical Character Recognition (OCR) acquires an image through the use of a device, usually a camera or scanner, and then converts it to digital text [5][6][7]. Then, supervised term weighting schemes are applied to assign a weight for each term in every document, enhancing text classification performance [8]. The documents will be assigned to their designated classes using different machine learning algorithms [9].

The researchers came up with the idea to design a classification model using different combinations of supervised Term Weighting Schemes (TWS) and Machine Learning Algorithms, as well as prove which combination of Supervised TWS and Machine Learning algorithms is the fastest and yields the results with the highest accuracy for classifying our dataset. Finally, this study will develop an application that will use the designed classifier model to categorize research papers while allowing users to import text images or use the device's camera for text image acquisition.

The subsequent sections of this paper cover various important aspects of the study, including: a literature review on text classification, OCR, term weighting schemes, and machine learning algorithms in Section II, an in-depth examination of the research methods used in the study in Section III, a presentation of the results and discussion of the findings in Section IV, and a conclusion summarizing the key takeaways and recommendations for future research in Section V.

## II. LITERATURE REVIEW

In this section, we present a comprehensive review of relevant literature pertaining to this study. This includes a detailed examination of research on Text Classification, Optical Character Recognition (OCR), Weighting Schemes, and various machine learning algorithms. The sub-sections will thoroughly understand the field's current state and serve as a foundation for this research.

### A. Text Classification

Text classification or also known as text categorization, is a technology for information organization and management wherein it has been proven to be effective and efficient [10]. In natural language processing, text classification is a crucial task and has been its foundation. Over the years, numerous research in this area has been published due to the unprecedented success of deep learning [11].

Through the use of the term frequency-inverse document frequency (TF-IDF), Latent Dirichlet Allocation (LDA), and K-Means clustering, [2] designed a research paper classification model wherein it classifies and clusters similar papers based on its abstract. First, a keyword dictionary which contains groups of keywords that have similarity in meaning, is constructed into one representative keyword or topic. However, yielding results will still cause high running time. In order to solve this problem, they used LDA to extract topic sets before calculating the word and document frequency using TF-IDF. Then, the set of data is classified into classes based on their similarity using K-means clustering, a clustering technique used to minimize distances between every data point and the nearest cluster or centroid. Finally, to evaluate the accuracy of their classification system, they used F-score, an evaluation metric used in text classification, combining precision and recall values.

### B. Optical Character Recognition

Over the past few decades, the area of pattern recognition has been a topic of study which is known as Optical Character Recognition. For many diverse styles of programs in different fields, Optical character recognition is the bottom of it, which we use in our daily life. These days, Optical Character Recognition is being used in many different areas of research [12][13].

P. Divya et al. (2021) developed a web-based optical character recognition application using flask and tesseract [14]. Their website allows users to upload image format data and convert it into machine-editable text in a fraction of a second. It can also read and convert handwritten data with a slightly lower accuracy compared to digitized text. Their OCR model has been proven to be accurate by testing a combined handwritten and digitized test set of 1000 images. In their study, they found that the best input that their system can convert to text is digitized black and white with an accuracy rate of 98%.

### C. Supervised Term Weighting Scheme

The selection of an appropriate term weighting scheme is important in text classification tasks as it has significant effects on its performance. Term Weighting Schemes (TWS) determine how texts would be represented in the vector space model. The terminology Supervised Term Weighting Schemes have been gaining popularity in the recent years while term frequency-inverse document frequency (TF-IDF) is still widely used. But its disadvantage is that it does not train text using the available categories [15][16] and is considered an unsupervised term weighting scheme, unlike the state-of-the-art supervised term weighting schemes: TF-IGM and TF-MONO.

Most of the popular novel supervised TWS focuses on assigning weights based on how the terms occur throughout the classes, which is a proven and effective method in term weighting. However, Dogan and Uysal (2020) believed that this information may not be enough to determine the terms' power in the document [17]. They proposed the novel STW scheme Term Frequency Max-Occurrence and Non-occurrence (TF MONO), which makes use of the non-occurrence information along with the max-occurrence information of terms in the document.

TF-MONO is a supervised TWS that uses the class with the max-occurrence as well as the non-occurrence information in the document frequency. The procedure of the MONO TWS is represented in Fig. 2. Fig. 1 illustrates the MONO TWS designed by [17] separated into seven (7) steps, and visualized by [18][19], which will be further explained in details.

The steps for performing MONO on a text collection are as follows:

- 1) Sort the document frequency of a term in descending order.
- 2) Divide the sorted document frequency into two groups: one for the highest class document frequency values and the other for the rest of the classes.
- 3) Represent the first group with a max-occurrence (MO) ratio and the second group with a non-occurrence (NO) ratio.
- 4) Calculate the MO ratio as the ratio between the quantity of text documents in the class where the term occurs most and its total quantity of text documents.
- 5) Calculate the NO ratio as the ratio between the quantity of text documents in the rest of the classes where the term does not occur and the total quantity of text documents in the rest of the classes.
- 6) Calculate the product of MO and NO ratios and assign it as the MONO (Local) weight of the term.
- 7) Calculate the MONO (Global) weight of the term by using the MONO (Local) weight and a balance parameter  $\alpha$  with a default value of 7.0.
- 8) Finally, two (2) term weighting schemes based on MONO (Global) collection frequency factor are shown.

### D. Machine Learning Algorithms

As the internet expands, the number of unorganized data is also increasing. Thus, intelligent programs that use machine learning in classifying documents have been researched and developed to efficiently access information. Some of the machine learning techniques used for document classification include Naïve Bayes, Support Vector Machine, Decision Trees, etc. [20]. A. Barua et al. (2021) used the most common machine learning methods, namely: Logistic Regression, Support Vector Classifier, Decision Tree(C4.5) [24], Naïve Bayes, Random Forest, and K-Nearest Neighbor, to classify articles about sports into four (4) different categories: Cricket, Football, Tennis, and Athletics. 80% of the data were used for training, while the other 20% were for testing [21]. Using F1-score for evaluation, the result shows that the "Cricket" category has the highest F1 value as it has the most data used

for training among all the classes. Meanwhile, the category with the lowest F1 value is “Athletics” due to its low number of training data. Regarding the machine learning models, Naïve Bayes has the best performance (98.53%) for identifying documents in the cricket class with unigram + bigram + trigram feature while KNN has shown poor performance on an imbalance dataset.

### III. METHODOLOGY

This section outlines the key components integral to the research study, which employs machine learning models for data analysis. These include the data sources, research design, data collection and preprocessing techniques, machine learning models, evaluation metrics, and the application simulation used to test the models. All these components work together to provide a comprehensive framework for conducting a thorough and systematic study, utilizing machine learning models to extract insights from data, and evaluate the performance of the models. The research framework and its implementation are illustrated in Fig. 1, providing a clear understanding of the methodology adopted in the study.

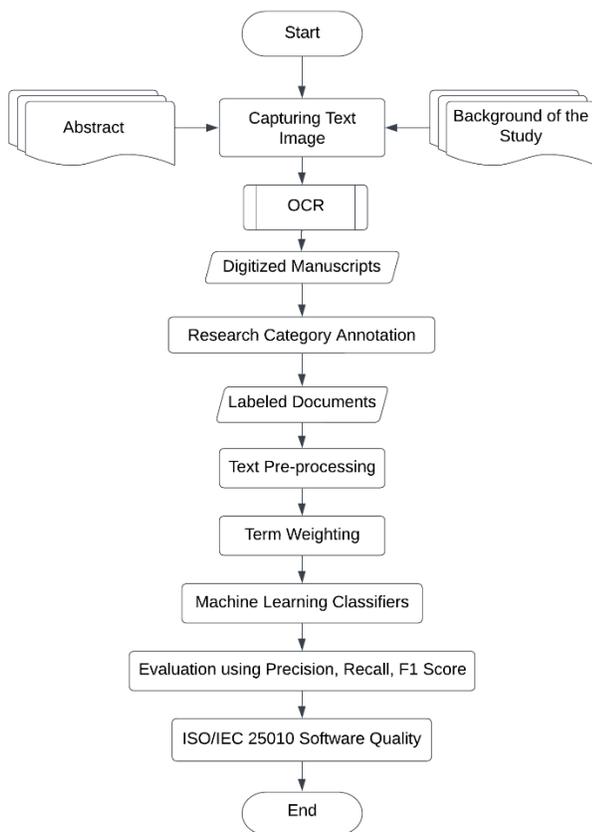

Fig. 1. Framework of the study

The *components* in the framework of the study includes the following:

#### A. Data

The data used in this study is gathered from the Abstract and Background of the Study (BOS) of research documents from ACLC College of Butuan, Saint Joseph Institute of Technology, and Caraga State University. A total of 462

research documents were gathered from the mentioned local schools. To address the lack of data, the researchers used online websites as a source of additional data, with a total of 519 research documents. However, the dataset is still imbalanced, with the feasibility study having only 99 documents. In order to make the dataset unbiased, oversampling is performed on the feasibility study, adding 99 more documents. Overall, there are a total of 1,121 research documents with four (4) categories: Capstone (313), Thesis (306), Case Study (304), and Feasibility Study (198).

#### B. Converting Research Papers to Image Format

Research papers acquired online are in .pdf image format. However, numerous research papers from local schools are not digitized. Therefore, it is necessary to capture images of the research documents' title, abstract, and background of the study, the parts of a research document necessary to be used as our data. The image format of the said images is .jpeg and can still be converted to digital text through OCR.

#### C. PyTesseract OCR

The images were processed one by one through a python script that utilizes PyTesseract, a well-known python Optical Character Recognition library, to convert text images into a digital format. This library allows for accurate and efficient conversion of images to text, making it an ideal choice for this task. The script iterates through all the images, performs the conversion and saves the digital text in a file, ready for further analysis.

#### D. Labeling Research Categories

The converted texts were then placed in a csv file for easy access and organization. The Pandas python library was used to facilitate this process, as it allows for efficient manipulation and storage of large datasets. Each text was labeled manually by researchers according to its predefined category to aid in the analysis and classification process.

#### E. Pre-Processing

Text pre-processing is an integral part of text classification as it can improve the overall quality of a dataset. It can clean the dataset by removing unneeded parts of the text, such as repetitions and spelling errors [22]. Text pre-processing includes four (4) basic processes: tokenization, stop words removal, stemming, and vector space model [23]. Tokenization involves the removal of spaces and taking unique words from the document. Stop word removal is the process of removing stop words which are prevalent words with little to no meaning in the document. Stemming converts all of the words in the document into their root words to reduce the unique words in the document. Vector space modeling, also known as vectorization or term weighting, assigns weight to unique words. To prepare the dataset for this study, the researchers preprocessed the text in the following order:

1) Removing all punctuations and transforming all characters to lowercase to standardize the text and make it easier to work with.

2) Tokenization was applied to split the text into multiple words which makes it more manageable for analysis.

3) Stop words were removed as they do not carry any significant meaning for the analysis.

4) Filtering the features by length was done to remove random words that hold no meaning, this helps to reduce the noise in the dataset.

5) Stemming was applied using Porterstemmer which reduces words to their base form, this helps to group similar words together, and enables better analysis.

These steps helped to clean the dataset, making it more organized and ready for the analysis. The preprocessing steps not only standardize the text but also make it more manageable and focused for analysis, which ultimately results in more accurate and meaningful results.

#### F. Term Frequency Distribution

In order to apply any term weighting scheme, it is crucial to first calculate the term frequency (TF) of each term in the dataset. This provides an understanding of the significance of each word across all documents in the dataset. However, simply counting the term frequency does not take into account other important factors, such as the occurrence of specific terms in certain categories. As a result, it is necessary to consider additional information to accurately calculate the weight of each term.

#### G. Supervised Term Weighting Scheme

Supervised Term Weighting Schemes such as TF-MONO and its square root variant, SQRT TF-MONO was used to assign weights to each term in the dataset. This helps to improve the performance of text classification by transforming the text in documents into vectors in the vector space (Feng et al., 2018). A balance parameter  $\alpha$  with a value of 6.0 was introduced to compute the global term weight value for each term.

#### H. Machine Learning Algorithms

The researchers utilized state-of-the-art machine learning algorithms to categorize the dataset. The data was split into two (2) sets: 70% for training and 30% for testing. The researchers then applied three (3) machine learning algorithms, namely Naïve Bayes, K-Nearest Neighbors, and Linear Support Vector Classifier, in combination with supervised term weighting schemes to compare their performance. The aim was to identify which combination of algorithm and term weighting scheme yields the best results.

#### I. Evaluating the Classification Model

The classification model's performance will be evaluated by calculating precision, recall, accuracy, and F1 score.

Precision - measures how many positive predictions are correctly predicted.

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (1)$$

Recall - measures how many true positive cases the classifier correctly predicted over the total number of positive case.

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (2)$$

F1 Score – measures by combining both recall and precision. Also known as the harmonic mean of the two, calculating their average.

$$F1\ Score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (3)$$

#### J. Application Simulation

The researchers chose to use Python as the primary programming language for the back-end of the study due to its interactive, object-oriented, and high-level nature. Additionally, Python offers a wide range of available modules and libraries, including the Scikit library, which makes it simple, flexible and dynamic in functionality. This made it an ideal choice for the implementation of the study, including the development of the REApp application. Furthermore, Python is a popular choice among researchers and developers because it is easy to learn, has a large community support, and is widely used in various applications such as web development, machine learning and data analysis.

#### K. ISO/IEC 25010 Software Quality

This software application will be evaluated in accordance with the ISO/IEC 25010 Software Quality standards, which provide internationally recognized guidelines for assessing the quality and performance of software systems.

## IV. RESULTS

The researchers conducted an evaluation of the effectiveness of PyTesseract OCR by selecting sample images of abstracts and backgrounds of the study from various research documents in their dataset. They performed OCR on the images and pre-processed the data to clean it.

Fig. 2 illustrates the visual representation of the abstract of a thesis titled "Safewatch: A Quarantine Symptom-Monitoring Web Application with Knowledge Discovery Using Apriori Algorithm and Naïve Bayes Classifier" and the results obtained after performing OCR on it.

Fig. 3 illustrates the visual representation of the background of the study for a capstone project titled "Barangay Information System with Decision Support System of Barangay Baan km.3 Butuan City" and the results obtained after performing OCR on it.

Fig. 4 shows the results of the pre-processing techniques employed in the extracted text of abstract and BOS. Table I illustrates the five terms with the highest frequency in the abstract dataset, along with their respective occurrences in each category.

Fig. 5 presents a word cloud comprising 200 of the most frequently occurring terms in both the Abstract and BOS datasets, arranged from left to right.

Table II presents the global factor term weights of the most frequently occurring terms in both the Abstract and BOS datasets. These values are generated from the computed results of the MONO Global method, taking into account an alpha value of 6.0. These global values will be multiplied with the term frequency if TF-MONO is to be calculated and the square root of the term frequency if SQRTF-MONO is to be calculated. It can be seen that the feature "system" has the

highest global weight of 0.029, indicating its prevalence in the abstract dataset. In contrast, the feature "custom" - which likely refers to stemmed customers - occurs more frequently in the BOS, suggesting that it is more prevalent in this dataset.

Table III displays the precision and recall scores for various combinations of term weighting schemes and machine learning algorithms used in this study for the Abstract dataset. The results indicate that the model using the squared root of TF-MONO trained with LinearSVC consistently performed the best, with a precision of 0.94, recall of 0.94, and F1 score of 0.94. However, as shown in Table 4, the SQRT TF-MONO model trained with MultinomialNB achieved slightly higher precision and recall scores, with values of 0.91 and 0.86, respectively. Additionally, the F1 score of the LinearSVC model still outperformed the classification performance of all five other trained models.

The researchers evaluated the application by conducting a survey that adhered to the ISO/IEC 25010 Standards. Twenty-five (25) participants completed the survey, comprising 15 questions divided into sections, each containing a minimum of 3 and a maximum of 4 questions. The results, displayed in Table IV, show the average percentage of responses for each

section and are rated on a scale of 5 to 1, with 5 indicating strong agreement and 1 indicating strong disagreement.

## V. DISCUSSIONS

The researchers developed an application that can classify the category of imported research papers based on four predefined categories. The application uses OCR to read text on image or pdf files and supports the classification of single or multiple research papers, and minor inaccuracies are seen in Fig. 2 and 3. Pre-processing was done in five steps to alleviate this problem, and the results are shown in Fig. 4, along with the topics extracted from the research document. The number of occurrences of each word was shown in Table I to prove the relevance of the words to each category. The results generated in Tables III and IV show that all combinations of supervised term weighting schemes and machine learning algorithms have high F1 Scores. According to the survey results, the majority voted "strongly agree" on all characteristics of ISO/IEC 25010 Standards Characteristics (see Table V). The study determined that the developed application could perform its intended functions and has met the ISO ISO/IEC 25010 Standards Evaluation Metric.

### ABSTRACT

The implementation of knowledge discovery, commonly referred to as data mining, has been considered a latent solution for the containment of the COVID-19 pandemic. The proponents developed a prototype symptom-monitoring web application as a helping tool for the concerned individuals who may have been exposed to COVID-19. By integrating Apriori Algorithm and Naive Bayes Classifier; Apriori Algorithm to mine association rules to predict the following occurring symptom based on confidence percentage, and Naive Bayes Classifier to analyze and predict the individual's risk exposure based on her/his details, the prototype system discovered that the highest risk exposure with 64% was if the individual was working on the frontline (frontliner) and the hroat are the common sequence of symptoms such as fever, cough and sore t indication with 56% confidence of risk exposure. The system aimed to address the alarming concern of being exposed to the virus due to manual monitoring, offer a platform for the individuals to track their symptoms within the entire seven-day monitoring course and produce data-driven predictions to give insights about the risk level of COVID-19 exposure. The proponents believe that with intensive research using sufficient data and the right tools for development, the prototype can become a potential tool to aid the community and healthcare organizations.

### ABSTRACT

## VI. CONCLUSION

The researchers were able to develop the classification model and application to eliminate the inconvenience and lessen the time consumption on classifying research documents for Students and Instructors. To identify which supervised term weighting scheme and machine learning algorithm can be best paired considering the evaluation metrics of each combination, the researchers used state-of-the-art supervised term weighting schemes and machine learning algorithms to simulate a classification on gathered dataset. As proven by the experiment results, the combination of SQRT TF-MONO and Linear SVC has the highest precision and recall values, and most importantly, F1 Scores of 0.94 both for the abstract and the background of the study datasets and, therefore, should be used as the classification model to classify research documents. Moreover, the researchers have developed an application prototype where users can import and classify research papers in bulk using the developed classification model. An ISO/IEC 25010 standards survey is conducted, and according to the results, most of the respondents have responded positively.

Finally, the researchers have concluded that the application can be helpful for research advisers, panelists, and reviewers

to speed up the classification time by categorizing multiple research papers at once instead of reading and manually analyzing them. Lastly, the researchers believe that the study can be improved in the future.

## ACKNOWLEDGMENT

The authors would like to express their sincere appreciation to Mr. Junell T. Bojocan of the Computer Education Department for his invaluable support in the BS Computer Science program, as well as to Mr. Gabriel Adolfo C. Malbas of the Research Extension and Innovation Department of ACLC College of Butuan for his generous financial support. The authors recognize the instrumental role of their contributions in completing this study.

**Abstract**—The mining of concealed information from databases using Association Rule Mining seems to be promising. The successful extraction of this information will give a hand to many areas by aiding them in the process of finding solutions, economic projecting, commercialization policies, medical inspections, and numbers of other problems. ARM is the most outstanding method in the mining of remarkable related configurations from any groups of information. The important patterns encountered are categorized as recurrent/frequent and non-recurrent/infrequent. Most of the previous data mining methods concentrated on horizontal data set-ups. Nevertheless, recent studies have shown that vertical data formats are becoming the main concerns. One example of vertical data format is Rare Equivalence Class Transformation (R-Eclat). Due to its efficacy, R-Eclat algorithms have been commonly applied for the processing of large datasets. The R-Eclat algorithm is actually comprised of four types of variants. However, our work will only focus on the R-Diffset variant and Incremental R-Diffset (IR-Diffset). The performance analysis of the R-Diffset and IR-Diffset algorithms in the mining of sparse and dense data are compared. The processing time for R-Diffset algorithm, especially for sequential processing is very long. Thus, the incremental R-Diffset (IR-Diffset) has been established to solve this problem. While R-Diffset may only process the non-recurrent itemsets mining process in sequential form, IR-Diffset on the other hand has the capability to execute sequential data that have been fractionated. The advantages of this newly developed IR-Diffset may become a potential candidate in providing a time-efficient data mining process, especially those involving the large sets of data.

**Keywords**—R-Diffset; IR-Diffset; dense data; sparse data; comparison analysis

## I. INTRODUCTION

The main objective of data mining (DM) is the process of identifying patterns for useful information in large data repositories [1-3, 36, 26, 30]. It plays a key role in the oversized data approach to acquire meaningful knowledge from a complex system. The approach includes collaborative studies in statistics, machine learning, data science, and database theory. Its goal is to learn about the past or predict the future by studying the present data. In addition, this approach, also known as "Knowledge Discovery in Databases" (KDD), focuses on finding patterns in databases, resulting in an association rule that may disclose important information. Some common patterns are found in the databases, such as clusters, sets of items, trends, and outliers [4]. In data mining, there are two types of tasks: prediction tasks and descriptive tasks. The prediction tasks attempt to determine the value of one attribute

depending on the value of another. These tasks incorporate techniques like statistics, categorization, regression, and forecasting [19]. Meanwhile, the descriptive tasks are to generate patterns in the database in order to extract the underlying relationships [29]. Some of the patterns generated are anomalies, clusters, correlations, and trends. Clustering, summarizing, association rules, pattern identification, and sequence discovery are some of the approaches used in this task [22]. There are two types of itemset mining in the database: frequent itemset and infrequent itemset. From the records of the previous studies, in frequent itemset mining, there are three well-known algorithms: Apriori [5, 6, 32], FP-Growth [7], and ECLAT [8, 18]. This research focuses on the vertical format by looking deeper into the equivalence class transformation (ECLAT) algorithm [8]. Tidset, Diffset, Sortdiffset, and Postdiffset are four extension variations introduced in ECLAT. In 2018, Jusoh et al. [9-10] introduced the R-ECLAT algorithm, particularly useful for mining infrequent itemsets. This algorithm is based on the ECLAT algorithm for mining infrequent itemsets [11-13]. In previous research, the R-Diffset was developed and executed in sequential processing for infrequent item mining as an extension of the Diffset algorithm. However, the current execution of data processing often faces the constraint of slowness, especially when dealing with large datasets.

In 2022, Man et al. [19-20, 27, 43] introduced a new incremental of rare pattern mining approach using R-Eclat named as Incremental Rare Equivalence Class Transformation, (IR-Eclat). The IR-Eclat, which was created especially for mining rare patterns is advantageous for dynamic databases because the volume of data increase linearly with time. For dynamic databases that are subject to the addition or deletion of items or records of transactions in the database, the incremental approach is advantageous. To apply mined knowledge of previously and scanning of a basic incremented database, it is necessary to use implementation of incremental mining.

An incremental approach is a new approach that has been executed sequentially on the splitted data. This incremental approach will complement the IR-Diffset algorithm to ensure that it can mine the infrequent itemsets faster. This new approach is introduced as IR-Diffset, where IR represents incremental-rare. As part of the R-Diffset algorithm, this study introduces an incremental approach to deal with the processing time issue. To simplify, this research is significant in determining the following aspects: How to reduce speedy processing time in mining infrequent pattern especially in huge dataset? The rest of the components are then organized as

follows: Section IIA discusses sparse and dense data. The basics of mining rare items are covered in Section IIB. R-Diffset and IR-Diffset are described in Section III. Section IV clarifies the discussion of the study. The study's results and the discussion are also described in Section IV. The research was concluded in Section V.

## II. RELATED WORKS

This section concerned on discussion regarding database, data mining and infrequent itemset mining. A database is known as a structured collection of data, dataset or record. It can be effortlessly rapid accessed, managed and updated data in conjunction with various data processing operations. Data mining is the process of extracting useful unknown knowledge from large datasets. However, mining infrequent (rare) itemsets may be more interesting in many real-life applications. However, this section also covers about sparse and dense data.

### A. Sparse vs Dense Data

Sparse data is a matrix [14] in numerical analysis, where the majority of the elements are zero. This section will discuss about sparse data, which are quicker to be processed and figured, compared to dense data. Although the number of zero-valued elements are not specified for a sparse matrix, the number of non-zero elements are standardized to be equal to the number of rows or columns, due to their similarities. However, if most of the elements are non-zero, the matrix will be identified as dense. The sparsity of a matrix is calculated by dividing the zero value elements with those of non-zeros (e.g.,  $p \times q$  for a  $p \times q$  matrix) [15]. The sparse matrix can be described in the following ways: array and linked list representation. In the array representation, the 2D array can be used to represent a sparse matrix in which there are three elements named as follows:

- Row: a row index containing a non-zero element.
- Column: a column index containing a non-zero element.
- Value: The non-zero element's value is placed at the index (row, column).

A sparse matrix is applied in linked list to portray the list of data structures. While there are three elements in the array representation (i.e., row, column, and value), the linked list representation on the other hand, comprises of four elements. The elements in the linked list are as follow:

- Row: a row index containing a non-zero element.
- Column: a column index containing a non-zero element.
- Value: The non-zero element's value is placed at the index (row, column).
- Next node: It records the next node's address.

When storing and processing sparse matrices on a computer, it is preferable to utilize specific algorithms and data structures that take advantage of the matrices' sparse structure. Sparse matrices, which are common in machine learning, have given rise to specialized computers. When applied to vast sparse matrices, typical dense-matrix structures and techniques

are sluggish and ineffective, as computation and storage are squandered on the zeros.

Sparse data compresses more effectively and hence take up less storage space. Some outsize sparse matrices are unmanageable using typical dense-matrix techniques.

The matrix *sparsity* is like density of zero elements in the sparse matrix and is defined as the number of zero elements divided by total elements in the matrix, which computed as:

$$\text{sparsity} = \frac{\text{number of zero elements}}{\text{number of total elements}}$$

The sparsity of a sparse matrix is always greater than 0.5.

In a dense matrix, most of the elements are non-zero. The dense matrix can be stored in a fixed-size array.

The sparse matrix, on the other hand, recorded only non-zero elements in a dictionary mapping an index  $(i, j)$  to its entry. As a result, you should only describe a matrix as sparse if the number of non-zero elements is relatively tiny in comparison to the total number of entries. This is generally advantageous if the non-zero elements are large (there are about  $n$  non-zero entries compared to about  $n^2$  zero entries). However, generating dense matrices is usually faster for extremely tiny matrices (e.g.,  $5 \times 5$ ), even with a large number of zero entries.

Fig. 1 depicts the characteristics of sparse and dense data. Dense data is the nature of the data itself, which is dense, which causes it to be slow. The data is dense and takes up a lot of space, and it is extremely difficult to process. In order to find other data using the dense data, it must first check each column one by one; without skipping a column. Sparse data indicates the nature of the data itself, which is sparse. Processing time for sparse data is faster compared to dense data because sparse data is not dense or compact; in the sparse data column, there is still an empty space, so processing the data will be faster and will not glitch in comparison to the dense data.

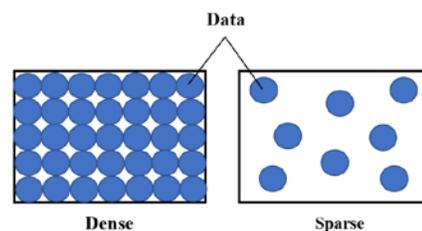

Fig. 1. Features of data-sparse and data-dense.

The theoretical background for sparse and dense data has been thoroughly discussed in this section. The next section will focus on one of the infrequent itemset mining.

### B. Infrequent Item Set Mining

Up to this date, the mining of non-recurrent data have been considerably developed. Non-recurrent or infrequent patterns are usually utilized in many disciplines such as biology, health, and security. In medical sector, the analysis of clinical conditions of patients are carried out to detect irregular patterns

or trends. The results will help the medical officers in deciding the needed treatments or prescriptions.

Infrequent itemset mining from a database is not as prominent as frequent itemset mining [39-40]. However, there are few areas where infrequent item mining is more applicable than frequent item mining [16]. The objective of IIM is to discover unusual, but informative, relationships between entries in a dataset. In [16] the concept of itemset for frequent pattern mining, were established based the pattern mining concept. The set of items were denoted as  $I = \{I_1, I_2, \dots, I_m\}$ . The itemset  $I$  will be accounted as frequent if and only if the occurrence frequency in the database equals or exceeds the minimum support threshold defined by the users [24-25]. In contrast, infrequent itemset mining requires that the frequency of occurrence in the database be equivalent to or lesser than the user-defined minimum support threshold. But, if the threshold is too low, infrequent itemset mining using the traditional frequent itemset mining method could be unsuccessful [33].

Infrequent itemset mining are receiving tremendous concern principally in the fields of networking and medicine. In networks, it is used to investigate any atypical incidences in any networks which are usually indicators of network breakdown or security breach. In medical, infrequent itemset mining may assist for the discovery of treatments for uncommon cases. The objective of infrequent itemset mining is to mine patterns with a support value smaller than the minimum threshold [34, 35]. Yet, the process of extracting rare patterns from the database, appears to be challenging.

In 2019, Man et al. [4, 28] proposed algorithm to address the discovery of infrequent itemsets mining from the transactional database based on Eclat algorithm. In support measure, IF-Diffset was proved to perform better upon encountering the infrequent itemsets of the transactional database.

An algorithm for extracting infrequent itemsets from weblog has been introduced by Bakariya et al. in 2019 [17]. Infrequent Itemset Mining for Weblog (IIMW) algorithm is a phased, top-down, broad-first algorithm for the recovery of infrequent item sets. A power set and lattice traversal approach had been utilized for this purpose. This approach followed the top-down mechanism, begun from top and carried out down to the bottom. By applying this approach, the computation of support for smaller itemsets were simpler than the larger itemset. This problem has been acknowledged as the challenges for the further application of this method.

To overcome the above-mentioned obstacles, Lu et al., later in 2020, [42] suggested an infrequent pattern mining algorithm using a top-down and depth-first traversing strategy. A negative itemset tree was applied to speed up the mining procedure, by compressing the datasets for a quicker counting process. Their itemset miner, denoted as NIIMiner had been verified to solve the problems of rare itemset mining.

In 2021, Darrab et al. [21] performed an extensive search of latest methods of rare itemset mining. It has been done by inspecting another efficient data structure with mining rare itemsets, the mining of most interesting rare itemsets, as well

as the mining rare of itemsets with multiple minimum support thresholds.

In 2021, Abu bakar and his fellow researchers [31, 37] developed a performance enhancement in Incremental Eclat (iEclat) model by embedding Critical Relative Support (CRS) in the mining of infrequent itemset. This was done in line to the increment of itemsets which produced higher cardinality of intersection between each item hence required the method of vertical mining.

In 2022, Cui et al. [41] introduced a novel fuzzy-based rare itemset mining algorithm called FRI-Miner, and successfully discovered valuable and interesting fuzzy rare itemsets in a quantitative database by applying fuzzy theory with linguistic meaning. The established algorithm was a success and has been shown to have an improved overall mining quality compared to the existing algorithm.

The previous paragraph of this section summarized the latest algorithm for infrequent itemset mining which are infrequent itemsets mining from the transactional database based on Eclat algorithm [4], Infrequent Itemset Mining for Weblog (IIMW) algorithm [17], Incremental Eclat (iEclat) model by embedding Critical Relative Support (CRS) in mining of infrequent itemset [31], Infrequent Pattern Mining Using Negative Itemset Tree (NIIMiner) algorithm [42] and Fuzzy-based Rare Itemset Mining (FRI-Miner) algorithm [41]. The next section will pay a focus on R-Diffset and IR-Diffset. The constraint of time, due to the large size of data, is among the main disadvantages often faced by the R-Diffset. For improvements, a new algorithm, known as incremental R-Diffset (IR-Diffset), which could help to fasten the process has been introduced.

### III. R-DIFFSET VS. IR-DIFFSET

This section will explain the theoretical background of R-Diffset and IR-Diffset. The technique, formula, and illustration model for R-Diffset and IR-Diffset in infrequent itemsets mining will also be presented. Similar techniques, called depth-first search are used for both R-Diffset and IR-Diffset.

#### A. R-Diffset

In [4], the extension of the diffset algorithm named as R-Diffset, has been introduced. It is executed via sequential processing specifically for infrequent itemset mining. Each item in a vertical database is associated with its corresponding tidset, i.e., the set of all transactions (tids) where it occurs. Thus, the size of tidsets is the primary factor affecting the running time and memory usage. The bigger the tidsets, the more time and memory are needed. However, existing data processing execution is often confronts the issue of large database with single format only. Before this, the execution time data processing in R-Diffset algorithm it is very time-consuming especially in sequential processing [38].

The R-Diffset algorithm concern to keeps track the differences in the tids (transaction IDs) of a candidate pattern from its generating infrequent patterns. It helps to decrease the size of memory required to store intermediate results as depicted in the below pseudocode. The line 6 till 8 in Fig. 2 illustrate that this algorithm will generate all itemsets with their

diffsets and supports. Line number 7 shows where it gets the diffset data, instead of getting intersection of tidsets data between column  $i$  and  $(i + 1)$  based on minimum support that has been set at line 5. All infrequent itemsets are generated by computing diffsets for all distinct pairs of itemsets and checking the support of the resulting itemset. This process is repetitive until all infrequent itemsets have been enumerated. Since the generated diffsets are a small fraction size of tidsets, so the intersection operations are performed extremely fast. The performance of R-Diffset shows a good improvement in execution time over R-Tidset variant in both dense and sparse databases.

Pseudocode R-Diffset
Input: $E((i_1, t_1), \dots, (i_n, t_n) P), s_{min}$ Output: $IF(E, s_{min})$
Begin //get minimum support 1. arrange data by itemset 2. looping = numOfColumns; 3. min_supp = number_of_rows * percentage_min_support 4. run tidset; 5. for (i=0; i<=min_support) 6. if (support<=min_support){ 7. get diffset data for column [i] with column [i+1]; 8. save to DB;} 9. Set next transaction data; 10. Write to text file the value for the current / last transaction data;} end

Fig. 2. Pseudocode for R-Diffset.

### B. IR-Diffset

This study presents a modified algorithm, which is an improvised version of existing R-Diffset, named as Incremental R-Diffset (IR-Diffset). This new approach serves as an alternative to speed up the processing time in infrequent itemsets mining, particularly those involving large datasets. IR-Diffset could be implemented with the data that has been sequentially splitted, incrementally. Incremental in itemsets refers to any additional new item which is being added or deleted to the existing itemsets in database whereas incremental in records of transaction refers to the additional transactions, added to the existing transaction. The IR-Diffset model is illustrated in Fig. 3.

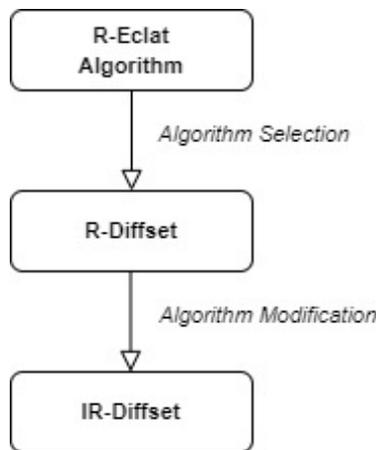

Fig. 3. IR-Diffset Model.

The incremental itemset will be added to the basic model of R-Diffset, establishing a new IR-Diffset model. The IR-Diffset algorithm will keep track the differences in the tids (transaction IDs) by counting each item for finding support which is less than or equal. As presented in Fig. 4, a slight modification of implemented code is at line 7 (while loop). The while loop functions to control flow statements by allowing itemsets to be executed repeatedly. For example, the itemsets in the loop will be performed repeatedly, as long as the variable  $i$  is less than looping. The variable ' $r$ ' at line 4, refers to the record of transaction. When variable ' $r$ ' is not equal to zero, the transactions will be run (i.e the condition is true) it will enter the looping. When variable ' $r$ ' is equals to zero, the process will be terminated. Then, line 8 refers to  $(i = 0; i < looping; i++)$ , which is  $i = 0$  means that the variable  $i$  is = to 0,  $i < looping$  means that the process will be run repeatedly as long as  $i$  is smaller than zero and  $i++$  means that each time the looping process take place, the new  $i$  will be  $i = i + 1$ . This incremental approach has been proposed to overcome the limitations of sequential processing in extracting infrequent itemsets. Then, the following are the key steps in IR-Diffset over the dataset:

Support counting is for finding the support through determination of supports of any  $k$ -itemsets on the intersecting tid-lists of its  $k-1$  subsets. First, the basic theory for support counting must be less than or equal to MSTV. Second, the result will be written and saved in the text file prior to preparation for the next row of transaction data. The minimum support threshold value (MSTV) is considered as a benchmark to discover a low occurrence in each dataset. MSTV is determined in terms of percentage [23].

$$\frac{\alpha}{100} * \beta \tag{1}$$

Where,  $\alpha$  = User specified minimum support value  
 $\beta$  = Total of records in datasets.

Pseudocode IR-Diffset
Input: $E((i_1, t_1), \dots, (i_n, t_n) P), s_{min}$ Output: $IF(E, s_{min})$
start //get minimum support sort data by itemset looping = num_of_column r = record_of_transactions min_supp = num_of_row * percentage_min_supp run tidset while r ≠ 0 do for (i=0; i<looping; i++) if(support<=min_support) get diffset data for column [i] with column [i+1]; add next transaction data; write to text file the value for the current / last transaction data; end

Fig. 4. Pseudocode for IR-Diffset.

The step-by-step process of IR-Diffset is presented in the above pseudocode. Other process steps in each of these variants are preserved as the original variant. The first dissimilarity is the basic theory for support counting where it will only consider the support that is less than or equal to MSTV. The second difference is the storage of results. The

value/result is written and saved in the text file prior to preparation for the next row of transaction data. This is for the purpose of saving memory space. In each loop, starting with the first loop, if the support is less than or equal ( $\leq$ ) to  $min\_supp$ , then,

1) Rather than utilizing intersection, IR-Diffset obtains the result of Diffset (difference intersection set) between the  $k^2$  and  $k^{th}+1$  columns and stores it in the database.

Table I shows the effectiveness of the comparative analysis and that clearly shows the technique, data format, execution time, process, and execution between R-Diffset and IR-Diffset algorithms with infrequent itemsets mining. R-Diffset and IR-Diffset use the same technique, depth-first search.

	R-Diffset	IR-Diffset
<b>Technique</b>	Depth first search	
<b>Data format</b>	Vertical	
<b>Time</b>	Faster intersection process	Less fast for intersection process
<b>Process</b>	Keeps track of differences in tidsets	-
<b>Execution</b>	Executes the infrequent itemsets mining process in sequential form	Executes sequentially on the data that has been split

Table I summarizes the differences of R-Diffset and IR-Diffset. The details of step-by-step processes for both R-Diffset and IR-Diffset are previously presented in Fig. 2 and Fig. 4, respectively. Line 6 to 8 in Fig. 2 illustrate that all itemsets will be generated by this algorithm together with their diffsets and supports. This algorithm is similar to those of IR-Diffset as portrayed in Fig. 4 (lines 9 to 11). The differences between these two pseudocodes can be seen in line 7 (while  $r \neq 0$ ) is used inside the pseudocode of the IR-Diffset. The term "min\_supp" is used in the pseudocode to refer to the minimum support threshold value, which is expressed as a percentage and is calculated by dividing the user-specified min\_supp value by 100 and multiplying it by the total number of rows (records) in each dataset. Then, starting with the first loop, if the support is less than or equal ( $\leq$ ) to min\_supp, then line number 10 shows where it gets the diffset data, instead of getting intersection of tidsets data between column  $i$  and  $(i + 1)$  based on minimum support that has been set at line 8 and saved to DB. The benefit of incremental storage structure lies in the fact that every candidate of itemsets in search space has the same itemset in database. Due to this, its support can be computed by a few simple database operations, removing the need of full scan of database. The rest of pseudocode lines for R-Diffset and IR-Diffset are same.

#### IV. DISCUSSION

All experimentations are carried out on an HP Notepad with an Intel® Core™ i7-3520M CPU running at 2.90 GHz and 8GB of RAM running Windows 10 64-bit. Open-

source software is used to implement the algorithm development software standard. For our database server, we use MySQL (version 5.6.25 - MySQL community server (GPL)), Apache/2.4.16 (Win32) OpenSSL/1.0.1i PHP/5.6.11, PHP as a programming language, and phpMyAdmin (version 4.8.4) to manage MySQL via the Web are all included in the package. Four datasets including chess, pumsb\_star, retails, and T40110D100K are used in this experimentation as described in Table II. The benchmark datasets were collected in their raw form from the Frequent Itemset Mining Dataset Repository (<http://fimi.ua.ac.be/data/>). The benchmark is also converted into Structured Query Language (SQL) format to make things easier.

Datasets	No. of Transactions	Length (Attributes)	Size (KB)	Category
Chess	3196	37	335	Dense
Pumb_star	49046	57	11526	Dense
Retails	88162	68	5143	Sparse
T40110D100K	100001	32	15116	Sparse

In order to facilitate and accelerate research, the datasets are limited to a thousand rows of randomly processed item sets for mining purposes. Our research is focused on R-Diffset and IR-Diffset. Fig. 5 depicts the performance assessment graph in terms of execution time (in seconds) for the four (4) datasets: chess, pumsb\_star, retails and T40110D100K.

The experiments on R-Diffset and IR-Diffset is successfully tested to determine the comparative performance between sparse and dense data. Fig. 5 summarizes that the execution time R-Diffset in dense data is 0.0001 slightly faster than IR-Diffset. But, in sparse data, the result shows that the execution time of IR-Diffset is 0.0003 faster over R-Diffset.

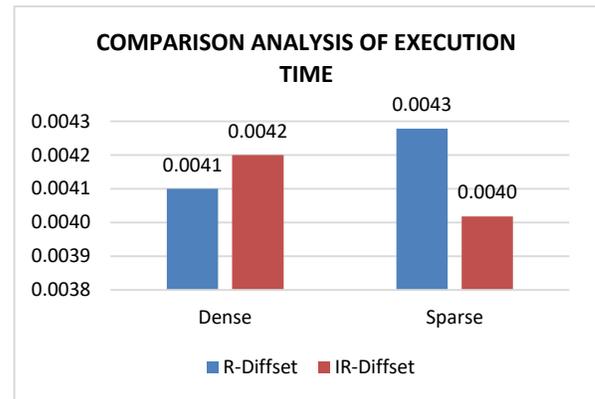

Fig. 5. Performance on R-Diffset and IR-Diffset for chess, pumsb\_star, retails, and T40110D100K

The difference of execution time for both algorithms may be caused by the property's nature of the data itself. Dense dataset is naturally looks like a compressed data where the space between the data is very small. Due to this characteristic, the process of mining infrequent itemset via incremental approach become slower when it needs to sequentially mining the infrequent itemset in several fractions. Finding every single of itemset in the dense data is incredibly challenging due to its dense characteristic. Nevertheless, it is very contrary compared

to the nature feature in sparse dataset. In sparse dataset, the feature between the data itself is sporadic and the space between each data is wide. Due to the wide space between each data, the discovery of the infrequent itemsets is a bit faster and less challenging.

## V. CONCLUSION

In this research, the performance comparison between R-Diffset and IR-Diffset has been analysed. The IR-Diffset have a better performance for infrequent itemset mining in sparse dataset although it slightly loses its advantages over R-Diffset in dense dataset. The incremental approach is introduced to overcome the limitations of sequential processing in extracting infrequent itemsets. The complementary of this approach is believed can be a solution of speedy processing time in mining infrequent pattern especially in huge dataset. Looking at the improvement performance of IR-Diffset in sparse dataset, it can be applied to the real dataset from various fields, such as finding a rare disease at certain areas. It might help on how to control and manage this disease from dispersion which might causes the increase number of patients.

## ACKNOWLEDGMENT

We would like to express our gratitude to the CREIM of UniSZA for providing financial support under UniSZA internal grant code (UniSZA/2021/GOT/02). Thanks to the corresponding authors, Dr. Julaily Aida Jusoh as the CREIM-UniSZA research project leader, Sharifah Zulaikha Tengku Hassan as the research assistant, and the grant participants. We would also like to thank all of the faculty members who helped us evaluate spelling problems and synchronization consistency and for their thoughtful remarks and recommendations.

National Sport Institute of Malaysia, Kuala Lumpur, Malaysia<sup>5</sup>

**Abstract**—Virtual reality (VR) technology is popularly applied in various sports training such as cycling, rowing, soccer, tennis and many more. In VR cycling, however, cyclists are not able to fully immerse themselves during the training due to the hardware and applications limitations required in the setup. In order to be fully immersed during the training, cyclists need to have similar effects to an outdoor training where they will experience cycling resistance, temperature effect, altitude, visual, and audio. For this reason, dedicated stimulus effectors or hardware are required to create these expected effects. On cycling resistance, a realistic cycling experience can be simulated by using a special device that simulates a resistance to the back wheel when cycling uphill in the VR simulation. In addition, the back wheel resistance would need to match the view displayed while paddling on an elevation slope. For higher immersion purposes, and the effect of temperature must be created that matches with the view visible in the display. For example, while the cyclist is on top of a virtual mountain, the cyclist would want to feel the effects of high altitude and low temperature. These stimulus effectors affect the realism experience while cycling in the VR simulation training. In the authors' previous papers, the setup using a combination of stimulus effectors including uphill elevation climb, altitude, temperature, interaction, visual, and audio were integrated into a product called vProCycle. The study tested on vProCycle was conducted with an assumption that virtual reality can enhance the experience of physical cycling training. The objective of this study is to determine whether or not vProCycle may improve cyclists' performance. This paper will discuss in detail the findings from data gathered during the experiment using vProCycle. More specifically, the findings are focused on the speed and the heart rate beats per minute which determine their performance improvement.

**Keywords**—Virtual Reality (VR); presence level; technology acceptance; cycling performance; VR cycling training; vProCycle

## I. INTRODUCTION

In this research, several literatures that focus on VR-based cycling training were reviewed in order to identify the current status of the effectors. This paper covers several topics including LR, system setup, experiment, conclusion and future works. According to Oxford Dictionary 2021, the biological meaning of effectors refers to a substance that carries out a response to the stimulus. Furthermore, stimulus refers to a substance or event that evokes a specific functional reaction to the human body. From the literature review, it is found that stimulus-effectors such as snow, water, and wind-effect can be applied in an event that evokes a specific reaction to the body

[1]. In a VR-based training, several stimulus-effectors can be applied to replicate an actual life experience. According to Bohil Corey, "VR technology creates a simulation across the effector arrays and is attached to devices to create an immersive virtual reality system" [1, 2]. Until now, the commonly used VR effectors among cyclists are visual, audio, and interaction [2, 3]. It is suggested by a few researchers that adding more effectors on top of the regular effectors (i.e. audio, visual and interaction) will generate a more immersive experience [3, 4, 5]. In the area of sports, researchers have used different types of combination effectors to improve cyclists' performance [4]. In relation to cycling performance training, it is suggested by the researchers that the following six effectors are utilised: altitude, uphill elevation climb, realistic visuals and audio, realistic interaction, and temperature. As discussed in the authors' previous study, these effectors are obtained from the survey conducted [6, 7].

This research focuses on Virtual Reality (VR) performance cycling training setups using a combination of stimulus effectors as explained in the authors' previous paper [5, 6]. From the author's previous study, vProCycle setup integrated a selected combination of effective stimulus effectors to be used for VR cycling training. The previous author's papers were focused on identifying which stimulus effector is most effective to be selected and integrated into vProCycle [5, 6]. vProCycle uses a combination of stimulus effectors: uphill elevation climb, altitude, temperature, interaction, visual, and audio. In the author's previous study, the technology acceptance and presence towards the vProCycle were analysed during the pilot study [7]. From this pilot study, Imran concluded that the vProCycle's participants have given a high score on the technology acceptance and perception of presence [7]. On the other hand, this paper focuses on the cyclists' heart-rate level measured in Beat Per Minute (BPM), and speed measured in Kilometres Per Hour (KMPH). The data collected can then be used to measure the cyclists' performance while undergoing physical training.

The key contribution of this paper can be divided into three. The first contribution of this paper is identifying the stimulus effectors that can be used for the vProCycle setup. The second contribution is the finding on the correlation between presence level and technology acceptance of the vProCycle setup. The third contribution is related with performance level where it is found that the new setup can be an effective alternative for cycling training. Based on these findings, it is logical to assume

that vProCycle can be used for producing a well-prepared cyclist.

## II. LITERATURE REVIEW

Training using vProCycle has several benefits. As mentioned earlier, vProCycle consists of uphill elevation climb, altitude, temperature, interaction, visual and audio. The first benefit is generated by uphill elevation climb. The positive effect of uphill elevation climb is supported by McIlroy and Al-Kefagy [8, 9]. They have found that the cyclists benefit from the training when they are able to view an uphill elevation climb displayed on the head mounted device. McIlroy and Al-Kefagy also claimed that the interactive view triggers the cyclists to exert more power to paddle forward in the simulation [8, 9]. When the cycling route changes from a steep elevation slope to a flat surface, the elevation would decline and less power is needed to paddle forward. As a result, cyclists will reduce the power required [9, 10, 11]. In the study conducted by Al-Kefagy [9], an urban city environment was used in his VR application E-bike. In his study, the back wheel resistance machine improved the cyclists' safety awareness, their balances, and increased their immersion level significantly.

The second stimulus effector that benefits the cyclist is called altitude. Training in a high altitude with less oxygen can prepare the cyclist for endurance to strengthen the lung capacity [10, 11, 12]. In a study conducted by Hoeg [10], altitude together with virtual reality technology were tested using the cycling track of the Tour de France. The participants were two elite cyclists training for competition where it was found that their performance had significantly improved. The experiment was conducted at 2000 feet above sea level with 20 percent less oxygen molecules in the air as compared to on the sea level [10]. Training at higher altitude would make cyclists to feel more difficult to cycle and get tired more quickly. When a cyclist trains at a higher altitude, the red blood cell delivers less oxygen to the muscles because of the lesser oxygen level in the air. The oxygen is used to produce energy which helps the muscles to move and perform activity. When training multiple times in high altitude, after the third week, the red blood cells will begin to produce more in the cyclist's body [11, 12]. The basic cycling training using altitude begins at 2000 feet above sea level for thirty minutes, one session a week for three weeks. Within the first 7-10 days, there is little to no difference in the number of red blood cells produced in the body. For the next two weeks, the human body produces more red blood cells. In the third week the human body begins to produce a significant amount of red blood cells that affect the cyclist to perform better [11, 12, 13].

The third stimulus effector is temperature, where it is set according to the altitude height. For example, if the height is set at 2000 metres above sea level, the temperature will be set to 20 degrees Celsius. Lower temperature benefits the cyclists to adapt to various body conditions which helps in physical endurance [13, 14, 15].

The last stimulus effectors are called visual and audio. Visual and audio benefit the cyclist by being able to view and hear the virtual environment. Visual and audio can benefit the cyclist when other stimulus effectors are working

synchronously [16, 17]. For example, if the visual displayed to the cyclist is on top of a mountain, then the effect experienced by the cyclist has to match with the view [18, 19, 20, 21].

In order to create an immersive experience simulation setup, integration of various effective stimulus effectors are required [5, 6]. Using a particular set of stimulus effectors, cyclists can adapt to the uphill terrain to improve performance. Adaptation to the uphill terrain cycling training can also be achieved by the familiarisation to the environment [22, 23]. In the study conducted by Mehdi [24], the seven cyclists were familiarised within three fixed-duration sessions of 12 minutes training. Cyclists were able to determine how much power output is required to reach the maximum speed required to reach the destination. In order to determine the effectiveness of the familiarisation to the training terrain, a better performance of speed and heart rate level from the cyclists need to be improved over the three sessions [25, 26, 27]. In another study, Darvish conducted a VR experiment of familiarisation sessions set for a continuous eight minutes where the speed was held for the final three minute[28]. In his experiment, the speed and heart rate (HR) of all 18 cyclists had improved in two sessions [28]. This indicates that the performance can be improved when cyclists are familiar with the environment and more immersive simulation experience would provide a better realism effect for the cyclists.

According to Mascaret an effective VR-based setups used for sport physical training requires a high level of technology acceptance and perception of presence immersion fidelity [29]. When the technology acceptance level is high together with the sense of presence, VR-based training will benefit athletes in improving their sport performance [29].

Table I shows the list of VR-based bicycle setup and its effectors. In this table, four of the previous research setups including vProCycle are shown where the differences between each setup in terms of effectors applied are listed. These four setups provide distinguished experiences to the cyclists.

TABLE I. LIST OF VR SETUP AND EFFECTORS

No.	List of VR bicycle setup and effectors	
	VR-based bicycle setup	Effectors
1	vProCycle	Altitude, uphill elevation climb, temperature, audio and high realistic visuals
2	Al-Kefagy [9]	Uphill elevation climb, audio and visuals
3	Hoeg [10]	Altitude, temperature, uphill elevation climb, audio and less realistic visuals
4	Wu [16]	Uphill elevation climb, audio and visuals

Table I shows four distinctive VR-based cycling training setups using different types of effectors. In the study conducted by Wu [16], he integrated uphill elevation climb, audio and visual into his VR-based bicycle setup. The visuals of the track used in Wu's experiment was based on the 360 recording video. Wu's [16] result shows that the cyclists were able to improve their speed performance using the setup. In another research conducted by Hoeg [10], he added another effector that simulates the altitude effects of a virtual mountain environment. However, in his research, the effector to generate

temperature was not integrated. It is expected that without this effector, the cyclist's would be less immersed as compared to the real world. In the experiment conducted by Al-Kefagy [9], the setup was similar to Wu's, except for the track displayed inside the HMD which was based on the 3D visuals environment created by the VR engine. It is suggested that with a 360 recording video the cyclists would be more immersed.

As discussed above, using a limited set of effectors may improve cyclists' performance. It is also anticipated that cyclists' perception of presence will improve when more effectors are integrated into the system [7].

### III. SYSTEM SETUP

This paper is a continuation from the authors' previous research [5, 6, 7], where the vProCycle used during the experiment is discussed in detail.

Table II shows the list of effectors and technology providers used in vProCycle. The six effectors are matched to a specific technology that provides a distinguished experience for the user.

The first effector, as shown in Table II is audio and visual. In this setup, HMD is used as the technology provider. There are many brand names of HMD available in the market such as Oculus and HTC VIVE. In this research, the Oculus Quest 2 unit was used to produce a full 360 degree viewing angle with an immersive audio effects. The second effector is called altitude effect. This effect is gained by using a chamber room, as seen in Fig. 1.

Fig. 1 shows a chamber room and the control panel that simulate altitude, temperature, oxygen level and humidity level. Fig. 1(a) shows the chamber room from the outside view and Fig. 1(b) shows the control panel that adjusts the settings for the simulation. The objective of using a chamber room is to create a high fidelity of realism to the VR simulation cycling training.

TABLE II. LIST OF EFFECTORS AND TECHNOLOGY PROVIDERS

No.	List of effectors and technology provider	
	Effectors	Technology provider
1	Audio and visuals	HMD
2	Altitude	Altitude chamber room
3	Uphill elevation climb	Backwheel resistance machine
4	Temperature	Altitude chamber room
5	Paddling interaction	Bluetooth device

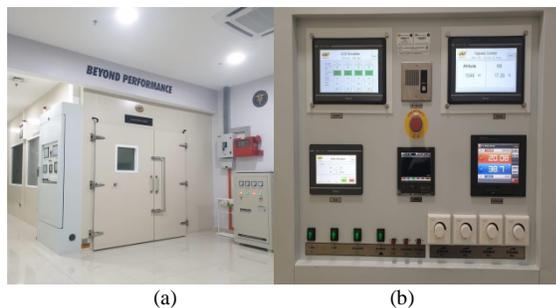

Fig. 1. Chamber room.

The third effector is called uphill elevation climb with the technology provider of a back wheel machine that grips the back wheel of the bicycle to provide a resistance effect. There are many brand names that provide back wheel machines such as Wahoo, Magene, Kinetic, and etc. In this research, Kinetic was used to provide an immersive effect of uphill elevation climb.

The fourth effector is called temperature. The temperature effect is simulated inside a chamber room through the control panel, as seen in Fig. 1(a) and (b).

The last effector is called paddling interaction. The paddling interaction is determined by a bluetooth device that affects the movement inside the virtual world. This bluetooth device is attached onto the bicycle paddle which calculates the Revolutions Per Minute (RPM) in real time. The bicycle in the virtual world would move forward based on the calculated RPM. There are many bluetooth devices available such as Magene, Vzfit, and Wahoo. In this research Magene was used to provide a realistic paddling interaction effect in the virtual simulation. Note that each brands requires their own applications downloaded and controlled using a handphone. Vzfit technology is the major component applied in vProCycle. Vzfit technology consists of the HMD application that connected with backwheel machine using a bluetooth device. Inside the chamber room, the altitude of the height is also set according to the virtual environment seen by the cyclist.

Many literature encourage the use of more distinctive stimulus effectors for a better VR application out-put. The individual stimulus effectors have already been investigated. However, a comprehensive study on a VR application that consists of several stimulus effectors have not been maximised used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, sc, dc, and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

Fig. 2 shows the setup of a VR cycling training system with the combination of uphill elevation climb, altitude, temperature, interaction, visual, and audio. This VR training system is named as "vProCycle system" with the intellectual property copyright number 2022/CR/15.71/OP.

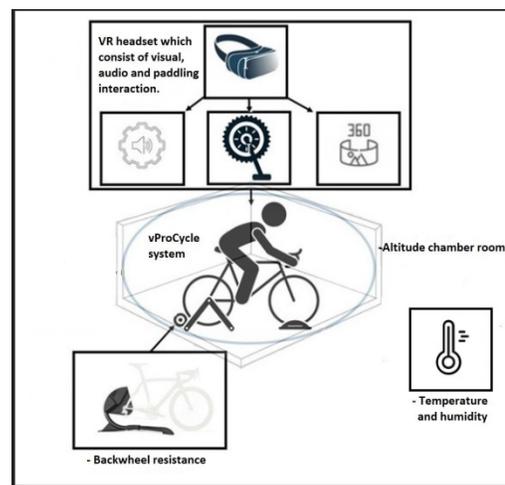

Fig. 2. Setup of the vProCycle

### A. Hardware and Technology Requirement

This experiment was conducted at The National Sport Institute Malaysia, involving 10 volunteers with different background skills. The volunteers were two elite cyclists and eight athletes from a university football team. During the experiment, the cyclists' speed in the virtual environment and the heart rate level (BPM) were collected. In this subsection, the cyclists' requirements and materials used to conduct the experiment are explained in detail below. The figure below shows the setup design during the experiment.

Fig. 3. The vProCycle system setup.

Fig. 4. The vProCycle system setup side view.

The vProCycle system experiment was conducted at the National Sport Institute Malaysia hypoxic chamber as seen in Fig. 3. The experiment setup includes a back-wheel machine, Bluetooth sensor on the bicycle paddle, VR HMD, and heart rate device. This setup was similar to the pilot study with the exception of a heart rate device that was strapped on the chest of the cyclists. The location of the scene in the HMD was L'Étape du Tour, France. Before undergoing a training session, a consent form was signed by the cyclists. The experiment was conducted in three separate sessions with an interval of one week apart, each session was a continuous, non-stop session for 30 minutes. All the cyclists were briefed on the warnings of training in the hypoxic chamber. The temperature and carbon dioxide level was different than on sea level which may cause vomiting, drowsiness, or headaches. Cycling training in

altitude for 30 minutes benefits long term endurance of at least three sessions in an interval of one week [8]. Note that all participants undergone training at 2000 metres above sea level (m.a.s.l), with 20 percent less oxygen as compared to sea level altitude and a temperature of 20 degrees. Fig. 4 shows the side view of the setup in the chamber room using vProCycle; different road bicycles can be mounted.

### B. Experiment Participant Requirement

The selection of the participants were based on the following criteria:

- Age: An individual aged 20 years to 50 years.
- Experience: Have participated in a local or international cycling competition or event.
- Role: Have represented a sport organisation, club or school.
- Type of training: Have trained using a stationary bicycle.
- Demography: No restriction.
- Gender: No restriction.
- Weight: 50kgs-80kgs.
- Height: 1.6m-1.9m.

In this research, ten cyclists that met the above criteria have participated in the experiment. The first criteria is the participants' age. The age is appropriate for cycling performance training [8-13]. The second criteria is the experience of the cyclists. These experiences enable the cyclist to safely undertake cycling training. The third criteria is on the role of the cyclist. The role refers to the types of organisation or entities that they have represented. The fourth criteria is on the type of training they have participated in order to prepare themselves for the upcoming events. As for the fifth, sixth; demography and gender, there is no restriction applied. The seventh and eighth; weight and height, the restrictions are as stated above. The weight and height restrictions are due to the hardware's limitation such as the height and the capacity of the bicycle.

### C. Experimental Material

The cyclists were required to cycle for thirty minutes in a virtual environment based on a realistic view of L'Étape du Tour, France. The distance of the training track of L'Étape du Tour, France was 13 KM in which the cyclists had to cycle as far as they can within the given time duration set. This location was set with many uphill elevation climbs and down hills. Based on the literature review, familiarization of terrain requires a minimum of three sessions and at least eight continuous minutes with an improved performance [26, 27, 28]. In this research, the technology acceptance questions were derived from the original TAM developed by Davis, 1989 [7]. Four questions for each of the TAM's factors were adopted. The presence questionnaire were adopted from the Witmer and Singer Presence Questionnaire. Example of the questions used are "When you bicycle forward, did the feeling of moving forward in the virtual world seem realistic?" and "When you

paddled the bicycle, did you feel the movement speed as realistic according to the change of view?" Both questionnaire (TAM and presence) were given after the cyclists had undergone the training session using vProCycle [7].

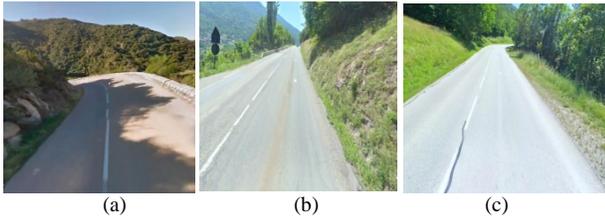

Fig. 5. Three views of L'Étape du Tour, France used during the experiment.

Figure 5 shows three images of the view seen in the HMD at L'Étape du Tour, France. Fig. 5(a) shows the road surface in between one to five degrees of elevation uphill slope curving to the steep left angle. Fig. 5(b) shows a steep elevation slope of 10 degrees. Fig. 5(b) also shows the view of climbing a steep uphill on the road side going straight. Fig. 5(c) shows a downhill slope of zero resistance going downhill curving to the right side. The familiarisation to uphill adaptation from cyclist in altitude requires a minimum of 3 consecutive sessions of an interval of 1 week in between each session [5, 6]. This is due to the body producing more red blood cells in the third week of training in altitude [10, 11, 12].

#### D. Findings

The experiment focuses on two different findings. The first finding is on the average speed of the ten cyclists using vProCycle during performance training. The second finding focuses on the average heart rate level based on the BPM. The two main data collected indicate the cyclists' performance which was measured by the average speed, the heart-rate level and the correlation between the two.

Fig. 6 shows the cyclists' average speed in kilometres per hour while using vProCycle in 3 sessions. P1 to P10 indicates participant 1 to participant 10, respectively. Speed is the distance divided by time. Distance is measured in kilometres and time is measured in minutes. Heart-rate level is measured by the amount of beats per minute (BPM) that the heart pumps.

In session 1, the lowest speed was retrieved from participant 3, 4, 5, and 6 at 10 KMPH, whereas the highest speed was reported at 16.7 KMPH by participant 10 and 12.7 KMPH by participant 9. In session 2, the lowest speed was recorded by participant 5 at 10.8 KMPH, while participant with the highest speed was participant 10 at 17 KMPH. In session 3, the lowest speed was recorded by participant 3 and 5 with both recorded an average speed at 12 KMPH, while the highest speed was recorded at 17 by participant 10. Each participant had improved their performance by increasing their speed from session 1, 2, and 3, subsequently. Speed is measured as the ratio of distance to the time in which the distance was covered, and the time period given for each session was 30mins. From the average speed, it could identify the average Kilometres Per Hour (KMPH), and how many kilometres (KM) they have reached by the end of each session. By capturing the data of KMPH and the KM from each session, analysis can be made to identify whether the participants have improved their speed

performance or not. Below is the analysis of each individual participant. In this analysis, the improvement from one to two KM was considered major while less than one was considered minor [10].

In relation to the KMPH, the cyclists' KMPH were lower in the first session and gradually increased during the consecutive sessions. It is logical that the cyclists' KMPH in the early session was lower due to the unfamiliar training conditions including altitude. It is also found that the changes in terms of KMPH between session 1 and session 2 was much higher as compared to session 2 and session 3.

As a summary, it can be seen that all participants' average speed increased throughout the sessions. All cyclists' speed performance improved when using vProCycle. The following is the findings on the participants' heart rate level based on BPM.

Fig. 7 shows the average heart rate based on the amount of beat per minute (BPM) with 90% of the cyclists' average heart rate (BPM) in session 1 was above 150. The lowest score reported in session 1 was 140 BPM and the highest was 172. In session 2, all cyclists were below 162 BPM whereas in session 1 four cyclists were above 170. The highest BPM score in session 2 was reported at 161 and the lowest was at 130. This would indicate that as compared to session 1, the heart rate BPM for all cyclists had dropped in session 2. This might be due to the fact that the cyclists may have not yet adapted to the new setup and not comfortable in the first session as compared to the second session within a one week interval.

In relation to the BPM, the cyclists who are not familiar with training at 2000 metres above sea level may find discomfort during the first session [24, 25, 26]. Due to the unfamiliar conditions of the altitude and uphill elevations, the cyclists' BPM would be higher in the first session compared to session 2 and session 3. The BPM indicates the endurance level of the cyclist when undergoing training. An increase in BPM usually occurs when the cyclists are required to exert more power when increasing their speed or climbing uphill [24, 25, 26].

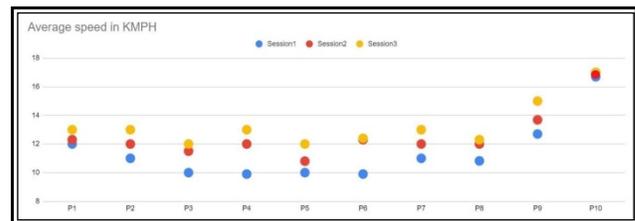

Fig. 6. Participants' average speed in kilometres per hour (KMPH)

Fig. 7. Cyclists' average heart rate in Beat Per Minute (BPM)

As a summary, all participants' BPM decreased throughout the sessions. It shows that their heart rate level improved when using vProCycle. Below are the findings on the participants' average heart rate level correlation to the average speed.

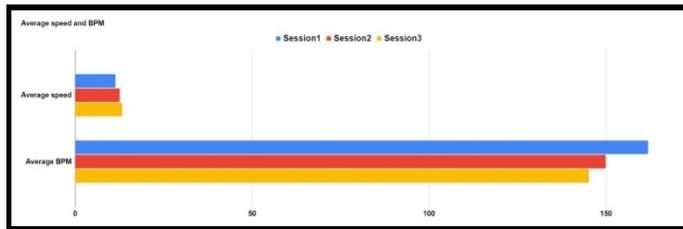

Fig. 8. Cyclists' average speed (KMPH) and heart rate in Beat Per Minute (BPM).

Heart rate level improved when using vProCycle. Below are the findings on the participants' average heart rate level correlation to the average speed.

Fig. 8 shows the cyclists' average speed on the top and the average BPM at the bottom. When the speed is high and the heart rate level BPM is low, this indicates that the cyclist is at a better cycling performance. The average speed of the cyclists in session 1 was reported at 11.402 KMPH, session 2 at 12.559 KMPH, and session 3 at 13.27 KMPH. The average speed in session 1 was at 11.402 KMPH as compared to in session 3 at 13.27 with the difference of 1.9 KMPH. This would indicate that the average speed of the cyclists between session 1 and 3 in this experiment would have improved by 1.9KM. The difference between the average speed of session 1 and 2 was 1.157 KMPH, which indicates that between session 1 and 2, the cyclists improved by 1.157 KMPH on average. For session 2 and 3, the average speed improved by 0.7 KMPH. There was a gradual increase of average speed from session 1, 2, and 3.

As shown in Fig. 8, the improvement in cyclists' performance was also found when analysing the negative correlation between the average speed and the average heart rate level. A negative correlation between the average speed and the average BPM means that while the speed is increasing, the BPM is also decreased.

Session 1 average BPM was at 161.9 BPM as compared to session 3 at 145.2 BPM, with the difference of 16.7 BPM. This would indicate that the cyclists have improved their BPM by 16.7 between session 1 and session 3. The difference between the BPM of session 1 and 2 was 12 BPM, which indicates that between session 1 and 2 the cyclists improved their BPM by 12. For session 2 and 3, BPM was improved by 4.7 BPM. There was a gradual decrease of BPM from session 1, 2 and 3. The lower the heart rate over session would mean that the cyclist is improving.

There is a correlation between speed KMPH and heart rate BPM, in which the higher the speed KMPH across the sessions would decrease the heart rate BPM. The reason for this is because as the cyclists train more frequently, their physical body become more adapted to the higher altitude, thus creating more red blood cells and is able to endure the harsh conditions of this cycling performance training.

As discussed above, all the participants' speed increased throughout the three sessions while their heart rate beat dropped. This indicates that while using vProCycle, participants' performances have improved as there is a negative correlation between the average speed and BPM from all cyclists. As discussed in the author's previous paper [7], the cyclists' were required to answer a questionnaire on TAM and perception of presence. In addition to TAM and perception of presence, an open interview was also conducted. From the interview, it was found that during the first session, all ten cyclists were not familiar with the altitude and uphill elevation climb which affected their performance. During the second session, all the cyclists stated that they had adapted to the training better. In the final session, the cyclists highlighted that they feel more confident resulting in better performance. Based on the average speed and heart rate level, all cyclists showed that they have improved in performance during the final session when using vProCycle.

#### E. Experimental Outcome

From this research, the outcome shows that cyclists' speed performance and heart rate have improved when cycling in the simulated VR terrain using vProCycle. This outcome also suggests that the cyclists' technology acceptance and perception of presence level as explained in the previous paper [5, 6] may have positively impacted the cyclists' performances. In the previous paper, it was found that cyclists gave high rating to both technology acceptance and perception of presence. The findings on the speed and heart rate level also suggest that with a high level of technology acceptance and perception of presence, positive correlations can be seen where cyclists' performance have improved when using vProCycle.

#### IV. CONCLUSION AND FUTURE WORK

In conclusion, this study shows how vProCycle may offer new possibilities in cycling training by combining various stimulus effectors. It is highlighted that distinctive stimulus effectors do greatly influence the performance level of participating cyclists when familiarized with the simulated terrain. This performance level is experienced by a realistic simulation integrated with the system. This simulation creates an experience as though the cyclist is cycling in the distinctive actual real environment. This high level of cyclists' performance thus generates a gradual improvement by the speed and heart rate level throughout the sessions.

It is found that the cyclist's performance has improved based on the real time data collected from the devices (RPM and heart beat rate) attached to the cyclist during the training. A negative correlation between the RPM and heart rate shows that there is an improvement in performance over three sessions.

Cyclists have positively accepted the vProCycle based on technology acceptance and perception of presence level questionnaires. Findings show a positive correlation between RPM and heart rate level with technology acceptance and perception of presence.

This study contributes to the fact that using highlighted distinctive stimulus effectors do greatly influence the performance level of participating cyclists. VR as a tool can be

used to simulate an effective cycling training destination when integration is set distinctively. For future work, a motion platform will be integrated with the vProCycle in order to simulate a tilting effect. This tilting effect occurs when cyclists are turning their direction based on the VR simulated road condition.

## V. INTELLECTUAL PROPERTY

The findings from this paper were conducted using vProCycle. vProCycle has been copyrighted (2022/CR/I5.71/OP).

**Abstract**—Indoor navigation is crucial, particularly during indoor disasters such as fires. However, current spatial subdivision models struggle to adapt to the dynamic changes that occur in such situations, making it difficult to identify the appropriate navigation space, and thus reducing the accuracy and efficiency of indoor navigation. This study presents a new framework for indoor navigation that is specifically designed for first responders, with a focus on improving their response time and safety during rescue operations in buildings. The framework is an extension of previous research and incorporates the combustibility factor as a critical variable to consider during fire disasters, along with definitions of safe and unsafe areas for first responders. An algorithm was developed to accommodate the framework and was evaluated using Pyrosim and Pathfinder software. The framework calculates walking speed factors that affect the path and walking speed of first responders, enhancing their chances of successful evacuation. The framework captures dynamic changes, such as smoke levels, that may impact the navigation path and walking speed of first responders, which were not accounted for in previous studies. The experimental results demonstrate that the framework can identify suitable navigation paths and safe areas for first responders, leading to successful evacuation in as little as 148 to 239 seconds. The proposed framework represents a significant improvement over previous studies and has the potential to enhance the safety and effectiveness of first responders during emergency situations.

**Keywords**—Space subdivision; indoor navigation; first responders; indoor disaster

## I. INTRODUCTION

Most of human life is spent indoors rather than outdoors. The average time spent indoors was 87%[1]. The increasing concentration of human populations in modern urbanized societies has aggravated the frequency and destruction of natural and artificial disasters. A United Nations study indicates that by 2050, 66% of the world's population is expected to be urban. Hence, buildings are increasingly significant, broad, and complex to accommodate them and guarantee all the requirements for protection and good well-being [2]. Buildings have been the primary focus of recent disasters, resulting in heavy damages and losses for public and emergency managers.

Residential building fires and fire deaths tend to increase yearly [3]. The increasing concentration of human populations in modern urbanized societies has aggravated the frequency and destruction of natural and manmade disasters. First responders are critical in responding to indoor emergencies,

such as those in high-rise buildings. First responders, also called emergency responders, are those in charge of saving lives, protecting property, and keeping the environment safe in the early stages of an accident or disaster[4]. In large or complex buildings, it can be difficult for first responders to navigate through the entire building at once, particularly in an emergency where time is of the essence. Indoor navigation is a critical aspect of emergency response. It allows first responders, such as firefighters and emergency medical technicians, to locate and assist those in need within a building or other indoor space quickly and safely.

To effectively navigate an indoor space, first responders need to locate themselves accurately within the space and determine the most efficient route to their destination. Indoor navigation can help first responders more quickly and efficiently navigate the building, allowing them to focus on responding to emergencies and providing assistance to those in need[5]. Indoor navigation is particularly challenging because buildings can be complex, with multiple floors, rooms, and corridors, making it difficult to determine one's location and direction. This is further complicated by the presence of smoke, low visibility, and other hazards that are often present during an emergency.

In an emergency, first responders must determine the safest route through the building to reach their destination as quickly and safely as possible. This may involve considering the combustibility of the building materials, the presence of hazards or obstacles, and the location of windows or other alternative exits. In large or complex buildings, it can be difficult for first responders to navigate through the entire building at once, particularly in an emergency where time is of the essence.

One approach to improving indoor navigation for first responders is using space subdivision. This technique involves dividing a building or other indoor space into smaller, more manageable units or sections, making it easier to navigate and orient oneself within the space. In addition to improving navigation, space subdivision can also help to improve communication and coordination among first responders. By dividing the space into smaller units, it becomes easier to provide specific and accurate directions and instructions and to communicate the location and status of individuals or resources within the space. The goal of space subdivision is to provide first responders with detailed, real-time information about the layout and occupancy of a building, which can help

them to reach the scene of an incident more quickly and safely.

In emergencies, there may be dynamic changes in the building, such as the spread of fire or smoke. It can be crucial for first responders to continuously update their navigation system to reflect these changes to stay safe and reach their destination as quickly as possible. Space subdivision can be used to identify which areas of the building are safe to navigate at any given time and to provide real-time updates to the navigation system.

In emergencies, first responders must determine the safest route through the building to reach their destination as quickly and safely as possible. Space subdivisions can be used to identify spaces with lower combustibility or windows that can be used as alternative exit routes and to determine the safest route through the building based on these characteristics. Overall, space subdivision can support indoor navigation for first responders in emergencies by allowing them to focus on navigating through smaller, more manageable areas of the building and staying safe.

Subdividing indoor areas is an important part of scene analysis that is used for a wide variety of purposes, including but not limited to navigation and evacuation planning [6]. Space Subdivision plays a vital role in indoor navigation [7]. The division of space in indoor navigation is basically to determine navigable and non-navigable spaces.

To improve the accuracy and efficiency of indoor navigation, current spatial subdivision models need to reflect the indoor context's dynamic changes ultimately. However, they also need help defining precise navigable space [8]. When responding to emergencies, first responders must be aware of the unexpected dynamic changes in indoor space. Hence a subdivision structure of indoor space that adapts to varied indoor spatial features and spatiotemporal dynamics is of considerable importance [9].

Several previous studies have discussed the space subdivision for indoor navigation. However, these studies have yet to reflect the dynamic conditions that often change when a disaster occurs in a building, especially during rescue operations by first responders. For this reason, this study proposes a space subdivision framework for indoor navigation for first responders.

This research aims to provide a new framework for indoor navigation that is specifically designed for first responders in emergency situations. This framework is based on the idea of dividing indoor spaces into smaller subspaces, which can be more easily navigated and searched by first responders. Some potential benefits of this approach are:

1) *Improved efficiency*: The proposed framework can help improve the efficiency of first responders during emergency situations. By providing a more structured and organized approach to navigating indoor spaces, first responders can quickly and efficiently locate individuals who need help or identify potential hazards.

2) *Enhanced safety*: The subdivision of indoor spaces can also help improve the safety of first responders by allowing

them to more easily identify potential hazards, such as structural damage or chemical spills. This can help reduce the risk of injury or harm to both first responders and those they are trying to help.

The main contributions of this research include the development of a novel framework for indoor navigation that takes into account the dynamic changes of the indoor context during fire emergencies, as well as the identification of suitable navigation paths and safe areas for first responders. The framework also incorporates an algorithm that is tested using Pyrosim and Pathfinder software, which calculates the walking speed factor and affects the path and walking speed of first responders. The experimental results demonstrate that the proposed framework can improve response times and increase the chances of successful evacuation for first responders.

The implications of this research are significant, as it can improve the safety and effectiveness of first responders during rescue operations in indoor environments. By accounting for dynamic changes in the indoor context, the framework can identify suitable navigation paths and safe areas for first responders that may not have been considered in previous research. The framework has the potential to become an essential tool for emergency response teams, enhancing their ability to navigate indoor environments during emergencies and improving their chances of success.

This rest of this article is organized as follows: Section II provides a review of related work. Section III outlines the proposed framework for indoor navigation, which involves dividing the space into smaller sections. Section IV goes into further detail about space subdivision and network derivation. Section V explains the algorithm used for path planning. Section VI describes the experiments that were conducted. Section VII presents and discusses the results of the implementation. Finally, Section VIII concludes the research by summarizing the findings and outlining future research directions.

## II. RELATED WORK

Some literature has extensively investigated the subdivision of space for indoor navigation. The approach usually uses well-defined building construction spaces such as rooms and corridors, builds connectivity between these spaces that use their semantics, and applies Poincaré Duality to obtain navigable networks [10]. Several semantic models have been established in this context to help with space identification and develop a navigation network [11]. The generation of an effective navigation network heavily depends on a reasonable subdivision of indoor space [12].

To create navigable subspaces for refined indoor navigation, indoor spatial subdivision, as the primary method of indoor space organization, has been extensively studied. The study [13] identifies four different steps necessary for a successful application for navigation through indoor spaces. The digital acquisition of available spaces (1), the structuring of acquired data (2), formalization of the data to establish relationships between different subspaces (3) and lastly applying the user requirements on the formalized and structured data (4). The subdivision of indoor space forms

subspaces into smaller parts. The research [14] divides indoor spaces into navigable and non-navigable areas by considering human social behaviour at different times and then redivide the navigable space by the Constrained Delaunay Triangulation.

Several methods for partitioning the fundamental indoor space have been developed in order to construct fine-grained indoor navigable space. It is a common practice to use a dedicated strategy (such as visibility graph, Delaunay triangulation, and convex hull cell) or regular gridding (such as square, hexagon, etc.) [15] to divide an entire indoor space in order to derive a 2D navigable network. This can be accomplished in a number of different ways.

A fine-grained and context-aware subdivision framework (FSS) is proposed in [10] to remodel the relevant 3D space for the arrangement of navigable indoor environments by injecting numerous materials. This is accomplished by rearranging the components in a specific order. The FSS framework is hailed as a landmark for its ability to depict indoor human interaction behaviors to date. It is an inspiration for better indoor environment modeling and cognition-based navigation.

The initial formation of the F-Space considers dynamic human activities; however, their significance in the fine-grained spatial subdivision of the indoor environment is overlooked. As a result, the F-Space needs to be fully navigable possible. Within this framework, the authors separated things into three categories according to their mobility: the capacity to change their location (static, semi-mobile, and mobile). After then, the interior space, also known as the environment, was divided into three distinct sections: object space, functional-space, and remaining-space. To be more specific, object space is the non-navigable portion of subspace that is occupied by semi-mobile objects. Functional space, on the other hand, is the subspace portion dedicated to the utilization of semi-mobile objects or the activities of mobile objects and is navigable under certain conditions.

Depending on the application, subdivisions can be done on 2D or 3D levels [16]. As found in [17], there are certain advantages and disadvantages of conducting 2D and 3D subdivisions. The key advantages of 2D subdivision are that all or most calculations may be performed in 2D, the user can retain just places occupied by pedestrians in memory, and triangles are not required for vertical pedestrian placement. On the other hand, if everything is viewed as a single 3D space or pieces of 3D spaces, simulated pedestrians can freely move throughout an area without having to check to see if they have entered another space for pedestrian dynamics purposes.

### III. SPACE SUBDIVISION FRAMEWORK

When conducting emergency rescues, first responders are often only provided with a floor plan map, even though the map already contains many objects in actual conditions, as shown in Fig.1.

However, this floor plan map may not accurately reflect the actual conditions of the space during the emergency situation. The map may have been created prior to any

changes to the space or may not be detailed enough to capture all the objects or obstructions that may be present.

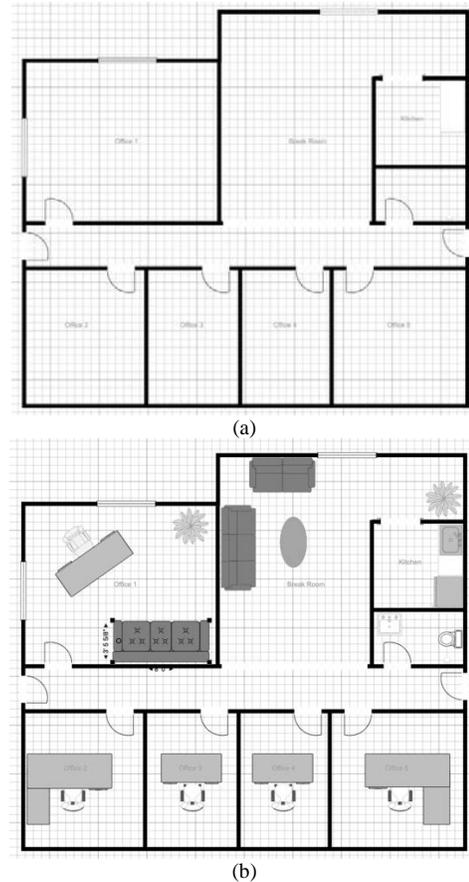

Fig. 1. Comparing the (a) Floor plan to the (b) Actual situation of an indoor space.

In addition, the floor plan map may not provide a clear or accurate representation of the space, making it difficult for first responders to navigate and locate individuals who need assistance. This can be especially challenging in complex indoor environments, such as large buildings or underground tunnels.

The proposed approach from this research, addresses these challenges by dividing the indoor space into smaller subspaces, which can be more easily navigated and searched by first responders. This approach provides a more detailed and accurate representation of the space, which can help first responders better understand the layout and locate individuals who need assistance.

By using a subdivision framework, the first responders can more easily identify potential hazards and obstacles within the space, which can improve their safety and reduce the risk of injury. Additionally, the framework can be integrated with existing technology, such as mapping and tracking systems, to provide real-time information on the location and movement of first responders within the indoor space.

Space subdivision can be a useful tool for indoor navigation for first responders in an indoor emergency situation, as it allows the building to be divided into smaller,

more manageable areas that can be navigated separately. This can be particularly helpful in situations where there are dynamic changes in the building, such as the spread of fire or the presence of smoke, as it allows the first responders to focus on navigating through a smaller area at a time rather than trying to navigate through the entire building at once.

Here are some ways in which space subdivision can help with indoor navigation for first responders in an indoor emergency situation:

1) *Identifying safe navigable spaces:* By dividing the building into smaller spaces, it can be easier to identify which areas are safe to navigate based on factors such as the combustibility of the material and the presence of hazards.

2) *Determining the safest route:* By dividing the building into smaller spaces, it can be easier to determine the safest route through the building based on the characteristics of each space. For example, the first responders might choose to navigate through spaces with lower combustibility or with windows that can be used as alternative exit routes.

3) *Providing real-time updates:* By continuously monitoring the building for dynamic changes and updating the space subdivision accordingly, it can be easier to provide real-time updates to the navigation system to reflect any changes in the safe navigable spaces.

We propose a classification of interior objects based on mobility and safety for first responders as a means of subdividing dynamic indoor settings. This classification would be used by first responders. This classification expands [10] original works.

In order to get a head start on our work, we will first go over the essential definitions of indoor objects and indoor subspaces following the FSS framework from [10]. The FSS framework categorizes indoor objects as either static S-objects (such as indoor fixed structures), mobile M-objects (such as humans), or semi-mobile SM-objects. Static S-objects include indoor fixed structures. The products have been sorted into these categories according to how mobile they are. Independent of the type of building being used, the S, SM, and M-objects provide direction for the space subdivision. They are utilized in defining the geometry, semantics, and topology of the subspaces that they physically occupy or are necessary for their access or utilization. The location of these objects will determine the areas that are open for navigation and those that must be avoided.

Meanwhile, the meanings of O-Space, R-Space and F-Space have been established. O-Space is a non-navigable subspace that SM-objects physically inhabit. R-Space refers to the area of space that is open to navigation and can be traversed at will. In contrast, F-Space is a subspace functionally occupied by SM-objects or motion-less M-objects for user interactions. To be more exact, F-Spaces are spaces that are not considered navigable unless they form an essential part of the navigation system.

It is essential to have a solid understanding of how a structure would behave in the event of a fire. The establishment of minimum construction criteria is done to

assist in maintaining the building's structural integrity for the amount of time necessary for evacuating the building or moving to a secure position within the building. The rate at which a fire will spread is directly proportional to the combustibility of the material it is burning. These two components are equally crucial to ensuring that both lives and property are not lost in a fire.

A building's structural integrity can be affected by a fire. Different materials have varying degrees of resistance to fire [18]. When there is a risk to the route's stability, it is impossible to travel along that route. When the length of the fire is greater than or comes dangerously close to exceeding the fire resistance duration of the building material, the stability of the route is jeopardized. Unsecured shafts or openings pose an additional risk to the safety of the firefighters and the operation as a whole, and the planning of the route should take care to avoid them.

The amount of smoke in a region affects vision, which, in turn, decides whether or not a path may be used. If a path is devoid of smoke, has adequate visibility, and is easily navigable. In certain circumstances, smoke will only be found above a predetermined height beneath the ceiling. The area below the smoke may then be free of smoke and suitable for passage.

The NFPA (National Fire Protection Association) 220 Standard on Types of Building Construction [19] defines the different types of building construction by basing it on the combustibility and the fire resistance rating of the structural parts of a building. When we speak of materials or assemblies having a specific fire resistance rating, we refer to the amount of time measured in minutes or hours that they have been able to withstand exposure to fire, as established by specific tests. In this study, we take combustibility as a factor in determining the definition of a static object by taking the categorization from NFPA 220 [19].

#### A. Definition 3.1

(Redefinition of S-objects): static (S-objects) as objects that can neither move by themselves nor be moved (e.g., construction elements such as walls, columns, stairs, etc.) [10]. In this paper it can be redefined as three types of objects based on combustibility:

- Scm (Static-Combustible) is a material that, in its intended form and under the anticipated conditions, will ignite and burn;
- Slcom (Static-limited combustible) is a material does not meet the standards for non-combustible material.
- Sncom (Static-non-combustible), in its intended form and under the predicted conditions, the material will not ignite, burn, support combustion, or emit flammable gases when exposed to fire or heat.

Still in the FSS [10], the agents are the primary dynamic actors that are considered. During the process of estimating a route and when actually navigating, the A-Spaces intend to take into account the dimensions of the objects as well as the required amount of space around them. An 'A-Space' is a

clearance space containing one or more agents and the SM objects they carry if they have any.

This clearance space can be characterized as A-Space. However, the study [10] only considered the available free space. In rescue operations carried out by first responders, free space is taken into account, but the most important aspect is the space that is considered safe from the worst possibilities, such as fire and other hazards. The study [20] described a safety zone as "an area identified by qualities that give freedom from danger, harm, or injury". In definition 3.2, we are redefining A-Spaces by considering the conditions that may occur in rescue operations.

### B. Definition 3.2

(Redefinition of A-Spaces): we re-identify two types of A-Spaces:

- a safe one (AS-Space) corresponding to the remaining space that give freedom from danger;
- a non-safe one (ANS-Space) corresponding to the remaining space that not give freedom from danger.

We took a case by taking a 3D floor plan of the 2nd floor of the Westport House from WRLD3D.com, and by adding a heatmap, we simulated an unsafe area caused by a fire. As seen in Fig. 2, the area given the red heatmap is ANS-Space, while the rest is AS-Space.

Fig. 2. AS-Space and ANS-Space within indoor building.

## IV. SPACE SUBDIVISION AND NETWORK DERIVATION

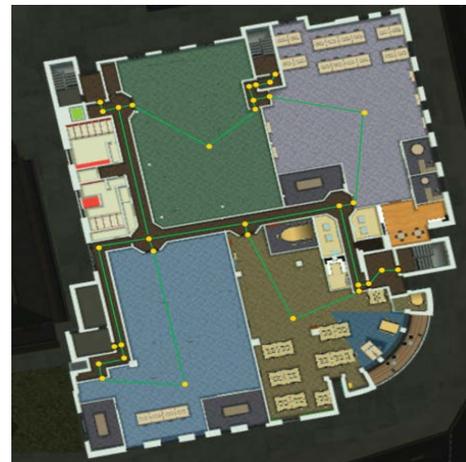

The navigation network is a crucial component of most navigation and evacuation approaches[21]. A navigation network in indoor navigation refers to a system of interconnected paths or routes that can be used to navigate through an indoor environment, such as a building. The navigation network may include information on the layout of the building, the location of exits, stairwells, and elevators, and the presence of hazards or obstacles. It may also include information on the characteristics of the spaces within the

building, such as the combustibility of the materials, the presence of windows, or the availability of emergency exits.

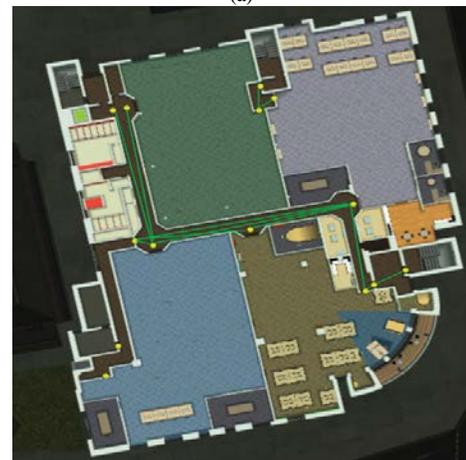

There are widely accepted methods for developing indoor navigation networks, such as medial axis transformation (MAT), visibility graph (VG), or mixtures of them [22]. In other studies, CDT (Constrained Delaunay Triangulation)[23], and generalized Voronoi diagram (GVD) are also used. In this study we use MAT and VG to create a navigation network.

Straight skeleton is the process of skeletonizing a geometric space. The straight MAT algorithm [24] generates a 3D indoor skeletal graph. Fewer vertices are added to the network, resulting in increased computing efficiency. Taneja et al. in [25] employed direct MAT to turn IFC-based data into a geometric topology network, which might serve as a navigational aid model. As can be seen in Fig. 3(a), we created a network using MAT based on the existing floor plan. While in Fig. 3(b) is the network derivation using VG.

Deriving nodes from existing building plans is the first and most essential step in developing an VG (visibility Graph)[26]. Based on their navigational functions, there are primarily two types of nodes in a VG [27]. First, a junction node denotes the intersection of at least two corridor segments. The second, portal nodes describe wall openings, such as those occupied by doors and windows in each room.

(a)

(b)

Fig. 3. Navigation network: a) MAT network and (b) VG network.

## V. PATH PLANNING

Safe routes are essential in indoor navigation for first responders because they help to ensure that the responders can reach their destination safely and efficiently, even in hazardous or challenging environments. This is especially important in emergency situations, where time is of the essence and responders may need to navigate through unfamiliar or potentially dangerous spaces. Common path findings utilizing typical navigation methods may not be sufficient in an emergency, as they may be too dangerous or unavailable due to damage. Critical in these situations is the ability of emergency and rescue professionals to find other and best routes [28].

In this study, we propose an algorithm for determining the safest path for first responders by taking into account factors such as the combustibility of materials and dynamic changes in the building such as fire. To create an algorithm for safe indoor navigation for multiple first responders that takes into account the combustibility of materials, dynamic changes in the building such as fire, and is based on space subdivision, we could consider the following steps:

- 1) Identify the start and end points of the route for each first responder.
- 2) Obtain a map of the building or structure, including information on the layout and location of rooms and corridors.
- 3) Divide the building or structure into smaller spaces, such as rooms and corridors.
- 4) Determine the combustibility of materials in each space. This information can be obtained through building codes or by consulting with the building's owner or management.
- 5) Use the map and combustibility information to identify potential hazards in each space, such as rooms or corridors with highly combustible materials.
- 6) Consider the potential for structural collapse and other hazards that could block the route such as smoke.
- 7) Based on this information, determine safe routes for each first responder that avoids or minimizes exposure to potential hazards. This can be done by selecting paths through the building or structure that avoid spaces with high hazards and maximize the use of spaces with low hazards.

Here is the pseudocode of our proposed algorithm:

```
PROCEDURE findSafeRoutes(starts, ends, map, combustibility)
    spaces <- list of all spaces in map
    routes <- empty list
    FOR EACH start, end IN starts, ends
        route <- empty list
        currentSpace <- start
        WHILE currentSpace != end
            nextSpace <- null
            lowestRisk <- infinity
            FOR EACH neighbor IN neighbors of currentSpace
                totalDistance <- distance between currentSpace and
```

```
neighbor
                totalHazardExposure <- 0
                riskOfCollapse <- 0
                IF neighbor has highly combustible materials
                    totalHazardExposure <- totalHazardExposure + 1
                IF neighbor is at risk of structural collapse
                    riskOfCollapse <- riskOfCollapse + 1
                IF neighbor is on fire or has high levels of smoke
                    totalHazardExposure <- totalHazardExposure + 10
                IF neighbor is a window and is suitable for exiting the
building
                    totalHazardExposure <- totalHazardExposure - 5
                totalRisk <- totalDistance + totalHazardExposure +
riskOfCollapse
                IF totalRisk < lowestRisk
                    lowestRisk <- totalRisk
                    nextSpace <- neighbor
            route <- route + (currentSpace, nextSpace)
            currentSpace <- nextSpace
        routes <- routes + route
    RETURN routes
```

This pseudocode defines a procedure `findSafeRoutes` that takes as input the start and end points of the routes for each first responder, a map of the building or structure, and information on the combustibility of materials in the building. The procedure returns a list of routes as output. The algorithm determines the safest route for each first responder by traversing the spaces in the building or structure, calculating the total distance, total hazard exposure, and risk of structural collapse for each possible next step, and selecting the step with the lowest total risk as the safest route. If a space is on fire or has high levels of smoke, the algorithm increases the total hazard exposure to prioritize avoiding these spaces. If a space is a window that is suitable for exiting the building, the algorithm decreases the total hazard exposure to prioritize using this space as an alternative exit. The algorithm continues this process until the end point is reached.

## VI. EXPERIMENT

An agent-based simulation is a well-established technique for modeling various applications, including evacuations[29]. ABM (Agent-based modelling) is a simulation technique in which an entity functions as an agent. The rules set, interactions with other agents and the surrounding environment determine the behavior of individual agents. These simulations can be used to test and evaluate different evacuation strategies, communication protocols, and other emergency response procedures in a safe and controlled environment. The simulation can be used to test different scenarios and evaluate the performance of the first responders. It can also help identify bottlenecks in the evacuation process and evaluate the effectiveness of different communication and coordination strategies. The results of the simulation can be used to improve training for first responders and to develop more effective emergency response plans.

In this research, Pathfinder is combined with Pyrosim. The smoke display file is imported into the FDS simulation

parameter data. FDS integration and passenger delay in smoke were investigated to allow ABM to limit agent speed due to smoke. In this study, the experiment was carried out in a six-story building, as seen in the Fig. 4.

The data we use uses the floor plan provided on Pathfinder. First, the IFC file is imported into Pyrosim to then create a building geometry model. In Pyrosim, we set a fire point with a power of 800.0 kW/m<sup>2</sup>, which is placed in a room on the 3rd floor of the building as shown in Fig. 4.

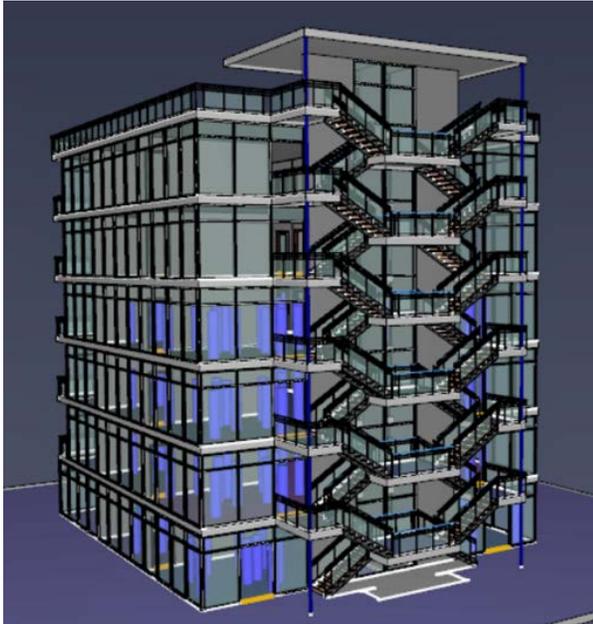

Fig. 4. Case study buildings.

Four visibility devices were installed in the building to record changes in the building's smoke levels. The bigger the smoke, the higher the total hazard exposure, as in the algorithm we proposed, which will increase the total risk.

In Fig. 5 we can see a fire simulation that occurred in the building. Smoke can affect the walking speed of first responders during an indoor evacuation by limiting visibility and making it difficult to navigate through the building. Smoke inhalation can also cause respiratory distress, which can slow down first responders. Additionally, the heat generated by a fire can make it physically challenging for first responders to move quickly through the building. This can be dangerous as it can cause them to become disoriented and lost, making it more difficult to evacuate the building and rescue those inside.

Visibility will be used to slow down people's walking speed. To achieve this, visibility will be measured in several areas within the model. The measurement location will be along the evacuation route, preferably stored on the floor where the fire occurred. Using the visibility distance measured at the location, the local velocity factor will be generated as a function of time. Responders will then reduce their speed and modify their route accordingly. [30] provides a walking speed function as a function of visibility. This is referred to as absolute walking speed in the paper, but we will treat it as a factor that slows the speed of each occupant. Fig. 6 depicts a

linear relationship between walking speed and visibility, which can be expressed by the Eq. (1):

$$\text{Walkingspeed} = \min(1, \max(0.2, 1 - 0.34 * (3 - \text{vis}))) \quad (1)$$

In Fig. 7, we can see the extracted navigation mesh from one of the floors of the building. This navigation mesh will be useful for responders in determining routes.

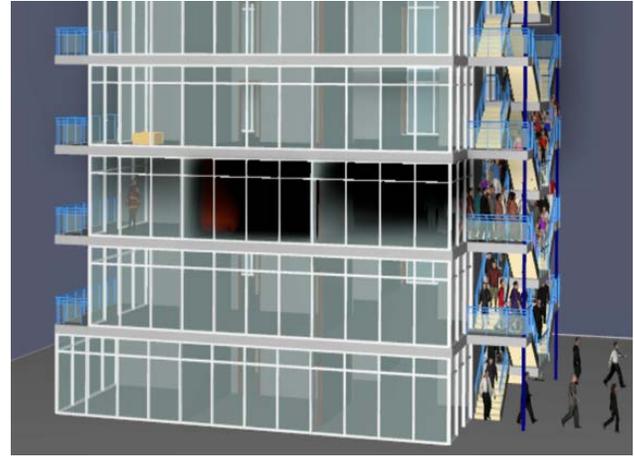

Fig. 5. Fire simulation scene in the building.

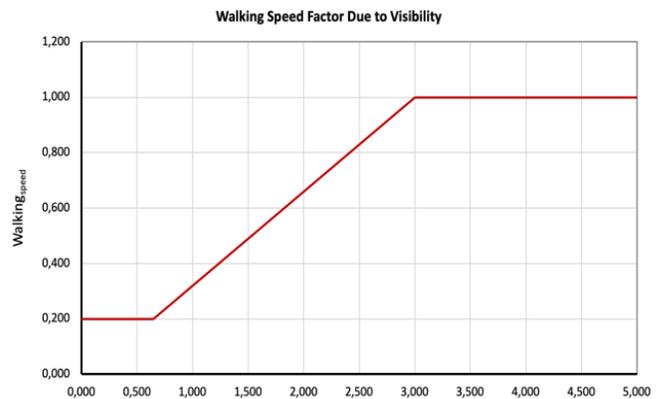

Fig. 6. Walking speed factor due visibility.

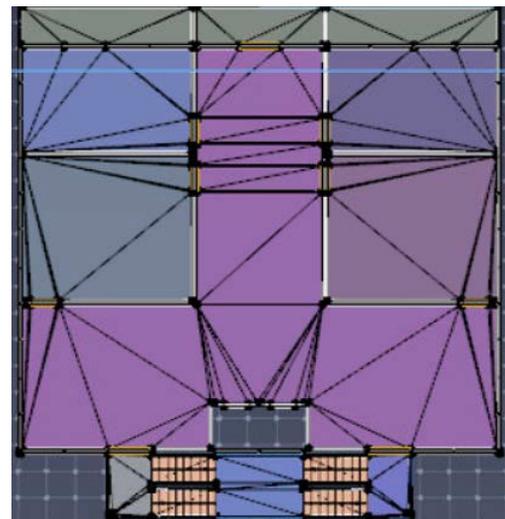

Fig. 7. Extracted navigation mesh.

Navigation mesh space subdivision is a method of breaking down an indoor environment into smaller, manageable sections for the purpose of pathfinding and navigation. This can be particularly useful for first responders, who may need to navigate through large, complex indoor environments such as buildings, airports, or shopping malls. By breaking down the environment into smaller sections, navigation mesh space subdivision can help first responders to navigate through an indoor environment more efficiently and safely by reducing the complexity of the environment and allowing them to focus on specific areas.

The simulation of route choice in this model employs a locally quickest path planning approach. This approach involves ranking routes hierarchically based on local information such as the location of people and the waiting times at exits.

Our model uses two profiles, Occupants and Responders. The number of occupants of the building is 360 people, and 90 people inhabit each floor. Occupants were only set for four floors, while for the floor where the fire occurred, five first responders were simulated during the experiment. The decision to set occupants for only four floors and to simulate five first responders was made to maintain a manageable size for the simulation, while still allowing for a realistic evaluation of the evacuation process and the response of first responders to the emergency situation. By limiting the number of floors with occupants, the experiment could focus on the behavior of the occupants in response to the emergency and the effectiveness of the evacuation procedures. The simulation of five first responders on the floor where the fire occurred was intended to evaluate their ability to navigate the space, locate the occupants, and carry out the evacuation process. Overall, the decision to set occupants for only four floors and simulate five first responders on the floor where the fire occurred was a deliberate choice to ensure a manageable size for the experiment while still providing a realistic evaluation of the evacuation and emergency response processes.

The occupants are assigned a profile with a normal speed of 0.8 m/s to 1.2 m/s. These profiles have a zero Priority Level. The responders' profile has a constant velocity of 1.19 meters per second and a Priority Level of 1. This means in the event of a conflict during movement, and responders will be given priority. However, when going through a smoke-filled room, the pace will decrease according to the value acquired by the visibility tool and then calculated based on the walking speed factor.

### VII. RESULTS AND DISCUSSION

This section summarizes the findings of the fire simulation, with a focus on the first responders, based on the assumptions provided in the previous section. Visibility measurement tools output data to csv files. An example of measurement result data can be seen in Fig. 8. The data was generated from four visibility measurement devices during the simulation run. After the simulation, the data from the visibility measurement devices is processed using the equation shown in the Speed walking Factor to calculate the velocity factor as a function of time based on visibility.

1	s	m	m	m	m
2	Time	visibility1	visibility2	visibility3	visibility4
214	42.20	1.50	18.89	15.50	30.00
215	42.47	1.49	19.16	15.19	30.00
216	42.61	1.48	19.43	14.89	30.00
217	42.86	1.48	19.69	14.59	30.00
218	43.04	1.47	19.94	14.23	30.00
219	43.24	1.47	20.11	13.90	29.88
220	43.43	1.47	20.24	13.53	28.54
221	43.63	1.47	20.34	13.16	27.13
222	43.82	1.47	20.41	12.81	26.00

Fig. 8. Result data from visibility device measurements.

Fig. 9 shows a graph of the velocity factor resulting from the measurements.

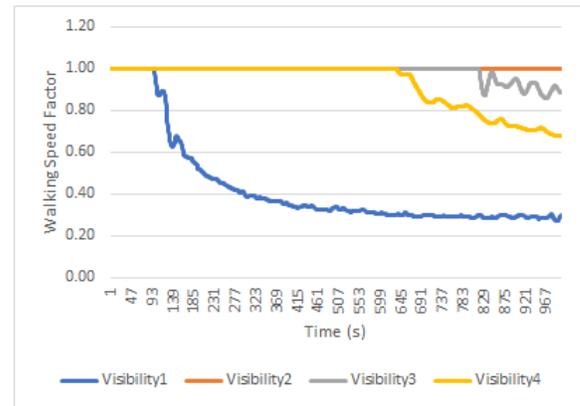

Fig. 9. Walking speed factor.

The time taken by the five responders to carry out the evacuation operation to the location where the fire/smoke occurred was measured during the simulation. The time taken for the responders to enter the building and return safely was calculated, and the results are presented in Table I. Table I compares the time required using the walking speed factor to the time that does not take the walking speed factor into account.

Table I and Fig. 10 shows that the smoke will affect the walking speed of each responder, where the speed will be slower according to the amount of smoke calculated from the visibility devices. In Table I, a non-factor column is an event where a fire does not occur and does not occur immediately. So that the walking speed of first responders is faster than when there is a fire. Smoke can greatly impact the visibility and the walking speed of first responders during indoor emergency operations. Smoke can obscure visibility, making it difficult for first responders to navigate through the environment and locate victims or exits. It also can cause respiratory issues and make it harder for first responders to move quickly through the environment. The smoke can greatly affect the walking speed of first responders, making it more difficult for them to navigate through the environment and locate victims or exits. This can have serious consequences in emergency situations, as it can delay response times and make it more difficult to rescue victims or contain fires.

TABLE I. COMPARISON OF EXIT TIME

Name	Exit Time (s)	
	Non-Factor	With Factor
Responder1	234.825	218.35
Responder2	188.275	148.275
Responder3	239.05	239.625
Responder4	226.025	219.6
Responder5	244.075	227.075

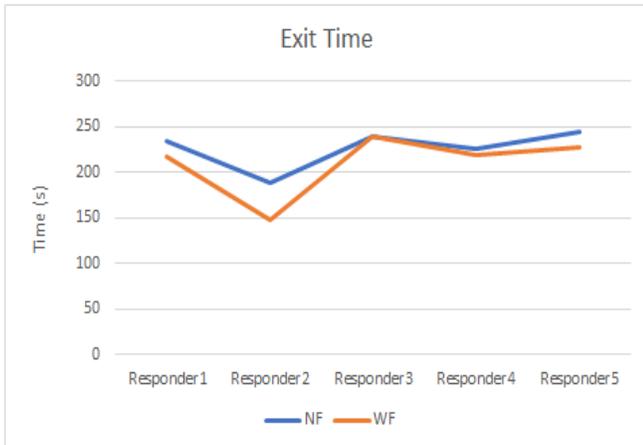

Fig. 10. Exit time from responders.

### VIII. CONCLUSION AND FUTURE WORK

The present study introduces a new framework for space subdivision in indoor navigation specifically developed for first responders. The framework expands upon previous research by including the combustibility factor as a key variable to consider in the event of a fire disaster in a building. Additionally, definitions of safe and unsafe areas for first responders were incorporated based on factors such as the level of hazard and smoke concentration. From these definitions, an algorithm was developed to accommodate the framework, which was then evaluated using Pyrosim and Pathfinder software. Pyrosim was utilized to create a fire model that was measured using a visibility device. The resulting measurements were then subjected to a walking speed factor calculation, which affected the path and walking speed of the first responders. The proposed framework enhances the response time and increases the chances of successful evacuation for first responders, ultimately improving their safety and effectiveness during rescue operations in indoor environments.

Unlike previous studies on indoor navigation, the proposed framework captures dynamic changes such as smoke levels that can impact the navigation path and walking speed of first responders. The experimental results demonstrate that the five simulated first responders were able to complete the evacuation process within 148 to 239 seconds when the fire occurred at a specific location in the building. By accounting for dynamic changes in the indoor context, the proposed framework can identify suitable navigation paths and safe areas for first responders that may not have been considered in

previous research. Thus, the proposed framework represents a significant improvement over previous studies, and has the potential to enhance the safety and effectiveness of first responders in emergency situations.

Future works from this research: integrating the proposed framework with other technologies, such as augmented reality, virtual reality, and internet of things (IoT), to enhance the navigation experience for first responders. Enhancing the cost function: The study should consider more factors in the cost function such as the time consumed by the first responders, the physical strain on them, and the risk of injury. Real-time monitoring: The study could explore the implementation of real-time monitoring systems to track the first responders' movements and provide them with real-time guidance.

SRM Institute of Science and Technology, Kattankulathur, Chennai 603203

**Abstract**—A healthy crop is required to provide high-quality food for daily consumption. Crop leaf diseases have more influence on agronomic production and our country. Earlier, many scholars relied on traditional techniques to detect and classify leaf diseases. Furthermore, classification at an early stage is impossible when there are not enough experts and inadequate research facilities. As technology progresses into our day to day life, an Artificial Intelligence subset called Deep Learning (DL) models plays a vital role in the automatic identification of groundnut leaf diseases. The essential for controlling diseases that are spread to the healthy development of groundnut farming. Deep Learning can resolve the issues of finding leaf diseases early and effectively. Most of the researchers concentrate on detecting leaf diseases by doing research in Machine Learning (ML) approaches, which leads to low accuracy and high loss. To achieve better accuracy and decreases the loss in the DL model by identifying the leaf diseases of groundnut crops at an early stage, we propose the Progressive Groundnut Convolutional Neural Network (PGCNN) model. This paper mainly focuses on identifying and classifying groundnut leaf diseases with a self-collected dataset which is collected from the various climatic conditions around the village located nearby Pudukkottai district, Tamil Nadu, India. The common diseases that occurred in those areas were gathered namely early spot, late spot, rust, and rosette. Model Performance metrics analysis was done to evaluate the model performance and also compared with the various DL architectures like AlexNet, VGG11, VGG13, VGG16, and VGG19. The proposed models have achieved a training accuracy of 99.39% and a validation accuracy of 97.58%, continuing with an overall accuracy of 97.58%.

**Keywords**—*Leaf Diseases Identification (LDI); Progressive Groundnut Convolutional Neural Networks (PGCNN); Self-Collected Dataset; AlexNet; VGG Models*

## I. INTRODUCTION

Agriculture is a major source of revenue for the farmers in India. Despite the fact that agriculture no longer makes up the majority of the country's Gross Domestic Product (GDP) and that other industries' contributions have grown more quickly, agricultural productivity has increased. Timely identification of crop leaf diseases is critical in agricultural yield, quality management, and decision-making. [1] This research builds the model based on CNN architecture for groundnut leaf diseases with five categories which was common in Gujarat area with the progressive resizing using cross entropy loss

function and achieved the results as 96.12% accuracy. The peanut, scientifically known as *arachis hypogaea*, it is a herbaceous yearly plant that belongs to the Fabaceae family and is cultivated for its oil, edible nuts, and nutritious snacks. The symptoms that are shown in the leaf diseases can be easily differentiated between the two infections based on their appearance, spot color, and shape. However, farmers must suffer as a result of inadequate agricultural income. Plants that produce peanuts are typically quite small and have slender stems and leaves that resemble feathers. The leaves are attached to the stalk in a manner that resembles a leaf and is arranged in pairs that alternate. [2] Describes the end-to-end Internet of Things (IoT) constructed system for groundnut leaf disease detection and castor oil plant leaf disease recognition. The vast majority of peanuts grown for commercial purposes are crushed up to extract their oil, which is then put to use in culinary endeavours. A pressed cake is produced as a by-product of oil extraction, and in addition to its use as animal feed, it is also put to use in the manufacturing of peanut flour. Raw kernels are frequently roasted into a snack food and consumed by roasted or boiled manner.

Here, the four types of diseased leaves were selected to experiment with disease identification: early spot, late spot, rust, and rosette. These four have been taken as unhealthy class for model creation in this paper. The above leaf disease images were gathered from the area namely Pudukkottai, Tamil Nadu, India in various climates. All the images are captured with a smartphone-branded VIVO V2029 model with a camera quality of 13 Mpx LED. Gathered images are transferred to the system for further processing, whether the leaf images were affected by diseases or not. To identify groundnut leaf diseases automatically we are proposing Progressive Groundnut Convolutional Neural Networks (PGCNN). The study [3] represents the idea for the recognition and classification on groundnut leaf diseases using the backpropagation procedure by the color transformation in leaves. Previously the traditional CNN architecture was used in many different research papers to identify leaf diseases but there no accurate identification was found. So, to address that problem we are developing the model with a progressive convolutional stack with customized pooling layers to reduce the size of the image and activation function as sigmoid for binary classification.

Convolutional neural networks (CNNs) have been demonstrated to perform well in a variety of image

classification tasks. We apply CNNs to the problem of identifying and classifying peanut leaf diseases in this paper. Peanut is a key food crop in many regions of the world, and leaf diseases can drastically limit productivity. Early and accurate disease diagnosis is critical for effective disease control. However, due to a large number of diseases and the similarity of symptoms among them, diagnosing peanut leaf diseases is frequently difficult. CNNs have been demonstrated to be effective in a variety of image classification tasks. Our CNN model achieves 96.7% accuracy on a held-out test set, which is much greater than the accuracy of a baseline model that uses traditional hand-crafted features.

The rest of the paper is sectioned by the following pattern: Section II details about the existing methods that are used for identifying and classifying the leaf diseases as literature review with various peer review journals; Section III describes about the datasets which was collected from the agricultural field from Pudukkottai district and also shows the sample leaves of healthy and unhealthy leaves; Section IV discusses the details of flow diagram of dataset and the proposed PGCNN model for leaf disease identification and classification among the groundnut self-collected dataset; Section V explains about the implementation details of PGCNN model and the results were achieved, as well as the discussion that was pertinent to them are presented; Section VI shows the results and discussion about the PGCNN model and plots the graphs for training and validation accuracy; Section VII compares our proposed model to the existing CNN architecture to show the proposed model works well than the existing model; and Section VIII concludes the paper with briefs about the proposed model results with future enhancement.

## II. LITERATURE REVIEW

### A. Identification of Diseases

In recent days, the identification and Classification of groundnut crop leaf diseases are done automatically by ML and DL algorithms. Identification of healthy or diseased leaves on groundnut crops is based on the features extracted from the leaves as yellow or brown changes in color from the original green texture of normal groundnut leaves. After identifying the healthy and diseased leaves, it has to be classified whether it is infected or not. Some of the research papers were taken as reference papers for this work to attain the solution with a Deep Learning model for the evaluation of leaf diseases on groundnut crops.

In [4] researcher has done the experiment to identify the Maize leaf diseases based on the feature enhancement and designed a neural network with the base as Alexnet architecture. DMS-Robust Alexnet architecture was proposed with dilated and multi-scale convolution to improve the quality of feature extraction. To avoid overfitting batch normalization is used, to improve the convergence and accuracy researcher used the activation function as PRelu, and Optimizer as Adabound and achieved 98.62% with DMS-Robust Alexnet.

In [5] author proposed a model with a deep learning approach called the Inception model and Rainbow

concatenation (INAR-SSD) model which is based on Improved Convolutional Neural Networks for apple disease detection. The major five types of leaf diseases were selected and implemented in the INAR-SSD model with a recognition performance of 78.80% in Apple Leaf Disease Dataset (ALDD).

The research [6] proposed the Leaf-GAN model to create four different types of leaf diseases for grape crops to identify the healthy or diseased images and fed the generated images to training. There were total of 4062 images before using Leaf GAN, after using augmentation techniques 8124 images are generated to reduce the overfitting problem. Upon CNN models Xception attains an accuracy of 98.70% on testing the datasets.

The study [7] proposed a fine-grained GAN method for identification of grape leaf spot disease to improve the training images to get good performance accuracy and also faster R-CNN is integrated with the above method. With the proposed method higher accuracy was achieved with Resnet-50 as 96.27%.

The study [8] achieved 98.75% and 96.25% of accuracy by implementing the pretrained CNN model called AlexNet and GoogleNet models. This model performed better than the traditional pattern recognition techniques. Here the researcher used five-fold cross-validation approach and crop selected for the plant disease identification is soybean.

The author [9] proposed Restructured Residual Dense Network (RRDN) for identification of tomato leaf diseases with datasets of AI challenger 2018. With residual and dense networks, which minimize the amount of parameters to increase computation accuracy, the result was 95% with top-1 average accuracy.

In [10] the study achieved top-1 level accuracy 94.33% by experimenting Deep Convolutional Generative Adversarial Network (DCGAN) to improve the tomato leaf disease recognition that increases the generalization ability. This network improves the performance, decreases the dataset collection cost and also establishes the diversity of generalization of DCGAN recognition models.

Also, [11] Proposed Deep Convolutional Neural Networks with multiclass classifier for detecting common rice crop diseases with the base model of AlexNet by SGD optimizer on the learning rate of 0.0001 and achieved 91.23% accuracy.

### B. Classification of Leaf Diseases

The research [12] proposed the pretrained model of modified InceptionResNet-V2 (MIR-V2) based on CNN by transfer learning to identify the illness of tomato leaves. This model is trained with both the public and custom dataset of 7 types of diseases. Model achieved the accuracy of 98.92% and F1-Score is 97.94%.

The research work in [13] proposed new model which is based on recognition and classification of groundnut crop leaf diseases. ICS algorithm is used for segmenting the leaves which are affected by diseases. Then MSO algorithm has been used for multiclass feature extraction and MO-DNN algorithm is used for disease classification of multi-classes. At last,

GLD-HML was proposed for analyzing the benchmark datasets to show the performance metrics achieved better than existing.

The authors in [14] used two pre-trained models namely EfficientNetB0 and DenseNet121 for feature extraction from the corn leaves to identify and classify the diseases. The results achieved by new model is 98.56% and compared with two existing model called ResNet152 and InceptionV3 achieved accuracy of achieved accuracy of 7% and 96.26% respectively.

In [15] researcher proposed the Deep Convolutional Neural Network (DCNN) which is based on the evolved concept of transfer learning. Here three types of optimizers were verified with the new model for tomato leaf diseases to identify which optimizer (Adam, SGD and RMSprop) works well for the model. The experimental results showed that the transfer learning model attained the good accuracy with Adam optimizers.

The study [16] utilized the DCNN model for determination and classification of groundnut crop leaves with different types of diseased leaves. This paper achieves accuracy of 95.28% with the optimizer of stochastics gradient with momentum method in DCNN model. Overall accuracy for the proposed model delivers 99.88%.

The research [17] proposed the new model for classifying the groundnut crops leaf as healthy and unhealthy with CNN algorithm with the image compression techniques as DCT, DFT and DWT. The results show that the overall computational time was reduced by comparing the CNN with ResNet50 architecture.

The author [18] created the method for precise detection and classification of groundnut leaf diseases, the method which is proposed by the author, algorithms named H2K which combines the strengths of the three-concept called Harris corner detector, the HOG, and the K-Nearest Neighbor classifier.

In [19] the researcher developed the system for the detection and classification of nutrient deficiency in groundnut leaf especially on nitrogen level. DCNN was implemented for the dataset to achieve the high accuracy and also achieved 95% for training, 92% for validation result.

### III. GROUNDNUT DATASETS

In the section we are going to describe about the groundnut dataset where we have collected from Pudukkottai district, Tamil Nadu, India. Here the detailed description of groundnut leaves and total number of leaves collected with various diseases occurred in the leaf with healthy leaf as on category. [20] explains about the disease-free plant growth which produces more productivity with ELM algorithm with normalization using the benchmark dataset and obtains the optimal learning and better generalization. The dataset is collected with the five types of diseases including healthy leaves to identify whether the leaves are affected by disease or not. In this paper, the commonly affected diseases are selected for the identification of the leaf diseases process. Because these are the diseases that were affected in the area where the

dataset was collected. Details and stages of leaf disease that occurred in groundnut crops are briefed as follows;

#### A. Dataset Description

First Early Leaf spot is a common disease that reduces yield significantly and can be found anywhere the groundnut is grown. This encompasses countries and regions such as the United States of America, Australia, Fiji, the Solomon Islands, Tonga and in Indian states such as Gujarat, Andra Pradesh, Karnataka, Tamil Nadu, and Maharashtra. It is estimated that the leaf spot causes a reduction in yields of at least fifty percent in countries located in the Pacific. Approximately one month after sowing, the first infection of early leaf spot leaf disease will take place. The symptoms manifest themselves on the leaf as a reddish-brown large spot that is not perfectly circular and is surrounded by a yellow halo. The lesion on the lower surface is a light brown color.

Secondly, we took Late Leaf Spot types for the identification of diseases. This type will have infections at the beginning approximately seven weeks after sowing and appear as mostly circular dark brown small spots without a yellow halo. Carbon black color will display in lower surface lesions caused by late leaf spots.

Thirdly, Plants that have been infected with rosette will have the symptoms of a solid clump or gnome shoots, and each will have a tuft of small leaves arranged in a rosette pattern. Chlorosis and mosaic mottling are characteristics of the plant. The infected plants will continue to be underdeveloped and produce the flowers, with the immature flower only a small percentage of the groundnut pegs will mature into nuts, and there will be no seeds produced.

Last, Rust disease infects every part of the plant that is above ground. In most cases, the diseases were discovered at the time of plants at six weeks old approximately. On the backside of the groundnut leaves, tiny eruptions that range in color from brown to dusty chestnut are known as uredosori.

TABLE I. TYPES OF GROUNDNUT DISEASES

Sl. No.	Disease Selected	Symptoms	Duration of disease attacks
1.	Early Leaf Spot	The reddish-brown spot upon the leaf is surrounded by yellow halo nature.	1 month from sowing the seed.
2.	Late Leaf Spot	Carbon black color that will occur under the surface of the leas.	7 weeks after sowing the seed.
3.	Rosette	Yellow color leaf with mottling of the foliage	2 or 3 weeks from sowing.
4.	Rust	Tiny pustules that range in color from brown to dusty	After completing 6 weeks
5.	Healthy	doesn't change its natural green color.	Same as the nature of groundnut leaf color as green

The Table I shows about the groundnut leves diseases name with symptoms and describes about the time when the diseases will attack the leaf.

### B. Early Leaf Spot (ELS)

- Fig. 1. shows the sample of early leaf spot diseases in groundnut crops are fungal diseases caused by the fungus *Cercospora arachidicola*. This disease can cause extensive leaf spots and defoliation in groundnut crops. About one month after sowing, this disease begins to affect the crop.

Fig. 1. Early leaf spot

- The disease affects all above-ground plant parts, especially leaves. The two infections' leaf symptoms differ in appearance, spot color, and shape. Both fungi damage the petiole, stem, and pegs. As infection spreads, lesions from both species merge and spotted leaves drop early. Severe infections impair nut quality and production.

### C. Late Leaf Spot (LLS)

- Fig. 2. represents the LLS fungal disease that affects groundnut crops. This disease is triggered by the fungus *Phaeoisariopsis personata* and is characterized by the thick brown or black dots on the leaves. The spots can vary in size and shape, and they may be surrounded by a yellow halo. The disease can cause the leaves to drop off the plant, which can reduce the plant's ability to produce nuts.

Fig. 2. Late leaf spot

- The binomial name of the LLS is *phaeoisariopsis personatum*. Mycelium and haustoria are produced by the fungus. The symptoms of LLS are defined as Conidia are cylindrical or obclavate, short, hyaline which are in high humidity for three days, if the temperature is as low as 20 degrees Celsius with droplets on the lower surface, heavy dosage of fertilizers like nitrogen, phosphorus, and magnesium deficiency in soil.

### D. Rosette Diseased Leaf (RoDL)

- Fig. 3. depicted the RoDL are affected with the viruses types and lead with stunted growth and reduced yields in groundnut crops. These diseases are spread by aphids and can be controlled by using insecticides. The affected plants appear as compressed clumps with tufts of small leaves appeared on the leaves. Chlorosis and mosaic mottling can be seen on the plant.

Fig. 3. Rosette leaf

- The affected plants leaf won't develop fully as they needed for the conversion of nuts from flowers, if they convert also, it won't be good seed to harvest.

### E. Rust Diseased Leaf (RuDL)

- The Fig. 4. shows the rust diseases in groundnut crops are caused by a fungus that affects the leaves of the plant. This can cause the leaves to turn yellow and eventually drop off. The fungus can also cause the nuts to become discolored and shrivelled. The scientific name of the leaf disease called rust is *Puccinia arachidis*.

Fig. 4. Rust leaf

- The disease attacks the plant's entire aerial structure. Rust leaf disease is discovered when the groundnut crops are grown till the week of 6, then this disease will get affect and won't get good maturity of the pods. On the lower surface of the leaves, little brown to uredosori will appear. The above disease can only infect the leaf if the following circumstances are met: the humidity value above 95% high, significant rainfall, and a low temperature (20-25 degrees Celsius).

### F. Healthy Leaf (HL)

- A healthy leaf in a groundnut crop is one that is free from disease, pests, and deformities. It should be a deep green color and be able to photosynthesize efficiently. The below Fig. 5. represents the healthy leaf of groundnut crop. The peanut, scientifically known as *arachis hypogaea*, is an herbaceous annual plant that belongs to the Fabaceae family and is cultivated for its oil and edible nuts.

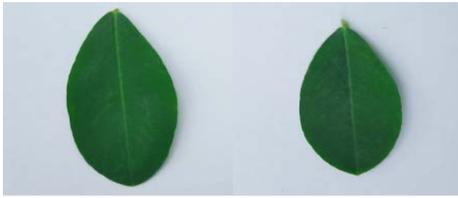

Fig. 5. Healthy groundnut leaf

- Plants that produce peanuts are typically rather tiny and have slender stems and leaves that resemble feathers. The leaves are attached to the stalk in a manner that resembles a leaf and is organized in alternate pairs. The peanut plant can produce yellow, orange, cream, or white flowers. These blooms give rise to 'pegs', which are distinctive floral structures that are pushed down into the soil to facilitate the growth of pods.

#### IV. FLOW PROCESS OF DATASET

The Fig. 6. provides a visual representation of the comprehensive real-time detection process. The first step in developing the GLDD is to collect images of both diseased and healthy groundnuts from an actual groundnut field. The initial GLDD is then subjected to several data augmentation procedures, during which it is manually annotated and expanded. The dataset was categorized into is split into two parts: healthy and unhealthy. In these two classes we have specified for training as 80% and testing as 20%. The findings of the detection include information on healthy and unhealthy classes. Groundnut Dataset Images were collected with the VIVO 2029 smartphone camera having 13 Mpx resolution to identify the groundnut crop leaves which is affected by diseases or not. This paper contains two categories healthy and diseased. In the diseased category we collected four types of leaves which are as follows with the number of leaves collected.

##### A. Dataset

Most of the dataset used for model building are taken from publicly available dataset. The study [21] also uses both the self-collected dataset and PlantVillage dataset for pepper leaf disease detection. Groundnut leaves are collected from the various fields located near the village of Pudukkottai district and also from various websites through google search engine. We have collected the five categories of leaves which is segregated with healthy and unhealthy leaves of groundnut crop. Groundnut leaf disease patterns change with the season and with other elements like humidity, temperature, a lack of NPK, and wetness.

Table II details about the dataset with 619 images of unhealthy and healthy groundnut leaves obtained, which correspond to five categories: Healthy Groundnut Leaf, ELS, LLS, rosette, and rust. These are the five leaf diseases which occurred commonly on the groundnut leaves that were chosen for two reasons. First, these common diseases can be seen with the help of images which were collected by camera itself. Furthermore, they are responsible for its significant yield decrease in groundnut crop cultivation. The above five categories of groundnut leaves are the most common diseases affected in the fields where we collected the images.

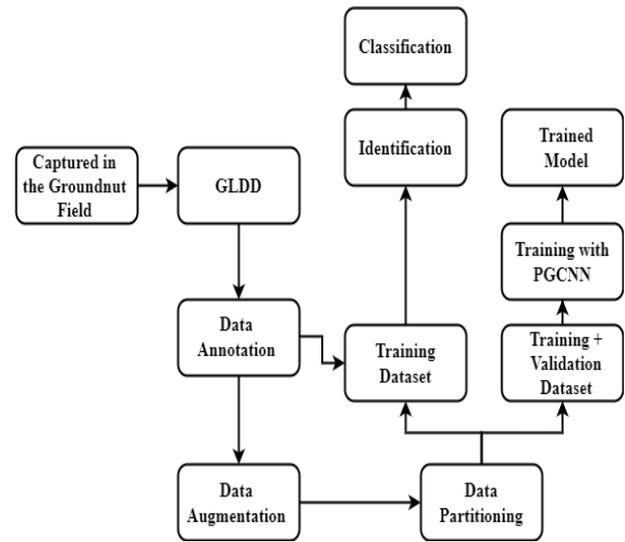

Fig. 6. Process flow of real-time detection of groundnut leaf diseases

TABLE II. DESCRIPTION OF GROUNDNUT DATASET

Sl. No	Name of the Diseases	Total No. of Images
1.	Healthy	190
2.	Unhealthy	429
<b>Total</b>		<b>619</b>

##### B. Progressive Groundnut Convolutional Neural Network (PGCNN)

1) *Input layer*: In this paper, the image size of 1380x1380x3 is given to the input layer of our model to detect whether the image is healthy or diseased. Then the images will get rescaled to 224x224x3 during the model training and testing to reduce the computational time. Here we are feeding single images of four different types of diseases with one healthy leaf category of images with no background to convolve the images with filters to identify the patterns of leaf images.

##### 2) Convolution Layer (Convnet + ReLU)

- From various types of convolution layers available in Keras API, we selected the Conv2D layer for this PGCNN model development because Conv2D layers are implemented over the spatial convolution over images. Arguments used for the Conv2D method are filters, kernel size, strides, padding, activation, and kernel initializers.
- Rescaled images of input image size 224x224x3 are convolved with 64 filters of size 3x3 kernel with strides value of (2, 2). The activation function used to take the value of feature map with "ReLU" as activation function for positive and negative values. While in convolution operation, various filters are used to detect the edges, patterns, etc., for extracting the features from the input images.
- In this paper we have used five conv2D layer to get good feature map. Operation performed by the

convolution layer uses the following equation in default, which had number of filters used in the convolution layer, filter size, padding and stride to convolve through the input image.

$$C_{out} = \frac{C_{in} + 2P - F}{S} + 1 \quad (1)$$

- $C_{out}$  represents the values which we can feed into next layer, which the input of image size 224x224x3 had been fed into the layer.  $C_{in}$  insists the size of the input image in convolution layer,  $P$  represents padding,  $F$  denotes the number of filters used in the convolution layer.

3) *Pooling*: The process of reducing the spatial dimensions (i.e., height and width of the input image) for making the computation faster by decreasing the training parameters. The pool size of the MaxPool2D is taken as (2, 2). There are 3 kinds of pooling to down-samples the input in pooling operations, they are Max Pooling, Average pooling, and Global Pooling. In this research paper, we use maxpooling2D operation to down-samples the input size of the groundnut leaf images. Max pooling chooses the most element from the feature map's filtered region. After max-pooling, the output is a feature map with the most prominent features of the preceding map.

4) *Fully Connected Layer (FC)*: The final Pooling or Convolutional Layers output is flattened to convert the matrix form into one-dimension vector and those are fed into the input of the fully connected layer. Fig. 7 explains fully connected layer is the layer which applies the linear transformation and has the input connection to every neuron into the output layer of another layer.

$$Z_{ij}(y) = f \sum_{k=1}^{n_H} w_{ij}y_k + w_{io} \quad (2)$$

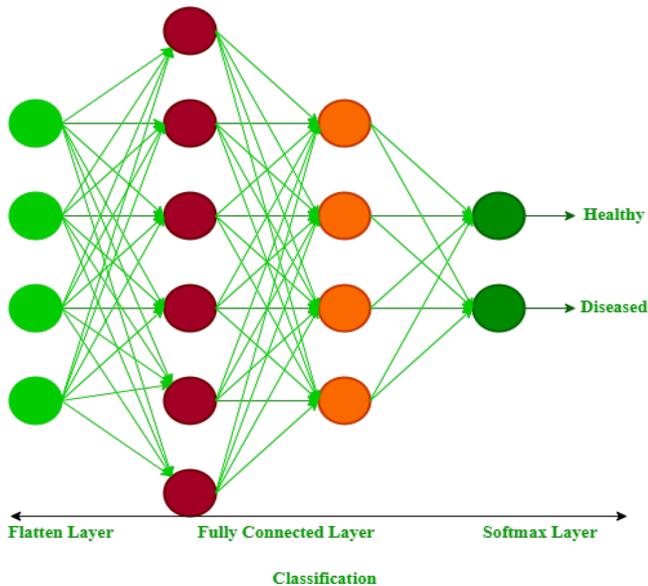

Fig. 7. FC for classification of groundnut leaf

The fully connected input layer (i.e., called flatten) is the conversion process from 2-dimensional array into a single dimensions array or linear vector. The output of the single vector is fed as the input for fully connected layer.

5) *Dense (or) output layer*: Leaky ReLU, Sigmoid, Tanh, ReLU, Softmax, and other activation functions can be used in the final layer for the output layer based on the research problem. This paper focuses primarily on the healthy or diseased category. Because we developed the model for binary classification, the sigmoid is the activation function used at the final layer of the Progressive Groundnut Convolutional Neural Network (PGCNN) to determine whether the leaf is healthy or diseased.

6) *Dropout layer*: This is one of the main characteristics of CNN. This layer is used to set the input value as 0 to skip some of the unwanted neurons to continue to next layer and also it prevents overfitting problem. Here we used 30% of neurons to be dropped out for fed the neurons into next level.

## V. IMPLEMENTATION DETAILS

### A. Groundnut Leaf Diseases Identification using PGCNN

Leaf diseases is a significant threat to agriculture, but we are facing the difficulty for the identification and classification of leaf diseases due to the lack of infrastructure development. To minimize the infrastructure cost and maximize the yield of groundnut cultivation artificial intelligence technology has evolved into farming methods also. DL is one of the subsection of Artificial Intelligence (AI), is causing a revolution in agriculture by replacing traditional methods with more efficient methods that assist farmers in the identification of leaf diseases with convolutional neural networks. The proposed PGCNN model experiments the leaf disease identification with two classes called healthy and diseased with five kinds of validation of the self-collected dataset as;

TABLE III. VALIDATION TEST WITH VARIOUS RATIO PERCENTAGES OF SELF-COLLECTED DATASET

Sl. No.	Dataset Validation %	Training Accuracy	Training Loss	Validation Accuracy	Validation Loss
1.	90-10%	98.74	03.99	91.94	0.2692
2.	<b>80-20%</b>	<b>99.19</b>	<b>03.23</b>	<b>91.94</b>	<b>0.3227</b>
3.	75-25%	98.70	03.49	92.90	0.2855
4.	70-30%	97.69	05.72	93.01	0.1745
5.	60-40%	97.30	08.77	90.32	0.4919

The Table III and Fig. 8 shows the various ranges of dataset splitting for training and testing (Validation) accuracy for an imbalanced dataset of groundnut leaf images. After plotting the table, we conclude that the dataset separation with ranges of 80% training and 20% testing works well and achieves a high of 99.19% training accuracy and 91.94% of testing accuracy than the other splitting.

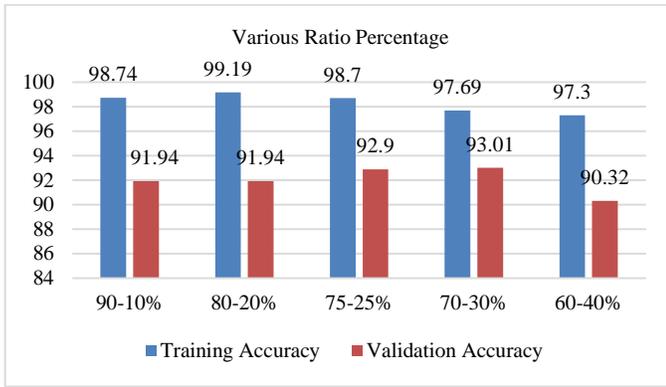

Fig. 8. Categories of ratio percentage

**B. Optimizers of PGCNN**

We have implemented five types of optimizers to reduce the loss value for our dataset which is self-prepared and validated with an 80% - 20% proportion. RMSprop, Adam, Adamax, Adagrad, and SGD were selected because these are similar to Adam optimizers with momentum.

TABLE IV. VARIOUS TYPES OF OPTIMIZERS TESTED IN PGCNN MODEL

Sl. No.	Optimizers	Training Accuracy	Validation Accuracy
1.	RMSprop	97.37	95.97
2.	<b>Adam</b>	<b>98.17</b>	<b>97.58</b>
3.	Adamax	96.56	91.13
4.	Adagrad	71.86	68.55
5.	SGD	78.34	76.61

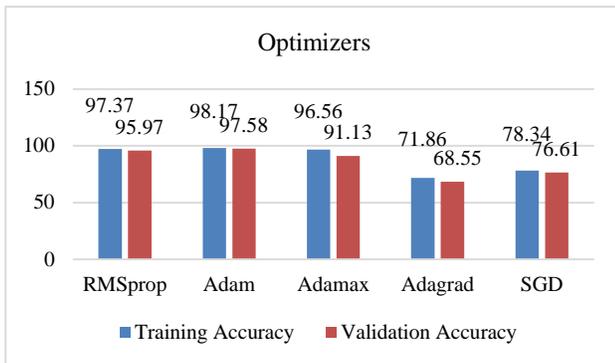

Fig. 9. Various optimizers

From the above Table V and Fig. 9 we achieved high accuracy in the Adam optimizer for training and validation with all the optimizers. The algorithm used for optimizing the PGCNN model is Adam achieves the good results in faster manner. Adam is named as adaptive moment estimation to converge the model in smooth way. This optimizer utilizes the two optimizer benefits, they are AdaGrad and RMSProp.

**C. PGCNN Model Flow Diagram**

The Fig. 10 shows the flow diagram of PGCNN model with sequence of layers which executes the model to achieve good performance. First the input image with the size of 224x224x3 has been fed into the classifier called sequential to

arrange the layers stacked one by one to form a entire network.

There are five convolutional layers constructed to convolve the image to extract the feature map as 16, 32, 64, 128 etc. First Conv2D layer with 64 filter to specify the depth of the filters and 3x3 dimensions of kernel/filter represents the height and depth of the matrix with padding same value, following the activation function as “ReLU” of non-linear function. Then to reduce the dimensionality of images we apply max\_pooling of 2x2 function. This reduces the size of the images with half the value from the previous layer input. By this way we are repeating five times of the convolution operation with filter of 64 on 3x3 size kernel by applying “relu” activation function with the conclusion of convolution is max\_pooling layer.

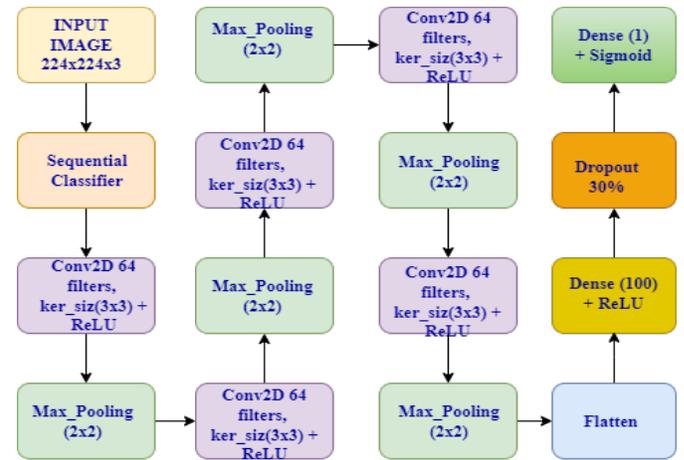

Fig. 10. PGCNN model flow diagram

TABLE V. VARIOUS RATIO OF PGCNN MODEL FOR TRAINING AND VALIDATION ACCURACY

Sl. No.	Sample Images	Training Ratio (%)	Validation Ratio (%)	Training Accuracy	Validation Accuracy
1	619	90	10	0.9910	0.9677
2		<b>80</b>	<b>20</b>	<b>0.9939</b>	<b>0.9758</b>
3		70	30	0.9954	0.9140
4		60	40	1.0000	0.8992

After completing the convolution operation we are applying the flatten() class to convert the two dimension image into one dimensional vector. With 100 nodes in our output layer we are having the dense layer as the previous layer of output layer to spread the probability of values from the fully connected layer by the activation function as “ReLU”. To improve the performance of PGCNN model and reduce the overfitting we added dropout function with 30% neurons to be dropped out randomly by selecting the important neuron and some of the neurons are ignored during training process. Dropout() is one of the type of regularization in deep learning models.

Finally, we concluded with dense layer with single neuron for binary classification and the activation function of “sigmoid” is used for the classification of PGCNN model as healthy or unhealthy images. We used sigmoid activation function because this function supports the binary classification for PGCNN model.

## VI. RESULTS

The model creation and executions were performed in TensorFlow framework. Dataset has been prepared by self-collected with the samples of total 619 groundnut leaves as two categories such as Unhealthy and Healthy options. The leaves were collected from the village near by Pudukkottai town, Tamilnadu at different times with different groundnut crops.

The Table VI, Fig.11 and Fig. 12 explains about the results for the various ratios for the proposed PGCNN model for the groundnut leaves disease identification and classification of healthy and unhealthy category. We have taken four different ratios as 90-10%, 80-20%, 70-30% and 60-40% respectively. From these compilations we have achieved the good training accuracy and validation accuracy in 80-20% ratio. So, we freeze that ratio for further evaluation for PGCNN model. With the minimum number of sample images, the proposed model achieved 99.39% as the accuracy of training the model and 97.58% as the accuracy of validation of PGCNN model. The 90-10% ratio also achieves good training accuracy as 99.10% and validation accuracy as 96.77% with the training loss of 0.0104%, validation loss as 18.79%. Next ratio tested with 70-30%, it achieves the training accuracy of 99.54% and validation accuracy of 91.40% with 0.0111% of training loss and 90.05% of validation loss. At last we have tested with the ratio of 60-40% which achieves the training accuracy of 100% and 89.92% of validation accuracy with the training loss of 0.0041% and 39.59% validation loss.

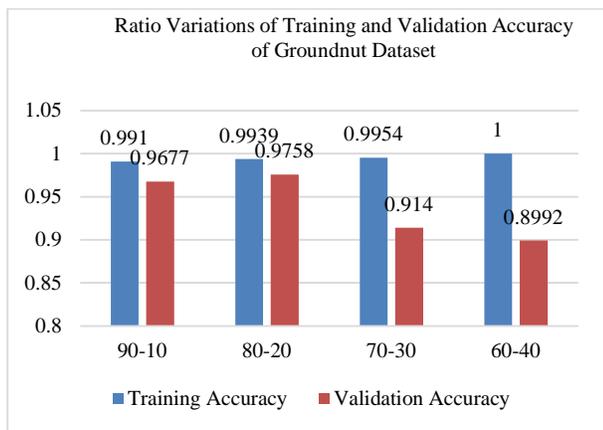

Fig. 11. Model training and validation accuracy graph

TABLE VI. VARIOUS RATIO OF PGCNN MODEL FOR TRAINING AND VALIDATION LOSS

Sl. No	Sample Images	Training Ratio (%)	Validation Ratio (%)	Training Loss	Validation Loss
1.	619	90	10	0.0194	0.1979
2.		80	20	0.0148	0.1806
3.		70	30	0.0111	0.9005
4.		60	40	0.0041	0.3959

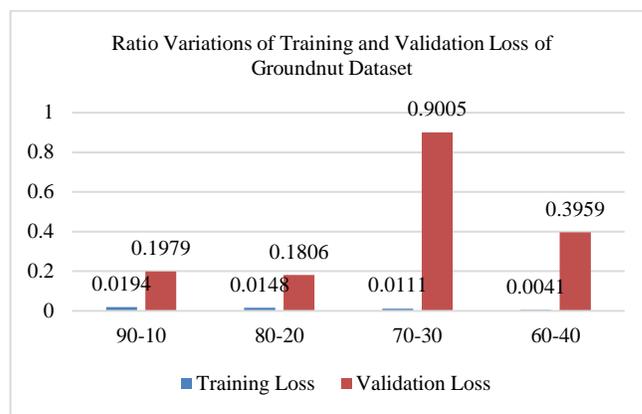

Fig. 12. Model training and validation loss

From the above details we have frozen the ratio for our PGCNN model as 80-20% for further evaluation of predicting the image as healthy or unhealthy. Because it ended up with good accuracy on both training and validation with less training and validation loss when compared to the other ratio results.

The Fig. 13. explains that the identification of groundnut leaves as healthy or unhealthy by the classes we defined in the dataset, it classifies the category by class names if it falls on healthy or unhealthy classes. And also it shows that the label defined as 1 for unhealthy class and 0 for healthy class.

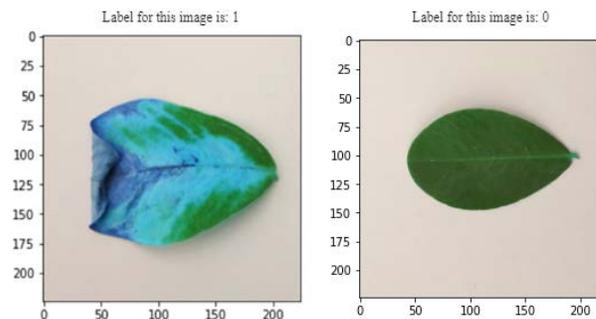

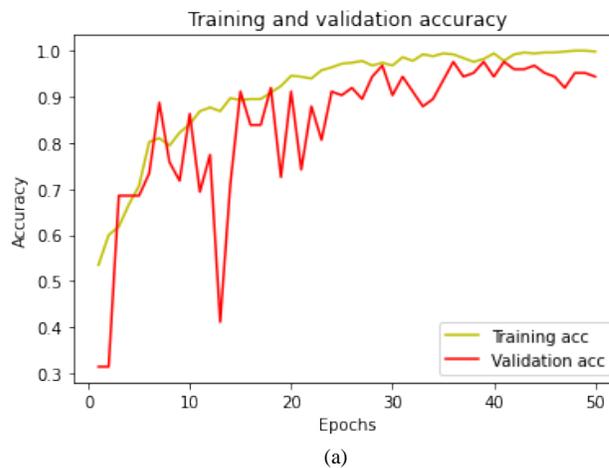

Fig. 13. Identification and classification of groundnut leaf as unhealthy or healthy

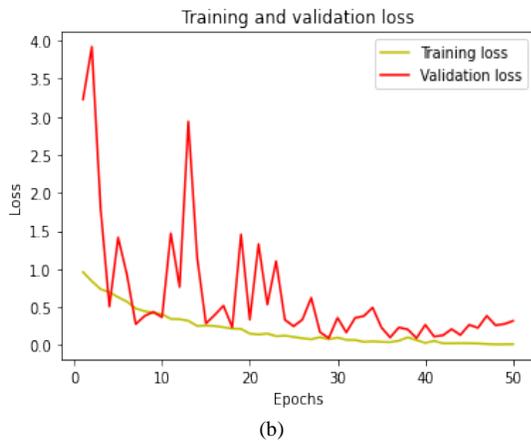

Fig. 14. (a). PGCNN model training and validation accuracy, (b). PGCNN model training and validation loss

The Fig. 14(a) and Fig. 14(b) shows that the graph for the proposed model of PGCNN training, validation of accuracy and loss against the groundnut dataset which was collected from the field located nearby the Pudukkottai district. The curve indicates how the model fits into the accuracy of both training and validation data. The training loss indicates that the training data learns well and it decreases over time to fit the curve as good fit. The validation loss jumps up and down to fit into the curve for model that learns the new data to fit the curve in good fit. The above model learns all data in a good manner to fit the curve of loss that decreases in certain time. Likewise, the training and validation accuracy curve also fits in good manner by gradual increase in the curve.

TABLE VII. COMPARATIVE ANALYSIS

Sl. No	CNN Models	Training Accuracy	Training Loss	Validation Accuracy	Validation Loss
1	PGCNN	0.9939	0.0194	0.9758	0.1806
2	AlexNet	0.9737	0.1039	0.7419	0.1148
3	VGG11	0.6949	0.6160	0.6855	0.6229
4	VGG13	0.6949	0.6159	0.6855	0.6228
5	VGG16	0.6949	0.6161	0.6229	0.6855
6	VGG19	0.6949	0.6161	0.6855	0.6229

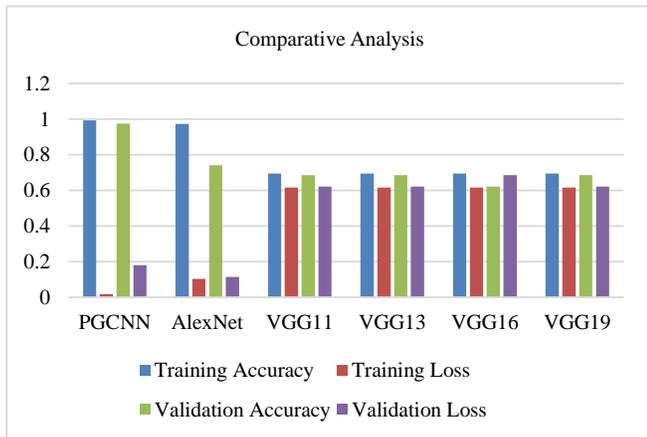

Fig. 15. Various model comparison on proposed PGCNN model

The Table VII and Fig. 15 shows that the comparative analysis of six CNN architecture including the proposed PGCNN model. It shows that PGCNN gives good accuracy and reduced loss for training and validation process. Here we have taken AlexNet, VGG11, 13, 16 and 19 models. The reason behind the model selection like VGG series is that we have built the model based on this architecture. By comparing the obtained results of proposed model with the pretrained models like VGG architectures. The proposed model has achieved the good results as compared to VGG model architecture.

## VII. DISCUSSION

This research paper discusses about the groundnut leaf diseases identification and classification as whether the leaf is healthy or unhealthy. For experimenting this dataset with appropriate base model we have gone through various paper as related works to concluded our model. With the use of literature review we confirmed to develop PGCNN model which we used CNN architecture as our baseline to implement the model. After implementing the model, we have compared with the pretrained CNN architecture for performance comparisons. We achieved the good performance accuracy compared to the pretrained models which has limited layers. The proposed model achieved the training accuracy of 99.39% and validation accuracy of 97.58%. Such that the training loss as 0.01% and validation loss as 0.18% respectively. These results achieved with 619 total images for the dataset which was collected from the fields. In future we are planning to collect more images for large dataset and also, we will be preparing our dataset to make as a benchmark dataset for publicly available for the researcher to use and explore it. In next section we concluded our research work that have done with the dataset by PGCNN model.

## VIII. CONCLUSION

This paper was implemented with the dataset which was collected from the real-life scenario of field located nearby Pudukkottai, Tamil Nadu, India. Groundnut dataset has two category of groundnut leaves namely healthy and unhealthy for identification of diseases from the leaves. The detailed description of the groundnut dataset has been listed under the Section IV. Here we focused to identify and classify the dataset with two classes. Five different CNN architecture were designed and executed to compare the proposed model whether the PGCNN model performs well when compared to the pretrained architectures like VGG11, 13,16, etc. we used performance metrics as accuracy for all the architectures, in that PGCNN achieves good accuracy for both training and validation process. The proposed PGCNN training accuracy was 99.39% and validation accuracy was 97.58%. The model loss also reduced as compared to other models as training loss 0.0194 and validation loss as 0.1806.

In future we will be focusing the dataset on multi-class classification to classify the leaves by their diseased names and incorporate it into the prediction-based solutions. We will be focusing on more data to be collected on various seasons and measures the performance.

# Enhancing Image for CNN-based Diagnostic of Pediatric Pneumonia through Chest Radiographs

Vaishali Arya, Tapas Kumar

Department of CSE, FET, Manav Rachna International Institute of Research and Studies, Faridabad, India

**Abstract**—In underdeveloped nations, severe lower respiratory infections are the principal reasons of infant mortality. The best treatments and early diagnosis are now being used to alleviate this issue. In developing nations, better treatment and prevention approaches are still required. Clinical, microbial, and radiographic clinical studies have a broad range of applicability within and across populations, and it much depends on the knowledge and resources that are made accessible in different situations. The most appropriate procedure is a chest radiograph (CXR), although pediatric chest X-ray techniques using machine intelligence are uncommon. A strong system is required to diagnose pediatric pneumonia. Authors provide a computer-aided diagnosis plan for the chest X-ray scans to address this. This investigation provides a deep learning-based intelligent healthcare that can reliably diagnose pediatric pneumonia. In order to improve the appearance of CXR pictures, the suggested technique also employs white balancing accompanied with contrast enhancement as a preliminary step. With an AUC of 99.1 on the testing dataset, the suggested approach outscored other state-of-the-art approaches and produced impressive results. Additionally, the suggested approach correctly classified chest X-ray scans as normal and pediatric pneumonia with a classification accuracy of 98.4%.

**Keywords**—Contrast enhancement; convolution neural network; pediatric pneumonia; radiography; white balancing

## I. INTRODUCTION

The most prevalent pathogens being the reason of mortality in kids is pneumonia. Pneumonia is a disease caused by infections such as viruses, bacteria, and fungi that enter the lungs and cause the alveoli to fill with inflammatory fluid. It's crucial to get this condition diagnosed early since it has devastating consequences, particularly in kids under the age of five, and can be controlled by doing so. More than 150 million kids below the age of five are affected with pneumonia annually, and 20 million of kids require hospitalization for treatment [1]. The most of pneumonia infections occur in developing and underdeveloped countries, where there is a lack of medical services, excessive urbanisation, pollution, and unclean air. Therefore, avoiding the condition from turning deadly can be greatly aided by early treatment and detection.

The conventional biological diagnostics are inadequate to determine the cause of pediatric pneumonia since blood cultures are insensitive, pulmonary aspirates are difficult to collect, and antigen assays have poor specificity [2]. Presently, the diagnosis of pneumonia is determined by the patient's symptoms, the results of a CXR, the growth and susceptibility of the bacteria found in throat swabs or sputum specimens, and blood tests. Early detection of pediatric pneumonia is crucial in

reducing repercussions since this illness is curable and may be prevented, particularly through vaccines. CXRs, while having a lower resolution than Magnetic Resonance Imaging (MRI) or Computerized Tomography (CT) scans, can nevertheless be utilized to conduct a wide range of evaluations. Radiographic diagnosis of pediatric pneumonia is very subjective and is reliant on the radiologist's skill and understanding. High definition MRI and CT scans make it simpler to detect pneumonia, though most radiologists prefer to utilize CXRs for evaluations due to the faster turnaround time and economical nature of the technology. Radio-opacities or white patches in the airways, especially in the alveoli, are typically seen on a scan of pneumonia and signify the existence of chronic effusion. Attributed to the reason that some illnesses might resemble similar indications, these radiological observations can be challenging for a trainee radiologist and result in incorrect positives and negatives. Fig. 1 displays examples of CXR pictures from the pediatric population that have been categorized as normal and pneumonia for this research.

Artificial intelligence (AI) has notably been utilized to diagnose pneumonia-related abnormalities in radiographic scans. Deep Learning (DL) techniques are the most well-known and commonly used approach for detecting and classifying clinical pictures in general, and pneumonia specifically, owing to the abundance of tagged CXR resources and ubiquitous, reasonably priced computer capacity. These technologies carry the potential and can diagnose numerous illnesses with conventional physician precision [3].

In earlier investigations, various unique data pre-processing methods have been demonstrated to be helpful in a wide range of applications [4], including voice recognition, hand motion detection utilizing sonography [5], and hand motion identification utilizing navigation systems [6]. In the job of classifying natural photographs, Convolutional Neural Networks (CNNs) has demonstrated excellent outcomes. Clinical scans, on the other hand, can be found in three-dimensional RGB, four-dimensional, or two-dimensional with grayscale files, whilst natural photographs are often found in two dimensional RGB file types. This necessitates a lot of adjusting. Another important distinction relates to illumination changes. In addition, natural images are typically recognised by their edges, fundamental shapes, relationships between nearby pixels, etc., while each pixel's illuminance extent or severity are not important characteristics for their identification. Conversely, when it comes to clinical scans, particularly CXR scans, each pixel's luminance is key for identifying the image's impacted areas. This is incredibly important for spotting anomalies in CXR scans. So, developing

a reliable and effective model for spotting anomalies in clinical scans requires good image pre-processing. Thus, current study adopts a technique that combines white balance and contrast enhancement as a stage in the pre-processing of input for picture improvement.

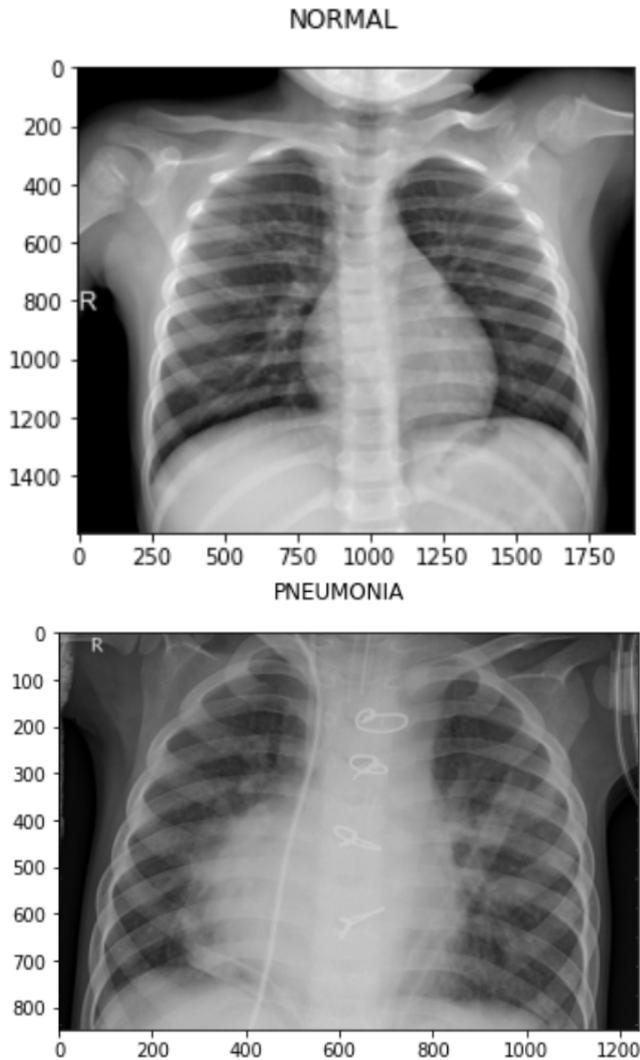

Fig. 1. Samples of CXR images.

The system takes advantage of a multi-layered CNN to accurately predict pneumonia by automatically extracting information from radiography scans. While screening pediatric pneumonia, computer assisted diagnostic (CAD) technologies can take the place of radiologist discretion. They are also useful in rural places or nations without access to technology, such as radiological competence, to corroborate diagnostic evidence. This study suggests a cutting-edge model that can distinguish between pneumonia and the usual. The key contributions of this research are listed below.

- With a remarkable good accuracy of 98.4%, the new proposed design can differentiate between pediatric pneumonia and normal.

- In addition to accuracy, the model's sensitivity, specificity, precision, and F1-score are all 0.9841, 0.9837, 0.9898, and 0.9867, respectively.
- The error symbolized by the False Positives (FP) and False Negatives (FN) is close to 1.6%.
- The efficiency of the suggested design is significantly better than the most recent models stated in the literature.

The manuscript is further divided into sections. Section II highlights the related work. Section III introduces the proposed model. Section IV elaborates the experiment conducted and results achieved. Section V, finally concludes this research.

## II. RELATED WORKS

Major innovations in deep learning have made it possible to automate CXR interpretation with accuracy on par with that of professional specialists [7, 8, 9, 10]. By decreasing ambiguities in explanation and encouraging increasingly broad use of radiological outcomes in scientific studies, automating the diagnosis through CXR may increase sample performance.

Transfer learning was used by Kermany et al. [11] to build a CNN model that could identify pneumonia in CXR scans. CXR images have been classified by Rajaraman et al. [12] as diagnose bacterial and viral pneumonia using a CNN-based approach. Rather than employing the entire picture, they trained CNN models using regions of concern that only contain the lungs. A 121-layer CNN model called CheXNet was created by Rajpurkar et al. [13]. One million CXR scans with 14 distinct illnesses were used to train CheXNet. 420 CXR scans have been used to evaluate the suggested model, and the findings were contrasted to those of professional radiologists. As a consequence, it has been discovered that the CNN model outperformed radiologists generally in spotting pneumonia. A CNN model was presented by Stephen et al. [14]. They built the CNN model from the beginning to classify images from a particular CXR scan to obtain outstanding generalization ability that they utilised to assess whether or not a patient has been afflicted with pneumonia. This differs from prior methods relying simply on transfer learning or classic handmade approaches.

Liang et al. [15] used backpropagation and expanded convolution techniques to achieve pneumonia diagnosis with a CNN framework. While categorising CXR scans, they additionally identified the transfer learning impact on convolutional networks. A sequential CNN model comprising eighteen layers that automatically diagnoses pneumonia has been suggested by Siddiqi [16]. Gu et al. [17] suggested a two-stage technique for discriminating between distinct types of pneumonia. The transfer learning approach has been employed by Rahman et al. [18] to conduct the pneumonia prediction leveraging four pre-trained CNN models. They used three distinct categorization techniques to label CXR scans. Three well-known CNN models have been employed by Togacar et al. [19] for the feature extraction step. Researchers built every model independently employing the same input, and based on the final fully linked layers of every CNN, they extracted 1000 characteristics. For the pneumonia identification challenge,

1000 characteristics have been produced, and these characteristics have been used as inputs to machine learning classifier. A CapsNet CNN architecture with multi-layered containers has been introduced by Mittal et al. [20] for the detection of pneumonia in CXR scans.

### III. PROPOSED MODEL

The objective of current research is to devise an automatic pediatric pneumonia recognition system that can assist in the absence of radiologist. Fig. 2 shows the strategy suggested in this research for identifying pediatric pneumonia utilizing CXR scans. The whole architecture is divided into four phases, i.e., pre-processing model, pre-trained model, interim model and outcome model.

#### A. Pre-processing Model

The image pre-processing model enrich the input by performing four operations i.e., image enhancement, normalization, resizing and data augmentation.

1) *Image enhancement*: Image enhancement start with white balancing followed by contrast enhancement. The image processing technique known as white balance is used to correct the colour integrity of a CXR scan. The scan recording technology does not perfectly capture light like the naked eye does because of the low illumination circumstances in clinical scans, which made certain portions of the scan look dark. The finished scan should thus accurately reflect the colours of the actual picture through image processing or restoration. This investigation's goal is to make the scan more visible so that the suggested model may identify important information from it. Through the separate stretching of the RGB channels, the white balance technique modifies the colours of the scan's layered structure. Stretching is done for the leftover colour range whilst discarding the pixel colours that are near the terminus of the RGB channels and are only employed by

0.05% of the pixels that comprise the scan. After this procedure, the minimum and maximum limit readings would not be adversely affected by pixel colours that were seldom existent at the channel's terminus when stretching [21]. In this solution, we have implemented a white balance as depicted in Eq. (1) and Eq. (2).

$$I_p = \frac{1}{3} \left( \sum_{i \in R,G,B} \frac{1}{W * H} \sum_{x=1}^W \sum_{y=1}^H \text{image}_i(x,y) \right) * p\% \quad (1)$$

$$\text{Image}_{\text{white\_balance}} = \text{Sat} \left( \frac{\sum_{i \in R,G,B} \text{image}_i - I_p * 255}{I_{99.05} - I_{0.05}} \right) \quad (2)$$

where  $I_p$  denotes the  $p^{\text{th}}$  aggregate percent of RGB channels, and  $\text{Sat}()$  performs saturation operation within the range of (0,255).  $\text{Image}_{\text{white\_balance}}$  presents the white balanced channels pixel values.

After the white balancing, contrast enhancement is achieved through Contrast Limited Adaptive Histogram Equalization (CLAHE) [22], which is an upgradation of adaptive histogram equation (AHE) [23]. AHE divides the original picture into a number of smaller pictures, sometimes referred to as tiles. This approach employs the intensity rebinding algorithm for every tile to be derived from the histogram of every tile, which is generated and correlates to various regions of the picture.

This technique over-intensifies the image, which brings noise into the picture [23]. To handle this noise, authors adopt the CLAHE algorithm. The CLAHE algorithm operates exactly like the AHE algorithm, except before generating the continuous distribution function, it slices the histogram at particular values to restrict the intensification. The histogram's over-intensified portion is further dispersed throughout the histogram. CLAHE had remarkable results in improving CXR scans in one of the earlier research [24] and was deemed helpful in analysing a wide range of medical pictures.

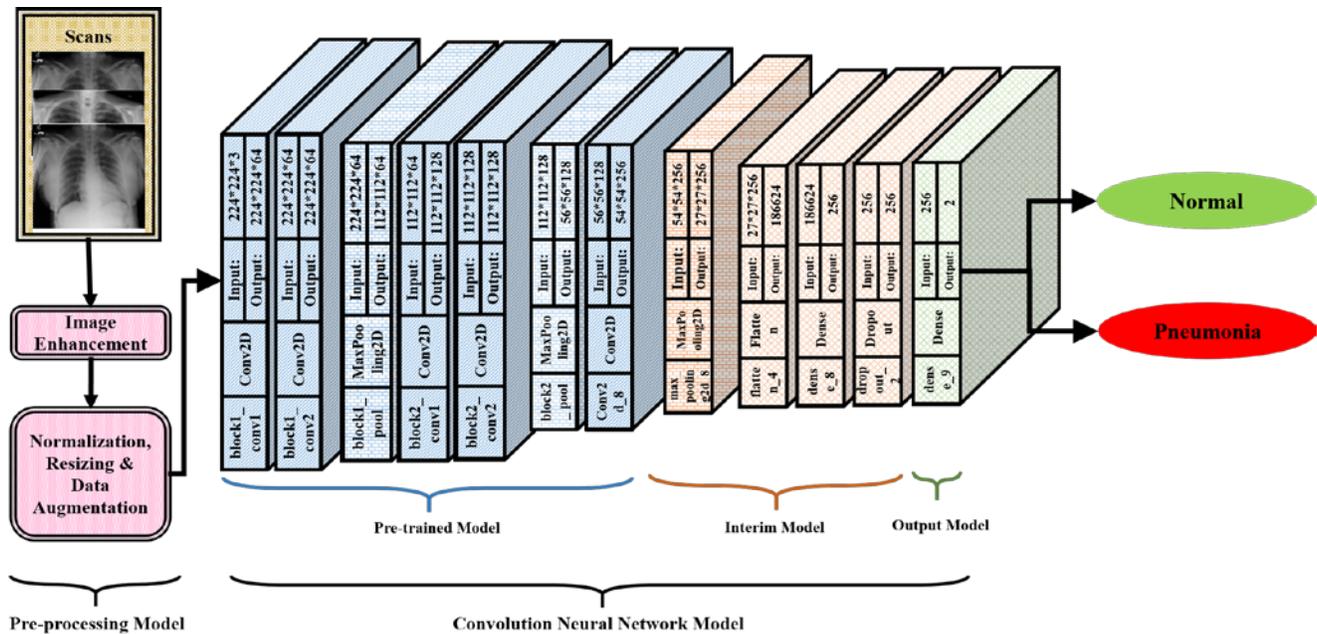

Fig. 2. Proposed model.

2) *Normalization, resizing & data augmentation*: Low-quality or low-resolution CXR scans have not been excluded; all of the CXR scans have been used, normalised, and resized to 224\*224\*3 as the current proposal specifies. A huge collection is needed for the neural network to be trained effectively. CNN models rarely generalise when built on a smaller dataset, which results in low test performance [25, 26]. One approach to resolving this issue is data augmentation, which effectively enhances the underlying dataset. There have been 3883 pneumonia-infected CXR scans and 1349 normal CXR scans in the train set employed in this research. Just the scans of the normal case have been augmented two times since the collection already provided adequate scans of the pneumonia incident. Authors augmented the CXR scans in three steps considering that not all augmentation techniques worked well with CXR images: *i*) random flipping (to negotiate directly with pneumonia signs on every edge of the CXR), *ii*) random shearing (to get a profound understanding of the relationship between pixels), and, *iii*) differing rotation [27]. After augmentation, there have been 3883 scans of pneumonia and 4047 scans of normal. Scans from the testing dataset have not been enhanced.

#### B. Convolution Neural Network Model

The proposed CNN model is divided into three phases 1) Pre-trained model, 2) Interim model, and 3) Outcome model.

1) *Pre-trained model*: The pre-processed scans are stuffed as input to the pre-trained model. This phase of the proposed model is a CNN framework with two convolution filtering layers on top and one pooling layer. Subsequently, one pooling layer and three convolution filtering layers are applied twice. The SoftMax conclusion is the result of three entirely interconnected layers that make up the architecture's intellect. One million ImageNet [7] annotated images with 224\*224\*3 colour images assigned to 1000 class labels are used to pre-train the classifiers. Authors have chosen the top seven layers of this framework to serve as our pre-trained model.

2) *Interim model*: Given the fact that our intended collection of CXR scans comprises "big 3-channeled images," authors initially make minor restructuring to the pre-trained model while keeping its core values. Through our own unique layers, we deliberately altered the final grades of the initial model. Our method employs three filters to create a three-channel extracted features while maintaining kernel size and latency hyper-parameters that are similar to the primary convolutional of the original incarnation. Authors utilize the legitimate activation function while applying the preliminary idea. Authors want to refine the previous concept for a "middleman" zone while both training and developing the layers to get the interim model. The last level of the interim phase is modified to anticipate certain classes since the large clinical images are more akin to CXR scans. This model's outcome is identical to the preceding tightly compacted layer input, with arbitrary vertices set to zero. The result would be labeled as  $Output_{interim}$ .

3) *Outcome model*: In order to connect the interim model results to the arena of CXR scan, which constitutes a last dense layer employing "softmax" activation function, authors adopt 224\*224\*3 inputs obtained from pre-trained model. Researchers can use a larger input dimension in addition to the advantage of translating a model of imaging modalities to the CXR arena. This has the benefit of producing more distinctive patterns since larger pictures contain greater info. Authors include a pre-trained model using the 3-channeled images from the result zone after 50 epochs of the interim solution. This output model distinguishes between normal and pediatric as  $Output_{final}$ .

$$Output_{final} = \max\_index \left( \frac{e^{Output_{interim_i}}}{e^{i1} + e^{i2}} \right) \quad (3)$$

where,  $Output_{interim_i}$  denotes the input vector,  $e^i$  presents the exponential function and  $\max\_index()$  operation calculates the index of class (i.e., 1 or 2) depicted by maximum instances of input vector.

#### IV. EXPERIMENTS AND RESULTS

This section provides the precise details of the tests that have been carried out to evaluate the suggested framework. The CNN model have been implemented using the Keras toolkit alongside TensorFlow. On a machine featuring 64 GB of RAM and an NVIDIA 1080 Ti graphics card, processing has been conducted.

##### A. Dataset

CXR scans of kids are much more troublesome than those of grownups. Particularly, poor posture and even the existence of limbs like arms and necks pose a challenge to educate the network and locate the pneumonia that is associated with the issue. A collection of CXR scans collected by Kermany et al. [28] has been employed in the investigation. This dataset comprises of 5856 scans of kids between the ages of one and five that have been classified as pneumonia and normal by qualified radiologists. Two subgroups of the training examples in the dataset have been provided: 1349 normal scans and 3883 pneumonia scans. Similarly, the testing dataset in the scans have been split into 234 normal scans and 390 pneumonia scans. 20% of the training examples has been employed for validation, and the remaining 80% for training. The adopted dataset has already secured the testing data. This data collection has been employed in several academic investigations, and various categorization techniques have been applied on it [29].

##### B. Results

The proposed framework has been trained to distinguish between scans of pediatric pneumonia and scans of normal CXR, and the prototype appears to have learnt how to address this issue successfully and effectively. It appears to have been successful in locating the properties associated with the particular category. Fig. 3 and Fig. 4 depict the accuracy and loss attained in the proposed model corresponding to 50 epochs, respectively. Considering accuracy and loss values, the suggested model generated the highest outcomes.

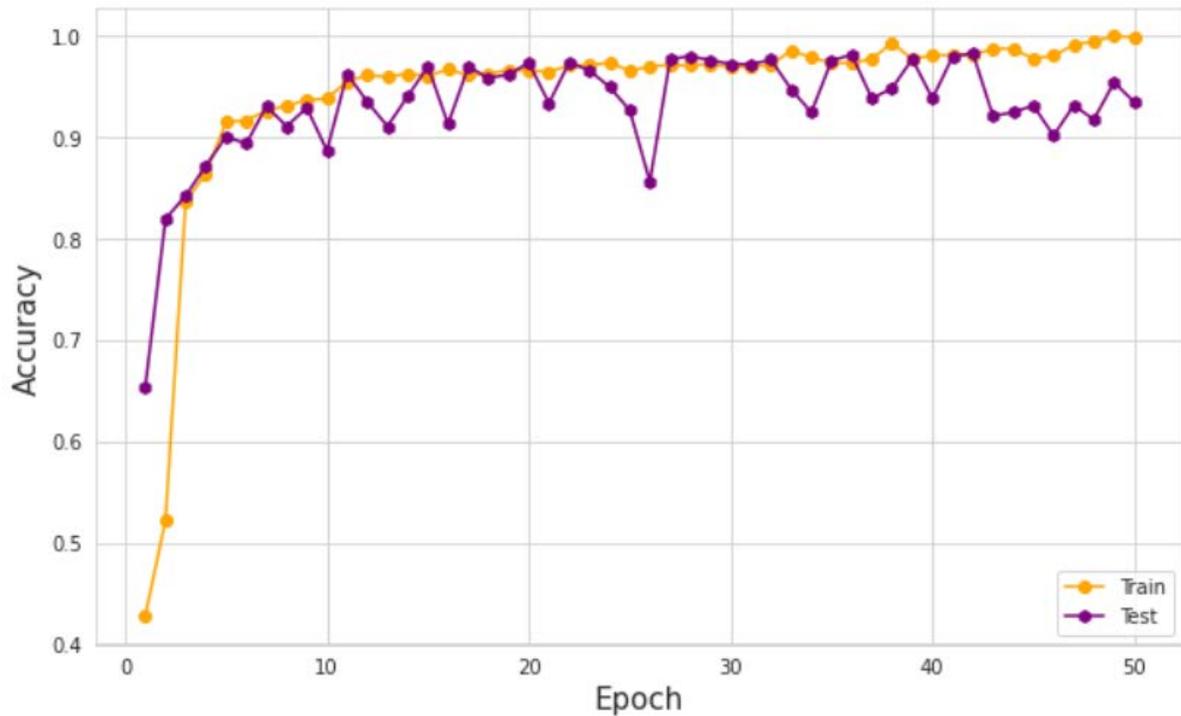

Fig. 3. Accuracy comparison of training and testing dataset.

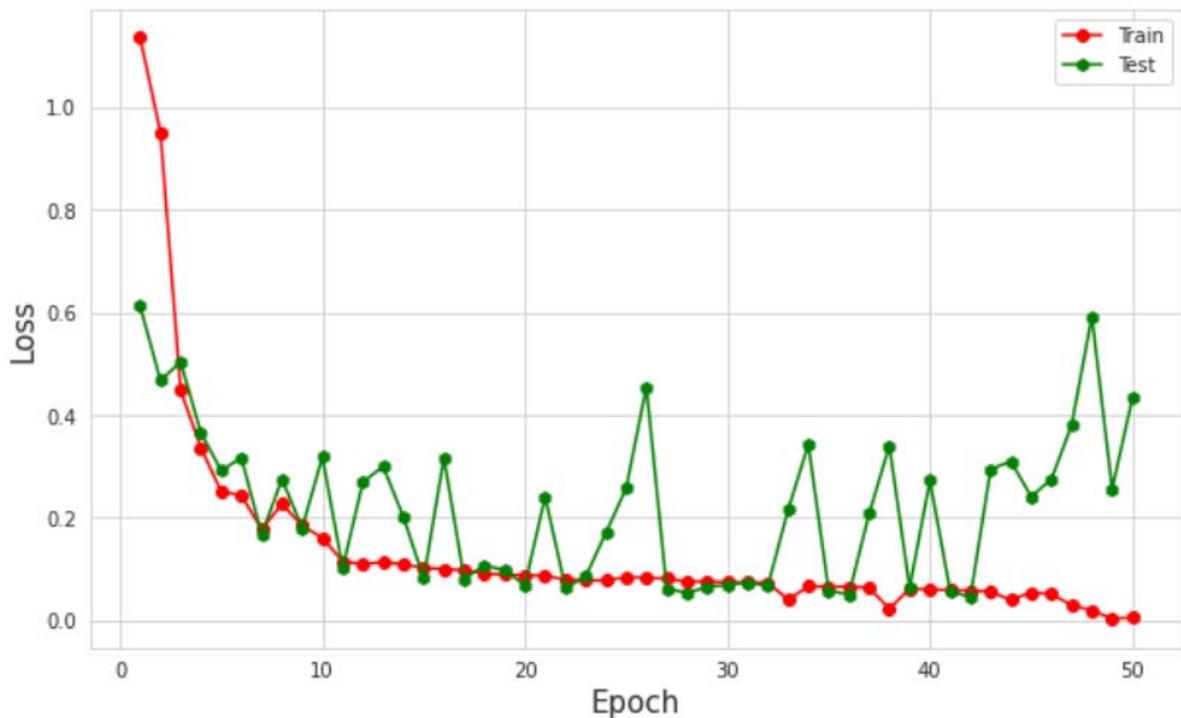

Fig. 4. Loss comparison of training and testing dataset.

The confusion matrix is depicted graphically in Fig. 5 of the classifier's effectiveness, in which the rows correspond to the forecasts and the columns to the original category. The amount of correctly and incorrectly classified scans is shown in the confusion matrix, and it is evident that the suggested framework has been able to distinguish between the underlying

categories with 98.4% accuracy. Further, the error symbolized by the False Positives (FP) and False Negatives (FN) is close to 1.6%. In addition to accuracy, the model's sensitivity, specificity, precision, and F1-score are all 0.9841, 0.9837, 0.9898, and 0.9867, respectively.

Output class	pneumonia	376 60.26%	6 0.96%	98.43% 1.57%
	normal	4 0.64%	238 38.14%	98.35% 1.65%
		98.95% 1.05%	97.54% 2.46%	98.4% 1.6%
	pneumonia	normal		
			Target class	

Fig. 5. Confusion matrix.

The Receiver Operating Characteristic (ROC) curve for the suggested model is depicted in Fig. 6. The curve illustrates a critical performance indicator for every classification model. The AUC is approximately one (0.991 for pneumonia and 0.986 for normal) and the slope in the graph is extremely close to the upper left corner, showing excellent result in differentiating between the two categories. The curve also demonstrates that the suggested model's capacity to distinguish between pediatric pneumonia and normal is nearly comparable.

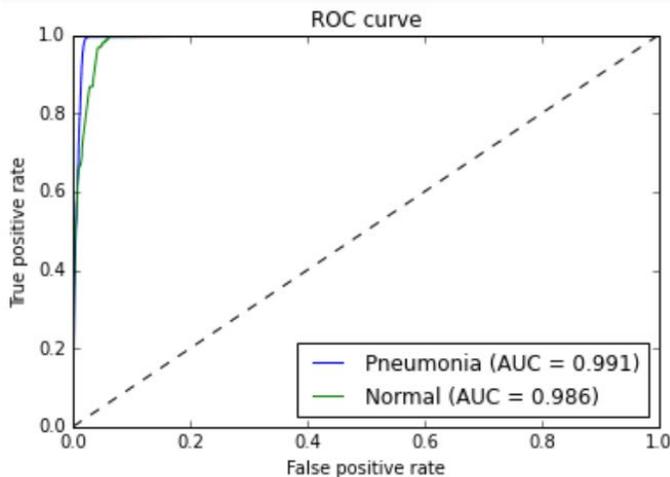

Fig. 6. Receiver operating characteristic curve.

### C. Comparative Study with State-of-the-Art Methods

In Table I, a comparison research is shown. The suggested approach is compared against other prevailing techniques' accuracy. In order to classify cases of pneumonia, Liang et al. [15], Zubair et al. [30], and Mahmud et al. [31] employed simple transfer learning techniques and reached accuracy levels of 90.5%, 96.6%, and 98.1%, respectively. Using specially designed CNNs, Rajaraman et al. [12] have been able to attain an accuracy of 96.2%. An accuracy of 96.36% has been obtained by Chouhan et al. [32] who developed an ensemble model to aggregate estimates from various deep learning

algorithms. The quantity of deep features has been decreased by Togacar et al. [19], who claimed accuracy of 96.84%. An accuracy of 98.0% was attained by Rahman et al. [18] using CNNs. Hashmi et al. [33] attained an accuracy of 98.3%. The strategy proposed in current research performed better than the existing approaches and achieved an accuracy of 98.4% with precision, recall, and AUC of 0.9898, 0.9841, and 0.991, respectively.

TABLE I. COMPARISON WITH STATE-OF-THE-ART METHODS

Model	Accuracy	Precision	Recall	AUC
Liang et al. [15]	90.50%	0.891	0.967	0.927
Rajaraman et al. [12]	96.20%	0.962	0.995	0.993
Chouhan et al. [32]	96.39%	0.9328	0.996	0.9934
Zubair et al. [30]	96.60%	0.972	0.981	-
Togacar et al. [19]	96.84%	0.9688	0.9683	0.968
Rahman et al. [18]	98.00%	0.97	0.99	0.98
Mahmud et al. [31]	98.10%	0.98	0.985	0.983
Hashmi et al. [33]	98.30%	0.9825	0.9814	0.9971
Proposed Model	98.40%	0.9898	0.9841	0.991

### V. CONCLUSIONS

The most common cause of mortality for kids under the age of five globally is pneumonia. Chest X-rays are evaluated by qualified radiologists to diagnose pneumonia. However, it takes a lot of time and is tiresome. Methodologies for biomedical image diagnostics have a lot of potential for use in clinical image analysis. In this study, authors provide an efficient deep learning algorithm for more accurate pediatric pneumonia detection from CXR scans. By using sophisticated pre-processing techniques to render CXR scans more visible, the suggested method collects low-level feature space, enabling recognition of complicated trends from clinical scans on a par with skilled radiologists. The suggested approach may aid in illness detection and support radiologists in the patient care. To evaluate the effectiveness of the suggested model, several metrics, including accuracy, sensitivity, specificity, precision, and AUC score, are calculated. On the testing dataset, the suggested model achieved a precision of 0.9898, an F1-score of 0.9867, an AUC score of 0.991, a sensitivity of 0.9841, a specificity of 0.9837, and an accuracy of 98.4%. Furthermore, based on the current evaluation criteria, the suggested model beats cutting-edge architectures.

# Long Short-Term Memory for Non-Factoid Answer Selection in Indonesian Question Answering System for Health Information

Retno Kusumaningrum\*, Alfi F. Hanifah, Khadijah Khadijah, Sukmawati N. Endah, Priyo S. Sasongko  
Department of Informatics, Universitas Diponegoro, Semarang, Indonesia

**Abstract**—Providing reliable health information to a community can help raise awareness of the dangers of diseases, their causes, methods of prevention, and treatment. Indonesians are facing various health problems partly due to the lack of health information; hence, the community needs media that can effectively provide reliable health information, namely a question answering (QA) system. The frequently asked questions are non-factoid questions. The development of answer selection based on the classical approach requires distinctive engineering features, linguistic tools, or external resources. It can be solved using deep learning approach such as Convolutional Neural Networks (CNN). However, this model cannot capture the sequence of words in both questions and answers. Therefore, this study aims to implement a long short-term memory (LSTM) model to effectively exploit long-range sequential context information for an answer selection task. In addition, this study analyses various hyper-parameters of Word2Vec and LSTM, such as the dimension, context window, dropout, hidden unit, learning rate, and margin; the corresponding values that yield the best mean reciprocal rank (MRR) and mean average precision (MAP) are found to be 300, 15, 0.25, 100, 0.01, and 0.1, respectively. The best model yields MAP and MRR values of 82.05% and 91.58%, respectively. These results experienced an increase in MAP and MRR of 18.68% and 46.11%, respectively, compared to CNN as the baseline model.

**Keywords**—Answer selection; health information; long short-term memory; LSTM; question answering

## I. INTRODUCTION

Providing reliable health information to a community can help raise awareness of the dangers of diseases, their causes, methods of prevention, and treatment. Indonesians are facing various health problems partly due to the lack of health information, including the dangers of smoking, nutritional problems (stunting and obesity), and serious diseases such as heart disease, cancer, and diabetes. Therefore, the community requires media that can provide health information appropriately, namely a question answering (QA) system.

The QA system is a natural language processing (NLP) application that provides specific answers to the questions/queries posed by the user. The QA system is different from a search engine in that the latter will return a set of documents that may contain answers, and users are required to read the documents and search for the exact answers or infer from the set of documents presented. Therefore, the process of finding answers in a QA system is more complex

than the process of finding documents presented by a search engine.

Various QA systems have been developed for both the non-Indonesian QA system and the Indonesian QA system. The following QA systems have been developed for non-Indonesian documents: the English QA system [1]–[3], Chinese QA system [4], Spanish QA system [5]–[7], and French QA system [8], [9]. The Indonesian QA system includes QA statistical and linguistic knowledge systems [10], syntactic-semantic processing QA systems [11], [12], QA systems based on machine learning cross-language QA systems [13], pattern matching QA-based systems [14], and pipeline-based cross-language QA systems [15]. In addition, the Indonesian language QA system has been developed for closed-domain QA [16]–[18].

QA systems are differentiated on the basis of the type of questions handled, which are divided into five categories: factoid, non-factoid, yes-no, list, and opinion [19]. Factoid questions have answers in the form of date, quantity, location, person, organisation, and name (in the form of nouns) in addition to the location, person, and organisation categories [13]. Non-factoid questions are those whose answers are generally used to understand something. Non-factoid questions have six categories: question definitions, reasons, methods, degrees, changes, and details [20]. Overall, the Indonesian QA system is still limited to factoid questions, with hardly any non-factoid questions. Related to health information, the types of questions that are commonly encountered are non-factoid questions.

Several studies have been conducted on non-factoid Indonesian QA systems but for non-health data domains. Moreover, these studies generally used a classical approach such as pattern matching and semantic analysis [21], case-based reasoning [16], and similarity score technique [19]. They provide a good performance only when all the patterns of the answer pairs have been defined, making it appropriate only for certain knowledge domains. In addition, the studies were generally implemented for non-factoid questions related to definitions, reasons, and method categories.

Now-a-days, deep learning models have been widely developed for solving several problems using various types of datasets, such as those containing images, signals, and text. Some examples of deep learning implementation using textual data include sentiment analysis [22], [23], machine translation [24], [25], summarisation [26], [27], and QA. A deep learning

model can be implemented in a QA system as a model for selecting the exact answer from a set of candidate answers, also known as the answer pool. The deep learning model does not require feature engineering, linguistic tools, or external resources [28]. Feature engineering is the stage wherein representative features, such as term frequency-inverse document frequency (TF-IDF) and bag-of-words, are determined. The linguistic tools are linguistic rules and syntax. The implementation of deep learning in a QA system requires a convolutional neural network (CNN). However, this model cannot capture the sequence of words in both questions and answers. This can be overcome by implementing long short-term memory (LSTM).

Therefore, this study aims to implement an LSTM as a model for selecting non-factoid answers in the Indonesian question answering system (IQAS) for Health Information. As mentioned earlier, the LSTM model has never been implemented for answer selection in the IQAS, neither in a specific data domain nor in the general data domain. Hence, the first step in this approach is to train the word2vec model on a health information corpus obtained from various popular health websites written in the Indonesian language. In addition, this study empirically analyses the effect of Word2Vec hyper-parameters, such the dimensions and the context window size, on the performance of the LSTM model in selecting the right answer to a question. Furthermore, the effect of varying the LSTM hyper-parameters on the performance of the LSTM model as a model for selecting exact answers from an answer candidate pool was studied; thus, we established the best answer selection model.

The contributions of this paper are summarised as follows:

- A pre-trained Word2Vec model for the Indonesian language, specifically on health information.
- An investigation related to the influences of the dimensions and context window size of Word2Vec on the performance of the LSTM model in selecting answers.
- An analysis of the influences of the hyper-parameters on the LSTM model, including the dropout, number of hidden units, learning rate, and margin size, on the performance of the LSTM model for answer selection.
- A pre-trained LSTM model for non-factoid answer selection in the IQAS for health information. Subsequently, it was implemented as a web-based application.

The rest of this paper is organised as follows. Section II describes related work, including a general description of the answer selection task and LSTM in detail. A detailed explanation of the proposed framework is presented in Section III, including descriptions of data collection, training process of Word2Vec, generation of the answer selection model based on the LSTM, and model evaluation. Section IV presents the experimental results. Finally, in Section V, we draw some conclusions from the results.

## II. RELATED WORKS

### A. Answer Selection Task

Answer selection is a subtask of the QA system that performs the process of selecting sentences containing the required information from a set of candidate answers [29]. Answer selection involves not only matching the terms in the question and answer but also finding the same semantic meaning from both the question and answer. Formally, the answer selection problem can be described as follows:

- There is a question  $q$  and answer candidate pool  $\{a_1, a_2, \dots, a_s\}$  that contains a set of answer candidates for a particular question.
- The aim of answer selection is to select the best answer candidates from the answer candidate pool.

Therefore, the answer selection task can be formulated as a ranking problem, giving better ranks to answers that are more relevant to the respective question. Some of the ranking function approaches include pointwise, pairwise, and list wise [30]. This study implements a pairwise approach to train the ranking function to give higher scores for correct answers and lower scores for wrong ones.

### B. Long Short-Term Memory

The LSTM model is a popular variation of the recurrent neural network (RNN) method. The RNN method is widely used to solve data problems whose order requires attention. The LSTM model overcomes the gradient vanishing problem of the RNN method. In addition, LSTM model is more capable of dealing with the context of long and sequential information. The LSTM model used in this study is the one introduced in [31].

The LSTM model is designed to solve the gradient vanishing problem using a gate mechanism. Its architecture has three gates, namely an input gate  $it$ , a forget gate  $ft$ , and an output gate  $ot$ , and a memory cell  $Ct$ . The LSTM can add or reduce information into the cell state, which is regulated by the gate. The input gate is responsible for determining new information to be added to the memory cell. The forget gate determines which information will be saved or deleted. Finally, the output gate is responsible for determining the information that will be used as output. Fig. 1 shows the LSTM cells.

The hidden state  $ht$  is calculated on the basis of the three LSTM gates. The size of the hidden state is determined by a parameter called the hidden unit. The hidden unit is a parameter in the LSTM that shows the vector dimension of the hidden state  $ht$  for each time step. Mathematically, the LSTM model is defined as follows:

$$i_t = \sigma(W_i x(t) + U_i h(t-1) + b_i) \quad (1)$$

$$f_t = \sigma(W_f x(t) + U_f h(t-1) + b_f) \quad (2)$$

$$o_t = \sigma(W_o x(t) + U_o h(t-1) + b_o) \quad (3)$$

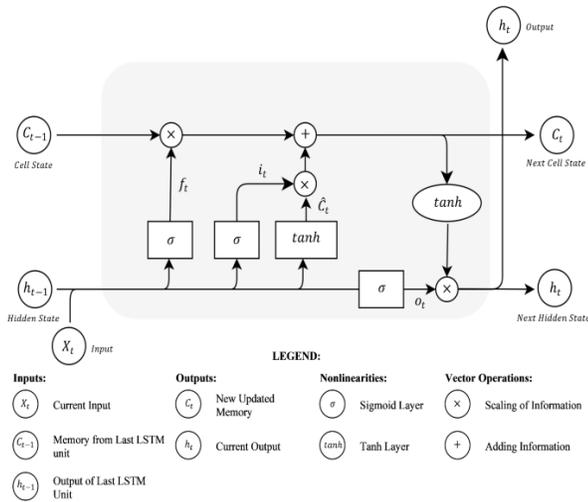

Fig. 1. LSTM cell

$$\tilde{c}_t = \tanh(W_c x(t) + U_c h(t-1) + b_c) \quad (4)$$

$$c_t = i_t * \tilde{c}_t + f_t * c_{t-1} \quad (5)$$

$$h_t = o_t * \tanh(c_t) \quad (6)$$

The LSTM architecture has three gates (input  $i$ , forget  $f$ , and output  $o$ ) and a cell memory vector  $c$ .  $\sigma$  is the sigmoid function.  $W$ ,  $U$ , and  $b$  are the network parameters.

### III. METHODOLOGY

This section describes the proposed framework used in this study, comprising four main processes. Fig. 2 shows its general description.

The research framework comprises four main processes: data collection, training process of Word2Vec, generating an answer selection model based on the LSTM, and model evaluation. The detailed explanations for each process are given in the following subsections.

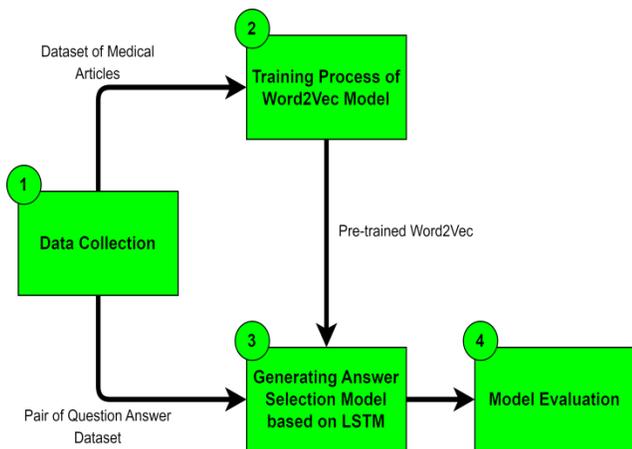

Fig. 2. Framework of this study comprising four main processes: data collection, word2vec training, LSTM-based answer selection modelling, and model evaluation

### A. Data Collection

In this process, two types of datasets are formed: a QA dataset (pair of question-and-answer datasets) and a health article dataset. The QA dataset was created by collecting question and answer pairs from popular health sites in Indonesia, namely hellosehat.com, alodokter.com, and halodoc.com. Non-factoid questions on topics of diseases and medicines are used as questions. The categories of the questions are definitions, reasons, and methods. In total, 750 pairs of questions and answers are formed, consisting of 355 pairs for definitions, 145 pairs for reasons, and 250 pairs for methods. The article dataset is established using all the articles from the three websites through data scraping.

### B. Training Process of Word2Vec Model

The Word2Vec model is a word embedding algorithm proposed in [32] to learn vector representations. Vector representations can efficiently capture the semantic meaning of the words represented. The word vector tends to obey the laws of analogy and describe intuition. Words known as synonyms have the same vector in the cosine equation, whereas antonyms have different vectors. Therefore, the representation of words in the vector space is useful for achieving better performance on NLP problems by grouping similar words.

The dataset used in Word2Vec training is the article dataset. The article dataset contains articles on diseases and medicines found on the three sites previously described. The number of vocabularies formed was 44,700. The Word2Vec model used is skip-gram, and the evaluation method is hierarchical softmax. Fig. 3 illustrates the skip-gram architecture.

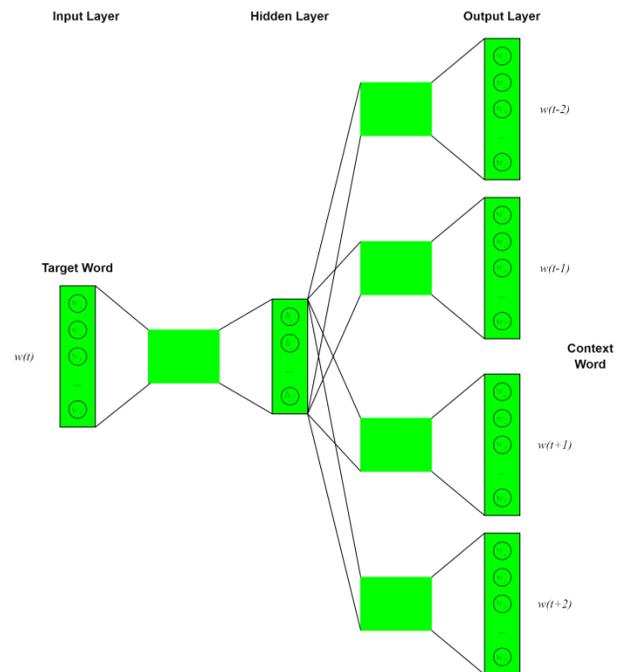

Fig. 3. Illustration of skip-gram architecture of Word2Vec model

### C. Generating Answer Selection Model based on LSTM

Modelling for answer selection uses a Siamese architecture. This type of architecture can be used to measure the relevance of candidate answers to a question. Fig. 4 shows the Siamese architecture of the LSTM-based answer selection model. In the embedding layer, the inputted sentences (i.e., the candidate answer and the question) are converted into vector representations generated by Word2Vec training. Thereafter, in the encoding layer, the same encoder is used to create distributed vector representations for the input sentences separately. The encoding layer adopts the QA-LSTM using a bidirectional LSTM (biLSTM) model. During the encoding process, the questions and answers do not have explicit interactions.

Bidirectional LSTM utilises both the previous and future contexts by processing in two directions and generates two independent sequences of LSTM output vectors. The two output vectors are concatenated as follows:

The implementation of max pooling was used to generate representations for the questions and answers based on the word-level biLSTM outputs. The relevance scores of the candidate answers to a question are obtained based on pooled vectors. Subsequently, using the cosine similarity measures the distance between the candidate's answer and the question.

### D. Model Evaluation

The evaluation techniques used are the mean reciprocal rank (MRR) and mean average precision (MAP), which are the standard metrics for information retrieval and QA. The MRR can be calculated as follows:

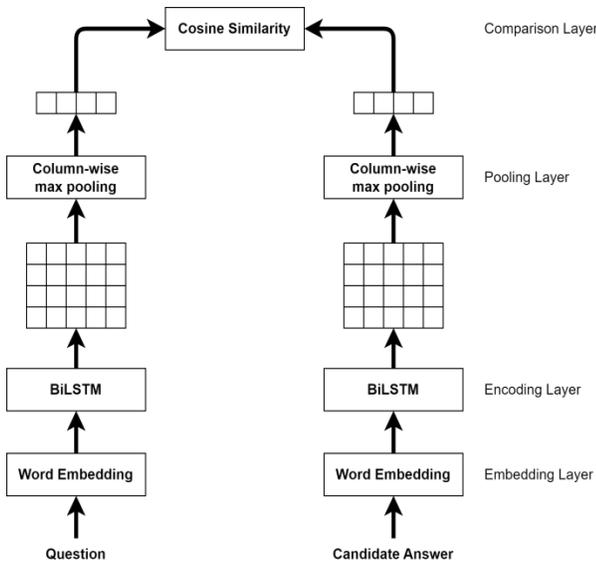

Fig. 4. Siamese architecture of LSTM-based answer selection

$$MRR = \frac{1}{|Q|} \sum_{i=1}^{|Q|} \frac{1}{rank_i} \quad (7)$$

The MAP can be calculated as follows:

$$MAP = \frac{1}{|Q|} \sum_{j=1}^{|Q|} \frac{1}{m_j} \sum_{k=1}^{|m_j|} Precision(R_{jk}) \quad (8)$$

## IV. RESULTS AND DISCUSSION

### A. Experimental Setup

The data used in this research are in the form of 750 question-answer pairs. There are 1564 unique answers collected in the answer space. With regard to the distribution ratio of the training and test data, 70% is for training and 30% is for testing. Following the data distribution, we have 525 pairs as training data and 225 pairs as test data. The pool size is 50. It was generated by sending the ground-truth answers to the pool and randomly sampling negative answers from the answer space until the pool size reached 50.

The experiment employs several hyperparameters of the Word2Vec model and LSTM. Each model is trained for 100 epochs. The Word2Vec hyperparameters are dimension (100, 200, and 300) and context window (5, 10, and 15). At the same time, the LSTM hyperparameters are dropout (0.25, 0.5, and 0.75), number of hidden units (50, 75, and 100), learning rate (0.00001, 0.0001, 0.001, and 0.01), and margin (0.05, 0.1, and 0.15).

### B. Experimental Scenarios

Several scenarios are established to determine the impacts of the various parameters tested on the performance of the proposed model; scenarios 1, 2, 3, 4, 5, and 6 are for the Word2Vec dimension, context window, dropout, hidden unit, learning rate, and margin, respectively. Fig. 5 shows the overview of these scenarios.

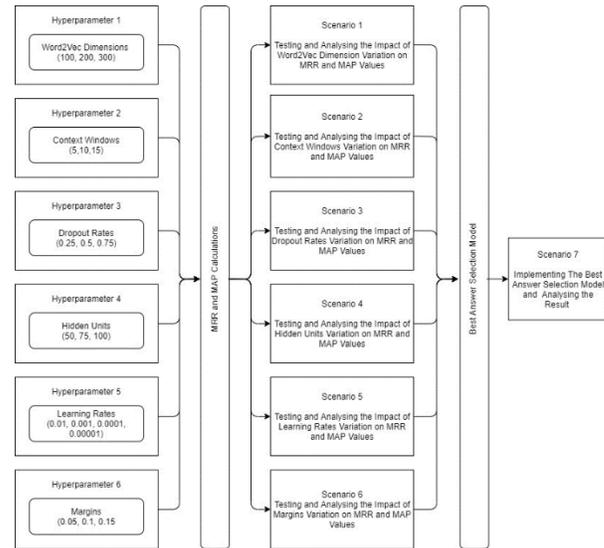

Fig. 5. Six hyperparameters are tested. Each combination produces a model that calculates the MRR and MAP values. The overall results are analysed through seven scenarios. The best model is obtained from the model that produces the best MRR and MAP values

### C. Experimental Results and Analysis

Scenario 1 is aimed at studying the impact of Word2Vec dimensions on the MRR and MAP results. Table I shows that the model yields the best averages of MRR (78.75%) and MAP (63.70%) when the Word2Vec dimension is 300. The MRR and MAP values are directly proportional to the dimensions of Word2Vec; therefore, the higher the dimensions of Word2Vec, the higher the MRR and MAP

values. The Word2Vec dimension represents the size of the learned word vector, or it can be referred to as the features of each word. A higher dimension tends to capture more information and better word representations.

Scenario 2 is aimed at studying the impacts of context window on the MRR and MAP results. The best averages of the MRR and MAP values are obtained when the context window is 15, as shown in Table II. From the table, it can be concluded that the averages of the MRR and MAP are directly proportional to the context window, which means that, the larger the context window size, the higher the average MRR and MAP values. The size of the context window defines the range of words to be included as the context of a target word. For instance, a window size of 5 takes five words before and after a target word as its context for training. A larger context window is required to answer non-factoid questions on health information because this type of question requires a longer answer. Moreover, answers related to health information typically have a long explanation.

Scenario 3 is aimed at studying the impacts of dropout rate on the MRR and MAP results. The best MRR and MAP values are 81.25% and 66.58% when the dropout value is set to 0.25. From the average MRR and MAP obtained for all the tested dropout values, it can be concluded that the dropout value is inversely proportional to the average MRR and MAP, which means that, the lower the dropout value, the higher the MRR and MAP. Dropout refers to ignoring units (i.e. neurons) during the training phase of a certain set of neurons. A higher dropout value indicates that more neurons are ignored, and this will cause the model to lose its ability to learn. Moreover, the dropout performed on the LSTM model can make the model to be more limited in keeping the memory. Therefore, lower dropouts are considered better for storing memory in the LSTM model. Table III lists the results of scenario 3.

TABLE I. PERFORMANCE COMPARISON WHEN VARYING THE WORD2VEC DIMENSIONS

Dimension	Average of MAP (%)	Average of MRR (%)
100	56.76	72.91
200	61.77	77.23
300	63.70	78.75

TABLE II. PERFORMANCE COMPARISON WHEN VARYING THE CONTEXT WINDOWS

Context Window	Average of MAP (%)	Average of MRR (%)
5	58.24	74.30
10	61.15	76.63
15	62.84	77.96

TABLE III. PERFORMANCE COMPARISON WHEN VARYING THE DROPOUT RATES

Dropout Rate	Average of MAP (%)	Average of MRR (%)
0.25	66.58	81.25
0.5	62.14	77.50
0.75	53.51	70.14

Scenario 4 is aimed to study the impacts of hidden units on the MRR and MAP results. As mentioned before, this study applies different numbers of hidden units: 50, 75, and 100. From Table IV, it can be concluded that the number of hidden units is directly proportional to the average MRR and MAP. The output dimension determines the number of dimensions for each word in the input sequence. Dimension implies the number of features to be remembered. The best averages of MRR and MAP are obtained under a hidden unit value of 100. This is because using more features provides a better representation than using fewer features.

Scenario 5 is aimed at studying the impacts of the learning rate on the MRR and MAP results. Several learning rates were set: 0.01, 0.001, 0.0001, and 0.00001. Based on Table V, it can be concluded that the learning rate is directly proportional to the averages of MRR and MAP. The best averages of MRR and MAP are obtained under a learning rate of 0.01. As explained in the experimental results section, all the models are trained for 100 epochs. The learning rate is a hyperparameter that helps control the degree of model change. A low learning rate may result in a long training process that could get stuck, making it difficult to converge. These results can be obtained because the epoch used tends to be small; therefore, a high learning rate will decrease the MRR and MAP values.

Scenario 6 is aimed at studying the impact of margin on the MRR and MAP results. As previously explained, there are three different margin values: 0.05, 0.1, and 0.15. The highest average MRR and MAP were obtained under a margin of 0.1, as listed in Table VI. No specific pattern is generated between the margins with the average MRR and MAP. Margin is a variable in the hinge loss function. The hinge loss function is an employed loss function that was minimised in this research. If the ground-truth answer has a score higher than the negative answer by at least a margin, the expression has a zero loss. Condition here implies margins as the optimum distance that can be produced between the ground-truth answer and negative answers. If the margin value is too low, the ground-truth answer and the negative answer will not be separated appropriately. The lower the margin, the smaller the distance between the ground-truth and negative answers. This condition can make relevant answers irretrievable. Meanwhile, if the margin is too high, the distance between the correct answer and the wrong answer will be even greater. This makes irrelevant answers be incorrectly taken as correct answers.

TABLE IV. PERFORMANCE COMPARISON WHEN VARYING THE HIDDEN UNITS

Hidden Units	Average of MAP (%)	Average of MRR (%)
50	58.16	74.15
75	61.12	76.62
100	62.95	78.11

TABLE V. PERFORMANCE COMPARISON WHEN VARYING THE LEARNING RATES

Learning Rates	Average of MAP (%)	Average of MRR (%)
0.00001	50.74	68.41
0.0001	54.14	70.95
0.001	62.56	78.10
0.01	75.53	87.72

TABLE VI. PERFORMANCE COMPARISON WHEN VARYING THE MARGINS

Margins	Average of MAP (%)	Average of MRR (%)
0.05	60.80	76.39
0.1	61.02	76.55
0.15	60.41	75.94

Based on the results of scenarios 1 to 6, the best answer selection model is obtained when using the following hyperparameters: word2vec dimension is 300, context window size is 15, dropout rate value is 0.25, number of hidden units is 100, learning rate is 0.01, and margin value is 0.1. This model yields MAP and MRR values of 82.05% and 91.58%, respectively.

Compared with previous research, this study also run experiments using CNN with an architecture consisting of 4 convolution layers (kernel size in 1, 2, 3, and 5) and one pooling layer. The word2vec dimension used in the test uses the same dimension, namely 300. The best parameter results for the CNN model include margin 0.15, hidden unit 100, dropout 0.25, learning rate 0.01, and context window 15. The MAP and MRR values obtained are 63.37% and 45.47%, respectively. An illustration of the difference between the CNN model and the proposed model can be seen in Fig. 6. It can be seen that the increases in MAP and MRR were 18.68% and 46.11%, respectively.

Subsequently, the best model is implemented for the QA application, which is given the name MediQA. Fig. 7 shows the sample result of the answer selection.

**Incorrect Answer**

**Question:**  
Apa itu tetanus? (*What is tetanus?*)

**Answer Pool:**  
Tetanus adalah kondisi kaku dan tegang di seluruh tubuh akibat infeksi kuman. Kaku dan tegang seluruh tubuh ini terasa menyakitkan dan dapat menyebabkan kematian. **Gejala tetanus akan muncul dalam 4-21 hari setelah terinfeksi.** Kuman atau bakteri tetanus masuk ke dalam tubuh melalui luka pada kulit, dan akan mengeluarkan racun untuk menyerang saraf. Bakteri ini bernama Clostridium tetani, yang banyak ditemukan pada tanah, debu, atau kotoran hewan. (*Tetanus is a stiff and tense condition throughout the body due to germ infection. Stiffness and tension throughout the body are painful and can cause death. Symptoms of tetanus will appear within 4-21 days after infection. Tetanus bacteria or bacteria enter the body through wounds on the skin and will release toxins to attack the nerves. This bacterium is called Clostridium tetani, which is found mostly in soil, dust, or animal feces.*)

**Selected Answer:**  
Gejala tetanus akan muncul dalam 4-21 hari setelah terinfeksi. (*Symptoms of tetanus will appear within 4-21 days after infection.*)

**Correct Answer:**  
Tetanus adalah kondisi kaku dan tegang di seluruh tubuh akibat infeksi kuman. (*Tetanus is a stiff and tense condition throughout the body due to germ infection.*)

(a)

---

**Correct Answer**

**Question:**  
Apa obat eksim? (*What is eczema medicine?*)

**Answer Pool:**  
Dokter biasanya akan melakukan diagnosis dengan memeriksa kulit dan sejarah medis anda. Dokter juga dapat menggunakan tes patch atau tes lainnya untuk mengeliminasi penyakit kulit lainnya atau mengidentifikasi kondisi yang menyertai eksim. **Obat-obatan yang umum untuk perawatan eksim meliputi hydrocortisone, antihistamin, corticosteroid.** (*The doctor will usually make a diagnosis by examining your skin and medical history. Doctors can also use patch tests or other tests to eliminate other skin diseases or identify the conditions that accompany eczema. Common medications for the treatment of eczema include hydrocortisone, antihistamines, corticosteroids.*)

**Selected Answer:**  
Obat-obatan yang umum untuk perawatan eksim meliputi hydrocortisone, antihistamin, corticosteroid. (*Common medications for the treatment of eczema include hydrocortisone, antihistamines, corticosteroids.*)

(b)

Fig. 8. Sample result of answer selection of definition question, (a) Sample of incorrect answer, (b) Sample of correct answer

As mentioned in the previous section, this study evaluates three questions: definitions, reasons, and methods. Fig. 8 shows a sample of the correct and incorrect answer results given by the MediQA application for the definition question type. Fig. 9 shows the same for the method question type. Both figures consist of two parts, the first part shows a result example of choosing the incorrect answer by the system, and the second part shows a result example of choosing the correct answer by the system. In the answer pool section, sentences in green indicate sentences that should have been selected as the correct answer. Meanwhile, sentences written in red are incorrect answer sentences and are output as answers by the system.

Incorrect Answer
<b>Question:</b> Bagaimana cara mengonsumsi disulfiram? (How to take disulfiram?)
<b>Answer Pool:</b> Dosis akan disesuaikan berdasarkan kondisi pasien, dengan jangka waktu pengobatan kurang dari 6 bulan. Obat ini dapat dikonsumsi sebelum atau setelah makan di pagi hari. <b>Berikut adalah beberapa efek samping yang dapat terjadi setelah menggunakan disulfiram: pusing, mudah merasa lelah, muncul jerawat, mulut terasa tidak enak (seperti rasa bawang atau metal).</b> (The dosage will be adjusted based on the patient's condition, with a treatment period of fewer than 6 months. This medicine can be taken before or after eating in the morning. <b>Here are some of the side effects that can occur after using disulfiram: dizziness, easy feeling tired, pimples appear, the mouth feels bad (like the taste of onions or metal).</b>
<b>Selected Answer:</b> Disulfiram adalah beberapa efek samping yang dapat terjadi setelah menggunakan disulfiram: pusing, mudah merasa lelah, muncul jerawat, mulut terasa tidak enak (seperti rasa bawang atau metal). (Here are some of the side effects that can occur after using disulfiram: dizziness, easy feeling tired, pimples appear, the mouth feels bad (like the taste of onions or metal).)
<b>Correct Answer:</b> Obat ini dapat dikonsumsi sebelum atau setelah makan di pagi hari. (This medicine can be taken before or after eating in the morning)

(a)

Correct Answer
<b>Question:</b> Bagaimana cara mengobati sakit tenggorokan? (How to treat a sore throat?)
<b>Answer Pool:</b> Sakit tenggorokan umumnya dapat diobati dengan banyak minum air dingin dan beristirahat yang cukup. Namun bila gejala masih berlangsung, segera ke dokter agar mendapat penanganan yang tepat. Dokter dapat melakukan pengobatan dengan memberikan obat parasetamol untuk meredakan rasa nyeri di tenggorokan atau memberikan obat antibiotik jika sakit tenggorokan disebabkan oleh infeksi bakteri. Ada beberapa cara untuk mencegah sakit tenggorokan, di antaranya: hindari berbagi perlengkapan makan dan minum dengan orang lain, hindari kontak dengan orang yang sakit, mencuci tangan sebelum makan. (A sore throat can generally be treated by drinking plenty of cold water and getting enough rest. However, if symptoms persist, immediately see the doctor. The doctor can take medication by giving paracetamol to relieve pain in the throat or giving antibiotics if the sore throat is caused by a bacterial infection. There are several ways to prevent sore throats, including: avoid sharing eating and drinking utensils with others, avoid contact with sick people, wash your hands before eating.)
<b>Selected Answer:</b> Dokter dapat melakukan pengobatan dengan memberikan obat parasetamol untuk meredakan rasa nyeri di tenggorokan atau memberikan obat antibiotik jika sakit tenggorokan disebabkan oleh infeksi bakteri. (The doctor can take medication by giving paracetamol to relieve pain in the throat or giving antibiotics if the sore throat is caused by a bacterial infection.)

(b)

Fig. 9. Sample result of answer selection of method question: (a) Sample of incorrect answer, (b) Sample of correct answer

The limitation of this study is that the proposed method focuses on selecting answers on IQAS for a particular domain (health information). At the same time, the need for open-domain QA in Indonesian is still very open. On the other hand, the current state-of-the-art language model reliable for many tasks is Bidirectional Encoder Representations from Transformers (BERT) [33]. The main advantage of BERT is context-sensitive word embedding, where the same word can produce different word embedding when the word has a different context. Word2Vec cannot do this. The Indonesian version of BERT has been developed and is commonly known as IndoBERT [34]. Therefore, it provides an opportunity for further research to apply IndoBERT and LSTM as a model for selecting answers in the Indonesian language open-domain QA.

## V. CONCLUSIONS

This study analyses various hyperparameters of Word2Vec and LSTM applied to non-factoid answer selection in an IQAS for health information. There are six scenarios to evaluate the effects of the hyperparameters on the MRR and MAP

results—first, the larger the dimension of Word2Vec, the better the MRR and MAP values. A dimension of 300 yielded the best MRR and MAP. Second, a context window size of 15 yielded the best MRR and MAP results, indicating that a more extensive context window can yield better MRR and MAP results. Third, a lower dropout value yielded better MRR and MAP values, and the best MRR and MAP were achieved under a dropout value of 0.25. Fourth, the optimum hidden unit value was found to be 100; the higher the number of hidden units, the better the MRR and MAP values. Fifth, a higher learning rate showed significant improvements in the MRR and MAP, given the relatively small number of datasets used in this research. Sixth, a margin of 0.1 produced the best MRR and MAP results. The best model yielded MAP and MRR values of 82.05% and 91.58%, respectively. These results experienced an increase in MAP and MRR of 18.68% and 46.11%, respectively, compared to CNN as the baseline model.

This research is still limited to selecting answers on IQAS for a particular domain (health information), while the need for open-domain QA in Indonesian is still very open. On the other hand, the latest language modelling developments, such as Bidirectional Encoder Representations from Transformers (BERT), have also been developed for Indonesian, commonly known as IndoBERT. Therefore, it provides an opportunity for further research to apply IndoBERT and LSTM as a model for selecting answers in the Indonesian language open-domain QA.

# Assessment of the Healthcare Administration of Senior Citizens from Survey Data using Sentiment Analysis

Ramona Michelle M. Magtangob<sup>1</sup>, Thelma D. Palaoag<sup>2</sup>

University of the Cordilleras, Baguio City, Philippines<sup>2</sup>

**Abstract**—Healthcare is most frequently used by older people and understanding how they feel about the way healthcare administration gives them the attention and support they need, is crucial to building a healthcare system that is effective in meeting their needs. This study determined the seniors' opinions on the healthcare administration by employing SurveyMonkey, a robust online survey tool as an opinion miner. The study used the Orange application, which made data processing simple, to gauge the seniors' opinions toward healthcare administration by analyzing text sentiment using the VADER Sentiment Analysis, which may distinguish between the polarity of positive, negative, or neutral emotions as well as their intensity. Results showed that the majority of seniors (51.1%) had a negative response to healthcare administration, whereas 47.9% had a neutral response and 1.0% had a positive response. Based on the study, the government should enhance its senior citizens' healthcare services to better satisfy their demands and ensure their happiness. This is clear from the respondents' feedback regarding the services they would like to utilize and how they believe they may be improved. Additionally, the findings provided sufficient information for future consideration to enhance seniors' satisfaction with developmental activities and programs and improve healthcare administration.

**Keywords**—Sentiment analysis; opinion mining; senior citizen; healthcare services

## I. INTRODUCTION

The world's population is aging swiftly, and senior citizens have the fastest rate of population growth. The World Health Organization claims that this trend is anticipated to continue [1]. Health and well-being are crucial for seniors, and the enhancement of their quality of life is a major concern for modern society due to their chronic health difficulties, including the available healthcare services. Due to the growing aging population and increasing life expectancy, seniors need care and access to sophisticated healthcare systems that might enhance their standard of living [2]. Understanding the care and support needs from their perspective and the larger context of their experiences with the services is crucial to successfully addressing those needs [3]. Indeed, we need to reconsider how healthcare administration is being served to senior citizens.

The Philippines is one of the nations with an aging population. As of 2015, 7.4% of the population was over 60 years old, and by 2045, 15.9% of people are expected to be over 60 years old [4]. Given the rapidly aging population, the

complexity of senior citizens' needs, the significance of health information in service delivery, and the difficulties associated with health information in general, it is crucial to ascertain the state of senior citizens' healthcare system to coordinate the country's healthcare services and promote healthy aging [5]. Increasing access to high-quality healthcare is of the utmost importance in emerging countries like the Philippines, and the government needs to be committed to enhancing the healthcare system, especially for vulnerable populations like senior citizens [6].

As the population of seniors increases, particularly in the provinces, their use of health services is becoming more important. Catanduanes is one of the provinces in Region V - Bicol, located in the Southeast part of Luzon in the Philippines. In order to reach its health goals, the provincial government is working hard to achieve health-related goals through its scorecards for planned activities to analyze health issues, however, the prevalence of various diseases continues to rise, despite the provincial government's attempts. This suggests that based on the province's geographic situation and demography, ongoing assessments of health services and inhabitants' health problems should be responsive and appropriate [7], most importantly for senior citizens.

In order to strengthen programs that can help manage the healthcare services of senior citizens, this study collects information on how healthcare services are being administered to them and how they feel about the care they received. By successfully recommending programs that have been proven beneficial and efficient for those in the city and those in the provinces, this study solves information gaps on the need to improve healthcare services given to senior citizens for their health and well-being.

The study will make use of sentiment analysis, a text classification technique that groups texts according to the sentiment of the thoughts they contain. To determine whether a textual analysis is positive, negative, or neutral, it aims to extract the sentiment polarity from the text. Natural language processing (NLP) research in this area is among the most active, with both text and data mining projects being conducted [8][9]. Sentiment analysis has previously been the topic of extensive research and it gives us a method for accurately comprehending sentiments and extrapolating important information from them, it is also a type of text classification that integrates NLP, machine learning, data mining,

information retrieval, and other academic areas [10][11]. A database can be created that contains precise information about healthcare management, including the quality of their services and suggestions for improvements, by efficiently gathering and analyzing the thoughts and opinions of senior citizens.

Using VADER Sentiment Analysis, which is also known as Valence Aware Dictionary for Sentiment Reasoning, this study's overall goal is to evaluate the healthcare administration for senior citizens and develop a methodology that enables them to contribute data that can be utilized to analyze their perceptions, experiences, expectations, and concerns about the healthcare services they received. A profiling and online survey were conducted on the sentiments/opinions of senior citizens towards healthcare administration using SurveyMonkey. Additionally, the Orange Data Mining application tool performed a sentiment analysis evaluation. The sentiment analysis of senior citizens' healthcare administration's online survey was done using the VADER method. Since it was considered to be a time and money-saving approach for minor evaluation efforts, researchers employed the SurveyMonkey software as an assessment tool to gather user comments and opinions [12].

The purpose of this study is to unearth the problem and hopeful insights of the senior citizens, as indicated by the sentiment analysis based on the completed survey. The importance of this study lies in the possibility that it may establish the foundation for the management of senior citizens' healthcare as it discovers opportunities for service enhancement. The researchers' goal in conducting this study is to provide guidance to government policymakers and healthcare administrators on how to prioritize meeting the needs of seniors in order to provide them with high-quality healthcare services. In addition, this may also help the provincial and rural health office to improve its services for older people in terms of health and wellness. By working to make it a reality, we are supporting the UN's third Sustainable Development Goal to promote health and well-being.

## II. RELATED WORKS

### A. Healthcare Services for Senior Citizens

Discussions about how seniors use healthcare services are becoming more and more crucial as the senior population increases. A study being conducted in South Korea aims to create an integrated healthcare service system that is centered on elderly citizens, meeting their needs in daily life and promoting well-being, wellness, and well-dying. A natural structure of regular care, professional care, and rehabilitation for senior members of society in line with the responsibilities of the patients, their families, and caregivers are required for the implementation of the integrated medical care system for elderly users presented in this study [13].

The study [14]'s goal was to determine what senior citizens need from "embedded retirement facilities (ERFs)," multipurpose, and community-based care facilities for the elderly in mainland China. This study is based on questionnaire data collected in northeast China. The findings show that senior citizens' healthcare services are deemed to be the most significant. Senior citizens use community-based facilities, but

decision-makers and facility administrators frequently fail to consider their needs. Seniors in China also tend to be inactive and largely silent in both formal and informal civic involvement because they typically believe that policymakers would take notice of and accommodate their needs.

The purpose of the [15] study is to evaluate older people's well-being to explore whether the data are consistent with previously announced changes in senior treatment in relation to the real resources provided to their patients. The respondents reported being generally satisfied with their lives. The results show that small-town residents felt substantially worse about their quality of life than seniors from large cities. This shows that the healthcare system continues to utterly fail to meet patients' actual demands, particularly in the elderly sector. Being open to a broader discussion about the diverse needs and resources that elderly people in rural and urban areas face is crucial for doing this.

The study of [6] attempts to assess the potential influences on elderly persons' use of healthcare in Davao City, in the Philippines. Various factors were discovered to be significant predictors of healthcare consumption through the use of multiple regression analysis. The findings demonstrated how socioeconomic demographic, personal characteristics and health insurance knowledge affect the way senior citizens use healthcare. By launching health insurance awareness campaigns and creating health-improving initiatives, policymakers and local government organizations may think about enhancing senior citizens' access to healthcare services.

### B. Sentiment Analysis on Healthcare Services

However, in order for various stakeholders to profit from the knowledge gleaned through sentiment analysis, a study by [16] proposes the use of sentiment analysis of hybrid techniques through the development of a module that makes it possible to integrate sentiment analysis functionalities in Web applications related to healthcare at the comment and entity levels. The healthcare industry is one of the least researched industries, however, researchers were aware of a few instances where sentiment analysis was applied to help various industries. Thus, a review of the literature was conducted to examine sentiment analysis utilized in various healthcare settings. The data produced after using sentiment analysis to understand how people feel about various healthcare-related topics enables various stakeholders to take decisions that are advantageous to them. These studies shown allow for validation that the module can be incorporated into Web applications, provide sentiment analysis functionalities to them, and provide various benefits based on the information obtained after using its functionalities without requiring a great deal of effort, like making better decisions or obtaining the reputation and knowing the opinion on aspects related to the healthcare domain.

Due to the vast amount of online information available on healthcare, [17] employed sentiment analysis in this field. They came to the conclusion that sentiment analysis has many advantages, one of which is its ability to use medical data to achieve the greatest results and improve the standard of healthcare. They offer approaches and methods for sentiment analysis employed in the medical field and look for additional

information to help users make the best decision regarding the subject under study.

### C. VADER Sentiment Analysis

VADER is also known as Valence Aware Lexicon and Sentiment Reasoner. The VADER vocabulary was created using conventional sentiment lexicons. Also, this work offers machine learning techniques for sentiment analysis as well as sentiment intensity and orientation lexicons. In order to better understand how the public feels about different entities, this sentiment analysis methods try to identify the feelings of written reviews. Emotions are linked to many characteristics of a product or service as part of the analysis of consumer feedback data. Moreover, VADER sentiment outperformed seven sentiment analysis lexicons, either better or equally well. [18][19][20].

According to a study by [21], VADER maintains and even improves on the advantages of conventional sentiment lexicons like LIWC or Linguistic Inquiry and Word Count: it is larger, yet just as easily examined, understood, and swiftly deployed without requiring substantial learning/training), and it is easily extended. VADER differs from LIWC in that it is both more perceptive of sentiment expressions in social media and more tolerant of generalization to other domains. This can be downloaded and used without charge from the website.

Other research confirms the ease of use of VADER's rule-based sentiment analysis. A compilation of lexical features and their corresponding emotion metrics make up this document. Several guidelines are developed based on the language's grammatical and syntactical usage, and these rules are utilized to assess the text's mood. VADER employs a rule-based method and assigns values to each word in the text in order to consider both the sentiment category and the intensity or strength of the text in addition to the sentiment category. It also performs far faster than machine learning algorithms [22][23].

VADER excels across a range of domain types. Compared to machine learning techniques, VADER has a number of advantages. It is firstly quick and computationally effective. The second advantage is that the terminology and regulations of the VADER are clear and not hidden. Because of this, VADER is easy to understand, build upon, and alter. By setting the threshold at 0.05, VADER is a preferable option if processing the sentiment quickly and if it was the only thing that had been planned. VADER also adheres to grammatical and syntactical rules for expressing and highlighting sentiment intensity. VADER outperforms Text blob and NLTK sentiment analysis technologies in terms of performance. [24].

According to empirical findings, the technique utilized is the best technique for ranking many choices. Additionally, users of the healthcare sector's decision-making processes and healthcare providers' goals for quality improvement can both benefit from ranking information.

## III. METHODOLOGY

This study is divided into four main phases, the first of which is the actual data gathering from senior citizens whose opinions will be utilized to determine the study's analysis of the government healthcare system. As can be seen, the data will be cleaned using a preprocessing procedure in the phase after which it will be tagged with the necessary sentiment labels using the VADER method. The orange data mining application will be utilized in this step. Preprocessing entails tidying up the text, making it all lowercase to make it easier to read, and removing any affixes from words to get them down to their root forms.

To understand more about the primary healthcare administration for seniors, particularly in the province, the researcher conducted a survey on senior citizens in Virac, Catanduanes. The study was carried out in the barangay San Isidro Village since it has the highest number of senior residents in the municipality. A total of 694 responses were gathered using the SurveyMonkey software which is an online survey tool. This online survey software makes designing and managing reliable online surveys easy. It is also a highly effective and well-known online platform.

This research demonstrates how to retrieve the required data from its source using the Orange Data Mining application and how to use tools to carry out text mining operations. The procedures, particularly when applying the classification technique using the VADER method of Sentiment Analysis of Orange Application, are shown in Fig. 1.

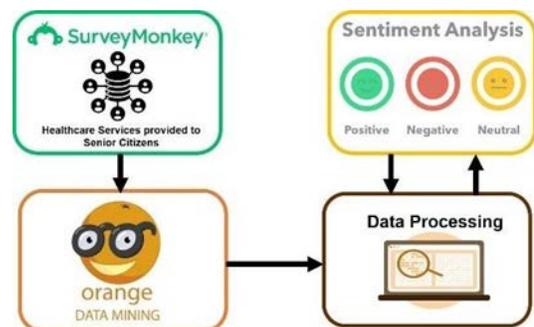

Fig. 1. Using orange data mining application for the sentiment analysis

### A. Data Collection and Gathering

To understand more about the primary healthcare administration for seniors, particularly in the province, the researcher conducted a survey on senior citizens in Virac, Catanduanes. The study was carried out in the barangay San Isidro Village since it has the highest number of senior residents in the municipality. A total of 694 responses were gathered using the SurveyMonkey software which is an online survey tool. This online survey software makes designing and managing reliable online surveys easy. It is also a highly effective and well-known online platform.

The survey provided was composed of three questions, the first was the name of the respondent, which was also optional, their age, and the third question asked about senior citizens' opinions of the healthcare services provided.

Fig. 2 shows the 694 data collected from the senior citizens' responses using the SurveyMonkey software. The responses were gathered and downloaded in a comma-separated (CSV) file that would be utilized in the following step.

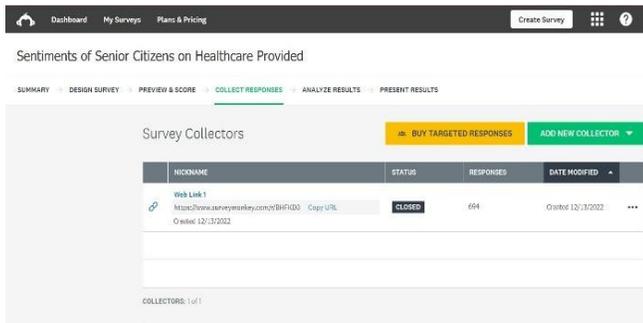

Fig. 2. Collected data using SurveyMonkey tool

**B. Data Processing**

Using the Orange Data Mining Application, the survey text corpus from the SurveyMonkey responses was imported and processed. The corpus goes through pre-processing to ensure that it was converted to lowercase and removed unwanted words. To verify the outcomes, a word cloud was additionally attached to the pre-process text widget.

Fig. 3 depicts the loading of SurveyMonkey survey text into the corpus, and Fig. 4 depicts the pre-processing of corpus texts acquired on senior citizens' opinions of the healthcare services offered to them by the governments.

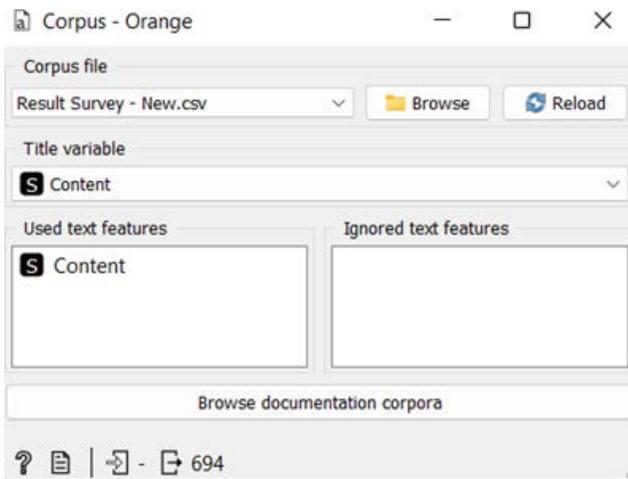

Fig. 3. SurveyMonkey text responses gathered

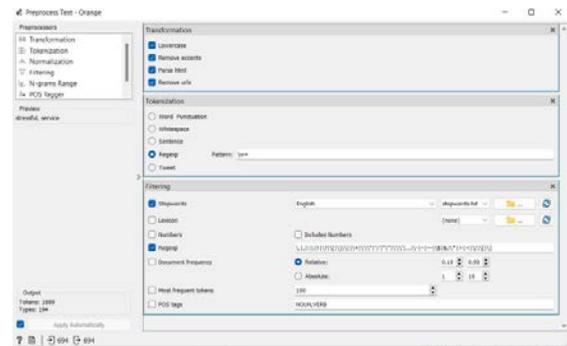

Fig. 4. Corpus texts' pre-processing

**C. Sentiment Extraction**

The analysis of the survey data, also known as sentiment extraction, is another important stage. This analysis used topic modeling and VADER sentiment analysis. In this instance, the comma-separated (CSV) file, which was processed prior to sentiment extraction, is extracted to obtain the widget. The CSV file was turned into the corpus by selecting text characteristics from the dialog box, which was then processed.

The sentiments taken from the SurveyMonkey tool, which had previously applied VADER sentiment analysis, are shown in Fig. 5. Additionally, it displays the text's measured emotions, whether they are neutral, positive, or negative.

**D. Using Sentiment Analysis**

Sentiment analysis was used in this study to determine whether the content of survey responses contained neutral, positive, or negative emotions. This kind of text analytics employs both machine learning and natural language processing (NLP). Fig. 6 shows the steps taken to achieve sentiment analysis for the survey of senior citizens. From the survey text corpus from responses from SurveyMonkey to the pre-processing of the text and word cloud, followed by the sentiment analysis using the VADER method, to repeating the pre-processing texts to ensure that there are no unwanted words included, and choosing the necessary columns to include in the result, to providing the corpus viewer to view the results of the sentiment analysis using the VADER method.

Ineffective health monitoring and counseling, technology to assist with procedures, inadequate service, and mobility issues were some factors that sparked criticism. These factors all had an impact on how they perceived the services offered to them.

Significant relationships were also discovered between respondents' perceptions of the standard of healthcare. Based on the study, the government should enhance its senior citizens' healthcare services to better satisfy their demands and ensure their happiness. This is clear from the respondents' feedback regarding the services they would like to utilize and how they believe they may be improved. However, this study has important limitations that could encourage additional development and research. Seniors' views expressed on social media and the Internet in the provinces may one day be evaluated for several reasons. A better healthcare system may be created in response to unfavorable comments in order to effectively address and support seniors' concerns and improve the government's provision of healthcare services. This will assist the government in creating a plan to satisfy the demands of senior citizens while providing a suitable healthcare system. This will also show how important it is to have a reliable healthcare system across the country, not only in urban and rural areas. This will guarantee that senior folks are treated with the respect they deserve and that information concerning their health is immediately updated.

#### ACKNOWLEDGMENT

The authors would like to express their gratitude to everyone who took part in this study, gave their time and expertise to provide the essential data, and took the time to carefully respond to the survey questions from the beginning of the project's conceptualization through its completion.

# Hierarchical Pretrained Deep Learning Features for the Breast Cancer Classification

Abeer S. Alsheddi

Computer Science Department, Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia

**Abstract**—Breast cancer is a common and fatal disease among women worldwide. Accurately and early diagnosing of breast cancer plays a pivotal role in improving the prognosis of patients. Recently, advanced techniques of artificial intelligence and natural image classification have been used for the breast cancer image classification task and have become a hot topic for research in machine learning. This paper proposes a fully automatic computerized method for breast cancer classification using two well-established pretrained CNN models, namely VGG16 and ResNet50. Next, the feature extraction process is used to extract features in a hierarchical manner to train a support vector machine classifier. Evaluating the proposed model shows achieving 92% accuracy. In addition, this paper investigates the effect of different factors, highlights its findings, and provides future directions for the research to develop more advanced models.

**Keywords**—Feature extraction; CNN models; Pretrained models; breast cancer classification

## I. INTRODUCTION

Breast cancer is the most common form of cancer in women, and invasive ductal carcinoma (IDC) is the most common form of breast cancer [1]. It is frequently occurring and increasingly fatal. Usually, a biopsy is taken from patients and then a pathologist must decide whether they have breast cancer or not. Manual diagnosis from slides is time-consuming and the decision itself depends on the expertise of the pathologist and their equipment. Image Processing and Deep Learning can be used to create models that complement doctors by automating and speeding up diagnosis to save time and minimize errors in detecting breast cancer. This problem is not new these days, one of the earliest DNN applications was on breast cancer images [2].

1) *Research problem*: in this paper, the main goal is to classify breast cancer images in the form of images into binary classification: IDC and non-IDC. To formulate the problem, let  $x$  be a 2D image that belongs to  $R^{m \times n}$  where  $R$  is the space of 2D images with width  $m$  and height  $n$ , and let  $Y = \{0, 1\}$  where 0 indicates no breast cancer (non-IDC) and 1 indicates to indicating breast cancer was found in the image (IDC). Then the problem of the breast cancer classification is to model a mapping  $f$  from  $R^{m \times n}$  to  $Y$ , such that,

$$f(\cdot, \theta): R^{m \times n} \rightarrow Y \quad (1)$$

where any value of  $x$  will be mapped to  $y$ ,  $f(x, \theta) = y$ , for any  $x \in R^{m \times n}$  and  $y \in Y$ .

2) *Research objective*: the main contribution of the proposed model in this paper is combining between two tasks; First: using multiple pretrained models to extract features; second: using a feature hierarchy concept during extracting the features. To achieve this contribution, two pretrained VGG16 [3] and ResNet50 [4] models that have excellent classification performance for natural image classification in the Image Large Scale Visual Recognition Challenges, are used to extract activations of different five convolution layers from each model, ten layers in total. Next, the features are reduced using pooling operations to be  $6 \times 6 \times 5$  at each pretrained model and then concatenated them to result a  $6 \times 6 \times 10$  layer. Finally, the resulting features feed to the support-vector machines (SVM) classifier [5]. The results show that the combined feature hierarchy from two pretrained models gets 92% accuracy higher than using a pretrained model individually.

The rest of the paper is recognized as the following. Section II reviews some of the state-of-art in the problem. Next, Section III provides the proposed method and Section IV presents its results and discusses them. Finally, Section V concludes the main results and provides some future directions.

## II. RELATED WORK

This section reviews some of the research that works on the breast cancer classification problem and gives information about the used methods. Table I summarizes the methods of these related works. Most research recently uses different techniques to deal with features and then applies the classification on these features instead of classifying the whole image using ANN.

TABLE I. METHODS SUMMARIZATION IN THE RELATED WORK

Types	Methods	Research
Feature extraction from pretrained models	Fuses activations from FC of three pretrained models	[6]
	Fuses the results of the classifiers and extracted activations from each FC in pretrained model	[7]
Transfer parameters	Fine-tuned pre-trained models with using logistic regression classifier	[8]
	Fine-tuned modified AlexNet model	[9]
Unsupervised learning with segmentation step	Selecting features using GA algorithm and CNN model for classification.	[10]
	Clustering using Lloyd's algorithm [11] for and CNN model for classification.	[12]
Feature selection	Feature selection using mRMR algorithm with 4 classifier: SVM, Naïve Bays, Function tree and End Meta	[13]

The researchers usually try to find a proper feature representation of images to train their model. One major way is using a pretrained DCNN to extract an image activation as its features. Several pre-trained models were used for this process. The proposed model in [6] extracts features from fully connected layers of three models, namely GoogleNet [14], VGG [3], ResNet [4] models. Then classifier was trained on these features. The accuracies of these three models individually were 93.5%, 94.15%, and 94.35% respectively, while the combination between them achieves 97.525% accuracy. Thus, fusing the features from different models leads to better classification compared to extracting from a single model. The other research [7] uses three pre-trained models, namely AlexNet [15], VGG16 [3] and ResNet-18 [4] to extract features and then uses them to train three SVM classifiers, one classifier for each pretrained model. Instead of combining the features, the research fuses the three results from each classifier by calculating the average and combining the probabilities for fusion to obtain the final decision score. It measures the performance using the receiver operating characteristics curve (AUC) and it achieves 83.83% and 97.55% for two different datasets. However, for both research, [6] and [7], FC layers contain usually a high number of activations than convolution layers which will consume more computation cost.

In transfer parameters, the learning assumes that the two models share some parameters that can learn effectively. The research [8] analyzes different pretrained models VGG [3] and ResNet [4] considering all activations values of the convolution layers without considering the fully-connected layers and using the same strategy of the previous research [16] but without using one pre-trained model, namely AlexNet [15] as done [16]. Next, the logistic regression classifier is to decide the predicted class. As a result, a fine-tuned pre-trained VGG16 achieves the best performance at 92.60% accuracy. The other research [9] uses the same strategy as AlexNet [15]. The authors adapted the AlexNet with some modifications in its architecture related to the normalization process and type of the activation function. These modifications provide different proposed models. Then they applied fine-tuned processing on the models and achieved individual model ranges between 75% and 77%, while the combining model 84% accuracy.

The other research [10] uses unsupervised learning to implement its model. The proposed model is based on k-mean algorithm [17] and the probabilistic model (GMM). The proposed model first finds the region of interest (ROI) and then applied the feature selection using genetic algorithms (GA) [18]. Next, the model applies the CNN algorithm to find out better results. The resulted accuracy achieved 95.8%. The other research [12] also uses the segmentation step before classification using Lloyd's algorithm [11] for clustering and CNN for classification. A 96% accuracy was achieved by the proposed methods. However, in both the previous research, the authors did not mention exactly the proposed CNN model that was used.

The feature selection is also used as a preprocess of classification in a hybrid approach [13]. It uses a minimum redundancy feature selection (mRMR) algorithm [19] to effectively identify object properties and narrow down their relevance and then can predict breast cancer. The proposed

approach uses four classifiers SVM, Naïve Bays, Function tree and End Meta to find out the best performance. The result shows that SVM outperforms at 99% accuracy on average by combining it with MRMR algorithm. However, the feature selection process may not be enough for training with large datasets without dealing with deep learning models. This proposed approach is not the only research that claims the outperformance of the SVM classifier. A number of research early and recently [20] [21] [22] [23] [24] compare different classifiers and reach the same result, such as the study in [25] focuses to compare random forest and SVM classifiers for breast cancer classification and claimed that the highest accuracies 95% is for SVM.

On the other hand, some research not related to breast cancer classification uses a feature hierarchy to represent the images in CNNs. The research [26] studies real-world video sequences. It uses different hierarchical features of convolutional layers in CNNs to deal with features at early layers that keep more fine-grained spatial details and are useful for localization. It claimed that dealing with multiple layers of CNN features to get better performance for learning video features and visual tracking.

In the end, the result shows that the concept of transfer learning can be successfully applied to the breast classification domain. The activations of the source model can be used as features in the target model in the breast classification domain with less implementation cost, i.e., using pretrained models instead of training from scratch. Moreover, the combination of the features from different neural networks improves the accuracy of the classifiers.

In addition, a common way in the previous research using the activations of the fully connected (FC) layer as features. However, FC layers contain a higher number of activations than convolution layers which consume more computation cost. Also, extracting features from different layers leads to a better performance in learning video features. Moreover, most of the previous research used accuracy as a metric to evaluate their proposed models.

### III. PROPOSED METHOD

The idea of the proposed solution is image classification by extracting a feature hierarchy from pretrained CNN models and then feeding it into a classifier instead of using the whole images as inputs to that classifier. Extracting features from different layers of a single network is shown to lead to better performance in previous research working on learning video features [26].

To build the proposed model, two sub-models are constructed, one for extracting features and the other for classification. Writing  $f_m$  for the final proposed model that its form maintained under composition  $f_c$  and  $f_t$ ,  $f_c$  for the classifier, and  $f_i$  for the features by

$$f_m = f_c(f_i(x), y) \quad (2)$$

where  $x$  is called the input images and  $y$  is the true class of the input images with two possible values 0 or 1, where 0 indicates to no breast cancer (non-IDC) and 1 indicates to breast cancer was found in the image  $x$  (IDC). Exactly, each

input  $x_i$ , where  $x_i \in \mathbb{R}^{m \times n}$  will be mapped to  $y_i$ , where  $y_i \in \{0,1\}$ . Fig. 1 displays the general diagram of the proposed method. While each component of the composition will be described in the following subsections supported by described figures.

A. FT: Feature Extraction Phase

Feeding the whole images into a classifier needs to extract features manually an extremely time-consuming process and needs a strong knowledge of the domain. Also, converting 2D images to 1D vectors increases the number of trainable parameters exponentially and it significantly can increase the chance of overfitting especially if the size of a dataset is less than the number of learnable parameters. Thus, a CNN model is used in this proposed model for extracting the features.

Pretrained CNN model is decided to be used because the process of training networks with a large number of parameters is time- and resource-consuming. Thus, two pretrained models VGG16 and ResNet50 are used in this paper which they are used previously on a similar domain [6] [7].

1) VGG16 model is a type of CNN Architecture proposed by Visual Geometry Group (VGG), Oxford University [3]. Using VGG16 with 16 learnable layers regarding the depth which is larger than 8 layers in AlexNet [15], as an example, gives important for achieving high performance [15]. Moreover, VGG16 shows excellent classification performance for different previous works natural image classification in the Image Large Scale Visual Recognition Challenges [27] and for different previous works [6] [7] [28].

VGG model contains 16 learnable layers separated into five groups where each group ends with a pooling layer. In this proposed model, a pretrained VGG model is used with the input size differs from the default size in VGG16. The input size is equal to 50x50 pixels to be the same size as the input dataset and the three fully connected layers are removed. Fig. 2 (a) is zoomed a portion of Fig. 1 that presents the feature extraction process in VGG16 model. The resulting sizes are presented on Table II after applying the following steps:

a) Creating a VGG16 model without the three fully connected layers due to the purpose of using VGG16 model as a features generator from its intermediate layers, not as a classifier.

b) Feeding the input into the VGG16 model and extracting feature maps at five intermediate layers. The layers are

c) The last layer (pooling layer) in each group, the red layer in Fig. 2 (a). Hence, five layers generate five different blocks of feature maps with different shapes.

d) To combine extracted feature maps from the previous step in a specific axis, the layers must have the same dimension on them. To unify the size to be the same 6x6 as the size of width and high, up/down sampling operations are applied. The down-sampling operation is applied to the first and the second extracted layers using the max pooling layer. The third layer is already having the same required size, so it does not need to change. The up-sampling operation is applied to the fourth and the fifth extracted layers using the transpose convolutional

layer that performs an inverse convolution operation. More detail about the values of their hyper-parameters is detailed in Section 4.1.

e) Each layer has a high number of channels which will increase the computation time. At the same time, the activated region of a channel is semantically meaningful and serves a similar role as the feature detectors to identify different features present in an image [29]. Thus, max pooling over the depth operation is applied to extract the maximum value of activation in a specific location (receptive field) among all channels and decrease the number of channels to only one channel. It is noteworthy that the utilized up-sampling method returns one channel by default. Thus, we can remove this step from the up-sampling layers.

f) Concatenating the five resulted from layers of the previous step on the depth axis to get one 6x6x5 layer. These feature maps will be concatenated with the resulting layer from the ResNet50 model which will be described in the next subsection.

2) ResNet50 model [4] consists of 48 convolution layers along with one max pooling and one average pool layer. The model has two types of connections: Identity connections between every two convolution layers and skip connections between some of them. The skip connections help to solve the vanishing gradient problem by allowing for the gradient to flow through these shortcut paths. Thus, it enables CNN models to get deeper and deeper without decreasing the accuracy by adding more layers to the network.

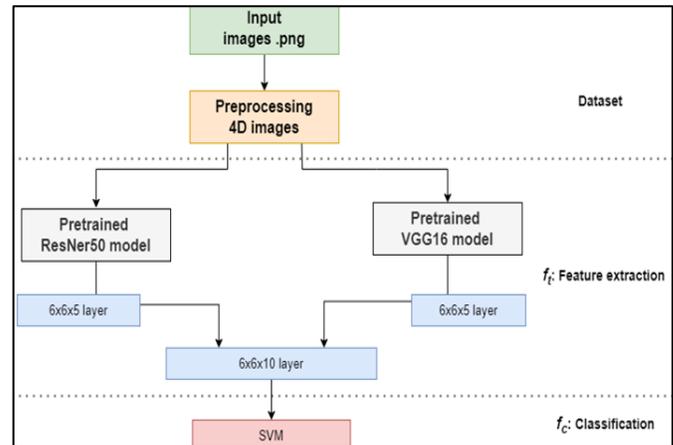

Fig. 1. Diagram of the proposed method

TABLE II. THE SIZES OF RESULTED FEATURES FROM VGG16 MODEL

Layer numbering	Extracted from Model	After up/down sampling	After depth pooling
1	25x25x64	6x6x64	6x6x1
2	12x12x128	6x6x128	6x6x1
3	6x6x256	-	6x6x1
4	3x3x512	6x6x1	6x6x1
5	1x1x512	6x6x1	6x6x1

In this proposed model, a pretrained ResNet model is constructed with the same VGG settings. Fig. 2 (b) presents the feature extraction process and the resulting dimension is presented on Table III applying the following steps:

a) Creating a ResNet model without the fully connected layer due to the purpose of using ResNet model.

b) Feeding the input into the ResNet model and extracting feature maps at the last layer in each group. In total, there are five layers that generate five different blocks of feature maps.

c) The width and high are unified to be 6x6 using up/down sampling operations. The down-sampling operation is applied to the first three layers using the max pooling layer. The up-sampling operation is applied to the fourth and the fifth extracted layers using the transpose convolutional layer.

d) Decrease the number of channels to one channel using the max pooling over the depth operation.

e) Concatenating the five resulted from layers on depth axis to be one 6x6x5 layer.

3) *VGG and ResNet combination.* After building the two models separately, the resulting layer of each model is 6x6x5 layer. The last step in the extracting phase is to concatenate these two layers on the depth axis to be 6x6x10 layers as Fig. 1 shows.

TABLE III. THE SIZES OF RESULTED FEATURES FROM RESNET50 MODEL

Layer numbering	Extracted from Model	After up/down sampling	After depth pooling
1	13x13x64	6x6x64	6x6x1
2	13x13x256	6x6x256	6x6x1
3	7x7x512	6x6x512	6x6x1
4	4x4x1024	6x6x1	6x6x1
5	2x2x2048	6x6x1	6x6x1

### B. Classification Phase

The main goal of this paper is to classify breast cancer in the form of 2D images into binary classification: IDC and not IDC. The resulting features from the pretrained models along with the corresponding labels (i.e., IDC or non-IDC) are then used to train binary non-linear SVM classifier. The SVM classifier performs a good result in different works of breast cancer classification [19] [20] [21] [22] [23] [24] [25].

In SVM implementation, feature scaling is a crucial step because the methodology of SVM considers the distances among inputs to select the maximum decision boundary. This distance is surely different for non-scaled and scaled cases. Thus, the scaled step is applied using standardized features [30] with a mean equal to zero and standard deviation equal to one,

$$z = \frac{x - \mu}{\sigma} \quad (3)$$

where  $x$  is the concatenated feature,  $\mu$  is the mean and  $\sigma$  is the standard deviation of these features. This step makes the features fall in a small range and leads to faster convergence in fewer iterations and then better performance [31].

## IV. RESULTS AND DISCUSSION

This section provides in detail the implementation of the proposed model and presents the results along with discussing it.

### A. Implementation

1) *Pretrained models construction.* The pretrained models are constructed using TensorFlow-Keras package with the same weights pretraining on ImageNet dataset [32] without changing or learning any weight. Thus, all convolution layers of the pretrained models are frozen. Moreover, the input size is equal to 50x50 pixels to be the same size as the input dataset. Although the default input size in the two pretrained models VGG16 and ResNet50 is 244x244 pixels, this proposed method discards the classification part with the fully connected layers to allow any input size. Table IV shows the value for each hyper-parameter in the construction.

2) *Extracting features phase.* To extract a feature hierarchy, ten temporary small models are constructed, five models for each pretrained model. Each small model is prepared to take the inputs equal to the input of the pretrained model and produce a block of feature maps as the output, which are used as features. Recall that the output layers of the small models are different regarding to producing five different layers in each pretrained model. Moreover, to unify the shape of the feature maps, different pooling layers in the Keras package are applied. In case of the layer size greater than 6x6, the down-sampling operation using the method *MaxPooling2D()* is applied, or in case of the layer size is less than 6x6, apply the transpose convolutional layer using the method *Conv2DTranspose()*. Moreover, the depth pooling operation is applied by the method *reduce-max()* to get a maximum element across a specific axis, here the depth. The assigned values for each parameter in the methods are presented on Table V. After unifying the shape of all feature maps, the method *concatenate()* is applied to concatenate all blocks of the feature maps among the depth axis.

3) *Classifier.* To can feed the features into the classifier, the array of the features must be reshaped to be 2D array with the number of inputs as the row and multiple of the 6x6x10 as the columns using the method *reshape()* in tensorflow package. The next step is applying the standardized features using the methods *StandardScaler()* and *transform()* in sklearn package.

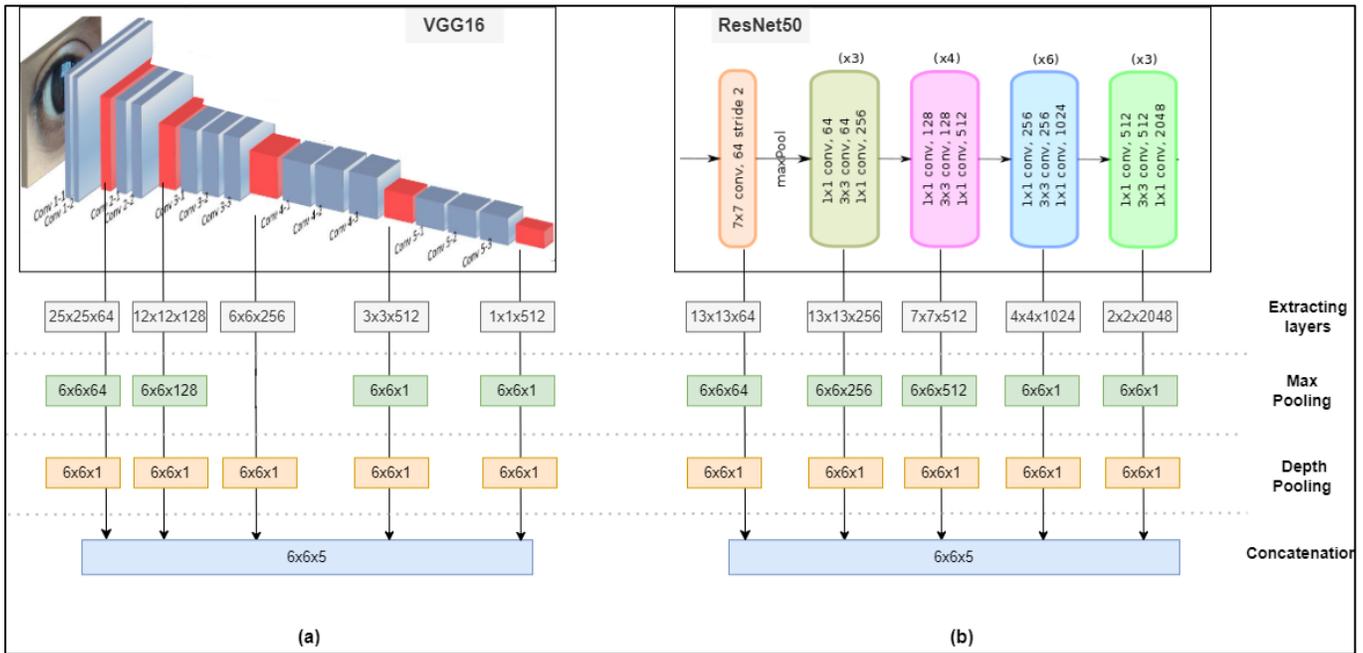

Fig. 2. Diagram of the pretrained (a) VGG16 (b) ResNet50 models.

After that, the non-linear SVM classifier is constructed from sklearn package using different methods. The method *SVC()* constructs the classifier by adjusting three hyper-parameters: regularization parameter *C* for giving a different level of regularization, the kernel parameter for enabling SVM to solve nonlinear classification problems when the inputs cannot be separated linearly, and the gamma parameter for considering as spreading of the inputs that are selected by SVM as support vectors and therefore affect the decision region. When the value of gamma is low, the curve of the decision boundary is very low and thus the decision region is very broad and vice versa. Different values are assigned to these three parameters to estimate the best values. Table VI presents the suggested values for each parameter. The method *GridSearchCV()* helps to loop through the three parameters and fit SVM classifier on the training set to select the best values. The best value is optimized by the cross-validation splitting parameter *CV*.

To complete training SVM classifier, the number of maximum iterations is fixed to 30,000 iterations because the convergence warning appears due to convergence issues. The other solution to overcome this issue is using standardizing features that helps to reach the convergence state faster.

TABLE IV. THE HYPER-PARAMETERS OF CONSTRUCTING PRETRAINED MODELS

Parameters	Values
weights	imagenet
Layer trainable	Fasle (freeze)

### B. Evaluation

1) *Cross-validation*. The cross-validation evaluates a classifier's performance by dividing the dataset into *k* parts. *K* is equal to 10 in this paper which is called 10-fold cross-validation. Thus, each image in this dataset will be used 9 times for training and once for testing. This validation then calculates the average between them to evaluate the classifier's performance. Thus, to evaluate the performance of the trained

classifiers, the cross-validation splitting parameter CV of the evaluation methods is assigned to 10 as 10-fold cross-validation.

2) *Performance metrics.* The Metric is accuracy as it is used in most of the previous works in Section II. Accuracy measures how many IDC and non-IDC images are classified correctly among all classifications. It shows overall how is the classifier classified correctly. Calculating the accuracy of the training set as an average over 10-cross-validation folds. Especially, the experiments are made in three cases for three SVM classifiers. Each SVM classifier is related to one of the following models: using only VGG16 model, only ResNet50, and using the combination of both models.

3) *Test platform.* The experiments are concurred using a personal laptop. However, the GPU in the laptop is not supported by python. Some of the tasks then run in long execution times and the memory of the laptop may not be enough. Thus, I have moved to use Google Colab Pro due to some commands could not be run using a free version of Google Colab.

4) *About the dataset.* The used dataset of the breast-cancer-image-classification is available in [33]. Fig. 3 shows the distribution of the dataset. The original images are for 279 patients with a small number of images scanned at 40x. However, overfitting is highly likely. Then, 50x50 patches were extracted including 198,738 negative examples (i.e., no breast cancer) and 78,786 positive examples (i.e., indicating breast cancer was found in the patch). Thus, the available dataset contains 277,524 patches in total. According to the figure, there is clearly an imbalance in the class data with over two times the number of negative data points than positive data points. However, in this work, the loading step, which loads the whole dataset into a programming notebook, has caused a crash multiple times after running the code in hours because of the available RAM space in Google Colab Pro. This leads to using a part of the dataset in the experiments with keeping the same percentage of imbalance in the class data.

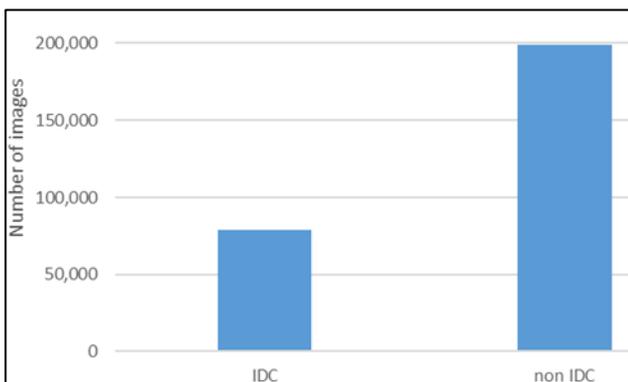

Fig. 3. The dataset distribution.

In this proposed method, to load and manipulate the images, the library image in Keras package is used. Then simple preprocessing is applied to stack all 50x50 images into 4D array to be able to deal with it in the implementation. Next,

the pixel values are normalized. The reason is that the pixel values can range from 0 to 256, where each number indicates a gray level value. The computation of large numeric values may get more difficult when sending these values through CNNs. We may lessen this by normalizing the numbers to a range of 0 to 1 by dividing the array by 255.

5) *Splitting dataset.* Train-Test split is a technique to evaluate the performance of the proposed model with giving 20% for the test set. The method *train-test-split()* in sklearn helps to split the images into training and test sets. The training set is used to train SVM classifier and then it calculates the accuracy of the training set as an average over 10-cross-validation. The training is also used to draw a learning curve. The test set is used to test the trained SVM classifier and then calculates the accuracy of the test set as an average over 10-cross-validation.

### C. Results

Different experiments were concurred to investigate the pretrained models and analyze the results trying to get a better performance. The best results are written down in this paper.

Table VII-A shows the overall comparison of the accuracy of the three cases. It shows the accuracy of training and test sets over the three classifiers from the three models. The values represent the mean of the accuracy which is the average value of accuracy among 10 different sizes of the training set along with their standard deviation values to represent the dispersion of accuracy values around the mean. The Table VII-B and Table VII-C represent values in the same manner as Table VII-A but investigate different effects. Table VII-B investigates the effect of swapping between the two steps of the methodology, Step 3 and Step 4. While Table VII-C investigates the effect of change the up-sampling methods. Table VIII shows the effect of applying standardization to the features on the accuracy of the combined SVM classifier, where the time is in seconds.

Fig. 4 shows the learning curve of the training and validation accuracy of the trained SVM classifier for varying numbers of training images. The x-axis shows the number of images that will be used to generate the learning curve. The y-axis shows the average of the accuracy values over 10 runs for each training subset size. The training and validation accuracies for different training set sizes in 10-cross-validation is measured to investigate influence of number of images on accuracy of the SVM classifier. Recall that the SVM classifier in this case is the combined SVM classifier.

### D. Discussion

Table VII-A shows both VGG16 and ResNet50 models give a satisfactory performance when using a feature hierarchy. The initialed experiments started without hierarchy, i.e., using only the last convolution layer as features but the result was lower. The result corresponds to the research [26], which confirms that the concept of feature hierarchy can be successfully applied to breast cancer classification. At the same time, the performance is better when the features from the two models are fused. This result shows the effect fusing of different pretrained models to get a better result than using each pretrained individually.

TABLE VII. THE ACCURACY OF THE THREE CLASSIFIERS FROM THE THREE MODELS

	Data sets	VGG16	ResNet50	Combination
A) Original	Training set	0.927±0.015	0.923±0.016	0.943±0.014
	Testing set	0.897±0.028	0.889±0.031	0.920±0.041
B) After swapping Step 3 & 4	Training set	0.923±0.013	0.923±0.015	0.943±0.021
	Testing set	0.892±0.030	0.890±0.036	0.908±0.033
C) After double operation	Training set	0.923±0.018	0.926±0.017	0.933±0.019
	Testing set	0.899±0.025	0.899±0.029	0.916±0.039

TABLE VIII. THE ACCURACY OF THE TWO CLASSIFIERS WITH/WITHOUT APPLYING THE STANDARDIZATION

Applied?	Data sets	Accuracy	Fit time	Fold time	Warning?
Yes	Training set	0.943±0.014	144.05 s	1054.24 s	No
	Testing set	0.920±0.041	-	128.61 s	No
No	Training set	0.897±0.011	186.02 s	1300.88 s	Yes
	Testing set	0.915±0.023	-	126.19 s	No

According to pretrained models, we can also observe from Table VII-A that the activations of pretrained model, that are trained on ImageNet dataset [32], can be used as features in the proposed model in the breast classification task with consuming less implementation cost, i.e., using pretrained models instead of training from scratch.

Moreover, the extracting steps shown on Fig. 2 describe applying up/down sampling (Step 3) before applying depth pooling (Step 4). However, both these two steps are related to unifying the shape of feature maps. Thus, if these two steps are swapped. i.e., applying up/down sampling after depth pooling, the result is almost the same with a small enhancement for the original case as shown on Table VII-B. One of the possible reasons is both operations work on getting the maximum value which will generate almost similar values in two directions.

Regarding up-sampling operations, different operations can be used other than the transpose convolutional layer. The other simple common type is using the method *UpSampling2D()* to double the dimensions of the input. After applying the simple double operation in the experiments, it gives almost the same result as Table VII-C shows with little enhancement for the original case. However, the key difference is in their learning. The simple double operation is a simple scaling up of the input without learning to achieve a less complicated in implementation. Whereas the transpose convolutional operation is a convolution operation whose kernel is learnt while learned the model to learn the best up-sampling for the task.

Turning to the normalization on Table VIII, the case of standardization (the top case) gives a faster result in fewer iterations. It can be considered as one of the solutions to overcome the warning of convergence issue that expresses that the estimation terminated early before reaching the convergence. Also, standardization achieves a better result in terms of accuracy. Especially for SVM classifier, the scaling helps to decrease the distances between inputs to select the maximum decision boundary.

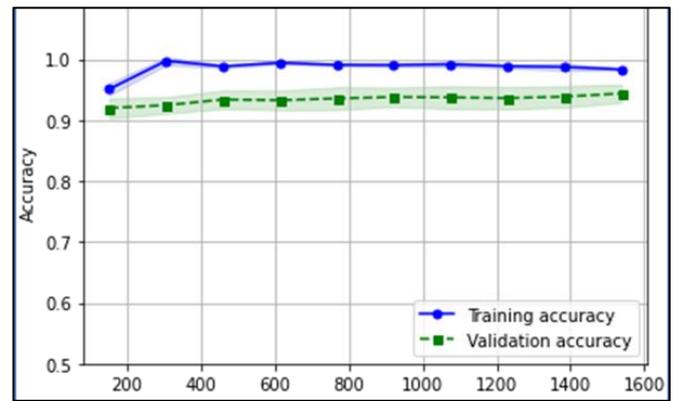

Fig. 4. The evaluation of the classifier over different examples.

The overall trend of Fig. 4 shows the effect of the number of images on the accuracy. The accuracy of the training set is higher than the validation set but with acceptable gap, i.e., the gap between them did not increase after a specific point to express about happening overfitting. One of the possible reasons is using the pretrained models with their learnable parameters, i.e. all layers are frozen and used the same weights. This helps to reduce the number of required images to reach the convergence.

Some other notes are appeared during the experiments. There are different possible sizes of the receptive field can be chosen to unify the shape of feature maps. When trying to unify the size to be 3x3, the resulting accuracy is almost the same in most cases, with little increase for 6x6 in other cases. However, more investigations in the future are better to be conducted on this size and other varied sizes to get adequate results about the effect of changing size on performance.

#### E. Comparing with the State-of-the-art

Ultimately, the results correspond to the research [26], which observes a good effect of using a feature hierarchy. While the proposed model in this paper uses the feature hierarchy for different domain, which is the breast cancer classification tasks.

At the same time, comparing to the other works provided in Section II, this proposed model seems to infer the same previous result [6] [7] about the effect fusing of different pretrained models to get a better result than using each pretrained individually. But in this paper, the combination is between a features hierarchy extracted from two models VGG16 and ResNet50.

#### V. CONCLUSION

IDC is the most common subtype of all breast cancers. Instead of manual diagnosis, it must find solutions to ease diagnostic burdens, especially in under-staffed laboratories and equipment. Thus, the goal of this paper is to classify breast cancer in the form of images into binary classification: IDC and not IDC. This paper proposes a CNN-based model for learning features of breast cancer images that combines two pretrained CNN models to extract a feature hierarchy and then feeds them into the SVM classifier. Besides, experimental results show that classification performance is higher in the

combined pretrained model and fusing the deep features from various layers from various pre-trained CNNs leads to better classification performance. In addition, other findings present the effect of some factors such as the normalization of training SVM classifier. However, those results are not the best results. It can be considered as a contribution, while the performance can be after the additional investigation in several factors, such as change the size of the receptive field of the features maps, number of pretrained models as well as other datasets with different pixel sizes may get another improvement.

In the future, this paper provides various recommendations that are expected to help in developing CNN models. First, combining other information along with the breast images during developing DNN models, such as changes in the breast shape and DNA sequences, may increase the accuracy of the classification. Second, the breast imaging modalities are better to consider during developing DNN models. Adopting new modalities of imaging may provide more accurate details, such as shear wave elastography (SWE) or magnetic resonance imaging (MRI). Third, while the enormous quantity of unlabeled photos is a valuable source of data, it cannot be used in supervised learning. Instead, the research can shift to training in an unsupervised manner, such as using clustering approaches. In the end, increasing research interest and rapid technological advancements creates a chance for researchers to continue to evolve models of breast cancer classification.

**Abstract**—Image captioning task is highly used in many real-world applications. The captioning task is concerned with understanding the image using computer vision methods. Then, natural language processing methods are used to produce a description for the image. Different approaches were proposed to solve this task, and deep learning attention-based models have been proven to be the state-of-the-art. A survey on attention-based models for image captioning is presented in this paper including new categories that were not included in other survey papers. The attention-based approaches are classified into four main categories, further classified into subcategories. All categories and subcategories of the attention-based approaches are discussed in detail. Furthermore, the state-of-the-art approaches are compared and the accuracy improvements are stated especially in the transformer-based models, and a summary of the benchmark datasets and the main performance metrics is presented.

**Keywords**—Image captioning; attention model; deep learning; computer vision; natural language processing

## I. INTRODUCTION

Image captioning is targeted to represent an image with a sentence that should be accurate and summarized. The problem of image captioning is similar to using a machine to translate a sentence, but in image captioning, the machine task will be translating an image into a sentence. So, it is necessary to visually understand the image before producing the caption. The caption of the image should be expressive through detecting the objects of the image and their attributes, finding the relationship between the detected objects and the place/activity where the objects are included.

The task of image captioning is very necessary for that it can be as an assistant to the impaired people by providing a brief description for the image while exploring the internet. Image captioning can be used in implementing self-driving cars by providing the agent with the ability to drive in a safe, fast and accurate way. Also, generating a caption for medical images automated the process of diseases diagnosis and treatment. In addition, it can be used to generate captions for the images included in the news articles. There are many other applications for image captioning, like in service robotics, military, education and image indexing.

In order to generate a sentence with reasonable linguistics and true semantics, Computer Vision (CV) methods are used to visually understand the image. In addition, Natural Language Processing (NLP) models are employed to generate a correct

sentence. The power of Deep Learning (DL) approaches in CV [1-7] and NLP [8-12] makes it the first choice for many approaches in image captioning. Convolutional Neural Network (CNN) was most commonly used in the vision part to get the image features. Then, Recurrent Neural Network (RNN) was used as a language model [13-16].

According to [17], deep neural network approaches in image captioning task can be categorized based on:

- Type of learning: (Supervised [18,19], Unsupervised [20,21] and Reinforcement Learning [22,23])
- Architecture: (Encoder-Decoder [24,25] and Compositional [26,27])
- Feature Mapping: (Visual Space [28,29] and Multimodal Space [30])
- Number of Captions: (Dense Captioning [31], Whole Scene Captioning [32])
- Language Model: (LSTM and others)

For the purpose of generating high quality captions, it was helpful to use advanced visual processing by considering the most salient features in the images while generating the caption words which is called attention model. The attention mechanism takes inspiration from the human visual system, which does not focus on all the scene parts but only on small parts of the scene. The salient features included in the image take precedence in encoding the image instead of the whole image. Attention has been used in different tasks, like machine translation and object identification. Moreover, many image captioning approaches employed the attention model and achieved a very good enhancement [33-37].

In this paper, a detailed survey for the attention-based approaches employed in image captioning is presented. In addition, a taxonomy of these attention-based models is provided including two new categories for categorizing the attention-based approaches. Most of the state-of-the-art articles for image captioning using attention-based models are included and compared with respect to the benchmark datasets and metrics.

The organization of this survey paper is as follow: In Section II, Literature review is presented. The attention mechanism and its taxonomy is presented in Section III, including four main categories of the attention models and their subcategories. The benchmark datasets in addition to the

popular performance metrics are introduced in Section IV. State-of-the-art models are compared in Section V. Finally, this survey paper is concluded in Section VI.

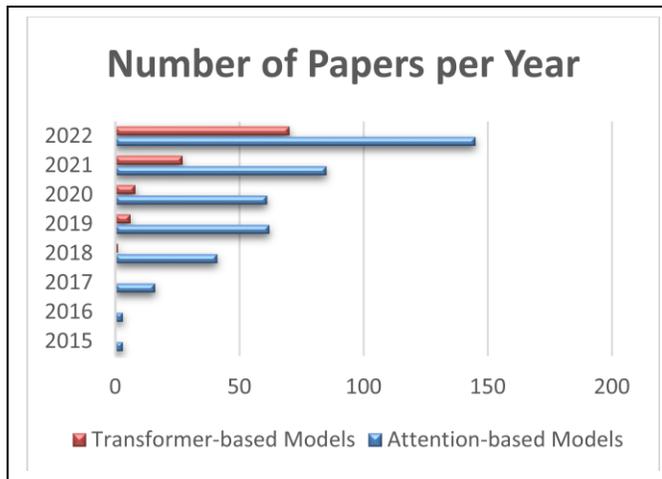

Fig. 1. Number of attention-based papers in image captioning per year

## II. LITERATURE REVIEW

Many surveys have been published for the deep learning techniques in image captioning [17, 38-42]. Some of these surveys [17, 38, 40-42] considered few attention-based approaches in image captioning because most of the attention approaches were issued after publishing these deep learning surveys. A comparative study for attention-based techniques was published by Khaing and Phyu [43]. Their survey presented a good comparative study of the attention-based models but without any categorization and moreover, the most recent reference in their survey was in the year 2018, and there is big progress in the attention-based methods starting from the year 2019 as shown in Fig. 1. The newest survey for attention-based models was presented by Zohourianshahzadi and Kalita [44]. In [44], they presented an evolution path of the attention models including hard and soft attention, semantic attention, spatial attention, adaptive attention, and bottom-up and top-down attention.

As per our knowledge, there is no detailed survey with a good taxonomy for the attention-based approaches employed in image captioning. Motivated by this gap in the existing image captioning survey papers, especially for the attention-based approaches, a detailed survey for the attention-based approaches employed in image captioning is presented in this paper by introducing new categories.

## III. TAXONOMY OF ATTENTION-BASED MODELS

Employing the attention mechanism in image captioning was motivated by the successful work achieved in neural machine translation [45] and object recognition [46, 47]. The attention was employed in the decoder part of the translation task to mitigate the encoder from the need to model all input sentence information [45]. Xu et al. [48] proposed captioning

approach by exploring the attention technique to consider the significant regions in the process of caption generation.

According to [48], the attention was applied at the decoder so that at every time step ( $t$ ), LSTM produced a new word depending on the hidden state ( $h_{t-1}$ ), the words produced at the previous steps and a vector called context vector ( $\hat{z}_t$ ). The context vector ( $\hat{z}_t$ ) represents the information of an appropriate location of the image at specific time step  $t$ . The context vector  $\hat{z}_t$  can be calculated using the annotation vectors, which are the features related to the image regions, and their assigned weights  $\alpha$ . The weights  $\alpha$  are assigned to every annotation vector  $a_i$ , ( $i = 1, \dots, L$ ) using Multilayer Perceptron depending on the previous step hidden state  $h_{t-1}$ . The attention model  $f_{att}$  used for calculating the weights had two variants either soft or hard attention depending on how the weights will be interpreted.

Variants of the attention model were proposed in image captioning research area, some researchers enhanced the model by employing the attention as multi-stages or by inserting information to guide the attention. However, the most notable variant of the attention is the transformer-based models as can be seen from Fig. 1, there is a big interest in applying the transformer-based models in comparison with the other categories.

In image captioning, the attention mechanisms can be categorized into four categories, as demonstrated in Fig. 2. According to Chen et al. [49], the visual attention-based approaches may concentrate on the spatial features or the semantic features, so visual attention is added as a category for characterizing the attention-based models. In addition, according to He et al. [50], the attention-based methods can be categorized based on applying the attention as single-stage in the decoder, two-stages, two-stages with scene graph or based on the transformer. This classification is added as subcategories into the category named Attention Blocks. In addition to these main two categories, in this survey paper, two new categories that were not included in other survey papers for characterizing the attention-based models are added, which are Number of Attention Layers and Guided-Attention.

### A. Visual Attention

Visual Attention [51, 52] is a significant technique in the human visual system. The brain targets a region or an object using computational capabilities with the guidance of low-level image features in a time step. The visual attention models can be divided into spatial and semantic attention.

1) *Spatial attention*: For spatial attention, the attention is demonstrated spatially at a specific region [48, 49, 53-56]. For each fixed location, attention weights are calculated related to this location at each iteration. Several approaches apply soft attention, which models the feature maps with the computed weights.

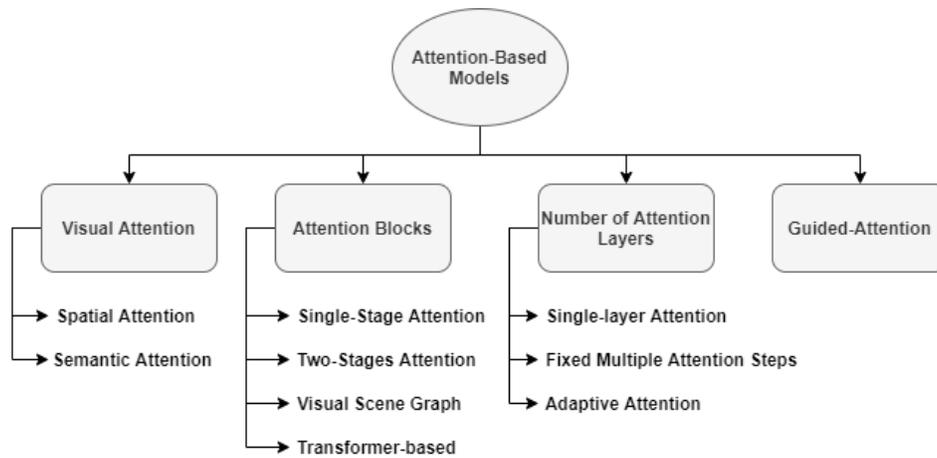

Fig. 2. Taxonomy of attention-based image captioning models

While other approaches use hard attention by selecting a set of regions which are salient from the feature map and concealing the other regions. Through applying the weighted pooling, some of the important spatial data may be lost. In addition, regularly the spatial attention is computed in the last convolutional layer, which leads to some analogous feature results for distinct regions because of the big size of the filter, resulting in ineffective spatial attention.

2) *Semantic attention*: Instead of attending to the fixed resolutions in spatial attention, other approaches proposed attending to the image's semantic concepts [57, 58]. Semantic attention is more like the human description of the image because people describe the most important objects and do not talk about all regions in the image. Attributes can be utilized from any image location even if there is no actual existence of these attributes within the image. For the purpose of attending to semantically necessary attributes, You et al. [57] employed a semantic attention framework that used top-down and bottom-up models. Bottom-up was used to select the semantic attributes, and top-down was used to decide when and where to apply the attention. Another approach was proposed by Gan et al. [58] in which they recognized the semantic tags and computed the probability of the tags to be utilized in forming the LSTM parameters. LSTM weight matrices were expanded to a group of weight matrices that are tag-dependent.

Using semantic attention requires extra resources that are important for detecting the relationship among the semantic concepts and the image.

### B. Attention Blocks

The attention-based models can also be categorized according to the block where the attention is applied. The attention can be applied as a single-stage in the decoder block, two-stages by obtaining bottom-up and top-down attentions, two-stages with injecting a graph network, or Transformer-based models.

1) *Decoder-based attention (single-stage attention)*: In decoder-based attention models, the attention is employed at the decoder. In the process of producing the caption words, the informative regions [59] are targeted in the attention by the

decoder. Depending on the LSTM hidden states and the previously predicted caption words, Xu et al. [48] proposed to use the attention module in the decoder of the captioning approach while generating the sentence words. A weighting matrix is introduced for each feature map receptive field then this weighted map and the last predicted word were forwarded to the language model for the purpose of predicting the next word.

2) *Two-stage attention*: Rather than attending to the salient regions like Decoder-based attention, Anderson et al. [53] presented a model that contains two-stage attention. Faster R-CNN [60] was employed in the bottom-up attention module. Then, the attention was distributed among the image regions using a top-down attention mechanism. They used two LSTM layers for the purpose of applying attention to the selected spatial features, the first layer was for the top-down attention, and the other was for the language layer. The drawback of their model is that it cannot handle object-object relationships.

An approach that is similar to [53] was introduced by Lu et al. [61]. Their proposed decoder determines whether the word will be visual and predicted according to a certain image region or the word will be predicted from the textual vocabulary. The essential advantage of their approach is in its availability to have additional object detectors, which can lead to producing different image captions. The main gap in two-stage attention models is that the models are lacking for getting the relationship between the image regions.

3) *Two-stage attention with graph*: To enhance the two-stage attention models, graph networks can be employed to discover the relationship among the detected regions which can result in enhanced features and accordingly improve the caption generation. Similar to [53, 62], Yao et al. [55] employed the attention mechanism for attending to the informative image regions. The key novelty in (GCN-LSTM) [55] is that they used two graphs for detecting the relationship between the image regions. A semantic graph was employed with the nodes representing the image regions and the edges representing the relationship between these detected image

regions. While the geometrical relations between the regions 'vertices' were demonstrated by the spatial graph. Then, Graph Convolutional Network (GCN) [63] was utilized to output relation-aware region representations.

The approaches presented in [55, 64] employed Faster R-CNN to identify the image objects and thus explore the relationships between regions of interest. Faster R-CNN was trained on the Visual Genome dataset [65]. While in [66], the visual relationships were modelled on Flickr30K [67] and MS COCO [68] and so the pre-established classes of the relations are not required.

The authors in [55] extended the approach to (GCN-LSTM-HIP) [69] to include a hierarchical tree of three levels which have the image as the root, the detected regions as the first layer and the instances/foreground of the regions at the leaf layer. Then, a Tree-LSTM [70] was employed for modelling the dependency structure and improving the features.

Another model presented by Guo et al. [71] which detected a set of visual semantic units 'VSUs' where the units represent the objects, attributes and the object's relationships. Semantic and geometry graphs were employed while the vertices representing the semantic units and the edges representing the connections between them differed from [55] that presented the relationships as edges. GCN was then introduced in [71] to output context-aware embeddings for the visual semantic units. Attention for the different kinds of units was applied via context gated attention (CGA). Another scene graph approach was presented by Yang et al. [72] that used the edges to represent the relationships in the graph. Language inductive bias was integrated into the captioning framework, and its features are represented via a scene graph auto-encoder (SGAE).

The main drawback in the graph scene-based models is that, however, the models made an enhancement to the performance compared to the two-stage models, but the need for additional models for scene graph construction is still a problem. Also, with respect to the computational cost, having two graphs is ineffective.

4) *Transformer-based*: Unlike the graph-based models, the transformer models don't include any graphs and thus don't need additional models for the graph construction. The transformer was originally designed for text translation [73]. The transformer is able to avoid any duplication by employing the attention in a comprehensive way between the input and the output. Extensive approaches were proposed to employ the transformer models in image captioning [74-85].

Huang et al. [86] proposed Attention over Attention (AoA) approach, which adds attention over the traditional attention. "Information vector" and "attention gate" were produced by the query and the attended results, then second attention was produced by element-wise multiplication between them. AoA was applied in the encoder to detect the relations between the objects. While in the decoder, AoA was employed for holding the relevant attention output and ignoring the deceptive results.

Captioning transformer with stacked attention module was proposed by Zhu et al. [76]. A multi-level observation was proposed in such a way that all transformer layers had the

opportunity for generating the sentence word. Average pooling was then employed to find the probability of the word by merging all the contributions.

Cornia et al. [74] proposed a transformer approach to consider low and high-level relationships by modelling them as multi-level. They utilized persistent memory vectors while encoding the relationships with prior information. In addition, rather than applying the attention only to the last encoding layer, all the encoder layers contributed to the sentence generation process and connected to the decoder layers in mesh-like connectivity.

A Multimodal transformer was proposed by Yu et al. [75], which is able to model three different relations, which are: word-to-word, word-to-object and object-to-object. Self-attention in the same modality and co-attention in distinct modalities were acquired. In addition, multiple views were employed in two designs: aligned and unaligned multiple views.

The conventional transformer was expanded with the addition of EnTangled Attention (ETA) and Gated Bilateral Controller (GBC) [77]. ETA gave the transformer the ability to use semantic concepts and visual information. The interconnection between the multimodal information was controlled by the GBC. Object relation transformer [78] was proposed in which geometrical information for the relationship between each pair of objects was included within the transformer through spatial attention.

He et al. [50] proposed a model with the idea of changing the internal structure of the transformer that was originally proposed to handle text. They introduced an expanded transformer that includes three parallel sub-transformer layers to handle three different relationships: parent, child, and neighbor.

### C. Number of Attention Layers

The attention models can be characterized according to the number of required attention steps either to attend once per word, attend with fixed steps or adaptively determine the number of required attention steps.

1) *Single-layer attention*: The attention operation is connected to the word generation procedure in the traditional attention-based framework [48]. The framework attended once to the image prior to generating the following word. The model attended to selected image regions in each iteration, and the computed attention features were sent to the RNN as input. The problem of attending once per word is that some important information may be lost, especially if the model attended to an incorrect region.

2) *Fixed multiple attention steps*: In order to enhance the single attention process by avoiding predicting incorrect words, several approaches attended multiple times to enhance the attended region and get the lost data [87, 88]. Du et al. [87] proposed a model that attended more times to the image per word and showed that it could improve image captioning without adding extra parameters. Two LSTMs model were

utilized, which have the ability to attend for arbitrary times and enable the flexibility of the attention operation.

Triple attention approach was proposed by Zhu et al. [88]. The attention is utilized to the input phase of the previous step LSTM hidden states. In addition, attention was also utilized in the output phase of present hidden states. Conditional embedding was used in addition to the word/image embedding at every input stage of LSTM. This way, the prior text information was coupled with image information, and accordingly, text and image information appeared in the input of the word generation procedure.

For the purpose of getting attention to different semantic abstractions, Chen et al. [49] applied the attention in a multi-layer since the lower layers are the dependent layers for the feature maps. The attention in their approach was approached to each entry of the feature maps, which are multi-layer. They also proposed channel-wise attention for applying the re-weighting process in every channel through the word generation process. The channel-wise attention could be viewed as the procedure of choosing the semantic concepts by paying more attention to the channels produced by filters indicated by the semantics.

A hierarchical approach (CNN+CNN) [89] was proposed such that they employed the CNN as a decoder besides being the encoder. Their hierarchical attention model learns the relationship of the attributes for all image regions and all levels. The dot-product operation used in their framework results in reducing the parameters and can be faster than Multi-layer Perceptron attention used in [48, 54]. The idea of hierarchical attention was also employed in [90-92]. Yan et al. [90] proposed a mechanism made up of global and local attention modules which related to the global CNN features, extracted by CNN encoder, and local object features, extracted by object detector, respectively.

Sequential attention was presented by Fang et al. [93] to take into consideration the sequential attention relationships in several time steps at word generation and correspondingly improve the visual data in caption generation. Another sequential attention was proposed by Liu et al. [94], in which the image was represented as a sequence of objects, and the attention was employed to consider all objects information during sentence word generation.

3) *Adaptive attention*: According to the previously presented approaches, sometimes there are no image regions corresponding to each sentence word. So, an adaptive attention approach [54] was proposed that includes a sentinel gate and spatial attention to determine where and when to attend in the caption generation. They presented an extension to LSTM that, rather than having one hidden state, they added a visual sentinel vector. In addition, a sentinel gate was proposed to determine whether the attention will be targeted to the visible sentinel or the image. Another adaptive attention approach was proposed by Deng et al. [95] that adaptively determine whether it is needed to depend on the language model or the visual signals. Their proposed approach can make the image captioning task more flexible by enhancing

the obligatory correlation between image regions and sentence words.

Adaptive semantic attention framework [96] was proposed to incorporate dual-LSTMs; the first LSTM works as a visual sentinel to acquire fine-grained representations. The second LSTM serves as a language model that produces the sentence words depending on the updated attended vector and first LSTM output.

Huang et al. [97] presented an adaptive attention time model (AAT). The model was learned to determine the number of required attention steps in each step of the decoder in order to produce the next word. Using AAT, the mapping between the image regions and caption words can be applied arbitrarily such that a caption word may attend to multiple regions and vice versa. Their approach doesn't add parameters gradient noise.

#### D. Guided Attention

For the purpose of enhancing the performance of image captioning approaches and generating accurate captions, some approaches inserted additional information guidance [98, 99] like the concept features that make a connection between the input image and the caption. In [100], the model was guided through semantic information acquired from the images and sent as extra input for the LSTM units. While in [101], the approach could be guided through concept features which are obtained from predicting the recurrent word existence in the captions. Another way for learning the features is by adding a network for guidance [102]. More similar to [102], Sow et al. [103] inserted a network for guidance, but rather than obtaining one vector for guidance, [103] obtained a sequential network for guidance which was able to adjust the guided vectors in the sentence generation process. They also utilized the Luong attention mechanism [104] that is an enhanced style of the attention technique.

Text-guided attention approach was presented by Mun et al. [105]. Related sample captions, namely guidance captions, were employed to get visual attention and produce appropriate captions. The related sample captions were obtained through the similar training images that participate in equivalent related regions with the input image. Topic-guided attention was proposed by Zhu et al. [106], which picked up the significant features by the information guidance through incorporating the topics within the image with the attention mechanism.

## IV. DATASETS AND PERFORMANCE METRICS

### A. Datasets

Different datasets have been presented in the research area of image captioning. The popular datasets, which are Flickr8K [107], Flickr30k [67], Microsoft COCO [68] and Visual Genome [65] are presented.

1) *Flickr8K [107]*: Dataset consists of about eight thousand images selected from six groups on Flickr.com and does not have a tendency to famous locations or people; instead, various situations and locations are represented. The dataset includes five captions for each image through human annotations.

2) *Flickr30K* [67]: Extension to Flickr8K, consists of 31,783 images. Flickr30k contains 8.7 objects per image, 44,518 object categories, 6.2 objects per category, 5 sentences per image and 16.6 expressions per image.

3) *Microsoft COCO dataset* [68]: A large-scale dataset that broadly used in image captioning task. MS COCO includes 328,000 images, 7.7 objects per image, 91 object categories, 2.5 million labelled instances, 27,473 objects per category and five sentences per image.

4) *Visual genome dataset* [65]: It is an image captioning dataset that considers the relationship modelling between objects. It generates captions for different image regions, unlike the other datasets, which generate the caption to the entire scene. The dataset includes more than 100 thousand images, 18 attributes, 21 objects per image, and 18 objects relationships.

### B. Performance Metrics

For the purpose of evaluating the image captioning techniques, different metrics were proposed to compare the output generated caption with the original caption. In this section, the main used performance metrics which are BLEU [108], ROUGE [109], METEOR [110], CIDEr [111] and SPICE [112] are presented.

1) *BLEU "Bilingual Evaluation Understudy"* [108]: It is originally introduced by IBM for the evaluation of machine translation. This metric measures the quality of the generated sentence by calculating its similarity with the original reference translations. N-grams of the machine-generated sentence are compared to those of the reference sentences and get the matching counter. The output score is higher, and the quality of the generated sentence is better when there are more reference sentences and there is a higher number of matches. The range of BLEU values is from zero to one, and a small number of generated captions can get one only if it is identical to the ground truth caption.

2) *ROUGE* [109]: It is originally introduced for the evaluation of text summarization. ROUGE metric calculates the quality of the text generated summary by counting the number of its n-gram, sequences of words, and pairs of words that overlapped with the reference summaries created by experts. ROUGE-N (N-grams), ROUGE-L, ROUGE-W, and ROUGE-S are the types of the ROUGE metric.

3) *METEOR* [110]: A metric utilized for evaluating the machine-generated texts by matching the unigrams of the machine-generated sentence and the reference sentences. Once this matching is computed, recall and precision of unigram and a measure of fragmentation were utilized for computing a METEOR score.
