4) *CIDEr* [111]: A metric utilized for evaluating the image descriptions. The five available captions of the dataset used in the other metrics are not enough for finding the consensus among the judgment of the human and the output captions. A consensus is a measurement for counting the

mutual n-grams between the ground truth and predicted captions and assigning low weights for the common n-grams.

5) *SPICE* [112]: The previously explained metrics depend on the n-grams and SPICE metric overcomes this restriction by employing a scene graph in which the reference and generated captions are converted to a graph-based semantic representation. SPICE is measuring if the objects and attributes are represented in the generated caption in an effective way in addition to their relationships.

## V. COMPARISON AND DISCUSSION

In this section, the performance of different state-of-the-art approaches is presented and discussed. In Table I, different approaches are compared with respect to their experimental results on the benchmark MS COCO dataset and the commonly used performance metrics BLEU-4 (B@4), METEOR (MT), ROUGE-L (R), and CIDEr (C).

From the beginning of using the attention mechanism in image captioning by Xu et al. [48], it has been shown that their approach obtained better performance on Flickr8k, Flickr30k and MS-COCO. The reason behind the better performance is that their approach considered the most relevant objects when generating the image caption. Moreover, they showed that the hard attention variant of their mechanism outperforms the soft attention on these benchmark datasets. After that, You et al. [57] showed that attending to the semantic attributes instead of attending to the spatial attention [48] can improve the results by generating semantically rich captions.

Further improvement in the results was obtained by introducing multiple attention layers, which can be used in a hierarchical structure or by using either a fixed or adaptive number of attention layers. Du et al. [87] achieved 38.1, 28.3, 58.0, 126.1 and 22.0 on BLEU-4, METEOR, ROUGE, CIDEr and SPICE, respectively. These results are higher than the results of hierarchical attention [89]. The hierarchical structure in [89] used the CNN as decoder; however, Du et al. [87] used two LSTMs model to enable attention at arbitrary times and make the attention operation more flexible.

The adaptive attention approach of Huang et al. [97] achieved 38.7, 28.6, 58.5, 128.6 and 22.2 on BLEU-4, METEOR, ROUGE, CIDEr and SPICE, respectively, which are higher than that of both Wang and Chan [89] and Du et al. [87]. The reason for their better performance is that their model was learned to determine the number of required attention steps in each decoder step, and the mapping between the image regions and caption words can be applied arbitrarily.

Anderson et al. [53] achieved a good performance by employing a two-stage decoder containing bottom-up attention and top-down attention. Yao et al. [55], Guo et al. [71] and Yang et al. [72] further enhanced the results of the two-stage decoder by introducing scene graphs for detecting the relationship between image regions. Yao et al. [69] achieved better results than [55, 71, 72] by introducing a hierarchical tree and using a tree-LSTM to model the dependency structure.

The best performance in Table I was achieved by Yu et al. [75] and Pan et al. [114]. In [75], Yu et al. used a multimodal transformer that can model three different relations, and the

model was designed in two views aligned and unaligned multi-view visual representation. However, Pan et al. [114] modelled second order interactions through proposing X-linear attention module plugged into transformer. Both of [75] and [114] are Transformer-based attention models which proves that Transformer-based models can achieve better results in comparison with other attention-based mechanisms. The big interest in applying the transformer, as can be seen from Fig. 1, comes from its ability to weight the importance of every input region and its ability to avoid any duplication by employing the attention in a comprehensive way between the input and the output. In addition, it can be parallelized in an effective way.

Employing the attention mechanism in image captioning started from the year 2015 [48] and it is getting more attention from that time since the number of research papers employed the attention is increasing every year as explained in Fig. 1. In addition, the authors have a tendency for using the scene graph with attention models and also great attention is going towards applying the transformer in the image captioning task due to its parallelization nature and better performance. In addition, part of the research in image captioning task recently is going towards applying the attention as multi-layer in order to enhance the predicted words or adaptively determine the number of required attention steps.

TABLE I. COMPARISON BETWEEN THE STATE-OF-THE-ART ATTENTION-BASED CAPTIONING APPROACHES

Ref.	Year	Category of the Attention	Results (C5)			
			B@4	MT	R	C
[48]	2015	Spatial Single Stage	25.0	23.04	-	-
[57]	2016	Semantic Single Stage	31.6	25.0	53.5	94.3

[117]	2022	Adaptive	38.5	28.3	57.5	120.7

## VI. CONCLUSION AND FUTURE WORK

In this paper, a survey was presented for the attention-based image captioning approaches. Four main categories of the attention-based approaches and their subcategories are summarized. Furthermore, the attention-based approaches were compared on benchmark datasets and popular performance metrics. As discussed in the paper, there is a great improvement in the image captioning task due to using the attention-based models especially using Transformer-based approaches. Although there is an impressive effect of using the attention-based models in image captioning, there is still room for improvement. Faster R-CNN is extensively employed as an encoder because of its ability to get effective detection results. However, training of Faster R-CNN is not a simple task, and it gives unsatisfied results in some cases, like when having images of low resolutions or when the objects are deformed or of small size. So, it may be better if other image encoders are used or when an enhanced version of Faster-RCNN is employed. In addition, another room for improvement can be found in the transformer-based models with introducing new transformer architectures, which may help in improving the quality of the result description.

# Towards an Automatic Speech-to-Text Transcription System: Amazigh Language

Ahmed Ouhnini<sup>1\*</sup>, Brahim Aksasse<sup>2</sup>, Mohammed Ouanan<sup>3</sup>  
Dept. of Computer Science FST, Moulay Ismail University, Errachidia, Morocco<sup>1</sup>  
Dept. of Computer Science FS, Moulay Ismail University, Meknes, Morocco<sup>2,3</sup>

**Abstract**—Various studies inside the domain of research and the development of automatic speech recognition (ASR) technologies for several languages have not yet been published and thoroughly investigated. Nevertheless, the unique acoustic features of the Amazigh language, for example, Amazigh's consonant emphasis, pose many obstacles to the development of automatic speech recognition systems. In this study, we examine Amazigh language voice recognition. We treat the problem by focusing on transitions in vowel and consonant sounds and formant frequencies of phonemes. We present a hybrid strategy for phoneme separation based on energy differences. This includes analysis of consonant and vowel features, and identification methods based on formant analysis.

**Keywords**—Speech recognition system; Amazigh language; analyzing formants and pitch; speech corpus; artificial intelligence

## I. INTRODUCTION

Automatic Speech Recognition (ASR) is used to transcribe human speech captured via a microphone into text that computers can understand in order to enhance human-machine (HM) communication. ASR has long been the subject of intense research. Formant frequencies have been studied for decades. ASR has long been a topic of active investigation. For many years, formant frequencies are believed to be an important factor in recognizing speech phonetic content [1]. To arrive at the stage of recognizing phonemes, we examine a specific case of this problem and focus on the vowels and consonants transition in the Amazigh language and the formant frequencies of phonemes that are important for determining the phonetic content of speech [2]. We trust that this effort, will highlight the importance of consonant-vowel changes and vocal parameter analysis in speech recognition.

We provide a strategy that includes separation of phonemes by differences in energy between consonants and vowels, vocal characteristics processing of phonetics units, and a recognizer algorithm based on formants. Formant analysis methods focus on associating physical aspects with phonology. This method determines speech types by analyzing linguistically distinct features of the speech.

The rest of this article is organized as follows: Section II describes the characteristics of the human voice and the Amazigh language. The remainder of Section III describes some mathematical and engineering techniques for language modeling, followed by a discussion of proposed phoneme recognition methods. Section IV provides further insight into the results and Section V concludes the article.

## II. CHARACTERISTICS OF SPEECH AND PHONETICS

### A. Human Ear and Acoustic Sound

Sound constitutes a wave that propagates in a material environment like small variations of pressure. This is perceptible via human ears at frequencies ranging from 20 Hz to 20 kHz. Nonetheless, the phonetic information is judged to be less than 10 kHz [3].

Due to the way sound signals are sifted, we modify the sufficient range because ears are not sensitive to stage distortion. This allows us to focus exclusively on complementary application modules.

### B. Human Voice

The human voice is a collaboration of breathing and multiple phonatory organs. In voiced phonemes, sound is first produced by the vibration of the vocal cords [4]. It is manipulated differently depending on the cavities it passes through, primarily the pharynx and mouth. These cavities act as resonators, increasing frequencies corresponding to the resonant frequencies of specific phonemes. These enhanced frequencies are known as "formants" and are the features that phonologists search in spectrograms to identify phonemes being pronounced [5].

The Fig. 1 shows the formants (F1, F2, and F3) superimposed on spectrogram of speech signal « he took holidays » showing the alternating voiced and unvoiced sounds. In the voiced situation, a formant structure is presented.

### C. Phonology and Phonetic

Phonetic by definition is study of phonetic units, the smallest particular phonetic unit being regularly defined as a phoneme. The opposition between the terms bath and bread, well, suggests that [b] and [p] are phonemes. In general, we can classify them as follows: classes and subclasses, more significant of which is "vowel" and "consonant".

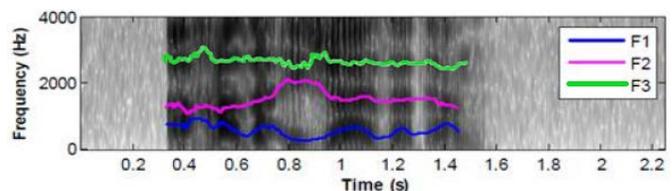

Fig. 1. Illustration of formants F1, F2, F3 of speech signal "he took holidays".

\*Corresponding Author.

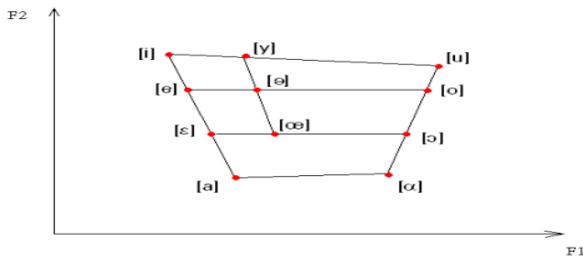

Fig. 2. Categorization of vowels using the vocal trapezoid.

Relatively vowels are lengthy-duration sounds with a flows and with considerable frequency characteristics consistency during times: in absence of highly pronounced prosodic features, formants appear horizontal on the spectrogram [6]. The vowel trapezoid, shown in Fig. 2 illustrates their location in the planes specified by initial both formants, indicating articulation position of language.

However, consonants represent phonemes that encounter an obstacle when articulated (such as labial vowels, toothy teeth, palate closure in [k], etc.). In comparison, they are considerably shorter than vowels and significantly variable in length during time. Could be sonorous or loud. In the resonant scenario, only current formants are present, see the Fig. 3.

D. Speech Signal Frequency Parameters

The bandwidth of voice signal is much larger than the telephone bandwidth (4 kHz) and includes all information's necessary to know to decode human voice.

The fundamental frequency refers to the speed of opening and closing of the vocal chords during phonation. Its value is proportional to the individual's phonatory system size [7]. Voice frequency vary between 80 and 600 Hz based on age and gender.

The spectrogram is a representation in three dimensions, where the X-axis represents time, the Y-axis represents frequency, and the Z-axis represents frequency levels (symbolized by gray levels). Fast Fourier transform (FFT) with sliding window is applied to acquire the voice signal.

E. Amazigh Language

The Amazigh language, commonly called Tamazight or Berber, is one of humanity's earliest languages. Now it extends from the Red Sea to the Canary Islands and from Niger in the Sahara to the Mediterranean Sea, including the northern section of Africa.

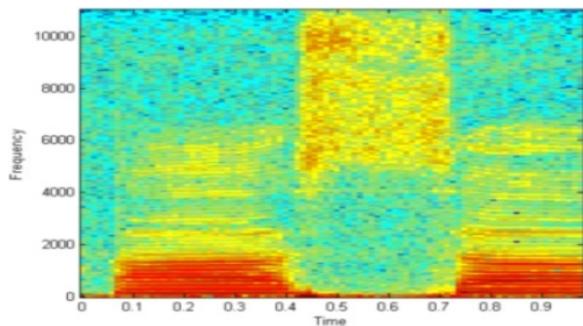

Fig. 3. Spectrogram of the syllable (asa).

In Morocco, Amazigh language is classified into three main regional's varieties, based on historical, geographical, and sociolinguistic factors: Tarifite in the north, Tamazight in Central Morocco and the south-east, and Tachelhite in the south-west and the High Atlas. Even though half of the Moroccan population are Amazigh speakers, the Amazigh language has been reserved exclusively for informal and familial domains: Boukous (1995) [8]. In the last decade, with royal generosity, the language was institutionalized and included in Moroccan school system.

Since February 2003, Morocco's official Amazigh alphabet system, known as Tifinaghe-IRCAM, has been used in Moroccan school programs and Amazigh historical studies. The system uses the alphabet describe in Table I [9]:

TABLE I. AMAZIGH LANGUAGE ALPHABET

<b>27 Consonants</b>	<i>labial</i>	ⵍ, ⵍ, ⵏ
	<i>dental</i>	ⵜ, ⵏ, ⵍ, ⵍ, ⵏ, ⵏ, ⵏ, ⵏ
	<i>alveolar</i>	ⵏ, ⵏ, ⵏ, ⵏ
	<i>palatal</i>	ⵍ, ⵏ
	<i>velar</i>	ⵏ, ⵏ
	<i>labiovelar</i>	ⵏ, ⵏ
	<i>uvular</i>	ⵏ, ⵏ, ⵏ
	<i>pharyngeal</i>	ⵏ, ⵏ
	<i>laryngeal</i>	ⵏ
<b>2 Semi-consonant</b>		ⵏ and ⵏ
<b>4 Vowels</b>	<i>full vowel</i>	ⵏ, ⵏ, ⵏ
	<i>Neuter vowel (schwa)</i>	ⵏ it has a specific status in phonology Amazigh.

The correct writing of words in the Latin letters closely resembles phonetic transcription and correctly conveys their pronunciation, includes twinned and vowel sounds.

Examples: /illa/ → « illa » → « il existe », « il est ». [10]

The pronunciation of Amazigh language varies from region to region [11].

III. TECHNOLOGIES AND METHODS

A. Fourier Analysis

Transform of Fourier permits a time-frequency processing at a resolution suitable for speech signals that are quasi-stationary on intervals of 10-100 ms.

1) *Fourier transform*: We are dealing with the pre-Hilbert sets of square integrables function  $L^2(\mathbb{R})$ , and the orthogonal family of sine functions  $e_f: t \rightarrow e^{j2\pi t} / f \in R$  (we restrict ourselves physically in concret pulses)). Preparing the projection portion of each sinusoid provided by the scalar product, and not ignoring the complex conjugate with respect to the second number, the Fourier transform  $H(f)$  (or  $FT(g(t))$ ) of a functions  $g(.)$  allows projection over the vector space through which the sinusoids:

$$FT(f) = \langle g(t) | e_f \rangle = \int_{-\infty}^{+\infty} g(t) e^{-j2\pi ft} dt \quad (1)$$

Where the variables  $t$  and  $f$  refer to time and frequency, respectively.  $FT(f)(t)$  is the transform of  $g(.)$ .

These transform would be employed in our study to investigate the contributions of each frequency range in the speech signal more qualitatively by evaluating the spectrogram, (Ohm's rule states that human ear is insensitive to the acoustic signal's phase) [12].

2) *Discrete fourier transformation*: The signal has now been expressed by sampling taken evenly throughout time by sampling continuous time  $\{x(n)/n \in [0, N - 1]$

To avoid edge effects, we convert them into an  $N$ -period signal. Following that; the discrete transform expressed as:

$$F(k) = \sum_{n=0}^{N-1} x(n)e^{-\frac{2i\pi kn}{N}} \quad (2)$$

The frequency observations is related to the  $\frac{k}{N}$  factor for  $k \in [0, \frac{N}{2}]$  If  $f_e$  represents the sample frequency, so  $= f_e \times \frac{k}{N}$ . It should be emphasized that because the received information is restricted to half of the period  $[0, N - 1]$ , this transformation is redundant. Indeed:

$$\begin{aligned} \forall k \in Z \quad F(N - k) &= \sum_{n=0}^{N-1} x(n)e^{\frac{2i\pi kn}{N}} e^{-2i\pi n} \\ &= \sum_{n=0}^{N-1} x(n)e^{\frac{2i\pi kn}{N}} = \overline{F(k)} \end{aligned} \quad (3)$$

As a result, modules are similar, with the term simply having the reverse indication. If we wish to evaluate the signal's about frequency scale of 10 kHz, we need to use a sampling frequency with 20 kHz [13]. Within reality, we employ the FFT (Fast Fourier Transform), which has a computational cost of  $O(N \log_2(N))$  rather than  $O(N^2)$  for straight computing, also use this redundancy to improve the computation.

### B. Convolution and Transformation

The convolution product in continuous-time of two functions is given as:

$$\forall t \in R, (f * h)(t) = \int_{-\infty}^{+\infty} f(\tau)h(t - \tau)d\tau \quad (4)$$

Convolution operators are commutative. Also, since there are associative equations, the following two are valid:

$$\forall t \in R, (f * h)(t) = (h * f) \quad (5)$$

As a consequence of commutativity:

$$((h * g) * f)(t) = ((h * f) * g)(t) \quad (6)$$

The Fourier transform of the two functions ordinary product is the convolution product of Fourier transforms. In addition, the Fourier transform of the two functions convolution product is the usual product of Fourier transforms:

$$\begin{cases} FT(g * h) = FT(g) \times FT(h) \\ FT(g \times h) = FT(g) * FT(h) \end{cases} \quad (7)$$

This finding is also valid for discrete cyclic representations. It will be applied in formants analysis as a result of the speech signal modeling adopted.

### C. Windowing Issue

Practically, in addition to the  $x$ -signal discrete, the observation time of  $2\tau$  has over. Consequently, we see the signal convolution using a window function [14]:

$$\Pi_{\tau}(t) = \begin{cases} 1 & \text{if } t \in [-\tau, \tau] \\ 0 & \text{if not} \end{cases} \quad (8)$$

As according (7), Fourier transformation of  $s(t) \times \Pi(t)$  being a convolution product between window and signal, following equation give gate function:

$$\int_{-\infty}^{+\infty} \Pi(t)e^{-i\omega t} dt = \int_{-\tau}^{\tau} e^{-i\omega t} dt = 2\tau \text{sinc}(\omega\tau) \quad (9)$$

This cardinal sinus has a central lobe with a width of  $2/\tau$ . As a consequence, when the observation period approaches zero, the spectrum expands. To resolve this issue, we use a zero-energy concentration window that restricts this phenomena. A Hamming window was used in our study [15], [16].

$$H(n) = 0.54 - 0.46 \times \cos(2\pi \frac{n}{N-1}) \quad (10)$$

### D. Formants and Pitch Examination

1) *Decoding problem from acoustic to phonetic*: Due to the continuous nature of speech signals, it is difficult to identify different linguistic units such as words, syllables and phonemes in the recorded signal. This problem is known as phonetic acoustic decoding. [17], [28]. We used a process allowing us to identify the transitions between consonants and vowels. The syllables corresponding to this case are available to qualify [18].

2) *Vowel-consonant (VC) and Consonant-vowel (CV) Transitions Detection*: Digital filtering is employed first to remove as much background noise as feasible [19].

The flowchart in Fig. 4 illustrates the identification of vowel-consonant and consonant-vowel transitions.

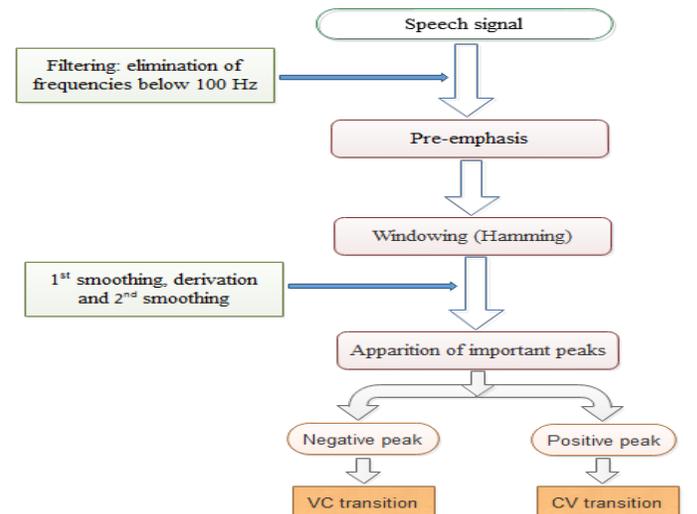

Fig. 4. CV and VC flowchart for detecting transitions [20].

3) *Formants*: Minimums and maximums presents in the vocal signal spectrum correlate to resonance and anti-resonance tract vocal, also named formants and anti-formants.

In general, the frequencies of analysed formants are: F1 is 200-900 Hz, F2 is 500-2500 Hz, F3 is 1500-3500 Hz, and F4 is 2500-4600 Hz.

The formants (F1, F2, F3, and F4) used in this study, for vowels and consonants found in word that recovered in order to differentiate the phoneme formants [21].

Formant analysis is used to identify consonants and vowels. Before formants can be recognized, they must be processed to make them clearer [22].

The chart in Fig. 5 represents this preprocessing.

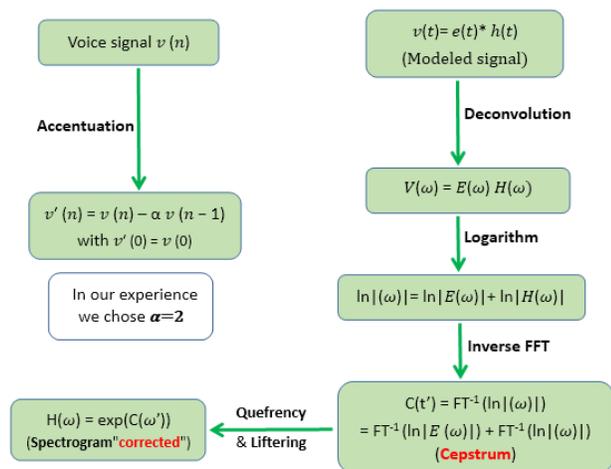

Fig. 5. Diagram for parameter preprocessing.

Once spectrum corrected was acquired, we search for every formant's in a carefully selected frequency band to increase the probability of finding the formant with the highest average amplitude.

Tables II and III show the predicted formant values (in Hertz) for a male voice. The extreme values of each formant have been specified.

TABLE II. A MAN'S VOICE'S ESTIMATED VOWEL FORMANT VALUE

Voyelle	Latin correspondence	F1	F2	F3	F4
[ɛ]	[i]	250	2250	2980	3280
[ɔ]	[u]	420	2050	2630	3340
[ə]	[a]	760	1450	2590	3280

TABLE III. A MAN'S VOICE'S ESTIMATED CONSONANT FORMANT VALUE

Consonne	Latin correspondence	F1	F2	F3	F4
[C]	[m]	300	1300	2300	2770
[l]	[n]	350	1050	2300	3470
[ʃ]	[l]	360	1700	2500	3300
[O]	[r]	550	1300	2300	2700

After the formant values have been obtained, we calculate the distance with every formant values in memory. Formant distance is strictly Euclidean; between both phonemes A and B, it is calculated as follows:

$$\text{dist}(A, B) = \sqrt{\sum_{i=1}^4 (F_A^i - F_B^i)^2} \quad (10)$$

4) *Pitch*: Pitch is a crucial component of human voice and widely recognized as perceptual fundamental of sound that is strongly attached to frequency and can be related to the vocal cord's vibration fundamental frequency, permitting audio frequency recognition. It is among the most essential auditory features of sounds, as well as quality and loudness [23], [30].

We used the "Get Pitch" command to extract the pitch, with set the pitch floor to 75 Hz, and set the pitch ceiling to 500 Hz.

E. Measurement Tools and Corpus

1) *Tools*: Phoneticians and academics utilize the open source program PRAAT [24] to identify various phonetic properties of speech. It is a very efficient software for analysing and recreating acoustic speech signal [25].

For collecting all of the characteristics presented in this study, wav files were registered and analyzed by PRAAT (see Fig. 6).

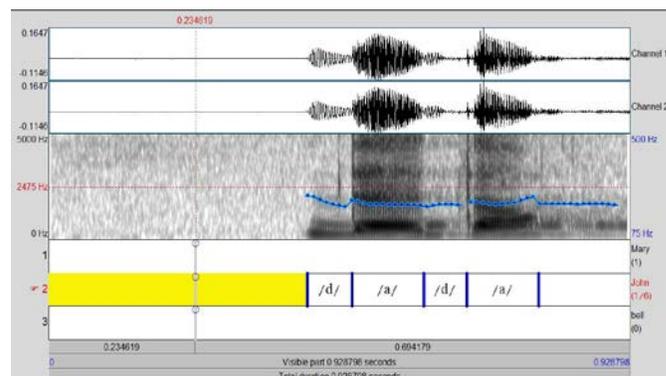

Fig. 6. Manual segmentation of the /dada/ syllable for the CVCV context.

2) *Measurements*: The foundations for measuring voice signals acoustically are pitch and the four formants, which are widely utilized as indicators of perceived speech quality [26]. The Table IV shows the Amazigh vowels used in this work.

TABLE IV. THE VOWELS AMAZIGH USED IN THIS STUDY

Tifinagh	English transcription	Latin correspondence	Arabic transcription	IPA
ⵢ	YA	A	يا	æ
ⵣ	YI	I	يى	i
ⵣⵓ	YO	U	يو	u

3) *Preparation of the corpus*: Ten persons (five women and five men) are chosen among a vocal database of Amazigh

people in Morocco comes from various regions with no distinctive geographical distribution. Age was used to coordinate subjects. The average age of the women was 35, ranging from 23 to 50 years. The men in this group range in age from 25 to 50 years, with an average of 36 years. Each speaker repeated the process 10 times. The total amount of evaluated words (10 speakers x 8 words x 10 repetitions), giving us 800 files to examine.

Our objective is to analyse the consonants, semi consonants, and vowels that are pronounced by studying the important voice parameters [27]. We manually recovered the vowels A, I, and U from Krad, Tanmirt, and Ayur words spectrograms. Based on the spectrogram of words Aghrum, Attas, and Tazalit, R, T, and Z are obtained consonants. More information about the database is shown in Table V.

TABLE V. RECORDING PARAMETERS USED IN THE CORPUS AMAZIGH PHONEMES PREPARATION

Parameter	Value
Sampling rate	22.05 kHz
Quantization	16 bits
Duration	2 second / syllabe
Wave format	Mono, wav
Corpus	10 Amazigh words
Speaker	10 (5 females + 5 males)
Accent	Moroccan Tamazight

4) *Materials*: In this study, we use a microphones and a computer having 8 GB of RAM and an Intel Core i7 processor running at 2.5 GHz. Our experience indicates that Windows 10 LTSB is the prevalent operating system. In a silent room, the microphone were placed between 4 and 10 centimeters from the individual's lips. We recorded the wav file with the parameters shown in Table V.

#### IV. RESULTS AND DISCUSSION

Fig. 7 represents our approach to determining the acoustical power of syllable [ara]. The Fig. 8 give the temporal derivatives of acoustical power shown in Fig. 7.

##### A. Authors and Affiliations

After a series of studies [29], it has been experimentally estimated that the transition occurs near the peak where the signal has lost or gained 66 percent in extreme difference of intensity while comparing both phonemes. Crosses appear on the chart to indicate the transitions.

The algorithm for phoneme separation is very effective as follows:

- The initial and final moments of silence were deleted;
- The speakers didn't blow into the microphone during recording, causing audio signal saturation and resulting in extremely big peak which the program interprets like a transition;

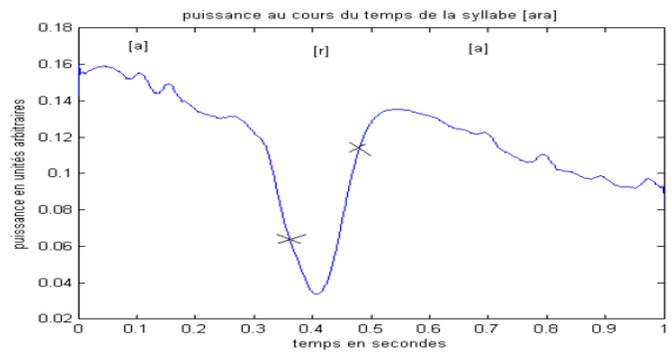

Fig. 7. Acoustical power of the word [ara].

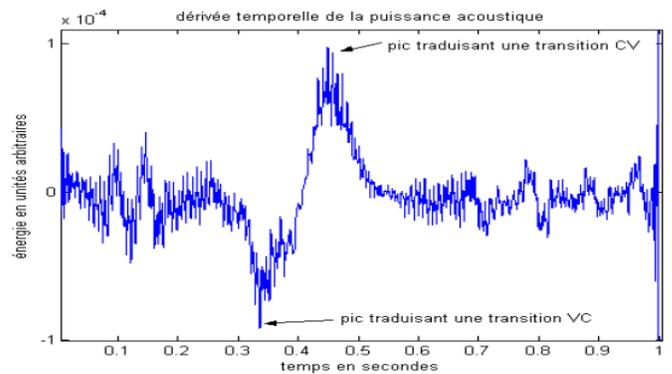

Fig. 8. Derivative of word's acoustical energy [ara].

This method achieves a 75% success rate, which is dependent on parameters such as geographic place, recorded material, as well as verbal difficulties of speakers.

#### V. CONCLUSION

This study examined the difficulty of automatic speech recognition for the Amazigh language. In specifically, we attempted to extract the vowels and consonants from the Amazigh voice signal. It is now possible to develop an Amazigh corpus to complement those that already exist. This approach opens the door to the socioeconomic growth of the Amazigh community in Morocco.

This methodology to voice recognition enabled us to detect and to exploit by solutions implemented, a number of phonetic and spectral characteristics of the Amazigh voice signal. Better identification of the issue parameters (accentuation coefficients, quefrencce cut cepstrum, etc.) in addition to a more precise analysis of formant transitions and trajectories and a main aspects of prosody in the speech are mostly feasible strategies to produce improved outcomes. In addition, speakers of a language like Amazigh should be proficient in both the language and the use of Information Technology resources.

**Abstract**—The fundamental concept behind the MDA (Model Driven Architecture) approach is the development of many models, first the Computation Independent Model (CIM), then the Platform Independent Model (PIM), and lastly the Platform Specific Model (PSM) for the concrete implementation of the system. Web applications are just one example of customized software that is now being developed at an increasing rate. Interaction Flow Modeling Language (IFML) was developed to represent the front end of any program that necessitates a powerful interaction with a user through the use of an interface, regardless of the technical details of its implementation. There are various modeling tools for IFML; the Webratio tool is an illustration that facilitates the generation of the entire web application. This article discusses the model transformations in the MDA's approach, starting from the CIM level up to the PSM level through the PIM level. To begin, we created the Business Process Model and Notation (BPMN) and IFML metamodels in Eclipse tool, we created also the BPMN model, and we get the IFML model by applying the shift rules in Atlas Transformation Language (ATL). Finally, we generated the application using a standard tool that implements IFML Webratio tool. A CRUD (Create, Read, Update, and Delete) features for the after-sales service case study were provided to illustrate the conversion strategy from the CIM level via the PIM level to the PSM level.

**Keywords**—MDA (Model Driven Architecture); CIM (Computation Independent Model); PIM (Platform Independent Model); PSM (Platform Specific Model); Model transformations; Graphical User Interfaces; BPMN (Business Process Model and Notation); IFML (Interaction Flow Modeling Language); Webratio tool

## I. INTRODUCTION

The core idea behind the MDA's methodology is the use of models at various points in an application's development lifecycle. MDA promotes requirements development (at the CIM level), design and analysis (at the PIM level), and eventually code (PSM level). MDA's primary goal is to create models that are independent of technological aspects to generate all application code automatically and significantly boost productivity [1].

It has been increasingly crucial to deliver tools and processes for web application development. Because of how complicated are the interfaces, the increased demand for Web

applications, and businesses' overall need to create applications quickly in recent years.

Model-driven architecture's rise demonstrates its value to engineering and its effectiveness in raising application quality, while reducing development time and boosting productivity. [2].

Recently, a new web engineering technology named Interaction Flow Modeling Language (IFML) was suggested for use in developing web and mobile applications [3]. It is an Object Management Group (OMG) standard that makes it easier to describe graphical User Interfaces for desktop computers, laptops, mobile phones, and tablets without regard to the platform on which they are used.

Several tools have been suggested for creating IFML models and codes, including the Webratio tool [4]; a model-driven project with code generators that can create functional applications from IFML models.

Our main goal of this article is to automatically generate graphical user interfaces from PIM to PSM using the Webratio tool. In this article, we are going to treat the model transformations in the MDA's approach, starting early from the CIM to PIM up to the PSM level.

We created in the first step the BPMN and IFML metamodels at Eclipse tool, the business process model of a case study named the after-sales service using the BPMN notation created also, then applied the transformation rules in ATL language [5]. We obtain the IFML model at the PIM level into Eclipse tool, finally, we import the IFML model in .xmi format [32] into the Webratio tool to get graphical user interfaces (GUI) code.

The key benefit of our work is that it uses two standards BPMN and IFML as well as a powerful commercial tool Webratio. To cover every step of the model transformations process in the MDA's approach, starting from the CIM level through the PIM level and up to the PSM level.

The article is structured as follows: in Section II we go into the fundamental techniques that underpin our strategy in the theoretical background, Section III presents the related works, in Section IV we will present our approach by describing the

CIM level to the PIM level transformation rules also the representation of the two metamodels BPMN and IFML. Section V provides a case study of the after-sales service illustrating our methodology starting from the CIM level to the PIM level up to the PSM level, a discussion and limitations are presented in Section VI, and we finish by outlining the ongoing and future work in Section VII.

## II. THEORETICAL BACKGROUND

### A. BPMN

The Object Management Group (OMG) established the Business Process Model and Notation (BPMN), a standard that gives businesses the ability to graphically describe and analyze their internal business processes and consistently communicate these processes. Additionally, the graphical notation makes it easier to understand how business transactions and collaborations across companies are performed [13]. A BPMN model does not accurately depict the system's functional behavior. BPMN's fundamental conceptual primitives are tasks, events, gateways, pools, lanes, and flows [14].

### B. IFML

The OMG developed the Interaction Flow Modeling Language (IFML), to define interaction flow models. These models are employed to explain user-application interaction on the front end.

IFML was created by developers with more than ten years of experience with Webratio tool and WebML. The OMG adopted it as a standard in March 2013 [15].

IFML offers multiple advantages to the design of UIs for desktop, mobile, and web applications. One of the five artifacts the IFML specification provides is IFML visual syntax [4]. The latter, however, is simplified and well-known to developers, which discusses the development of various tools for creating IFML diagrams.

### C. Webratio Tool

Some technologies are designed for IFML model creation and code production for the creation of web and mobile applications. Webratio tool [16] focuses on rapid developments using model-driven development and code generation.

It is a commercial web development tool. When the Webratio tool was launched in 2001, it was built using WebML [17]. Later, the Webratio tool used IFML to replace WebML.

The entire process of modeling a web application is supported by the Webratio tool. Typically, one begins by developing the application's data model, or "domain model". This model defines all the data types that the web application will use.

Site views can be made once the domain model has been established. Each of these site views includes an IFML model. The developer can generate the designed web application after modeling it in IFML.

Last but not least, Webratio tool enables the direct deployment of the web application to a remote server.

As a tool, Webratio facilitates IFML web development from conceptual modeling through execution and also enables the entire web system generation with a click when the created IFML models are valid.

## III. RELATED WORK

We relate the previous works that discuss the application of the model-driven development approach to obtain graphical user interfaces.

The authors in [5] represent a methodology that permits a semi-automatic conversion from the CIM level to the PIM level using the MDA's approach, BPMN, and IFML standards. Several rules for semi-automating the conversion from the CIM level to the PIM level were developed. To achieve this an order management case study was provided to demonstrate the transformation strategy.

In [6] a technique for the model-driven creation of a Graphical User Interface for Internet Applications utilizing IFML was described. Model-driven engineering-related frameworks and technologies were used by the authors.

The construction of a prototype Qt/Taurus code generator based on the IFML standard and appropriate modeling tools, which are expanded to provide platform-specific code generation was described by the researchers in [7].

The goal is to enable low-code development in SKA GUI design, increasing the effectiveness, reliability, and coherency of the UI that is created.

A basic GUI use case is provided to fully illustrate the software development life cycle, starting with requirements and incorporating IFML modeling, Qt/Taurus automatic coding, interface evaluation, and validation.

The authors of this article [8] explored the modeling tools for IFML and presented a comparative analysis while taking into account several criteria. In this study, IFMLEdit.org, Webratio tool, IFML Editor, and MIA-studio were all studied and compared as potential IFML tools. Each tool has advantages and disadvantages.

This paper [9] suggested a modeling approach for creating user interfaces that are based on IFML. First, it describes the benefits of the model shifting process, the Webratio tool, and the extension of IFML to web applications.

Second, a detailed method for mapping IFML to the design environment is provided. The authors presented IFML for the web application, which can fully satisfy the expectations of the user. Its primary benefit is that it makes creating the project's front-end interface simple and quick.

AutoCRUD is a Webratio tool plug-in that aims the development of CRUD operations automatically by producing IFML specifications, the plug-in raises the efficiency of Web developers according to Rodriguez-Echeverria et al. [10].

In this work [11] authors provided a new method for creating the user interface for mobile applications, and implementing it with the Android operating system.

By establishing a language for the creation of graphical user interfaces, the Technology Neutral DSL (Domain-specific language) is designed to be cross-compiled to generate native code for a diversity of platforms.

The development of software applications incorporating a multi-experience User Interface is explored in this study through model-driven approaches [12].

The authors explained how elevating the abstraction level at which these interfaces are defined allows for quicker development, better deployment, and better integration of each interface with the rest of the software system and any other interfaces it may need to cooperate with.

They provide a new Domain Specific Language (DSL) for describing various CUI kinds and demonstrate how this DSL may be a component of an integrated modeling environment that can explain the relationships between the modeled CUIs and the other models of the system.

#### IV. METHODOLOGY

The CIM model is intact by the application's technical details and includes both business process requirements and client needs.

BPMN is a standard for creating business processes. Application interface modeling is done using IFML, it comes

with a suite of tools for modeling user interaction and computer program behavior graphically.

In our methodology, we used the Eclipse tool to transform the BPMN model (CIM level) into the IFML model (PIM level) according to the MDA approach.

First of all, we created the BPMN and IFML metamodels shown in Fig. 2, Fig. 3, and Fig. 4 in Eclipse tool, then the creation of the BPMN model from the BPMN business process as a ".xmi" file from the BPMN metamodel, and we finally obtain the IFML model in ".xmi" file too by applying the transformation rules shown in Fig. 1 written in ATL language [5].

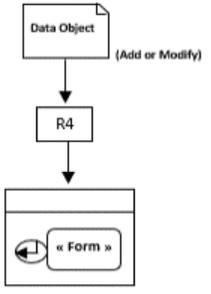

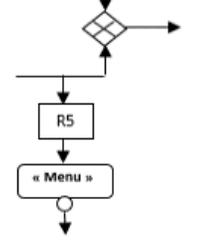

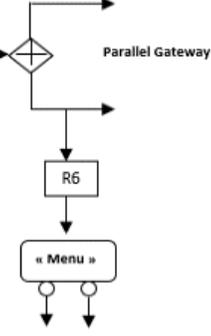

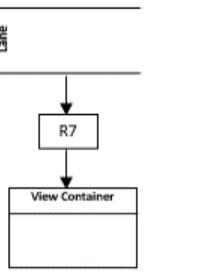

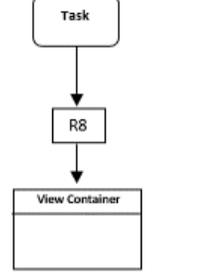

Lastly, we import the xmi file obtained to the commercial tool Webratio to generate the user interfaces automatically at the PSM level.

#### A. The CIM Level to the Pim Level Conversion Rules

BPMN models to IFML models transformation rules are shown in Fig. 1 every converting rule is defined in ATL and human language and represented by a schema.

Firstly, it is necessary to define the PIM level metamodel and the CIM level metamodel to describe ATL's transformation rules.

Human Language	Graphical representation	Transformation rule in ATL
-Each "State" of "Data Object" becomes "View Component"		<pre>Rule R 1{   from   stt: MMbpmn!StateObject   (stt.isTransformableStateObject ())   to   vcp : MMifml!ViewComponent{     Name &lt;- stt.name   } }</pre>
-Each "Display" state of "Data Object" becomes "View Container" with "List" view component plus "On Select Event"		<pre>Rule R 2{   from   stt : MMbpmn!StateObject   (stt.isTransformableStateObject () and   stt.isDisplay())   to   cn : MMifml!Container {     Name &lt;- '«WebPage»'+stt.name)   vcp : MMifml!ViewComponent(name&lt;-   '«List»',   ContainerBelongs&lt;-cn.name)   Osev : MMifml!OnSelectEvent{     ViewComponentBelongs&lt;-vcp.name)   } }</pre>
-Each "Delete" state of "Data Object" becomes " View Container" with "Delete" action plus simple event		<pre>Rule R 3{   from   stt : MMbpmn!StateObject   (stt.isTransformableStateObject () and   stt.isDelete())   to   cn : MMifml!Container {     Name &lt;- '«WebPage»'+stt.name)   ac : MMifml!Action (name&lt;- 'Delete',   ContainerBelongs&lt;-cn.name)   sev : MMifml!SimpleEvent(   ViewComponentBelongs&lt;-ac.name)   } }</pre>

<p>-Each "Add or Modify" state of "Data Object" becomes "View Container" with "Form" view component plus "On submit event"</p>		<pre> Rule R 4{   from   stt : MMBpmn!StateObject   (stt.isTransformableStateObject () and   (stt.isAdd() or stt.isModify()))   to   cn : MMifm!Container (   name &lt;- '&lt;WebPage&gt;'+stt.name)   vcp : MMifm!ViewComponent(   name&lt;-'Form'+ stt.name,   containerBelongs&lt;-cn.name)   osev : MMIFML!OnSubmitEvent(   ViewComponentBelongs&lt;-ac.name)   } </pre>
<p>-Each "Exclusive Gateway" becomes "Menu" view component with simple event corresponding transition in output "Exclusive Gateway"</p>		<pre> Rule R 5{   from   exl : MMBpmn!Exclusive   (exl.isTransformableEclusive ())   to   vcp: MMIFML!ViewComponent (   name&lt;- '&lt; Menu &gt;'+exl.name })   Rule R {   from   fl : MMBPMN!Flow   (fl.isTransformableFlow() and   fl.OutputisDecisionState())   To   MMIFML!SimpleEvent(name&lt;-fl.name,   ViewComponentBelongs&lt;-   Fl.NameDecisionStateOutput() )   } </pre>
<p>-Each "Parallel Gateway" becomes "Menu" view component with "Events" corresponding transition in output "Parallel Gateway"</p>		<pre> Rule R 6 {   from   prl : MMBpmn!Parallel   (prl.isTransformableParallel ())   to   vcp: MMIFML!ViewComponent (   name&lt;- '&lt; Menu &gt;'+prl.name })   Rule R {   from   fl : MMBPMN!Flow   (fl.isTransformableFlow() and   fl.OutputisDecisionState())   To   MMIFML!SimpleEvent(name&lt;-fl.name,   ViewComponentBelongs&lt;-   Fl.NameDecisionStateOutput() )   } </pre>
<p>-Each "Lane" becomes "View Container"</p>		<pre> Rule R 7{   from   ln : MMBpmn!Lane   (ln.isTransformableLane())   to   vcn : MMifm!ViewContainer (   Name &lt;- ln.name   )   } </pre>
<p>-Each "Task" becomes "View Component"</p>		<pre> Rule R 8{   from   tsk : MMBpmn!Task   ((not tsk.isManual()) and   (tsk.isTransformableTask()))   to   vcn : MMifm!ViewContainer (   Name &lt;- tsk.name   )   } </pre>

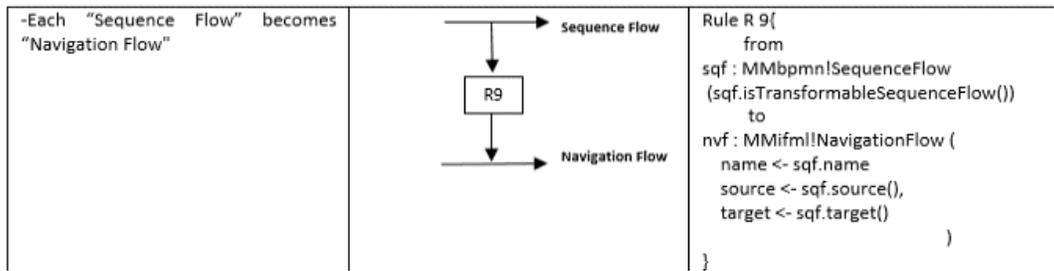

Fig. 1. CIM level to the PIM level transformation rules.

**B. CIM Level: BPMN Metamodel**

At the CIM level, BPMN was utilized to describe the business process because business processes are computationally independent, the OMG standard for business process modeling is named BPMN. Fig. 2 displays the BPMN metamodel [18].

**C. PIM Level: IFML Metamodel**

IFML Metamodel that uses the UML metamodel's main data types provides a set of UML metaclasses as the foundation for IFML metaclasses and presumes that the IFML ContentModel is defined in UML [19], [20].

The IFML metamodel is illustrated in Fig. 3 and Fig. 4.

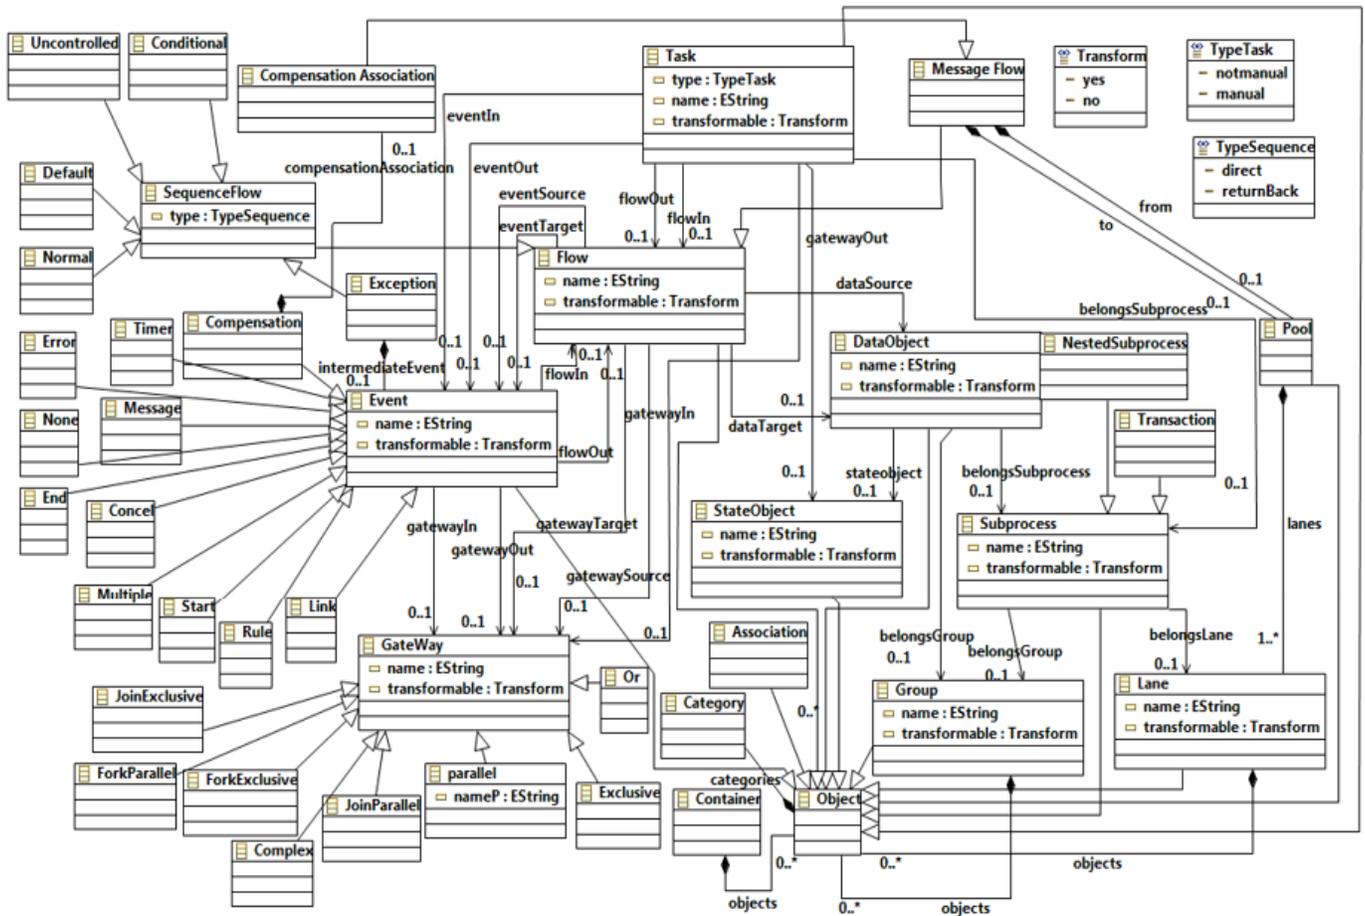

Fig. 2. The BPMN metamodel.

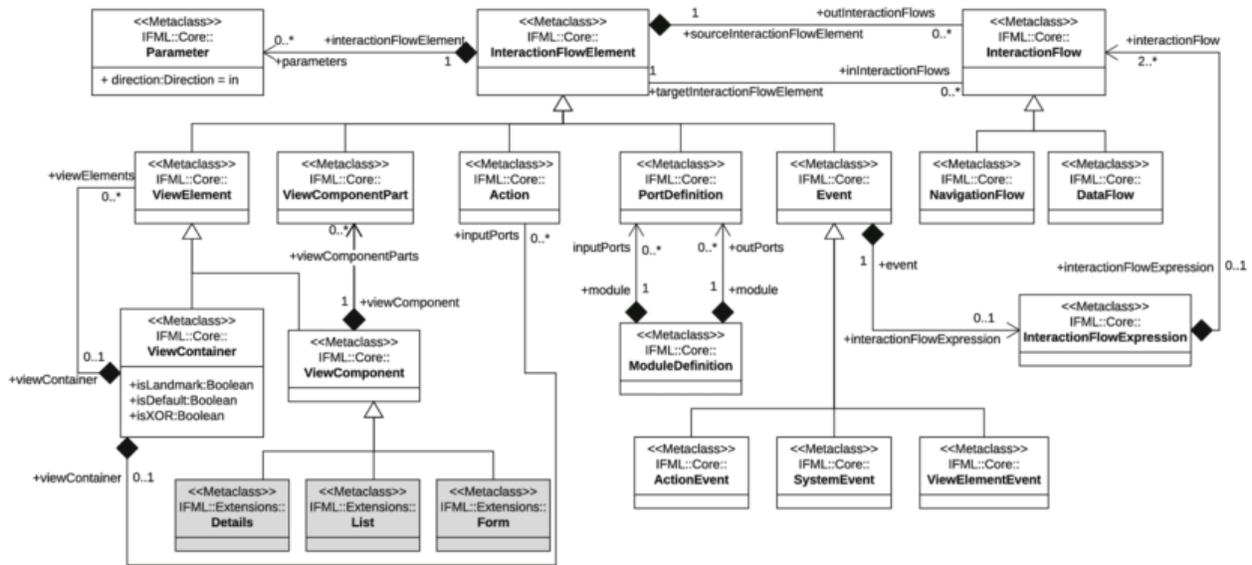

Fig. 3. IFML metamodel 1.

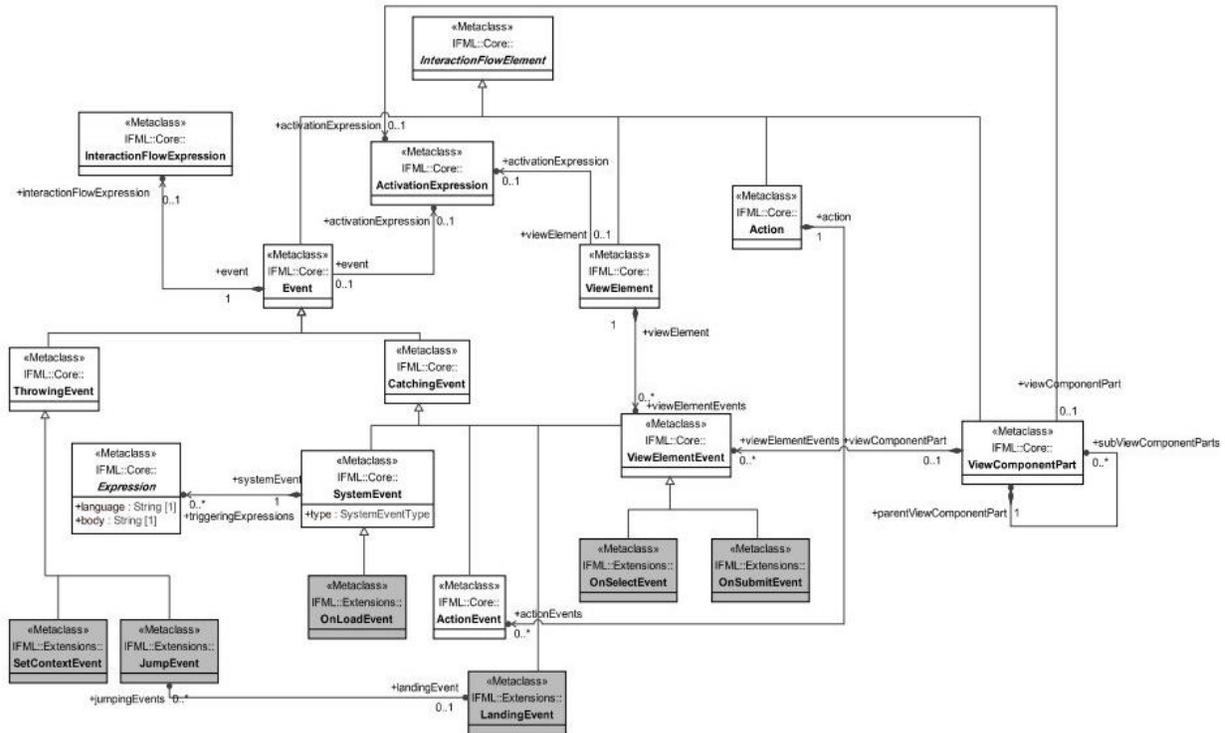

Fig. 4. IFML metamodel 2.

## V. CASE STUDY

The after-sales service is described, in which a customer can make CRUD operations (Create, Read, Update, and Delete) relating to a complaint if there is a problem regarding his order.

The process begins with authentication using a username and password. If the client is already registered on the

platform, he has access to a menu with four features, including add, modify, delete, and consult a complaint. If not, he must register to use the remaining features.

### A. CIM Level

The CIM level is illustrated by the BPMN diagram and BPMN business process, the first one is represented in Fig. 5, and the second is displayed in Fig. 6.

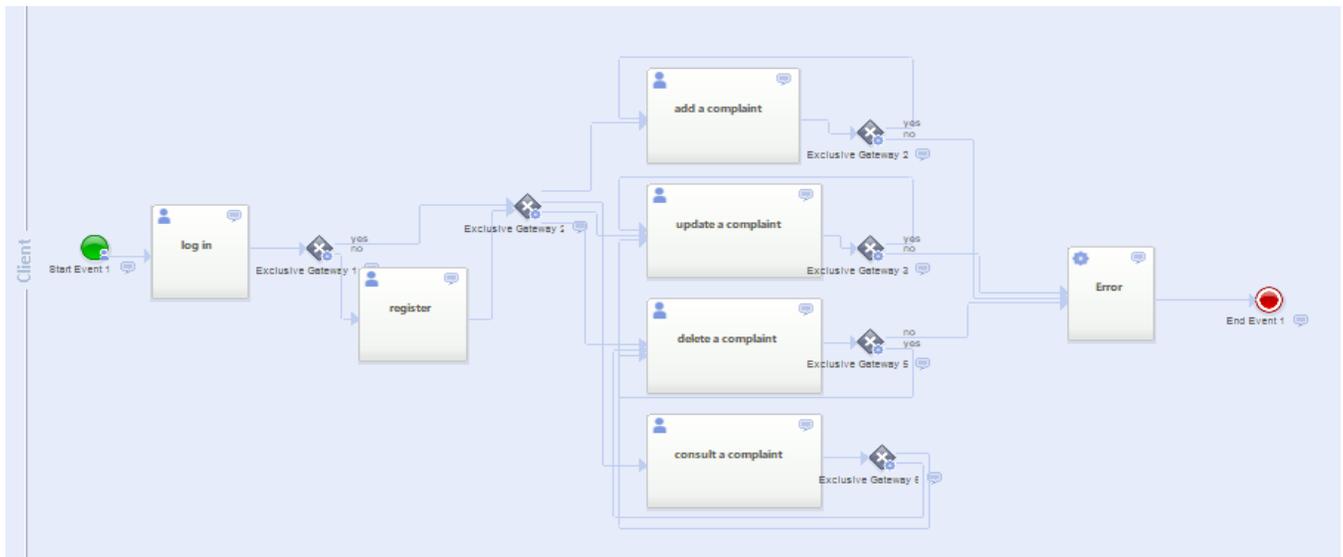

Fig. 5. BPMN diagram of the after-sales service.

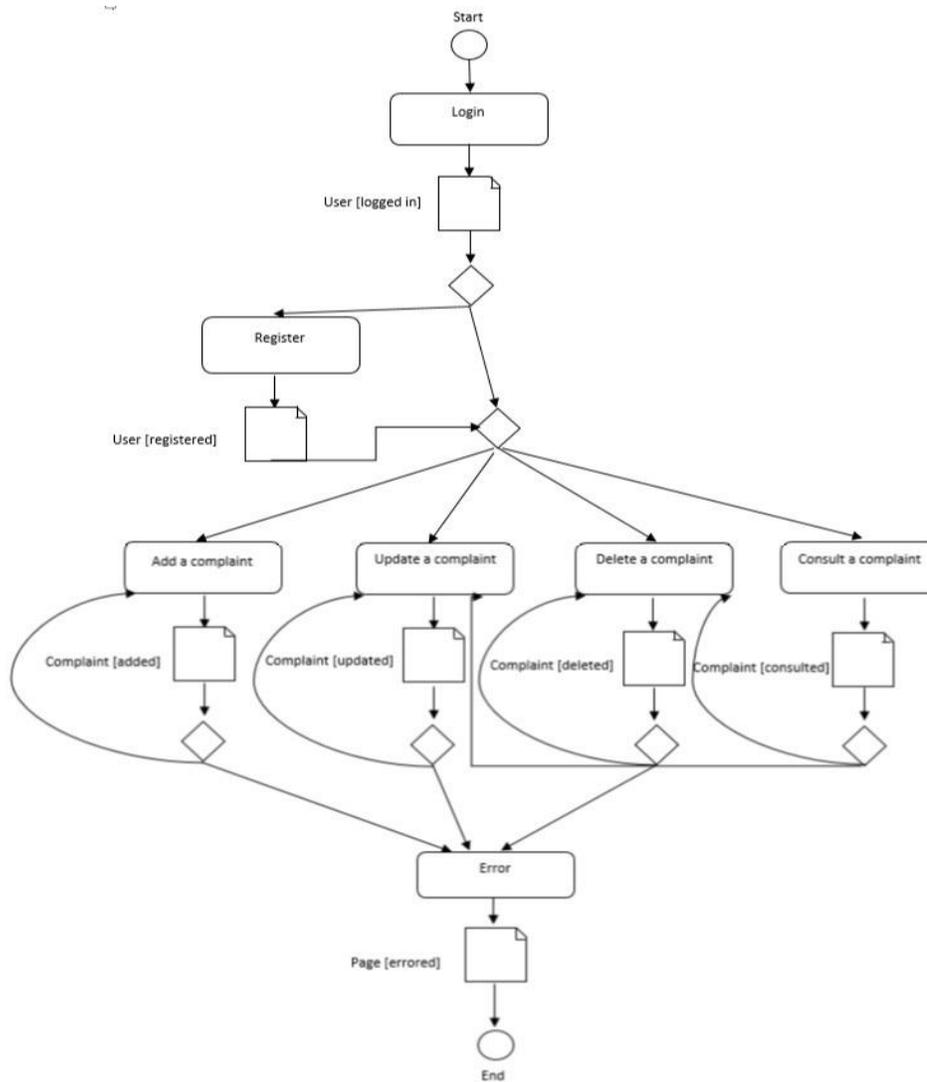

Fig. 6. BPMN business process diagram of the after-sales service.

### B. PIM Level

Webratio is the most powerful commercial tool available among others [8]. Some of the characteristics that motivated us to choose to work with this tool are:

- Provides graphical modeling; the IFML components are expanded further by this tool, so that users can design IFML diagrams for web applications.
- Based on the Eclipse and Webratio tools respond quickly.
- It is suitable for academic researchers.

We obtained the after-sales service front-end interfaces designed with the IFML language, by applying the shift rules from CIM to PIM. [5].

IFML development process involves modeling the application's domain first, then creating an IFML model using IFML language, and then converting the created model into a software system.

1) *Domain model*: A clear and accessible overview of information related to the application domain is provided by the domain model.

We don't suggest a novel modeling language for domain model modeling because a UML-based OMG standard is IFML; rather, we utilize UML class diagrams.

The case study's Domain model is described in Fig. 7 we added a table named complaint, User, Group, and Module are tables provided by default by the Webratio tool.

2) *IFML model*: In our case study, we include only two important elements in the example: the login/registration function and the client's space.

The public is the application's main page, allowing the user to authenticate himself to access the proposed features (Login page) or to register if it is his first connection to the application.

Otherwise, an error message is displayed, Fig. 8 shows the "Public" site view.

The site view Public contains an action definition (a description of a business logic that could be triggered by an event in an IFML model.) [21] "Register", which will allow the creation of a new user in the database and Fig. 9 shows its modeling.

The action definition Register begins with the input port, which receives the parameters from the user's registration form. The parameters are passed to the "Create User" operation which is based on the Entity "User."

We utilized a Data Flow to bind the information from the Input Port to the Output Port, the information between the input port and the corresponding "Create User", and the latter to the output port.

When these operations are completed successfully, the Action Definition must exit via the "Success" OK Port, otherwise, the "KO Port" handles the failed execution.

The complaint is the space dedicated to the user where he can perform one of the operations provided by CRUD (Create, Read, Update, or Delete a complaint).

In Fig. 10, the interface modeling is displayed.

In the site view Complaint, four areas were used to model CRUD operations. Each area is composed of pages and actions definitions, and also utilized view components (List, Form).

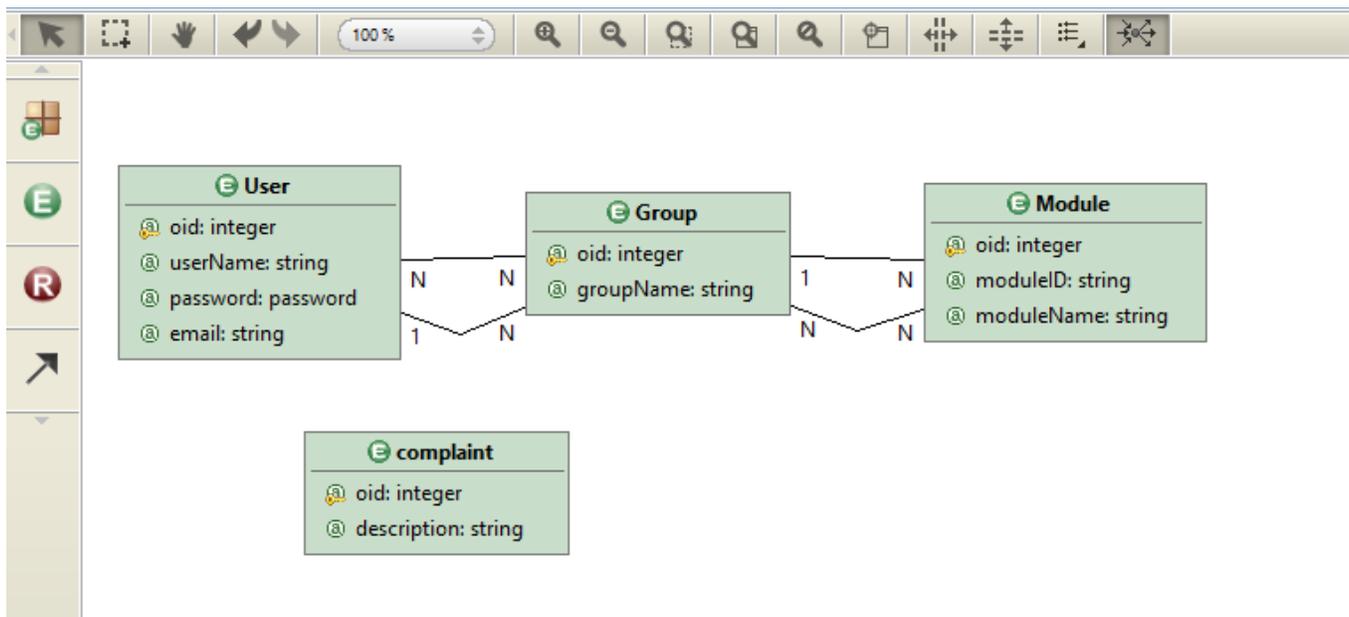

Fig. 7. Domain model of the after-sales service.

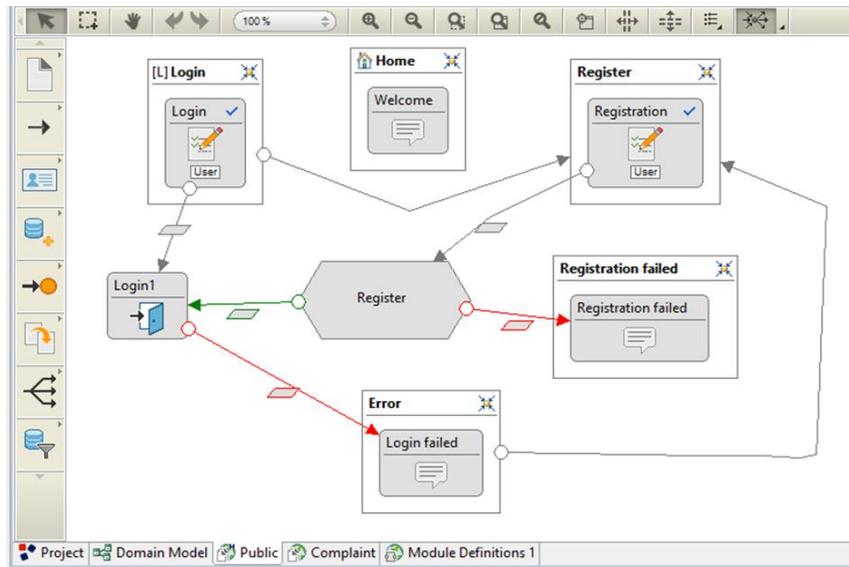

Fig. 8. Site view "Public".

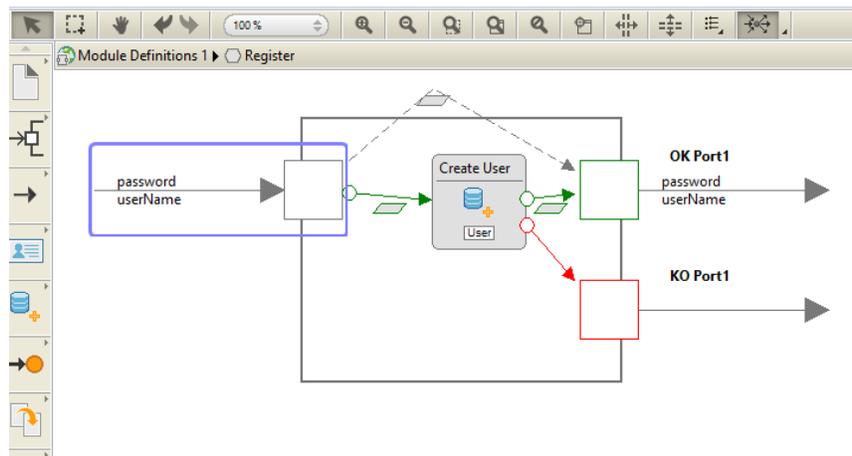

Fig. 9. Action definition "Register".

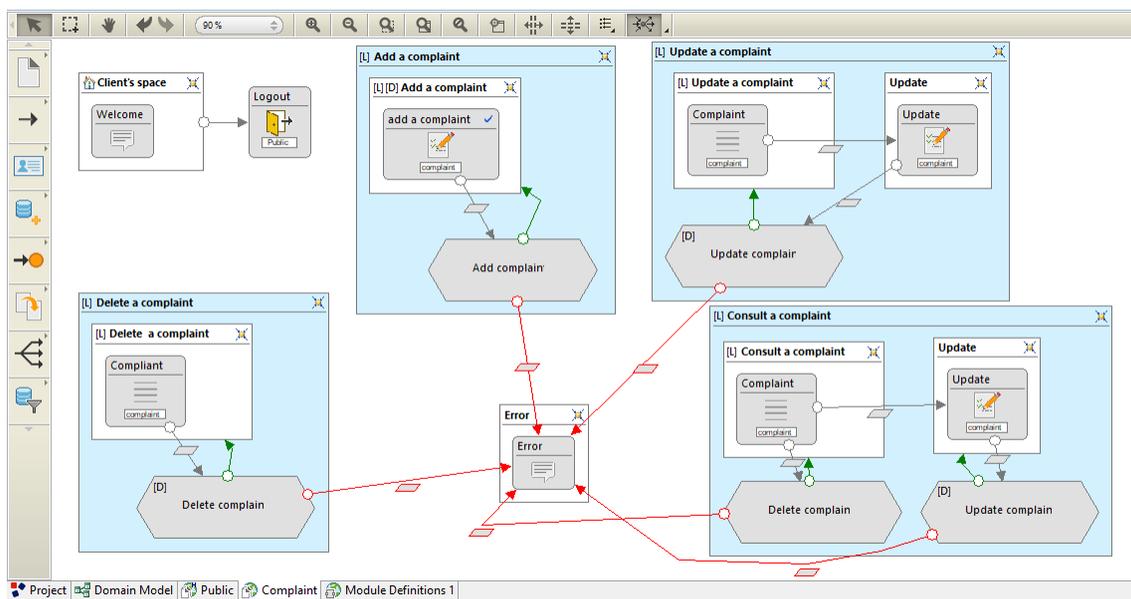

Fig. 10. Site view "Complaint".

To make the connection between the different pages and actions definitions we used flows (flow, OK flow, and KO flow) with parameters binding between source and target elements.

For example, to add a complaint we have a page named complaint containing a form. When the user presses the button “save”, the action definition Add a complaint is triggered, using a flow going from the form to the action definition, by editing parameters binding.

If the addition is done successfully we return to the Add a complaint page, otherwise we are redirected to an error page.

### C. PSM Level

In this paragraph, we will present some of the graphical user interfaces obtained by generating the application of the IFML model using the Webratio tool.

Fig. 11 shows the authentication page which provides the user to authenticate himself through a username and password.

Otherwise, he must register first by entering his personal information, and Fig. 12 displays this operation.

Another interface where the user can add a complaint is shown in Fig. 13.

Fig. 11. "Login" graphical interface.

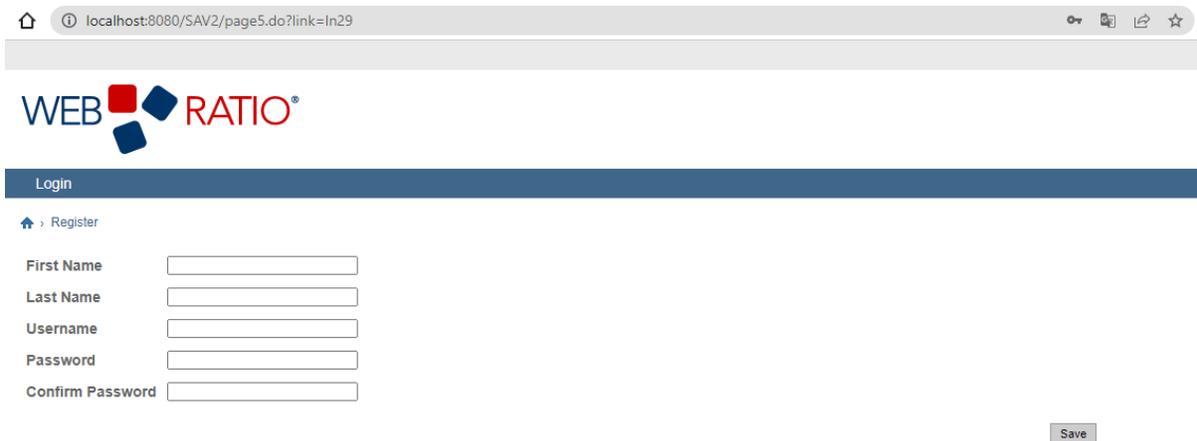

Fig. 12. "Register" graphical interface.

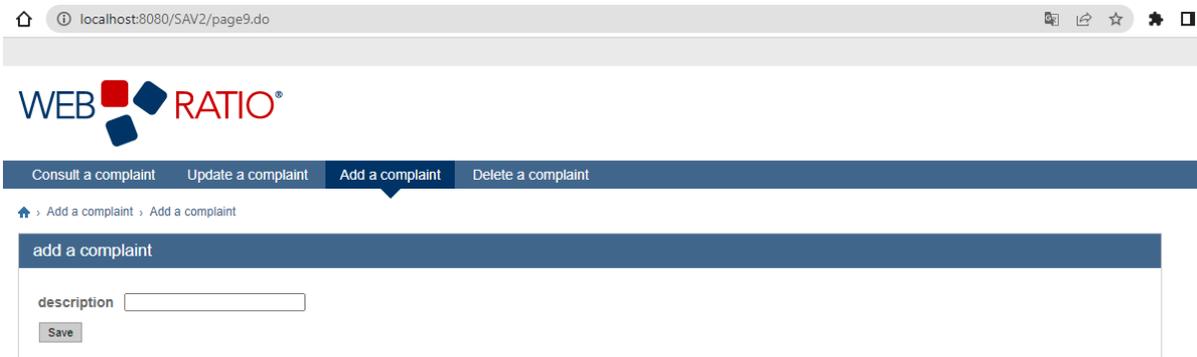

Fig. 13. "Add a complaint" graphical interface.

## VI. DISCUSSION AND LIMITATIONS

We may infer from an analysis of the works shown in Table I, that they can be divided into two groups. Those who were interested in the CIM to PIM shift and those who were interested in the PIM to PSM shift.

We can say that the majority of works use UML diagrams to present the different levels of the MDA approach, except [25] which used the BPMN standard that is utilized for business process modeling.

The UML class diagram is often utilized in most PIM to PSM transformations, IFML as a recommended standard for the modeling front-en interfaces at the PIM level is not widely used in the studied papers apart in [30].

The work [31] treated the model conversions in the MDA approach from the CIM level to the PSM via the PIM level, by using two models the first is for requirement and the second is a mathematical model represented by a graph.

The major advantage of our work which differs from other researches [33-40] is the fact that it covers all the model

transformations process in the MDA's approach. Starting from the CIM via the PIM level up to the PSM level, utilizing two standards BPMN and IFML, and a powerful commercial tool Webratio.

In our case study, we have limited it to CRUD operations, we can still extend it to cover other aspects of after-sales service, also the process of our methodology is semi-automatic in the importation of the xmi file in Webratio tool.

The CIM level to the PIM level shift is implemented in the Eclipse tool automatically, the IFML model is obtained in an xmi format [32] and imported into the Webratio tool to finally get the user interfaces.

The advantage of using IFML modeling is that the front-end interface of the program can be created quickly also the application is generated with a click.

But the technology has some disadvantages, for example, even though IFML modeling is still relatively a new technology, it is still best suited for modeling small programs rather than programs for large and medium-sized businesses.

TABLE I. COMPARISON OF PREVIOUS WORKS

Our methodology	Yes	BPMN	Yes	IFML

## VII. CONCLUSION

Developing software is easier with MDA's approach because it generates applications automatically from models in a shorter period and with absolutely no source code involvement.

Typically, web applications are built using Webratio's tool robust architecture, it is a consolidated industrial reality that enables any model to be created. In this sense, we suggested this work which highlighted the different model transformations.

Our methodology adheres to the MDA principles and suggests defining the various MDA levels' characteristics, as well as the CIM level to the PIM level shift rules utilizing two standards BPMN and IFML, till automatically generating the user interfaces utilizing the Webratio tool.

This is done by creating the two metamodels BPMN and IFML in Eclipse tool, after we elaborated the BPMN model of the case study then, by applying the shift rules in ATL language, we obtain the IFML model under .xmi format.

Finally, we imported this file in Webratio tool to get the graphical user interfaces.

The objective of improvement is the creation of a tool that will allow the model transformations from the CIM level until the obtention of the graphical user interfaces that will automatize the whole process of model transformations.

**Abstract**—Search engines are the instruments for website navigation and search, because the Internet is big and has expanded greatly. By continuously downloading web pages for processing, search engines provide search facilities and maintain indices for web documents. Online crawling is the term for this process of downloading web pages. This paper proposes solution to network traffic problem in migrating parallel web crawler. The primary benefit of a parallel web crawler is that it does local analysis at the data's residence rather than inside the web search engine repository. As a result, network load and traffic are greatly reduced, which enhances the performance, efficacy, and efficiency of the crawling process. Another benefit of moving to a parallel crawler is that as the web gets bigger, it becomes important to parallelize crawling operations in order to retrieve web pages more quickly. A web crawler will produce pages of excellent quality. When the crawling process moves to a host or server with a specific domain, it begins downloading pages from that domain. Incremental crawling will maintain the quality of downloaded pages and keep the pages in the local database updated. Java is used to implement the crawler. The model that was put into practice supports all aspects of a three-tier, real-time architecture. An implementation of a parallel web crawler migration is shown in this paper. The method for efficient parallel web migration detects changes in the content and structure using neural network-based change detection techniques in parallel web migration. This will produce high-quality pages and detection for changes will always download new pages. Either of the following strategies is used to carry out the crawling process: either crawlers are given generous permission to speak with one another, or they are not given permission to communicate with one another at all. Both strategies increase network traffic. Here, a fuzzy logic-based system that predicts the load at a specific node and the path of network traffic is presented and implemented in MATLAB using the fuzzy logic toolbox.

**Keywords**—Web crawler; incremental crawling; fuzzy logic-based system; fuzzy logic toolbox

## I. INTRODUCTION

The Internet's numerous data sources, dynamic page production, and quick rate of change present a number of challenges for web crawling. All web crawlers are constructed using common components and must be scalable, reliable, and able to utilize available bandwidth effectively. When building a web crawler, politeness is a crucial issue that needs to be taken

into consideration [1]. Crawlers should refrain from overtaxing a web server by making numerous page requests quickly [2]. Web crawlers should adhere to the guidelines set forth by website administrators and should self-identify while seeking pages. The crawlers note a delay between two requests being sent to a web server simultaneously. Request Intervals are the name given to this waiting period [3]. Typically, 30 seconds elapses between downloads. A queue shuffling mechanism is used to enforce this waiting period; the queue is shuffled into a random order and distributed evenly among URLs coming from the same web server. The other crawler, similar to Mercator, implements their URL queue as a group of sub-queues, with a queue for each domain [4]. Each search engine keeps a central database of web pages on hand. In response to the query of user, search engine creates indexes for the repository. A web crawler, sometimes known as a spider, robot, or web pot, is a program that searches the Internet and collects web pages. Beginning with the seed URLs, the web crawler downloads the web document for those URLs. It takes new links from these downloaded documents and extracts them. Next, it is determined whether or not the extracted URLs have already been downloaded. URLs are redistributed to crawlers for additional downloading if it is confirmed that the documents have not already been downloaded. Up until there are no more URLs available for download, the process is repeated. Every day, a crawler downloads millions of online pages. The scheduler, multi-threaded downloader, queue for URLs and storage for text and metadata are all components of a web crawler. The search engine database must be updated often, and such updates must be incorporated by the web crawling system. To get over the processing bottleneck, multiple instances of this component operate simultaneously connected with very high bandwidth [5]. The HTTP protocol is used by web crawlers to download and process web pages from the internet. The downloader and the processor are the two components that make up the web crawling system. The processor receives the web pages that were downloaded by the downloader and processes them further. The HTTP protocol is used throughout this operation to download online pages. To download web pages, the downloader sends HTTP-GET queries. The pages are subsequently sent to the processor for additional processing and database integration. In order to download online pages from web servers, downloader adheres to a number of best practices. TCP Connection reusability,

\*Corresponding Author.

Compression, Conditional GETs, varying refresh frequency, and DNS caching are a few of the optimization strategies used on downloader to get around network constraints [6].

#### A. Reusability of TCP connections

To conserve time and network traffic, downloader maintain one TCP connection open for each IP address and utilize it repeatedly until the server's entire contents have been downloaded [7]. Web servers compress web pages before transmitting them to the requesting client in order to save network traffic [8]. Downloader use conditional GETs, which are defined in the HTTP protocol. Conditional GETs download the page if it changes after a certain date [9]. Different websites have different refresh rates; some are updated every few minutes, while others don't change for a year. More crucial than others are certain pages. Because of this, search engines sift through pages that are significant and likely to see frequent updates.

#### B. DNS Caching

DNS resolves and URL downloads are two factors that contribute to network congestion. Additional DNS server bottlenecks could occur, which would impact performance. DNS cache is used by the downloader or site crawling component to boost performance. When the size of the web expands, centralized web crawling techniques become inefficient. Only a very small portion of the web is crawled by search engines, and they frequently ignore significant pages. Because of this, simultaneous web crawlers are employed to reduce network and other bottlenecks.

The task of the processor is to gather, process, and store the downloaded web documents in the database of the search engine. It is responsible for collecting information from online documents and putting it in the database. The method involves taking keywords from a web page and ranking them. The database stores the frequency and position of keywords. In order to extract information, the processing component processes strings.

The remainder of this article is arranged accordingly. Section II reviews the related works. Section III gives a case study of crawler load, Section IV details about FIS and Fuzzy Logic. Section V gives the proposed solution, including the components. Section VI is having result discussion. Lastly, Section VII concludes the work.

## II. RELATED WORK

An illustration of a distributed publication system is the Web. Based on how they handle requests, the two models are centralized and distributed. In a distributed architecture, a central location generates the query, which is subsequently sent to a few distant locations for processing. The distant stations then relay their findings to the central location. The combined results are displayed to the searcher at a central location. Under contrast, one system in the centralized approach maintains the entire index there. The single central index is then used to test the searcher's query. When using a distributed design, the difficulty of searching each database is decreased because the index collection is spread across a number of databases. NetFind, WAIS, and Harvest are examples of the distributed

model. The authors of [10] introduced NetFind, a system that addressed the problem of finding information about people on the Web by employing a distributed search technique. WAIS employed a distributed set of indexes and a vector-space retrieval paradigm. WAIS struggled with its dearth of content.

According to the developers of [11], a Digest should only be used to convey queries to servers that have answers to such queries. Each server in the system creates a digest, which is then sent to a central site, containing a portion of the content that is available there. Archie, Veronica, and all search engines on the Internet are examples of the centralized paradigm. A number of existing extensively used documents (FTP files) were indexed by Archie [11]. The Gopher system could be searched thanks to Veronica [12]. Content from participating Gopher sites was downloaded and indexed at a single location. Publishing and accessing materials became simple thanks to the web. Additionally, it made following links easier [13]. The WWW Virtual Library is a method for finding resources on the Internet. A hierarchy was used to arrange the Virtual Library. Its quality was not exceptional because it was made by humans [14]. Three searchable indexes—the RBSE index, the WWW Worm, and Jumpstation—became well-known later in 1993. Each offered a searchable interface to a database of Web sites that was created automatically. Search engines like Lycos, InfoSeek, Yahoo, AltaVista, and Excite are a few examples. To fulfill a single searcher's request, the Meta search does numerous remote search engine queries. SavvySearch and MetaCrawler are two examples. These Meta engines use servers with content duplication. Because each search engine has a few unique documents in its index, meta-search is preferred. Additionally, as each search engine refreshes pages at a different rate, certain search engines will have current web content. Better results may be obtained via Meta search engines. Meta-search engines' disadvantage is a performance slowdown. AltaVista, Fast, and Google are a few examples of search engines.

A distributed system can scale by adding components, duplicate or distribute services so they are always available, and choose its components carefully to lower overall costs [15]. Three areas of distributed systems research are load balancing, resource allocation, and the overall design of distributed systems [16]. The goal of distributed system research is to create platforms that are consistent, dependable, and available. Locus, V Distributed System, and Eden are early distributed system models. Amoeba and Emerald are modern examples of distributed systems. The Coign system's creators claim that their system is capable of performing the kinds of optimizations that programmers often perform. Parallel searches are carried out simultaneously on all servers, integrated, ranked, and provided to the searcher. Ninja offers a platform for creating easily configurable, scalable Web services. The objective of Ninja is to reduce the administrative burden involved in managing a sizable cluster of systems [17]. Both distributed systems at the node level and parallel systems at the processor level require load balancing. The authors of [18] proposed a number of methods for assigning labour as well as detailed models for doing so. [19], which investigated load balancing in Amoeba, found that centralized decision-making outperforms distributed techniques. The Domain Name

System (DNS) has been used to disperse queries among several servers by having name servers answer with a list of addresses for a certain name. The authors of [20] suggested a mechanism for monitoring the load of the constituent systems.

In [21], the authors suggested DNS-based approaches that return server addresses in accordance with a model of the communication cost between the client and server. These methods address the issue of availability by limiting the addresses that name servers can distribute to servers that are known to be responsive. Very few significant pages are concealed within a big number of unimportant pages. How to get a good sample is the fundamental issue in web characterization? Pages containing scant or insignificant information should be excluded. It's important to gauge a website's importance. Web pages can be sampled using either vertical sampling or horizontal sampling. Web pages are gathered via vertical sampling, which is based on domain names. At many levels of the hierarchy, vertical sampling is possible. Vertical sampling at the highest level chooses nations with top-level domains like .in, .it, .au, etc. When vertical sampling is carried out at the second level, pages created by participants in the same institution or organization are collected (e.g. integraluniversity.ac.in).

A horizontal sample is the gathering of web pages based on selection criteria other than domain names. There are two ways to gather data: first, by employing a log of transactions in a major organization's proxy; and second, by using a web crawler. It is simple to locate popular pages when using a proxy, but the revisit duration cannot be adjusted because it depends on people. When using a web crawler, the popularity of the page must be approximated, but the revisit period may be adjusted.

### III. CASE STUDY OF CRAWLER LOAD

The quality of the data gathered during a crawl can always be enhanced. The sort of web graph search is determined by the ordering of the URL queue. By considering the pages' in-link factors, the queue can be sorted. The breadth first search can enhance the caliber of pages that are downloaded [22]. On the Internet, there are a lot of spam sites and indefinitely branching crawler traps whose pages are dynamically produced and made to have a very high in-link factor [23]. The various network metrics, including geographic distance and latency, are covered in this section.

#### A. Definition 1: Geographic Distance

On the Internet, there are resources that give a mapping between IP addresses and geographical data. Longitude and latitude are extracted from registrar address data by the existing Internet service [24]. Two hosts are controlled by the same ISP if their latitude and longitude are identical [25]. A pair of Internet hosts' latitude and longitude can be found, and their geographic separation can be determined by utilizing the spherical coordinates of the earth.

#### B. Definition 2: Latency

There are numerous methods for calculating the Round Trip Time between two Internet hosts. The UNIX Ping utility is used in the first technique, and the Trace route utility is used

in the second way [26]. The ICMP ECHO queries used by the Ping program are occasionally restricted or altered by ISPs. Some routers may prevent the TTL-restricted UDP packets that Trace route transmits [27].

#### C. Definition 3: Correlation between Metrics

Geographic distance and latency are strongly correlated [28]. The association between distance and RTT is stronger since the observations have lower linear distance values. A minimum end-to-end RTT is implied by linear distance along a path [29]. RTT and linear distance have a stronger correlation than RTT and end-to-end distance.

The client throughput in a conventional and active network was shown in Fig. 1. The X-axis indicates throughput, bits received by the clients at each simulated time, and Y-axis displays client's requests arrival rate [30]. Crawler throughput is proportional to client throughput for active indexing with 0% overhead. This establishes the comparability of the remaining samples. The throughput rapidly declines as the systems get saturated when both simulations reach a similar throughput of roughly 222 bits per tick. 140 bits per tick remain the consistent throughput at that point [30].

The throughput of a typical network crawler was shown in Fig. 2. The X-axis shows the overall arrival request rate, and the Y-axis shows the bits amount per simulated time unit that Web crawlers are receiving. The requests are started by both crawlers and actual customers. The typical client request delay for active indexing is shown in Fig. 3. The Y-axis indicates the delay in normal client response, and the X-axis reflects the rate at which requests are created by human clients. In traditional networks with 20 or 40 percent crawler traffic, the typical client delay is higher [30].

The relationship between request delay of crawler and the overall request arrival rate is seen in Fig. 4. As shown in the Fig. 3 and Fig. 4 the two curves are comparable, suggesting that the increased crawler load has no effect on the delay experienced by crawler sites [30].

The percentage of client requests that are always fulfilled is shown in Fig. 5. When the request arrival rate is low, all requests are nevertheless completed. The completion rates of customer requests have significantly decreased, as evidenced by the 20 percent and 40 percent crawler cases [30].

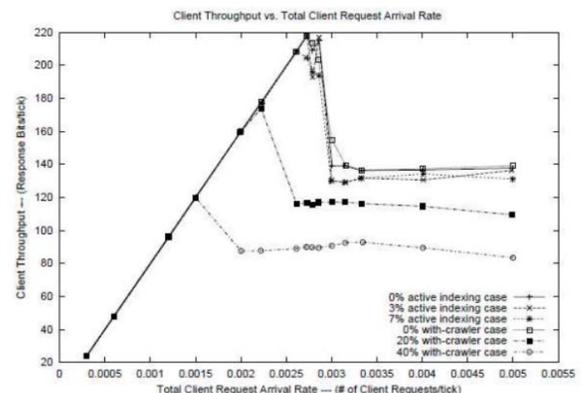

Fig. 1. Throughput of client in all cases [30].

#### IV. FIS AND FUZZY LOGIC

A FIS makes inferences from a knowledge base using a fuzzy inference engine (FIE). The FIE, represents the methods required for formalizing results and reasoning with the data in the knowledge database, is comparable to the brain of expert systems[31]. Boolean algebra's adaptation to deal with insufficient truth is fuzzy logic. Fuzzy logic illustrates the degree of truth of propositional logic. Everything in Boolean algebra may be stated in terms of binary numbers, or zero and one. Boolean algebraic values are replaced with the degree of truth in fuzzy logic.

The erroneous patterns of thinking are recorded using the level of truth. In an environment of ambiguity and uncertainty, this method of thinking is crucial to how humans make decisions. The membership function in fuzzy sets is comparable to the indicator function in classical set theory. Curves represent membership functions. According to member functions, every input space point is translated to a value lies between 0 and 1. A membership function has a triangular, bell-shaped, and trapezoidal shape. The universe of discourse is the name of the input space.

A fuzzy inference system is simpler to construct and has a very simple conceptual foundation. Three steps make up a fuzzy inference system: the input stage, the output stage, and the processing stage [32]. Input is translated into membership functions in the input step. At the processing stage, the appropriate rule is triggered, and each rule's result is generated before being combined. The output stage next transforms the outcome into output. The inference engine is the level of processing. The foundation of an inference engine is a set of IF-THEN logic rules. The THEN sub-statement is "consequent" if the IF sub-statement is "antecedent." A knowledge database contains n number of rules that are specific to fuzzy inference subsystems. The steps of the FIS are as follows:

- Fuzzification.
- Application of Fuzzy operators.
- Implication.
- Output Aggregation.
- Defuzzification.

Fuzzification of inputs is the process of assessing an input's degree of membership in its fuzzy sets using membership functions [33]. Fuzzy sets are used as the input and crisp values are produced during the defuzzification process. In fuzzy systems, there are two popular inference techniques. Ebrahim Mamdani proposed the first approach, the Mamdani fuzzy inference method, in 1975. Takagi-Sugeno-Kang proposed the second method, the Takagi-Sugeno-Kang fuzzy inference method, in 1985[34]. Numerous aspects of these approaches are comparable, such as the fuzzifying of the inputs and fuzzy operators. While Mamdani's inference uses fuzzy sets as its output membership functions. Sugeno's approach is computationally effective and functions well with adaptive and optimization strategies and uses output membership functions

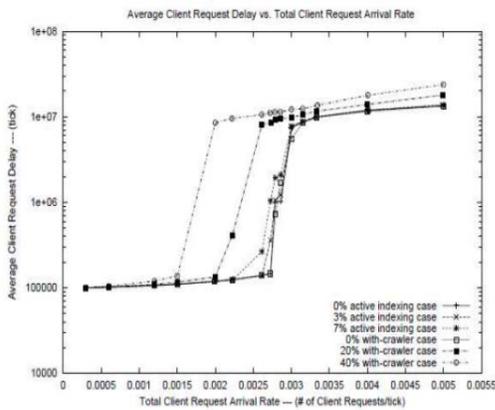

Fig. 2. Throughput of crawler.

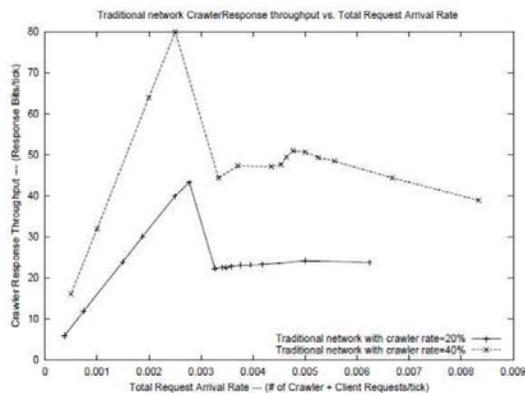

Fig. 4. Total request arrival time vs. average crawler request delay [30].

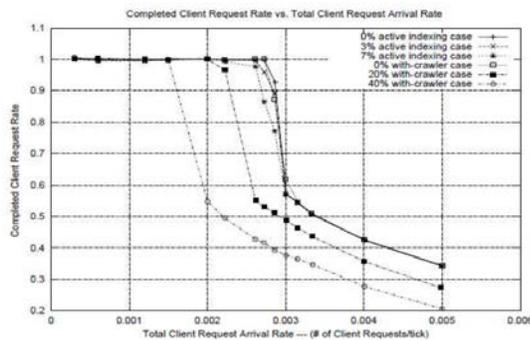

Fig. 5. Completed client request rates in all cases [30].

that are linear and constant. It also functions well when analysed mathematically.

The crawling procedure keeps the quality up. The web crawling is carried out using one of the two methods listed below: either the web crawlers are permitted to communicate with one another or they are not. Both methods add to the load on the network [35]. Here, a fuzzy logic-based method that predicts the load at a specific node and the path of network traffic is presented and implemented in MATLAB using the fuzzy logic toolbox.

### V. PROPOSED SOLUTION

These are the major steps of the proposed solution.

- a) Using a Fuzzy Inference System to Fix the Network Traffic Issue with Parallel Crawler Migration.
  - b) Using the membership function editor.
  - c) Using the Rule Editor to specify rules for a fuzzy inference system.
  - d) Rule Evaluation.
  - e) Adding up the results of the rule.
  - f) Removing fuzziness from the output value.
- 1) FIS to Solve Network Traffic problem in migrating parallel Crawlers.

The fuzzy set is the foundation of fuzzy logic theory. Every point in the input space is assigned a membership value between 0 and 1 that is defined by the curve known as the membership function. A fuzzy set is one that lacks a definite crisp border. Fuzzy Logic Toolbox includes the following tools for creating and customizing fuzzy inference systems:

- a) Fuzzy Inference System (FIS) Editor.
- b) Membership Function Editor.
- c) Rule Editor.
- d) Rule Viewer.
- e) Surface Viewer.

The Mamdani method is employed since it is well-liked for gathering knowledge. It enables us to speak more humanely when describing the expertise [36].

2) Defining FIS variables and fuzzification of the input variables using membership function editor.

a) *gaussmf*: The built-in membership function for the Gaussian curve in the fuzzy toolbox is known as *gaussmf*.  $y = \text{gaussmf}(x, [\text{sig } c])$  [37] gives the syntax (Fig. 6). The fuzzy toolbox's symmetric Gaussian function is dependent on the two parameters and as stated by.

$$f(x; \sigma, c) = e^{-\frac{(x-c)^2}{2\sigma^2}}$$

For example if  $y = \text{gaussmf}(x, [2 \ 5])$ .

`plot(x,y).`

`xlabel('gaussmf, P=[2 5]').`

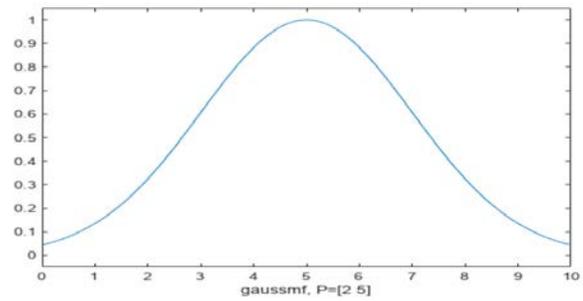

Fig. 6. Gaussmf Curve.

b) *trimf*: In the fuzzy toolbox, *trimf* is the built-in membership function with a triangular shape (Fig. 7). The triangular curve is a function of a vector  $x$  and depends on three parameters when the syntax is  $y = \text{trimf}(x, \text{params})$ ; if  $y = \text{trimf}(x, [a \ b \ c])$ :

$$f(x; a, b, c) = \begin{cases} 0, & x \leq a \\ \frac{x-a}{b-a}, & a \leq x \leq b \\ \frac{c-x}{c-b}, & b \leq x \leq c \\ 0, & c \leq x \end{cases}$$

Or,

$$f(x; a, b, c) = \max\left(\min\left(\frac{x-a}{b-a}, \frac{c-x}{c-b}\right), 0\right)$$

The triangle's base is indicated by first parameter  $a$  and third parameter  $c$ , while the triangle's peak is shown by second parameter  $b$  [38]. For example:

`x=0:0.1:10;`

`y=trimf(x,[3 6 8]);`

`plot(x,y)`

`xlabel('trimf, P=[3 6 8]')`

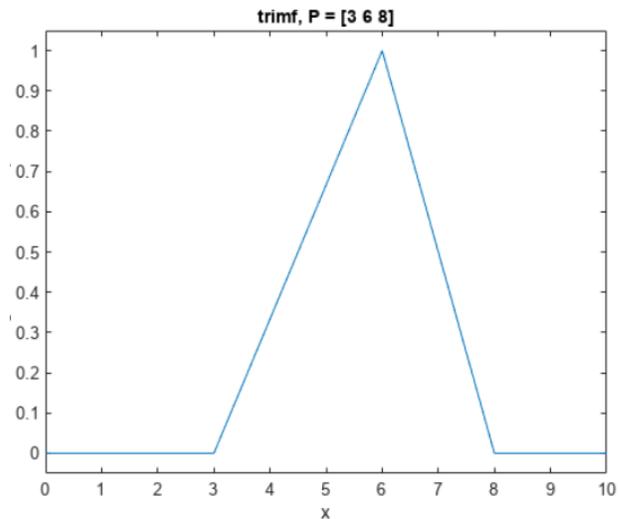

Fig. 7. Trimf function.

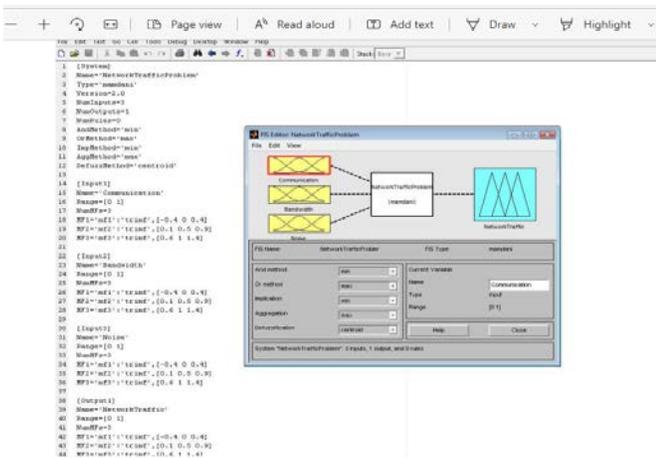

Fig. 8. FIS editor for network traffic problem.

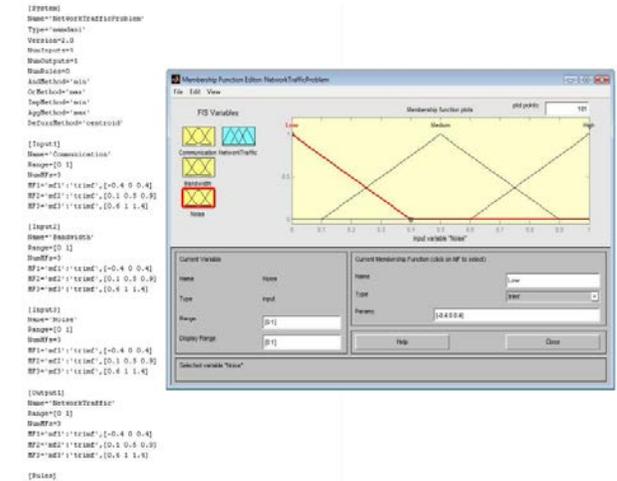

Fig. 11. FIS variable noise.

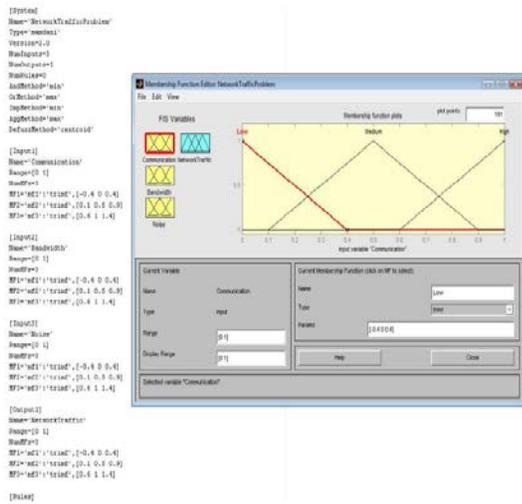

Fig. 9. FIS variable communication.

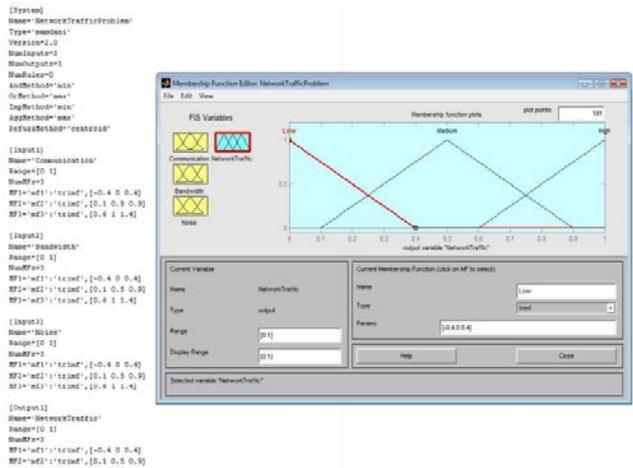

Fig. 12. FIS output variable network traffic.

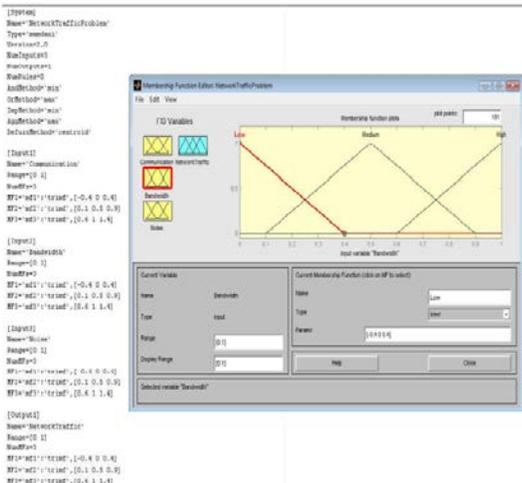

Fig. 10. FIS variable bandwidth.

The FIS editor for the Network Traffic Problem is shown in Fig. 8. The FIS variable Communication is shown in Fig. 9. The FIS variable Bandwidth is shown as a Fig. 10. The FIS variable Noise is shown in Fig. 11. The FIS output variable Network Traffic is shown in Fig. 12.

**Lemma 1.** When  $n$  is the total number of network nodes, the technique has a worst-case time complexity of  $O(n)$ .

**Proof.** Steps 1 and 3 of the method take a fixed amount of time. In the worst case situation, a node may have  $m$  number of gateways within its communication range, hence Step 2 can be finished in  $O(m)$  time. The node selects a CH in Step 4 in  $O(n)$  time and  $O(m)$  processing time after resetting its backup set (Step 4.2) in Step 4. (Step 4). The worst-case execution time for Step 4 is  $O(m) + O(n)$ , or  $O(n)$ , if  $n > m$ . (Step 4). Step 4 shows that the worst-case processing time of the algorithm is  $O(n)$ .

**Lemma 2.** The algorithm's worst-case message exchange complexity is  $O(1)$  per node or  $O(n)$  across the network's  $n$  nodes.

**Proof.** During the cluster creation phase, a node calculates the cost values of the CHs within its communication range and

sends a join request to the selected CH. Nodes that cannot communicate with any CHs, however, broadcast a HELP request message (step 4.1). It will send a join request message to join the cluster using multi-hop communication if it finds a node that can help. Therefore, in the worst scenario, a node only needs to send two messages for the cluster to form. As a result, each node's message complexity,  $O$ , is constant (1). The network's overall message exchange complexity is  $O$  as a result (n).

3) Using the Rule Editor to specify rules for a fuzzy inference system to solve the network traffic issue when migrating parallel crawlers.

VI. RESULT AND DISCUSSION

The algorithm is integrated with the aforementioned module. The MATLAB Compiler is used to generate the code. The Implementation is tested against current web crawlers and designed to function on active websites.

The load produced by a conventional crawler is shown in Table II. The load produced by a single threaded crawler is shown in Table III. The load produced by an agent-based crawler is seen in Table IV. The load created by migrating parallel web crawlers is shown in Table V. The graph in Fig.

16 to Fig. 19 depict the network load created by various methods. Three websites are used in the analysis and comparison of the methods. Since an HTML page typically weighed 205 KB, the network traffic produced by the conventional centralised crawling strategy was 555 KB. While in our method, the pages were compressed on the server, and the traffic load that was discovered was 70 KB. As seen in the above Fig. 20, the load incurred after five visits to the pages was 2896 KB, 1355 KB, 597 KB, and 379 KB, respectively, and after 10 visits, the load was 5740 KB, 2709 KB, 1224 KB, and 774 KB, respectively. Additionally, this resulted in less network traffic.

## VII. CONCLUSION

This paper discusses the crawling process using one of the two following approaches: either allowing crawlers to communicate among themselves freely or forbidding them from doing so altogether. Both approaches increase network traffic. Here, a fuzzy logic-based method that predicts the load at a specific node and the path of network traffic is presented and implemented in MATLAB using the fuzzy logic toolbox. The experimental findings demonstrate that the network demand is decreased when a parallel web crawler is migrated.

## ACKNOWLEDGMENT

We thank the Deanship of Scientific Research, Prince Sattam Bin Abdulaziz University, Alkharj, Saudi Arabia for help and support.

# A Privacy-Centered Protocol for Enhancing Security and Authentication of Academic Certificates

Omar S. Saleh<sup>1</sup>, Osman Ghazali<sup>2\*</sup>, Norbik Bashah Idris<sup>3</sup>

Studies-Planning and Follow-up Directorate, Ministry of Higher Education and Scientific Research, Baghdad, Iraq<sup>1</sup>

School of Computing, Universiti Utara Malaysia, Kedah, Malaysia<sup>1,2</sup>

**Abstract**—Academic certificate authentication is crucial in safeguarding the rights and opportunities of individuals who have earned academic credentials. This authentication helps prevent fraud and forgery, ensuring that only those who have genuinely earned certificates can use them for education and career opportunities. With the increased use of online education and digital credentials in the digital age, the importance of academic certificate authentication has significantly grown. However, traditional techniques for authentication, such as QR code, barcode, and watermarking, have limitations regarding security and privacy. Therefore, proposing a privacy-centred protocol to enhance the security and authentication of academic certificates is vital to improve the trust and credibility of digital academic certificates, ensuring that individuals' rights and opportunities are protected. In this context, we adopted the Challenge Handshake Authentication (CHA) protocol to propose the Certificate Verification Privacy Control Protocol (CVPC). We implemented it using Python and Flask with a Postgres database and an MVT structure for the application. The results of the implementation demonstrate that the proposed protocol effectively preserves privacy during the academic certificate issuance and verification process. Additionally, we developed a proof of concept to evaluate the proposed protocol, demonstrating its functionality and performance. The PoC provided insights into the strengths and weaknesses of the proposed protocol and highlighted its potential to prevent forgery and unauthorised access to academic certificates. Overall, the proposed protocol has the potential to significantly enhance the security and authenticity of academic certificates, improving the overall trust and credibility of the academic credentialing system.

**Keywords**—Academic certificates; privacy-centered protocol; privacy preservation; challenge handshake authentication protocol

## I. INTRODUCTION

Academic certificates are important documents that verify an individual's educational achievements and qualifications, serving as proof of their knowledge, skills, and competencies in a particular field of study. Employers, educational institutions, and other organisations often use academic certificates to evaluate an individual's qualifications for a job or further education opportunities. A study by the National Center for Education Statistics (NCES) found that in 2020, about 42% of the US population aged 25 and over had at least a bachelor's degree, which is an increase from 29% in 2000. This increase in the number of college graduates highlights the importance of

academic certificates, as employers and institutions require higher levels of education and skills [1], [2], [3].

Moreover, academic certificates play a crucial role in career advancement. A study by the Georgetown University Center on Education and the Workforce revealed that a worker with a bachelor's degree earns about \$1 million more in median lifetime earnings than a worker with only a high school diploma. In conclusion, academic certificates are important documents used to verify an individual's education and qualifications. They are becoming increasingly important as the number of college graduates increases, and employers and institutions require higher levels of education and skills, playing a vital role in career advancement. Academic certificate forgery is a severe issue affecting educational institutions, employers, and individuals [26], [31].

A study by the International Association for Educational Assessment (IAEA) suggests that academic certificate forgery is a growing problem worldwide, with an estimated 5-10% of all certificates being fraudulent. The rate of diploma fraud was 0.1% among the 3.5 million students whose records were checked in the United States, according to a study by the National Student Clearinghouse Research Center. The most common form of fraud was the use of a false high school diploma to gain admission to college [22]. In India, a study by the Centre for Media Studies found that up to 40% of engineering graduates in India may have fake degrees. The study revealed that many students could obtain fake degrees from unaccredited institutions or by paying bribes to officials. In China, a study by the China Academic Degrees & Graduate Education Development Center found that the rate of academic certificate forgery was about 3.15% among the population of college graduates, with most of the forgeries in the fields of engineering and medicine. While the methodologies of these studies may differ, they all suggest that academic certificate forgery is a widespread problem with severe consequences for educational institutions, employers, and society as a whole [1], [2], [3].

Therefore, it is essential for institutions and employers to have proper measures in place to detect and prevent certificate forgery to ensure that only qualified individuals are awarded and recognised for their education. Academic certificate verification is a critical process that helps mitigate the problem of academic certificate forgery by checking the authenticity of an academic certificate to ensure that a legitimate institution

\*Corresponding Author.

issued it and that the individual who holds the certificate completed the coursework and earned the degree.

A graduation certificate, also known as a diploma or degree certificate, is a document awarded to a student upon successfully completing a course of study or program, including the student's name, the name of the institution, and the degree or diploma earned. It typically includes the student's grades or other academic information in some cases. It serves as official proof of the student's educational achievements and is often required for further education or employment. Some universities, colleges, and vocational schools also provide an official transcript with the graduation certificate.

However, ensuring privacy in academic certificate issuance and verification systems is a critical concern [32]. The proposed Privacy-Centered Protocol for Enhancing the Security and Authentication of Academic Certificates is based on the Challenge Handshake Authentication (CHA) protocol and offers several key contributions that could revolutionise the academic certificate issuance and verification process. Firstly, the protocol prioritises the privacy of certificate holders by ensuring that personal information is not disclosed during the verification process. Secondly, it employs the CHA protocol, which uses a challenge-response mechanism to enhance the security of academic certificates. Additionally, the protocol is tamper-proof and uses digital signatures to ensure the authenticity of certificates. It is also easily accessible to all stakeholders and compatible with commonly used devices, making it a practical solution for academic institutions. Finally, the protocol is designed to be compatible with emerging technologies such as blockchain [8], ensuring its longevity and continued relevance. Overall, the proposed protocol focuses on privacy, security, tamper-proof nature, accessibility, and compatibility, making it a promising solution for enhancing the security and authentication of academic certificates. The next subsections will discuss the importance of graduation certificates and the related security and privacy requirements.

#### A. Importance of a Graduation Certification Verification (GCV) System

A Graduation Certification Verification (GCV) system is of paramount importance in the modern job market and academic landscape. The system provides a reliable and secure means of verifying the authenticity of academic certificates, which is essential for employers, academic institutions, and government agencies. With the increasing prevalence of certificate fraud, a GCV system is critical for maintaining the integrity of the certification process and preventing fraud. By ensuring that only authentic certificates are accepted, a GCV system can help improve the job market's quality, reduce the risk of hiring unqualified candidates, and maintain trust in the certification process. Moreover, a GCV system can help to simplify and streamline the certification process, saving time and reducing costs for employers and academic institutions. Overall, a GCV system is essential for ensuring the accuracy and integrity of academic certificates and maintaining trust in the certification process.

#### B. Security and Privacy Requirements of a Graduation Certification Verification (GCV) System

A Graduation Certification Verification (GCV) system requires high security and privacy to ensure the authenticity of academic certificates. The system must protect the privacy and security of certificate holders' personal information and the confidentiality of the certificate itself. The following are some of the security and privacy requirements of a GCV system:

- **Authentication and Authorisation:** The GCV system must implement strong authentication and authorisation protocols to ensure that only authorised stakeholders can access and modify data [27],[28].
- **Data Encryption:** The system should use encryption technology to protect data in transit and at rest, ensuring that data is not accessible to unauthorised parties [26],[27],[28].
- **Secure Storage:** The system must use secure storage mechanisms to protect the confidentiality and integrity of the data, preventing unauthorised access and data loss.
- **Privacy Protection:** The GCV system must ensure that the certificate holder's personal information is protected, including their identity and other sensitive information[26],[27],[28].
- **Data integrity:** The system must ensure that the data stored in the system is authentic and cannot be tampered with. This can be achieved by using techniques such as digital signature, hash functions, and encryption [5].
- **Non-repudiation:** The system must provide a mechanism to ensure that the certificate holder cannot deny their ownership of the certificate. This can be achieved by using digital signature and public key infrastructure [6].
- **Access control:** The system must have a mechanism to control who can access the certificates and what they can do with them. This can be achieved by using role-based access control, access control lists, and permission-based systems [7],[28].

Ensuring security involves safeguarding user and stakeholder privacy and preventing unauthorised access, use, modification, or destruction of data to maintain information confidentiality. This defines the system's ability to provide protection [29]. Preserving privacy is widely considered to rely on access control technology, which is regarded as the most vital aspect [30]. By implementing these security and privacy requirements, a GCV system can protect the integrity of the certification process, prevent fraud, and maintain the trust of stakeholders. Implementing these requirements can also help ensure compliance with data protection regulations, such as GDPR, HIPAA, and CCPA.

## II. LITERATURE REVIEW

The issuance and verification of academic certificates are critical processes in the academic world. The need for accurate, reliable, and secure verification of academic certificates has become increasingly important with the rise of online education and the prevalence of certificate fraud. This has led to the development of various techniques and technologies for academic certificate issuance and verification, which range from traditional methods to more modern and sophisticated approaches. In this literature review, we will explore the different techniques that have been proposed for academic certificate issuance and verification, including paper-based methods, electronic certificates, and digital signatures. We will examine the advantages and limitations of each approach, as well as their effectiveness in addressing the challenges of certificate fraud, privacy, and security. By understanding the various techniques and technologies used for academic certificate issuance and verification, we can gain insight into the future of this critical area of academic administration.

Traditional techniques for academic certificate issuance and verification have been used for decades, typically involving paper-based certificates and manual verification processes. While these methods have proven effective in many cases, they have limitations that have led to the development of more advanced technologies. In this literature review, we will explore the advantages and disadvantages of traditional techniques for academic certificate issuance and verification, including the use of paper-based certificates, manual verification processes, and the challenges of fraud prevention, privacy, and security.

Paper-based certificates have been the most widely used method for academic certificate issuance, and their validity has been verified by manual methods. However, this process is time-consuming, resource-intensive, and prone to error. Manual verification of certificates can be time-consuming and inefficient, and it may also require significant resources. Moreover, paper-based certificates are vulnerable to fraud, and they can be easily replicated or falsified. Despite the limitations of paper-based certificates, they are still in use, particularly in developing countries, where the lack of digital infrastructure and resources makes it difficult to implement more advanced technologies. In these situations, the use of paper-based certificates remains the only viable option, and efforts are being made to improve the security and validity of paper-based certificates.

QR codes are two-dimensional barcodes that can store large amounts of data in a small space, making them a popular choice for academic certificate issuance and verification. The use of QR codes can help to reduce the risk of fraud, simplify the verification process, and increase the efficiency of certificate issuance. QR has been used to store information such as the student's name, degree name, graduation year, and name of the University, making it easy for employers and institutions to verify the authenticity of the certificate[9],[10].

In [33], the research proposes a system for issuing degree certificates that includes a digital signature and a QR code tag. The QR code tag contains the graduate student's data, such as name, GPA, CGPA, and institution alias. The Higher

Education Certificate Authentication System (HECAS) generates the digitally signed QR code, which is sent to the central HECAS server for verification. A smartphone application is required to authenticate the certificate by scanning the QR code. The proposed system aims to provide a secure and efficient way of issuing and verifying degree certificates.

In [34], the research proposes a system for real-time student identity card authentication using a QR code and a smartphone scanner. The system generates a unique QR code containing a student's matriculation number and other details, which is embedded in the identity card. A software application pre-installed in the smartphone scanner functions as a QR scanner, allowing for quick and efficient authentication. The proposed system aims to enhance the quality of authentication and overcome the problem of location and connectivity issues. The research shows that the smartphone scanner is an effective and faster means of authentication compared to other traditional means. The system offers a promising solution to the lack of innovation in information technology, particularly in developing countries like Nigeria.

In [35], the paper proposes a barcode-based academic certificate authentication system that uses cloud-based services to enhance security and accessibility. The system generates a unique barcode for each certificate, which can be scanned and verified using a mobile application. The authors suggest that the system could help reduce fraud and improve the verification process for academic certificates.

In [36], the paper presents a QR code-based certificate authentication and verification system for higher education. Barcodes are used to improve security and accessibility. The system generates a unique QR code for each certificate, which can be scanned and verified using a mobile application. The authors note that the system could help prevent the production and distribution of fraudulent certificates.

In [37], the paper proposes a barcode-based certificate verification system for distance education. Barcodes are used to improve the security and efficiency of certificate verification. The system generates a unique barcode for each certificate, which can be scanned and verified using a mobile application. The authors suggest that the system could help reduce the time and cost associated with traditional certificate verification methods.

Using QR codes for academic certificate issuance and verification can pose some risks in terms of privacy and security. While QR codes offer a convenient and efficient way to verify certificates, they can also contain sensitive information that could be at risk of data breaches, hacking or misuse. For example, if the QR code contains personal data such as a student's academic history, it could be used for discriminatory purposes if it falls into the wrong hands. Moreover, QR codes can be easily replicated, potentially leading to fraudulent certificates being produced. To address these issues, it is important to take appropriate security measures such as encryption, access controls, and data privacy policies. Institutions or organisations may also need to use other technologies and methods to supplement QR codes, depending on their specific requirements [11], [12], [13], [14].

In [38], the researchers proposed a verification system based on watermarking that uses a combination of visible and invisible watermarks to authenticate digital certificates. The system uses an encryption scheme based on a secret key to ensure the security of the embedded watermark and employs a unique identifier to prevent the certificate from being duplicated. The system was tested on a sample set of certificates and demonstrated high accuracy in verification.

In [39], the researchers proposed a certificate verification system that uses a combination of QR codes and watermarks. The system embeds a unique watermark into each certificate that can be used to verify its authenticity. The system also includes a QR code that can be scanned to access additional information about the certificate holder. The system was tested on a sample set of certificates and showed high accuracy in verification.

While watermarking can offer a secure method for academic certificate issuance and verification, there are still potential drawbacks in terms of privacy and security. One of the main concerns is that someone with the right tools and knowledge can remove or alter watermarks, leading to fraudulent certificates being produced. Moreover, watermarking could lead to the possibility of certificate forgery, as attackers may be able to replicate the watermark and create counterfeit certificates. Embedding watermarks may also raise concerns regarding data privacy since the watermarks may contain personal information that could be accessed or misused. Therefore, it is important to complement watermarking techniques with additional security measures, such as encryption, access controls, and policies to protect the privacy of personal data.

In [40], the researchers proposed an RFID-based certificate verification system that uses a combination of hardware and software components. Each certificate is equipped with an RFID tag that contains a unique identifier and other relevant information. When the certificate is presented for verification, an RFID reader scans the tag and sends the data to a central server, which validates the information and returns a response indicating the certificate's authenticity. The system was tested on a sample set of certificates and showed high accuracy in verification.

In [41], the researchers proposed an RFID-based verification system that uses a unique identifier and a cryptographic key to authenticate digital certificates. The system employs an RFID reader to scan the certificate and transmit the data to a central server, which uses the cryptographic key to verify the authenticity of the certificate. The system was tested on a sample set of certificates and showed high accuracy in verification. The researchers also noted that the use of RFID technology can help prevent certificate fraud since the RFID tag is difficult to replicate or alter without the proper tools and knowledge.

However, there are potential drawbacks to using RFID technology for academic certificate issuance and verification. One concern is that the use of RFID technology could result in unauthorised access to personal data since the RFID tag contains sensitive information. Attackers may use unauthorised RFID readers to intercept the data or copy the RFID tag's

content. Furthermore, the use of RFID technology may raise concerns about data protection and privacy since RFID tags are capable of tracking individuals and monitoring their movements. Additionally, the cost of implementing RFID technology may be higher than other methods, which could be a barrier to adoption for some institutions. Therefore, it is essential to take appropriate measures to protect the privacy of personal data and prevent unauthorised access or interception of the RFID data.

However, watermarking relies on the visibility of the watermark, which can be difficult to detect in low-resolution images and can be removed through image manipulation [15], [16]. Table I shows the comparison between QR-Code, Barcode, watermarking and RFID.

TABLE I. COMPARISON BETWEEN QR-CODE, BARCODE, WATERMARKING AND RFID

Technique	Advantages	Disadvantages	References
QR Code	Can be read quickly and easily using a smartphone camera; Can store a large amount of data in a small. Can be easily integrated into existing systems.	Can be easily replicated or forged. Can be easily damaged or obscured, making it difficult to read.	[17], [18], [19]
Barcode	Can be read quickly and easily using a barcode scanner. Can store a limited amount of data in a small space. Can be easily integrated into existing systems.	Can be easily replicated or forged. Can be easily damaged or obscured, making it difficult to read.	[17], [18], [19]
Watermarking	Can be used to embed hidden information in the certificate that can be used to verify authenticity. Can be difficult to replicate or forge.	Can be easily damaged or obscured, making it difficult to read. Can be computationally expensive to create and verify.	[17], [18], [19]
RFID	Can be read quickly and easily using an RFID reader. Can store a large amount of data in a small space. Can be used for contactless authentication.	Can be easily replicated or forged. Can be easily damaged or obscured, making it difficult to read. Can be expensive to implement and maintain.	[17], [18], [19]

### III. THE PROPOSED DESIGN OF CENTRALIZED CERTIFICATE VERIFICATION PRIVACY CONTROL PROTOCOL (CVPC PROTOCOL)

The proposed design of the Centralized Certificate Verification Privacy Control (CVPC) protocol aims to address the shortcomings of traditional techniques such as QR codes, barcodes, watermarking and RFID for academic certificate issuance and verification. The CVPC protocol utilises a centralised server for certificate issuance and verification, which is responsible for maintaining the integrity and authenticity of the certificates. This centralised server is

responsible for generating and issuing digital certificates, as well as verifying the authenticity of the certificates when requested. The CVPC protocol utilises a combination of advanced cryptographic techniques, such as digital signatures and hash functions, to ensure the integrity and authenticity of the certificates. The digital certificates are issued with a unique digital signature, which is generated by the centralised server using the private key of the issuing institution. The digital signature ensures that the certificate has not been tampered with or modified in any way. The CVPC protocol also utilises a unique identification number, which is embedded in the digital certificate and is used to verify the authenticity of the certificate. This identification number is generated by the centralised server and is based on the student's personal information, such as their name, date of birth, and the institution they graduated from. The CVPC protocol also includes a privacy-preserving mechanism, which allows the student to control who has access to their personal information and the digital certificate. The student is provided with a private key, which is used to encrypt the personal information and digital certificate. The private key is stored on the student's device and is only accessible by the student.

With this proposed solution, three main objectives were sufficed. Primarily:

- The privacy aspect. The student can lock and unlock their certificates.
- Only authorised entities can exist in the system with sufficient authorisation and access control.
- Timely verification of certificates by third parties.

From the previous details, privacy was a major drawback in most of the existing solutions when it came to certificate verification. The process itself is quite troublesome, especially for verifiers. The first components towards sufficing the objectives of this research start with developing a privacy-first solution that allows the user to control how the public views the certificate in a centralised environment. Fig. 1 shows the design for the proposed centralised certificate verification privacy control protocol.

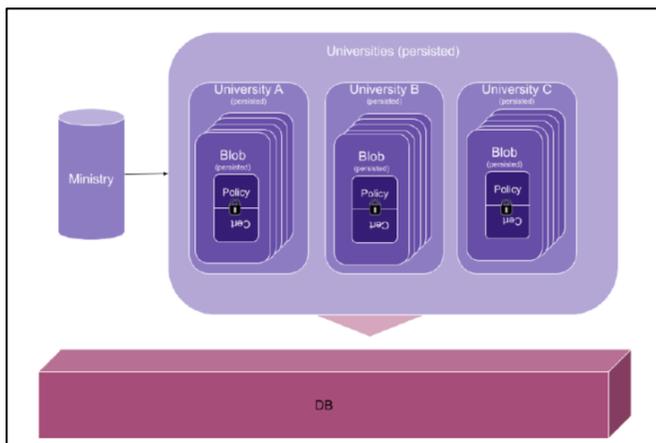

Fig. 1. The proposed centralised certificate verification privacy control protocol.

The number of ministries in the world is finite  $n(\text{Ministry}) = x, \{x = \text{constant} \mid x > 0\}$  and usually there is one per country  $\text{Ministry}_x \subset \text{Country}_x$  which is usually responsible for the quality of education in their respective countries. The ministry of education can go under different names like the case of Mexico it is called Secretariat of Public Education [16]. Nevertheless, this should not have any impact on the design since the ministry is an entity that controls and generates universities  $\{\text{University}_1, \dots, \text{University}_n\} \in \text{Ministry}_x \mid n \geq 1$ . The set of ministries based on the proposition above is finite hence they are hard coded into the system (by their official admin emails); Each Ministry is able to only create universities in the system. Each university is created by one and only one ministry. For the cases where there are different branches of a single university in different countries, this would neither be impacted nor will it cause the system to behave wrongly. For example, Birmingham University, originally situated in the UK and precisely England, would be created by the Ministry of Education in the UK. Birmingham University also has a branch in Malaysia. The Malaysian Ministry of Education would create the latter. Each university issues its own certificates. However, in the proposed solution, as a certificate is generated a privacy policy is also generated and attached to that generated certificate as shown in the design Fig. 1. By default, the certificate is locked, which means any third party attempting to view the certificate will not be able to see its details. When the university creates a certificate, another task is triggered in the background, generating a student for that certificate. The way this is achieved is by using the registered email of the student in that university. This is to suffice for authentication. The student would get an activation token that allows them access to the certificate and policy. The student after activating their account would be able to control how each piece of information is displayed to third parties. The mechanism used to achieve the above is an adaptation from the Challenge Handshake Authentication Protocol (CHAP) which is shown in Fig. 2. CHAP suffices when a link is between a server and a client [20],[23],[24].

- The server sends a challenger message to the client.
- The client responds.
- The server checks if the response matches the expected value, then the authentication is acknowledged, and the connection happens otherwise it is terminated.

The Challenge Handshake Authentication protocol was adopted in the proposition of the certificate verification privacy control protocol (CVPC). CHAP operates by first establishing a connection between the user and the network resource. The network resource then sends a challenge message to the user, typically a random string of characters or a nonce, which the user must use to generate a response message. The user generates the response by running a one-way hash function on the challenge message using a shared secret key known only to the user and the network resource. The resulting hash value is then sent back to the network resource, which compares it to its own calculation of the expected response. If the two values match, the user is authenticated and granted access to the network resource. Details are shown in the next section. The Challenge Handshake Authentication Protocol (CHAP)

proposed by [20],[21], which was discussed in the previous section, was adopted in that same manner in the CVPC protocol. It is used when a ministry adds a university, and a university issues a certificate and assigns a student. The adoption and the implementation of Challenge Handshake Authentication protocol (CHAP) in academic certificates verification use case is given in Fig. 3. It shows how the relationship between the university and the students.

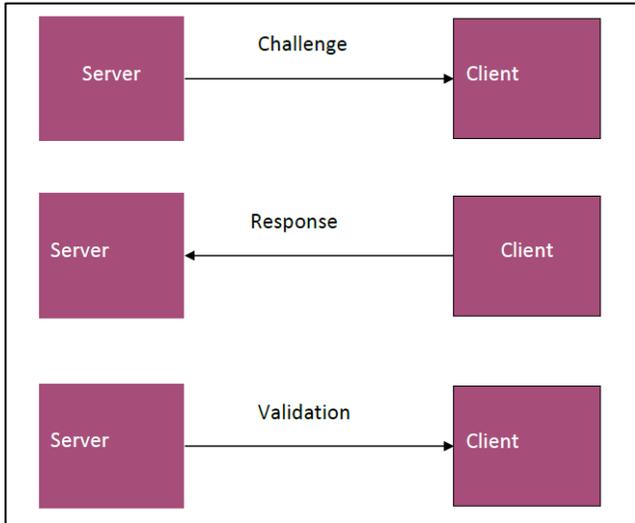

Fig. 2. Challenge Handshake Authentication Protocol (CHAP).

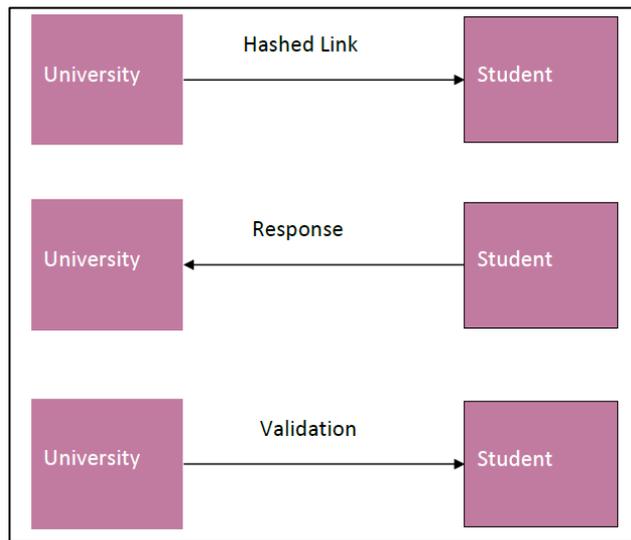

Fig. 3. Implementation of Challenge Handshake Authentication Protocol (CHAP) in academic certificates verification use case.

The proposed CHAP Certificate Verification Privacy Control Protocol used is based on the following steps:

Step 1: A request is sent to the student's email. The request is in the form of a signed link that is specific to that student, and the link contains a token. The token results from hashing of a user's identifier with the student's email and a timestamp. The timestamp is important to validate the lifespan of the link. The link is meant to be active for a pre-defined period of time

to minimise hanging certificates. Meaning certificates in the system without confirmed students.

Step 2: The students from their official emails access the link supplied. This step acts as a response to the request sent by the server. It is important to note that each link is unique to the student and can only be accessed from their official email, which requires authorisation and access control.

Step 3: The server validates the authenticity of the token sent by the student by decrypting it and retrieving the email address hashed in the token, using the same student identifier that was used to sign the token. If the token is valid, the student is directed to the certificate and policy and can unlock the certificate.

The proposed protocol uses HMAC and SHA-512 to sign the hashed link. HMAC stands for Keyed-Hashing for Message Authentication and is a widely used message authentication code based on cryptographic hash functions like MD5 and SHA-1. The student identifier acts as a namespace for the URL and is unique to each student. Therefore, the student identifier is usually the student's username or ID. This adds an extra layer of privacy since no two tokens can be decrypted using the same parameters. Since each email and student identifier is unique, each link is specific to a single student.

Based on what has been discussed in the previous section the following protocol is proposed (CVPC protocol).

Step 1: The ministry adds a university using CCVPC proposed,  $CCVPC(University) \in Ministry$ .

Step 2: The university adds students using CCVPC,  $University \rightarrow CCVPC(Student_n)$ ,  $n \in \text{list of students in university}$ .

Step 3: The university issues certificates with Privacy Policy,  $University \rightarrow PsxCs$ ,  $P=Policys$ ,  $C=Certificates$ ,  $s=\{Student_0, \dots, Student_n\}$ .

Step 4: Privacy Policy adds a layer of protection to the Certificates  $Ps(Cs)$ .

Step 5: All inbound traffic hits the Privacy Policy first.  $Inboundrequest \rightarrow Ps \rightarrow Cs$ .

Step 6: Student lock/Unlock their certificates sufficing privacy  $L(Cs)$ ,  $U(Cs)$ ,  $L=Lock$ ,  $U=Unlock$ .

Step 7: Students share ids of certificates with the third parties and based on the privacy policy they are able to see the information  $T(PsCs) \ni Student_n \Rightarrow U(Cs)$ ,  $T=Third\ party$ .

#### IV. THE PROPOSED VERIFICATION OF CERTIFICATES BY THIRD PARTIES

The third party can simply use a fixed id supplied by the student to access the certificate and validate the information.  $T(PsCs) \ni Student_n \rightarrow U(Cs)$ ,  $T=Third\ party$ ,  $Ps=Student\ Policy$ ,  $Cs= Student\ Certificate$ ,  $U=Unlocking$ .

The student can after being authorised into the system using the CCVPC proposed will be able to control each element of his/her certificate. Such that.

Studentn → L(Cei), ei ∈ Certificates | Student=Studentn where.

ei represents several elements like the GPA, transcript and other necessary information that is issued with the certificate. The CCVPC is a component of the proposed centralised certificate verification privacy protocol. This design ensures that the system remains free of unwanted parties. Access control is managed by authorised entities, each of which has their own control rights in the system. For example, universities issue certificates, but can only participate in the system through ministries. This control mechanism ensures proper authorisation, verification, and limits fraud. In addition, the CCVPC protocol ensures privacy by controlling who has access to the L(Cs) and U(Cs) of certificates - only the students themselves have this access. Thanks to the CCVPC protocol, no unauthorised entities can exist within the system.

## V. IMPLEMENTATION AND RESULTS

The proposed design was implemented in Python, a widely-used programming language that is particularly effective for large-scale web applications. The web framework Flask was used with Python, while the database was implemented with Postgres, an open-source database that natively supports JSON objects. The application was structured according to the MVT architecture, which stands for Models, Views, and Templates. Models describe the database, while Views implement the business logic, and Templates provide the front-end interface with HTML and CSS. In the following subsections, we will explore the different layers of the application in more detail.

- common
- models
- resources
- static
- templates
- app.py
- blacklist.py
- config.py
- db.py

### A. The Model Layer

The model folder contains all the entity models that were defined. These models represent the various actors involved in the use case, with the exception of the third party. Since third parties do not require an identity in the system, they can simply use the ID provided by the student to facilitate the verification process. In this process, several actors are involved, including the ministry, the university, students, and third parties. The ministry's responsibility is to add universities to the system, while the university takes charge of certificate issuance. Students have the ability to lock and unlock their certificates for privacy preservation. Finally, third parties are responsible for verifying the certificate. In the proposed protocol design, there are several actors involved, as depicted in Fig. 4. Additionally, this research includes the implementation of the Ministry class in Python, as demonstrated in Fig. 5.

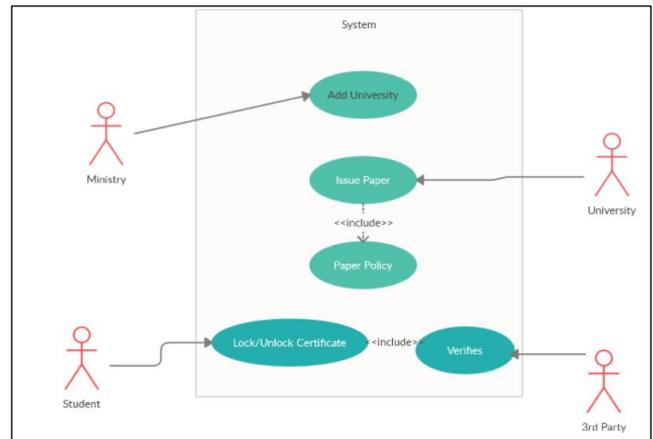

Fig. 4. Actors involved in the proposed protocol.

```

class MinistryModel(db.Model):
    __tablename__ = "ministries"
    __table_args__ = (UniqueConstraint("id"),)
    id = db.Column(db.Integer, primary_key=True)
    is_verified = db.Column(db.Boolean, default=False)
    name = db.Column(db.String(120), unique=True)
    country = db.Column(db.String(120), unique=True)
    password = db.Column(db.String(128))
    
```

Fig. 5. The implementation of the ministry class in python.

The same principle applies to both universities and students, with an additional class of permissions that facilitates control over the privacy of certificates. This permission class is linked to the student class through the use of student IDs.

### B. The View Layer

The logic that connects the front end to the model layer is implemented in this layer. Specifically, the ministry resource includes the following resources:

- Ministry(Resource).
- MinistryRegistration(Resource).
- MinistryList(Resource).

Each of the resources listed above serves a specific purpose. For example, the ministry resource exposes an API call that returns details about the ministry associated with a given email address.

- class Ministry(Resource):
- def get(self, email):
- email = email.lower().strip().
- Ministry = MinistryModel.find\_by\_email(email).
- if Ministry:
- return Ministry.json().
- return {"message": "Ministry not found"},

The Ministry Registration resource takes in the necessary information to create a new ministry. The creation of a ministry is pre-defined. The pre-defined entities are added using the post method exposed by the Ministry Registration resource above. The last Resource MinistryList(Resource) allows super admin to list existing ministries or it can also serve the general query the list of ministries registered in the system.

### C. Application Front End Layer

The student is able to control the permission using the endpoint /permissions/<int:student\_id>.

In this section, the proposed system's app screens illustrate various tasks, including adding a university to the system, the university's view for adding a certificate, the student's view for managing permissions, and the third-party's view of the application. Fig. 6 displays a screenshot of the university addition process, while Fig. 7 showcases a screenshot of the university adding a certificate. Furthermore, Fig. 8 demonstrates how a student can preserve their privacy. The student view for managing permissions is shown in Fig. 9, which displays a screenshot of a third-party verifying a certificate shared by the student.

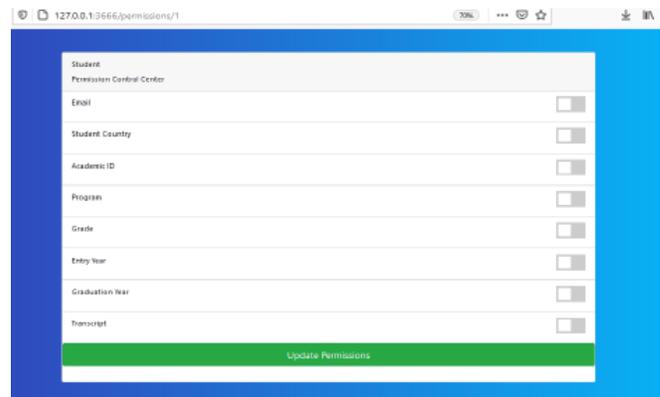

Fig. 8. Screenshot of how a student can preserve their privacy.

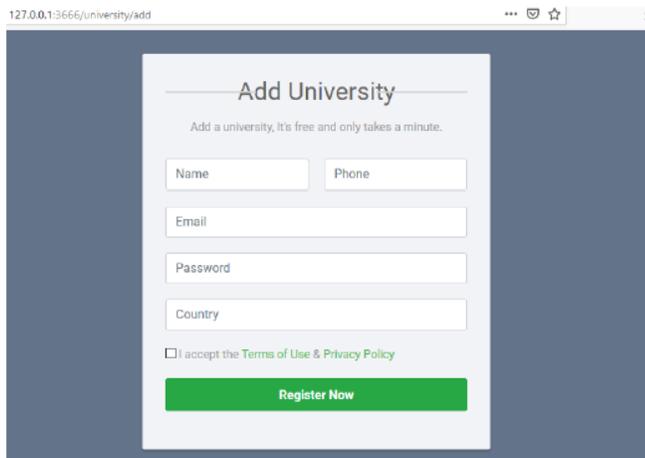

Fig. 6. Screenshot of adding a university.

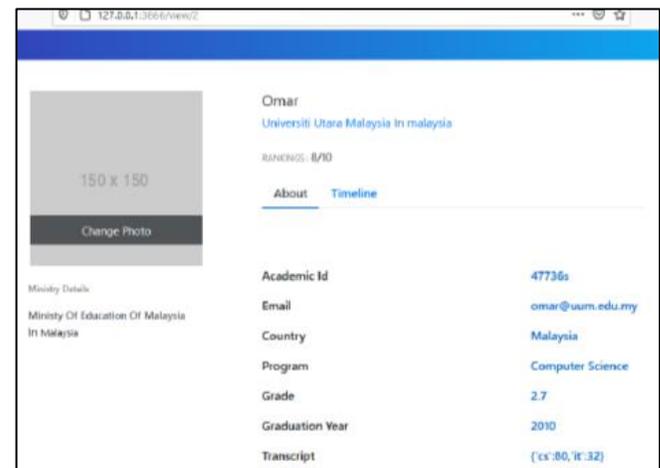

Fig. 9. Screenshot of third-party verifying the certificate shared by the student.

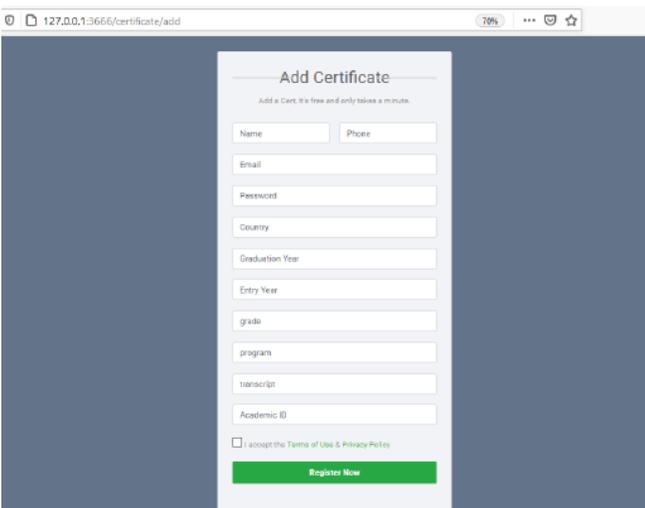

Fig. 7. Screenshot of adding a certificate by the university.

## VI. DISCUSSION

The Privacy-Centered Protocol for Enhancing the Security and Authentication of Academic Certificates based on the Challenge Handshake Authentication (CHA) protocol has the potential to significantly enhance the security and authenticity of academic certificates. The protocol's key contributions, including its focus on privacy, tamper-proof nature, and compatibility with emerging technologies, make it a promising solution for academic institutions. One of the most significant benefits of the proposed protocol is its emphasis on privacy. The protocol ensures that personal information is not disclosed during the verification process, providing an extra layer of protection to certificate holders. This privacy-centric approach is essential in today's digital age, where data breaches and identity theft have become significant concerns for individuals and organisations alike. Another significant advantage of the proposed protocol is its tamper-proof nature. The use of digital signatures ensures the authenticity and integrity of academic certificates, making it easy to detect fraudulent certificates. This tamper-proof nature can significantly enhance the overall trust in the academic certificate issuance and verification process, providing a more secure means of verifying academic credentials. The protocol's compatibility with emerging technologies such as blockchain is also noteworthy. The integration with blockchain technology can further enhance the

security and reliability of academic certificate verification. Blockchain technology provides a decentralised and tamper-proof way of storing and verifying data, making it an ideal solution for enhancing the security and authenticity of academic certificates. Despite the potential benefits, the adoption of the proposed protocol may face challenges. One of the challenges is the adoption and integration of the protocol into existing systems. It may require significant changes to the existing infrastructure and systems, which can be time-consuming and costly. Additionally, compatibility with emerging technologies such as blockchain requires a certain level of technical expertise, which may be a barrier to some organisations. In conclusion, the Privacy-Centered Protocol for Enhancing the Security and Authentication of Academic Certificates based on the CHA protocol is a promising solution for enhancing the security and authenticity of academic certificates. The protocol's emphasis on privacy, tamper-proof nature and compatibility with emerging technologies makes it a practical and robust solution for academic institutions. While there may be challenges to its adoption, the benefits of adopting the protocol far outweigh the potential challenges, providing a more secure and reliable means of verifying academic credentials.

#### VII. BENEFITS OF PRIVACY CENTRALISED VERIFICATION CONTROL PROTOCOL FOR ACADEMIC CERTIFICATES ISSUANCE AND VERIFICATION

Proposing a new privacy-centralised verification control protocol for academic certificates issuance and verification is important for several reasons [25], including:

- **Security:** Traditional methods of academic certificate authentication, such as QR code and barcode, are vulnerable to tampering and replication. A new privacy-centralised verification control protocol can enhance the security of the certificate verification process by incorporating advanced security techniques such as digital signature, encryption, and biometrics.
- **Privacy:** Centralised certificate verification systems can be a potential privacy breach, as they can expose the personal information of certificate holders to unauthorised access. The new privacy-centralised verification control protocol aims to preserve the privacy of the certificate holders by implementing a privacy-preserving protocol that protects the personal information of the certificate holders from unauthorised access.
- **Scalability:** The proposed protocol can handle a large number of requests and users, which is crucial in today's digital era where the use of digital credentials has increased.
- **Compliance:** The proposed protocol can ensure compliance with various privacy regulations and standards, such as GDPR, which is increasingly important as organisations have to comply with more stringent regulations to protect personal data.

In summary, proposing a new privacy-centralised verification control protocol for academic certificate issuance

and verification is crucial to ensure the security, privacy and scalability of the system, as well as to provide an efficient user experience and compliance with regulations.

#### VIII. EVALUATION OF THE PROPOSED PROTOCOL

Evaluating a proposed design of the Centralized Certificate Verification Privacy Control Protocol (CVPC Protocol) is crucial to ensure its effectiveness and efficiency in improving the security and privacy of academic certificate authentication. One way to evaluate the proposed protocol is by developing a proof of concept (PoC) and testing it with real-world scenarios and data. The PoC can be used to demonstrate the functionality and performance of the proposed protocol and provide insights into its strengths and weaknesses. The PoC development process can involve several steps, such as designing the system architecture, implementing the proposed security measures and privacy-preserving protocols, and testing the system with simulated or real-world data. The PoC can be evaluated based on various performance metrics, such as security, privacy, scalability, and usability. For example, the security of the proposed protocol can be evaluated by assessing its resistance to various security threats, such as tampering and replication. The proposed protocol's privacy can be evaluated by examining its compliance with various privacy regulations and standards, such as the General Data Protection Regulation (GDPR). Similarly, the protocol's scalability can be evaluated by assessing its capacity to accommodate a significant number of requests and users. Additionally, the usability of the proposed protocol can be evaluated by analysing its user interface and user experience.

#### IX. CONCLUSION

In conclusion, the proposed Design of Centralised Certificate Verification Privacy Control Protocol (CVPC Protocol) addresses the need for improved security and privacy in the realm of academic certificate authentication. The implementation of the proposed protocol involved the use of several technologies, including Python, Flask, and a Postgres database, as well as the utilisation of an MVT structure. Through the utilisation of these technologies and methodology, the proposed protocol has effectively demonstrated the preservation of privacy throughout the academic certificate issuance and verification process. A proof of concept was developed to further validate the functionality and performance of the protocol, which revealed its potential to prevent certificate forgery and unauthorised access. The CVPC Protocol proposed presents a promising solution for improving the security and privacy of academic certificate authentication. Future work involves building the protocol based on a blockchain platform.

#### ACKNOWLEDGMENT

This research was supported by Ministry of Higher Education (MoHE) of Malaysia through Fundamental Research Grant Scheme (FRGS/1/2018/ICT04/UUM/02/17).

# A Systematic Literature Review on AI Algorithms and Techniques Adopted by e-Learning Platforms for Psychological and Emotional States

Lubna A. Alharbi

Department of Computer Science, University of Tabuk, Saudi Arabia, 71491

**Abstract**—Computers are becoming increasingly commonplace in educational settings. As a result of these advancements, a new field known as CEHL (Computing Environment for Human Learning) or e-learning has emerged, where students have access to a variety of services at their convenience. Using an e-learning platform facilitates more efficient, optimized, and successful education. They allow for personalized instruction and on-demand access to relevant, up-to-date material. These e-learning strategies significantly impact learners' emotional and psychological states, which in turn affect their abilities and motivations. Because of the learner's physical and temporal detachment from their tutor, encouraging learners can be challenging, leading to frustration, doubt, and ambivalence. The learner's drive to learn will be weakened, and their emotional and psychological state will be badly impacted as a result, both during and after the learning session. This research aimed to learn about the methods currently used by research facilities to analyze human emotions and mental states. The findings reveal that only e-learning has been used in education and other fundamental technologies, including machine learning, deep learning, signal processing, and mathematical approaches. A wide variety of e-learning-focused real-world applications make use of these methods. Each study subject is explained in depth, and the most frequently used methods are also examined. Finally, we provide a comprehensive analysis of the prior art, our contributions, their ramifications, and a discussion of our shortcomings and suggestions for future research.

**Keywords**—Psychological states; emotional states; e-learning; online platforms; solutions

## I. INTRODUCTION

Technology has become an integral part of our lives in the twenty-first century, prompting a reevaluation of fundamental beliefs on the part of professionals, educators, and students in order to re-design or re-engineer the educational and training infrastructure. In addition, these technology tools play a crucial role in enabling students and educators to reap its many benefits [1]. The education community is left with the difficult task of increasing the number of creative and original graduates while keeping costs down by applying cutting-edge technical and ecological methods [2]. This process has been a deliberate evolution from the traditional Gurukula methods to the present day, when the digital world has invaded the realm of education and revitalized the student body by providing them with a dynamic, interactive, and electronic environment on which to study. There have been many shifts in the previous few decades, and the meaning of "e-learning" had to adapt. Web

1.0 (the web of knowledge), Web 2.0 (the web of communication), Online 3.0 (the web of interaction), and now Web 4.0 (the web of integration) are all instances of the great progression seen in the world of the web.

## II. LITERATURE REVIEW

Due to the accessibility of new technologies and their capacity to generate and maintain stakeholders, e-learning has risen to the fore in today's ever-changing and dynamic online environment. The term "e-learning revolution" describes the widespread adoption of technological aids to education. To promote safe, cooperative, constructivist, and long-term knowledge exchange, the education sector and its allies hope to usher in an era of paperless learning made possible by technological advancements. As the pace of the technical education revolution quickens, it becomes more difficult for stakeholders to keep up with their commitments [2].

No concerns or pressures were placed on either the educational institutions or the students due to the annual 15.4% increase in e-learning worldwide [3]. However, this study was undertaken during COVID-19, and a lot has changed since then. As a consequence of worldwide limitation measures established to curb the spread of COVID-19 [5], more than 60 percent of students throughout the globe today get the majority or all of their education online, including lectures and a variety of assessments on numerous platforms.

### A. Psychology and Emotional States

Psychological and emotional health is crucially important in many aspects of daily life. A person's emotional state is the overall emotional tone of their personality (especially with regard to pleasure or dejection). While the nature of a state may change over time, the concept of a "psychological state" refers to a more stable mental situation.

1) *Types of emotional states*: Researchers in [15], have identified 27 distinct human emotions: awe, admiration, amusement, anger, calmness, confusion, disgust, empathy, excitement, fear, horror, enchantment, entrancement, joy, nostalgia, relief, romance, sadness, satisfaction, sexual desire, and surprise. Moreover, Fig. 1 shows how multimodal settings and sources might identify an individual's emotional state. In addition, Table I outlines the various sorts of feelings that are significant to the surroundings, which gives concrete instances of how each of the seven emotion types is evaluated and how they tend to act.

TABLE I. ENVIRONMENTALLY RELEVANT EMOTION TYPES [4]

Emotion Type	Appraisals	Action-Tendency
Self-condemning Emotions (Guilt, Shame, Embarrassment)	Own Norm violations	Correction (e.g., repair the environmental damage)
Other-condemning Emotions (Anger, Disgust, Contempt)	Others' norm violations	Punishment (e.g., punish those responsible for environmental destruction)
Self-praising Emotions (Pride)	Own positive norm deviations	Support oneself (e.g., in-group favoring pro-environmental behavioral intentions)
Other -praising Emotion (Elevation, Admiration, Awe, Being Moved, Gratitude, Love)	Others' positive norm deviations	Support the source (e.g., protect nature)
Other-suffering Emotions (Compassion, /Empathy, Emotional Contagion)	Other's suffering	Help those in need (e.g., victims of environmental destruction)
Threat-related Emotions (Fear, Anxiety, Hopelessness)	Anticipated negative consequences	Escape (e.g., fleeing from climate change)
Hedonistic Emotions (Joy, Pleasure, Amusement)		Reinforcement (e.g., enjoying car driving predicts car use)

2) *Types of psychological states:* The distinction between the two perspectives is: Extraversion: Libido that is directed outward is known as extroversion [7]. With an extrovert, the subject's interest in the object shifts in a positive direction. To be introverted is to direct one's libido inward toward the subject's own core. This fact conveys the nature of the subject-object relationship. The focus shifts away from the item and back to the subject. These four roles include: There are two senses: Synergy of Sensation and Intuition Separate evaluations: Feelings and ideas In particular, it is important to note how the perceiving functions can be effective for the diagnostic a subjective process to get in relation to patients and for creativity, while the thinking and feeling processes are related to rationality and can well serve to scientific ideas. Learning styles and personality types in medical school 5 Understanding the different personality types can help provide insight into how pupils' learning styles come into play. Whereas psychological types are highlighted in [6] and scientist pinpoints emotions in [15] also plays a significant role. Emotional and psychological visualization in e-learning environments shown in Fig. 2.

This psychodiagnostic test proposes highlighting four types of learning styles:

1) *Concrete experience:* In-the-moment reflection and problem-solving that prioritizes intuitive, emotional, and visceral processes over logical, scientific ones. The best learning environments for people with such strong relational and social abilities contain minimal organization, direct participation in real-world challenges, and a willingness to share personal information and perspectives.

2) *Reflective observation:* stressing observation and comprehension over application, with a tendency to grasp the

meaning of ideas and circumstances. Subjects who exhibit this form of learning are experts at identifying causation and deducing consequences. They exhibit composure, impartiality, and independent judgment by seeing the same problems from diverse perspectives.

3) *Abstract conceptualization:* skill in working with ideas and concepts in accordance with logical principles, using mostly rational thought rather than emotion in the learning process. There is a predisposition toward quantitative reasoning, planning, and design in these fields. Precision, discipline, analysis, and the organic arranging of conceptual systems are expressed as values by these topics.

4) *Active experimentation:* propensity to take action to influence reality (regarding situations or individuals). His philosophy emphasizes doing as opposed to thinking, which compels him to approach life with a strong dose of pragmatism, placing importance on how things work rather than their intrinsic worth or ultimate significance. People who have this skill can influence their environments to get what they want. These findings have the potential to illuminate medical treatment that takes into consideration patients' own awareness of their own preferences in learning styles, personality traits, and so on.

Fig. 1 and Fig. 2 depict the visualization of emotional recognitions in human from different sources.

**B. Learning Types**

Technology-based education can be referred to by a variety of names, including e-learning, m-learning, and d-learning [1]. e-Learning can replace conventional schooling or work in tandem with it (e-learning m learning). e-Learning goes under many names, including e-education, distant learning, and online education.

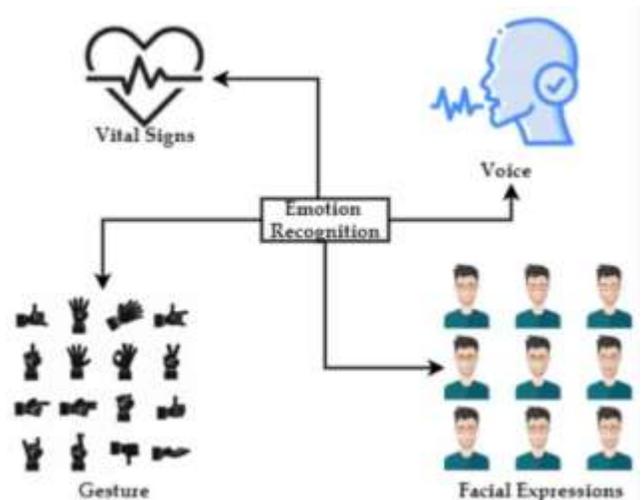

Fig. 1. Human emotional recognition of different sources [60].

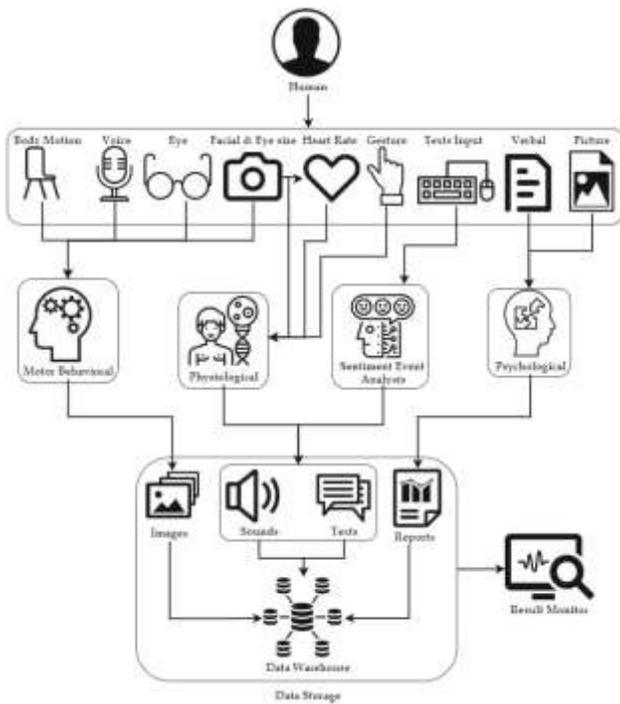

Fig. 2. Visualizations of emotional cartography for e-learning heuristic multimodal approaches [60].

The authors describe e-learning in [3, 8] as "the wide variety of applications and processes that leverage available electronic media and resources to offer vocational education and training." According to research [9], e-learning is "the use of multiple web-based, web-distributed, or web-capable technological instruments for education." Increasing numbers of individuals are becoming aware of the multiple advantages of e-learning [10], which include mobility, accessibility, and cheap cost. Considering these advantages, education may become a lifelong pursuit. According to [11], having limitless access to lectures assists students in retaining the essential information for formal education.

Higher education institutions are also adopting e-learning technology to expand the learning community and facilitate the flow of knowledge between students and teachers [12]. Due to its convenient scheduling, e-learning has the potential to attract more students who are otherwise unable to pursue higher education because of their other responsibilities at home or at work. In fact, this benefits not only the students, but also the teachers.

The founding of the National Center of e-learning and Distance Learning (NCEDL) in the Kingdom of Saudi Arabia in 2005 [13] involves at least nine institutions. This crucial role was created to enhance the overall e-learning experiences of students in schools by adopting and applying the finest e-learning techniques from across the globe [14]. According to the National Center for e-learning and Distance Learning, the NCEDL has participated in various e-learning system initiatives, including the Learning Portal, which gives students remote access to online learning resources and offers instructors training in the use of e-learning technologies.

To further encourage educational institutions to embrace e-learning, the center has created the Award for Excellence in e-learning, for which around 42 institutions are now competing. Since its inception in 2011, a large number of students and graduates have enrolled in courses at the Saudi Electronic University (SEU). Since then, King Abdelaziz University has developed several technological tools to enhance its e-learning system, including the Learning Management System (LMS), which provides access to over 16,000 e-books and other online academic materials for freshmen and juniors [14]. In addition, Tables II and III outline the kinds of e-learning systems, their major components, and their definitions.

TABLE II. E-LEARNING SYSTEM DEFINITION PRIOR RESEARCH [1]

Types of E-Learning System	Prior Research	Definition
Blended Learning	[16,17,18,20]	A mix of traditional and online classes.
Flipped Classroom	[17,20,21]	Focus on the individual learner by distributing preparatory readings and videos online.
ICT Supported Face-to-Face Learning	[22,23]	The integration of ICT with conventional teaching methods.
Synchronous Learning	[17,21,24]	A real-time interaction distance learning.
Asynchronous Learning	[17,21,24]	Non-real-time interaction distance learning.

TABLE III. E-LEARNING CRITERIA AND PRIOR RESEARCH [1]

Factors	Prior Research
Student Characteristics	[22,25-27]
Instructor Characteristics	[10,22,25-27]
Learning Environment	[10,22,25,27]
Instructional design	[10,22,25,27]
Support	[10,22,25-27]
Information Technology	[19,22,29,25,26,28]
Technology Knowledge	[10,22,25-27]
Course	[10,18,19,22,25,27]
Level of Collaboration	[10,19,26,27]
Knowledge Management	[10,19,26,27]

Researchers in [1] claim that e-learning, focusing on the online, is utilized in educational settings to teach and learn about a wide variety of electronic technologies (e.g., television, radio, CD-ROM, DVD, mobile phone, Internet, etc.). According to the definition, e-learning encompasses studying with web-based training facilities, such as digitally collaborative and technology-assisted distance learning offered by virtual universities and classrooms. It is possible to define e-learning innovation as any form of e-learning seen as a novel by its target audience, whether it be a new piece of technology or a new approach to teaching.

It's undeniable that e-learning has had and will continue to have a significant impact on educational progress around the globe. It also presents exciting new possibilities for developing countries eager to advance their educational infrastructure. In

addition, it facilitates the transition of the next generation of educators to the pedagogies of learning made possible by the digital age technologies. It's also been said that the internet and other modern technology are used to help education and training in ways that go well beyond the traditional classroom.

e-Learning, or education delivered by electronic means such as the Internet, CDs, DVDs, and mobile phones, arose in the 1980s as an alternative to traditional classroom instruction. Other benefits of online education have contributed to its rapid expansion in recent years. The following are some definitions of e-learning. e-Learning uses computer network technology to convey knowledge and instructions to humans, typically over the internet.

- The term "e-learning" refers to a wide range of uses and procedures, including using many online multimedia content delivery systems, including the World Wide Web, Internet video SD-ROMs, television, and radio. All of these resources are available to students to educate themselves.
- Web-based education, computer-based education, virtual classrooms, and digital collaboration are all examples of e-learning. Content can be distributed in a variety of ways, such as on the web, intranets, wide-area networks (WANs), CDs, DVDs, radio, television, satellite, and even cassette tapes.

“The experiential aspect of online education involves motivation, interest, experimentation, and repetition.

As indicated, the four significant e-learning perspectives illustrated in Fig. 3 are equally important in making electronic devices conceivable as tools for the delivery of educational institutions, and they are interconnected. The cognitive viewpoint analyses the function of the brain and its processes in learning from a logical standpoint. Smart learning systems and adaptive learning technology can be used to optimize learners' progress in an e-learning environment based on cognitive pedagogical models; similarly, virtual (simulated) worlds and other structured learning environments can facilitate students' comprehension of the subject matter.

Social media and other collaborative platforms can be used to facilitate conversation and learning through observation and imitation, and students can be coached through the use of the system in a short amount of time.

The emotional perspective considers the feelings of the learner and their environment. The researchers highlight several emotions as closely linked to integrating cognition, motivation, and behavior. These include pride, frustration, relief, resistance, fear, expectancy, hopelessness, anxiety, confidence, a complex, and jealousy.

Focus is placed on the skills and behavioral outcomes of the learning process from a behavioral viewpoint, emphasizing role-playing and practical application in real-world scenarios. Central to the contextual view is the learners' contacts with others, their discovery of the importance of collaboration, and the impact of their peers.

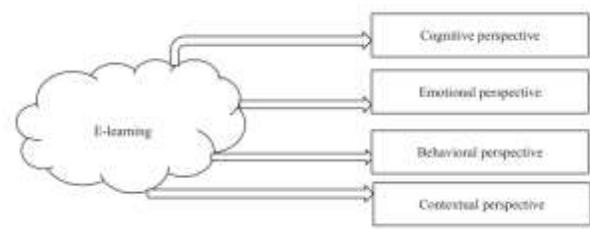

Fig. 3. Fundamental perspective of e-learning [1].

Table IV, illustrates the advantages and disadvantages of e-learning which focuses on the advantages of adopting it and as well as facing challenges by having it.

TABLE IV. ILLUSTRATES THE MOST COMMON ADVANTAGES AND DISADVANTAGES OF E-LEARNING [1]

Advantages	Disadvantages
<ul style="list-style-type: none"> <li>• Easy Access, individual instructions , different, flexibility, motivating and interesting, self-learning and self-improvement, feedback and evaluation, efficient and cost-effective strategy</li> </ul>	<ul style="list-style-type: none"> <li>• Required knowledge and skills, lack of equipment, isolation, missing social contact, negative attitude, technical defect, stressful and consumed more time, lack of co-curricular activities, lack of teacher training program</li> </ul>

### C. Challenges in e-Learning

Some difficulties arise from mediating technology [2] by putting forth consistent work overtime is the biggest obstacle to creating a learning company. Getting people interested in a new concept is straightforward, but consistently implementing it is far more challenging. When individuals are motivated and ready to learn, course content and organizational policies that are strategically aligned work together to use existing talent to accomplish corporate objectives. Administrators, instructors, and students of e-learning encounter a variety of hurdles. In the Web 0 era, students experienced a range of difficulties, including a fear of technology (7.24%) and bandwidth issues (3.0%); now, students suffer a lack of support from senior management (3.6 percent).

The current generation of e-learners has a new difficulty: getting businesses to recognize their degrees earned online. Web 0 implementation was problematic due to learners' epistemic beliefs and bandwidth availability. In seven pieces, educators from different generations of online education express their greatest worry about students' lack of willingness to learn. A designer's work is difficult due to the constant developments and upgrades of technology.

Dropout rates (11.97%) are a big obstacle for implementers. Still, dispersion in learner requirements (7.24%), synchronization of the most recent design and technology (5.07%), and unsuitable structural design (3.2%) have been significant issues for designers. 7.99 percent of firms described dealing with cultural opposition to be challenging. It has been observed that resistance to change is lessening as the Internet evolves. e-Learning stakeholders prioritized access to sophisticated technology and bandwidth for continued online course delivery (Diffusion of Innovation Theory) and the learning community's acceptance of online learning (Technology Acceptance Model).

The knowledge gap between the intended audience and the rest of the population filled by taking serious efforts. These efforts were made to make e-learning extremely interactive (Engagement theory). By keeping the goal of the learner interested and motivated (ARCS Theory). In today's world, students need to be engaged from the very beginning of a course if they are to remain motivated throughout its duration. This places a premium on the designer and implementer creating highly relevant, interactive, and individualized courses. One of the most important aspects of successful e-learning [2] is using the most appropriate and up-to-date technology for delivering the course.

This paper will adhere to the following structure. In Section III, we see an example of a research methodology with three major stages: review planning, review execution, and review reporting. Section IV presents the discussion. In Section V, the results of the chosen articles, study goals, standard processes, data formats, and performance approaches are discussed. Section VI discusses existing research, their contributions, managerial implications, and a conclusion that includes limitations and potential study pathways.

### III. RESEARCH METHODOLOGY

This Systematic Literature Review (SLR) methodology was based on the ideas presented in [30, 31]. Research is conducted in three distinct stages. As part of this preliminary preparation, we will discuss the steps of identifying research subjects, developing review procedures, and checking their accuracy. In the second, we discuss finding and choosing relevant research; in the third, we present the steps involved in writing and validating the SLR; and in the fourth, we discuss the process of information synthesis. Fig. 4 shows the progression of the three phases.

#### A. Plan Review

In this first stage of the research process, the relevant searching strategy is outlined alongside the key research questions and the establishment of review methods.

- *RQ #1*: What are the types of emotional and psychological states found and used in different types of learning?

The study's goal is to establish the utility of emotional and psychological states detected in the learning environment by organizations such as education sectors, development and training centers, and researchers for their models, frameworks, or applications. Nowadays, e-learning is being used, which has some emotional and psychological effects.

- *RQ #2*: Which type of algorithms and techniques admitted for the emotional and psychological states in e-learning platforms?

This study seeks to identify the approaches businesses, industries, and centers use in learning platforms such as online or e-learning and face-to-face learning.

- *RQ #3*: How emotional and psychological states observed/examined in e-learning platforms?

This study's subject is related to the algorithms, techniques, or models that are implemented in e-learning or face-to-face platforms, as well as identifying and evaluating the performance of these techniques in various e-learning platforms. This study aims to gain a comprehensive understanding of the procedures employed in Learning types and techniques. This review aims to look at models, frameworks, and applications that use e-learning and face-to-face approaches to address emotional and psychological difficulties.

1) *Review protocols*: The development and validation of the review protocol affirm the use of appropriate keywords to search for related articles and literature sources.

a) *Searching keywords*: To guarantee that the evaluation closely covers deep learning technologies for dental informatics, we attempted to focus our search to the most relevant specific keyword. As a result, we started with the terms and then proceeded to the next steps:

- i) Extracting the key terms from our study questions.
- ii) Using different terminology.
- iii) Adding keywords from relevant publications to our search terms.

As indicated in Table V, we used the primary alternatives and added the "OR operator" and "AND operator" to find the most immediately relevant works in the literature.

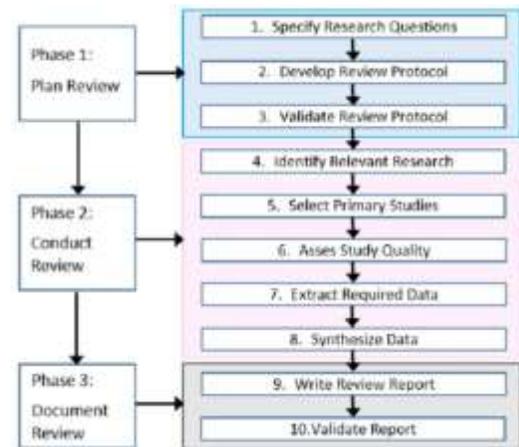

Fig. 4. SLR process.

TABLE V. INCLUSION AND EXCLUSION CRITERIA DESCRIPTION

ID	Keywords
1	("Psychological states" OR "psychological effect") AND ("Emotional states" OR "Emotions") AND ("Learning" OR "E-Learning")
2	("Psychological states" OR "psychological effect") AND ("Emotional states" OR "Emotions") AND ("Online Learning" OR "E-Learning")
3	("Psychological states" OR "psychological effect") AND ("Emotional states" OR "Emotions") AND ("Learning" OR "E-Learning") AND ("Tools" OR "Techniques")
4	("Psychological states" OR "Psychological effect") AND ("Emotional states" OR "Emotions") AND ("Learning" OR "Online Learning" OR "E-Learning") AND ("Tools" OR "Techniques")

b) *Literature resources:* The databases Web of Science, Scopus, ACM Digital Library, Springer, Science Direct, and IEEE Explorer were used to find relevant publications for primary review research. These databases, which include ISI, Scopus indexed papers, and publications from major conferences, provide the most comprehensive coverage of quality literature on our topic. The search phrase was developed by utilizing the extensive search possibilities provided by each of these databases. Our search included the years 2013 through 2022.

2) *Conduct review:* We used the research questions, keywords, and protocols as a reference to conduct the review in this step. This phase mostly deals with article inclusion and exclusion, as seen in (A) and (B) of Table VI.

TABLE VI. (A) INCLUSION CRITERIA DESCRIPTION AND (B) EXCLUSION CRITERIA DESCRIPTION

(A) Inclusion Criteria
The research was relevant to psychological and emotional states.
The research was directly related to the learning platforms.
The research was conducted using techniques and algorithms used by learning platforms.
The research is used in multiple domains.
The research was conducted for the analysis of algorithms and techniques performance in Learning Platforms.
For duplicate publications of the same study, the newest and most complete one was selected. This is recorded for only one study whose related work appeared two times.
(B) Exclusion Criteria
Studies unrelated to emotional and psychological states in dance, music, or any other field than education and health were excluded. Because traditional forecasts and visualizations are referred regarded as having "emotional and psychological effects," these results appeared in our search.

a) *Study selection:* Study selection is shown in its entirety in Fig. 5. There were a total of 1779 items found through the search. After sorting by title, keyword, and inclusion/exclusion criteria, we narrowed the list down to 150 articles. The criteria for inclusion and exclusion are listed in (A) and (B) of Table VI, respectively. Fifty-two papers were disqualified as a result of questionnaire-based predictions, and another 68 were disqualified because they dealt with other concepts, such as a theoretical model or a conceptual framework. Thirty items are crossed off the list after careful reading of the articles.

The selection criteria for relevant articles based on keywords are described in Table VI. Duplicate articles and those that do not address all of the research questions are omitted.

The quality checklist criteria for study evaluation are included in Table VII. The questions are primarily meant to assist in the selection of studies that are more relevant, thorough, and comprehensive in nature.

b) *Data extraction:* In order to obtain the data which are needed to address our research questions and contributions, we used the data-extraction methods highlighted in Table VIII.

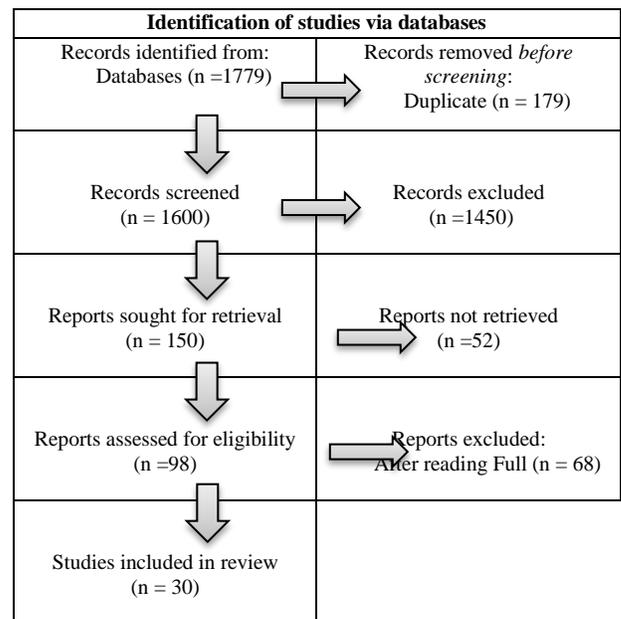

Fig. 5. Process of identifying relevant studies.

TABLE VII. QUALITY CHECKLIST

No.	Questions
1	Was there a strong focus on emotional and psychological states?
2	Was the study able to describe how emotional and psychological states is applied in learning?
3	Is there any algorithm or technique used to evaluate emotional and psychological states in education and medical learning that has been proposed?
4	Is the study concentrating on the basic learning approaches for Learning systems?
5	Is there any mention of core approaches used in the study?

TABLE VIII. DATA EXTRACTION

Study
Study Research Problem Contributions
RQ1: Psychological States
RQ2: Emotional States
RQ3: Techniques or algorithms used by learning platforms

c) *Information synthesis:* At this point, the retrieved data were pooled in order to respond to the research questions. For our research questions, we used the approach of narrative synthesis. Consequently, we used tables and graphs to describe our findings.

d) *Report review:* Four research questions were answered using information taken from primary studies. In describing the findings, strict adherence was made to the recommendations presented in [29,30].

#### IV. DISCUSSION

Emotions play an essential role in many facets of everyday life. We describe them as the predictable reactions we always have to unforeseen stimuli [32-37]. There is a short duration to these responses, which can be physical (muscle twitching,

trembling, etc.), behavioral (angry, fleeing, aggressive, immobile, etc.), physiological (sweating, redness, discomfort, pallor, accelerated pulse, palpitations, feeling ill, etc.), or psychological (positive or negative thoughts). Numerous studies have shown that emotions may alter the quality of learning if the learner's motivation is seen as a barrier to achievement [38-43]. Whether in a classroom setting, under test conditions, or in the comfort of one's own home, the process of learning is always accompanied with a complex and nuanced range of feelings [44-48]. Emotional influences on training in the workplace are the focus of this research. How emotions play a crucial role in learning, especially at a distance.

## V. RESULTS

In Table IX, 43 research met the criteria for inclusion. 15 research focused on emotional states utilized in e-learning platforms, and another 13 studies covering the various AI-based methods for assessing these states. Whereas 15 studies helped in addressing the question about the methods employed to assess mental health.

TABLE IX. RQ STUDIES

<i>RQ</i>	<i>Studies</i>
Emotional and psychological States	15
Emotional and psychological states evaluation techniques	13
Techniques or algorithms used by learning platforms	15

RQ #1: What are the types of emotional and psychological states found and used in different types of learning?

Effective feedback systems may aid in re-engaging and encouraging learners in these circumstances [32], which can eventually lead to enhanced learning. Therefore, in an e-learning situation, a successful system should be able to read the learners' emotions and evaluate their attention to deliver intelligent feedback that enhances the learners' learning experience. In e-learning circumstances, embodied conversational agents (ECAs) can give learners with effective and intelligent feedback. Sadly, creating these systems can be very difficult. Matching emotional states to facial expressions might be difficult when working with emotion recognition.

To overcome this, Paul Ekman attempted to map typical facial expressions for emotions like contempt, fear, fury, sadness, and surprise [34]. In addition, the effective identification of emotion by a computer in the late 1990s from IBM Watson was a significant milestone. Appropriate feedback systems may assist learners in regaining their footing and motivating them, eventually leading to enhanced learning. Embodied conversational agents (ECAs) [33] can provide effective and intelligent feedback in e-learning to students. Effective systems should be able to interpret learners' emotions and evaluate their attentiveness in order to deliver feedback that enhances their educational experiences.

However, developing these systems may be quite challenging. In emotion identification, it may be challenging to correlate emotional states to visual expressions. To overcome this, Paul Ekman attempted to map typical facial expressions

for emotions like contempt, fear, fury, sadness, and surprise [34]. In addition, late in the 1990s, when machines were able to identify emotion from both static photos and audio-visual input, 2 Wireless Communications and Mobile Computing drew further attention to this topic.

According to the literature, information about an individual's emotions may be gleaned by observing the face as a whole and paying close attention to the usage of the different facial muscles. [35] This is known as the sign-judgment strategy.

Using the Facial Action Coding System (FACS), facial expression action units (AUs) may be categorized and categorized according to emotion [36]. Automatic engagement recognition is another fascinating field. A real-time engagement recognition system might be used extensively in the following scenarios: (i) instructors working in distance education might get instant feedback based on their students' interest levels; (ii) participants' responses could be utilized to identify specific video segments. (iii) utilizes computer vision technologies that may evaluate student engagement in a distinct manner by examining body position, hand movements, and facial indications [37].

Learning, human intelligence, and emotion are all interconnected. Focus, learning motivation, and self-regulated learning are all impacted by emotions in learners. Through self-regulated learning and engagement, emotions, especially happy emotions, have a greater impact on academic performance. In e-learning, it is frequently seen that students become noisy during the same lectures or even courses as a result of unfavorable feelings. Additionally, associated learning material is activated in the long term memory by emotion. Positive feelings can thereby enhance students' ability to study more, perform well in assessments, and amass substantial knowledge. Numerous scientists have studied the identification of emotion in e-learning as a result of the connection between emotion and learning. Several scientists to investigate the e-ability learning's to recognize emotions.

A crucial aspect of every person is their emotional state, which affects their behavior, judgment, capacity for thought, adaptability, wellbeing, and interpersonal connections [38]. Emotions have a significant impact on human behavior, and human practices like e-learning must take this into account [39]. According to a study on the impact of experimentally induced positive and negative emotions on multimedia learning, students with the greatest previous knowledge or working skill could counterbalance the emotional influence on learning results.

According to [40, 41], e-learning promotes not just the learning process but also the connection between learning and emotion. As a consequence of the expansion of Learning Management Systems, traditional face-to-face learning is gradually being replaced by e-learning (LMS). Noteworthy is the significance of the data sources employed for emotion categorization. In typical classroom education, a teacher may alter his or her teaching style by analyzing students' facial expressions and body movements. However, this becomes difficult in e-learning situations.

According to study, a single data modality may not be able to capture the whole knowledge of the learning process. Therefore, several data sources are predicted [42, 43] to increase the accuracy of emotion classification [44]. EEG, EDA, eye tracking, audio, video, RB, and ECG are included in these data streams.

The authors of [45] also show the relevance of establishing robust user models and learning via the fusion of knowledge and technology. In reality, Learning Analytics and Knowledge (LAK) has recognized the significance of incorporating dynamic behavioral data in addition to traditional e-learning data (e.g., MOOCs, LMS data, etc.) [46]. Combining physiological data, such as electroencephalogram (EEG) or electrocardiogram (ECG), with external behaviors, such as eye movement or facial expressions, is a potential way for recording the sentiments and experiences of learners, according to [44]. According to the authors of [47], Multimodal Machine Learning (MML) is an approach for handling multimodal data sources as well as Data Harmonization of data [64].

Learning using diverse (multimodal) sources enables you to see how multiple modalities interact and provides a comprehensive understanding of how natural events operate. Recent research [48] indicates that incorporating multimodal data boosts accuracy and provides a better knowledge of the learner's emotions and experiences. Appendix A discusses the RQ1 in further detail.

RQ #2: How emotional and psychological states observed/examined in e-learning platforms?

This research question aims to identify how emotional and psychological states are measured by the techniques or algorithms used to measure them. Selected studies in this Research question show that the e-learning domain is used as it shows a high impact on higher education institutes. State types shown in Appendix B are both psychological and emotional as education institutes implemented it to understand e-learning's impact on students ethically and morally. The learning type mentioned in these studies is e-learning.

Whereas the techniques used to identify the states are diverse, such as AI, ML, DL, Signal system, mathematical representation. The techniques under AI, ML and DL are BiLSTM, Feed-Forward Neural Network, Hierarchical attention network, CNN, DESNet, SVM, Naïve Bayes, Logistic regression, Linear SVC and multinomial NB, Random Forests. Signal systems uses the concept of mathematical representations to measure the states. The techniques or methods are Gaussian mixing model (GMM), Partial least square structural equation modeling method, Gabor filter bank, MFCC features.

RQ #3: Which type of algorithms and techniques admitted for the emotional and psychological states in e-learning platforms?

Algorithm and techniques adopted by e-learning platforms for emotional and psychological states shown in Appendix C.

#### A. Contribution

To the best of my knowledge, this is the first SLR to discuss the emotional and psychological states as one unit, the

mathematical methods, and signal and AI-based techniques applied in e-learning platforms. The main scientific contribution of this SLR is that it will be helpful for the government to adopt measures for mental health by putting criteria for psychological and emotional states. As well as practically implemented in Higher Education Institutes to check teaching and learning performance. Also, this SLR focuses only on the AI and related tools which are widely used nowadays and help organizations to implement emotional and psychological state measures while teaching and conducting training through e-learning platforms.

Based on the findings and discussion, the information provided by this SLR will be helpful for researchers and stakeholders in applying these approaches and techniques, which deal with the wide variety of e-learning training and webinars. As previously said, the most current approaches for machine learning, deep learning, and neural networks would aid in retrieving, representing, and displaying recently used data.

#### B. Implication for Practice

This study has several practical implications on the provision of e-learning platform technology in higher education institutions and training institutes around the globe. It will help the government reduce the percentage of psychological and emotional pressure in youth and young children and helps in making work balance environment in all organizations in the country. Also, it will enhance the learning capabilities in students and teachers by adopting the latest tools and techniques that are mentioned in Appendix B and C.

#### C. Limitations

Only e-learning department was targeted, and the major focus was health and education. The studies are excluded related to learning dance, music, art, craft, sports and so on. The included studies are only that are written in English. The studies that only focuses on implementation of AI algorithms are included and all theoretical and conceptual models are excluded.

#### D. Future Suggestions

Emotional and psychological factors affect the public due to sudden changes in state and federal governing bodies. Emotional and psychological factors effects on public due to the retirement of favorite players from sports, politics, school, college or university. Emotional and psychological factors affect public due to inflation rate and change in prices in daily use items. Emotional and psychological factors effects on public due to political and shocking news related to interfaith harmony.

In addition, comparative research based on online, hybrid/blended formats are required to understand how the outcomes vary and how these changes impact the e-learning design framework. Comparative studies of the effectiveness of e-learning systems at various levels, such as the impact felt by learners vs. the effects experienced by instructors, are necessary.

## VI. CONCLUSION

Education may be improved, streamlined, and made more effective through an online learning platform. The development of e-learning has made it possible for students to get an education whenever and wherever they like. They make it possible to receive customized instruction and information at any time. These online instructional methods profoundly influence learners' mental and emotional states, affecting their skills and motivation. Distance between tutor and student, both in terms of space and time, makes it difficult to inspire students, who may experience a range of emotions from annoyance to uncertainty to ambivalence.

The student's motivation to learn, as well as his or her emotional and psychological well-being, will take a serious hit as a result, both during and after the class. This study aimed to investigate the techniques now employed by academic institutions for analyzing human sentiments and mental states. Only e-learning, alongside other fundamental technologies like machine learning, deep learning, signal processing, and mathematical techniques, has been employed in the field of education, as shown by the results.

These strategies are employed in a wide range of practical applications, emphasizing online education. The most common research techniques are analyzed, and each topic is presented in detail. In conclusion, we offer a detailed assessment of the state of the art, our contributions, and their implications, as well as our limitations and recommendations for future study.

**Abstract**—To support a wide range of applications, cloud computing has a variety of services. It has a number of positive acceptance tales as well as a couple of negative ones including security breaches. The versatile usage of cloud services to store sensitive and personal data in cloud become hesitated by many organizations because of security issues. A new model of relying on a third-party auditor (TPA) has been adopted to improve trust and entice adoption between cloud clients (CC). Hence, we require a dynamic approach to control the privacy and integrity problem that occur across the cloud computing. Decentralized Attribute based encryption techniques and FHE approach is used to overwhelmed the issues. In this proposed scheme, the integrity checking is verified and auditor by the TPA without have any knowledge of the data content and double encryption is performed on the data stored in cloud. the data owner encrypts the data using ABK-XE (Attribute Based Key generation with XOR encryption) technique and send it to tag server whose encrypt the data again using ECEA (Elliptical Curve Elgamal) algorithm and generate the signature and unique ID using SHA-1 algorithm then store the data in Cloud Environment. The proposed algorithm is an integration of auditing scheme with Symmetric key Encryption and Homomorphic Encryption.

**Keywords**—Cloud computing; data integrity; ABK-XE; ECEA Algorithm; SHAI

## I. INTRODUCTION

Cloud computing [1] is a ground-breaking computing model that has caught the interest of individuals from various fields, including academia and industry. Cloud computing is a large-scale distributed computing paradigm driven by economies of scale in which a pool of abstracted, virtualized, constantly increasing, managed computing power, storage, platforms, and services is supplied on demand to external clients through the Internet [2].

The fundamental component of the cloud is cloud storage, which directs the user's attention to data storage. However, the cloud server is not completely trustworthy, therefore the user confronts several security risks and problems while storing data in the cloud [3]. Data integrity is among the most serious privacy concerns since data hosted on cloud servers is not physically possessed by users and they have no control over it. While some people are prepared to give up their privacy in exchange for the benefits of software services, businesses and governments will never do so [4]. The integrity checking technique provides an efficient approach to examine the data

integrity on a cloud server. The client sends an integrity challenge to the cloud server, which creates a proof of the original data. If the evidence passes the verification procedure, the data is shown to be complete. Although numerous systems have been developed to assist data owners in ensuring the integrity of their data. Nonetheless, there are certain difficulties to be addressed. When the integrity verification is taking place, the public verifier is generally interested in the client data and attempts to get it. It is extremely risky for the owner to keep the data secret in light of the aforementioned issues. Encryption of the data is the simple way to make data secure but this method is not at all a good choice for the data user.

To solve the aforementioned issue, this work proposes an effective double encryption technique, and the verification process is done without knowledge of the original data, i.e., it is hidden from the public verifier. The contribution to the paper is listed:

- 1) A thorough understanding about the elliptical curve encryption.
- 2) A privacy preservation system with two tier encryption methodology.
- 3) Detail study about the existing system and usage of bilinear mapping, signing and verifying system.

The remainder of the paper is organized as follows. Section 2 gives a synopsis of the related research. The technique and mathematical formula are described in Section 3. Section 4: Explain the proposed system and its details. Section 5 examines and compares the performance of our system to that of other plans. Section 6 finishes with conclusions.

## II. RELATED WORK

Juels et al. [5] suggested the idea of “proof of retrievability (PoRs)”. This system not only validates the integrity of data saved in the cloud, but it also assures data retrievability through the use of error-correcting code. Nonetheless, it Private audit is performed.

Yu et al. [6] introduced the ID-based RDIC and its security architecture, which featured protection against a rogue cloud server and privacy from an external auditor with zero knowledge. The RDIC protocol does not leave information about the stored data auditor during the DRIC operation. In the generic group template, the new structure is proven to be

secure against a rogue server and achieves zero knowledge confidentiality against an auditor.

Ateniese et al. [7] developed a “Provable data Possession” (PDP) paradigm to achieve data integrity. The author [8] presented Another scheme scalable PDP scheme, which allows for block adding, updating, and deletion.

Sasikala et al. [9] presented a Remote Data Integrity Checking (RDIC) is critical for developing safe cloud storage. It allows users to validate the integrity of outsourced data without downloading the full file. The author also evaluated and assessed current RDIC techniques based on factors such as integrity testing method, cryptographic model, auditing mode, and data recovery. Finally, it sheds insight on unresolved topics such as research directions in the design of the RDIC procedure.

Yong et al. [10] presented an attribute-based cloud information integrity auditing protocol to reduce key management difficulties. The suggested technique requires significantly less calculation in validating the auditing reaction, resulting in reduced time consumption.

Yannan Li et al. [11] explored the difficult key management problem in cloud data integrity checking by presenting fuzzy identity-based auditing. Author introduced the concept of fuzzy identity-based data auditing, in which a user's identity may be regarded as a set of descriptive properties.

Feng et al. [13] provided a public remote integrity checking technique that protects user identification. This scheme, however, only supports file-level integrity verification.

Yu et al. [14] presented a novel identity-based public RDIC system that protects data privacy. However, the integrity testing of this technique necessitated a significant computational cost.

Tong et al. [15] devised a technique that delivers indistinguishable privacy (IND-privacy) as compared to TPA for both data content and timestamp. It build the authenticator with the randomizable structure-preserving signature to connect the content and timestamp in the authenticator and allow efficient timestamp updating (SPS). Furthermore, in the auditing phase, they use the Groth-Sahai proof and range proof to offer IND-privacy and ensure timestamp validity.

Zhang et al. [16] developed an RDIC technique that uses indistinguishability obfuscation to preserve data privacy while improving performance. However, this method is rigid and difficult to implement in practice.

Chen et al. [17] introduced a public verification technique based on algebraic signatures that employed a short bit string compressed by a data block to accomplish efficient integrity verification without comparing to original data. Unfortunately, it is vulnerable to a replay attack. It also does not enable dynamic data update.

### III. METHODOLOGY

It is necessary to develop a powerful audit model that solves the issue related to the existing system. The proposed

model is made in such a way that the cloud user (CU) can stored the data without heisting, since the data is stored in encrypted form (Fig. 2). The CU can send request to verify the data integrity through TPA. The TPA only send the request and accept the response from the proof-server (PS) without having a computational overhead. Also, it will not provide any information related to use file that is stored in cloud database (CS).

#### A. Preliminaries

Some of the basic Mathematical approach used in the auditing schemes and in the system model.

1) *Bilinear maps*: A bilinear mapping  $e: G_1 \times G_2 \rightarrow G_t$  where  $G_t$  is the multiplicative cyclic group of prime  $p$  with following properties.

- a)  $e$  is bilinear for all  $a, b \in Z_p$
- b)  $e$  is non-degenerate
- c)  $e$  is efficiently computable.

2) *Elliptic curve Elgamal Algorithm (ECEA)*: The Elliptical curve [12] with Elgamal algorithm converts the plaintext  $M$  to a point  $P_m$  on the elliptical curve  $E$ . The arithmetic operation on elliptical curve is as follows:

a) *Addition of two points*: Suppose  $A = \{X_a, Y_a\}$  and  $B = \{X_b, Y_b\}$ , where  $A \neq B$  that lie on elliptical curve  $e$ . the sum of  $A + B$  reults a third point  $C \{X_c, Y_c\}$  as shown in Fig. 1.

b) *Double pointing*: Let  $A = \{X_a, Y_a\}$  be a point lies on  $e$  adding the point  $A$  to itself is called Double pointing.

$$P + P = 2P$$

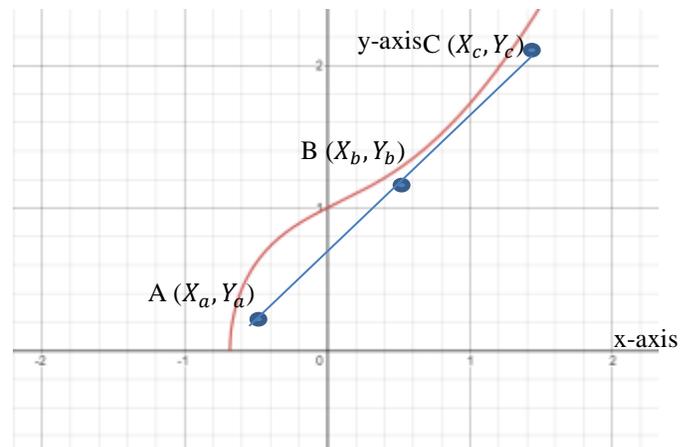

Fig. 1. Elliptical curve of  $A + B = C$ .

c) *Multiplication*: Suppose  $k$  is an integer  $A$  is a point  $(X_a, Y_a)$  then,

$$K_p = \frac{A + \dots + A}{K \text{ times}}$$

So, in this proposed scheme, the computation speed on the ECEA is reduced by using decimal representation of message. So that double pointing and addition operation can be avoided. This scheme involves the following procedures as; Suppose user  $A$  and  $B$  wishes to communicate with each other. The common parameter known by both users will be  $p$  and  $G$ , where  $p$  is the prime number and  $G$  is the base point in the

elliptical curve. Let user A and B choose their private key  $\alpha_a$  and  $\alpha_b$  over an interval  $[1, p-1]$  and generate the public key  $\beta_a = \alpha_a G$  and  $\beta_b = \alpha_b G$ .

The message or file M is divided into n block  $m_1, m_2, \dots, m_n$  which is then convert into decimal values  $d_1, d_2, \dots, d_n$  respectively such that the multiplication of basepoint and the decimal point transform to a point in E as:

$$\begin{aligned} p_{d1} &= d_1 G \\ p_{d2} &= d_2 G \\ &\vdots \\ p_{dn} &= d_n G \end{aligned}$$

Then user A computes the secret key K by multiplying with private key  $\alpha_a$  and B's Public key  $\beta_b$  as:

$$K = \alpha_a * \beta_b$$

This k value is added with the Decimal elliptical point to obtain cipher text as:

$$\begin{aligned} C_1 &= p_{d1} + K \\ C_2 &= p_{d2} + K \\ &\vdots \\ &\vdots \\ &\vdots \end{aligned}$$

$$C_n = p_{dn} + K$$

Therefore, the cipher text  $C = \{C_1, C_2, \dots, C_n\}$ . The plain text is obtaining by subtracting the secret key K as:

$K' = \alpha_b * \beta_a$  performing the following operation as:

$$\begin{aligned} p_{d1} &= C_1 - K' \\ p_{d2} &= C_2 - K' \\ &\vdots \\ &\vdots \\ p_{dn} &= C_n - K' \end{aligned}$$

Thus, obtain decimal values is converted to original values  $m_1, m_2, \dots, m_n$ .

**Proof,**

$$\begin{aligned} C_1 - K' &= C_1 - \alpha_b * \beta_a && (\because K' = \alpha_b * \beta_a) \\ &\Rightarrow p_{d1} + K - \alpha_b * \beta_a && (\because C_1 = p_{d1} + K) \\ &\Rightarrow p_{d1} + \alpha_a * \beta_b - \alpha_b * \beta_a && (\because K = \alpha_a * \beta_b) \\ &\Rightarrow p_{d1} + \alpha_a * \alpha_b G - \alpha_b * \alpha_b G \\ &&& (\because \beta_a = \alpha_a G \\ &&& \beta_b = \alpha_b G) \\ &\Rightarrow p_{d1} + \alpha_a * \alpha_b G - \alpha_b * \alpha_b G \\ &\Rightarrow p_{d1} \end{aligned}$$

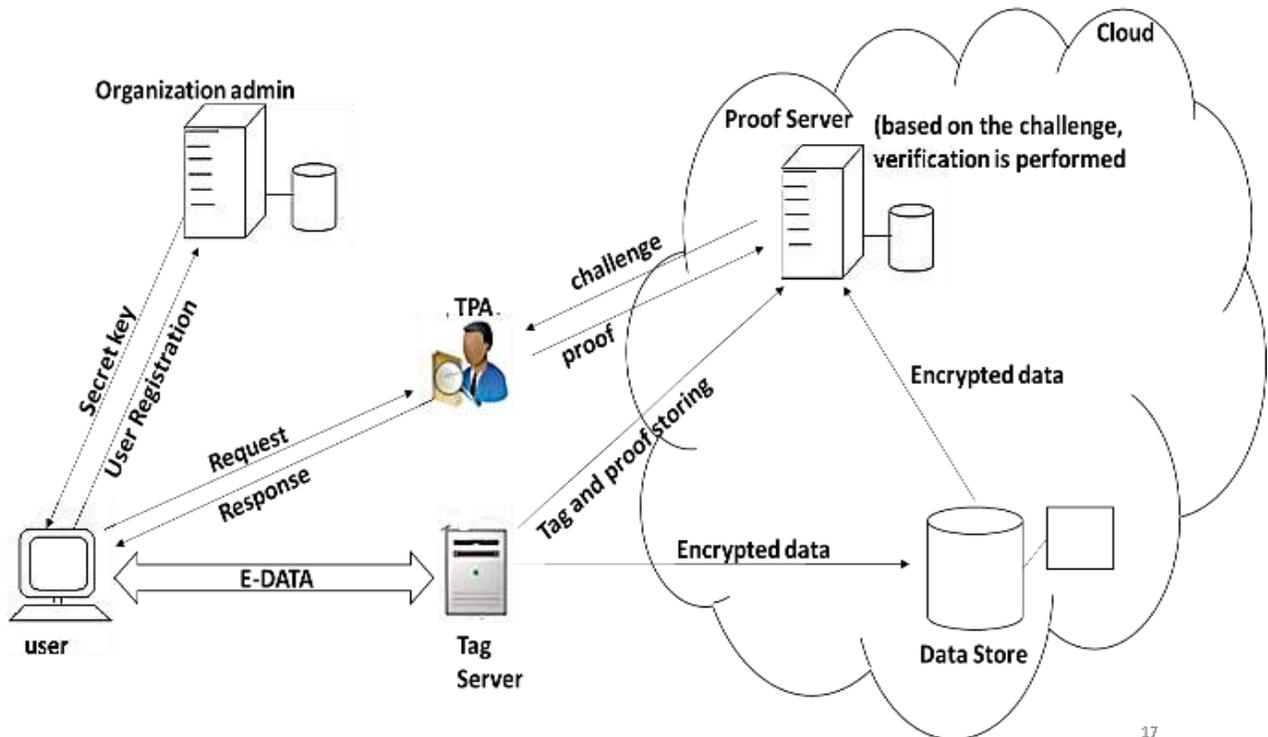

Fig. 2. Proposed system.

#### IV. PROPOSED SCHEME

The proposed scheme shows a threshold hybrid combination of encryption; this scheme is divided into CU encryption. TagServer processing, PS verification, TPA challenges.

1) *CU encryption*: In this cloud User (CU) encryption the file or data that he/she wishes to store in cloud by using its attribute UID and PW. This encryption/decryption is divided into two phases:

a) *Key generation process*: This generates a symmetric key based on user attributes:

- i. User will provide its password as the seed value, that will be convert into byte form as:

$$\text{byte } b[] = \text{byte}(\text{PW})$$

- ii. Calculate the sum as:

$$B = \sum_{i=0}^{b.length} b(i)$$

- iii. Applying log function and convert the value to a factor of 64

$$k_b = \log B$$

- iv. Using the bilinear paring the  $b(i)$  will be multiplied by  $k_b$  so that we obtain the symmetric key array  $A[i]$ ,

for each  $i = 0$  to  $b.length$

$$A[i] = k_b * b(i) \text{ mod } 64$$

end

b) *Encryption process*: The generated key  $A[i]$  will be XoR with the file  $F = \{f_1, f_2, \dots, \dots, f_n\}$  as follows.

- i. The file  $F$  is divided into  $n$  blocks of size 64 bits as  $= \{f_1, f_2, \dots, \dots, f_n\}$ , the last is padded with zeros if required.
- ii. Each block is XoR with the symmetric key as:

$$C[i] = \sum_{i=1}^n f[i] * A[i]$$

- iii. This obtain  $C(i)$  will be combined together to form the encrypted file  $E_A(F)$

The above algorithm is shown in Fig. 3.

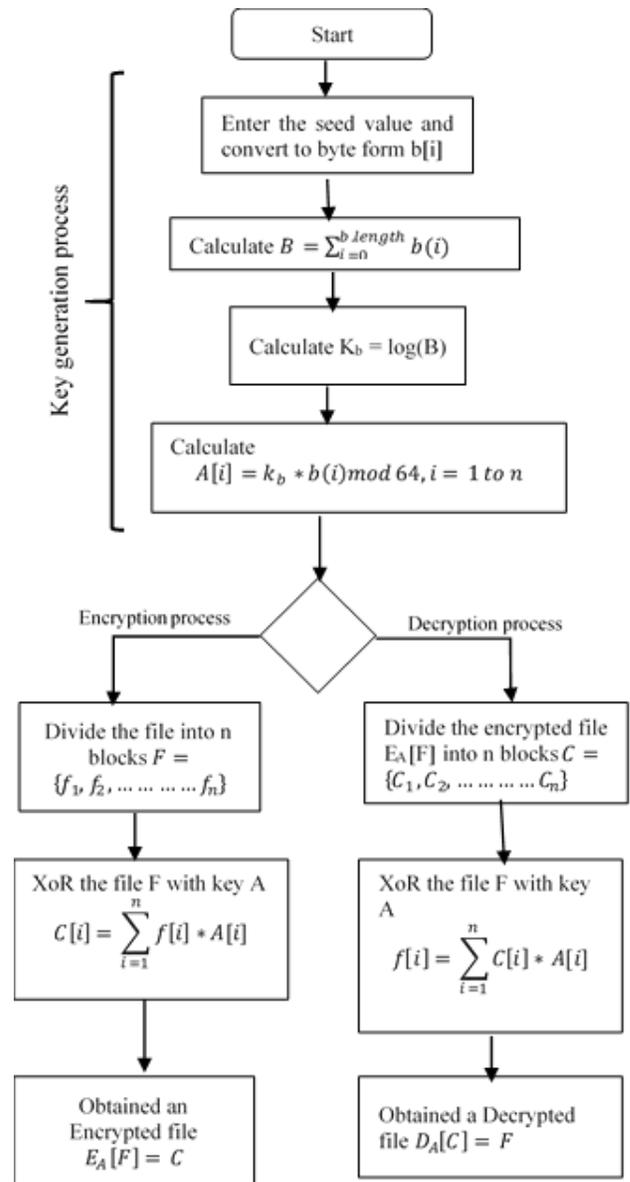

Fig. 3. User side encryption and decryption process.

2) *TagServer Processing (TSP)*: TSP plays a curial role in the scheme. Here the encrypted file  $E_A[F]$  received from the user undergoes ECEA encryption process and obtain the encrypted form as  $C^* = \text{Encrypt}_{ECEA}(E_A[F])$ . Then TSP calculates the Signature of the encrypted file  $C^*$  by using SHA-1 algorithm. Thus, signature digest is of the form 160-bit represented as  $Sig_{C^*} = MD(C^*)$ . TSP transfers the encrypted file  $C^*$  to cloud data store; also store the signature along with the unique file Id  $(Sig_{C^*} | F_{id})$ . TSP also send its public key and file Id to cloud user so that the CU can decrypt the file directly from the data store  $(F_{id} | \beta_b | T_1)$  as shown in Fig. 4.

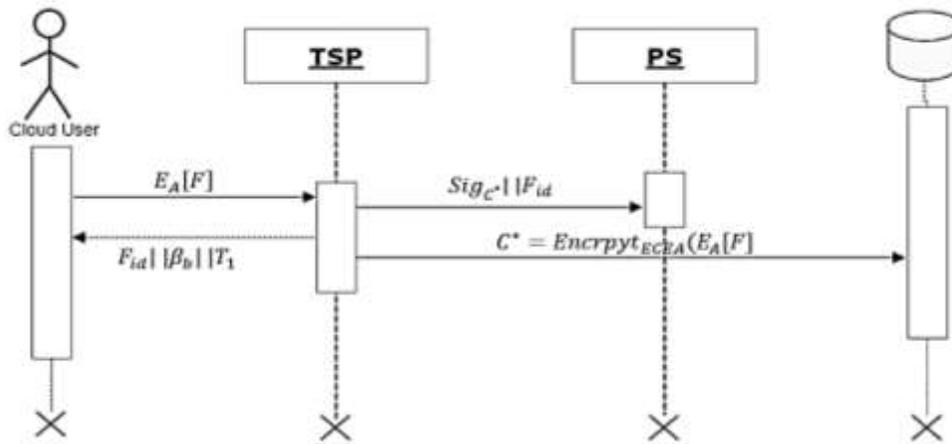

Fig. 4. Working of TSP.

3) *TPA challenges and Proof Server verification*: When the cloud user CU require to verify the file, it sends a challenge request to TPA as  $ChalR_Q = F_{id} || ID_{cu} || T_2$ . The auditing of the file is performed by sending a request to the TPA by the cloud user CU. The receive request  $ChalR_Q$  will be transmitted to proof Server PS.

The PS Retrieve the file from the data store using the  $F_{id}$ , compute the signature of the file  $Sig_{C^*}$  using SHA-1 Algorithm

and compare the signature store by TSP ( $Sig_{C^*}$ ) and new compute signature  $Sig_{C^*}^1$ . This comparison declared that the file stored in the data store is altered or not. This response  $Res_Q$  will be intimated to TPA which then forward to CU with the assurance of it file integrity is maintained.

Here the TPA and PS doesn't have direct access to the original file F so the semi trust issues is solved by using this scheme also it provides high assurance of data integrity in the cloud environment as shown in Fig. 5.

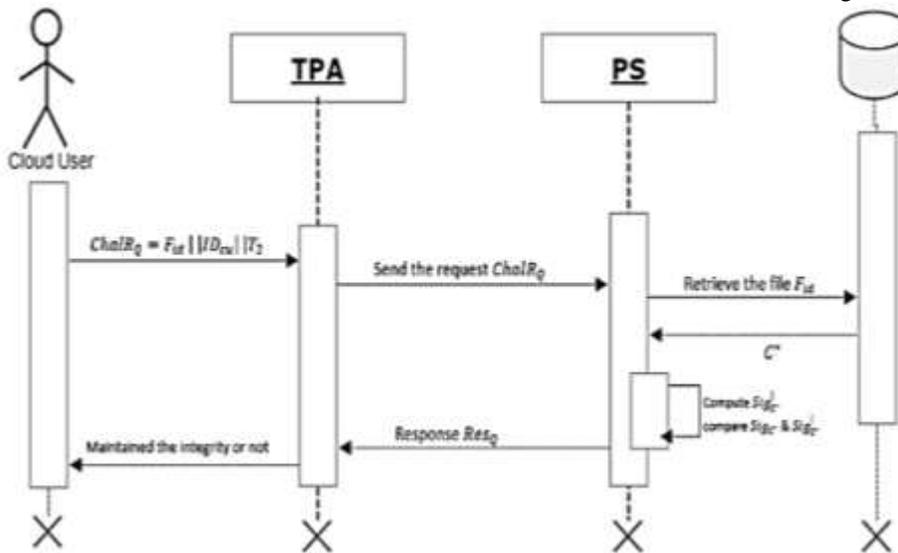

Fig. 5. Working process of TPA and PS.

## V. PERFORMANCE EVALUATION

The proposed scheme performance is summarized as follows.

### A. Computation Cost

The above specified algorithm contains operations such as multiplication, paring operation, addition and subtraction operation with the time  $T_m, T_p, T_a, T_s$  on the curve G respectively. The Time taken for other operation such as hash function and logarithm is were less so the computation cost for such operation can be negligible cost. Suppose the cloud user

contain  $m$  blocks in total,  $cl$  challenge is passed to TPA for checking the integrity of data block in cloud. The computation cost in TagServer algorithm for encrypting to run  $m$  times to encrypted the  $m$  blocks and generated the signature is  $(T_m(m + 1)) + mT_a$ . The computation cost at TPA to transfer the challenge is negligible cost. The computation cost at the proof Server is  $(cl + 1)T_m + clT_a$ . The verification cost of the proposed scheme is  $T_p + (cl + 1)T_m + clT_a$ . The decryption algorithm computation cost is  $(T_m(m + 1)) + mT_s$ . The below Table I shows the computation cost of our proposed model with Scheme [13] and [15].

TABLE I COMPUTATION COST COMPARISON

COST	SCHEMES		
	[13]	[15]	Proposed model
Encryption cost	$2T_{ex} + T_m$	$2T_{exp} + T_m$	$(T_m(m + 1)) + mT_a$
Proofgeneration	$2T_p + (cl + 1)T_{ex} + clT_m$	$(cl + 1)T_{ex} + (cll - 1)T_m$	$(cl + 1)T_m + clT_a$
Verification process	$clT_p + (cl + 1)T_{ex}$	$2T_p + (cl + 2)T_{ex} + (cl + 1)T_m$	$T_p + (cl + 1)T_m + clT_a$
Decryption process	$2T_{ex} - 1 + T_m$	$2T_{exp} - 1 + T_m$	$(T_m(m + 1)) + mT_s$

**B. Experimental Results**

To evaluate the efficiency of the proposed model, the model and compared model is implemented in Intel i5 core with windows 10 operating system, 8GB RAM and 1TBB hard disk. All the experiment was carried out by using different User of cloud environment for which the minimum configuration of 1 CPU is to make the research cost effective. It is simulated using CloudSim with NetBeans framework (Java language).

The main section of the proposed system is the encryption of encrypted file and generation of signature done by the tag server; verification of data integrity performs by the proof server. This scheme is evaluated by considering variable size block from 1KB to 100KB, as a result its encryption time, siggeneration time, sigverification time is obtained in millisecond(ms) as shown in the Table II. This result show that as the block size increases the encryption, signature generation or verifying time is less than the time taken for the 1 KB block. The result of the proposed scheme is shown in Fig. 6 and 7.

The efficiency of algorithm used for proof generation and verification is evaluated. Furthermore, we implemented the scheme [13] and [15] under the same experiment setting and make an efficiency comparison with each other. In the experiment the number of challenges in the system is increased. Thus, the result which is illustrated in Fig. 8 shows the efficiency of the algorithm when the challenges has increased from 100- 1000. Fig. 8 shows our scheme is little more efficient than the scheme [13] and [15] in proof generation. From Fig. 9, the verification purpose our scheme requires 5 second for 1000 challenge block and scheme [15] and [13] require almost 6.1 second for the same block.

TABLE II PROPOSED SYSTEM TIME COMPLEXITIES

Block size	TIME		
	Encrypting time	Proof generation	Proof verification
1 KB	185417	1138	1690
10 KB	183250	938	1234

## VI. CONCLUSION

In cloud environment, data privacy is very much essential one. In this paper, we have proposed a technique which is a combination of symmetric and asymmetric encryption. The proposed scheme is a combination of XoR encryption and ECEA encryption with SHA-1 algorithm, which is suitable for integrity auditing of data stored in cloud computing. The existing schemes are meant to provide integrity maintenance for numerous data stored in cloud, but it doesn't provide dynamic data operation, data are visible to TPA totally.

The proposed scheme preserved the confidentiality of the file attributes and simplified the key management system in the traditional cloud facts. This scheme efficiently and effectively supports auditing tasks such as guaranteeing the TPA integrity, secure storage, overall control in the system. The result of the implementation which is shown above defines that the proposed scheme provides 0.1% more security than the existing protocols. This paper explains the complete details about the construction, implementation and experimental results of the proposed model.

# Design of a Hybrid Recommendation Algorithm based on Multi-objective Collaborative Filtering for Massive Cloud Data

Xiaoli Zhou

Sichuan Top IT Vocational Institute, School of Information Engineering, Chengdu, 610000, China

**Abstract**—The current recommendation technology has some problems, such as lack of timeliness, the contradiction between recommendation diversity and accuracy. In order to solve the problem of lack of timeliness, the time factor is introduced when constructing the self-preference model. The cold start problem in the collaborative filtering algorithm is solved by the hybrid similarity calculation method, and the potential preference model is constructed. The two are fused to obtain a hybrid recommendation algorithm to improve the recommendation performance of the algorithm. For the problem of multi-objective contradiction, the NNIA algorithm is used to further optimize the candidate results of mixed recommendation, and the final recommendation list is obtained. Through verification experiments, the results show that the recall rate and accuracy of the fused preference model are better than those of the non-fused model, and the accuracy is 9.57% and 8.23% higher than that of SPM and PPM, and the recall rate is 9.97% and 7.65% higher, respectively. CBCF-NNIA algorithm has high accuracy and diversity of recommendation, and can provide users with rich and diverse text content to meet their own needs.

**Keywords**—Self preference; collaborative filtering; potential preferences; mixed recommendation; multi-objective optimization

## I. INTRODUCTION

With the advent of the information age, data has become a decisive factor in the development of the industry, and any decision needs to rely on data to speak. In the face of massive data resources, storing them in the cloud to form cloud data that is easy to manage is beneficial for users to access relevant information [1]. The constant development of current Internet technology and communication technology has led to a rapid increase in the amount and speed of information and data dissemination, making it impossible for users to precisely find useful information and making a large amount of information unavailable, which leads to information overload [2]. The personalized recommendation system can analyze the user's interest preferences according to the user's behavior habits, and recommend the content related to the user's interest to the user without the user's initiative to provide information. The excellent performance makes the recommendation system widely used in many fields [3-4]. At present, there are many commonly used recommendation methods. Collaborative Filtering (CF) recommendation is the earliest recommendation method. However, with the growth of data size, data sparsity, system could start and other problems are unavoidable. The hybrid recommendation algorithm can integrate multiple recommendation algorithms, and research the combination of

collaborative filtering and content recommendation method to form a cascade hybrid recommendation algorithm. It is expected that the hybrid recommendation algorithm can effectively alleviate the cold start problem of the system and improve the accuracy of the recommendation results. In view of the contradiction between the diversity and accuracy of the recommendation results, the multi-objective immune optimization algorithm is studied and introduced to further optimize the recommendation list. It is expected that this method can find the best recommendation results, which can achieve the diversity of the results while ensuring the accuracy of the recommendation, and meet the multiple needs of users.

## II. RELATED WORK

The research team of Tian proposes a book recommendation system based on a hybrid recommendation algorithm to address the problem of users finding appropriate books quickly. The system combines collaborative filtering with content recommendation algorithms, improves the user item rating matrix, and uses clustering algorithms to solve the data sparsity problem. Through practical application, the results show that the hybrid recommendation method studied can provide users with more accurate book recommendations [5]. Wang scholars have studied a hybrid recommendation algorithm based on interest models in order to improve user satisfaction on e-commerce websites. The algorithm uses collaborative filtering to mine users' potential interests and a content recommendation algorithm to construct a model of users' existing interests, and the two are combined to recommend highly accurate and interesting products for users. Experimental results show that the hybrid recommendation algorithm can provide a better service experience for users [6]. Jiao W et al. faced the problems of data sparsity and cold start in traditional recommendation algorithms and used K-means, weighting for optimization, while introducing adjustment factors to combine collaborative filtering with dichotomous networks. Relevant experimental data show that the hybrid recommendation algorithm studied is operable and has better recommendation accuracy than the comparison algorithm [7]. Liu et al. propose a personalized service recommendation system in order to improve the competitiveness of manufacturing service platforms, and use a hybrid algorithm to solve the composite service problem. In this algorithm, customer preferences are quantified by clustering, and composite services are optimally ranked by ranking genetics. The analysis results of real cases show that the performance of

the studied recommendation algorithm is good and has some practical value [8].

Nafis et al. studied a travel platform based on a hybrid recommendation algorithm in order to help tourists make personalized travel plans. The platform can recommend relevant resources according to tourists' preferred tourist attractions, and through relevant experimental analysis, the platform provides high accuracy of information resources, which can effectively promote the development of read tourism [9]. Pirasteh et al. team members addressed the situation that collaborative filtering has a cold start, which leads to poor recommendation effect, by capturing various similarities between items and finding out hidden preferences in items to alleviate the problem due to the number of items. The team members have been able to mitigate the low quality of recommendations due to insufficient number of items by capturing various similarities between items and finding hidden preferences in items. Simulation experimental data show that the diversity of similarities can provide more reliable results for users and achieve high quality personalized recommendations [10]. Hu The researchers studied an improved particle swarm optimization algorithm based on multiple criteria combined with diverse adaptations, while using bacterial foraging to improve the convergence of the algorithm in the face of problems such as multi-objective contradictions and unsatisfied constraints in solving hybrid recommendation models. The experimental results show that the convergence and diversity of the studied algorithm are better than the comparison algorithm, and the results of the recommended model solving are highly accurate, have wide coverage, and can provide users with diverse results [11]. Ajaegbu scholars propose an algorithm to improve similarity measurement based on traditional measures in order to alleviate the problems of data sparsity and cold start of collaborative filtering. The performance of the algorithm is analyzed on different data, and experimental results show that the algorithm retains the advantages of existing measures while mitigating the disadvantages of traditional methods [12].

By summarizing the achievements of domestic and foreign researchers, researchers have proposed different improvement measures for the shortcomings of existing recommendation algorithms. Among them, the hybrid recommendation algorithm can effectively integrate the advantages and disadvantages of different recommendation algorithms to achieve accurate and efficient target recommendation, but the contradiction between accuracy and diversity needs further research. Therefore, the research will combine content-based recommendation and collaborative filtering to form a cascaded hybrid recommendation algorithm in order to achieve highly accurate recommendation results. At the same time, in the face of the contradiction between diversity and accuracy, the immune optimization algorithm is introduced into the recommendation results. It is expected that the multi-objective hybrid recommendation algorithm studied can achieve accurate recommendation and multiple needs of users.

### III. HYBRID RECOMMENDATION ALGORITHM FOR CLOUD DATA BASED ON MULTI-OBJECTIVE COLLABORATIVE FILTERING

#### A Recommendation Algorithms based on Own Preference Models

The rapid development of information technology has intensified the problem of data overload, and the massive amount of data has caused many problems for users. In the constant search for solutions, personalized recommendation has emerged, and recommendation systems can effectively filter distracting information and improve data usage [13-14]. Collaborative filtering is a classical algorithm in recommendation systems. The core idea is to find the nearest neighbors by calculating the similarity, and to find the content of interest to the user in the nearest neighbors and recommend it to the target user. Commonly used calculation formulas are such as modified cosine similarity, Pearson, Jaccard similarity, etc. Through similar user groups, some potentially preferred content will also be recommended to the target customer, reflecting the diversity of recommendation results of collaborative filtering [15-16]. As the data expands, the likelihood of different users being interested in the same content among themselves gradually decreases, and the problem of data sparsity cannot be avoided. In addition, when a new user or item appears, relevant attribute information does not exist and the system is unable to make a recommendation resulting in a cold start problem. In the field of textual data recommendation, Content Based Recommendations (CBR) is based on the analysis of users' historical data, and by constructing interest models, the similarity between the interest model and the content of the item reflects the user's preference for the content. However, the recommendation results lack some diversity and cannot effectively explore the potential preferences of users [17]. Therefore, in the field of text data recommendation, research will combine CBR and CF to form a hybrid recommendation algorithm, effectively integrate the advantages of the two, and achieve personalized and diversified content recommendation. At the same time, there is a contradiction between the diversity and accuracy of the recommendation results. In order to alleviate the contradiction between the two, the text data recommendation problem is transformed into a multi-objective optimization problem through modeling, and the immune optimization algorithm is used to optimize the candidate text set to generate the final recommendation list.

The Self Preference Model (SPM) is built on the basis of CBR, which can intuitively reflect the user's own interests, and the whole construction process is shown in Fig. 1. The text features are obtained by pre-processing the user's browsing history, using a vector space model to represent the text features, introducing a time factor to adjust the text model, and finally obtaining the user's own preference model.

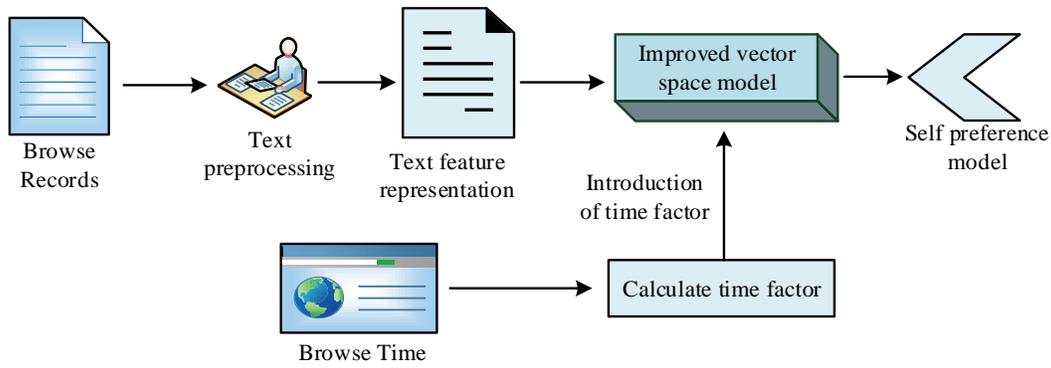

Fig. 1. Construction process of self-preference model.

In the text pre-processing stage, special characters such as emoticons and face characters are removed, and then the text is divided into sequences of word order using the word separation technique jieba. To avoid excessive word sequences that increase the computational effort, meaningless word sequences such as conjunctions, auxiliaries and stop words are usually screened out of the feature word sequences, while verbs, nouns and adjectives are retained in the word sequences. Representation of text features is a key technique in CBR, where key content features are used to represent text information and build a text model. Suppose there is a text dataset  $H = \{h_1, \dots, h_a, \dots, h_m\}$ ,  $m$  is the total amount of text, after the textual sub-word processing, the main feature word order of the text set is  $g$  dimensional composition vector  $F = \{f_1, \dots, f_j, \dots, f_g\}$ , the feature vector of any text  $h_a$  is  $h_a = \{w_{a1}, \dots, w_{aj}, \dots, w_{ag}\}$ ,  $w_{aj}$  represents the weight of the feature word in the text  $h_a$ , the higher the weight value, the more important the feature word  $f_j$  in the text  $h_a$ . The TF-IDF (Term Frequency-Inverse Document Frequency) representation is often used to calculate the weights of feature word sequences in different texts, and the TF is used to count the frequency of feature words in a text set.

$$TF(a, j) = \frac{f(a, j)}{\max Others(a, j)} \quad (1)$$

In eq. (1),  $TF(a, j)$  is the frequency of the feature word in the text  $h_a$ ,  $f(a, j)$  is the absolute frequency of the feature word in the text  $h_a$ , and  $\max Others(a, j)$  is the most frequent feature word in the text  $h_a$ . The IDF is used to represent the distribution of the feature word in the document and to count the frequency of the feature word, which is calculated in eq. (2).

$$IDF(j) = \log\left(\frac{M}{M(j)}\right) \quad (2)$$

In eq. (2),  $M$  represents the number of all texts and  $M(j)$  represents the number of texts where the feature term  $j$  is present.  $IDF(j)$  The larger the number, the lower the number of occurrences of the feature word in the text set. The formula for calculating the weight of a feature word  $w_{aj}$  is shown in eq. (3).

$$w_{aj} = TF(a, j) * IDF(j) \quad (3)$$

After calculating the weights of all feature words, the weight matrix  $HM$  of the text set  $H$  is obtained as shown in eq. (4).

$$HM = \begin{bmatrix} w_{11} & w_{12} & \dots & w_{1g} \\ w_{21} & w_{22} & \dots & w_{2g} \\ \vdots & \vdots & \dots & \vdots \\ w_{m1} & w_{m1} & \dots & w_{mg} \end{bmatrix} \quad (4)$$

Using the text that the user has read as a feature vector, the weight matrix  $HM_u$  for the set of texts that the user  $u$  has read is shown in eq. (5).

$$HM_u = \begin{bmatrix} w_{u11} & w_{u12} & \dots & w_{u1g} \\ w_{u21} & w_{u22} & \dots & w_{u2g} \\ \vdots & \vdots & \dots & \vdots \\ w_{um1} & w_{um1} & \dots & w_{umg} \end{bmatrix} \quad (5)$$

As users' interests change, text recommendations need to be time-sensitive, and analyzing users' recent behavioral data can improve prediction accuracy. Therefore, the study introduces a time-factor adjustment model matrix to obtain users' real-time interest preferences. Define the set of texts read by the user  $u$   $H_u$ ,  $t_0$  is the current time,  $t_i$  is the user's browsing time, and the time factor is calculated by eq. (6).

$$\varepsilon_i = \frac{e^{-(t_0-t_i)}}{\sum_{h_{uj} \in H_u} e^{-(t_0-t_j)}} \quad (6)$$

In eq. (6)  $e$  is a constant. The introduction of a time factor to adjust the weights of the weight matrix  $HM_u$  gives the user's own preference model as  $SPM_u = (W1_{u1}, W1_{u2}, \dots, W1_{ug})$ , where  $W1_{ua} = \sum_{h_{aa} \in H_u, w_{uaj} \in HM_u} \epsilon_i * w_{uaj}$ .

**B Hybrid Recommendation Algorithm with Fused Preference Models**

In practice, if only one's own preferences are considered, the recommendation results lack a certain degree of richness, and it is necessary to explore the potential preferences of users to improve user satisfaction [18]. The Potential Preference Model (PPM) is built by extracting the user's browsing history to form a matrix of user behavior and finding nearest neighbors through a mixture of behavioral and content similarity calculations to solve the problem of not being able to categories similar users due to text diversity [19]. When using CF for recommendation, it is transformed to recommend the feature words of interest to the nearest neighbors, which can effectively avoid the cold start problem, and the construction process is shown in Fig. 2.

In the user behavior matrix, suppose the user set is  $U = \{u_1, u_2, \dots, u_n\}$ ,  $n$  is the total number of users and the text set is  $H = \{h_1, h_2, \dots, h_m\}$ , according to the user's browsing history, when the user  $u$  reads the text  $a$ , then  $x_{ua} = 1$ , and vice versa, the user's behaviour matrix  $X_{n \times m}$  can be expressed as eq. (7).

$$X_{n \times m} = \begin{bmatrix} x_{11} & \dots & x_{1a} & \dots & x_{1m} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{u1} & \dots & x_{ua} & \dots & x_{um} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{n1} & \dots & x_{na} & \dots & x_{nm} \end{bmatrix} \quad (7)$$

The user's level of interest will change over time. To calculate the similarity of user behavior if only the same behavior exists between users is considered, ignoring the time

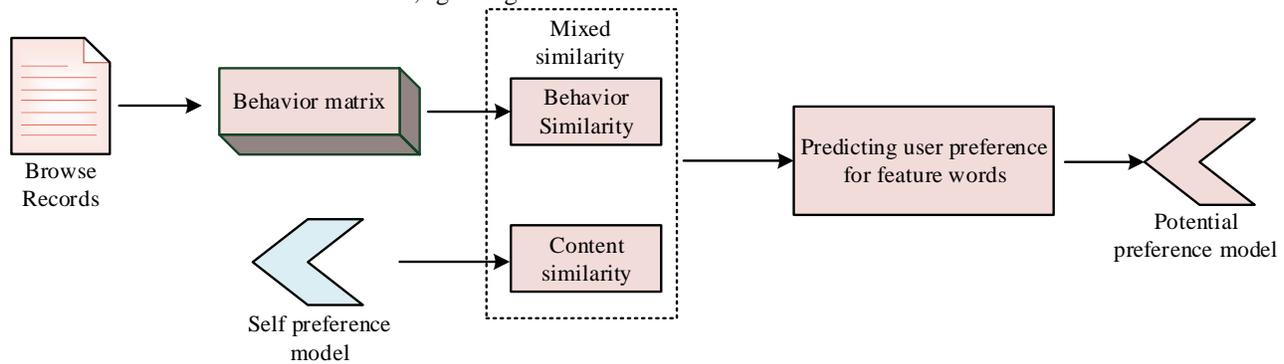

Fig. 2. Potential preference model construction process.

difference in user browsing will affect the level of interest in text recommendations, the time difference in user browsing behavior is defined as time decay, and its formula is eq. (8).

$$t_a = 1 / (1 + \delta |t_{ua} - t_{ra}|) \quad (8)$$

In eq. (8),  $\delta$  represents the time decay factor,  $t_{ua}$  and  $t_{ra}$  represent the time that users  $u$  and  $r$  spent viewing the same text  $a$ , and  $|t_{ua} - t_{ra}|$  represents the time difference between users  $u$  and  $r$  viewing the text  $a$ . The smaller the difference, the greater the similarity between users. At the same time, the influence of the external environment can also lead to user interest, for example, the coverage of popular events will make users interested in the field for a short period of time, and after the heat has passed, users' interest will return to its original state. Therefore, we need to take the external heat factor into account, and define the heat difference between users reading the same text at different times as  $k_a$ , which is calculated by eq. (9).

$$k_a = 1 / \log(1 + |N(a)|) \quad (9)$$

In eq. (9),  $N(a)$  represents the set of users who have viewed the text  $a$ . The more people read the text, the hotter the text is and the more likely users are to view the text due to its hotness, and the larger  $N(a)$  is, the greater the difference in hotness  $k_a$  is. Therefore, the formula for calculating the similarity of user behavior, taking into account the temporal differences in the generation of browsing behavior and the heat of the text, is eq. (10).

$$sim_{act}(u, r) = \frac{\sum_{a \in H(u) \cap H(r)} \eta * t_a + (1 - \eta) * k_a}{\sqrt{|H(u)| |H(r)|}} \quad (10)$$

In eq. (10),  $H(u)$  and  $H(r)$  represent the set of texts viewed by the user  $u$  and  $r$ , and  $\eta$  represents the moderator, with larger values indicating a greater influence of temporal differences and smaller values indicating a greater influence of text hotness,  $\eta \in [0,1]$ . Content similarity is calculated by the own preference model, and the user's content similarity is calculated by eq. (11).

$$sim_{con}(u,r) = \frac{PSM_u * PSM_r}{|PSM_u| \times |PSM_r|} \quad (11)$$

By combining the behavioural similarity with the content similarity through a weighting factor, the formula for the mixed similarity is eq. (12).

$$sim(u,r) = \chi sim_{act}(u,r) + (1-\chi) sim_{con}(u,r) \quad (12)$$

In eq. (12),  $\chi$  represents the weighting factor and  $\chi \in [0,1]$ . When  $\chi = 0$  only content features are considered, the larger  $\chi$  is, the greater the degree of influence of user behavioural features. The set of nearest neighbours of the user  $u$  is  $N(u)$  and the potential preference model is  $PPM_u = (W2_{u1}, W2_{u2}, \dots, W2_{ug})$ , where  $W2_{ua} = \sum_{r \in N(u)} \frac{sim(u,r)}{\sum_{r \in N(u)} sim(u,r_x)} W1_{ra}$  is used to find the nearest neighbors of the user's mixed similarity.

SPM can reflect the user's own preferences and has obvious personalization characteristics, while PPM can expand the user's interests and has diversity characteristics. The fusion of the two can ensure that the recommended content can meet the user's own preferences and enhance the diversity of content. When fusing SPM and PPM, the measurement between personalization and diversity should not be simply mixed.  $\max()$  function can take the feature vector with greater weight in the two models as the final preference vector of the user, which is selected as the fusion function, and the Fusion Preference Model (FPM) constructed is  $FPM_u = (W3_{u1}, W3_{u2}, \dots, W3_{ug})$ , where  $W3_{ua} = \max(W1_{ua}, W2_{ua})$ .

A fusion preference model is used to calculate the similarity between users, select users with greater similarity as nearest neighbors, predict the interest of users in candidate text sets from the browsing records of nearest neighbors, and recommend results according to the degree of preference, and the preference prediction formula is eq. (13).

$$P(u,a) = \sum_{r \in N(u)} sim(u,r) x_{ra} \quad (13)$$

In eq. (13),  $x_{ra}$  indicates whether the user  $r$  has generated a view record for the text  $a$ , and if so,  $x_{ra} = 1$ , and if not,  $x_{ra} = 0$ .

### C NNIA-based Multi-objective Optimization Recommendation Algorithm

In recommendation systems, there is a conflicting status quo between the diversity and accuracy of recommendation results. To alleviate the conflict between the two, the text data recommendation problem is transformed into a multi-objective optimization problem through modelling. Multi-objective optimization problems are common in everyday life. In solving multi-objective problems, the objectives are so interlocked that finding the best solution that satisfies all the objectives is impossible, so a trade-off between the objectives is needed to find the relatively better solution [20]. In the field of textual data recommendation, the first consideration is the accuracy of the recommendation results. High accuracy can improve user satisfaction and also measure the level of interest in the recommendation results. The objective function for accuracy is chosen as the similarity matching function and is calculated by eq. (14).

$$\begin{cases} y_v = \frac{1}{L} \sum_{c \in R} 1 - sim(c, P_u) \\ sim(c, P_u) = \frac{1}{|P_u|} \sum_{a \in P_u} sim(c, a) \end{cases} \quad (14)$$

In eq. (14),  $L$  represents the length of the list of all recommendations,  $P_u$  represents the set of texts that the user  $u$  has viewed, and  $sim(c, a)$  represents the similarity between the text  $c$  and the text  $a$ .  $y_v$  The smaller the value, the more similar the recommendation is to the text the user has viewed and the better the accuracy of the recommendation. To help users find more interesting text data, diversity is taken into account and the objective function of diversity is eq. (15).

$$y_D = \frac{1}{L(1-L)} \sum_{c,a \in R, c \neq a} sim(c, a) \quad (15)$$

From eq. (15), the smaller  $y_D$  is, the smaller the similarity between the texts in the recommendation list, which means the richness and diversity of the recommendation content is better. Considering diversity and accuracy, it is found that the smaller the  $y_v$  and  $y_D$ , the better. Therefore, the final objective function is minimization, and the specific expression is eq. (16).

$$Min : Y = \{y_v, y_D\} \quad (16)$$

The Non-dominated Neighborhood Immune Algorithm (NNIA) has excellent evolutionary performance and is used to solve multi-objective problems due to its fast convergence and robustness. A certain proportion of each superior antibody is cloned, and the population is then crossed and mutated to enhance the diversity of the population and avoid local optima. During the crossover operation, the same gene loci in the two parent individuals are inherited, and the remaining positions are randomly crossed with a probability of [0,1]. The mutation operation is carried out for the parent individuals. The crossover and mutation operations are shown in Fig. 3.

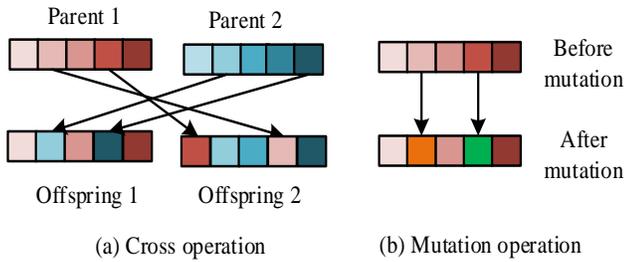

Fig. 3. Crossover and mutation operation.

Using the NNIA algorithm, it is necessary to encode the texts in the candidate set with real numbers. Let the encoding of an antibody be  $z\{z_1, K, z_b, K, z_l\}$ ,  $z$  denotes any user,  $z_b$  denotes the recommended text number, and each text has a unique number. The candidate text set obtained from the fusion preference model is optimized by crossover and variation operations to produce the final recommendation list. The

specific process of text data recommendation using NNIA algorithm is shown in Fig. 4. The user text candidate set data program generated by the fusion preference model is used to encode the candidate text set in real numbers. Set the maximum number of iterations, population size, crossover and mutation probability and other related parameters to randomly generate the initial antibody population. Identify the dominant antibody and clone the dominant antibody. Place the cloned individuals in the temporary population. Select the individuals with the lowest density according to the population density to enter the new population and update the dominant population. The new dominant population is cloned, crossed, and mutated to continue to update the dominant population until the maximum number of iterations is reached, and finally the best recommendation list of text recommendation is output.

The NNIA algorithm can be used to generate a series of recommendation lists with different recommendation targets, personalized to the specific needs of the user, increasing user satisfaction and loyalty.

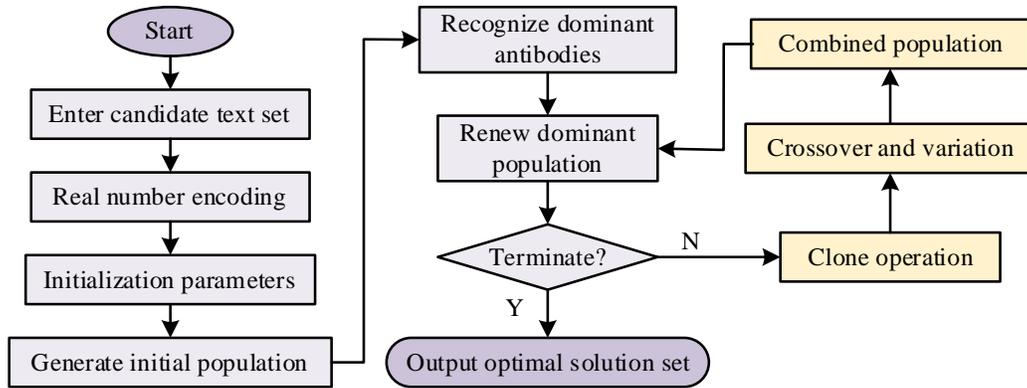

Fig. 4. NNIA algorithm text recommendation process.

#### IV. PERFORMANCE ANALYSIS OF MULTI-OBJECTIVE COLLABORATIVE FILTERING-BASED DATA-MIXING RECOMMENDATION ALGORITHMS

##### A Performance Validation of Hybrid Recommendation Algorithms Incorporating Preference Models

In order to determine the values of the parameters present in the latent preference model (PPM), namely the temporal

decay factor  $\delta$ , the text heat modifier  $\eta$  and the mixed similarity weighting factor  $\chi$ , Fig. 5 shows the variation in the accuracy of the recommendation results for different temporal decay factors  $\delta$  and modifiers.  $\eta$

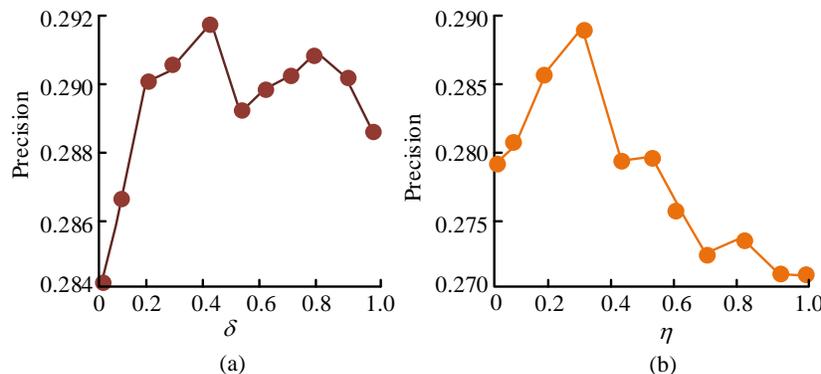

Fig. 5. Recommended accuracy when  $\delta$  and  $\eta$  have different values.

As can be seen in Fig. 5(a), the accuracy of the recommendations fluctuates as the value of  $\delta$  increases, and the experimental results show that there is a maximum accuracy of the recommendations at  $\delta=0.4$ . In Fig. 5(b), as the value of  $\eta$  increases, the recommended accuracy curve increases to a peak and then gradually decreases, showing the maximum accuracy at  $\eta=0.3$ . In the case of  $\delta=0.4$  and  $\eta=0.3$ , the best weighting factor  $\chi$  was analysed, and the accuracy curves for different values of  $\chi$  are shown in Fig. 6.

As can be seen in Fig. 6, the best accuracy of the recommended results is obtained at  $\chi=0.7$ . The experimental analysis finally resulted in the accurate values of each parameter when constructing the PPM, i.e.  $\delta=0.4$ ,  $\eta=0.3$ ,  $\chi=0.7$ . In order to investigate whether the recommendation performance of the fusion preference model (CBCF) is better than before fusion, the study conducted comparison experiments with SPM and PPM, and Fig. 7 shows the comparison results of the accuracy and recall of the three models' recommendations.

As can be seen in Fig. 7(a), the trend of all three models decreases as the amount of recommended text increases, but the accuracy of CBCF is always higher than the comparison algorithms, with a maximum increase of 9.57% and 8.23% over the accuracy of SPM and PPM. As can be seen in Fig. 7(b), the pattern of change in recall is opposite to the pattern of change in accuracy, with the higher the number of recommended texts, the greater the recall. the recall of CBCF is higher than the other two models, with a 9.97% and 7.65% improvement over the SPM and PPM recall. The fusion of

models can effectively improve the accuracy of recommendations. Fig. 8 shows the F value and recommended coverage results of the three models.

As can be seen from Fig. 8(a), the change trend of the F value curve of the three models is similar. With the increase of the recommended text, the F value rises to the highest value, and then decreases gradually. The maximum F value of CBCF is 0.493, and the maximum values of SPM and PPM are 0.438 and 0.461 respectively. Compared with the comparison model, the F value of CBCF is 0.055 and 0.032 higher. Fig. 8(b) shows the results of recommendation coverage. It can be seen that with the increase of the number of recommended texts, the coverage of the three models is on the rise, and the coverage of CBCF is always higher than that of the comparison model. Compared with SPM and PPM, the coverage increased by 10.04% and 16.45%. Relevant data shows that the fusion of models can effectively improve recommendation performance.

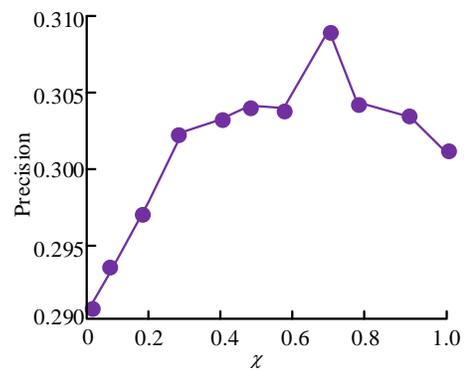

Fig. 6.  $\chi$  Recommended accuracy rate for different values.

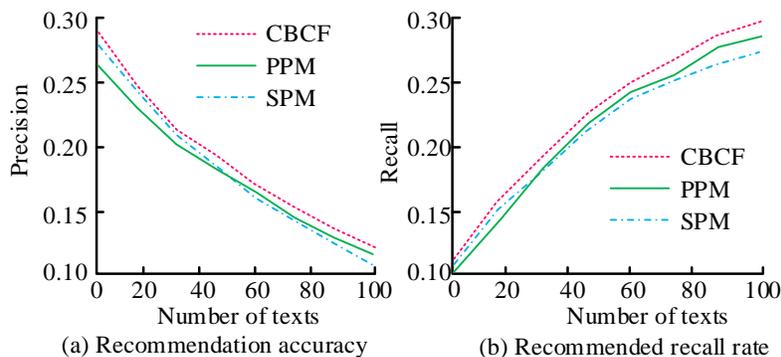

Fig. 7. Comparison results of accuracy and recall rate recommended by three models.

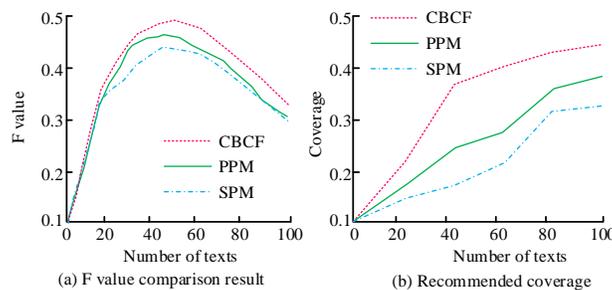

Fig. 8. F value and recommended coverage results of the three models.

**B Analysis of the Effectiveness of the Hybrid Recommendation Algorithm based on NNIA Multi-objective Optimization**

To verify the performance of the NNIA multi-objective optimization recommendation algorithm, the maximum number of iterations of the algorithm was set to 300, the number of nearest neighbors to 25 and the size of the dominant population to 50. The top 50 non-dominated solutions were selected as the recommendation result solution in NNIA according to the degree of density, and one user was randomly selected for presentation, and the results are shown in Fig. 9.

The distribution of the user 27 recommended solution set in the target space is illustrated in Fig. 9, where it can be seen that the NNIA optimized recommendation algorithm can effectively obtain 50 different solutions. The leftmost solution is the one with the highest accuracy and the worst diversity among all solutions, while the rightmost solution is the one with the best diversity and the lowest accuracy among all solutions. From the distribution of the solution set, as the value of the diversity function increases, the value of the accuracy function decreases, indicating that there is a contradiction between the two indicators in the recommendation process, which is in line with the law of the recommendation process and verifies the effectiveness of the NNIA multi-objective algorithm.

To analyses the performance of the studied NNIA multi-objective optimized hybrid recommendation algorithm (CBCF-NNIA), it was compared with Recommendations Based on User Browsing (BUB), Personalized recommendation based on user interest (PBUI) and Hybrid recommendation with fused preference model (CBCF) in terms of accuracy, diversity of recommendation results. The accuracy and diversity of recommendation results are compared. The accuracy and diversity of recommendation results are compared.

As can be seen in Table I, the mean accuracy of the recommendation lists of 9 out of 10 users outperformed the other three comparison algorithms, and the maximum accuracy of the recommendation lists of the remaining 1 user outperformed the comparison algorithms. The experimental

data shows that the recommendation list given by the CBCF-NNIA algorithm studied is not necessarily the most accurate, but can give more accurate recommendations than the other three comparison algorithms.

Diversity can indicate the variability between texts in a list. The smaller the diversity value, the greater the similarity between texts and the richer the content. Table II shows the recommended diversity results for several algorithms.

As can be seen in Table II, the mean value of the diversity of the recommendation lists of 8 out of 10 users is lower than the other three comparison algorithms, and the minimum value of the diversity of the recommendation lists of the remaining 2 users is lower than the comparison algorithms. The experimental data suggests that the CBCF-NNIA algorithm does not give the best diversity of recommendation lists, but can give richer recommendations than the other three comparative algorithms. The study selected 50 sets of experimental data to calculate the average accuracy and average diversity of several recommendation algorithms, and the overall comparison results are shown in Table III.

As can be seen in Table III, the accuracy and diversity of the recommended results of the studied CBCF-NNIA algorithm outperform the comparison algorithm, which provides users with textual content that meets their needs as well as being rich and diverse.

## V. DISCUSSION AND CONCLUSION

The research determines the parameter values in the PPM model through the accuracy changes of the recommendation results under different parameter values. The results show that the recommended accuracy of PPM is the best when  $\delta = 0.4$ ,  $\eta = 0.3$ ,  $\chi = 0.7$ . The PPM considers the impact of user browsing time difference, external environment and other user behavior characteristics on user interest, and the recommendation results will be more accurate. By analyzing the accuracy, recall, F value and coverage of the recommendation results, the recommendation performance of the three models is compared. The results show that the various index values of CBCF are higher than those of the comparison model. This is because CBCF is a model integrating SPM and PPM models, which can ensure that the recommended content not only meets the user's own preferences, but also improves the content diversity. When the model is fused, the personalization and diversification are measured, and the feature vector with larger weight in the model is used as the user's final preference vector, so as to construct the CBCF model. Therefore, CBCF model combines the advantages of the two models and can effectively improve its recommendation performance. The performance of CBCF-NNIA algorithm is analyzed from the diversity and accuracy of recommendation results. The results show that the algorithm can better take into account the diversity and accuracy of recommendation results, and meet the user's personalized and rich and diverse needs of text. In order to solve the contradiction between recommendation diversity and accuracy, the problem is transformed into a multi-objective optimization problem. The NNIA algorithm has fast convergence speed and good robustness. It uses crossover and mutation operations to enhance the diversity of the population and avoid the occurrence of local optimization. Introducing

NNIA into CBCF can effectively obtain the content list with high accuracy and good diversity.

The rapid development of Internet technology has made the problem of information overload increasingly serious, and recommendation systems are one of the effective techniques to improve information utilization. Faced with the shortcomings in existing recommendation algorithms and the conflict between recommendation accuracy and diversity, the study combines recommendation algorithms with multi-objective optimization algorithms and proposes an NNIA multi-objective optimization hybrid recommendation algorithm. Experimental tests determine the relevant parameters of the hybrid recommendation model. The results of the comparison experiments showed that the accuracy and recall of the hybrid recommendation algorithm were higher than those of the model before the hybridization, with the accuracy improving by 9.57% and 8.23% over SPM and PPM respectively, and the recall improving by 9.97% and 7.65% respectively. The results are consistent with the personalized recommendation law. By exploring the performance of CBCF-NNIA recommendation accuracy and diversity, the results show that the algorithm can effectively obtain content lists with high accuracy and good diversity, which can meet the multiple needs of different users and improve user satisfaction. Although the research has achieved certain results, there are still many shortcomings. The recommendation process mainly considers textual content data, and subsequently, factors such as text labels and categories are also taken into account, while the problem of data sparsity has not been effectively solved, which will be investigated in the future.

**Abstract**—Cloud computing is one of the significant technologies that is used to provide seamless internet surfing for large-scale applications and data storing purposes. The cloud is described as a large platform that enables users to access data from the internet without needing to buy storing space in their equipment such as a computer. Many studies have analysed the load-balancing technique on the cloud to distribute tasks equally between servers using the Equally Spread Current Execution (ESCE) algorithm. ESCE, which is a dynamic load balancer, has quite a few problems such as average level performance and too long of response time which affected the Quality of Services. This research has simulated a cloud computing concept using the ESCE Load Modelling technique with the CloudAnalyst simulator for three servers of Data Center (DC) locations. The ESCE was simulated to enhance its algorithm's performance as a load balancer and higher throughput in the cloud environment. The result shows that ESCE average overall response time is shortest when the DC is located at R0 with response times of 15.05s, 13.05s with 10 VMs, and 8.631s with the Optimize Response Time brokerage policy. This research is significant to promote notable load-balancing technique testing for virtualized cloud machines data centers on Quality of Services (QoS) aware tasks for Internet of Things (IoT) services.

**Keywords**—Equally spread current execution (ESCE); optimize response time brokerage; cloud computing; load balancer; data modelling

## I. INTRODUCTION

Pay-as-you-go online computing services, such as apps, storage, and processing power, are referred to as cloud computing. Due to how simple and affordable it is to use large-scale applications, the demand for this technology has greatly increased [1]. A significant aspect of this environment is the scalable delivery of IT infrastructure and applications as a service, according to the definition of cloud computing, which is end user-focused on how they may experience the cloud environment such as data storage for the information technology for education, remote monitoring and mobile robot for surveillance application [2-5].

Fig. 1 presents the illustration of cloud computing as a user device accessing the internet and communication exists between servers, applications, and databases. Cloud computing may be utilised as an interface for the integration to quickly

complete a variety of client requirements, in just one click. The biggest issue with this system is managing a large number of client requests that could total millions at one time[6, 7]. Mainly maintaining and enhancing prior software investments while responding to environmental changes is the major objective of current application adaptation[8]. The private cloud, the public cloud, the hybrid cloud, and the community cloud are the four cloud computing deployment methods that are based on research and are grouped by their distribution and physical location[9]. Three types of cloud service models are Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS).

Concerning effectively managing user requests, load-balancing methods must be used [10]. Load-balancing serves as a tool for assignation and also controls the system's overall rendering [11]. The Equally Spread Current Execution (ESCE) is one of the algorithms that act as a load balancer to process user requests. ESCE algorithm (LBA) allocates user requests equally to all virtual machines (VM) bound to the data centre [12]. This kind of load balancer keeps track of the inventory of virtual machines and their current availability. However, depending on the suggested work or goal of the cloud environment, the algorithms' efficacy is unclear [13]. Each algorithm varies depending on the type of load-balancing within the bounds of cloud computing [14]. The turn-based Round Robin load-balancing solution has its unique algorithm [15]. The first server will receive the first request, the second server will receive the second request, and so on. Following distributing tasks after determining their size, the Equally Spread Current Execution algorithm uses a spread spectrum technique.

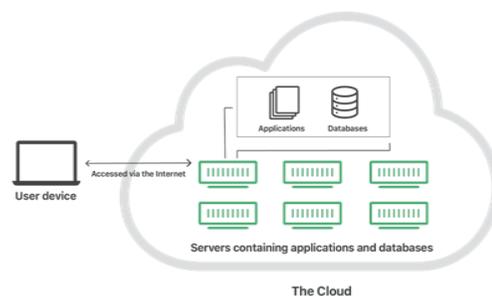

Fig. 1. Illustration of cloud computing

Additionally, this algorithm performs average in terms of response rate and has excessively long mediocre minimum and maximum response times [16]. Response time-wise, the Equally Spread Current Execution algorithm is excessively slow. This is a result of the algorithm's lengthy check of the request size. The algorithms must first successfully assess the availability status of each machine before allocating them to the available virtual machines. This causes system delays and reduces the effectiveness of the entire load-balancing strategy. When compared to other load balancers now in use, the performance of this method is in the middle of the pack [17]. Equally Spread Current Execution was not the best load-balancing strategy when compared to the others. An earlier study compared it to other load-balancing methods including Round Robin and Throttled Load-balancing [18]. It does not, however, qualify as the worst technique either. The issue is that it is not the best technique to employ at the moment.

Cloud computing is Internet-based computing that offers a pool of customizable computing resources such as networks, storage, servers, applications, and services without requiring interaction with the service provider and with little administration effort[19]. The RR protocol's moving horizon estimation problem for a class of discrete time-delay systems. To avoid data collisions, communication between the sensor nodes and the remote state estimator is carried out over a shared network, with only one sensor node able to transmit data at any given time. The RR protocol organizes the transmission order of sensor nodes, with the selected node gaining network access modelled as a periodic function. The device model is reformulated into a linear system without delays due to lifting technology. The problem at hand aims to construct a moving horizon estimator that minimizes the estimation error. In matrix inequality, a proper condition is defined to ensure ultimate boundedness [16]. In cloud computing, the cloud infrastructure cannot handle the flow of information independently with the profusion of data, devices, and interactions [7]. Load-balancing distributes all workloads across each node in a shared or mutual system to maximize resource utilization and reduce job response time. The most important aspect of cloud computing is scheduling, which includes workloads and workflow scheduling under the platform as a service model. The infrastructure as service task to VMs scheduling which machine is decided by the scheduler should go on which job or VMs[20]. Evaluating the energy required for communication between the devices participating in this process and the suggested method's appropriateness for handling optimization problems like VM placement is necessary[21]. Load-balancing is a method of reassigning the entire load to the various nodes of a collaborative system to improve resource efficiency and the job's response time while avoiding a situation where specific nodes are overloaded and others are underloaded. A load-balancing algorithm involved in identity ignores the system's previous state or behavior, relying instead on the system's neighboring behavior. This load can be measured in terms of CPU, memory use, sluggishness, or network load[22]. Load-balancing's primary aim is to enhance device efficiency and functionality for today's QoS for IoT services in communication and data transfer. It is used in cloud computing systems to provide successful alternative solutions in the event of a system failure and to ensure the best possible

use of system components. Load-balancing techniques are divided into two main models Static Model and Dynamic Model. First is Static Load-balancing: Static load-balancing occurs in a static environment where the output of algorithms is unaffected by the system's current state. As a result, user expectations do not change over time [23]. Second is Dynamic Load-balancing: The system's state has a significant impact on balancing the efficiency of the algorithms. Since resources are versatile in a dynamic environment, algorithms efficiently perform load-balancing[24].

An increasing number of computation-intensive and delay-sensitive mobile apps keep appearing alongside the evolution of smart Mobile Devices (MD). The task migration issue in the context of cloudlet federation is the primary topic of this research[25]. Considered a cloudlet federation scenario involving three distinct Cloudlet service Providers (CLP) and a remote cloud. Cloudlet federation can efficiently minimise cloudlet deployment and management expenses by pooling resources among CLPs. Task migration faces new obstacles because CLPs vary in their user and resource counts.

Proactive dynamic VM consolidation is used in this research to improve resource utilisation and performance without sacrificing the energy economy[26]. The suggested algorithm creates a fine-grained categorization that takes workload considerations into account by utilising machine learning techniques to create complementary profiles that reduce cross-application interference by strategically colocating HPC and non-HPC workloads. Real HPC workloads were simulated for the study using CloudSim. The outcomes proved that, in terms of the metrics in important areas, the suggested algorithm beats all heuristic methods[26-28].

This research examined the performance of the Equally Spread Current Execution load modelling method for Quality of Service, QoS aware task placement for the Internet of Things (IoT). Since the ESCE load modelling technique requires communication between the data centre and load balancer, the procedure results in overhead [29]. Intended to examine the behaviour of a large distributed system, this project investigated the study of ESCE load modelling using the CloudAnalyst simulator. The user-friendly interface of the CloudAnalyst simulator made it easier for analysts to set up simulations. This research has successfully analysed the performance of ESCE in various situations and proven that it works efficiently by implementing the correct configuration according to the scale of the application.

The paper is divided into five main sections. The Introduction section provides a brief overview of the problem and research question, as well as an introduction to the relevant literature. The theoretical and proposed work section brief the overview of the research gap and the literature review, including the proposed work and some of the mathematical modelling techniques. The Methodology section outlines the research methods used, including the data sources and analysis technique. The Results section presents the findings of the research, while the Discussion section discusses the implications of the research and its implications for future research. Finally, the Conclusion section summarizes the research and provides suggestions for further research.

## II. THEORETICAL AND PROPOSED WORK

Critical analysis of vast amounts of data, including energy production and consumption, is required to develop a secure and sustainable energy system [30]. Due to the high demand for cloud services, much research has been done to improve the performance of the current existing load-balancing. Upon enabling the stability of cloud environments, load-balancing is a key role to ensure no node in the load-balancing is unequally utilized than the other [31]. A study has proposed a genetic algorithm-based task scheduling for load-balancing which demonstrated that the proposed method results exceed the performance of current load-balancing techniques [32]. Proposed algorithms are known to surpass basic static and dynamic load-balancing since their method has attempted to solve problems by creating an alternative to minimize the response time such as designing hybrid algorithms in taking a part of existing algorithms and attaching additional processes in the algorithm.

Another study analyzed the response time of dynamic load-balancing, their results showed that all algorithms used in the simulation, THR, ESCE and Particle Swarm Optimization (PSO) gave the same results when the resource is homogenous. Otherwise, entitled to swarm intelligence ability that the task can be executed more efficiently[33]. Most proposed work has proven that the existence of a variety of cloud computing aspects needs more systematic and advanced algorithms to cater for the complicated environment [34]. According to a study, analysis is done to compare the performance between three existing load-balancing types namely the Round Robin (RR), Equally Spread Current Execution (ESCE) and Throttle (THR) using CloudAnalyst by broker policy grouping and load-balancing which results showed that THR has the best performance compared to the other two as prevents overload efficiently by thresholding the available VMs list [35]. The analysis is done by different data centre policies in the same simulation scenario with nine possible load-balancing approaches and five different workloads which have obtained 45 different results. Their work is quite similar to this analysis as they reviewed the performance of the load-balancing method to compare the results and determine which one has the best performance analytically.

In another comparative study done to evaluate the performance of algorithms, the increasing number of users has been used as a variable as they claimed much previous research has not considered the increasing number of users as a contributor to the improvement of algorithms whereas in the simulation to compare three algorithms, RR, ESCE, and THR they have placed UB user base and data centres in the same region by neglecting the effect of geographical distance [36]. Their results proved that algorithms performance does increase with user numbers as initially in the simulation with 5000 users, no significant difference can be seen between the three algorithms' results. Another simulation has been done to analyze performance by using different service broker policies using four data centres all located in different regions but having the same amount of VMs which is 50 [37]. Simulation is done alternately for three different broker policies to analyze performance based on response time, request processing time and cost the results given THR has the best performance with a

small processing cost compared to the others. While another study has focused on various policies utilized for load-balancing, a simulation was done between all six different user bases that are utilized with four data centres and in these data centres 25 VMs, 50 VMs 75 VMs, and 100 VMs respectively announces to the 4 DCs [38]. The load-balancing algorithms compared are RR, ESCE, THR and First Come First Serve (FCFS) algorithms. The peak hour users set for those 6 user bases vary with each other and concluded that RR has the best integrated performance. Next is a comparative analysis comparing THR, RR, ESCE, FCFS, and Shortest Job First (SJF) [39]. In this analysis, they optimized 6 user bases in all 6 regions respectively with 4 data centres in R0, R4, R2, and R3 containing 15 physical machines consolidated with 10 VMs each. The results showed that FCFS performed the best when it is compared on a data centre processing time basis while ESCE performed best when it comes to the lowest total cost. They showed that a different basis can give different results.

Analysis of the load modelling utilizing Equally Spread Current Execution (ESCE) load-balancing is the goal of this study. The CloudAnalyst simulator, an expanded piece of software created from the CloudSim toolkit, will be used as the approach abandoned for data collecting. A programmer called CloudSim toolkit is used to track internet behavior based on settings made in the simulation configuration. The CloudAnalyst simulator separates the user's global location into a few zones. Any region can be selected for the simulation, and the number of data centres can be adjusted correspondingly. The initial configuration setup will be the subject of the simulation.

### A. Modelling Technique

This algorithm works based on load sets assigned to virtual machine sets at a given time. The mathematical model is defined by the following equations to calculate the processing time for a task to be executed. Eq. (1) is given by  $n$  as the number of sets for the load ( $L$ ) or requests that need to be scheduled to servers.

$$L = \{L_1, L_2, \dots, L_n\} \quad (1)$$

Eq. (2) is given by  $k$  as the number of sets for virtual machines ( $V$ ) in a particular data centre ( $D$ ).

$$V = \{V_1, V_2, \dots, V_k\} \quad (2)$$

Eq. (3) is given by  $DL$  as the current data centre load.

$$DL = \{VL_1, VL_2, \dots, VL_k\} \quad (3)$$

Eq. (4) shows to find a function where the load set can be mapped (multiply) into virtual machine set ( $VL$ ) and  $f(L)$ , forming load  $VL_i$  of each virtual machine  $V_i$  to be essentially equal.

$$VL_1 \approx VL_2 \approx \dots \approx VL_k \quad (4)$$

Eq. (5) shows to calculate the time needed to allocate all tasks to virtual machine  $V_i$ , take  $\tau_0$  as the time to execute task  $L_0$ .

$$t_i = \sum_{0 \in f(L_i)(i=1, \dots, n)} \tau_0 \quad (5)$$

When there is only one virtual machine, which means  $k=1$  and all available tasks will be executed serially on that one virtual machine, Eq. (6) shows the execution time will be the summation of all time and can be calculated as  $T_1$ .

$$T_1 = \sum T_0 (0 = 1, \dots, n) \quad (6)$$

And when  $k>1$  which means there are more virtual machines available, all available tasks can be allocated (shared equally) to multiple servers. Making the serially executed task before becoming parallel since multiple virtual machines are working simultaneously. Thus, Eq. (7) shows the time needed to execute a task is calculated as  $T_k$ .

$$T_k = \max_{i=1, \dots, n} t_i \quad (7)$$

In conclusion, the goal is to solve the function to get the minimum of time needed to execute a task.

### III. METHODOLOGY

This section explains the details of the flow chart of the proposed study and the simulation for the analysis of Equally Spread Current Execution Load Modelling for Cloud Computing.

#### A. Flow Chart

Fig. 2 shows the ESCE algorithm flowchart which depicts how the algorithm handles user requests. To ensure equal loads for every virtual machine (VM) involved in the algorithm, ESCE uses the spread spectrum approach. Receiving a request, ESCE uses the spread spectrum approach. Receiving a request, the load balancer updates the index table with the VM status count and scans the request in the index table before allocating it to an available VM. The parallelogram represents the beginning of the user request, the square shape of the process carried out by the simulator to evaluate the request before sending it to the virtual machine, and the diamond is the choice made by the load balancer of which virtual machine to send the user request to be processed. The virtual machine count and availability are stored in data storage with a cylinder shape.

#### B. Simulation

Equally Spread Current Execution (ESCE) is a cloud analytic methodology that is used to optimize the performance of cloud services. It is a cost-effective method of achieving higher throughput in the cloud. ESCE works by dynamically spreading the current execution load across multiple servers in order to evenly distribute the load. This helps to reduce the load on any one server, thus increasing the overall performance of the cloud. Additionally, ESCE can also be used to improve the scalability of the cloud environment. By leveraging multiple servers, the cloud can handle larger workloads without experiencing any performance degradation. ESCE is an effective way to improve the performance and scalability of cloud services and can be implemented in a variety of cloud environments.

The simulation is started by identifying the desired system components such as virtual machines, storage, network components and the desired number of resources for each component. A simulation tool that will be used to measure the performance of the system was developed using CloudAnalyst. This tool should include the ability to measure system performance and resource utilization. The simulation began

with powering the software application. The user base (UB), data centre (DC), and load-balancing policy were identified in the simulation configuration, in this example, the Equally Spread Current Execution (ESCE). Execute the simulation tool and analyze the results. This includes measuring the average response time, resource utilization, throughput, and scalability of the system. The entire simulation lasted for 60 minutes. The number of data centres and virtual machines is a controlled variable in this simulation. The changes in outcome were determined by both variables. Based on a few initial setups, this software was used to simulate and study the cloud environment. The Equally Spread Current Execution (ESCE) load balancer paradigm was employed in this study to examine load-balancing performance. Response time, data centre processing time, and virtual machine (VM) cost are the outcomes tracked. The system configuration and workload have been optimized to achieve the desired performance and re-run the simulation tool and analyze the results. Fig. 3 illustrates how the CloudAnalyst simulator, an extension of the CloudSim toolkit, simulates scenarios based on internet behavior [40]. Build with a clear graphical user interface, the simulator's main objective is to separate experimentation activity from mapping exercises so the modeler may focus on the issues rather than the technicalities.

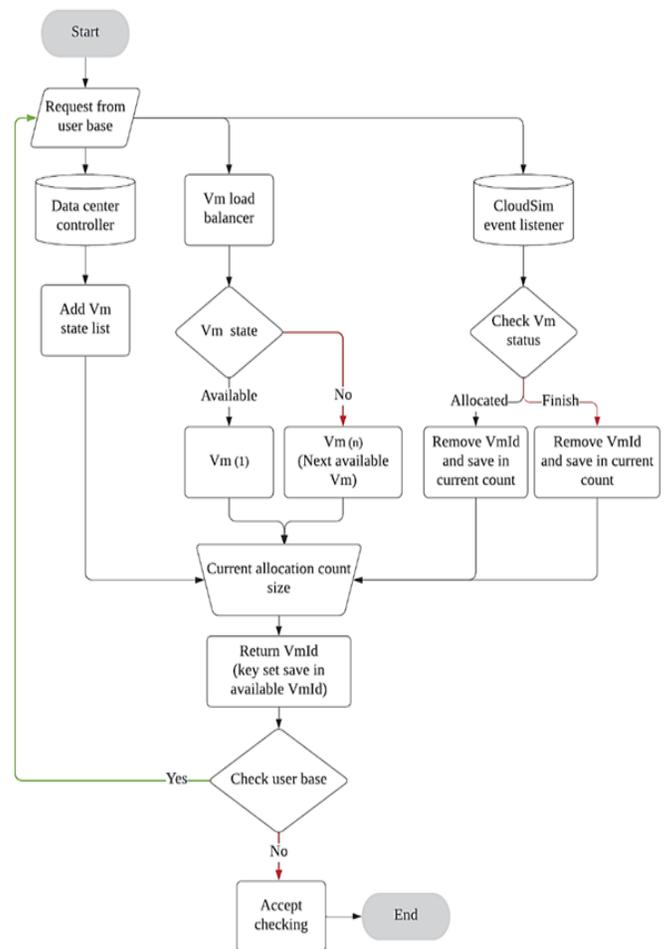

Fig. 2. ESCE execution process flowchart

Fig. 3. Graphical user interface (GUI) of CloudAnalyst

#### IV. RESULT AND DISCUSSIONS

This section describes the result of the simulation and the discussions for the simulation in the CloudAnalyst toolkit. This analysis was run in the CloudAnalyst simulator, the data is worked from an application “Facebook” known to be one of the examples of cloud computing applications. North America, Africa, and Oceania have been chosen to be the regions where user bases are assigned. The software identified these regions as R0, R4 and R5 respectively. There are more than these three regions in the software to be selected from, but they are chosen based on the approximate distance from each other to balance the outcome of simulation scenarios. The statistics of Facebook users in 2022 showed that R0 has 201.3 million users, R4 is the region with the highest number of users at 242.2 million and lastly, and R5 with 21.0 million.

##### A. Configurations

Table I presents the user number details for peak and off-peak hours. Table II presents the detailed settings for different simulation scenarios. There are a few different scenarios for simulation testing to get the desired results. Based on the statistical information, each region was set to only 10% of the total user number for peak-hour users and 5% for off-peak hours. The number of requests coming in is assumed to be once per five minutes for R0 and R5, while once per ten minutes for R4. The data size for a request is set to 100b. All simulation scenarios were run for 60 minutes with user grouping factor in user bases at 1000, request grouping factor in data centres at 100 and executable instructions length per request at 500 bytes. The load-balancing policy used is the Equally Spread Current Execution Load (ESCE) since it is the main objective of this analysis. The data centres are set to a memory of 1024 Mb. Other unmentioned configurations are unchanged in their default settings.

##### B. Response Time

Response time is the time taken to respond to requests coming in from clients. Lower response time means the load-balancing algorithm is doing a good job. Fig. 4 shows the analysis of the DC location as the variable. Three different simulation scenarios run with one DC in each simulation with the DC being located at R0, R4 and R5 alternately. Average overall response time showed DC located at R0 having the shortest response time compared to DC located at R4 and R5.

TABLE I. User NUMBER FOR PEAK AND OFF-PEAK HOURS

Region	User number	
	Peak Hour(million)	Off-Peak Hour (million)
R0	4.026	2.013
R4	4.844	2.422
R5	0.420	0.210

TABLE II. DETAILED SETTINGS FOR DIFFERENT SCENARIOS

Simulation	DC Number	Different scenarios		
		VM Number	DC Location (Region)	Service Broker Policy
1	1	100	R0	Closest Data Centre
2	1	100	R4	Closest Data Centre
3	1	100	R5	Closest Data Centre
4	1	1000	R0	Closest Data Centre
5	1	10	R0	Closest Data Centre
6	3	100	R0, R4, R5	Closest Data Centre
7	3	100	R0, R4, R5	Optimise Response Time
8	3	100	R0, R4, R5	Reconfigure Dynamically with Load

Fig. 4. Average overall response time analysis based on one data centre (a) at a different location

Fig. 5 shows the result of the simulation run with three different numbers of VMs. 10 VMs gives the shortest response time analysis at 13.05 seconds among all three followed by 100 VMs at 15.05 seconds and 1000 VMs at 15.25 seconds. 100 and 1000 VMs gave only slightly different result from each other but is still significant with the difference being approximately 0.2 seconds which is quite big since original data are analyzed in milliseconds.

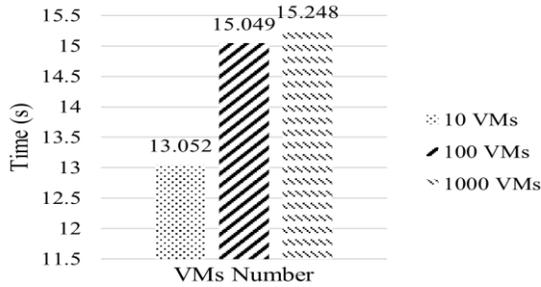

Fig. 5. Average overall response time analysis based on one data centre at a different number of VM

Fig. 6 presents the result given by applying different brokerage policies in three different simulations to analyze the response time given by each brokerage policy. The Optimize Response Time Brokerage policy has the shortest response time at 8.63 seconds, followed by reconfigure dynamically with load at 13.31 seconds response time and the closest data centre at 13.40 seconds. Response time is also observed by region and all three regions gave different results depending on the variables carried out for each simulation. Fig. 7 illustrates the result of response time with different DC locations. This result showed that all three locations gave R5 the shortest response time.

Fig. 8 presents all VMs number categories that had the same result with R5 being the region with the shortest average response time. Fig. 9 shows that given three DC in total with one at each region respectively, R5 also have the shortest response time among the three regions which is small compared in number.

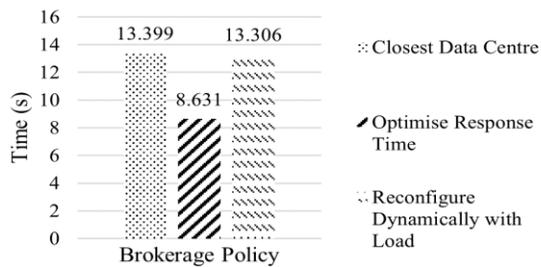

Fig. 6. Average overall response time analysis based on three data centres for different brokerage policy

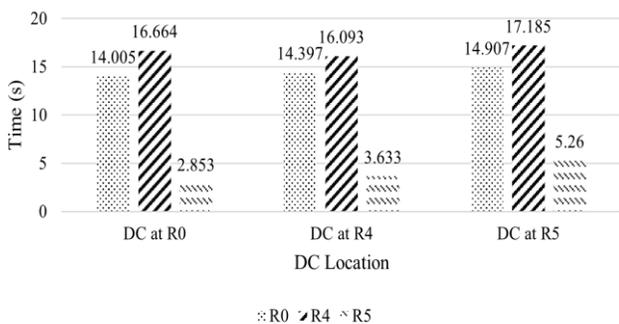

Fig. 7. Average response time by region based on one data centre at a different location

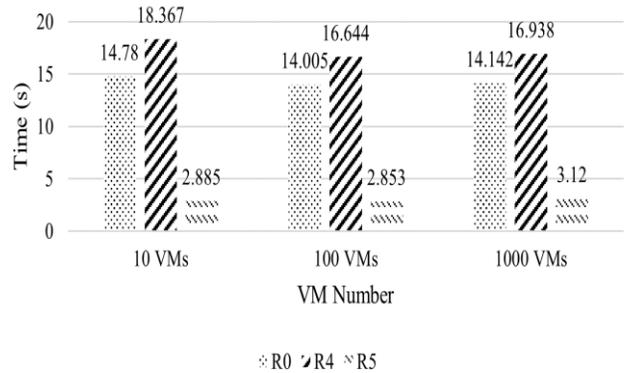

Fig. 8. Average response time analysis by region based on one data centre with a different number of VM

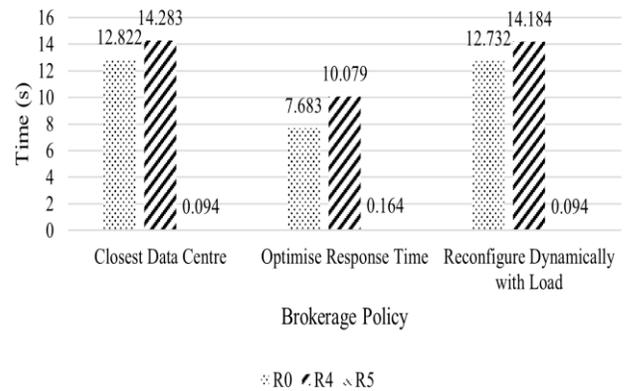

Fig. 9. Average response time analysis by region based on three data centres for different brokerage policies

### C. Average Data Centre Processing Time

The data centre processing time analyzed the DC capability to work under different conditions. Fig. 10 shows one DC placed at different locations giving the shortest average processing time of 14.55 seconds when located at R4. Fig. 11 shows processing time took only 12.38 seconds for 10 VMs in one DC compared to 14.71 seconds for 100 VMs and 14.90 seconds for 1000 VMs.

Fig. 10. Average DC processing time analysis based on one data centre at a different DC location

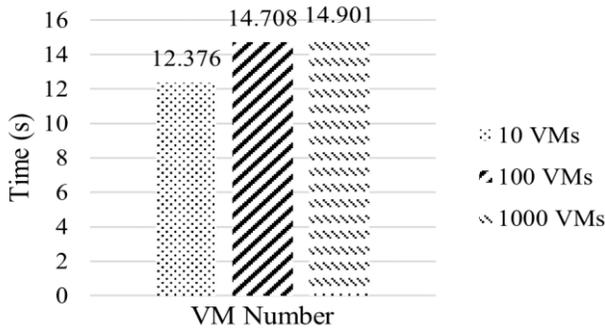

Fig. 11. Average DC processing time analysis based on one data centre with a different number of VM

Fig. 12 describes the result of DC processing time for the simulation with different brokerage policies. Results showed that Optimize Response Time Brokerage policy gave the shortest processing time for the data centre at 8.36 seconds compared to the other two brokerage policies.

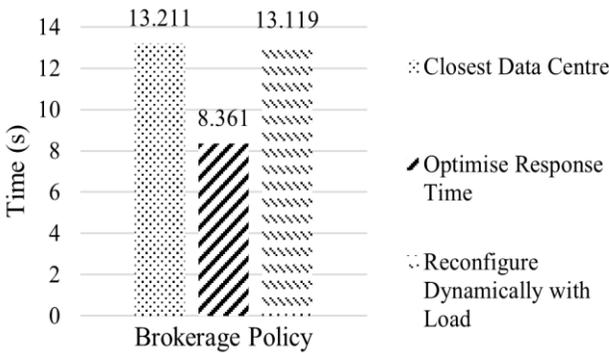

Fig. 12. Average DC processing time analysis based on three data centres for different brokerage policy

**D. Resource Utilization (Cost)**

Defined to check the utilization of resources. It is related to cost. Resource utilization in a system should be maximized to avoid clients paying for any unused resources. All cost used in the simulation is as shown in Table III.

One data centre with 100 VMs would cost approximately 10\$ each. Brokerage policy simulation only used one data centre for each different brokerage policy. Fig. 13 shows that all cost does not differ much from each other.

TABLE III. COST-DETAILED SETTING FOR EACH DC

Category	Price (\$)
Cost per VM (\$/hr)	0.1
Memory Cost (\$/s)	0.05
Storage cost (\$/s)	0.1

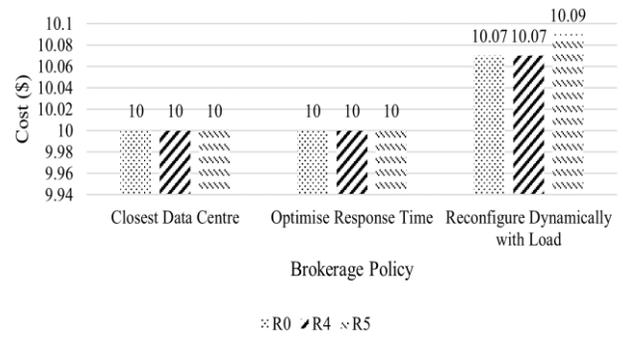

Fig. 13. VM cost analysis by region based on three data centres for different brokerage policy

VM cost would differ depending on how much VM is assigned in a data centre. Fig. 14 shows the result for the simulation of different DC locations but all having one data centre at a time and 100 VMs. Each DC cost the same since all have the same VM number. Fig. 15 shows a clear difference since the three simulation uses a different amount of VM in one data centre. 10 VMs is the cheapest since 1 VM used per hour only cost 0.1\$. 1000 VMs cost only 80\$ and not 100\$ since normally cloud plan offers some discount for certain packages subscribed.

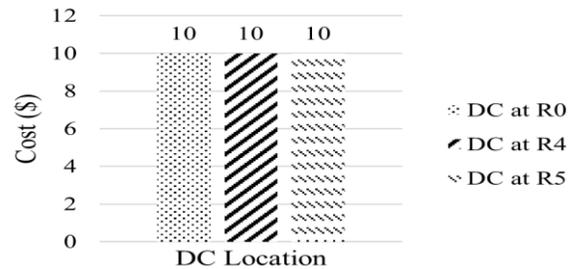

Fig. 14. VM cost analysis based on one data centre at a different DC location

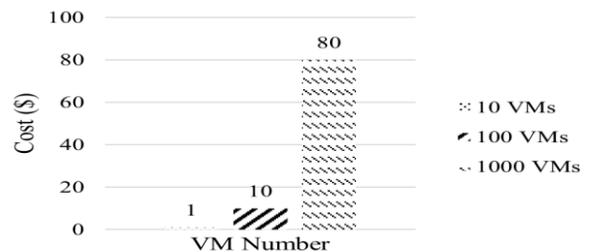

Fig. 15. VM cost analysis based on one data centre with a different number of VM

Fig. 16 shows three data centres would cost approximately 30\$ since one data centre costs 10\$. The reconfiguring dynamically with load brokerage policy gave off 30.22\$ since the machine worked according to load changes. The 0.22\$ difference is the result of algorithm work to be reconfigured according to load.

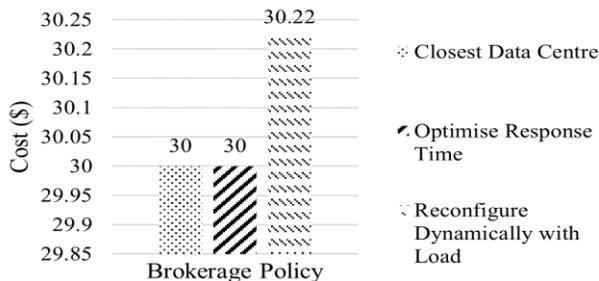

Fig. 16. VM cost analysis based on three data centres for different brokerage policy

Data transfer costs depended on the DC location. Data transfer costs would be higher if the distance between the DC location and the region where requests come from is quite far. Fig. 17 shows that in the closest data centre and reconfigure dynamically with load brokerage policy the region with the cheapest data transfer cost is R5 since the DC location is closer to any of the other two regions but, in optimizing Response Time Brokerage policy, the algorithm had to work based on the policy despite the location of DC. Hence, the cheapest cost for this brokerage policy only went as low as 106.91\$ at R0. The total data transfer cost for one data centre at a different location is lowest when DC is located at R0 and R5 with both being 385.11\$. Data transfer cost is calculated at a total of DC transferring data to all assigned regions. Fig. 18 illustrates there is only one data centre at a time which would make all three regions assigned to the one DC to carry out task execution work.

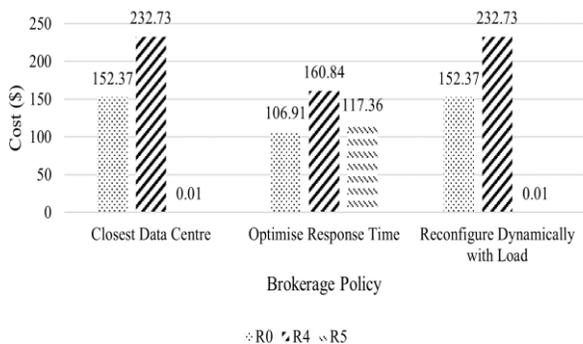

Fig. 17. DT cost analysis by region based on (a) three data centres for different brokerage policy

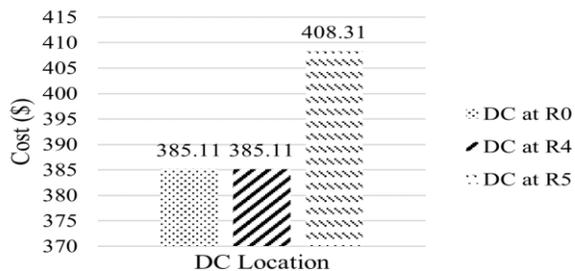

Fig. 18. DT cost analysis by region based on one data centre at a different DC location

Fig. 19 shows 100 VMs and 1000 VMs having the same results of 385.11\$ while 10 VMs costs 504.3\$. This is because the lower number of VMs had to do more work to execute data before transferring it to the user in their respective regions.

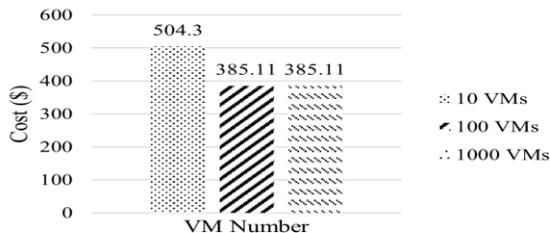

Fig. 19. DT cost analysis based on one data centre with a different number of VM

Fig. 20 illustrates the brokerage policies have equal same results of 385.11\$ in data transfer cost since simulations were carried out with one data centre located respectively at each region. All regions have their own data centre to process tasks.

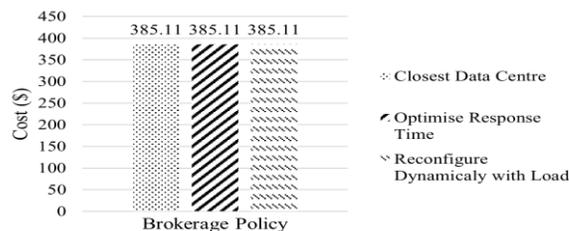

Fig. 20. DT cost analysis by region based on three data centres for a different brokerage policy

## V. CONCLUSIONS

This study has successfully analysed the three main factors of cloud computing which are off-peak resource utilisation, minimum data processing time, and minimal average response time. To optimize the response time brokerage policy for cloud computing, a simulation for the equally spread current execution load has been developed. This simulation has considered the current workload of each cloud system, the expected workload in the near future, and the existing resources of each system. The goal of the model is to ensure that the workload is evenly balanced across the cloud systems, to ensure that no one system is overloaded while another is underutilized. The result of this simulation was able to allocate the workload among the cloud systems in a way that optimizes response time and meets the goals of the system. This can be done by assigning the workload to the system that can best handle it, or by using techniques such as load-balancing or resource scheduling. It should also consider the future growth of the cloud system. This can be done by allowing for future increases in workloads.

## ACKNOWLEDGMENT

Authors would like to thank Research Management Centre (RMC), Universiti Teknologi MARA, Shah Alam, Selangor for the support funding in this research from grant no. 600-RMC/GPMST5/3(038/2021) and Institute for Big Data

Analytics and Artificial Intelligence (IBDAAI) in supporting this research.

# Research on the Derivative Rule and Estimation Methods of Intelligent High-Speed Railway Investment Estimation

Yang Meng, Chuncheng Meng, Xiaochen Duan\*

College of Management, Shijiazhuang Tiedao University, Shijiazhuang, Hebei 050043, China

**Abstract**—Taking the investment estimation of intelligent construction of high-speed railway as the research object, based on the historical data of investment of similar high-speed railway projects, this paper builds an explanatory structure model, establishes a system dynamic (SD) model of investment estimation of intelligent construction of high-speed railway, and puts forward suggestions for supplementing the labor value theory and improving the value-added tax. The paper carries out in-depth research and analysis in the following aspects: 1) the list of influencing factors for investment estimation of intelligent construction of high-speed railway in the feasibility study stage is constructed, and the interpretative structural model (ISM) is constructed to sort out the relationship between the influencing factors; 2) the SD model of intelligent construction cost estimation of high-speed railway is established to improve the accuracy of investment estimation of intelligent high-speed railway construction; 3) put forward suggestions and schemes for improving investment estimation content of intelligent construction of high-speed railway under high intelligence; 4) improve and supplement the labor value theory and the value-added tax base.

**Keywords**—High-speed railway; intelligent construction; investment estimation; interpretative structural model; system dynamics

## I. INTRODUCTION

The level of intelligence in the future will largely affect the competitiveness of countries in the field of high-speed railroads, which brings pressure on the intelligent transformation of China's high-speed railroads while providing a huge opportunity for development. However, with the rapid development of high-speed railway construction under high intelligence, the human labor required in the construction process of high-speed railway is becoming less and less, and "machine instead of human" is becoming more and more common at the construction site; in the near future, less humanized and unmanned will become the mainstream of high-speed railway engineering construction [1]. The corresponding content and method of investment estimation of high-speed railway construction under high intelligence are only suitable for the low and medium intelligence level. With the enhancement of intelligence, the labor cost and management cost are greatly reduced and the robot cost increases, i.e., the content and structure of investment estimation is undergoing a fundamental change. The value-added tax (VAT) calculation theory based on the labor theory of value, where human labor creates new value, is under attack.

Therefore, it is important to analyze and study the characteristics of the factors influencing the investment estimation of intelligent construction of high-speed railroads and their mechanism of action, construct an investment estimation system for intelligent construction of high-speed railroads based on system dynamics, establish a case empirical system to accompany the system for empirical analysis, and propose improvements to the labor value theory and VAT billing base.

With France, Germany and Japan as the prominent examples, all countries in the world have launched research on intelligent railroad construction [2]. German railroads aim to achieve information management and widely promote building information modeling (BIM) technology. In 2014, it proposed to apply 5D BIM technology to the whole process management of German railroad construction and started the intelligent change with the iTWO 5D BIM platforms, such as Bahnhof Horrem station, Rastatter tunnel, Filstal bridge, etc [3, 4]. France, one of the traditional railroad powers, now also places the development of railroad information technology in its development strategy, for example, the digital French railway strategy officially launched in 2015, which strives to focus on the construction of Internet for railroad stations, trains, and road networks and plans to build a railroad system with convenient transportation, strong competitiveness, and close relevance to future transportation from 2031 to 2040 [5, 6]. The United Kingdom expects significant cost reductions in digital signaling, intelligent infrastructure and train control after 2027 and takes applications of intelligent technologies as a daily means of operating the railway network [7]. Japan has taken the lead in the development of intelligence in the field of construction and has started the construction of intelligent coverage of public works management ten years ago to successfully realize the paperlessness of all information in the whole life cycle of construction, which has greatly improved the efficiency of construction and also reduced construction costs [8].

In recent years, Chinese scholars have carried out many research works on the application of system dynamics in the field of engineering construction. Zhou constructed a model of project cost management system based on system dynamics to realize the dynamic evaluation of project costs [9]. Yue uses the system dynamics method to build the project quality system model to realize the quality management of construction projects [10]. Mao constructed a system dynamics model based

on the framework of “BIM-cooperative subject”, pointed out the importance and relationship of relevant influencing factors, and guided the development direction for proposing the strategy of synergy effect of cooperative subject [11]. Gao constructed a risk model for engineering projects based on system dynamics theory and verified it with petroleum projects, which provides a development direction for engineering project risk management [12]. By establishing a system dynamics model for resource allocation of engineering projects, Zhong et al. proposed that the resource allocation strategy should be formulated based on the matching between the characteristics of project operation mode and multiple resources [13]. Based on the system dynamics model, Liu et al. studied the relationship between engineering schedule and cost management [14]. Chen et al. constructed a system dynamics model to study the logical relationship between the factors influencing the cost of prefabricated building and selected rational measures to optimize the cost, improving the current situation of cost management of prefabricated construction projects [15].

In summary, many scholars have used system dynamics to study engineering investment estimation, but most of the studies focus on tunnel investment, component cost, or estimation of part of the cost of the overall project such as material cost, and the system dynamics-based intelligent construction investment estimation for high-speed railway is currently not reported in the literature. This paper explored the method of intelligent construction investment estimation for high-speed railways, identified the factors influencing intelligent construction investment estimation for high-speed railways, constructed an interpretative structural model (ISM) model to explore the interactions between the factors, and built a system dynamic (SD) model. Moreover, SD, scenario simulation, and case inference were used to study the trend of various cost changes of intelligent construction of high-speed railway under high intelligence (70-100%). According to the evolution trend, the corresponding investment estimation cost content and rate improvement methods were proposed to provide academic theoretical basis and support for the investment estimation decision of high-speed railway under high intelligence.

This paper took the intelligent construction investment estimation of high-speed railway as the research subject, constructed the ISM to sort out the relationship of influencing factors of intelligent construction investment estimation of high-speed railway; on this basis, the SD model of intelligent construction investment estimation of high-speed railway was constructed to achieve high-precision estimation; finally, intelligent construction cost correction scheme and tax rate increase correction scheme were proposed under high intelligence (70%-100%).

## II. RELATED BASIC THEORIES

### A. Interpretative Structural Model Theory

The interpretative structural model (ISM) often presents the results of analytic hierarchy process in a skeleton diagram, which clearly and intuitively illustrates the role of every element in the interaction relationship, and it shows obvious advantages in sorting out the complex, multi-layered factor

relationship [16]. Considering the intelligent construction investment estimation of high-speed railway as a whole, the ISM can quickly sort out the relationship between its influencing factors and thus find the key influencing factors. The specific steps are shown below.

Firstly, the correlation relationship between factors is determined, and an adjacency matrix is constructed. The interaction relationship between influencing factors is analyzed. If factor  $S_i$  has influence on factor  $S_j$ , then it is stipulated that there is a direct influence relationship between them; otherwise, it is considered that there is no direct influence relationship between them.

The next step is to determine the recursive relationship between factors in two steps. The first step is to calculate the reachable matrix, and the other step is to determine the level division of different factors.

1) *Find the reachable matrix.* A reachable matrix describes the extent to which the factors can be reached after a certain length of pathway between them through the matrix form, which often requires the indirect role of intermediate factors. Boolean matrix operation rules make the following provision:

when  $(A + I)^{K-1} \neq (A + I)^K = (A + I)^{K+1}$ ,  $(A + I)^{K-1}$  is the desired reachable matrix M.

2) *Divide the hierarchical structure.* Based on the obtained reachable matrix M, the reachable set and the prior set of the factors are obtained, and the influencing factors are divided into different hierarchies.  $R(S_i)$  represents the reachable set, which is the set of all factors that can be reached from  $S_i$ , i.e., the set of factors that can be directly influenced by  $S_i$ ;  $A(S_i)$  represents the prior set, which is the set of all factors that can reach  $S_i$ , i.e., the set of factors that have direct influence on it. Based on this, the intersection set  $C(S_i)$  of the them is obtained.

When the reachable set and the intersection set contain exactly the same influencing factors, they are classified as influencing factors at the same layer. Based on this, the rows and columns where such factors are located are removed, and the remaining influencing factors are classified again by the above method, and so on until all factors are stratified.

### B. System Dynamics Model

SD is a highly dynamic scientific method of analysis based on the whole process of a system [17], which can solve complex and nonlinear systemic problems. The main parameters of the model are divided into four categories: constants, initial values, linear functions, and table functions.

1) Estimation of the constants and initial values with the GM(1,1) model.

Step 1: calculate the cumulative generation sequence.

$$x^{(1)}(k) = \sum_{i=1}^k x^{(0)}(i), k=1, 2, \dots, n \quad (1)$$

Step 2: find the mean series.

$$z^{(1)}(k) = \frac{x^{(1)}(k) + x^{(1)}(k+1)}{2}, k = 1, 2, \dots, n-1 \quad (2)$$

Step 3: calculate intermediate parameters  $C, D, E, F$ .

$$C = \sum_{k=2}^n z^{(1)}(k), D = \sum_{k=2}^n x^{(0)}(k), E = \sum_{k=2}^n z^{(1)}(k) * x^{(0)}(k), F = \sum_{k=2}^n z^{(1)}(k) \frac{\sum_{i=1}^n \sum_{j=1}^m q_j x_{ij}}{\sqrt{(\sum_{i=1}^n \sum_{j=1}^m p_j x_{ij})^2 + (\sum_{i=1}^n \sum_{j=1}^m q_j x_{ij})^2}} \quad (12)$$

Step 4: development coefficient  $a$  and grey action quantity coefficient  $b$ .

$$a = \frac{CD - (n-1)E}{(n-1)F - C^2} \quad (4)$$

$$b = \frac{DF - CE}{(n-1)F - C^2} \quad (5)$$

2) Estimation of the values of the factors of the linear functional relationship.

Step 1: determine the subjective weights using the G1 method.

It is assumed that the impact evaluation index system for investment estimation of high-speed railway construction projects has  $n$  evaluation indexes,  $\{x_1, x_2, x_3, \dots, x_n\}$  and  $w_i$  is the subjective weight of the  $i$ -th indicator. The expert survey method determines that these  $n$  elements have the following relationships:

$$x_1 \geq x_2 \geq x_3 \geq \dots \geq x_n \quad (6)$$

The ratio of the importance degree of evaluation indicator  $x_{i-1}$  to  $x_i$  is  $w_{i-1} / w_i$ , denoted as:

$$r_i = \frac{w_{i-1}}{w_i} (k = n, n-1, \dots, 3, 2). \quad (7)$$

Then, the subjective weights are calculated:

$$w_n = (1 + \sum_{i=2}^n (\prod_{k=i}^n r_k))^{-1} \quad (8)$$

$$w_{i-1} = r_i w_i (k = n, n-1, \dots, 3, 2) \quad (9)$$

Step 2: the entropy method is used to determine the objective weight.

The characteristic weight of the  $i$ -th expert under the  $j$ -th indicator is calculated:

$$p_{ij} = \frac{x_j}{\sum_{i=1}^m x_{ij}} \quad (10)$$

Step 3: the comprehensive weighting method determines the final weight.

The subjective weight is  $p_j$ , and the objective weight is  $q_j$ .

$$k_1 = \frac{\sum_{i=1}^n \sum_{j=1}^m p_j x_{ij}}{\sqrt{(\sum_{i=1}^n \sum_{j=1}^m p_j x_{ij})^2 + (\sum_{i=1}^n \sum_{j=1}^m q_j x_{ij})^2}} \quad (11)$$

The weight coefficient is substituted into the formula:

$$w_j = k_1 p_j + k_2 q_j \quad (13)$$

The final weight is obtained.

3) Estimation of the values of the factors of the table function relationship.

In the whole system flow chart, there is not only a linear function relationship between the factors, but also a table function relationship, for example, the relationship between material dynamic management capability and management intelligence level and the relationship between material dynamic management capability and material unit price influence factor.

### III. MODEL CONSTRUCTION

#### A. Construction Ideas

The intelligent construction system of high-speed railway is a dynamic and complex large system, involving many influencing factors, and the influencing factors are complex, stochastic, dynamic, and coupled, making the intelligent construction investment of high-speed railway show time-series non-linear dependent variable characteristics, such as non-linear, stochastic, dynamic, changeable, and prominent. Moreover, the intelligent construction system of high-speed railway in China is at the world leading level, so there are less historical data to draw on. For these reasons, this thesis used structural explanatory equations, historical data, literature questionnaires, and expert interviews to mine the factors influencing the intelligent construction investment of high-speed railways, used case inference and SD methods to analyze the evolutionary trends and derived mechanisms of the intelligent construction investment estimation, and constructed the corresponding investment estimation prediction and improvement model to effectively improve the accuracy and reliability of the intelligent construction investment estimation.

#### B. Model Composition

1) Influencing factor structure explanatory equation identification module.

a) Preliminary identification based on literature analysis method: We obtained more than 200 papers by searching the keywords of "intelligent high-speed railway", "intelligent construction", "investment estimation factors", and "investment estimation index". Twenty-three papers that cover a wide range of factors and were included in recent time were screened according to the criteria of citation frequency and the grade of journals and selected as the basis for identification to summarize the influencing factors of investment estimation of intelligent construction of high-speed railways.

b) *Additional identification based on the case study method:* To supplement the impact of intelligence on investment estimation, this paper took Beijing-Zhangjiakou and Beijing-Xiongan high-speed railways and three typical intelligent construction projects with large difficulties in the Zhengzhou-Wanzhou high-speed railway as examples to sort out the influencing factors of high-speed railway investment estimation.

c) *List of factors influencing investment estimation for intelligent construction of high-speed railways:* According to the feedback results of the expert pilot survey, the initial set of influencing factors was determined. Seventeen influencing factors were finally determined after questionnaire survey and analyzing and processing the data with SPSS software, including labor, material and machine costs, management costs, design depth, management efficiency, degree of economic development in the region, traditional construction machine configuration, intelligent robot configuration, construction site management level, dynamic material management capability, professional quality of management personnel, project complexity, resource allocation efficiency, intelligent degree of geological exploration, intelligent degree of construction, degree of equipment mechanization, information construction level, and intelligent degree of management.

2) Analysis of the evolutionary trend and derivative mechanism of the impact of influencing factors on investment Intelligent construction investment estimation for high-speed railways was viewed as a holistic system in which every influencing factor interacts with each other. A matrix was constructed for the influencing factors of the intelligent high-speed highway construction investment estimation using an ISM algorithm to quickly sorted out the direct or indirect relationships between the influencing factors [18].

a) *Determine the correlation between factors and construct the adjacency matrix:* The influencing factors were considered as a system consisting of 17 elements. An adjacency matrix was constructed:  $A=[a_{ij}]17 \times 17$ , where  $a_{ij}$  indicates the interaction relationship between the influencing factors. The value of  $a_{ij}$  was 1 when  $S_i$  had a direct influence on factor  $S_j$ ; the value of  $a_{ij}$  was 0 when factor  $S_i$  did not have a direct influence on factor  $S_j$ ; the cells on the diagonal of factor  $S_i$  were all recorded as 0.

b) Determine the recursive relationship between factors.

Step 1: Based on MATLAB platform, final reachable matrix M was calculated.

Step 2: A hierarchical structure division table of the factors influencing the investment estimation of intelligent construction of high-speed railways was sorted out, as shown in Table I.

c) *Construction of an ISM:* The influence factor structure was drawn according to the reachable set, antecedent set, and factor hierarchy decomposition results, as shown in Fig. 1.

3) *Investment estimation module based on case inference and SD:* System dynamics analysis was considered based on

the complex factors and the nonlinear and changeable characteristics of the estimation process.

a) Construction of cause-and-effect diagram of intelligent construction investment estimation system for high-speed railways.

Based on the influence paths obtained from the ISM, the study analyzed the cause-effect relationship, the overall and local feedback mechanism of the system, and the feedback loops in the system for the intelligent construction investment estimation system of high-speed railways and further clarified the polarity of the variables in the system and their mutual influence. The system feedback relationship is shown in Fig. 2.

b) The overall flow chart of the intelligent construction investment estimation system of high-speed railways.

A model flow diagram was established as shown in Fig. 3 by taking the investment estimation cost of intelligent construction of high-speed railways, labor cost, material cost, construction machine use cost, robot cost, enterprise management cost, equipment purchase cost, and the estimated investment cost at the project proposal stage as state variables and taking changes in labor cost, material cost, construction machine use cost, robot cost and enterprise management cost and willingness to invest as rate variables.

4) Trend analysis module for the evolution of investment estimation based on case inference and SD.

On the basis of the above model, the evolution trend of investment estimation was analyzed by inputting 50%, 60%, 70%, 80%, 90%, and 100% intelligence levels.

5) Improvement module for investment estimation derivative mechanism and estimation method.

Based on the above trends of investment estimation evolution, the corresponding derivative mechanisms and laws were deduced, and suggestions for improving labor value theory and the current investment estimation preparation methods were proposed.

TABLE I. RESULTS OF THE HIERARCHICAL DIVISION OF KEY INFLUENCING FACTORS

Levels	Factors
Level 1 (direct apparent influencing factors)	Labor, material and machine costs; management cost
Level 2 (indirect influencing factors)	Project complexity; resource allocation efficiency; professional quality of management staff; management efficiency; degree of economic development in the region; material dynamic management capacity
Level 3 (indirect influencing factors)	Design depth; intelligent robot configuration; construction site management level; traditional construction equipment configuration; information management level
Level 4 (decisive influencing factor)	Intelligent degree of geological exploration; intelligent degree of construction; degree of equipment mechanization; intelligent degree of management

#### IV. MODEL APPLICATION (INTRODUCTION TO PROJECT COMPLEXITY)

Models were applied in the construction of a high-speed train (HST) project, which started in 2019, with a bridge-tunnel ratio of 94%. It was constructed by mature tunnel intelligent construction technology and is a highly intelligent high-speed railway construction project. System dynamics analysis was applicable due to its complex factors and the non-linear and changeable characteristics of the estimation process. Simulations were performed based on the constructed SD model. The main parameters and equations were set, including constants, initial values, linear functions, and table functions.

##### A. Estimation of Constants and Initial Values

With the extension of the construction period, the costs showed exponential situation growth, and the data involved were poorly available. The above characteristics indicated that it was reasonable to adopt the GM(1,1) model. This paper only shows the prediction of other costs of engineering construction, as shown in Table II, and the remaining costs were predicted in the same way.

The grading ratio test values were all within the standard range interval [0.672,1.501], which met the requirement of the construction of the GM(1,1) model. The results obtained according to equations 4 and 5 are shown in Table III, and test difference ratio  $C = 0.0027 \leq 0.35$ , i.e., the accuracy of the constructed model met the requirement, so other costs spent in engineering construction was predicted using the model, as shown in Table IV.

TABLE II. GRADING RATIO VALUES UNDER THE GM(1,1) MODEL

Case	Original value	Grading ratio $\lambda$	Original value + translation conversion shift value (shift = 0)	Converted grading ratio $\lambda$
1	402.868	-	402.868	-
2	393.157	1.025	393.157	1.025
3	385.965	1.029	385.965	1.029
4	387.421	0.996	387.421	0.996

Note:  $\lambda$  = data in the previous period/data in the current period

TABLE III. THE RESULTS OF GM(1,1) MODEL CONSTRUCTION

Development factor a	Grey action quantity b	Posterior test difference ratio c
-0.0110	377.2902	0.0027

TABLE IV. PREDICTIVE VALUES OF OTHER COSTS OF ENGINEERING CONSTRUCTION

Serial number	Original value	Predicted value
1	402.868	402.868
2	393.157	393.157
3	385.965	385.965
4	387.421	387.421
Backward one period	-	393.123
Backward two periods	-	392.441
Backward three periods	-	410.041
Backward four periods	-	405.263

**B. Estimation of the Values of Factors of the Linear Functional Relationship**

Taking the construction site management level as an example, its subtrees were the degree of management intelligence, the degree of construction intelligence, and the degree of equipment mechanization. The subjective and objective weights were calculated by the comprehensive weighting method by taking these subtrees as the boundary point.

Step 1: determine the subjective weights using the G1 method.

Suppose that  $x_1, x_2,$  and  $x_3$  are the degree of management intelligence, the degree of construction intelligence, and the degree of equipment mechanization, respectively; experts believed that these three elements had the following relationship:  $x_1 \geq x_2 \geq x_3$ , and  $r_2 = \frac{w_1^*}{w_2^*} = 1.2, r_3 = \frac{w_2^*}{w_3^*} = 1.2, r_2 \cdot r_3 = 1.44, r_3 = 1.2, \sum_{k=2}^3 (\prod_{i=k}^3 r_i) = 2.64$ .

According to Equations 7, 8, and 9,  $w_1 = 0.33, w_2 = 0.396,$  and  $w_3 = 0.275$ .

Step 2: Determine objective weights by the entropy method.

The scores given by experts are shown in Table V.

TABLE V. SCORES GIVEN BY EXPERTS

Factors	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5
Degree of management intelligence	0.2	0.2	0.1	0.2	0.2
Degree of construction intelligence	0.3	0.2	0.3	0.3	0.2
Degree of equipment mechanization	0.4	0.4	0.3	0.3	0.4

The calculation results of equation 10 are shown in Table VI.

TABLE VI. FEATURE WEIGHT

$j$	$p_{ij}$					$e_j$	$g_j$	$w_j$
1	0.222	0.222	0.111	0.222	0.111	1.581	0.581	0.327
2	0.231	0.154	0.231	0.231	0.154	1.591	0.591	0.334
3	0.222	0.222	0.167	0.167	0.222	1.6	0.6	0.338

Step 3: determine the final weights using the comprehensive weighting method.

According to equations (11) and (12),  $k_1 = 0.669, k_2 = 0.715$ . The final weights were calculated using equation (13). After normalization,  $w_1 = 0.328, w_2 = 0.365,$  and  $w_3 = 0.307$ , i.e., construction site management level =  $0.328 * \text{the degree of management intelligence} + 0.365 * \text{the degree of construction intelligence} + 0.307 * \text{the degree of equipment mechanization}$ .

**C. Estimation of the Values of Factors of the Table Function Relationship**

It was assumed that the data on the degree of management intelligence were accurate; the dynamic management capability of materials would be improved as the degree of management intelligence increased. The corresponding table function was established according to the statistical law, as shown in Table VII.

TABLE VII. TABLE FUNCTION RELATIONSHIP

Management intelligence degree	0	0.1	0.2	0.3
Material dynamic management capability	0.73	0.78	0.83	0.89

The material dynamic management capability = WITH LOOKUP (the degree of management intelligence) Lookup([(0,0)-(1,1)], (0,0.73), (0.1,0.78), (0.2,0.83), (0.3,0.89)).

Resource allocation efficiency and management efficiency were represented by linear functions and table functions. The model constructed in this paper successfully passed the structure, assignment, and unit consistency tests.

**D. Model Simulation and Result Analysis**

Simulation settings were performed in Vensim software to simulate the intelligent construction investment estimation results of the XC section of the HST high-speed railway. The comparison between the results and the actual data of the project suggested that the error between the estimated cost of the intelligent construction investment of high-speed railway in the first year simulated by the system and the actual value was 4.62%; the error between the two-year cumulative investment estimation and the actual investment was 1.83%. This suggested that the accuracy met the requirements, and the model simulation results could be considered to be in line with the reality.

The experimental results of the SD model proposed in this paper were compared with the experimental results of other high-speed railway intelligent construction investment estimation models that can be found in the related literature, i.e., the grey-wolf optimizer-support vector machine (GWO-SVM) estimation model [19] and the improved back-propagation neural network (BPNN) prediction model [20], and the specific data are shown in Table VIII. The error rate in Table VIII is the error between the two-year cumulative investment estimation and the actual investment, and it was seen that the error rate of this model was 1.83%, which was smaller other estimation models. It verified the accuracy of the SD model in the field of investment estimation for intelligent construction of high-speed railway.

TABLE VIII. THE EXPERIMENTAL RESULTS OF DIFFERENT ESTIMATION MODELS

Model	Error rate
The SD model	1.83%
GWO-SVM estimation model	3.14%
The improved BPNN prediction model	3.23%

V. SCENARIO SIMULATION OF THE EVOLUTIONARY TREND OF THE ESTIMATED COST OF HIGH-SPEED RAILWAY INVESTMENT UNDER HIGH INTELLIGENCE

The investment cost was simulated by taking the degree of management intelligence as an example to review the composition of the investment estimation content of the intelligent construction of high-speed railways. Intelligent management refers to the management of the whole process of construction with the help of information management system in the process of high-speed railway construction management. As the degree of intelligent management increases, fewer managers are required, and corporate overheads are reduced. Comprehensive intelligence degree of the high-speed railway project = IF THEN ELSE (investment willingness  $\leq$  0.45,  $0.65 \times$  the intelligent degree of geological exploration +  $0.2 \times$  the intelligent degree of construction +  $0.15 \times$  the intelligent degree of management,  $0.3 \times$  the intelligent degree of geological exploration +  $0.35 \times$  the intelligent degree of construction +  $0.35 \times$  the intelligent degree of management).

The relationship between investment costs and the change of comprehensive intelligence degree of high-speed railway project is shown in Table IX. The labor cost and management cost decreased with the improvement of the intelligence degree, while the robot cost increased significantly, as shown in Fig. 4 and 5. This deviated from the content of traditional railroad investment estimation, so the estimation content and taxable base need to be improved.

TABLE IX. VARIATIONS OF DIFFERENT COSTS WITH THE IMPROVEMENT OF THE COMPREHENSIVE INTELLIGENCE OF HIGH-SPEED RAILWAY PROJECT

Degree of intelligence	Labor cost	Material cost	Construction machine use cost	Robotic cost	Management cost	Profit	Tax
50%	2210.45	15746.13	2746.83	2.29	63.07	1453.81	2444.48
60%	1822.25	14849.78	2471.82	13.13	50.44	1344.52	2260.71
70%	1515.99	14216.74	2236.55	18.71	40.15	1261.97	2121.91
80%	1145.99	13036.42	1850.11	25.68	31.10	1126.25	1893.71
90%	457.54	12065.18	1554.47	224.97	20.57	1002.59	1685.78
100%	0	11406.18	1065.27	492.93	9.70	908.19	1527.05

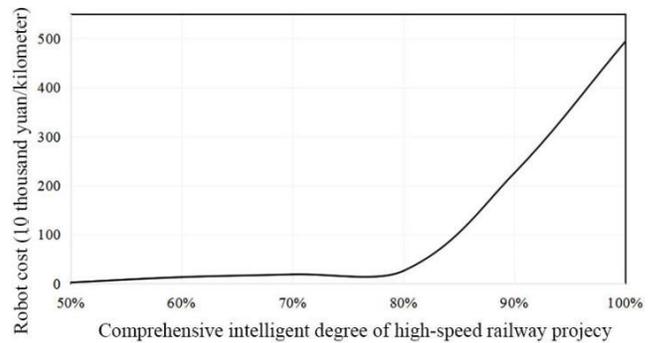

Fig. 5. Trend graph of robot cost change.

VI. STUDY ON THE DERIVATION MECHANISM OF HIGH-SPEED RAILWAY INVESTMENT ESTIMATION UNDER HIGH INTELLIGENCE

At present, the theoretical basis of high-speed railway intelligent construction investment estimation is labor value theory, and machines and robots are only materialized labor, which is only transfer value; the calculation method theoretically takes the increased value of labor cost, management cost, and depreciation cost as the profit and tax billing base, but actually the profit and tax are calculated based on the cost excluding tax. Therefore, under 70-100% high intelligence, the estimated cost and calculation method of intelligent construction investment of high-speed railways need to be revised. Based on this, this paper proposed the amendment of intelligent civil and erection costs and the amendment of tax rate increase.

A. Intelligent Civil and Erection Cost Content Amendment

The cost components and content of intelligent civil and erection costs under high intelligence were adjusted using value theory, system theory and artificial intelligence. The specific elaboration is shown below.

- 1) *Material cost*: With the deepening of construction site intelligence, the dynamic management ability of materials is improved, and thus the material cost is reduced.
- 2) *Construction machine use cost*: Traditional construction machines are replaced by intelligent equipment such as robots on a large scale to significantly reduce construction machine use cost.
- 3) *Robot cost*: A new item of “robot cost” was created, mainly for robot depreciation, while construction equipment use cost becomes the cost of using traditional equipment.
- 4) *Enterprise management cost*: With the continuous improvement of the degree of intelligence, enterprise management cost is greatly reduced; when complete intelligent is realized, enterprise management cost will include the senior management salary.
- 5) *Profits and taxes*: In the case of complete intelligence, there are few labor and management costs. If the robots are still regarded the transfer value of physical labor and excluded from the VAT base, it will seriously affect the profits of enterprises and VAT, resulting in a significant reduction in profits and value added of enterprises.

### B. Rate Increase Amendment

With the development of intelligent production, robots, like people, are a source of surplus value creation. If the rate is not changed, it will seriously affect the profits of enterprises and taxes such as VAT, which will affect the national tax revenue. Therefore, the tax rate should be increased, and profits and VAT should be calculated according to the current cost excluding tax.

### C. Improvements and Supplements to the Labor Theory of Value

1) *Analysis of unmanned construction value sources:* The overall value ( $W$ ) of a conventional railroad investment should be expressed as:  $W = C + V + M$ , where  $C$  denotes constant capital,  $V$  denotes variable capital, and  $M$  is surplus value. Due to intelligence and unmanned construction, the robot's production is a mature production chain. In the production process, the means of production ( $C'$ ) and the mental and physical labor of scientists and workers ( $V'$ ) are all necessary and are also the source of surplus value ( $M'$ ), and at this moment the value of the robot is:  $W' = C' + V' + M'$ . Then, the value generated by the intelligent high-speed railway can be written as:  $W = W' + C_2 = C' + V' + M' + C_2$ . Based on this, when the intelligent construction of the high-speed railway is carried out, the cost of purchasing robots already includes the mental labor of the scientists and the physical labor of the workers who produce these robots.

2) *Changes to the labor value theory brought about by the fully intelligent construction of high-speed railways:* The only source of surplus value is still labor, but the source of labor has changed to labor and robot capital, which is the inevitable result of the rapid development of intelligence. With the development of intelligent technology, the demand for labor is getting lower and lower, and it may even produce the phenomenon of creating robots through the labor of robots in the future. Nevertheless, it is undeniable that although human labor creation is no longer reflected in every production line, the source of surplus value creation is still human, and human and human labor must be the source of value creation, which is an indispensable condition for the creation of artificial intelligence robots.

## VII. CONCLUSION

This paper briefly introduced the ISM and the SD model. The relationship between the factors affecting the intelligent construction investment estimation of high-speed railway was sorted through the ISM model, and the SD prediction and improvement model was constructed for the intelligent construction investment estimation of high-speed railway. Simulation experiments were carried out in the construction of HST high-speed railway. It was found that the error between the first-year estimated cost of intelligent construction investment in system simulation and the actual value was

4.62%; the error between the two-year cumulative investment estimate and the actual investment was 1.83%. The results prove that the SD model has high accuracy and is feasible in the investment estimation of intelligent construction of high-speed railway.

**Abstract**—It is crucial to know crop growing in order to increase agricultural productivity. In sugarcane's case, monitoring growth can be supported by remote sensing. This research aimed to develop an early warning for sugarcane growth using remote sensing with Landsat 8 satellite at a crucial phenological time. The early warning was developed by identifying regional sugarcane growth patterns by analyzing seasonal trends using linear and harmonic regression models. Identification of growth patterns aims to determine the crucial phenological time by calculating the statistical value of the NDVI spectral index. Finally, monitoring the sugarcane growth conditions with various spectral indices for verification: NDVI, NDBaI, NDWI, and NDDI. All processes used Google Earth Engine (GEE) as a cloud-based platform. The results showed that sugarcane phenology from January to June is crucial for monitoring and assessment. The value of the four corresponding indices indicated the importance of monitoring conditions to ensure a healthy sugarcane region. The results showed that two of the four regions were unhealthy during particular periods; unhealthy vegetation values were below 0.489 and vice versa, one due to excess water and the other due to drought.

**Keywords**—Google earth engine; landsat 8; monitoring and assessment; sugarcane health

## I. INTRODUCTION

Sugarcane is a raw material for the sugar industry that plays a strategic role in Indonesia's economy, with a crop area of 413.05 thousand ha in 2019 [1]. Sugar consumption in Indonesia continues to increase. In 2023, it will reach 7.15 million tons, in line with Indonesia's population growth rate [2]. However, domestic sugar production has not been able to meet Indonesia's sugar needs [2]. In response to the increasing demand for sugar, Indonesia has declared the aim of self-sufficiency by increasing sugarcane production and productivity through policies and programs in the "on-farm" aspect [3]. In an effort to support the sugarcane production and productivity in Indonesia, it is essential to apply the proper technology, including remote sensing by satellite for early warning of sugarcane growing at crucial phenological times.

An early warning detects potential incidents and is beneficial in managing and preventing factors that cause crop loss, such as insufficient or excessive irrigation, disease, and pests. In addition, early warning at crucial phenological times helps identify and measure factors that affect plant growth, especially sugarcane. Through early warning, sugarcane regions experiencing stress can be identified and classified so that farmers can change their practices to increase sugarcane

productivity and production. Then, knowing the condition of plants at the peak of phenology can also help in agricultural planning and management.

The application of remote sensing to sugarcane crop conditions has evolved in the last decade, for example, monitoring the growth phase of sugarcane by satellite in West Java, Indonesia [4]; the role of NDVI in mapping sugarcane conditions around oil and gas fields [5]; assessment of sugarcane conditions based on NDVI [6]; monitoring sugarcane growth [7]; sugarcane yield estimation and forecasting in smallholder farming conditions [8]; prediction of sugarcane yield based on NDVI and nutrient concentration [9]; and prediction of crop yields from MODIS relative vegetation health in Africa [10]. However, to monitor sugarcane growth, there has been no early warning during the crucial times of sugarcane phenology. In previous studies, plant growth was only through a cooperative data approach, not based on plant phenology knowledge. In addition, the method in the previous study was based on vegetation parameters only. Meanwhile, in this study, plant growth with several parameters based on satellite data was built with linear regression based on phenological knowledge.

On the other hand, available and open remote sensing data can now be analyzed with more affordable computing, and a free cloud platform can be used for geospatial analysis, namely Google Earth Engine (GEE). GEE, as a cloud platform, is efficient for geospatial analysis [11], which is helpful for precision agriculture, with its availability of comprehensive and open data, for example, for monitoring vegetation's current state and dynamics [12]. GEE applications have also been widely used to solve agricultural problems, for instance, mapping sugarcane by integrating multitemporal Sentinel-2 images [13]; rice mapping based on SNIC segmentation [14]; and object-oriented crop classification [15].

This research offers a solution to issues of production and productivity in building an early warning for sugarcane conditions at crucial phenological times through monitoring and assessment. The method of creating an early warning include several approaches: (1) analyzing seasonal trends in the region using linear regression and harmonic models to identify sugarcane growth patterns; (2) assessing the condition of sugarcane through statistical analysis of the Normalized Difference Vegetation Index (NDVI) spectral index at the crucial phenological phase; and (3) monitoring sugarcane conditions with various spectral indices, based on typical use, and having accurate results for condition interpretation, with

NDVI as the vegetation index, Normalized Difference Bareness Index (NDBaI) as the fallow land identification, Normalized Difference Water Index (NDWI) as a water content indicator, and Normalized Difference Drought Index (NDDI) as a drought indicator. The four spectral indices serve as a system of checks and balances to assess sugarcane conditions. All processes were performed on GEE as a cloud-based platform. Therefore, this research aimed to develop an early warning of sugarcane growth using remote sensing at a crucial phenological time. From the solutions offered, farmers can better anticipate particular practices, and the government can increase productivity and sugarcane production in a more sustainable manner through precision farming.

This paper is described in systematics: materials and methods used for early warning with several parameter indicators, building knowledge of plant phenology; and the results section to determine plant status using remote sensing data. The conclusions and recommendations section reports findings for future research.

## II. MATERIALS AND METHODS

### A. Study Area

This study was carried out at sugarcane plantations of Djengkol Kediri, East Java Province, Indonesia, with a coordinate polygon of (Lat: 112.199, Long: -7.892). The area was selected because (1) East Java is the largest producer in Indonesia, with Djengkol Kediri as the second largest [2]; (2) the plantations in the area support the economy, and are the basis for the sugar self-sufficiency program; (3) it is a representation and model for other fields. As shown in Fig. 1.

In the study area (Fig. 1), the region was selected based on the sugarcane plantation and divided into four regions: (1) region A: relatively flat terrain with a mean elevation of 260 m above sea level; (2) region B: relatively flat terrain with a height of 264 m; (3) region C: sloping terrain (left to right) with a mean elevation of 267–272 m; (4) region D: sloping terrain (left to right) with a mean elevation of 273–276 m. The four regions are planted with the same sugarcane variety.

### B. Maintaining the Integrity of the Specifications

The image data used in this study were sourced from the Landsat 8 satellite, available at GEE “LANDSAT/LC08/C01/T1\_TOA”. The public image collections were filtered with by using several timescales and criteria: (1) image collection from 2015 to 2020 was used to analyze seasonal sugarcane trends to obtain cropping patterns in the study region and to mask clouds; (2) cloud-free image data from 2014 to 2017 were used for the assessment of sugarcane conditions; (3) 2019–2020 was used for monitoring data on sugarcane health and cloud-free image collection. In addition, all image collection timescales used a resolution of 15 m, increasing the resolution shown in Fig. 2 through the Brovey transformation approach by blending the panchromatic [16] (Formula 1):

Fig. 1. The study area in the sugarcane plantation of Djengkol Kediri, Indonesia

$$R_{in} = R_{in} / (R_{in} + G_{in} + B_{in}) \times P_{in} \quad (1)$$

where  $R_{in}$  = Band 4,  $G_{in}$  = Band 3,  $B_{in}$  = Band 2, and  $P_{in}$  = Band 8 (panchromatic).

Fig. 2. RGB image 30 m (left) and the result of image sharpening through panchromatic blending, 15 m (right)

### C. Sugarcane Phenology

Plant phenology can identify and obtain important information about vegetation [17]–[19]. Sugarcane (*Saccharum officinarum*) is a type of grass with unique characteristics. Sugarcane phenology has four phases: (1) germination—this phase lasts for 15–20 days while new shoots are growing; (2) tillering—the sugarcane plants grow tillers for 4–6 months during this phase, and up to 50% of each sugarcane stalk grows leaves; (3) grand growth during this phase, lasting for 5 months, sugarcane height elongates and plants grow to maturity; and (4) maturity: this phase, which occurs during the 3 months before harvest, includes vegetative decline and sucrose accumulation of up to 55% per dry weight of sugarcane [20]. The leaf area index (LAI) value reaches its maximum when the plant is 6 months old, decreasing slowly afterward [6], [20].

Sugarcane phenology generally lasts 10–12 months. In this study area, sugarcane phenology (Table I) proceeds as follows: from early October to November is seeding and budding, January to April is stem elongation, May to August is the period of sugar accumulation and ripening, and September is the harvest period.

TABLE I. TIME OF SUGARCANE PHENOLOGY IN STUDY AREA

Crop	Years/Month	Periods	
Sugarcane	2019	Oct	SE
		Nov	SE
		Dec	SL
	2020	Jan	ST
		Feb	ST
		Mar	ST
		Apr	ST
		May	SA
		Jun	MA
		Jul	MA
		Aug	MA
Sep	HA		

Note: HA: harvest stage; SE: seeding stage; SL: seedling stage; ST: stem elongation stage; SA: sugar accumulation stage; MA: maturation stage.

D. Spectral Indices

Plants can absorb and reflect unique light waves. This phenomenon is carried out by chlorophyll in the mesophyll tissue of leaves (photosynthesis) [21]. As a basis for remote sensing using satellites, the brightness value received by satellite sensors in a particular band was used to identify plants. The spectral index works by calculating the wavelength of the band composition.

There are many types of indices, and only four were used in this study, namely (1) Normalized Difference Vegetation Index (NDVI), which describes the greenness of a plant. It is based

on a mathematical combination of visible red light and near-infrared radiation (NIR) channels, which are used as indicators of the presence and condition of vegetation [22], as illustrated in Formula 2; (2) Normalized Difference Bareness Index (NDBaI) is used to separate fallow or open land from other types of cover using Landsat image data [23]. It is very sensitive for distinguishing between fallow, semi-fallow, and cultivated areas. The index uses the short infrared (SWIR) and thermal infrared (TIR) bands, as shown in Formula 3; (3) Normalized Difference Water Index (NDWI) is used to determine the water content of vegetation [24]. It is obtained from a combination of green and red bands, as presented in Formula 4; (4) Normalized Difference Drought Index (NDDI) aims to identify the presence of drought in vegetation [25] based on a comparison of the NDVI and NDWI index values, as illustrated in Formula 5.

$$NDVI = (NIR - RED) / (NIR + RED) \tag{2}$$

$$NDBaI = (SWIR - TIR) / (SWIR + TIR) \tag{3}$$

$$NDWI = (NIR - SWIR) / (NIR + SWIR) \tag{4}$$

$$NDDI = (NDVI - NDWI) / (NDVI + NDWI) \tag{5}$$

where NIR = Band 5, RED = Band 4, SWIR = Band B6, and TIR = Band 10.

The NDVI spectral index value was used as the primary reference for monitoring sugarcane conditions obtained from the assessment results, while the other three spectral indices (NDBaI, NDWI, and NDDI) were used for verification.

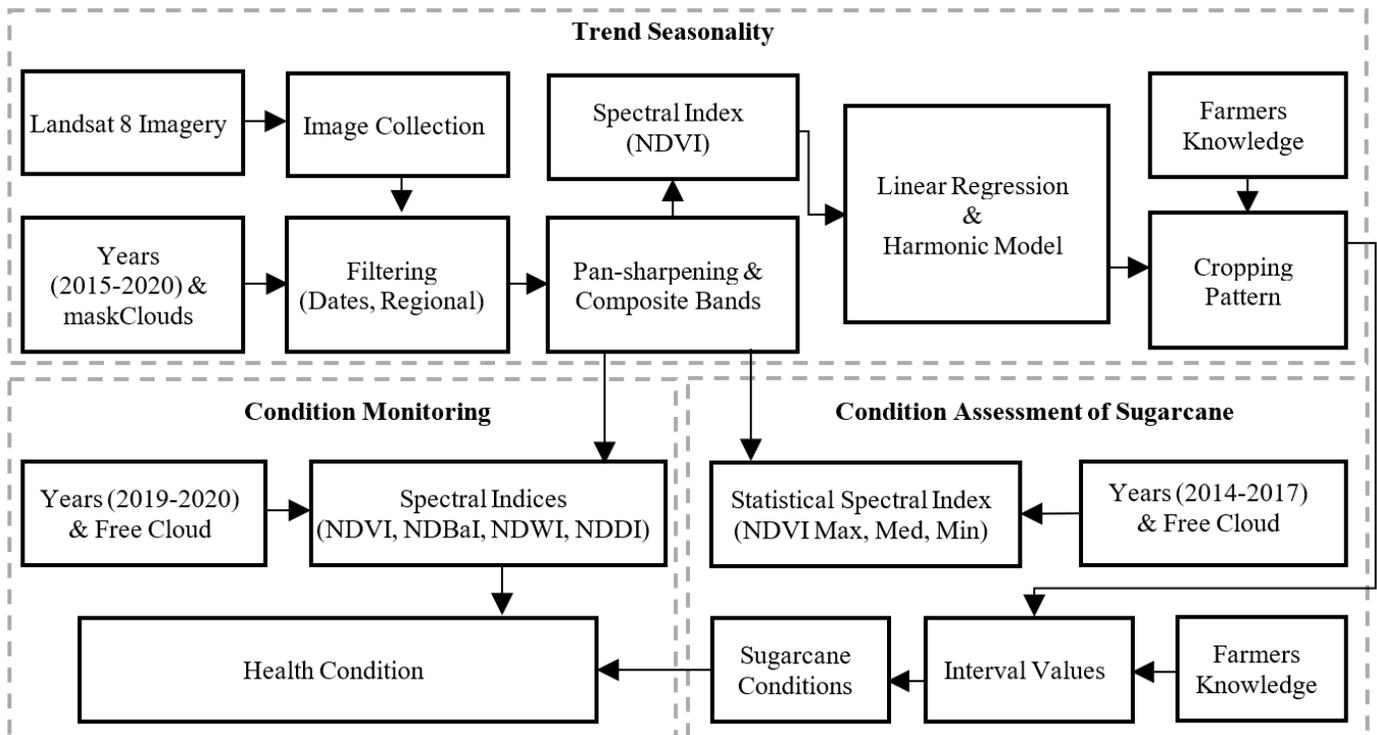

Fig. 3. The study area in the sugarcane plantation of Djengkol Kediri, Indonesia

E. Methodology

Three primary processes were carried out to create an early warning for sugarcane planting conditions (Fig. 3): (1) identification of sugarcane growing patterns by analyzing seasonal trends using a harmonic model (NDVI input); (2)

assessing the condition of sugarcane using the NDVI spectral index; and (3) monitoring sugarcane condition with various spectral indices (NDVI, NDBaI, NDWI, and NDDI). All processes were performed on GEE as a cloud-based platform.

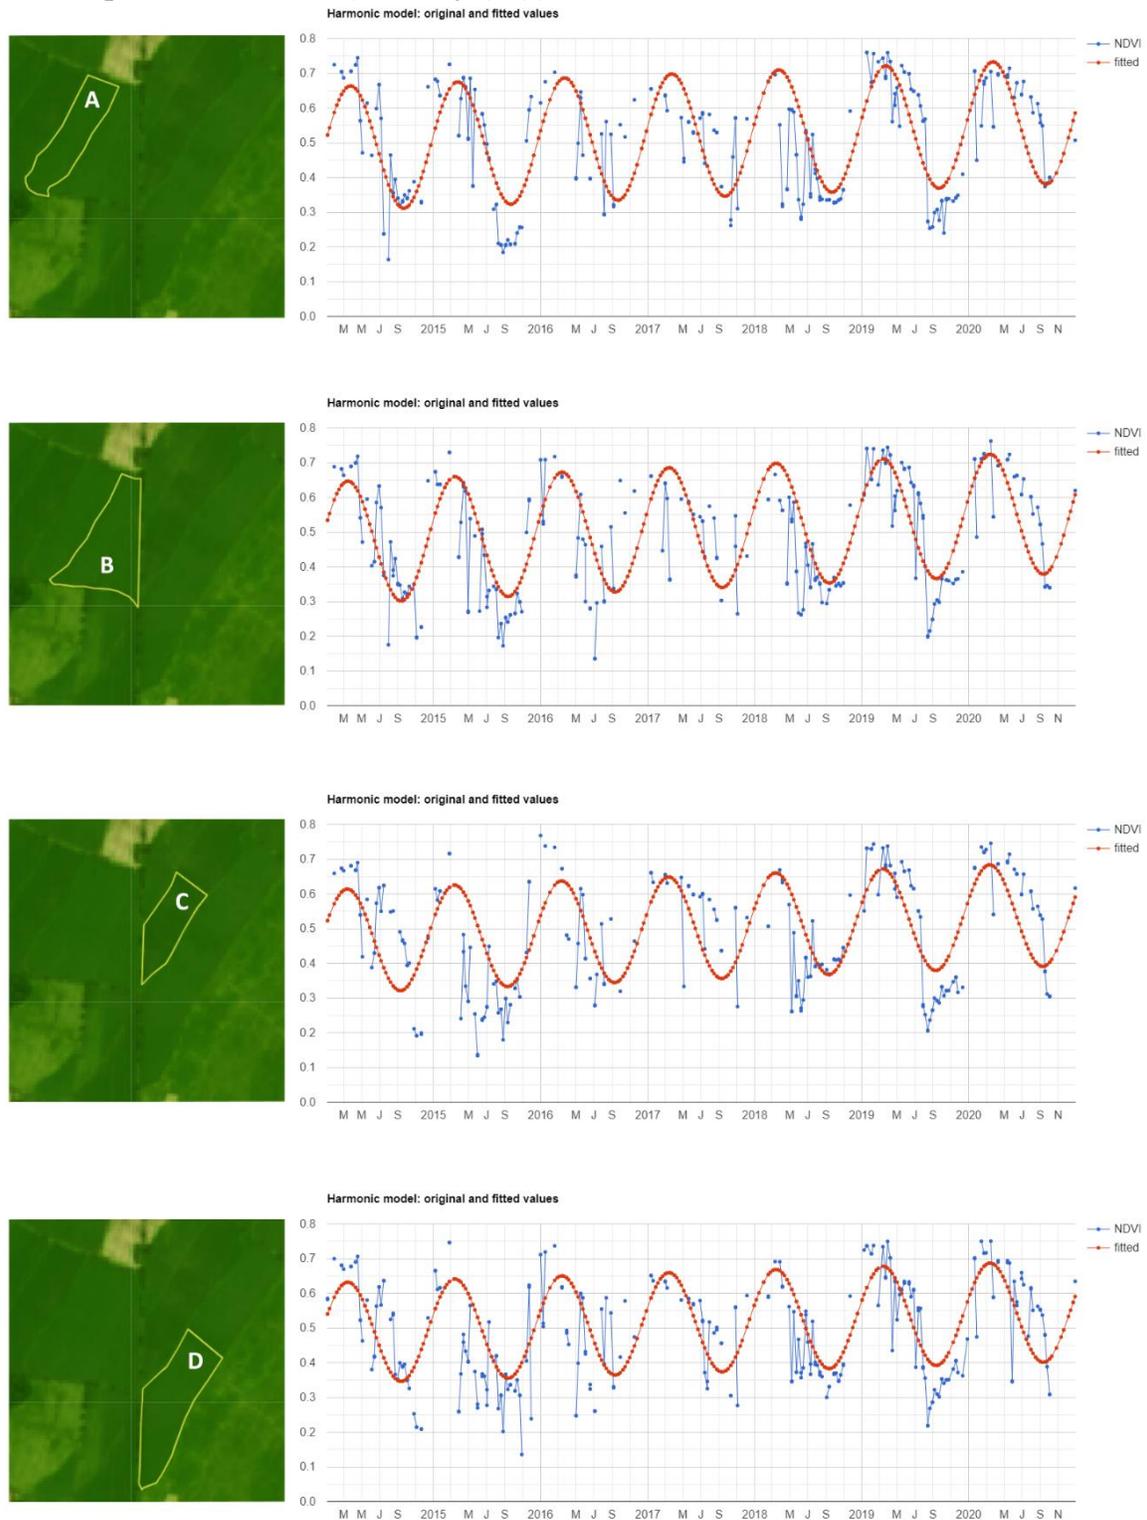

Fig. 4. The frequency of the sugarcane planting pattern based on NDVI values

F. Trend Seasonality

Monitoring seasonal changes in vegetation activity and plant phenology is very important in condition monitoring. In sugarcane, it is necessary to analyze seasonal trends based on phenology using multitemporal data. In GEE, a seasonal trend analysis can be constructed with time series data through temporal data (NDVI) with linear regression (Formula 6) [26]. The seasonal forecast is then built by combining the linear model with the harmonic model (Formula 7) [26].

NDVI values were integrated and used as the basis for seasonal trend analysis (Fig. 4) from image collection data for 2015–2020 in each region (A, B, C, D) by filtering out the masking clouds.

$$p_t = \beta_0 + \beta_1 t + e_t \tag{6}$$

$$p_t = \beta_0 + \beta_1 t + A \cos(2\pi\omega t - \varphi) + e_t$$

$$= \beta_0 + \beta_1 t + \beta_2 \cos(2\pi\omega t) + \beta_3 \sin(2\pi\omega t) + e_t \tag{7}$$

where  $A$  is the amplitude,  $\omega$  is the frequency,  $e_t$  is the random error, and  $\varphi$  is the phase.  $\beta_2 = A \cos(\varphi)$ , and  $\beta_3 = A \sin(\varphi)$ , implying  $A = (\beta_2^2 + \beta_3^2)^{1/2}$ , and  $\varphi = \tan^{-1}(\beta_3/\beta_2)$ . To fit this model to the time series, we set  $\omega = 1$  (one cycle per unit time) and use ordinary least squares regression.

G. Sugarcane Assessment

The purpose of the assessment was to determine the condition of sugarcane. This was based on crucial phenology and used as a reference for an early warning of sugarcane conditions that could predict possible problems emerging in the sugarcane crop. This assessment was developed on phenological knowledge obtained from planting patterns (from analysis of seasonal trends). The results showed the importance of assessing the condition of sugarcane at intervals from January to June. There were several procedures included to assess sugarcane conditions: (1) image data were used for assessment of sugarcane conditions based on cloud-free image

collection data from 2014 to 2017; (2) the locations used were the four regions (A, B, C, D); (3) NDVI spectral information was used as a parameter to determine the condition of sugarcane, then statistical calculations were performed (maximum, median, minimum); (4) the NDVI spectral value of the Landsat 8 image was verified with the farmers’ knowledge on the current condition within the region (A, B, C, D) under prior normal conditions.

III. RESULTS AND DISCUSSIONS

A. Sugarcane Cropping Pattern

Information on sugarcane cultivation patterns in the study area was obtained from the analysis of seasonal trends. The sugarcane cropping pattern was identified through the NDVI value by harmonic model analysis (Fig. 4). The planting pattern became the basis of knowledge for the monitoring and assessment of sugarcane. The sugarcane planting pattern in the study area follows: (1) the cropping pattern begins in October and ends in September of the following year, which applies to all regions (A, B, C, D), as verified with local farmers’ knowledge of appropriate conditions (Table I); (2) the peak NDVI index value occurs six months after planting; (3) the crucial phenology occurs from January to June; therefore, this period was used as a reference for monitoring sugarcane conditions (from two months before peak plant growth to three months after, in preparation for harvest).

B. Assessment of Sugarcane Condition

Sugarcane conditions were assessed from the values of the NDVI spectral index. Based on statistical calculations of the NDVI value of the entire region (A, B, C, D) and the results of local knowledge of the planting pattern, the condition of sugarcane crops from January to June was the focus of the early warning. The interval value for each of those months was the reference for monitoring sugarcane conditions, as shown in Fig. 5.

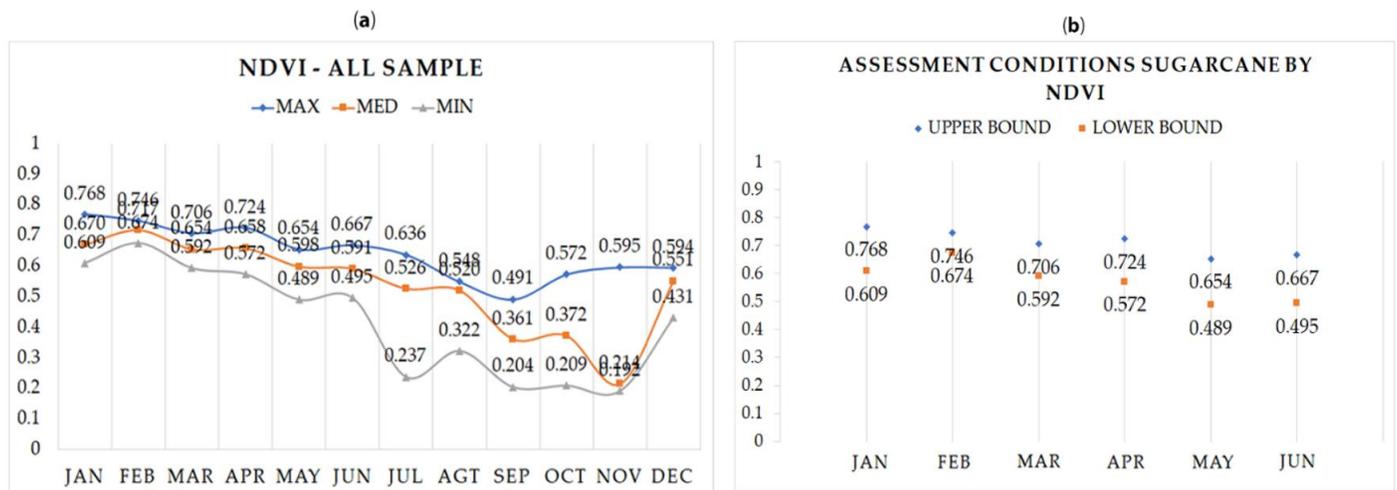

Fig. 5. Results of sugarcane condition assessment: (a) The statistical values from the combination of all sample regions; (b) Sugarcane conditions based on statistical calculations of NDVI values in the crucial months of January to June

C. Assessment of Sugarcane Health

The sugarcane plants were monitored from January to June in 2019–2020 (two periods of planting). The sugarcane condition was measured based on the NDVI spectral index value generated from the sugarcane condition assessment process. Furthermore, to verify the condition, comparisons were made through other spectral indices such as NDBaI, NDWI, and NDDI. The condition of healthy vegetation is the ability to absorb blue- and red-light energy to trigger photosynthesis and create chlorophyll.

Plants with more chlorophyll can reflect more near-infrared energy than the unhealthy variants [21], [27], hence, the spectra of absorption and reflection in visible. Thus, plant spectra of absorption and reflection in visible and infrared wavelengths can provide information about plant health and productivity.

From the results of monitoring the condition of sugarcane plants (Fig. 6), and verified by other spectral values (NDBaI, NDWI, and NDDI), sugarcane condition monitoring was categorized as follows:

- Regions A and B were in good health. The NDVI value belonged to the healthy condition interval value (results of the sugarcane assessment). In addition, the comparison of the other spectral index values (NDBaI, NDWI, and NDDI) was appropriate, as shown in Fig. 7.
- In region D, in April 2019, the NDVI value decreased, signaling an unhealthy condition (Table II). Compared with other spectral data, the value of the NDWI spectral index increased; this showed that region D in April was excessively moist. However, this condition normalized in the following month, as shown in Fig. 7.

TABLE II. NDVI VALUE IN THE MONITORING FOCUS PHASE. VALUES IN RED INDICATE AN UNHEALTHY CONDITION

Year/Month		Region			
		A	B	C	D
2019	Jan	-	-	-	-
	Feb	0.749	0.730	0.709	0.728
	Mar	0.761	0.764	0.721	0.746
	Apr	0.733	0.727	0.698	0.451
	May	0.729	0.739	0.696	0.693
	Jun	0.713	0.716	0.672	0.664
2020	Jan	0.642	0.715	0.629	0.646
	Feb	0.675	0.719	0.711	0.696
	Mar	0.734	0.768	0.693	0.756
	Apr	0.636	0.706	0.702	0.679
	May	0.685	0.728	0.458	0.698
	Jun	0.663	0.659	0.368	0.667

- In region C, in May–June 2020, the NDVI value decreased until near the harvest period (Table II), indicating the sugarcane plants were in an unhealthy condition. Together with the other spectral index values (the NDWI values decreased, while the NDDI values increased), this showed that the unhealthy condition of region C sugarcane in May–June was due to lack of water, as shown in Fig. 7.

#### D. Discussions

The early warning was beneficial to find the factors that affected the growth of sugarcane plants. An early warning was developed based on a crucial phenological time. Phenology helps to obtain necessary information on plants, such as detecting, classifying, and monitoring plants [17]–[19], [28]–[30]. An early warning based on crucial phenology can anticipate problems with sugarcane crops and suggest practices to increase sugarcane productivity and production. In addition, early warning at crucial phenological times also provides knowledge concerning general sugarcane conditions. Although the primary index is only NDVI, it can describe the condition of sugarcane plantations when combined with other additional indices such as NDBaI, NDWI, and NDDI, unlike previous studies that only applied NDVI [5], [6], or estimates of sugarcane health conditions [8] that ignored sugarcane phenological time.

The early warning results based on phenological time show that the four regions (A, B, C, and D) had different challenges. Both regions A and B were in a healthy condition, while region D in April 2019 and region C in May–June 2020 were unhealthy. The four regions are in adjacent planting areas, but the four regions have different terrain. Regions A and B are on flat terrain, while regions C and D have sloping field characteristics.

Based on verification from other indices (NDBaI, NDWI, and NDDI), sugarcane in region D in April 2019 experienced a decrease in NDVI and NDDI value while NDWI rose, indicating that region D was waterlogged. To ensure the correct assessment of the sugarcane condition, we added a rainfall indicator in the study area [31], as shown in Fig. 8. In region D for April 2019, rainfall was still common, and in March 2019, the rainfall was relatively high. In region D, April 2019 had the potential to be waterlogged. However, this returned to normal by the following month.

In region C, May–June 2020, the sugarcane was in a drought condition. Rainfall data showed low rainfall duration and intensity, as shown in Fig. 8. Sloping terrain makes it essential for region C to apply early warning as a solution to anticipate adverse conditions. When discussed with farmers, sugarcane-growing regions need to improve water irrigation management, especially for regions characterized by sloping land. Irrigation improvement is in process with a trial of drip irrigation in August 2020.

This early warning showed factors that affected the condition of sugarcane crops. The practice of this approach to research helps early warnings become more considerate to ensure dynamic plant conditions. So solving the problem of early warning of plant growth becomes more certain against uncertain conditions. However, a drawback, namely the limited once-per-month data, results in the daily details of the sugarcane condition remaining unknown.

#### IV. CONCLUSION

Factors affecting sugarcane growth were identified using an early warning, which can help anticipate adverse conditions. In this study, it has been shown that monitoring the condition of sugar cane as an early warning, based on the phenology from

January to June, describes the condition of the sugar cane using various indicators. The sugarcane conditions in each region were different. Regions A and B were in a healthy condition throughout the monitoring phase. In contrast, regions C and D were in unhealthy conditions for part of the time. Region D had excess water in April 2019, and Region C had a drought in May–June 2020. Conditions unhealthy are based on vegetation values below 0.489. As for health conditions, it is at the opposite vegetation value.

Suggestions for future research, early warning can be solved by sharp satellite, which has a sharper resolution with a range of data available daily. In addition, early warning indicators can be combined with data related to climate change.

#### ACKNOWLEDGMENT

We thank the Institut Teknologi Telkom Purwokerto, and Department of Computer Science, IPB University for supporting this research. We also thank the anonymous reviewers for their constructive comments and advice.

# Fault Tolerance Smart Egg Incubation System with Computer Vision

Emilijan Petkov, Teodor Kalushkov, Donika Valcheva, Georgi Shipkovenski

Department of Mathematics and Informatics, University of Veliko Tarnovo, Veliko Tarnovo, Bulgaria

**Abstract**—Reliability of incubators is one of their most important specifications. Development of wireless, cloud and computer vision based technologies gives new possibilities for work process control and increasing fault tolerance. Regardless of whether the hatching is in the field of mass production or in the breeding of rare species of birds, detecting a critical situation and sending timely notifications can prevent serious losses. Experience shows that network isolated solutions are not reliable enough and good management requires complex algorithms that are beyond the capabilities of a local, single controller. Even with the duplication of some sensors and actuators, incubators without external connection are high risk due to the fact that their controller is a central point in the architecture and can fail, leaving the farmer with no alert about the accident. The report presents a solution that uses periodic checks from cloud structures on the condition and operability of the incubator. In parallel, a video surveillance system analyzes the internal environment and the condition of hatching chicks. When potential and real risks occur, the system sends notifications to the responsible persons even to his or her wrist. Additionally, the proposed smart egg incubation methodology has been found to reduce the amount of time required for farmers to oversee the incubation process by up to 50%, allowing them to focus on other important tasks while still ensuring optimal hatching conditions for their eggs. Overall, the proposed methodology offers a significant improvement in egg incubation efficiency and reliability, with potential applications in both commercial and personal settings.

**Keywords**—Hatching; incubation; computer vision; cloud architecture; sending alerts; smart farming; internet of things

## I. INTRODUCTION

### A. Defining the Research Problem

Smart farming, like industrial production, follows the steady trend of replacing manual human labor with automated systems. Innovative solutions manage not only purely mechanical activities but also digital ones implementing artificial intelligence and computer vision in many systems to generate feedback for control and corrections of processes during their operation. In this way, the possibility of human error is reduced to the lowest possible values and the dependence on the labor market is minimized. The ultimate goal that is achieved through these trends is a significant increase in efficiency and respectively productivity. First smart farming solutions that have been developed include systems with controllers, sensors and actuators, but without video cameras.

The prerequisites for the development of computer vision based smart farming include:

- Offering cameras with high matrix resolutions and the ability to capture many frames per second on a lower price.
- Development of new network standards for high-throughput wireless communications.
- More accessible cloud technologies that provide the ability to process more complex algorithms in image analysis.
- Ability to customize processing load distribution between on-premises and cloud structures.
- The trends for a non-expansive increase in a farm production.

It is a hard task to list all the examples in this area, but some of them may be referred to as a representative sample. In crop production, a large group of computer vision based applications aims to recognize the fruits of plants in order to pick them [1,2]. Some others analyze pictures of plant leaves to find diseases and determine their condition [3,4,5]. The outcomes of such systems can be used for appropriate subsequent treatment (spraying) of the plants [6].

There are no less in a number of examples of computer vision systems in animal husbandry. Examples for animal farming include counting of silkworm eggs [7]. Sometimes in animal farms, the processes of image acquisition and processing can be significantly complicated due to the more intensive motor activity of animals compared to that of plants. Such case with pigs is described in [8]. It describes the algorithms for separating individual animals from a group in which they are close to each other. Of course there are again examples of recognizing health problems of animals from the processed images [9,10]. Feeding process control is also a possible target of the computer vision system in a smart farm [10]. This paper explains how to recognize pigs with low weight. Poultry farms are no exception to the implementation of intelligent machine vision solutions. In this scenario infertile egg detection is a key feature [11].

Some interesting applications corresponding with smart farming also exploit computer vision methods. Baoming Shan uses image analyses of eggs in vaccine production from embryos [12]. Fertility detection is again targeted in the results, although the field of use in this case is pharmacy.

A large number of papers [13,14,15,16] oriented to a human incubators describe machine-vision mechanisms for monitoring the state of babies. Different type of cameras can monitor movements, temperature and persistence of a newborn. From the recorded movements, it is possible to draw conclusions about certain behavior according to a health condition and thus detect critical situations. The described systems are traditionally used in combination with standard sensors and controllers that upgrade the information from the images.

All listed examples above lead to the conclusion that computer vision can be very helpful into the hatching process and may increase the reliability, by protecting the eggs and new chicks from injury and exposure to adverse conditions in the incubator's internal environment.

### B. Importance of the Problem

Today the share of small farms that breed several species of animals is decreasing compared to that of large and strictly specialized in certain breeding. Therefore, methods and devices for hatching a large number of chickens are sought in poultry farming. In case of hatchery failure, this approach makes the potential losses significantly greater.

Apart from hatching for mass production, with the right settings, the small, modern, intelligent hatcheries can also be used for breeding exotic species of birds and reptiles. This scenario is also associated with a high risk of failure because eggs are usually very rare.

### C. Purpose and Tasks of the Research

In order to reduce the possibility of harmful consequences in the situations described above, it is necessary to increase the reliability of the hatcheries using modern methods. This main purpose can be divided into the following tasks:

- Selection of building modules.
- Implementing cameras in the hatcheries so that operators can monitor the interior.
- Creation and implementation of a computer vision system in the hatchery.
- Preserving the functionalities for reliable notifications of the operator in a problematic situation.
- Analysis of possibilities and selection of a model for building the connections between the devices, the cloud environment and the operators.
- Implementation of a prototype corresponding to the selected model.

### D. Hypothesis

Cloud technologies can be a key tool to increase the reliability. The integration of a computer vision system can be realized locally through a controller and a smart camera, but such solutions are too expensive. On the other hand, using a microcomputer and camera is an alternative, but using an operating system can generate new potential points of failure (opportunities for viruses, attacks, sudden reboot problems, etc.). Cloud structures provide an optimal solution because

they do not require computing potential from the controllers, but possess the necessary for the implementation of the functions desired by the user.

### E. Expected Benefits

The results of research, described in this paper try to offer a model for building a modern incubator with maximal fault tolerance, level of automation, flexible control and visual feedback for the users. Suggested devices should also allow comfortable parameters observation (charts) and optimization of the processes. Following this line of thought can be defined a new system of incubators as Fault Tolerance Smart Egg Incubation System with Computer Vision (FTSEISCV). The reader should note that this is a development of another study on smart incubators. Prior publication on development of Smart Egg Incubator (SEI) can be seen at [17].

The main contributions of the proposed smart egg incubation system include advanced features such as microcontroller-based control and monitoring, camera-based hatching detection, and precise regulation of temperature, humidity, and airflow parameters, which collectively provide farmers with an efficient, reliable, and user-friendly solution for egg incubation. Additionally, the system's ability to reduce the amount of time required for farmers to oversee the incubation process by up to 50% can have a significant impact on productivity and profitability, while also improving hatching success rates and reducing the risk of losses due to incubation-related issues.

### F. Organization of the Paper

The paper contains an overview of historical development of incubators in the second part and analysis of used models up to the moment in the third. Next fourth part represents the proposed, improved model, selected hardware components for the experimental prototype, used software and cloud structures. User interface and control management are also explained in this part. The paper finishes with conclusions and references.

## II. OVERVIEW OF EXISTING SOLUTIONS ON THE TOPIC

The first incubators from 20th century were made from a wooden box with a pot-like container attached to the side (Fig. 1) [18].

Fig. 1. An old incubator from 1913.

They included a thermometer and required almost constant monitoring by farmers.

Electronic analog-element managed systems increased the automation. They included humidity and temperature sensors

and actuators like heaters, fans, evaporators and mechanisms for eggs rotation.

After IC chips implementation, some advanced and more complicated functions were able to be performed. Specific to this period is the transition from analog to digital signal processing.

Until a few years ago the only accessible option to increase reliability was realized by duplicating individual elements of the incubator. Thus, when one of the elements fails, the backup one takes over its functions. However, these solutions often do not work if the controller module fails and therefore require regular checks from operator to prevent disaster.

First notification developments were realized through mobile network gateways. At this moment were implemented alerts for the operators, when incubation parameters exceed the preset limits. Unfortunately, if the cellular network is not available or if the user is temporarily unavailable (due to personal reasons sometimes), the notifications are not repeated and thus the desired level of trust is not guaranteed.

Programmable controllers allow full automatic control during the whole incubation. In addition to temperature and humidity, sensors in modern incubators also measure the percentage content of oxygen, carbon dioxide and ammonia compounds in the air.

The limitations of existing egg incubation systems, such as poor temperature and humidity control, inconsistent egg rotation, and limited hatching success rates, motivated the development of the proposed smart egg incubation system with advanced features like microcontroller-based control and monitoring, camera-based hatching detection, and precise regulation of temperature, humidity, and airflow parameters.

The next step in the upgrade of the modern incubators is realized with the expansion of the World Wide Web and their digital transformation in the industry [19] into Internet of Things devices. Initial attempts in this direction were aimed to monitor the processes and environment and control them over the network, only by the operators. At this point, in addition to cellular networks, notifications could now be sent and received in parallel or alternatively via the Internet. This kind of device operation can be defined as a third layer of the mentioned model above.

### III. OUTCOME OF THE RESEARCH ON THE EXISTING SOLUTIONS AND A PARTICULAR CONCEPT

As an outcome of research on the existing solutions, can be made a conclusion that the first incubators were built only on one layer, namely a device level. Then the users did not have own terminal devices for monitoring and control, and also cloud structures did not exist in this period. On objective reasons, it was necessary for the operators to be constantly near to the hatcheries. Later solutions were constructed over two-layer model. It contains client and device layers, because users already own a primitive mobile device like pagers, 1G or 2G phones. Connections between levels in this case were straight and were built primarily over mobile networks.

Thinking about the possibility of incubators being connected to the Internet and controlled by client devices, such as computers and smart phones, cloud technologies were chosen as the most intelligent solution to achieve the goal set in the research. The Cloud comes in as an intermediate layer (between Device and Control) to store and process data, as well as provides services such as video streaming, notifications, routines deployment, and more. Therefore, the chosen model for creation the FTSEISCV, is an adaptation of the three-layer model known from the IoT architecture, namely Application–Network–Perception model [20,21].

In the present research an adaption to Device–Cloud–Control was realized. Device stands for the new smart incubator, Cloud – for the cloud solutions and Control – for the farmer’s computers and mobile devices.

The adapted three-layer model shown in Fig. 2 incorporates the additional cloud layer that enables the realization of the IoT concept and a wide variety of additional services as a part of next step in global network development [22]. The cloud layer mediates between user devices and the managing controller part. The connections between the layers are now realized with priority over the Internet. The three-layer model is of increased complexity, but provides functional flexibility in many ways, including improved reliability. Therefore, the three-layer model is the choice on which is based this study.

Fig. 2. Three-layer model.

Following modern trends, there is no need to try implementation of new layers, but improvement of the current ones and optionally dividing any of them into different parts. On device level except sensors, controllers and actuators, additional imaging devices can be introduced. On a cloud level a solution can be to migrate some of the functionalities in order to prevent overload in a controller part (device level) and to provide an external point of operability testing. Cloud layer also takes care to guarantee secure notification to the user.

Here are a few examples of state-of-the-art egg incubators that you can find online:

- GQF Manufacturing "Sportsman 1502" Cabinet Incubator: This large-capacity incubator can hold up to 1368 quail eggs or 270 chicken eggs. It includes a digital control system for temperature and humidity, and automatic egg turning. It also features a built-in fan for improved airflow [23].

- R-Com "20 MAX" Egg Incubator: This incubator features a microprocessor-based control system with automatic temperature and humidity adjustment. It also includes an automatic egg turning system and a built-in fan for improved airflow [24].
- Farm Innovators "Model 4250" Digital Circulated Air Incubator: This compact and affordable incubator uses a digital thermostat and fan to provide precise temperature and humidity control. It includes an automatic egg turner and a clear plastic dome for easy observation [25].

By exploring these and other state-of-the-art egg incubators available on the market, the reader can gain a better understanding of the features and capabilities that are available in today's incubation systems, and compare them with the features and capabilities of the presented here smart egg incubation system.

#### IV. DEVELOPMENT OF FTSEISCV

The development of the whole system includes creation of its conceptual model, device architecture, cloud functionalities and control applications. All devices, cloud components and applications are designed to work as one unified system. The basic part of every system is its model. So, first step is to emphasize the model of the new system.

##### A. Model

Creation of conceptual model is based on the scientific analysis, conducted and described in the previous point (Fig. 3).

It presents a number of SEI in the Device layer that connects to the cloud solutions via the Internet. On the other side are the control devices in the Control layer that communicate with the cloud solutions. As a result, the farmer has all the data and functions necessary to control the SEI.

Prototype planning details include a segmentation of the components along the layers of the adopted model and an organization of the connections between them in an optimal way. After extensive analysis and partial approvals, the model presented in details on Fig. 4 has been created.

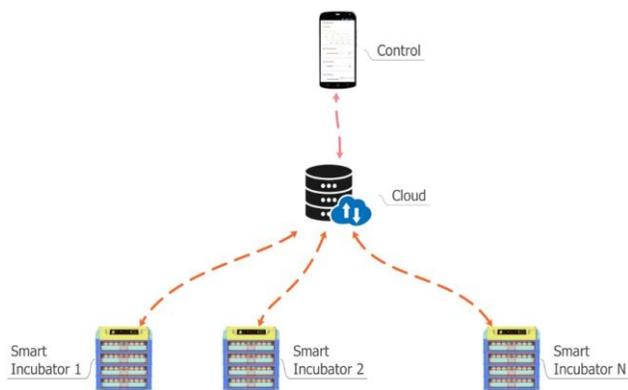

Fig. 3. Conceptual model of FTSEISCV.

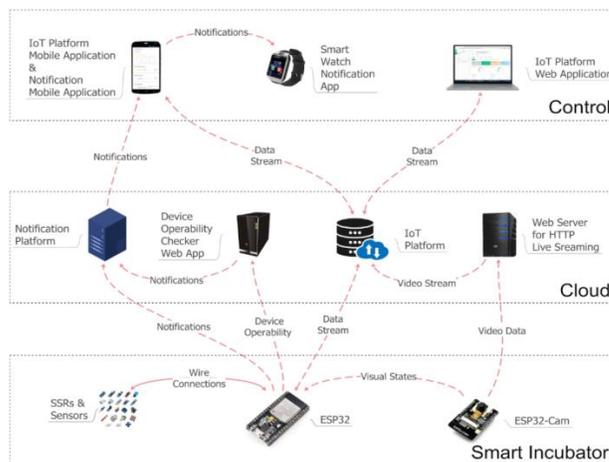

Fig. 4. Detailed model of FTSEISCV.

##### B. SEI Architecture and Components

Selection of the hardware for the FTSEISCV in the device layer is based on components that are available relatively cheap and at the same time does not compromise on their reliability and performance. The popular development environment and the support of many already created libraries for the components are other main criteria.

In practice, one of the innovations of the developed system is the provision of fault tolerance, which does not rely only on failsafe elements. On the second level, it is guaranteed by the cloud structures and the well-chosen connections between the components. Additional cloud applications ensure this functionality.

Fig. 5 represents all selected components for the incubator.

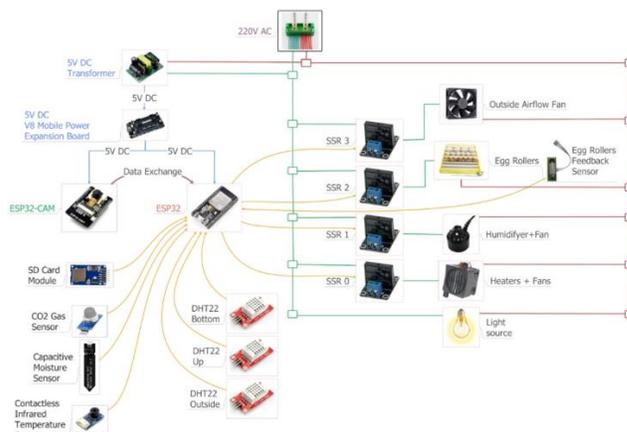

Fig. 5. SEI architecture.

There are three DHT22 temperature and humidity sensors. They fully cover the requirements for accuracy, working range, consumption and supplying digital values to the controller. Two are located inside to monitor the homogeneity of the hatching environment. The third one is placed outside to increase the attention of the operator in the case of too great differences in the external environment compared to the internal one, because in such situations they imply increased risks and overloads.

Capacitive moisture sensor located outside works as a level meter gauge in the outer water container of humidifier, which is used to increase the humidity if necessary. Capacitive humidity sensors are more suitable than resistive ones, because when measuring the resistance between the individual electrodes electrolysis occurs and they corrode and fail.

Contactless infrared temperature sensor is placed inside and is directed at the shell of one of the eggs. It acts as system feedback, supplementing the readings of the DHT22 sensors and increases reliability.

The CO<sub>2</sub> gas sensor is most actively used in the hatching phase and aims to notify the farmer of a potential suffocation danger to the chicks. When they have already hatched, they become active, breathe rapidly, releasing carbon dioxide accordingly.

Another sensor is positioned on the egg rollers and provides feedback for rotation process. It is an encoder that switches its logic states between of zero and one with a certain frequency determined by the speed of rotation. To work reliably, it must be well sealed and waterproof.

The SD Card Module shown on the schematic is optional and can be used to store the data read from the sensors before being sent to the cloud database. When this module is not used, these functions can be performed by pre-allocated partitions of controller memory.

As mentioned above, the controller occupies a central place in the hardware architecture. That is why its choice is one of the most important to achieve the planned global goals. By using Texas Instruments or Nordic Semiconductors devices for example, can be achieved really good final solutions, but the value of the incubator in these cases will increase significantly. On the other hand, NodeMCU (ESP8266) is also a possible solution, but the potential for future development and its lower reliability when performing more functions; it is not the best choice. Compared to it, ESP32 offers not one but two computing cores, double the clock speed, more input-output pins, more SRAM memory and an additional Bluetooth channel for communication in parallel with WiFi. ESP32 is also suitable because of its ability to use the ArduinoIDE programming environment, which is free and has a wide variety of already developed and available libraries.

To implement the computer vision system, it is necessary to select a suitable camera. Variants with a USB connection are not suitable, because the ESP32 controller will have to transmit simultaneously the video stream and data from the sensors via WiFi. This can create conflicts and competition for the communication channel and thus reduce reliability. The purchase of smart cameras with their own computer vision system and/or Wi-Fi connection to the cloud structures is an inappropriate optional solution because it can again lead to an excessive increase in price and for one reason or another, not covers the requirements for full compatibility between all system components. In accordance with the stated requirements, the best choice remains ESP32 Cam. Through its Wi-Fi channel that is parallel and independent compared to that of the ESP32 controller, the camera can stream video to the network. If direct communication with the controller is

required for data transmission, one of the additional GPIOs or the Bluetooth connection can be used. An additional functionality that may not be used is the SD card slot with which the camera is equipped. The ESP32 Cam is available on the market with variable focal length lenses that are selected according to the specific internal hatchery design.

AC/DC power supply 2A 5V is used for the controller, camera and sensors. Its rated power significantly exceeds the total power consumed. An additional V8 mobile power expansion board with its own battery is selected to protect the controller and camera from unwanted reboots. It operates as UPS in the event of a central power failure. Thanks to it, in such a critical situation, the system can continue to monitor the readings from the sensors and send data if there is an available access point, even though the actuator parts are not active.

The actuators on the Fig. 5 are light source, outside airflow fan, egg rollers, humidifier with fan and heaters with fan. They all use 220V mains power supply. Heaters maintain the necessary internal temperature, and their fan aims to spread the heat evenly inside. In conditions of excessive heating or too high humidity, the internal environment in the hatchery is normalized by means of the external airflow fan.

In contrast to heaters, practical tests have shown that humidifier should be placed outside the incubator. Its fan conducts the moisture evaporated from the water through specially designed pipes to the interior.

Egg rollers are placed on a common frame and are rotated simultaneously by a stepper motor attached to a worm gear mechanism. The position of its shafts can be adjusted according to the size of the eggs being incubated.

Every computer vision system needs appropriate lighting source. Therefore, the camera in SEI needs lighting with a stable intensity to work correctly. In the experimental prototype, this role is performed by a constantly glowing 7W LED lamp.

The connection between the controller and the actuators is performed by 4 electronic solid state relays. They are significantly more reliable than electro-mechanical ones because they do not have the possibility of the contacts self-welding during operation.

### C. Functional Capabilities

Blynk cloud solution has been chosen for the practical implementation of the system. Blynk allows registration of multiple devices. In this particular case, the SEI software that works with the main ESP32 controller and the auxiliary ESP32 Cam was developed. Blynk supports the device with proper version of the software automatically. The software communicates with Blynk to transmit the values from the sensors, the states in which the incubators are at a particular moment, the video stream and others.

The system is designed to be controlled by the farmer's control devices (computer and mobile phone). For this purpose graphical user interface in Blynk application has been developed for mobile devices and computers (Fig. 6). It allows the user to start, stop and pause the incubators, to set the values of temperature, humidity, critical temperatures, critical

humidity, etc. that the incubators have to control, to watch the video stream from inside the incubator and many others. The GUI allows the user to send commands to the SEIs through a terminal window in order to control them or to receive specific information for their states (Fig. 7).

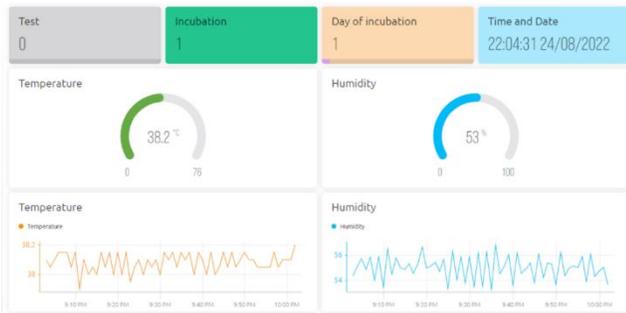

Fig. 6. Graphical user interface in Blynk.

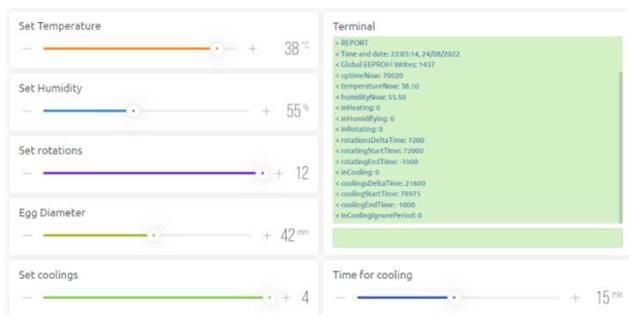

Fig. 7. Terminal window in Blynk.

Telegram has been chosen as a notification platform. When critical notifications appear, they are sent from the SEIs through Telegram to the mobile phone and eventually to the smart watch of the farmer. At that moment the user can react immediately to prevent damage of the production.

A special application has been created to check the operability of the devices at any time. If it detects a problem with a device it sends a proper notification through Telegram to the farmer.

An algorithm for vision inspection of the eggs has been developed and implemented to work in the ESP Cam modules. Its purpose is to detect the moment of hatching a chicken from an egg. If the module detects such an event, it sends a proper notification to the farmer. Then the farmer can observe the incubator on the video stream or at place (Fig. 8).

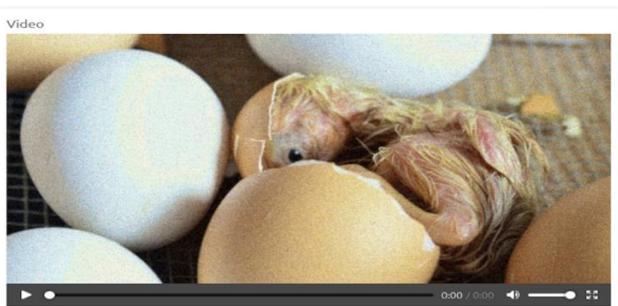

Fig. 8. Video stream interface through the IoT cloud platform.

## V. CONCLUSIONS AND FUTURE WORK

A real prototype has been assembled for approbation of the proposed FTSEISCV model. Partial and complete tests show stable results, proving a high degree of reliability, functional conveniences and a high degree of automation that guarantees a minimal commitment of users to the incubation process. By multiplying through a clustered approach, the system can be used on an industrial scale without compromising the intended performance.

Further researches will be focused on finding an optimal position of multiple cameras for the target area, management of the parallel video streams, improvement of computer vision algorithm and implementing of proactive features in the incubation control.

**Abstract**—Cellular abnormality leads to brain tumour formation. This is one of the foremost reasons of adult death all over the world. The typical size of a brain tumour increases within 25 days due to its rapid growth. Early brain tumour diagnosis can save millions of lives. For the purpose of early brain tumour identification, an automatic method is necessary. MRI brain tumour detection improves the survival of patients. Tumour visibility is improved in MRI, which facilitates subsequent treatment. To distinguish between brain MRI images with tumour and images without tumour is suggested in this paper. Many approaches in the field of machine learning including Support Vector Machine, Artificial Neural Networks, and KNN classifier have been developed for solving these issues. But these methods are time consuming, inefficient and require complex procedures. For a Computer Assisted Diagnosis system to aid physicians and radiologists in the identification and categorization of tumours, artificial intelligence is used. Deep learning has demonstrated an encouraging efficiency in computer vision systems over the past decade. In this paper, identification and classification of brain tumour from MR images employing BGWO-CNN-LSTM method is proposed. The proposed method on a testing set with 6100 MRI images of four different kinds of brain tumours is utilized. In comparison to earlier research on the same data set, the suggested approach achieved 99.74% accuracy, 99.23% recall and 99.54% specificity which are greater than the other techniques.

**Keywords**—Brain tumour; BGWO; LSTM; CNN; MRI dataset

## I. INTRODUCTION

The brain is a massive, intricate part that governs the entire nervous system in humans and comprises an estimated hundred billion nerve cells. This vital organ was grown in the brain's cerebral cortex. As a result, any brain abnormalities could be dangerous for people's health. Brain tumours are among the most serious of these disorders [1]. For the proper operation of the human body, the majority of the cells which are produced in the body split to become new cells. Older or

damaged biological cells expire as new ones proliferate. New cells then replace the old ones. Occasionally, when the body does not require them, new cells are produced. Extra cells produced in the body build a form of tissue known as a tumour. The delicate bodily functioning is distorted by a tumour positioned in the brain area. Due to its position and tendency to spread, it is extremely dangerous and difficult to cure [2]. Tumors can be classified as either cancerous as well as non-cancerous. Both benign and malignant brain tumours are recognized as dangerous conditions. The tumour spreads throughout the skull, flattening the other development. Primary tumours and secondary tumours are the two different categories of brain tumours. The primary tumour arises in the tissues of the brain, and the secondary tumour spreads from other body regions to the skull [3]. Pituitary tumours, gliomas and meningiomas are a few kinds of primary brain tumours. Tumors that form in brain tissues apart from nerve cells and blood vessels are referred to as gliomas in context. Pituitary tumours are lumps that reside within the skull; however meningiomas safeguard and surround the central nervous system and the brain. [4]. The meninges covers the brain within the skull, is where meningioma tumours first appear. These tumours are benign because of their sluggish growth. The malignant tumours known as gliomas begin in the brain, spinal cords, and nearby glial cells, which are nerve cells [5]. Developing an efficient therapy for brain tumours depends on an early and precise diagnosis of the condition. The pathologic grade, type, and tumour stage at the point of diagnosis significantly influence the treatment mode selection [6]. A significant aspect of investigation in the range of medical imaging is early detection and categorization of brain tumours, which helps doctors choose the most practical way to proceed to rescue patient's lives [7].

For instance, doctors may employ radiation, surgery or chemotherapy to treat tumours. However, it always relies on the shape, nature, and size of a tumour. Clinically relevant

technology, such as Magnetic Resonance Images, produces extensive information on tumour and normal regions in the type of their slices. Furthermore, not all slices can be seen as tumours with the naked eye of a human. Therefore, correct assessment of a brain tumour necessitates the use of a skilled radiologist. Therefore, in order to identify a tumour in MR images without the use of humans, automated machines are always necessary [8]. The categorization of brain tumours has been approached from a variety of perspectives [9]. The investigators convey a variety of strategies, including super pixel-based brain tumour segmentation, multifractal features, salient structural topographies with RBF SVM kernel, and clustering-based segmentation with SVM[10]. ML methods rely on manually created characteristics, which limit the method's resilience. The efficiency of the deep learning-based algorithms, however, is substantially greater because they dynamically identify useful characteristics [1]. The current automated and semi-automated disorder analysis procedure's main goal is to create a reliable disease recognition system to help the physician with diagnosis and treatment planning [11]. The majority of image processing methods are utilized for tumour diagnosis. The goal of segmenting the image is to divide an image into uniform districts, thereby identifying the structures of the district [12]. The Magnetic Resonance Images plays an integral role in sophisticated research studies of the human brain. Magnetic Resonance scans may reveal important details about the composition of soft tissue. Additionally, the superiority of diagnosis and brain pathology are significantly enhanced by Magnetic Resonance imaging [3]. A doctor performs a biopsy to screen for tumours by taking a lesser sample of tissue and examining it under a microscope. Even though a biopsy can detect abnormalities with accuracy, people usually experience pain throughout the procedure. Second, doctors must be cognizant of the precise position and size of the tumour before doing surgery [13]. Therefore, MRI or CT scans are the most common approaches for evaluating the structure of a brain tumour. Nevertheless, MRI provides an accurate view of the structural development of brain tissues, whereas CT scans expose people to radiation that is harmful to their health [2].

Traditional ML strategies for categorization tend to concentrate on only limited or elevated features employ some manually created features to close these gaps, and call for effective feature extraction and categorization procedures. Deep CNNs, a recent innovation in DL, have attained achievement in the categorization of images [14]. Nowadays, a significant part of investigation in the health care zones is the automated recognition and segmenting the organs on medical images. There have been several techniques created that cover all geographical localizations and imaging modes. These researches, which make use of complicated blob-based algorithms, shared a recognition rates that seemed hard to enhance without complicating the feature extraction techniques significantly. Additionally, DL methods outperform typical machine learning techniques, which are constrained in their ability to analyse visual features in their natural form, time-consuming, dependent on professional expertise, and demanding a lot of work for parameter tuning [15].

In this study, three pathogenic categories of brain tumours precise and automatic categorization system including glioma, meningioma and pituitary tumour was provided. For extracting the features from brain MRI images, the remedy makes use of deep transfer learning model CNN [6]. It can be used in a variety of fields, such as object recognition, speech recognition, and image categorization. The DL mechanism is frequently utilized with CNN because it makes it simple to handle the hidden, input, and output layers [16]. Utilizing tested classifiers, the collected characteristics are categorised. Next, a thorough assessment of the suggested system is made. When tested on the open dataset, the suggested system outperformed all similar research in terms of classifier performance. Additionally, the suggested approach is found to deliver respectable results with fewer training data [6].

The following is a list of this article's main contributions:

- The system begins by collecting and processing a large set of input images using an MRI dataset.
- A Gabor filter is then employed to further analyze the input images that were generated.
- The impacted portion is then segmented through Otsu thresholding.
- A hybrid optimization technique combining the Bat and Grey Wolf performs feature extraction.
- After that, classification is carried out with the CNN-LSTM model.
- The efficiency of the developed approach is then verified and contrasted with those of other pre-trained models.

The residue of the article is arranged as follows: Section II deliberates the closely related studies. The proposed method, block diagram, flowchart and algorithms are thoroughly summarized in Section III. In Section IV, the experimental method of the suggested brain tumour categorization and recognition system is covered in detail. Section V illustrates the research findings and contrasts them with existing systems. The conclusion is organized in Section VI.

## II. RELATED WORK

Jaeyong Kang et al. [1] introduced a technique for categorising brain tumours using a combination of deep features and ML classifiers. The idea of transfer learning and various pre-trained DCNN are employed in this suggested framework to collect deep features from brain MRI. Different machine learning classifiers subsequently examine the deep features that were gathered. An ensemble of deep features consisting of the top 3 deep features that consistently outperform other machine learning classifiers is chosen, combined, and utilized to determine the result. Three distinct brain MRI datasets which are freely accessible are employed to compare the performance of machine learning classifiers, deep feature extractors, and an ensemble of deep features for the categorization of brain tumours. However in some circumstances, the Support Vector Machine with Radial Basis Function (RBF) kernel surpasses conventional ML classifiers, mainly for large datasets. According to experimental

observations, this method suggests that an ensemble of deep features can greatly increase efficiency. Even though our suggested strategy performs well, more research is required to minimize the model's structure so that it can be implemented on an actual medical diagnosis process utilizing knowledge filtering techniques. Siva Raja and Antony Viswasa rani [3] created a combined deep auto encoder with a Bayesian fuzzy clustering (BFC) method that is based on segmentation to categorize brain tumours. The non-local mean filter is originally utilized in the pre-processing phase for noise elimination purposes. Then, the BFC technique is employed to separate brain tumours. Following segmentation, reliable attributes are collected by utilizing Wavelet Packet Tsallis Entropy and Scattering Transform techniques. In order to categorise the tumour component for the brain tumour classification procedure, a combined strategy of the DAE oriented Jaya optimization algorithm combining softmax regression method is used. A MATLAB framework is applied to perform the suggested strategy. In comparison to other techniques, the simulated outcomes from the BRATS 2015 database demonstrated that the suggested strategy acquired a significant amount of classification accuracy of 98.5%. However, the more prevalent technique that will be employed to enhance the accuracy by combining more than one classifier based on the huge library of medical images and the precise classification strategy is not discussed.

Shahariar Alam et al. [2] presented a mechanism for identifying human brain tumours in an MRI image that combines the template-based K means and enhanced fuzzy C means (TKFCM) algorithms. Initially, the template-based K-means method is employed in this suggested technique to effectively choose a template created on the gray-level intensity of the image, which greatly initialises segmentation. Eventually, the enhanced FCM clustering method is employed for sensing tumour place by upgrading membership function that is derived on the basis of the characteristics of tumour images such as Energy, Homogeneity, Correlation, Dissimilarity, Entropy and Contrast. The revised membership is calculated by the cluster centroid distances to cluster data points by employing the Fuzzy C Means algorithm that gives better outcomes. According to simulated outcomes, the suggested technique is more effective at identifying diseased and normal brain tissues with only a slight loss in gray-level intensity. Additionally, compared to other techniques, this method predicts human brain tumours in a matter of seconds. However, the accuracy is left undiscussed. Rupa Ezhil Arasi and Suganthi [17] suggested a Soft Computing techniques of Clinical Support System for Classifying Brain Tumours. The brain MRI image is pre-processed by applying Genetic Optimized Median Filter in the presented Clinical Support System, and then the brain tumour zone is segmented by applying Hierarchical Fuzzy Clustering Technique. The GLCM feature extraction approach is utilized to capture the characteristics of the tumour region. The Brain Tumour Image Segmentation dataset is employed to accurately classify the tumour using the Lion Optimized Boosting Support Vector Machine method. As a result, the suggested clinical support system provides a comprehensive framework for the recognition and categorization of brain tumours, assisting the physicians in a proper assessment of the tumour. The findings

show that the suggested approach accurately categorises the tumour with a 97.69% accuracy rate. The primary benefit of the suggested approach is that it also evaluates tumour size and identifies the forms and phases of tumour. However, diagnostic errors are not recognized.

In order to improve images, Muhammad Sharif et al. [18] introduced a triangular fuzzy median filtering that supports in precise segmentation utilizing an unsupervised fuzzy system technique. In this method, Similar texture (ST) features are validated by utilising retrieved Gabor features over each person's tumours. Extreme learning machine ELM obtains these similar texture behaviours, and the reduction ELM omits one for tumour classification. On the BRATS 2013, 2012, 2015, 2014 datasets and on the 2013 Leader board, the method is tested. The suggested method yields superior outcomes and requires less computing time. However, managing distorted images and segmentation precision is not improved. Javaria Amin et al. [19] developed an innovative method on the basis of LSTM technique and MRI is offered to address the issues with automatic brain tumour categorization. To enhance the image quality of the multi-sequence MRI, N4ITK and 5×5 sized Gaussian filters are first utilised in this approach. The 4 layer deep LSTM framework is typically provided for classifying. The best hidden units including 200 HU and 225 HU are taken for every layer. In order to achieve superior outcomes, these disguised or hidden components were selected after intensive experimentation. The SISS-ISLES 2015 dataset and various BRATS dataset variants are employed to validate the findings. The approach was also tested using actual brain tumour patients from Pakistani ordinance factories, with a 0.97 DSC. The outcomes show that the proposed strategy gives radiologists additional assistance in accurately classifying brain tumours. The suggested technique had an accuracy rate of up to 98%. However, classifying subtumoural region and measuring the severity level of tumour region is not discussed.

Shah Rukh Khan et al. [13] introduced a Partial Tree, an association rule classifier with a sophisticated characteristic set to identify brain tumours according to their grade. The suggested method is evaluated by applying a 10-fold cross-validation procedure, and it is contrasted with other mechanisms including Random Forest, CART, Naïve Bayes and Random Tree. In this technique, threshold segmentation and masking are performed to magnetic resonance images as pre-processing processes prior to feature extraction. Depending on the grey level of the pixels, threshold segmentation isolates them into different sections. An intensity value called as the threshold determines categorization. The outcomes demonstrate that a partial tree with an enhanced feature set outperforms the existing approaches. Additionally, certain more sophisticated features should be utilized to boost performance. Arunkumar et al. [20] developed a new method of segmenting brain tissues from Magnetic resonance images. The main vision - based simulation methodologies utilized in the method are image segmentation, non-ROI filtering and image enhancement on the basis of texture and HOG features. ANN is employed in a fully automated framework technique for MRI brain tumour segmentation and categorizing to accurately pinpoint the

ROI's position. In order to evade non ROI and choose the exact object in brain MRI, the filtering out non ROI technique has been employed in perspective of histogram analysis. Nevertheless, using the textural features can determine the type of tumour. For the comparison of the automated and human segmentation processes, 200 MRI samples are employed. The results analysis proves that fully automatic model on the basis of trainable segmentation outperforms traditional methods and ROI texture-based brain diagnosis. 92.14% accuracy in diagnosis was recorded, with 94 specificity and 89 sensitivity. However, the brain trainable segmentation challenge was frustratingly difficult because of the enormous variability in brain tumour size and position in the images.

Bahadure et al. [21] introduced a comparative methodology on the basis of magnetic resonance images of brain tumour Segmentation and categorization by applying genetic algorithm. In this method, various segmentation strategies are compared to enhance the efficiency of tumour identification, and the better segmentation methodology is chosen by contrasting their segmentation scores. Additionally, the genetic algorithm is utilized for the automated identification of tumour stage in order to increase accuracy rate. Extraction of pertinent features and region computation assist the categorization phase choice. Depending on sensitivity, accuracy, specificity, segmentation score and dice similarity index coefficient, the study outcomes of the suggested methodology are assessed and verified for both quality and performance assessment on MR brain images. The experimental outcomes averaged a dice similarity index coefficient of 93.79%, indicating improved overlapping between radiologists' subjectively and automatically derived tumour regions. However, the discussion about a research of reliable technique for the huge medical image database and a discriminating classifier strategy by integrating more than one classifier is not recognized. Diaz-Pernes et al. [22] introduced a fully automatic brain tumour segmentation and classification technique that employs use of a multiscale DCNN. The functioning of the human visual system aided as motivation for this approach. The proposed neural framework is capable of performing tumor-specific MRI image analysis. The technique's efficiency on a dataset of 3064 MRI image slices from 233 patients that is publicly visible is contrasted with other traditional ML and DL approaches. In the assessment, this approach significantly performed with a tumour classification accuracy of 0.973. This technique helps doctors to diagnose brain tumours, and the presented segmentation and categorization technique can be utilised to solve various imaging issues in the field of medicine. However, it is not explained how the suggested multiscale CNN for segmentation could be applied to other research areas, like satellite imaging.

The aforementioned literature review provides a clear picture of the techniques that have been developed, the more common technique that will be used to increase accuracy by combining multiple classifiers based on the vast library of medical images, and the precise classification approach are not included, and diagnostic errors that are not recognized. There is no discussion of classifying the sub tumoural region

or determining the tumor location's severity level. The huge variation in size and location of the brain tumors in the images made the brain trainable segmentation problem painfully challenging. To solve these problems, the BGWO-CNN-LSTM approach is suggested in this study for the detection and classification of brain tumors using MR images. The observations support the assertion that the suggested strategy makes it simple for clinical experts to make decisions about diagnosis and scanning.

### III. PROPOSED METHODOLOGY

The presentation is the automatic process for the lesion and imaging stages of brain tumour identification. MRI tests are done on the proposed system. As a result of its high contrast, spatial resolution, and low radiation MRI seems to be more effective at detecting tumours. The location and size of a brain tumour can be determined by MR scans [12]. The presented approach contains five main steps: image acquisition, pre-processing, segmentation of images, feature extraction and classification. Various methodologies are used during pre-processing to split the region of interest. The Gabor filter is utilized for the pre-processing stage. The next phase is image segmentation, where the normal and abnormal regions are separated using K means clustering. Next, the feature extraction is done by applying Bat and Grey Wolf Optimization (BGWO) algorithm. Finally, CNN-LSTM is utilized for classification. The developed method is outlined in Fig. 1.

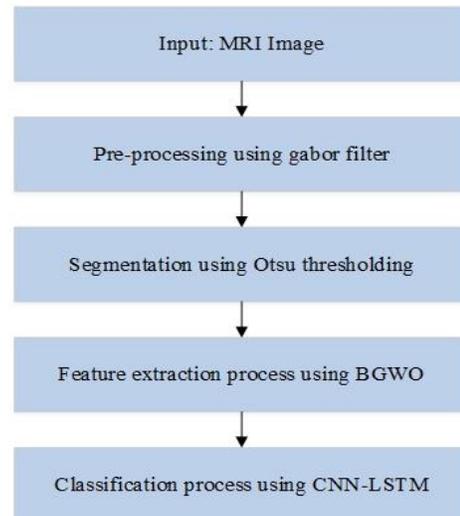

Fig. 1. Overall process of the developed method.

#### A. Data Collection

The effectiveness of the developed detection system relies on the database that is utilized in every medical assessment operation. The dataset utilised in this research was obtained from BRATS 2015 that contains a distinct version of BRATS that is designed to address medical imaging challenges. The BRATS 2015 imaging dataset, that can display an upgraded form of new cases reported with greater efficiency, was derived from BRATS 2012 and BRATS 2013 [16]. The dataset contains 6100 MRI images of the human brain that are categorized into 4 categories: meningioma, pituitary, glioma,

and normal. The dataset is splitted into 80% of training data and 20% of testing data. The description of database is shown in Table I.

TABLE I. DATASET DESCRIPTION

Disease type	Training data	Testing data	Total
Pituitary	1205	195	1400
Meningioma	1327	473	1800
Glioma	534	366	900
Normal	1602	398	2000

### B. Pre-processing

The brain MRI datasets entirely contain unwanted gaps and areas, which leads to inadequate categorization accuracy. Therefore, it is vital for image cropping to eliminate unnecessary portions and use relevant data. The cropping approach is applied for calculating extreme points. For pre-processing, import the primary MR images. Then, in order to create binary images, perform thresholding to the MR images. In this research, Gabor filter is applied. When the Gabor filter is utilized for texture features, it effectively examines if the image contains any particular frequency information or particular directions in a restricted region around the pixel or region of evaluation. Gabor filters are utilized in the study of multi-resolution images which is like human vision cortex since every filter exhibits a sensory neuron which is responsive to a certain frequency. This is because of the band-pass nature and chosen direction qualities of Gabor filters [18].

Gaussian function in the  $f(a, b)$  domain's spatial coordination is defined using the Gabor filter. Assume the Fourier transform of  $f(a, b)$  denoted by  $F(m, n)$  that is a function of the frequency components  $(m, n)$  given in Eq. (1).

$$f(a, b, \sigma, \beta) = \left( \frac{1}{2\pi\sigma_a\sigma_b} \right) \exp \left[ -\frac{1}{2} \left\{ \frac{a^2}{\sigma^2} \right\} + 2\pi r\beta a \right] \quad (1)$$

In the Gabor filter, the Gaussian window is adjusted by  $\sigma$  among the appropriate axis while the Gaussian function is combined in the Fourier domain.  $\beta$  represents the Gabor filters' centre frequency. The filter results are displayed in Eq. (2) with a good response at the frequency centre.

$$K(\mu, w, \sigma, \beta) = \exp \left\{ -\frac{1}{2} \left( \frac{(\mu-\beta)^2}{\sigma_\mu^2} + \frac{w^2}{\sigma_w^2} \right) \right\} \quad (2)$$

$$\text{Where } \sigma_\mu = \frac{1}{2\pi\sigma_a} \text{ and } \sigma_w = \frac{1}{2\pi\sigma_b}$$

### C. Segmentation using Otsu Thresholding

After pre-processing, Otsu thresholding is utilized for segmentation process. Otsu is an automated threshold selection technique for segmenting data depending on region. Gray levels are used in the unsupervised, nonparametric Otsu threshold method. Otsu threshold criterion utilises an image's gray-level histogram, and the threshold procedure determines a normalised value in the [0, 1] range [23]. The probability distribution is represented in Eq. (3).

$$a(t) = \frac{ht}{H} \quad (3)$$

Where,  $a(t)$  is the probability distribution,  $H$  represents the total no. of image pixels, and  $h$  is the histogram count for pixel value  $t$ .

Eq. (4) and (5) employ the probability distribution  $a(t)$  to derive the class probability. Every image pixel is divided into the classes of background and object, with a threshold, separating them. The class probability is expressed as,

$$u_0 = \sum_{m=1}^l a(t) \quad (4)$$

$$u_1 = \sum_{m=l+1}^k a(t) \quad (5)$$

Following, the class mean which is denoted by  $\mu$  is represented as,

$$\mu_0 = \sum_{m=1}^l \frac{ta_t}{u_0} \quad (6)$$

$$\mu_1 = \sum_{m=l+1}^k \frac{ta_t}{u_1} \quad (7)$$

Eq. (6) and (7) are substituted in Eqns. (8) and (9), respectively.

The following equations are employed to form the class variance equation:

$$\sigma_0 = \sum_{m=1}^l [t - \mu_0] 2 \frac{a(t)}{u_0} \quad (8)$$

$$\sigma_1 = \sum_{m=l+1}^k [t - \mu_1] 2 \frac{a(t)}{u_1} \quad (9)$$

The formula for weighted within-class variance is illustrated in Eq. (10)

$$\sigma_u^2 = u_0\sigma_0^2 + u_1\sigma_1^2 \quad (10)$$

Where,  $u_0$  is the weight of the background,  $u_1$  is the weight of foreground,  $\sigma_0$  is the variance of background and  $\sigma_1$  is the variance of the foreground.

The performance of segmenting the brain tumour is evaluated through the performance rate after the Otsu approach is applied to the synthetic image which is given in Eq. (11).

$$\text{Performance} = \frac{\text{No. of pixels of object after segmentation}}{\text{No. of pixels of object before segmentation}} \quad (11)$$

Generally, a successful segmentation of an image occurs when all of the object's pixels are separated from the background without any additional or subtracted pixels. When segmenting an image, the performance is less than 1, which suggests that some pixels related to the object were mistakenly categorised as background and object. If the rate of performance is 1, then an object's pixels have all been completely segmented.

### D. Feature Extraction and Selection using BGWO Algorithm

1) *Bat optimization algorithm*: A meta-heuristic search technique called the BAT algorithm [24] imitates the action of bats. This optimization method utilizes the echolocation system of bats to find food and distinguish it from other objects. Bats make quick, loud pulses that detect an echo and return to their ears. BAT determines the distance, kind of

object and the time it takes for it to return. The bat's position and velocity matrices,  $a$  and  $p$ , are updated by bat algorithm in the  $d$ -dimensional search area is represented in Eq. (12) [25].

$$a_m^l = a_m^{l-1} + (p_m^{l-1} - p_{best}) \times g_m \quad (12)$$

Where  $l$  is the current iteration, and  $p_{best}$  is the best global solution.

2) *Grey wolf optimization algorithm*: The grey wolf optimizer (GWO) method [26] is a swarm-based method that derives from nature and imitates the hierarchical society of wolves and their behaviour in encircling, approaching and attacking the prey. The grey wolves social behaviour during the hunting process is portrayed statistically to solve an optimization issues by applying the GWO algorithm. The wolves in GWO iterations assess the potential hunting circumstances and revise their status as necessary. The encircling process' mathematical expression is given by,

$$\vec{G}(s+1) = \vec{G}_a(s) - \vec{P} \times \vec{R} \times \vec{G}_a(s) - \vec{G}(s) \quad (13)$$

In the equation preceding,  $s$  stands for the current iteration,  $\vec{G}_a$  and  $\vec{G}$  stand for the hunt and hunter position vectors and  $\vec{P} = 2\vec{p} \cdot \vec{c}_1 - \vec{p}$  and  $\vec{R} = 2\vec{c}_2$  stands for coefficient vectors.  $\vec{c}_1$  and  $\vec{c}_2$  are random numbers between 0, 1 that permit the wolves change their position in the hunt space. The best exploration factor equation is represented in Eq. (14)

$$\vec{G}(s+1) = \frac{\vec{G} + \vec{G}_2 + \vec{G}_3}{3} \quad (14)$$

A novel hybrid combination of BGWO using the fitness values is given in Eqn. (15),

$$a_m^l = a_m^{l-1} + (p_m^{l-1} - p_{best}) \times \vec{G}(s+1) \quad (15)$$

### E. Classification

1) *Convolutional neural network*: The CNN is the deep neural network. It aims to discover the underlying and intrinsic characteristics from guided processing of 2-Dimensional or 3-Dimensional images. These characteristics are suitable for classifying anatomical structures and identifying aberrant structures. An input layer is associated with a number of pooling layers, output layer and convolutional layer in a standard CNN architecture.

a) *Convolutional layer*: The convolutional layers perform a convolution operation by using convolution kernels and the raw input data to create new attribute values. The model was developed to collect features from dataset images, so the input data should be in the procedure of structured matrix. When compared to the input matrix, the convolution kernel is comprehended as a narrow window that organises coefficient values into a matrix. This window "slides" around the input matrix, performing a convolution process on every

patch while moving. A convolved structure, is a feature variable established by the coefficient values and the allocated dimension element of the filter. Convolved features which are often more useful than the principal features of the input data can be produced by applying various convolution kernels to the input data. Hence, the approach performs better. The basis of a CNN is a convolutional layer, because the majority of computations are completed at this layer. It is a quality extraction layer that pulls out the regional features via the filters and produces a convolutional calculated feature map and exits the kernel function and goes to the pooling layer. The convolutional layer is expressed in Eq. (16).

$$P_m^{(a)} = \sigma(G_m^{(a)} + \sum_{n=1}^{s(a-1)} P_n^{(a-1)} * U_{m,n}^{(a)}) \quad (16)$$

Where the operator  $*$  denotes the convolution operation,  $\sigma$  is an activation matrix, and  $U_{m,n}^{(a)}$  is the filter linking the  $n^{th}$  feature map in layer  $a-1$  with the  $m^{th}$  feature map in layer  $a$  is a function that is employed to increase nonlinearity.

b) *Pooling layer*: Typically, the pooling layer is applied following the convolutional layer. The pooling layer's job is to streamline the data in the output of the layer of convolution. The pooling layer creates a compressed feature map using each feature map's data from the convolutional layer. The most popular techniques are max-pooling and average pooling. There is no learning happening in this tier. Size  $N \times N$  filters have been chosen in this layer. The average pooling and max pooling layer is represented in Eq. (17) and (18).

$$\bar{a} = \frac{1}{L} \sum_{(m,n) \in G} a_{m,n} \quad (17)$$

$$a_{max} = \max_{(m,n) \in G} (a_{m,n}) \quad (18)$$

Where  $a_{m,n}$  is the number of each pixel in area  $G$  and  $L$  is the area's pixel count.

c) *Dense layer*: In Dense layer, the Long-Short Term Memory (LSTM) method has been utilized. In particular, LSTM neural networks [27] are a subclass of recurrent neural networks with learning capabilities across time employing feedback connections. This technique develops short-term memory and gathers data from it by utilizing cyclic links on their hidden layer and collect information from time series and sequences. A memory cell and the three major gates of input forget and output make up every LSTM unit. By utilizing this framework, the LSTM choose which information needs to be "forgotten" and which needs to be "remembered," creating a controlled data flow and learning for the long term dependencies. Eq. (19) predicts the performance operation of LSTM unit. The layers of the developed method are shown in Fig. 2.

$$a_u = \sigma(P_u m_s + R_u n_{s-1} + t_u) \quad (19)$$

Where  $R$  and  $P$  are weight matrices,  $m_s$  represents the input,  $\sigma$  is the sigmoid function, and  $t$  is the bias term vector.

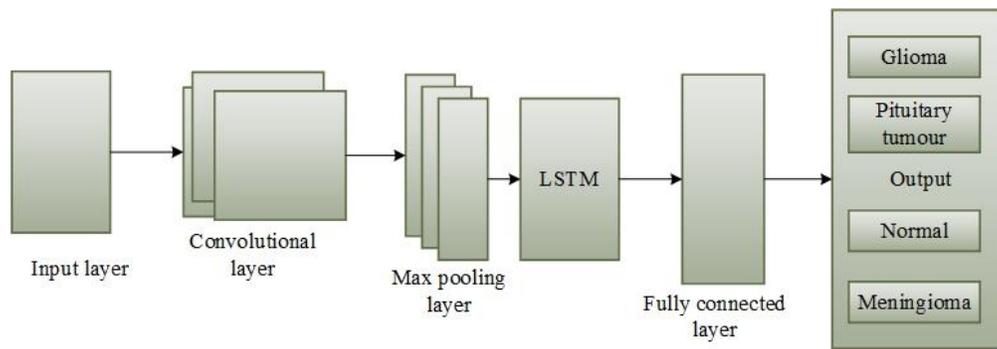

Fig. 2. Layers of the developed CNN and LSTM model.

d) *Output layer*: The output layer also known as fully connected layer is the completely linked layer's neurons rely on all regions of the brain's prior layer. In this layer, data is transformed into a 1-D matrix beneath the layer. There may be variations in each model's overall amount of fully connected layers. Eq. (20) is employed for feed forward in this layer.

$$a_m^s = \sum_n u_f^{s-1} v_n^{s-1} \quad (20)$$

Where  $s$  is the number of layer,  $v_n^s$  is the value in the created output layer,  $m$  and  $n$  is the number of neuron,  $u_f^{s-1}$  is

the hidden layer weight,  $v_n^{s-1}$  is the input neuron input and  $a_m^s$  is the value of the activation function in the output layer.

The brain tumours have been correctly classified based on MRI images. Pituitary tumour, glioma, normal brain and meningioma have been discovered. The CNN-LSTM framework utilizes Bat and Grey Wolf Optimization (BGWO) algorithm for extracting the features and the overall process BGWO-CNN-LSTM is shown in Algorithm 1 and Fig. 3.

#### IV. RESULTS

The developed method is examined using MRI dataset. Using the Gabor filter, 6100 MRI scans of brain tumours were gathered and pre-processed. The tumours in the images are so severe. So, it is impossible for the average person to quickly spot them. Pre-processing MR images is crucial for improving the vision impact of the image before processing. Typically, the dataset's gathered images are of bad quality and the noise should be filtered out and the image is sharpened. Gabor filter is utilised as a pre-processing step. Following that many traits are initially implicitly collected. With the aid of an enhanced Otsu thresholding method, the tumour is then identified. After that, the feature extraction method utilizes the bat and grey wolf algorithm. Subsequently CNN-LSTM is utilised for classification. The proposed model achieves performance matrices of recall, accuracy, and specificity. 4100 images of

brain tumours and 2000 photos of tissue are found by extracting and segmenting image features. Utilizing efficient spot images, training and testing dataset is produced. The proposed model's effectiveness is shown, and it achieves the best levels of recall, specificity, and accuracy in the identification of brain tumours. In every MRI imaging of a brain tumour, there is an error rate based on abnormal tissue. Depending on the true negative, true positive, false positive and false negative values, these can be quantified. The recall, accuracy and specificity of the technique have been evaluated on all of the images in the dataset for this research.

##### A. Accuracy

One of the frequently employed metrics for classification techniques is accuracy. It indicates the proportion of accurate estimates of overall predictions. The evaluation of actual

classification is known as accuracy. According to image analysis, the accuracy is a per cent that represents the total amount of pixels that have been correctly classified in relation to the total amount of pixels in the image. It assesses every single correctly placed pixel in an image. Accuracy is expressed in Eq. (21).

$$Accuracy = \frac{True_{pos} + True_{neg}}{True_{pos} + True_{neg} + False_{pos} + False_{neg}} \quad (21)$$

### B. Specificity

The quantity of precisely determined true negatives is measured by specificity. Using Eq. (22), the specificity value is calculated as,

$$Specificity = \frac{True_{neg}}{True_{neg} + False_{pos}} \quad (22)$$

### C. Recall

Recall is the ratio of true positives and false negatives to correct positive forecasts. The percentage of forecasts that have been appropriately identified as tumour is expressed. Eq. (23) is employed to represent recall.

$$Recall = \frac{True_{pos}}{True_{pos} + False_{neg}} \quad (23)$$

TABLE II. PERFORMANCE MATRIX COMPARISON ON THE BASIS OF ACCURACY, SPECIFICITY AND RECALL

Method	EKF-SVM	Genetic Algorithm	ANN	Proposed BGWO-CNN-LSTM
Accuracy	98.02%	92.03%	92.14%	99.74%
Specificity	94.15%	91.42%	94%	99.54%
Recall	96.44%	92.36%	89%	99.23%

The test results of the BGWO-CNN-LSTM classifier with those of other classifier methods including Extended Kalman filter with Support Vector Machine (EKF-SVM) [28], Genetic algorithm [21], Artificial Neural Networks (ANN) [20] based on the statistical characteristics of recall, accuracy and specificity is illustrated in Table II. On the basis of disease categories such as glioma, pituitary tumour, meningioma and normal, the findings are compared. 80% of image dataset are employed for training and 20% of images are employed for testing the data. The performance matrix of the suggested approach's recall, specificity and accuracy were found to be 99.23%, 99.54% and 99.74% which is higher than the existing approaches of EKF-SVM, Genetic algorithm and ANN is illustrated in Fig. 4.

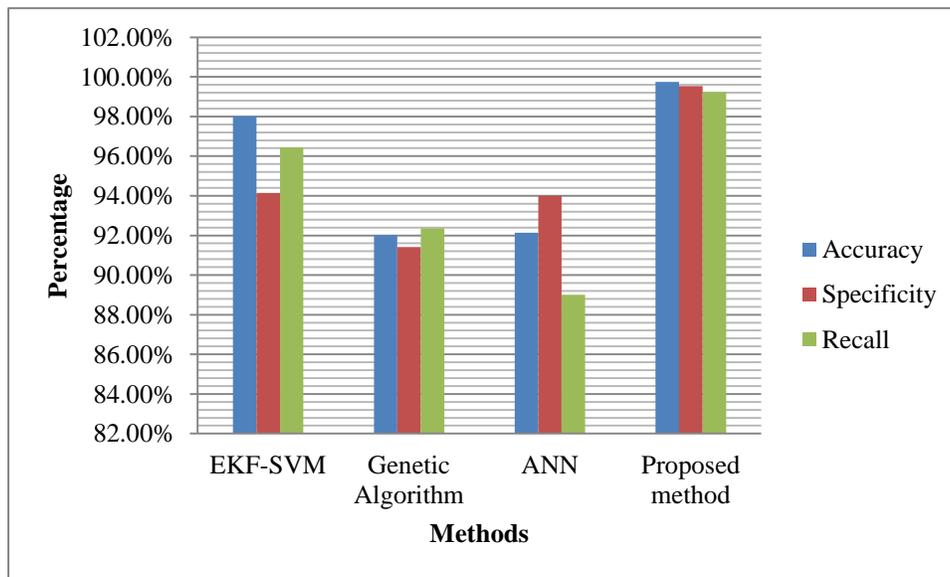

Fig. 4. Performance comparison of the developed and existing models.

## V. DISCUSSION

The brain MRI dataset was used in this research work to apply a combined mechanism to recognize and classify the tumor on the images. The created method uses supervised hybrid CNN and LSTM algorithms and is intended to discriminate between normal and pathological tumors in brain pictures. Brain tumour detection techniques including Extended Kalman filter with Support Vector Machine, Genetic algorithm and ANN are trained and evaluated in order to compare their characteristics with those of traditional networks. The findings demonstrate that the suggested BGWO-CNN-LSTM model, out of these four strategies, produces greater specificity, accuracy and recall as shown in Fig. 4. A degree of recall, specificity and accuracy of 99.23%,

99.54% and 99.74% are attained using the BGWO-CNN-LSTM method. The comparison demonstrates that the suggested approach outperformed the alternatives. The suggested approach demonstrates that the BGWO-CNN-LSTM is the better approach for the recognition and classification of a brain tumour.

## VI. CONCLUSION

One of the serious disorders is brain tumour identification and classification due to aberrant cell proliferation or portable spread across the body. This research work has applied a combined mechanism on brain MRI images to identify and categorise the tumour utilising the MRI dataset. Employing supervised hybrid CNN and LSTM approaches, the developed

method is designed to distinguish among normal and abnormal tumours in brain images. The input images have undergone the main pre-processing processes of normalisation, as well as the extraction of major characteristics from the pre-processed image using the Gabor filter and threshold-based segmentation approach called Otsu thresholding. To categorize brain MRI images, hybrid CNN and LSTM algorithms are applied to the labelled segmented features. It is utilized to categorize the tumours such as pituitary tumour, glioma, meningioma and normal brain. Finally, the proposed approach achieved 99.74% accuracy, 99.23% recall and 99.54% specificity. Comparison of supervised and unsupervised learning in recent technologies verifies that the suggested BGWO-CNN-LSTM method works better than other well-known CNN-based architectures for classifying the tumours. Further research could improve feature extraction algorithms by incorporating additional texture and form features and employing big datasets.

**Abstract**—The performance of treating the cardiac diseases is dependent on the kind of drug being selected. There exist numerous decisive support systems which work according to certain characteristics and factors like drug availability, and popularity. Still, they struggle to achieve expected performance in supporting the medical practitioner. To handle this issue, a multi feature drug curing rate based drug compound selection and recommendation system (MDCRSR) is presented. The method utilizes medical histories and data set of various medical organization around the disease considered. Using the traces, the method identifies the drug compounds and features to perform preprocessing which eliminates the noisy data points. Further, the features of the traces are extracted to perform training with genetic algorithm. At the test phase, the method estimates the fitness measure for different drug combination and compounds by measuring their Drug Curing Rate (DCR). The method performs cross over and mutation to produce various populations of drug compounds. According to the curing rate, the drug compound pattern or population is selected and ranked. The ranked results are populated to the medical practitioner. The method improves the performance of recommendation system as well as drug compound selection.

**Keywords**—Decisive support Systems; GA; DCR; drug selection; compound selection; fitness; recommendation system; cardiac disease; RMDCRSR

## I. INTRODUCTION

The human society faces variety of diseases but not all of them are harmful and claim the human life, but there are few diseases which would claim the human life without giving any time. The cardiac disease is one among them which occurs in various ways and they can be classified as Dextrocardia, Tachycardia, Bradycardia, Hyperkalcaemia, Sinoatrial block, and Myocardialischaemia. Among these diseases, few of them instantly block the heart and leads to cardiac arrest and lead to death. However, by identifying the disease at the early stage, they can be treated with set of drugs. For other diseases, there are varieties of drugs available in various compounds, each of them differs with their efficiency in curing the disease. Here it is about the selection of exact drug for any disease with the available drug compounds.

The medical practitioners are capable of identifying the disease and even they require set of automated decisive

support system in the classification and detection of any disease. Also, they have lot of drugs and compounds in front of them, and they can choose any of them to serve with patients. But, the efficiency of curing the disease cannot be justified and the performance of curing the disease is highly dependent on the combination of drugs being selected. As, there are numerous drugs, the medical practitioner would confuse in the selection of exact drug and compounds. To handle this issue, a real time drug and compound selection approach is discussed.

The recommendation systems are over the decisive support systems which consider variety of medical logs and features. According to the features and traces, the recommendation system identifies set of features in terms of drugs and would measure their performance according to their success and failure. By measuring the value of performance, they can be ranked and populated to the medical practitioner to serve the patient. For example, towards cardiac disease there are many drugs available like Aspirin, Lidocaine, Disopyramide, Procainamide which are used towards arrhythmic diseases. However, these drugs are available, the performance of the drug must be considered while selecting a drug.

The optimal selection of drug is dependent on how efficient the drug compound is in curing the disease. It is more important to identify the exact drug and to perform this, the Genetic algorithm has been adapted in this paper. Genetic algorithm is a scientific approach of searching the drug more effective in curing the disease. The genetic algorithm is applied in several scientific problems of medical issues and the same can be used in the selection of drugs in this model. The drugs of any disease would come on different milligrams and applied to several diseases. The GA algorithm would search on the optimal combination of drug towards any disease by measuring Drug Curing Rate (DCR). The RMDCRSR algorithm estimates the fitness.

## II. RELATED WORKS

There are number of approaches available towards recommendation generation and drug selection for heart diseases. This section details set of approaches related to the problem.

A sentiment analysis-based drug recommendation scheme is presented in [1], which take the reviews of sentiment analysis and support the decision-making problem. The sentiment measurement scheme uses the drug rating and selects according to the patient conditions. Accordingly, recommendations are generated. Similarly, in [2], an implicit feedback based approach cross recommendations (IFCR) which uses epileptics' medical history in identifying the relation of syndrome among drugs. A context aware approach towards hypertensive drugs is presented to support recommendations on personalized scope [3]. The method uses Semantic Web Rule Language (SWRL) to generate recommendations. A detailed review on several recommendation system is presented in [4], to support healthcare professionals.

A user preference-based recommendation scheme is developed in [5], where the recommendations are generated with two approaches and the user can select accordingly. An android based application is developed to support the selection of required medication to manage diabetic in [6]. The recommendations are generated according to the input made.

A group-based approach is discussed in [7], with a consensus reaching process to stimulate the recommendations related to the group users. An evidence-based recommendation scheme is presented in [8], which uses physical activity, exercise in diabetes patients. A naïve bayes classification approach towards disease prediction and drug recommendation is presented in [9], which uses the profile of patients like blood pressure, heart rate, cold and fever in classification where the drug selection is performed according to the symptoms. Similarly, for the hypertensive patients a physical activity recommendation system is presented in [10], which uses the user profile in recommendation generation named HyperModel2PAR.

A genetic algorithm based multi expert scheme (GA) MES-GRS-GA is presented in [11], which discuss consensus scheme towards group recommendation system. A predictive system is designed towards supporting cardiac disease in [12], which analyzes various machine learning algorithms and their results. A Fourier transformation-based heart disease prediction system (FTHDPS) is presented towards predicting chronic heart diseases with time series dat. ANN has been used in recommendation generation [13].

An intelligent HRS using Restricted Boltzmann Machine (RBM)-Convolutional Neural Network (CNN) is presented in [14], which uses the big data in recommendation generation. A hybrid diagnosis scheme for coronary artery disease is presented in [15], with neural network. Similarly, a Fuzzy analytic hierarchy process (Fuzzy\_AHP) technique is presented towards cardiac disease which estimates global weights for various features of individual and classification is performed with ANN [16]. A Congenital Heart Disease diagnosis scheme is presented in [17], which uses BPNN towards recommendation.

Towards providing security for software components a Mamdani fuzzy inference system is presented in [18], which evaluates different security measures and produces recommendations. A multiple kernel learning adaptive neuro fuzzy inference (MKL with ANFIS) is presented towards diagnosis of heart disease which support the classification of individuals [19]. A detailed review on drug recommendation is presented in [20], which used several articles. A relational connection based heterogeneous model is presented in [21], which uses drug, proteins and drugs with side effects. The DTIPred is discussed according to random walk and convolutional neural network. The model integrates various interactions and representations.

A cognitive intervention-based approach is designed in [22], which clubs the result of three different approaches in drug recommendations. A meta-analysis of randomized controlled trial based anti-inflammatory drugs towards cardiac disease is presented in [23]. At last, a cross sectional long term follow up scheme with transanal endorectal pull-through (TERPT) is presented in [24] to support diagnosis and surgery.

#### A. Multi Feature Drug Curing Rate Based Recommendation System with GA

The proposed multi feature drug curing rate based recommendation system reads the medical data set. According to the traces available, the method first preprocesses the data set to remove the noisy records. Further, the method finds the drugs list and their compounds to extract different features. Using the features extracted, the method applies genetic algorithm to estimate the fitness value of different drug compound to select optimal and efficient drug compound towards specific disease. According to the fitness function, the method computes the value of multi feature drug curing rate based on which the drugs are ranked to support medical practitioner. The detailed approach is presented in this section.

The architecture of proposed RMDCRSR model is presented in Fig. 1, and shows various functional components of the mode. Each of the functional stages is discussed in detail in this section.

#### B. Preprocessing

The medical data set given has been fetched here and the preprocessing algorithm finds the list of features available in the entire trace from the data set. According to the features identified, the traces are traversed to verify the features presence with value. If a trace without the feature and value is identified, then it has been removed from the data set. Such traces removed with noisy records are used to perform feature extraction.

Consider the data set given is Meds, which contains  $\emptyset$  records and each has k number of features, then the noise removal is performed as follows:

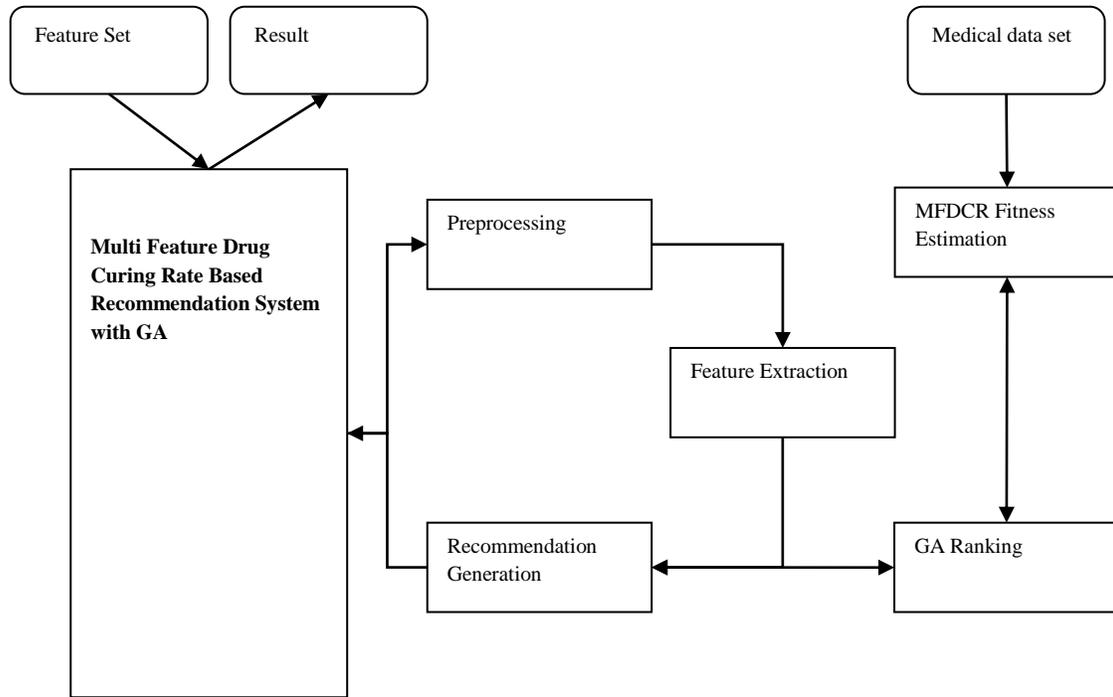

Fig. 1. Architecture of proposed MDCRSR model.

First the list of features are identified using equation (1). Features list  $F_{e\ list} =$

$$F_{e\ list} = \bigcup_{i=1}^{size(Meds)} (Meds(i).features \setminus F_{e\ list}) \cup F_{e\ list} \quad (1)$$

Now, the noisy records are identified and eliminated as follows:

$$Medsp = \bigcup_{i=1}^{size(Meds)} (if\ Meds(i) \in (\forall\ features\ (F_{e\ list}))? Medsp \cup Meds(i): Meds \cap Meds(i)) \quad (2)$$

Such noise removed data set has been used to extract the features and to support decision making.

### C. Feature Extraction

The data set preprocessed contains number of features and this phase extract several features from the data set. First, the traces belong to specific disease are identified and separated. With the traces separated, the set of drugs given for the disease has been identified and their subsequent compounds are identified. For example, for arrhythmic disease number of drugs would be used and at each drug there would be different manufacturer and volume of drug available, the feature extraction module, finds such drugs and volumes in distinct manner and collects the drugs and compounds. Identified drugs list and compounds are used to perform drug analysis to support recommendation generation. Medical Data set is considered as  $P_{mds}$  and drug vector as  $DV$ . The proposed

system will read the medical dataset and initialize the drug list  $DI$ .

For each record  $r$  Identify set of drugs  $D_s =$

$$D_s = \bigcup_{i=1}^{size(P_{mds})} Drugs \in p_{mds}(i) \quad (3)$$

For each drug  $d$

$$DI = \bigcup_{i=1}^{size(D_s)} D_s(i) \in DI? D_s \cap D_s(i): DI \cup D_s(i) \quad (4)$$

Drug vector  $Dv = \{DI\}$

The feature extraction algorithm identifies the list of drugs according to varying compounds and volumes. According to the drugs identified, the method performs recommendation generation.

### D. MFDCR Fitness Estimation

The fitness function of the proposed model estimates the fitness value by computing the multi factor drug curing rate (MFDCR). Each drug has specific curing rate on specific disease and according to that the method computes the DCR value for each disease. Based on the value of DCR, the method computes the value of MFDCR. It has been measured according to the difference on different logs status. To measure the value of fitness, the method split the traces of disease under success and failure classes. Once the traces are split, then the fitness value is measured as follows:

Consider the population given is  $p = \{D1, D4, D7, D9, D11\}$  where  $Dx$  represent the drug name and according to that

the fitness value is measured in terms of multi feature drug curing rate (MFDCR). Similarly, consider the trace set Sdt contains the traces of drugs with success treatment and Fdt represent the traces of drugs with failure treatment, then the method computes the Drug Curing Rate as follows:

First the drug trace has been identified as follows:

$$\text{Success Drug Trace ST} = \left( \sum_{i=1}^{\text{size}(Sdt)} Sdt(i) \in Dk \right) \&\& Sdt(i).state == Success \quad (5)$$

$$\text{Failure Drug Trace FT} = \left( \sum_{i=1}^{\text{size}(Sdt)} Sdt(i) \in Dk \right) \&\& Sdt(i).state == Failure \quad (6)$$

According to the values of equation (5, 6), the value of drug curing rate is measured as follows:

$$DCR = \frac{\text{Dist}(\text{Size}(ST) - \text{Size}(FT))}{\text{size}(ST) + \text{size}(FT)} \quad (7)$$

According to the drug curing rate of different drugs, the value of fitness function as MFDCR has been measured as follows:

$$MFDCR = \frac{\sum_{i=1}^{\text{size}(DI)} DI(i).DCR}{\text{size}(DI)} \quad (8)$$

Where, DI-represent the drug list and size(DI) represent the total number of drugs. According to the value of MFDCR, the fitness of the drugs pattern or population has been verified.

#### E. GA-Ranking

The proposed modified genetic algorithm finds the drugs list and their compounds. With the set of drugs, the method initially generates the population according to the size of drug list. For the populated drug compound, the method computes the MFDCR fitness value. If the fitness value greater than the threshold, then the population is selected as the result as recommendation. Otherwise, the process is iterated by generating different combinations by crossover operation and mutation operations. In this algorithm, the crossover and mutation operations are generated by computing the combinations with the number of drugs available in the earlier population. At each population, the method computes the value of MFDCR value. Finally, the method is iterated till an optimal drug composition is selected according to the value of MFDCR and threshold. Also, the method tries to reduce the number of compositions or drugs by choosing the drug population according to the MFDCR value. Finally, top few drug compositions or populations are populated as result to the user.

The proposed method Takes the Medical data set Meds, Disease D and returns Recommendations Rc.

When MFDCR < Th then

$$\text{Population set Ps} = \underset{i=1}{\text{GenerateCombinations}(i, p)}^{\text{size}(p)} \quad (9)$$

For each population pi

$$MFDCR = \text{Fitness}(pi)$$

If MFDCR > Th then

Population list PI = Rank Populations by MFDCR.

Recommendations Rc = PI

The genetic algorithm based ranking approach reads the data set and generates the initial population and computes the fitness value. According to the threshold the recommendation are generated and if the value of MFDCR is less than threshold, the process is iterated by performing crossover and mutation functions on the population of drug given. According to the value of MFDCR, the combinations of drug are ranked to produce recommendations to the user.

### III. RESULTS AND DISCUSSION

The proposed real time multi feature DCR based drug recommendation scheme with Genetic algorithm has been implemented and evaluated for its performance under various parameters. The evaluation has been performed according to the data set maintained by different medical organizations and the efficiency of the methods are measured on various factors. The performance of the proposed algorithm has been evaluated with MIMIC-III data set. MIMIC-III is an open source database provided by American critical care unit located at Beth Israel Deaconess Medical Center, Boston in the period of 2001 and 2012, which has been obtained from MIMIC-III. It covers variety of information from general patient details, intensive care unit features obtained, treatment details, diagnosis reports from lab, clinical and various other details at different stage with the improvement with the treatment and Data includes vital signs, medications, laboratory measurements, observations and notes charted by care providers, fluid balance, procedure codes, diagnostic codes, imaging reports, hospital length of stay, survival data, and more. In total it covers thousands of features in 26 tables which can be used to perform analysis on heart diseases.

TABLE I. ANALYSIS ON RECOMMENDATION GENERATION

Recommendation Generation Performance			
	50 Drugs	100 Drugs	200 Drugs
SWRL	73	79	83

MFDCR_GA	87	92	97

#### A. Performance

In the Table I performance of recommendation generation has been measured at different number of drugs cases. In each test case, the proposed MFDCR\_GA approach has produced higher recommendation performance than other approaches.

The performance of different methods in recommendation generation has been measured and presented in Fig. 2. The proposed MFDCR\_GA has produced higher performance at different number of drugs cases.

In Table II false ratio of recommendation generation has been measured for different approaches and the proposed MFDCR\_GA based approach has produced less false ratio than other approaches.

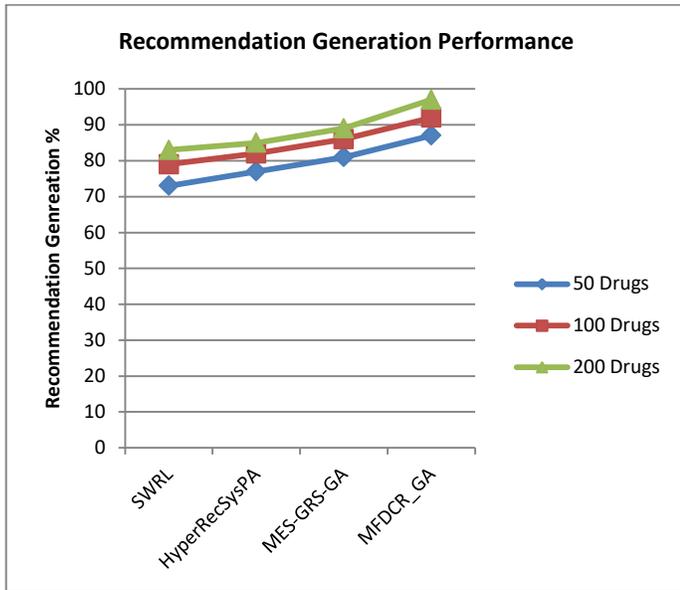

Fig. 2. Performance on recommendation generation.

TABLE II. ANALYSIS ON FALSE RATIO

False Ratio in Recommendation Generation			
	50 Drugs	100 Drugs	200 Drugs
SWRL	27	21	17
HyperRecSysPA	23	18	15
MES-GRS-GA	19	14	11
MFDCR_GA	13	8	3

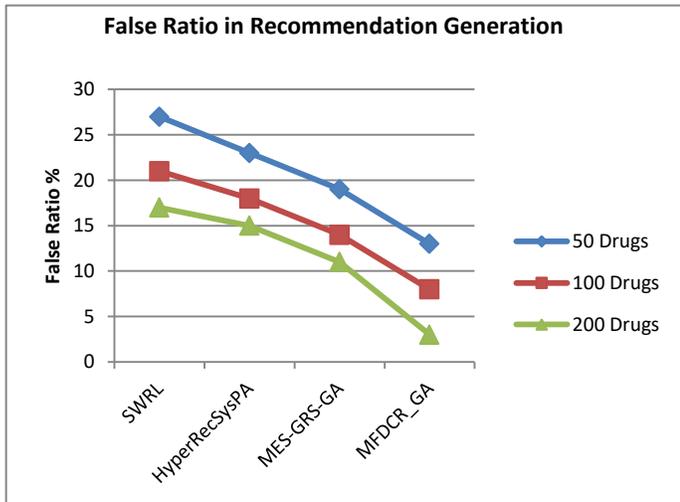

Fig. 3. False ratio in recommendation generation.

The ratio of false recommendation produced by the methods are measured and presented in Figure 3. In each test case, the proposed MFDCR\_GA approach has produced less false ratio than other approaches.

In the table 3 time complexity in recommendation generation has been measured for different approaches and the proposed MFDCR\_GA based approach has produced less time complexity than other approaches.

TABLE III. TIME COMPLEXITY

Time Complexity in Recommendation Generation

MFDCR_GA	23	28	39

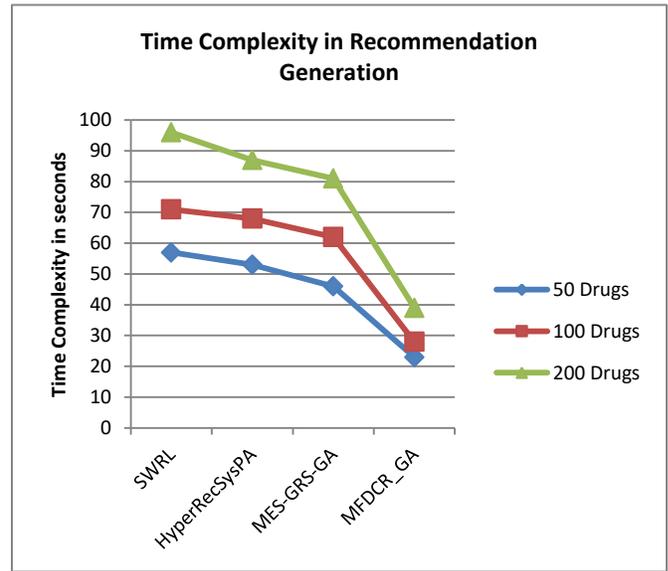

Fig. 4. Analysis on time complexity.

The time complexity in recommendation generation has been measured and presented in Fig. 4, where the proposed MFDCR\_GA has produced less time complexity than other approaches.

#### IV. CONCLUSION

This paper presented a detailed implementation of multi feature DCR recommendation system with Genetic algorithm. The method reads the data set and finds set of drugs for different disease class. Further the value of drug curing rate is measured on each drug towards various disease classes. Also, the method computes the multi feature drug curing rate (MFDCR) towards various disease classes. According to the value of MFDCR the drugs and their compounds are ranked to generate recommendation to the medical practitioners. The proposed approach has been evaluated with MIMIC-III database and the method improves the performance of recommendation generation with least false ratio and time complexity.

# The Predictors of Mobile Banking Usage: A Systematic Literature Review

Mohammed Abd Al-Munaf Hashim, Prof. Dr. Zainuddin bin Hassan

College of Computing and Informatics (CCI), Universiti Tenaga Nasional, Kuala Lumpur, Malaysia

**Abstract**—Mobile banking has become an essential method to conduct banking transaction. However, number of users worldwide are still limited. The purpose of this study is to review the literature and understand the status of m-banking adoption, usage, and loyalty. Keywords were used to search for related articles in three databases namely, Web of Science (WoS), Scopus, and Google scholar. Filtering process was conducted to select the most related articles. This has resulted in reviewing 45 articles. The findings showed that number of articles pertaining to m-banking is increasing. Malaysia and Indonesia have the largest number of articles. The technology acceptance model (TAM) is being used widely in the m-banking literature and most of the reviewed studies are empirical with adequate sample size. This explains the increased usage of structural equation model (SEM). The most critical factors for m-banking adoption, usage, and loyalty are service quality, trust, perceived usefulness, perceived ease of use, security, risk, privacy, and social influence. Future research is suggested to examine the m-banking in different region and using mediating and moderating variables to explain the variation in the adoption.

**Keywords**—M-banking; TAM; Service quality; Loyalty; UTAUT

## I. INTRODUCTION

Mobile banking is a new technology that enables the access and the execution of financial transaction using mobile device. This trend has been increasingly used by users around the world with varied percentage.

In developed countries, it was noted that three out of ten are using m-banking to settle their financial transaction. The percentage reduced in other non-developed countries. M-banking is beneficial for users and the banks as it reduces the physical effort of users and enable them to conduct their transactions without the need to visit banks or going through routines and paperwork. On the other hand, the m-banking speed the service process and reduce the workload of employees at banks and it also reduces the financial operational cost for banks. However, it has been observed that the use of m-banking by users is still limited and more studies are needed to understand the application and the adoption of users regarding the use of m-banking.

Previous studies with the opinion that the perceived usefulness (PU) and perceived ease of use (PEOU) are critical factors for the adoption [1, 2, 3]. On the other hand, the privacy, security, and trust were identified as the most important variables in the context of m-banking [4, 5, 6]. Other studies related the usage to the service quality [7, 8]. Literature regarding the critical factors that lead to the usage of m-

banking has no agreement on the variables that can be deployed to enhance the utilization of m-banking. However, it has been observed that the use of m-banking by users is still limited and more studies are needed to understand the application and the adoption of users regarding the use of m-banking. Theoretical framework has been deployed by previous studies to enhance the explanatory power of the m-banking. One of the widely used theoretical models is the technology acceptance model (TAM) by Davis [9].

TAM is with the opinion that the adoption is mainly related to the perception of users regarding the PEOU and the PU of the technology. On the same context, one of the emerging models is the unified theory of acceptance and use of technology (UTAUT) by Venkatesh et al. [10]. UTAUT deployed four main variables and considered these variables as critical for the adoption of any new technology. These variables include the effort expectancy (EE), performance expectancy (PE), social influence (SI), and facilitating condition (FC). Other theoretical models are used also in the literature. These include the information system success (IS) success which relates the usage of a new technology to the quality of service, system, and information as well as the satisfaction of users.

There is no agreement in the literature regarding the predictors of m-banking or the theoretical model that explain the loyalty to use m-banking. Previous studies are in general empirical and there is a need for a review to understand the status of the literature. Accordingly, this study aims to review the literature and identify the most critical theories and predictors in the context of m-banking. The study also aims to provide the stakeholders with the research gaps and the directions of future works. Based on the fact that this study is a literature review study, the next section discusses the methodology of conducting the systematic literature review (SLR) followed by a summary of the reviewed studies. The findings are discussed as well as the limitation and direction of future work.

## II. RESEARCH METHODOLOGY

This study is an SLR that aims to understand the status of the literature and identify the critical factors for adopting m-banking. To fulfil this objective, the study used specific keywords to look for articles. The keywords include m-banking, predictor of m-banking, m-banking usage, and theories of m-banking. Reliable databases were searched to extract the articles (Fig. 1). Web of Science (WoS), Scopus, and google scholar were used to find the articles.

A total of 399 articles were found related to the issue. However, to have an updated view, the articles between 2016 and 2021 were selected. This has reduced the articles to 187. Further filtering using the language i.e., English language or the scope i.e., theoretical article and remove technical articles. This has further reduced the articles to 76 articles. A full reading was conducted on these 76 articles, and this has resulted in 45 articles that are related to the m-banking adoption.

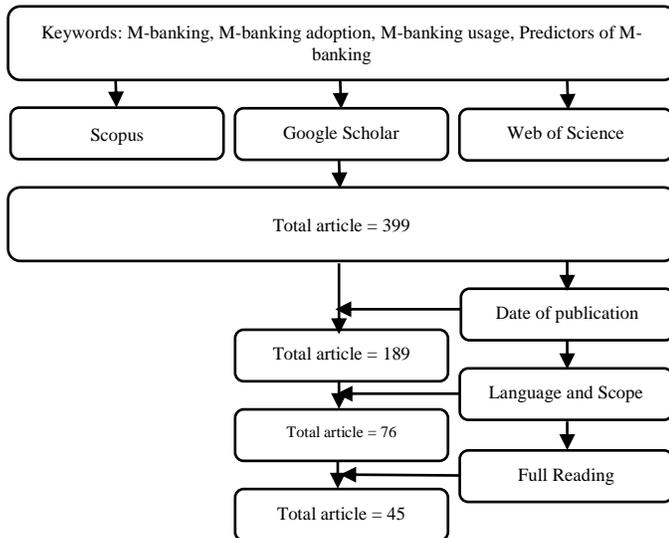

Fig. 1. Process of selecting the articles.

### III. SUMMARY OF REVIEWED STUDIES

The reviewed studies can be divided into categories based on the theoretical framework. Previous studies deployed TAM. For example, Zhao, Chen and Wang deployed TAM to examine the satisfaction and loyalty of using M-banking [1]. The findings showed that social influence and the psychological ownership has greater effect than the variables of TAM. Similarly, the findings of Rubiah Abu Bakar indicated that variables such as security and privacy are more critical than the PEOU of m-banking [11]. Yuan et al. also deployed TAM to examine the effect of satisfaction and technology fit along with variables of TAM. The findings indicated that satisfaction, PU, task-technology fit, and risk positively associated with customer' loyalty [2]. Moreover, the results showed that confirmation, PEOU, and task-technology fit positively impact PU.

Yun Min Low deployed TAM to examine the loyalty of using m-banking. The findings showed that subjective norms, PEOU and convenience risk are critical factors for the usage of loyalty [12]. Liébana-Cabanillas et al. found that customer loyalty has been significantly influenced by satisfaction [13]. Munoz-Leiva et al. and found that TAM can explain the intention to use the M-banking [14]. Abdinoor and Mbamba found that the TAM model integrated with cost and awareness are useful in explaining the intention to use M-banking [15]. Aliza Kasim found that variables of TAM and facilitating conditions are positively influencing the customer intention to use M-banking [16]. Priya, Gandhi et al. utilized TAM and found that customer's behavioural intention and satisfaction in

using the service are significantly influencing by PU, PEOU, perceived credibility, and structural assurance [17]. Moreover, the positive mediating effect of customer satisfaction has confirmed on the relationship among the related factors and behavioural intention. Meanwhile, the effect of perceived risk on behavioural intention to use the service has been reported to have insignificant effect.

Mostafa and Eneizan indicated that facilitating conditions and self- efficacy are positively affecting on PEOU and PU factors. Furthermore, the results have indicated a positive impact of PEOU and PU on costumer's behavioural intentions to accept and use M-banking technology [18]. Nawaz and Yamin utilized TAM and found that PEOU and PU have a direct positive impact on the behavioral intention to use the service. Trust found to have a positive impact on customer behavioral intention to use m-banking [19]. Mutahar proposed perceived value as a moderator in among the variables of TAM [20]. Ezeh and Nwankwo utilized TAM and found that PEOU, financial cost and perceived credibility have significant effect on intention to use m-banking [21]. Malaquias and Hwang also found that PEOU and PU as well as trust and social influence affect the actual use of m-banking [22]. Mulia et al. added the customer intimacy as a variable and deployed TAM to examine the user satisfaction and loyalty of using m-banking. The findings showed that Customer intimacy affected the directly the customer satisfaction and the loyalty [23].

Another theoretical framework that has been used by the reviewed studies is the unified theory of acceptance and use of technology (UTAUT). De Sena Abrahão et al. deployed UTATU and included variables such as cost and risk to examine the behavioural intention to use m-banking [24]. The findings showed that large portion of the variation can be explained by UTAUT. Maduku found that variables of UTAUT as well as self-efficacy and structural awareness affected positively the behavioural intention to use m-banking [25]. Zendeudel, Paim et al. found that PE, EE, cost and trust are significantly affecting the customer intention to use M-banking [26]. Singh and Srivastava found that trust, security, privacy, and social influence affected the intention to use M-banking [27]. Baabdullah, Alalwan et al. found that UTAUT variables can explain the loyalty to use M-banking applications [28].

The third theoretical model that has been used is the IS success. This model was deployed to emphasize on the service, system, and information quality. For instance, Mohd Thas Thinker, Amin et al. deployed the model to explain the loyalty of using m-banking. The findings showed that usability, customer service, satisfaction and trust in m-banking service influencing the continuance intention or loyalty toward using m-banking service. In addition, continuance usage or loyalty is positively affected by trust and customer satisfaction mediator factors [29]. Sharma and Sharma uses the model also to explain the actual use of m-banking. The study found that satisfaction and intention to use are significantly influenced by the service quality and trust which leads to influencing the actual usage of the service [30]. Expressly, a more trustable service with better quality will help in keep the current customer using the service and attract a new wave of users to join the system. Service quality theory has been used also in the literature of M-

banking. For example, Suariedewi and Suprapti deployed the theory to explain the e-loyalty of m-banking [8]. Similarly, Zhou et al. used the theory to explain the m-banking service quality and loyalty [7].

Mixed theories were used in few numbers of previous studies. Kumar, Israel et al. combined ECT and SDT to explain the continuous of usage and loyalty to m-banking. The findings showed that the continuance intention to use m-banking is influencing by the following factors: satisfaction, intrinsic regulation and identified regulations, while influenced by expectation-confirmation, trust, and quality factors effect stingingly in the customer satisfaction [31]. UTAUT and IS success theories were combined in the study of Windasari and Albashrawi and the findings based on gender suggested that service quality affected PE and EE of male but not female. Information quality affected the facilitating condition of male but not female. PE, EE, and FC affected the loyalty. Service quality affected satisfaction of female and satisfaction affected the loyalty [32]. Symbolic value theory and brand equity theory were combined in the study of Esmaeili et al., the findings showed that usability affected trust and satisfaction. Perceived risk affected loyalty and relative advantage affected customer loyalty [33].

Large number of the reviewed studies did not deploy any theory, and this can be seen in the different studies [34, 35, 36, 37, 38, 4, 39, 40, 5, 6, 41, 42, 43]. Most of these studies focus on the security, privacy, and risk of using m-banking. Table I shows a summary of the reviewed articles which include the author, years, country, sample, and theory.

#### IV. FINDINGS

The findings of this study are derived using frequency analysis. The analysis was conducted after extracting the information of the articles. The analysis is conducted using excel sheet and it includes the year of publication, country, theoretical framework, approach, sample size, and data analysis technique. More importantly, the analysis included the most critical factors for m-banking.

##### A. Year of Publications

The year of publication is given in Fig. 2. It shows that the number of articles has increased between 2016 and 2018 and

this could be due to the notion that the application of m-banking has increased during this period. Number of articles reduced between 2019 and 2022 and this could be due to the searching criteria for articles in this period (see Fig. 2).

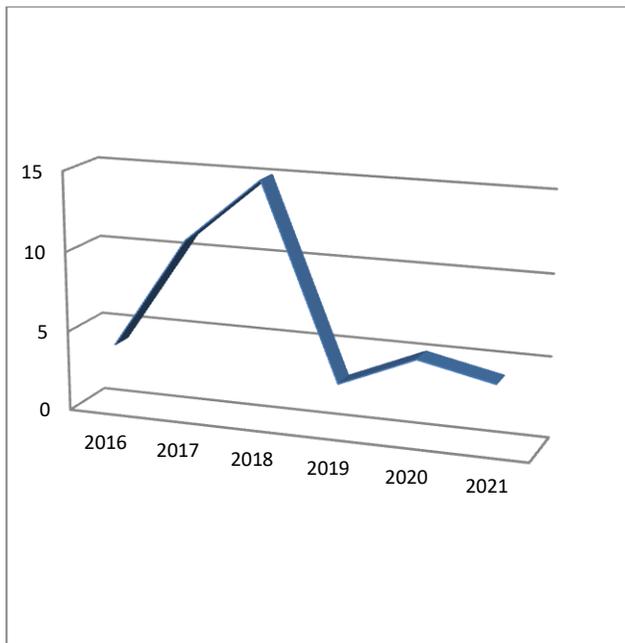

Fig. 2. Year of publications.

### B. Country of Origin

The country of origin is where the research has been conducted. It can be seen that the number of articles in Malaysia is the highest followed by Indonesia, India, and Bangladesh. This could be also due to the wide spread of M-banking by banks in the Asian region. Fig. 3 shows the distribution of articles based on country of origin.

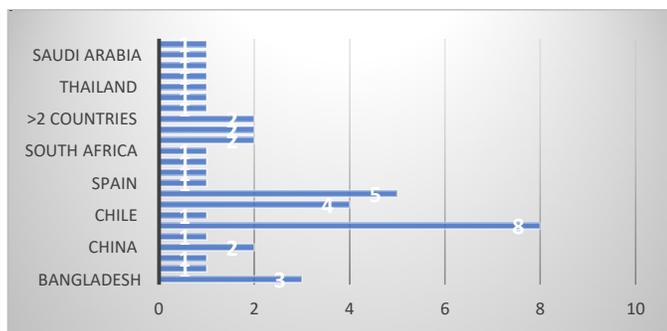

Fig. 3. Country of origin.

### C. Sample Size

The sample size of the reviewed studies is shown in Fig. 4. The minimum sample size has been used in the reviewed studies account to 105 and the maximum is 927 with mean score of 373. This means that on average, there are 373 respondents in the reviewed studies. This average indicates that there is a shift in the analytical approach. Fig. 5 shows the sample size.

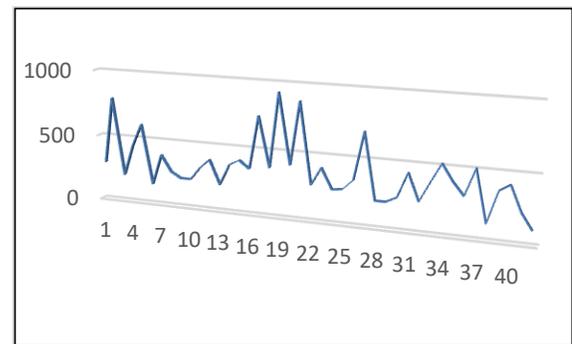

Fig. 4. Sample size.

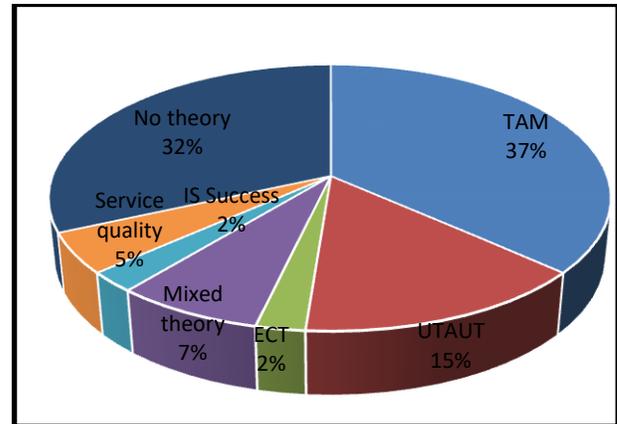

Fig. 5. Theoretical framework.

### D. Study Approach

The study approach is shown in Fig. 6. It can be seen that there are 98% of empirical studies while review studies accounted to 2%. This shows that the literature is empirical in nature and limited numbers of review studies were conducted.

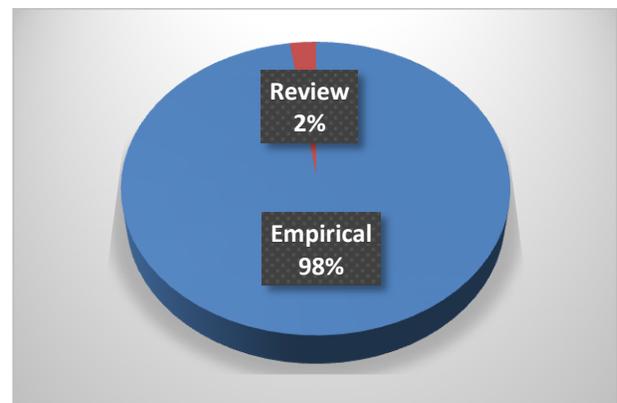

Fig. 6. Theoretical framework.

### E. Statistical Tools

The statistical tools that have been used by the reviewed studies to analyses and explain the findings are shown in Fig. 7. It can be seen the SPSS has been used by 41% of the reviewed studies followed by PLS with 32%, AMOS with 20% and LISREL with 7%. The first generation of data analysis represented by SPSS accounted to 41% while the second

generation known as structural equation modelling (SEM) and includes LISREL, AMOS, and PLS accounted to 59%. This confirms that there is a shift toward using advance analytical tools to examine the association among the variables. Again, this is also confirmed from the mean of sample size which is 373. This is because the use of SEM requires a minimum of sample size of 200.

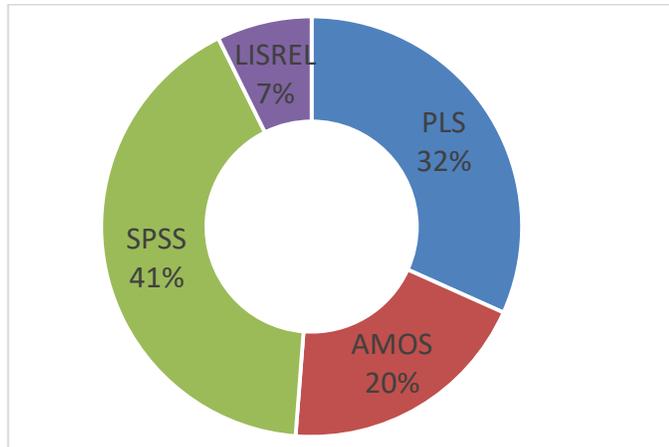

Fig. 7. Analytical techniques.

#### F. Critical Factors

Factors of the 45 articles were extracted and a frequency analysis was conducted to identify the most related articles. The findings showed that service quality is one of the most critical factors for user satisfaction and loyalty to use m-banking. This followed by trust, PU, PEOU, security, and perceived risk as well as privacy, and social influence. These variables have been identified by prior literature to be critical for the behavioral and actual behavior toward using the m-banking by customers in various countries as shown in Fig. 8.

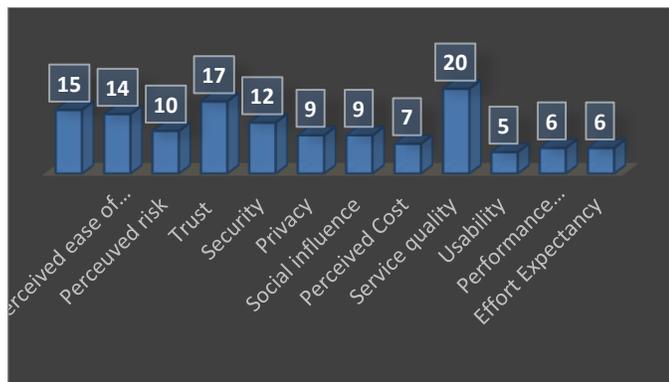

Fig. 8. Critical factors for m-banking.

#### V. DISCUSSION AND IMPLICATIONS

This study was conducted to review the literature pertaining to the m-banking usage and adoption by users. The study also aimed to identify the gaps and the direction of future work as well as the predictors of using the m-banking. The finding showed that the number of articles published is increasing and this is a signal that the awareness about m-banking is also increasing. The country of origin shows that Malaysia is a leading country in m-banking studies followed by Indonesia.

This could be due to the lifestyle of the people in these countries as online banking has become the norm and the preferred method of settling the financial transaction. In term of the theoretical model, the literature showed that TAM is still dominating the research of m-banking followed by to a less degree with UTAUT. Emerging theories such as IS success is used by limited number of studies. The quantitative approach is used widely by the literature and sample size is adequate for the analyses of the studies. In addition, the use of SEM is increasing in the literature.

In terms of the predictors, the service quality is the most important predictor of m-banking loyalty, adoption, and usage. This is followed by trust and the variable of TAM such as PEOU and PU. Security, perceived risk and privacy as well as social influence are also critical for the usage of m-banking. This finding is in line with the findings of previous literature who found that the service quality and trust as well as security and privacy along with the variables of TAM are critical for the m-banking usage [1, 2, 12, 8, 45].

Accordingly, this study suggested that these factors can represent the predictors of users of m-banking across various countries and region. In addition, the study suggests that TAM is one of the most used theoretical frameworks. Therefore, decision makers are suggested to focus on the service provided by the m-banking application. Creating trust between the banks and the customers is essential for enhancing the intention to use the application. In addition, the security procedures is vital for the increase adoption of m-banking. The PU and the ease of using the application can be important variables for the adoption of m-banking.

#### VI. CONCLUSION, LIMITATION, AND FUTURE WORK

This study has been conducted to describe the literature about the m-banking adoption and to understand the predictors and theoretical foundation of the literature. The findings showed that there is an increase in the awareness and academic research into m-banking. The finding also showed that countries such as Malaysia, Indonesia, and India have received largest number of research into m-banking. TAM is still the dominating theoretical framework followed by UTAUT with empirical approach is overwhelming in the literature. The sample size is sufficient and larger than 200 responses which indicate that there is a shift toward using SEM which requires more than 200 responses. More importantly, the findings showed that service quality is the most important and widely frequent variable in the literature followed by trust, PU, PEOU, security, risk, social influence, and privacy.

The study reviewed 45 articles extracted from Scopus, Woos, and Google scholar. The number of articles is limited due to the searching criteria, scope, and year of publication. Future studies can expand the scope, year of publication to increase the number of the reviewed article and the generalization of the findings. The findings showed that there is limited number of review studies and therefore, it is suggested for more studies to review the literature of m-banking. In term of the year of publication, number of articles between 2019 and 2021 has decreased and researchers are suggested to conduct more studies and especially in the time of COVID-19 where the online banking has become essential for

all individual and organization to finalize their financial transaction. Research into m-banking is high in Asian countries such as Malaysia and Indonesia. However, few studies observed in other countries. Thus, more studies are suggested in other countries and region such as the Middle East, and Africa to have clearer view about the m-banking worldwide.

In term of theoretical framework, the TAM is widely used followed by UTAUT. However, mixed theories or combined theories have been used by a few numbers of studies. Therefore, it is suggested that the future research should include the more theories such as the TAM and social exchange theory or TAM and IS success, UTAUT and IS success and these theories can explain more the aviator in technology adoption such as m-banking. It was also noted that few of the previous studies have deployed mediator or moderator. Thus, future studies can incorporate moderating variables such as trust, innovativeness, education, gender, and IT knowledge. Mediating variables can be the enjoyment and playfulness of m-banking.

The critical variables identified in this study include service quality, trust, PU, PEOU, risk, security, social influence, and privacy. Future researcher can examine empirically the effect of these variables on the m-banking adoption to provide the decision makers with empirical view that can lead to more usage of m-banking.

#### ACKNOWLEDGMENT

I am deeply grateful to my supervisor Prof. Dr. Zainuddin bin Hassan, for providing invaluable guidance, support, and encouragement throughout my research. His expertise and knowledge have been instrumental in shaping the direction and outcome of this study. I also extend my heartfelt thanks to my family and friends who have been a constant source of love and support during this journey. Their unwavering belief in me has been a source of strength, and I am grateful to have them in my life.

This research would not have been possible without the support and encouragement of these individuals. I am eternally grateful for their contributions, and I dedicate this work to them.

# A Novel Approach: Tokenization Framework based on Sentence Structure in Indonesian Language

Johannes Petrus<sup>1</sup>, Ermatita<sup>2\*</sup>, Sukemi<sup>3</sup>, Erwin<sup>4</sup>

Informatics, Universitas Multi Data Palembang, Palembang, Indonesia<sup>1</sup>  
Department of Computer Science, Universitas Sriwijaya, Palembang, Indonesia<sup>2,3,4</sup>

**Abstract**—This study proposes a new approach in the sentence tokenization process. Sentence tokenization, which is known so far, is the process of breaking sentences based on spaces as separators. Space-based sentence tokenization only generates single word tokens. In sentences consisting of five words, tokenization will produce five tokens, one word each. Each word is a token. This process ignores the loss of the original meaning of the separated words. Our proposed tokenization framework can generate one-word tokens and multi-word tokens at the same time. The process is carried out by extracting the sentence structure to obtain sentence elements. Each sentence element is a token. There are five sentence elements that is Subject, Predicate, Object, Complement and Adverbs. We extract sentence structures using deep learning methods, where models are built by training the datasets that have been prepared before. The training results are quite good with an F1 score of 0.7 and it is still possible to improve. Sentence similarity is the topic for measuring the performance of one-word tokens compared to multi-word tokens. In this case the multiword token has better accuracy. This framework was created using the Indonesian language but can also use other languages with dataset adjustments.

**Keywords**—Token; tokenization; multi-word; sentence structure; sentence elements

## I. INTRODUCTION

In the current era, the amount of information is increasing very rapidly [1], a lot of information is available in text form from various types of documents such as magazines, e-books, research results, social media, emails, pdf files, video, audio, images, and large amounts of business content. Experts predict the volume of text documents will grow by 80% by 2025. To be useful, text data must be processed into information with text mining techniques [2].

To be processed, text data needs to be prepared at the text-pre-processing stage. This stage is the first important step of any data mining process to achieve better accuracy [3]. This process will change the data from its original form into a form that is easier to observe and explore [4]. One of the activities in pre-processing is tokenization besides case folding, filtering/stop-words removal, lemmatization, stemming [5], [6] including normalization and removing irrelevant words [7]. Stopwords are the least important words in a sentence, and ignoring them can help identify the most important words [8].

Tokenization is a fundamental process in almost all Natural Language Processing applications. The standard approach is single-word tokenization, in which the input string is split word

by word using spaces as separators [9]. Most NLP research uses this kind of tokenization technique, such as by [10] in semantic similarity, [4][9] in text classification, [11], [12] in information retrieval, [13], [14] in clustering, [15]–[17] in sentiment analysis, and much more.

Usually tokenization separates each word in a sentence as one token based on the spaces between words, but in fact, not all words in a sentence can be separated. There are words that must remain in pairs so that the meaning of the sentence remains correct. Separating a sentence into its constituent words can result in the meaning of a word deviating far from its actual context [18].

There are several publications that state that tokens are not just one word, but can be several words or even one sentence [10][13][14][19]. There is also research into finding multi-word expressions (MWE) or combinations of words that must be paired to make sense, such as by [20]–[23]. Most of this research was conducted for documents in English and other languages, including languages that do not recognize spaces as separators between words, such as Mandarin, Japanese or Thai. Research on Indonesian language texts is still limited. All the research above is only for finding word pairs and not for tokenization.

Methods that have been used in previous research include statistics, linguistic, dictionaries, and machine learning. The statistical method calculates the frequency of co-occurrence of two words. Linguistic methods match grammatical patterns based on the types of word labels. Searching for word pairs in the dictionary, that's the dictionary method. Machine learning methods use a set of datasets to predict the output.

Tokens consisting of several words are referred to as multi-word tokens. Multi-word tokens must be in the same sentence and same sentence element. In paragraphs that contain many sentences, it is necessary to segment the sentences so that each sentence is separated from each other. In order to segment a sentence, it is very important to know where the sentence boundaries are. It is not easy to find sentence boundaries because there is ambiguity from sentence boundary punctuation.

In Indonesian there are 5 sentence elements, namely Subject (Subjek), Predicate (Predikat), Object (Objek), Complement (Pelengkap) and Adverb (Keterangan) known as SPOK in Indonesia [24]. The subject and predicate elements must be present, while others may or may not be present. Each sentence element contains one or more words as word pairs.

Word pairs can only be formed in the same sentence element. Therefore, it is important to be able to perform sentence structure extraction. This is not taken into account by previous studies. By extracting the sentence structure, each sentence element can be treated as a token, at least for Subject and Object. This paper proposes a new method for sentence tokenization based on sentence structure in Indonesian. This new method of sentence tokenization will generate single-word and multi-word tokens simultaneously. That's our contribution. To our best knowledge, there is no research on this. This research uses Indonesian, but can be adapted to other languages that use spaces by customizing and retraining the dataset.

To find out the effectiveness of single-word and multi-word tokens, a sentence similarity test was carried out on both types of tokens. From the test results, it shows that multi-word tokens are able to determine word similarity better than single-word tokens.

This paper divided into several sections. In Section II, we review the related work on multi-word tokenization including multi-word expression, Section III, we give an overview of the proposed method including sentence segmentation, sentence structure extraction and dataset preparation. Section IV, we provide the result and discussion, and finally, Section V, concludes this paper.

## II. LITERATURE REVIEW

This paper is inseparable from the previous studies that have been conducted by researchers. The previous studies are summarized in this section, especially those related to multi-word tokenization. There are several methods used in previous research, such as statistics, linguistics, dictionary, and machine learning. We found two research in Indonesian language, that is [25] which perform 2-word extraction to obtain multi-word expression candidates by applying some rules and filtering using a dictionary. Researcher [26] also used rule-based methods and built two dictionaries (close class tagging and multi-word expression dictionary). This dictionary will store two or more words with POS tags of nouns, verbs and adjectives. The study [27] examines the tokenization process using a phrase detection-based approach.

Research in Serbian language with agricultural engineering domain conducted by [28] provides a hybrid approach by combining linguistic and statistical information. The Candidate terms are obtained using the frequency of occurrence of text sequences in the corpus. In an effort to obtain multi-word expressions, the author in [20] examined an implementation in Turkish used four methods: first, statistical methods to calculate high co-occurrence frequencies, second, linguistic methods through POS patterns, third, candidates from idiom dictionaries, and the last is specialized domains such as term dictionaries. Research that presents a method for identification of chemical terms as multi-words was conducted by [23]. In his research, the Multiword Identifying and Representing (MIR) method was implemented to recognize multi-word phrases in chemical literature with an unsupervised data-driven model and the identified phrases were added to the vocabulary. This research uses statistical and linguistic methods without expert annotations. Author in [29] created the MwTEXT architecture,

for automatic extraction of multi-word terms from unannotated computer science domain English documents. This method uses statistical, linguistic, and logic-based methods and hybrid techniques and focuses only on lexical patterns such as (N P N), (N P N + N), and (N P N P N).

The study [21] built a hybrid approach with the combination of Bi-LSTM + word correlation level and K-Means Clustering to detect MWEs for multiple languages without manual features. Author in [30] proposed a neural network model for learning fixed-size word representations from arbitrary chunks with word embedding. Implementation in French created MWE for Russian dictionary (RuThes). Multi-word expression recognition measure based on similarity of phrase distribution and word components is used for statistical and linguistic methods as well as for word embedding. Author in [31] focus on annotating different types of lexicalized and institutionalized phrases with main goal is to identify MWEs that are perceived as complex by readers and need to be simplified overall. A number of hand-crafted features form the basis for predicting MWE complexity.

From the previous research above, as far as we know, there is no research with a method based on sentence structure as proposed by this research.

## III. PROPOSED METHOD

The general tokenization process is shown in Fig. 1. This process works by receiving input in the form of sentences and identifying each word as a token by using spaces as separators between words, resulting in single word token. The number of tokens equals the number of words.

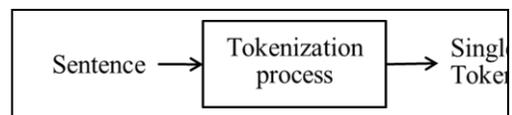

Fig. 1. General tokenization process.

This tokenization method is widely used, but it can also cause inaccuracies, such as:

1) The same word or token, will be considered to have the same meaning even if it is in a different order so that only one token will be used and the other tokens will be ignored [32]. Example :

Token in English : 'sakura', 'dewi', 'looks', 'at', 'sakura', 'tree', 'in', 'Japan.'

Token in Indonesian : 'sakura', 'dewi', 'memandang', 'pohon', 'sakura', 'di', 'Jepang'

The first token and the fifth token, will be considered to have the same meaning even though they are semantically different. One of them will be ignored.

2) When two or more words are combined and form a whole, a new meaning will be created that is different from each of the constituent words. Example :

Token in English: 'green table'

Token in Indonesian: 'meja hijau'

In Indonesian, 'meja hijau' means the court, a place to find the truth. If these two words are separated into 'meja' and 'hijau' then the meaning becomes different, the first is a piece of furniture that has a flat surface as a table top and legs as a support and the second is one of the base colors.

3) Not only the word meaning problem, but also the Part-of-Speech (POS) ambiguity problem. The POS of a single word token can vary. For example, separating the two words 'memberi makan' (in English: feeding), consists of the word 'memberi' with POS as the verb and the word 'makan' as the noun (since it is something that is given), but in other contexts such as 'kuda makan rumput', the POS of the word 'makan' is as a verb.

From the previous description, it is known that there are words that cannot be separated or must still be combined. Current tokenization methods does not accommodate this.

The main elements of the proposed tokenization framework are shown in Fig. 2. The framework has two stages, namely sentence segmentation and sentence structure extraction.

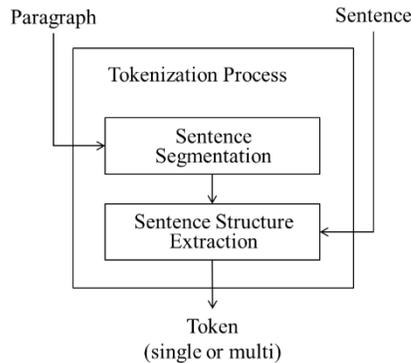

Fig. 2. The tokenization framework block diagram.

The input can be in the form of paragraphs or sentences. If the input is a paragraph, it will go through the sentence segmentation stage. This stage will split the paragraph into separate sentences. These sentences, whether they are new input or output from the first stage will be processed in the sentence structure extraction stage.

The output is a sentence structure with its elements (SPOK). Each sentence element is a token. In other words, sentence structure extraction is a tokenization process. These tokens are then used in natural language processing applications.

#### A. Sentence Segmentation

The task of sentence segmentation can be performed by detecting sentence boundaries [33]. The general pattern of a sentence is that it begins with a capital letter and ends with a special punctuation mark such as a period, question mark, or exclamation mark. The ability to recognize punctuation is a key requirement for knowing sentence boundaries to divide a paragraph into sentences. In this study the sentence segmentation process is described in Fig. 3.

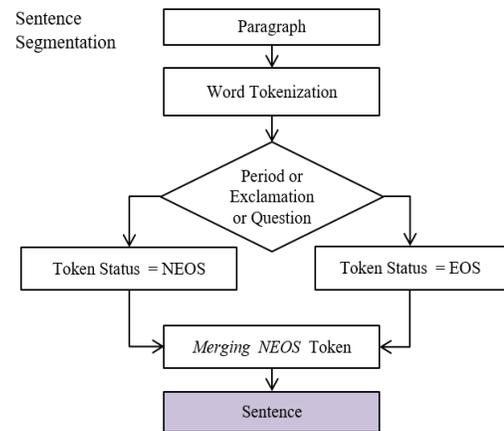

Fig. 3. Sentence segmentation diagram.

1) Word Tokenization, is a tokenization process as commonly used, breaking text data into words [8][34]. If there are punctuation marks then they will be attached to this token.

2) Punctuation Checking, is the process of checking the punctuation attached to the token, one of which is a period, question mark, or exclamation mark.

3) If the punctuation on the token is one of the three sentence-ending punctuation marks, the token will be assigned EOS status. Otherwise, it will be assigned NEOS status.

4) Combining NEOS Tokens. All NEOS will be combined into one sentence after finding EOS.

All tokens with NEOS status are combined into one new sentence and tokens with EOS status become the last word in the sentence. The next token will be the first word of the next sentence. This sentence will be used as input for the next process.

#### B. Sentence Structure Extraction

There are five sentence elements in Indonesian, namely Subject (Subjek), Predicate (Predikat), Object (Objek), Complement (pElengkap) and Adverb (Keterangan). Each sentence consists of at least a Subject and a Predicate and these two elements are arranged sequentially. The sentence elements Object, Complement and Adverb can be used or not used. The combination of these sentence elements forms a sentence structure pattern like SP, SPO, SPOK, SPOE, SPK, SPE, SPEK and SPOEK. Each word or words in each element of the sentence is a unit. Words or tokens that are in different sentence elements cannot be combined into one unit.

The sentence extraction process will identify sentence elements and classify each word in each sentence element.

This will facilitate the tokenization process, especially in determining multi-word tokens. The sentence structure extraction method in this study is as shown in the Fig. 4.

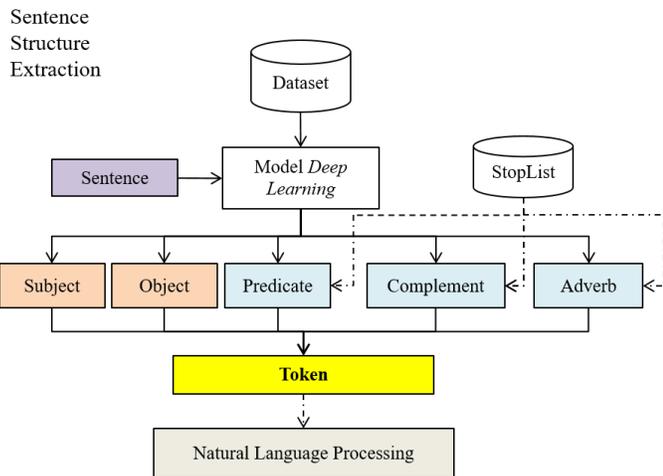

Fig. 4. Sentence structure extraction diagram.

The stages of the extraction process are as follows:

1) The process will accept input in the form of simple and active sentences.

2) A pre-trained deep learning model will predict sentence structure of the input sentence. The model has been trained using a dataset containing a collection of simple and active sentences in Indonesian, complete with labels. The embedded label is the identity of the sentence structure in the BIO tagging format. Label B (for "beginning") indicates as part of a multi-word token with position as the first word. The label I (for "inside") also indicates as part of a multi-word token with the position as the next word and the label O (for "outside") indicates as a stand-alone token or single word token. The dataset is in csv file format with an example as shown in Fig. 5.

This dataset contains 45,079 tokens from 4,740 sentences in Indonesian, with a minimum token range of 2 words and a maximum of 17 words per sentence. The distribution of each sentence element contained in the dataset is shown graphically in Fig. 6.

Fig. 5. Sentence structure dataset.

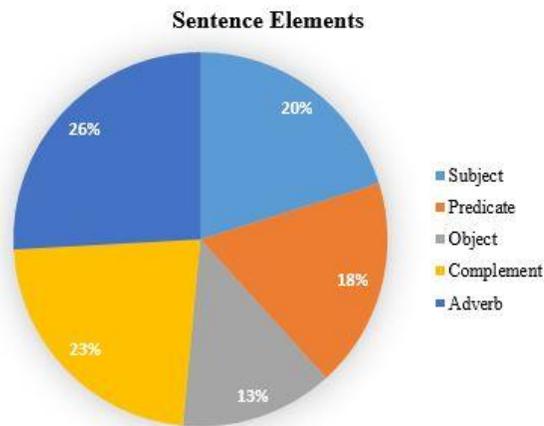

Fig. 6. Distribution of sentence elements in the dataset.

This dataset was trained using the pre-trained Bidirectional Encoder of Transformers (BERT) model. By dividing 80% as training data and 20% as test data and 10 epochs, an F1-score of 0.7 was obtained. These results show that the model and dataset that have been built are good enough, but need to be improved in the future.

3) The output of this process is a sentence structure prediction with sentence elements, namely Subject (SUB), Predicate (PRE), Object (OBJ), Complement (PEL), and Adverb (KET). There are nine types of adverbs in the dataset so there are thirteen sentence elements as listed in Table I.

Each token or word must be a member of one of the sentence elements. Each sentence element can consist of one or more than one word.

The output of the predicted sentence element will be written in the format of a BIO-tag label and the abbreviation of the sentence element, e.g. 'O-SUB' consists of the label O and the abbreviation SUB which means the word has no word pairs and with the Subject role.

TABLE I. SENTENCE ELEMENTS

No.	Sentence element		Abbreviation
1.	Subject	Subject	SUB
2.	Predicate	Predicate	PRE
3.	Object	Object	OBJ
4.	Complement	Complement	PEL
5.	Adverbs	Adverbs of time	KWK
6.		Adverbs of place	KTM
7.		Adverbs of purpose	KGU
8.		Adverbs of situation	KKD
9.		Adverbs of manner	KCR
10.		Adverbs of tools	KAL
11.		Adverbs of identity	KID
12.		Adverbs of participant	KPE
13.		Adverbs of condition	KSY

For sentence elements with more than one word, the first word will be labeled B ('beginning') and the remaining words will be labeled I ('inside' in BIO tags), e.g. 'B-SUB', 'I-SUB', 'I-SUB' which means there are three words that have the role of Subject and as one unit or one token. Such tokens are referred to as multi-word tokens. These tokens are then used in the NLP process.

#### IV. RESULT AND DISCUSSION

The experimental results of the proposed tokenization framework are quite good. In this section, the output will be discussed and sentence similarity tests will be conducted based on single word tokens and multi-word tokens.

##### A. The Output

As mentioned earlier, the outputs of this tokenization framework are sentence structures and sentence elements. Each sentence element can consist of a single word called a single-word token or multiple words called a multi-word token. One word means one token, multiple words also means one token. The number of sentence elements indicates the minimum number of tokens. Table II shows an example.

The first sentence consists of two words, the prediction results show that the first word is the Subject (O-SUB) and the second word is the Predicate (O-PRE). Both are independent because they are labeled O. Then each word is a single word token.

The second sentence consists of seven words. The first word 'Tim' is labeled 'B-SUB' and the second word 'Argentina' is labeled 'I-SUB' which indicates that both are in the same group which is Subject (SUB). So both should remain as one with the meaning of a group of soccer players from Argentina. Separating the two words will lose the original meaning. That is, the Subject is a combination of the words 'Tim' and 'Argentina' to become 'Tim Argentina'. This is a multi-word token.

Likewise, the fourth to seventh words are adverb groups (KTM), so these four words are a single unit. In this second sentence, there is also a word labeled 'O-PRE', namely 'win'. This means that the word 'win' has the role of a Predicate that stands alone, and is a single word token.

Therefore, it can be seen that the second sentence only has three tokens for Subject, Predicate, and Adverb. More details in Table III.

In the third sentence, there are three groups of sentence elements consisting of more than one word, namely words labeled Predicate (PRE), Object (OBJ), and Complement (PEL). Only the subject (SUB) stands alone because it is labeled O. The complete information can be seen in Table IV.

In Table IV, it is clear that the Subject is a one-word token 'Prajurit', the Predicate is a multi-word token 'mulai memasuki', on the Object there are two words 'area pertempuran' as multi-word tokens and the Complement consists of three words 'dengan senjata lengkap' as multi-word tokens.

##### B. Sentence Elements as Token

As explained earlier, a sentence element can be a token. A sentence extraction result that produces three sentence elements means it has three tokens. A sentence will have at least two tokens. Tokens can be single-word tokens or multi-word tokens.

TABLE II. INPUT AND PREDICTION OF SENTENCE ELEMENTS

No	Lang	Input Sentence	Output Prediction	
			Tokens	Sentence Elements
1.	INA	Amir mandi	['Amir', 'mandi']	['O-SUB', 'O-PRE']
	EN	Amir takes a bath		
2.	INA	Tim Argentina menang di Piala Dunia 2022	['Tim', 'Argentina', 'menang', 'di', 'Piala', 'Dunia', '2022']	['B-SUB', 'I-SUB', 'O-PRE', 'B-KTM', 'I-KTM', 'I-KTM']
	EN	The Argentina team won in the 2022 World Cup		
3.	INA	Prajurit mulai memasuki area pertempuran dengan senjata lengkap.	['Prajurit', 'mulai', 'memasuki', 'area', 'pertempuran', 'dengan', 'senjata', 'lengkap']	['O-SUB', 'B-PRE', 'I-PRE', 'B-OBJ', 'I-OBJ', 'B-PEL', 'I-PEL', 'I-PEL']
	EN	Soldiers began to enter the battle area with full weapons.		

TABLE III. SENTENCE STRUCTURE FOR EXAMPLE NO. 2

Source	Tim Argentina menang di Piala Dunia 2022						
Initial Token	Tim	Argentina	menang	di	Piala	Dunia	2022
Output Labels	B-SUB	I-SUB	O-PRE	B-KTM	I-KTM	I-KTM	I-KTM
Sentence Elements	Subject		Predicate	Adverb of Place			
Proposed Token	'Tim Argentina'		'menang'	'di Piala Dunia 2022'			
	Multi-word		Single word	Multi-word			

TABLE IV. SENTENCE STRUCTURE FOR EXAMPLE NO. 3

Source	Prajurit mulai memasuki area pertempuran dengan senjata lengkap.							
Initial Token	Prajurit	mula i	memasu ki	area	pertempura n	denga n	senjat a	lengka p
Output Labels	O-SUB	B-PRE	I-PRE	B-OBJ	I-OBJ	B-PEL	I-PEL	I-PEL
Sentence Element	Subject	Predicate		Object		Complement		
Proposed Token	'Prajurit'	'mulai memasuki'		'area pertempuran'		'dengan senjata lengkap'		
	Single word	Multi-word		Multi-word		Multi-word		

However, not all multi-word tokens derived from sentence elements can be assigned as end tokens. The contents of multi-word tokens can be words that do not provide important information.

In the second sentence above, there is the word 'di' in the adverb of place with a multi-word token. The multi-word token

in the third sentence contains the word 'mulai' in the Predicate and the word 'dengan' in the Complement. These words can be ignored and have no effect on the token. Such words are known as stopwords.

From the example sentences above, stopwords can appear in Predicate, Complement, or Adverb. There are almost no stopwords in Subject and Object. Therefore, multi-word tokens in Predicate, Complement, and Adverb need to be filtered first. These unnecessary words will be removed before providing tokens. Filtering is done by comparing the contents of the multi-word tokens of the three sentence elements with a database containing words that fall into the category of stopwords.

### C. Evaluation

The outputs of this framework are single word tokens and multi-word tokens. To get an overview of the two types of tokens, the following is an evaluation of both in determining sentence similarity.

The evaluation is done using the token lexical similarity method. Overlap Coefficient, Jaccards Index, Jaccards Distance, Dice Coefficient and Cosine Similarity methods will be used for single word tokens, while Dice-Index Coefficient for multi-word tokens.

Some of the stages of evaluation are as follows:

1) Defines a set of single-word tokens and multiple-word tokens in sentences.

2) Perform statistical calculations:

a) For single word token.

- Counts the number of tokens in the sentence, which is mathematically symbolized as  $|K_1|$ .
- Counts the number of tokens that appear in both sentences, symbolized as  $|K_1 \cap K_2|$ .
- Counts the number of tokens derived from the two sentences, and is symbolized as  $|K_1 \cup K_2|$ .

b) For multi-word tokens:

- Counts the core (head) token on each token, symbolized as  $|h_1|$  and  $|h_2|$ . Head is a word whose meaning is included in the meaning of another word.
- Perform token combinations according to the token order.
- Counts the number of core tokens (head) present in both multi-word tokens, symbolized as  $|h_1 \cap h_2|$ .
- Sum the core (head) tokens, symbolized by  $|h_1| + |h_2|$ .
- Counts the number of tokens present in both multi-word tokens and is symbolized as  $|M_1 \cap M_2|$ .
- Counts the number of tokens from both multi-word tokens, symbolized as  $|M_1| + |M_2|$ .

c) Measuring sentence similarity

Measuring the similarity between sentence1 and sentence2 basically determines how many similarity tokens there are in each sentence divided by the normalization factor.

The sentence similarity measurement function used is as follows:

- Overlap Coefficient: is the size of the overlap of the sets  $K_1$  and the sets  $K_2$  divided by the smallest size between  $K_1$  and  $K_2$ .

$$OC(K_1, K_2) = \frac{|K_1 \cap K_2|}{\min(|K_1|, |K_2|)} \quad (1)$$

- Jaccard Index: is the Intersection over Union size of the sets  $K_1$  and  $K_2$ .

$$JI(K_1, K_2) = \frac{|K_1 \cap K_2|}{|K_1 \cup K_2|} = \frac{|K_1 \cap K_2|}{|K_1| + |K_2| - |K_1 \cap K_2|} \quad (2)$$

- Jaccard Distance: Measures the degree of difference of the two sets, or by subtracting 100% with the Jaccard Index.

$$JD(K_1, K_2) = 1 - JI(K_1, K_2) = \frac{|K_1 \cup K_2| - |K_1 \cap K_2|}{|K_1 \cup K_2|} \quad (3)$$

- Dice Coefficient: measures two times the number of tokens shared in both sentences divided by the total number of tokens in both sentences.

$$DC(K_1, K_2) = \frac{2|K_1 \cap K_2|}{|K_1| + |K_2|} \quad (4)$$

- Cosine Similarity, with the formula:

$$CS(K_1, K_2) = \frac{|K_1 \cap K_2|}{\sqrt{|K_1| \cdot |K_2|}} \quad (5)$$

The following three sentences are used as test data.

1)  $K_1$  = “walikota solo memberikan apresiasi kepada Agnes.” (The mayor of solo city gave his appreciation to Agnes.)

2)  $K_2$  = “agnes monica adalah penyanyi solo wanita berbakat.” (agnes monica is a talented female solo singer.)

3)  $K_3$  = “pemerintah kota solo mendapat hibah dari pangeran arab saudi.” (she solo city government received a grant from the prince of saudi arabia.)

By using the formula described above, the calculation results are as follows in Table V. From the table, it can be concluded that the first sentence is more similar to the second sentence.

Meanwhile, the proposed tokenization process generates tokens according to the sentence structure as follows:

For  $K_1$ , S=“walikota solo”, P=“memberikan”, O=“apresiasi”, C=“kepada agnes”.

For  $K_2$ , S=“agnes monica”, P=“adalah”, O=“penyanyi solo wanita”, A=“berbakat”.

TABLE V. SENTENCE SIMILARITY FOR SINGLE WORD TOKEN

	$K_1$	$K_2$	$K_3$	$K_1, K_2$	$K_1, K_3$	$K_2, K_3$
$ K_n $	6	7	9			
$ K_x \cap K_y $				2	1	1
$ K_x \cup K_y $				11	14	15

Overlap Coefficient	0.3333	0.1667	0.1429
Jaccard Index	0.1818	0.0769	0.0714
Jaccard Distance	0.8182	0.9231	0.9286
Dice Coefficient	0.3077	0.1429	0.1333
Cosine Similarity	0.3086	0.1443	0.1336

For  $K_3$ ,  $S$ ="pemerintah kota solo",  $P$ ="mendapat",  $O$ ="hibah",  $A$ ="dari pangeran arab saudi".

Multi-word token similarity measurement uses the concept of lexical similarity based on identifying the common sequence of each token. It is based on the hypothesis that the head is a hyponym of the same term, which is denoted as  $h_n$ . The visualization of the hyponyms of the multi-word tokens in the above three sentences is shown in the Fig. 7 below.

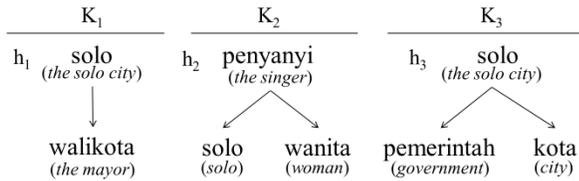

Fig. 7. Hyponyms referring heads.

The word sequence of the multiword token  $P(t)$  references the set of all sequences in  $t$ . The lexical similarity between multi-word tokens  $t_1$  and  $t_2$  is measured based on the Dice-like coefficient formula as follows:

$$KMK(M_1, M_2) = \frac{|P(h_1) \cap P(h_2)|}{|P(h_1)| + |P(h_2)|} = \frac{|P(t_1) \cap P(t_2)|}{|P(t_1)| + |P(t_2)|} \quad (6)$$

The numerator in the formula indicates the set of shared constituents (constituents present in both tokens), while the denominator refers to the total number of constituents.

The multi-word token obtained from sentence structure extraction are shown in Table VI.

TABLE VI. MULTI-WORD TOKEN

Stc	Multi-word Token	Core Token (head)		Constituent order	
		$P(h)$	$ P(h) $	$P(t)$	$ P(t) $
$K_1$	'walikota solo'	'solo'	1	{walikota, solo, walikota solo}	3
$K_2$	'agnes monica'	-	-	-	-
	'penyanyi solo wanita'	'penyanyi'	1	{penyanyi, solo, wanita, penyanyi solo, solo wanita, penyanyi solo wanita}	6
$K_3$	'pemerintah kota solo'	'solo'	1	{pemerintah, kota, solo, pemerintah kota, kota solo, pemerintah kota solo}	6

TABLE VII. SENTENCE SIMILARITY LEVEL FOR MULTIWORD TOKEN

Formula	Description	$K_1, K_2$	$K_1, K_3$	$K_2, K_3$
$ P(h_x) \cap P(h_y) $	The sum of the same terms in both heads	0	1	0
$ P(h_x)  +  P(h_y) $	The total number of terms on each head	2	2	2

$ P(t_x) \cap P(t_y) $	The sum of the same terms in both constituents	1	1	1
$ P(t_x)  +  P(t_y) $	The total number of terms on each constituents	9	9	12
Similarity		0.11	0.61	0.08

By using the Dice-like coefficient formula, the level of similarity of multiword tokens is obtained as shown in Table VII.

From the table above, the multi-word tokens in the first sentence are similar to the third sentence compared to the second sentence, and the multi-word tokens in the second sentence are very different from the third sentence.

From the similarity measurement of the two sentences above, there is a difference in results between single word tokens and multi-word tokens. The measurement with single word tokens concludes that the first sentence and the second sentence are more similar than the other sentences.

While the measurement with multi-word tokens states that the first sentence and the third sentence are more similar than the first and second sentences. Both have the same measurement result, that the second and third sentences are least similar.

In human judgment, the first and third sentences are similar, just like the measurement results of multi-word tokens. This shows that multi-word tokens also have advantages and can help NLP work.

#### D. Performace

To evaluate the quality of the proposed method, we conducted a manual evaluation of 100 sentences. The evaluation was done by checking the supposed multi-word tokens and then compared with the multi-word tokens extracted by the proposed method, with the results as shown in the Table VIII.

From the table, we can calculate Precision and Recall using the following formula:

$$P = \frac{\text{Correctly extracted multi-word tokens}}{\text{Total extracted multi-word tokens}} \quad (7)$$

$$R = \frac{\text{Correctly extracted multi-word tokens}}{\text{Multi-word tokens should be}} \quad (8)$$

TABLE VIII. EXTRACTED MULTI-WORD TOKEN

Number of sentences	Number of tokens	Correctly extracted sentence structure	Extracted		
			Correctly extracted multi-word tokens	Total extracted multi-word tokens	Multi-word tokens should be
100	709	84	204	221	237

And the results are  $P = 0.92$  and  $R = 0.86$ . The success of extracting multi-word tokens correctly is quite dominant, out of 221 multi-word tokens extracted, 204 of them are correct. While the R value has a value of 0.86 which is obtained from 204 correct multi-word tokens out of 237 multi-word tokens that can be generated. These results provide information that

the proposed method is able to extract sentence structure and at the same time produce multi-word tokens that are quite accurate.

We also conducted a comparison with three other studies on multi-word tokens or similar from [21], [27] and [29]. Methods used by [21] are hybrid to train a multi-word expression detector for multiple languages without any manually encoded features. The methods used by [27] is a rule-based. The methods used by [29] are statistical, linguistic and logic-based methods and hybrid techniques, for the automatic extraction of multi-word terms from unannotated computer science domain English documents.

A comparison between these four methods is shown in Table IX.

TABLE IX. METHOD COMPARISON

Liang et al. [21]	Putranto et al. [27]	Thanawala et al. [29]	Propose Method
a hybrid approach, which combines Bi-directional LSTM (Bi-LSTM), phrase head word expansion and cluster to identify three types of multi-word expression	a rule that contains combinations of word classes that are most likely to form phrases.	Using shallow parsing and syntactic structure analysis and using a rule-based linguistic approach pattern.	Sentence structure extraction
compound nouns, verb construction and idiom.	Verbal, Nominal, Adverbial, Pronominal, Adjectival phrase rule.	Lexical patterns such as (N P N), (N P N + N), (N P N P N).	Dataset model
Sequence features, word correlation degree and three types of multi-word expression	The classification model obtained is more optimal.	Output in various forms of noun phrases	Output in form of sentence element
Precision = 0.92	0.79	0.87	0.92
Recall = 0.92	0.84	1.00	0.86

Each method has advantages and disadvantages. However, by preparing and training the sentence structure dataset, the proposed method is excellent in predicting the sentence structure elements. Each element is a token, either a single token or a multi-word token. Thus, this method does not rely on manually constructed lexical patterns. The method is highly adaptable and evolves as new data becomes available.

## V. CONCLUSION

A tokenization process that generates single-word tokens and multi-word tokens simultaneously is possible. This is proposed through this research. To our knowledge, we are the first to propose this tokenization method based on sentence structure, which is expected to inspire new research with new ideas. Providing a complete dataset is a very important factor for successful sentence structure prediction. The predicted sentence element (SPOK) can consist of one or more words, i.e. tokens. Multi-word tokens are more accurate than single-word tokens in terms of sentence similarity.

Multi-word tokens are worthy of further research. In the future, we will enhance the dataset with passive sentences and

also apply this approach for use in other types of cases such as NER.

India<sup>2</sup>

**Abstract**—Since farming is becoming increasingly more expensive, efficient farming entails doing so without suffering any losses, which is what the current situation desires. Weeds are a key issue in agriculture since they contribute significantly to agricultural losses. To control the weed, pesticides are now evenly applied across the entire area. This approach not only costs a lot of money but also harms the environment and people's health. Therefore, spot spray requires an automatic system. When a deep learning embedded system is used to operate a drone, herbicides can be sprayed in the desired location. With the continuous advancement of object identification technology, the YOLO family of algorithms with extremely high precision and speed has been applied in a variety of scene detection applications. We propose a YOLOv7-based object detection approach for creating a weed detection system. Finally, we used the YOLOv7 model with different parameters for training and testing analyzed on the early crop weed dataset and 4weed dataset. Experimental results revealed that the YOLOv7 model achieved the mAP@0.50, f1score, Precision, and Recall values for the bounding boxes as 99.6, 97.6, 99.8, and 95.5 respectively on the early crop weed dataset and 78.53, 79.83, 86.34, and 74.24 on 4weed dataset. The Agriculture business can benefit from using the suggested YOLOv7 model with high accuracy in terms of productivity, efficiency, and time.

**Keywords**—Weed detection; YOLOv7; early crop weed; deep learning

## I. INTRODUCTION

As of right now, losses from pests, diseases, and weeds can account for up to 40% of annual crop yields worldwide. In the years to come, this proportion is anticipated to rise sharply. Currently, the principal method of weeding in fields is to spray herbicides across a huge region. Leaving pesticide residues in the soil, this practice not only wastes resources but also pollutes the environment. As a consequence, precision spraying [1][2] effectively controls the growth of weeds in a field while using less pesticide, improving utilization, and avoiding chemical residue.

Quick and accurate weed detection in crop fields is crucial because it may serve as a foundation for the development of precision spraying systems. Many researches have been done so far on image-based techniques for the automated identification and categorization of weeds. For the purpose of enhancing weed detection accuracy in rice fields, [3] retrieved 101-dimensional characteristics from a picture of a weed, including color, shape, and texture. They achieved a recognition rate of 91.13 percent using deep belief networks

with fusion features. Two different classification techniques are presented by [4] to identify weed density in photos. Based on the grey level co-occurrence matrix (GLCM), the first approach used a Support Vector Machine (SVM) to get an accuracy of 73 percent, while the second method combined a Random Forest classifier with invariant scale and rotation moment features to achieve an accuracy of 86 percent. These methods have the drawback of not being effective against sedges and wide-leaf weeds. The artificial neural network (ANN) employed by [5] to identify various types of weeds was optimized using the bee algorithm (BA), and the ANN-BA attained an accuracy of 88.74 percent for the right channel and 87.96 percent for the left channel. The techniques utilized in the aforementioned research were aimed at enhancing recognition in conventional machine vision. Due to the minimal hardware requirements for operation, they are well-suited for practical deployment. However, the majority of these techniques only tested the effectiveness on low-density samples. The difficulties of opacity, clumping, light change and other natural environment characteristics are challenging to overcome.

Deep learning has been used to address weed detection issues in agriculture. Researchers have had success using various deep learning models for this task. In [6], employed the small YOLO-v3 for real-time application in a field of strawberry and tomato plants and succeeded in detecting goose grass with an accuracy of 82 percent. With the use of pre-trained Faster R-CNN, [7] achieved 65 percent accuracy, 68 recall, 66 F1 score, and 0.21 s inference time in recognizing late-season weed in soybean fields. The author [8] used Inception-ResNet-v2 as the basis and achieved F1 scores of 72.7 percent (at IoUall) and 96.9 percent for identifying agricultural plants and weeds (at IoU0.5). The study [9] used the Mask R-CNN to accurately extract weed from the "cranesbill seedling dataset." In [10] the author categorized the weed *Rumex obtusifolius* with a VGG-16 classification accuracy of 92.1%. The research [11] discovered that VGG-19, which had been tweaked to generate binary output, had the greatest classification accuracy of 98.7 percent for detecting volunteer potatoes in sugar beet in a comparison of Inception-v3 with AlexNet, VGG-19, GoogLeNet, ResNet-50, and ResNet-101.

Convolutional neural networks have been used by some researchers in recent years to try to detect weeds in rice fields. Fully convolutional networks were utilized by [12] to classify pixels in high resolution unmanned aerial vehicle (UAV)

imagery taken from a rice field (FCN). Their method had an accuracy rate of 91.96 percent and an average mean intersection over union (mean) of 84.73 percent. Using a semantic segmentation model called SegNet, IoU. In [13], detected the pixels in the image that corresponded to rice seedlings, weeds, and the backdrop. They can address the category imbalance by finding the class weight coefficients. Their approach has a greater accuracy of 92.7 percent when compared to FCN and U-Net.

However, the bulk of important research has only been able to recognize the leaves of certain plants, rather than actual photographs with intricate backgrounds in real settings. The techniques have poor stability and accuracy when applied to identify weeds in rice fields [15].

Large-scale weed picture collections must be carefully curated to create high-performing weed identification algorithms. Images of weed may be captured on a variety of platforms [16], incorporating field robots [18], portable camera sensors, and unmanned aerial vehicles (UAV) [17]. DeepWeeds [19], Early crop weed dataset [21], Open Plant Phenotype Database [22], and Dataset of food crops and weeds [23] are only a few examples from a recent assessment of 19 publicly accessible datasets for weed identification and plant recognition, published in [20]. These datasets are all made up of RGB (red-green-blue) photos. Currently, a large number of researches have demonstrated the effectiveness of deep learning object detectors in weed identification. These studies include those using the YOLO series, Faster R-CNN, Mask R-CNN, RetinaNet, and EfficientDet.

The YOLOv7 approach had been used in this study to address this issue and significantly enhance the performance for weed detection in the early weed dataset [21] and to assess the performance of a newly formed 4weed dataset [14] that has had no machine learning models applied to it up to this point. Finally, studies show that the YOLOv7 proposed in this study may successfully handle the problems related to weed identification in crops, achieving high accuracy and outstanding efficiency.

## II. METHODOLOGY

To build a framework for weed identification, we must finish data collection, model training, and multi-class plant species classification. Two main datasets were used in this study: The Early Crop Weeds dataset and the 4weed dataset. The dataset contains photos with varied resolutions that were translated into the same dimensions using the deep learning model input layer. After creating a suitable dataset, the gathered data is separated into 90% training and 10% testing sets. YOLOv7 is then trained for agricultural weed detection utilizing those data. The performance of the trained model is evaluated using multiple parameters. Fig. 1 depicts the proposed approach used for weed identification.

### A. Dataset

The early crop weed detection dataset contains 308 images that are taken from the early crop weed classification dataset [21] and the objects of interest are annotated with bounding boxes. This dataset contains 308 RGB images of four species at early growth stages. It includes images of 25 cotton, 67 velvet,

121 tomato, and 95 nightshade. Fig. 2 shows sample instances of the early crop weed detection dataset images.

The 4Weed [14] collection includes 618 RGB photos in total, which were collected at Purdue University under challenging field circumstances. The collection includes photos of four weed species that are often seen in corn and soybean production systems: Giant Ragweed, Foxtail, Cocklebur, and Redroot Pigweed Fig. 3.

The final dataset included 150 Giant Ragweed photos, 170 Redroot Pigweed images, 35 Cocklebur images, and 73 Foxtail images. You may get the dataset at <https://osf.io/w9v3j/>.

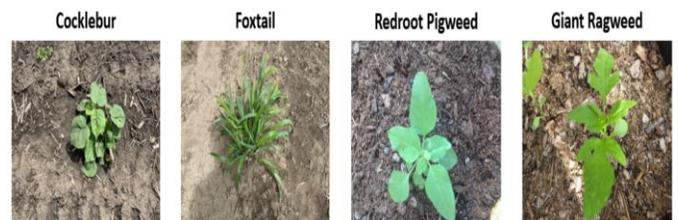

Fig. 3. Sample images of the 4weed dataset.

B. You Only Look Only Once (YOLOv7)

In this research, a computer vision-based recognition and detection technique is provided for object detection. The most recent Yolov7 model was used. Yolov7 is a single-stage object detection technique. You Only Look Once Yolov7's network structure diagram is depicted in Fig. 4 [25]. Overall, the YOLO-V7 technique resizes the input picture to 640x640 before feeding it into the backbone network, producing three layers of feature maps of varying sizes via the head network, and then outputting the prediction result using RepConv [24]. RepConv is utilized to build a planned reparametrized convolution architecture with increased gradient variation for various feature maps [24]. The soft labels generated by the

optimization process are used by the lead head and auxiliary head learning processes, together with the introduction of the auxiliary detecting head. In order to acquire more accurate findings, the soft labels that were produced from it ought to more faithfully represent the distribution and relationship between the source data and the object [26]. Silu activation function, ELAN structures, and MP structures make up the YOLOv7 backbone, by managing gradient pathways and deeper networks, the ELAN structure can effectively learn and converge. Fig. 4 depicts the ELAN and E-ELAN network structures. Down sampling is performed using the MP structure as shown in Fig. 4.

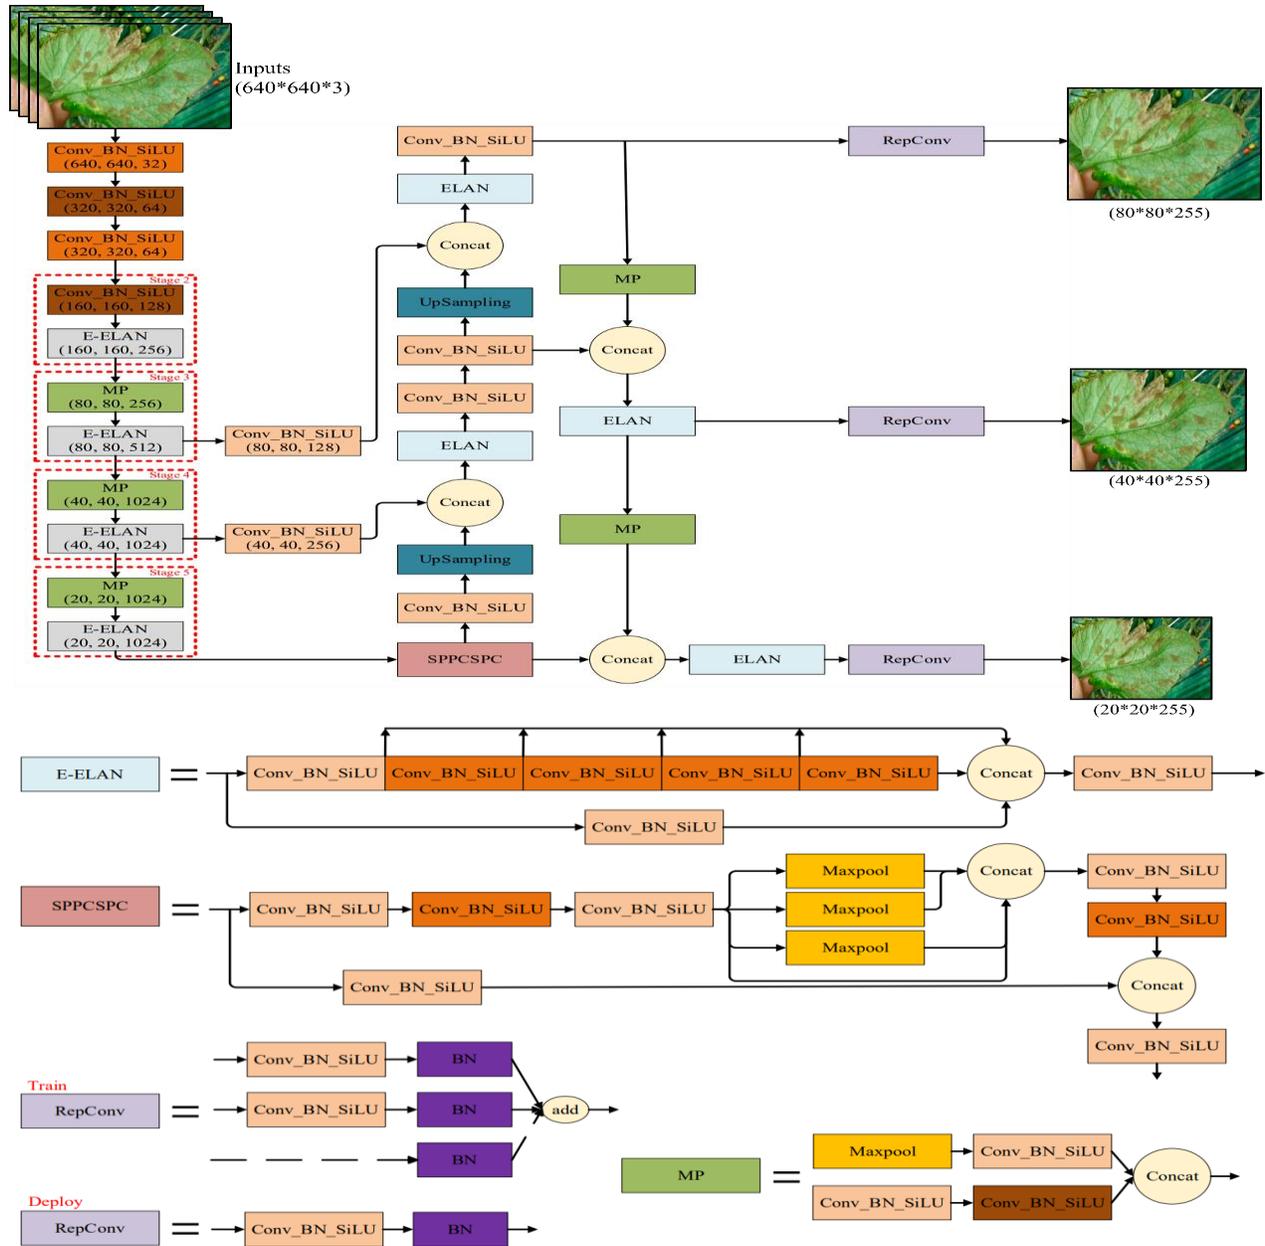

Fig. 4. YOLOv7 architecture.

### III. RESULTS AND DISCUSSION

#### A. Performance Metrics

The most often used metric to evaluate object identification systems are mean average precision (mAP). Comparing the detected box to the corresponding ground truth box allows the mAP to determine its score. The connection between the predicted bounding box coordinates and the actual bounding box is characterized by intersection over union. The projected bounding box coordinates and the truth values should match more closely, according to higher IoU values.

$$IoU = \frac{\text{area of overlap}}{\text{area of union}} \quad (1)$$

The proportion of true positives to all correctly predicted outcomes is referred to as precision. Precision evaluates how accurately a model category a sample as positive.

$$\text{Precision} = \frac{\text{True positives}}{\text{True positives} + \text{False positives}} \quad (2)$$

The proportion of true positives to all the predictions is known as recall. Recall gauges the accuracy with which a model can find positive samples. The most positive samples are discovered when recall is higher.

$$\text{Recall} = \frac{\text{True positives}}{\text{True positive} + \text{False Negatives}} \quad (3)$$

The average area of the precision-recall curve below a given IoU threshold is known as the average precision at IoU ( $AP^{IoU}$ ).  $AP^{IoU}$  is a performance indicator for a certain class or category. To indicate the overall detecting performance, mean average precision at a threshold IoU ( $mAP^{IoU}$ ) is calculated and denoted as follows: =

$$mAP^{IoU} = \frac{1}{N} \sum AP_n^{IoU} \quad (4)$$

$$n \in \{class1, class2, \dots, classN\}$$

One of the often-employed measures for assessing the effectiveness of machine learning algorithms is the F1 score. F1 scores are calculated using the harmonic mean of recall and accuracy. The F1 score value is an indicator of how well categorization systems can anticipate outcomes.

$$F1Score = 2 \times \frac{\text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \quad (5)$$

#### B. Performance Evaluation

The model was trained and tested using the cloud-based Google Colab environment, which has access to the NVIDIA Tesla T4 GPU. The YOLOv7 model's training process was started using pre-trained weights derived from the COCO dataset rather than starting from scratch.

We evaluate the effectiveness of the YOLOv7 model developed using the early crop weed dataset and 4Weed dataset. This model trained over 50 epochs. YOLOv7 provides superior mAP than prior trained models, as shown in Table I.

The YOLOv7 model was evaluated using random testing pictures, and the results are displayed in Fig. 5 and Fig. 6. The collected findings suggest that the model can successfully identify agricultural weeds.

TABLE I. COMPARISON OF WEED DETECTION MAP

Model	Dataset	mAP
RetinaNet R101 -FPN[27]	Three weed dataset(Cotton, Carpetweed, Morningglory weed, and Palmer Amaranth weed.)	79.98%
YOLOv5n[27]	Three weed dataset(Cotton, Carpetweed, Morningglory weed, and Palmer Amaranth weed.)	76.58%
Proposed-YOLOv7	Early weed dataset (cotton, velvet weed, tomato, and nightshade weed)	99.6%
Proposed-YOLOv7	4Weed dataset (Giant Ragweed, Foxtail, Cocklebur, and Redroot Pigweed)	78.53%

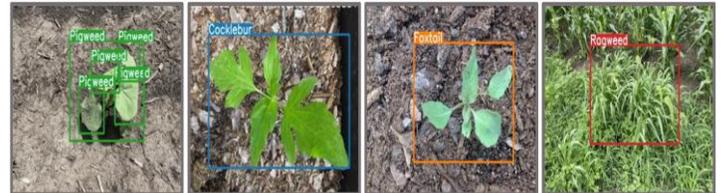

Fig. 5. Early crop weed detection results of YOLOv7.

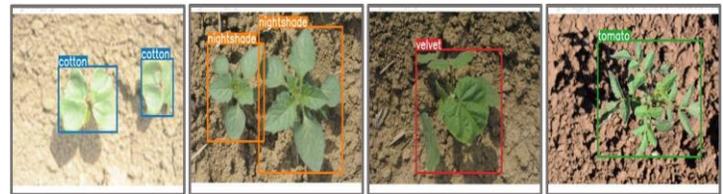

Fig. 6. 4Weed detection results of YOLOv7.

Three different types of losses were produced throughout the YOLOv7 training and validation process: bounding box loss, objectiveness loss, Classification loss, precision, recall,  $mAP@0.5$ , and  $mAP@0.5:0.95$ . Fig. 7 and Fig. 8 show that throughout training, every loss value displayed a decreasing trend, and the model did not exhibit any overfitting. While the validation loss converged near the conclusion of the training, the training loss did so early on. The minimal value in the training and validation loss curves was attained after 50 training epochs with batch size 16.

The Normalized confusion matrix evaluated on test images using YOLOv7 Trained model is plotted as shown in Fig. 9 and Fig. 10.

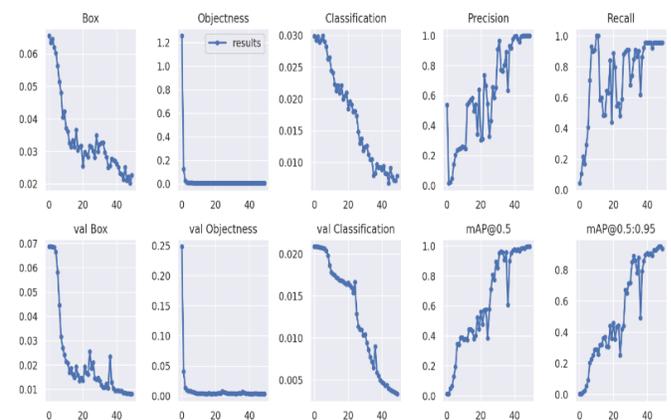

Fig. 7. Performance measures of YOLOv7 on early crop weed dataset.

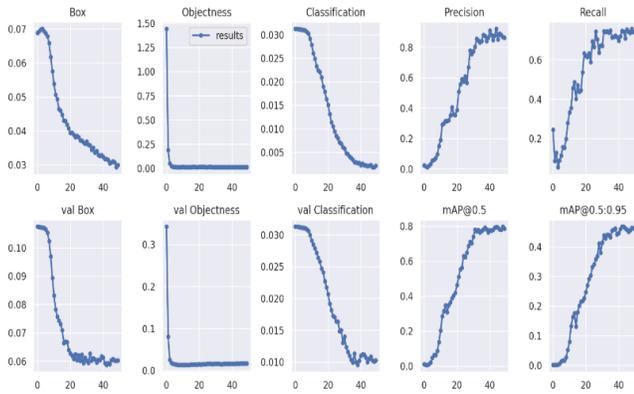

Fig. 8. Performance measures of YOLOv7 on the 4weed dataset.

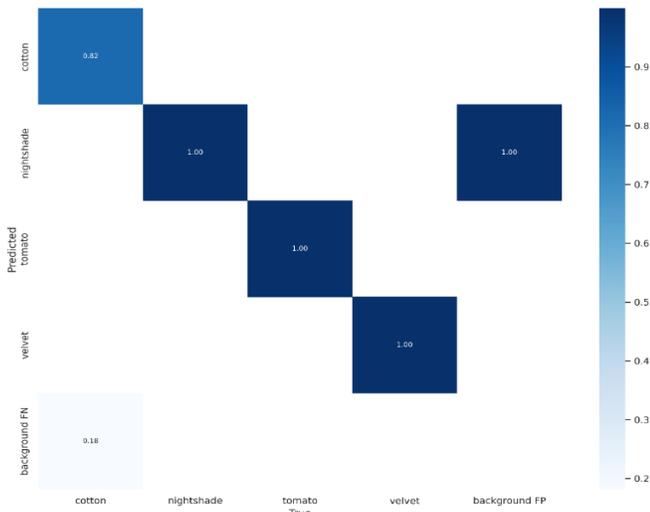

Fig. 9. Confusion matrix of YOLOv7 on early crop weed dataset.

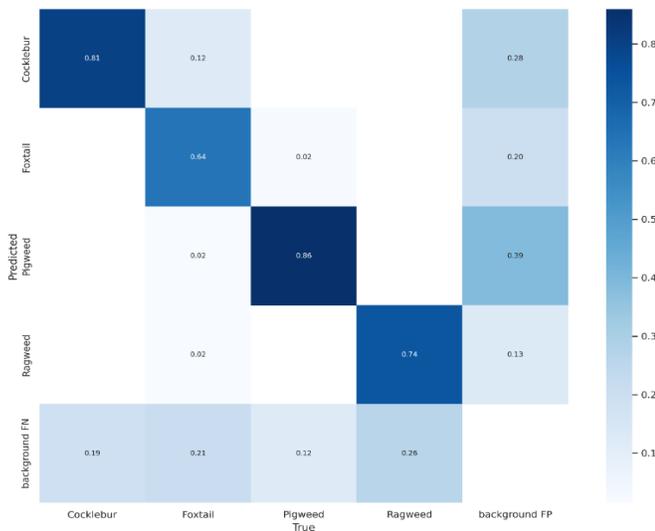

Fig. 10. Confusion matrix of YOLOv7 on 4weed dataset.

The performance of the YOLOv7 model on Early Crop Weed dataset is evaluated using performance metrics mAP, F1score, Precision, Recall, and Precision-Recall. The mAP,

F1score, Precision, and Recall of YOLOv7 on early crop weed dataset after training for 50 epochs are 99.6, 97.6, 99.8, and 95.5. The graphs of these metrics as shown below in Fig. 11 to 14.

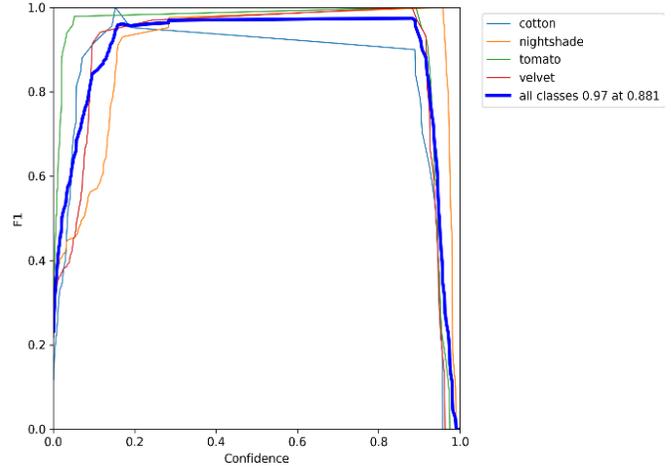

Fig. 11. F1 score of early crop weed dataset.

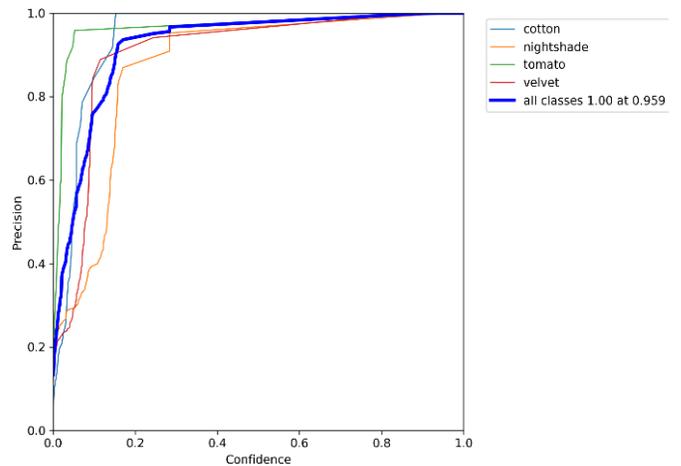

Fig. 12. Precision of early crop weed dataset.

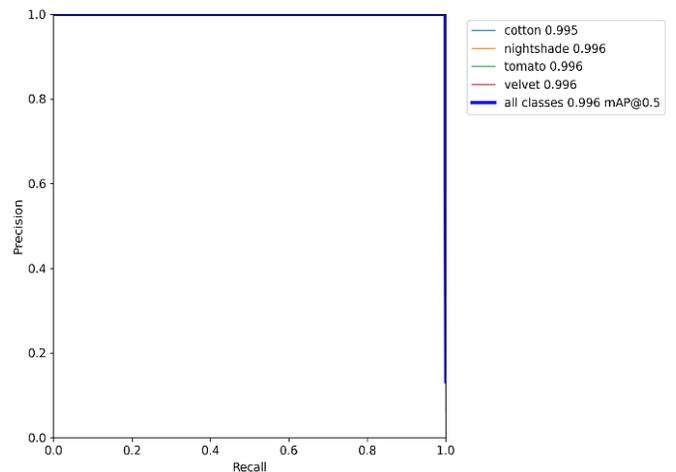

Fig. 13. Recall of early crop weed dataset.

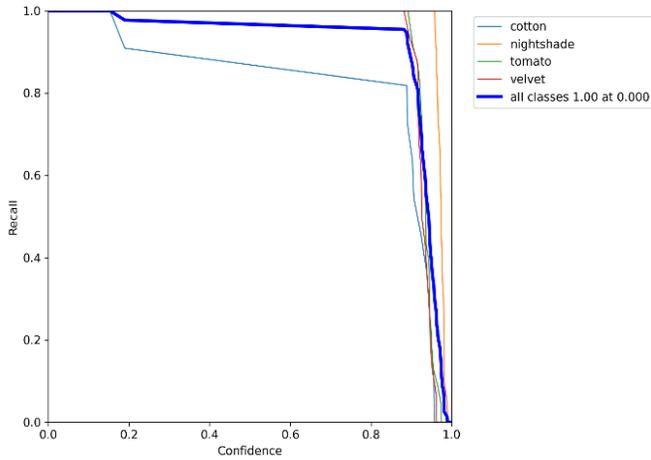

Fig. 14. Precision-recall graph of early crop weed dataset.

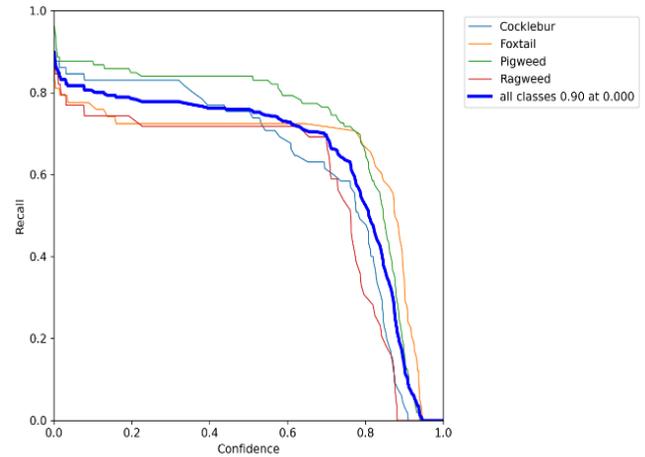

Fig. 17. Recall of 4weed dataset.

The performance of the YOLOv7 model on 4Weed dataset is evaluated using performance metrics mAP, F1score, Precision, Recall, and Precision-Recall. The mAP, F1score, Precision, and Recall of YOLOv7 on the 4weed dataset after training for 50 epochs are 78.53, 79.83, 86.34, 74.24. The graphs of these metrics as shown below in Fig. 15 to 18.

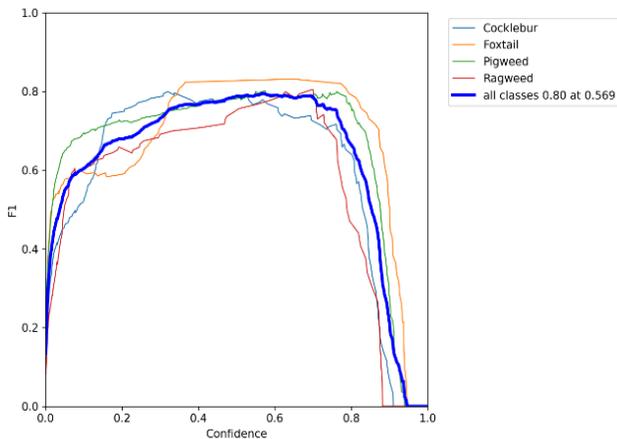

Fig. 15. F1 score of 4weed dataset.

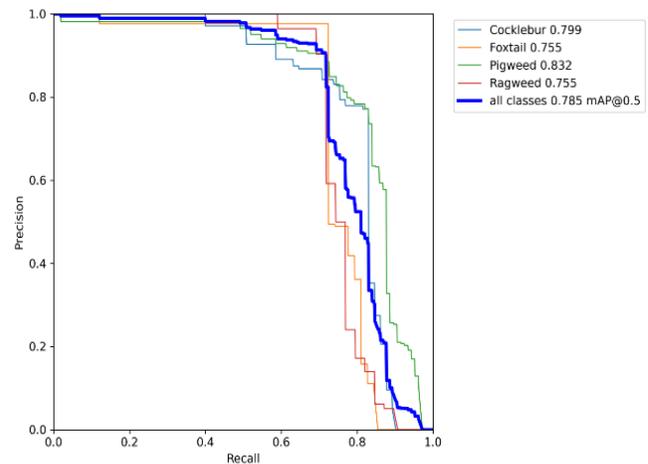

Fig. 18. Precision-recall graph of of 4weed dataset.

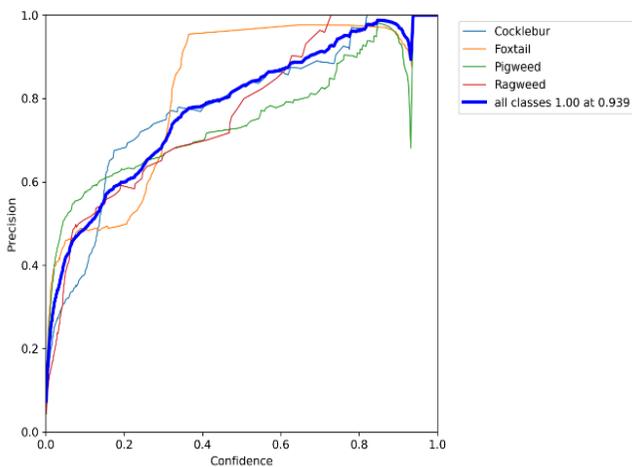

Fig. 16. Precision of 4weed dataset.

The YOLOv7 model have inherent limitations that affect its accuracy for plant weed detection, such as difficulty in detecting small or occluded weeds, or misclassifying non-weed objects as weeds. This study used a limited dataset for training and testing the YOLOv7 model, which could affect the accuracy and generalizability of the results.

#### IV. CONCLUSION

Weeds increase agricultural cultivation costs and lower crop yields. Machine vision plays a significant part in precision agriculture by helping to locate weeds on agricultural land. For the purpose of weed detection using machine vision in this work, we use the early crop weed dataset and the 4weed dataset. On the datasets, the one-stage object detector YOLOv7, which is based on deep learning, was tested for weed detection. The mAP@0.5 detection accuracy for the early crop weed dataset is 99.6 while the mAP@0.5 detection accuracy for the 4weed dataset is 78.53. Because of its quicker inference speed, YOLOv7 has strong promise for real-time applications. By enhancing model training and data augmentation methods, increasing the dataset, and improving the model, further research is still required to increase the accuracy of weed detection. Additionally, field experiments

and demonstrations using trained models deployed on a machine vision system with onboard computer hardware in real-world field settings are required for further model assessment and updating.

**Abstract**—In this paper, a novel adaptive threshold Sobel edge detection algorithm based on the improved genetic algorithm is proposed to detect edges. Because of the influence of external factors in actual detection process, the result of detection is often not accurate enough when the configured threshold of the target image is far away from the real threshold. Different thresholds of images are calculated by improved genetic algorithm for different images. The calculated threshold is used in edge detection. The experimental results show that the image processed by the improved algorithm has stronger edge continuity. It is shown that proposed algorithm has a better detection effect and applicability than the traditional Sobel algorithm.

**Keywords**—Genetic algorithm; Sobel operator; edge detection; adaptive threshold

## I. INTRODUCTION

As one of the most important parts of image processing, edge detection is of great significance to image high-order feature extraction, target recognition, image segmentation and many other fields. The image edge refers to the area where the grey value of adjacent pixels changes dramatically [1]. Various edge detection methods have been proposed. According to different detection principles, it can be divided into first-order differential operator, second-order differential operator and modern edge detection algorithm. The first-order differential operators include Sobel operator, Robert's operator, Prewitt operator, etc. The second-order differential operators include Laplace operator, Canny operator, LOG operator, etc. Modern edge detection algorithms include wavelet transform, neural network algorithm, etc. [2-3].

For different edge detection algorithms, many optimization strategies have been proposed to obtain better detection effects. Image edge detection is greatly affected by noise. In the process of Sobel edge detection, the mean filtering method of median filtering is commonly used to remove noise. However, this method has a general effect of removing salt and pepper noise. To better remove noise, soft threshold wavelet denoising is applied to Sobel operator edge detection[4]. In order to meet the real-time requirements of PC ports, an eight-direction adaptive threshold Sobel operator edge detection algorithm is proposed, which's mapping is realized on FPGA [5]. The adaptive threshold edge detection algorithm based on fuzzy divergence uses adaptive threshold to detect the target image [6].

With the rise of artificial intelligence, the application of artificial intelligence algorithms in the field of image processing has become a hot topic. In aerospace, remote sensing, medical and other high-end industries, the accuracy of image processing is required to be high. In view of this situation, artificial intelligence algorithm has great advantages. In addition, deep learning algorithm and neural network algorithm are applied in edge detection [7-9]. In the processing of complex images, artificial intelligence algorithm has advantages. However, the artificial intelligence algorithm has the disadvantages of large amount of calculation, long time for edge detection and the need to train the algorithm in advance when detecting the edge of specific image. In practical applications, the edge detection algorithm is required to have the characteristics of fast response, low hardware requirements, wide range of detection targets and so on.

The research of traditional image edge detection is still widely concerned. For the limited edge extraction of Sobel operator in horizontal and vertical directions, the quantum of non-maximum suppression and double threshold technology are adopted to improve it [10]. For the noise problem in Sobel operator edge detection, median filter algorithm, mean filter algorithm, weighted kernel norm minimization image denoising algorithm and traditional Sobel algorithm are usually used to achieve better detection effect [11]. However, the Sobel edge detection algorithm still needs to manually set the threshold [12].

To solve this problem, an adaptive threshold edge detection algorithm based on improved genetic algorithm is proposed. According to different target images, different thresholds are calculated and used for edge detection to avoid the problem of low accuracy of edge detection caused by improper manual threshold setting.

## II. PRINCIPLE OF SOBEL EDGE DETECTION

As a common edge detection algorithm, Sobel operator combines Gaussian smoothing and differentiation to calculate the gradient value of image brightness function. The main method is to make the weighted difference between the gray values of the upper, lower, left and right fields of the target pixels, and then smooth the image. The greater the weight close to the target pixel, the greater the impact on the target during convolution [13-14]. The steps of the Sobel operator to determine the image edge are as follows:

Step 1: Horizontal operator  $Sobel_x$  and vertical operator  $Sobel_y$  are used to convolute the target image. The horizontal and vertical operators of Sobel algorithm are described as follows:

$$Sobel_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} Sobel_y = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix} \quad (1)$$

Step 2: The convolution value of Sobel operator in  $x$  and  $y$  directions is calculated by:

$$\begin{aligned} G_x(x, y) &= [F(x+1, y-1) + 2F(x+1, y) + F(x+1, y+1) \\ &\quad - F(x-1, y-1) - 2F(x-1, y) - F(x-1, y+1)] \\ G_y(x, y) &= [F(x-1, y+1) + 2F(x, y+1) + F(x+1, y+1) \\ &\quad - F(x-1, y-1) - 2F(x, y-1) - F(x+1, y-1)] \end{aligned} \quad (2)$$

where  $G_x$  and  $G_y$  are the convolution value in  $x$  and  $y$  direction, respectively.  $F(x+n, y-m)$  refers to the gray value of the point. Then the gradient vector is calculated by:

$$G = \sqrt{G_x^2 + G_y^2} \quad (3)$$

Step 3: By comparing with the preset threshold, it is determined that the point is an image edge when the value of the point is greater than the threshold, otherwise is not.

The classic Sobel edge detection operator uses the gray weighting algorithm of the top, bottom, left and right of the target pixel to determine whether it is an edge pixel. This method can not only extract the edge of the target image but also smooth the noise. However, the effect is not very well when the edge extraction is fine or the image threshold is not set properly.

### III. IMPROVED SOBEL EDGE DETECTION ALGORITHM

If the threshold setting in the traditional Sobel operator edge detection algorithm is unreasonable, the accuracy of edge detection is not high. However, the threshold setting is manual, and different images need to be set according to experience. In this way, a large number of pictures cannot be processed automatically. In this paper, adaptive genetic algorithm and traditional Sobel edge detection algorithm are combined. Different thresholds of images are calculated by genetic algorithm for different images. The calculated threshold is used in edge detection. The process of the improved Sobel edge detection algorithm is shown in Fig. 1.

Fig. 1. Flow chart of improved Sobel edge detection algorithm.

#### A. Improved Sobel Edge Detection Algorithm

The genetic algorithm is a computational model of the biological evolution process that simulates for the natural

selection and genetic mechanism of Darwin's biological evolution theory. It is the method to search the optimal solution by simulating the natural evolution process. Genetic algorithm was proposed by Professor Holland firstly. It is a general solution to solve the search algorithm, especially suitable for the calculation of the optimal solution. The genetic algorithm has been widely used in many fields such as production scheduling, automatic control, image processing, machine learning and so on [15-17].

The basic operation of the genetic algorithm includes three basic operators: selection, crossover, and mutation. The genetic operation of an individual population is carried out under random disturbance, so the migration process of the optimal solution is also random. It should be emphasized that this random migration is different from the traditional random search, and the search of genetic operation is efficient and directional. The specific manifestations of genetic operation are as follows:

1) *Selection*: The operation of choosing high-quality individuals in the population and eliminating low-quality individuals is called selection. The purpose of the selection operation is to transfer the genes of high-quality individuals to the next generation. The criterion of selection is based on an appropriate individual fitness assessment. At present, the commonly used fitness evaluation methods include the roulette selection method, fitness proportion method, random traversal sampling method, local selection method and others. And roulette selection method is used most widely.

2) *Crossover*: In the process of biological evolution, genetic recombination plays a key role. Similarly, in the genetic algorithm, crossover operator operation is the core of the whole genetic algorithm. Cross operation means recombining part structure of two-parent individuals to obtain a new individual through cross replacement and achieving the purpose of recombining the desired gene. The crossing modes include single-point crossing and multi-point crossing and uniform crossing. The most common is single-point crossing.

3) *Mutation*: The operation of the mutation operator in the genetic algorithm is to change a certain gene of an individual and to achieve the purpose of changing individual genes. The mutation operation not only increases the diversity of the population and prevents premature convergence, but also enhances the local search ability of the genetic algorithm and accelerates the convergence. Common mutation methods include real-valued mutation and binary mutation.

The above operations are the basic operations of the genetic algorithm. The effect of the genetic algorithm is largely related to the population size, iteration times, crossover probability and mutation probability set by the three genetic operators. In this term, this paper adopts an adaptive genetic algorithm compared with the traditional genetic algorithm. By calculating individual fitness, the algorithm adopts different crossover and mutation probabilities for individuals with different fitness, to increase the individual diversity of the population and achieve the purpose of rapid global convergence. The specific improvement details are as follows.

1) *Setting different crossover probabilities according to the individual fitness of the population:* For individuals with the highest fitness do not select cross, and their genes are directly transmitted to the new offspring. For the individuals with the lowest fitness, selecting complete crossover and covering their original genes, then the fitness of their offspring is greatly improved. For other individuals, the crossover probability is determined according to the specific situation. This improved crossover operator not only ensures the individual diversity of the population, but also makes the individual fitness converge rapidly in the direction of the optimal solution. The mathematical expression of the improved cross-operation principle is defined as follows:

$$P_c = \begin{cases} k_2, & f_c = f_{\min} \\ k_1 \frac{f_{\max} - f_c}{f_{\max} - f_{\min}}, & f_c \neq f_{\max}, f_{\min} \\ k_3, & f_c = f_{\max} \end{cases} \quad (4)$$

where  $P_c$  is the probability of crossover, and  $f_c$  is the individual with greater fitness in the two individuals of the parent generation.  $f_{\max}$  and  $f_{\min}$  are the maximum and minimum fitness of the individual in the population.  $k_1, k_2, k_3$  are constants between 0 and 1, and  $k_2 > k_3$ .

2) *Adaptive mutation probability:* Mutation operation is an indispensable link in genetic algorithm, which mainly ensures the diversity of population genes. Through the combined action of crossover and mutation, the population will rapidly converge towards the optimal solution. In the mutation operation, the mutation probability is used to represent the intensity of mutation. Usually, a smaller value is required to prevent the mutation operation from misoperating the genes of excellent individuals in the population. In order to prevent the premature convergence of the population caused by the misoperation of the mutation operation on the excellent individuals, the adaptive improvement is made in this paper. The mathematical principle is shown:

$$P_m = \begin{cases} k_5, & f_c = f_{\min} \\ k_4 \frac{f_{\max} - f_c}{f_{\max} - f_{\min}}, & f_c \neq f_{\max}, f_{\min} \\ k_6, & f_c = f_{\max} \end{cases} \quad (5)$$

where  $P_m$  is the mutation probability,  $f_c$  is the one with greater adaptability among parents, and  $f_{\max}, f_{\min}$  are the maximum fitness and minimum fitness of the population.  $f_4, f_5, f_6$  are constants between 0 and 1, and  $k_5 > k_6$ . Through the adaptive improvement of crossover operation and mutation operation. The flow of the adaptive genetic algorithm is shown in Fig. 2.

### B. The Principle of Calculating the Optimal Threshold by Genetic Algorithm

In the process of using genetic algorithm to calculate the image threshold, the maximum inter class variance of the image is used as the best fitness function to calculate the threshold.

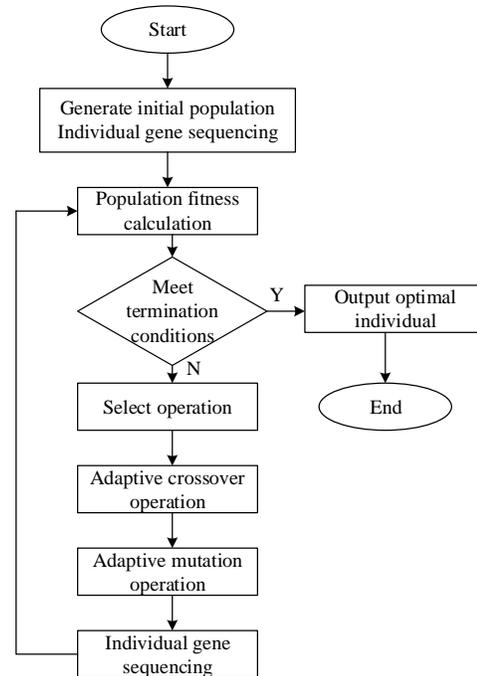

Fig. 2. Flow chart of improved genetic algorithm.

Let  $(x, y)$  be the coordinate of a pixel on the image, and the value range of the gray level of the image is  $G = \{0, 1, 2, \dots, L-1\}$ , where 0 represents the darkest pixel and  $L-1$  represents the brightest pixel. The gray level of the point whose coordinates are  $(x, y)$  is  $f(x, y)$ . Let  $t \in G$  the segmentation threshold,  $B = \{C_0, C_1\}$  be a binary gray level, and  $C_0, C_1 \in G_0$ , then the expression result of the function  $f(x, y)$  on the threshold  $t$  is:

$$f_t(x, y) = \begin{cases} C_0 & f(x, y) \leq t \\ C_1 & f(x, y) > t \end{cases} \quad (6)$$

If the number of pixels with gray  $i$  is  $m_i$ , the total number of image pixels is:

$$M = \sum_{i=1}^{L-1} m_i \quad (7)$$

The probability of occurrence of gray level  $i$  is

$$P_i = \frac{m_i}{M} \quad (8)$$

The traditional maximum inter class variance method is used for image segmentation. Let  $f(x, y)$  be the image to be segmented. The gray scale range of the image is  $\{0, 1, 2, \dots, L-1\}$ . The threshold  $t$  divides the pixels in the image into two categories:  $C_0 = \{0, 1, \dots, t\}$ ,  $C_1 = \{t, t+1, \dots, L-1\}$ .  $C_0$  and  $C_1$  represent the target and background respectively.

Normalize the histogram of the image to obtain the probability distribution of the gray level as follow:

$$P_i = n_i / N, P_i \geq 0, \sum_{i=0}^{L-1} P_i = 1 \quad (9)$$

where  $n$  is the number of pixels with gray scale  $i$ ,  $N$  is the number of all pixels of the image,  $P_i$  is the probability of occurrence of gray level  $i$ . The probability of occurrence of  $C_0$  and  $C_1$  is:

$$\begin{aligned} \omega_0 &= \sum_{i=0}^t n_i / N = \sum_{i=0}^t P_i \\ \omega_1 &= \sum_{i=t+1}^{L-1} n_i / N = \sum_{i=t+1}^{L-1} P_i = 1 - \omega_0 \end{aligned} \quad (10)$$

The mean values of  $C_0$  and  $C_1$  are respectively.

$$\begin{aligned} \mu_0 &= \sum_{i=0}^t n_i * i / \sum_{i=0}^t n_i = \sum_{i=0}^t P_i * i / \omega_0 \\ \mu_1 &= \sum_{i=t+1}^{L-1} n_i * i / \sum_{i=t+1}^{L-1} n_i = \sum_{i=t+1}^{L-1} P_i * i / \omega_1 \end{aligned} \quad (11)$$

Let  $\mu$  be the mean value of the whole image,  $\mu = \sum_{i=0}^{L-1} P_i * i$ .

When the threshold is  $t$ , the gray value is  $\mu_t = \sum_{i=0}^t P_i * i$ . The average value of sampled grayscale is  $\mu = \mu_0 \omega_0 + \mu_1 \omega_1$ . The variance between the two classes is:

$$\sigma^2 = \omega_0 (\mu_0 - \mu)^2 + \omega_1 (\mu_1 - \mu)^2 = \omega_0 \omega_1 (\mu_0 - \mu_1)^2 \quad (12)$$

when  $\sigma^2$  is maximum,  $t$  is the optimal threshold.

### C. Adaptive Threshold Sobel Edge Detection Algorithm

The traditional Sobel needs to manually set the image threshold. When the manually set threshold is close to the real image threshold, the effect of image edge detection is preferably. However, in practice, image acquisition is greatly affected by external factors such as illumination, which makes the threshold values of different images vary greatly. The effect of traditional Sobel operator in image edge detection with different thresholds is not ideal.

To solve this problem, this paper combines the genetic algorithm with the traditional Sobel edge detection algorithm and proposes an adaptive threshold Sobel edge detection algorithm. Setting different thresholds for different images avoids the influence of external factors on image segmentation and has a better effect. The implementation steps of the algorithm are as follows:

- 1) Import the target image, determine the parameter set according to the actual problem, encode the parameter set, set the initial parameters, etc.
- 2) The population individuals are selected, crossed, and mutated adaptively and iterated to the optimal individuals, which means calculating the threshold of the image.
- 3) Pass the threshold in step 2) to the classical Sobel edge detection algorithm to avoid manually setting the threshold.
- 4) Compare the threshold with the convolution value calculated by the convolution operator to judge the image edge.
- 5) Complete edge detection and output the target image.

The above is the whole process of the adaptive threshold Sobel edge detection algorithm.

## IV. EXPERIMENTAL RESULTS AND ANALYSIS

In this section, we present the results by the proposed algorithm and the traditional Sobel algorithm.

### A. Initial Parameter Setting

Take the person image shown in Fig. 6(a) as the test image to test the edge detection process of the algorithm. The initial parameter settings are shown in Table I.

The three groups of initial parameters in Table I are tested respectively to obtain the best fitness curve and the best threshold curve under the three groups of parameters. The best fitness curve and the best threshold curve of the three groups of parameters are shown in Fig. 3, Fig. 4, and Fig. 5.

TABLE I. INITIAL PARAMETERS OF CHARACTER IMAGE EDGE DETECTION

Initial parameters	Population quantity	Number of iterations	Crossover probability	Variation probability
Group 1	10	100	0.8	0.5
Group 2	5	50	0.6	0.4
Group 3	20	200	0.9	0.7

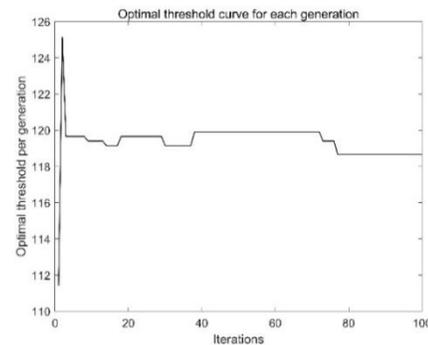

Fig. 3. Group 1's optimal threshold.

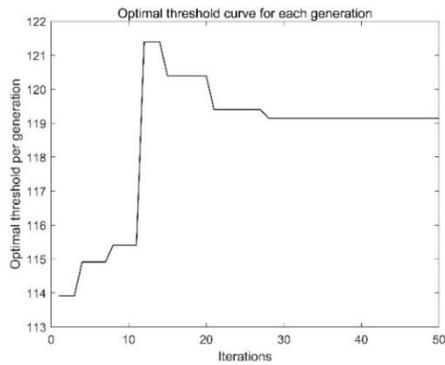

Fig. 4. Group 2's optimal threshold.

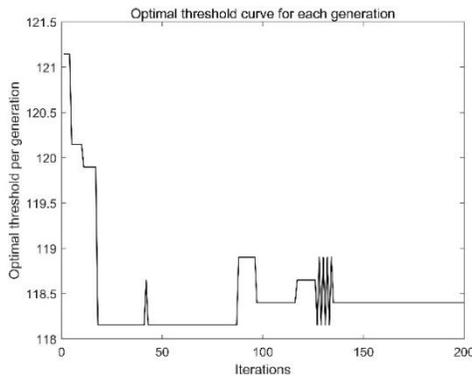

Fig. 5. Group 3's optimal threshold.

In group 1, the optimal threshold is 118. In group 2, the optimal threshold is 120. In group 3, the optimal threshold is 118. In the group 2 of data, the optimal solution will converge in advance due to the small number of populations and iterations. The calculation of image threshold is inaccurate. Although the image threshold calculation of the group 3 of data is accurate, the amount of calculation increases and resources are wasted due to the excessive parameter setting. Comprehensive comparison shows that the group 1 of data not only ensures the accuracy of calculation, but also has a moderate amount of calculation. Therefore, in the following image processing, the group 1 of parameters are used as the original parameters to calculate the threshold of the image.

### B. Edge Detection Process

According to the initial parameters of group 1, the threshold value of the image in Fig. 6(a) is calculated, which is 118. Before edge detection of the target image, the image needs to be processed. First, the grayscale image shown in Fig. 6(b) is obtained by grayscale processing of Fig. 6(a). In order to make the experimental process closer to the real detection process, random salt and pepper noise is added to the gray image to simulate the random noise in the process of image acquisition. The noise diagram shown in Fig. 6(c) is obtained. After the above preparations are completed, the threshold value detected in Section 4A is transferred to Sobel operator to detect the edge of the target image. Finally, the edge detection effect shown in Fig. 6(d) is obtained.

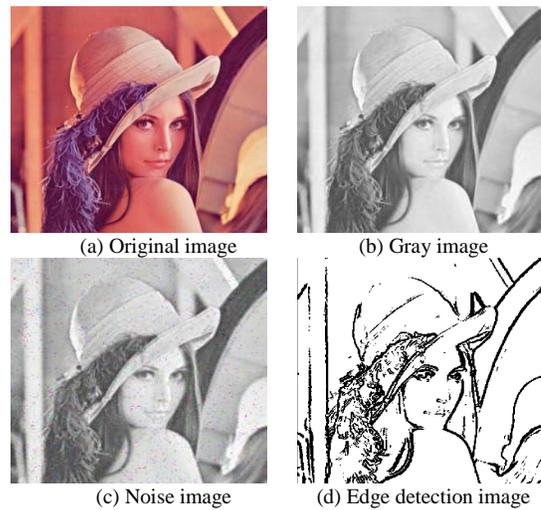

Fig. 6. Edge detection process.

As shown in Fig. 6, the algorithm in this paper has a good effect on the edge detection of the target in the noisy environment. The contour of edge detection is clear. The image details are complete. The image information is completely saved, which can meet the further processing of the target image. At the same time, the algorithm overcomes the problem that the edge detection effect is not ideal due to the large gap between the image threshold and the set threshold. The threshold of the target image is calculated by genetic algorithm. The calculated threshold value is then transferred to the Sobel operator to replace the manually set threshold value. Finally, the purpose of adaptive threshold edge detection is achieved.

### C. Analysis of Experimental Results

In order to show the edge detection effect of the algorithm under different images, this paper uses three examples to compare the algorithm with the traditional Sobel algorithm with different thresholds. The traditional Sobel operator setting threshold and adaptive threshold of each image are shown in Table II. The comparison diagram of different thresholds of the three examples is shown in Fig. 7, Fig. 8, and Fig. 9.

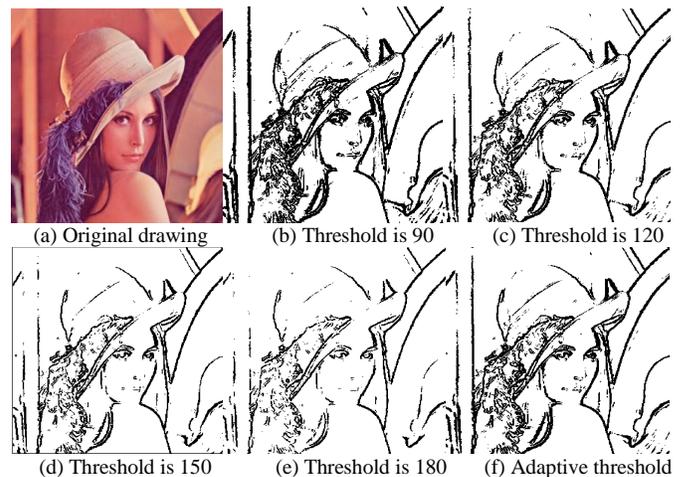

Fig. 7. The example 1 of edge detection of human image under different thresholds.

TABLE II. THRESHOLD SETTING OF DIFFERENT IMAGES

Image name	Example 1	Example 2	Example 3
Threshold 1	90	90	90
Threshold 2	120	120	120
Threshold 3	150	150	150
Threshold 4	180	180	180
Adaptive threshold	118	143	88

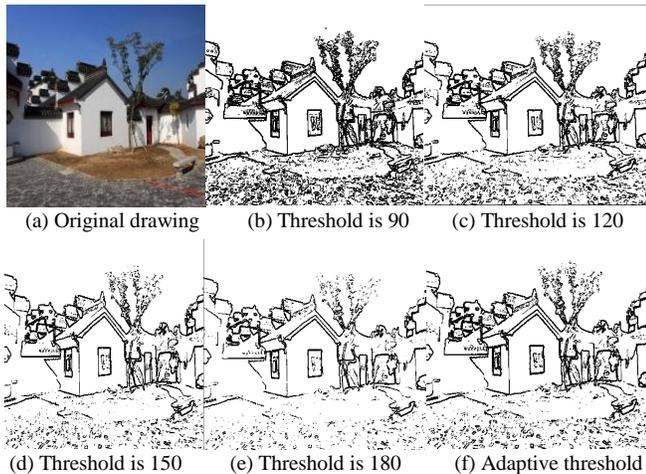

Fig. 8. The example 2 of edge detection of building image under different thresholds.

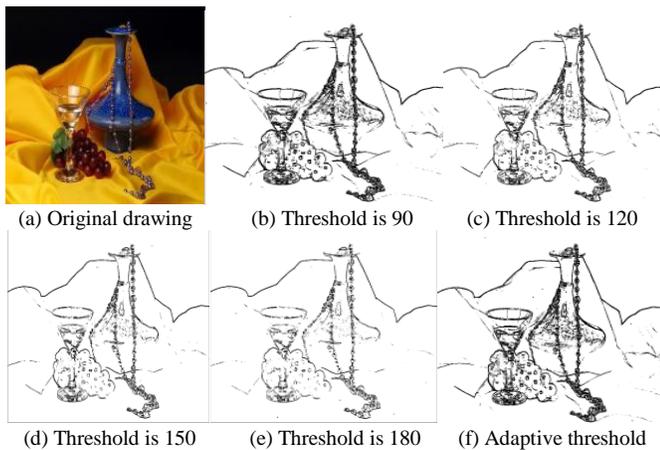

Fig. 9. The example 3 of edge detection of still life image under different thresholds.

## V. CONCLUSIONS

In this paper, Sobel edge detection algorithm based on the genetic algorithm is proposed. Compared with the traditional Sobel algorithm, it does not need to set the threshold manually, which avoids the poor detection effect caused by different image thresholds. This algorithm has great improvement. The image edge is located accurately. The image details are well

preserved. It can adapt to images with different thresholds and has great practical application value.

**Abstract**—Users may now choose from a vast range of compiler optimizations. These optimizations interact in a variety of sophisticated ways with one another and with the source code. The order in which optimization steps are applied can have a considerable influence on the performance obtained. As a result, we created a revolutionary compiler optimization prediction model. Our model comprises three operational phases: model training, feature extraction, as well as model exploitation. The model training step includes initialization as well as the formation of candidate sample sets. The inputs were then sent to the feature extraction phase, which retrieved static, dynamic, and improved entropy features. These extracted features were then optimized by the feature exploitation phase, which employs an improved hunger games search algorithm to choose the best features. In this work, we used a Convolutional Neural Network to predict compiler optimization based on these selected characteristics, and the findings show that our innovative compiler optimization model surpasses previous approaches.

**Keywords**—Compiler optimization prediction; feature extraction; feature exploitation; improved hunger games search algorithm; convolutional neural network

## I. INTRODUCTION

As per Moore's Law, the density of transistors doubles every 2 years. Compilers, on the other hand, progress at a pace of a couple percent of year. Compilers were vital tools for connecting written software to destination hardware. In the field of compilers, there's several unresolved research issues [1]. Compilers play a crucial role in software development. Its core objective is to boost software productivity [2].

Compilers were liable for two tasks: translation as well as optimization. They must first effectively convert programmes into binary. Secondly, they must discover the most cost-effective translation. There are numerous valid translations, each of which performs distinctively. The great majority of studies and technological activities are centered on this second performance objective, which has been referred to as optimization. The objective was mislabeled because, until recently, most people rejected obtaining an ideal translation as a difficult and impractical task [3]. Compilers are now being improved so that every code block in a programmed may be transformed into an efficient application [4]. Traditional compiler optimization seems to be a difficult process with no assurances of producing the most effective and quickest target code [5]. A compiler enables a multitude of code optimizations that could be activated or disabled via a compilation flag in

order to enhance the throughput of compiled applications. Nevertheless, because the influence of compiler optimizations largely dependent on programme features (e.g., programme structures), the identical optimizations may not surely result in the identical runtime speed boost when implemented to various programmes [6].

Furthermore, there's an infinite range of flag combos owing to the enormous count of optimization flags. Users may find it difficult to comprehend all of the flags including their combos, and to correctly decide which flags should be activated or disabled in attempt for built programmes to attain the desired runtime performance [7]. Compilers for machine learning (ML) tackle a lot of optimization issues in order to convert an ML programmed, which is often expressed as a tensor computational graph, into an efficiently executable for a hardware destination [8]. Prior efforts [9] – [14] have permitted optimizations that are implemented at the very same point in the compilation pipeline, notably the loop conversion phase. However, since compiler modifications are arranged as passes to minimize complication and also have rigorous ordering limitations, this is unfeasible in production compilers.

With a compiler's optimization capabilities influencing so many parts of product development, understanding and evaluating a compiler's optimization technology is more critical than ever. In this work, an improved optimization prediction model was created, which not only decreases computational time but also enables the compilers with faster convergence, more stable balance, and high-quality outcomes by selecting appropriate optimization. Our work made the following contributions:

- Several high-level characteristics may arise from the coefficients as a result of improved entropy extraction, which boosts the compiler optimization prediction.
- An Improved Hunger Game Search optimization was proposed to provide a very competitive performance to the compiler with less computational time.

The following is the flow of this article: Section II covers some previous relevant research, Section III gives a brief presentation of our proposed compiler optimization prediction model, Section IV gives the outcomes of our work, and Section V contains the conclusion, while the following section includes the references for this work.

## II. RELATED WORKS AND REVIEW

Some of the researches presented by various researchers on compiler optimization were reviewed here.

Hui et al. [15] presented the ALIC iterative compiler optimization parameters estimation model, which has minimal overheads. Firstly, the target programmes were defined using static-dynamic characteristics format depending on feature significance, as well as an early optimization prediction model was built using the classifier. Subsequently, for every sample, a dynamic amount of sample observation methodology was being used. The most beneficial test from the collection of candidate samples typically the chosen and labeled with each mark increase the count of sample data. The optimization prognosis system is then built by using intermediate prediction network, which actively learns candidate samples.

Tiago et al. [16] suggested a new exploration approach to determine a compiler optimization strategy. This hybrid methodology utilizes previously created sequences for a series of training programmes in order to uncover optimizations as well as their deployment order. A clustering method selects optimizations during the first stage, and then a metaheuristic algorithm determines the order wherein the compiler would execute every optimization in the latter. The LLVM compilers as well as an I7 processor have been used to assess this strategy.

Supun et al. [17] developed HUMMINGBIRD, a unique prototype scoring technique that incorporates featurization operators with classic ML designs (e.g., decision trees) into a limited collection of tensor operational processes. This method decreases infrastructure overhead by using current investments in Neural Net compilers but also runtimes to produce efficient calculations for both CPU as well as hardware accelerators. The findings indicate that HUMMINGBIRD performs compatible.

Mircea et al. [18] introduced MLGO1, a methodology for comprehensively incorporating machine learning methods into an industrial compiler— LLVM. It's the first time ML has been fully integrated in a sophisticated compiler run in a real-world context. It's in the LLVM main repository. As contrasted to the state-of-the-art LLVM -Oz, we apply two alternative ML techniques to train the inlining-for-size method: Policy Gradient as well as Evolutionary Algorithms.

Aleksandar et al. [19] presented a revolutionary JIT compiler inlining approach that gradually investigates a program's call network and switches between inlining as well as optimizations. Three new heuristics have been developed to steer this inliner. Graal, a dynamic JIT compiler for the HotSpot JVM, was used to create this technique. Benchmarks such as Java DaCapo, Scalabench, and others were utilized to test the suggested algorithm.

Conventional systems to prediction model creation frequently employ a random selection search strategy, which can often lead to information redundancy. Moreover, the sample program gets exposed to a fixed number of repetitive measurements due to the influence of run-time disturbances. Unfortunately, if there are few sounds, the recurrent measurements will lead to a significant loss of iterative

compilation time overheads. Decreasing iterative compilation overheads and predicting an appropriate compiler optimization with less computational time and increased compiler performance was still challenging.

## III. PROPOSED COMPILER OPTIMIZATION PREDICTION MODEL

This proposed compiler optimization model comprises three working phases: model training, feature extraction [24, 25], as well as model exploitation (feature selection). First, the inputs were fed into the model training phase, which tries to match the right weights as well as bias to a learning algorithm [26, 27] in order to minimize a loss function throughout the validation range. The retrieved characteristics, such as static, dynamic, as well as improved entropy, were then transferred to the model exploitation phase [21], where the optimal features were chosen utilizing the improved chaos game optimization. These optimized features were given to Convolutional Neural Network for prediction of compiler optimization. The architecture of our improved compiler optimization prediction model is given in Fig. 1.

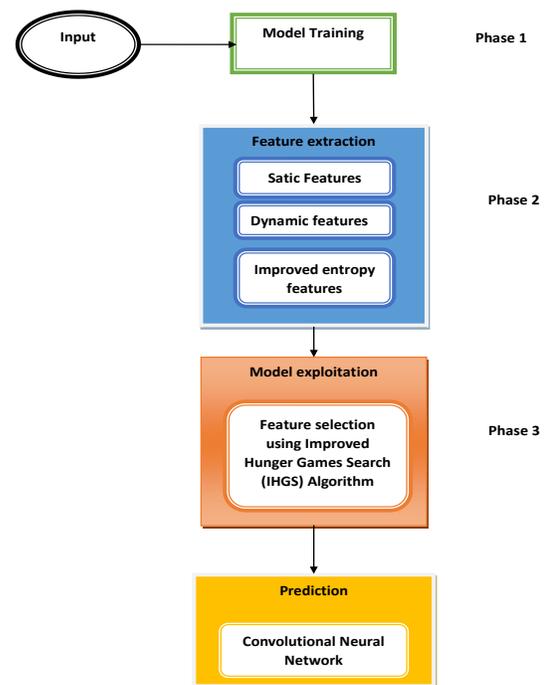

Fig. 1. Proposed improved compiler optimization prediction model architecture.

### A. Model Training Phase

The initialization and candidate sample set generation takes place in the model training phase. The initialization model will be built in the training set with some labeled samples. The initialization model will be used as the intermediate prediction model later. The candidate samples set include both the unlabeled samples in the training set and the labeled samples with the number of observations.

### B. Feature Extraction

Outputs from model training phase were given to the feature extraction phase to extract the static, dynamic and improved entropy features [26, 27].

1) *Static features*: The values of static features do not vary over time and are set for every sample. The lists of the static features extracted in this work were shown in Fig. 2.

2) *Dynamic features*: The values of dynamic features fluctuate over time and are not constant. Fig. 3 depicts the dynamic characteristics retrieved in this work.

3) *Improved entropy feature extraction*: The count of coefficients is generally so large that it is challenging to utilize them directly as features for categorization or prediction. As a result, several high-level features might emerge from these coefficients for improved prediction. Entropy seems to be a tool for measuring the uncertainty of data content in specific mechanisms, and it is frequently employed in signal analysis, pattern recognition, pattern matching, and other fields. . Some kinds of entropy include Shannon entropy (SE), log energy entropy (LEE), Renyi entropy (RE), as well as Tsallis entropy (TE). Renyi entropy is utilized to retrieve features from input data in this work. Entropy may be estimated via energy. Wavelet energy, described as Eq. (1), will be used to assess the data of the coefficient  $a$  of the  $b$ -th node at the  $c$ -th level.

$$E_{a,b,c} = \|d_{a,b,c}\|^2 \quad (1)$$

The total energy for the  $b$ -th node at the  $c$ -th level may then be determined utilizing Eq. (2)

$$E_{a,b} = \sum_{c=1}^M E_{a,b,c} \quad (2)$$

Where  $M$  indicates the number of node matching coefficients Eq. (3) may be used to compute the probability of the  $c$ -th coefficient at its associated node:

$$\rho_{a,b,c} = E_{a,b,c} / E_{a,b} \quad (3)$$

Where the sum of  $\rho_{a,b,c}$  equals 1.

Renyi Entropy of order  $q$  ( $q \geq 0$  and  $q \neq 1$ ) gets described as

$$RE(s) = \frac{1}{1-\beta} \log \left( \sum_{a=1}^M \rho_a^q \right) \quad (4)$$

The parameter of  $q$  in RE should be optimized to provide better results. In our work, the improved entropy features were extracted using the eq. (5)

$$RE(\rho) = \frac{1}{1-\beta} \log \left( \sum_{a=1}^M \rho_a^\beta \right)^{1/\beta} * \omega_a \quad (5)$$

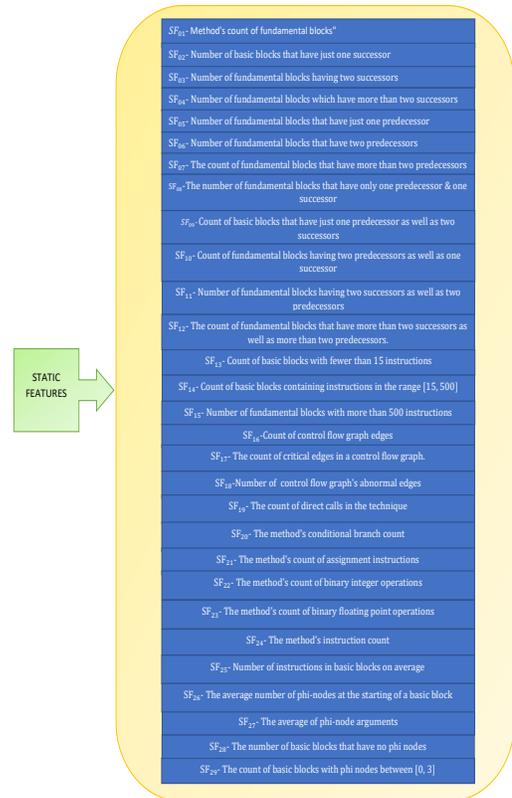

Fig. 2. Extracted static features.

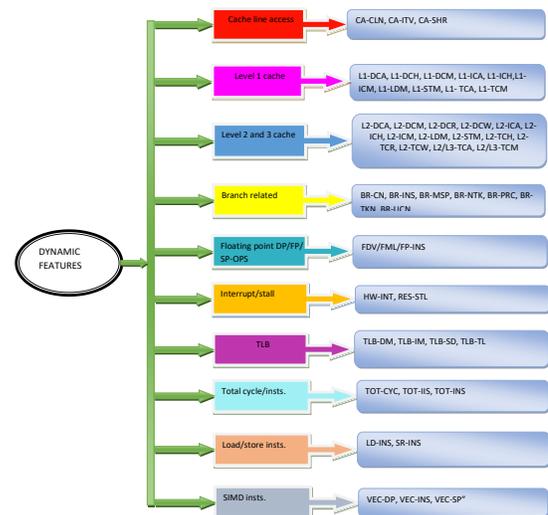

Fig. 3. Extracted dynamic features.

Here  $\omega_a$  denotes the weight, which is calculated by

$$\omega_a = \frac{\rho_a^\beta}{\sum_{b=1}^m \rho_b^\beta} \quad (6)$$

Following the calculation of the entropy of each terminal node, the entropies of all terminal nodes are concatenated to form a feature vector. These features were sent to the model exploitation phase for feature selection.

### C. Model Exploitation

The feature selection procedure is taking place during this model exploitation phase. When creating forecasting models, feature selection is the technique of minimizing the count of input variables. It is preferable to limit the count of input variables in order to reduce modeling computational costs and, in certain situations, increase model performance. For that reason we used an improved HGS Optimization.

1) *Improved Hunger Game Search (IHGS) Optimization:* The HGSO technique is influenced by normal animal behaviors including terror of being eaten by predators as well as hunger. The mathematical modelling of the HGSO strategy is explained in this portion of the publication. The modelling is based on social selection and hunger-driven behaviour.

This section quantitatively models the approaching behaviour of hunger. Eq. (7), which explains the foraging hunger as well as individual supportive communication activities, contains the game instructions. The contraction mode is imitated by the mathematical formula in Eq. (7).

$$\overline{Z}(t+1) = \begin{cases} \overline{Z}(t) \cdot (1 + \text{randn}(1)), & r1 < l \\ \overline{W}_1 \cdot \overline{Z}_d + \overline{R} \cdot \overline{W}_2 \cdot |\overline{Z}_d - \overline{Z}(t)|, & r1 > l, r2 > H \\ \overline{W}_1 \cdot \overline{Z}_d - \overline{R} \cdot \overline{W}_2 \cdot |\overline{Z}_d - \overline{Z}(t)|, & r1 > l, r2 < H \end{cases} \quad (7)$$

where  $\overline{Z}(t)$  signifies the location of all individuals,  $\overline{Z}_d$  indicates the position of the best individual,  $\overline{W}_1$  and  $\overline{W}_2$

seem to be hunger weights of hunger,  $\overline{R}$  is between [-a, a], r1 and r2 seem to be random numbers between [0, 1], randn(1) denotes a normal distributed random number, and t seems to be the count of current iterations. The parameter l represents the HGSO algorithm's control variable that governs the algorithm's sensitivity. H stands for variation control for all locations.

2) *Opposite behavior learning:* Amongst the most effective instructional procedures, opposition-based learning (OBL), has been extensively embraced as an excellent learning phase to improve the searching capabilities of algorithms. When assessing a solution Y to a given issue, a novel opportunity will be gained that brings the candidate solution closer to the optimal solution if the opposing solution of Y is estimated at the same time. The opposing number as well as opposite point notions were described as follows.

OBL is a learning approach that is centered on the inverse number  $Y^o$ . Y is described as a real number,  $Y \in [e, f]$ .  $Y^o$ 's opposite may be defined as (8), where e, f are the bounds.

$$Y^o = e + f - Y \quad (8)$$

When  $Y = (Y_1, Y_2, \dots, Y_D)$  seems to be a point in a D-dimensional space,  $Y_j, \dots, Y_D$ .  $e_j$  as well as  $f_j$  represent the current population's low and high borders, which vary with

each iteration. An opposing point in several dimensions has been described as

$$Y_j^o = e_j + f_j - Y_j, j = 1: D \quad (9)$$

In our work, to generate chaotic opposite solution we have used the following equation

$$Y_j = lbj + \text{rand} * (efj - lfj) \quad (10)$$

Here rand was generated using the sine map.

$$z_{u+1} = \frac{e}{4} \sin(\pi z_k) \quad e \in (0, 4) \quad (11)$$

Variation control for all positions H stated in eq. (12)

$$H = \text{sech}(|F(i) - BF|) \quad (12)$$

where F(i) represents the cost function value of every population,  $i = 1, 2, \dots, n$ , BF represents the best cost function value acquired during the latest incarnation, and Sech represents the hyperbolic function and thus is equal to  $(\text{sech}(x) = \frac{2}{e^x + e^{-x}})$ .

In our work, we used the reciprocal of the hyperbolic function Csch, which is expressed in eqn., (13)

$$H = \text{Csch}(|F(k) - BF|) \quad (13)$$

$$\text{Here Csch} = \frac{2e^x}{2e^x - 1}$$

Eqn., (14) gives the expression for  $\overline{R}$ .

$$\begin{aligned} \overline{R} &= 2 \times h \times r - h \\ h &= 2 \times \left(1 - \frac{t}{\text{Max}_{iter}}\right) \end{aligned} \quad (14)$$

Where  $\text{Max}_{iter}$  denotes the maximum number of iterations and rand denotes a random number between [0, 1]

3) *Hunger role:* This portion quantitatively models the hunger behavior of all individuals during the search. The formula for  $\overline{W}_1$  is given in Eq. (15).

$$\overline{W}_1(k) = \begin{cases} \text{hungry}(k) \cdot \frac{N}{SHungry} \times ra4, & ra3 < l \\ 1 & ra3 > l \end{cases} \quad (15)$$

The expression for  $\overline{W}_2$  is presented in Eq. (16).

$$\overline{W}_2(k) = (1 - \exp(-|hungry(k) - SHungry|)) \times ra5 \times 2 \quad (16)$$

where N represents population size, hungry means population starvation, SHungry represents the total of population starvation, i.e., sum(hungry), as well as ra3, ra4, and ra5 signify random values between [0, 1]. Each population's starving is quantitatively represented in Eq. (17).

$$\text{hungry}(k) = \begin{cases} 0 & \text{AllFitness}(k) == BF \\ \text{hungry}(k) + H_{new}, & \text{AllFitness}(k) = BF \end{cases} \quad (17)$$

where  $AllFitness(k)$  would be the present iteration's cost function value for every population. Depending on the real starving, a new starvation  $H_{new}$  is added. The equation represents the formula for  $H_{new}$ .

$$H_{new} = \begin{cases} LH \times (1 + ra) & TH < LH \\ TH, & TH \geq LH \end{cases} \quad (18)$$

$$TH = \frac{F(k) - BF}{WF - BF} \times ra \times 2 \times (UB - LB) \quad (19)$$

where  $H_{new}$  has been constrained to a lower bound LH, ra would be a random number among [0, 1], WF as well as BF seem to be the worst best fitness acquired during the latest iteration, respectively, F (k) has become the fitness of every population, ra would be a random number between [0, 1], and LB as well as UB are indeed the lower and upper boundaries of the dimensions, respectively. The selected features were sent to the CNN for compiler optimization prediction.

#### D. Prediction using CNN

Convolutional networks were deep training strategies that extract information from input pictures by convolving them with filters or kernels. Convolution of a GCG picture with a  $f_s C f_s$  filter learns the same characteristic on the whole picture. After each action, the window moves, and the feature maps learn the characteristics. The feature maps record the image's local receptive area and operate with mutual weights as well as biases. Equation (20) depicts the output matrix size without padding, whereas Equation (21) depicts the convolution procedure. Padding has been utilized to keep the size of the given picture constant. The output picture size is the same as the input image size in a 'SAME' padding, and there is no padding in a "VALID" padding. Equation depicts the output matrix size with padding (22).

$$GCG * f_s C f_s = G - F + 1 \quad (20)$$

$$o = \sigma \left( m + \sum_{v=0}^2 \sum_{q=0}^2 w_{v,q} \chi_{\alpha+v,m+q} \right) \quad (21)$$

$$GCG * f_s * f_s = (G + 2P - f_s) / (S + 1) \quad (22)$$

Here, O is the output, P is the padding, S is the stride, m is the bias,  $\sigma$  is the sigmoidal activation function, w is a 3x3 weight matrix of shared weights and  $\chi_{p1,p2}$  is the input activation at position p1,p2. The output O provides the prediction results.

## IV. RESULTS AND DISCUSSION

### A. Simulation Setup

The unique methodology for compiler optimization utilizing IHGS was implemented in Python. The standard performance evaluation group created the SPEC CPU2006 training set to evaluate general-purpose CPU performance [20].

The input scale of the SPEC2006 benchmark may be split into test, train, as well as reference scales; we utilize the reference scale to test." In this case, analysis was performed for multiple measures such as accuracy [22,23] and error metrics such as MSE, MSLE, and so on. In addition, IGHS outperformed the HGS, PRO, CMBO, ARCHOA, DO, as well as GOA models.

### B. Performance Analysis

The research on diverse metrics including accuracy, sensitivity, specificity as well as precision was detailed here. Here, the analysis was done for LPs (Learning Percentages) of 60, 70, 80 and 90 over HGS, PRO, CMBO, ARCHOA, DO, GOA models which is shown in Fig. 4. For 60 LP, CMBO and HGS achieve the accuracy rate of 0.69 and 0.76 whereas our proposed IHGS model achieves the accuracy rate of 0.84. At 80 and 90 LPs our proposed IHGS achieves the accuracy rate of 0.9 and 0.94 which is higher than other models. When our proposed IHGS achieves the precision value of 0.9, ARCHOA, CMBO models achieves only 0.8 and 0.81 for 60 LP which proves the superiority of proposed IHGS model. For 80 and 90 LPs, PRO model attain the sensitivity and specificity values of 0.83, 0.85 and 0.83, 0.85 while our proposed IHGS method achieves the values of 0.85, 0.93 and 0.89, 0.94 which proves that our proposed IHGS method achieves high performance for the compiler optimization identification than other conventional models.

The most often employed KPIs to estimate forecast accuracy were MAPE, MAE, RMSE(MSE), as well as MSLE which were analyzed for the models such as HGS, PRO, CMBO, ARCHOA, DO and GOA for 60, 70, 80 and 90 LPs which is compared with our proposed IHGS model that is shown in Fig. 5. "MAE is indeed a metric of error between matched observations reflecting the same phenomena in statistics." The MAE should be less to increase forecast accuracy. Our proposed IHGS method obtain the MAE value of 0.48, 0.45, 0.42 and 0.4 for 60, 70, 80 and 90 LPs which is lower than other conventional methods. MSLE may be regarded of as a measurement of the ratio between true as well as forecasted values. When HGS method achieves the high MAPE values of 2.3, 1.5, 0.7 and 2.0 for 60, 70, 80,90 LPs, our proposed IHGS method obtain the values of 0.5, 0.4, 0.3 and 0.2. Unlike MAE, RMSE doesn't really handle every error in the same way. It prioritises the most critical errors. That implies that a single large mistake might result in a very bad RMSE. Our proposed IHGS approach yields MSE values of 0.49, 0.46, 0.43, as well as 0.42 for all LPs, which is lower than other standard approaches. In statistics, the MAPE, also referred as the MAPD, is specified as "a metric of prognosis accuracy of a forecasting technique". "The MSE or MSD of an estimator in statistics estimates the average of the squares of the errors, or the average squared difference between the predicted as well as real values." For optimized prediction, the MSE and MAPE must be lower. When the CMBO approach produces MSLE values of 0.27, 0.22, 0.23, 0.26, our proposed IHGS method achieves lower values of 0.23, 0.22, 0.21, 0.20, demonstrating that our proposed IHGS method can outperform other standard compiler optimization forecasting models.

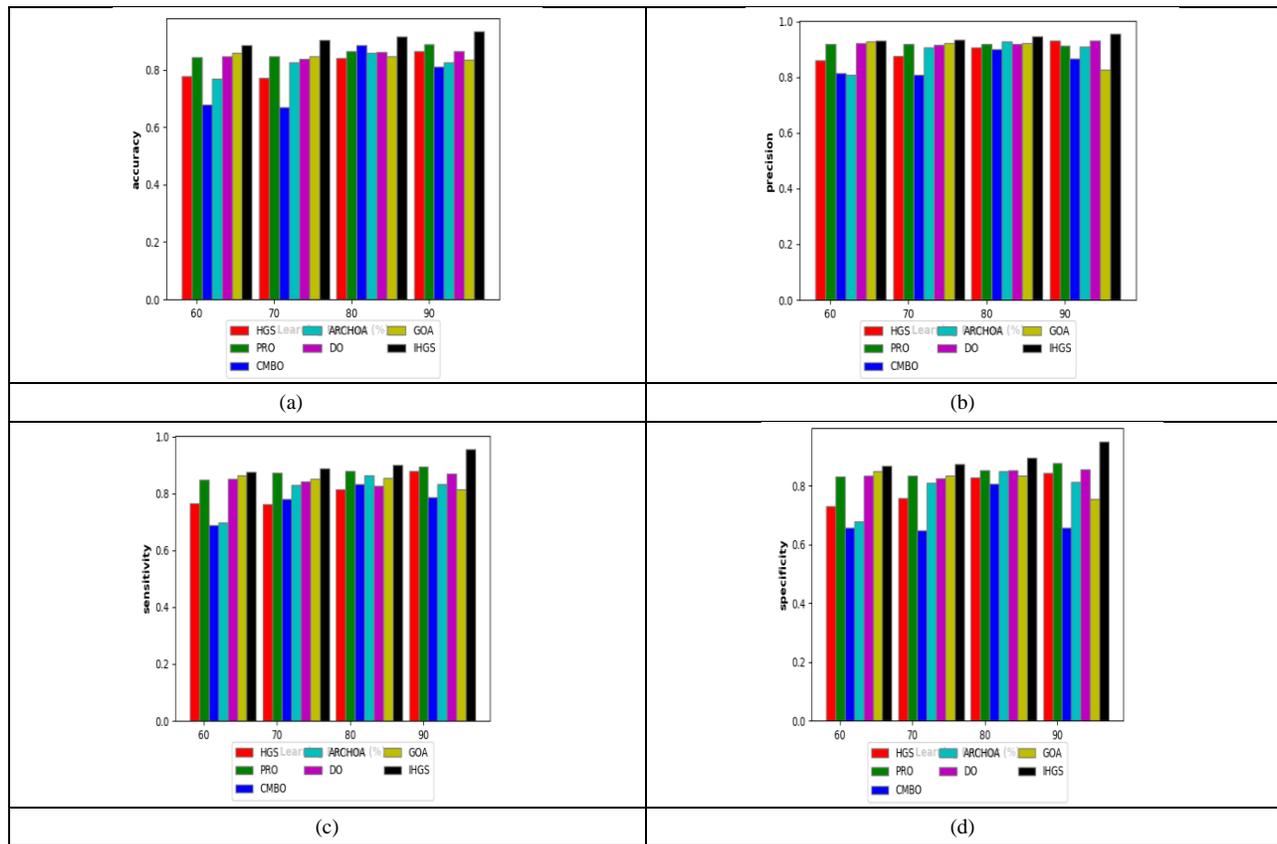

Fig. 4. Comparison of performance matrices such as (a)Accuracy, (b)Precision, (c) Sensitivity, (d) Specificity.

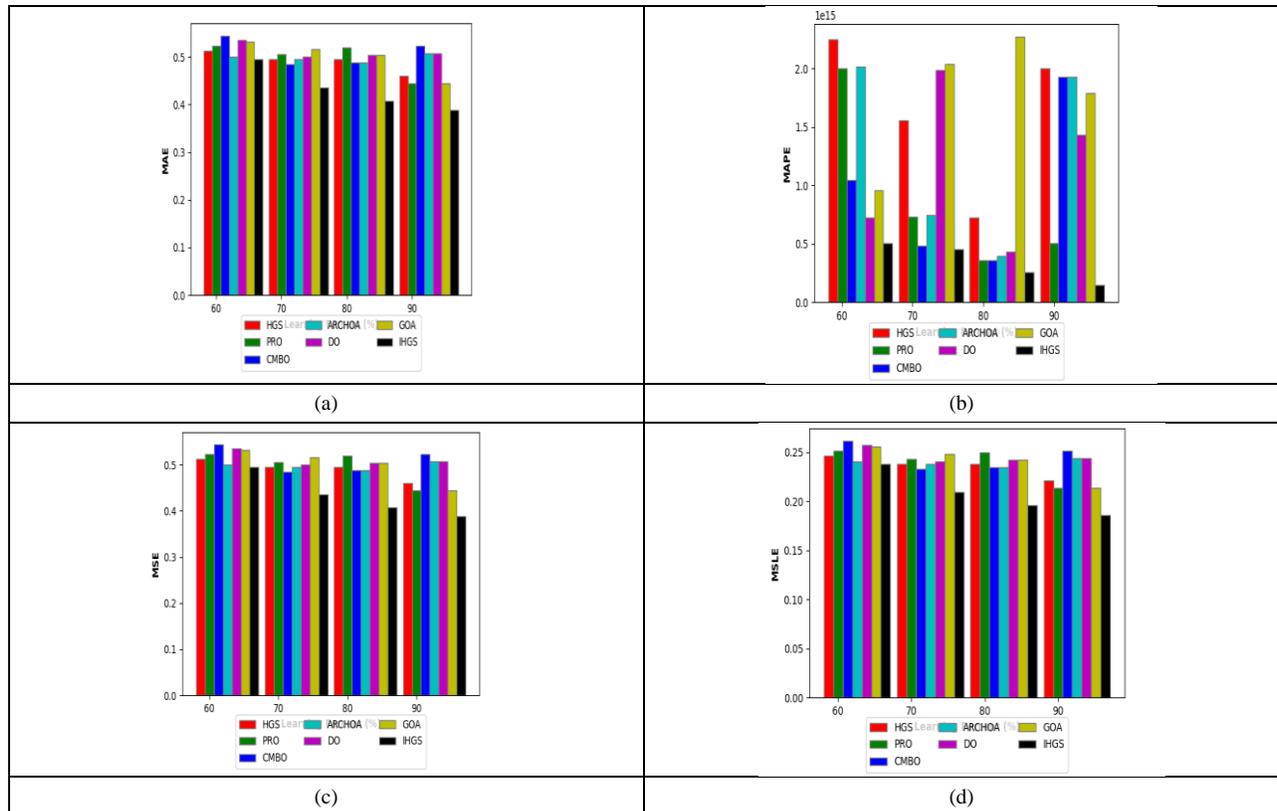

Fig. 5. Comparison of performance such as (a) MAE, (b) MAPE, (c) MSE, (d) MSLE.

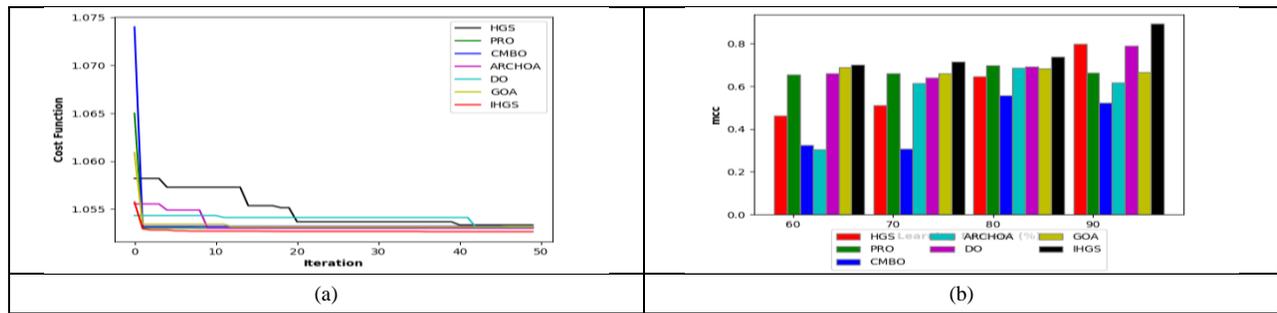

Fig. 6. Comparison of MSC and Cost function values for different LPs.

The cost function for 0-50 iterations was evaluated in this work, to assess the performance of our proposed IHGS model which is shown in Fig. 6(a). When cost function of CMBO is 1.074, our proposed method obtains the value of 1.052 for iteration 0 whereas 1.058 and 1.062 for GOA method which states that IHGS method has the lowest cost function for all five iterations. A more trustworthy statistical rate known as the Matthews correlation coefficient (MCC) was evaluated, which yields a high score only if the prediction performed well in all the confusion matrix classes which are given in Fig. 6(b). MCC values of all the LPs were 0.67, 0.68, 0.7 and 0.9 for our proposed IHGS method which proves our prediction was performed well with good results.

The F-measure is derived as the harmonic mean of accuracy as well as recall, with equal weighting for each. It

enables a system to be assessed utilizing a single score that accounts for both accuracy and recall that is useful for reporting system performance as well as comparing models. With F1 measure, fnr, fpr, as well as npv values were also estimated and compared with conventional models which is shown in Fig. 7. In comparison to the CMBO as well as ARCHOA approaches, our proposed IHGS method achieves f1 measure values of 0.9, 0.92, 0.93, and 0.95 for all LPs. The IHGS approach produces npv value of 0.92 for 90 LP, whereas the CMBO and ARCHOA methods yield relatively low values such as 0.6 and 0.68. Our proposed IHGS technique achieves fpr values of 0.13, 0.12, 0.11, and 0.05, and assessed fnr values of 0.13, 0.12, 0.11, and 0.04, which are lower than other traditional methods, demonstrating that IHGS method achieves superior performance than other methods.

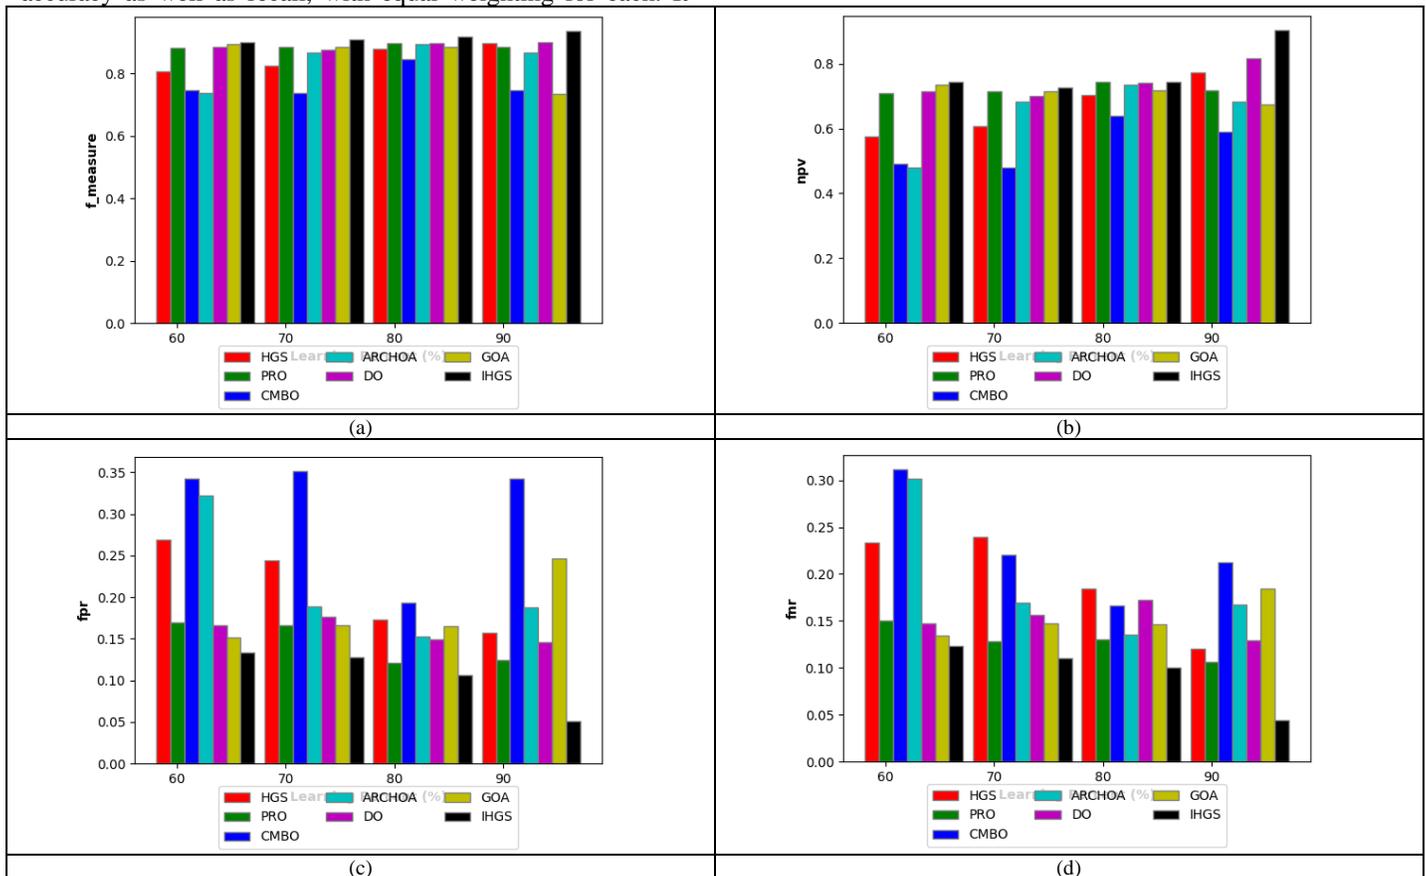

Fig. 7. Comparison of performance matrices (a) F1 measure, (b) fnr, (c) fpr, (d) npv values.

The computation time for each method which is compared with our proposed IGHS method is shown in Table I which shows that IGHS method have low computational time of 55.64. Accuracy and error matrices also compared with without optimization, to evaluate the performance of our proposed IGHS method which is given in Tables II and III. Without optimization our proposed method achieves only 88% accuracy whereas, with optimization it achieves 95% accuracy.

TABLE I. COMPUTATIONAL TIME COMPARISON FOR CONVENTIONAL AND PROPOSED APPROACHES

Methods	Computation time
HGS	76.2114
PRO	200.538

## V. CONCLUSION

Selecting the optimal, or even a good, combination of optimizations for an unpredictable programmed on an arbitrary design is a task so tough that traditional manual analysis approaches are impractical. For that reason, a novel optimization prediction model with improved optimization was developed in this work, which has three working phases including model training, feature selection as well as feature exploitation phase. First, the inputs are being sent to the model

training phase that aims to link the appropriate weights as well as bias to a learning algorithm in order to minimize a loss function throughout the validation range. The retrieved characteristics, including static, dynamic, and enhanced entropy, were then transferred to the model exploitation phase, where the best features was determined using the improved chaos game optimization. These improved characteristics were fed into a Convolutional Neural Network to predict the appropriate compiler optimization.

# Design of an English Web-based Teaching Resource Sharing Platform based on Mobile Web Technology

Yan Zhang

Huanghe Jiaotong University, Basic Education Department, Jiaozuo, 454950, China

**Abstract**—Thanks to the booming technology of computers and multimedia, student-centered online teaching resource platforms have become an important way for students to learn. However, English teaching resource platforms at the present stage fail to effectively integrate the massive and scattered learning resources. Based on this, the study proposes an English online teaching resource sharing platform based on mobile Web technology, using the SOAP protocol to deploy heterogeneous data resources as Web services to achieve interchangeability between heterogeneous resources. In addition, to enhance the efficient use of learning resources by students, the study proposes a hybrid algorithm based on collaborative filtering algorithm and sequential pattern mining algorithm to achieve personalized sequential recommendation for students. The results show that the platform created by the study exhibits excellent performance in terms of resource transfer capability, achieves efficient teaching resource sharing in a short response time and also shows that the proposed recommendation algorithm is highly accurate.

**Keywords**—Web service; SOAP; English teaching resources; sharing platform; personalised recommendation

## I INTRODUCTION

With the continuous promotion of education reform, the value of online education has begun to emerge, which has a positive impact on the development of education in all disciplines [1]. English, as a basic language discipline, in the process of combining with online education, in addition to its own development towards diversification and multidisciplinary integration, it also acts as the language carrier of other disciplines [2]. Therefore, English teaching research is particularly important. At present, many colleges and universities are organizing English teachers and educational technicians to integrate teaching resources, develop online courses, provide students with a good internal environment, and realize the sharing of teaching resources [3]. However, the current multimedia resource sharing platform has caused the problem of excessive platform resources due to insufficient recommendation accuracy and low efficiency [4]. In this way, teachers need to carry out a lot of repeated work, and students and teachers' information acquisition ability is insufficient to improve teachers' teaching efficiency and students' learning autonomy [5]. In order to effectively integrate heterogeneous and dispersed English teaching resources and improve the quality of online English education, the research is based on mobile Web technology and resource recommendation optimization, and an online English teaching resource sharing platform is constructed.

The education platform is constructed by means of resource replacement, access protocol, user information encryption and algorithmic assistance. The MD5 algorithm is designed based on SOAP to ensure the user's information login security. In order to provide personalized learning services for students at different levels, a hybrid optimization algorithm recommendation model is proposed based on collaborative filtering algorithm and sequential pattern mining algorithm. The algorithm model can effectively improve the efficiency of recommendation, improve the accuracy of recommendation of English teaching resources, and better adapt to the current English education environment.

The research innovatively applies the combination of Web technology and English education resource recommendation method to the optimization of English education, providing a reference for the selection of the optimization direction of multi-class online education. In addition, the sequence mining method is incorporated into the collaborative recommendation algorithm, and the comprehensive efficiency of the recommendation algorithm is proposed, which provides a reference for the development of educational resource recommendation.

The research content mainly includes four parts. The second part is a summary of the research status of the construction of educational resources platform at home and abroad; The third part puts forward the construction of the English shared resources platform based on web services, Part A establishes the framework of the education resources platform, describes the construction of the MD5 encryption module, Part B constructs the online learning resources recommendation framework based on web logs, and specifically analyzes the optimization of the recommendation algorithm; The fourth part verifies the application effect of the English online teaching resource sharing platform. The results show that the English online teaching resource sharing platform based on mobile Web technology and resource recommendation optimization has good application effect.

## II RELATED WORKS

In a web environment, resource allocation is a very important issue [6]. Yuan et al. proposed a new neural network path sorting algorithm based on path sorting after improving and analyzing the traditional algorithm, and used a path sorting based on random walk patterns and a neural network path sorting algorithm to solve the link prediction problem in online learning [7] Gu designed a recursive algorithm-led online training model using a web programming language as an example, and by testing the web programming language, it can

be seen that this training method has greatly helped students' learning effect [8]. To further improve the development of online courses, Zhang scholars developed a Mocoas-based mobile learning platform, and the experimental results showed that the platform can well meet the multiple teaching and learning needs of learners [9]. Fang scholars developed an online teaching assessment system based on machine learning, which can effectively assess the quality of teaching and learning in schools, which has good application prospects [10]. To address the problem of schools only being able to teach remotely during the epidemic, Christianson designed a remote web poll to improve students' immediate engagement in a virtual environment, which experimentally proved to be positively experienced by students [11]. Scholars such as Zhou used a WEB web-based teaching platform, using principal meta-analysis and clustering algorithm to classify students' performance and evaluate their learning effectiveness, and the experiment proved that this function can effectively help teachers improve their teaching [12]. Zhang's team attempted to use blockchain technology in the sharing of English teaching resources, and through the analysis of its algorithm, designed a representation layer, business layer and data layer as the core English teaching resources sharing platform, but the process of building the platform was tedious and consumed a lot of human and material resources [13]. Scholars such as Park S E proposed a resource sharing platform based on collaborative recommendation algorithm and introduced it to a hybrid recommendation-based system in recommending learning resources, but as the security of the platform was not taken into account, making the platform vulnerable to malicious attacks [14].

With the advent of the "Internet+" era, education informatics is placing increasing emphasis on the use of artificial intelligence technology to improve teaching effectiveness and quality. In intelligent teaching, intelligent recommendation is the key to realizing knowledge resources. After analyzing and comparing existing personalized recommendation technologies, Xu proposed a personalized recommendation algorithm based on content recommendation and collaborative screening, and the experimental results showed that the personalized recommendation algorithm has high correctness and effectiveness [15]. Based on the user interest model, Li et al. generated a user profile file by classifying the user's queries and generating a snapshot of the user's personal information through point-and-click, and the experimental results showed that the user profile was highly similar to the user's interests [16]. Chaabi's research group proposed a user interest model from a generalized to a specific hierarchy, which can effectively differentiate the interest characteristics of different classes [17]. Ohtomo et al. argue that users' interests when reading news can be divided into two categories, short term interests and long-term interests, with short term interests tending to be related to the timeliness of popular information and changing rapidly, while longer term interests tend to reflect users' real interests [18]. In contrast, Chen's team used a multi-strategy machine to build long-term and short-term interest patterns, and through an in-depth analysis of this system, a new content-based fusion algorithm was proposed and designed [19]. To improve the efficiency of the recommendation model, Wang combined the recommended

content with a collaborative filtering algorithm to provide a specific model for the actual and potential hybrid algorithm, and experimental results showed that the knowledge resource-based recommendation system was effective in improving the usability of the collaborative filtering part [20].

From the research of many scholars, it can be seen that the current research of online English education platform is still in the stage of rapid development, and the development of educational resources and the efficiency of the promotion of educational recommendation ability still do not match. In order to further improve the efficiency of recommendation and the utilization of resources, a resource sharing platform based on Web technology is designed. The collaborative filtering algorithm and sequential pattern mining algorithm are organically combined to form a new hybrid recommendation model, which aims to contribute to the research of English education resource recommendation.

### III WEB TECHNOLOGY PRACTICE FOR ENGLISH ONLINE TEACHING RESOURCE SHARING PLATFORM

#### A. Design of a Web Service-based English Shared Resource Platform

The intelligent network mobile teaching platform can provide learners with rich teaching resources and a student-oriented teaching environment. However, due to the wide distribution of network teaching resources, the diverse and complex structure of network resources between different campuses and the inability of data resources to cross the restrictions of platforms and firewalls, the resources between campuses cannot be shared effectively, resulting in the waste of campus teaching resources [21]. In order to solve the above problems, the study combines both sides of the teaching body with the trial module and builds an English resource sharing platform, using resource replacement - access protocols - user information encryption and algorithmic assistance to optimize the design of the platform system.

Service Oriented Architecture (SOA) is a component model that connects different functional units of services in an application by defining clear interfaces and contracts. web services are an effective way to implement SOA by abstracting applications and resources in a unified form through a standardized approach to service usage and by supporting It supports the sharing and collaboration of teaching and learning resources in a distributed environment. Among the technologies related to web services, web services are often used to solve integration problems across web applications due to their loosely coupled nature. Compared to traditional technologies, it not only solves the problem of incompatibility between heterogeneous systems, but also allows any user to make changes to the mechanism without affecting the normal operation of the platform. SOAP uses hypertext transfer protocol as the carrier form to achieve the construction of SOAP message structure model under the construction of each SOAP sub-element to ensure the integrity of SOAP messages, and the XML model as the encoding method for the exchange of resources, and its specific exchange process is shown in Fig. 1. The specific exchange process is illustrated in Fig. 1.

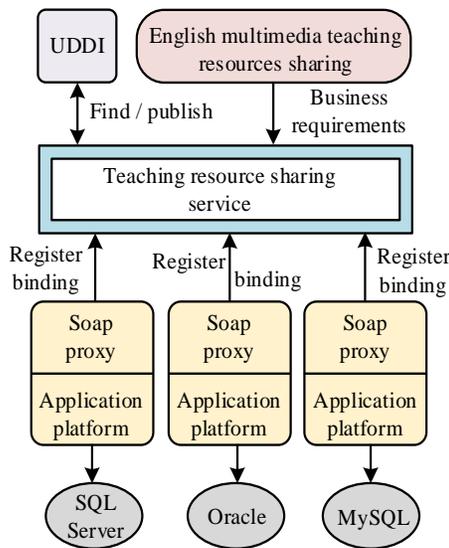

Fig.1. SOAP resource exchange process.

SOAP can effectively ensure that network service providers can realize the query of resource data, information update and sharing of different data types of each database. In order to further ensure the normal operation of the English multimedia resource platform and the confidentiality and security of user information data, the study is based on the MD5 information abstraction algorithm to accelerate the security of the platform information while ensuring high-quality services for users and realizing the optimal design of the platform security. The MD5 algorithm can effectively extend the length of the data and achieve a continuous distribution of bits at intervals of 512 times, thus forming a combination with regularity. Under the assumptions of the four MD5  $F(a,b,c)$ ,  $G(a,b,c)$ ,  $H(a,b,c)$ ,  $I(a,b,c)$  basis by bit can be expressed as eq. (1).

$$\begin{cases}
 F(a,b,c) = (a \& b) \mid ((\neg a) \& c) \\
 G(a,b,c) = (a \& c) \mid (b \& (\neg c)) \\
 H(a,b,c) = a \wedge b \wedge c \\
 I(a,b,c) = b \wedge (a \mid (\neg a))
 \end{cases}
 \tag{1}$$

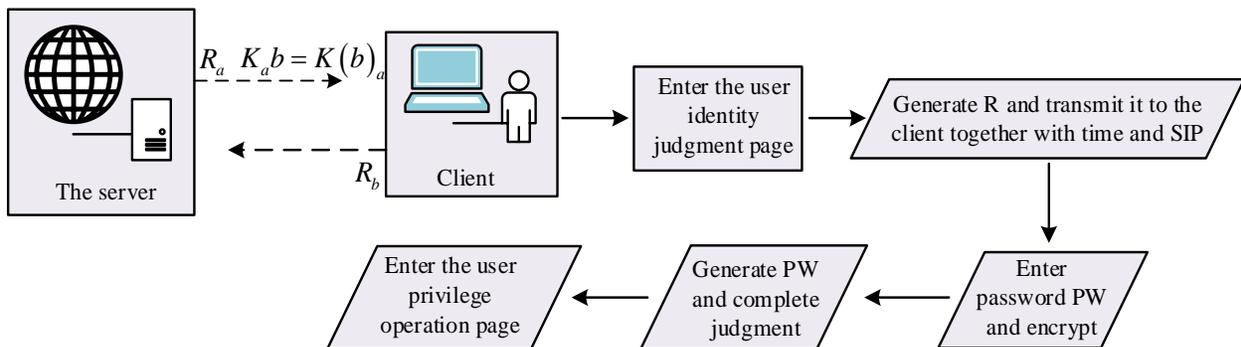

Fig.2. User identity verification process.

$Y_j$  The conversion of the grouping of  $(a,b,c)$  can be achieved in the form shown in eq. (2).

$$a_j = b + ((a + X(b,c,d) + Y_j + t_i) \lll s)
 \tag{2}$$

In the study the buffer corresponding to the MD5 algorithm is used as the link variable and the derivation of the message digest is implemented with the help of the buffer, which is represented as shown in equation (3). And after defining the four link variables, the weights corresponding to the variables are transformed with the help of equation (1) to realize the message data in order to achieve the confidentiality of the user information.

$$\begin{cases}
 A = 0X01234567 \\
 B = 0X89abcdef \\
 C = 0Xfecba98 \\
 D = 0X76543210
 \end{cases}
 \tag{3}$$

When the MD5 algorithm is used to verify user information on the resource sharing platform, it uses Ra random values to achieve circular encryption processing of the scheme, and increases the types and combinations of verification information data to reduce malicious attacks by illegal users and avoid leakage of user data, thus strengthening the overlay encryption of data, and its verification process is shown in Fig. 2.

When the information scheme is encrypted, in order to avoid the loss of resources under the platform due to the increased number of calibration repetitions, the server adds random values with immediate time characteristics to the string generation process by forming a completely new string from the random value R, the user password PW, the current time TIME and the address of the SIP connection protocol, as shown in eq. (4).

$$RA = R \mid TIME \mid SIP
 \tag{4}$$

The client also encrypts the plain text of the received password, as shown in eq. (5).

$$PW' = K(PW)
 \tag{5}$$

The server processes the generated sequence in depth using the MD5 algorithm to obtain the end-user's credentials and sends the MD data to the server, a process defined by eq. (6).

$$MD = MD5(R_a | PW') \quad (6)$$

The server application uses the MD5 algorithm to verify the encrypted text of the user's password and sends a confirmation message; the encrypted text is sent to the client and the passage of the user's credential information is used as a signal to achieve login. The research proposes a teaching resource platform that can effectively introduce SOAP into the construction of the platform to meet the demand characteristics of different users, on the basis of including the teaching sides module and the auditor module, and build a resource platform based on the cloud computing environment, whose overall structure as shown in Fig. 3.

As can be seen in Fig. 3, the software structure of the cloud computing environment as a platform for carrying content is divided into three layers: a data access layer, a business logic layer and a user performance layer. The data access layer enables the upload, audit and publication of learning materials and the download of matching resources with a list of completed learning materials, i.e. the resource download interface allows the setting of resource download links and binding them to the key values of the corresponding source files, providing users with an efficient resource download function. Finally, the audit resource fields and page call methods are retrieved by the teaching audit module to ensure that the resource platform can achieve good audit and coverage

of all learning resources and thus continuously enrich the types of teaching resources to meet the learning needs of students.

### B. Web Log-Based Online Learning Resource Recommendation Framework Design

As the amount of information carried on the Internet continues to grow, information referral methods have also flourished. In the vast amount of learning resources, it is difficult for learners to quickly find the information that meets their needs [22]. Therefore, the study proposes a hybrid recommendation algorithm based on the web-based learning platform logs by analyzing the logs of the above-mentioned web-based shared English learning platforms to uncover the characteristics of the resources and the preferences of users in the web environment. The hybrid recommendation algorithm combines a collaborative filtering algorithm and a sequential pattern mining algorithm in order to achieve a personalized recommendation model with real-time adaptability to the learning platform. The goal of collaborative filtering is to filter out data with similar characteristics from the database to form a single dataset, making the data as differentiated as possible between datasets based on different points of interest, while data belonging to the same dataset are as similar as possible. Assuming that each user in the learning platform for online educational resources  $X$  corresponds to a set of learning resources  $I_x$ , where the resource  $i \in I_x$ , which represents that the user has studied this resource  $i$ , has also been rated by the user, the user's scoring matrix for the resource is shown in Fig. 4(a).

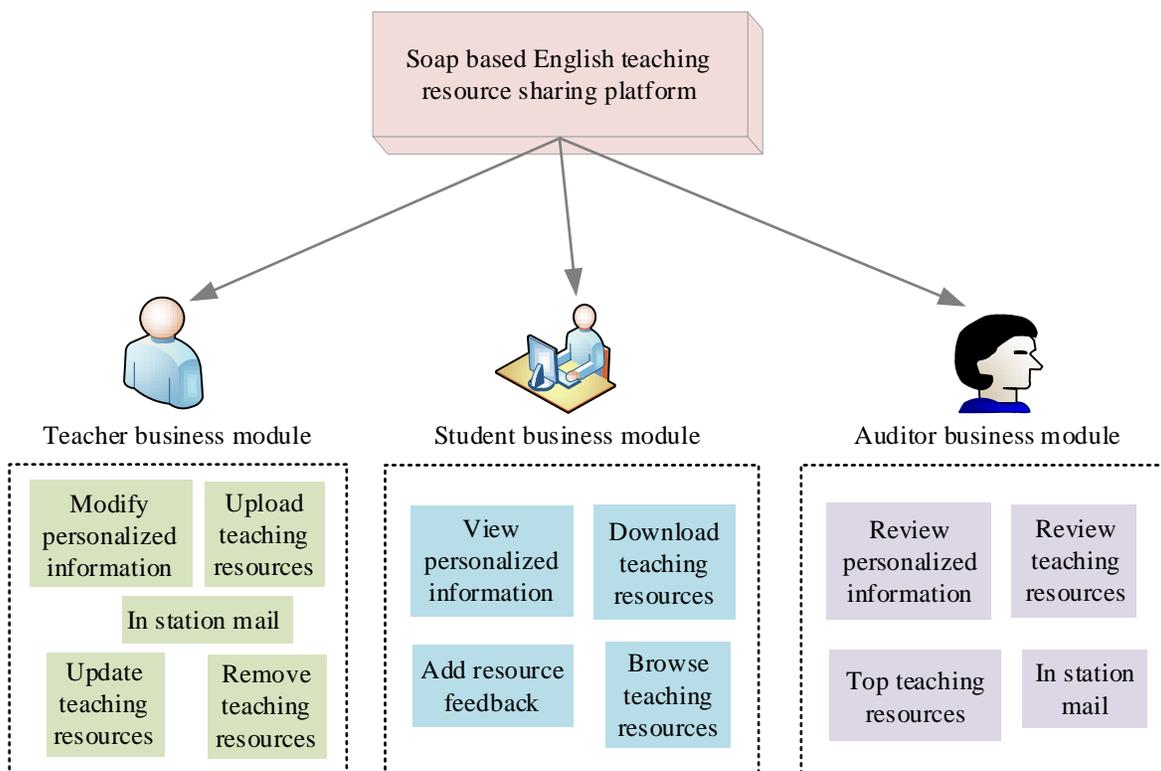

Fig.3. Schematic diagram of English multimedia teaching resource sharing platform based on SOAP.

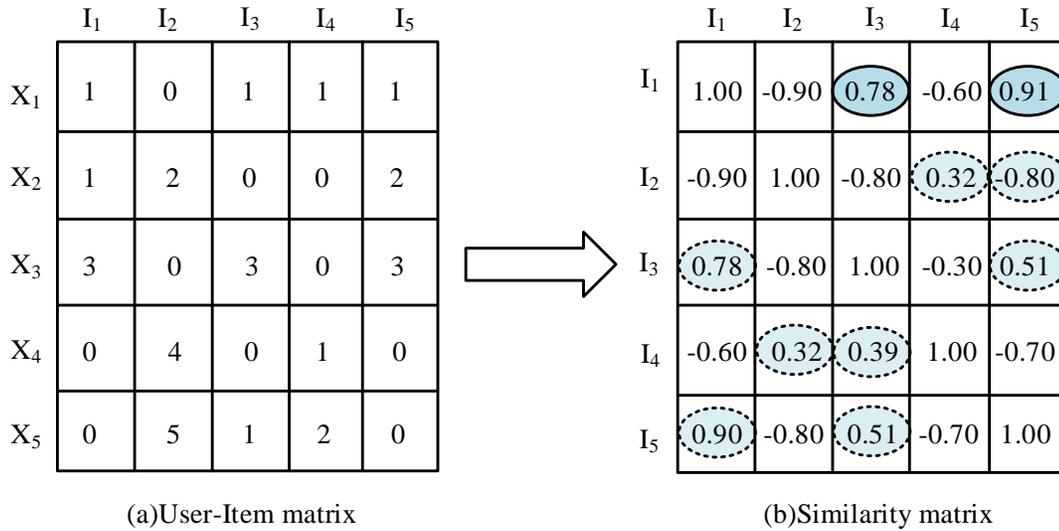

Fig.4. User resource rating and similarity matrix between resources.

Adjusted Cosine Similarity (ACS) is used to measure the similarity of two learning resources  $i$  and  $j$  as shown in eq. (7).

$$sim(i, j) = \frac{\sum (R_{x,i} - \bar{R}_x)(R_{x,j} - \bar{R}_x)}{\sqrt{\sum (R_{x,i} - \bar{R}_x)^2} \sqrt{\sum (R_{x,j} - \bar{R}_x)^2}} \quad (7)$$

In equation (7),  $R_{x,i}$  denotes the score rated by the user  $x$  for the resource  $i$ ,  $R_{x,j}$  denotes the score rated by the user  $x$  for the resource  $j$ , and  $\bar{R}$  is the total mean value of the ratings given to the resource by multiple users. From the user-resource rating matrix in Fig. 4(a), a similarity matrix between different resources can be derived, as shown in

Fig. 4(b). The additional  $k$  ( $k \leq n$ ) resources that have the highest possible similarity to the current resource are selected to form an ensemble of resources that are highly similar to the current resource. From equation (8), the possible values of the preferred resource  $i$  for each user  $x$  can be predicted.

$$P_{x,i} = \frac{\sum_{t \in N} (sim(i, t) * R_{x,t})}{\sum_{t \in N} (\|sim(i, t)\|)} \quad (8)$$

In equation (8),  $N$  represents a set of resources similar to the resource  $i$  and  $R_{x,t}$  is the rating given to the resource by its user  $x$ . The predicted result matrix is shown in Fig. 5(a), while Fig. 5(b) shows the set of resource suggestions that are likely to be preferred for the user.

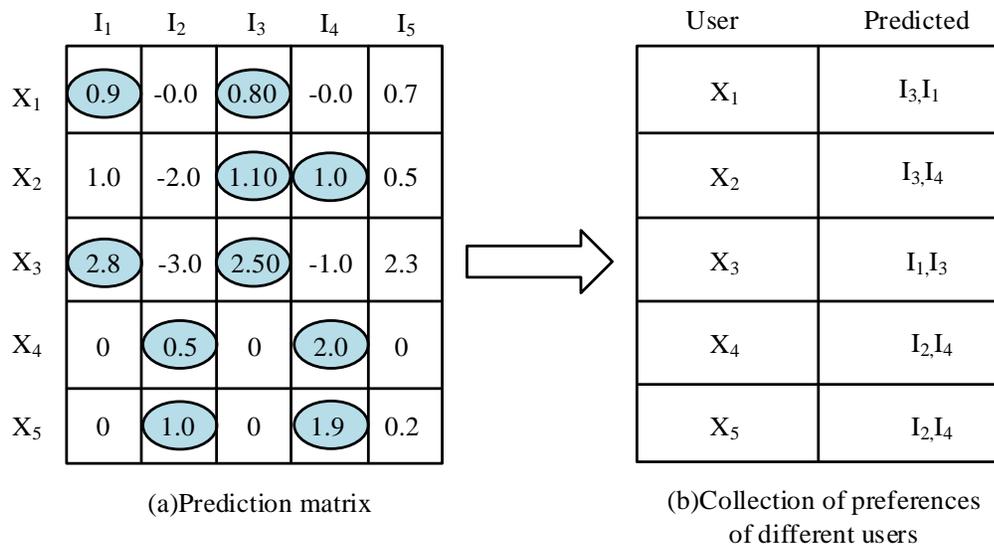

Fig.5. User prediction preference matrix.

The set of user-preferred resources generated by the collaborative filtering algorithm is obtained by similarity, and the order of these resource recommendations does not follow a specific learning path. Since the process of learning English is coherent, the list of recommended resources displayed in the learning platform should follow the learning path of the English subject. The study introduces a sequential pattern mining algorithm based on a collaborative filtering algorithm to arrange the list of English learning resources according to the learning order. In the web-based teaching platform, the key to the sequential pattern mining algorithm is to search for a series of resources that meet the least supported order of learning frequency on a specific set of input data sequences  $S$ , each list is a sequence of frequent learning resources, the specific algorithm flow is shown in Fig. 6.

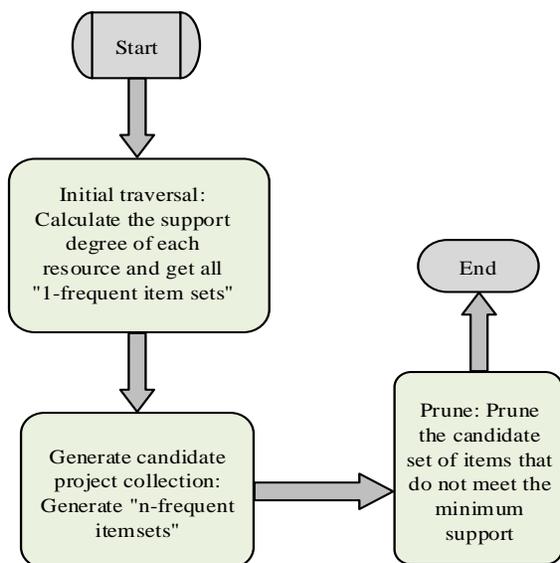

Fig.6. Flow chart of sequential pattern mining algorithm.

As can be seen from Fig. 6, the support degree of each resource is calculated during the initial search, and the set of all 1-frequency elements is obtained after the initial search, and the candidate set of n-frequency elements is generated from the set of n-1 ( $n > 1$ ) frequency elements. Finally, the candidate sets that do not meet the minimum support are removed by pruning branches. Since users may change their interest in learning

content over time when they are learning online, the user resource scores in the web logs do not objectively reflect the current user ratings and interests in the learning resources. The study introduces a damping function in the collaborative filtering algorithm to adjust the weight of learning resources rated by previous users, as shown in eq. (9).

$$Weight = \frac{2}{1 + e^{-(t-t_0)}} \quad (9)$$

In equation (9),  $t_0$  denotes the current time, and the closer the learning resource is to the current time, the higher weight is given to it, and the process of calculating the similarity between resources is also given a higher weight, when  $t \rightarrow t_0$ ,  $Weight \rightarrow 1$  and  $Value \rightarrow 1$ . Since the calculation of similarity between resources is performed when the user is offline, when calculating the relevance of n resources,  $O(n^2)$  space complexity is consumed to store the calculation results, increasing the space load and the efficiency of the recommendation algorithm decreases as the number of user visits increases. Therefore, the study selects only the most similar resources among the similar resources k as elements of the similar set in the computation process, which can greatly reduce the time complexity of the algorithm to a linear order of magnitude. In summary, the design of the study's proposed weblog-based online learning resource recommendation framework is shown in Fig. 7.

As can be seen in Fig. 7, offline pre-processing and filtering of user learning traces and resource records is performed to collect material that users may frequently access or want, and finally the merged resources are categorized according to the specific relationships between the different data to provide personalized services to users. And a tracking module is added to track whether users accept personalized recommendations from the platform as a way of tuning the data for future recommendations. To address the problem of new users with no learning history in online learning, the study groups and classifies new users based on the demographic information of users in the platform, and likewise groups and classifies new resources based on the resource topics in the resource database, thus solving the problem of cold processing in the design of the recommendation framework.

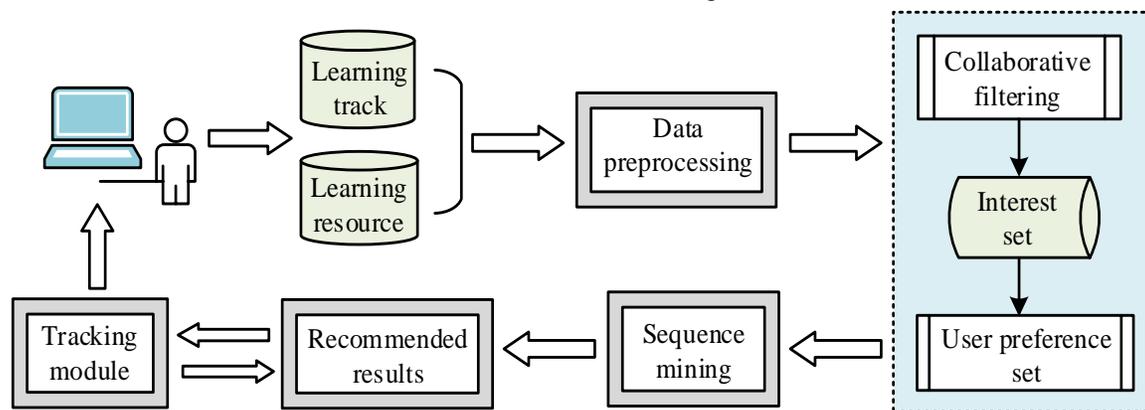

Fig.7. Web log-based recommendation framework for online learning resources.

#### IV SIMULATION TESTING OF THE ENGLISH SHARED RESOURCE PLATFORM AND THE PERFORMANCE OF PERSONALISED RECOMMENDATIONS

In order to demonstrate the reliable performance of the researched and developed universal platform for shared resources (denoted as Platform 1), the collaborative recommendation-based English teaching resource management platform proposed by Hu Ting scholars (denoted as Platform 2) and the blockchain-based virtual English teaching resource platform jointly designed by WANG P and QIAO S H.E (denoted as Platform 3) were used as experimental control, and the three platforms were used as a common platform for real English multimedia teaching materials on virtual hardware of the same scale and hardware standard. To make the experimental results more intuitive and to better prevent the problem of low variability of performance data due to the low concurrency of the system, the study selected 1200 sets of concurrent data with similar configuration parameters for testing. In addition, each test lasted around 3 minutes to fully account for the impact of the virtual environment and to protect the web hosts from high concurrent loads. The resource upload throughput results for each platform are shown in Fig. 8.

As can be seen from Fig. 8, as the concurrency continues to increase, the number of resource interactions handled by Platform 1 is higher than the other two benchmark platforms, and the curve changes less than the other two platforms. This indicates that the platform proposed in the study has a good load balancing capability in handling resource sharing requests, with each node of the platform handling user requests, which distributes the concurrency evenly to each node, allowing more resource requests to be handled. A graph of the response time results for each platform is shown in Fig. 9.

As can be seen in Fig. 9, the response times of the platforms created by the Institute are all lower than the response times of the benchmark platforms. Due to network congestion caused by concurrent transmissions, the response times of the platforms created by Platform 2 and Platform 3 increased dramatically, while failing to meet the requirements of a wide range of users, thus extending the response time of the shared resources. The results show that the platform designed in this study performs better, has better response speed and processing speed, can respond to users' daily access needs, and has strong load processing capacity.

To test the superior performance of the personalized recommendation model designed in this study, the experimental design and recommendations were compared using a weighted evaluation criterion, and the experimental results with different parameter settings were analyzed. Before evaluating the performance of the recommendation framework, the effect of the size of the parameter similarity set and the variation of the minimum support on the experimental results were determined. The study recommends resources to users based on similarity sets of different sizes and calculates the corresponding REM values for different minimum support cases, and the experimental results are shown in Fig. 10.

As can be seen from Fig. 10, the REM value decreases as the similarity set increases. However, the curve does not change significantly when the set of similarity goes from 7 to

10. Considering that the spatial complexity increases as the set of similarity increases, the study chose a similarity set size of 6 as the optimal value for subsequent experiments. The REM value changes as the minimum support increases. The REM value decreases when the minimum support is 0.1-0.5 and increases from 0.15 onwards. Therefore, in order to obtain more accurate recommendations, the minimum support was set to 0.15 in subsequent experiments. After the optimal parameter values were obtained, the parameters of each algorithm were set to the best value chosen and then tested. The results of the resource recommendations were categorized into three cases. The results of the collaborative filtering algorithm, the results of the generic sequence extraction algorithm, and the results obtained by a hybrid algorithm of collaborative filtering + sequence mining consisting of weighting, switching and merging, noting the above algorithms as Algorithm 1, Algorithm 2 and Algorithm 3, respectively. In the experiments, users pre-selected and ranked the topics of interest and their browsing. Their browsing history was also recorded by the platform. The resources of interest recommended by the platform to the users were then processed and calculated by different types of hybrid models and the correct recommendations were compared with the actual recommendations using the REM formula. The comparison of the recommendation results of each algorithm is shown in Fig. 11 and 12.

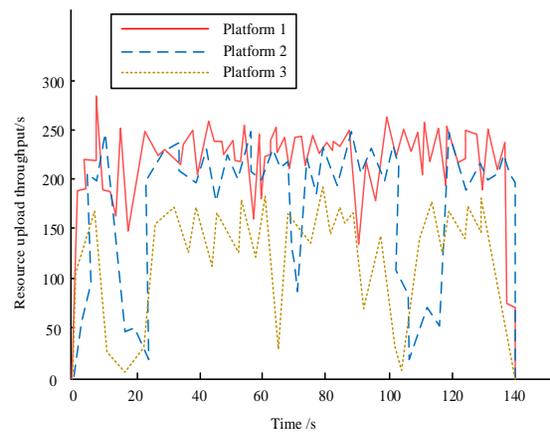

Fig.8. The upload throughput of English teaching resources on each platform.

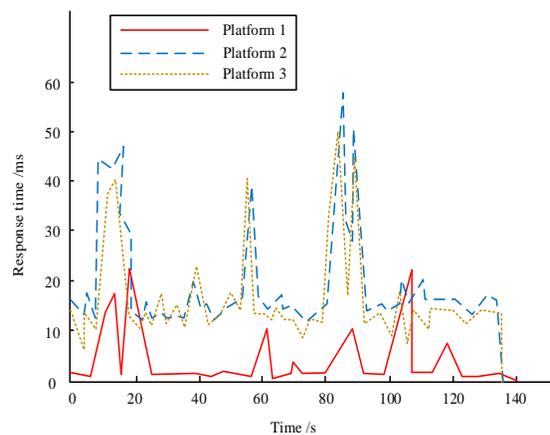

Fig.9. Response time by platform.

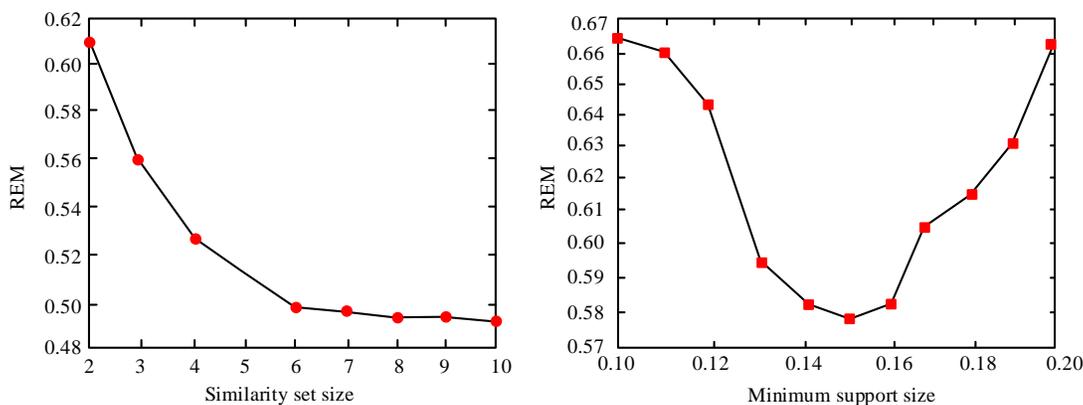

Fig.10. REM value variation under different similar set sizes and minimum support.

When the minimum support was chosen to be 0.15, the trend of REM changes as the size of the similar set expands from 2 to 10 as shown in Fig. 11. The simulation results show that as the similarity set expands, the REM values of all types of algorithms decrease, with the most obvious decreasing trend for the optimization algorithm 3 proposed in the study, and the REM value of algorithm 1 has almost no relationship with the size of the similarity set. The REM value of this hybrid algorithm model tends to be the smallest when the similarity set is greater than 6, which indicates that the algorithm is most accurate at a minimum support of 0.15, and the accuracy stabilizes when the similarity set size reaches 7.

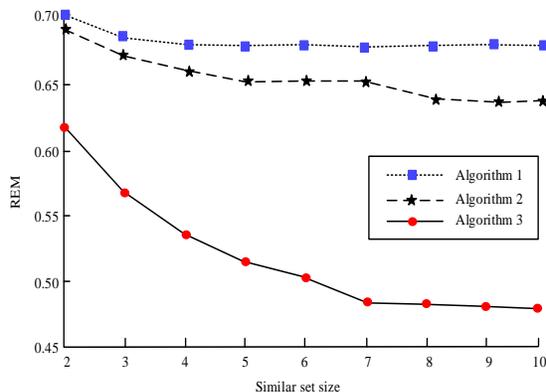

Fig.11. REM changes with the size of similar sets under specific support.

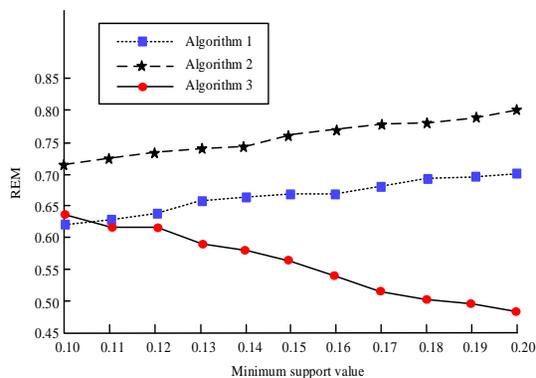

Fig.12. Change of REM with minimum support under specific similar set size.

When the size of the selected similarity set is 6, the trend of the REM values of each type of algorithm is shown in Fig. 12 as the minimum support degree increases from 0.1 to 0.2. The simulation results show that the larger the value of minimum support is taken, the gradually increasing REM value and decreasing accuracy of algorithms 1 and 2, while the continuous decreasing REM value and gradually increasing accuracy of the hybrid algorithm. In summary, the platform created by the research shows good performance in terms of resource transfer capability, achieving efficient teaching resource sharing in a short response time, and the proposed hybrid algorithm has the smallest REM value and the highest accuracy.

## V CONCLUSION

In response to the problems of scattered English online teaching resources that are difficult to achieve centralization and inefficient education resource recommendation, the study constructed an English online education resource sharing platform based on Web services. Simulation results show that the created platform performs well in terms of resource transfer capability and can achieve efficient teaching resource sharing in a short response time. The hybrid algorithm of collaborative filtering combined with sequence mining proposed in the study performs well in the validation of the recommendation algorithm. Compared with other algorithms, it has the smallest REM value and the highest accuracy rate. The simulation results prove that the English web-based educational resource sharing platform constructed by the study can perform the educational resource sharing task better and complete the English educational resource recommendation. There are also some shortcomings in this study; not enough user security authentication information is collected, and it is not effectively verified in the security module. It is expected that the in-depth research on this part will be strengthened in future research. In addition, the platform is not rich enough in features, and it is expected that more practical features will be added to the platform in the subsequent research to enhance the usefulness of the platform.

# A Study of Encryption for Multimedia Digital Audio Security

Xiaodong Zhou\*, Chao Wei, Xiaotang Shao

School of Literature-Journalism and Communication, Sanjiang University, Nanjing, Jiangsu 210012, China

**Abstract**—Driven by the development of multimedia, the encryption of multimedia digital audio has received more attention; however, cryptography-based encryption methods have many shortcomings in encryption of multimedia information, and new encryption methods are urgently needed. This paper briefly introduced cryptography and chaos theory, designed a chaos-based encryption algorithm that combined Logistic mapping and Sine mapping for confusion and used a Hopfield chaos neural network for diffusion, explained the encryption and decryption process of the algorithm, and tested the algorithm. It was found that the keys obtained by the proposed algorithm passed the SP800-22 test, and the correlation between the three encrypted audio and the original audio was 0.0261, -0.0536, and 0.0237, respectively, all of which were small, and the peak signal-to-noise ratio (PSNR) values were -0.348 dB, -7.645 dB, and -3.636 dB, respectively, which were significantly different from the original audio. The NSCR and UACI were also closer to the original values. The results prove that the proposed algorithm has good security and can encrypt the actual multimedia digital audio.

**Keywords**—Multimedia digital audio; chaotic theory; encryption; logistic mapping; sine mapping; security

## I. INTRODUCTION

The dissemination speed of multimedia information is increasingly accelerated with the development of computer technology [1]. Relying on the Internet, mobile terminals, etc., digital images, video, audio, and other multimedia information is generated and transmitted all the time, which facilitates people's communication and exchange and also brings new challenges to information security. Multimedia information is mostly transmitted and stored in public environment, and under the influence of network, it spreads faster and wider, and the danger of information leakage is also greater [2]. Encryption can effectively improve the security of multimedia information, so multimedia encryption has also become an important content [3]. At present, many methods have been applied in the encryption of texts and images; however, compared with them, audio has greater redundancy and higher relevance, so the traditional text and image encryption methods are not applicable to audio. Therefore, encryption for digital audio has become a common concern for researchers [4]. Singh et al. [5] compared the performance of dynamic advanced encryption standard (AES) and standard AES for audio encryption and analyzed the quality of the algorithms by histogram, correlation, etc. Babu et al. [6] converted audio data to image data, studied the encryption and decryption of audio using a fractional order hyperchaotic system, and verified the security of the system through analysis. Wang et al. [7] proposed an encryption

method using a chaotic system and deoxyribonucleic acid (DNA) coding and found that the method performed well in multichannel audio processing through comparative experiments on different types of audio. Zaid et al. [8] proposed two chaos-based permutation algorithms: Arnold cat mapping and Baker mapping. The experiments showed that both algorithms can provide reliable security, but in most cases, Arnold cat mapping performs better. At present, there are still many challenges in multimedia digital audio encryption, and the security of existing methods cannot meet such encryption needs yet. Therefore, in order to find out a more suitable encryption method for multimedia digital audio, this paper designed a chaos-based method and proved the reliability of the method through experiments. This work provides a new method for the research of multimedia digital audio encryption and also provides theoretical support for the in-depth research of multimedia information encryption. This paper first briefly introduces cryptography and chaos theory in Section II. It describes the encryption and decryption method based on Logistic mapping, Sine mapping, and Hopfield chaotic neural network designed in this paper. Section III presents the experiments on the proposed encryption and decryption method used to prove its security for multimedia digital audio encryption and decryption. Section IV is the conclusion section, which briefly summarizes and reflects on the research of this paper.

## II. CHAOS-BASED AUDIO ENCRYPTION ALGORITHM

### A. Cryptography and Chaos Theory

A simple password system generally consists of several components, as shown in Fig. 1.

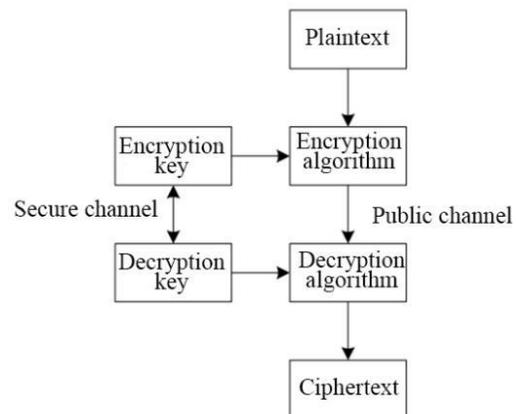

Fig. 1. A simple password system.

As shown in Fig. 1, the plaintext is the original message to be encrypted, written as  $M$ . The ciphertext is the encrypted message, written as  $C$ . It is assumed that there is an encryption algorithm  $E$ , then the encryption process is written as:  $E(M) = C$ . Let the decryption algorithm be  $D$ , then the decryption process is written as:  $D(C) = M$ .

For audio information with high redundancy and high correlation, traditional encryption algorithms, such as AES and DES [9], are unable to encrypt effectively. Chaos contains characteristics such as ergodic, unpredictable, and random, and it can be applied to encryption to get good results [10]. In the Devaney's definition of chaos [11], for mapping  $f$  in the metric space  $V$ , if it is chaotic, then the following conditions are satisfied:

- 1) There exists  $\delta > 0$ , for any  $\varepsilon > 0$  and  $x \in V$ , there exists  $y$  and natural number  $n$  in the  $\varepsilon$  neighbourhood of  $x$  such that  $d[f^n(x), f^n(y)] > \delta$ ;
- 2) For any open sets  $X$  and  $Y$  in  $V$ , there exists  $k > 0$  such that  $f^k(X) \cap Y \neq \emptyset$ ;
- 3) The periodic orbit of  $f$  is dense in  $V$ .

Chaos is usually determined using the Lyapunov exponential method [12]. In a one-dimensional chaotic system, there exists an orbit:  $x_0, x_1 = f(x_0), \dots, x_n = f(x_{n-1}), \dots$ . A perturbation  $\delta x_0$  is added to  $x_0$ . After  $n$ -step iterations, the resulting perturbation is written as:

$$\delta x_n = f'(x_{n-1})f'(x_{n-2}) \dots f'(x_0)\delta x_0. \quad (1)$$

The Lyapunov exponent is written as:

$$\Lambda = \lim_{\delta x_0 \rightarrow 0} \lim_{n \rightarrow \infty} \frac{1}{n} \log \left| \frac{\delta x_n}{\delta x_0} \right| = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} \log |f'(x_i)|. \quad (2)$$

When  $\lambda > 0$ , it means that the orbit is sensitive to the initial value, i.e., it is a chaotic orbit.

Classical chaotic systems include the following types.

1) Logistic mapping [13]:  $x_{r+1} = \mu x_r(1 - x_r)$ , where  $r$  is the number of iterations and  $\mu$  is the system bifurcation parameter,  $\mu \in (0,4)$ . When  $3.5699456 < \mu \leq 4$ , the system is in a chaotic state.

2) Henon mapping [14]:  $\begin{cases} x_{r+1} = -px_r + y_r + 1 \\ y_{r+1} = qx_r \end{cases}$ . When  $p = 1.76$  and  $q = 0.1$ , the system is in a chaotic state.

3) Sine mapping [15]:  $x_{r+1} = \mu \sin(\pi x_r)$ . When  $\mu \in [3.48, 4]$ , the system is in a chaotic state.

4) Lorenz chaotic system [16]:  $\begin{cases} x' = -\delta(x - y) \\ y' = -xz + \gamma x - y \\ z' = \alpha x - bz \end{cases}$ , where  $\delta, \gamma$ , and  $b$  are the system control parameters. When  $\delta = 10, \gamma = 28, b = 8/3$ , or  $\delta = 16, \gamma = 40, b = 4$ , the system is in a chaotic state.

### B. Audio Encryption Algorithm

One-dimensional chaotic mapping is simple in the chaotic system. In order to improve the security of chaotic encryption, this paper proposes an improved method, i.e., combining two one-dimensional chaotic mappings. Logistic mapping has the problem of uneven data distribution, and the same defect also

exists in the Sine mapping. Therefore, they are combined to obtain the Logistic-Sine-coupling mapping (LSCM), and the corresponding equation is:

$$x_{r+1} = (\mu x_r(1 - x_r) + (4 - \mu) \sin(\pi x_r) / 4) \bmod 1. \quad (3)$$

When  $\mu \in (3, 4]$ , the system is in a chaotic state.

With the continuous development of neural networks, their applications in fields such as artificial intelligence are becoming more and more widespread, and neural networks also carry the chaotic characteristics. Hopfield neural networks are enough to meet the requirements of cryptography and have good performance in encryption [17]. It is divided into two types, discrete and continuous. The discrete type is used in this paper, and its expression is:

$$x = -x_i + \sum_{i=1}^3 w_{ij} v_i, \quad (4)$$

$$v_i = \tanh(x_i) = \frac{e^{x_i} - e^{-x_i}}{e^{x_i} + e^{-x_i}}, \quad (5)$$

where  $w_{ij}$  is the weight matrix. The three-dimensional Hopfield neural network with high operational efficiency and a good chaotic state is called Hopfield chaotic neural network (HCNN), and the corresponding equation is:

$$\begin{cases} x'_1 = -x_1 + 2 \tanh(x_1) - \tanh(x_2) \\ x'_2 = -x_2 + 1.7 \tanh(x_1) + 1.7 \tanh(x_2) + 1.1 \tanh(x_3) \\ x'_3 = -x_3 - 2.5 \tanh(x_1) - 2.9 \tanh(x_2) + 0.56 \tanh(x_3) \end{cases} \quad (6)$$

In multimedia digital audio encryption and decryption, the LS mapping is used to perform confusion operation on audio, and then HCNN is used to generate diffusion sequence. First, the encryption process is as follows:

- 1) The original audios from the left and right channels are read and denoted as two sets of audio  $A (L \times 2)$ .
- 2) Hash operation is performed on the original audios to get hashed value  $h$ :  $h = \text{hash}(A, 'SHA - 512')$ .
- 3) The key generation process is as follows.  $\text{hex2dec}$  is a function that converts a hexadecimal hash code to a decimal number, and  $m$  is the number of iterations.

$$\begin{cases} x_{01} = \text{hex2dec}(h(1:25)) / (L \times 10^{24}) \\ x_{02} = \text{hex2dec}(h(26:50)) / (L \times 10^{24}) \\ x_{03} = \text{hex2dec}(h(51:75)) / (L \times 10^{24}) \\ x_{04} = \text{hex2dec}(h(76:100)) / (L \times 10^{24}) \\ x_{05} = \text{hex2dec}(h(101:125)) / (L \times 10^{24}) \\ m = 10000 + \text{hex2dec}(h(126:128)) \end{cases} \quad (7)$$

4) Initial values  $x_{01}$  and  $x_{02}$  are processed to obtain initial values  $x_1$  and  $\mu$  of LSCM:  $\begin{cases} x_1 = \text{mod}(x_{01}, 1) \\ \mu = \text{mod}(x_{02}, 1) \end{cases}$ , where  $\text{mod}$  is the modulo operation. Then, the LSCM is subjected to  $m$  preiteration to fully reach the chaotic state, and then it is iterated  $2L$  times to obtain the chaotic sequence:  $\begin{cases} X_1 = \{x_{11}, x_{12}, \dots, x_{1L}\} \\ X_2 = \{x_{21}, x_{22}, \dots, x_{2L}\} \end{cases}$

5) Random sequences  $X - H_1$  and  $X - H_2$  without repetition are generated based on  $X_1, X_2$ , and two arrays of natural numbers  $H_1 = \{1, 2, \dots, L\}$  and  $H_2 = \{1, 2, \dots, L\}$  to confuse audio A. Then,  $A'$ :  $\begin{cases} A'(1:L, 1) = A(X - H_1(1:L), 1) \\ A'(1:L, 2) = A(X - H_2(1:L), 2) \end{cases}$  is obtained.

6)  $x_{03}, x_{04}$ , and  $x_{05}$  are substituted into the three-dimensional HCNN to obtain three diffusion sequences:  $\begin{cases} Y_1 = \{y_{21}, y_{22}, \dots, y_{2L}\} \\ Y_2 = \{y_{31}, y_{32}, \dots, y_{3L}\} \\ Y_3 = \{y_{41}, y_{42}, \dots, y_{4L}\} \end{cases}$ .

7) Exclusive OR diffusion is performed to obtain encrypted speech  $C$ :  $\begin{cases} C_1(i) = bitXOR(B_1(i-1), Y_1(i)) \\ C_2(i) = bitXOR(B_2(i-1), Y_2(i)) \end{cases}$ , where  $bitXOR$  is the bitwise exclusive OR function and  $Y_1, Y_2$  and  $Y_3$  are the chaotic sequence obtained by HCNN.

8) To further improve the encryption performance,  $Y_1, Y_2$ , and  $Y_3$  are combined two by two for three times of diffusion to obtain the final encrypted speech and complete the encryption of the audio.

The decryption process of multimedia digital audio is as follows:

- 1) The encrypted audio is read.
- 2) Initial values are obtained using LSCM and HCNN in accordance with the same steps as encryption to get chaotic sequences  $X_1$  and  $X_2$  needed for decryption.
- 3)  $X_1$  and  $X_2$  are used to obtain decrypted diffusion sequences  $Y_1, Y_2$ , and  $Y_3$ .
- 4) The encryption process is reversed to perform decryption diffusion on the encrypted audio, followed by confusion. Finally, the decrypted audio is obtained.

### III. AUDIO ENCRYPTION ALGORITHM SECURITY ANALYSIS

Experiment was carried out in Windows 10 environment, 3.4GHz processor, and 4G RAM. In the chaotic system, the value of  $\mu$  was set as 3.707 and 3.808, respectively, and initial values  $x_{01} = 0.7, x_{02} = 0.8$ . The audios to be tested were all in wave format. The first three audios, named audio1.wav, audio2.wav, and audio3.wav, came from the Internet, and the other three audios came from THCHS-30 voice library [18]. Audios in THCHS-30 voice library were collected in a quite office environment at a sampling frequency of 16 kHz, the total duration of those audios was 30 hours, and the sampling size was 16 bits. Three audios were randomly selected from the library for experiments, named audio4.wav, audio5.wav, and audio6.wav. Taking audio1.wav as an example, the result of encryption and decryption using the proposed method is shown in Fig. 2.

Fig. 2 shows the original audio waveform of audio1.wav, and Fig. 3 shows the audio waveform obtained after audio1.wav was encrypted. It was found from the comparison between Fig. 2 and 3 that the encrypted audio did not have similarities with the original audio and was not associated with the original audio, which showed that the audio encryption method was effective and could encrypt the audio well. Fig. 4 shows the audio waveform obtained after decrypting the encrypted audio. The comparison between Fig. 2 and 4 showed that the correct original audio was obtained after decrypting

using the proposed method, which proved the usability of the method.

First, the randomness of the key was tested using 15 items in the SP800-22 test package from National Institute of Standards and Technology (NIST) test, and the randomness was judged by the P value. The higher the P value, the stronger is the randomness. The results of the key test are displayed in Table I.

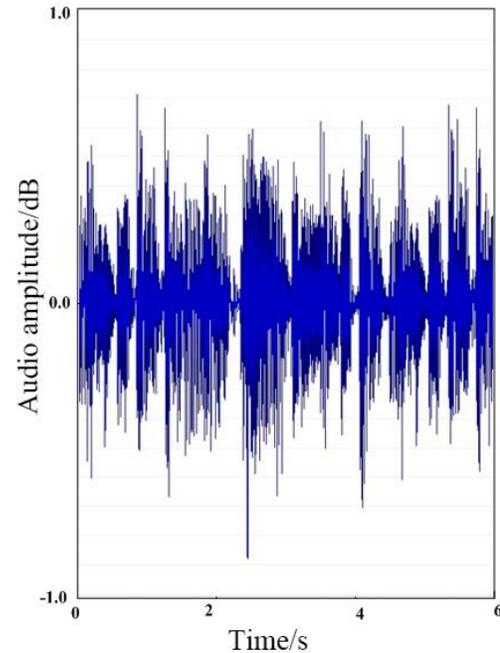

Fig. 2. Original audio.

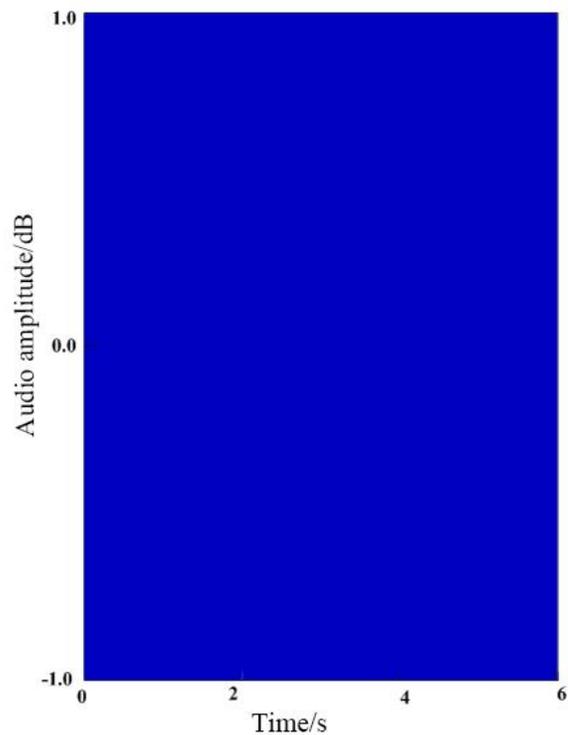

Fig. 3. Encrypted audio.

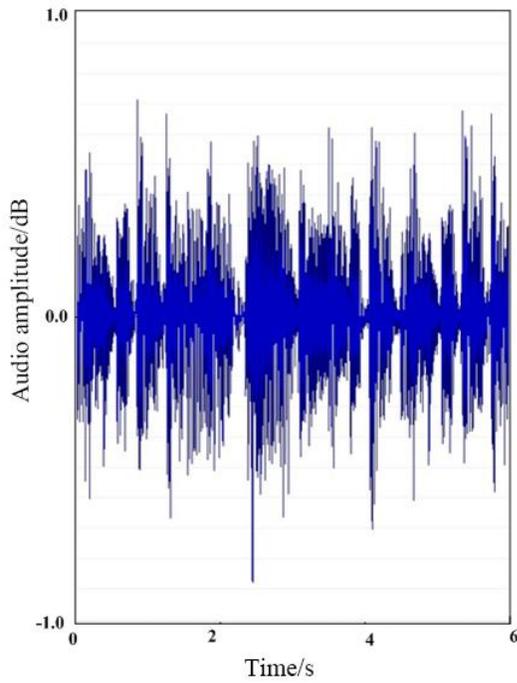

Fig. 4. Decrypted audio.

TABLE I. SP800-22 TEST RESULTS

Statistical test	P value	Result
Frequency	0.6788	Pass
Block Frequency	0.4795	Pass
Cumulative Sums	0.0945	Pass
Runs	0.3152	Pass
Longest Run	0.0528	Pass
Rank	0.7958	Pass
FFT	0.5746	Pass
Non Overlapping Template	0.9954	Pass
Overlapping Template	0.9925	Pass
Universal	0.1452	Pass
Approximate Entropy	0.9258	Pass
Random Excursions	0.6521	Pass
Random Excursions Variant	0.9654	Pass
Serial	0.4215	Pass
Linear Complexity	0.8752	Pass

It was seen from Table I that the keys generated using the proposed method could pass the SP800-22 test, and the P values were all greater than 0.01, indicating that the keys had good randomness and were suitable for encrypting multimedia digital audio.

The correlation coefficient reflects the correlation between two data. If there is a small correlation coefficient between the encrypted audio and the plaintext audio, it means the less similarity between the plaintext and the ciphertext. The correlation coefficient is calculated as follows:

$$r = \frac{\sum_{i=1}^n (A(i) - \bar{A})(B(i) - \bar{B})}{\sqrt{\sum_{i=1}^n (A(i) - \bar{A})^2 \sum_{i=1}^n (B(i) - \bar{B})^2}} \quad (8)$$

where  $\bar{A}$  and  $\bar{B}$  are the mean values of A and B. The correlation coefficient of the audio before and after the encryption by the proposed method was calculated, and the results were compared with Mohamed's method [19], as shown in Fig. 5.

It was observed in Fig. 5 that the correlation between the six encrypted test audios and the original audio was small, and the coefficients were 0.0261, -0.0536, 0.0237, 0.0227, -0.0577, and 0.0219, respectively. Compared with Mohamed's method [19], the audio correlation before and after encryption by the method proposed in this paper was smaller, indicating that the similarity between the ciphertext and the plaintext was lower, i.e., the method was safe.

The peak signal-to-noise ratio (PSNR) reflects the quality of signal compression. The larger the value of PSNR, the better is the quality of signal compression, and the closer to the original audio. Conversely, if the PSNR value of the encrypted audio is smaller, it means that it is more different from the original audio. The PSNR calculation formula is:

$$PSNR = 10 \log_{10} \left( \frac{\max A}{\sqrt{MSE}} \right)^2 \quad (9)$$

$$MSE = \frac{1}{M \times N} \sum_{i,j} (A(i,j) - B(i,j))^2 \quad (10)$$

where M and N are the width and height of the audio, A and B are the original and encrypted audio. The PSNR obtained by the method proposed in this paper was compared with the results in Tamimi's study [20] and Liu's study [21], as shown in Fig. 6.

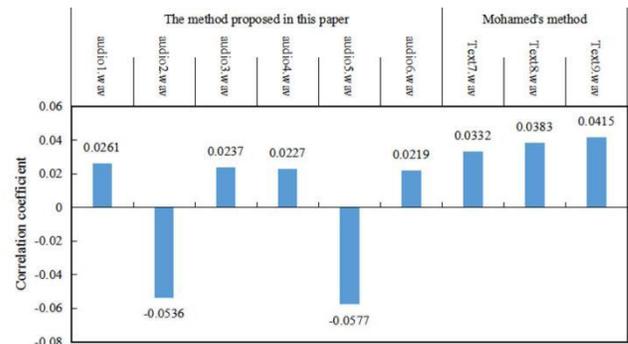

Fig. 5. Comparison of correlation coefficients before and after encryption.

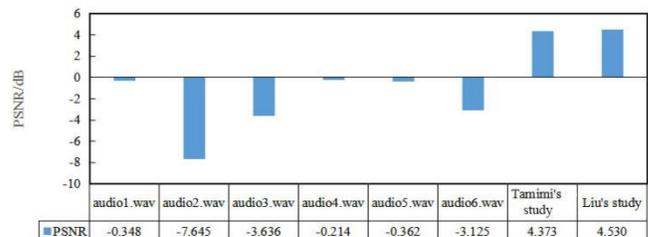

Fig. 6. Comparison of PSNR.

It was observed in Fig. 6 that the PSNR of the six audios were -0.348 dB, -7.645 dB, and -3.636 dB, which were small, and the PSNR was 4.373 dB in Tamimi's study [20] and 4.530 dB in Liu's study [21]. The PSNR values obtained in this paper were smaller; indicating that the audios encrypted by the method proposed in this paper had higher security and was more resistant to attacks.

Finally, the performance of this method against differential attacks was analyzed based on the indexes of the number of samples changes rate (NSCR) and the uniform average change intensity (UACI). The following equations are:

$$NSCR = \frac{\sum_{i=1}^L |Sign(B(i)-B'(i))|}{L} \times 100\%, \quad (11)$$

$$UACI = \frac{1}{L} \sum_{i=1}^L \frac{|B(i)-B'(i)|}{2^{8-1}} \times 100\%, \quad (12)$$

where  $B(i)$  is the encrypted audio,  $B'(i)$  is the encrypted audio with one original audio sampling data randomly changed, and  $Sign$  is the sign function. When the audio signal was 8 bit, the ideal values of NSCR and UACI were 100% and 33.33%, respectively. The average values were taken after several tests and compared with the results in Soliman's study [22] and Shah's study [23], and the results are shown in Fig. 7.

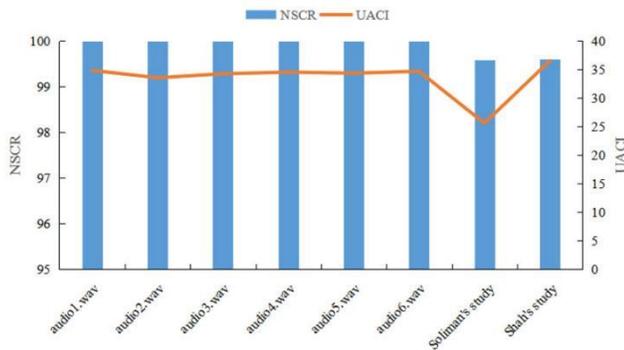

Fig. 7. Comparison of NSCR and UACI.

It was observed in Fig. 7 that compared with Soliman's study [22] and Shah's study [23], the NSCR obtained by the proposed method was always above 99.99%, which was closer to the ideal value (100%), and the UACI obtained by the proposed method was 34.8542%, 33.5628%, 34.2587%, 34.5515%, 34.3637%, and 34.6987%, which was closer to the ideal value (33.33%). These results verified the performance of the chaos-based audio encryption method in resisting differential attacks.

It was concluded from the above experimental results that the method proposed in this paper had a good encryption and decryption performance for multimedia digital audio, the encrypted audio files were not similar to the original files, and the original audio was well recovered after decryption. From the security point of view, the key obtained by the method had good randomness and passed the SP800-22 test. Then, from the comparison of different indicators, the experiments on six different audios revealed that the correlation between the audio before encryption and after decryption obtained by the method was very small, and the PSNR was also significantly smaller compared with the results in other literature, suggesting good

resistance to attacks. The experimental results prove the superiority of the method for multimedia digital audio encryption and the reliability of the encryption method combining different chaos methods and further verify the usability of chaos theory for multimedia information encryption.

#### IV. CONCLUSION

This paper designed a chaos-based encryption method for the encryption of multimedia digital audio, combined LSCM with HCNN to realize the encryption of digital audio, and analyzed its security. It was found that the key obtained by the proposed method could pass the SP800-22 test, with good randomness, and the encrypted audio had less correlation with the original audio (below 0.03), smaller PSNR value, above 99.99% NSCR value, its UACI was closer to the ideal value (33.33 %), and its resistance to differential attacks was strong. The method can be further applied in practical multimedia digital audio encryption. However, there are also some shortcomings in this paper, such as the small scale of experimental data and no practical application. In future research, further studies can be conducted in hardware implementation and encryption system design to understand the operability of the method in a practical environment.

# Digital Twins for Smart Home Gadget Threat Prediction using Deep Convolution Neural Network

Mrs. Valluri Padmapriya, Dr. Muktevi Srivenkatesh

Department of Computer Science-GITAM School of Science, GITAM Deemed to be University,  
Visakhapatnam, Andhra Pradesh, India

**Abstract**—Digital twin is one of the most important innovations in the Internet of Things (IoT) era and business disruption. Digital twins are a growing technology that bridges the gap between the real and the digital. Home automation in the IoT refers to the practice of automatically managing and monitoring smart home electronics by use of a variety of control system methods. The geysers, refrigerators, fans, lighting, fire alarms, kitchen timers, and other electrical and electronic items in the home can all be managed and monitored with the help of a variety of control methods. Digital twins replicate the physical machine in real time and produce data, such as asset degradation, product performance level that may be used by the predictive maintenance algorithm to identify the product functionality levels. The purpose of this research is to design the framework of Digital Twin using machine learning and state estimation algorithms model to assess and predict home appliances based on the probability rate of smart home system gadgets functionality. The main goal of this research is to create a digital twin for smart home gadgets that are used to monitor the health status of these devices for increasing the life time and to reduce maintenance costs. This research presents a Deep Convolution Neural Network based Logistic Regression Model with Digital Twins (DCNN-LR-DT) for accurate prediction of smart home gadget functionality levels and to predict the threats in advance. The proposed model is compared with the traditional models and the results represent that the proposed model performance is better than traditional models.

**Keywords**—Digital twins; deep learning; convolution neural network; logistic regression; internet of things; smart home; IoT gadget functionality; threat prediction

## I. INTRODUCTION

Modern industry and the country's economy depend critically on Industrial revolution 4.0 and smart manufacturing. Industry 4.0 intends to create a global networked infrastructure that addresses compatibility and interoperability problems within and between all levels of automated systems and factories, enhancing the agility and flexibility of manufacturing methods [1]. Advanced robotics, which acts as an agent acting that appears in every area of production lines, is equally essential to smart factory. Digital Twin (DT) is attracted increasing scientific attention as a result of the extensive research and development on Industry 4.0 and Artificial Intelligence (AI) [2]. The network and data serve as the foundation of DT as a digital representation of a physical

object, the algorithm and modeling serve as the core, and the application and service serve as the application. The expenses of manufacturing businesses rise as a result, and at the same time, their organizational structures and operational procedures face enormous difficulties [3]. In light of this, AI-powered DT technology is anticipated to adapt conventional model-based techniques to changing boundary conditions and offer a demand-oriented, real-time competent evaluation basis to effectively assist decision-making in multi-objective challenges [4]. Numerous studies have already discussed and characterized DT from the standpoint of broader concepts and technology, as well as some sectors, without a specific focus on AI, such as product design, modelling and simulation, and problem diagnosis and prognostics [5]. Various engineering implementation scenarios pose unique problems [6]. The systematic and thorough integration of domain-specific knowledge is much more crucial for the foundation of DT and AI. In the context of the environment and circular economy, there is currently still a dearth of thorough industry-focused reviews of AI and DT technology.

The National Aerospace and Space Administration describes the idea of DT as an act involving, multiscale, statistical simulation that makes use of physical models, sensor feeds, fleet histories, etc. to mimic the twin's daily activities [7]. Any corporation can gain from having electronic information, and even an individual may value their data to the point that they simply cannot risk losing it. In recent years, the availability of low-cost sensors and open-source middle-ware software has opened up interesting research areas in the robotics field. In particular, the next generation of simulation models called DT [8], which represents a continuous virtual replica of physical systems, has gained increasing attention. It can be used to create a simulation of a smart home including assistive/service robots and human users. It has applications in the optimization of robots and smart home settings [9]. For example, finding the optimal number and configuration of sensors especially when new robots or users are introduced [10]. As another example, monitoring in real-time, further analysis and learning of edge cases and rare situations in DT for the safety of human users, e.g., by pushing those events from simulation to real-world and vice-versa. In practice, such optimization should be carried out over a variety of houses and users. The digital twin can be created in all scenarios [11]. The digital model and process is shown in Fig. 1.

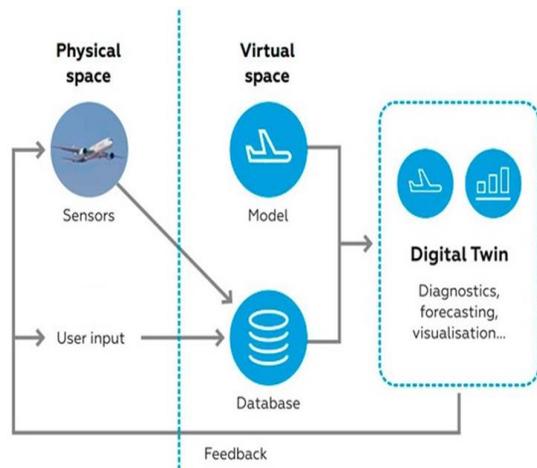

Fig. 1. Digital twin.

With the mounting deployments of the Internet of Things (IoT) systems, the significance of the concept of a digital illustration of physical things has gathered trivial interest in the recent years. Digital Twin is basically a living model of the physical skill or system, which will repeatedly adapt to changes in the milieu or operations and bring the best business outcome. It can also be rapidly, quickly and easily scaled for quick deployment for the other, similar applications [12]. Building a smart home is often an essence for deploying all the sensors, software, network, and physical assets. The data collected and analysis results are shared to the digital twin and can be monitored by an individual [13]. These digital proxies are expected to be built from the domain knowledge of subject matter experts as well as the real-time data collected from the devices [14]. Digital twin is the skill to craft a virtual depiction of the physical elements and the dynamics of how an IoT device operates and device act in response right through its lifecycle [15].

The IoT was motivating the design of digital twins so businesses could take action on data that crosses both the physical and digital worlds. Being able to see it, before DT is build, it has been a long-time aspiration for the manufacturing industry [16]. The technology called Digital Twins which makes it a reality. It allows users to understand how a product would perform before you build. Today's proliferation of sensors, faster computing power and capturing data has grown exponentially [17]. The current acceleration in the usage of digital twins is mostly possible with the Internet of Things and the minor costs of technologies that boosted both IoT and digital twin. This illustrates how a digital twin route sensor generated data from an instrumented advantage and influences replication to forecast malfunction and make out in capabilities [18]. This makes possible an industry to take appropriate action to straight away to correct troubles and optimize the asset's recital [19]. Digital Twin is also called as a replica of an object; it's more than a blueprint or a schematic, virtual twins, shadows, and device virtualization. The process of digital twin creation is shown in Fig. 2.

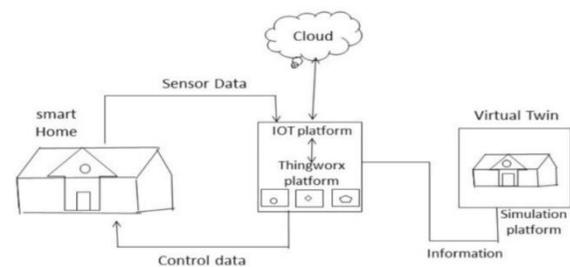

Fig. 2. Digital twin creation.

One of the most important technologies in the Fourth Industrial Revolution is the digital twin, a digital representation of a physical product, service, or production process. Because of the integration of the digital and physical realms, users may now proactively prevent issues through the study of data and the close observation of systems [20]. A digital twin design and system built on a common data standard are described in this research. It describes how to use edge devices, business intelligence, and realistic visualization to create a digital twin for integrated control monitoring [21]. The system's automated generation of digital twin models enables constant communication among field engineers for data collection, designers for modeling, and design engineers for layout changes [22]. As a result of this method, participants can better concentrate on their specific responsibilities in the creation of digital twins.

## II. LITERATURE SURVEY

Due to its critical role in maintaining the availability of several crucial services, the development of safety monitoring and management systems for Critical Infrastructures has attracted increasing attention and concern over the past few years. Due to the unique traits of these systems and the operators' innate reluctance to acts that can cause downtime, this task is difficult. Digital twins can offer a reliable environment for information security or evaluation of prospective mitigation methods to be used in response to certain conditions since they are accurate virtual replicas of physical items or processes. However, one's on-premises implementation can be costly, implying a sizeable CAPEX for whom the return will currently rely on the capacity to intend and deploy an appropriate support infrastructure as well as implement efficient and scalable collection of data and processing mechanisms able to make use of the resources acquired. Sousa et al. [2] proposed an off-premises method for designing and deploying Digital Twins to protect critical infrastructures. In order to help the creation and testing of Machine Learning models to counteract security concerns like Denial-of-Service attacks, such Digital Twins are created utilizing real-time, highly accurate duplicates of Programming Logic Controllers. A significant portion of the predicted CAPEX for the on-premises model was converted like on, pay-as-you-go OPEX through the ELEGANT validation approach, which benefited from the functionality of the Fed4Fire federalized testbeds.

The World Wide Web's structure is comparable to that of the Digital Twin Web, which is made up of conceptual digital twins transmitted through Digital Twin Servers and documented as digital twin findings analyzed by Autiosalo et al. [3]. First before Digital Twin Web can be utilized effectively, standards must be developed; having an easily available server implementation that can encourage the creation of those standards. A Digital Twin Web host built on Git that is open-source and user-friendly is called Twin base. Twin base maintains digital twin papers in a repository, updates them using Git workflows, and then makes them accessible to users through a static web server. Users can view these documents using a library or a standard web browser. The browser interface allows for the free initialization of new server instances. Twin base was created using GitHub, Pages, and Actions, but it can be modified to accommodate different hosting options or self-hosting. To enable the development of derived and alternative server implementations, the author defined Twin base's fundamental architecture. The author offered the idea of a digital twin identity registry in order to answer the need for permanent, openly available, and transferable IDs for the Digital Twin Web. According to performance measurements, depending on the identification registry, the median reaction times for obtaining a digital twin file from Twin base was around 0.4 and 1.2 seconds.

Innovative solutions are required to assure the electrical system's resilience due to the rising frequency of cyberattacks on it. In order to establish a useful framework that can react to various threats on a collection of interconnected micro grids, this work leverages on the development in the Internet of Everything. In order to assure the cyber-physical system's efficient functioning, Saad et al. [6] offered a IoT-based DT of the system that communicates with the control system. The power cyber-physical and DT delivery over the IoT cloud is mathematically formulated. The proposed cybersecurity paradigm, in contrast to others in the literature, can lessen both solitary and group threats. The security protections are put into place utilising cloud computing, and the architecture was evaluated on a distributed system of control. Single-board computers are employed to implement the physical controllers.

In this study, Quan et al. [7] discussed the problem of binary classification for mixed static and dynamic data. The dynamic factors in the novel type of information vary over time and are captured at specific time points, like mixed numerical and categorical data. Due to the significant correlation in each variable caused by this discrete form, more shape and vary over time must be studied, necessitating the urgent need for an effective fusion model. To meet the challenge, the author suggested a novel fusion approach in which the separate findings from variables are converted to function  $f$  via grounds expansion, combined with barely changed via a combination logistic regression model and then the key features are chosen using a group grappling hook penalty term.

The goodness-of-fit criterion has been extensively utilised in the past to assess overall calibration of forecasts. The test aids in determining the significance of inaccurate predictions, which could point to model flaws. As data is created sequentially, the goodness-of-fit test, which is typically

conducted at the conclusion of data collection, may not be able to identify changes in the woman's fit. In order to assess the goodness-of-fit at every time point and give an early warning if major changes take place during model fitting, Qiu et al. [8] looked at the possibilities for employing a new online gawd test.

Sharing data and information from various sources helps scientific partnerships, but maintaining privacy is a top priority. Concern over a possible privacy data leak is growing among researchers, sponsors, and the general public. In order to safeguard the storage and processing for sensitive information in a distributed setting, cutting-edge security techniques have been created. They do not, however, offer any security against information leaking from data analysis results performed by Kim et al. [11]. Studies on differential privacy, a cutting-edge paradigm for privacy protection, have addressed this issue with intriguing findings, but most of them need not be applicable to distributed scenarios. Combining privacy and security procedures is a logical answer to the issue, although simplistic approaches could produce subpar analytical results.

A digital replica of the actual system called as a DT is revolutionizing the way of life. Cyber-Physical Systems (CPS), the IoT, Big Data, Edge-Computing (EC), Artificial-Intelligence (AI), Machine Learning (ML), and other technologies were combined to create DT. DTs are created to improve a variety of applications in business, medicine, smart buildings, smart homes, etc. It's still in the early stages of development. By merging the substantial knowledge on technologies used in the development of DT in industrial and healthcare, this study fills in the gaps analyzed by Khan et al. [12]. The study of DT characteristics, tools and communication technologies used to create DT models, standards and reference models, as well as the researcher's current work in smart factory as well as healthcare, are the main topics of the paper.

A comprehensive range of sensors and actuators, as well as revealing abilities with high-level interface for realistic human contact, enable Pepper, a humanoid robot, to exhibit body language, perceive, and interact with its surrounding environment. In this paper, Cascone et al. [13] described experiences centered on the connection of the digital-twin with both the copies of the smart products in a smart home in order to present the creation of V-Pepper, the Pepper digital replica. Although Pepper robot has hands and arms, its motors and actuator are not strong enough to sustain lengthy testing sessions and training program to learn how to securely handle objects. Here, the metaphor of the digital twin is essential. Machine learning processes can be smoothly transferred to/from the digital-twin with a significant speedup, keeping the physical robot from degrading, by creating a virtual and trustworthy clone of the robot. The given case study provides an inspiration for ambient-assisted functioning in elder care as a practical application. The experience, along with the entire development and design process, has shown that VPepper and the smart cities offer intriguing potential for the physical correctness of the simulation and the accessibility of machine learning tools that may be translated and utilised for actual settings.

### III. PROPOSED METHOD

Home automation includes the use of smart home applications. Instead of just saving power by turning things on and off, smart homes do a lot more [23]. Using these programs gives the impression that users are physically holding and manipulating the virtual things. Users explore using it for things like locking doors, turning off lights and fans, and even controlling the temperature in the fridge [24]. Depending on what users find most useful in the future, users can add on to the functionality of smart homes, transforming the surroundings into a more pleasant and stress-free place to live [25]. The safety and security of useful devices is paramount, and an automated system may help users feel at ease by alerting when to do things allowing users to control who has access to smart devices [26]. Many people find it tedious to constantly check their home gadgets about their working conditions and alerting users about the upcoming issues for hardware devices about their functionality [27].

The advent of digital twin technology can be traced to the development of both virtual technology and data collecting technology [28]. A digital twin is an identical copy of a physical object or person that exists in the real world. The connection and its digital counterpart have multiple possible implementations. Production management, manufacturing, healthcare, smart cities, and other fields all rely heavily on digital technology [29]. Currently, the primary focus of digital twin development is on optimising industrial production. Now that more data can be acquired because to advancements in communication and digitalization technologies, it's time to figure out how to put all that knowledge to good use. As a result, there is a lot of interest in, and momentum behind, the concept of digital twin. All physical entities, including humans, can have their functions monitored, understood, and optimised with the help of digital twins, which also provide constant feedback to enhance quality of life [30]. The ideal way to define a digital twin is as the seamless exchange of information between a real world machine and its digital counterpart. This research introduces the concept of a Digital Twin and explains how it can be applied in various house hold settings as well as the Internet of Things network for better functionality with extended lifetime.

In order to visualize the plans for the twin home, it is necessary to double-check that the planned physical system has successfully received data from sensors, stored it in a database, and run any necessary analytical procedures. An ecosystem was proposed to facilitate the interconnection of IoT devices and sensors, the exposition of the worth of IoT data, the creation of enterprise-level devices, and the authorization of end-users. As the go-between for the sensor and the digital information, and also as the home simulation model, a deep learning model is adopted. The digital duplicate was purpose-built to demonstrate its worth. To begin, a physical assertion is built into smart objects which use sensors to gather information on their current status, work environment, or location. All of the data collected by the sensors is transferred to a central system to be analyzed. This information is analysed in light of existing company metrics and other relevant context details.

Environmental sensors monitor conditions and trigger responses according to those readings in order to cut down on power use and also raise alerts if any prior repair is required. Data collected by sensors revealed the extent to which resources were utilized. The proposed model framework is shown in Fig. 3.

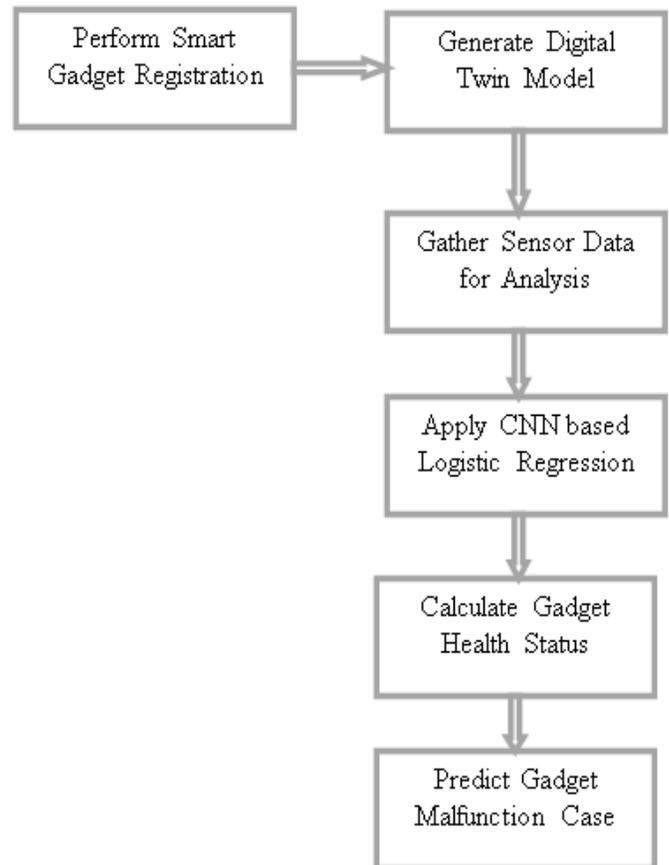

Fig. 3. Proposed model framework.

Digital twin concepts are used to outline a three-stage process for designing a smart home system. Plan, Construct, and Run. The process of making a Digital Copy to begin, a modelling software to produce a digital twin is used. A Digital Twin can be made in a few hours on a computer. Use software to make a virtual model of a Smart Home's infrastructure before constructing the real thing. The software we have here allows us to create a working model of the house. Optimizing device or system performance, reducing unscheduled downtime, and allowing engineers to digitally test solutions before physically repairing something are all possible with digital twins created in this research. The stage of design is critical. Using the IoT platform, the home was equipped with sensors, controllers, and actuators that are linked to a data acquisition component that takes data samples and provides insightful analytical results. This research presents a Deep Convolution Neural Network based Logistic Regression Model with Digital Twins (DCNN-LR-DT) for accurate prediction of smart home gadget functionality levels and to predict the threats in advance.

Algorithm DCNN-LR-DT

**Step1:**

Initially perform the smart gadget registration in the smart home for monitoring the devices performance. The smart gadget registration helps in creating a digital twin with a identity and the process of registration is performed in eq.1.

$$SGD[L] = \sum_{d=1}^N getGDaddr(d) + Node(ID) + TimStamp(getTime()) + Th \quad (1)$$

Here getGDaddr() is used to get the device logical address for further monitoring, Node(ID) represents the physical address to recognize the device and monitoring the malfunctions, Timestamp() is used to get the current time and Th is the threshold value considered. The Smart Gadget Health Status is shown in Fig. 4.

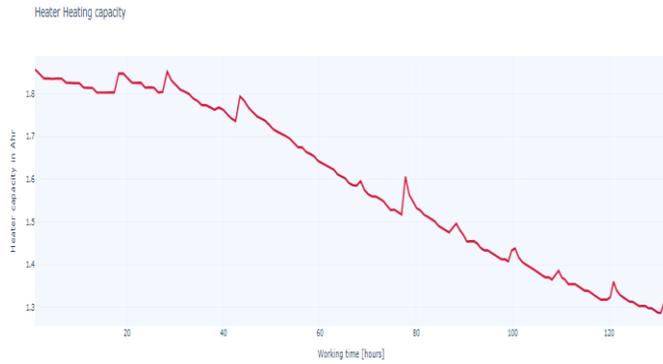

Fig. 4. Smart gadget health status.

**Step2:**

After registration of the gadgets, the digital twin identity is provided and the model generates an accurate digital twin model for gathering the data and analyzing the functionality of the gadget. The digital twin generation is performed in Eq. (2).

$$DigTwin(SGD(L)) = \sum_{d=1}^M getData(SGD(d)) + \sum_{d=1}^M \frac{F(setsimm(SGD(d)))}{count(SGD(d))} \quad (2)$$

Here getData() is used to gather the sensor data and the setsimm() is used to create a simulation model of the gadget using the sensors for monitoring the device functionality. The comparison of physical model is shown in Fig. 5.

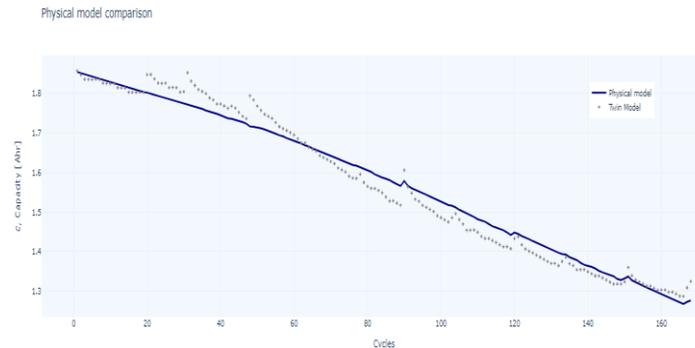

Fig. 5. Comparison of physical model.

**Step3:**

The sensor data is gathered by the central monitoring authority for analyzing the gadgets working process and malfunctions by the smart gadgets and the sensor data analysis is performed in Eq. (3).

$$CS(P) = \frac{\lambda + SGD_{avg} + getsimm(SGD(d, \lambda))}{count(SGD) + \beta} + \sum_{d=1}^M getMax(SGD(d)) \quad (3)$$

$\beta$  is the data interceptions from the sensors, that is the multiple data items collected.  $\lambda$  is the device functionality normal parameter that is set as fixed value. getMax() is used to get the device maximum attribute data for analyzing the device functionality.

**Step4:**

To identify the malfunctions in the device working process, CNN based Logistic Regression model is applied for analyzing a predicting the functionality as in Eq. (4) and Eq. (5).

$$LogReg(f(x)) = \frac{1}{1 + e^{-(x-\mu)}} + \frac{1}{1 + e^{-(\beta_0 - \beta_1 \mu)}} \quad (4)$$

$$MF(SGD(L)) = \sum_{d=1}^L \frac{dStat(LogReg(d))}{\lambda} + \delta(CS(d)) - \tau \quad (5)$$

$\mu$  is the location parameter of the gadget and  $x$  is the scaling attribute,  $\beta$  is the data interceptions from the sensors.  $\lambda$  is the device functionality normal parameter and  $\tau$  is the noisy data gathered from the sensor.  $\delta$  is the model used for highly correlated value set. The error rate between Physical Twin and Digital Twin is shown in Fig. 6.

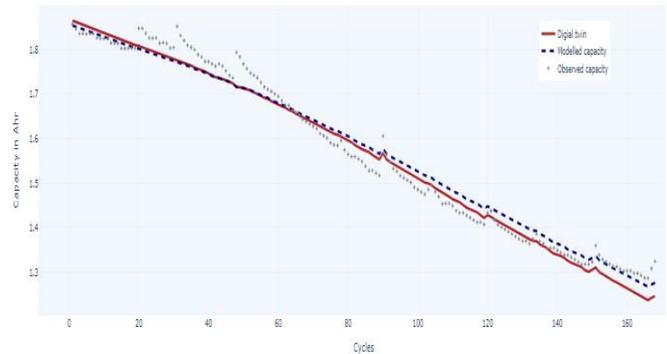

Fig. 6. Error rate between physical twin and digital twin.

**Step5:**

The gadget health status is calculated and updated to the user and the malfunction cause by the sensors is identified and the health status is calculated in Eq. (6).

$$SGDHS(CS(M)) = \sum_{d=1}^M \lambda + \beta * (\maxattr(CS(\lambda)) - \frac{\minattr(\lambda)}{\tau})^2 + \sum_{d=1}^M \lambda * (\tau - \frac{\beta * CS(d)}{count(MF)})^2 \quad (6)$$

Done

#### IV. RESULTS

Digital twin is used to describe physical items that also include digital data. It is also thought of as a technology for symbolizing simulation techniques. The concept of a digital twin is related to other technologies such as cyber physical and digital shadow systems. The connection between these ideas has to be investigated. Designing, running, and repairing the product all make use of digital twin technology. Large volumes of data have been generated by these applications, necessitating a data analysis system for use in fault prediction and maintenance. It is possible to solve the issue with the help of digital twin technology, which acts as a connection between the real and virtual gadgets. Data is the lifeblood of the digital twin concept. Radio Frequency Identification (RFID) tags and readers consist of a variety of elements and sensors. These components are picked and combined so that the digital twin can collect comprehensive data. When it comes to transmitting data to a digital twin via central server, it can be challenging and expensive if the data in question comes in huge volumes and a wide variety.

Data-related technologies, such as data gathering, data mapping, data processing, and data transmission, vary widely depending on the specific use case. To make this data into a digital twin, standard data interfaces are needed. This research presents a Deep Convolution Neural Network based Logistic Regression Model with Digital Twins (DCNN-LR-DT) for accurate prediction of smart home gadget functionality levels and to predict the threats in advance. The proposed model is compared with the traditional Cloud-Based Digital Twinning for Structural Health Monitoring Using Deep Learning (CbDT-SHM) model. The proposed model is implemented in python and executed in Google Colab. The dataset is gathered from the link <https://www.kaggle.com/datasets/prasannaakella/digital-twin-gadget-health>. The results represent that the proposed model performance is efficient than the traditional models.

Equipment like sensors, gadgets, appliances, and other equipment that collect and share data via the web are examples of Internet of Things smart devices. Embedded with other Internet of Things gadgets, they are pre-programmed for certain uses. The smart gadgets in which digital twin will be created will be registered with the model for analysis. The Smart Gadget Registration Time Levels of the proposed and existing models are shown in Fig. 7.

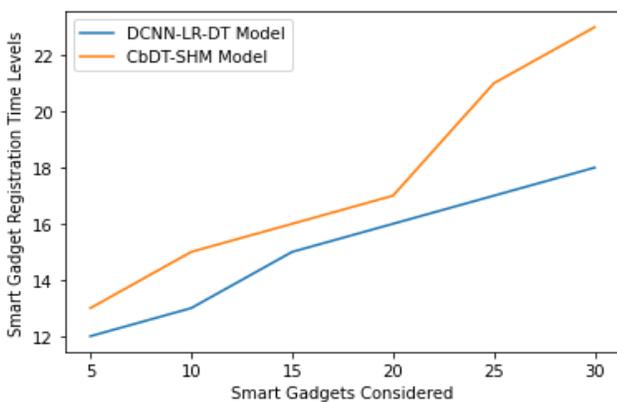

Fig. 7. Smart gadget registration time levels.

For a digital twin to be constructed, information about a physical item or process is needed so that an intangible model can be developed to replicate the actions and states of the physical one. Information collected throughout the product's lifetime may include design documents, production procedures, and engineering blueprints. The Digital Twin Setup Time Levels of the existing and proposed models are compared and the results are shown in Fig. 8.

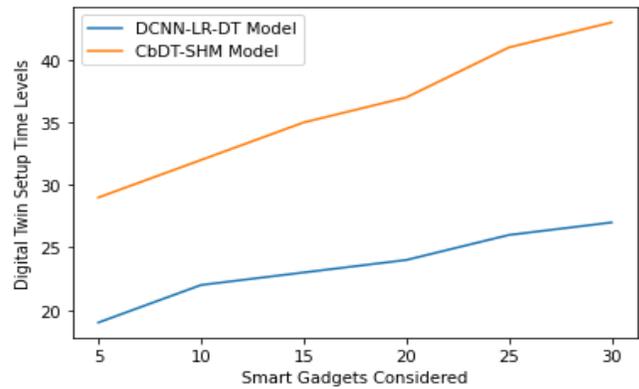

Fig. 8. Digital twin setup time levels.

A digital twin is a digital representation of the physical or system that extends its lifetime, is upgraded from real-time data, and employs simulation, advanced analytics and reasoning to support decision-making. The duplicate can be utilised alongside a prototype to provide input on the product's development or can serve as a model in its own right to mimic what may occur with a tangible version of the product after it is constructed. The accuracy levels of digital twin setup is shown in Fig. 9.

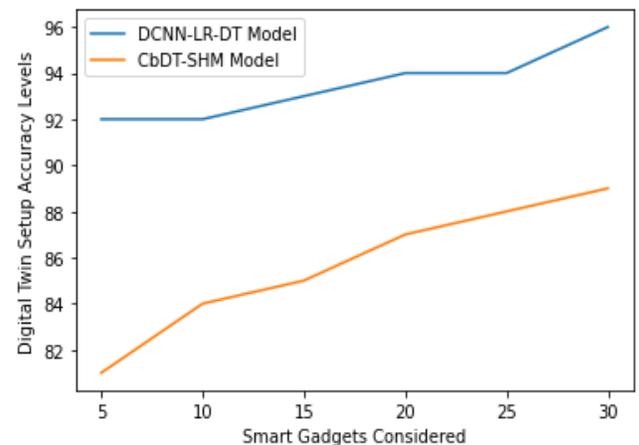

Fig. 9. Digital twin setup accuracy levels.

Data gathered through IoT sensors for processing. Anything from a home thermostat to a motor vehicle could be included in this category. The internet portion of IoT refers to the devices' ability to communicate with one another, share information, and transfer that information across networks for further processing. The sensor data gathered will be used for identification of smart devices working status. The Sensor Data Gathering Time Levels of the proposed and existing models are shown in Fig. 10.

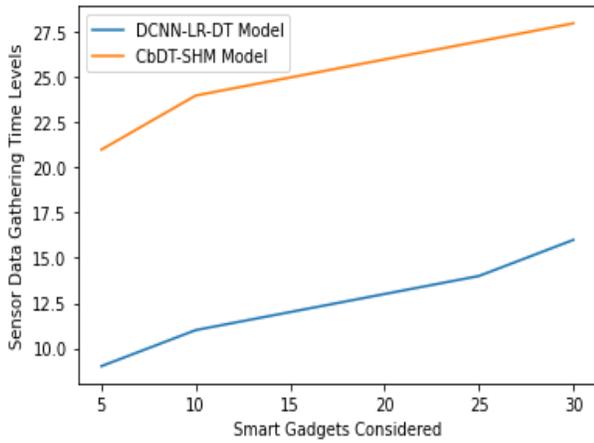

Fig. 10. Sensor data gathering time levels.

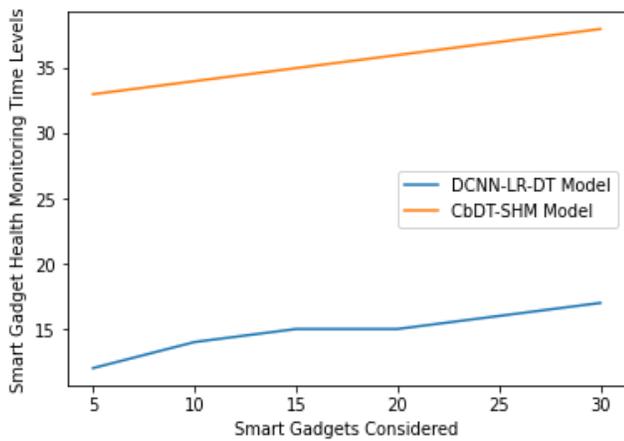

Fig. 11. Smart gadget health monitoring time levels.

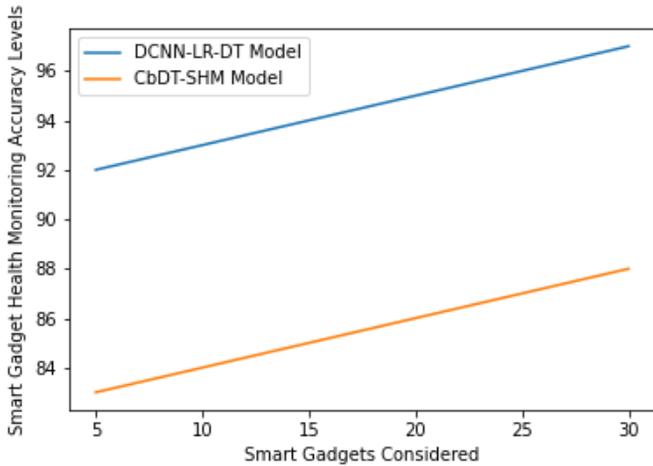

Fig. 12. Smart gadget health monitoring accuracy levels.

In essence, a digital twin is a living representation of a physical talent or system that can continually adjust to new conditions and operations to yield optimal results for the organization. It is also easy to scale up and deploy quickly for use with comparable applications. Deploying all of the sensors, software, networking, and physical assets is crucial to the

construction of a smart building. The concept of a digital twin, or a continuous virtual reproduction of a physical system, has been gaining popularity. It can be used to simulate a smart house, complete with human occupants and robot helpers. Useful in optimizing robotic systems and even the comforts of a smart home for smart gadget health monitoring and suggesting the users for taking necessary actions for long life of gadgets. The Smart Gadget Health Monitoring Time Levels of the proposed and existing models are shown in Fig. 11 and the Smart Gadget Health Monitoring Accuracy Levels comparative results are represented in Fig. 12.

## V. DISCUSSION

The current study explores the potential of digital twins in predicting smart home gadget functionality levels and identifying threats in advance. The proposed model, based on a Deep Convolution Neural Network and Logistic Regression, achieved a high level of accuracy (97%) in identifying hardware risks of smart home gadgets. This study contributes to the growing interest in digital twin technology and its applications in the field of IoT. The results of this study suggest that digital twins can be a valuable tool in improving the efficiency and performance of smart home devices. By providing a virtual representation of physical objects, digital twins can monitor and optimize their functions. Moreover, digital twins can provide constant feedback to enhance the quality of life of individuals using smart home devices. Therefore, the implementation of digital twin technology in smart homes has the potential to significantly enhance the overall user experience.

## VI. CONCLUSION

In the era of IoT and technological advancement, digital twins have emerged as a game-changing invention. The digital twin concept integrates and makes extensive use of cutting-edge technologies such as deep learning, machine intelligence, cloud services systems, big data configurations, software analytics, and the IoT, thereby radically altering IT business efficiency and lowering investment costs. The concept of a digital twin, which bridges the gap between real-world and digital environments, is gaining popularity. The advent of digital twin technology can be traced to the development of both virtual technology and data collecting technology. A digital twin is an identical copy of a physical object or person that exists in the real world. The connection and its digital counterpart have multiple possible implementations. Currently, the primary focus of digital twin development is on optimising industrial production. Now that more data can be acquired because to advancements in communication and digitalization technologies, it is time to figure out how to put all that knowledge to good use. As a result, there is a lot of interest in, and momentum behind, the concept of digital twin. All physical entities, including humans, can have their functions monitored, understood, and optimized with the help of digital twins, which also provide constant feedback to enhance quality of life. The ideal way to define a digital twin is as the seamless exchange of information between a real-world machine and its digital counterpart. This research presents a Deep Convolution Neural Network based Logistic Regression Model with Digital Twins model for accurate prediction of smart home gadget

functionality levels and to predict the threats in advance. The proposed model is limited to check the health status of smart home gadgets. With a focus on various levels, the difficulties and future opportunities of Intelligence DTs in advanced robotics and smart manufacturing can be examined.

**Abstract**—Academic certificates are integral to an individual's education and career prospects, yet conventional paper-based certificates pose challenges with their transport and vulnerability to forgery. In response to this predicament, institutions have taken measures to release e-certificates, though ensuring authenticity remains a pressing concern. Blockchain technology, recognised for its attributes of security, transparency, and decentralisation, presents a resolution to this problem and has garnered attention from various sectors. While blockchain-based academic certificate management systems have been proposed, current systems exhibit some security and privacy limitations. To address these issues, this research proposes a new Decentralised Control Verification Privacy-Centered (DCVPC) protocol based on Hyperledger Fabric blockchain for preserving the privacy of academic certificates. The proposed protocol aims to protect academic certificates' privacy by granting complete authority over all network nodes, creating channels for universities to have their private environment, and limiting access to the ledger. The protocol is highly secure, resistant to attacks, and allows improved interoperability and automation of the certificate verification process. A proof-of-concept was developed to demonstrate the protocol's functionality and performance. The proposed protocol presents a promising solution for enhancing security, transparency, and privacy of academic certificates. It guarantees that the certificate's rightful owner is correctly identified, and the issuer is widely recognised. This research makes a valuable contribution to the area of blockchain-based academic certificate management systems by introducing a new protocol that addresses the present security and privacy limitations.

**Keywords**—Blockchain technology; hyperledger fabric blockchain; privacy preservation; decentralized control verification privacy-centered (DCVPC) protocol; academic certificates

## I. INTRODUCTION

Academic certificates such as diplomas and transcripts are essential documents that certify an individual's successful completion of a course of study and enable them to pursue diverse employment opportunities within their field [2]. Nonetheless, conventional paper-based certificates are challenging to transport and susceptible to fraudulent activities. As a result, employers and job seekers have lost trust in the verification process, which is now costly and time-consuming.

In response, several institutions have introduced electronic certificates. However, determining authenticity continues to be a prevalent issue. The application of blockchain technology presents a possible solution to this issue by utilising digital

certificates that guarantee authenticity and discourage counterfeiting. Blockchain-based systems like Blockcerts and Block.co have been developed by universities such as MIT and the University of Nicosia (UoN), where students are given control of their own digital credentials and can share them with potential employers [1],[2],[3],[4],[5],[6],[7],[8],[9]. The implementation of decentralisation, peer-to-peer networking, and cryptography in these systems ensure security and immutability. Although the present systems solve the problem of authenticity, they do not tackle other challenges such as fake universities and impersonation.

The objective of this research is to propose a novel protocol based on Hyperledger Fabric to address the challenges associated with managing academic certificates and safeguarding the privacy of identities. In comparison to other blockchain technologies, Hyperledger Fabric provides increased access control and flexibility in protecting privacy. To showcase the efficacy of the proposed protocol, a proof-of-concept will be developed as part of the study.

This paper presents an innovative approach to address a crucial issue in the education sector, which is the secure, transparent, and privacy-preserving management of academic certificates. Academic certificates, such as diplomas and transcripts, play a vital role in enabling individuals to access education and career opportunities. However, traditional paper-based certificates are inconvenient to transport and prone to forgery. Although e-certificates have been developed to address this issue, verifying their authenticity is still a significant challenge. Blockchain technology has emerged as a promising solution due to its features of security, data integrity, transparency, and decentralisation for managing academic certificates.

However, current blockchain-based systems have some limitations when it comes to ensuring security and privacy, which this research aims to address. This study aims to address the following research questions and objectives: How can a protocol based on the Hyperledger Fabric blockchain that is decentralised, privacy-centred and ensures the privacy of academic certificates be developed? Can this proposed protocol enhance the security, transparency, and privacy of academic certificates while facilitating automation and interoperability in the certificate verification process?

This paper introduces the proposed protocol and its implementation and evaluates its functionality and performance, contributing to the development of more secure

\*Corresponding Author.

and privacy-preserving systems for managing academic certificates. The DCVPC Protocol presents a novel and privacy-centred approach to academic certificate verification that utilises the capabilities of the Hyperledger Fabric blockchain. This protocol offers an innovative means of preserving the privacy of academic certificates by enabling decentralised control and verification of these crucial documents. The protocol empowers individuals to regulate access to their certificates, allowing them to disclose only the necessary information. Furthermore, the use of blockchain technology guarantees that certificates are tamper-proof and immutable, enhancing the overall security of the verification process.

The DCVPC Protocol represents a significant advancement in the area of academic certificate verification, providing a secure and innovative solution that has the potential to become an industry standard.

## II. BLOCKCHAIN TECHNOLOGY AND ITS BENEFITS FOR ACADEMIC CERTIFICATES ISSUANCE AND VERIFICATION

The concept of blockchain was first introduced in the Bitcoin white paper in 2008. This distributed ledger leverages consensus and cryptographic techniques to provide a secure and transparent record-keeping system [10],[11],[12],[13],[16]. Since each block contains transactions and a unique hash value, it is difficult to alter or tamper with a block without being detected [16]. Before a transaction can be added to a block in a blockchain network, a consensus must be reached among a group of nodes. As shown in Fig. 1, a block consists of a header and a body, where the body contains the transaction data. The header contains several components, including the Merkle root, a Nonce, a timestamp, and the hash of the previous block. The hash of the previous block is passed to a hash function, which returns a hash value. By recording the hash of the previous block in the current block, the blockchain expands when new blocks are added and linked to it, while also providing an efficient way to detect any attempts at tampering with previous blocks. The timestamp is used to timestamp every newly generated block. The block creation and verification processes only need to be executed once. Merkle trees are binary trees where the labels of non-leaf nodes are the concatenation of the hashes of its child nodes, and the labels of leaf nodes are the hashes of individual transactions in the block body. The Merkle root, also known as the root hash of a Merkle tree, is used to verify the transactions in a block. Instead of verifying each individual transaction in a block, it is sufficient to compare their Merkle root [27]. The structure of a blockchain network is illustrated in Fig. 1, which shows that each block header contains information about the previous block, including its Merkle root, Nonce, timestamp, and hash. The Merkle root refers to the hash of the initial node in a Merkle tree. To further explain the structure of a Merkle tree, let us take the third block as an example of a transaction representation, TX.

The education sector can greatly benefit from the use of blockchain technology due to its various advantages, such as increased security, low cost, improved data access controls, increased accountability and transparency, identity authentication, increased trust, effective student record

management, support for learners' career decisions, and enhanced learner interactivity [28]. The use of blockchain technology in the education sector provides a secure and efficient way of managing academic records and transactions. Due to its decentralised nature, blockchain ensures that only intended recipients have access to shared data or transacted funds, reducing concerns about data safety. The ability to control who can view the saved information is one of the main characteristics and benefits of blockchain. Academic documents such as transcripts, degrees, and student and instructor files can be securely stored, and the blockchain ensures the authenticity of digital certificates and the security of users' identities.

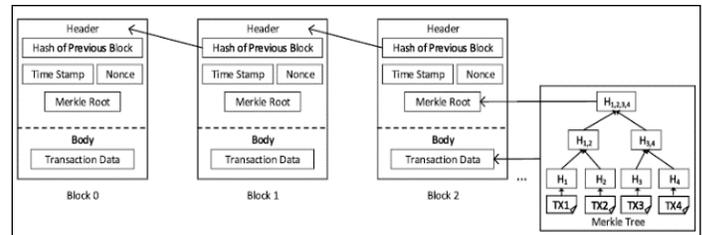

Fig. 1. Blockchain structure.

Blockchain technology also streamlines the process of managing students' personal information, and its adoption in education may reduce the possibility of trading mistakes between parties [28]. Blockchain technology is becoming increasingly important for academic certificate issuance and verification. Traditionally, verifying academic credentials has been a cumbersome and often unreliable process that involved contacting educational institutions and relying on paper records.

The implementation of blockchain technology offers a potential solution for the challenges associated with managing academic certificates. By using a secure and decentralised system, digital credentials can be stored and shared, providing a higher level of trust and transparency in the credential verification process. Utilising blockchain technology allows for tamper-proof certificates to be issued by academic institutions, which can be easily verified by employers and other interested parties. This not only enhances the efficiency of credential verification but also improves the overall integrity of the hiring process.

Furthermore, blockchain technology allows students to exert greater control over their academic records and share them securely and selectively, creating new prospects within the education sector. The implementation of blockchain technology in the issuance and verification of academic certificates has the potential to revolutionise the education industry by enhancing the accuracy and accessibility of academic credentials.

Blockchain technology is widely recognised as a transformative technology for academic certificate issuance and verification. This innovative technology provides a secure, decentralised system for storing and sharing digital certificates, which allows academic institutions to issue tamper-proof credentials that can be easily verified. By leveraging blockchain technology, students can exercise greater control

over their academic records and share them securely and selectively with potential employers and other interested parties.

Moreover, blockchain technology is increasingly recognised as a game-changer for academic certificate issuance and verification. This innovative technology provides a secure, decentralised system for storing and sharing digital certificates, allowing academic institutions to issue tamper-proof credentials that are easily verifiable in real-time, thereby speeding up the hiring process and reducing the risk of fraud. Additionally, the use of blockchain technology enables students to have greater control over their academic records and share them securely and selectively with potential employers or other interested parties. The immutability and tamper-proof nature of blockchain technology ensure that academic certificates cannot be altered or duplicated, providing a higher level of trust and transparency. In summary, the use of blockchain technology for academic certificate issuance and verification offers significant benefits, including greater efficiency, transparency, and security [30],[31].

### III. IMPORTANCE OF HYPERLEDGER FABRIC FOR PRESERVING THE PRIVACY DURING THE PROCESS OF ACADEMIC CERTIFICATES ISSUANCE AND VERIFICATION

The use of Hyperledger Fabric in the process of academic certificate issuance and verification is essential in preserving privacy and security [41]. Academic certificate management involves the exchange of sensitive personal information, making privacy a significant concern. Hyperledger Fabric's architecture enables academic institutions to maintain control over their data, ensuring that private information is not shared with unauthorised parties. The platform provides a secure and private environment where all participants have access to information necessary for the verification process without compromising privacy.

Furthermore, the modular design of Hyperledger Fabric allows for the integration of various identity management systems, providing more precise control over information access. This feature empowers academic institutions to uphold privacy and data security throughout the process of certificate issuance and verification, guaranteeing that sensitive information is only accessible by authorised parties. Consequently, the platform offers a more efficient, reliable, and secure approach to academic certificate management that safeguards the privacy of both students and institutions [25],[26].

Hyperledger Fabric is a highly flexible and scalable platform that enables the deployment of various solutions through a modular subsystem architecture. This feature makes it possible for institutions to scale up to increasingly complex systems. In academic certificate management, Hyperledger Fabric is essential in maintaining privacy and data security during the issuance and verification process. The platform has several key components that work together to preserve privacy. Firstly, its modular architecture allows academic institutions to define their own data access policies and identity management systems, providing control over who has access to sensitive

information. This ensures that only authorised parties can view and verify academic credentials. Additionally, Hyperledger Fabric uses distributed ledger technology to provide a tamper-proof record of all transactions on the network. This feature ensures that certificates cannot be altered or duplicated, which enhances the credibility of the verification process.

Furthermore, Hyperledger Fabric employs a consensus mechanism to ensure that all network participants agree on the authenticity of a transaction before it is recorded on the ledger. This approach guarantees that all participants have a shared view of the network, making it more secure and reliable. Hyperledger Fabric also offers a modular and flexible framework that can be tailored to the unique requirements of various academic institutions. This adaptability enables institutions to integrate their existing systems and processes with the Fabric network, preserving the privacy of their data. Collectively, these components make Hyperledger Fabric an influential tool for academic certificate issuance and verification. It safeguards privacy while ensuring the security and authenticity of academic credentials [29].

The transaction flow in Hyperledger Fabric begins when a client initiates a transaction request by submitting a proposal to the endorsing peer. The endorsing peer then checks the validity of the proposal and simulates the transaction to ensure that it meets the defined rules and regulations. If the transaction is deemed valid, the endorsing peer endorses it by adding a digital signature to the transaction.

Once endorsed, the transaction is sent to the ordering service, which is responsible for ordering the transactions and creating a block. The ordering service ensures that transactions are ordered based on a consensus algorithm and sends the ordered transactions back to the peers. The peers then validate the transaction by checking the endorsement policy and comparing the digital signature of the endorsing peers. If the transaction is valid, the peers commit the transaction to the ledger, making it immutable and tamper-evident.

Hyperledger Fabric also supports private data, which is only visible to parties that have explicit access to it. This is achieved by storing private data off the main ledger and providing access to authorized parties only.

In summary, the transaction flow in Hyperledger Fabric involves several parties, including clients, peers, and orderers, and ensures secure and efficient transactions by utilizing endorsement policies, consensus algorithms, and distributed ledgers. The platform's modular architecture and support for private data make it an ideal solution for enterprises looking to implement blockchain-based systems.

The use of private channels in Hyperledger Fabric enables network participants to have secure and private communication within a subset of the network. The transaction flow in Hyperledger Fabric is carefully designed to ensure the security, scalability, and reliability of the blockchain network, making it an ideal solution for enterprise-grade applications [29]. Fig. 2 illustrates the transaction flow in the Hyperledger Fabric blockchain.

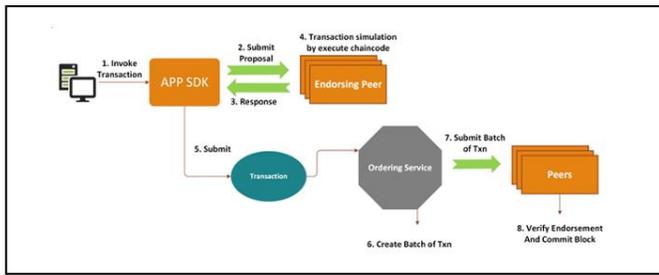

Fig. 2. Transactions flow in hyperledger fabric blockchain.

#### IV. SECURITY AND PRIVACY FEATURES ADOPTED IN HYPERLEDGER FABRIC BLOCKCHAIN

Hyperledger Fabric employs several techniques to ensure the security and privacy of academic certificate issuance and verification processes [18],[33],[34]. Firstly, Fabric employs a permissioned blockchain architecture that restricts access to authorised parties, offering a high level of security against unauthorised access. This feature is particularly crucial in academic certificate management, where the exchange of sensitive personal information necessitates robust security measures. Secondly, Fabric's modular architecture allows for the integration of various identity management systems, enabling academic institutions to maintain control over their data and define their data access policies. This feature is crucial in preserving the privacy of student data, ensuring that private information is not disclosed to unauthorised parties. Thirdly, Fabric leverages distributed ledger technology, which offers a tamper-proof record of all transactions within the network. This feature guarantees the integrity and immutability of academic certificates, ensuring that they cannot be altered or duplicated [24]. This provides a high level of security and authenticity to the certificate issuance process. Fourthly, Fabric's consensus mechanism ensures that all participants in the network agree on the authenticity of a transaction before it is added to the ledger. By achieving consensus, Fabric ensures that all network participants share a unified view of the network, resulting in a more secure and reliable system. Finally, Fabric's private channels enable the creation of secure and private communication within a subset of the network, further preserving the privacy of sensitive data. In summary, the security and privacy preservation techniques utilised in Hyperledger Fabric are well-suited for academic certificate issuance and verification applications. These techniques provide a reliable and secure way for academic institutions to manage certificates while maintaining the confidentiality and data security of all relevant parties [35], [36], [37], [47].

#### V. LITERATURE REVIEW

Blockchain technology offers a potential solution for secure and reliable management of academic certificates due to its distributed ledger architecture and tamper-proof design. Academic institutions can use blockchain technology to issue and verify certificates efficiently and securely. The use of blockchain technology in academic certificate management has gained significant attention in recent years, with various studies exploring its benefits and limitations.

This literature review aims to provide a comprehensive overview of the existing research concerning the use of

blockchain technology for academic certificate issuance and verification. The review will cover various aspects of blockchain technology, including its distributed ledger architecture, consensus mechanisms, privacy features, and security protocols. Additionally, the review will discuss the challenges and opportunities associated with the use of blockchain technology in academic certificate management, and identify areas where future research is needed to further explore this field. The survey aims to offer a thorough comprehension of the present research state concerning the application of blockchain technology in the issuance and verification of academic certificates, and the possible ramifications for academic institutions and stakeholders.

The research [42] explores the potential of blockchain technology in providing a transparent and secure method of recording and maintaining educational certificates and important records. The study highlights the use of digital certificates for evaluating students' academic and extracurricular achievements, and proposes blockchain technology as a secure platform for storing and maintaining them. The research provides an overview of various blockchain-based digital certificate verification systems that employ different authentication techniques and blockchain platforms. It stresses the importance of blockchain technology in ensuring the safety, accessibility, and up-to-date status of digital assets. The study also identifies potential challenges and issues related to academic certification processes in the future. In summary, the research underscores the significance and potential of blockchain technology for academic certificate issuance and verification.

The study [43] introduces a blockchain-based system for the issuance and verification of academic certificates. The system comprises four principal components, namely a verification application with federated identity, an issuing application that involves multi-signature and BTC-address-based revocation, a blockchain, and a local database implemented using MongoDB. The issuing applications manage the primary business logic associated with certificate application, examination, signing, and issuance. They merge the certificate hash with a Merkle tree and send the Merkle root to the blockchain while also handling certificate revocations. The verification application is responsible for verifying the authenticity and integrity of the issued certificates. It includes a web-based page and an Android-based application that retrieves transaction messages through the blockchain API and compares them with the verification data from the receipt. The blockchain acts as a trust infrastructure and a distributed database for storing authentication data, while the MongoDB database manages JSON-based certificates and provides high availability and scalability. Overall, the proposed system leverages blockchain technology to ensure the security and integrity of academic certificates and offers a dependable platform for their issuance and verification.

The study [44] suggests a blockchain-based resolution to tackle the issue of counterfeit educational certificates in Vietnam. The proposed system, referred to as the Vietnamese Educational Certification blockchain (VEcefblock), utilises blockchain technology's features such as anti-forgery information, transaction verification, and smart contracts to

guarantee data transparency and user confidence. The investigation analyses the latest blockchain research and applications to provide insight into the proposed solution. It also presents the development principles of VEcefblock, which involves designing the architecture, business processes, and data mapping structure. Hyperledger Fabric is the blockchain platform used, and the proposed solution is evaluated for performance on the Amazon EC2 cloud. The study underscores the practicality and feasibility of using blockchain technology to address certificate management issues and social problems in Vietnam.

The study [45] introduces a prototype for digital education certificates that uses blockchain technology to enhance the administration and validation of distance education. The prototype is built with a permissioned blockchain, PKI-CA, a digest algorithm, and interactive data authentication via digital signatures. Digital certificates can be issued and verified instantaneously through QR codes or dynamic authorisation codes. Test results demonstrate the prototype's accurate performance with a high throughput of transactions. The proposed system aims to guarantee impartiality and authenticity in education management by ensuring the traceability of student activities and preventing data leakage.

The ongoing research [46] aims to employ blockchain technology to enhance the verification of certificate authenticity. The first stage has led to the development of a prototype, which enables the registration of academic institutions, their faculties, student cohorts, and the issuance of certificate awards. The certificates issued are recorded on the blockchain, ensuring that third parties can verify their authenticity independently of the academic institution, even in the event of its closure. The next stage seeks to expand the prototype to include the registration of medical records, with a focus on ensuring the privacy of sensitive data and granting the owner control over user access to the documents. The final stage involves collecting user and corporate feedback on the proposed prototypes.

MIT Media Lab collaborated with Learning Machine to develop Blockcerts, which uses the Bitcoin blockchain for security. However, this approach slows down transactions, increases prices, and reduces usability. To obtain a diploma using Blockcerts, candidates must install the Blockcerts Wallet software and generate public and private keys. The private keys are stored on users' mobile devices, while MIT receives their public ones. The blockchain stores the diploma's hash value and the date and time it was generated. Graduates can receive digital diplomas that include their public and private keys, which they can use to prove ownership. Graduates can also use the Blockcerts Wallet to share their diplomas with third parties, such as school administrators, future employers, or educational institutions for further education. The system's advantages and drawbacks are discussed in [7], [8], and [11].

There are several benefits for students to use Blockcerts. First, it offers 24/7 access to accredited certification from any location and is valid for the life of the blockchain. Second, students' identities remain private since the blockchain stores only the encrypted hash of their diplomas. Lastly, Blockcerts reduces costs for students by digitising certificates,

empowering schools with greater control over students' academic qualifications, and simplifying the verification process [14].

It has been found that an unauthorised individual could potentially create a fraudulent academic credential using the methods employed by Blockcerts, although [15] found this to be feasible. It is not possible to authenticate the Blockcerts issuing public key. Nevertheless, the use of Blockcerts helps to standardise credentials across universities, streamline the verification process for verifiers, and digitise certificates, all of which have a positive impact on students' time and financial investments.

According to a study [15], one issue with Blockcerts is that it does not provide evidence that the owner of a public key is the authorised issuer. This shortcoming allows unauthorised individuals to produce counterfeit academic credentials that appear to be genuine by impersonating the credential-granting organisation. To tackle this issue, researchers at Birmingham University have proposed a cryptographic digital certificate system called BTCert. BTCert aims to establish a dependable federal ID to verify the legitimacy of the issuing institution, enhance certificate authentication through multiple signatures, and devise a secure revocation method to increase the credibility of certificate revocation.

Birmingham University students and alumni can view their certificates by logging in using their BU credentials. The system allows students to submit their credentials to a third party for verification, and institutional administrators can use it to manage student enrolment, issue certificates with digital signatures, and authorise certificate revocation [6],[11]. Similar to Blockcerts, BTCert generates digital certificates by linking transaction hash values with certificate hashes, and the Merkle root for a certificate set is included in the transaction. The authenticity of the certificate is verified by comparing it to the hash value of the local receipt on the Bitcoin blockchain. The BTCert system comprises a blockchain, an issuing application, a local database, and a verification application. The issuing application is primarily responsible for handling certificate revocation, publishing the Merkle root to the Bitcoin blockchain, and combining the certificate's hash value with a Merkle tree. JSON-based certificates are managed using the local database, while the blockchain stores authentication data [19].

The University of Nicosia was the first institution to use Bitcoin's blockchain to create digital credentials. Students' digital fingerprints are saved on the blockchain, and they can use a verification tool to send a certified PDF version of their diploma to others, avoiding any unnecessary costs. Block.co makes it easy to safely and quickly trade credentials, thus preventing diploma mills. Block.co decides whether to grant a degree after compiling a list of qualified students and assessing a sample application. Diploma forgery is impossible due to the blockchain's digital fingerprinting capabilities, and the degree may be quickly earned and verified by anyone [6],[20].

According to a study [21], a proposed blockchain infrastructure for sharing student information could benefit educators, students, and businesses. The infrastructure is mostly decentralised, as it does not depend on a single server to

access learner data but instead utilises a centralised database. The paper does not provide specifics on implementation or experimental analysis. The authors suggested a blockchain-based infrastructure for archiving student records [22], and the results indicate that storing academic information on the blockchain is more cost-effective than using cloud storage. Smart contracts could utilise access control management to protect users' personal information, which would need to be stored securely with multiple database vendors. However, the study does not provide any concrete outcomes that can be tested or implemented.

According to the authors [23], BcER2 is a database based on blockchain technology for storing academic credentials, including diplomas. The researchers implemented their design using an open-source framework called Hyperledger Composer, as described in the article, which provides a high-level design overview, but no implementation details or test results. Central New Mexico Community College uses blockchain to store student records, enabling students to have greater control over their academic information. Students can download their credentials to any device by using their wallet address. However, their strategy appears to rely on on-chain storage, which is both expensive and inherently unscalable.

#### VI. GAPS AND ISSUES IN TERMS OF PRIVACY-PRESERVING WITH CURRENT BLOCKCHAIN-BASED PLATFORMS IN THE CONTEXT OF ACADEMIC CERTIFICATES ISSUANCE AND VERIFICATION

Although blockchain-based platforms offer several benefits regarding the secure, transparent and decentralised storage and verification of academic certificates, privacy preservation issues remain. One concern is that current blockchain-based platforms may not prioritise privacy and could expose sensitive information to unauthorised parties [32]. Additionally, the public visibility of blockchain transactions and certificates could jeopardise students' privacy and academic records. Furthermore, current platforms may lack reliable mechanisms for identity verification and access control, which can lead to fraudulent activities or unauthorised access to academic records. The non-compliance of current platforms with data protection regulations such as GDPR may also cause legal and ethical problems. Researchers and developers are working on privacy-enhancing solutions, such as the use of zero-knowledge proofs, homomorphic encryption, and multi-party computation, to address these gaps and issues [38], [39], [40], [41]. Therefore, this study aims to suggest a design for the Certificate Verification Control Protocol (DCVPC) based on the Hyperledger Fabric blockchain.

#### VII. RESEARCH METHODOLOGY

The Design Science Research Methodology (DSRM) could be a suitable research methodology for this study. DSRM is widely used in information systems research and concentrates on creating and assessing creative solutions to practical problems [48]. This approach is particularly appropriate for this study since it entails designing and executing a new

protocol based on the Hyperledger Fabric blockchain to protect the confidentiality of academic certificates. The first phase of the methodology defines the problem, which in this case is the lack of privacy in conventional paper-based academic certificates. The second phase involves designing a solution to the problem, which in this case is the proposed DCVPC protocol. The third stage involves creating a model of the suggested solution, which would necessitate constructing and testing the protocol in a real-world setting. Finally, the fourth phase involves assessing the efficiency and effectiveness of the proposed solution. In general, the DSRM methodology could offer a structured approach to developing and evaluating the suggested protocol and could lead to an innovative solution to the issue of preserving the privacy of academic certificates.

#### VIII. THE PROPOSED DESIGN OF CERTIFICATE VERIFICATION CONTROL PROTOCOL (DCVPC)

The initial stage in the design process was to develop a privacy-focused system that allows schools to issue certificates while giving the recipients centralised access to their data. To preserve the confidentiality and integrity of the parties in the network, only approved entities can join the network. However, this does not fully address the importance of decentralisation in this study. Decentralisation ensures that no single entity can exert undue control over the information, and the distribution of power is equalised. Additionally, tracking every alteration can prevent fraudulent and illegal adjustments. Transferring the solution to the Hyperledger network would be the next step towards achieving decentralisation. The previous sections explained why Hyperledger was chosen over competing alternatives. In comparison to other options, Hyperledger's orderer node distinguishes it. Bitcoin and Ethereum, two of the most prominent blockchains, use a consensus form known as probabilistic [25]. In this setting, nodes do not delegate decision-making authority to a central authority; instead, they compete to solve a computational problem  $f(x)$ . When a node successfully solves the problem and adds it to the chain, the probability of the previous block being legitimate increases as the number of blocks in the chain grows, as shown by the expression  $P(\text{block}_{i-1} \text{ valid}) > P(\text{block}_i \text{ valid})$ . This means that the consensus is based on the  $P$  value, which indicates how likely it is that the newly added blocks are valid (Block<sub>i</sub> valid). Hyperledger, on the other hand, uses a deterministic consensus rather than a probabilistic one [28]. When the orderer determines that a transaction should be recorded in the ledger, that decision is conclusive and applies to all affiliated organisations. Each organisation's peers will validate the transaction before sending it to the orderer, who will then package it and send it back to the peers for a final commit.

The proposed protocol comprises several entities, including the ministry, the university, and the student. The ministry is integrated into the system as a hardcoded entity, while universities are represented as organizations, and the channel encompasses the smart contracts. Fig. 3 shows the overall design of the proposed protocol.

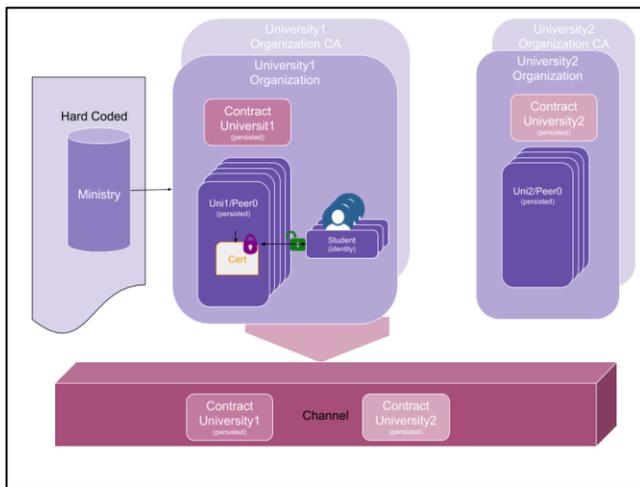

Fig. 3. The desing of the proposed decentralised certification verification privacy control protocol.

Since there is a finite number of ministries, they must be hard-coded into the Hyperledger's inception state. As an alternative, a trustworthy ministry may be hard-coded into the system and would then be able to invite other ministries to join the blockchain, granting them administrative access and allowing them to establish their own affiliated institutions. To maintain confidentiality, a channel is integrated into the suggested architecture.

Knowing one another is a precondition or perhaps a need in educational settings. Anonymity shouldn't play a defining role in the system since it runs counter to the logic of the actual world, where universities should be well-known institutions; it's also crucial to distinguish between anonymity and privacy, which are sometimes confused with one another. It makes no sense that different ministries or universities in other nations have no connection with each other, nor does it make sense that the ministry's own institutions are completely separate. In the actual world, the infrastructure dictates that the entities must be acquainted with one another and work together in some kind.

As a result of the channel implemented by Hyperledger, a relationship can exist among the network's nodes. Assume there are universities under various ministries, and these institutions have partnership programs, such as students taking classes at other universities. In this instance, the suggested protocol can ensure this. Using Hyperledger channels, governments can link together educational institutions so that students, faculty, and researchers from all over the world can easily share data. Hyperledger's architecture makes it possible to propose a solution that preserves privacy on the network and organisational level, making it an excellent place to introduce the protocol. This will ensure that universities worldwide can maintain control over their own data, regardless of which ministry or country is responsible for it. Within the bounds of etiquette, they are free to pursue a romantic partnership in secret. To protect the confidentiality of the network planned for issuing and verifying academic credentials, we present a novel protocol based on the Hyperledger fabric network. The following are the 11 steps of the suggested protocol, and its mathematical algorithm representation is presented in Fig. 4.

Step 1: The ministry, which is the higher authority in the network, creates organisations which are universities.

Step 2: Each ministry creates a channel that connects the universities, authenticated by that ministry.

Step 3: Each university (organisation) creates its own peers under it.

Step 4: Each company's peers maintain their own copy of the ledger and check all transactions before they are permanently recorded.

Step 5: Only universities can host the ledger.

Step 6: The university organization generates Identities for students.

Step 7: The university organization (admin) is the only entity that can issue certificates in the network.

Step 8: All certificates issued are locked in their initial state until the student issues an unlock command.

Step 9: The student can lock and unlock certificates.

Step 10: Third-party entities only need the certificate id, keys and the owner's name to validate and authenticate the certificate.

Step 11: No entity can authenticate a certificate if it is locked.

The suggested protocol gives unrestricted power over the network nodes. By using the channel to merge universities, they can have their own private domain, allowing for information sharing and complete privacy control over each entity. Ministries generate channels to prevent dubious organisations from operating within the network. Universities generate students, which limits the number of random users in the network. In addition, only peers generated by universities are authorised to host the ledger, reducing the risk of an attack and limiting the amount of access. With a decentralised approach, the final commit takes place only when the majority of connected peers approve.

1. MinistryN,  $N \in \{\text{list of countries}\}$ ,  $n(\text{Ministry}) = x$ ,  $x$  is a constant
2. Each MinistryN has  $\{University1, \dots, University \mid i > 0, i = \text{identification of university}\}$
3. MinistryN  $\rightarrow$  ChannelM,  $M = \text{MinistryN}$
4. MinistryN  $\rightarrow$  UniversityMi  $\mid$  UniversityMi  $\in \{\text{MinistryN}\}$ ,  $M = \text{MinistryN}$ ,  $i = \{\text{identification of university}\}$ ,
5.  $\forall$ UniversityMi  $\exists$  MinistryM
6.  $\{\text{UniversityM1}, \dots, \text{UniversityM}\} \subseteq \text{ChannelM}$ ,  $M = \text{MinistryN}$
7. UniversityMi  $\rightarrow$  Peeri,  $\{i \in N\}$
8. Ledger  $\subseteq$  Peer0, ..., Peeri
9. University<sub>admin</sub>  $\rightarrow$  Identities,  $\{s \in \text{Students}\}$
10. University<sub>admin</sub>  $\rightarrow$  Certificates,  $\{s \in \text{Students}\}$
11. Students,  $s \in \text{Students} \rightarrow \text{Lock/Unlock}(\text{Certificates})$

Fig. 4. The mathematical representation of the proposed protocol for preserving the privacy of identities of hyperledger fabric blockchain.

## IX. IMPLEMENTATION AND RESULTS

The implementation of the DCVPC protocol for privacy preservation in a blockchain-based academic certificates management system using Hyperledger Fabric would involve the following steps:

- **Setting up the Hyperledger Fabric network:** This would include installing the necessary software and dependencies, creating the network, and configuring the various components, such as the peer nodes and the ordering service.
- **Developing the smart contract:** The smart contract would be responsible for managing the academic certificates on the blockchain. It would include functions for creating, issuing, and verifying certificates and managing access control.
- **Creating channels:** channels would be created for each university participating in the network. These channels would provide a private environment for each university to manage its own academic certificates.
- **Implementing access control:** Access to the ledger would be restricted and controlled through the use of digital identities and verifiable credentials. Only authorised entities, such as universities and students, could access and make changes to the ledger.
- **Implementing the certificate verification process:** The certificate verification process would be automated using smart contracts. Verifiers would be able to easily access and verify the authenticity of certificates using the public key of the university.
- **Developing the user interface:** A user-friendly interface would be developed for universities and students to interact with the blockchain and manage their academic certificates.
- **Testing and evaluating the proposed protocol:** The proposed protocol would be tested and evaluated using a proof-of-concept to demonstrate its functionality and performance.
- **Deployment:** The final implementation would be deployed on a production network and made available for use by universities and other stakeholders. In the next subsections, the implementation steps are discussed.

### A. Installing the Hyperledger Fabric on the Local System

Setting up a Hyperledger Fabric network involves several steps including the following:

- **Installing the Hyperledger Fabric software:** This includes downloading the Hyperledger Fabric binaries, setting up the necessary environment variables, and installing any additional dependencies such as Go, Docker, and Node.js.

- **Setting up the network:** This includes creating the necessary configuration files for the network, such as the network topology and the configuration of the peer nodes and ordering service.
- **Starting the network:** This includes launching the peer nodes, ordering service, and other components of the network using the command line interface.
- **Joining peers to the network:** After the network is started, other peers can join the network by connecting to one of the existing peer nodes and obtaining the necessary configuration files.
- **Creating channels:** channels can be created by one of the existing peer nodes on the network, and other peers can join these channels by obtaining the necessary configuration files.
- **Installing and instantiating chaincode:** Smart contracts, also known as chaincode, can be installed and instantiated on the network by one of the existing peer nodes.
- **Setting up the SDK:** In order to interact with the network, a software development kit (SDK), such as the Hyperledger Fabric SDK for Node.js needs to be installed and configured.

To set up the Hyperledger Certificate-VPC network, certain prerequisites needed to be fulfilled. The network requires the use of Linux/macOS operating systems to function correctly. The latest version of Hyperledger Fabric (v. 2.2) was installed on the Linux operating system version, as depicted in Fig. 5.

The aforementioned prerequisites were installed successfully by following the official Hyperledger documentation. For the installation, Hyper-V containing Ubuntu 14.04.3 LTS was used on a Windows 10 operating system. Fig. 6 displays a screenshot of Hyperledger Fabric running on the local system.

1. **cURL** — latest version
2. **Docker** — version 17.06.2-ce or greater
3. **Docker Compose** — version 1.14.0 or greater
4. **Golang** — version 1.11.x
5. **Nodejs** — version 8.x (other versions are not in support yet)
6. **NPM** — version 5.x
7. **Python 2.7**
8. **Install Samples, Binaries and Docker Images**

Fig. 5. Prerequisites needed to run the hyperledger fabric.

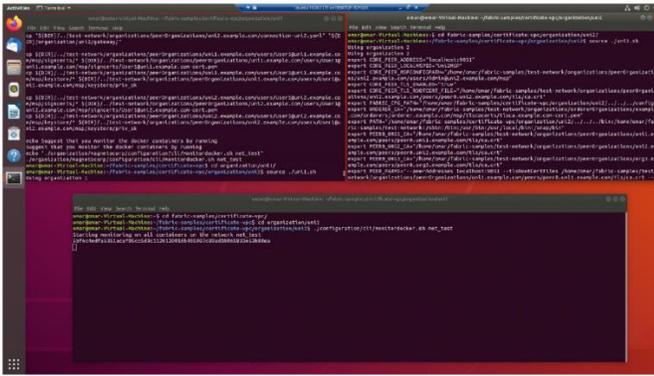

Fig. 6. Screenshot of hyperledger fabric running on the local system.

### B. Hyperledger Certificate-VPC Network

There are several requirements needed to be considered before creating the Certificate-VPC network, and they are as follows:

- Define the network actors.
- Define the peers.
- Define the channel.
- Define the transactions.

The proposed Hyperledger Certificate-VPC infrastructure setup is easily scalable, and the prototype proposed would contain one ministry that creates two universities, and each university creates two users and a peer. The network will suffice for the following:

- Certificate-VPC represents the whole network. One ministry over Hyperledger, which contains two organisations.
- Currently, there are two universities: university1 and university2. There are one or more peers for every organisation.
- A peer can be either a committing peer or an endorsing peer. We set up each organisation with one peer where chaincodes are installed in order to streamline the network configuration. Additionally, this peer commits to verifying transactions within a block.
- Despite the fact that a network may have more than one channel, as shown by the prior design, the Hyperledger Certificate-VPC is only constructed with one channel (the privacy channel).
- A channel is connected to a ledger (blockchain file) to log channel transactions.
- Transactions in Hyperledger Certificate-VPC are issuing, locking, unlocking, and requesting to verify the certificates.

After defining the requirements mentioned previously, setting up the Certificate-VPC network design is described in the next sections.

### C. Setting up the Hyperledger Certificate-VPC Network

To set up the Certificate-VPC network, certain Hyperledger Prerequisites are required, with Linux/MacOS being the preferred operating system. Running the network on Windows can be problematic due to issues with docker. Each main component of the network operates on its own docker. The key components of any Hyperledger network are organisations (in this case, universities) with their respective certificate authority and orderer, which has its own certificate authority. In this study, a ministry with the highest authority in the network will establish two universities/organisations, with the term "university" used to represent an organisation in the Hyperledger to avoid confusion. Uni1 and Uni2 are two hypothetical universities that belong to the ministry in the blockchain's genesis state. The namespace for the Hyperledger network is the URL for the solution, such as CertificateVerificationPrivacyControl.com. To simplify things, example.com is used, and components in the network are reached via a subdomain, such as order.example.com for the orderer and uni1.example.com and uni2.example.com for the universities. Each university has at least one peer represented in its own node as peer0.uni1.example.com. The universities and the orderer have been established, with each university having its own set of users, including students and peers. The administrators possess administrative privileges, whereas the users are granted client access, as demonstrated in Fig. 6. The only missing component is the channel that links these organizations together, as depicted in the illustration provided in Fig. 7. Once the CA server has been set up and all the necessary components have been added to the network, the network is considered to be partially operational. At this stage, two organizations and the orderer have been established, as displayed in Fig. 7. Each organization consists of both users and peers, with administrators possessing administrative privileges, while users are granted client rights.

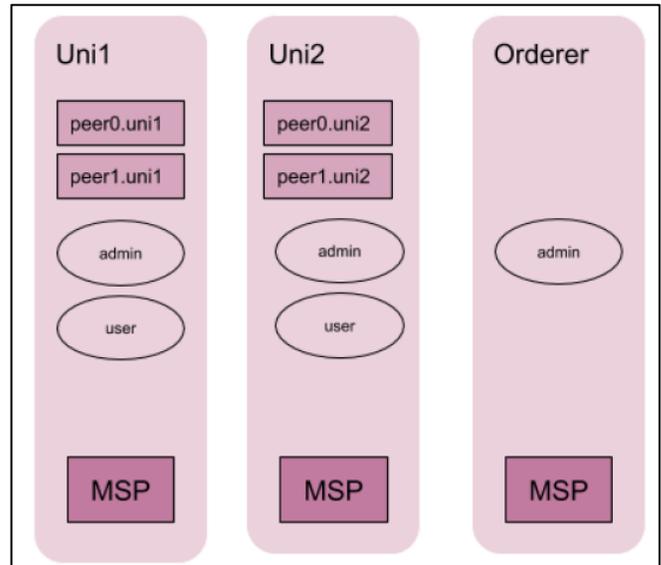

Fig. 7. Components of the created protocol.

With the DCVPC protocol, different types of policies at different layers have to be considered including the following:

1) *Network layer policy*: The policy describes the administrative capabilities of the network, which include the role of the ministry in adding universities and channels as outlined below.

- MinistryN,  $N \in \{\text{list of countries}\}$ ,  $n(\text{ministry}) = x$ ,  $x$  is a constant.
- Each MinistryN has  $\{\text{University}_1, \dots, \text{University}_i \mid i > 0, i = \text{identification of university}\}$ .
- MinistryN  $\rightarrow$  add  $\text{University}_i \mid i > 0, i = \text{identification of university}$ .

2) *Channel layer policy*: This policy outlines the administrative privileges of members at the channel level. This policy permits universities operating under a particular ministry to share a channel and host replicas of the ledger to facilitate their contribution to the network. During the initial phase, all universities created by the ministry will share a single network.

Fig. 8 shows that a channel has been successfully created on Hyperledger Fabric, which includes three organizations represented as universities. The process involved defining the channel configuration, including the policies, orderer settings, and member organizations, where the three universities would be the member organizations. The channel was then created using the Hyperledger Fabric CLI tool or SDK, and during the channel creation process, each university was required to join the channel by creating and signing a certificate and submitting a request to the orderer to join the channel. Once all three universities had joined the channel, they were able to interact with each other and share data, such as academic certificates. This channel provided a secure and private means of communication between the member organizations, ensuring that all transactions were validated and recorded accurately.

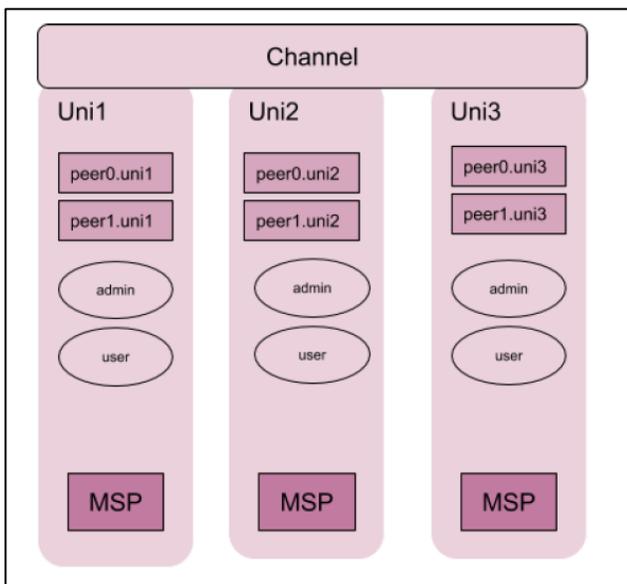

Fig. 8. Channel generation.

3) *Endorsement policy*: The policy being discussed outlines the criteria that must be met to establish the legitimacy of a transaction before it can be recorded on the blockchain. It's important to note that the endorsement policy, if set to something other than the default, would be defined in the configtx.yaml file. By default, the majority of organizations must approve the chaincode before it can be committed to the channel, which will be detailed in the following steps. This policy is sufficient for the design of DCVPC. Once the peers have joined the network, the ledger will consist of three blocks: the initial block created when the channel was established, and two additional blocks for each peer that joins the channel. With this step, most of the proposed design requirements for DCVPC are satisfied.

#### D. Universities Set Up Network starter

To set up the Hyperledger Fabric network, the first step is to generate all required digital certificates, identities of users, and components in the network. This involves using tools such as Hyperledger Fabric's cryptogen or a certificate authority deployed to each organization. To allow entities to use the network, each organization has a Membership Service Provider (MSP) or Certificate Authority (CA) responsible for generating crypto material, which includes private keys and digital certificates. The MSP acts as an identifier for each organization, and all organizations must know each other's MSPs to validate resulting identities. It is essential for university identities to be known and not anonymous, reflecting real-life situations where ministries oversee and monitor universities. Therefore, it is important to identify all file paths for each identity file in the docker-compose configuration file. After generating the crypto material, the necessary components such as organizations, peers, and orderers are started through the use of docker containers. All organizations participating in the network must know each other's MSPs to ensure the validity of transactions [17].

In the design of the blockchain network, the Membership Service Provider (MSP) is essential to identify the organisations participating in the network. An example of this is if an organisation called UUM generates a user named Ahmed using its MSP, other organisations should be able to identify from the signature that Ahmed belongs to UUM, and that UUM is a part of the network. All organisations within the network know each other's MSPs, making it crucial for university identities to be known and not anonymous. This reflects real-life situations where ministries tend to publicise and monitor the universities they oversee. It is also essential for external entities to identify the existing universities. Hiding the identity of universities within the network does not reflect real-life situations, so it was critical to consider this in the design process. The docker-compose configuration file identifies all file paths for each identity file. As shown in Fig. 9, Uni1's identity files are identified in the Docker-Compose configuration file.

```

    - peer0_uni1.example.com:/var/hyperledger/production
  working_dir: /opt/gopath/src/github.com/hyperledger/fabric/peer
  command: peer node start
  ports:
    - 7051:7051
  networks:
    - test
```

Fig. 9. Uni1 identity files are identified in the docker-compose configuration file.

In the volumes block, we can observe that the MSP configuration is mapped to the path peers/peer0\_uni1.example.com/msp. When the network is loaded, all the necessary files will be installed in this location. Hyperledger Fabric provides two methods to generate crypto material in the network: using a tool called cryptogen or a certificate authority server. Cryptogen streamlines the identity setup process by automating the generation of crypto material with minimal manual setup. Hyperledger also includes ready-made scripts, such as network.sh, to accelerate the setup process. By executing the network.sh script, the required identities are created using cryptogen and all necessary files are loaded into the corresponding folder path specified in the docker-compose configuration. The command to accomplish this is "cryptogen generate --config=<> --output=<>," with "config" referring to the configuration file defined for each organisation and orderer node inside the cryptogen/\*\_yaml folder. Certain configurations must be in place before starting the network, including each node's configuration in the cryptogen configuration file. The "Count" parameter under "Users" sets the number of users to generate for the university. Once the network.sh script has been executed, the running docker images can be listed, as shown in Fig. 10. Each docker container hosts a specific component in the network.

```
docker images
REPOSITORY          TAG                 IMAGE ID            SIZE
hyperledger/fabric-peer:latest   79617691          79617691            2.8GB
hyperledger/fabric-orderer:latest 79617691          79617691            2.8GB
hyperledger/fabric-peer:latest   79617691          79617691            2.8GB
```

Fig. 10. List of the docker images running.

The Docker configuration file that sets up the network can be found in the file named docker-compose-test-net.yaml. Once the network is up and running, you can access the ledger on either peer using the command docker exec <container-id> peer channel getinfo -c <channel-name>.

By starting the necessary containers and setting up the network, we can observe that the blockchain height is seven blocks, and we will explain the reason behind this shortly. Instead of using the container ID, we can refer to the peer using

its name, which in this prototype includes two organizations, uni1 and uni2, and one orderer. For each organization, we have added specific files, and you can find the list of Hyperledger Fabric files in Fig. 11.

```
ls -ll organizations/peerOrganizations/uni1.example.com/
16:17 ca
16:17 connection-uni1.json
16:17 connection-uni1.yaml
16:17 msp
16:17 peers
16:17 tlscacerts
16:17 users
```

Fig. 11. List of hyperledger fabric files.

The directories for peers and users contain lists of the respective peers and users associated with the organisation. An example of this can be seen in Fig. 12, which displays two main users - Admin and User1.

```
16:17 Admin@uni1.example.com
16:17 User1@uni1.example.com
```

Fig. 12. Users of each organisation.

When we navigate to the users' folders, we can find two sub-folders - msp and tls. The msp folder contains information related to the Membership Service Provider, including the credentials for the user. For instance, for the admin user, we can see the following information inside the msp folder. Additionally, the tls folder contains Transport Layer Security certificates that ensure secure communication between nodes. To get a better understanding of the contents of these folders, refer to Fig. 13, which displays their contents for all users.

```
16:17 admincerts
16:17 cacerts
16:17 config.yaml
16:17 keystore
16:17 signcerts
16:17 tlscacerts
```

Fig. 13. Users of MSP and Tls folder.

The "keystore" directory stores the private key, while the "signcerts" directory contains the certificate for each user. We can determine a user's assigned role by running the command 'openssl x509 -in organizations/peerOrganizations/uni1.example.com/users/User1@uni1.example.com/msp/signcerts/User1@uni1.example.com-cert.pem -noout -subject'. In the case of User1, the role is set as a client. The "ca" directory holds all cryptographic materials, including the private key and certificate for uni1, which can be viewed by running the 'ls'

command. Although "cryptogen" is fast and easy to use, it lacks flexibility when adding or loading entities to the network after deployment. For more control over the certificate generation process, we can use the Fabric CA server. This server hosts the CA, which consists of the private key and CA certificate. To start the network using the Fabric CA server, we can use the same script as before but with the option '-ca'. This will prompt the Fabric-CA-Client tool, which assigns a Fabric CA Admin to manage the addition of entities to the network. To assign the admin for the first university (admin:adminpw are the login details, which can be changed), we can execute the command shown in Fig. 14.

```
fabric-ca-client enroll -u
https://admin:adminpw@localhost:7054 --
caname ca-uni1 --tls.certfiles
${PWD}/organizations/fabric-ca/uni1/tls-
cert.pem
```

Fig. 14. Sample code for fabric-CA-client to assign a fabric CA admin

When adding users to the network, the script './network.sh' calls another script named 'registerEnroll.sh'. This script is responsible for registering and adding users to the network, along with their respective roles. To add a user named Ahmed to the first university, we need to follow these two steps:

Register Ahmed as a client by executing the following code shown in Fig. 15:

```
fabric-ca-client register --caname ca-uni1 --id.name ahmed
--id.secret ahmedpw --id.type client --tls.certfiles
${PWD}/organizations/fabric-ca/uni1/tls-cert.pem
```

Fig. 15. Sample code for registering the users.

Note that if Ahmed were an admin instead of a client, the 'type' parameter would be set to 'admin'.

Generate Ahmed's MSP by executing the code shown in Fig. 16.

```
fabric-ca-client enroll -u
https://ahmed:ahmedpw@localhost:7054 --caname ca-uni1 -M
${PWD}/organizations/peerOrganizations/uni1.example.com/
users/Ahmed@uni1.example.com/msp --tls.certfiles
${PWD}/organizations/fabric-ca/uni1/tls-cert.pem
```

Fig. 16. Sample code for generating the users' MSP.

Once the network is up and running, Ahmed will be successfully registered, as shown in Fig. 17.

```
omar@onar-Virtual-Machine:~/fabric-samples/test-network$ ls organizations/peerOrganizations/uni1.example.com/users/
Admin@uni1.example.com Ahmed@uni1.example.com User@uni1.example.com

Similarly if we add a user Omar to the second university this is what we get:

omar@onar-Virtual-Machine:~/fabric-samples/test-network$ ls organizations/peerOrganizations/uni2.example.com/users/
Admin@uni2.example.com Omar@uni2.example.com User@uni2.example.com
```

Fig. 17. Output of user get registered.

### E. Channel Creation

Creating a channel in Hyperledger Fabric can be easily accomplished by using the same script used to start the network with the command './network.sh createChannel'. In this command, '\$CHANNEL\_NAME' is the variable that sets the channel title. Behind the scenes, a tool called configtxgen is used to create the initial transactions, including the configuration transaction and the peer update transaction for each peer in the intended organizations. These initial transactions prepare the genesis block in the network, which is block #0 and sets the channel. Once the genesis block is set, peers can join the channel using the same block. For example, Fig. 18 displays sample code for creating a channel, while Fig. 19 shows the configuration file of the created channel.

```
peer channel create -o localhost:7050 -c $CHANNEL_NAME
--ordererTLShostnameOverride orderer.example.com -f
./channel-artifacts/${CHANNEL_NAME}.tx --outputBlock
./channel-artifacts/${CHANNEL_NAME}.block --tls --cafile
$ORDERER_CA
```

Fig. 18. Sample code for creating the channel.

```
Configtx.yaml

<<< *ChannelDefaults
Application
<<< *ApplicationDefaults
Organizations:
- *Uni1
- *Uni2
Capabilities:
<<< *ApplicationCapabilities
```

Fig. 19. The configuration file of the created channel.

After the process of setting up the CA server and adding the components to the network, the network is somewhat ready. So to package the smart contract into a chaincode, the command is as follows:

```
peer lifecycle chaincode package unicontr.tar.gz --lang node --  
path ~/contract --label cp_0 ./contract
```

In the above command, the lang specifies the execution language. ~/contract is the path to the smart contract to package. The end result of the above command is a tar.gz file that the admin of that active university can install. The installation is straightforward using the command install. Peer lifecycle chaincode install unicontr.tar.gz . After the installation step is done, the approval process should take place. Each installed chaincode has its own identifier which will allow for determining which chaincode to approve. Because the identifier is a long string, it is easier just to export it as an environment variable. The approval command initiated by the admin is as follows:

```
peer lifecycle chaincode approveformyorg --orderer localhost:7050 --ordererTLSHostnameOverride orderer.example.com --channelID mychannel --name papercontract -v 0 --package-id $PACKAGE_ID --sequence 1 -tl
```

An example of the results of implementing a Certificate Verification Privacy Control Protocol (DCVPC) based on the Hyperledger Fabric blockchain might include:

- Improved security: The use of Hyperledger Fabric blockchain ensures that the certificate issuance and verification process is secure, as all transactions are recorded on a tamper-proof ledger.
- Increased transparency: The CVPC protocol allows for increased transparency during the certificate issuance and verification process, as all transactions are recorded on the blockchain and can be easily audited.
- Reduced fraud: The use of smart contracts and digital signatures in the CVPC protocol can greatly reduce the possibility of fraud, as all certificates are verified and authenticated on the blockchain.
- Improved privacy: The CVPC protocol includes privacy-preserving protocols such as zero-knowledge proofs (ZKP) and homomorphic encryption (HE) to ensure that the personal information of certificate holders is protected during the process of issuance and verification.
- Better interoperability: The use of Hyperledger Fabric blockchain allows for better interoperability among different systems, as the CVPC protocol can communicate with other blockchain networks.
- Automated certificate verification process: smart contracts and blockchain technology automate the certificate verification process and make it more efficient.

## X. DISCUSSION

In this study, we introduce a novel protocol, called Decentralised Control Verification Privacy-Centered (DCVPC), which utilizes Hyperledger Fabric blockchain technology to preserve the privacy of academic certificates. The DCVPC protocol aims to address the limitations of current blockchain-based academic certificate management systems in terms of security and privacy. This is achieved by providing complete authority over all network nodes, establishing private environments for universities, and limiting access to the ledger.

The DCVPC protocol has been designed with a strong emphasis on security, and it is resistant to attacks by restricting access to the ledger and requiring approval from the most connected peers before committing any changes. Additionally, the use of Hyperledger Fabric blockchain technology improves interoperability and automation in the certificate verification process.

We implemented the proposed protocol and developed a proof-of-concept, demonstrating its effectiveness in preserving privacy during the academic certificate issuance and verification process. Our proof-of-concept provided valuable insights into the strengths and weaknesses of the DCVPC protocol and highlighted its potential for preventing forgery and unauthorized access to academic certificates.

One of the significant advantages of the DCVPC protocol is its use of digital identities and verifiable credentials for access control. This ensures that only authorized entities can access and manage academic certificates on the network, which helps to prevent fraud and forgery. Consequently, only deserving individuals can utilize their certificates for education and career opportunities.

In conclusion, the DCVPC protocol has shown promising results in preserving the privacy and security of academic certificates, preventing unauthorized access, and providing a trusted and reliable verification process. By utilizing Hyperledger Fabric blockchain technology and digital identities, our proposed protocol presents a significant step towards achieving a transparent and trustworthy academic certificate management system.

In conclusion, the proposed DCVPC protocol, based on the Hyperledger Fabric blockchain, is a promising solution for improving academic certificates' security, transparency and privacy. Furthermore, we can apply the protocol to other blockchain-based systems to manage educational credentials and enhance it further by incorporating other privacy-enhancing technologies, such as zero-knowledge proofs.

## XI. CONCLUSION

Academic fraud is a significant concern, including both impersonation of certificate recipients and the fabrication of educational institutions. The fake university problem arises when a non-legitimate institution creates a seemingly acceptable academic certificate, while the impersonated receiver problem arises when a person pretends to be the legitimate certificate recipient. Managing authority is also a significant challenge in academic certificate management. Access to resources should be tailored to the responsibilities of

each role. The diploma system involves students, universities, and verifiers, but educational authorities play a crucial role in overseeing institutions at all levels, despite not directly issuing certificates.

This study highlights the importance of Hyperledger Fabric for managing the privacy aspect of academic certificate management systems. We have developed Decentralised Control Verification Privacy-Centered (DCVPC) based on the Hyperledger Fabric blockchain to address these issues. The DCVPC protocol can significantly improve the certificate issuance and verification process by leveraging the security and transparency of the blockchain, as well as privacy-preserving protocols such as zero-knowledge proofs (ZKP) and homomorphic encryption (HE). Additionally, the interoperability and automation of the process provided by the Hyperledger Fabric blockchain can make the process more efficient and streamlined.

It is important to note that the specific results will depend on the particular requirements and constraints of the application, as well as the specific implementation of the DCVPC protocol on the Hyperledger Fabric blockchain. Nonetheless, the DCVPC protocol based on the Hyperledger Fabric blockchain shows great promise in significantly improving the certificate issuance and verification process while preserving the privacy of certificate holders. By addressing the challenges of authority management, academic fraud, and privacy, the DCVPC protocol presents a significant step towards achieving a trustworthy and transparent academic certificate management system.

**Abstract**—Breast cancer is a type of cancer that develops in the cells of the breast. Treatment for breast cancer usually involves X-ray, chemotherapy, or a combination of both treatments. Detecting cancer at an early stage can save a person's life. Artificial intelligence (AI) plays a very important role in this area. Therefore, predicting breast cancer remains a very challenging issue for clinicians and researchers. This work aims to predict the probability of breast cancer in patients. Using machine learning (ML) models such as Multilayer Perceptron (MLP), K-Nearest Neighbor (KNN), AdaBoost (AB), Bagging, Gradient Boosting (GB), and Random Forest (RF). The breast cancer diagnostic medical dataset from the Wisconsin repository has been used. The dataset includes 569 observations and 32 features. Following the data analysis methodology, data cleaning, exploratory analysis, training, testing, and validation were performed. The performance of the models was evaluated with the parameters: classification accuracy, specificity, sensitivity, F1 count, and precision. The training and results indicate that the six trained models can provide optimal classification and prediction results. The RF, GB, and AB models achieved 100% accuracy, outperforming the other models. Therefore, the suggested models for breast cancer identification, classification, and prediction are RF, GB, and AB. Likewise, the Bagging, KNN, and MLP models achieved a performance of 99.56%, 95.82%, and 96.92%, respectively. Similarly, the last three models achieved an optimal yield close to 100%. Finally, the results show a clear advantage of the RF, GB, and AB models, as they achieve more accurate results in breast cancer prediction.

**Keywords**—Prediction; models; machine learning, cells; breast cancer

## I. INTRODUCTION

Breast cancer can be classified as a type of cancer that occurs in the cells of the breast. Both men and women can get it, although women are more likely than men to suffer from it. The process of breast cancer begins with the uncontrolled

growth of cells in the lining of the breast [1]. At first, there are no symptoms of pain or cancerous growth, and has a low potential for metastatic growth and is limited to the lobe where it grows without generating any symptoms [2],[3]. Symptoms of breast cancer can include anything from a small lump in the breast to changes in the shape of the breast or changes in the color of the skin [4], to identify breast cancer early, it is important to undergo early detection tests, as there are many types of breast cancer and many of them do not cause symptoms at first. Lobular carcinoma in situ, for example, is a type of cancer that occurs in the area of abnormal milk-producing cells of the breast. Invasive lobular carcinoma, which develops in the lobules of the milk-producing mammary glands, people with this symptom experience thickening of the breast tissue, swelling of the breast, and change in skin texture. Ductal carcinoma in situ, this type of cancer usually does not cause symptoms, it is discovered through mammography and invasive ductal is the most common type of cancer accounting for approximately 80% of cases [5]–[7]. There is solid evidence that alcohol consumption, growing older, having dense breasts, family history, radiotherapy treatments, obesity and exposure to radiation increase the risk of breast cancer [2], [8] in turn, it has been shown that prolonged breastfeeding, the development of the physical activity, avoiding harmful consumption of alcoholic beverages and refraining from smoking save, avoiding prolonged use of hormones reduce the risk of breast cancer [8], [9], [10]. Also, mortality from breast cancer in 2020 was 684,996 worldwide, representing 24% of all cancers. While it is true, in recent years the rates of breast cancer events and mortality have been decreasing worldwide [11]. For example, China has the highest rate of breast cancer, with 17.1%; Africa reached 2.5%; the United States at 4%, Japan at 7%; Morocco at 12.5%; Hungary at 2.1% [12]. As shown in Fig. 1, the countries with the highest rates of breast cancer are present in all continents; the continent of Asia concentrates the highest number of deaths from breast cancer.

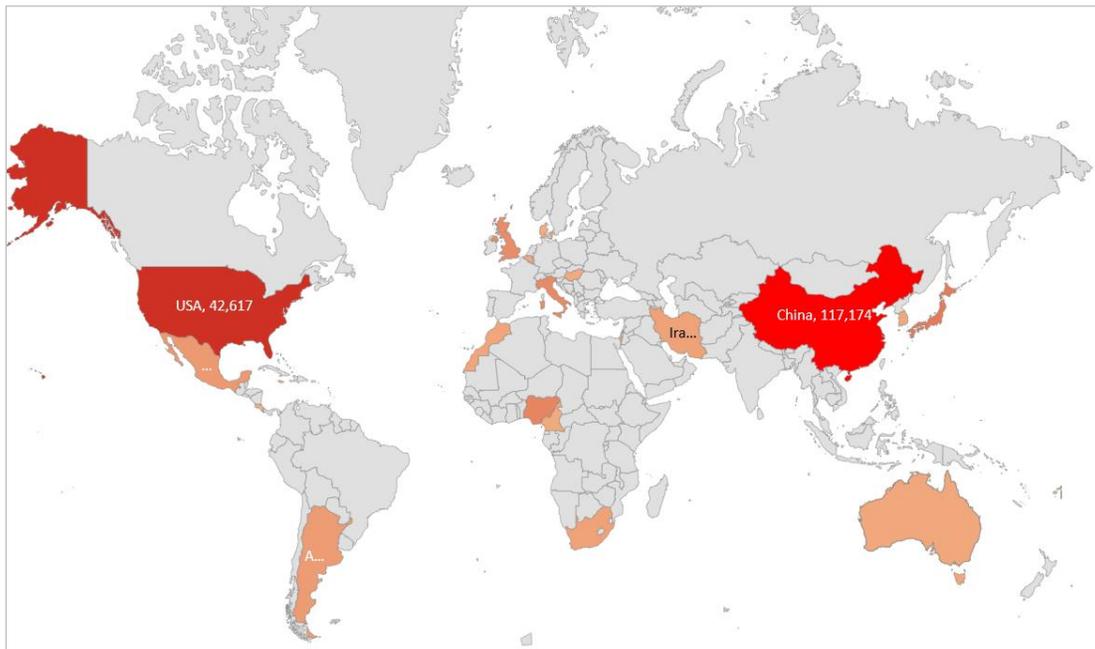

Fig. 1. Breast cancer by country 2022.

In the last decade, technology has undergone impressive development, and with it, ML models are becoming increasingly popular for breast cancer prediction. These models can be used to analyze large patient data sets, such as mammograms, to identify patterns associated with breast cancer development [13]. From these data, ML models can accurately predict a person's risk of developing breast cancer. The accuracy of these models can be further improved by incorporating additional factors such as lifestyle, diet, and family history [14], [15]. With the increasing availability of high-quality datasets and technological advances, ML models are becoming increasingly reliable for breast cancer prediction [16], [17]. There are many types of ML models that can be used to predict the probability that a person will develop breast cancer [18] in this paper we use the classification models such as MLP, KNN, AB, Bagging, GB, and RF, considering that they have excellent performance and performance to analyze and correlate the measurements of the established features. Using features associated with cancer cell imaging, breast cancer can be predicted using ML models. This field of action is in constant development from two deans to after [19], [20].

This paper uses the Wisconsin breast cancer diagnostic dataset to predict and diagnose the likelihood of breast cancer in patients by analyzing six ML models. The dataset is composed of digitized mammogram images and consists of 569 observations and 31 attributes [21]. It also incorporates nine parameters set on a scale of 1 to 10 with values categorized into "benign" or "malignant" tumors.

The article's organization is divided into the following sections. In section II, we describe the most important works that have been done in the area of models of ML. In section III, you will find a description of the method and examples of its application. A summary of the results and discussion of the study can be found in Section IV. Lastly, in Section V, we will present the conclusions that have been reached.

## II. PREVIOUS STUDIES

WHO, American Cancer Society, and scholars have published work related to breast cancer. For example, in [22], [23] they analyzed six ML models with the aim of determining the degree of accuracy of each of them. For this, they used three parameters such as age, cell type with cancer, and cell interface receptors. Also, in [24] developed a predictive model to categorize people with breast cancer using the logistic regression (LR) model, GB model, decision tree (DT), and RF model. Obtaining the following results for the LR model 81.9%; GBT with 82%; RF with 82.8%, respectively. Similarly, in [25] they proposed a model to detect breast cancer using ML models. The tests were performed on a dataset consisting of 317,880 clinical observations. The proposed model achieved an accuracy of 91.22%, and a false rejection rate of 112%. Also, in [26] they used a strategy with feature selection, extraction, and classifier algorithms for breast cancer diagnosis. This study included 762 patients with breast cancer and 138 people without cancer. ML algorithms were used a: 1) LR; 2) SVM; 3) Bagging; 4) GNB; 5) DT; 6) GB; 7) K-NN; 8) BNB; 9) RF; 10) AB, 11) Extra Trees (ET) and 12) MLP. The models that achieved the best results were: LR+MLP with 94%. ML models have demonstrated their contribution to the prediction and early diagnosis of cancer. For example, in [27] they conducted a study to predict and diagnose breast cancer using ML models, for which they used parameters such as specificity, sensitivity, precision, accuracy, precision, and F1 score. The GBDT model obtained a score of 96.77 outperforming all other models. The advancement of Artificial Intelligence (AI) has allowed ML techniques and algorithms to become increasingly efficient in prediction, as evidenced in [28] where they developed a model using ML algorithms to identify and classify different types of cancer. They applied the RF, SVM, and RF models to correctly classify breast cancer cases, obtaining a result: sensitivity of 97.12%, specificity of

96.14%, and accuracy of 97.11%. Artificial intelligence has played a very important role in clinical fields, so much so that, in [29] they evaluated the repeatability of ML model types such as re-regressive, multiclass classification, binary rating, and ordinal classification. The results indicated that classification accuracy improved significantly in most environments. Breast cancer negatively affects the quality of life of patients. In view of this, in [28] they selected an appropriate model to classify and predict the causes that lead to contracting breast cancer, for this purpose they used 970 people with breast cancer. As a result, the SVM model showed the highest sensitivity and an accuracy of 91%, demonstrating that the application of ML algorithms helps the classification of characteristics and the optimization of the genetic algorithm. Accurately distinguishing malignant and benign tumors in patients is crucial to saving lives. That is why in [30] they developed a technique for binary classification of malignant tumors of breast cancer, for which they used three pre-trained convolutional neural network (CNN) models such as RestNet-50, EfficientNetb0, and Inception-v3, applying transfer learning and fine-tuning. The proposed method achieved an accuracy of 98.92%, a sensitivity of 99.87%, a specificity of 97.97%, and an F1 score of 0.9987. In the same line, [30] developed an algorithm based on artificial neural networks (ANN), with the purpose of predicting breast cancer, achieving the following results: accuracy of 98.74%, and an F1 score of 98.02%. Computer-assisted breast cancer screening improves the chances of early detection and diagnosis. So, in [31], [32] proposed a breast cancer screening technique to assess the probability of recurrence of individuals with cancer. The model was trained with 6447 patients diagnosed with breast cancer, the data features were classified with conventional ML and CNN. The best accuracy yielded 88.8%, accuracy 89%, and an F1 score of 0.5. The rapid growth of ML models such as CNNs has promoted the massive use of these technologies in biomedical image classification. For example, in [33] they developed an ML technique to classify breast cancer from histopathological images. The model has been tested with the publicly available BreakHis dataset and has obtained significant accuracy.

### III. METHODOLOGY

This section presents the theoretical basis of the MLP, KNN, AB, Bagging, GB, and RF models and the development of the work to predict and diagnose breast cancer.

#### A. Multi-layer Perceptron

The MLP is an ANN type. It uses backpropagation to train the network [34]. The MLP is composed of multiple layers, each of which is connected to all the others, forming a directed network [35]. The MLP learns a feature from a set of inputs and combines the various features into a set of outputs [36]. The layers usually have weights and polarization units that are adjusted during training. It should be noted that, with the exception of the input nodes, each node in the network is a neuron using a nonlinear activation function, and its equation is given by the following equation and is represented by the following Eq. (1).

$$h_{1j} = f\left(\sum_{i=1}^n w_{ij}x_i + b_j\right) \quad (1)$$

MLP is widely used in supervised learning, where it can learn to classify and predict data. In equation (1),  $h_{1j}$  is defined as node  $j$  of the hidden layer  $h_1$ ,  $w_{ij}$  represents the input gate of node  $j$  of the hidden layer  $h_1$  and  $b_j$  is the bias. In MLP network training, loss functions play an important role. The feature vectors are modeled by the network using loss functions, which are evaluated based on how well the architecture models them. As shown in Fig. 2, the multilayer perceptron model.

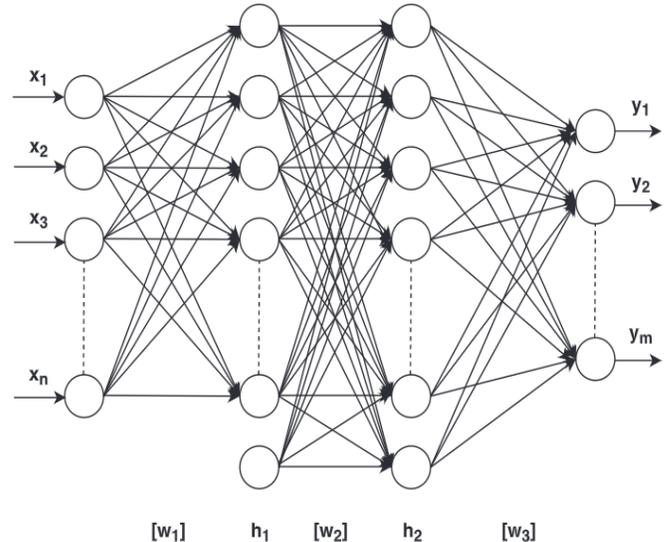

Fig. 2. MLP architecture.

MLPs are limited by their structure, as they are not as flexible as deep learning networks, but they can still be powerful classifiers. Moreover, they do not require large amounts of data, which makes them suitable for many applications [34]. This is the number of training epochs that increases the loss function and gradually reduces its error through optimization.

#### B. K-Nearest Neighbor

As a nonparametric supervised learning classifier, the K-NN algorithm uses proximity to perform classifications and predictions to perform classifications and predictions, respectively [35]. The algorithm stores the attribute vectors and labels used during its training phase so that the algorithm can be retrained [36]. To label the unlabeled vector,  $K$  is set as a user-defined variable, and a label is assigned among the training attributes that are considered most relevant to classify the vector [37]. As for distance metrics for continuous variables, Euclidean distance is used, which is limited to real-valued vectors, for which Eq. (2) is used, and for discrete variables, the overlap metric is used [38].

$$d(x, y) = \sqrt{\sum_{i=1}^n (y_i - x_i)^2} \quad (2)$$

The use of the K-NN model in ML mainly has a better performance in classification and prediction. For example, in data processing, estimating values, automatic recommendations, finance, credit data, in health, its best results have been in predicting the risk of heart attacks, breast cancer, and prostate cancer [39].

### C. AdaBoost

AB is an ML classification algorithm; its principle is based on building strong classifiers by combining basic or weak classifiers. This classification algorithm works on adaptive sampling to select the between samples [40]. This algorithm iteratively trains the weak classifiers, for which it uses weighted data to incorporate it into an ensemble, to then have the strong classifier [41], as shown in Fig. 3.

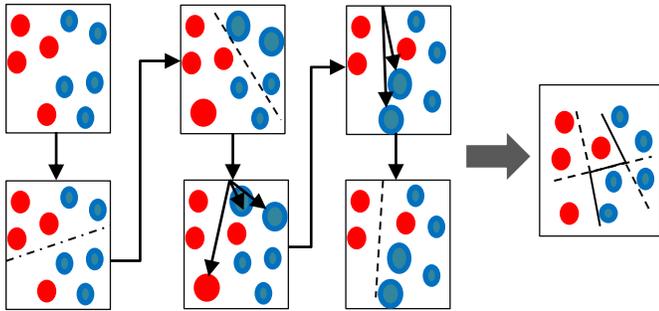

Fig. 3. AB algorithm scheme of work.

Fig. 3 shows that the AB algorithm generates several weak classifiers, where each of the classifiers has a set weight in its performance. Finally, the prediction is obtained by combining the weak classifiers and voting by weight.

### D. Bagging

The bagging model is an ML technique used to improve the accuracy and stability of classification algorithms. It works by combining multiple weak classifiers to form a more robust prediction model [42]. The idea is to create multiple versions of the classifier, each with a different set of parameters, and then combine the results from all of them to produce a better overall prediction [43]. These types of algorithms are run in parallel and seek to take advantage of the independence that exists between single-classifier algorithms, given that the best classifier is chosen by the majority. The Bagging implementation process follows the following steps: Step 1: multiple subsets are created from the data set; Step 2: the base model is created in each of the training subsets; Step 3: each model learns in parallel with each training set; Step 4: the final predictions are determined by combining the predictions of all models.

### E. Gradient Boosting

This classifier combines several weak predictors into a single strong predictor [44]. Using this method, the accuracy of the predictors can be increased by adding predictors sequentially to a set of predictors, each of which corrects the previous one [44]. Basically, the goal of this technique is to find the best predictor for a given problem by iteratively training the model using weak predictors, and gradually improving them until they become strong learners just before solving the problem [45]. This technique has many applications, from data mining to ML or IA.

### F. Random Forest

In the ML field, RF is an algorithm that works as an ensemble. To make predictions, a large number of decision trees are used together to create the decision tree [46]. A decision tree is created using a random subset of the data, and then the results of each tree are combined to make a final prediction, based on the results of all the trees [47]. In terms of classification and regression areas, RF is an extremely powerful algorithm. It can handle large data sets and can be used for both supervised and unsupervised learning. Fig. 4 shows what the model prediction looks like for a new observation.

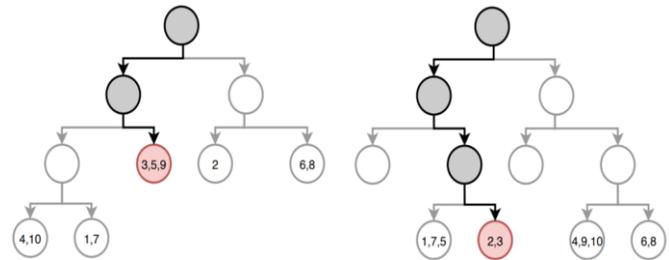

Fig. 4. RF algorithm flowchart.

### G. Understanding Data

According to the American Cancer Society (ACS), a lump is one of the most common symptoms of breast cancer [1]. Several benign breast conditions can cause cancer-like symptoms. However, some of these disappear with time and others require medical treatment. These conditions include cysts, mastitis, hyperplasia, sclerosing adenosis, intraductal papilloma's, fibroadenoma, radial scar, fatty necrosis, and phyllodes tumors. Fig. 5 shows some signs of breast cancer, such as: retracted or inverted nipple, breast or nipple pain, lumps, redness/rash, and changes in skin texture.

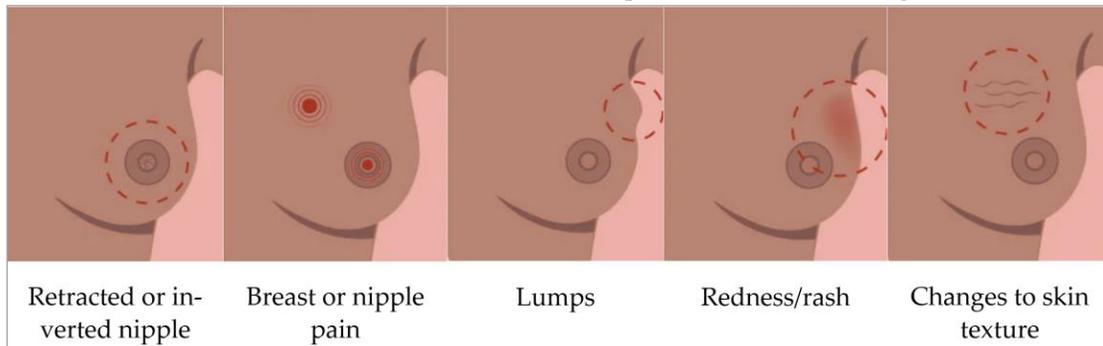

Fig. 5. Signs of breast cancer.

For this work, the Wisconsin Breast Cancer Diagnostic Dataset was used to identify and predict breast cancer. For this purpose, six classification models were used: MLP, K-NN, AB, Bagging, GB, and RF. In addition, univariate analysis, bivariate analysis, and correlation analysis are used for exploratory data analysis (EDA). To evaluate the accuracy of the model, the following methods are used: confusion matrix, classification report, and AUC. The dataset corresponds to digitized images of samples and is composed of 569 observations and 31 attributes: diagnosis, Radius-mean(R-ME), Texture-mean(T-ME), pe-perimeter-mean (P-ME), area-mean(A-ME), smoothness-mean(S-ME), compact-ness-mean(C-ME), concavity-mean(CO-ME), concave points-mean(CP-ME), sym-metry-mean(S-ME), fractal dimension-mean(FD-ME), radius-se(R-SE), tex-ture-se(T-SE), perimeter-se(P-SE) area-se(A-SE), smoothness-se(S-SE), compact-ness-se(C-SE), concavity-se(CO-SE), concave points-se(CP-SE), symmetry-se(S-SE), fractal-dimension-se(F-D-SE), radius-worst(R-WO), texture-worst(T-WO), perimeter-ter-worst(P-WO), area-worst(A-WO), smoothness-worst(S-WO), compact-ness-worst(CO-WO), concavity-worst(C-WO), concave points-worst(CP-WO), sym-metry-worst(S-WO) and fractal-dimension-worst(F-D-WO).

H. Data Cleansing

The data cleaning process, for this case study, was performed using Python programming language was performed using a variety of libraries and techniques. Among the libraries used were Pandas, NumPy, SciPy, Scikit-learn, and NLTK. The Pandas library was used to read data, clean it and manipulate it. It is useful for dealing with missing values, outliers, and other problems. The NumPy library was used to perform calculations on the data, such as mean, median, mode and standard deviation. SciPy and Scikit-learn are declared for the use of ML and statistical analysis. Also, it is used to perform regression, clustering, and other types of analysis. NLTK library is declared for further use for data processing. Also, it will be used to extract text features, such as sentiment analysis and keyword extraction. We then proceeded with loading the dataset and identifying each of the variables, as shown in Table I. The number of variables and the type of data for each of the variables. In addition, in this section, we try to eliminate all duplicate data, handle outliers and deal with incorrect data.

I. Exploratory Data Analysis

EDA is an approach to data analysis for organizing key features. Primarily, EDA is used to see what the data can say beyond the formal task of modeling or hypothesis testing. EDA is also used to check the data for interesting features or outliers that may suggest the need for further examination. In addition, EDA can be used to evaluate the assumptions of a model before fitting it to the data. In order to visualize the data graphically, the diagnosis column first had to be enumerated so that Malignant(M)=1, Benign(B)=0. Then, the ID column was set for the dataset, the ID column will not be used for ML. For this, the countplot(), plt.figure() and print() functions were used. As shown in Fig. 6.

Now, for a better understanding of the content of Table II, it is important to have basic knowledge about variance, standard deviation, number of samples, or the maximum and minimum values. This type of information provides a better understanding of what is happening with the data. Therefore, before visualization understands standardization, feature extraction, and feature selection.

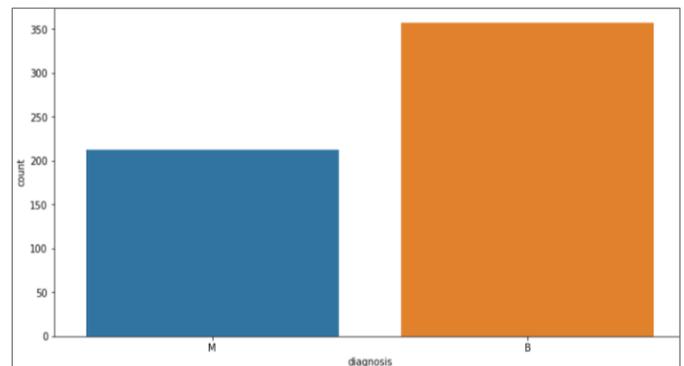

Fig. 6. M and B cancer diagnosis count.

75%	[15.780000]	[21.800000]	[104.10000]	[782.700000]	[0.1053000]	[0.1304000]
max	[28.110000]	[39.280000]	[188.50000]	[2501.00000]	[0.1634000]	[0.3454000]

For better visualization of the data, we used the seaborn library, but we classified the features into three groups because the differences between the feature values were so high that it was impossible to observe them, as shown in Fig. 7. Each group includes 10 features for a more effective presentation of the data.

Fig. 7 can be seen. For example, that the T-ME features, the median of M and B appear separate, so it can be very useful for classification. The FD-ME feature, however, does not separate the median of the M and B, so the median in this case cannot be used to classify the data. For reasons of space, the following groups are not shown. In the classification, it was also shown that the variables C-WO and CP-WO are very similar. However, it cannot be stated that they are correlated with each other, in the case of being correlated; one of the two variables is eliminated. To compare the two characteristics more deeply, the joint plot is used.

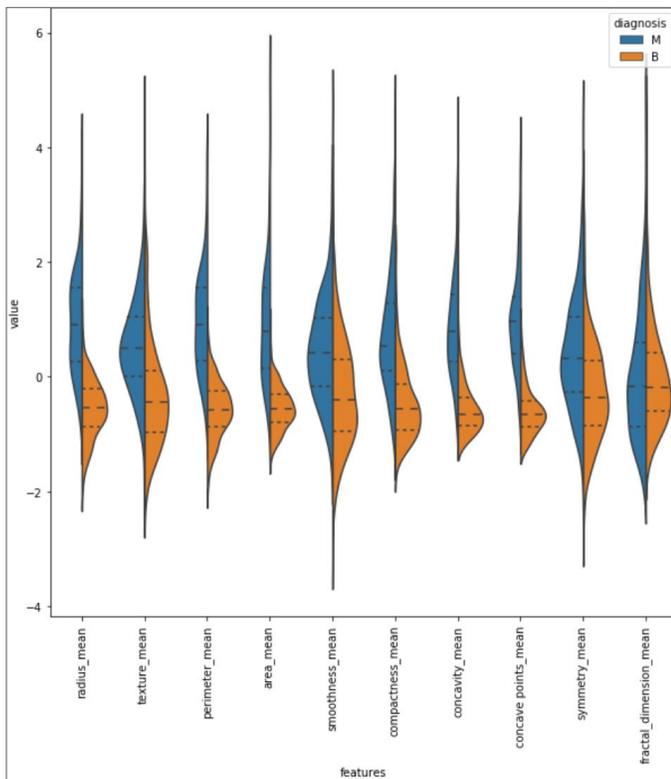

Fig. 7. Standardization and classification of characteristics.

In the next step, features are selected using correlations, univariate features are selected, recursive feature elimination with cross-validation is performed, and attribute categorization is performed. MLP, K-NN, AB, Bagging, GB, and RF classification are used to train the model and predict. As shown in Fig. 8, the R-ME, M-ME, and A-ME features are correlated with each other, so only the A-ME feature will be used. In this way, the features that are correlated are found, with support of the classifiers. C-ME, CO-ME, and CP-ME are correlated with each other, so only CO-ME is chosen. In addition, R-SE, P-SE, and A-SE are correlated, so only A-SE was used. R-WO, P-WO, and A-WO are correlated, so I use A-WO. CO-WO, C-WO, and CP-WO are correlated, so C-WO was used. C-SE, CO-SE, and CP-SE are correlated, so I use CO-SE, T-ME, and T-WO are correlated so I use T-ME, A-WO, and A-ME are correlated so I use A-ME. Specifically, X and Y are not correlated at all; the correlation seen in Fig. 8 is such a strong correlation by chance.

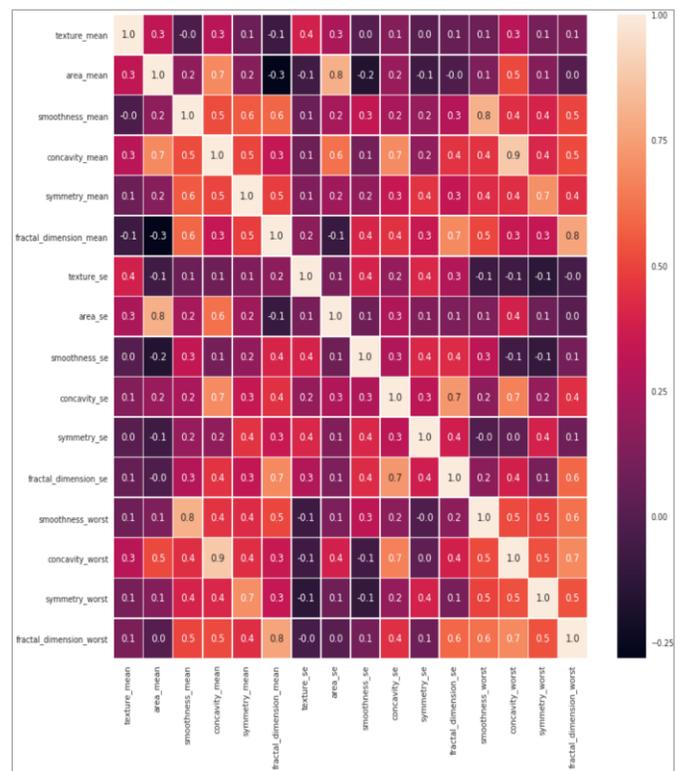

Fig. 8. Numerical correlation of variables.

As part of this work, we use the normalization technique for feature scaling to convert feature values into a mean-centered distribution with unit standard deviation, and this feature scaling method has been widely used in ML algorithms. There are several types of neural networks, such as MLP, K-NN, AB, Bagging, GB, and RF. For example, there is a requirement to normalize features in algorithms such as K-NN and MLP. As a result of the different properties measured by the dataset at each scale, there are heterogeneous features among the datasets at each scale.

**J. Model Training and Testing**

In univariate feature selection, SelectKBest is used which eliminates all features except those with high scores. This method allows choosing the number of features to use. For example, the number of features(k)=5, which means that the model must find the 5 best features, this is achieved with the following function: SelectKBest(arg, k=5).fit(x\_train, y\_train). The results are presented in Table III.

The next step consists of preparing the MLP, K-NN, AB, Bagging, GB, and RF models for training and validation using the train\_test\_split(), project\_data.drop(),

X\_train.select\_dtypes() and Pipeline() functions. The latter allows training the model with the data by adjusting its parameters to create a model that can accurately predict the result while evaluating the model to ensure its accuracy and reliability.

Then the prepare\_model() function is used to compile the model with a given number of features. It takes the features as an argument and returns a compiled model as its output. Also, the function prepare\_confusion\_matrix(y\_true, y\_pred) is used to print the confusion matrix, as shown in Fig. 9. Similarly, the function prepare\_classification\_report() is used to generate the classification report for the given results. Finally, the prepare\_roc\_curve() function allows preparing the receiver operating characteristic (ROC) curve and calculates the false positive rate and the true positive rate, which allows for measuring specificity, and sensitivity, among others. After the evaluation, the following results were obtained [Bagging: 99.78021978021978%; K-NN: 96.7032967032967%; RF: 100.0%, AB: 99.56043956043956%; GB: 100.0% and MLP: 96.26373626373373626%]. It should be noted that only four models have been presented in Fig. 9: Bagging, K-NN, AB, GB.

#### IV. RESULTS AND DISCUSSION

After training the MLP, K-NN, AB, Bagging, GB, and RF models, on the data set, a learning algorithm is created and used for training. The performance of the models with

unobserved data is then evaluated. The evaluation of each of the models was performed by testing their performance on unseen data. Metrics such as accuracy, precision, recall, F1 score, and ROC curve are used to determine model performance as shown in Table IV.

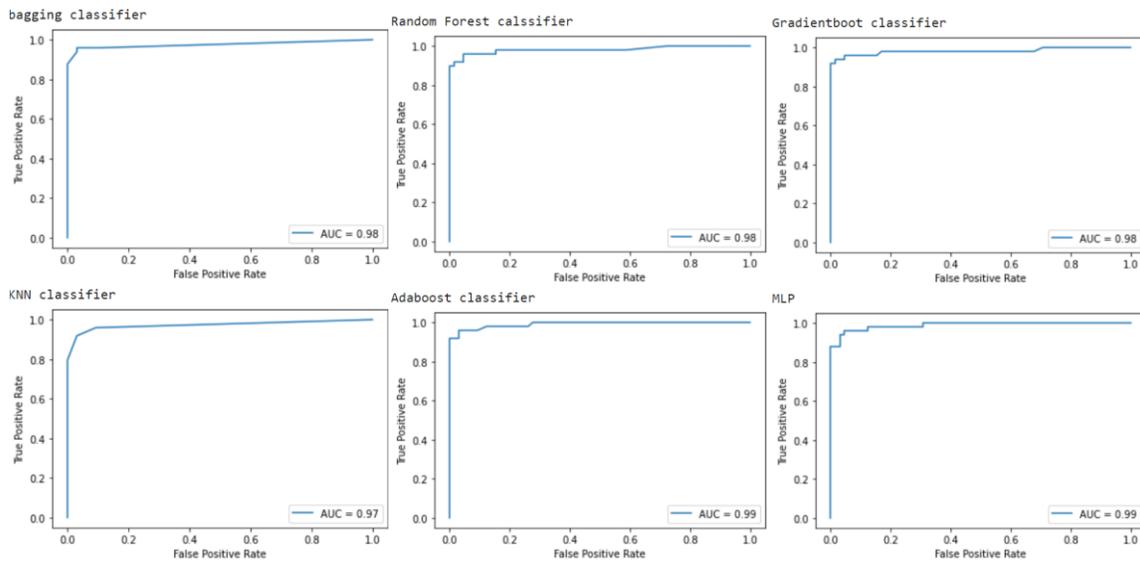

Fig. 10. Performance curve of ML models.

The false positive rate for each model is calculated in a similar way. For example, in the case of the Bagging technique, it helps to improve stability and accuracy by creating various models; in the K-NN model it is the ratio of false positives to the total number of points; in the RF model, it is the rate of false positives that the classifier incorrectly identifies a negative event (e.g., a "no" or a "0") as a positive event (e.g., a "yes" or a "1"); in the AB model the "false positive" rate and the true positive rate depend on the algorithm, the complexity of the data analyzed and the parameters used for the classifier. In general, the false positive rate is quite low, and the "true positive" rate is quite high for AB and in the MLP model, the false positive rate is the probability of misclassifying a true negative case as a positive case. In much the same way the true positive rate is calculated. For example, in the Bagging model, the true positive rate is the proportion of correctly classified positive cases divided by the total number of positive cases; similarly, in the RF and GB model, the true positive rate is the rate at which the classifier correctly identifies a positive event (e.g., a "yes" or a "1"); in the MLP model, the true positive rate is the probability that it correctly classifies a true positive case. Now, for each model, we evaluated the AUC (AUC) performance curve. For example, the models used in this work; Bagging, K-NN, RF, AB, GB, and MLP, obtained the following performance: 98%, 97%, 98%, 98%, 99%, 98%, and 99%, respectively. Fig. 10 shows that the performance curve of each of the models is optimal, reaching practically on average 98%, this makes it possible to opt for any of the models used in this work to classify and predict breast cancer.

For the training and validation of each model used, we worked with an adequate data set. The results shown in Fig. 10 and Table IV show that the performance of each model was successful in cancer prediction accuracy. These results showed superiority in the same ML models in [24] and [26] where the Bagging and K-NN models achieved a performance of 96.47% and 96.40% in predicting Breast Cancer. These results do not determine that one is better than the other, on the contrary, the

performance rate varies according to different factors, and one of them is the volume of data with which it is trained. On the other hand, in [26] they developed a model to predict breast cancer, for which they used the RF model, with which they achieved an accuracy performance of 97.1%, very similar to the 98% accuracy obtained in this work. AI has played a very important role in clinical fields, and models such as AB have contributed a great deal in this field, since it is the model that has achieved the best results, reaching 99% in this study. Likewise, in [29] in the binary classification of malignant tumors of breast cancer, it reached 99.92% accuracy, which makes it the best model for classifying and predicting breast cancer. Similarly, the GB model, which is an excellent classifier by adding predictors sequentially, achieved a 98% performance rate in training, which is also in agreement with the results obtained in [30], where they used the GB model for the purpose of predicting breast cancer, where it achieved a 98.74% performance rate. Finally, the MLP model is characterized as one of the best predictors, this predictor learns a feature from a set of inputs and combines the different features in a set of outputs, the performance rate of this model has been 99%, and it is a result with a high pre-accuracy rate, which allows it to be a reliable option for the prediction of breast cancer. Also, [20], [21] used this model with three clinical factors: age, cancer cell type, and cell surface receptors, obtaining satisfactory results, with a performance rate of 98%. The summary of the analysis of the 6 models used in this work to predict breast cancer is presented in Table V.

TABLE V. SUMMARY OF THE ANALYSIS

Model	Train Accuracy	AUC SCORE
Bagging	99.56	0.97
KNN	95.82	0.97
RF	100	0.98
Adaboost	100	0.96
GB	100	0.97
MLP	96.92	0.98

## V. CONCLUSIONS

Prediction of different types of cancer is one of the most complex fields of medical engineering and AI. In this work, 6 ML models were trained for breast cancer prediction, for which the Wisconsin breast cancer diagnostic dataset was used, with the purpose of predicting and diagnosing in patients the probability of having breast cancer. The dataset corresponds to digitized images of samples and is composed of 569 observations and 31 attributes. Also, the performance of the results of each of the models was analyzed, as shown in Fig. 10. Also, the behavior was compared in the context of the work developed: the Random Forest classifier, Adaboost, and Gradientboot, achieved the best results of 100%, more accurate in terms of breast cancer prediction. The normalization technique was used for feature scaling with the purpose of converting the feature values into an input distribution at the mean with a unit standard deviation. This can be seen in the numerical correlation of variables in Fig. 8, also, Table III shows the univariate characteristics. Table V shows the accuracy of each model: Bagging 99.56%; KNN 95.82%; Random Forest 100%; Adaboost 100%, Gradientboot 100%; and MLP 96.92%. The main contributions of this work consist of the evaluation of 6 ML models for breast cancer prediction. Likewise, the results keep a clear originality of this work, and at the same time confirm that the results obtained in this work are related to other similar works that used ML techniques applied to breast cancer prognosis.

In the future, a possible development that would complement the use of the models would be the development of a mobile application based on services to consume the implemented model. The most important contribution of this work is that doctors through ML models can analyze the data of breast cancer patients in a personalized way to predict their effectiveness, constituting a support tool for health. Limitations of this work include: 1) The data used for training may be biased, which means that there may be biases between terms; 2) the quality of ML model data depends on the quality and volume; if the data is limited, the results will be inaccurate; 3) in terms of resources, training ML models requires a processor with a high responsiveness.

# Placement of Edge Servers in Mobile Cloud Computing using Artificial Bee Colony Algorithm

Bing Zhou\*, Bei Lu, Zhigang Zhang

College of Artificial Intelligence, Jiaozuo University, Jiaozuo, Henan, 454000, China

**Abstract**—Utilizing smart mobile devices for entertainment, education, and social networking has grown recently. Even though mobile applications are getting more sophisticated and resource-intensive, the computing power of mobile devices is still constrained. Mobile phone applications can perform better by shifting parts of their functions to cloud servers. However, because the cloud is frequently positioned far from mobile phone users, there may be a significant and unpredictable delay in the data transfer between users and the cloud. It is crucial for mobile applications since customers value rapid responses greatly. Users of mobile phones can get close-up access to information technology and cloud computing services thanks to mobile edge computing. In this article, the main goal is to use an artificial bee colony meta-innovative algorithm to solve the problem of placing edge servers in mobile edge computing. Moreover, load balancing between servers is one of the challenges discussed in this article. To deal with this issue, determination the locations of the servers using considering the distribution of workload between servers as a cost function in the artificial bee colony algorithm is a focused issue in this study. The results of the proposed method are compared with the load balancing criteria. The results of K-means compared to the clustering method show the superiority of the proposed method with regard to the loading criteria compared to this clustering method.

**Keywords**—Artificial bee colony algorithm, k-means, server placement, mobile cloud computing

## I. INTRODUCTION

Now-a-days, smart mobile devices have become more critical for smart life [1-3]. In order to accelerate the growth of smart cities, it is necessary to increase the data transfer rate and the amount of infrastructure that is utilized by the services and application programs that make up the smart city [4, 5]. Due to the limited resources of mobile devices, mobile phone users do not experience the same levels of satisfaction as desktop device users, despite the fact that mobile applications are developing and becoming more computationally intensive [6]. Principally, we have a number of users in this issue. Users have a number of requests, and servers have the duty to respond to users' requests. Since each user has a specific position, each server must respond to the requests of users who are close to that server as much as possible. User requests are distributed between servers as a load. Loading part of the activities of mobile phone applications in remote-rich clouds is an effective technique to boost their performance [6–10]. However, because the cloud is frequently situated very distant from mobile phone users, there may be a significant and unpredictable delay in the data transfer between the two parties. It is undesirable for mobile applications, including augmented reality apps and

mobile multiplayer gaming systems, where consumers value quick responses highly.

Mobile phone edge computing enables users of mobile phones to access cloud computing and information technology services inside radio access network coverage [11,12]. In order to decrease the delay, this technique moves the capacity for calculations and storage from the main network to the edge network. Edge servers can be installed nearby so that devices can offload part of the duties associated with their mobile applications, thus enhancing the quality of mobile user experiences.

Most studies have concentrated on offloading mobile user workloads to cloudlets to reduce mobile device energy consumption, and this strategy implies that clouds are already in place [13-16]. The impact of putting edge servers and loading mobile phone user workload onto them on mobile application performance has not received much consideration. In mobile edge computing, edge server deployment should take into account both the ideal location and the maximum number of edge servers. For this purpose, three points should be considered, which include the physical location of the edge servers, the planning of the number of edge servers, and the network deployment requirements. According to these three cases, in this article, we intend to choose the optimal location for deploying edge servers by using an artificial bee colony meta-initiative algorithm. The placement of the edge server in mobile edge computing environments has not received much research attention.

Numerous studies on cloudlet location have been conducted recently [17, 18]. The typical definition of a *cloud* is a network of computers that operate as a loader for users of mobile phones [19, 20]. Users of mobile phones can access edge servers close to base stations in the context of mobile edge computing [21]. To reduce the access delay between mobile phone users and distant clouds, edge servers can currently be considered download locations for mobile users. By sending calculations and storage capacity from the primary network to the Edge server, this problem is resolved [22]. It is believed that there are many similarities between cloudlet placement and edge servers [23, 24]. Mike Jia et al. [25] presented a load shedding system model for multi-user mobile task loading. They studied cloudlet placement and mobile user allocation to cloudlet. Then, with the aim of activating the location of the cloudlet in areas with high user density, they implemented an algorithm and, while balancing their workload, assigned mobile phone users to the contracted packages.

\*Corresponding Author.

Zichuan Zhu and colleagues [16] utilized numerous wireless programs to investigate the cloudlet positioning issue. In order to reduce the access time between mobile users and cloudlets servicing users, they first defined this problem as a new cloudlet placement problem that assigns  $K$  locations to various key crucial sites. Second, they created an effective solution after defining the issue as integer linear programming. Studies [26, 27] about the computing burden for mobile edge cloud computing are also available. In a multi-channel wireless interference environment, Hu Chen et al. [28] investigated the issue of multi-user computing load for mobile edge cloud computing. They created a distributed computing offloading technique that attained the Nash equilibrium and characterized the distributed computing load decision problem for mobile phone users as a multi-user computing offloading game. Mike Jia et al. [25] only focused on the workload balance of cloudlets. Other studies [29-31] only on delay Access are examined, despite the fact that the aforementioned studies are successful in addressing the issue of cloudlet placement.

In this study, it is researched to find the position of servers that result in the optimization of coverage and balanced response to users' requests using the artificial bee colony meta-innovative method, which is motivated by the inspirations of previous studies. The steps of this study include studying the methods of the past, introducing the proposed method, and simulating this method. For this purpose, the MATLAB programming environment is used.

In this environment, the initial conditions for deploying edge servers in cloud computing are simulated using an artificial data set. In this simulation, variables such as the location of servers, base stations, and the number of user requests are considered. The results of this simulation are compared with the method based on K-means clustering. For the implementation of the Internet of Things, mobile edge computing has grown in importance [32]. Edge servers are smaller and less vulnerable to attacks since they are scattered over the mobile edge computing ecosystem. In addition, edge servers may function as private clouds to help with the issue of data leaking. There seems to be a need to employ a way to locate the server based on mobile edge computing technologies.

The rest of this paper presents the proposed method in Section II. The results and discussion discuss in Section III. The paper concludes in Section IV.

## II. PROPOSED METHOD

In this section, a method for determining the location of servers in mobile edge computing is introduced. This method uses an artificial bee colony meta-initiative algorithm. In this method, by using this algorithm, we try to optimize a cost function, which leads to determining the location of the servers in such a way that the load balance between the servers is observed.

The primary objective of the problem of locating servers for mobile edge computing is to locate servers for proper and ideal user request response. The quantity of users must be taken into account first for this. These users each have a number of requests, which they submit to the server. The

servers must respond to the requests of the users. In fact, each server receives a number of requests from users and must respond to these requests. According to the stated conditions, the location of the servers should be such that the servers follow the main goal. The main purpose of servers, in addition to responding to users' requests, is to distribute the load proportionally and optimally among themselves. In fact, servers should be located, so user requests are distributed among them. The position of the users and the number of requests of the users are known in this problem. However, the position of the servers should be answered as unknown in this problem. An artificial bee colony meta-innovative algorithm has been used to determine the location of the servers. The steps of the proposed method include:

defining and assigning values to the used variables,

creating a data set,

simulating the proposed method on the data set to determine the location of the servers, and

simulating the K-means clustering method on the data set to determine the location of the servers.

The comparison of the results obtained from the proposed method and the K-means clustering method with the load balancing criterion is introduced in the following stages of the proposed method.

### A. Variables Under Study

In order to determine the status of the servers in the problem under consideration, the users and the requests of the users must be determined. According to the situation and the number of user requests, the values of the servers should be determined as unknown. In this study, the number of users, the position of users in the form of  $x$  and  $y$  coordinates in two-dimensional space, and the number of user requests are considered variables. Since real data is unavailable in this problem, synthetic data is used to value the studied variables. As an example, the position of the number of users is shown in Fig. 1.

The values of the users' coordinates are randomly assigned in the range  $[a-0]$ . The number of requests of each user is also a random number in the range of  $[1-w]$ . By assigning values to these variables, the used data set is produced.

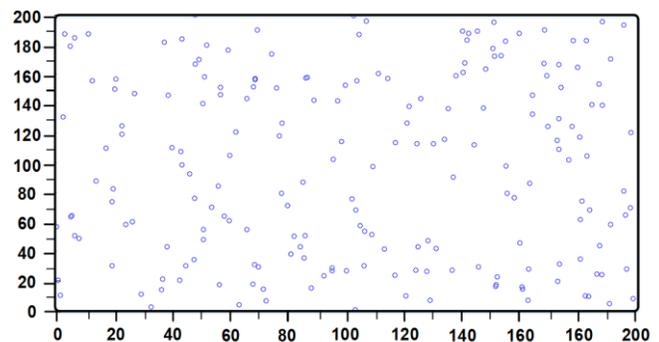

Fig. 1. The position of users in a specific area.

### B. Artificial Bee Colony Algorithm to Servers Determine Location

In the issue of determining the location of the servers, it is necessary to determine the location of each server so that the servers can answer the requests of the users in a way that the division and distribution of the load are balanced between them. To determine load balance, it is necessary to have a relationship that determines the amount of load between servers, calculated according to Eq. (1). The artificial bee colony algorithm determines the optimal value for the load balance relationship [33].

$$WB = \sqrt{\frac{\sum_{i=1}^k (T^i - T)^2}{k}} \quad (1)$$

Where  $k$  represents the number of servers,  $T^i$  represents the number of requests that server  $i$  should respond.  $T$  indicates the average number of requests of all servers. In this regard, the lower the WB value indicates the existence of balance and load balance between servers. In order to respond to each user's request, a server must be assigned, and that server will answer the user's request. The location of servers and users are shown with two-dimensional coordinates. The closest server answers each user's request. Euclidean distance relationship is used to determine the distance between servers and a user. If we have  $k$  servers to respond to the request of user  $j$  according to equation (2), server  $i$  should be selected so that these servers have the smallest distance from user  $j$ .

$$\arg \min_{i \in (1,k)} (\sqrt{(x_j - x_i)^2 + (y_j - y_i)^2}) \quad (2)$$

Where  $x_i$  and  $y_i$  represent the x and y position of server  $i$ ,  $x_j$  and  $y_j$  represent the x and y position of server  $j$ . Since the goal and the unknown problem is to determine the location of the servers, by using the artificial bee colony algorithm, the initial location of the servers is generated as the initial population. By going through the steps of the bee colony algorithm to minimize equation (1) as a cost function, the most optimal position is determined for the servers. The stages of the artificial bee colony algorithm are according to Fig. 2.

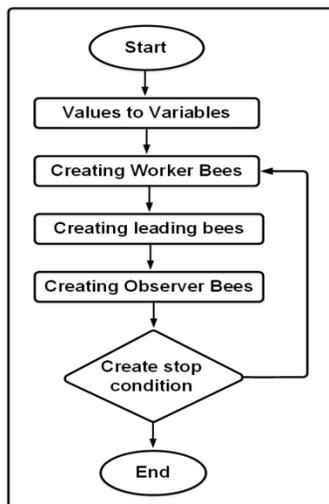

Fig. 2. Steps of artificial bee colony algorithm.

By having the location of server  $k$ , the closest server to that user is determined for each user using equation (2). After the closest server has been assigned to each user, the load balance between the servers can be determined by equation (2). For each population produced in the steps of the artificial bee colony algorithm, the fitness of this population is also determined by equation (2). The stages of production of worker bees, observers, and leaders lead to searching in the state space and producing better answers to the investigated problem.

### C. Proposed Method Evaluation

In the problem of determining the location of the servers in calculating the mobile edge, two important criteria and metrics for the location of the servers are considered. The combination of these two criteria, which includes the determination of the closest server to each user and the distribution of user requests, leads to the creation of a standard called load balance. Since the servers have to perform the users' tasks in the end, the servers' location should be such that all servers can be balanced in terms of workload. In the problem of determining the location of servers, load balancing means balanced distribution of user requests between servers. The proposed method uses the load balance criterion as a cost function in the artificial bee colony algorithm. The results obtained from the proposed method have been compared with the K-means clustering method to evaluate the proposed method. In the K-means clustering method, users are placed in  $k$  clusters, and each cluster's center is considered the server's location. In fact, the K-means clustering algorithm groups two-dimensional points that are the coordinates of users into  $k$  clusters. Users in a cluster send their requests to the server head of the current cluster. With this assumption, the load balance is also determined by the K-means clustering method according to equation (1). The evaluation of the proposed and K-means clustering methods is done by comparing the load balance value. The method with less load balance is the more suitable method for determining the location of the servers.

## III. RESULT AND DISCUSSION

In this section, the simulation of the proposed method is examined. According to the proposed method stated in the previous section, the steps of the proposed method are simulated in this section. This section includes the introduction of the data set, performing some tests on the data set, and reviewing the results obtained from the various tests.

### A. Dataset Used

To simulate the proposed method, it is necessary to set and select the variables and data set. The first part of the data set is the simulation environment. In the simulation environment, the position of users and servers is determined. The simulation environment is a square with side  $a$ . The second part of the data set is the users. Variables related to users include the number of users, the position of each user, and the number of requests for each user. The third part of the data set is the servers. The variables related to servers also include the number of servers and the location of each server. The required variables are introduced in Table I.

The position of each user is shown as a point in two-dimensional coordinates. The value of  $x$  for the  $i$ -th user is in a

specific range in the interval between  $xf-xe$ . The value of  $y$  for the  $i$ -th user is also within the specified range in the interval  $yf-ye$ . Each server also has a location. The position of each server, like the position of each user, is shown as a point in two-dimensional space. The range of  $x$  and  $y$  values for each server is the same as the range of these values for users. Each user also has a number of requests. The number of requests of user  $i$  is determined by a number in the range  $wf-we$ . Since users and servers are shown with two-dimensional coordinates, the distance between a user  $i$  and server  $j$  is represented by the symbol  $d_{ij}$ . Euclidean distance, according to Eq. (1) is used to calculate the distance between a user and a server.

The position of each user and the number of requests of each user are randomly determined within the specified range. The position of each server is also unknown and is calculated and determined by the proposed method. In the proposed method, an artificial bee colony meta-initiative algorithm is used. The variables of this algorithm are the number of repetitions and the number of the initial population. The values of these variables are shown in Table II.

### B. Results Evaluation

In this section, the variables stated in the previous section are set. Having the data set in this section, several different tests are performed. In these experiments, the proposed K-means clustering methods are compared with each other. These different experiments which are simulating and determining the position of the servers. The main difference is in the valuing of the studied variables. This section consists of the results of three experiments. In these tests, the number of users, the position of users, and the range determined for the position of users are considered different from each other. The values of the variables in the first experiment are according to Table III.

The results obtained from this experiment with four different executions are according to Table IV. This experiment has been done with four different implementations.

The position of users and servers in each of these four tests in the proposed method and the K-means clustering method is according to Fig. 3 to 10.

The values of the cost function in the artificial bee colony algorithm are according to Fig. 11 to 14.

In the first experiment with the criterion of workload balance, the results of the proposed method are better than the k-means clustering method. In this test, even in Fig. 7, the selection of two servers with a close location shows that the proposed method has considered even close locations in the search space. Although this happens randomly, the ability to search in the state space in the proposed method is better than the k-means method. In these four implementations, the proximity of the servers to each other or the distance between the servers did not have such a big effect on the results of the load balance. In other words, the artificial bee colony method in different repetitions is able to find several answers in different situations, but with the results of the load balance approximately to find the same. In contrast, in the k-means method, the distance between the servers in different executions is not so different from each other. Although the answers generated for the location of the servers are different,

the distance between the servers in each of these four executions is greater than the executions of the proposed method. In the graphs of the cost function values in the proposed method, the proposed method has converged in many iterations. The values of the variables in the second experiment are according to Table V.

The results obtained from this experiment with four different executions are according to Table VI.

Each of these four tests in the proposed method and the k-means clustering method is according to Fig. 15 to 26.

In the second experiment, with the criterion of workload balance, the results of the proposed method are better than the k-means clustering method. In this test, the number of users and requests are the same as in the first test, but the position of the users is randomly assigned in a larger range than in the first test. The results of the load balance values in this experiment are almost similar to the values in the first experiment since the number of user requests did not differ from the first experiment. In this case, it is only proportional to the situation of new users of the servers. The proposed method and the k-means method determine that the servers are positioned so that the load balance values are not much different from the first test. The position of the servers in the proposed method is better than the k-means method in terms of distance variation in each execution. In fact, the proposed method has produced answers that the results of the location of the servers are close to each other in some executions and far from each other in others. Despite the production of various answers, the results of load balance in different implementations with the proposed method are not much different. The values of the variables in the third experiment are according to Table VII.

The results obtained from this experiment with four different executions are according to Table VIII.

Each of these four tests in the proposed method and the k-means clustering method is according to Fig. 27 to 34.

The values of the cost function in the artificial bee colony algorithm are according to Fig. 35 to 38.

In the third experiment with the criterion of workload balance, the results of the proposed method are better than the k-means clustering method. In this experiment, the number of users, the position of the users, and the number of user requests differ from the first experiment. The number of users in this test is twice the number in the first test. The position that can be selected for assigning values to the coordinates of users is also twice the first test. The number of requests of 200 users in the third test is similar to the first. That is, the number of requests of the first 100 users in the third test is similar to the 100 users of the first test. The number of requests of the second 100 users is similar to the 100 users of the first test. In this experiment, the location of the servers in the proposed method is better than the k-means method in terms of distance variation in each execution. In fact, the proposed method has produced answers that the results of the location of the servers are close to each other in some executions and far from each other in others. Despite the production of various answers, the results of load balance in different executions with the proposed method are not much different. In this section, the main goal is to

simulate the proposed method. The results of the proposed method have been compared with the k-means clustering method with the criterion of load balance. In order to simulate the proposed method, three tests have been performed in this

section. The results obtained from these tests show the superiority of the proposed method over the k-means clustering method with load balancing criteria and generating various answers for the servers' location.

TABLE I. VARIABLES USED

Variable Name	Variable Symbol
Limited simulation environment	A square with side a
Number of users	n
The position of each user i	$x_i \in [x_f - x_e]$ $y_i \in [y_f - y_e]$
Number of requests per user i	$w_i \in [y_f - y_e]$
Number of servers	k
Server position j	$x_j \in [x_f - x_e]$ $y_j \in [y_f - y_e]$
The distance between user i and server j	$d_{ij}$

#### IV. CONCLUSION

In the problem of determining the location of the servers, it should be possible to determine the location of the servers in the edge computing environment in mobile computing in such a way that by having  $k$  servers, these servers respond to the requests of the users in such a way that the load of the servers is balanced. In other words, the servers should be in a position to be able to respond to the requests of nearby users, and the number of requests that the servers respond to should be balanced. A criterion called load is used to balance and distribute user requests between servers. The major contribution of this study is to employ a meta-innovative artificial bee colony algorithm to address the issue of where to locate edge servers for mobile edge computing. Moreover, one of the difficulties covered in this essay is load balancing between servers. This study's main focus is on determining the server placements using the artificial bee colony method while taking workload distribution between servers into account as a cost function. The proposed method's outcomes are contrasted with the load balancing criterion. The comparison of K-means results to the clustering approach demonstrates the proposed method presented results superiority with regard to the loading criteria. For future study, the proposed method can be implemented in real scenarios. Furthermore, other optimization algorithms including Particle Swarm Optimization (PSO) can be investigated and the result compared to current study to address the better solution.

**Abstract**—Medical area focused on automating skin cancer detection after the pandemic era of "Monkey Pox". Previous works proposed ANN mechanisms to classify the type of skin cancer. However, all those models implement layers of ANN with standard estimator components like hidden layers implemented using the ReLu activation function, several neurons are generally a power of two and others, but these values are not always perfect. Few researchers implemented optimization techniques for tuning the estimators of A.I. algorithms, but all those mechanisms require more resources and don't guarantee the best values for each estimator. The proposed method analyzes all the essential estimators of every possible neural network layer. Then it applies a modified version of Bayesian optimization because it avoids the disadvantages of Grid and Random optimization techniques. It picks the best estimator by using the conditional probability of naive Bayesian for every combination.

**Keywords**—Conditional probability; naive Bayesian; bayesian optimization; grid search; optimization techniques; estimators

## I. INTRODUCTION

Most researchers utilize machine learning to identify skin cancers but suffer from overfitting and more resource consumption. The problem can be solved using artificial neural networks, but traditional networks become complicated for smaller datasets. So, the proposed research aims to customize the parameters of the network by performing "Hyper Parameterization".

Hyperparameter tuning is required for behavioural control of the machine-learning model [11]. Hyperparameters can be configured differently for each machine-learning model. Our expected model parameters will yield less-than-ideal outcomes if the hyperparameters are not appropriately tweaked to optimize the loss function [12]. This implies that our model has further problems. When building a model from a particular dataset, hyper-tuning identifies the potential optimal sets of hyperparameters. A single training task executes several trials for hyperparameter tweaking. The task of hyperparameter tweaking involves meta-optimization [27]. The hyperparameter tuner produces the hyperparameter setting, those results in the best-performing model after assessing various hyperparameter settings. By employing the algorithm and the defined limits of hyperparameters, hyperparameter tuning runs multiple training sessions on your dataset to determine which model version is the best.

### A. Hyper Parameter Tuning

The accuracy of models for machine learning can be significantly increased by using hyperparameter adjustment.

Hyperparameter tuning is identifying a collection of appropriate hyperparameter variables for a prediction model and applying this adjusted algorithm to any piece of data. The model's efficiency is maximized by employing that collection of hyperparameters, which minimizes a preset loss function and produces better results with fewer errors. To use an Exhaustive Grid Search in Scikit Learn is a well-known and conventional method for hyperparameter tweaking [13]. Every permutation of each collection of hyperparameters is tested using this procedure. This approach allows us to locate the ideal set of values within the variable search space. Since this approach must test every permutation in the grid size, it typically consumes more computer resources and requires a long time to run. Multiplication of all the variables will determine the size of the parameter grid. Each time a random collection of hyperparameters is tested, the model's performance is recorded. After multiple repetitions, it returns to the mixture with the most significant outcome.

### B. Types of Hyper Tuning

Irrespective of the type of machine and deep learning models, these tuning algorithms help achieve the minimum error rate with minimum learning rate.

1) *Grid search*: Grid search optimization takes much time to compute every possible combination of estimators. Suppose we have two parameters for designing the ANN in which parameter-1 can be estimated in X ways, and parameter-2 can be estimated in Y ways. The system needs X into Y ways to apply grid search for this type of neural network. So this can be claimed as an exhaustive search.

2) *Random search*: Random search only checks some possible estimated values [14]. It randomly selects a few values from each parameter, so this will reduce the number of ways than grid search since random search doesn't cover all possible combinations. So this tuning process only guarantees the best values.

3) *Successive halving*: The S.H.A. (Successive Halving Algorithm) algorithm can optimize hyperparameters and solve multi-armed bandits challenges. The algorithm's primary goal is to correctly determine the best arm within a strict budget, a constrained time or resource [15]. The algorithm consistently evaluates each arrangement. The weakest performers are removed at the conclusion of each round. The procedure repeats itself until only one configuration is left, with the remaining configurations being examined twice as much as in

the previous round. S.H.A. is effective because it uses minimal resources and eliminates data at each level.

Whether or not to look for several configurations in S.H. is still being determined. Some desirable configurations that may initially converge slowly will be eliminated early if  $n$  is large. This makes identifying the best allocation approach in the indefinite time frame possible. S.H. requires dynamic updating. Before using the S.H. technique, the hyperparameters must be manually set. Due to its iterative nature, Successive Halving works well enough on huge datasets. The wide range of cross-validation folds could also be used as the budget for successive Halving. A sufficient budget can prevent good configurations from being terminated too soon. In contrast, an excessive budget can cause subpar configurations to continue for an extended period and waste resources.

4) *Bayesian optimization*: When deciding which set of hyperparameters to examine next, Bayesian optimization takes into consideration previous assessments. It allows itself to concentrate on those regions of the dimensional space that it considers will provide the most hopeful validation scores by selecting its value, also known intelligently. This method often needs fewer iterations to reach the ideal set of hyperparameter values [16]. Most significantly, it ignores those regions of the dimensional space that it thinks won't contribute anything. As a result, only settings predicted to produce a better validation score are sent through for evaluation, reducing the number of repetitions a model must be trained for validation. It is especially helpful when these assessments are at high costs, when derivatives are absent, or the matter in question is non-convex.

The paper is divided into five sections; the introduction discusses the need and types of hyper optimization techniques. The literature survey section discusses the merits and demerits of the existing approaches. The proposed methodology discusses the customization of the neural network layers with the help of enhanced Bayesian optimization. The results and discussion section elaborates on the metrics obtained by the proposed and compares them with the existing ones. The conclusion section discusses the proof of validity by measuring loss and accuracy.

## II. LITERATURE SURVEY

In [1], MehwishDildar et al. offered a thorough analysis of deep learning methods for early skin cancer detection. The paper concentrated on traditional methods for skin cancer diagnosis, such as ANN, K.N.N., CNN, and GAN. The writers created multiple stages of selection standards. This work aims to evaluate existing models and develop the best N.N. technique for skin cancer detection. The data was filtered using an automated search engine that was developed. Neural networks have been taught to categorize photos and differentiate between photographs of various skin disorders.

Additionally compared were SVM, B.P.N., and three-layer N.N. Due to a shortage of different data, artificial neural networks are trained for skin lesions using tiny data sets.

According to the authors, the auto-organization approach, which is still under investigation, may enhance image processing accuracy in the future, particularly in the medical industry.

In [2], Mariam Nawaz et al. developed a deep learning-based segmentation solution that is completely automated. The model uses fuzzy K-means clustering and region-based convolutional neural networks (RCNN). The model applies RCNN using preprocessed data. Using precise localization, faster RCNN could detect skin lesions with accuracy and precision. Various than melanoma, the approach can be applied to other skin conditions. F.K.M. clustering separates the impacted portion of photos from the discovered results. A deep learning framework is faster than RCNN. Faster RCNN relies on the input generic object suggestions, which employ hand-coded models like Edge Box, Selective search, etc. Three datasets are used to apply the model. The proposed model has a chance of being overfitted. This model requires less computing. The F.K.M. model is useful in resolving to overfit.

In [3], Ulzii-OrshikhDorj et al. concentrated on classifying skin cancer using deep CNN and ECOC SVM. The feature extraction method makes use of trained AlexNet. ECOC SVM is employed for classification, along with three fully linked layers. Some photographs in the collection are clear, but others are not because they were pulled from the internet. The work can be expanded by adding the ABCD rule— asymmetry, border, colour, and diameter—for each cancer report. There are four different types of cancer in total. To cut down on noise, the photos are cropped. The pooling layer reduced the size of the input neuron in the CNN. The model's primary goal is quick categorization. Using a deep CNN model, using RGB images allows for detecting actinic keratoses, basal cell carcinoma, melanoma, and squamous cell carcinoma [26].

In [4], Mohammad Ali Kadampur and Sulaiman Al Riyale combined and suggested a model-driven cloud architecture. This is used to build models that help in skin cancer prediction and is based on deep learning algorithms. The metric area beneath the curve for the deep learning algorithm was 99%. Despite the model's lack of programming components, the machine can deal with issues including slowness, accuracy, and a shortage of dermatologists. The suggested model can categorize cell pictures and spot skin cancer. The model is not integrated into the REST API. According to the article, there are now more design options for deep learning classifiers regarding general methods and looping patterns. The paper described the D.L.S. tool's features and showed how to build a deep learning model.

In [5], Andre Esteva et al. used a single CNN-trained end-to-end using images with simple pixels and illness labels as input to demonstrate classification. A computer technique is created that could help doctors and patients keep track of skin blemishes and spot cancer early. Dermatology is built to be automated. No handcrafted components are necessary for the system. By putting the model to the test, the biopsy-proven images are verified. The writers designed the CNN to mimic dermatologists' performance. By putting the biopsy photos to

the test, the model is verified. The authors explored the internal properties that CNN learned using T-SNE. Mobiles can be used to deploy this strategy. Several virtual circumstances can be classified using this method, provided there are enough training instances. Saliency maps are created to see the pixels a network focuses on for prediction.

In [6], Ravi Manne et al. summarised numerous studies on utilizing CNNs to categorize skin lesions. CNN has demonstrated incredible image processing power. The research covered a wide range of adversarial approaches in clinical contexts, including colour balance adjustments and input image rotation and translation that can result in incorrect categorization. The authors also noted the variables influencing the findings. Instead of using all the positive data, which would skew the system and produce only good outcomes, the factors are mentioned as vulnerabilities to adversarial assaults. The inks (blue) in dermoscopic images also hurt CNN classification, suggesting that the model may give accurate results if negative input is included. The authors discovered that improperly categorized photos might produce inaccurate results.

In [7], Khalid M. Hosny et al. introduced a system that automatically classifies skin marks. A deep learning network which is pre-trained serves as the model. AlexNet is trained via data segmentation and fine-tuning. In the system to train and evaluate the suggested model, the ph2 dataset is used. The deep convolutional neural network (DCNN) model divides the three forms of skin cancer visible in colour photographs. Any image can be processed and used in the proposed method. Since it is unnecessary, there is no preprocessing. A softmax layer has taken the place of the categorization on layer. The model eliminates the requirement for photographs with labels. To create a deep neural network, labelled images are necessary. The size of the convolution layer is decreased using the pooling layer. The weights have been refined using backpropagation to include additional weights for categorizing skin lesions. Based on dataset photos, the weights are changed using S.G.D. Stochastic Gradient Descent.

In [8], JinenDaghrir et al. introduced a hybrid technique to diagnose melanoma skin cancer. The model examines any suspect lesions. Three distinct approaches are included in the model. Using a set of features including borders, texture, color, etc, a convolutional neural network and two conventional machine learning classifiers are developed. The ABCDE signals are used in the model as melanoma markers. Based on five features, this trait can distinguish benign skin lesion that develops into malignant melanoma. Using colour enhancement on the RGB's blue component, DoG Filtering is used to detect hair. The 124 x 124-pixel pictures that the CNN architecture that is being suggested uses [24]. The CNN contains nine layers, including three convolutional layers with ReLU activation and three with maximum spatial pooling. Strange skin lesions need to be researched. To achieve better results, adopting semi-supervised learning should be the main focus.

In [9], Vidya M & Dr Maya V Karki suggested an approach that employs the ABCD rule for feature extraction. To extract features for the early diagnosis of skin lesions,

GLCM and H.O.G. are utilized. The preprocessing enhances the clarity and quality of skin lesions while lowering artefacts such as hair, skin color, etc. Using Geodesic Active Contour, which separates each instructional section, segmentation was carried out. For extracting attributes, including symmetry, border, color, and diameter, the ABCD scoring system is employed. The retrieved characteristics are sent straight to the classifiers. A clear skin lesion site can be obtained using dermoscopy, improving visual impact. The obtained accuracy is 97.32%. G.A.C. detects the largest changes to the entire skin lesion, typically produced around its edges. RGB images are transformed into grayscale and put through a median filter to reduce the noise. On the same, neural networks may be used.

TABLE I. MERITS AND FUTURE SCOPE WORK ANALYSIS OF EXISTING SYSTEMS

Author	Algorithm	Merits	Demerits
MehwishDildar	S.L.R.	Suggesting auto organization approaches.	Need to implement automation in the model, focused only on NN-based models.
Mariam Nawaz	Faster RCNN	FKM clustering is also used	Chance to overfit
Ulzii-OrshikhDorj	CNN and ECOC SVM	The noise was removed, and RGB images improved the properties of the image.	Can add ABCD rule and implement to get better results.
Mohammad Ali Kadampur	Deep learning and cloud.	Used D.L.S. tools, can deal with	Not implemented into an API
Andre Esteva	CNN	Uses simple pixels and saliency maps are used.	No required number of training records
Ravi Manne	ESLER	Focussed on many issues like misclassification and dermoscopic images.	Need to include the operating results of various models.
Khalid M. Hosny	DCNN	Transfer learning, any mage can be preprocessed.	The weights keep changing
JinenDaghrir	MCNN	ReLU activation function, two ML classifiers.	Should implement for semi-supervised data.
Vidya M	Hybrid feature extraction	Uses ABCDE signs, images conversion into grayscale	Neural networks provide better results.
Shunichi Jinnai	FRCNN	Robust, high classification accuracy	It would help if you also used N.N. for generalization. The project should be implemented socially.

In [10], Shunichi Jinnai et al. built a dataset by randomly choosing items and annotating them with bounding boxes. The model that is being suggested is a quicker, region-based CNN called FRCNN. By combining convolutional features from R.P.N. and Fast R CNN into a single network, FRCNN is the result—a classification system based on neural networks that use clinical images rather than dermoscopic ones. , Robustness, high classification accuracy, and speed were all displayed by the model. A momentum stochastic gradient

descent optimizer is utilized, with the VGG-16 as a foundation. To employ wearable technology in public, the network must be socially implemented. The skin cancer prognosis should be used to lower treatment expenses. Reduced patient wait times and unneeded visits are desirable [25]. It is important to test the neural network's generalization using images thoroughly. The overall analysis of the existing approaches is presented in Table I.

### III. RESEARCH GAPS IDENTIFIED

- 1) Unsupervised models to solve the non-linear data have increased the dimensionality of the space.
- 2) Traditional neural networks make the model learn more number of generalized features rather than specific elements.
- 3) Backpropagation in neural networks makes the model update the weights more randomly to get optimized results.

### IV. PROPOSED METHODOLOGY

The proposed methodology contains 34 attributes in the dermatology dataset. Using machine learning approaches like decision trees or ensemble methodologies also takes many resources to build the tree for simple datasets. So the proposed model implemented customized neural networks instead of static neural networks. The components of the ANN, along with their estimators, are presented below in Table II.

#### A. Input Layer and its Estimators

In general, the input, without performing any transformations, passes the raw information obtained from the input vector to the hidden layers. It multiplies every value of the feature with random weights and then implements the activation function.

TABLE II. COMPONENT DESCRIPTION OF NEURAL NETWORK

Components	Remarks	Estimators	Description
Input Layer	The input layer, along with the input shape, contains activation and several neurons which can be customized.	Number of neurons	Any integer value. Generally, it is equal to the number of features in the dataset.
		Activation Functions	Based on the differentiable properties of the neurons, they are classified into 10
Hidden Layer	Depending on the activation function applied and other metrics, it transforms the input into the desired result using the dot product.	Kernel Size	This helps the CNN to process the imaging unit by unit because, without this, the system has to process $n*n*3$ at a time. Generally, the system works efficiently with an odd number of filters.
		Padding	The system needs to add some bits in terms of padding values to provide accurate results. In general, two types of paddings are available.
		Stride	It defines the step size, representing the number of pixels to ignore. In general, it will be any n value.
		Activation	Based on the differentiable properties of the neurons, they are classified into 10
Pooling Layer	The neural network size is reduced using the strides and pool size. There are three types of pooling mechanisms.	Pool size	It's a two-dimensional filter that maps the features.
		Stride	It defines the step size, representing the number of pixels to ignore. In general, it will be any n value.
Output Layer	Generally, it is a fully connected layer that produces the desired output based on several neurons and activation functions.	Number of neurons	It depends on the type of classification that the application needs.
		Activation Function	Only 3 possibilities exist for the output layer. Linear, sigmoid and softmax
Optimizer	The updation of neuron weights from one layer to another is performed using optimizers.		There are 6 types of optimizers available
Loss Function	It defines the model's standard by computing the difference between the actual and predicted values.		In general, there are 9 types of loss functions available. Since the proposed dataset is a multi-classification problem, it uses only 3 types of loss functions.

TABLE III. IMPLEMENTED ACTIVATION FUNCTIONS FOR INPUT AND HIDDEN LAYERS

S.No	Activation Function	Description	Merits
1	Elu	It uses the natural gradients to activate the positive values. It suddenly jumps the mean values [18]	It is low computation, and most values are zero centred
2	Selu	This will always scale the values in such a way that the mean should be zero and the variance should be one	In every iteration, it internally performs the normalization
3	Relu	These output values will never enter into saturation point	The computations are faster
4	Leaky Relu	The model uses simple linear components and adjusts in values in terms of smaller decimal places	It solves the problem of dying Relu
5	Sigmoid	It transforms all the input values between 0 to 1 and produces S- a shape curve	It is easy to differentiate, and prediction values are clear
6	Softplus	It is a derivative of the sigmoid and tanh combination	It always generates smooth curves between -1 to +1
7	Softsign	It transforms the linear values into non-linear values	It is efficient in solving the regression problems
8	Tanh	It is very effective when dealing with negative values and values closer to zero.	When the gradient values are small, then tanh improves the performance.

1) *Activation function*: The activation function is a non-linear change we apply to input before passing it onto the next neuronal layer or finishing it as output [17]. The network can use crucial information and ignore unnecessary data points using activation functions. An activation function takes the values produced by one network level and changes them in a certain way to transfer them to another layer or range of values. The proposed model implements one input layer and three hidden layers. For all these layers, the model passes all the activation functions that suit the dataset as a list of arguments and choose the highest probability as the best parameter. Table III presents the list of activation functions implemented in the proposed model.

### B. Hidden Layers and its Estimators

The proposed model implements all the hidden layers as fully connected layers. The basic principle for any neural network is "the network in which all the hidden layers with the same amount of neurons will have more success rate"[20]. So the proposed model implemented all the hidden layers with the same number of neurons. The hidden layers solve the complex problems by constructing the feature map vector that computes the correlation between each input feature and output class label. In the proposed model, after each hidden layer, it implements an integrated layer that normalizes and drops out the threshold values that are less than the alpha cut. Choosing several hidden layers plays a major role in constructing a neural network. Traditional researchers mentioned that the number of layers should be less than the number of neurons, and also it should be tested from a cross-validation test. Hidden layers are famous for automatic dimensionality reduction, i.e., the number of neurons should be less than the original dimensionality. The below section defines the process of customization.

1) *Customization of neurons count*: The neuron is triggered if the input to an activation function exceeds a threshold; otherwise, it is deactivated. In extremely unusual circumstances, bias will only have one input layer, with the

number of input layer neurons equivalent to the number of features in the data [19]. Bias may rarely have just one input layer, with the number of neurons in the input layer equaling the number of features in the data. At the same time, using the model as a classifier or regressor affects the number of neurons in the output. If the algorithm is a regressor, then the output layer will only include one neuron; however, if the system is a classifier, it may contain one or more neurons, depending on the model's classification label. . As a result, the goal variable affects the count of neurons present in the output layer. The amount of training data, the anomalies, the complexity of data that must be learned from, and the kind of activation functions employed all impact the rate of neurons and layers needed for the hidden layer. Equation 1 presents the computation of the number of optimistic neurons in any layer of the neural network

$$Neurons\_Count = \frac{\text{number of records in dataset}}{\text{bias\_factor} * (\text{input\_neurons} * \text{output\_neurons})} - (1)$$

Fig. 1 denotes integrating hidden layers with drop-out layers to get the normalized values from each layer.

### C. Output Layer and its Estimators

The number of neurons in the output layer equals the number of class labels available in the dataset. Since the proposed model uses a multi-classification dataset, the last layer of a fully connected pattern uses the softmax activation function. It calculates the relative possibilities for all 6 classes and uses an exponential function to normalize the data [21]. This normalization makes the model such that the total 6 class probabilities are summated to 1. But the proposed model uses the softer version of softmax so that all the prediction class label is 1 and other class labels are 0.

### D. Optimizers

An optimizer is a technique or procedure to modify the different parameters that can more efficiently reduce the loss [22]. Different types of optimizers are presented in Fig. 2.

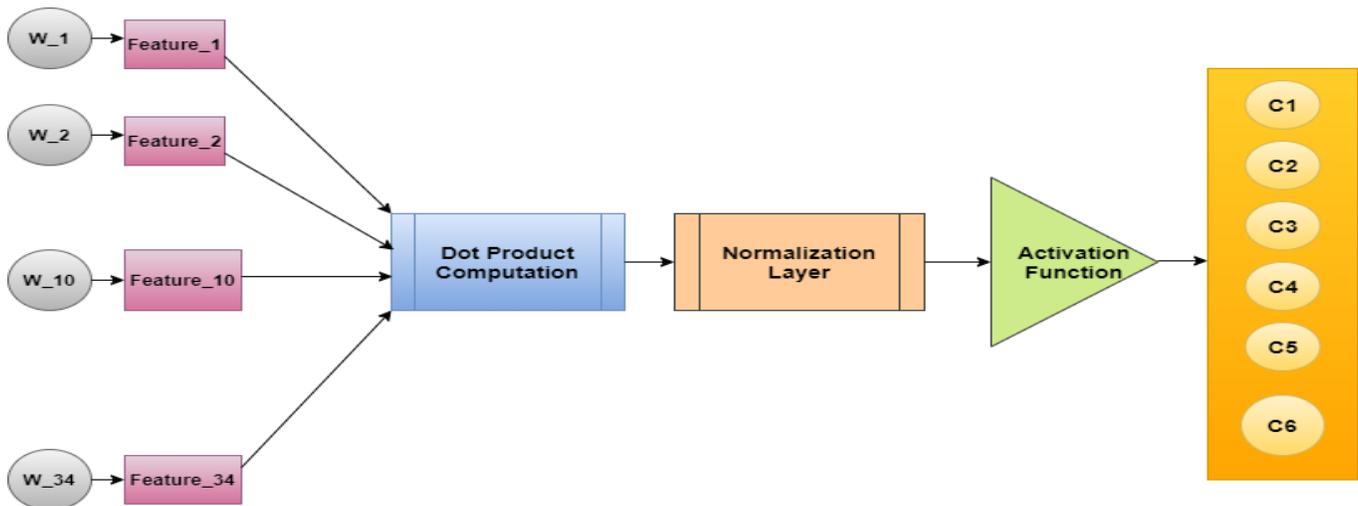

Fig. 1. Integrated architecture of hidden layers.

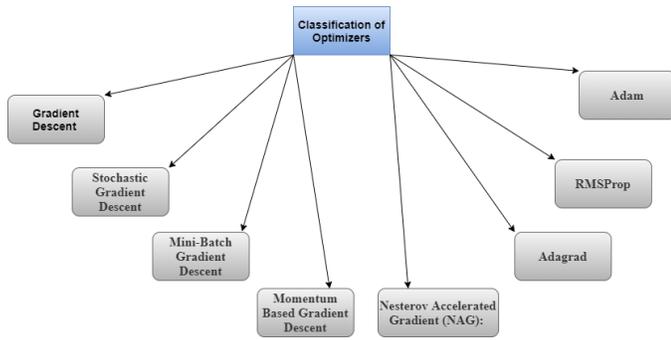

Fig. 2. Classification of optimizers.

1) *Gradient Descent (G.D.)*: Calculus is used by the G.D. optimization method to modify the parameters and consistently find the local minimum. This strategy is also used in neural network backpropagation, where the revised parameters are distributed across the various layers based on when the minimal loss is attained.

2) *Stochastic gradient descent*: Every iteration involves updating the model's parameters. It entails testing the loss function and updating the model after each training sample. Thanks to the stochastic gradient, you can pick the data batches at random. It implies you only have to sample a small part of the dataset.

3) *Mini-batch gradient descent*: Only a bit of the dataset is used in the Mini-Batch Gradient Descent to generate the loss function. As a result, all of the datasets need not be analyzed in memory thanks to batching.

4) *Momentum-based gradient descent*: The gradient descent optimization procedure can ride across flat regions of the search space and overcome the oscillations of noisy gradients by adding momentum. This enables the search to acquire inertia within the search space in a specific direction.

5) *Nesterov Accelerated Gradient (N.A.G.)*: The strategy used in this case was to first update the parameters with the history component before calculating the derivative, which can move the parameters ahead or backwards. This approach, called the look-ahead technique, is more efficient since it can result in fewer oscillations and more time being saved if the curve moves slowly as it approaches the minima.

6) *Adagrad*: The Adagrad optimizer attempts to provide this adaptability by slowing down the training rate according to the modified history of the gradients. The learning rate does not require manual tweaking.

7) *RMSProp*: RPPROP discretely modifies the step size for each weight using the gradient sign. This approach expedites the optimization method by reducing the total of function estimations to find the local minima.

8) *Adam*: Rather than stochastic gradient descent, an alternative optimization approach called Adam can be employed to develop deep learning models. Adam creates an optimization approach that can manage sparse fluctuations in noisy conditions by combining the best elements of both the RMSGrad and AdaProp algorithms.

### E. Loss Functions

The parameter that defines how far the algorithm's current output deviates from the desired output is called the "loss function" [23]. This method is used to judge how well an algorithm matches the data. The parameters that the model learns are established by minimizing a certain loss function, and the loss functions provide a goal against which the model's performance is measured loss functions based on cross-entropy - The distinction between two probabilistic is quantified by cross-entropy. The difference between the probability distribution produced by the activity that produced the data and the distribution that the process model is calculated. The binary cross-entropy is well suited to obtaining one of two outcomes in binary classification scenarios. Multiclass classification uses categorical cross-entropy. In regression circumstances, the model expectation and choices related are real-number values and mean squared error is used. Since the proposed model is a multi-classification problem with six discrete class labels, it implemented "sparse\_categorical\_crossentropy", whose mathematical representation is presented in equation x. since the loss function computes the difference between true and predicted labels let us consider true class labels as  $Y_{true}$  and predicted as  $Y_{predict}$

$$Sparse(Y_{true}, Y_{predict}) = -\frac{1}{n} * \sum_{i=0}^n [y_{true_i} * \log(y_{predict_i}) + (1 - y_{true_i}) * \log(1 - y_{predict_i})] \quad (2)$$

The proposed model considers three estimators as static and assumes all these estimators with the best values. The remaining component estimators are dynamic and are chosen by the optimizer values of the hyper-tuning process. The architecture of the proposed model is presented in Fig. 3.

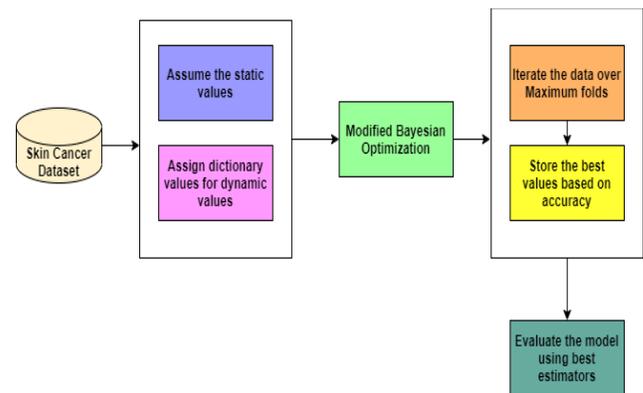

Fig. 3. Workflow of the proposed model.

## V. RESULTS AND DISCUSSION

Table IV denotes the best parameters for every estimator of the component that suits the given dataset for the detection of skin cancer. The proposed model assumes few initial configurations, like it is a designed neural network with three hidden layers, the last dense layer uses softmax function because of the multi-classification, and it implements sparse categorical loss function to evaluate the model.

Fig. 4 denotes the sample screenshot of epochs which have designed the neural network using the best parameters. The training epochs also display the loss and accuracy of training data along with validation loss accuracy. Loss values in almost all iterations are equal to zero for training. So the proposed system is efficient.

Fig. 5 represents the accuracy analysis of existing models with the proposed one to prove state of the art. On X-axis, it denotes the models implemented by the different researchers for identifying skin cancer the Y-axis denotes the percentage accuracies. DCNN has achieved 98% among the existing models. It is the highest accuracy. So when compared to DCNN, the proposed model has achieved +1.65% more.

TABLE IV. BEST ESTIMATORS OF SKIN CANCER DETECTION

S. No.	Estimator Name	Estimator Value
1	Number of neurons in the input layer	47
2	Number of neurons in hidden layer-1	4

Fig. 6. 1<sup>st</sup> Best parameters found at 23<sup>rd</sup> iteration.

Fig. 6 represents the iterations performed by the modified Bayesian optimization, in which it sets the iterations to 25 and folds to 2. Out of the 50 iterations, it has achieved its first best values at the 23<sup>rd</sup> iteration and processes the data until it completes all the data processing units. The target is the objective function based on which iteration is best or normal. The higher the target higher the chances of maximization.

Fig. 7 projects the accuracy obtained with the customized ANN by performing 10-fold cross-validation to prove state of

the art. The model designs different layers with different activation functions but with a standard number of neurons. Every layer is designed with popular activation functions, but most of the folds got 100% accuracy, representing overfitting. Finally, the average score for the entire iteration with 10 cross-fold validation is "98.6%", less than the proposed model.

## VI. CONCLUSION

Identifying Erythemato-Squamous disease using the deep learning approach increases the efficiency of the automation system. The proposed model helps the doctors diagnose the disease with this automation system and predicts the disease at the early stage. Disease identification using the machine learning system has high misclassification and error rates. So few researchers used standard ANNs to train the model with much data and more epochs. But these models are not appropriate because different datasets need different estimators. The proposed model uses optimization techniques to identify the best value for every possible estimator. The model uses a modified version of Bayesian optimization and finds the best values for 11 estimators. The model assumes fixed values like loss functions, number of layers, and number of epochs. Existing optimization techniques need more iterations and memory space. The system to reduce the iterations modifies the Bayesian optimization by comparing the previous iterations and stores only the best values. The model highlights the best values and runs the model till it gets saturation values. Using this model, it has achieved 99.65%. In future work, the model extends the hyper-tuning process by defining a search space, where it can find the parameters depending on the similarity between the attributes and limiting the search space helps the model acquire the learning faster.

**Abstract**—The idea of noisy states can be derived through a quantum relative entropy over a given time period and construct the average value of  $X$  at time based on the system variables. A random Hermitian matrix is used to represent the quantum system observables with BATH states. The Hudson-Parthasarathy (HP equation) context for stochastic processes allows us to simulate quantum relative entropy using quantum Brownian motion. The Sudarshan-Lindblad's density evolution matrix equation was already derivable in generalized form in my previous work. This paper's goal is to illustrate how the HP equation may be used to estimate the density matrix for noise in a perturbed quantum system of a stochastic process. The last stage involves using MATLAB to estimate and simulate a random density matrix and measure the quantum average  $T_r(\rho(t)X)$  at various times. These formulas would be helpful in determining how sensitive the evolving/evolved states are to changes in the Hamiltonian of the noise operators in a sensitivity/robustness study of quantum systems.

**Keywords**—Schrödinger equation; Ito calculus; quantum relative entropy; Hudson-Parthasarathy equation; quantum noise

## I. INTRODUCTION

The origin of Quantum mechanics in 1925, has been expressed to solve many problems and conceived as a generalization of classical mechanics with an added quantum indeterminism [1]. A number of open problems in quantum information theory revolve around whether certain quantities are additive or not. The oldest one was the Holevo capacity method. According to this conjecture, entangled signal states do not improve quantum channel capacity. A second additivity conjecture concerns the minimum entropy of the quantum channel's output [2-4]. As a result, the linear Hilbert space structure is given priority while the probabilistic structure is added almost as an afterthought. It has the unfortunate consequence that in the standard approach to Quantum Mechanics, the dynamical and probabilistic aspects of quantum theory are not quite compatible. There are two distinct modes of wave function evolution: the linear Schrödinger evolution and the probabilistic wave function collapse [5].

A brief but interesting discussion is given on the computation of atomic transition probabilities when the atom interacts with an electromagnetic field. We then calculate using this expression of the atomic state, the average value of an observable on the quantum system as a function of time in terms of the information bearing sequence and use these formulae to derive estimates of the information sequence from a continuous measurement of the observable average [6-9].

After this, we obtain a more accurate description of the measurement and estimation process. When the quantum system is in a pure or mixed state, the measurement of an observable causes the state of the system to collapse to one whose range is contained in the orthogonal eigen-projection of the observable associated with the eigenvalue of  $X$  that has been observed as the outcome. After such a measurement at time  $t_1$ , the system again evolves from the collapsed state under the same Hamiltonian upto time  $t_2 > t_1$  when once again the same observable is measured. Again the state of the system collapses to a state decided by the corresponding eigen-projection and the system evolves from this collapsed state. If  $P$  is the eigen-projection and  $\rho$  is the state just prior to the measurement, then the probability of observing the corresponding outcome is  $T_r(\rho P)$ . In this way, we are able to compute the joint probability of measuring a subset (possibly repeated) of eigenvalues of the observable at a finite set of times  $t_1, \dots, t_N$ , with each time the measurement being made, the system collapsing to a state corresponding to the associated eigen-projection [9-13]. Using quantum measurement models, we examine what kind of measurements can be made on quantum systems, as well as how to determine the probability that a measurement will yield a certain result. In order to find out the effective measurement of quantum states, that technique is very important because there should be a minimum uncertainty of the state with sensitivity to their environment.

One way to describe the output of a single mode, stabilized laser is as a coherent state. An analogy between quantum-mechanical and classical particles oscillating in a harmonic potential is coherent states [5], [7], [11] [24]. Coherent state are eigenstates of the annihilation operator. Coherent states are eigenstates of the annihilation operators' fields. In quantum field theory, creation and annihilation operators' fields are used to correlative the electromagnetic four potential vector field. Thus in a coherent state, one part of the electromagnetic field has defined amplitude and phase. The state  $|n_1, n_2, \dots, n_N\rangle$  correspond to  $n_j$  photons or the  $j^{\text{th}}$  type being present in the bath. Thus  $|n_1, n_2, \dots, n_N\rangle$  is an eigenstates of the number operators  $a_k^\dagger a_k$  with eigenvalue  $n_k$  [8], [10], [19-23].

A bit flip is the only possible error in classical computing while bits are being transferred. Since any rotation or phase shift in Hilbert space represents an error, there are an endless number of distinct faults that could happen for a single qubit in the quantum scenario. During the measurement, a compatible

subspace is projected from the quantum state. When the error is measured, it is brought down to a level that is reasonable for the measurement. In comparison to quantum noise, classical noise has fewer degrees of freedom, making it commutative unitary quantum noise. Classical noise can be created as a particular instance of quantum noise by taking into account the approximate states of both. The novelties of this approach are;

- The time-dependent creation, annihilation, and conservation are introduced in the unique method for quantum stochastic calculus developed by Hudson and Parthasarathy (HP), which satisfies the quantum Ito calculus formula for the product of time differentials of these processes.
- It is demonstrated that the quantum Ito formula of HP naturally evolves into a spectral commutative version of the classical Ito formula for Brownian motion and the Poisson process.
- The Boson Fock space, which is a family of non-commuting operators that specialize to Brownian motion when the state is selected appropriately [12–15], is shown to provide the basis for creating fundamental quantum noise processes in this paper [10–11].
- The linear stochastic model is generalized by HP equations.
- The Schrödinger equation defines a system's unitary evolution when it is coupled to a noisy environment. Because particles can move from the system into the bath and from the bath back into the system, total probability is conserved, which explains why system tensors with BATH exhibit joint unitary evolution [25–29].
- In the HP theory, quantum noise is just a family of non-random operators in Fock Space. When we examine the stochastic linear operator in particular states, randomness appears in all situations. The quantum theory naturally incorporates randomness [14–19]. The classical Ito table is generalized by the quantum Ito tables.

As a result, our main contribution to this study is that infinite-dimensional systems, such as the HP equation, must be truncated in order to achieve a finite-dimensional approximation, which can then be easily reduced utilizing MATLAB through discrimination approaches. We have determined how quickly the respective entropies of the two quantum systems change. Based on their geometric measure of entanglement, some mixed states should allow for the analytical calculation of the rate of change of quantum relative Von Neumann entropy. The principle can be regarded of as a generalization of both the maximum entropy principle and the minimal entropy production principle, both of which are frequently employed in non-equilibrium thermodynamics. This justifies the employment of the principle in the context of optimum learning systems [30–34]. With the use of the symmetric tensor product of a specific Hilbert space, we create the Boson Fock space, which can explain any number of bosons. The Boson Fock space serves as the foundation for

creating fundamental quantum noise processes, such as the noncommuting family of operators that, given the right state selection, specialize to Brownian motion and Poisson processes. A tensor product connects the system Hilbert space to the Boson Fock space, also known as the noise Bath space. Then, we construct the creation, annihilation, and conservation operator fields in the Boson Fock space in accordance with R.L. Hudson and K.R. Parthasarathy's wonderful methodology.

The rest of this paper is written as follows: In Section II, Observable of Quantum Systems using mathematical representations is described. In Section III, the mathematical model of quantum relative entropy for the evolution of two quantum systems is described. In Section IV, the NSER (noise-to-signal energy ratio) to validate the performance criterion is computed. Concluding thoughts are discussed in Section V.

## II. OBSERVABLE OF QUANTUM SYSTEMS

A finite level of a quantum system  $\{A, B\}$  and each system can be described by a finite dimension of Hilbert space  $\{H^A, H^B\}$ . An element of Hilbert space  $H$  is an  $n \times n$  Hermitian matrix with complex entries, called ket vector  $|u\rangle$  and if the same function is linear of the Hilbert space then it is bra vector  $\langle v|$ . The density matrix of a quantum mechanical system is used to compute the mean value of observables. An operator on a Hilbert space with unit trace that is positive semidefinite is called a density operator  $\rho$ . In order for an operator to be considered positive semi definite, it must be Hermitian and have no negative (necessarily real) eigenvalues [5], [22]. Let  $\rho$  is a density matrix of a quantum system and  $X, Y$  two observable on the same Hilbert space. Assume that,  $\text{Tr}(\rho X) = \text{Tr}(\rho Y) = 0$ . Note that  $\text{Tr}(\rho[X, Y])$  is a purely imaginary complex number. A system observable is changed into a system plus noise variable after a finite amount of time by this unitary evolution, which operates on the tensor product of the system and noise Hilbert space. Based on observations made up to time  $t$ , an estimate of this noisy observable at each time  $t$  is required. In order to do this, the measurement process must, however, satisfy the non-demolition property, which requires that the measurement Von Neumann algebra is Abelian and that the measurement at time  $s$  commutes with the state at time  $t$  for time  $t \geq s$ .

Suppose the observable  $X$  evolves in time as  $X(t) = e^{itH} X e^{-itH}$ ,  $t \geq 0$ . Then,  $X(t)$  satisfies the Heisenberg equation of motion for observables:

$$\frac{dX(t)}{dt} = i[H, X(t)].$$

Let  $\rho$  be a density matrix on the same Hilbert space then  $\text{Tr}(\rho(t)X) = \text{Tr}(\rho X(t))$ . For all observables  $X$ , then  $\rho(t) = e^{-itH} \cdot \rho \cdot e^{itH}$  and deduce that,

$$\frac{d\rho(t)}{dt} = i[H, \rho(t)].$$

Therefore, these results can be interpreted in terms of Schrödinger's wave mechanics and Heisenberg's matrix mechanics. Let  $\rho_A$  and  $\rho_B$  be two destiny matrices on  $\mathbb{C}^d$  (both are positive definite with trace one). So, to determine a unitary matrix  $U$  such that  $\|\rho_B - U\rho_A U^*\|$  is a minimum, where  $\|\cdot\|$  denotes Frobenius Norm [23].

Let  $U$  be the optimal unitary matrix. Then for any Hermitian matrix  $H$  must have,

$$\frac{d}{dt} \|\rho_B - Ue^{itH}\rho_A e^{-itH}U^*\|_{t=0}^2 = 0$$

This gives,

$$\text{Tr}((\rho_B - U\rho_A U^*)U[H, \rho_A]U^*) = 0$$

or equivalently,

$$\text{Tr}((U^*\rho_B U - \rho_A)[H, \rho_A]) = 0$$

or

$$\text{Tr}([\rho_A, U^*\rho_B U]H) = 0$$

For all Hermitian matrices  $H$ . It follows that  $U$  must satisfy  $[\rho_A, U^*\rho_B U] = 0$  or  $[U^*\rho_A U, \rho_B] = 0$ . By performing an average over the bath noise variables at each time, we are able to describe how system observables evolve when they are corrupted by bath noise in a way that ensures the system observable always remains a system observable.

### III. MATHEMATICAL MODEL OF QUANTUM RELATIVE ENTROPY

A quantum relative entropy is evolving in between two quantum systems  $\rho_A(t)$  and  $\rho_B(t)$  are density matrices satisfying the Sudarshan- Lindblad equation [33]:

$$\rho'_A(t) = -i[H_A, \rho_A(t)] - \frac{1}{2}\theta_1(\rho_A(t))$$

$$\rho'_B(t) = -i[H_B, \rho_B(t)] - \frac{1}{2}\theta_2(\rho_B(t))$$

$$\text{Where, } \theta_1(X) = \sum_{k=1}^p (L_k^* L_k X + X L_k^* L_k - 2L_k X L_k^*)$$

$$\theta_2(X) = \sum_{k=1}^p (M_k^* M_k X + X M_k^* M_k - 2M_k^* X M_k)$$

Assume  $H_2 - H_1$  and  $M_k - L_k$  upto  $O(\epsilon)$ , then calculate upto  $O(\epsilon^2)$ .

$$\frac{d}{dt} \text{Tr}(\rho_A \log \rho_A) = \text{Tr}\left(\frac{d\rho_A}{dt}\right) + \text{Tr}\left(\rho_A \frac{d}{dt} \log \rho_A\right)$$

$$\text{so by } \rho_A = e^{Z_1}, \rho_B = e^{Z_2},$$

$$\rho'_A = e^{Z_1} \frac{I - e^{-adZ_1}}{adZ_1} (Z'_1)$$

Thus,

$$Z'_1 = \rho_A^{-1} \sum_{r=1}^{\infty} c_r (\text{ad}Z_1)^r (\rho_A^{-1} \rho'_A)$$

$$\text{Tr}(\rho_A \frac{d}{dt} \log \rho_A) = \text{Tr}(\rho_A Z_1)$$

$$= \sum_{r=1}^{\infty} c_r \text{Tr}(\rho_A (\text{ad} \log \rho_A)^r (\rho_A^{-1} \rho'_A))$$

(since  $\text{Tr}(\rho'_A) = 0$ ), so

$$\frac{d}{dt} \text{Tr}(\rho_A \log \rho_A) = \text{Tr}[\rho'_A \log \rho_A] \text{ and,}$$

$$\frac{d}{dt} \text{Tr}(\rho_A \log \rho_B) = \text{Tr}(\rho'_A \log \rho_B) + \text{Tr}(\rho_A Z'_2)$$

$$Z_2 = \log \rho_B, \text{ then } Z'_2 = \frac{\text{ad}Z_2}{1 - e^{-\text{ad}Z_2}} (\rho_A^{-1} \rho'_B)$$

$$\text{Tr}(\rho_A Z'_2) = \text{Tr}\{\rho_A (\text{ad}Z_2 \sum_{m=0}^{\infty} e^{-m \cdot \text{ad}Z_2} (\rho_B^{-1} \rho'_B))\}$$

$$= \sum_{m=0}^{\infty} \text{Tr}(\rho_B^m \rho_A \rho_B^{-m-1} [Z_2, \rho'_B])$$

$$\text{so, } \frac{d}{dt} S(\rho_A, \rho_B) = \frac{d}{dt} \text{Tr}(\rho_A \log \rho_A - \rho_A \log \rho_B)$$

$$= \text{Tr}(\rho'_A \log \rho_A) - \text{Tr}(\rho'_A \log \rho_B) - \text{Tr}(\rho_A Z'_2)$$

$$= \text{Tr}(T_1(\rho_A) \log \rho_A) - \text{Tr}(T_1(\rho_A) \log \rho_B)$$

$$+ \sum_{m=0}^{\infty} \text{Tr}(\rho_B^m \rho_A \rho_B^{-m-1} [\log \rho_B, T_2(\rho_B)])$$

$$\text{Where, } T_k(\rho) = -i[H_k, \rho] - \frac{1}{2}\theta_k(\rho), k = 1, 2 \dots$$

Special case  $\theta_1 = \theta_2 = 0$  (No noise). Then, in this case we find

$$\frac{d}{dt} S(\rho_A, \rho_B) = i \text{Tr}\{(H_A - H_B)[\rho_A, \log \rho_B]\}$$

When it comes to general terms  $\rho_B = \sum_{\alpha=1}^p p_{\alpha} |e_{\alpha}\rangle \langle e_{\alpha}|$  is the spectral representation of  $\rho_B$  with  $p_{\alpha} > 0, \forall \alpha$ . Then let  $X = [\rho_A, \log \rho_B]$ , we get

$$\rho_B^N [\rho_A, \log \rho_B] \rho_B^N =$$

$$\sum_{\alpha, \beta=1}^p (p_{\alpha}/p_{\beta})^N |e_{\alpha}\rangle \langle e_{\beta}| \langle e_{\alpha}| X |e_{\beta}\rangle$$

If we assume that  $p_{\alpha} > p_{\beta} \Rightarrow \langle e_{\alpha}| X |e_{\beta}\rangle = 0$  then,

$$\lim_{N \rightarrow \infty} \rho_B^N [\rho_A, \log \rho_B] \rho_B^N =$$

$$= \sum_{\alpha, \beta: p_{\alpha} = p_{\beta}} |e_{\beta}\rangle \langle e_{\alpha}| X |e_{\beta}\rangle = X$$

and we then get

$$\frac{d}{dt} S(\rho_A, \rho_B)$$

$$= i \text{Tr}\{(H_A - H_B)X\} + i \text{Tr}\{H_B X\}$$

We note that

$$X = [\rho_A(t), \log \rho_B(t)] \equiv X(t)$$

$$= [U_1(t)\rho_A(0)U_1^*(t), U_2(t)\log \rho_B(0)U_2^*(t)]$$

$$= U_1(t)\rho_A(0)U_1^*(t)U_2(t)\log \rho_B(0)U_2^*(t)$$

$$- U_2(t)\log \rho_B(0)U_2^*(t)U_1(t)\rho_A(0)U_1^*(t)$$

Where,  $U_1(t) = \exp(-itH_A), U_2(t) = \exp(-itH_B)$

Now assume,  $U_1^*(t)U_2(t) \xrightarrow{t \rightarrow \infty} \Omega$ , (scattering matrix)

$$\begin{aligned} \text{Then, } \lim_{t \rightarrow \infty} T_r((H_A - H_B)X(t)) \\ = \lim_{t \rightarrow \infty} T_r\{U_2^*(t)U_1(t)(H_A - H_B)U_1(t)\rho_A(0)\Omega \log \rho_B(0)\} \end{aligned}$$

Now,

$$\frac{d}{dt} U_2^*(t)U_1(t) = -iU_2^*(t)(H_A - H_B)U_1(t)$$

$$\text{Write, } \Omega = \Omega(\infty) = \lim_{t \rightarrow \infty} U_1^*(t)U_2(t);$$

$$\Omega(t) = U_1^*(t)U_2(t).$$

$$\text{Then, } U_2^*(t)(H_A - H_B)U_1(t) = -i\Omega'(t),$$

$$\text{and we get, } \lim_{t \rightarrow \infty} T_r((H_A - H_B)X(t))$$

$$= i T_r\{\Omega'(\infty)\rho_A(0)\Omega(\infty)\log \rho_B(0)\}.$$

If  $\Omega'(\infty) = 0$  then this vanishes and we get,

$$\lim_{t \rightarrow \infty} \frac{d}{dt} S(\rho_A(t), \rho_B(t)) = i T_r\{H_B X(\infty)\}$$

We've seen that

$$\frac{d}{dt} S(\rho_A, \rho_B) = i T_r\{H_A[\rho_A, \log \rho_B]$$

$$+ i \lim_{N \rightarrow \infty} T_r\{H_B \rho_B^N[\rho_A, \log \rho_B] \rho_B^{-N}\}$$

$$- i T_r\{H_B[\rho_A, \log \rho_B]\}$$

$$\text{Let, } \Omega(t) = U_1^*(t)U_2(t).$$

Then,

$$\begin{aligned} & [\rho_A, \log \rho_B] \\ &= U_1(t)\rho_A(0)U_1^*(t)\log \rho_B(0)U_2^*(t) \\ &= U_1(t)\rho_A(0)\Omega(t)\log \rho_B(0) \\ & \quad U_2^*(t) \end{aligned}$$

So,

$$i T_r\{(H_A - H_B)[\rho_A(t), \log \rho_B(t)]\}$$

$$= i T_r\{U_2^*(t)(H_A - H_B)U_1(t)\rho_A(0)\Omega(t)\log \rho_B(0)\}$$

$$= -T_r\{\Omega'(t)\rho_A(0)\Omega(t)\log \rho_B(0)\}$$

and,

$$T_r\{H_B \rho_B(t)^N[\rho_A(t), \log \rho_B(t)]\rho_B(t)^{-N}\}$$

$$= T_r\{H_B U_2(t)\rho_B(0)^N U_2^*(t)U_1(t)\rho_A(0)$$

$$U_1^*(t)U_2(t)\log \rho_B(0)\rho_B(0)^{-N} U_2^*(t)\}$$

$$- T_r\{H_B U_2(t)\rho_B(0)^N \log(\rho_B(0))U_2^*(t)$$

$$U_1(t)\rho_A(0)U_1(t)U_2(t)\rho_B(0)^{-N} U_2^*(t)\}$$

$$= T_r\{H_B \rho_B(0)^N \Omega(t)\log \rho_B(0)\rho_B^{-N}$$

$$- T_r\{H_B \rho_B^N \log \rho_B(0)\Omega^*(t)\rho_A(0)\Omega(t)\rho_B^{-N}\}$$

Also note that

$$T_r\{U_2^*(t)(H_A - H_B)$$

$$U_1(t)\rho_A(0)\Omega(t)\log \rho_B(0)\}$$

$$\begin{aligned} &= T_r\{U_2^*(t)U_1(t)H_A \\ & - H_B U_2^*(t)U_1(t)\rho_A(0)\Omega(t)\log \rho_B(0)\} \\ &= T_r\{(\Omega^*(t)H_A \\ & - H_B \Omega^*(t))\rho_A(0)\Omega(t)\log \rho_B(0)\} \end{aligned}$$

So,

$$\frac{d}{dt} S(\rho_A(t), \rho_B(t)) =$$

$$\lim_{N \rightarrow \infty} i \lim_{N \rightarrow \infty} T_r\{H_B \rho_B(0)^N [\Omega^*(t)\rho_A(0)\Omega(t)\log \rho_B(0)] \rho_B^{-N}(0)\}$$

$$+ i T_r\{(\Omega^*(t)H_A - H_B \Omega^*(t))\rho_A(0)\Omega(t)\log \rho_B(0)\}$$

Let,  $\rho_B(0) = \sum_{\alpha=0}^r p_\alpha(\alpha)p_\alpha$  be the spectral distinct positions of  $\rho_B(0)$ . Thus  $\{\rho_A(0), \dots, \rho_r(0)\}$  are distinct,  $\sum_{\alpha} p_\alpha(0)T_r(p_\alpha) = 1$ ,  $\sum_{\alpha} p_\alpha = I$ ,  $P_\alpha P_\beta = P_\alpha \delta_{\alpha\beta}$ ,  $P_\alpha^* = P_\alpha$ .

In this paper, the rate of change entropy of the two quantum systems is solved and the parameters of the Hamiltonians of the noise operators are determined, which will yield the exact value of the relative entropy of entanglement.

Let us consider,

$$\rho'_A(t) = -i[H_A, \rho_A(t)] \text{ and}$$

$$\rho'_B(t) = -i[H_A, \rho_B(t)] - \frac{1}{2}\theta(\rho_B(t))$$

Where,

$$\theta(X) = L * LX + XL * L - 2LXL *$$

Then,

$$\frac{d}{dt} T_r(\rho_A \log \rho_A) = 0$$

$$\frac{d}{dt} T_r(\rho_A \log \rho_B)$$

$$= T_r(\rho'_A \log \rho_B) + T_r(\rho_A Z'_2)$$

$$Z'_2 = \frac{adZ_2}{1 - e^{-adZ_2}} (\rho_B^{-1} \rho'_B)$$

$$= adZ_2 \sum_{m=0}^{\infty} e^{-m.adZ_2} (\rho_A^{-1} \rho'_B)$$

$$= adZ_2 \left( \sum_{m=0}^{\infty} \rho_B^{-m-1} \rho'_B \rho_B^m \right)$$

So,

$$T_r(\rho_A, Z'_2) = \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, \rho'_B] \rho_B^m)$$

$$= -i \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, [H_B, \rho_B]] \rho_B^m)$$

$$- \frac{1}{2} \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, \theta(\rho_B)] \rho_B^m)$$

$$\begin{aligned} & \frac{d}{dt} T_r(\rho_A \log \rho_B) = \\ & T_r(\rho'_A \log \rho_B) - \iota \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, [H_B, \rho_B]] \rho_B^m) \\ & - \frac{1}{2} \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, \theta(\rho_B)] \rho_B^m) \end{aligned}$$

In conclusion, the change in relative entropy of the two quantum systems is given below;

$$\begin{aligned} & \frac{d}{dt} S(\rho_A, \rho_B) = \\ & \frac{d}{dt} T_r(\rho_A \log \rho_A - \rho_A \log \rho_B) \\ = & T_r(\rho'_A \log \rho_A) - T_r(\rho'_A \log \rho_B) - T_r(\rho_A Z'_2) \\ & \frac{d}{dt} S(\rho_A, \rho_B) = -T_r(\rho'_A \log \rho_B) \\ & + \iota \sum_{m \geq 0} T_r(\rho_A \rho_B^{-m-1} [Z_2, [H_B, \rho_B]] \rho_B^m) \\ & + \frac{1}{2} \sum_{m \geq 0} T_r(\rho_B \rho_B^{-m-1} [Z_2, \theta(\rho_B)] \rho_B^m) \end{aligned}$$

Where,

$$\theta(\rho_B) = L * L \rho_B + \rho_B L * L - 2L \rho_B L *$$

In order to calculate in time, the initial signal of observable X, the noisy Schrödinger equation is simulated by using a large set of exponential vectors in the Boson-Fock space for noisy baths, and an orthogonal basis for the signal Hilbert space.

#### IV. RESULTS AND DISCUSSIONS

The observable with the ideal theta value is shown in this section, along with a graphic of the noise to signal energy ratio.

##### A. The Expectation Value of an Observable of Two Quantum System

This paper is used to determine the average value X, which is expressed by  $X = T_r(\rho X)$  of the state of a quantum-mechanical system as described by its density operator  $\rho$  with  $T_r(\rho) = 1$ . The definition of the observable X, which is a  $2 \times 2$  random Hermitian matrices, as well as the values of  $H_0$  and  $V$ , constitute the first step in the analysis. It computes this matrix's eigenvalues and accompanying eigenvectors.

By comparing the expected value of an observable in a mixed state with the expected value of the observable in several mutually orthogonal pure states, one can obtain the expected value of the observable in the mixed state [12-15]. Our results are explaining the quantum average measure value to extra the information with effecting of the AWGN and stochastic noise and we will evaluate the performance of our algorithm in the presence of BATH states, that is, compute the noise to signal ratio of the given estimate of  $\delta\theta$ , that is,  $E(|\delta(\theta) - \delta'(\theta)|^2)$ . Using functional analysis and strict mathematics, it is possible to generate the quantum noise. In particular, we demonstrate how some important stochastic processes from classical probability theory, such as the Brownian motion and Poisson processes, can be viewed as special cases of quantum stochastic processes, which are a family of non-commuting observables in a particular type of Hilbert space called the

Boson Fock space when observed in particular states. The randomly generated two Hamiltonian of the given system and find the Eigenvalues through MATLAB.

And,

$$\begin{aligned} H_A &= \text{rand}(2,2) + j * \text{rand}(2,2); \\ H_A &= [ 0.8178 \quad 0.4275 - 0.0756i; \\ & \quad 0.4275 + 0.0756i \quad 0.0225] \end{aligned}$$

The Hermitian matrix equation of the Hamiltonian of the first system is given below;

$$\begin{aligned} H_A &= (H_A + H_A') / 2 \\ H_B &= \text{rand}(2,2) + j * \text{rand}(2,2); \\ H_B &= [ 0.4229 \quad 0.3464 - 0.0307i; \\ & \quad 0.3464 + 0.0307i \quad 0.4709] \end{aligned}$$

$$\delta X = \begin{array}{|c|c|c|c|} \hline \begin{array}{c} -0.070838082586555 \\ - 0.000000000000000i \end{array} & \begin{array}{c} -0.015815573941431 \\ + \\ 0.007750834345286i \end{array} & \begin{array}{c} -0.015815573941431 \\ + \\ 0.007750834345286i \end{array} & \begin{array}{c} 0.071195946682088 - \\ 0.010664577493442i \end{array} \\ \hline \begin{array}{c} -0.015815573941431 \\ - 0.007750834345286i \end{array} & \begin{array}{c} 0.070838082586553 + \\ 0.000000000000000i \end{array} & \begin{array}{c} 0.070838082586553 + \\ 0.000000000000000i \end{array} & \begin{array}{c} 0.015815573941431 - \\ 0.007750834345286i \end{array} \\ \hline \begin{array}{c} -0.015815573941431 \\ - 0.007750834345286i \end{array} & \begin{array}{c} 0.070838082586553 + \\ 0.000000000000000i \end{array} & \begin{array}{c} 0.070838082586553 + \\ 0.000000000000000i \end{array} & \begin{array}{c} 0.015815573941431 - \\ 0.007750834345286i \end{array} \\ \hline \begin{array}{c} 0.071195946682088 \\ + \\ 0.010664577493442i \end{array} & \begin{array}{c} 0.015815573941431 + \\ 0.007750834345286i \end{array} & \begin{array}{c} 0.015815573941431 + \\ 0.007750834345286i \end{array} & \begin{array}{c} -0.070838082586553 \\ + \\ 0.000000000000000i \end{array} \\ \hline \end{array}$$

The Hermitian Matrix equation of the Hamiltonian of the second system is given below;

$$H_B = (H_B + H_B^*) / 2;$$

First, initialize the states and choose the value of  $A_1, A_2, P_1$  and  $P_2$  for estimating the theta. So, the estimated value of  $\theta$  is 0.33 for  $2 \times 2$  matrices, additionally, if we increase the size of the qubit, the estimated values of  $\theta$  is 0.28 for  $3 \times 3$ . Then second, we are designed  $\delta X$  for  $2 \times 2$  matrices, consider  $\delta\theta = 0.33$  with a random noise generating from random AWGN.

Since the collapse postulate is taken into account, continuous measurement is not covered in this section. A single measurement is known to cause the system's state to collapse to the eigenstate of the measured observable, which corresponds to the observed result. Since the metric above only displayed the minimal value of the observable, it is clear that, for each time index of T, the value of our error energy function approaches zero or its smallest value.

**B. NSER (Noise- to-Signal Energy Ratio) of Entropy**

We can use the NSER as a performance index to calculate the impact of this noise on the error energy. This chart, which is displayed below, shows how noise to signal energy ratios can remain low over an extended length of time, which verifies a successful performance. Using the Frobenius norm, we must minimize the error function or cost function.

The error function has to be determined the optimum operators  $L_1, L_2, S$ , so that  $\int_0^T \|\rho_s(t, u) - \rho_d(t)\|^2 dt$  is a minimum. Assuming the function  $u(t), 0 \leq t \leq T$  and H given.

$$NSER = \frac{\|\rho_s(t, u) - \rho_d(t)\|^2}{\rho_d(t)^2} = \frac{\zeta_{min}}{\rho_d(t)^2}$$

**Algorithm 2:** NSER (Noise – to – Signal Energy Ratio) of entropy

**Data:** Using the Frobenius norm, we must minimize the error function or cost function.

**Result:** NSER should be remains less than unity. initialization;

```

while While condition do
    instructions;
    if condition then
        instructions1:  $\delta\theta$  is minimum;
        instructions1:  $\theta$  is minimum;
        then
            X ← minimum
        then
            instructions3:  $\rho$  ← minimum
    then NSER =  $s(t, u) - d(t)^2 / (d(t)) = min / (d(t))$ 
    else
        instructions4: NSER is minimum;
    Outcome: Rate of the change of Entropy is minimum
    Final:
         $\frac{dS(\rho_A - \rho_B)}{dt} = \frac{dT_{r(\rho_A \log(\rho_A) - \rho_B \log(\rho_B))}}{dt}$ 
    end
end

```

Where,  $\zeta_{min}$  is the error energy function value and  $\rho_d(t)$  is the desired density function. We show through simulation that the NSER of entropy stabilizes to a small value, supporting the information inequality that states conditionally reducing entropy decreases information. A better design, one with a lower SER, might theoretically be obtained by first averaging over the noise distribution and then minimizing with respect to the nonrandom functions (see Fig. 1).

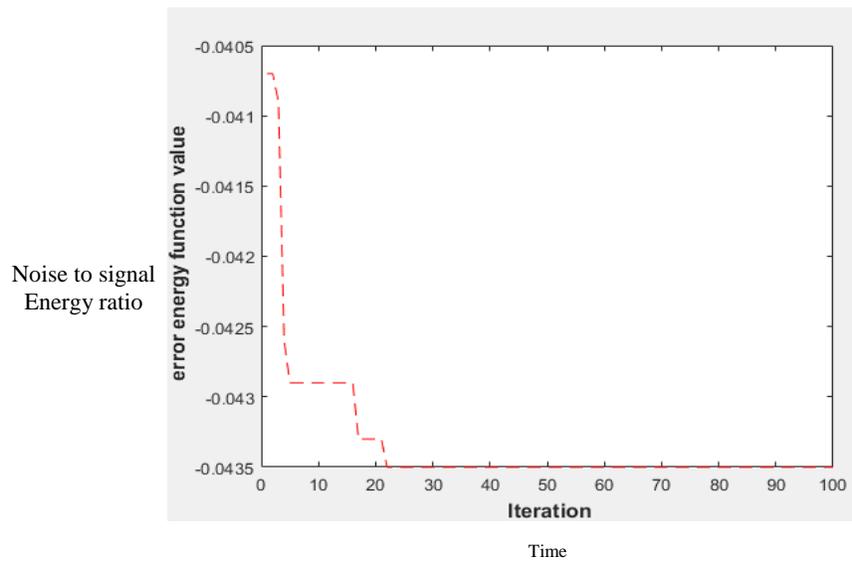

Fig. 1. Noise-to-signal energy ratio plot for quantum system

Since reducing noise effects and highlighting the signal process is the whole purpose of collecting measurements, the NSER should gradually decrease with time.

$$\frac{d}{dt}S(\rho_A, \rho_B) = \frac{d}{dt}T_r(\rho_A \log \rho_A - \rho_A \log \rho_B)$$

We compute NSER, and it remains less than unity. We also showed how to use stochastic differential equations to calculate the relative entropy of two quantum systems plus bath density, i.e. stochastic system density. Through simulations, we are justifying that the rate of change of relative entropy stabilizes to a value less than  $\theta(\rho_B)$ , which realistically justifies the information inequality stating that conditioning reduces entropy. The idea will be helpful to research communities in applied mathematics, physics, and quantum information theory who seek to investigate the variety of applications of classical and quantum stochastics to issues of physics and engineering, to sum up the conclusion.

## V. CONCLUSIONS

We have determined the quantum relative entropy rate between two mixed states using noisy Schrödinger equations with varied Hamiltonians and Lindblad operators. For our calculations, we applied the conventional formula for calculating the exponential map of matrices. We may compute the rate of relative entropy as the asymptotic limit  $t \rightarrow \infty$  based on the scattering matrices connected to the pair of Hamiltonians that generate the two states. It is important to look into the circumstances in which the asymptotic relative entropy rate for the Hamiltonian and Lindblad operators continues to be below the specified threshold. The asymptotic limit in this scenario would ensure that there is a short gap between the two states. Conditioning is known in classical information theory to decrease entropy, specifically  $H(X/Y) \leq H(X)$ . As a result, we anticipate that in the quantum setting, the entropy of the filtered state will be reduced using HP equations based on detecting the noise process. In further work, we will also extend this formalism to Belavkin's quantum filtering

theory based on the Hudson-Parthasarathy quantum stochastic by demonstrating that when this equation for a particle travelling in a potential with damping and noise is characterized in terms of the Wigner distribution function, then it is exactly the same as the Kushner-Kallianpur stochastic filter but with quantum correction terms stated as a power series in Planck's constant.

# Research on Automatic Detection Algorithm for Pedestrians on the Road Based on Image Processing Method

Qing Zhang

Zhangjiajie College, Jishou University, Zhangjiajie, Hunan 427000, China

**Abstract**—Accurate detection of pedestrian targets can effectively improve the performance level of intelligent transportation and surveillance projects. In order to effectively enhance the accuracy of detecting pedestrian targets on the road, this paper first introduced the traditional pedestrian target detection algorithm, proposed the faster recurrent convolutional neural network (RCNN) algorithm to detect pedestrian targets, and improved it to make good use of the convolutional features at different scales. Finally, support vector machine (SVM), traditional Faster RCNN, and optimized Faster RCNN algorithms were compared by simulation experiments. The results showed that the optimized Faster RCNN algorithm had higher detection accuracy and recall rate, obtained a more accurate target localization frame, and detected faster than SVM and traditional Faster RCNN algorithms; the traditional Faster RCNN algorithm had higher detection accuracy and target frame localization accuracy than the SVM algorithm.

**Keywords**—Pedestrian detection; recurrent convolutional neural network; scale-invariant feature transform; support vector machine; characteristic scale; Difference of Gaussians operator

## NOMENCLATURE

$D(x, y, \sigma)$ : The DoG operator.

$DR$ : The target frame predicted by the algorithm.

$G(x, y, \sigma)$ : The Gaussian filter function.

$G(x, y, k\sigma)$ : The Gaussian filter function.

$GT$ : The actual target frame in the image.

$IoU$ : The degree of target frame overlap.

$I(x, y)$ : The original image.

$P$ : The precision.

$R$ : The recall rate.

## I. INTRODUCTION

Economic development continues to improve people's living standards, and the pressure on traffic management increases as more and more vehicles are used in travel [1]. The progress of computer technology has promoted the emergence of intelligent transportation, and the detection of pedestrians is an important component of intelligent transportation [2]. Accurate detection of pedestrians can effectively improve the level of intelligent driving, intelligent monitoring, and other

technologies. For example, in intelligent driving, more accurate pedestrian detection can assist drivers to make safe avoidance of pedestrians and reduce the occurrence of traffic accidents; in intelligent monitoring, computers replace humans to make recognition of pedestrians in monitoring videos, track pedestrians, and judge the behavior of pedestrians, thus improving the security level. Manual identification is relatively accurate and is also more intuitive when identifying pedestrians in video images, but human energy is limited and cannot maintain focused attention for a long time, so replacing humans with machines to automatically detect pedestrians is the current trend. Although the detection of pedestrians in images by image processing techniques is not intuitive, it is relatively more comprehensive in measuring targets with smaller scales in images. The traditional pedestrian target detection algorithm uses a feature extraction algorithm to extract image features before classification by a classification algorithm. In the traditional pedestrian target detection algorithm, feature extraction and recognition and detection of images can be considered relatively independent, and the features extracted by the feature extraction algorithm are often statistical local features, which are difficult to reflect image features comprehensively. As deep learning algorithms and computer performance improve, convolutional neural networks (CNNs) have been applied to pedestrian detection. Compared with the traditional detection method, CNNs combine image feature extraction and recognition together and integrated the local features extracted using convolutional kernels into global features, thus making the detection of pedestrian targets more accurately.

Some relevant literature is reviewed below. Xu et al. [3] reconstructed a target detection model called YOLOv3, proposed YOLOv3-promote, and introduced an attention mechanism. They found that the inference speed of the method was faster than the original model and the parameter volume was reduced to one-tenth. Xia et al. [4] put forward a pedestrian detection algorithm based on multi-scale feature extraction and attention feature fusion and found that the algorithm had good detection performance. Liu [5] proposed a deep residual network-based adaptive scale pedestrian detection algorithm and found that the algorithm was applicable to pedestrians of different scales. Yang et al. [6] designed a pedestrian target detection algorithm based on a single shot multibox detector. Subsequent simulation experimental results on VOC2007 and data\_sub showed that the maximum value of mAP was 77% and the maximum

accuracy was 96.31%. Zhang et al. [7] designed a pedestrian target detection algorithm based on the histogram of oriented gradient and support vector machine (SVM). They found that the algorithm greatly reduced the computational effort when feature extraction was performed only on candidate regions, thus improving the detection efficiency. Pei et al. [8] designed a multispectral pedestrian target detection algorithm combining visual optical images and infrared images based on deep CNNs and performed simulation tests on the public multispectral benchmark dataset. They found that the log-average miss rate of the algorithm reached 27.6%. Shojaei et al. [9] used transfer component analysis and maximum independent domain in pedestrian target detection. The experimental results on the dataset of INRIA showed that the pedestrian target detection algorithm with domain adaptation had less classification error. Wang et al. [10] designed an algorithm using image fusion and deep learning to improve the performance of unmanned aerial vehicles for detecting pedestrians on the ground in low-illumination environments and verified the excellent performance of the algorithm through experiments.

The previous text is a review of some studies related to pedestrian target detection, and different researchers have used different approaches to identify and detect pedestrian targets. In general, the basic principle of these pedestrian target recognition and detection methods is to extract pedestrian features from images and recognize them based on the extracted features. However, the extracted image features under different scales were not fully considered in the above-mentioned studies; therefore, in this paper, the image features at different scales were utilized.

This paper studied intelligent algorithms for pedestrian target detection on roads. This paper was written in the following structure. The abstract starts with a general statement of the full paper. The introduction gives a brief overview of the related literature. Then, the pedestrian target detection algorithm is described, including the traditional SVM algorithm and the improved Faster RCNN algorithm. Then, the simulation experiment is described. In the experiment, the SVM algorithm, traditional Faster RCNN, and improved Faster RCNN algorithms were compared. The final conclusion summarizes the results of this paper. The contribution of this paper is to optimize the Faster RCNN algorithm for pedestrian target detection, so that it can make full use of the convolutional feature maps at different scales, providing an effective reference for accurate and fast detection of pedestrian targets on the road. The limitation of this paper is that the types of images used in the training of the algorithm were not comprehensive enough, so the richness of the types of images required for algorithm training will be increased to improve the generalizability of the algorithm in the future.

## II. AUTOMATIC DETECTION ALGORITHM FOR PEDESTRIANS

### A. Traditional Pedestrian Target Detection Algorithm

A video consists of multi-frame images, so the detection of pedestrians in the video can be considered as fast detection of pedestrians in the image. The traditional pedestrian target detection algorithm extracts features from the images in the candidate frames, uses a classification algorithm to classify and

identify the images in the candidate frames according to the extracted features, and takes the candidate frames judged to be pedestrians as the output. Its specific steps are illustrated in Fig. 1.

1) An input image is pre-processed. A plural number of candidate boxes are added to the image. The size of the candidate boxes is determined according to the actual application.

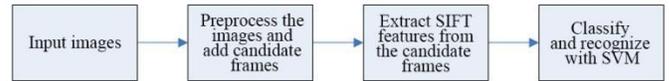

Fig. 1. Traditional pedestrian target detection algorithm.

2) Scale-invariant feature transform (SIFT) feature extraction is performed on the image in the candidate frame. The extraction of SIFT features requires the Difference of Gaussian (DoG) operator [11] to construct a Gaussian difference pyramid. The calculation formula of the DoG operator is:

$$D(x, y, \sigma) = (G(x, y, k\sigma) - G(x, y, \sigma)) \times I(x, y), \quad (1)$$

where  $D(x, y, \sigma)$  denotes the DoG operator, whose scale factor is  $\sigma$ ,  $G(x, y, \sigma)$  and  $G(x, y, k\sigma)$  are the Gaussian filter functions, whose scale factor is  $\sigma$  and adjacent to  $\sigma$ , respectively, and  $I(x, y)$  is the original image. Then, the local extreme points of the image in every scale in the Gaussian difference pyramid composed of DoG operators are searched. The gradient histogram is constructed by choosing the appropriate neighborhood range with the extreme point in every level of the pyramid as the center [12]. Eventually, the histograms corresponding to the main direction of every extreme point and the direction greater than 80% of the gradient peak of the main direction are merged as the SIFT feature.

3) The SIFT features of the collected image sample are separated into a training group and a test group. The training group is used to train and fit the SVM to get the classification function. After the training, the SVM classification function is used to determine whether the image in the candidate frame is a pedestrian according to the SIFT features of the image sample.

### B. Pedestrian Target Detection Algorithm using Convolutional Neural Network

In the traditional pedestrian detection algorithm described in the previous text, the features of the image are firstly extracted before recognition by the SVM, which simply means that the extraction of the image features and the recognition of the image are independent of each other. Moreover, the extracted SIFT features are statistical, which are difficult to fully reflect the features of the image and will affect the detection accuracy of the algorithm.

A CNN, as a deep learning algorithm [13], can extract local features of images by convolutional kernels, and the plural features obtained from the plural convolutional kernels can be

combined into global features, taking into account the global and local. The Faster RCNN algorithm is a CNN algorithm for detecting pedestrian targets. It first extracts the convolution feature map of the image through the convolutional and pooling structures of a conventional CNN and obtains the candidate target frame from the map through a regional proposal network (RPN) [14]. After the convolutional features in the candidate target frame are pooled by region of interest (ROI), whether the target frame is a pedestrian is determined in the fully connected layer, and regressive calculation is also performed on the target frame that is judged as a pedestrian in the fully connected layer to get the coordinates of the target frame in the original image.

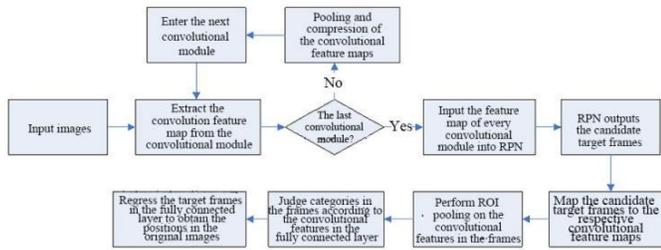

Fig. 2. Pedestrian detection process of the optimized Faster RCNN algorithm.

The convolutional and pooling structures of the CNN in the Faster RCNN algorithm will produce convolutional feature maps of different scales. In this paper, in order to make good use of the convolutional features of different scales to improve pedestrian detection accuracy, some improvements are made to the Faster RCNN algorithm. The optimized detection process is presented in Fig. 2.

- 1) A pre-processed image is input into the input layer.
- 2) Convolutional features are extracted in the convolutional module.
- 3) Whether the convolutional module is the last convolutional module in the conventional CNN structure is determined. If not, the convolutional features are pooled and compressed. The compressed convolutional feature map is input into the next convolutional module for the operation in step 2; if it is, the convolutional feature map of the last convolutional layer obtained in every convolutional module is input into the RPN.
- 4) The candidate target frame is obtained after calculation in RPN: In this structure, the pixel points in the feature map are regarded as anchor points, and every anchor point generates nine candidate frames with three scales and three length-width ratios with itself as the center [15]. The candidate frame score is calculated according to the convolution features in the candidate frame; the higher the score, the higher the probability of the candidate frame being the target frame. Some candidate frames with high probability are selected and mapped to the original image according to the ratio of the feature map where the candidate frame is located to the original image, and the candidate frames that are beyond the boundary of the original image are deleted. Some candidate frames with high probability are chosen from the remaining candidate frames again as the output of RPN.

5) The candidate target frames calculated by RPN are mapped to the respective convolutional feature maps to which they belong, i.e., the candidate target frames are mapped to the feature maps from which they are obtained.

6) ROI pooling operation [16] is performed on the convolutional features in the candidate target frame. The convolutional map in the target frame is divided into regions according to the required size for ROI pooling, and every region is processed by max-pooling. For example, if the feature map with a size of  $9 \times 9$  in the target frame needs to be compressed into a size of  $3 \times 3$ , the feature map in the target frame is divided into regions in a size of  $3 \times 3$ , every region is processed by max-pooling, and the result is taken as the value of the corresponding region.

7) The convolutional features processed by ROI compression are input into the fully connected layer to determine whether they are pedestrians, and the position of the target frame in the original image is calculated [17].

The improvement of the optimized Faster RCNN algorithm compared to the traditional Faster RCNN algorithm is that instead of using only the convolutional feature map given by the last convolutional module, convolutional feature maps of different scales in the previous convolutional module are used, making full use of the convolutional features of different scales.

### III. SIMULATION EXPERIMENTS

#### A. Experimental Setup

The algorithm in Fig. 3 has five convolutional modules. Convolutional modules 1 and 2 both have two convolutional layers, and there are 32 convolutional kernels in a size of  $3 \times 3$  in every layer [18]. Convolutional modules 3, 4 and 5 all have three convolutional layers, and there are 64 convolutional kernels in a size of  $3 \times 3$  in every layer. Convolutional modules 1~4 have 1 pooling layer after every module, every pooling layer uses a pooling frame in a size of  $2 \times 2$ , and the mean-pooling is used in the pooling frame. The RPN module is a fully convolutional structure. Convolutional feature maps obtained from convolutional layers 2, 4, 7, 10, and 13 are all used to calculate the candidate target frames in the RPN. The ROI pooling layer compresses the convolutional features in the candidate target frames, and the compressed size is  $6 \times 6$ . The fully connected layer recognizes the category of convolutional features after ROI pooling to determine whether the image in the target frame is a pedestrian. Moreover, the regressive calculation is conducted on the candidate target frame to obtain the coordinates of the target frame in the original image.

The images collected by the author were used as the dataset for the simulation experiment. The images came from a variety of scenes, not limited to traffic intersections. After preliminary removing images with too blurred pedestrians and too dark backgrounds, 15,210 images were left, and the scenes included traffic intersections, parks, supermarkets, subway stations, neighborhoods, etc. Sixty percent of the images were used as the training samples, and the remaining 40% as the test samples.

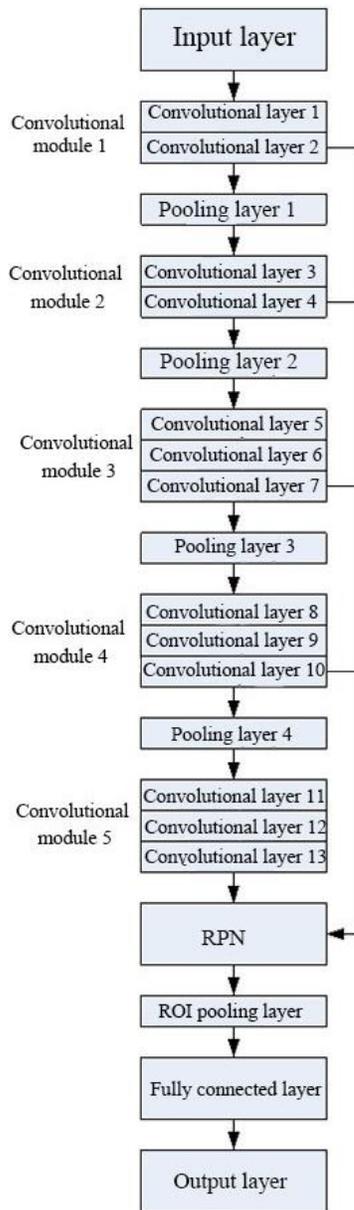

Fig. 3. Basic structure of the improved faster RCNN algorithm.

In the simulation experiment, two detection algorithms, the SVM algorithm and the traditional Faster RCNN algorithm, were also tested to further verify the performance of the improved Faster RCNN algorithm. The SVM algorithm identified pedestrians in the images with SIFT features, and the size of the target frame used for extracting SIFT features was  $6 \times 6$ . The basic structure of the traditional Faster RCNN algorithm was similar to that of the optimized Faster RCNN algorithm, and their only difference was that the convolutional feature maps in convolutional layers 2, 4, 7, and 10 were not input into the RPN.

### B. Evaluation Criteria

Target detection for pedestrians is a binary classification problem, i.e., to determine whether the target in an image target frame is a pedestrian, so the performance of the detection algorithm can be evaluated using a confusion matrix [19], as

shown in Table I. The detection precision and recall rate are calculated using the following equations:

$$\begin{cases} P = \frac{TP}{TP + FP} \\ R = \frac{TP}{TP + FN} \end{cases}, \quad (2)$$

where  $P$  is the precision and  $R$  is the recall rate. In addition, the detection speed of the pedestrian target detection algorithm is also quite important. Here, frame per second (FPS) was used to measure the detection speed of the algorithm, i.e., the number of images detected per unit time.

In addition to the above evaluation criteria, the author also used Intersection over Union (IoU) to measure the target frame positioning accuracy of the algorithm. The calculation formula of IoU is:

$$IoU = \frac{DR \cap GT}{DR \cup GT}, \quad (3)$$

where  $IoU$  stands for the degree of target frame overlap,  $DR$  denotes the target frame predicted by the algorithm, and  $GT$  denotes the actual target frame in the image.

### C. Experimental Results

The SVM algorithm and traditional Faster RCNN algorithm were compared with the optimized Faster RCNN algorithm. Due to the limitation of space, only some of the detection results are displayed. Fig. 4 shows the pedestrian target detection results of three algorithms for the same image. It was seen from Fig. 4 that the SVM algorithm marked the relatively obvious pedestrians in the image but missed smaller pedestrians, and moreover, it identified two pedestrians as one pedestrian among the marked pedestrians, so it was not very effective in recognizing pedestrian targets overall. In the result of the conventional Faster RCNN algorithm, more pedestrians were detected than in the SVM algorithm, and the two pedestrians that overlap in the picture were also distinguished, but it also missed smaller pedestrian targets. The improved Faster RCNN algorithm not only detected and distinguished relatively significant pedestrians but also detected smaller pedestrian's targets, so its detection performance was the best.

Fig. 5 shows the precision and recall rate of the SVM, traditional Faster RCNN, and optimized Faster RCNN algorithm for the test set. The precision of the SVM algorithm for pedestrian target detection was 75.3%, and the recall rate was 73.8%; the precision of the traditional Faster RCNN algorithm for pedestrian target detection was 86.7%, and the recall rate was 85.7%; the precision of the improved Faster RCNN algorithm had a precision of 96.6% and a recall rate of 95.4%.

TABLE I. CONFUSION MATRIX

	Pedestrian actually	Background actually
Judged as pedestrian	$TP$	$FP$
Judgment as background	$FN$	$TN$

Fig. 4. Partial detection results of three pedestrian target detection algorithms.

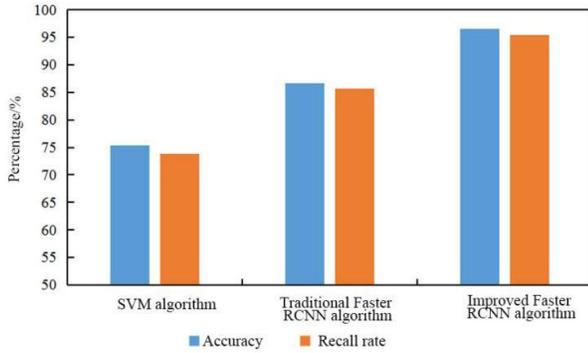

Fig. 5. Detection performance of the three algorithms.

Fig. 6 shows the detection speed of SVM, traditional Faster RCNN, and improved Faster RCNN algorithms for the test set. The detection speed of the SVM, traditional Faster RCNN, and improved Faster RCNN algorithms for pedestrian targets was 10.36 FPS, 21.33 FPS, and 33.51 FPS, respectively. It was seen from Fig. 6 that the SVM algorithm had the lowest detection speed, the traditional RCNN algorithm had a detection speed higher than the SVM algorithm, and the improved Faster RCNN algorithm had a detection speed higher than the traditional RCNN algorithm.

Fig. 7 shows the target frame localization accuracy of the three pedestrian target detection algorithms. The IoU of the target frame of the SVM, traditional Faster RCNN, and improved Faster RCNN algorithms was 67.3%, 79.8%, and 93.4%, respectively. It was observed in Fig. 7 that the target frame obtained by the SVM algorithm in the process of pedestrian detection had the lowest degree of overlap with the actual target frame, the degree of overlap between the target frame obtained by the traditional Faster RCNN and the actual target frame was higher than that of the SVM algorithm, and the degree of overlap between the target frame calculated by the improved algorithm and the actual target frame was higher than that of the traditional Faster RCNN algorithm.

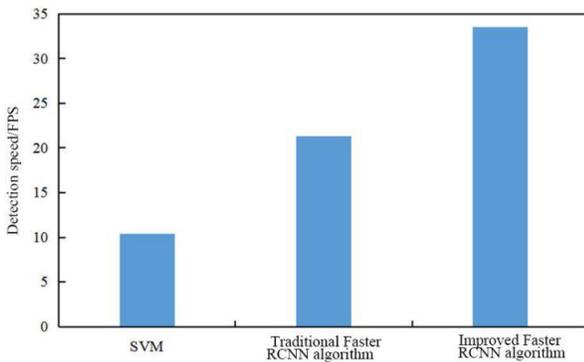

Fig. 6. Detection speed of three pedestrian target detection algorithms.

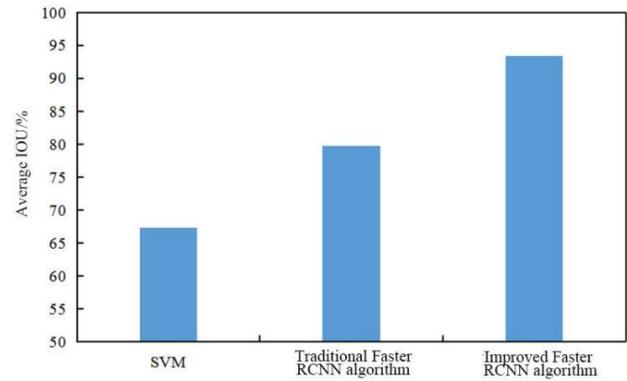

Fig. 7. Target frame localization accuracy of three pedestrian target detection algorithms.

Based on the comparison results of detection accuracy and speed among the three pedestrian target detection algorithms, it was found that the improved Faster RCNN algorithm had the best detection performance, followed by the traditional Faster RCNN algorithm, and the SVM algorithm performed the poorest. The reasons are shown below. The SVM algorithm extracted SIFT features when detecting pedestrian targets, which were statistical features that could not fully reflect the features in the image, so it was difficult to distinguish overlapped pedestrians in the image in the detection process, and the fixed size of the target frame also made it inflexible to distinguish smaller pedestrian targets. The traditional Faster RCNN algorithm used the convolutional structure of a CNN to extract the local and global features of the image, so it performed better than the SVM algorithm in recognition, but only the convolutional features of the last convolutional layer were used in the calculation of the candidate target frame. Even if the target frames with three length-width ratios were used, it was difficult to effectively use the multi-scale features, so the traditional algorithm missed the pedestrians. In the improved Faster RCNN algorithm, the convolutional features of different scales were fully utilized in the calculation of candidate frames, so it effectively recognized smaller pedestrian targets in the images. Moreover, the SVM algorithm used fixed-size target frames for recognition and identified all the target frames, leading to a low detection speed and decreased localization accuracy of the computed target frames; the traditional Faster RCNN algorithm used RPN to pre-compute candidate frames, which reduced the repetitiveness of target frame selection, and different scales of candidate frames improved the localization accuracy of small targets; the improved Faster RCNN algorithm used convolutional features of different scales in the computation of target candidate frames and further improved the localization accuracy of target frames for small pedestrians by using target frames of different scales.

#### IV. CONCLUSION

This paper compared the SVM, traditional Faster RCNN, and improved Faster RCNN algorithms in simulation experiments after improving the traditional Faster RCNN algorithm. The experimental results are shown below. (1) The detection results of some images showed that the improved Faster RCNN algorithm effectively distinguished the pedestrians in the image as well as the background and also

achieved better detection results when facing small target pedestrians in the image compared to the other two algorithms. (2) In terms of detection accuracy for pedestrians in images, the detection accuracy and recall rate of the improved Faster RCNN was 75.3% and 73.8%, respectively; the traditional Faster RCNN algorithm was 86.7% and 85.7%, respectively; the SVM algorithm was 96.6% and 95.4%, respectively. (3) In terms of the detection speed, the detection speed of the SVM algorithm was 10.36 FPS, the traditional Faster RCNN algorithm was 21.33 FPS, and the improved Faster RCNN algorithm was 33.51 FPS. (4) In terms of the localization frame accuracy, the IoU of the target frame of the SVM algorithm was 67.3%, the IoU of the traditional Faster RCNN algorithm was 79.8%, and the IoU of the improved Faster RCNN algorithm was 93.4%.

**Abstract**—Data testing is a vital part of the software development process, and there are various approaches available to improve the exploration of all possible software code paths. This study introduces two contributions. Firstly, an improved version of the Multi-verse Optimizer called Testing Multi-Verse Optimizer (TMVO) is proposed, which takes into account the movement of the swarm and the mean of the two best solutions in the universe. The particles move towards the optimal solution by using a mean-based algorithm model, which guarantees efficient exploration and exploitation. Secondly, TMVO is applied to automatically develop test cases for structural data testing, particularly path testing. Instead of automating the entire testing process, the focus is on centralizing automated procedures for collecting testing data. Automation for generating testing data is becoming increasingly popular due to the high cost of manual data generation. To evaluate the effectiveness of TMVO, it was tested on various well-known functions as well as five programs that presented unique challenges in testing. The test results indicated that TMVO performed better than the original MVO algorithm on the majority of the tested functions.

**Keywords**—MVO; optimization; testing; swarm intelligence; multi-verse optimizer

## I. INTRODUCTION

The term "optimization" describes the process of identifying the most optimal search solutions that are likely to resolve a particular issue. There is more than one conventional and meta-heuristic optimization strategy available. The standard techniques are gradient-based and have a faster execution time than convergence. On the other hand, these methods are not applicable to multimodal functions that are neither differentiable nor predictable. Thus, this technique does not allow for the discovery of the global optimal solution. Due to the fact that they start with only one point, it gets trapped at the local optimal value. There are many other search strategies that can be used to solve this problem; however, most of them require additional assistance that is based on exponential time, which makes them more time-consuming [1]. As a result, meta-heuristic optimization approaches have become the most widely used approach. Meanwhile, intelligent algorithms are increasingly used in the development of applications, testing, and the making of business decisions in today's world [2][3].

The use of meta-heuristics has been increasingly widespread over the past two decades. Computer researchers in a wide variety of domains are familiar with meta-heuristic techniques such as the Genetic Algorithm, multi-verse, and Particle Swarm Optimization, amongst others. Because of its ease of use, adaptability, and absence of approaches requiring derivation, meta-heuristic has garnered a lot of attention in recent years [4] [5]. Techniques for testing software include both black-box and white box testing. In the black-box method of software testing, the tester is only privy to the system's architecture. He or she is not privy to any information regarding the program's internal design and does not have access to the source code. Its purpose is to guarantee that the system accepts all of the necessary inputs in the way that was described and produces results that are accurate. White box testing, also known as structural testing, focuses on investigating the internal logic and structure of the source code being tested. During the structural test, each possible code path will be checked for a predetermined set of test information inputs. It is very important to select a diverse control flow way to test since there are a large number of paths for test succession, and performing the tests in succession can be difficult. Finding connections between system components, choosing those paths, creating test data for every path, and assessing test results are only a few examples of the many problem viewing paths involved in software testing [6].

The white box test criteria for software testing, such as branch coverage, focus on the process of locating a group of test cases that increases the likelihood of error discovery. Within the context of this approach, an experiment will serve as the indication that triggers the calling of the test routines with specific input group values. After that, those drivers will make a comparison between the output and the one that was relied upon. Utilizing known inputs that can be put to use but will ultimately prove to be impossible, allowing for an infinite supply of them. As a result, the primary focus of automated software testing is on the process of naturally locating the smallest set of inputs in order to broaden the scope of the test criteria [7]. When it comes to the process of developing test cases for critical path coverage testing, the concept of linear coded sequence is absolutely necessary. It is possible that the productivity of the development of all of these important paths

can be increased, and at the same time, it will be appropriate to create test cases with the assistance of a variety of testing tools so that those tested programs can be investigated. This can be done through all of the important paths [8].

It has been shown by the "No Free Lunch" theorem [9] that metaheuristics do not always succeed in solving optimization issues. Results show that metaheuristic optimization works well for one type of optimization issue but not another. For the aforementioned causes, it is important to create a more efficient optimization metaheuristic algorithm [10], [11].

The primary contribution of this study is the introduction of an improved version of the Multi-verse Optimizer, named the Testing Multi-Verse Optimizer (TMVO). Instead of focusing on a specific region, TMVO takes into account the mobility of the swarm and the average of the two best solutions across the universe. A mean-based algorithm model is employed to guide particle movement towards the optimal solution. TMVO's proposed movement equations enable effective space exploration and utilization, and also address the issue of poor convergence, providing an additional benefit by escaping local minima.

The second contribution of this study involves the application of TMVO algorithm, an enhanced swarm intelligence metaheuristic, to address the issue of single objective optimization in the automated generation of test cases for structural data testing, particularly path testing. Rather than automating the entire testing process, TMVO focuses on centralizing automated procedures for collecting testing data. The proposed TMVO achieves this goal by directing the swarm based on the past performance of the top three solutions discovered by the swarm. The population search history is also utilized to provide an alternative answer, which is the mean of the three best spots identified so far, thus improving the particles' ability to explore the space. This results in more opportunities for the swarm particles to be discovered and utilized, thereby increasing the likelihood of achieving a global optimum while avoiding a local minimum challenge. To overcome these challenges, the direction of particle flow is switched with each cycle.

Due to the absence of a universally applicable metaheuristic that can be used to address all optimization issues, and the fact that no metaheuristic has proven to be effective for solving all identified optimization problems, many swarm intelligence studies have focused on optimizing specific systems.

Route testing is a methodology for testing software that involves a search of the program domain for test cases that, when combined with the code, will cause the program to follow a specified path. Path testing is an optimization issue with no unique solution due to the unlimited number of possible pathways in a program. Consequently, it is only realistic to pick a fraction of these paths for testing. If the pathways to be tested have been clearly described and an adequate fitness function has been constructed, then TMVO might be used for this purpose. In this work, a test case is treated as a representative of a generation, with the chosen target route serving as the endpoint toward which the algorithm is directed.

This study aimed to address one of the most well-known problems in software testing by proposing an improved swarm intelligence metaheuristic method, called TMVO, to resolve the route testing problem. The TMVO method was created to address the aforementioned issues and proposed a better route for the swarm particles to follow, improving the movement strategy of a swarm of particles. To evaluate the algorithm's efficacy, a battery of benchmark functions was used, and its exploitation, exploration, global optimal solution, and best path-finding abilities were tested across these three domains. The results were compared to those of a popular metaheuristic technique, and several indicators, both visual and statistical, were used to assess the quality of the output. The proposed enhanced technique successfully solved the single-objective optimization issue in software testing.

The following goals have been set for this research; the first goal is to propose an improved MVO optimization method by averaging the best places in the search space, which is informed by the past motion of the particles. The second goal is to use the superior movement approach to increase the efficacy of swarm movement in path testing and test data collection. The third goal is to use the created metaheuristic to address the MVO premature, to converge problem and the local optima entrapment problem. The fourth goal is to compare the proposed enhanced method to existing optimization algorithms through empirical testing using standard benchmark functions and testing software.

In this work, the Testing Multi-Verse Optimizer (TMVO) is presented as an improved Multi-verse Optimizer. Instead than focusing on a single place, TMVO considers the swarm's mobility and the mean of the two best options in the universe. Using a mean-based algorithm model that has been suggested, particles will migrate toward the ideal solution. The recommended movement equations of TMVO ensure the effectiveness of space exploration and utilization. In addition to resolving the issue of poor convergence, it also escapes the local minimum.

This study makes a contribution through enhancing MVO in solving the problem of path testing by enhancing the test data generation. It also provides a comprehensive analysis of the algorithm's movement strategy, equations, pseudo-code, and parameters. When it comes to solving software testing issues, the algorithm offers a more effective path testing method for getting to best tested path. TMVO has been evaluated and validated in comparison to a number of well-established functions. In addition to this, it provides a solution for a problem involving a single optimization problem in software testing.

The remaining part of this study is organized as follows. The related works are reviewed in more detail in Section II. The methodology including different types of software testing, and the path coverage test is described in Section III. In Section IV, the experimental results and discussion are presented where Section V concludes this study.

## II. RELATED WORK

The Multi-Verse optimizer, often known as the MVO, was first suggested to be developed by Mirjalili and colleagues

[12]. They came up with an original algorithm that was inspired by nature and gave it the name Multi-Verse Optimizer (MVO). The white hole, the black hole, and the wormhole are the three natural phenomena that serve as the inspiration for this algorithm's design. The demand for these models arises from the requirement to independently carry out exploration, exploitation, and vicinity search. Biswas [13] presented an ant colony optimization (ACO)-based method that produces groups of ideal pathways and ranks them in order of preference. In addition, using these methodologies leads in the grouping of test data inside the area so that similarity may be used as input for the paths that are constructed. The proposed methods ensure comprehensive software coverage with little duplication of effort. In [14], the authors employed an approach dubbed "propagation error" to analyze the growth of defects. Through the development of test cases, we are able to activate seed faults and provoke associated potential issues. The testing procedure involves triggering and correlating these flaws. Clever algorithms are used in this method, with the aim of permanently designing test cases to disperse data about seed flaws. All faults and related defects that were before invisible are now easily discernible thanks to propagation routes.

Aspect oriented programming (AOP) is recommended by Jain et al. [15], [16] as a method for crawling into program modules without modifying their source code and component in order to investigate regions where faults are suspected to exist. AOP execution places an emphasis on making use of system cut points. In addition to this, it includes crucial code at each execution point for the purpose of testing. To improve the effectiveness of conventional random testing and random partition testing approaches, some researches suggested using Dynamic Random Testing, also known as DRT. The DRT is presented as a potential further improvement to the testing's viability. In order to decide on those upgrades for a testing profile that is more reasonable, it is necessary to have access to additional historical testing data along with an estimation of the rate at which defects are identified for each subdomain in real time, for example. This exemplifies one instance of the symbolization that the Java-based DSU system provides. In this approach, system tests that were developed for both older and newer versions of the program can be updated, and it purposefully tests whether or not an incremental upgrade can result in a failed test.

Testing software is widely regarded as an effective strategy for ensuring the quality of software in both the academic and commercial settings. The quality of the test data has an effect on the testing process and is also an essential component in determining how well software is tested. As a natural part of the software development life cycle, software testing may be carried out either automatically or manually as a matter of course. Both approaches have their advantages and disadvantages. The creation of test data is the initial step in the software testing process. In the testing process, there are a few various procedures that need to be carried out. These procedures include the development of test data, the prioritizing of test cases, and the reduction of test cases. The initialization of the test data is the method that is the most difficult aspect of testing in these methods. According to [17],

there would be a variety of sub-tasks amongst test cases, test appropriateness, and test data [18].

Test cases are the conditions that are going to be set, and the analyzer is going to use those to determine whether or not the specified function fits in suitably. The gathering of test cases will ensure that the test is suitable. Test data are a special sort of data that is used for evaluating different software applications. They can be easily recognized from other types of data. In addition, it will serve as the feed for the system's input. It is possible that this will serve as the principal test for the data or the field validations for any software applications. Creating test data for very simple programs is not a tough undertaking. On the other hand, producing the data for extensive initiatives might be challenging [19]. There is a wide variety of software available that can be used to generate test data [20], including intelligent test data generators, test data generators that use path oriented principles, and test data generators that use goal oriented. Creating test data would involve the use of several methodologies, such as UML diagrams; nevertheless, the development of test data would be dependent on graphical user interfaces. The coverage-based testing methodology, which consists of a collection of conditions that absolutely need to fulfill all of the prerequisites, could be used to generate test data [21]. A wide variety of coverage strategies, including branch coverage, function coverage, and statement coverage, are all viable options.

However, there is no assurance that the flaws in the test data will be uncovered by every converge method. The offered strategies leverage objective function for test data creation. The test data that are generated as a result of the objective function give the best possible possibility for defect detection. The space and path disparity functions are the goal functions. In order to get the space disparity, we need to first measure the distance that separates each of the test suites. Next, we need to calculate the path disparity by working backwards from the branch condition through the control flow graph [22], [23]. Because product testing must take into account both the long term and the cost-benefit analysis, extensive testing may not be carried out. Since a wide variety of methods and resources are used to automate the processes [24], it's possible that the use of such mechanizations for testing has become essential as of late. Successful testing requires the identification of code routes, the creation of a test data suit for those paths, a testing procedure on the Software Under Test (SUT) using the data, an evaluation of the results, and the production of quality models.

Successful testing would examine as many test cases as possible that are similar to those already performed. As an added cost-cutting measure, it is important to prioritize paths with the expectation that the majority of errors will be found in the preliminary phases of the process, and to identify appropriate paths and test data from among the many possible options. Path testing is a very useful technique for finding bugs in software components [25], [26].

### III. METHODOLOGY

In this section, we describe the procedures and techniques employed to carry out the study, including data analysis, and statistical methods. The research design and settings are also discussed in detail. This section provides a detailed account of

the methods used to answer the research questions and provides a clear understanding of how the research was conducted.

#### A. Types of Testing

It is of vital importance to clarify here the main types of testing since testing is used in this study to test the research hypothesis. The testing of software can be divided into two categories: static testing and dynamic testing.

In static software testing, the reviewer completes code reviews by walking through hypothetical inputs to the SUT while outwardly accompanying the real program flow. Static testing is a type of software testing. This method requires the reviewer to invest their time, and the reviewer themselves need to be an expert as well as possess the necessary skills to evaluate the code. It is possible to specify from these variables the paths that might not be executable. This is made possible by the enhancements to static testing that let the code be symbolically evaluated. This is done by gathering distinct paths and variables regarding code execution. This methodology could be used to aggregate these variables in order to provide a demand solver with the information it needs to decide which routes and paths were previously infeasible.

When performing dynamic testing, the SUT code may actually be executed using the test inputs that have been provided. The observed behaviors of the SUT are compared to its typical behaviors, and the test is either successful or unsuccessful depending on whether the observed behaviors match the technique that is relied upon to conduct the test. There are two different kinds of testing that may be done on dynamic systems: black-box testing and white box testing. The outcome of an output defect is what is understood to be a software defect [27].

In black-box testing, the system is evaluated without the tester having any prior knowledge of the system's underlying architecture. In black-box testing, the individual performing the testing does not have access to the program's source code. He or she needs knowledge regarding the modeling of the framework. In this section, the tester generally connects with the software through the user interface by providing inputs and testing outputs. However, the tester is not expected to have any prior knowledge regarding how to operate input. The accuracy of software objectives is checked for throughout the black-box testing process. These objectives can be tested using the inputs and outputs domain. This demonstrates that the program in question has both an input and an output; results from output failures are regarded to be software flaws [28].

Testing with a black-box can be used to identify problems with data structures, error functions, and interfaces. Black-box eliminates system techniques. It detects errors that are caused by faults in the software in order to find out what the problem is with the output. It is possible to use it to identify incorrect functions, which produced undesirable output at executed, inaccurate conditions. This is due to the fact that incorrect functions generate inaccurate outputs anytime they are put into action.

Testing procedures that provide information regarding the internal specification and design of the system are referred to

as white-box testing. It is not unusual for this to be referred to as structural testing. It includes testing for anything to do with program logic, including testing for loops, testing conditions, and testing based on data flow. Even if there is only an incomplete software definition, this will assist in the discovery of flaws. The goal of white box testing is to ensure that each possible path in software has been explored by the test cases.

White box testers have access to the system's source code and are therefore familiar with its architecture. The tester begins by analyzing the source code, then uses the knowledge from the source code to generate a variety of test cases, and finally, particular code routes are utilized in order to achieve a desired amount of code coverage [29]. It is guaranteed by the test cases that each of the program's independent pathways has been followed at least once. Each internal data structure would be tested to ensure the system's dependability. Each loop is run until it reaches its boundaries while staying within its operational constraints. White-box testing is a technique that can be utilized by software engineers in the process of designing test cases. This technique involves practicing distinct paths within a module, practicing legitimate true and false decisions, executing loops at their limits and inside their operational limits, and practicing inner data structures to guarantee that they are correct. It would appear that test cases need to be modified whenever implementation is altered. In this article, we have simply utilized the black-box testing approach to evaluate the functionality of two separate lines based on different test cases utilizing BVA and Robustness testing. White box testing, on the other hand, covers testing the majority of the program's code. Changing the requirements under test conditions will help identify typographical problems [30].

#### B. Path Coverage Test

The testing technique known as "coverage basic path testing" refers to testing strategies that are designed to cover the fundamental path of the software. The test target is the fundamental flow of the program when it is executed using this method. After gathering test information for the program input space, taking those test data into consideration as input, and then eventually running the program, it carries out the fundamental path by running the program and executing it. The participation of the fundamental routes group is required in order to carry out the genuine testing technique. The following is a list of features that are shared by all fundamental paths: 1) Each and every path in the program is completely autonomous; 2) Each and every edge in the program is accessible; and 3) Any paths in the program that do not have a position with the path set can potentially be achieved through the use of paths linear operation in the fundamental path set. The fault propagation path is a way that will show the advancement of defects where mistakes originate in software nodes; they may gradually propagate on different nodes. This method will be referred to as the fault propagation path. During the procedure that is used to repair errors that have already been created, past errors will be used to determine which paths have the greatest potential for error propagation. This will help correct errors that have already been made. Inaccurate historical data will be used as a source of this knowledge, and it will be used to define these routes.

The MVO algorithm uses the expansion rate as the determining factor for the value of the function for each and every search. In addition, every particle in the search zone has a similar appearance to an elected solution as well as a variable in an elected solution. Greater expansion rates result in greater and lower possibilities of the existence of those hypothesized white holes and black holes, respectively. These higher expansion rates also bring search agents or universes with higher rates to transfer items through those white gaps. White holes are recommended as a result of reduced inflation rates, which also reduce the expansion rates that should be used to transport items into black holes. As a result, the probability of black holes is increased, and white holes are offered as a result. Wormholes, disregard the flatland rates; they would be the explanation for the arbitrary sending of the object to the best universes. The MVO algorithm contains a wheel choice component that can be used for scientific demonstrations of white holes and black holes, as well as the return of objects to the search area. The search agents are arranged in each iteration according to their expansion rates, and once a search agent is chosen, it must be assigned a white hole. These various characteristics of the universes are supported by MVO. It makes use of wormholes in order to transport irregular things through the search region, and it does so by exploiting those wormholes. These wormholes randomly switch the positions of those objects in the search region, preventing them from claiming their expansion rates in any scenario. Wormhole connections have to be helped along between our reality and the finest possible universe.

### C. The proposed Multi-Verse Optimizer (TMVO)

This sub-section introduces the proposed TMVO, including the algorithm steps, pseudo-code, the strategy, TMVO's operations, and its parameters, and theoretical conclusion.

TMVO is a stochastic swarm optimization algorithm with a revolutionary exploration and exploitation movement approach for locating optimum solutions to optimization problems. TMVO is based on enhancing MVO movement strategy by taking the top three solutions in the swarm for the automatic development of test cases for structural data testing, particularly path testing. Since the original MVO algorithm lacked the ability to effectively cover both the exploration and exploitation stages of the search process, the TMVO algorithm was developed to solve this problem. In addition, TMVO addresses the premature convergence issue that arises with certain implementations of the MVO algorithm. TMVO algorithm advises focusing exploration and exploitation efforts on the following points: White holes would be a higher amount of time on make in the universes for secondary expansion rates, which they transmit items on distant universes. This is because white holes consume an inordinate quantity of matter and energy. In addition to this, assist them in improving their rates of expansion. Black holes would appear in universes with low expansion rates, and as a result, they provide a higher probability of items being accepted from other universes. This is because low expansion rates result in more compact universes. This adds another layer to the possibility of claiming an increasing inflation rate for universes that have a lower expansion rate. White and black hole tunnels have a tendency to transport from worlds the objects with rising expansion rates

to the folks with low expansion rates; in this method, the general inflation rate concerning known universes will be moved forward across the span from those repetitions. Wormholes have a propensity to appear in any universe at random, regardless of the expansion pace, or something along those lines due to the many properties of. Through all of the repetitions, the universe remains preserved. If there is a sudden shift, white/black hole tunnels need universes, which will lead to an inquiry of the search space. Unanticipated progressions are also helpful in determining the ideal local solidity. Random wormholes re-expansion of the variables from variables of the universes around the finest result gained in this way in those course about iterations, thus ensuring that exploitation is performed around those the overwhelming majority guaranteeing area of the search region. WEP Adaptive values expansion will concentrate exploitation by using an optimization procedure. This is because the occurrence of wormholes in universes is a likelihood. TDR Adaptive values reduce the journey variable distance near the best universe. This is a method that expands the precision of a local search through iterations. The joining of those indicated by the algorithm is ensured by checking the exploitation of local search comparative of the amount derived from the number of iterations.

The following are the main steps involved in TMVO:

The first step, which is named initialization, involves initially populating the algorithm's parameters with random values. Second, the suggested motion equations will be used to iteratively improve upon these initial best guess answers.

The second step: the algorithm's designated equations are utilized to progressively enhance the outcomes until a stopping criterion is met.

The third step: The algorithm's optimal solution is determined by balancing the values of the goal function and comparing the resultant comparisons.

The pseudo-code for the TMVO algorithm is displayed in Fig. 1.

1. Define the set of all universes,  $U$ .
2. Define the set of all portfolio weights,  $w$ .
3. Define the set of all groups,  $G$ .
4. Initialize the current universe,  $u$ , and the current portfolio weights,  $w$ .
5. Evaluate the performance of the current portfolio,  $P$ , in the current universe,  $u$ .
6. For each group,  $g$ , in  $G$ :
  - a. Select a subset of universes,  $U'$ , from  $U$  that belong to group  $g$ .
  - b. For each universe,  $u'$ , in  $U'$ :
    - i. Calculate the portfolio weights,  $w'$ , that maximize the expected return in universe  $u'$ .
    - ii. Evaluate the performance of the portfolio,  $P'$ , in universe  $u'$  using weights  $w'$ .
  - c. Select the universe,  $u^*$ , and the corresponding portfolio weights,  $w^*$ , that result in the highest performance in the subset of universes.
7. Select the group,  $g^*$ , and the corresponding universe,  $u^{**}$ , and portfolio weights,  $w^{**}$ , that result in the highest overall performance.
8. Update the current universe and portfolio weights to  $u^{**}$  and  $w^{**}$ , respectively.
9. Go to step 5 and repeat the process.

Fig. 1. TMVO pseudocode.

An exploration phase and an exploitation phase are separated by a population-based method, as we saw in the previous section. For MVO space exploration, it has employ white hole and black hole ideas. On the other hand, the wormholes help MVO make better use of the search spaces. We treat every possible answer as if it were its own world, with each variable representing a different type of thing that may be found in that universe. The value of the fitness function is used to determine the inflation rate that is applied to each solution. As time is a standard concept in both cosmology and multi-universe theory, we employ it throughout this study rather than iteration.

However as in MVO, the TMVO universes are optimized using the following criteria: If inflation rates are high enough, white holes are almost guaranteed to form. Black holes are less likely to form with greater inflation rates. Third, items in universes with a higher inflation rate are more likely to be sucked into white holes.

The number of items that enter the universe via black holes is larger in universes with a lower inflation rate. No matter the pace of inflation, things in all worlds may eventually make their way through wormholes to the best universe at random.

TMVO Pseudocode show that the normalized inflation rate serves as a roulette wheel for selecting and determining white holes. The likelihood of sending things through white hole or black hole tunnels increases as the inflation rate decreases. When solving the maximizing problems, -NI must be replaced with NI. Since the universes must swap things and experience sudden changes in order to traverse the search space, the exploration can be ensured using this approach.

The previously mentioned method allows for unabated object exchange across worlds. We assume that each universe is equipped with wormholes that allow its things to randomly travel through space, allowing for the preservation of cosmological variety while also allowing for the possibility of exploitation. Wormholes are capable of altering the objects of universes at random, regardless of their inflation rates. We assume that wormhole tunnels are constantly built between a universe and the best universe generated so far in order to supply local modifications for each universe and have a high likelihood of enhancing the inflation rate utilizing wormholes.

The suggested methods have varying degrees of computing complexity, which are determined by the number of iterations, the number of universes, the roulette wheel mechanism, and the universe sorting mechanism. Every iteration includes the process of sorting the universe, and we use the Quicksort algorithm, which, in the best case scenario, has a complexity of  $O(n \log n)$ , and in the worst case scenario, has a complexity of  $O(n^2)$ . The selection from the roulette wheel is carried out for each variable in each universe throughout the iterations, and its complexity ranges from  $O(n)$  to  $O(\log n)$ , depending on the implementation.

The followings are some observations that are concluded in order to gain an understanding of how the suggested algorithm could, in theory, have the ability to solve optimization problems:

- White holes are more likely to form in universes that have high inflation rates since this increases the likelihood that they will be able to transmit things to other universes and help those universes increase their inflation rates.
- Black holes are more likely to emerge in worlds with low inflation rates because these holes have a larger likelihood of receiving things from other universes since inflation rates are lower. This once more raises the possibility of increasing inflation rates for those universes that now have low inflation rates.
- The general or average inflation rate of all universes steadily improves over the course of the iteration process, as white and black hole tunnels tend to carry objects from universes with high inflation rates to those with low inflation rates.
- Because wormholes tend to form at random in any world, independent of the inflation rate, the variety of universes may be kept intact throughout the course of several iterations of the simulation.
- Wormhole and black hole tunnels need the sudden transformation of universes, which ensures the thorough investigation of the search space.
- Sudden shifts are helpful in resolving local optimalities that have stagnated.
- During the iterative process, wormholes randomly reposition some of the variables in the universes surrounding the best solution gained thus far. This facilitates exploitation all over the most promising area of the search space.
- The existence probability of wormholes in universes is gradually increased when adaptive WEP settings are used. As a result, the process of optimization places a strong emphasis on exploitation.
- To enhance the precision of local search during iterations, adaptive TDR values are used to decrease the variable's traveling distance around the best universe.
- By placing a greater emphasis on exploitation and local search in relation to the number of iterations, the suggested algorithm's convergence is ensured.

#### IV. EXPERIMENTAL RESULTS AND ANALYSIS

##### A. Evaluation of TMVO over the Benchmark Functions

To test the performance of TMVO, experiments had been run over well-known benchmark functions that represent unimodal and multi-modal functions that have been used by many researchers [31][32][33].

The cost functions of the benchmark unimodal function (F1-F7) are displayed in Table I, and those for the multimodal functions (F8-F14) are displayed in Table II. In order to get reliable statistical findings, the experiment needs to be carried out  $n$  times before any meaningful conclusions can be drawn about the performance of meta-heuristic algorithms. Each run needs to be carried out until  $m$  numbers of iterations have been

completed, and this is for the purpose of verifying if the algorithm is stable. In most cases, the statistical and output metrics, such as the average, the standard deviation, as well as the minimum and maximum values, of the best solution in the most recent iteration are measured and registered for comparison studies of the algorithms. For the purposes of acquiring, recording, and verifying the outcomes of the TMVO algorithm, the exact same process and experimental approach have been adhered to throughout. In addition to computing the error, it is important to determine how much the findings deviate from the ideal value.

TABLE I. UNIMODAL FUNCTIONS MATHEMATICAL FORMULATION (F1-F7)

No.	Formula
F1	$f1(x) = \sum_{i=1}^n x_i^2$
F2	$f2(x) = \sum_{i=1}^n  x_i  + \prod_{i=1}^n  x_i $
F3	$f3(x) = \sum_{i=1}^n \left( \sum_{j=1}^n x_j \right)^2$
F4	$f4(x) = \max i\{ x_i , 1 \leq i \leq n\}$
F5	$f5(x) = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2]$
F6	$f6(x) = \sum_{i=1}^n (x_i + 0.5)^2$
F7	$f7(x) = \sum_{i=1}^n ix_i^4 + \text{random}(0,1)$

TABLE II. MULTIMODAL BASIC FUNCTIONS (F8-F14)

No.	Formula
F8	$f8(x) = \sum_{i=1}^n -x_i \sin \sqrt{ x_i } * \sum_{i=1}^n ix_i^4 * \text{random}(0,1) *$
F9	$f9(x) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]$
F10	$f10(x) = -20 \exp \left( -0.2 \sqrt{\frac{1}{n} \sum_{i=1}^n x_i^2} \right) - \exp \left( \frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i) \right) + 20 + e$
F11	$f11(x) = \frac{1}{4000} \sum_{i=1}^n x_i^2 - \prod_{i=1}^n \cos \left( \frac{x_i}{\sqrt{i}} \right) + 1$
12	$f12(x) = \frac{\pi}{n} \left\{ 10 \sin(\pi y_1) + \sum_{i=1}^{n-1} (y_i - 1)^2 [1 + 10 \sin^2(\pi y_{i+1})] + (y_n - 1)^2 \right\} + \sum_{i=1}^n u(x_i, 10, 100, 4)$ $y_i = 1 + \frac{x_i + 1}{4} u(x_i, a, k, m) = \begin{cases} k(x_i - a)^m & x_i > a \\ 0 & -a < x_i < a \\ k(-x_i - a)^m & x_i < -a \end{cases}$
F13	$f13(x) = 0.1 \left\{ \sin^2 + \sum_{i=1}^n (x_i - 1)^2 [1 + \sin^2(3\pi x_i + 1)] + (x_n - 1)^2 [1 + \sin^2(2\pi x_n)] \right\} + \sum_{i=1}^n u(x_i, 5, 100, 4)$
F14	$f14(x) = -\sum_{i=1}^n \sin(x_i) \cdot \left( \sin \left( \frac{ix_i^2}{\pi} \right) \right)^{2m}, m=10$

The average, on the other hand, compare the overall performance of the method. All of the statistical analyses that were carried out allow us to establish beyond a reasonable doubt that the results were not the product of random chance. In each of the algorithms, the population size was set at fifty, and the maximum number of iterations was set at one thousand. It is important to keep in mind, however, that the maximum number of iterations and the number of particles (possible solutions, for example) should be determined by experimentation when dealing with situations that occur in real life.

It is necessary to conduct tests a total of n times if one wishes to achieve reliable statistical findings from meta-heuristic algorithms. In addition, for the purpose of validating the consistency of the method, each iteration must be carried out until the m<sup>th</sup> time. In order to create TMVO, report on its performance, and then validate its efficacy, the identical experimental process was carried out.

The effectiveness of the TMVO algorithm that was proposed has been assessed. It has been proved that there is a set of statistical measurements that includes the average, the standard deviation, the minimum, the maximum, and the error measurement. These measurements have been determined through the process of experimentation throughout the course of the twenty-three benchmark functions shown in the Tables (1-2).

The primary regulating parameters of these algorithms, the number of search particles and the maximum iteration, have been set to the values of 50 and 1000 respectively so that a fair comparison can be made between them. To achieve the highest possible level of performance, the settings for the various governing parameters of each algorithm are taken from the most recent version of the source code. Each of the algorithms is executed fifty times on each of the test functions, and the outcomes of these simulations are presented later in this study. It is important to note that the results of the algorithms are standardized in the range [0, 1] by employing the min-max normalization so that their performances may be compared across a variety of test functions.

We have evaluated the performance of TMVO on a set of well-known benchmark functions utilized by many researchers to measure the performance of optimization algorithms.

The benchmark sets for multimodal hybrid functions are categorized from function 15 to function 23 and the mathematical formulations for hybrid composition functions are shown in Table III.

The Lower Bound (LB), Upper Bound (UB), dimension (Dim), and F<sub>min</sub> of the benchmark-evaluated functions are displayed in Table IV.

TABLE III. MULTIMODAL HYBRID FUNCTIONS (F8-F14)

Multimodal Functions Formula (F15- F23)
$f15(x) = \sum_{i=1}^{11} \left[ a_i - \frac{x_1(b_i^2 + b_i x_2)}{b_i^2 + b_i x_3 x_4} \right]$

$f16(x) = 4x_1^2 - 2.1x_1^4 + \frac{1}{3}x_1^6 + x_1x_2 - 4x_2^2 + 4x_2^4$
$f17(X) = \left(x_2 - \frac{5.1}{4\pi^2}x_1^2 + \frac{5}{\pi}x_1 - 6\right)^2 + 10\left(1 - \frac{1}{8\pi}\right)\cos X_1 + 10$
$f18(x) = [1 + (x_1 + x_2 + 1)^2(19 - 14x_1 + 3x_1^2 - 14x_2 + 6x_1x_2 + 3x_2^2)]x[30 + (2x_1 - 3x_2)^2x(18 - 32x_1 + 12x_1^2 + 48x_2 - 36x_1x_2 + 27x_2^2)]$
$f19(x) = -\sum_{i=1}^4 C_i \exp\left(-\sum_{j=1}^3 a_{ij}(x_j - p_{ij})^2\right)$
$f20(x) = -\sum_{i=1}^4 C_i \exp\left(-\sum_{j=1}^6 a_{ij}(x_j - p_{ij})^2\right)$
$f21(x) = -\sum_{i=1}^5 [(X - a_i)(X - a_i)^T + C_i]^{-1}$
$f22(x) = -\sum_{i=1}^7 [(X - a_i)(X - a_i)^T + C_i]^{-1}$
$f23(x) = -\sum_{i=1}^{10} [(X - a_i)(X - a_i)^T + C_i]^{-1}$

The comparison between the proposed TMVO algorithm and the MVO algorithm in terms of mean fitness value is tabulated in Table V. Comparing TMVO algorithm with MVO over the tested functions F1-F23 showed that TMVO has very competitive results. In the unimodal functions (F1-F7) the TMVO has shown better results and outperformed MVO over all the seven functions. Regarding the multi-modal functions (F8-F12), TMVO was also achieved better mean fitness values than MVO except F8. Moreover, the proposed algorithm is competitive over the expanded multi-modal functions (F13, F14). The results have shown that when testing the algorithm TMVO over the multi-modal hybrid functions (F15-F23), the TMVO outperformed MVO in most cases and achieved the same fitness value in three cases.

The proposed TMVO achieved better fitness values in most cases due to the fact that TMVO offers additional exploration points inside the search space. TMVO takes the two best possible solutions and utilizes them to find a new solution at each iteration. It drives closer and closer to the global optimum by updating the current particle location to the position that is optimal between these two points.

*B. Evaluation of TMVO in Test Data Generation for Path Testing*

The experimental results testing is carried out on five benchmark programs, which are presented in Table VI. The fitness value is a numerical number that represents individual

quality in comparison with the existing local solution in order to seek for the optimum local solution that has the least amount of fitness value possible. The option that results in the lowest overall fitness value will be the one that we consider to be the most viable solution. The fitness value is computed by applying Korel's route distance relation to each variable. The fitness path distance is calculated by adding up each variable's fitness value at each point along the path. To start, a series of random test instances are generated so that the process can begin. Utilizing points that were picked at random allows for the improvement of the existing solution. Perform a calculation to determine the fitness value of each potential solution. Each swarm is assigned a fitness value, and then each swarm searches for the local minimum value within the search zone to see whether a higher value can be found. If we can, the new value is saved, and the old value is replaced with it. Arrange candidate solutions in order of increasing fitness, beginning with the best. The onlooker phase begins with the most optimal solution to fitness. If the termination requirements are deemed to be complete, an onlooker local search will be issued; otherwise, it will be used to improve candidate solution fitness. In case that the phase is completed without satisfying the finishing conditions, the phase to replace sources that have reached the maximum number of tries will be initiated.

We utilized the five variables in Program1, which are (x, y, z, j, k). First, if  $j - 80 \geq 0$ , the distance at variable j will be zero; if variable  $k - 70 \geq 0$ , the distance at variable k will be zero; if variable  $x - 60 \geq 0$ , the distance at variable y - 50 = 0; this is the Korel branch distance relation. Specific details and results including the fitness value are tabulated in Table VII. It is of vital importance to correctly interpret the values in Table VII. The letters A, B, C, D, and E represent the Korel's route branch distance of the variables j, k, c, y, and z respectively.

The following equation is utilized to determine the fitness value that is used for the path of Program1. This value, which is the sum of the distances that were indicated before, is computed as follows:

$$F = (J - 80) + (K - 70) + (X - 60) + (Y - 50) + (Z - 25) \quad (1)$$

In Program2, we utilized the five variables (x, y, z, j, k). If the first variable (j) has a distance of zero, then the second variable (k) also has a distance of zero. (if (k) - 65 >= 0), the third variable (x) has a distance of zero. if (x) - 55 >= 0, the fourth variable (y) has a distance of zero if (y) - 45 = 0, and the fifth variable (z) has a distance of zero if (z) - 35. The Korel's route branch distances of the variables in Program2 and the fitness values are displayed in Table VIII.

Eq. (2) has been used to get the fitness value that should be utilized for the path of program 2, which is 54. This value represents the sum of the distances that were indicated earlier.

$$F = (J - 75) + (K - 65) + (X - 55) + (Y - 45) + (Z - 35) \quad (2)$$

TABLE VIII. KOREL'S ROUTE BRANCH DISTANCES OF THE VARIABLES J, K, X, Y, AND Z ALONG WITH THE FITNESS VALUES (PROGRAM 2)

In Program3, the five variables (x,y,z,j,k) are also employed to evaluate the proposed algorithm. The Korel branch distance relation states that if the value of the first variable, j, is greater than or equal to 60, then the value of the second variable, k, is greater than or equal to 80. If the value of the third variable, x, is greater than or equal to 45, the value of the fourth variable, y, is less than or equal to 75, and the value of the fifth variable, z, is 45. Table IX tabulates the outcomes when applying the TMVO over Program3. The symbols (A, B, C, D, E) represent Korel's Route Branch Distances of the variables (j, k, x, y, z) respectively.

25	88	84	97	31	16	63	110

In Program4, we employed three variables (x, y, z). If  $j - 60 \geq 0$ ,  $k - 80 \geq 0$ , and  $x - 45 \geq 0$ , then the distance between the first and third variables is zero, as predicted by the Korel branch distance relation. Refer to Table X. The symbols (C, D, E) represent Korel's Route Branch Distances of the variables (x, y, z) respectively.

Using Equation 4, we can determine that the fitness value for path of program4 is 33, which is the total of the distances we determined before.

$$F = (J - 57) + (K - 68) + (X - 34) \quad (4)$$

Four variables were employed which are j, k, x, and y in Program5. In the Korel branch distance relation, if the value of the first variable, j, is zero, then the value of the second, k, is also zero, and so on. If the value of the third variable, x, is also zero, then the value of the fourth one, y, is also zero. Table XI tabulates 25 different cases along with their fitness values.

Path 5 of Program5 uses a fitness value of 39, which is the total of the distances discussed before. The fitness value is calculated according to Equation5.

$$F = (J - 45) + (K - 30) + (X - 40) + (Y - 35) \quad (5)$$

## V. CONCLUSION

In this study, Testing Multi-Verse Optimizer (TMVO), an improved Multi-Verse Optimizer, is presented. However, rather than focusing on a single place, TMVO considers the swarm's mobility and the mean of the two best solutions in the universe. Using a recently suggested mean-based algorithm model, particles will progress toward the ideal solution. TMVO's recommended movement equations ensure efficient space exploration and utilization. In addition, it eliminates the problem of low convergence and escapes the local minimum. TMVO has been applied for the generation of test data for software structural testing, specifically route testing, that takes use of the Multi-Verse optimization algorithm. The proposed algorithm has been exhaustively tested through the creation of test data for the path coverage criteria and its subsequent application to a set of test programs. Additionally, five distinct programs and codes have been utilized in order to complete this evaluation. The results showed that the algorithm was successful in finding the best tested path for the test data, which led to an improvement in performance. The performance of TMVO is tested over several well-known functions. The results have shown that TMVO outperform original MVO algorithm over most of the tested functions.

However, this study presented two contributions. Firstly, an improved version of the Multi-verse Optimizer called Testing Multi-Verse Optimizer (TMVO) was proposed, which considered the movement of the swarm and the mean of the two best solutions in the universe. The particles moved towards the optimal solution by using a mean-based algorithm model, which guaranteed efficient exploration and exploitation. Secondly, TMVO was applied to develop test cases for structural data testing, specifically path testing, in an automated manner. Instead of automating the entire testing process, the focus was on centralizing automated procedures for collecting testing data. Automation for generating testing data was becoming increasingly popular due to the high cost of manual data generation. To evaluate the effectiveness of TMVO, it was tested on various well-known functions as well as five programs that presented unique challenges in testing. The test results indicated that TMVO outperformed the original MVO algorithm on the majority of the tested functions.

Despite the success of TMVO, there are still several areas where the algorithm can be further developed and tested. This includes algorithmic parameter tuning where most optimization algorithms have several tuning parameters that need to be set for optimal performance. Future research can explore automated parameter tuning techniques such as machine learning algorithms to improve the performance of TMVO. In addition to that, testing TMVO on large-scale problems where researchers can focus on testing TMVO on large-scale optimization problems and analyzing its scalability and efficiency.

**Abstract**—Non-insulin-reliant, one of the most serious illnesses is diabetes mellitus, often known as type 2 diabetes, and it affects a large number of people. Between 2 and 5 million individuals worldwide die from diabetes each year. If diabetes is identified sooner, it can be managed, and catastrophic dangers including nephropathy, heart stroke, and other conditions linked to it can be avoided. Therefore, early diabetes diagnosis aids in preserving excellent health. Machine learning (ML), which has recently made strides, is now being used in a number of medical health-related fields. The innovative, nature-inspired Firefly algorithm has been shown to be effective at solving a range of numerical optimization issues. While using alliterations, the traditional firefly method employed a fixed step size models for semi-supervised learning (SSL). The firefly is effective for solving classification issues involving both a sizable number of unlabelled data and a limited number of samples with labels. The fuzzy min-max (FMM) family of neural networks in this regard provide the capability of online learning for tackling both supervised and unsupervised situations. Using a special mix of the two proposed algorithms, one of which is utilised for optimization and the other for making early predictions of type 2 diabetes. The findings for the training and testing phases for the parameter's accuracy, precision, sensitivity, specificity, and F-score are reported as 97.96%, 97.82%, 98.10%, 97.82%, and 97.95% which, when compared to current state-of-the-art methods, are finer.

**Keywords**—Fire Fly Algorithm (FFA); machine learning (ML); Semi-supervised Min-Max (SSMM)

## I. INTRODUCTION

Diabetes mellitus (DM) is the collective metabolic disorder in which people have high blood sugar levels, either because their pancreas is incapable of producing enough insulin or because their cells are unable to react to the insulin that is generated. This leads to a number of medical conditions such as polydipsia, polyuria, and polyphagia. DM is still a problem for public health everywhere in the world. This is increasingly the leading cause of death in affluent nations and is now ranked fourth or fifth among non-communicable diseases globally. In the entire world, 300 million people are predicted to have diabetes or be at risk for developing it by 2025. In the past few years, developing nations like India have had the highest growth in DM. There were 425 million diabetics worldwide as of 2017 [1], and research by the International Diabetes Federation in 2017 [2] predicted that number will rise to 625

million by 2045. Diabetes mellitus is a collection of endocrine disorders characterized by decreased glucose absorption and brought on by absolute or relative insulin deficiency. In addition to a chronic history, the disease is characterized by a disruption of all forms of metabolism. When our body's blood sugar, also known as blood glucose, is too high, we have diabetes mellitus (DM). People can develop diabetes at any age, and there are three main types: type 1, type 2, and gestational diabetes. Many hormonal and other changes that take place in the body during pregnancy are thought to be the cause of gestational diabetes, whereas other women see an increase in insulin resistance.

Type II diabetes is a chronic metabolic disorder that affects millions of people worldwide. It occurs when the body either does not produce enough insulin or is unable to use the insulin it produces effectively, resulting in high levels of glucose in the blood. Early detection of type II diabetes is crucial for effective management and prevention of complications. Predictive modeling techniques have shown great promise in identifying individuals who are at a high risk of developing type II diabetes before clinical symptoms appear. By leveraging machine learning algorithms and advanced analytics, healthcare professionals can identify individuals who are at risk of developing type II diabetes and implement preventative measures to reduce the likelihood of disease progression. This can ultimately lead to improved health outcomes and a reduction in healthcare costs associated with managing type II diabetes.

The entire paper is divided into five sections where Section I consists of introduction. Section II deals with related works, Section III deals with experimental results, Section IV deals with results of the work, and Section V deals with conclusion of the work.

## II. RELATED WORKS

Mohebbi et al. demonstrated that it was possible to use CGM signals to detect T2D patients in [3], where they offered a unique deep learning approach for the identification of type 2 diabetes. To solve the difficulties of implementing DL approaches. The authors of [4] concentrated their talks on generalised approaches, reinforcement learning, natural

language processing, deep learning in computer vision, and healthcare today (Table I).

TABLE I. VIEWS OF VARIOUS AUTHORS

Author	Contribution	Methodology	Advantages	Limitations
DPML [5]	Prediction of Type 2 diabetics	SVM, XGBoost, RF, LR	Early prediction	Works for only specific datasets not for all existing datasets
FFCSA [6]	Classification of diabetics	KNN Classifier	Notable accuracy of considered parameters	Works for static datasets not for existing
ADNNC [7]	random test and trail	DNN	High accuracy	Computation time
EDDN [8]	Prediction and classification	DNN	High accuracy	Works for limited size of data

**EFA: Firefly algorithm**

```

Begin
  Objective function  $f(x), x = (x_1, x_2, \dots, \dots, x_d)^T$ 
  Light intensity  $f_p = f(x_p)$  i.e.,  $I(r) = I_0 e^{-\gamma r^2}$ 
  Light absorption coefficient  $\gamma$ 
  While ( $t < \text{Max generation}$ ) do
    For  $s x_p \in P$  do
      For each  $x_q \in q$  do
        If  $(x_p) < f(x_q)$ , firefly  $p$  towards  $q$ 
        Vary  $\beta$  with distance  $r$  via  $\exp(-\gamma r_{pq}) \|X_p - X_q\| = \sqrt{\sum_{k=1}^d (x_{p,k} - x_{q,k})^2}$ 
         $X_{p,t+1} = X_{p,t} + \beta_0 \cdot e^{-\gamma r_{pq}^2} \cdot (X_{q,t} - X_{p,t})$ 
         $X_p = X_p + \beta_0 \cdot e^{-\gamma r_{pq}^2} \cdot (X_q - X_p) + \alpha (rand - \frac{1}{2})$ 
        Evaluate the solution and update the light intensity
      end
    end
  Fireflies are ranked and current global best  $x_p^{max}$ 
end
end
  
```

In population-based optimization techniques, efficient global exploration and local exploitation control is essential for locating the ideal solution. Therefore, during the initial stages of optimization, it is preferable to encourage individuals to roam around the whole search space rather than grouping around local optima. In order to quickly locate the best solution, it is crucial to increase convergence toward the global optima during the last stages.

**EFA: Firefly algorithm**

**Input :** UCI diabetic dataset

**Output :** Type 2 diabetic classification

**For each considered sample do**

Hyperbox membership is computed

$$b_j(A_h, V_q, W_q) = \frac{1}{2d} \sum_{p=1}^d [\max(0, 1 - \max(0, \gamma \min(1, a_{hp} - w_{qp}))) + \max(0, 1 - \max(\gamma \min(1, V_{pq} - a_{hp}), 0))]$$

For the criteria to be satisfied

$$\sum_{p=1}^d (\max(w_{q^*p}, a_{hp}) - \min(V_{q^*p}, a_{hp})) \leq d\theta$$

All hyperboxes belonging to other classes are represented as

If  $v_{q^*p} < v_{qp} \leq w_{q^*p} < w_{qp}$ , then  $\delta^{new} = \min(\min(w_{rp} - v_{q^*p}, w_{q^*p} - v_{q^*p}), \delta^{old})$

else

if

$v_{qp} < v_{q^*p} < w_{q^*p} < w_{qp}$ , then  $\delta^{new} = \min(w_{q^*p} - V_{qp}, \delta^{old})$

else

if

$v_{q^*p} < v_{kp} \leq w_{q^*p} < w_{kp}$ , then  $\delta^{new} = \min(\min(w_{q^*p} - v_{rp}, w_{kp} - v_{q^*p}), \delta)$

Overlap exists then contraction begins

If  $V_{q^*p} < V_{rp}$  then,  $v_{q^*p} < V_{rp} < w_{q^*p}$ ,  $\delta^{new}$

If  $V_{qp} < V_{q^*p} < W_{q^*p} < W_{rp}$  then  $w_{q^*p}^{new} = v_{rp}^{new} = \frac{v_{rp}^{old} + w_{q^*p}^{old}}{2}$

else

If  $v_{qp} < v_{q^*p} < w_{q^*p} < w_{qp}$ , then  $\delta^{new} = \min(w_{q^*p} - V_{qp}, \delta^{old})$

else

If  $v_{q^*p} < v_{kp} \leq w_{q^*p} < w_{kp}$ , then  $\delta^{new} =$

$\min(\min(w_{q^*p} - v_{rp}, w_{kp} - v_{q^*p}), \delta^{old})$

else

If  $V_{rp} < V_{q^*p} < W_{rp} < W_{q^*p}$  then,  $w_{rp}^{new} = v_{rp}^{new} = \frac{w_{rp}^{old} + v_{q^*p}^{old}}{2}$

Current sample encoding using new hyperbox,  $V_{q+1} =$

$W_{q+1} = A_h$

End

The algorithm provided appears to be a variant of the Fuzzy ARTMAP algorithm, which is a type of artificial neural network that uses fuzzy logic to perform pattern recognition and classification. The algorithm takes as input the UCI diabetic dataset and aims to perform classification to predict whether an individual is likely to have type II diabetes. For each sample, the algorithm computes hyper box membership using a formula that takes into account the attributes of the sample and the weights associated with the hyper boxes. The

hyper boxes represent regions in the input space that are assigned to a particular class (in this case, type II diabetes or not). The criteria for a hyper box to be considered a member of a class is that it must satisfy a certain threshold (represented by the value  $\Theta$  in the algorithm). If a hyper box overlaps with a hyper box belonging to a different class, the algorithm performs a contraction step to adjust the boundaries of the hyper boxes to reduce overlap. If the hyper box is not a member of any class, the algorithm creates a new hyper box to represent the current sample. This new hyper box is initialized with the attributes of the current sample, and the classification decision is based on whether the new hyper box satisfies the classification criteria. Overall, the algorithm is a type of supervised machine learning algorithm that uses fuzzy logic and neural networks to perform classification of the input data. It is designed to be able to adapt to new input data and adjust the hyper boxes accordingly.

Over the past ten years, machine learning and data categorization have paid a lot of attention to semi-supervised learning (SSL). Finding the target class (i.e., label) to which a data sample belongs is referred to as data classification. To do this, a collection of labelled data samples are used for model training, and the input samples are then mapped to the associated classes using the underlying learning technique. The new, unseen test samples are then categorized into the appropriate classes using the trained model. A hyper box membership function is defined as

$$f(x, \gamma) = \begin{cases} 1, & \text{if } x\gamma > 1 \\ x\gamma & \text{if } 0 \leq x\gamma \leq 1 \\ 0 & \text{if } x\gamma < 0 \end{cases}$$

Each supervised and unsupervised FMM network has a different topology made up of a variety of hyper boxes that were built up gradually (see Fig. 1). Each hyper box creates a feature boundary in a d-dimensional unit cube and is represented by a set of minimum and maximum vertices ( $I^d$ ). The value of  $[0, 1]$  determines the hyper box size; a tiny result in several hyper boxes, each of which has a small size, and vice versa.

Early prediction of Type 2 Diabetes is a growing area of research and many studies have been conducted to explore this topic. One unique approach for early prediction of Type 2 Diabetes is the use of artificial intelligence and machine learning algorithms. For example, a recent study by Wang et al. [9] (2021) used machine learning algorithms to predict the risk of Type 2 Diabetes in a Chinese population based on demographic and lifestyle factors. Another study by Noh et al. (2021) [10] used artificial intelligence to predict the risk of Type 2 Diabetes based on clinical data from electronic health records.

In addition, several studies have explored the use of biomarkers for early prediction of Type 2 Diabetes. For instance, a study by Senn et al. (2020) [11] investigated the use of a blood-based biomarker called plasma branched-chain amino acids ( BCAAs) to predict the risk of Type 2 Diabetes in a cohort of Finnish individuals. Similarly, another study by Li et al. (2020) [12] explored the use of urinary metabolites as a biomarker for early prediction of Type 2 Diabetes in a Chinese

population. Furthermore, there has been research into the use of genetic information for early prediction of Type 2 Diabetes. A study by Wang et al. (2020) [13] investigated the use of genetic risk scores to predict the risk of Type 2 Diabetes in a Korean population. Another study by Bancks et al. (2021) [14] used a genetic risk score and lifestyle factors to predict the risk of Type 2 Diabetes in a diverse population in the United States. Overall, these studies demonstrate the potential of various approaches for early prediction of Type 2 Diabetes, including the use of artificial intelligence and machine learning algorithms, biomarkers, and genetic information.

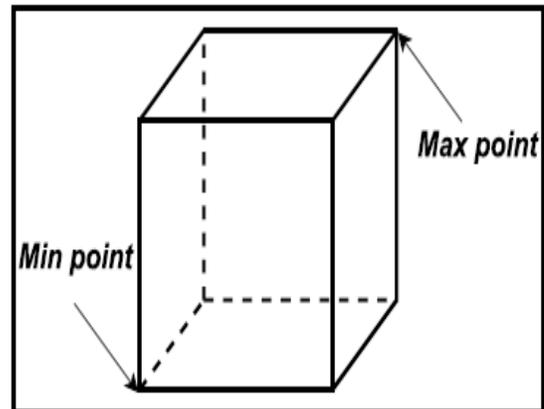

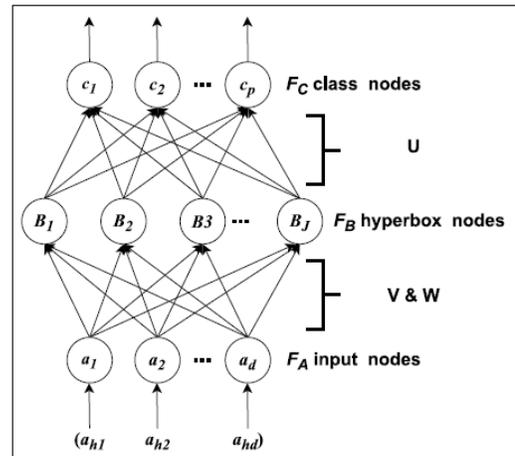

Fig. 1. (a), (b) Supervised FMM network and a 3D hyperbox.

### III. EXPERIMENTAL SET UP

Utilizing the Visual Studio IDE, a specific User Interface (UI) is created in order to connect to the server and obtain performance metrics for both existing and suggested methods. The proposed system is implemented in Visual C++ and the existing methods are implemented in Common Language Runtime (CLR) libraries. The UI is operated on a machine that connects to the server using an 8 GB RAM and an Intel Core i5-7200 processor operating at 2.7 GHz. Through the I2K2 cloud server intermediary infrastructure, Amazon Server is rented. The server has 100GB of High IOPS Solid State Hard Drive (SSD), 2GB of RAM, 2 Virtual CPU Computational Cores, and a 99.99% uptime guarantee. For Single Admin Windows Operating System and Single User Remote Desktop Server (RSD) Client Access License (CAL) included, the

software licenses are provided by the I2K2 service. Dataset [15] is considered to carry out the results (see Fig. 2).

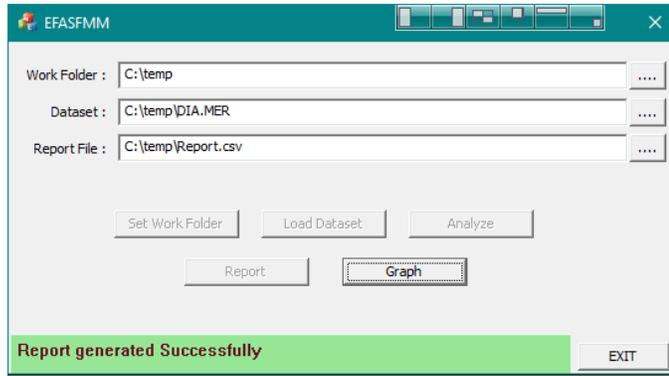

Fig. 2. UI for running the proposed approach.

#### IV. RESULTS

The model is trained and tested with the dataset with a ratio of 60-40. The results are considered in terms of accuracy, precision, specificity, sensitivity and F-Score.

##### A. Accuracy

70	89.08	79.8	96.48	96.63	98.09

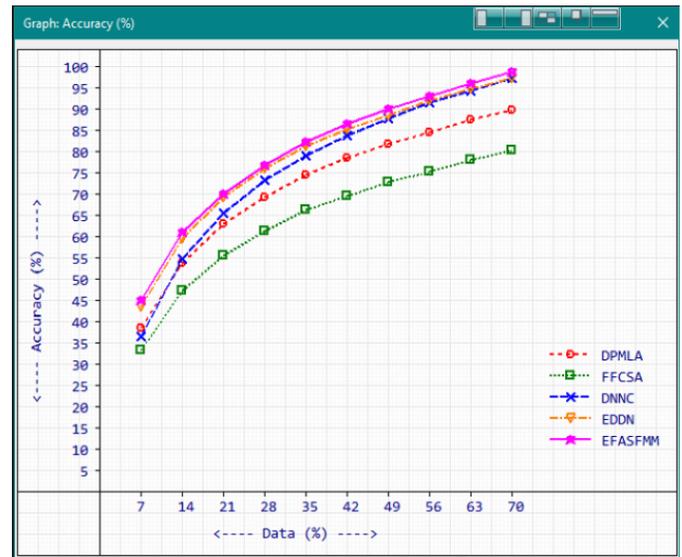

Fig. 4. Graphs of accuracy obtained during testing.

Accuracy values are referred in the Table II for training and Table III for testing. During training the average values of accuracy for the existing and proposed approaches such as DPMLA, FFCSA, DNNC, EDDN and EFASFMM observed are 72.20%, 64.06%, 76.45%, 78.87% and 80.04%. During testing the average values of accuracy for the existing and proposed approaches are given as 89.21%, 79.66%, 96.60%, 96.63% and 97.96%. Accuracy graphs are shown in Fig. 3 and Fig. 4 during training and testing.

##### B. Precision

Precision values are referred in the Table IV for training and Table V for testing. The corresponding graphs for precision during training and testing are shown in Fig. 5 and 6, correspondingly.

During training the average values of Precision for the existing and proposed approaches such as DPMLA, FFCSA, DNNC, EDDN and EFASFMM observed are 73.73%, 63.75%, 75.59%, 79.03% and 79.72%. During testing the average values of precision for the existing and proposed approaches are given as 90.68%, 79.63%, 95.45%, 96.74% and 97.82%.

TABLE IV. PRECISION OBTAINED DURING TRAINING

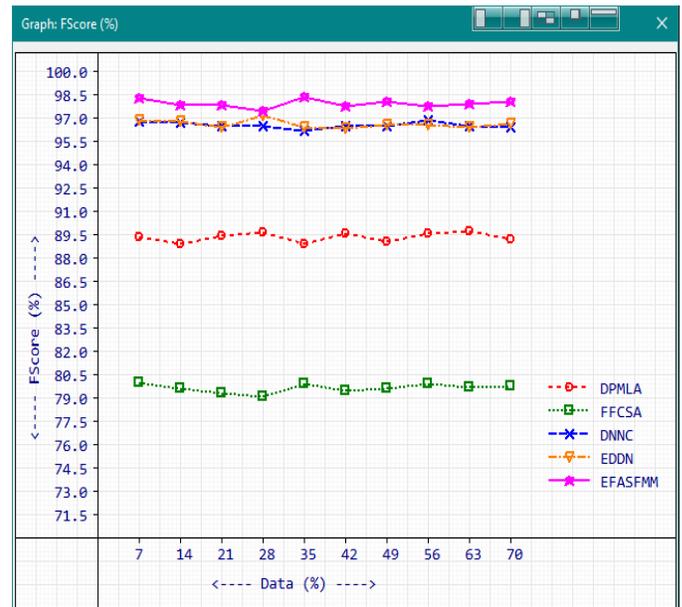

Fig. 12. F-score graph obtained during testing.

During training the average values of specificity for the existing and proposed approaches such as DPMLA, FFCSA, DNNC, EDDN and EFASFMM observed are 72.61%, 63.91%, 76.29%, 78.92% and 79.96%. During testing the average values of specificity for the existing and proposed approaches are given as 89.36%, 79.65%, 96.56%, 96.63% and 97.95%.

V. CONCLUSION

Finding the best diabetes treatment primarily depends on early illness detection. One of the most common diseases in the world is diabetes. Whatever the sort of sickness, it is a frequent problem for doctors, medical professionals, and scientists to forecast the disease in its early stages. The main cause of this is a lack of awareness in developing and underdeveloped nations. A person's life can be saved by ignoring paradoxical events, diagnosing the sickness early, and taking the right medication. The upgraded firefly technique and the semi-supervised min-max approach algorithm are combined in an original way in the current paper. Where the min-max strategy is employed for the early diagnosis of type 2 diabetes and the firefly algorithm is used for optimization. The proposed approach is unique in that

it achieves the best results in terms of the metrics taken into account, including accuracy, precision, sensitivity, specificity, and F-Score. The type 2 diabetes dataset is used in the sense of a 60-40%. The results for the factors that were taken into consideration during training and testing are presented as follows: 80.00%, 79.72%, 80.20%, 79.88%, 79.96%, and 97.96%, 97.82%, 98.10%, 97.82%, 97.95%. The suggested method is beneficial for both training and testing purposes, as well as for the early diagnosis of type 2 diabetics while taking into account minimal computational time and highly accurate findings. The primary problem facing researchers in the current situation is identifying the causes of retinopathy in type 2 diabetes.

# Development of a Mobile Application to Reduce the Rate of People with Text Neck Syndrome

Rosa Perez-Siguas, Hernan Matta-Solis, Eduardo Matta-Solis, Hernan Matta-Perez, Luis Perez-Siguas, Randall Seminario Unzueta, Victoria Tacas-Yarcuri

TIC Research Center: eHealth & eEducation, Instituto Peruano de Salud Familiar, Lima-Peru

**Abstract**—Now-a-days, it is no surprise that mobile devices have become a very useful tool in the daily tasks of many people worldwide. This is thanks to their various features such as portability, connectivity, entertainment, work tool, etc. However, due to the bad posture that users have when using them, a syndrome called "Text Neck" is produced. This is caused by prolonged use of the devices looking down and tilting the head at different angles. The degree of inclination of the head causes a detrimental effect on the neck joints, so that the greater the degree of inclination the effect of the weight of the head on the neck increases detrimentally. However, currently mobile devices have sensors that help in monitoring the activities of users, in this sense, there is the gyroscope that allows the completion of the position and the accelerometer that tells us the amount of movement of the device. In this sense, a mobile application has been developed that by monitoring the information of the angle of inclination of the device and the time it remains in the same, allows notifying users to adopt a proper position. The aim is to reduce the number of people affected by text neck syndrome.

**Keywords**—Accelerometer; android; firebase; gyroscope; mobile devices; sensors; text neck

## I. INTRODUCTION

Today, we find that mobile devices such as cell phones, tablets or e-books have become essential attachments in the daily lives of millions of people worldwide [1]–[6]. According to statistical data collected in 2021, the number of mobile device users will exceed 3.8 million, representing 48.53% of the world's population [1]. This popularity in the massive use of mobile devices is due to the various activities that can be performed with them, in this sense, users can exchange information, access the Internet, play in mobile applications, and other types of activities [5], [7], [8] They also allow for fluid communication between users through the use of text messages and social networks [1]–[3], [8]

However, beyond the popularity that mobile devices have achieved, due to prolonged use and poor posture of users, health-related problems have been identified [1]–[10]. The problem is now known as "Text Neck" syndrome, a term coined by American chiropractor Dr. Dean L. Fishman [1], [3], [6]–[8]. However, this syndrome is produced due to the downward inclination of the users' neck and the excessive forward bending when using mobile devices [1], [3]–[7], [10]. In this sense, the greater the angle of inclination, the greater the

weight that falls on the neck joints, being 12 kg at an angle of 15 degrees, 18 kg at an angle of 30 degrees, 22 kg at an angle of 45 degrees, and 27 kg at an angle of 60 degrees [1], [2], [5], [6], [9], [10]. As a result, the user may experience many ailments ranging from neck pain, neck stiffness, reduced mobility, headaches, postural disturbances, rounded shoulders [1], [6], [7], [10].

On the other hand, nowadays cellular devices have a wide range of sensors that allow the detection and monitoring of many activities [11]–[13]. In this sense, the accelerometer and the gyroscope can be found as complementary sensors in the measurement of certain activities [11], [14]–[17]. Therefore, due to the precision that cell phones possess [13], [18], activities such as swaying in the elderly can be monitored [19], establish the frequency of the footprint [14], detection of abnormal behaviors [11], determine the degree of sedentary lifestyle of the users [17] and video stabilization through the use of the gyroscope [20]. Now, these sensors can be used to detect the time that a person has been using the cell phone and the position in which it is used. This information can be provided by the accelerometer and gyroscope, then through an application developed in Android can be analyzed for the purposes of the case [11], [12], [14], [15], [19], [20].

Therefore, taking into account the information that can be obtained through the sensors of mobile devices, we developed a mobile application that allows the monitoring of the position in which it is used by users through the gyroscope; the time the user uses the device in a specific position taking into account the viewing angles. The purpose of our research is the development of a mobile application to notify users of the excessive use of mobile devices and the position in which it is used, with the aim of reducing the rate of people suffering from text neck syndrome.

Next, the activities carried out within the present research project are detailed, in this sense, in Section II we specify the methodology that has been used to obtain the main objective of our project, in Section III we show the results obtained after implementing our application, in Section IV we made a comparison of the contributions obtained with those of other authors, and finally in Section V we show the conclusions that we have reached after having carried out the present research project.

## II. METHODOLOGY

### A. Determination of Angle of Inclination

Text neck syndrome is characterized by the angle of inclination generated in the user's neck when tilting the head forward to view mobile devices [1], [5], [7], [9], [10], [21]. Thus, as shown in Table I, as the degree of inclination of the user's neck increases, there is a direct effect on the weight exerted on the spine [1].

TABLE I. HEAD WEIGHT ACCORDING TO THE ANGLE OF INCLINATION

Angle of inclination of the neck	Force exerted on the neck
0°	4,54 – 5,44 kg
15°	12,25 kg
30°	18,14 kg
45°	22,23 kg
60°	27,22 kg

Likewise, Fig. 1 shows graphically the angle of inclination of the neck forward and the weight effect equivalent to each one for the reader's better understanding.

Taking into account that the sensors are located inside the mobile devices, the detection of the information of the users' neck inclination angles must be related to the inclination angles of the devices where our device is running. Consequently, the calculation of the tilt angles taken by the mobile devices in relation to the users' neck tilt angles was performed.

In that sense, the users' neck inclination angles vary in an incremental range of 15°. Likewise, the initial angle is 0° and the maximum angle of inclination is 60°, where it is possible to identify the inclusion of four increments to get from the minimum to the maximum angle of inclination.

Tilt interval range = 15°

Now, before continuing with the calculations, it was taken into account that users seek the best position of the mobile device for viewing the various desired contents. Therefore, after performing an analysis of the way in which mobile devices are held by users, a correlation was found between the angle of inclination and the angle at which the mobile device is held.

In effect, the mobile devices when held cover different angles of a quadrant. Taking into account the aforementioned, the calculation of the range of degree intervals that the devices have in the different positions was carried out, resulting in 22.5°.

Cell interval range = 22.5

The angles of inclination that the mobile device can take can be seen more clearly in Fig. 2, taking 90° as the starting point, which are traveled in intervals of 22.5° until reaching 180°. On the other hand, Table II shows the equivalence of each of the degree intervals in both the inclination of the user's neck and the angle at which the mobile device is held.

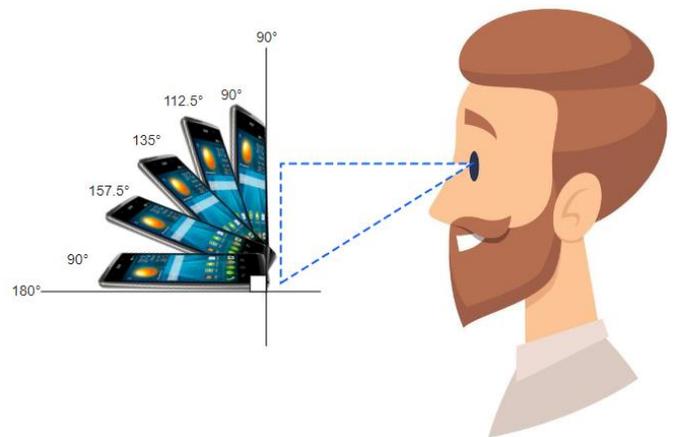

Fig. 1. Tilt angles of the mobile devices

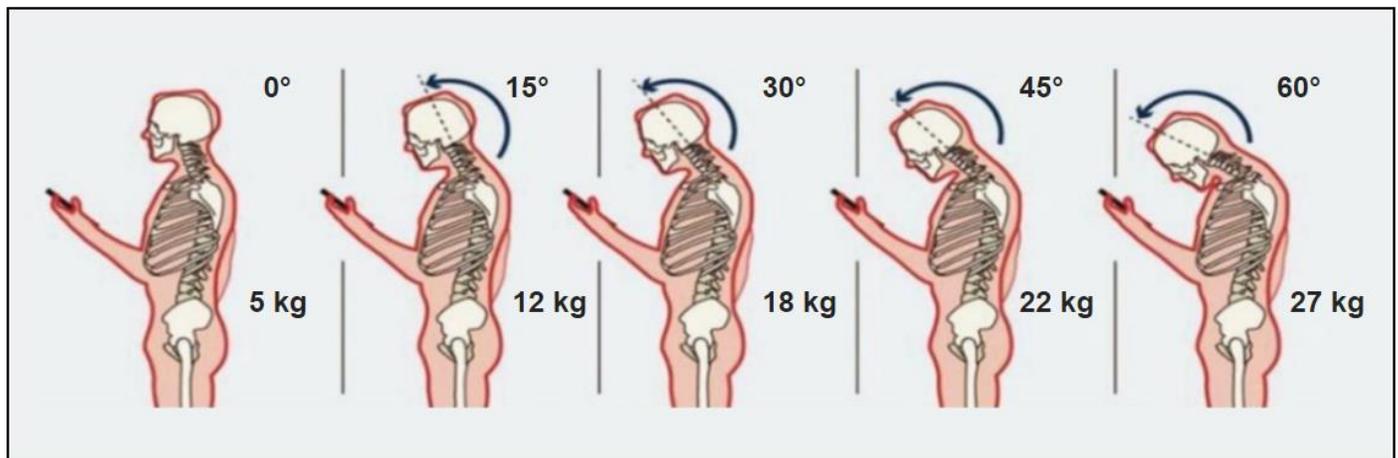

Fig. 2. Angle of inclination of the neck and the equivalent weight effect on the spine

TABLE II. EQUIVALENCE OF USER ANGLES AND MOBILE DEVICES

Angle of inclination of the neck	Tilt angle of the mobile device
$0^\circ < 15^\circ$	4,54 – 5,44 kg
$15^\circ < 30^\circ$	12,25 kg
$30^\circ < 45^\circ$	18,14 kg
$45^\circ < 60^\circ$	22,23 kg
$60^\circ$	27,22 kg

**B. Flowchart**

In this section, as can be seen in Fig. 3, the actions that are evaluated within the application are detailed, as well as the path that must be followed for the evaluated actions. This diagram gives a clearer idea of the actions that must be programmed within our application, as well as determining the evaluation criteria at the time of the application's decision-making process. In this sense, the application is started when the cell phone is unlocked by the user; then the angle of inclination of the mobile device is determined by analyzing the gyroscope information; then the amount of inertia that the device carries in the position carried by the user is determined; then the application proceeds to keep track of the time in which the device is used in an inappropriate position; and finally the device makes a notification for the user to take the necessary measures to avoid the use of the device in that position.

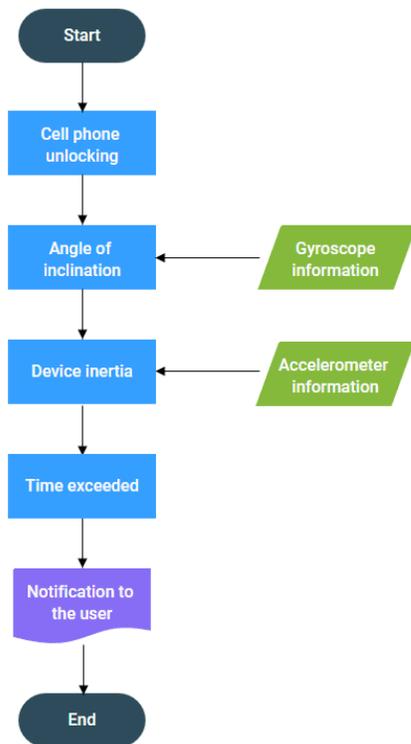

Fig. 3. System flow diagram

**C. Prototyping of the Application**

In this section, the respective prototyping of the different phases that are part of this application was carried out. In this sense, a detailed analysis of the actions that are framed in its workflow was carried out, resulting in the necessary modules

for the correct fulfillment of the objectives of this research project.

Now, our project was developed keeping a user-friendly design through the use of colors that allow the understanding of the messages. In this sense, the modules were developed:

1) *Welcome and login:* As part of the development of this module, we took into account the need to keep track of those users who make use of our application. Therefore, as can be seen in Fig. 4(A) where the Welcome module is shown, the application icon has been placed at the beginning; then a phrase that allows users to identify the purpose of the application; the login button that allows access to the login form; and finally a couple of options that ask the user about the possession of an account. Also, in Fig. 4(B) login module we include as title the name of the application; as in the previous model, the icon of the application is shown; then the data required to complete this form are shown, which are the username and password; likewise, the options to remind the user and the login button are shown; finally, the user is given the possibility to access our application through the use of their social networks such as Facebook, Google, Twitter, and LinkedIn, since they are the most used social networks today [22].

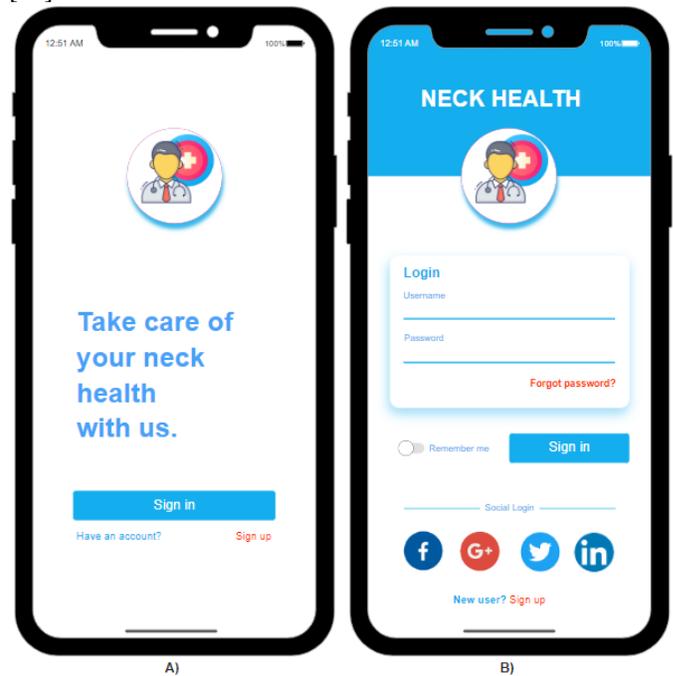

Fig. 4. A) Welcome module. B) System login module

2) *Main menu:* For the development of this module we took into account the functions to which the user requires access within our application. In this sense, as can be seen in Fig. 5 of the main menu, a couple of buttons have been implemented, the first one gives the user the possibility to access the current tilt status, and the second button allows the user to access the statistics of the use of the cell phone.

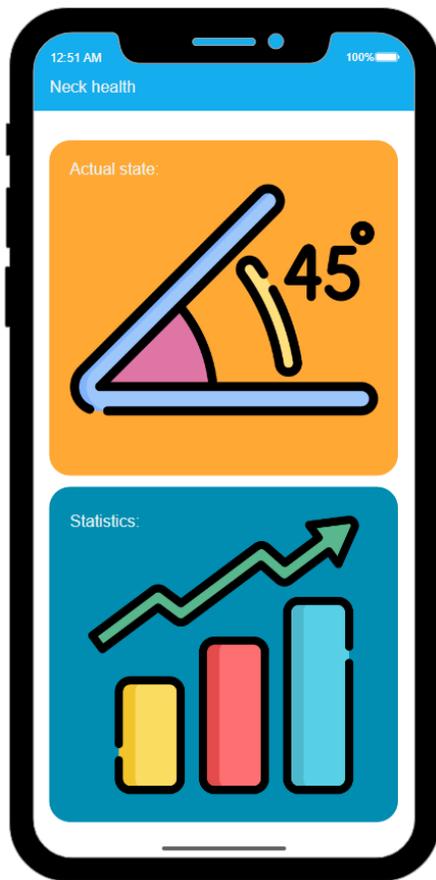

Fig. 5. Módulo de menú principal

#### D. Hardware

As part of the development of our research project, the hardware technologies necessary for the project to meet the previously stated objective were determined.

1) *Accelerometer*: This sensor allows us to obtain information on the acceleration of the device during the time it is used by the user, which makes it possible to determine the amount of inertia and other daily activities [11], [15]–[17].

2) *Gyroscope*: This sensor has the ability to detect the tilt angles in which the devices that have it implemented [15], [18], [20], this is of utmost importance since it is very much in line with the main objective of our research project.

3) *Smartphone*: Mobile devices that have a great acceptance by the general public, surpassing 80% of North American users [13]. Thus, these mobile devices have several sensors, among which are included the accelerometer and the gyroscope, both being complementary in the detection of movement and determination of activities by the users of these mobile devices [11], [12], [15], [23], [24]. Taking into account the characteristics and the utilization rate of these devices, it has been determined as the ideal device for the implementation of our research project.

#### E. Software

Within the development of this project, the following software technologies were selected due to their characteristics and features.

1) *Android*: It is an operating system that is used in a large number of mobile devices which allows you to run a large number of applications according to the needs of users [25]. It also allows the implementation of many functions for the management of user data [26]. Taking into account these characteristics, this operating system was used for the deployment of our mobile application.

2) *Android studio*: This IDE has a large number of features that allow the correct development of mobile applications for the solution of the diverse needs that users have [25]. In this sense, this IDE allowed us to carry out the correct development of the software infrastructure necessary to achieve the objective of our research project.

3) *Firebase*: This allows us to handle a large amount of unstructured data or commonly known by the name of NO-SQL [26]. This technology allows us to handle a large amount of data in real time and other features that are easy to implement in Android applications [27]–[29]. Therefore, this technology was used for the storage of user account data and usage data of their mobile devices.

### III. RESULTS

Once the development of our mobile application has been completed, we will analyze the results obtained after its implementation.

#### A. Implementation of the Application

Initially, the application was installed on a mobile device with the Android operating system. Fig. 6 shows how the application has been deployed by means of an icon that has been added to the main screen, through the use of this icon the user can access the application system.

#### B. Current status of the Device

After the user has successfully authenticated, the system will allow the user to enter the main menu of the system. At this point, the application, when used for the first time, will require the user's authorization to access certain features and data of his mobile device. Then, the user will be able to access the main menu of our application where you can see the options to which the user has access.

Now, among the options shown in the main menu is the Actual State option. This option collects the gyroscope information that is integrated inside the mobile device. Fig. 7 shows the result of the information obtained from the gyroscope sensor by means of which the angle of inclination that the device has at that moment and its equivalent angle of inclination in the user's neck can be given as a result.

Fig. 6. The application shows the angle of inclination and the equivalent weight

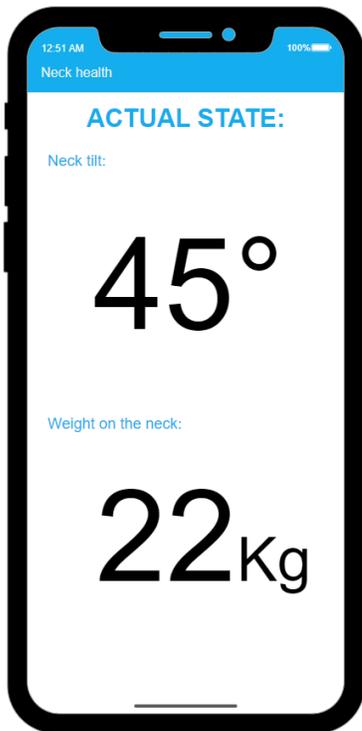

Fig. 7. Application deployment on a mobile device

This module allows the user to have immediate access to information on the tilt angles of both their device and the equivalent angle their neck is taking in relation to the tilt of the mobile device. This allows users to correct their neck position and change the way they are using their mobile devices by adapting better positions that safeguard their health.

### C. Device Usage Statistics

As part of the options implemented within the application, we find the statistics option. As shown in Fig. 8, this module presents the statistics options according to the day, week, month and year; in each of the above-mentioned cases a statistical table is presented where the frequency of incidence in the angles of inclination can be appreciated; likewise, in the lower part of the module the application shows which is the largest angle registered according to the statistical option that has been selected by the user.

This module allows users to keep track of the angles at which the mobile device is used, in this sense, in view of the data shown by the application, the user has the possibility to keep track of the change in their habits in the use of mobile devices. Therefore, the application is an extremely important tool to keep track of the angles of inclination that users have with respect to the use of mobile devices.

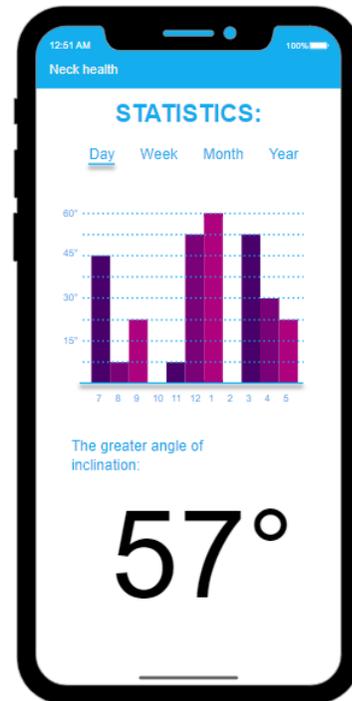

Fig. 8. Module for statistics of the device's tilt angles

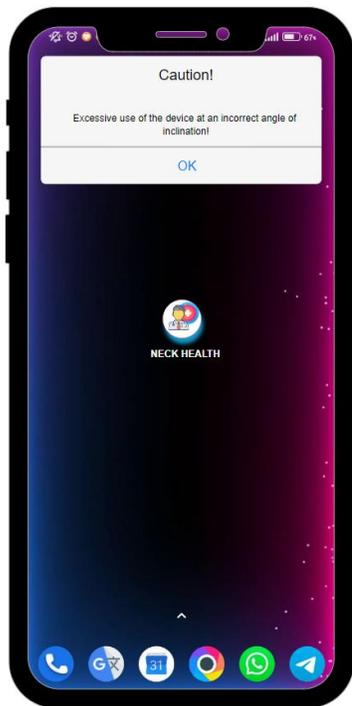

Fig. 9. Notification to the user about excessive use of the cell phone at an improper tilt angle

#### D. Notification of Tilt Angle

In this module, after the system detects an inadequate angle of inclination of the device and an excessive use of time, a notification is made. In Fig. 9 it can be seen that the application notifies the user of the excessive use of the device by means of a message: "Excessive use of the device with an incorrect angle of inclination", by means of this notification the user can become aware that he is taking a bad position of the mobile device allowing him to change it to safeguard his health.

#### IV. DISCUSSIONS

In this section, we show the differences of our research work in the various topics that coincide in those works that have been used as a basis for the development of the same.

In this section, we show the differences of our research work in the various topics that coincide in those works that have been used as a basis for the development of the same [1], [2], [4]–[8]. Indeed, several research studies have collected data on the use of various methodologies and recommendations to counteract the effects caused by this syndrome on users [1], [3], [9], [10]. However, the development of a system that allows the user to become aware of the moment in which the position adopted when using a mobile device is detrimental to their health is not performed. Therefore, this research project implements a system that allows the user to become aware of these bad postures when using mobile devices.

At present, mobile devices such as cell phones have become very popular, reaching 81% of acceptance by Americans [13]. They are also used to monitor the physical activities of their users through the use of various sensors [11], [12], [14], [19]. Among the sensors most commonly used in activity monitoring are the gyroscope and the accelerometer

because they provide accurate information [11], [14]–[16], [18], [20]. In this sense, the information provided by these sensors can be used to determine where the device is being used, in addition to knowing precisely how long the user is in that position.

#### V. CONCLUSIONS

In conclusion, it is possible to use the information of the tilt angle of the mobile devices through the use of the gyroscope and accelerometer sensors of the mobile devices. This information allowed the system to show the user the current tilt angle of the device. It is of utmost importance that the user is aware of the misuse of the device, since this allows the user to change position quickly in order to avoid falling into the text neck syndrome. Also, having a record of the activity that has taken place over time, greatly helps the user to keep track of their progress. Finally, the notifications provided by the system allow the user to have a timelier knowledge of their incorrect position during the use of the device, allowing it to make an immediate change in its position.

# An Early Warning Model for Intelligent Operation of Power Engineering based on Kalman Filter Algorithm

Haopeng Shi, Xiang Li, Pei Sun, Najuan Jia, Qiyang Dou\*

State Grid Gansu Electric Power Company, Pingliang Power Supply Company, Pingliang Gansu 744000, China

**Abstract**—The accurate early warning of intelligent operation of power engineering can find the abnormal operation of substation equipment in time and ensure the safe operation of substation equipment. Thus, an early warning model for intelligent operation of power engineering based on Kalman filter algorithm is constructed. In this model, the noise elimination method of substation equipment inspection image based on particle resampling filter algorithm is introduced. After removing the noise information of operation situation inspection image of substation equipment, the gradient direction histogram feature, lab color space feature and edge contour feature in the image are extracted by the multi-feature extraction method for intelligent operation of power engineering based on multi-feature fusion. These features are combined to form the feature description set of equipment operation situation. The feature description set is used as the identification attribute set of the anomaly identification and early warning model for intelligent operation of electric power engineering based on Kalman filter algorithm to complete the anomaly identification and early warning of equipment operation situation. The test shows that when the model is used to observe the temperature change trend of the top layer of the transformer, the temperature error is very small, and the early warning accuracy for the abnormal temperature of the top layer of the transformer is very high, so the abnormal operation of the substation equipment can be found in time.

**Keyword**—Kalman filter; power engineering; intelligent operation; early warning model; image denoising; feature extraction

## I. INTRODUCTION

With the development of industrial revolution, electric power plays an important role in the development of human society. Problems in urban power supply system will cause serious consequences for people's daily activities and even the whole society. Therefore, ensuring the safe and stable operation of power system has become an extremely important part of the national strategic energy security system. To realize the safe and reliable operation of the power grid, it is necessary to continuously improve the automation level of the substation, so as to achieve the purpose of reasonable allocation of power supply equipment and effective supervision and management of the substation equipment [1].

The development of substation automation is mainly affected by the following aspects. First, the construction of substation automation system is inseparable from information technology. The development of information technology makes the information source and amount faced by power enterprises continue to grow. Therefore, enterprises also put

forward relatively high requirements for the work efficiency and response speed of the processing system [2]. Secondly, the automation level of the substation mainly involves fault detection and fault isolation. On the one hand, the wide distribution of low-voltage substation has resulted in the large number and scattered nodes of low-voltage substation. Therefore, the staff must upload patrol inspection data in real time, accurately and efficiently. On the other hand, due to the long-term exposure of power equipment to the field, it often bears the effects of normal mechanical load and power load, as well as external forces such as lightning strike, pollution, strong wind, earthquake, flood, landslide and bird damage, and may even be endangered by the theft of power equipment by some criminals. These factors will cause aging, oxidation and corrosion of various components in the substation. If they are not found and eliminated in time, the existing hidden dangers will develop into faults, thus posing a threat to the security and stability of the power system [3]. Therefore, in order to fundamentally ensure the safe and stable operation of the power grid and the safe supply of power, it is necessary to carry out regular and irregular inspection of each substation, timely find hidden dangers, prevent them before they happen, and reduce the failure rate of power equipment to the lowest.

At present, the traditional manual inspection, video monitoring, comprehensive maintenance vehicle and other methods are mainly used for substation inspection in China's power system. For some enterprises, the cost is too high, the operation is difficult to implement, and it is not easy to promote. At the same time, it is difficult to eliminate the impact of human factors in the inspection work. Therefore, how to absorb the modern management experience of foreign advanced power enterprises and make full use of advanced mobile technology in the construction of intelligent inspection system for substation has become very important.

## II. JOURNALS' REVIEWED

Xie, S studied the intelligent inspection technology of substation electrical equipment based on 5G. Based on 5G communication technology, intelligent patrol robots, video surveillance, AR glasses, mobile patrol APP and other terminals are integrated to realize all-round intelligent patrol of the substation, with poor early warning effect [4]. Yang Qiong designed an intelligent patrol inspection system for substation, which introduced GPS and PDA technology, and was characterized by the storage of equipment information in the upper management system and all management of equipment, defect information, historical data and patrol inspection. Patrol inspectors could complete the information collection of equipment only by arriving near the corresponding patrol

inspection equipment. After the patrol inspection, the corresponding equipment information should be transmitted to the background database for storage through a certain communication mode. The comprehensive cost of this system was relatively high [5]. Zhang F. researched the inspection method combining PDA and RFID. This inspection method was a non-contact automatic identification technology, which could read and identify the electronic data stored in the card without contact. The reader / writer emitted energy in an area to form an electromagnetic field. When the RF tag passed through the area, it detected the signal of the reader / writer and sends the stored data. The reader / writer received the signal sent by the RF tag, decoded and checked the accuracy of the data to complete the identification, so as to achieve the purpose of patrol inspection [6].

Compared with other methods, RFID technology has the characteristics of non-contact identification, high-speed identification, multi-target simultaneous identification, and strong confidentiality. It is widely used in vehicle identification and production process control, but the immunity of radio frequency technology needs to be optimized. In order to discover the abnormal operation of substation equipment in time and realize the efficient and intelligent operation early warning of power engineering. On the basis of previous studies, this paper establishes an intelligent operation early warning model of electric power engineering based on Kalman filter algorithm, which is mainly used for intelligent patrol inspection of electric power engineering, in order to provide some help for timely early warning of abnormal conditions found in the patrol inspection process.

### III. EARLY WARNING MODEL FOR INTELLIGENT OPERATION OF POWER ENGINEERING

The early warning of intelligent operation of power engineering needs to be completed by using intelligent technology. At present, the application of intelligent inspection robot is no longer strange in the field of power engineering. The intelligent inspection robot has replaced the traditional manual inspection mode. The early warning model for intelligent operation of power engineering based on Kalman filter algorithm constructed in this paper belongs to one of the core technologies applied to the equipment of intelligent inspection robot. Before introducing the specific application technology of the model, the structure of the intelligent inspection robot is analyzed. The structure diagram of its operation mode is shown in Fig. 1.

The intelligent inspection robot system consists of a base station layer and a robot mobile station. The base station layer receives and processes patrol inspection data through its database, data processing and video monitoring modules, which is equivalent to a monitoring background. It also has the functions of image processing and pattern recognition, which can automatically identify equipment defects and automatically warn. The communication layer is divided into two modules: the wireless bridge base station and the wireless bridge mobile station. It provides data transmission channels for the base station and the robot mobile station through the wireless network transmission protocol. Wireless communication is used between the mobile robot and the monitoring background

[7]. In addition, when the robot loses power, it can automatically return to the charging room for self-charging. The model in this paper is mainly installed on the intelligent inspection robot equipment to help the robot find the abnormal situation of intelligent operation of power engineering in real time and give real-time warning. The intelligent operation warning problem of power engineering studied in this paper is mainly to identify and warn the operation situation of substation equipment.

#### A. Noise Elimination Method for Inspection Image of Substation Equipment based on Particle Resampling Filter Algorithm

When the intelligent inspection robot performs the inspection task of operation situation of substation equipment, the collected infrared image is affected by external factors, so there is inevitably noise information, which directly affects the image quality [8]. For this reason, this paper uses the noise elimination method of inspection image of substation equipment based on particle resampling filter algorithm to remove the noise information of inspection image and optimize the image quality [9].

The particle filter algorithm uses the large number theorem to solve the nonlinear non Gaussian estimation problem in Bayesian estimation through Nonparametric Monte Carlo, which is applicable to any nonlinear non Gaussian random problem that can be expressed in state space [10]. The posterior probability density of noise particles is estimated through a group of observed random noise samples in the state space of noise particles in the inspection image, and the mean value of noise samples is used to replace the integral operation to obtain the minimum variance of noise filtering effect.

The infrared image state equation and noise observation equation of operation situation inspection of substation equipment are modeled as follows:

$$\begin{cases} y_h = g(y_h, u_h) \\ l_h = k(y_h, m_h) \end{cases} \quad (1)$$

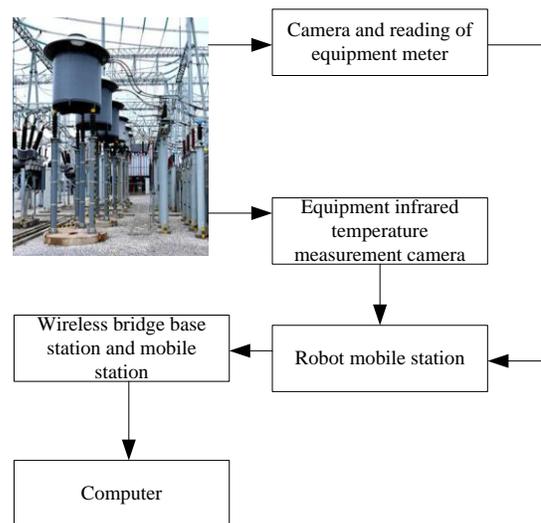

Fig. 1. Structure diagram of operation mode of intelligent inspection robot.

Where,  $u_h$  is the actual noise level during patrol inspection image acquisition;  $m_h$  is the measurement noise level of patrol inspection image;  $g(\cdot)$  is the transfer function of patrol inspection image quality;  $k(\cdot)$  is the measurement function of patrol inspection image quality.  $y_h$  is a group of filter state values of weighted particle with conditional distribution obtained by Monte Carlo simulation sampling at time  $h$ . Each noise particle uses its gray value at the patrol inspection image position as the characteristic value, and  $l_h$  is the observation value of noise particle filter at time  $h$ .

Through the probability density function  $q(y_h | l_{1:h-1})$  of the spatial state of the noise particle swarm optimization system at time  $h-1$  based on the Chapman-Kolmogorov equation, the state of noise information in the patrol inspection image of substation equipment's operation situation at time  $h$  is observed:

$$q(y_h | l_{1:h-1}) = \int q(y_h | y_{h-1}) q(y_{h-1} | l_{1:h-1}) dy_{h-1} \quad (2)$$

Where,  $l_{1:h-1}$  is the noise observation value from 1 to  $h-1$ .

The Bayesian formula is used to derive the prior probability  $q(y_h | l_{1:h-1})$  and the posterior probability  $q(y_h | l_{1:h})$  from the noise observation value at time  $h$ . According to the law of large numbers, when the number of noise particles is very large, the particle filter is approximate to the posterior probability of the patrol inspection image quality state [11]. Namely:

$$q(y_h | l_{1:h}) \approx \frac{1}{M} \sum_{j=1}^M \varpi_h^j \beta(y_h - y_{1:h}^{j(n,f)}) \quad (3)$$

Where  $M$  is the number of noise particles;  $\varpi_h^j$  is the weight of noise particle  $j$  at time  $h$ ;  $\beta$  is a Dirac function;  $y_{1:h}^{j(n,f)}$  is the  $j$ -th noise particle gray value located at the patrol inspection image  $(n, f)$  of operation situation of substation equipment from 1 to  $h$ . Generally, the noise particle set cannot be directly sampled from the posterior probability. The prior density that is easy to realize is selected as the importance density function, and the particles with uniform distribution are optimized through maximum likelihood estimation, so that the optimized particle distribution is closer to the posterior probability density. Only a small number of noise particles can achieve high estimation accuracy, thus reducing the amount of calculation [12]. Then the weight is updated to:

$$\varpi_h = \varpi_h^j q(y_h | l_{1:h}) \quad (4)$$

Weight normalization:

$$\hat{\varpi}_h = \frac{\varpi_h^j}{\sum_{j=1}^M \varpi_h^j} \quad (5)$$

The optimal image quality of patrol inspection of substation equipment's operation situation is output:

$$\hat{y}_h = \sum_{j=1}^M \hat{\varpi}_h^j y_h \quad (6)$$

After several iterations of particle algorithm, only a small number of effective noise particles have non-zero important weights, and most of the important weights of noise particles tend to zero. Therefore, the noise cannot be effectively eliminated in the process of infrared image denoising. In order to prevent the weight degradation of noise particles, resampling method is adopted to reduce the impact of noise on the image quality of patrol inspection of substation equipment's operation situation to a certain extent [13].

The main idea of resampling is to remove the noise particles with small weight, retain and copy the noise particles with large weight, and sample the particles with large weight for many times, so as to increase the chance of noise elimination for the particles, and sample less for the particles with small weight [14]. Firstly,  $m$  uniformly distributed random numbers  $\{\varepsilon_i; i=1, 2, \dots, m\}$  are generated in the interval  $[0, 1]$ , and then the weights of noise particles are accumulated:

$$d_h = \sum_{j=1}^h \hat{\varpi}_h \quad (7)$$

Where,  $h=1, 2, \dots, m$ ;  $d_h$  is the cumulative value of noise particle weight.

The resampled noise particles only account for a small part of the whole particle swarm. Such particles can no longer effectively describe the posterior probability distribution of patrol inspection image quality status. As each particle is sampled independently, the process includes cycle and comparison operations, which increases the computational complexity of particle filter for patrol inspection image of substation equipment's operation situation [15].

Resampling makes the noise particles with higher weight be sampled for many times, and the sampling results contain many repeated noise particles, thus losing the diversity of particles and reducing the filtering performance. In order to solve the problem of resampling dilution, the effective particle number threshold is used to optimize the filtering effect of patrol inspection image of substation equipment's operation situation.

Suppose  $\{\hat{\omega}_h^1, \hat{\omega}_h^2, \dots, \hat{\omega}_h^M\}$  is the set of normalized weights of noise particles, and the sample variance of particle weights is:

$$U(\hat{\omega}_h) = \frac{1}{M} \sum_{j=1}^M [\hat{\omega}_h - \text{mean}(\hat{\omega}_h)]^2 \quad (8)$$

Where  $U(\cdot)$  is the variance function;  $\text{mean}(\cdot)$  is the mean function.

Effective particle number threshold  $M_{\text{eff}}(\hat{\omega}_h)$  of the degradation degree of noise particles is measured:

$$M_{\text{eff}}(\hat{\omega}_h) = \frac{1}{\sum_{j=1}^N (\hat{\omega}_h)^2} \quad (9)$$

In this way, the effective noise particles are classified according to the weight value, which effectively reduces the complexity of the algorithm, and the random method increases the diversity of noise particles. In order to avoid too small noise particles in the patrol inspection image of substation equipment's operation situation, the lower limit of noise variance is set as  $\alpha_{\min}$ , and the maximum noise variance is set as  $\alpha_{\max}$ . The attenuation factor  $\eta$  is used to estimate the noise reduction rate. When the noise in the patrol inspection image of substation equipment's operation situation is small, a small number of particles can be used to describe the noise distribution. When the noise is large, the sampling range of particles is expanded and the number of particles is increased. Sigmoid function is used to express the relationship between the number of noise particles  $M_h$  and uncertainty measure  $o_h$  at time  $h$ .

$$M_h = \frac{2M_{\text{eff}}(\hat{\omega}_h)}{1 + \exp(-\eta o_t + \eta \cdot \eta_{\min})} \quad (10)$$

Among them, the uncertainty measures  $o_h = \theta_t^x \theta_t^z$ ,  $\theta_t^x$  and  $\theta_t^z$  are the actual noise and observation noise in the patrol inspection image of substation equipment's operation situation at time  $h$ . In this way, the noise particles with smaller weight are discarded and replaced by the noise particles with larger weight for multiple noise elimination. The noise particles with larger weight are erased after the patrol inspection image is resampled to complete the noise elimination of the patrol inspection image of substation equipment's operation situation [16].

### B. Multi-Feature Extraction Method for Intelligent Operation of Power Engineering based on Multi-Feature Fusion

In order to identify the abnormal situation in the inspection process of substation equipment's operation situation, it is

necessary to extract the image features of substation equipment's operation situation after de-noising in Section IIIA. The image features of inspection are very important in the process of substation equipment's operation situation awareness. Therefore, this paper will comprehensively consider the edge, gradient and color features in the infrared image during intelligent inspection of substation equipment. A multi-feature extraction method for intelligent operation of power engineering based on multi-feature fusion is proposed. The feature description set of equipment operation situation is composed of gradient direction histogram (HOG) feature, lab color space and edge contour, which is used as the identification attribute set of the anomaly identification and early warning model of intelligent operation of power engineering based on Kalman filter algorithm.

1) *Gradient feature extraction*: The gradient of patrol inspection image of substation equipment's operation situation includes image edge contour and texture information, which can be used for image analysis and recognition. In the process of extracting the image features of substation equipment's operation situation inspection, this paper simplifies the calculation process of HOG features, improves the calculation efficiency, and can better describe the gradient features of substation equipment's operation situation. In the 5\*5 cell, 9 bin histograms are used to calculate the gradient information of these 25 pixels. That is, the 360 ° gradient direction of the cell is divided into nine direction intervals, and each pixel in the cell is weighted projected in the histogram with the gradient direction. The weight is the gradient amplitude, and the amplitude of the histogram in each direction forms an eigenvector [17].

The gradient of all pixels in the patrol inspection image of substation equipment's operation situation after noise removal is calculated, and the gradient amplitude is:

$$F(x, y) = F_x(x, y) + F_y(x, y) \quad (11)$$

Where,  $F_x(x, y)$  and  $F_y(x, y)$  are the gradient amplitudes in direction  $x$  and  $y$  of each pixel in the inspection image of the substation equipment's operation situation after noise removal.

The gradient direction is:

$$\mu(x, y) = \tan^{-1} \frac{F_x(x, y)}{F_y(x, y)} \quad (12)$$

The weighted projection of each pixel in the cell within the uniform interval in the gradient direction  $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$  is calculated as:

$$F_k(x, y) = \sum_{\mu(x, y) \in c_k} F(x, y) \quad (13)$$

Where,  $F_k(x, y)$  is the cumulative value of gradient amplitude in different gradient directions in the cell;  $c_k$  represents the range of different gradient directions.

2) *Color feature extraction:* After de-noising, the component L in the lab color space of the inspection image of substation equipment's operation situation expresses the human eye's perception of brightness. The output color scales of components a and b are more uniform and balanced. Compared with RGB and CMYK color models, the lab space has a broader color gamut and is independent of physical equipment.

Therefore, in order to preserve the wide color gamut and rich colors as much as possible, and better quantify the colors, this paper uses the lab color model as the color feature, that is, the patrol inspection image of substation equipment's operation situation after noise removal is transformed into the lab color space model, and the lab color space is divided into three feature vector sets.

3) *Edge profile features:* The edge of the inspection image of substation equipment's operation situation after noise removal refers to the area where the local gray level of the image changes significantly. It is the most basic feature of the image and contains useful information for identification. Therefore, this paper extracts the direction, first-order and second-order differentiation of the image as the edge contour feature vector set of the de-noising patrol inspection image of substation equipment's operation situation [18]. Among them, the first-order and second-order differential are realized by Sobel differential operator.

To sum up, the extracted feature vectors of inspection image of substation equipment's operation situation after noise removal are used to form a feature descriptor. Each feature vector is a feature channel, and each feature channel is a matrix block with the same size as the image.

### C. Anomaly Identification and Early Warning Model for Intelligent Operation of Power Engineering based on Kalman Filter Algorithm

The characteristic information of the patrol inspection image of substation equipment's operation situation extracted in Section IIIB is used as the identification attribute set of the intelligent operation anomaly identification and early warning model of power engineering based on the Kalman filter algorithm. The Kalman filter algorithm mainly includes two processes: prediction and correction, that is, observation and update. The observation process mainly uses the time updating equation to establish a prior estimate of the current substation equipment's operation situation, so as to calculate the current state variables and error covariance estimates in time, and construct a prior estimate for the next time state; In the correction process, a posteriori estimate of the current state of substation equipment's operation situation is established based on the prior estimate of the prediction process and the current measurement variables by using the measurement update

equation through feedback. This process is called the prediction correction process.

In order to apply the Kalman filter algorithm to the intelligent operation early warning of power engineering, it is necessary to construct the description equation and measurement equation of substation equipment's operation situation based on the Kalman filter algorithm, and then establish the real-time optimal estimation model of substation equipment's operation situation [19]. Then the equation describing the operation situation of substation equipment is:

$$\alpha_{oil,h} = \Omega \alpha_{oil,h-1} + B_2 \begin{bmatrix} \alpha_{oil,h} \\ N \end{bmatrix} + V_{h-1} \quad (14)$$

Where,  $\alpha_{oil,h}$  is the operation situation of substation equipment at time  $h$ ;  $\Omega$  is the characteristic information of patrol inspection image of substation equipment's operation situation extracted in subsection 2.2;  $B_2$  is the gain of control input of substation equipment;  $V_{h-1}$  is the process excitation noise, which is generally considered to obey the normal white noise and does not change with time. It represents the observation error of substation equipment's operation situation between  $h-1$  and  $h$ ;  $N$  is the observation times of operation situation of substation equipment;  $\alpha_{oil,h-1}$  is the operation situation of substation equipment at time  $h-1$ .

The observation equation of the operation situation of substation equipment at time  $h$  can be expressed as:

$$L_K = H_k \alpha_{oil,h} + W_K \Omega \quad (15)$$

Where,  $H_k$  is the gain of actual variable  $\alpha_{oil,h}$  of substation equipment's operation situation to the observation variable  $L_K$  of substation equipment's operation situation;  $W_K$  is the change range of operation situation of substation equipment.

After determining the state equation and observation equation of the operation situation of the substation equipment, the Kalman filter algorithm estimates the operation situation of the substation equipment, which can carry out the two main processes of the Kalman filter: "time update (observation)" and "state update (correction)". Through repeated update and correction, the most accurate results can be obtained to realize the observation of the operation situation of the substation equipment. Firstly, it should establish the time update equation for the operation of substation equipment:

$$\hat{\alpha}_{oil,h}^- = \Omega \hat{\alpha}_{oil,h-1}^+ + B_2 \begin{bmatrix} \alpha_{amb,h} \\ N \end{bmatrix} \quad (16)$$

$$Q_K^- = (1 - B_1)^2 \cdot Q_K^+ + P \quad (17)$$

Where, "-" stands for a priori and "+" stands for a posteriori.  $\hat{\alpha}_{oil,h}^-$  is the prior state estimation of step  $h$  when the operation situation of the substation equipment before step  $h$  is known, that is, the prior state estimation of time  $h$  using time  $h-1$ .  $\hat{\alpha}_{oil,h-1}^+$  is a posteriori state estimation when the measurement variable  $L_K$  is known in the operation situation of substation equipment, and it is also the optimal estimation result of the state at  $h-1$ .  $Q_K^-$  is the covariance of the error of prior estimation, and  $P$  is the process error of substation equipment's operation situation estimation. In the updating process, the state estimation is optimized by using the prior estimates and observations of the current state, which is called a posteriori state estimation.  $Q_K^+$  is the covariance of the error of the calculated posterior estimate.

The verification equation for the estimation results of substation equipment's operation situation is:

$$\hat{\alpha}_{oil,h}^+ = \Omega \hat{\alpha}_{oil,h}^- + F_h (L_K - H_k \hat{\alpha}_{oil,h}^-) \quad (18)$$

$$F_h = \frac{Q_K^-}{Q_K^- + S} \quad (19)$$

$$Q_K^+ = Q_K^- (1 - F_h) \quad (20)$$

In Eq. (18) to (20),  $S$  is the variance of the operation situation estimation error of the measured substation equipment. A posteriori estimate  $\hat{\alpha}_{oil,h}^+$  is composed of a linear combination between a priori estimate  $\hat{\alpha}_{oil,h}^-$  and the observation variable  $L_K$  of substation equipment's operation situation;  $F_h$  is the Kalman gain, whose function is to minimize the posterior estimation error covariance  $Q_K^+$  to ensure that the recursion can be carried out continuously. The magnitude of the residual value reflects the inconsistency between the observed value and the actual value. The greater the residual value is, the greater the inconsistency is. Otherwise, it is true. Eq. (17) to (20) constitute the five processes required for Kalman filter iterative observation. In the iterative process, equations (18) and (20) need to feed back the obtained posterior results to equations (17) and (18) in order to update the information of each step. In this way, the model can realize the real-time estimation of the operation situation of substation equipment and the real-time early warning of intelligent operation of power engineering.

The early warning program is mainly completed by the alarm device. The circuit of the alarm device is composed of high decibel active alarm. Because the driving ability of the single chip microcomputer is not enough, this circuit uses NPN triode to drive the alarm. The LED display circuit consists of two decoders 741138, eight row drivers 4953 (each chip

controls two rows), eight column drivers (each chip controls eight columns), and sixteen 1588 common anode diode lattice modules. Therefore, the LED display is a 1664 dot matrix. Four Chinese characters can be displayed at the same time. In normal state, the screen displays yellow "normal operation" and red "fault operation" in case of fault, accompanied by alarm sound [20]. The alarm flow of this device is shown in Fig. 2.

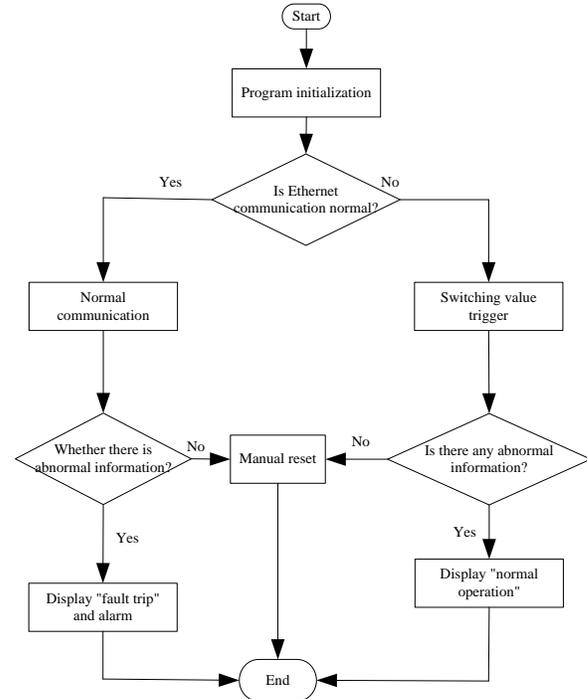

Fig. 2. Alarm process.

As shown in Fig. 2, the alarm device will first judge whether its Ethernet communication is normal. If the normal communication represents that the device can operate normally, it will judge whether there is any abnormal information touch device; if yes, it will display "fault operation" and sound light alarm. If there is no abnormality, it will display "normal operation" and reset manually.

#### IV. RESULTS

The model is installed on an intelligent substation inspection robot to test the application effect of the model. The test content is mainly divided into the processing effect, situation recognition and early warning effect of intelligent inspection image of substation equipment's operation situation,.

##### A. Analysis on Processing Effect of Intelligent Patrol Inspection Image of Substation Equipment's Operation Situation

As shown in Fig. 3(a) and Fig. 4(a), when the model in this paper inspects the operation situation of transformers and insulators in substations, there are different degrees of noise information in the captured intelligent inspection image of operation situation. The effect pictures of this model after noise removal are shown in Fig. 3(b) and Fig. 4(b).

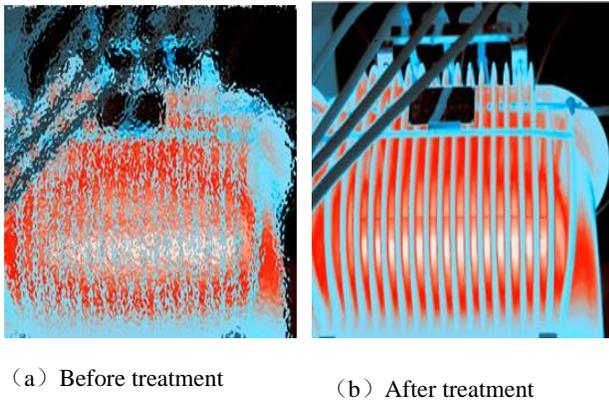

Fig. 3. Intelligent inspection image of transformer operation situation.

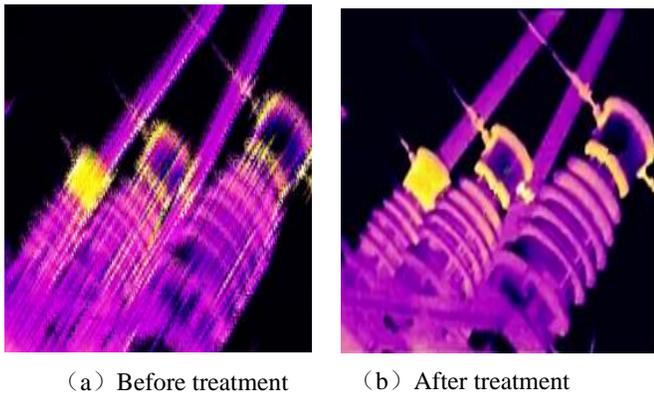

Fig. 4. Intelligent inspection image of insulator operation situation.

From the analysis of Fig. 3 and Fig. 4, it can be seen that the model in this paper has a good denoising effect on the transformer and insulator images of the patrol substation when inspecting the operation situation of the transformer and insulator in the substation. From the visual point of view, the image definition after denoising is improved and the image details are more significant.

### B. Abnormal Situation Identification and Early Warning Effect

The model in this paper is used to monitor the top temperature of the transformer shown in Fig. 3 in real time. The actual value of the top temperature of the transformer is shown in Fig. 5, and the ambient temperature is shown in Fig. 6.

The Kalman filter algorithm in the model of this paper can use the new patrol information to continuously observe and modify the new state estimates, so it can observe the top temperature in real time. The initial noise state of the state equation can be obtained from the statistical value of the variance function, and the variance of the observation error can be obtained from the statistical value of the temperature sensor error. The system state equation is used to optimally estimate the state variable, that is, the top temperature. The recognition results are shown in Fig. 7.

As shown in Fig. 7, the difference between the identification result of the transformer's top temperature and

the actual value of the model in this paper is very small, which can well reflect the dynamic change of temperature. As long as the given system's initial value does not deviate too far from the real initial value, the Kalman filter algorithm can converge to the final value.

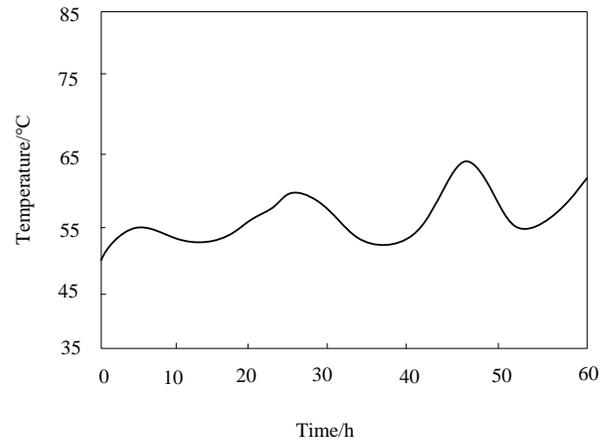

Fig. 5. Actual value of transformer top temperature.

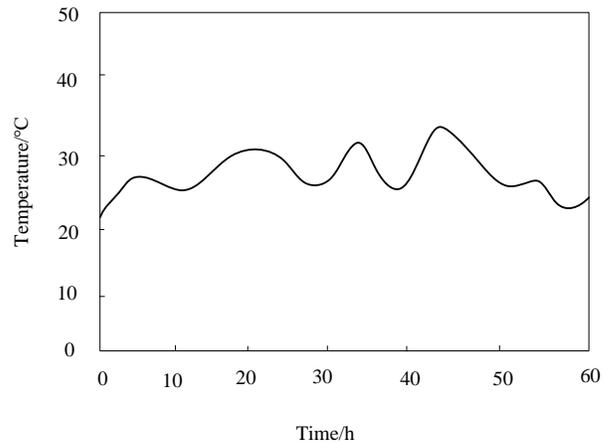

Fig. 6. Ambient temperature for intelligent operation of electric power engineering.

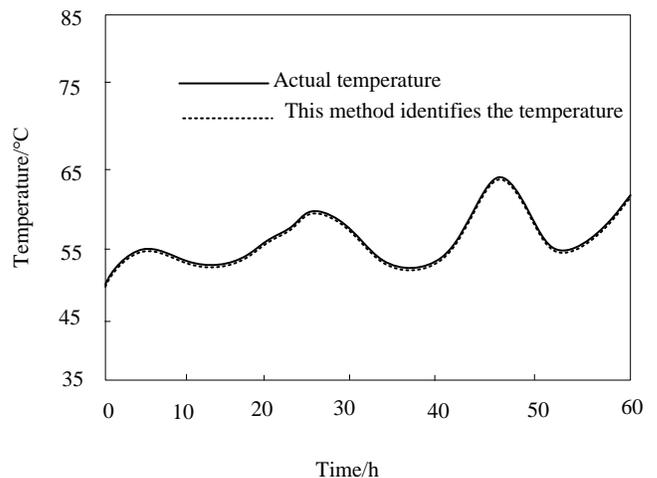

Fig. 7. The identification results of transformer top temperature by this model.

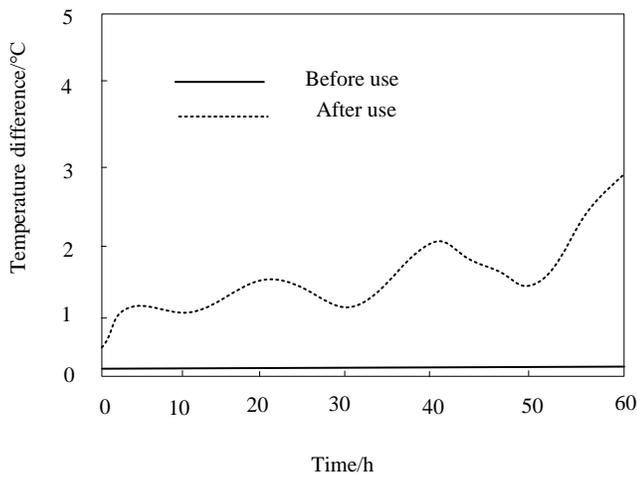

Fig. 8. The error variation of transformer top temperature identification results before and after the model is used in this paper.

Before and after the intelligent inspection robot uses the model in this paper, the error of the top temperature identification result of the transformer is shown in Fig. 8.

As shown in Fig. 8, when the model in this paper uses Kalman filter algorithm to observe the top temperature of

transformer, the temperature error is less than 0.5°. When the model in this paper is not used, the observation error of intelligent inspection robot on the top temperature of transformer is more than 2°. This shows that the model in this paper has high observation accuracy on the top temperature of transformer. The reason is that the Kalman filter algorithm can continuously predict and correct the top temperature of transformer, and the observation error is minimized. Therefore, this model can be well applied to the abnormal identification of transformer top temperature.

The abnormal early warning effect of the model in this paper after identifying the top temperature of transformer is test, and the results are shown in Table I.

By analyzing the data in Table I, it can be seen that after the model identifies the top-level temperature of the transformer, there is only a 1-minute delay in the early warning time for the abnormal state of the top-level temperature of the transformer on February 2, 2022, but the number of early warnings is consistent with the number of abnormal occurrences. The model in this paper has verified the early warning effect of intelligent operation of power engineering and can accurately give early warning.

TABLE I ABNORMAL EARLY WARNING EFFECT OF TOP LAYER TEMPERATURE OF MODEL TRANSFORMER

Abnormal occurrence date	Abnormal occurrence time	Warning time	Number of exceptions	Warning times
2022/1/23	10:58	10:58	5	5
2022/2/2	9:20	9:21	1	1
2022/3/25	8:01	8:01	2	2
2022/4/14	12:36	12:36	3	3
2022/5/8	20:25	20:25	5	5
2022/5/13	2:36	2:36	4	4
2022/6/1	17:25	17:25	1	1
2022/6/3	13:33	13:33	1	1
2022/6/4	12:45	12:45	1	1

## V. DISCUSSION

Based on the research content of this paper, at present, the intelligent inspection robot is mainly used in the intelligent operation inspection of power engineering. However, the intelligent inspection robot is not perfect, and it also has shortcomings in practical application:

1) *Meter data reading*: Patrol inspection robots are equipped with high-definition cameras that can be zoomed. According to the design idea, their advantages in reading meter data are far greater than the visual inspection of operation and maintenance personnel during manual patrol inspection. In the station, the installation position of some meters and meters is too high for manual vision to see the pointer, number and other contents in the meters and meters. In this case, the traditional inspection is conducted with the help of a telescope. The zoom camera of the intelligent inspection robot can not only shorten the meter interface several times the distance, save time and

effort, but also save the meter interface as a picture for later analysis. However, in practical application, it is found that this advantage cannot be fully exerted, which is mainly manifested in that when the surface of the high-voltage meter in the station or the camera of the inspection robot becomes dirty due to the accumulation of pollutants and impurities in the air, the camera simply cannot obtain a clear meter image. In addition, the camera also fails to focus. For the problem that the camera surface of the inspection robot is polluted, a self-cleaning device similar to the automobile wiper can be added in the subsequent improvement to properly solve it. As for the phenomenon of surface pollution, the problem of non-inspection robot itself can only be solved by manual cleaning during each power outage and maintenance of power grid equipment. Focusing failure is caused by the camera algorithm or the auto focusing technology adopted. It is recommended to configure the camera with active auto focusing mode, which

can greatly reduce the occurrence of focusing failure by combining the advantages of infrared ranging and ultrasonic ranging focusing methods and focusing mode based on image processing. At present, there are many researches and explorations on the research, development and application of inspection robot in the intelligent inspection system and the diversification of inspection functions, but the more advanced cutting-edge technologies are neglected in the hardware. High performance hardware equipment is more conducive to the advanced functions of the inspection robot.

2) *Infrared thermometry*: In the process of infrared temperature measurement, the layout of equipment in the station is complex and staggered, and the inspection robot is restricted by the fixed inspection path, positioning point and the traveling channel in the actual site designed in the system. It is unable to compare the maximum temperature and hot spot of the equipment from 360 ° directions flexibly like manual inspection, and there is inaccurate alignment. Therefore, the temperature information obtained is too large deviation from the actual situation, or even wrong. The problem of alignment and misalignment can be solved by optimizing the system and adding a distance monitoring unit. The function of the distance monitoring unit is to determine the reasonable distance between the tested equipment and the inspection robot. Only the equipment within a reasonable distance set in the system can be selected by the infrared camera, so as to effectively avoid the wrong selection of objects within the abnormal range such as the sum for temperature measurement in similar cases. However, in order to realize the full angle comparative temperature measurement like manual inspection, it is obviously impossible to realize it at the software level of the robot inspection monitoring system due to the factors such as the distribution of roads in the substation, the height of the inspection robot, the battery life and so on. Therefore, the infrared temperature measurement function cannot replace the accurate temperature measurement in the existing technical stage, and can only be used as a way of universal temperature measurement in a large area.

Therefore, the above two problems should be paid more attention in practical application.

## VI. CONCLUSION

With the rapid development of China's economy, higher requirements are put forward for the safe operation of power transmission network, power plant facilities and other infrastructure. Major power companies have invested a lot of manpower and material resources in the inspection and maintenance of lines and facilities. However, due to the limitations of technical conditions, there are many deficiencies in the power inspection link, such as low inspection efficiency and difficult management. At the same time, the original manual records and reports also greatly limit the modernization of power operation management. Intelligent inspection of substation equipment is applicable to the power supply facilities management department of the power supply company. It helps to reduce the workload of inspection

personnel and facilities management personnel and improve work efficiency. The research content of this paper is the early warning of intelligent operation of power engineering, which is simply the abnormal identification and early warning of substation equipment's operation situation. In order to accurately identify and early warning the abnormal state of intelligent operation of power engineering, this paper constructs an early warning model of intelligent operation of power engineering based on Kalman filter algorithm, and verifies its application value in experiments. However, in the experiment, the model in this paper has a one minute delay in identifying the abnormal operation situation of substation equipment. In the future research work, the application effect of the model will be gradually optimized to provide effective assistance for power equipment monitoring.

**Abstract**—Tiny air sacs in one or both lungs become inflamed as a result of the lung infection known as pneumonia. In order to provide the best possible treatment plan, pneumonia must be accurately and quickly diagnosed at initial stages. Nowadays, a chest X-ray is regarded as the most effective imaging technique for detecting pneumonia. However, performing chest X-ray analysis may be quite difficult and laborious. For this purpose, in this study we propose deep convolutional neural network (CNN) with 24 hidden layers to identify pneumonia using chest X-ray images. In order to get high accuracy of the proposed deep CNN we applied an image processing method as well as rescaling and data augmentation methods as shear\_range, rotation, zooming, CLAHE, and vertical\_flip. The proposed approach has been evaluated using different evaluation criteria and has demonstrated 97.2%, 97.1%, 97.43%, 96%, 98.8% performance in terms of accuracy, precision, recall, F-score, and AUC-ROC curve. Thus, the applied deep CNN obtain a high level of performance in pneumonia detection. In general, the provided approach is intended to aid radiologists in making an accurate pneumonia diagnosis. Additionally, our suggested models could be helpful in the early detection of other chest-related illnesses such as COVID-19.

**Keywords**—Pneumonia; deep learning; CNN; chest X-rays; radiology

## I. INTRODUCTION

Pneumonia is an infection of the lungs that can be caused by viruses, bacteria, or fungus. In principle, the condition is brought on by a wide range of bacteria, including fungal environmental pollutants, or even physical harm to the lungs caused by smoking or other forms of pollution [1]. Being a common disease, it also has the potential to be fatal [2]. Regarding modern solutions for pneumonia detection, it is hardly surprising that computer vision is an important field of study for artificial intelligence (AI), primarily since it provides answers to a wide range of issues that nowadays people encounter. Biomedical image analysis using artificial intelligence is one of the computer vision areas that has repeatedly shown to be beneficial.

Recent years have seen a rise in the use of deep models, particularly CNN models, as the dominant method for the

categorization of clinical imaging. This is due to the fact that selecting which features to retrieve in conventional approaches to computational intelligence is a time-consuming process that also varies depending on its object [3-5]. These studies have made use of CNNs with a variety of architectural styles and methodological approaches, which were conducted using X-ray images. In order to get more favorable outcomes, CNN-based models require a substantial number of training samples [6]. It is quite problematic to gather medical imaging due to the process of collecting and identifying healthcare data which is complicated by time-consuming privacy rules and the explanations of medical professionals. According to researchers [7], transformation-based data augmentation has been proved to be a suitable method for classifying images. Image enhancement methods may help prevent overfitting during the training phase, which ultimately results in a more accurate model being created.

The majority of the strategies discussed here use transfer learning, which means the deep learning methods were initially trained on the data unrelated to pneumonia diagnosis. The usage of convolutional neural networks created from scratch in a number of image processing algorithms [8] shown that a simpler structure might achieve a higher precision than numerous pre-trained older models used in transfer learning. Throughout this work, we propose creating a cutting-edge deep convolutional neural network as a precise solution for the pneumonia detection issue. The primary innovation in the proposed network is the use of dropout in the convolutional portion of the model, as compared to a large number of other models, which only employ dropout in the fully connected portion of the neural network, which is where the bulk of the attributes are learned. This study establishes the suggested network's ability to perform correct classification even with a small number of training features, providing accompanying illustrations as to how this characteristic might increase predictive performance.

The remainder of this study is as follows: next section reviews the related works in the area of pneumonia detection. Section III describes the data used in this study and the division of the data into training, test and validation sets. Section IV

describes materials and methods including the proposed deep CNN for automated pneumonia detection. Section V demonstrates the obtained results and compares them with the state-of-the-art studies. Section VI discusses the proposed model referencing advantages, challenges and future perspectives. Finally, we conclude the study referencing the main results.

## II. RELATED WORKS

In the past few years, the subject of artificial intelligence known as "deep learning" has had an incredible amount of growth, quickly becoming an integral feature for computational intelligence in a variety of domains, including text processing, speech analysis, image analysis, audio and video processing, and etc. CNNs, have shown themselves to be useful tools for a broad variety of applied problems. The common driving factors of this phenomenon are considered to be an appearance of massive datasets as well as increasingly powerful computing systems. To bridge the gap from high-level representation and low-level attributes, CNNs take as input source data, such as photos, and then execute a series of convolutional operations to gain knowledge rich information about the images. This ensures that the inputs are accurately mapped to the original values. Impressively, it has been recently discovered that CNNs can correspond or even surpass human quality in visual problems such as the classification of image features.

Pneumonia is a leading cause of mortality, accounting for more than four million deaths annually [9]. In terms of timely detection methods, chest X-rays is a prominent diagnostic tool for pneumonia. As for its advantages, chest X-rays are less expensive and can be performed anywhere in the world. Since the indications of pneumonia in X-ray data are not always coherent or readable to the human eye, the software may assist the medical expert in making a diagnosis of pneumonia owing to its fast rate and objective repeatable judgment, not least because of the computer has a high degree of objectivity. Besides, there are a few different decision making systems available, which may be used for the diagnosis and classification of pneumonia. It should be noted that the COVID-19 pandemic was the impetus for a fresh wave of research towards the creation of such diagnostic techniques. In due course, deep learning techniques will provide the backbone of the majority of the innovative approaches. In order to diagnose viral pneumonia [10] used VGG-16 architecture, Resnet-50 convolutional neural network, and Inception-V3 image recognition model, as well as transfer learning, and obtained from 71% to 88% accuracy on around 600 test photos.

Brunese et al. [11] developed a multiclass pneumonia identification system that was based on VGG16 structure and visual debugging method. Using this framework, they were able to obtain an accuracy of 96.2% on a collection of 6500 CXR pictures. When Panwar et al. [12] paired the VGG-19 network and GradCAM strategy, they managed to attain an overall accuracy of 95.6% within the context of a three-class pneumonia classification. In a similar manner, Ibrahim et al. [13] provided a method for the diagnosis of three classes of pneumonia by using VGG and Res-Net152V2 networks. Based

on their own collection of X-ray pictures, they got recall values ranging from 93–97%.

A surprising 98.62% efficiency was achieved using a three-stage hybrid model that was suggested by Jin et al. [14] and consisted of a feature representation, a feature selection, and a SVM classification stage. Karthik et al. [15] used the Channel-Shuffled Dual-Branched convolutional neural network to differentiate between several forms of pneumonia using a variety of datasets that were made accessible to the public. The researchers achieved scores ranging from 94% to 98%. When Quan et al. [16] applied combination of the DenseNet and CapsNet architectures, they obtained a recall of 96% on a COVID-19 dataset with a limited sample size, but with an accuracy of 90.7% on a bigger collection of pneumonia X-ray data. Alhudhaif et al. [17] applied a convolutional neural network that is 201 layers deep and obtained 90% and 95% accuracy and recall values on 6000 X-ray images, using the dataset provided by Kaggle. The design known as Mask R-CNN was used by Jaiswal et al. [18] in order to identify specific areas of the lung that were affected by pneumonia. The so-called CovXNet approach was developed by Mahmud et al. [19], a convolutional neural network that extracts a wide range of attributes from X-ray images by using depthwise convolution with varying dilation convolution rates. Based on 4697 X-ray pictures, Wang et al. [20] trained a visual geometry group architecture using what is likely the most extensive CXR picture dataset that is currently available. This dataset was released by the RSNA Pneumonia Detection Challenge and contains more than 120,000 individual images. When it came to the diagnosis of pneumonia, they had a success rate of 94.62%. The reader is encouraged to consult more recent review studies, such as [21-23], for further information about the current state of the art.

## III. DATA

The dataset consists of 5863 chest X-ray images collected in 2018 from the Women's and Children's Medical Center and the Laboratory of Regenerative Medicine and Healthcare in Guangzhou City [24]. Chest X-ray scans were taken as part of standard clinical examination, and the study objectives didn't include collecting data for this task. The data has been divided into Training, Test, and Validation sets, each of them containing subfolders for the image category as normal and pneumonia. X-ray images have a size of more than 1000 pixels per measurement and occupy more than 1.2 GB of memory.

Table I demonstrates train/test split of the applied dataset. Normal is a label for an X-ray of the healthy chest image, without signs of infectious and inflammatory lung diseases. Pneumonia label is a sign that characterizes a sick patient who has been diagnosed with pneumonia (Fig. 1). Before publication, all chest images were initially checked by removing low-quality unreadable images, as well as by muffling noise in the images. Diagnoses were determined by two highly qualified doctors. In order to prevent human error, all images were retested by a third expert before the machine learning model was trained. All these tests provide confidence in the authenticity and data integrity.

TABLE I. DATASET DESCRIPTION

Dataset	Normal	Pneumonia	Percentage	Dataset
Training	1341	3875	89.68%	Training
Test	234	390	6.7%	Test
Validation	8	8	0.28%	Validation

#### IV. MATERIALS AND METHODS

##### A. Block Diagram

A block diagram was built to show in detail what steps you need to go through and how to implement the model. A graphical representation of the entire process using diagrams and blocks is the best way to demonstrate the work process to audience. In its turn, our project has similar development stages, like in another image classification tasks. Each block

shows one development step. Sub blocks may occur within the blocks. They indicate a particular stage for the methods or functions that will be used. Arrows describes the right sequence of working process in our project. In total, creating an algorithm for classifying chest images takes 7 development stages. The process of solving the classification of X-ray images can be represented as a sequence of steps shown in Fig. 2.

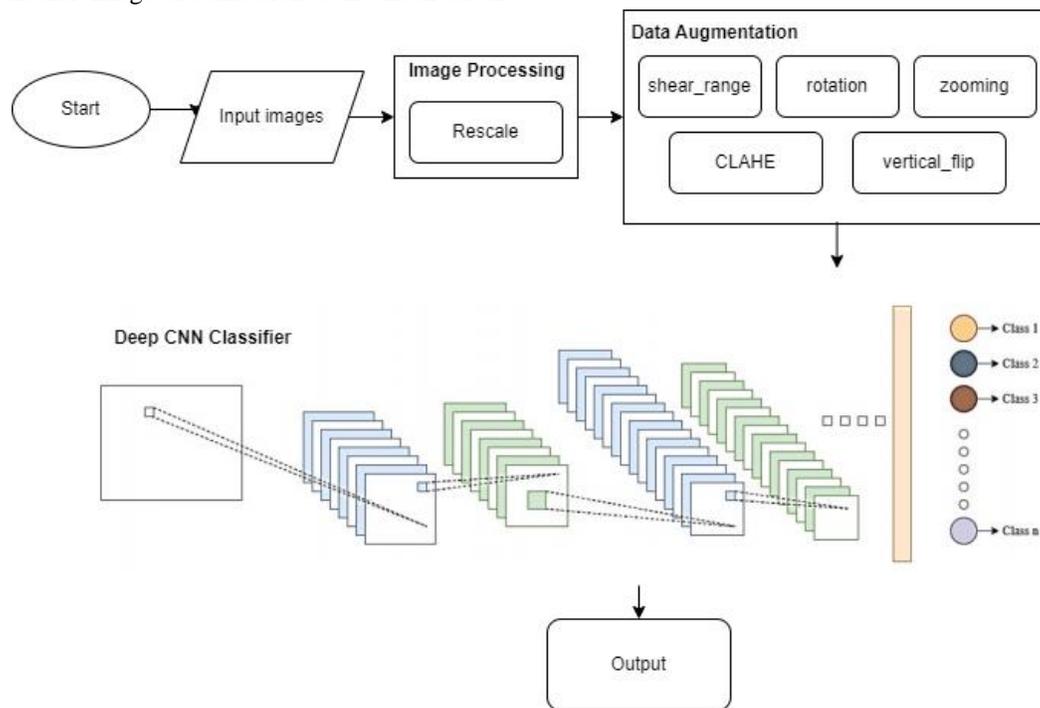

Fig. 2. The proposed framework architecture

The scheme begins with data input, this is the initial part where images are selected for further processing and submission to the model input. The first step of the algorithm is scaling, a constant that will multiply the data before any other processing. Since our source images consist of an RGB color model in the range 0-255, these values are very difficult to calculate. Therefore, we focus on values between 0 and 1, scaling by a factor of  $1/255$ , which is followed by data augmentation. Initially, the data has an imbalance of classes, and data augmentation is a powerful tool that in almost every case helps to increase the efficiency and reliability of the model. Afterwards, the clean data is used to build a CNN architecture. The algorithm takes an input data, assigns importance to various areas/objects in the image, and tries to distinguish one from the other. All parameters are optimized by minimizing the error on the training set by the backpropagation method.

### B. Image Preprocessing

As mentioned earlier, our data has 1000 pixels per chest image and a size of more than 1.2 GB, which means that we would not have enough memory space to simultaneously process such many images. To solve this problem, we needed to find a more efficient way to submit and process data.

To prevent memory loss, a data generator was created using the Python Keras library, which can be employed on top of the GPU installation. It generates our dataset on multiple cores in real-time and immediately transfers to our deep learning model. Separately, the image generator was also built for training, testing, and validation data. For training, we used data augmentation to prevent an imbalance within classes. The rescale argument is defined with the parameter  $1.0 / 255.0$ . After processing the image, we can see the outcome in Fig. 3.

### C. Data Augmentation

In case of class imbalance, Data Augmentation is the main part of image processing, which increases the number of objects of a smaller class as well as the accuracy of the model and creates variability in the data. The general scheme of data augmentation is illustrated in Fig. 4.

As shown in the figure, first the chest images pass through the transformation functions, which are initially determined by a medical specialist. Although there are numerous methods of image processing, such as rotation, shift, brightness, shift inten-

sity, horizontal flip, etc. each individual case employs their own augmentation methods. In our position, the training and test data splitted 80% to 20%. It can be noticed that the classes in the training data are noticeably different, so, in order to solve this problem, we used the following data processing techniques.

A data magnification is a method which generates new images by shifting elements in the image. The methodology is based on a shift or a slice of the image from both the X and Y axes. The measure of the shift or the probability of direction is set by the user as the `shear_range` argument for the `ImageDataGenerator` function. We used a small coefficient so that the change in the shape of the chest is insignificant (`shear_range = 0.2`). Example in Fig. 5.

The technique can change the angles at which our object is located. In the latest updates, images can be changed not only along the horizontal axis, but also to tilt in any direction. Moreover, the rotation method can improve the model and make it more stable on new data. In general, this method is beneficial for overtraining. If all images are served in a fixed position, it can improve the variety of images and increase the variation, which prevents the model from retraining. We used the `rotation_range = 10` argument of the `Image Data Generator` function (see Fig. 6).

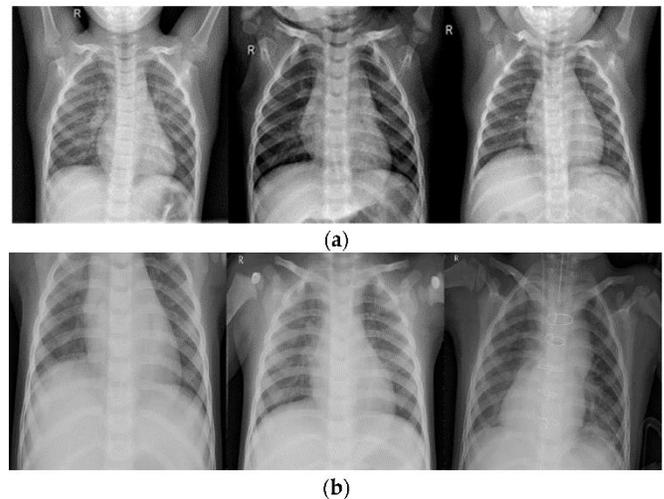

Fig. 3. Image before and after rescaling

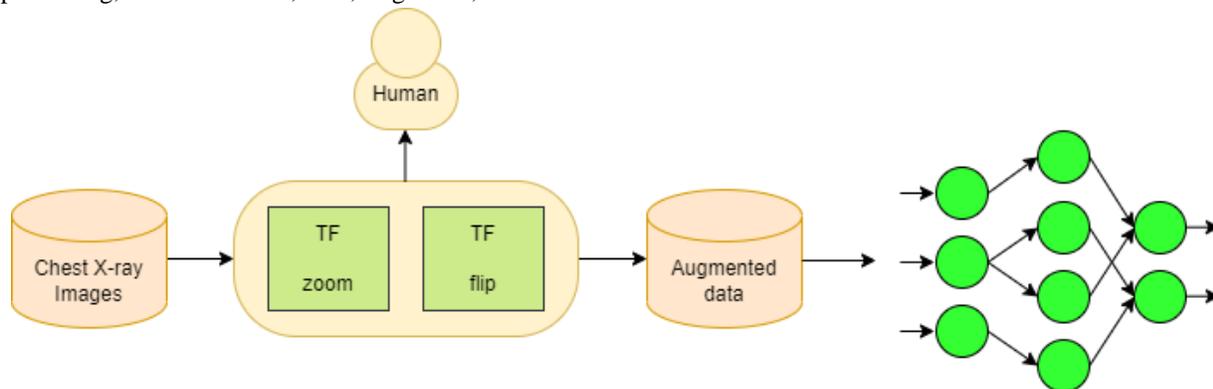

Fig. 4. The scheme of data augmentation (TF - transformation functions)

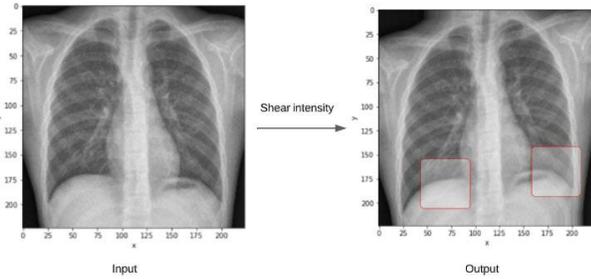

Fig. 5. Image after tuning share intensity

Fig. 6. Rotated image

The method simply increases the scale of the input image and can also add additional pixels around the image. It can take an integer, a floating-point number, and a tuple with numerical values as an argument. There are some restrictions, if the supplied number is less than 1.0, then it enlarges the image, if less than 1.0 it reduces. In our example, a coefficient equal to 0.3 is used.

A processing method that changes the contrast of an image; it is a modified AHE method, it prevents excessive noise amplification in the image, limiting contrast enhancement by setting a threshold that cuts off the histogram before calculating the cumulative distribution function. To use it in our data processing, a function was created, and was passed as an argument to the preprocessing\_function method ImageDataGenerator.

#### D. Proposed Model

Today convolutional neural networks are extensively used for classification, image segmentation and object detection projects. The principle of the algorithm is as follows, it assigns importance to each area of the image, and based on the weights, learn to distinguish one from the other. The architecture of a convolutional neural network is illustrated in Fig. 7.

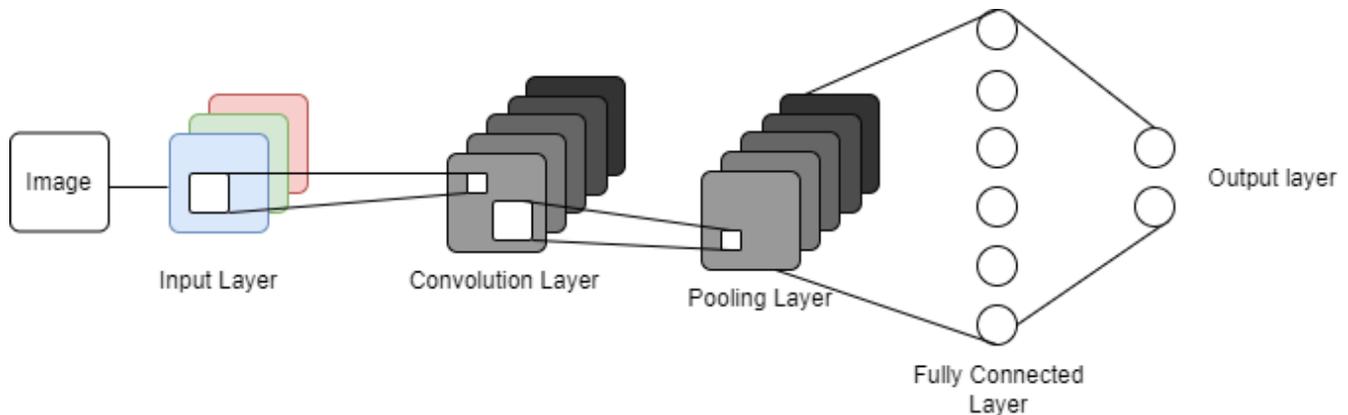

Fig. 7. Convolutional neural network architecture

As shown in the picture, the training steps can be divided into several stages: input layer, convolution layer, pooling layer, fully connected layer and output layer.

The first step of the algorithm is to prepare the image in the correct format to pass the model. In order to achieve this goal, we translated the images into a matrix view. If the input images have a black-and-white appearance, then in matrix form they will be of size  $n = m$ , which means the matrix will be in two-dimensional. Nevertheless, most often in the real world, the data will be colored, and due to this they will need to be stored in a three-dimensional matrix. In addition to width and height, the data includes a third channel, which is called chromatic. As soon as the images are ready, we move to the convolution layer.

Convolutional layer is considered as the main CNN layer. At this stage, the matrix form of our image takes a filter (core). The number of filters is determined arbitrarily with a size of  $3 \times 3$  or  $5 \times 5$ . This filter passes through the image and extract activation cards. During the pass, the filter is multiplied by the pixels in the image and summed by the formula:

$$x_j^l = f\left(\sum_i x_i^{l-1} * k_j^l + b_j^l\right) \quad (1)$$

Here,  $x_j^l$  is a feature map I (output of l layer),  $f(x)$  is an activation function, "\*" is a convolution operation of input x of the map, layer l,  $b_j^l$  is the coefficient of the layer l for the feature map j.

Pooling layer – the main goal in a CNN is to collect and reduce the dimension of the activation map. Regardless of what kind of unifying layer you use, it will always reduce the amount of computing effort of the network. The main two functions that are most often used in practice are:

- Average Pooling: Calculates the average value for its plot.
- Max Pooling: Selects the maximum value of the field in the activation map.

A fully connected layer is the most recent and basic layer of a convolutional neural network. It provides our ready and processed data to identify the answer. A fully connected layer combines all the previous layers, smoothest and transforms into a vector view.

In the last fully connected layer, various activation functions are used. As an activation layer, we take rectified linear unit (ReLU).

Our developed model consists of six convolutional neural networks. For the first layer, preliminarily processed images are submitted in a matrix format with a size of  $224 \times 224 \times 3$ . After each layer, max pooling is applied to lower the activation card. In the last block, convolution alignment is applied and sent as an input layer for the fully connected layer. The last output of the fully connected layer is two nodes that show whether a person is sick or not. To determine it, the softmax activation function is used. Adam was chosen as the optimization algorithm for the convolutional neural network. Thanks to this method, weights and learning rates are selected and changed, as well as model losses are reduced.

In order to characterize the correctness of our solutions, the loss function categorical cross entropy is used. The loss function has the following general form:

$$x_j^l = f\left(\sum_i x_i^{l-1} * k_j^l + b_j^l\right) \quad (2)$$

Here:  $\hat{y}_i$  is the  $i$ -th response of the model;

$y_i$  is the corresponding true value;

*outputsize* is the number of scalar values in the output of the model;

This loss describes our model very well and shows how two discrete probability distributions are distinguishable from each other. Architecture of the entire convolutional neural network is illustrated in Fig. 8.

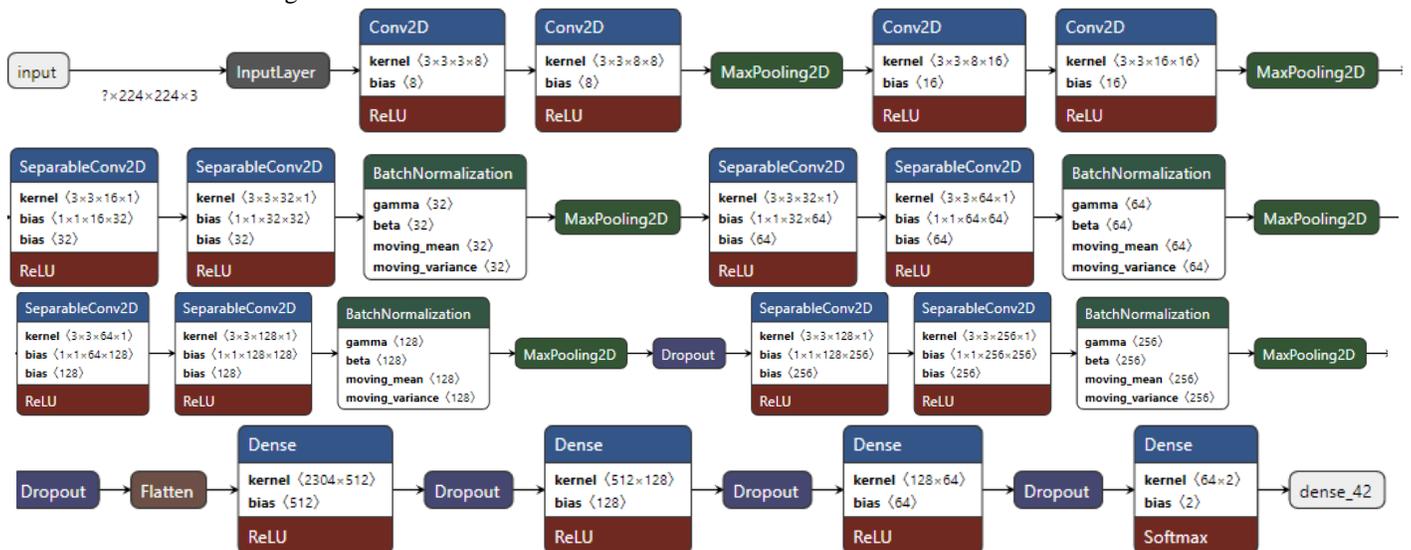

Fig. 8. Architecture of the proposed CNN model

### E. Normalization

Normalization is one of the main methods of preprocessing. It is used to standardize data, in short, converts data into the same range to reduce the computational time of the algorithm. The lack of normalization can lead to the complexity of the net-work and reduce the learning rate. In addition to standardization, it also helps to regularize the CNN model, which is one of its unintended advantages.

Specifically for our model, we used batch normalization. It is important not to get confused, since batch normalization is not used for source data, and it is activated between network layers. The data is divided into small chunks with an average value of 0 and a standard deviation of 1. After processing, each element of the original data simulates a standard normal distribution. Here you can see the batch normalization formula.

$$Z^N = \left( \frac{z - m_z}{s_z} \right) \quad (3)$$

Where:  $s_z$  – standard deviation of output data (neurons);

$m_z$  – average value of output data (neurons);

$z$  – input value for normalization;

### F. Evaluation Metrics

Evaluation criteria include Accuracy, Precision, Recall, and AUC-ROC curve. In this section, we explain each of the evaluation parameters that applied in current research.

Confusion Matrix: With the help of the confusion matrix, we can see in more detail how our model behaves in various situations (see Fig. 9). It not only shows the model's response errors, but also their types. Thus, such breakdown of the response helps to prevent limitations related to accuracy.

Accuracy: This is the ratio of the proportion of correct answers of the model to all its variables. For binary classification, the precision formula is defined as

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

Precision: This is the ratio of the model's true-positive responses to the total number of positive predictions. For example, if the precision value turned out to be 0.6, it means that if the model predicts that the patient has pneumonia, then it is correct for 60% of cases. Precision formula:

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

Recall: The recall characterizes the ability of the model to identify correctly positive samples. This means that for a good classification model, the recall should be closer to one. For example, if recall = 0.8, it means that the model determines 80% of pneumonia diseases. The formula for recall:

$$Recall = \frac{TP}{TP + FN} \quad (6)$$

AUC-ROC: The Receiver Operator Characteristic (ROC) is a probability curve that shows the ratio of TPR and FPR. They, in turn, separate the "signal" from the "noise". The Area under the Curve (AUC) is the area under this curve. The wider and larger it is, the better the classification model works.

### V. EXPERIMENTAL RESULTS

The accuracy of the model for training data has reached up to 91%, which indicates that the model classifies chest images adequately. However, it would be unpractical to reckon only one metric, in the light of an imbalance of classes. Therefore,

we compared other metrics as well, and Precision and recall are kept around 90 percent, and the quality of validation data has decreased. This happens because on the validation data we have only 16 new images that the model has not seen before, so the system operated correctly on 13, only 3 images have an erroneous result, which is a very good indicator.

More detailed statistics can be seen in Fig. 10, where the model's responses are recorded point-by-point for each case. Our neural network correctly found 372 patients with pneumonia and identified 194 healthy patients, while in some images the system mistakenly classified patients. In most cases, there is an ambiguity in the pictures, or the low quality of the pictures.

Fig. 11 demonstrates the AUC-ROC curves obtained by the proposed deep CNN on all the five folds of cross-validation. The obtained results show that, the proposed deep CNN gives high accuracy between 0.979 to 0.988 AUC-ROC value in pneumonia detection problem.

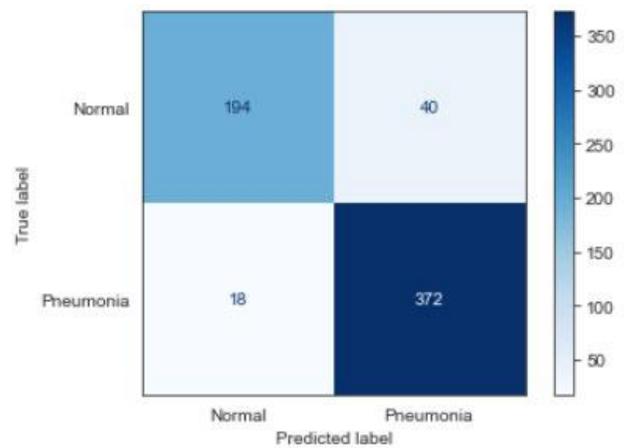

Fig. 9. Confusion matrix.

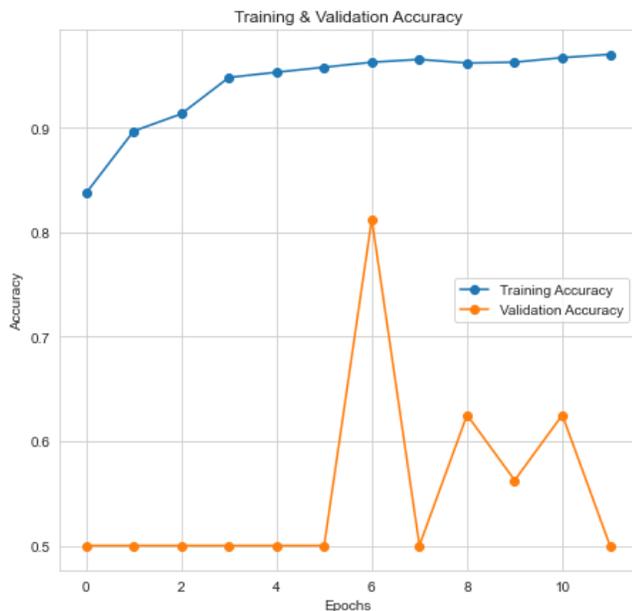

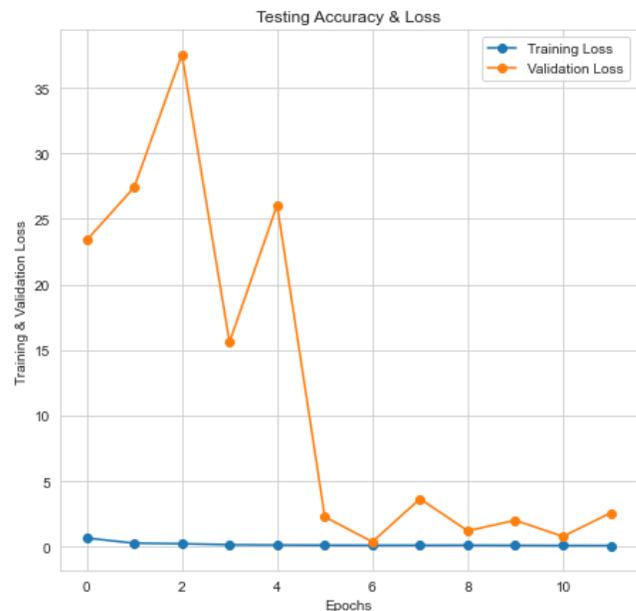

Fig. 10. Training and validation accuracy

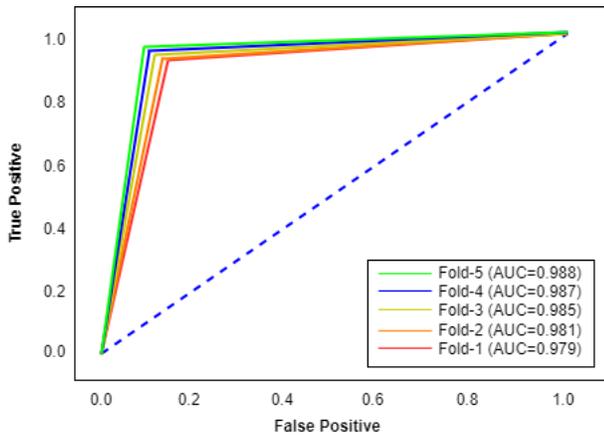

Fig. 11. AUC-ROC curve of the obtained results.

Fig. 12 demonstrates several examples of the obtained results using the proposed deep convolutional neural network, while Fig. 12(a) illustrates the case that the proposed model found no trace of pneumonia when ground truth coincides with that decision. Fig. 12(b) demonstrates that there is a pneumonia when the ground truth is pneumonia. Fig. 12(c) shows the case that the model found as a pneumonia, when there is no pneumonia that coincides the false positive case.

Table II compares the proposed deep convolutional neural network with the state-of-the-art studies that dedicated to deep learning based pneumonia detection. The results show that the proposed deep convolutional neural network shows high performance in terms of different evaluation parameters including accuracy (97.2%), precision (97.1%), recall (97.43%), F-score (96%), and AUC (98.8%).

a) Predicted class is false, ground truth is false    b) Predicted class is true, ground truth is true    c) Predicted class is true, ground truth is false

Fig. 12. Experimental results.

TABLE II. DATASET DESCRIPTION

Approach	Dataset	Number of images	Results
Proposed model	Kaggle CXR dataset [24]	5863	97.2% accuracy, 97.1% precision, 97.43% recall, 96% F-score, 98.8% AUC
EfficientNet B3 Model [25]	Dataset of X-ray images	13569	93.9% accuracy, 96.8% recall
COVID-net model [26]	COVIDx dataset	13975	92.4% accuracy, 88.6% recall
COVID-ResNet model [27]	Kaggle's COVID19 Global Forecasting dataset [28]	13945	96.23% accuracy, 96.92% recall
Customized CNN [29]	Chest X-Ray dataset [30]	5856	93.6% accuracy
CNN [31]	Chest X-Ray dataset [30]	5840	94.40% accuracy
VGG 16 [32]	Chest X-Ray dataset [30]	5856	84.5% accuracy
DenseNet-121 [33]	PadChest dataset [34]	5232	92.8% accuracy

## VI. DISCUSSION AND FUTURE RESEARCH

The experiments' results show that the proposed model, which is a lightweight CNN, not only performs a smaller number of calculations compared to the majority of deep learning models, but it also performs better in terms of important evaluation parameters as accuracy and recall. This can be observed when the number of variables is almost equal to an order of magnitude. Therefore, utilizing the depthwise separable convolution is beneficial in this situation. In light of the advent of deep learning, the majority of image processing

models now includes a huge number of attributes and need a significant amount of computation, making them unsuitable for implementation in embedded devices. When it comes to diagnosing pneumonia, which is a fairly frequent condition, there is also necessity to consider how to complete it in a timely and accurate manner in locations where medical equipment and medical professionals are unavailable. One of the reasons why we suggest utilizing the proposed deep CNN for pneumonia diagnosis is because of this particular benefit.

Recently some studies [15, 16] tried to develop a model from scratch or to adapt an existing model for the aim of identifying pneumonia. Next researches [13,14,17] concentrated on applying transfer learning and pretrained models. Meanwhile, Mahmud et al. [19] utilized a dataset from Kaggle [34], while Wang et al. [20] used training data from Mendeley, while the majority of studies [29-32] applied the Chest X-ray dataset [30]. In contrast to this work, a few other scholars [13, 15] did not employ any kind of data augmentation technique in their work.

Table II demonstrates that the proposed model has a recall of 97.43%, which makes sensitivity the most essential parameter in medical applications since it reveals the proportion of positive diagnoses that are accurate. When compared to the approach that has been proposed, all of the prior work [25-27, 29, 31-36] has been shown to produce a lower accuracy, sensitivity, precision, and F1 score than the way that has been recommended. In addition to this, the size of the dataset that they employed is far lower than the one that was used in this work. The structure of the suggested model is straightforward, which indicates that it converges quickly and does not call for a significant amount of processing resources. On the other hand, the generalization power of the recommended model is not on par with that of pretrained models. Only 5852 CXR images were utilized for the training of the suggested architecture, in contrast to the millions of photos that were used for the training of the pretrained models. The picture dataset that was employed for this research is insufficient to develop a credible CNN model with a high level of accuracy and to include all of the intrinsic image characteristics associated with pneumonia. In conclusion, the researchers who carried out the earlier studies did not provide sufficient information to carry out an exhaustive analysis; furthermore, they did not divulge the methodology that they applied in order to validate their data, and it is unclear whether or not they made use of cross validation like the current investigation did.

The fact that this study came up with almost faultless outcomes lends credibility and dependability to the applied methodology [37-40]. Lastly, the recommended model will have an influence on medicine. With the help of the proposed models, medical professionals working in rural regions will be able to diagnose pediatric pneumonia in a timely manner that is both cost-effective and accurate. In terms of older patients and younger children in particular, prompt and precise diagnosis of pneumonia may lessen the likelihood of deadly consequences from the disease. The interpretation variability and subjectivity issue that might arise while reading a chest X-ray radiograph can be helped by the suggested model. It may also be used to help inexperienced radiologists in distant places that lack professional radiologists to make a proper choice about a patient's treatment. The last phase is to create a mobile app that can differentiate between pneumonia and chest X-ray images, which will be used by airport personnel.

## VII. CONCLUSION

Our final task is to carry out this project in medical institutions, since AI helps hospitals, especially those with limited resources, quickly to examine suspected patients for

further diagnosis and treatment. In a few seconds after taking chest-X ray, the radiologist receives a notification about whether the patient needs to be assigned a high priority and enter a protocol for the treatment of pneumonia or not. More traditional methods may take longer to process due to an increase in the number of infected. Thus, AI has three valuable features during a serious outbreak:

- 1) Patients with symptoms are admitted to hospitals in large numbers, while AI can help to prioritize patients quickly.
- 2) AI serves as a supplement to the diagnosis of pneumonia, since the capabilities of the laboratory, even in cities with good equipment, are insufficient to work at a pace with the increase in the number of suspected cases. AI is an important supplement in an outbreak of a disease with high infectivity.
- 3) AI can easily compare changes and events in the lungs with different examinations of the same patient, which can be tedious and difficult for doctors, especially in the context of an epidemic situation.

All things considered, we firmly believe that that our project helps doctors for diagnosing pneumonia, provide immediate help to sick people and save time for doctors as well as patients.

**Abstract**—Infertility is a disease which scientists around the world are concerned with. The disease of infertility also is a worldwide health concern of many people in the community. The andrologists are continually searching for further developed techniques for any related problems. The intracytoplasmic sperm injection (ICSI) method is a widely recognized strategy for accomplishing pregnancy and considered as one of the best methods for infertility treatment worldwide. Choosing the best sperms are done using the vision through the specimen which is reliant on the abilities and the cleverness of the embryologists and as such inclined to human errors. Subsequently, a system that detects the normal sperms automatically is required for speedy and more precise outcomes. Deep learning approaches are usually effective for classification and detection purposes. This paper uses the Residential Energy Services Network (ResNet-50) deep learning architecture to recognize human sperms after classification of human sperm heads. The ResNet-50 proposed model achieved an accuracy of 96.66%. This proposed model demonstrated its efficiency at the detection of healthy sperms. The healthy sperms are used for the injection into eggs by the andrologists who always look for easier and more advanced methods in order to increase the success rate of ICSI process.

**Keywords**—Healthy sperms; sperm heads; infertility; classification; convolution; ResNet-50

## I. INTRODUCTION

Infertility is the failure of couples to accomplish pregnancy after twelve months despite having sex regularly [1]. The issue of the most couples around all countries is the infertility, around 30-40% of them associated with irregularities of male parameters as reported by WHO [2]. The main mission in the ICSI technique is the determination of the optimum sperms which can be used for fertilization of eggs. Embryologists select healthy sperms relying on the sperm shape by visual evaluation. This operation is difficult, tiring and prone to human errors. So, many researchers tend to AI approaches for finding better solutions for the detection of healthy sperms automatically.

The motivation of the paper comes from the need of laboratory technicians for automatic program to perform selection for healthy sperms that can be injected into oocytes. There are many precautions and conditions for the examination of sperm cells. The oversight processes about principles of quality, observation, testing, handling, protection, and storing of sperms are usually based on WHO guidelines [2]. Additionally, conditions in the space of assessment, capturing and the specifications of an equipment that influence

the vision of semen sample by the laboratory technician for the assessment. There is an extra factor influencing the precision in visual assessment which is the cleverness of the andrologists regarding other parameters that affect the sperm selection. To decrease the time of examination of sperms, computer vision and the processing of images have been utilized. Some previous studies did not prove their efficiency because of staining factors, fundamentally it is useful for the research purposes with neural network architectures that are designed using reinforcement learning [18], [19]. Also, there are many algorithms that are used for this purpose and will be discussed in detail next in the literature review section.

The examination of semen sample mostly performed according to the morphology [24]. Some consultations from the andrologists are needed when the examination of morphology is completed successfully. Subsequently, the right decision is taken about the healthy sperms that are suitable for injection process. According to the morphology also, computer-aided sperm analysis is done using the artificial intelligence [20].

The morphology of sperms is the most important parameter for the assessment of the sperm which defines the range of integrity of the shape and size of sperms. There are many factors that affect the quality of human semen [23]. The morphology of sperms is assessed under microscope after the general test of semen which also indicate the percent of morphology abnormalities [21], [22].

New advancements in optics and robotized microscopy have made experts ready to view and record huge number of images. The WHO guidelines are important for the selection of sperms and for the male infertility recognition. It is essentially to inspect the sperms for checking their validity for the injection [25]. The analysis of sperms is usually done according to the morphology and the motility of sperms.

The assisted reproductive technology (ART) is needed for the recognition of the best ways for the finding the healthy sperms for raising the rates of fertilization, and live birth. This system proved its advantages for getting good results with better accuracy for obtaining the normal sperms, which are referring to the normal sperm heads, which can be utilized in ICSI process after the detection using this system. The healthy sperms are used for the injection into eggs by the andrologists and then the fertilized egg is transferred into the uterus. One of the advantages of this study is its ability to deal with non-stained images that is similar to the captured images from microscope. The studies that deal with stained images are not

applicable because the stain is harmful for the human sperms and make them not suitable for the injection process.

Examination of images from in-vitro tests are normally restricted for andrologists at labs and andrology centers where they are responsible for the sperm processing with special tools. Besides, their perceptions follow particular precautions and rules and the semen microbiome has an impact on the infertility and affect the function of sperms [3]. Currently, the manual selection for healthy sperms can cause problems and it cannot be as accurate as automatic systems for sperm selection. On the other side, the automatic systems are labour saver, and it is not necessary for laboratories to provide skilled technicians for sperm selection in the intracytoplasmic sperm injection process. These reasons motivate us to propose a method which provides automated detection for the best sperms that can be used for increasing the success rate of ICSI process and for getting higher pregnancy success rate.

The main parts of the paper are arranged as follows: Section II explains the literature review for this paper. Section III explains the material and methods, showing the dataset, and describes the stages of preprocessing used in this paper. Section IV describes the proposed model for healthy sperm detection. Section V shows the results of this model. Section VI presents the conclusions of this research and refers to the fields of future work.

## II. LITERATURE REVIEW

Many studies about the analysis of sperms automatically using deep learning and machine learning that is important for the process of the intracytoplasmic sperm injection. Jason et al. presented a model for sperm classification of sperms by VGG16 architecture with high accuracy [4]. Soroush et al. introduced a model for the assessment of sperms with three parts [5]. Abolghasem et al. presented a method for sperm recognition with tail and neck with accuracy of 93.2% [6]. Miahi et al. improved an architecture for vacuole abnormality recognition with an accuracy of 91.66% [7]. Prabakaran et al. presented a CNN network for the detection of abnormal sperms with abnormal dimensions with 98.99% of accuracy and approved the efficiency of the program [8]. P., Zuhdi et al. [9] introduced DeepSperm, a profound brain network that utilizes a particular discovery layer to identify little items. The creators expanded the info goal of the organization, utilized a dropout layer and played out an information increase procedure in view of immersion and openness changes. The acquired outcomes beat the cutting-edge regarding accuracy, speed and computational calculations. S. Hicks et al. proved the importance of deep learning in the processing of videos of movable sperms. They used three videos in which labelled manually by the andrologists, the labels were bounding boxes for the egg, catheter and sperm. YOLOv5 model was used for tracking and detection of sperms. The three used videos were separated as two videos for training and one video for validation. The accuracy of eggs' tracking reaches 92% and for ICSI pipette reaches 94%. The author concludes the importance of deep learning for the detection of sperms for performing successful intracytoplasmic sperm injection process [10].

Ruth Marín et al. proposed the deep learning for and studied the effectiveness of transfer learning for the segmentation of sperms. They used public dataset (SCIAN-SpermSegGS) in which evaluated using Mask RCNN and U-net. The U-net model reaches 95% of segmentation for sperm head which consider a promising result for using the computer assisted systems for this purpose [11]. Lee et al. developed an algorithm for the detection of the human sperms with machine learning using microsurgical testicular sperm extraction utilizing bright-field microscopy in which the sperms were collected from healthy men. The algorithm used the CNN based on the U-Net architecture. In this study, the algorithm achieved 91% PPV and this make the rare sperms can be detected with biopsy samples using machine learning [12].

Raffael Golomngi et al. presented automated deep convolutional network the deep learning VGG19 was used for the implementation with accuracy reaches 93%. This method used labelling with bounding boxes for the detection of sperms. This study shows its success on images acquired by the optical microscope [13]. Aristoteles et al. used deep learning approaches for healthy sperms detection using video tracking using deep learning with result 90.31% average precision sperms and the system detects the non-sperm parts automatically rather than the manual methods that require more time and high costs [14]. Ahmad Mashaal et al. proposed a system for the recognition of healthy sperms using VGG16 deep learning model and used Otsu's thresholding method for the segmentation of sperm head and other methods for the enhancement of images with accuracy reached 97.92% [17].

## III. MATERIAL AND METHODS

This section is divided into two parts, description of sperm head dataset, preprocessing methods of sperm head images with showing the impact of these methods on images. In the first part, all information about the dataset. In the second part, the main preprocessing methods for images will be explained.

### A. Dataset

The Dataset is free for using, used by McCallum et al [15]. The dataset was processed before using, and then classified into normal and abnormal sperm heads with the aid of andrologists. Dataset is divided into test dataset, validation dataset and training dataset. The dataset contains 1200 images which divided into 240 images for testing, 240 images for validation, and 720 images for training, the dataset divided into 2 classes as healthy and unhealthy sperm as represented in Fig. 1.

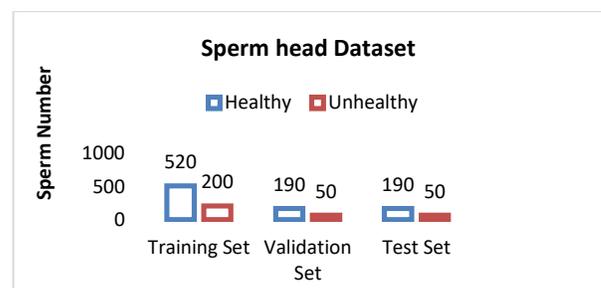

Fig. 1. Number of Normal and Abnormal Sperm Head Dataset.

## B. Preprocessing

Image preprocessing through this research is explained as the following:

1) *Image denoising*: In this step, the median filter is used for removing the salt and pepper noise for all images for making the images more suitable for the proposed method.

2) *Image normalization*: This method is used for changing the range for values of pixel intensity in image for getting a better contrast image, this process is used for adjusting the contrast of sperm head images as shown in the image Fig. 2. The linear normalization of an image is represented as the following formula:

$$O = \frac{255*(i-n)}{(m-n)} \quad (1)$$

where O is the output channel and it is the output value which is calculated, I is the input channel, n is the lowest value for pixel intensity and m is the highest value for pixel intensity.

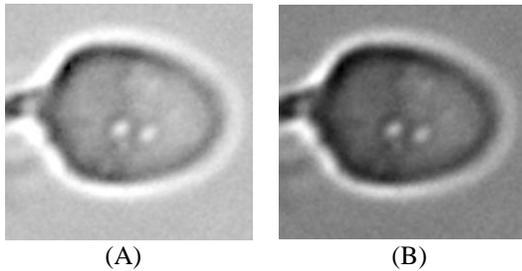

Fig. 2. Pre-processing of images. (A) Image before normalization. (B) Image after normalization.

3) *Image augmentation*: Data augmentation is a method used usually for changing the shape of images and make them little different using versatile parameters that modify the images for increasing the number of training images. Data augmentation of images is done while the training of sperm images. This is performed by ImageDataGenerator class of deep learning Keras library with using different augmentation parameters. The data augmentation is so important for increasing the accuracy of validation and training curves and for decreasing the loss of validation and training curves while training through epochs. The data augmentation contribute to minimize the overfitting.

## IV. THE PROPOSED RESNET-50 MODEL

The architecture ResNet-50 is one of the powerful deep neural networks which is used for classification tasks [16]. The ResNet-50 is used in this paper for classification of sperm heads for the best sperm detection that can be utilized in the injection into oocytes during performing the ICSI process. The convolution process is the method in which the two arrays of same or different sizes are multiplied to be merged giving third result, but it is necessary that the two arrays have the same dimensions. The mask or the matrix of convolution used may be called 'Kernel' and it is used to move over the convolution getting the required information with fewer dimensions and help in the convolution operation.

We can manage the image using this operation and get results with many processing operations for images including image sharpening, image blurring, controlling the contrast of the image and decreasing and increasing the brightness of the image.

The resulted image of this process is resulted from the rolling of the mask over all pixels of image and the final result of the multiplications are combined together and a particular calculation operation is applied resulting new pixel value that takes place in the new image and these steps are repeated for all pixels.

In this study, the better sperms can be identified utilizing ResNet50. In the beginning, the images were collected, some operation methods are important before accessing by ResNet-50. The proposed ResNet-50 model was effective in this process and it is composed of layers of convolution followed by some layers as shown in Fig. 3. The salt and pepper noise was eliminated by median filter and the training and evaluation of model should be done. Therefore, any unknown image will go through preprocessing steps after insertion for the detection. The preprocessing stages contribute to increasing the rate of success of this model then the success of the detection method with high rates. The convolution algorithm is necessary to be implemented using the convolution equation as the following:

$$O(u, v) = (F * C)(u, v) = \sum_x \sum_z M(u - X, v - Z)C(x, z) \quad (2)$$

where C is the convolution kernel of size x, O is the feature map of the output, F is the feature map of the input and (u, v) is the size of image.

Convolution steps can be described as:

- Multiplying the filter with the input image using the convolution equation.
- Multiplying each element with the element in the position then the results will be summed producing one output value.
- These steps will be reiterated by sliding the filter over the image for obtaining the output.

Average pooling in this proposed model is used for down sampling feature maps by computing the average value in each patch of a feature map. Fully connected is a layer which has multiple neurons. Dropout layer and batch normalization used for avoiding the overfitting problems. The sigmoid function is the output function and it is used for sperm head detection. The sigmoid function can be represented as the following,

$$S(x) = \frac{1}{1 + e^{-x}} \quad (3)$$

where S(x) is the sigmoid function of a variable x

The rectified linear unit (ReLU) is an activation function that makes the output like the input directly if it is positive, otherwise, makes the output zero. The ReLU activation function can be given as the following:

$$f(x) = \max(0, x) \quad (4)$$

where f(x) is the ReLU activation function of a variable x.

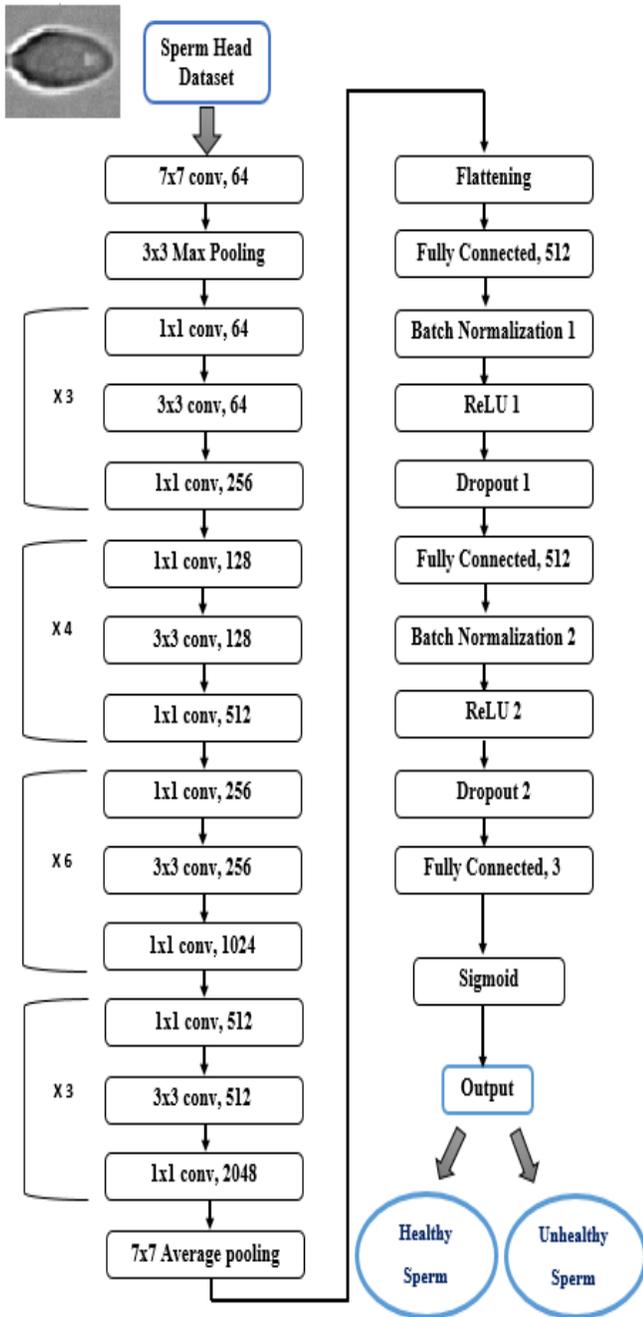

Fig. 3. The proposed resnet-50 model for healthy sperm detection.

### V. RESULTS AND DISCUSSION

The results of this proposed model demonstrated their effectiveness for the detection of normal sperms that can be utilized for the ICSI process with high accuracy. The proposed ResNet-50 model is an efficient deep learning model for classification of images and proved that in this study. In this paper, we got 165 TP value, 5 FN value, 3 FP value and 67 TN value as shown in the confusion matrix in Table I. The proposed model proved its efficiency with high accuracy reaches 96.66%, sensitivity equals 97.06%, precision equals 98.21%, Specificity equals 95.71% and F1 Score equals

97.63% as shown in Table II according to the formulas [5]–[9]. The accuracy considered as the fraction of total results that is predicted correctly to the overall number of samples. The precision is known as the proportion of values of true positive to overall predicted positive values, the sensitivity is the proportion of true positive values to total actual positive values, and the specificity is the proportion of values of true negative to the overall negative values. The detection results of this model are Normal or Abnormal as shown in Fig. 4 for the inserted unknown images. The performance of the proposed model is shown in Fig. 5 with training and validation accuracy respectively reached 97.82% and 98.41% after training with 120 epochs. The training and validation loss respectively reached 1.4026 and 1.5254. The ResNet-50 proposed model in this study is more suitable for sperm detection than other models with simpler preprocessing stages. The advantage of this proposed model is the possibility of getting accurate results quickly for making the ICSI process much easier for the andrologists.

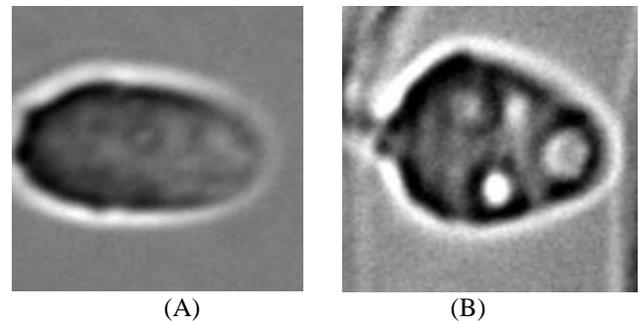

Fig. 4. Results of unknown images. (A) Normal sperm result. (B) Abnormal sperm result.

$$Accuracy = \frac{TN+TP}{TN+TP+FP+FN} \quad (5)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (6)$$

$$Precision = \frac{TP}{TP+FP} \quad (7)$$

$$Specificity = \frac{TN}{TN+FP} \quad (8)$$

$$F1\ Score = \frac{2 * Precision * Sensitivity}{(Precision+Sensitivity)} \quad (9)$$

## VI. CONCLUSION AND FUTURE WORK

In this proposed model, the normal human sperms needed for the intracytoplasmic sperm injection process are recognized automatically. Andrologists are interested in easier tools for the optimum selection of healthy sperms for injection process into eggs. This study proved a technique using ResNet-50 and its outputs have been accepted and approved by the embryologists. In this paper, ResNet-50 proved the efficiency of the recognition of normal sperm and that is better than machine learning. The proposed deep learning model ResNet-50 resulting in high accuracy of 96.66% and this is one of the advantages of this study rather than the other model results in relative studies part. The ResNet-50 model has given its advantages for the detection of healthy sperms with automatic system in a quick and accurate way. The technology in methods of sperm selection is needed for the recognition of the best sperms that are required for raising success rate of ICSI operations. This system proved its distinction for obtaining good results with better accuracy for obtaining the normal sperms which referring to the normal sperm heads that can be utilized through ICSI process. One of the advantages of this study is its ability to deal with non-stained images that is similar to the captured images from microscope. Most of studies deal with stained images that are not applicable because the stain is harmful for the human sperms and make them not suitable for the injection process.

In the future, various models of deep learning can be utilized for achieving more accurate results. Developing algorithms for the detection of sperms using videos which can be built in microscope for real time detection of live sperms.

# Research on Image Sharpness Enhancement Technology based on Depth Learning

Wenbao Lan\*, Chang Che

School of Civil Engineering, Harbin University, Harbin, 150086, China

**Abstract**—Image technology is widely used in security, traffic, monitoring, and other social activities. However, these images carrying detailed information will have feature distortion due to various external physical factors in social ingestion, transmission, and storage, resulting in poor image quality and clarity. Resolution determines the definition of an image. Super-resolution reconstruction is the process of transforming a low-resolution picture into a high-resolution image. To enhance the image clarity, this experiment introduces the advantages and disadvantages of the Super Resolution Convolutional Network (SRCNN) and Fast Super Resolution Convolutional Neural Network (FSRCNN) model and then constructs an image super resolution method based on DSRCNN. The algorithm consists of two sub-network blocks, an enhancement block and a purification block. The model first uses two Convolutional Neural Networks (CNN) to obtain complementary low-frequency information that improves the model's learning ability; next, it employs an enhancement block to fuse the image features of two paths via residual operation and sub-pixel convolution to prevent the loss of low-resolution image information; finally, it employs a feature purification block to refine high-frequency information that more accurately represents the predicted high-quality image. It is found that the PSNR and SSIM of the DSRCNN model can reach 33.43dB and 0.9157dB, respectively.

**Keywords**—Super resolution convolutional network; fast super resolution convolutional neural network; dual super-resolution convolutional network; deep learning; image definition; super resolution; image enhancement

## I. INTRODUCTION

Pictures captured in social life are often affected by the light, shelter, poor shooting equipment, and other factors. Such shootings have poor visibility, low contrast, high noise, and other shortcomings [1]. These shortcomings make the image definition fail to reach the ideal state, which affects the regular operation of some links to social activities. Picture sharpness is directly related to the image resolution. High-resolution images have more detail and are of superior quality [2]. Processing a series of low-resolution images to obtain high-resolution images is called super-resolution reconstruction. Traditional image super-resolution reconstruction is mainly based on interpolation, machine learning, and multiple images. Researchers value the super-resolution reconstruction technology based on deep learning algorithms because of the ongoing changes in computing technology [3]. The deep learning algorithm mainly learns the high-level semantic features of data through the transformation of multi-level nonlinear structure. It can achieve reasonable and effective prediction and analysis of data [4]. Classical depth learning algorithms include SRCNN, FSRCNN, VDSR, etc. These

super-resolution reconstruction technologies can improve image clarity, but there are still some limitations in operation efficiency and visual effects [5]. Therefore, this experiment suggests an image definition improvement technique based on deep learning algorithms to improve the picture quality with inadequate definition, aiming to add reference value to image applications in social activities such as security, traffic, monitoring, etc.

## II. RELATED WORK

At present, the application of depth learning is very broad, and it has been dabbled in various research fields. Wang S et al. used depth learning algorithm to recognize tumor images, and introduced the whole process of depth learning algorithm in pathological image segmentation in detail. The research shows that the deep learning algorithm has obvious advantages in recognition accuracy, overall computational efficiency and generalization performance. In addition, integrating in-depth learning into the field of pathological image analysis is a far-reaching experiment in medicine [6]. Huang and other researchers found that traditional machine learning methods had limited prediction ability for landslide prone environmental factors, so they proposed a FC-SAE algorithm based on deep learning. To predict categorization, the system employs both high-level and low-level information about environmental elements. The simulation results show that the prediction rate and accuracy rate of FC-SAE can reach 85.4% and 85.2%, higher than other algorithms of the same type, so it has a good application prospect [7]. Sharma and other scholars explored deep neural networks based on machine learning. For the goal of conducting research on the use of machine learning and deep learning in different sectors, they examined and improved the current machine learning and deep learning algorithms. The final survey results show that the accuracy of deep learning algorithms has been significantly improved [8]. Zhang and other researchers conducted research on deep learning algorithms in the field of geological engineering. This paper mainly studies the application of FNN, RNN, CNN and GAN depth learning algorithms in geotechnical engineering, compiles a detailed summary containing literature, cases and depth learning algorithms, and prospects the application of depth learning algorithms in geotechnical engineering [9]. Aslan and others found that malware is constantly developing and seriously endangering the network security environment. Based on this malignant situation, they propose to use deep learning algorithm to detect malicious software. The suggested deep learning algorithm is a novel hybrid architecture that combines two comprehensive pre-training network models, which makes it different from conventional approaches. The

experimental findings demonstrate that the model can classify malware with an accuracy of 97.78% [10]. Bamisile and other scholars used machine learning algorithm and depth learning algorithm to predict solar radiation. SVR, RF, and their learning models as well as ANN, CNN, and RNN deep learning models are each utilized in the experiment to forecast solar radiation, and the outcomes of these predictions are compared. The final results show that the deep learning model has better accuracy and takes less time than the machine learning model in solar radiation prediction [11].

For the research of image enhancement technology, most researchers have made contributions to it. An underwater image enhancement approach based on MLE was suggested by Zhang and other researchers to address the issues of poor color and low visibility of underwater photos. The method first adjusts the color and detail of the image by the principle of minimum color loss, then uses the integral graph to calculate the mean and variance of the image block, and finally introduces a color balance strategy to balance the color difference of the image. The outcomes of the experiment demonstrate that this technique is very applicable to picture enhancement [12]. Ike C and other researchers proposed a single image super-resolution method based on wavelet. The experiment combines wavelet transform with local regularization anchored domain regression model and applies it to image restoration. Experimental results show that the proposed method is effective and superior in denoising, deblurring and super-resolution reconstruction tasks [13]. Zhang and other scholars proposed a method that can enhance the image contrast while improving the embedded data, namely the improved RDH-CE model. The model offers an adaptive pixel modification technique and extracts several characteristics to aid K-means clustering. According to the final testing findings, this technique has a greater accuracy level for complicated assessment [14]. Liu and other researchers used MSRCR algorithm and guided filtering method to de fog the image. To provide a better visual impact, this approach may successfully address the issues of poor picture lighting, color distortion, and edge loss while preserving the color saturation of the image [15]. A band restricted biphasic technique was suggested by Su et al. to enhance the quality of the reconstructed picture. By using this technique, the precise spatial frequency components impacted

by the spatial offset of DPHs may be removed, preventing the picture quality from being compromised. According to the outcomes of the simulation experiment, the strategy enhances the definition of the rebuilt picture by 36.84% [16]. To solve the serious distortion problem of underwater images, Liu et al. proposed an image enhancement method based on object guided dual confrontation contrast learning, which uses contrast prompts in the training phase. The experiment demonstrates that the suggested strategy enhances the image's visual quality and increases the detector's precision [17].

Deep learning algorithm is favored by researchers in various fields for its convenient and powerful performance, and its application is also more extensive. In recent years, the research on image enhancement technology has never stopped, and many scholars have used different algorithms to explore it. In conclusion, deep learning algorithm and image enhancement technology have made considerable progress. It is an innovative attempt to apply the depth learning algorithm to the image definition enhancement technology, so this experiment starts to study this topic.

### III. CONSTRUCTION OF IMAGE DEFINITION ENHANCEMENT MODEL BASED ON DEPTH LEARNING ALGORITHM

#### A. Research on Image Super-resolution Model based on Depth Learning

The resolution of an image determines its definition, and super resolution is the resolution of an image that has been enhanced using a variety of efficient techniques. Super Resolution refers to the technique of processing a number of low-resolution photographs to produce high resolution images (SP), which mainly includes the reconstruction of a single image and the reconstruction of multiple images [18-19]. Super Resolution Convolutional Network (SRCNN) is a milestone for depth learning algorithm to achieve super-resolution image reconstruction [20]. SRCNN uses a three-layer convolutional neural network to achieve image reconstruction, that is, to preprocess the low-resolution image through cubic interpolation. Fig. 1 illustrates the three components that make up the SRCNN model, namely block precipitation and representation, nonlinear mapping and reconstruction. The three modules correspond to three convolution operations in the network.

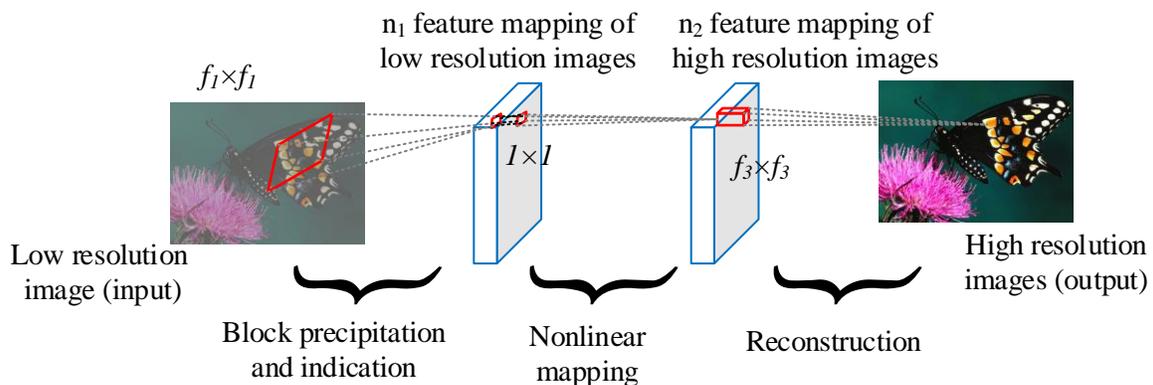

Fig. 1. Network structure of SRCNN.

$B$  represents low resolution image;  $A$  represent real high-resolution images; the mapping function of the network is  $f(\cdot)$ . Consequently, the equation for block precipitation and module expression in SRCNN is as follows:

$$f_1(B) = \max(0, W_1 * B + \delta_1) \quad (1)$$

In Formula (1),  $W_1$  represents the weight of the convolution core of the block precipitation module;  $\delta_1$  indicates the offset of the convolution core of the block precipitation module.  $\max$  represents the corresponding ReLU activation function;  $f_1(B)$  represents block precipitation. The nonlinear mapping of the network is called "convolution+activation", and its functional expression is:

$$f_2(B) = \max(0, W_2 * f_1(B) + \delta_2) \quad (2)$$

In Formula (2),  $W_2$  represents the weight of the nonlinear mapping module's convolution kernel,  $B_2$  represents the offset of the convolution kernel of the nonlinear mapping module;  $f_2(B)$  represents a nonlinear mapping. The network reconstruction process is the third convolution operation. Unlike the two modules mentioned above, the activation function is no longer used in this process. Its function expression is:

$$f(B) = W_3 * f_2(B) + \delta_3 \quad (3)$$

In Formula (3),  $W_3$  represents the weight of the convolution core of the reconstruction module,  $\delta_3$  represents the offset of the convolution core of the reconstruction module, and  $f(B)$  represents the reconstruction. The advantage of SRCNN model is that it contains fewer parameters than other deep convolution neural networks. As a result, by using fewer learning parameters, it may significantly minimize the number of calculations required by the model, thus improving the overall model operation efficiency. The loss function of SRCNN is the mean variance between the super resolution image  $f(B)$  and the original real high resolution image  $A$ . The specific calculation formula is as follows:

$$L(\theta) = \frac{1}{n} \sum_{i=1}^n \|f(B_i; \theta) - A_i\|^2 \quad (4)$$

In Formula (4),  $n$  represents the number of samples in the training set,  $f(B_i, \theta)$  represents the minimum reconstructed image, and  $A_i$  represents the high-resolution image. The loss of mean variance represents the loss mean of a batch, which is an evaluation index of commonly used image high-resolution algorithms. Although the classic SRCNN network has been able to repair low resolution images with different coefficients, the SRCNN network still has limitations that cannot meet the real-time requirements. Thus, FSRCNN network came into being. FSRCNN network consists of five parts: feature extraction, compression, mapping, expansion and transpose

convolution [21-22]. The FSRCNN network is used to extract and compress the image features, and then the activation function pair is used for nonlinear mapping. The activation function of FSRCNN may activate the gradient of the negative half axis in addition to the SRCNN's activation function. The precise formula may be written as follows:

$$g(x_i) = \max(x_i, 0) + a_i * \min(0, x_i) \quad (5)$$

In Formula (5),  $x_i$  represents the input signal of the activation function in the  $i$ -th channel;  $a_i$  represents the coefficient of the negative part. The activation function has more stable performance. The calculation complexity of FSRCNN model can be expressed as:

$$O\left\{\left(25d + sd + 9ms^2 + ds + 81d\right)S_{LR}\right\} = O\left\{\left(9ms^2 + 2sd + 106d\right)S_{LR}\right\} \quad (6)$$

In Formula (6),  $d$  represents the characteristic layer before compression;  $s$  represents the compressed feature layer; And both meet  $s < d$ .  $m$  indicates the number of layers of the volume. It can be seen from Formula (6) that the computational complexity of FSRCNN model is in linear proportion to LR image, and its computational complexity is also less than SRCNN. The loss function calculation formula of FSRCNN can be expressed as:

$$\min_{\theta} \frac{1}{n} \sum_{i=1}^n \|f(B_s^i; \theta) - A^i\|_2^2 \quad (7)$$

In Formula (7),  $A^i$  represents the  $i$ -th high-definition image in the data set;  $B_s^i$  represents the  $i$ -th resolution image in the dataset.  $f(B_s^i; \theta)$  represents the output of the model. Compared with SRCNN network, FSRCNN network is mainly improved in three aspects, namely, the change of feature dimension, the replacement of convolution core with more mapping layers and the sharing of mapping layers. Although SRCNN and FSRCNN both improve the quality of super resolution images, they are generally slow and not suitable for real application scenarios. The research on the application of depth learning algorithm to the improvement of super-resolution image quality needs to be further deepened.

### B. Improvement of Image Definition Enhancement Model based on Fusion of Depth Learning Algorithm

In this experiment, a dual super resolution CNN (DSRCNN) is designed based on SRCNN and FSRCNN models. The network consists of two sub network modules, enhancement blocks and feature purification blocks. Two sub network blocks enhance the super resolution performance of the network by extracting complementary low-frequency features; the enhancement block gathers several high-frequency characteristics via residual operation and sub-pixel convolution; the feature purification block uses multiple stacked convolutions to refine high-frequency features [23-24]. The process of extracting complementary low-frequency features from two sub network blocks of DSRCNN model is as follows:

$$O_{TSEB} = f_{TSEB}(I_{LR}) = \left( Cat(O_{TSEB_1}, O_{TSEB_2}) \right) \quad (8)$$

In Formula (8),  $O_{TSEB_1}$  and  $O_{TSEB_2}$  represent the output of two subnetworks, and  $Cat$  represents the connection operation. In the second stage, the two subnetworks select the combination of reusing residual operation and convolution to enhance the effect of local level information. The formula can be expressed as:

$$O_{TSEB_k} = R(O_{L1} + O_{L2} + O_{L5} + O_{L7} + O_{Li} + \dots) \quad (9)$$

In Formula (9),  $O_{(TSEB_k)}$  represents the output of  $k$  sub network,  $O_{Li}$  represents the output of the  $i$ -th convolution layer, and  $R$  represents ReLU function. The purpose of the model's enhancement block is to combine the original picture data and gain deeper data. This module first obtains the original image and deeper information, and obtains the characteristics of the first layer in the sub network:

$$\begin{aligned} O_{(EB_1)} &= Subp(R(O_{L1})) \\ O_{(EB_i)} &= Subp(O_{TSEB}) \end{aligned} \quad (10)$$

In Formula (10),  $O_{(EB_1)}$  stands for the shallow layer's high-frequency properties, and  $O_{(EB_i)}$  for the deep layer's high-frequency features.  $Subp$  represents sub-pixel convolution technology. Then, the second level features are obtained from the features in the residual operation fusion formula (10), and its functional expression is:

$$O_{EB} = f_{EB}(O_{TSEB}) = R(O_{(EB_1)} + O_{(EB_i)}) \quad (11)$$

In Formula (11),  $O_{(EB)}$  represents the output of the enhancement block, serves as the purification block of the feature,  $+$  represents a residual operation, and  $f_{EB}$  represents the function of the enhancement block. The feature purification block equation can be expressed as:

$$I_{SR} = f_{FLB}(O_{EB}) = C\left(R\left(C\left(R\left(C\left(R\left(C\left(R\left(C\left(O_{EB}\right)\right)\right)\right)\right)\right)\right)\right)\right) \quad (12)$$

Formula (12) constructs a five layer feature purification block, which contains four convolution operations and activation functions, and can be used to build high-quality predicted images. In Formula (12),  $C$  represents the convolution operation, and  $I_{SR}$  represents the predicted SR image. The DSRCNN's execution procedure may be stated as follows:

$$I_{SR} = f\left(f_{EB}\left(f_{TSEB}\left(I_{LR}\right)\right)\right) = f_{DSRCNN}\left(I_{LR}\right) \quad (13)$$

In Formula (13),  $f_{TSEB}$  represents the function of two subnets,  $f_{EB}$  represents the function of enhancement block,  $f_{FLB}$  represents the function of feature purification block, and

$I_{LR}$  represents the given LR image. DSRCNN mainly obtains complementary low-frequency information through dual CNN to improve the learning ability of the model. Then, to prevent the loss of low resolution picture information, the enhancement block merges the image characteristics of two separate image routes using residual operation and sub-pixel convolution. In order to properly reflect the anticipated high-quality picture, high-frequency information is refined using the feature purification block [25]. The above process is described in detail in Fig. 2.

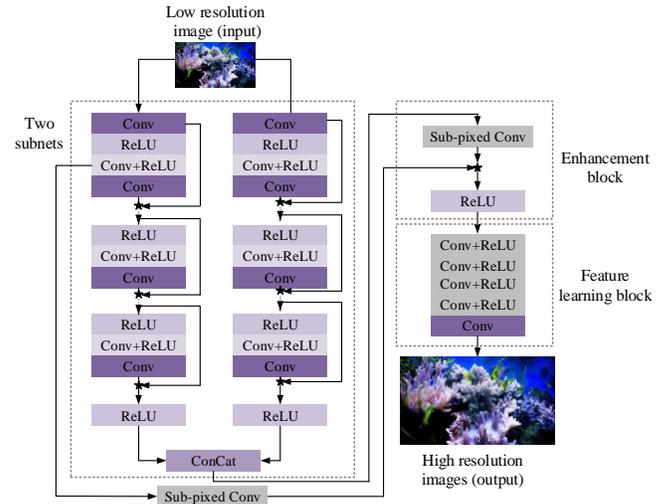

Fig. 2. Network architecture of DSRCNN.

The difference between the actual high-quality picture and the anticipated SR image serves as the mean square error, which is how the loss function of DSRCNN is still stated. The specific function expression is:

$$l(p) = \frac{1}{2N} \sum_{(k=1)}^N \left\| f_{DSRCNN}(I_{LR}^k - I_{HR}^k) \right\|^2 \quad (14)$$

In Formula (14),  $I_{LR}^k$  represents a given low resolution image,  $I_{HR}^k$  represents a given high resolution image,  $N$  represents the total number of training samples, and  $p$  represents the parameter set for training a DSRCNN. The value of  $l(p)$  is calculated from the training pair  $\{I_{LR}^k, I_{HR}^k\}$ . PSNR and SSIM can be selected as quantitative and objective evaluation indicators for model evaluation. Suppose the length and width of a noise image are  $M$  and  $N$  respectively,  $K$  represents the noise image,  $I$  represents the clean image, and their mean variance formula is:

$$MSE = \frac{1}{mn} \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} [I(i, j) - K(i, j)]^2 \quad (15)$$

In Formula (15),  $i$  represents the feature in the  $i$ -th column of the picture,  $j$  represents the feature in the  $j$ -th column of the picture, and the formula of PSNR can be expressed as:

$$PSNR = 10 \cdot \log_{10} \left( \frac{MAX_I^2}{MSE} \right) \quad (16)$$

PSNR is measured in dBs. The less the value is, the less the picture will be warped. The PSNR index, which bases its judgment of picture quality on the associated pixel error, ignores the visual properties of the human eye. Because the human eye has a high visual sensitivity to space, brightness, color, etc., the evaluation results of PSNR are often inconsistent with the subjective feelings of the human eye. Structural similarity requires difference processing for target images  $X$  and  $Y$ .  $\mu_x$  and  $\mu_y$  respectively stand for the mean values of images  $X$  and  $Y$ ,  $\sigma_x$  and  $\sigma_y$  respectively stand for the variances of images  $X$  and  $Y$ , and  $\sigma_{xy}$  stands for the covariance of images  $X$  and  $Y$ . The formula is as follows:

$$\begin{aligned} \mu_x &= \frac{1}{M \times N} \sum_{i=1}^M \sum_{j=1}^N X(i, j) \\ \sigma_x &= \left( \frac{1}{M \times N - 1} \sum_{i=1}^M \sum_{j=1}^N (X(i, j) - \mu_x)^2 \right)^{\frac{1}{2}} \\ \sigma_{xy} &= \frac{1}{M \times N - 1} \sum_{i=1}^M \sum_{j=1}^N (X(i, j) - \mu_x)(Y(i, j) - \mu_y) \end{aligned} \quad (17)$$

SSIM assesses how similar pictures are in terms of structure, contrast, and brightness. The contrast formula is as follows:

$$\begin{aligned} l(X, Y) &= \frac{2\mu_x\mu_y + C_1}{\mu_x^2 + \mu_y^2 + C_1} \\ c(X, Y) &= \frac{2\sigma_x\sigma_y + C_2}{\sigma_x^2 + \sigma_y^2 + C_2} \\ s(X, Y) &= \frac{\sigma_{xy} + C_3}{\sigma_x\sigma_y + C_3} \end{aligned} \quad (18)$$

In Formula (18),  $c_1$ ,  $c_2$  and  $c_3$  are three constants, and there is no coefficient of any variable between them, but they cannot be removed. The formula of SSIM can be expressed as:

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \quad (19)$$

SSIM has a value range of 0 to 1. The picture distortion decreases with increasing value, and image quality and clarity increase. In the calculation process, it is also necessary to cut the global pixels of the image, and the structural similarity obtained is the global structural similarity.

#### IV. PERFORMANCE VERIFICATION OF IMAGE DEFINITION ENHANCEMENT MODEL BASED ON DSRCNN

To more accurately verify the image super-resolution reconstruction performance of the model, four data sets, Set5, Set14, BSD100 and Urban100, were selected for the experiment, and the contrast experiments were carried out under the conditions that the image magnification coefficient

was 2 times, 3 times and 4 times. Set5 consists of five images: children, birds, butterflies, flowers and women. 14 photos make up the data set known as ‘‘Set14,’’ which is often used to evaluate the effectiveness of image super-resolution models. The BSD100 dataset contains 100 daily life events, which are often used for image denoising and super-resolution testing. Urban100 is an image data set with the theme of street view, in which the images show complex color characteristics, and their objects have clear shapes and corners. The conditions under which Set5 and Set14’s photos were taken are the same. BSD100 and Urban100 both provide 100 photos in natural color. The experimental training set and test set each include 100 natural photos, and the image data in the data set DIV2K is chosen. Table I shows the settings of other experimental parameters.

TABLE I. EXPERIMENTAL PARAMETER SETTING TABLE

Experimental parameters	Set value	Experimental parameters	Set value
Batch size	64.000	Training step	600000
Parameters Beta1	0.900	Epsilon	100000000
Parameters Beta2	0.999	Learning rate of model training 1	0.0004
Initial learning rate	0.001	Learning rate of model training 2	0.00005

Fig. 3 shows the visual test results of SRCNN model, FSRCNN model and DSRCNN model on visual graphics. To create these visual graphics, select a specific area of the anticipated super-resolution image as the observation area. The data in the figure shows that the PSNR and SSIM values of SRCNN model are 27.002 and 0.928; PSNR and SSIM values of FSRCNN model are 30.783 and 0.8666; The PSNR and SSIM values of the DSRCNN model are 33.783 and 0.9688. It can be observed from the above data that in the three models, since DSRCNN’s PSNR and SSIM values are the greatest, its images exhibit the least amount of distortion. This demonstrates that the DSRCNN model performs superior to the other two models.

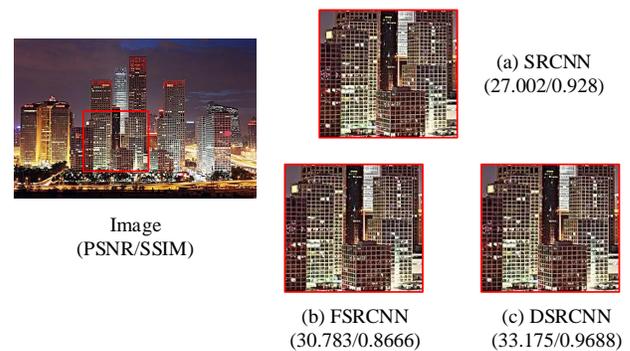

Fig. 3. Visual diagram of three models.

Table II shows the comparison of PSNR and SSIM values of different modules of DSRCNN in Urban100 dataset with twice the image magnification factor. The results in the table demonstrate that local residual learning is efficient for the development of model performance as the PSNR and SSIM values of the DSRCNN network are better than those of the DSRCNN model with residual learning method. It is observed

that the DSRCNN model is superior to the DSRCNN with only one subnet, and the two subnets in the table model contribute to the performance improvement of the model. The PSNR value of DSRCNN with enhancement block is 0.454dB higher than that of DSRCNN without enhancement block, which verifies the improvement of network performance by enhancement block. The PSNR and SSIM values of the DSRCNN model with feature purification block are 0.16dB and 0.011dB higher than those of the DSRCNN model without feature purification block, respectively, which proves that the feature purification block can improve the network performance. As a result, the three modules in the DSRCNN model proposed in the experiment all have different contributions to their own performance improvement, and this model can improve the image quality.

To better compare the performance of the DSRCNN model proposed in this paper, in addition to the comparison with the SRCNN model, the experiment also selects six other popular depth learning models, a total of 10 models, to conduct experiments to compare and analyze their performance. The popular models selected are Bicubic model, CNF model, MemNet model, CARN-M model, WaveRestNet model and LESRCNN-S model. Fig. 4 displays the variations in PSNR and SSIM values for the chosen model on the Set5 dataset at 2, 3, and 4 times the original picture size. When the image is magnified twice, the DSRCNN model can have the next highest PSNR value, 37.74dB. When the image magnification is 3 times, the DSRCNN model has the highest PSNR value, 34.17dB. When the image magnification is 4 times, the DSRCNN model achieves the highest SSIM value of 0.8907. On the whole. The DSRCNN model shows relatively stable performance on the Set5 dataset.

Fig. 5 displays the changes in PSNR and SSIM values for several models using the Set14 dataset with picture magnifications of 2, 3, and 4. When the image is magnified twice, the PSNR value of the DSRCNN model is 33.43, which is the highest among all models. At the same time, its SSIM

value is 0.9157, which is the highest among all models. When the magnification of the image is 3 times, the PSNR of the DSRCNN model is still the highest among all models, 30.24, and its SSIM value is 0.8402, which also keeps the highest record. When the image magnification is 4 times, the PSNR value of the DSRCNN model is 28.46, and the SSIM value is 0.7796. Although it has decreased, it still maintains the highest value of all models. On the Set14 dataset, it is clear that the DSRCNN model performs well.

Fig. 6 displays the variations in PSNR and SSIM values for several models on the BSD100 dataset at 2, 3, and 4 times the original picture size. When the image magnification is 2 times, the PSNR value of the DSRCNN model is 32.05 and the SSIM value is 0.8978. When the image magnification is 3 times, the PSNR value of the DSRCNN model is 29.01 and the SSIM value is 0.8029, ranking first among all models. When the image magnification is 4 times, the PSNR value of the DSRCNN model is 27.50, and the SSIM value is 0.7341, which is also in the first place. This shows that on the BSD100 dataset, the DSRCNN model still has better performance than other models.

TABLE II. COMPARISON OF PSNR VALUE AND SSIM VALUE OF DIFFERENT MODULES IN DSRCNN ON URBAN100 DATASET WITH TWICE IMAGE MAGNIFICATION FACTOR

Methods	Urban100
	PSNR/SSIM
DSRCNN with one sub-network ,without RLO	31.675/0.9236
DSRCNN with one sub-network and EB_S, without RLO,	31.221/0.9181
DSRCNN with one sub-network EB_S andRO,without RLO	31.061/0.9170
DSRCNN with EB_S , without RLO	31.648/0.9237
DSRCNN without RLO	31.700/0.9237
DSRCNN	31.834/0.9253

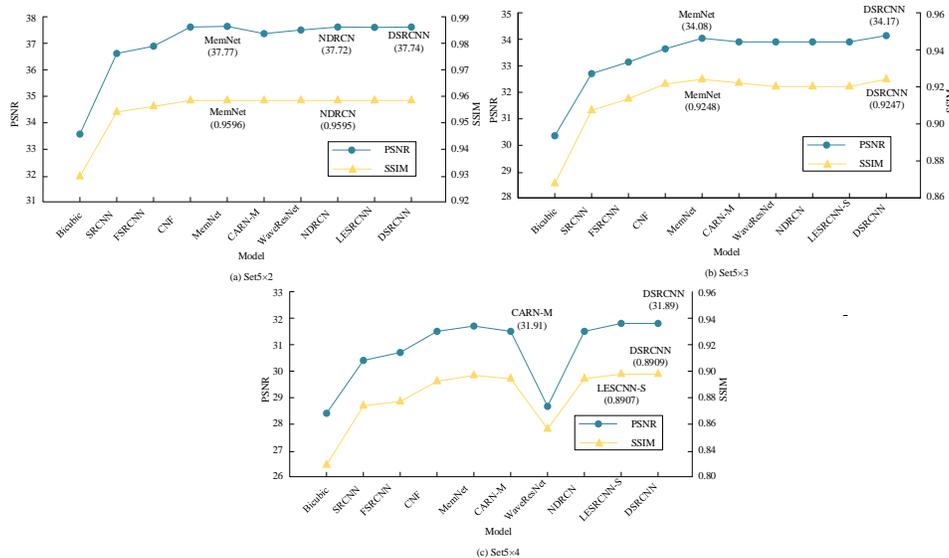

Fig. 4. Changes of PSNR and SSIM values of different models on Set5.

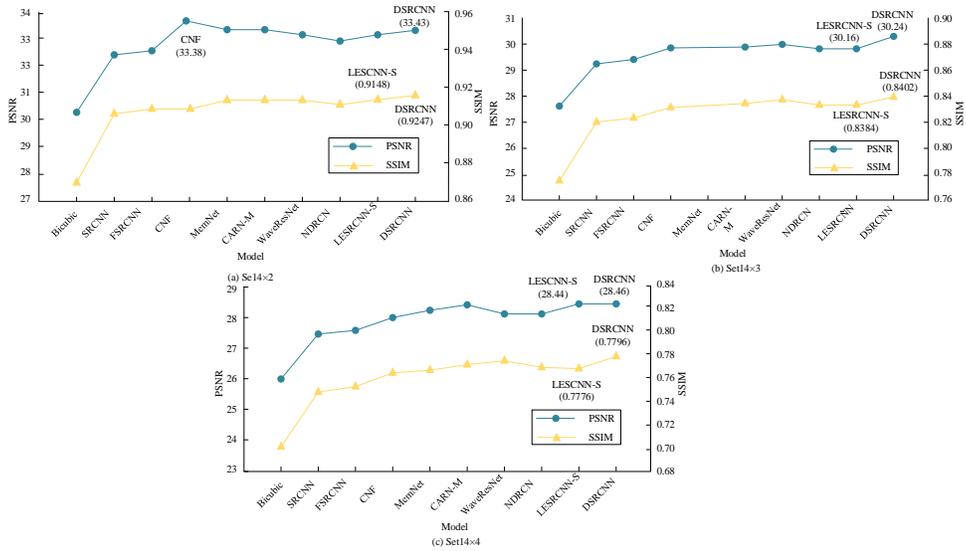

Fig. 5. Changes of PSNR and SSIM values of different models on Set14.

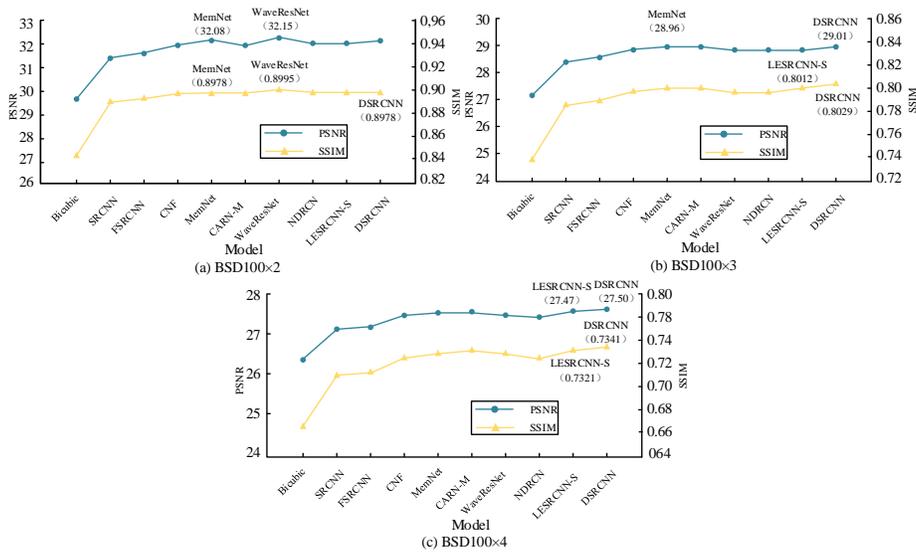

Fig. 6. Changes of PSNR and SSIM values of different models on BSD100.

Fig. 7 displays the variations in PSNR and SSIM values between models using the Urban100 dataset with picture magnifications of 2, 3, and 4. When the image magnification is 2 times, the PSNR value of the DSRCNN model is 31.83, and the SSIM value is 0.9252, which is the highest among all models. When the image magnification is 3 times, the PSNR value of the DSRCNN model is 27.76, and the SSIM value is 0.8483, ranking the highest among all models. When the image magnification is 4 times, the PSNR value of the DSRCNN model is 25.94, and the SSIM value is 0.7815, which is always the first of all models. This shows that the DSRCNN model also has good performance on the Urban100 dataset.

Fig. 8 shows that on the dataset Urban100, when the magnification factor is 4 times the visual effect of different models, the data in the figure shows that the PSNR and SSIM values are highest for the DSRCNN model. To test the effectiveness of the DSRCNN model based on the deep learning algorithm, four distinct datasets are chosen. The

results showed that the PSNR and SSIM values of DSRCNN model fluctuated in different data sets for different models, but among the 10 chosen models, image processing performance as a whole was best. This shows that the DSRCNN model can handle the image processing, making the final image less distorted, improving its separation rate, and thus enhancing the image clarity.

Table III shows the network complexity analysis results of DSRCNN and the four models selected in the experiment. It can be seen from the table that the number of parameters of DSRCNN model is much smaller than that of the other models on the Urban100 dataset with 2, 3 and 4 times of image magnification. In addition, its number of operations (Flops) is also less than other models. The comparison results further reflect the superior data processing ability and performance of DSRCNN. At the same time, it also verifies the innovation of DSRCNN for image data processing methods.

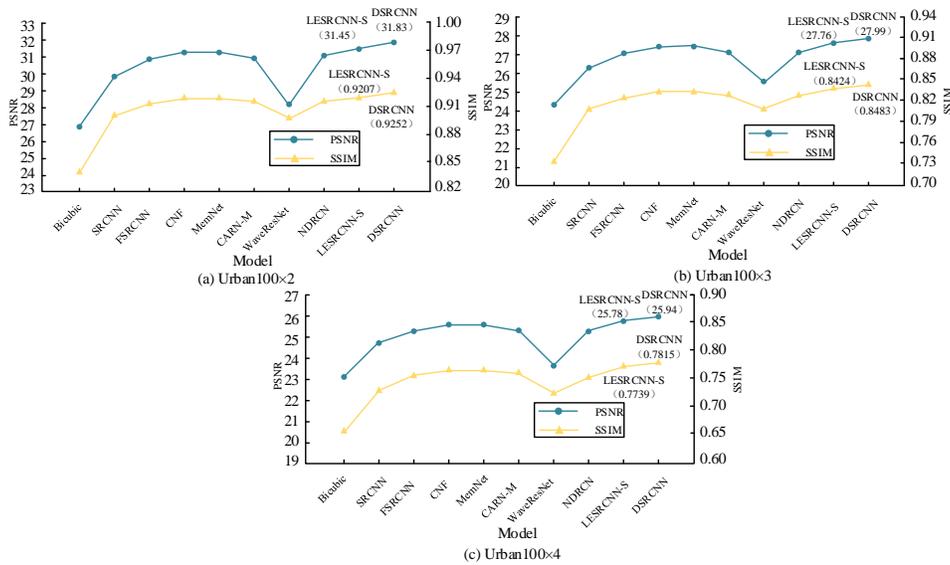

Fig. 7. Changes of PSNR and SSIM values of different models on Urban100.

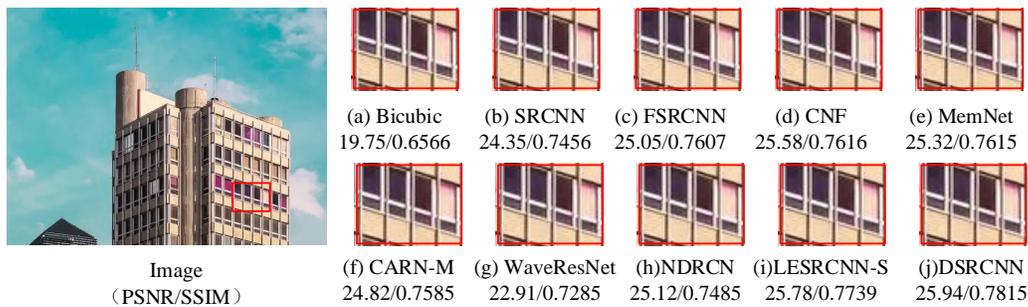

Fig. 8. Visual effects of different models.

TABLE III. COMPARISON OF MODEL PARAMETERS

Methods	Scale×2		Scale×4		Scale×6	
	Parameter quantity(K)	Flops(G)	Parameter quantity(K)	Flops(G)	Parameter quantity(K)	Flops(G)
WaveRe Net	664	10.90	675	11.23	789	12.35
LESRCNN-s	557	9.12	603	10.12	667	11.24
SRCNN	879	29.06	978	30.14	1023	31.23
FSRCNN	789	11.09	856	12.03	964	12.99
DSRCNN	550	5.56	563	6.23	574	7.02

## V. CONCLUSION

Image technology is widely used in security, traffic, monitoring, and other social activities because it can carry detailed information. To improve the distortion in the process of image acquisition, transmission and storage, the DSRCNN model for image super-resolution reconstruction is established from the perspective of image super-resolution reconstruction and depth learning technology. This experiment aims to improve the image definition. In social ingestion, transmission, and storage, image features will be distorted due to various external factors, resulting in poor image quality and clarity. In this experiment, a DSRCNN model is built for image super-resolution reconstruction from the viewpoint of image super-resolution reconstruction and depth learning techniques to

improve the definition of the picture. At first, the performance of the DSRCNN model, SRCNN model, and FSRCNN is compared. The PSNR and SSIM values of the SRCNN model are 27.002 and 0.928. The FSRCNN model is 30.783 and 0.8666, the DSRCNN model is 33.783 and 0.9688, and so on, which verifies that the DSRCNN model has superior performance. To further explore the DSRCNN model, four different data sets are selected to verify the model performance. Under various picture magnifications, the PSNR and SSIM values of DSRCNN models in various data sets likewise change. In the data set Set14, when the magnification is 2, the DSRCNN model has the highest PSNR and SSIM values, 33.43 and 0.9157, respectively. Therefore, the DSRCNN model can effectively process the image, reduce image distortion, and improve its resolution, enhancing image clarity.

This experiment basically achieved the purpose of the experiment. In the future, we can consider putting forward effective solutions to the visual shape differentiation in the DSRCNN model.

**Abstract**—The detection of falls has emerged as an important topic for the public to discuss because of the prevalence and severity of unintentional falls, particularly among the elderly. A Fall Detection System, known as an FDS, is a system that gathers data from wearable Internet-of-Things (IoT) device and classifies the outcomes to distinguish falls from other activities and call for prompt medical aid in the event of a fall. In this paper, we determine either fall or not fall using machine learning prior to our collected fall dataset from accelerometer sensor. From the acceleration data, the input features are extracted and deployed to supervised machine learning (ML) algorithms namely, Support Vector Machine (SVM), Decision Tree, and Naïve Bayes. The results show that the accuracy of fall detection reaches 95%, 97 % and 91% without any false alarms for the SVM, Decision Tree, and Naïve Bayes, respectively.

**Keywords**—Fall detection; machine learning; acceleration data; SVM; decision tree; Naïve Bayes; IoT

## I. INTRODUCTION

Human falling is feared because it may have both physical and psychological consequences. Compared to younger individuals, elderly have a higher chance of fall [1]. According to the World Health Organization (WHO), elderly represent 20 percent of the world's population [2]. By 2030, the global population aged 60 and more is estimated to reach 1.4 billion, and by 2050, it is estimated to increase from 962 million to 2.1 billion, compared to 2017 [1]. Falls has perturbing influence on the elderly, which may shorten their life expectancy. People older than 65 years often experience a fall every year at a rate of around one-third of the population. In addition to ageing, falling incidents also caused by a few other variables, including environment, level of physical activity, and cardiovascular problems. This can cause bodily harm, and the treatment for these injuries often requires a long stay in medical healthcare centers. The fear of falling, which limits older individuals' ability to engage in their Activities of Daily Life (ADL), is the major physiological problem they face. This concern leads to activity limitation, which may lead to insufficient gait balance and reduced muscle, both of which hinder an older adult's mobility and independence. Therefore, remote wearable technologies are necessary to monitor, detect, and avoid falls to enhance the quality of life in general (QoL). As a result of this, a knowledge of falls may be split into two categories: fall prevention and fall detection. It is possible to consider fall detection to be the process of detecting a fall via the use of sensors or cameras to contact medical personnel. For the

purpose of detecting and preventing falls, several systems that make use of a variety of sensors and algorithms have been created [2]. Referring to the dataset source [3], we learn that there is no machine learning applied, and SisFall dataset [4] are bias to western body structure, contras to this work preference that aims for Asian-based ADLs. For this reason, we have applied different machine learning algorithms to classify our previous collected data.

In this paper, we used the ASEAN experiments by own database, where do not depends on the other database and this is what distinguishes the work of this paper. Fig. 1 shows the overview of the system procedure.

Section II discusses the literature review. Section III overviews the machine learning algorithms employed in this work. The research methodology including data collection is explained in Section IV. Section V discusses the results. Section VI concludes this work.

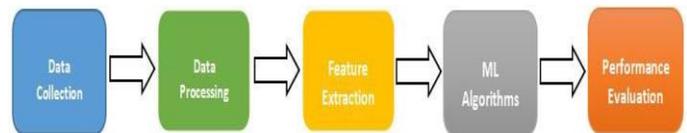

Fig. 1. The overview of system procedure.

## II. LITERATURE REVIEW

Ali et al. [5] compared the classification accuracy and execution speed of the J48 and to AdaBoost classifiers for fall detection. The proposed fall prototype was built by varying many distinguishing parameters, including velocity, geometric orientation, and geometric location. The results showed that 99.03 % fall detection accuracy. The execution time of the J48 classifier was 0.01 milliseconds, whereas the execution time of the AdaBoost classifier was 0.025 milliseconds.

Nevertheless, the effectiveness of these classifiers simplifies complex subjects, such as people wearing identical clothing or having the same backdrop colour. Min et al. [6] studied the area under the ROC curve (Receiver operating characteristic), they analysed the performance of faster recurrent neural network (RCNN). The proposed system identified falls by analyzing the situation. Based on deep learning and activity characteristics, they proposed a unique technique for recognizing human falls on furniture. Include other human characteristics, such as speed of motion, centroid, and aspect ratio. The outcome was an AUC of 0.941% and a

precision of 93%. Zhang et al. [7] developed a fall detector using the Support Vector Machine (SVM) algorithm. The detector was equipped with a single accelerometer worn at the waist. Accelerations in both directions, variations in acceleration, and other factors were among the features for machine learning. Their method successfully detected falls approximately 96.7% of overall cases. The suggested approach included the incorporation of an accelerometer into a mobile phone for the purpose of determining the occurrence of falls. The body-fixed sensor made detection more difficult, putting the mobile phone in a pocket or wearing it around the neck made it more difficult. About 93.3% of occurrences, the mobile phone system properly triggered the warning.

Using five wireless accelerometers and a wireless heart rate monitor, Tapia et al. [8] developed a real-time method for automated detection not only of physical activities, but also in certain situations, by utilizing a wireless heart rate monitor and five separate triaxial accelerometers. The shoulder, the wrist, the hip, the thigh, and the ankle were attached to the accelerometers. A predefined window size was used to recover the characteristics from the time and frequency domains of the signal. Some of these characteristics are the Fast Fourier Transform (FFT) peaks, variance, energy, and correlation coefficients. Classifiers, such as C4.5 and Naive Bayes were used in order to separate activity into the following three categories: postures (such as standing and sitting), activities (such as walking and cycling), and other activities (running, using stairs, etc.). When subject-dependent training was used, the recognition accuracy for these three classes was 94.6%, but subject-independent training resulted in just 56.3% of accuracy.

Xiong [9] also introduced a skeleton-based 3D consecutive-low-pooling neural network (S3D-CNN). Compared to existing methodologies, the proposed method fared the best on publicly available and user-collected datasets. Wang et al. [10] proposed a fall detection system comprised of many sensors. They used Multisource CNN Ensemble (MCNNE) architecture to enhance the accuracy of detection. They discovered that MCNNE outperforms both a single CNN structure and a multitude of ensembled bi-model structures. Hnoohom et al. [11] used sensor data from accelerometers and gyroscopes to compare the performance of conventional ensemble learning. Whether the sensor is placed on the arm or the waist, the study's results imply that strategies based on ensemble learning may improve detection accuracy.

Considering all the above aspects in the proposed system there is no analysis for the current data-set which used in this study. It shows the obtained results of comparison by using different machine learning algorithms to detect elderly fall.

### III. MACHINE LEARNING ALGORITHMS

ML gives the system the ability to learn from the dataset and the patterns in the data by using them as inputs. During the data gathering procedure, sensors offer information of several fall parameters. Then, machine learning techniques are employed to categorize or detect fall behaviour depending on the application requirements. The following is kinds of the machine learning (ML) algorithms that are commonly utilized for fall detection and prevention, and used in this work as

well [2].

#### A. Support Vector Machine

The support vector machine (SVM), which is a kind of supervised machine learning model, may be used to determine the location of a hyperplane in a space that has  $n$  dimensions (where  $N$  is the number of features that distinctly divide the data). Although the support vector machine, also known as an SVM, may be used for both, classification and regression analysis, the former is where its principal application resides. Linear and non-linear support vector machines (SVM) are the two different types of this kind of machine. The linear classifier works on the assumption that all of the data points may be linearly divided into groups. As a consequence of this, it differentiates between the two classes by picking the hyperplane that maximizes the margin in the best possible way. Before determining a discriminant function, the non-linear classifier that is most usually employed maps the data using a kernel. This step is followed by the determination of the function. This discriminant function is linked to the hyperplane in the space that has been transformed. In addition to this, the kernel is used for pattern analysis in a number of other machine learning techniques [2]. Support Vector Machine (SVM) has one of the highest fall classification accuracies among the machine learning methods examined [12]. Where, the findings revealed that the linear SVM was one of the optimal classifiers for this cross-dataset validation strategy, as it accurately discriminated a fall event from typical day-to-day activities with a great accuracy rate and comparably high sensitivity and specificity [13].

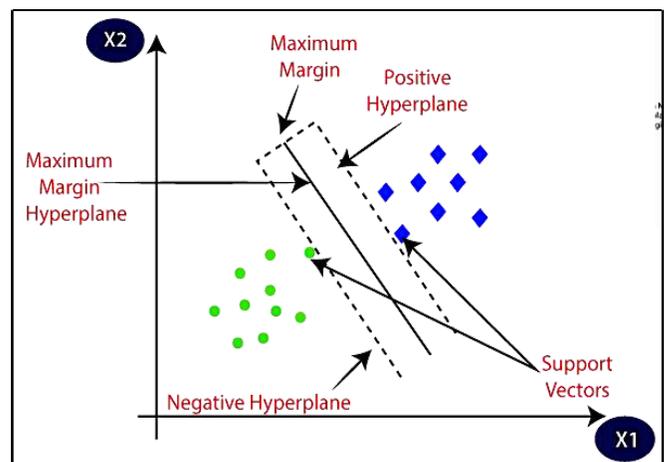

Fig. 2. Support vector machine.

Fig. 2 shows the classification of two distinct categories utilizing a decision boundary or hyperplane, which is this best decision boundary. Where, the aim of the SVM method is to generate the optimal line or decision boundary that divides  $n$ -dimensional space into classes, so that subsequent data points may be readily classified.

#### B. Decision Tree

A decision tree is a classifier that recursively splits the instance space. The decision tree consists of nodes that connect to form a rooted tree. This shows that the decision tree is a directed tree with a "root" node that lacks incoming edges.

Each internal node of a decision tree partitions the instance space into two or more sub-spaces according to a discrete function of the input attribute values. In the most common and straightforward example, each test examines a single attribute, splitting the instance space depending on the attribute's value. For quantitative attributes, the condition provides a range [3].

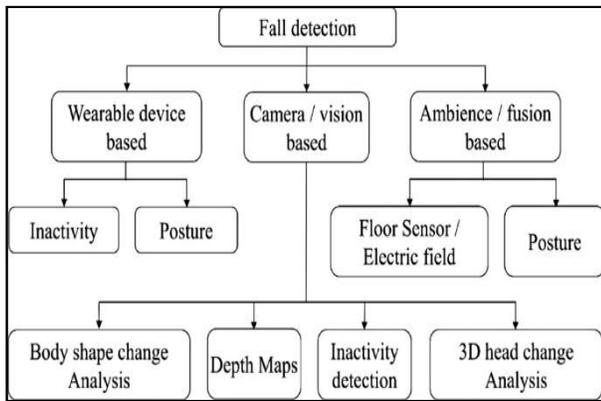

Fig. 3. Decision tree machine learning.

Fig. 3 illustrates different fall detection methods that make use of accelerometers, gyroscopes, or maybe both of them.

### C. Naive Bayes

The Naive Bayes algorithm is another supervised learning technique based on the Bayes Theorem. It is one of the simplest and most extensively used classification algorithms that may provide accurate predictions quickly. The Bayes theorem is used to generate classifications based on probability. On the basis of classes, uneven gait and falls may be immediately and readily identified [2]. It is a probabilistic classifier, which means that it makes its predictions based on the likelihood that an item would be found.

In Fig. 4 that has been shown below, it is an example that illustrates how Naive Bayes classifier has distinguished between the data points that have a fine border. The Gaussian curve in its original form has been applied here.

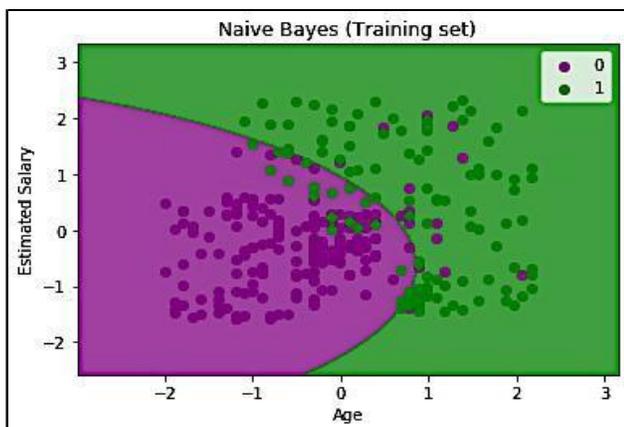

Fig. 4. Naive Bayes machine learning.

The preceding algorithms are generally used in fall

detection and prevention applications. Additionally, there are other algorithms such as Logistic Regression and Dynamic Time Wrapping, exist for similar applications (DTW). Another method for recognizing falls is to see them as an anomaly detection issue. Auto-encoders are utilized to detect falls in such systems. Auto-encoder learns features via ADL model training. Based on the reconstruction inaccuracy, fall actions are thus classified as an abnormality. It includes an encoder, a decoder, and a code layer. An encoder learns and compresses the input's essential characteristics. The code layer is the intermediate layer that includes important and compressed data information. In contrast, the decoder converts the data back into the original input. This approach may aid in reducing the complexity of data, obtaining required gait characteristics, and detecting unobserved falls [2].

## IV. METHODS

### A. Hardware Device Setup

The hardware involves a wearable device known as transmitter (FDS-Tx), which consist of the main controller (Arduino Pro mini), the wireless transmission module (XBee Pro) and the main component, a sensor (ADXL335 accelerometer). Before start the data collection, FDS-Tx will be attached to the volunteers' garment, specifically slightly above the right chest area. The device working system is, upon start, the user/volunteers' movements data will be recorded by accelerometer and sent to the receiver (FDS-Rx) via wireless transmission medium to the workstation. There, the computation take place to get the results of the volunteer's conditions (Fall or Normal). Details of the hardware description can be referred to work in [14]. Fig. 5 illustrates the setting of sensor on the user 0.

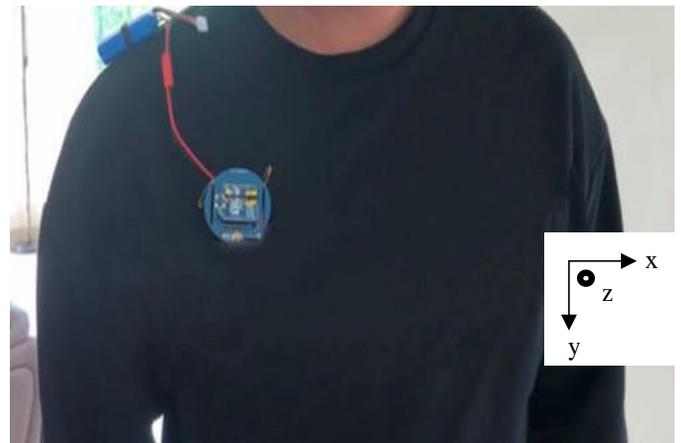

Fig. 5. Location of FDS-Tx on the user [26].

### B. Data Acquisition

ADXL335 three-axis accelerometer provides analogue voltage readings for X, Y, and Z acceleration (Fig. 6). An accelerometer can determine the tilt angle touching the earth by detecting the acceleration due to gravity. By measuring the dynamic acceleration, the accelerometer can determine the device's speed and direction of movement. Accelerometer with an analogue interface show accelerations by a range of voltage levels. In general, these values oscillate between the ground and the supply voltage. The micro-controller's ADC may then

be used to read this value. For detecting a fall using accelerometer, presently, there are two sorts of detection approaches: analytical methods and machine learning methods [15]. The X and Y axes have a bandwidth selection range of 0.5 Hz to 1600 Hz, while the Z axis has a bandwidth selection range of 0.5 Hz to 550 Hz. In general, accelerometer is low-power devices. Typically, the needed current is between a micro to milli amp [16].

The data acquisition is based on the Activity list as in the Table I. Three (3) activities are performed for 3 times each for better analysis process which will be discussed in the next section [3].

TABLE I. TEST SCRIPT

Code	Activity	Trial s	Duration (s)
F01	Fall forward while walking caused by a trip	3	15
F02	Fall to the right while walking caused by a trip	3	15
F03	Fall to the left while walking caused by a trip	3	15

Equipment setup are consisting of the FDS-Tx and FDS-Rx hardware, and safety mats in a closed venue with adequate sizes for 10 to15 seconds of straight walk. 10 volunteers are involved in this session with the detail of age, height, weight and gender are recorded for further analysis reference. During data acquisition, volunteers will walk straight on the normal carpeted composite structure, and then falls on a safety mats to reduce the forces during fall impact. Fig. 6 demonstrates the volunteer performing one of the activities.

Fig. 6. A volunteer performing F03 activity under researcher supervision [15].

In this part, we present an overview of the framework used to identify ADLs and falls occurrences, as well as an explanation of the activity recognition technique (Fig. 7).

C. Data Processing

Data implementation: Google Colab product used for machine learning applications was used to process the available data [12]. After the data was collected and the needed libraries and packages were obtained and imported, the process of implementing the coding started. As a precaution, a unique ID of the data-set was specified within the drive to allow a seamless download. The data on the status activities of the

elderly consists of four input features (X-axis, Y-axis, Z-axis accelerations, and total MAG) and 1 output feature (STATUS), which are viewed through the panda’s package.

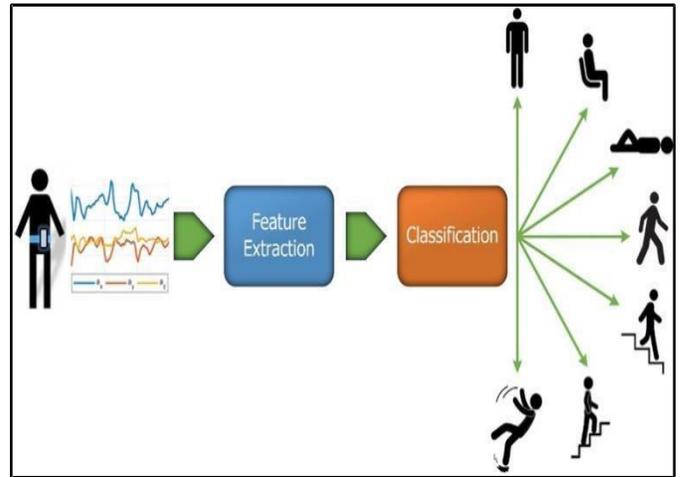

Fig. 7. Illustration of the activity recognition framework.

The data was distributed into Normal and Fall activities. Among 2245 activity, 1788 was Normal, and 457 was for Falling. Using Google Colab software, a categorical feature encoding was used. This feature converts non-numeric features to numbers for ease of machine learning. The STATUS of the Normal activity is precisely encoded as 1, while Fall activity is encoded as 0.

D. Data Set

Collected Data-set: The real datasets should be created, as current datasets including samples from 10 people that are physically different and with 3 different activities. Where number of trials for each activity is 3, and the total number of data is 84. Two (A01 and A02) out of ten participants only perform 2 activities because of personal health problem. To be clarified, the data set has been arranged as shown below in Fig. 8:

X-ACCEL	Y-ACCEL	Z-ACCEL	TOTAL MAG	STATUS
X-ACCEL is the acceleration of x-axis in g unit				
Y-ACCEL is the acceleration of y-axis in g unit				
Z-ACCEL is the acceleration of z-axis in g unit				
TOTAL MAG is the total magnitude of the three axis				
STATUS shows whether the person was fallen labeled as 'FALL' or was not fallen labeled as 'NORMAL'				

Fig. 8. Arranging of data set.

Accuracy measurement: To validate the accuracy of the results, the SVM machine learning algorithm was used and compared with the Decision Tree and Naive Bayes machine learning algorithms. The data is divided into 80-20% training-testing set splits where 1796 and 449 samples are used for training and testing, respectively.

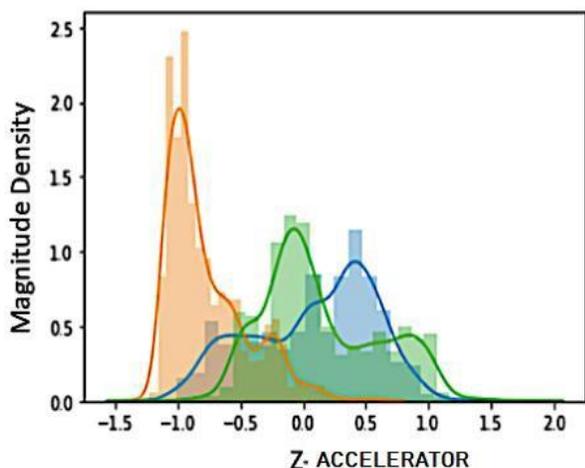

Fig. 9. Accelerometer input features.

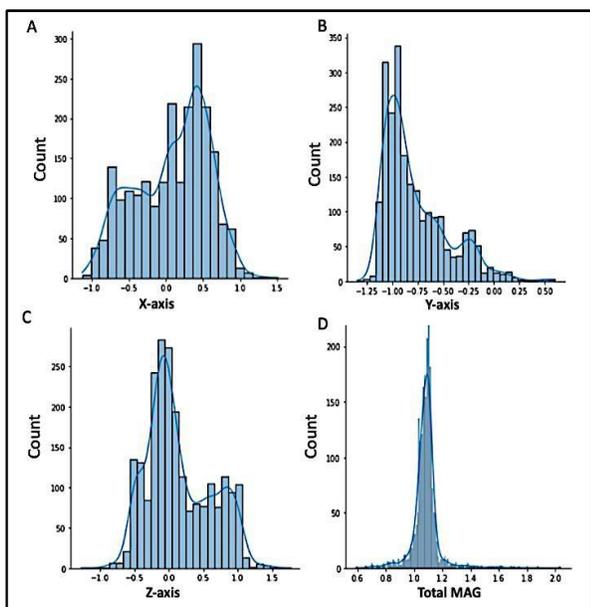

Fig. 10. Accelerometer input features of x-, y-, z- axes accelerations, and total MAG.

## V. RESULTS AND DISCUSSION

### A. Input Features Distribution

The data distribution of the X, Y, Z, and total MAG was assessed before applying the machine learning algorithms and found that the data was skewed and abnormally distributed (Fig. 9). A separate axial distribution of each axis was plotted and presented abnormal distribution (Fig. 10A, B, and C). However, the total mag feature exhibits a normal distribution (Fig. 10D). These results suggest that the dataset used in this study composes a suitable confusion matrix, which can be used to understand the classification model and correctly predict the possible errors.

### B. Machine Learning Accuracy Measurement

The training and testing accuracy of the proposed machine learning algorithms (SVM, Decision Tree, and Naive Bayes) was measured. However, the testing accuracy was used to rank

the algorithms as it offers consistent and more reliable results. Surprisingly, the Decision Tree algorithm provided the best accuracy (97%). SVM algorithm showed a relatively high accuracy of 95% as well (Fig. 11). Taken together, current measurements suggest that the best algorithm for fall detection is the Decision Tree machine learning algorithm. Indeed, employing Decision Tree will result in 100 % accuracy since a portion of training data is utilised for testing. The decision tree learns about the data during training, and if the same data is used to forecast today, it will provide the same outcome.

Therefore, a decision tree outperforms other machine learning algorithms.

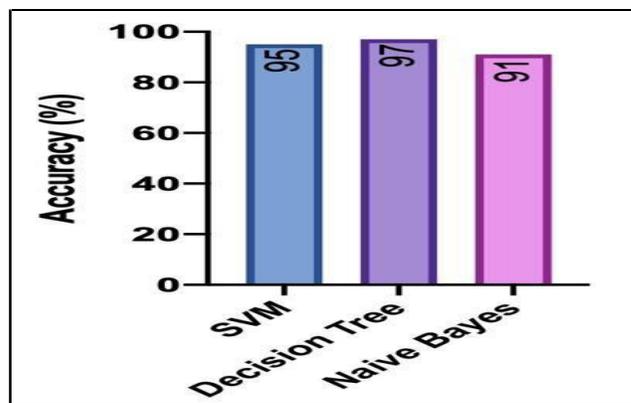

Fig. 11. Comparison of algorithms accuracy.

Fig. 12 shows the confusion matrix of the predicted results for Naive Bayes, SVM and decision tree algorithms. Where, DT carried out best performance comparative the other classification methods by getting 97% accuracy, whereas Naive Bayes shows the least performance by attaining 91% accuracy.

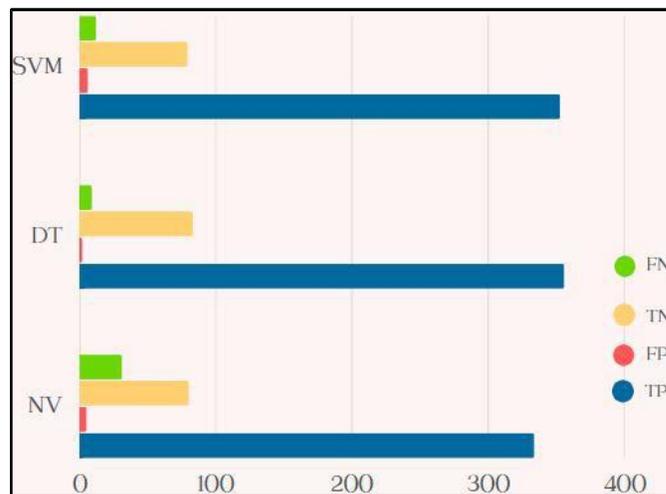

Fig. 12. Classification results using confusion matrix.

## VI. CONCLUSION

The purpose of this research is to compare some ML-based fall detection system as offline. It examines the systems based on a variety of characteristics including data-sets, confusion matrix and accuracy. The performance accuracy of the SVM,

Decision Tree, and Naive Bayes classification algorithms was tested using real-world acceleration data gathered from public databases. Using the training data, the internal parameters of these algorithms have been enhanced. Thereafter, the performance of the trained algorithms has been evaluated using the test data. The findings exposed that the SVM, Decision Tree, and Naive Bayes algorithms achieve an overall accuracy of 95%, 97%, and 91%, respectively. As next steps, it can be work on data generated by a combination of different types of sensors and vital signs sensors which may be worn by elderly people staying in old-age care homes or even their own homes. Also, the system may have another machine learning algorithms to support the end-to-end functionality.

#### ACKNOWLEDGMENT

This research work was funded by Universiti Teknologi Malaysia with the grant number R.K130000.7356.4B513 for financial support and device. Then, we would like to thank all those anonymous participants especially from UNITEN for their insightful contribution in the experiment.

# Online Teaching Design and Evaluation of Innovation and Entrepreneurship Courses in the Context of Education Internationalization

Chengshe Xing

Yiwu Industrial & Commercial College, School of Foreign Studies, Yiwu, 322000, China

**Abstract**—In the context of the internationalization of education nowadays, courses in innovation and entrepreneurship have been strongly promoted, and the content and number of topics, etc. of this type of courses are rapidly climbing. In order to enable target users to quickly select courses that they may be interested in, one changed collaborative filtering algorithm based on a multi-feature ranking model is used to extract and rank the features of online courses based on several factors, and then combine the collaborative filtering algorithm to recommend them to users. The results of experiment show that the numerical valuation of accuracy rate and recall rate of the improved algorithm are more than those of the other algorithm with different conditions, and in most cases higher than those of the LDA algorithm, and the user's evaluation of the recommendation effect also has the highest rating value of the improved algorithm, with the ratings of 4.3, 4.7 and 4.4 in the three groups, and the overall average score is 4.47, indicating that the improved algorithm has significant optimization performance and is suitable for teaching innovation and entrepreneurship in online courses.

**Keywords**—Online course; Collaborative filtering algorithm; Ranking model

## I INTRODUCTION

Traditional teaching suffers from single teaching mode, unbalanced teaching resources and low teaching efficiency. As the process of education informatization accelerates, more and more information technology and intelligent algorithms are applied to the education field and improve the existing teaching quality from them. With the increase of people's reliance on online teaching, educational resources have started to grow explosively in recent years, and many domestic and foreign experts have started to research on personalization of educational resources. The application of recommendation models to online teaching can not only improve the learning efficiency of learners and save their time in finding materials, but also improve the existing teaching models and educational resources. Based on this, recommendation models have become a hot research topic in the field of education. In recent years, innovation and entrepreneurship courses have been of high interest and attention, and in the context of the current internationalization of education, the content required for innovation and entrepreneurship courses has been increasing, which has led to an increasing demand for online courses in related directions [1]. The industry of teaching online courses has become increasingly mature, and course recommendations are often made in online courses to shorten the time of user

selection or to give suggestions for them [2]. For teaching recommendations in online courses, the core of the recommendation system is the recommendation algorithm used, and the performance of the recommendation algorithm directly affects the final recommendation results [3]. There are several recommendation methods, among which the most commonly used are different types of collaborative filtering algorithms. Collaborative filtering algorithms have the advantages of fast computational rate and high accuracy, but also have drawbacks such as cold start problem [4]. Therefore, in order to make the collaborative filtering algorithm fully applicable to the teaching recommendation of courses, the traditional collaborative filtering algorithm must be improved and achieve the desired effect. Currently, collaborative filtering is one of the most mature techniques in recommender systems, which uses the similarity of interests or features to find the nearest neighbors and then recommend the target users. Although this algorithm has high recommendation quality, it still faces the problem of data sparsity, where users generate more evaluations for mature domains and fewer evaluations for unfamiliar or new domains, thus causing the cold start phenomenon. If we can learn users' preferences or features from mature domains and use them in the recommendation of new domains, it will greatly alleviate the problem of data sparsity in new domains.

## II RELATED WORK

For the research and improvement of collaborative filtering algorithm, many experiments have been successfully conducted by scholars at home and abroad. Liu came up to a changed clustering-based collaborative filtering algorithm for reference by introducing a function of decay time and item attribute vector and characterizing items and user interest vector to describe users, and projecting recommendation candidate sets in clusters, and the result of experiment showed that the algorithm can solve the data sparsity and problem of new items [5]. Xu et al. established object meta-classification by introducing a new dependency function based on Gaussian kernel and extended classification method for information of input statistics data, and recommended results by computing the dependency between the features of classification set and the features set of target objects. The results of experiment show that, compared with conventional algorithms, the new hybrid has higher speed and better performance [6]. Chen's team calculates the similarity between users by combining the collaborative filtering algorithm with other algorithms, and computes users' calligraphy words in addition to the main

recommended calligraphy words based on the preliminary recommendation results to get the final recommendation results [7]. Panda team designed a collaborative filtering recommender based on normal filter for recommender systems to recommend personalized objects to strict users. The algorithm determines the average user rating for each object, computes the number of users who bought corresponding objects. Then uses min-max normalized way to find the number of users who have been normalized for each object in a specific range to scale the average user rating, and finally tested and found to predict user ratings more accurately [8]. Yu et al. came up to a cross-domain algorithm based on feature collaborative filtering construction and locally weighted linear regression by constructing features in different domains and using these features to represent different auxiliary domains. Also, they used a locally weighted linear regression model to solve the regression problem. Results of experiment show that this regression algorithm effectively solves the data sparsity problem by transferring useful data of knowledge from the auxiliary features domains [9].

Jiang's team proposed a slope-one algorithm to calculate the similarity between users by selecting trusted data and adding this similarity to the weighting factor of the changed algorithm to obtain the final recommendation equation. The base of new algorithm is the fusion of trusted data. User similarity under collaborative filtering algorithm acts more accurately than traditional algorithms [10]. Osval Montesinos-López et al. developed a project-based collaborative filtering package for multi-trait and multi-environment data and used it to study the prediction accuracy of precious data under phenotypic and genomic selection. The results of simulation experiment showed that package was more accurate for studying genomic prediction and data predictions are more accurately [11]. Zhang et al. designed a coverage-based collaborative filtering algorithm to provide brilliant recommendations for new users, improved previous collaborative filtering by reconstructing a decision class with detailed analysis of new user characteristics, and used a coverage-based the results showed that the improved algorithm significantly outperformed the existing working algorithm [12]. Li et al. in view of the increasingly serious problem of information overload and the fact that the traditional recommendation algorithm does not take the social relationship of users as the basis of recommendation, a combination algorithm with social information and dynamic time window is proposed. Through dynamic time window comparison, the time function is introduced to determine the corresponding time weight of user interest at different times. Finally, the practicability and effectiveness of the proposed method are verified. The experimental results show that the performance of the proposed algorithm is better than that of the traditional collaborative filter synthesis algorithm [13]. Yildirim studied the relevance between users through online social networks and used a multi-type improved collaborative filtering algorithm used for shopping recommendations, and the experimental results showed that the numerical valuation of accuracy rate under the changed algorithm recommendations is higher [14]. Han et al. based on the improved k-means clustering of small batches, an improved time weighted collaborative algorithm based on small batch

K-means is proposed. The algorithm combines Pearson correlation coefficient with k-means algorithm, uses the improved k-means clustering algorithm of small batch to cluster the sparse scoring matrix, and introduces Newton cooling time weighting to improve user similarity. The experimental results are obviously superior to the traditional algorithm in all aspects [15].

From the above research results, it can be found that there are a large number of studies related to the personalization technology of collaborative filtering algorithm, and a considerable number of studies in different fields are used to improve the traditional collaborative filtering algorithm, but there are relatively few studies on the personalized teaching technology based on algorithm about collaborative filtering, so the research is based on the personalization technology of algorithm about collaborative filtering to design an innovative entrepreneurial network for each target user. Therefore, the research is based on the personalization technology of algorithm about collaborative filtering to design an innovative entrepreneurship web course for each target user to enhance the learning interest and learning ability of target users in the context of internationalization of education.

### III IMPROVED COLLABORATIVE FILTERING ALGORITHMS BASED ON MULTI-FEATURE EXTRACTION RANKING MODEL AND ITS APPLICATION

#### A. Application of Collaborative Filtering Algorithm and Ranking Model to Online Courses

Along with the rapid development of internationalization of education, the content of innovation and entrepreneurship courses that can be learned, gradually increased, and at the same time the personalized requirements of course learning also increased. In this context, experiments are conducted to study the personalized recommendation of courses, and the collaborative filtering recommendation algorithm is widely used in the recommendation algorithm and is suitable for the context of internationalization of education under big data. There are two tasks in the collaborative filtering recommendation system, which are rating prediction and Top-N recommendation. The rating prediction is mainly to predict the rating of items not rated by users according to their characteristics, while the Top-N recommendation recommends the N most likely items of interest to users based on the rating and the rating prediction.

Collaborative filtering algorithms are classified into memory-based collaborative filtering algorithms, model-based collaborative filtering algorithms, and content-based collaborative filtering algorithms. Due to the current explosive growth in the amount of information on the Web, the rapid increase in the information available to users makes a single type of collaborative filtering algorithm no longer applicable, and practical applications also usually mix multiple types of methods to adapt to more complex practical situations [16]. While in Top-N recommendation mainly neighbor models, the most commonly used one is the K-nearest neighbor model. K-nearest neighbors use the K most similar items or user ratings for weighting and use them as a basis to predict user ratings for unknown items [17]. The nearest neighbor algorithm focuses on the similarity calculation, and the closer

the similarity result is 0 to 5, the higher the similarity is, and the closer the users or objects are to each other. The cosine similarity and Pearson coefficient for similarity calculation are shown in equation (1) and equation (2), respectively.

$$\omega \cos(y, z) = \frac{r_y \cdot r_z}{|r_y|^2 \cdot |r_z|^2} \quad (1)$$

$$\omega_{pearson}(y, z) = \frac{\sum_{b \in B(r_{y,b} - \bar{r}_y)(r_{z,b} - \bar{r}_z)} (r_{y,b} - \bar{r}_y)(r_{z,b} - \bar{r}_z)}{\sqrt{\sum_{b \in B(r_{y,b} - \bar{r}_y)^2} (r_{y,b} - \bar{r}_y)^2} \sqrt{\sum_{b \in B(r_{z,b} - \bar{r}_z)^2} (r_{z,b} - \bar{r}_z)^2}} \quad (2)$$

In Eq. (1) and (2),  $r_y$  and  $r_z$  are the target vectors of the neighboring targets  $y$  and  $z$ , respectively. Cosine similarity is suitable in the absence of ratings by and loss vector space pinch cosine values for similarity judging, while Pearson coefficient is suitable in the case of both ratings and can eliminate rating noise and minimize the influence of users differing in rating stringency [18]. After completing the similarity calculation, the aggregation method is used to predict the numbers of rating on unknown objects as shown in equations (3) and (4).

$$r_{c,s} = \frac{1}{\sum_{c' \in U} |sim(c, c')|} \sum_{c' \in U} sim(c, c') \cdot r_{c',s} \quad (3)$$

$$r_{c,s} = r_c + \frac{1}{\sum_{c' \in U} |sim(c, c')|} \sum_{c' \in U} sim(c, c') \cdot (r_{c',s} - r_{c'}) \quad (4)$$

Both  $r_c$  and  $r_{c'}$  in Eq. (3) and (4) are the average ratings of the target users  $c$  and  $c'$ , respectively. Eq. (3) represents the aggregation function that does not consider the difference in users' rating styles, while Eq. (4) corrects the aggregation function for the difference in rating styles by calculating the deviation between the weighted and used rating values and the corresponding mean score difference values of the target users. The similarity determination recommendation process is shown as Fig. 1.

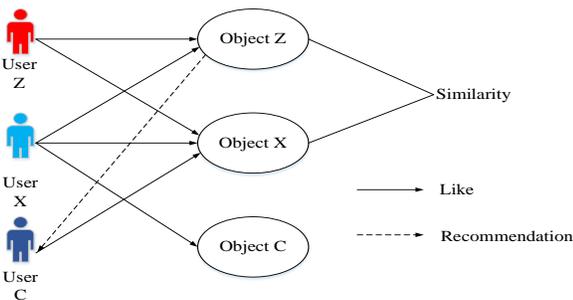

Fig. 1. User based collaborative filtering algorithm.

In practical applications, algorithms about collaborative filtering need to extract project features and target user features, and the extraction of user features is actually a supervised classification problem, so classification algorithms in machine learning can be used, including decision tree algorithms and linear classification algorithms, in addition to the nearest neighbor algorithm [19]. So, in order to be able to design a reasonable web-based distance course, the experiment requires feature extraction of course items and course learning users and reasonable recommendations using collaborative filtering algorithms, etc. The formula for the target user's number of rating of the item is shown in equation (5). In equation (5), the set of nearest neighbors is represented by  $S_u$ ,  $\bar{R}_u$  and  $\bar{R}_n$  mean the average ratings of users  $u$  and  $n$  on the objects each, the similarity on two users is represented by  $sim(u, n)$ , and the ratings of users  $n$  on the item  $j$  are represented by  $R_{n,j}$ .

$$P_{u,j} = \bar{R}_u + \frac{\sum_{n \in S_u} sim(u, n) \cdot (R_{n,j} - \bar{R}_n)}{\sum_{n \in S_u} sim(u, n)} \quad (5)$$

The content-based collaborative filtering algorithm will make the k most similar items (x1, x2, x3, x4 ....) based on the similarity of the target item x evaluated by target user .xk) get their corresponding similarity S (i.e., Sx1, Sx2, Sx3, Sx4 ..... Sxk), and then obtain a weighted average, which is based on the ratings of all those similar items by the target users, and then with the similarity of the target items as the weights, and use this result as the final rating of the target items by the target users. Finally, a number of top items are selected to be recommended to users based on the magnitude of the predicted value. A simple schematic of this algorithm is shown in Fig. 2.

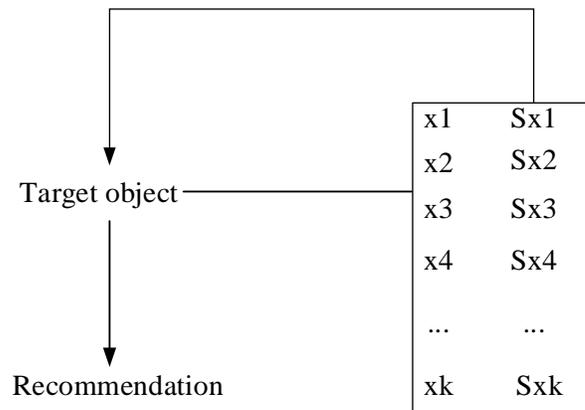

Fig. 2. Object based collaborative filtering algorithm.

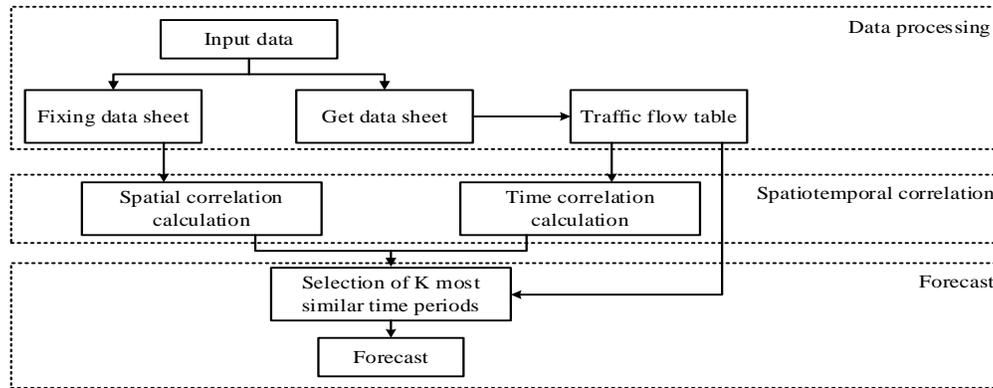

Fig. 3. Recommended schematic diagram of K proximity.

In order to fit the demands of the online teaching process for the main purpose, the dataset of the online course contains five data tables, and they are basic course information, course chapter information, basic user information, user learning and collection records and course creator information. Before the normal operation of the online course, the course information, course creator and user information need to be analyzed, at this time, the method of ranking learning can be used, and the ranking learning is integrated into the recommendation algorithm, and the weight parameters of multiple ranking models are learned by machine learning methods, and the best combination model is obtained in the training set to get better recommendation results [20]. Sorting learning usually requires the use of support vector machines, which are mainly divided into three types of methods: point-level methods, pair-level methods, and list-level methods, and their collaborative filtering k-neighborhood recommendation process is shown in Fig. 3.

The experiments are chosen to transform the ranking problem into a classification problem using a pairwise ranking method with fast training speed and moderate training complexity. Suppose from  $x_1$  to  $x_n$  are the feature vectors of documents, which are from  $d_1$  to  $d_n$ , at this point define a new training sample, where the positive samples are from  $x_1-x_2$  to  $x_1-x_n$ , negative samples are from  $x_2-x_1$  to  $x_n-x_1$ . Then a binary classifier is trained to classify these new samples. The document classification uses the support vector machine approach with a linear scoring function as shown in equation (6).

$$f(x) = \omega^t (x_u - x_v) \quad (6)$$

In equation (6)  $\omega$  is the marginal term and  $t$  is the time variable parameter. This method is integrated into the recommendation algorithm of course items, where the target users are ranked according to their preferences for the course items, and a matrix of users' access or learning time for the course items is established, and the input of the algorithm is a user-program evaluation matrix  $R(m, n)$  as shown in equation (7). The rows and columns in Eq. (7) represent the user and the item, respectively, and the element in the  $R_{ij}$ .

row of the  $j$  column in the matrix refers to the user's  $i$  numbers of rating on the object  $j$ .

$$R(m, n) = \begin{bmatrix} R_{1,1} & R_{1,2} & R_{1,3} & R_{1,4} & \cdots & R_{1,5} \\ R_{2,1} & R_{2,2} & R_{2,3} & R_{2,4} & \cdots & R_{2,5} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ R_{m,1} & R_{m,2} & R_{m,3} & R_{m,4} & \cdots & R_{m,5} \end{bmatrix} \quad (7)$$

### B. Improvement of Collaborative Filtering Algorithm Based on Multi-Feature Ranking Model

Conventional collaborative filtering algorithms based on ranking learning still have their limitations due to the shortcomings of traditional collaborative filtering algorithms such as cold start problem, sparsity problem and data density problem. Therefore, we designed an improved collaborative filtering algorithm based on multi-feature ranking and tested its applicability to the instructional design of an online course [21]. Considering each type of collaborative filtering algorithm, the experiment uses a user-based nearest neighbor recommendation algorithm. The similarity between all users is calculated, not by mixing all but by combining any two users. The similarity between the two is calculated by defining the collaborative filtering preference value of user  $x$  for course  $i$  as shown in equation (8). In equation (8),  $r(y, i)$  represents the rating of course 2 items by user  $y$  and  $i$  is the total number of users.

$$pref(x, i) = \frac{\sum_{y=1}^k sim(x, y) \cdot r(y, i)}{\sum_{y=1}^k sim(x, y)} \quad (8)$$

The obtained preference value results range from 1 to 5, and the higher the value is, means the higher the user's favorite preference for the course item. This preference value is used as a preference feature and applied in feature extraction, which is mainly associated with the calculation of similarity of the administrators, the time complexity of the calculation process and the number from users and items [22]. Since in the learning of online courses, courses with similar contents are not repeatedly studied by users, so in order to maximize the expression of users' interest bias, the

experiment uses a subject model for content preference feature extraction, i.e., a subject-based collaborative filtering algorithm for user preferences. Firstly, the course text information is abstracted into a subject vector, with the name and introduction as the course information, and the course learning record, personal filled-in interests and user learning record as the user profile. The course information and user profile are combined. The distribution of the courses that users have studied on the subject vector space is calculated as a weighted average, after which the similarity between the feature vector about users and the feature vector of courses is calculated [23]. After performing the similarity calculation, the user feature vectors and the subject-based user preferences are calculated as shown in Eqs. (9) and (10). In equation (9) and equation (10),  $\gamma_h$  represents the feature vector about the course  $h$ ,  $\gamma_g$  is the feature vector of the corresponding user,  $\gamma_h$  and  $\gamma_g$  are the same, and  $m$  is the number of courses that the corresponding user has taken.

$$\gamma_g = \frac{1}{m} \sum_{h=1}^m \gamma_h \tag{9}$$

$$pref(g, h) = \frac{\gamma_g \gamma_h}{\sqrt{(\gamma_g \gamma_g)(\gamma_h \gamma_h)}} \tag{10}$$

In addition to the above-mentioned features, feature extraction also takes into account the influence of the course lecturer itself and the popularity of the course. Since the influence of a course instructor cannot be directly quantified in the short term, the combined popularity of all the courses of the instructor is used as the influence of the instructor, and the popularity of the course should be studied first. The extraction of course popularity features should take something account number which is the numerical results of learners with user ratings, the number of scores with the ratio of the number of scores to the number of learners of the course. The feature extraction for calculating the popularity of a course is shown in equation (11).

$$val(u, i) = 0.2c_i + s_i \cdot d_i \tag{11}$$

In equation (11),  $c_i$  denotes the numerical valuation of learners for the course  $i$ ,  $d_i$  denotes the number of raters for the course  $i$ , and  $s_i$  denotes the all to aver numerical valuation after rating the course  $i$ . Since ratings are usually on a 5-point scale, to balance the any possible influence of the numerical results of learners and ratings on the course popularity value, the numerical result of learners is multiplied by a factor of 0.2. After deriving the absolute score of popularity, the calculation of similarity on popularity is shown in equation (12).

$$pref(u, i) = -\frac{r_i}{m} + 1 \tag{12}$$

In equation (12),  $m$  is the summary number of classes under the respective category, and  $r_i$  indicates the rank number on the course  $i$  in terms of the absolute value of its popularity among these courses. Similarly, the similarity value ranges from 0 to 1 and the closer to 1 means higher the similarity.

After obtaining the similarity of popularity, we can obtain the influence and popularity of the corresponding tutors as shown in equation (13). In equation (13),  $prefteach(u, i)$  represents the similarity of influence of tutors,  $prefhot(u, j)$  represents the similarity of popularity of different courses taught by tutors,  $m$  is the total number of courses, and  $C$  is a coefficient to consider the relationship between users and tutors, because users may have different values of  $C$  depending on whether they follow a tutor or not, and whether they have already taken a course. If you have not taken a lesson with a tutor and do not follow them, the value is 1.

$$prefteach(u, i) = C \cdot \frac{1}{m} \sum_{j=1}^m prefhot(u, j) \tag{13}$$

After all features are extracted and similarity is calculated, these recommendations are integrated using multi-feature ranking learning. A simple schematic representation of machine integration learning is shown in Fig. 4.

For a given user and project course, each pair of relationship is reflected as a vector  $x$ , each dimension in the vector which in this situation refers to the different features extracted, and the vector dimension is the number of features, at this time the ranking function is  $f(x) = Wx$  and  $W$  is the weight vector [24]. In this model, training sets are established according to the user learning of different courses, and the courses are grouped in each two items, and the first  $i$  group in the training set is shown in equation (14).

$$D_i = (x_{i1} - x_{i2}), i \in N^* \tag{14}$$

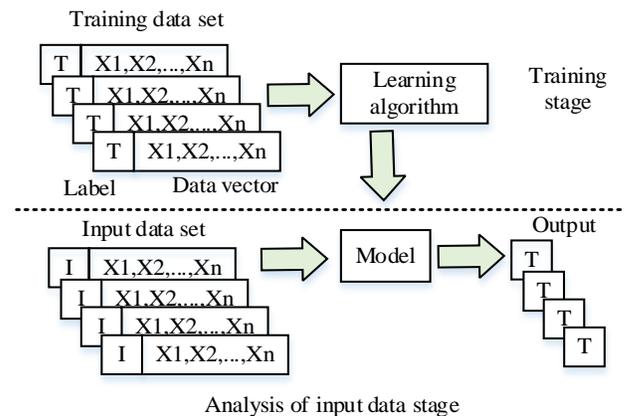

Fig. 4. Simple schematic diagram of machine sequencing calculation.

For each two sets of courses, the difference of the feature vectors of the two course items is used as the sample marker, and the samples that cannot be sorted by the sorting

relationship are ignored, and they are divided into two sets according to the different features of the two courses, which are positive and negative samples, after the sorting training is performed on these sample data [25]. The loss function for the ranking training is shown in equation (15). The same in equation (15)  $\omega$  is the marginal term and  $t$  is the time variable parameter.

$$lossf = \min \sum_{i=1}^m \max[1 - \omega^t (x_{i_1} - x_{i_2})] + \frac{1}{2} \|\omega\|^2 \quad (15)$$

The learning process of machine group sorting is then shown in Fig. 5. After that, the desired result of the predecessor is calculated.

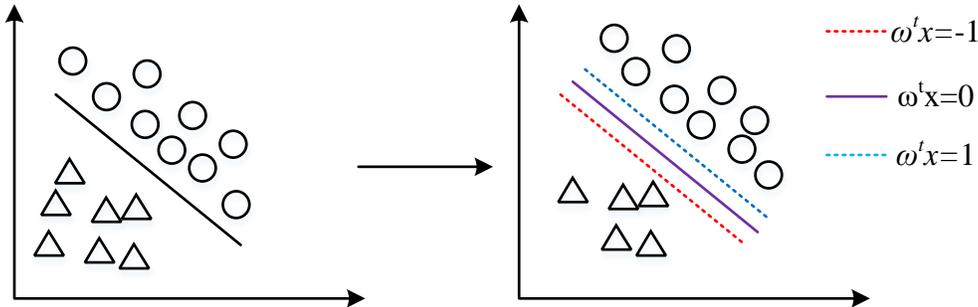

Fig. 5. Simple diagram of support vector machine learning.

#### IV DISCUSSION

The above research method optimizes the traditional collaborative filtering model and finally designs an improved collaborative filtering algorithm based on multi-feature ranking. In order to test the performance of the algorithm and explore whether the improved collaborative filtering algorithm is suitable for online teaching course recommendation, this section of the research content firstly selects a series of evaluation indexes for evaluating the strengths and weaknesses of different algorithms, and then compares the performance of evaluation indexes of different algorithms under the same test data set. The commonly used evaluation metrics for prediction scoring accuracy include mean absolute error, root mean square error, and standardized mean absolute error.

$$MAE = \frac{1}{I_T} \sum_{(u,i) \in I_T} |r_{ui} - \tilde{r}_{ui}| \quad (16)$$

Eq. (16) shows the formula of Mean Absolute Error (MAE) MAE, where  $I_T$  represents the test set.  $r_{ui}$  represents the actual rating of item  $i$  by user  $u$ .  $\tilde{r}_{ui}$  represents the predicted rating of item  $i$  by user  $u$ . The Mean Absolute Error can show the absolute error between the predicted and actual ratings, and the smaller the value, the better the recommendation effect of the algorithm.

$$RMSE = \sqrt{\frac{1}{I_T} \sum_{(u,i) \in I_T} (r_{ui} - \tilde{r}_{ui})^2} \quad (17)$$

Eq. (17) represents the calculation formula of root mean square error (RMSE) RMSE.

$$NMAE = \frac{MAE}{r_{\max} - r_{\min}} \quad (18)$$

Eq. (18) is the calculation formula of normalized mean absolute error (NMAE) NMAE.  $r_{\max}$  indicates the maximum value of the scoring range.  $r_{\min}$  indicates the minimum value of the scoring range. According to the above three average indicators, the commonly used recommendation algorithm and the improved algorithm in this paper are tested.

TABLE I. PERFORMANCE OF EVALUATION INDICATORS OF DIFFERENT ALGORITHMS IN THE SAME DATA SET

Recommended algorithm	MAE	NMAE	RMSE
Collaborative Filtering	26.54	13.27	5.15
Apriori	29.28	14.64	5.41
K-Means	18.35	9.18	4.28
BPNN	24.65	12.33	4.96
Algorithm in text	12.56	6.28	3.54

Table I shows five different types of recommendation algorithm models, including traditional collaborative filtering algorithm, Apriori algorithm based on association rules, K-Means algorithm based on clustering recommendation, Back Propagation Neural Network (BPNN) BPNN and improved collaborative filtering algorithm proposed in the paper. The MAE, NMAE and RMSE values of the five algorithms under the same recommendation data set are compared. According to Table I, the MAE values of the five algorithm models are 26.54, 29.28, 18.35, 24.65 and 12.56 respectively; NMAE values are 13.27, 14.64, 9.18, 12.33 and 6.28 respectively; The RMSE values are 5.15, 5.41, 4.28, 4.96 and 3.54 respectively. It can be seen that the improved collaborative filtering algorithm proposed by the research has good recommendation performance. Next, the algorithm is applied to the recommendation of online teaching resources for innovation and entrepreneurship courses, and the recommendation effect of collaborative filtering algorithm before and after improvement is compared. The accuracy

and recall rate are used to evaluate the recommendation accuracy of the recommendation model.

TABLE II. RELATIONSHIP BETWEEN RECOMMENDATION RESULTS AND USERS

User information		System recommendation	The system does not recommend
Users are interested		True-Positive ( $N_{tp}$ )	False-Negative ( $N_{fn}$ )
User is not interested		False-Positive ( $N_{fp}$ )	True-Negative ( $N_{tn}$ )

Table II shows the user's response to the recommendation system. As shown in Table II, there are four situations. That is, the user is interested in the recommended content of the recommendation system. The user is not interested in the recommended content of the recommendation system. The system does not recommend to the user but the user is interested. The system does not recommend to the user and is not interested.

$$P = \frac{N_{tp}}{N_{tp} + N_{fp}} \quad (19)$$

Eq. (19) shows the calculation formula of the recommended accuracy of the model. Accuracy can clearly represent the recommended performance of the model.

$$R = \frac{N_{tp}}{N_{tp} + N_{fn}} \quad (20)$$

Eq. (20) shows the calculation formula of the recommended recall rate of the model. The recall rate can indicate the probability that the content that users are interested in is recommended.

## V EXPERIMENTAL RESULTS AND COMPARATIVE ANALYSIS OF THE THREE ALGORITHMS

### A. Experimental Results of Feature Extraction and Model Training Prior

The experiment calculates user preferences based on common interval and topic-based user preferences, and randomly tries 80% of the training set and 20% of the training set. User course matrix test set. In order to calculate user preferences based on public filtering, use the marked value of KNN positive parameter K to capture the curve between the same value K, as shown in Fig. 6. Fig. 6 shows that the attack curve K is out of position. In order to fully study the needing rate, count and pick the value K 20 for the experiment.

Using Linear Discriminant Analysis (LDA) to calculate topic-based user preferences, the topic is the most important parameter in the algorithm, the experiment will be LDA as a separate recommendation algorithm for each user to select the corresponding topic vector as the most similar course as a result of the recommendation for that user, the number of topics and LDA recall results obtained are shown in Fig. 7. It can be seen that the recall rate gets one small increase with increase of the number of topics, and the number of

topics with a number of 100 is used for comprehensive consideration in Fig. 7.

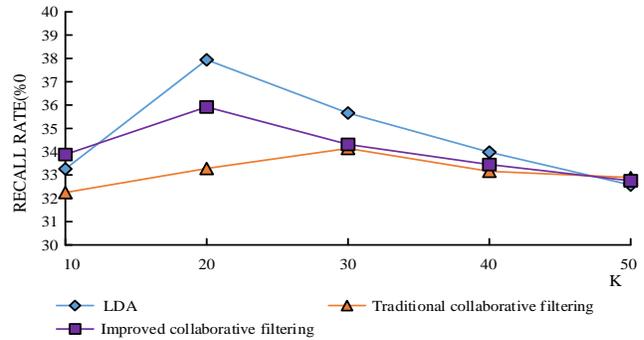

Fig. 6. Parameter K curve about recall rate.

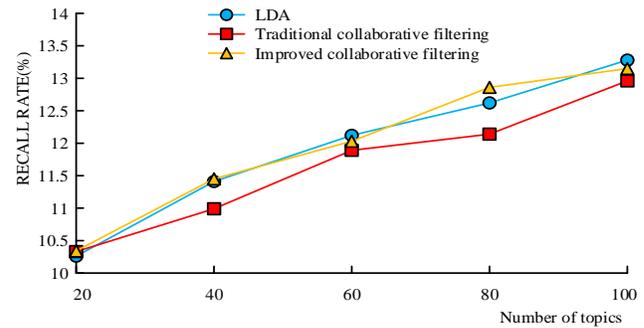

Fig. 7. Result curve of LDA about the number of topics.

### B. Analysis and Evaluation of the Results for the Online Course Algorithm

After learning the ranking function at the training, a ranking model is used to recommend courses according to their ranking and consequently generate the user's interest labels. The algorithm is then tested experimentally, along with two other algorithms, the regular algorithm about collaborative filtering and the linear discriminant analysis algorithm, and the effectiveness of the algorithms is measured and the results compared mainly by accuracy and recall.

The accuracy results of the three algorithms with different number of recommendations are displayed in Fig. 8. It can be seen, which are the truth that the accuracy rates of the three algorithms show a significant upward trend with the increase in the number of recommendations, which means that the recommendation algorithms should increase the number of recommendations from Fig. 8. When the number of recommendations is small, the accuracy rate of the improved algorithm is significantly higher than that of the traditional algorithm and the LDA algorithm, and when the number of recommendations gradually increases, the accuracy rate of the improved algorithm is still significantly higher than that of the traditional collaborative filtering, and at this time, although the accuracy rate is higher than that of the LDA algorithm, it will no longer be significant as the number of recommendations increases, indicating that algorithm which came up from the research is significantly better than the traditional algorithm and better than the LDA in general.

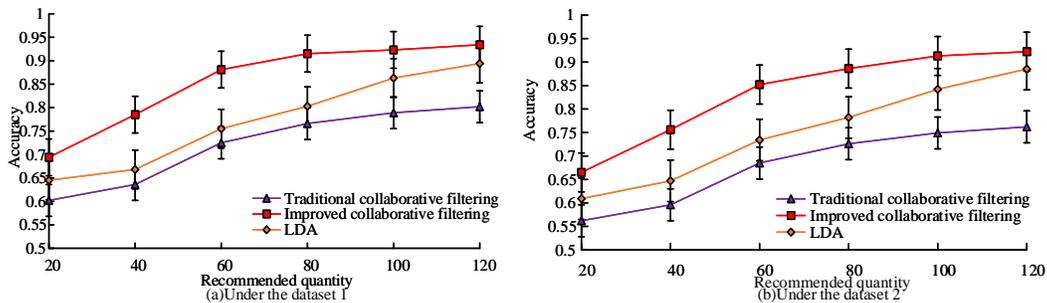

Fig. 8. Recommended quantity and accuracy results of three algorithms.

Fig. 9 shows the results of canceling many of the three proposed algorithms. As shown in Fig. 9, the cancellation rate of these three algorithms also increases with the increase of the number of recommendations. Among the three algorithms, the improved filter synthesis algorithm always has higher inverse speed than the traditional algorithm. When the recommendation number is low, the inverse value of LDA Algorithm is lower than the improved algorithm. The difference between LDA output coefficient and standard algorithm output coefficient gradually decreases, and the amount of recommendation increases, slightly higher than the improvement rate of the algorithm; among them, 120 recommendations.

For the same number of comments, the impact of the number of consumer training on the repeatability results is shown in Fig.10. Fig. 10 shows that the download rate of the three algorithms usually increases with the increase of the number of user training. When the number of user training is more, the calculation can play a better role. The extraction rate of the improved link filtering algorithm between the three algorithms is much higher than that of the traditional

algorithm, and is always higher than that of the LDA Algorithm. When the number of training users increase, the download rate of the improved algorithm is significantly higher than the LD rate. The table improved algorithm is better than the other two algorithms, and when the number of courses increases in a certain amount of pasta, the advantage of the improved algorithm is greater.

The impact of the number of user learning courses on the accuracy results is shown in Fig. 11. From Fig. 11, it can be seen that the accuracy of the three algorithms shows an overall upward trend as the number of user-learning courses increases, indicating that the algorithms can play a better recommendation effect when the number of user-learning courses is more. The accuracy of the improved algorithm among the three algorithms is always higher than the other two algorithms, and the difference between the improved algorithm and the LDA is more significant as the number of courses increases, indicating that the improved algorithm will have a superior performance as the number of courses increases.

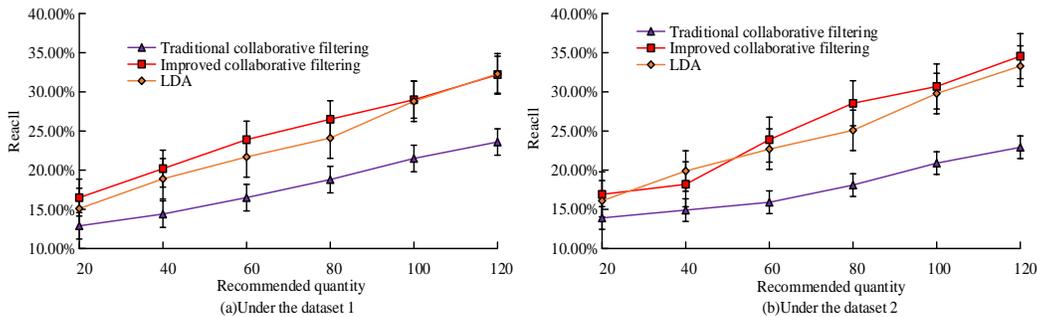

Fig. 9. Results of recommended quantity and recall rate of three algorithms.

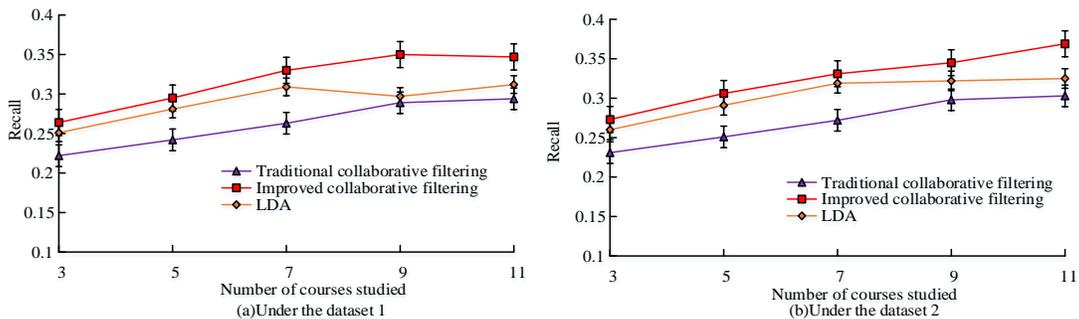

Fig. 10. Results of number of learning courses and recall rate of three algorithms.

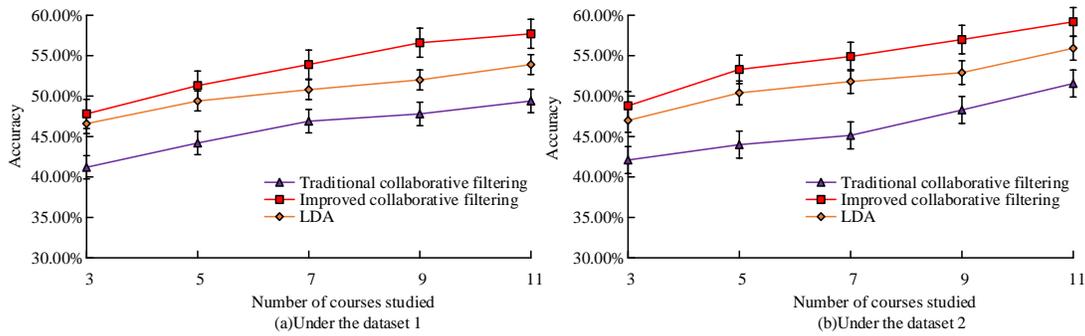

Fig. 11. Results of number of learning courses and accuracy of three algorithms.

The results of the recommendations were transmitted to the target users, the target users were divided into two large flat-rate groups, the results of the evaluation of the target users were taken from the sample and the results of each algorithm assessment were broken down into an average of five groups and then the average result for each group was calculated, - obtain the results of the evaluation referred to

in Fig. 12. Fig. 12 shows that, with the exception of the third group, the improved algorithm rates are higher than the other two and that the difference between the improved algorithm and the third group algorithm is lower, which fully indicates that the improved algorithm designs a course with higher performance than the class and is suitable for online courses training.

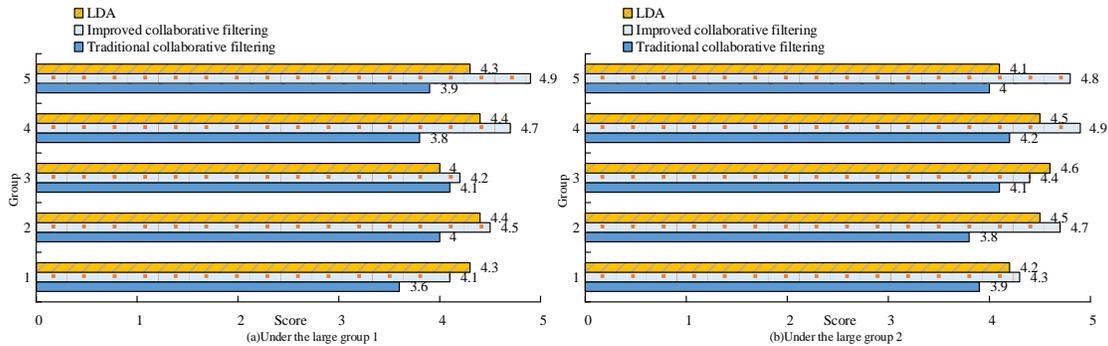

Fig. 12. Comparison of evaluation results of three algorithms.

## VI CONCLUSION

The research uses a modified cooperation filtering algorithm based on a multifunctional classification model, which is tested and compared with the regular cooperation filtering algorithm and LDA algorithm after sample training. Experimental results show that the maximum accuracy and recall rate of the improved algorithm is 92.2% and 32.2% respectively for different recommended quantities which are significantly higher than the traditional algorithm; the maximum level of accuracy with an improved algorithm cancellation rate is 57.7% and 34.7% respectively for different numbers of learning courses which are significantly higher than the other two algorithms. The overall mean of the improved algorithm is 4.46, which is higher than the other two algorithms in 5 with 5. Experimental results show that the improved algorithm works much better than the traditional algorithm and, in many cases, better or much better than the LDA algorithm. Although some results have been obtained in the study, the total number of samples selected in the experiments is still small and the overall shortage of random sampling results due to the small number of samples is the main direction for further studies and optimization in the future.

## VII FUTURE WORK

In this study, an improved collaborative filtering algorithm based on a multi-feature ranking model is used to construct a recommendation model for teaching innovation and entrepreneurship online courses in the context of internationalization of education. After testing the performance of the model, it is found that the constructed model has better recommendation effect, higher accuracy rate, and higher user satisfaction for innovation and entrepreneurship online courses. Although the research conducted in this paper has achieved certain results and optimized the traditional collaborative filtering algorithm to a certain extent, the following shortcomings still exist.

- 1) Although the improved collaborative filtering algorithm is applied to the course recommendation model, it may cause some bias to the experimental results because more pre-processing is not performed on the adopted educational data set.
- 2) Whether the constructed recommendation algorithm model is applicable to other e-learning recommendations for different majors is not explained in the paper. Subsequent research should attempt to apply the model to more online course recommendations for different majors.

3) In the current recommendation field, there are also more studies on the optimization of collaborative filtering algorithm, and the subsequent research should combine more advanced algorithms to optimize collaborative filtering and thus improve the recommendation accuracy.

**Abstract**—One of the most studied machine learning challenges that recent studies have shown the susceptibility of deep neural networks to is the class imbalance problem. While concerted research efforts in this direction have been notable in recent years, findings have shown that the canonical learning objective, empirical risk minimization (ERM), is unable to achieve optimal imbalance learning in deep neural networks given its bias to the majority class. An alternative learning objective, group distributionally robust optimization (gDRO), is investigated in this study for imbalance learning, focusing on tabular imbalanced data as against image data that has dominated deep imbalance learning research. Contrary to minimizing average per instance loss as in ERM, gDRO seeks to minimize the worst group loss over the training data. Experimental findings in comparison with ERM and classical imbalance methods using four popularly used evaluation metrics in imbalance learning across several benchmark imbalance binary tabular data of varying imbalance ratios reveal impressive performance of gDRO, outperforming other compared methods in terms of g-mean and roc-auc.

**Keywords**—Class imbalance; deep neural networks; tabular data; empirical risk minimization; group distributionally robust optimization

## I. INTRODUCTION

Owing to increased data availability, novel learning architectures and accessibility to commodity computational hardware devices, deep neural networks (DNNs) have become the de facto tool for a wide range of machine learning (ML) tasks in recent times; leading to state-of-the-art performance in several computer vision, natural language processing and speech recognition tasks. DNNs are characterized by several layers of hidden units that enable learning of useful representations of a given data for improved model performance [1, 2]. This alleviates the need for domain experts and hand-engineered features, a common prerequisite for traditional ML methods.

A pervasive problem that has plagued traditional ML methods in the last couple of decades which DNNs are not immune to is the class imbalance problem [3-6]. This problem, also termed long-tailed data distribution problem in computer vision, occurs when the distribution of the constituent classes

of a training data is highly disproportionate such that one or more classes have significantly larger number of training samples (majority class(es)) than other(s) (minority class(es)). Given that most ML methods are built to minimize the overall classification error with the assumption that each sample contributes equally, the learning algorithms tend to be bias towards the majority class; thus, resulting in partial or total disregard of the discriminative information of the minority classes by the learning algorithm. What makes this problem even more interesting is that, in most cases, the minority classes are often the classes of interest. Several manifestations of this problem abound in many real-life application domains of ML like medical diagnosis [7, 8], fraud detection [9-11], flight delay prediction [12, 13] amongst others.

The knowledge that learning from imbalance data negatively impacts the performance of DNN has resulted a marked increase in research on deep learning-based approaches to tackle the problem in recent years, with findings showing that traditional approaches to addressing imbalance problems can be successfully extended to DNN [3, 5]. Thus, many deep learning studies have addressed the imbalance problem at the data level mainly by data resampling [14-16] while some have done so at the classifier level, largely through cost sensitive learning approaches [17-22]. Oversampling and undersampling are two common data resampling approaches used in DNN. However, the susceptibility of the former to noise and overfitting due to added samples [23] as well as the characteristic loss of valuable information peculiar with the latter [3] remain major drawbacks of this category of imbalance methods. On the other hand, the core idea behind the cost sensitive methods is to assign different misclassification cost/weights to the training samples to scale up/down the misclassification errors depending on the class they belong [17, 24]. While there are several implementations of this method, the most commonly used cost sensitive approach in imbalanced deep learning research is reweighting [20, 25], where weights are assigned to different class samples based on either the inverse of the class frequencies [20, 26, 27] or their square root [28]. Despite its widespread adoption in DNN, reweighting methods have been found to be unstable in severely imbalanced cases; yielding poor performance that compromise the performance of the majority class [20, 23, 29,

30]. Inspired by the drawbacks of the commonly used methods, this study seeks to address the imbalance problem from a different perspective, through the learning objective.

The canonical training objective in DNN is the empirical risk minimization (ERM) which entails minimizing the average per sample training loss over the entire training data [31]. This training objective has the capacity to fit a given training data perfectly and still produce impressive accuracy on an unseen test data [32]. However, training a DNN using such objective on an imbalanced data has been shown to be bias to the majority class samples despite fitting the training data perfectly in most cases [32, 33]. The trained DNN is unable to generalize the learnt representations to the minority class samples at inference/test phase. In contrast to ERM, this study explores minimizing the maximum between the majority and minority class losses for improved imbalance learning. This is analogous to distributionally robust optimization (DRO) which seeks to minimize the expected loss over possible test distributions that the model is expected to perform well on [34, 35]. Specifically, group DRO (gDRO) proposed in [32] is investigated in this study in the context of classical class imbalance problem in DNN where the training and test data are similarly imbalanced. Rather than seeking reduction in the generalization gap between the training and test accuracies of the worst group, the performance of gDRO on binary imbalance datasets of varying imbalance ratios is investigated in comparison to popular imbalance methods in DNN. The performance of these methods is compared using four popular evaluation metrics in imbalance learning.

The rest of this article is outlined as follows: Section II provides the requisite background on ERM and gDRO followed by Section III which contains the methodology as it relates to the benchmark datasets, selected imbalance methods, DNN architecture and other experimental settings. The experimental results and discussions are presented and discussed in Section IV and Section V respectively before concluding in Section VI.

## II. THEORETICAL BACKGROUND ON ERM AND GDRO

Given a training data  $\mathcal{D}_t = \{(x_i, y_i)\}_{i=1}^N$ , where  $y \in \mathcal{Y}$  and  $x \in \mathcal{X}$  represent the target labels and the input features respectively,  $f_\theta$  is a prediction function parameterized by  $\theta$  that learns to correctly map each input feature  $x_i$  to the corresponding output label  $y_i$ . The aim is to find the set of parameters  $\theta$  that minimize the risk in (1).

$$\min_{\theta} \mathbb{E}_{(x,y) \sim \mathcal{D}_t} [\ell(y, f_\theta(x))] \quad (1)$$

where  $\ell$  and  $f_\theta(\cdot)$  stand for the loss function and predicted output respectively. Equation (1) is approximated using the training set,  $\mathcal{D}_t$ , as in (2). This training objective is known as empirical risk minimization (ERM). In other words, the ERM aims to minimize the average per instance training loss.

$$\text{ERM} = \min_{\theta} \frac{1}{N} \sum_{i=0}^N \ell(y_i, \{f_\theta(x_i)\}_{c=1}^C) \quad (2)$$

A popular  $\ell$  used in deep learning is the cross-entropy loss:

$$\ell(y_i, \{f_\theta(x_i)\}_{c=1}^C) = -\log p(y_i | x_i; \theta)$$

$$= -\log \left( \frac{\exp(f_\theta(x_i))}{\sum_{c=1}^C \exp(f_\theta(x_c))} \right) \quad (3)$$

The pseudocode for ERM is shown in Algorithm 1 below. In a classification problem, each output label  $y_i$  belongs to one of  $C$  classes and the aim of  $f_\theta(\cdot)$  is to ensure that each input  $x_i$  is classified to the correct class  $c \in \{1, \dots, C\}$ .

---

### Algorithm 1: Empirical Risk Minimization Training

---

**Input:** Training Data  $\mathcal{D}_t = \{(x_i, y_i)\}_{i=1}^N$ ; no of Epochs,  $E$ ; Batch size,  $b$ ; Learning rate  $\eta$   
**Output:** Trained Model  
 Initialise model parameters  $\theta_0$   
**for**  $t = 1, 2, \dots, E$  **do**  
     randomly split  $\mathcal{D}_t$  into  $n$  equal-sized minibatches;  $|B| = b$   
     **for**  $B \in \{1, \dots, n\}$  **do**  
         perform forward pass for model  $f_\theta$   
          $\nabla_{\theta} L(\theta_t) \leftarrow \frac{1}{|B|} \sum_{i=0}^b \nabla_{\theta} L(y_i, f_\theta(x_i))$  #Compute loss and  
         perform gradient step  
          $\theta_{t+1} \leftarrow w_t - \eta \cdot \nabla_{\theta} L(w_t)$  #Update model parameters in  
         backward pass  
     **end**  
**end**

---

Unlike ERM, where the average per sample loss over the entire training data is minimized, gDRO minimizes the worst group error. Thus, gDRO presumes group annotations over the training data i.e., every training sample is a triplet  $\{(x_1, y_i, g_1), \dots, (x_n, y_n, g_n)\}$  where the  $g_n$  stands for the group annotation of the  $n$ th sample. On the contrary, no group annotations based on spurious correlations are assumed in this study. Rather, a typical case of class imbalance where samples belonging to the minority class are fewer than those of the majority class is the focus of this study. Thus, number of samples belonging to each class is denoted as  $N_c$ . Hence, instead of (2), (4) is used to update the DNN in gDRO in this study; where  $\frac{1}{\sqrt{N_c}}$  is for the group adjustment as in [32].

$$\text{gDRO} = \min_{\theta} \max_{c \in C} \left\{ \frac{1}{N_c} \sum_{i=1}^{N_c} \ell(y_i, f_\theta(x_i)) + \frac{1}{\sqrt{N_c}} \right\} \quad (4)$$

The pseudocode for group DRO training is presented in Algorithm 2.

## III. MATERIALS AND METHODS

### A. Benchmark Datasets

Nineteen (19) carefully selected binary class benchmark imbalanced datasets from Keel<sup>1</sup> and UCI<sup>2</sup> data repositories are used in this study. Details such as the sample size, number of features, fraction of majority and minority samples in percentage are presented in Table I. The degree of imbalance in each dataset is indicated by the imbalance ratio (IR) which is the ratio of the majority to minority samples size. Likewise, the degree of complexity of each dataset is shown using mean silhouette coefficient of its samples (S.Coeff) [36]. The S.Coeff values ranges between -1 and +1. Values around zero indicate overlapping class clusters, whereas values close to +1 and -1

<sup>1</sup> <https://sci2s.ugr.es/keel/index.php>

<sup>2</sup> <https://archive.ics.uci.edu/ml/datasets.php>

indicate well separated and highly overlapped class clusters respectively.

**Algorithm 2:** Group Distributionally Robust Optimization Training

**Input:** Training Data  $\mathcal{D}_t = \{(x_i, y_i)\}_{i=1}^N$ ; classes,  $c \in \{1, \dots, C\}$ ; no of Epochs,  $E$ ; Batch size,  $b$

**Output:** Trained Model

Initialize parameters of model  $f_\theta$

for  $t = 1, 2, \dots, E$  do

    randomly split  $\mathcal{D}_t$  into  $n$  equal-sized minibatches;  $|B| = b$

    for  $B \in \{1, \dots, n\}$  do

        perform forward pass for model  $f_\theta$

        for  $c = \{1, \dots, C\}$  do

$L_c(\theta_t) \leftarrow \frac{1}{N_c} \sum_{i=1}^{N_c} \ell(y_i, f_\theta(x_i)) + \frac{1}{\sqrt{N_c}}$  # compute loss for each class

        end

$\nabla_\theta L(\theta_t) \leftarrow \nabla_\theta \{\max(L_c(\theta_t)_{c=1}^C)\}$  # perform gradient step with worst group

$\theta_{t+1} \leftarrow \theta_t - \eta \cdot \nabla_\theta L(\theta_t)$  # update model parameters in backward pass

    end

end

**B. Methods for Handling Class Imbalance**

In addition to ERM and gDRO, experiments were also carried out using four classical imbalance methods and compared. These methods were chosen to cover commonly used imbalanced methods in DNN research and their hybrid.

- Random Oversampling (ROS)
- Random Undersampling (RUS)
- Cost sensitive reweighting (COST): The weights assigned to majority and minority class samples are determined by the inverse of  $N_c$ ; where  $N_c$  is the number of samples belonging to class  $c$ .
- Hybrid of random undersampling and oversampling (RUSROS): This involves initially randomly undersampling the majority class by 50% before randomly oversampling the minority class samples till it equals the majority class size.

Overall, the performance of six methods (ERM, gDRO, ROS, RUS, COST and RUSROS) on the imbalance datasets are compared in this study.

**C. DNN Architecture**

Unlike convolutional neural networks (CNN), where a wide range of benchmark architectures are available [37], determining an appropriate DNN architecture for tabular data is nontrivial due to the sparsity of representative works addressing pertinent issues such as the ideal network depth and width as well as the best activation functions for this class of models. While in recent years several novel architectures have been proposed in representative studies [38-41], no single method provides a reliable performance across multiple tasks. Hence, deep fully connected otherwise known as deep multilayer perceptron remains the quintessential baseline architecture for modelling structured data [41] and thus, used in this study. Besides, deep fully connected neural networks are

natural fit for imbalanced data with capability of yielding impressive results when the hyperparameters are optimized [42].

TABLE I. BENCHMARK DATASETS

Data	# Samples	# Features	% Maj Class	% Min Class	IR	S.Coeff

ReLU activation function is widely used in deep learning class imbalance research [14, 43], hence the same is adopted in the DNN model used in this study. Batch normalization and 0.5 dropout rate are applied after each ReLU activation of each hidden layer to avoid overfitting. Likewise, to optimize a DNN model for each dataset, representative imbalance studies have often resulted to grid search for hyperparameters optimization [14, 44, 45]. Similarly, 80% of each imbalanced data was used for hyperparameter optimization via grid search. Only the depth and width of each DNN model are optimized as in [14]. A network width of 50 neurons per hidden layer was found to be sufficient for the models to overfit the data after experimenting with widths of 512, 300, 100, 50 and 32 neurons respectively. The depth of these models was optimized starting with a depth of two (i.e., 2-hidden layers) and varying it up to six. The optimal DNN architecture for each imbalanced dataset

was determined via the best mean AUC over 5-fold cross validation [42]. The AUC results for optimal number of layers and architecture for each dataset is presented in Table IV of the appendix.

#### D. Experimental Setup

10-fold cross validation approach was employed for model training and validation for each combination of dataset, model and imbalance method. All DNN models were trained to stop early if there are no improvement in the validation error after 10 successive epochs. Adam stochastic optimization with learning rate of 0.001 was used in model training. Each model weights were randomly initialized with uniform distribution and Xavier variance [46] with zero bias before training with batch stochastic gradient descent. The minibatch sizes were set to range from 1/32 to 1/100 of each respective dataset sample sizes. The training procedure is illustrated in Fig. 1.

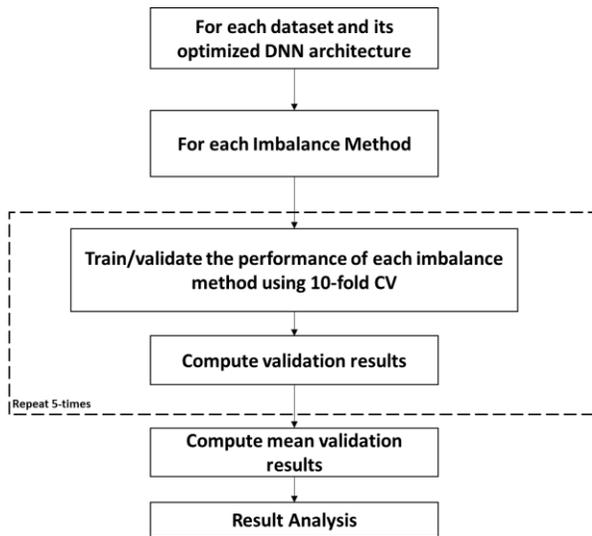

Fig. 1. Training procedure

To further ensure credibility of our findings and handle associated inconsistencies resulting from randomization and stochastic nature of the training process, the experiment for each combination was repeated five times with varying random seeds; resulting in different initial parameters for each repetition [47]. The mean validation results across the repetitions are reported. In all, 5,700 experiments were conducted. Given the large number of models that is required to be trained, a commodity hardware GPU, Nvidia Geforce GTX 960M, on a core i5 Dell Inspiron 7559 machine was leveraged to speed up the experiments. All experiments were implemented in Pytorch deep learning framework [48].

#### E. Evaluation Metrics

The inadequacy of accuracy and error rate as measures of classification performance of imbalance datasets is well documented in the literature [49]. Thus, four complementary evaluation metrics that have been used in imbalance learning research have been adopted in the study. Each of this metrics is described in what follows. Note that FP, FN, TP and TN are false positive, false negative, true positive and true negative respectively.

- Receiver Operating Characteristic Area Under the Curve (ROC-AUC): The ROC is a plot of the true positive rate ( $\frac{TP}{TP+FP}$ ) against the false positive rate ( $\frac{FP}{FP+FN}$ ) across all possible discrimination thresholds. From this plot, the AUC which is the area under the receiver operating characteristic (ROC) curve can be calculated and used as a performance measure of classification model.
- Precision-Recall AUC curve (PR-AUC), perhaps inspired by the ROC-AUC, is a plot of precision on the y-axis ( $\frac{TP}{TP+FP}$ ) against recall ( $\frac{TP}{TP+FN}$ ) on the x-axis. The area under the PR-curve is also used as a measure of the performance of binary classification models. The AUC implementation used in this work is calculated using the trapezoidal rule.
- F1-Measure, a widely used evaluation metric, is another measure of evaluation used in this study. It is the harmonic mean of precision and recall (i.e.,  $\frac{(1+\beta^2) \times Recall \times Precision}{\beta^2 \times Recall + Precision}$ ). The beta ( $\beta$ ) parameter shows the trade-off between precision and recall. Our interest is to detect both majority and minority classes with equal preference, hence, the  $\beta$  parameter is set to 1.
- Geometric mean (g-mean) is the final evaluation metric used to evaluate the models. In case of binary classification, g-mean is the squared-root of the product of recall and true negative rate (TNR) ( $\sqrt{\frac{TP}{TP+FN} \times \frac{TN}{TN+FP}}$ ).

Additionally, the Friedman test [50] is also used in this study to detect differences in the experimental results across multiple attempts, when the normality assumption may not hold. Thus, this test is used to reject the null hypothesis that the compared methods produce similar performance across the different datasets and DNNs in comparison to their mean rankings. Then, as recommended in [51], pairwise posthoc analysis using Wilcoxon signed-rank test [52] with Holm's alpha (0.05) correction [53] was used for comparison. A visualization of the comparison is presented using a critical difference diagram [54].

## IV. RESULTS

Multiple benchmark datasets enabled a fair comparative analysis of ERM, gDRO and the imbalance methods across a wide range of imbalance ratios. The mean ( $\pm$ standard deviation) of the validation performance of each method across the respective evaluation metrics for each dataset over five repetitions of the experiment (as shown in Fig. 1) are presented in Fig 2. The overall average performance of each method in addition to the number of times each method ranks first for each evaluation metric is also presented in Table II. Similarly, a bar plot showing the average ranking of each method per dataset is presented in Fig. 3.

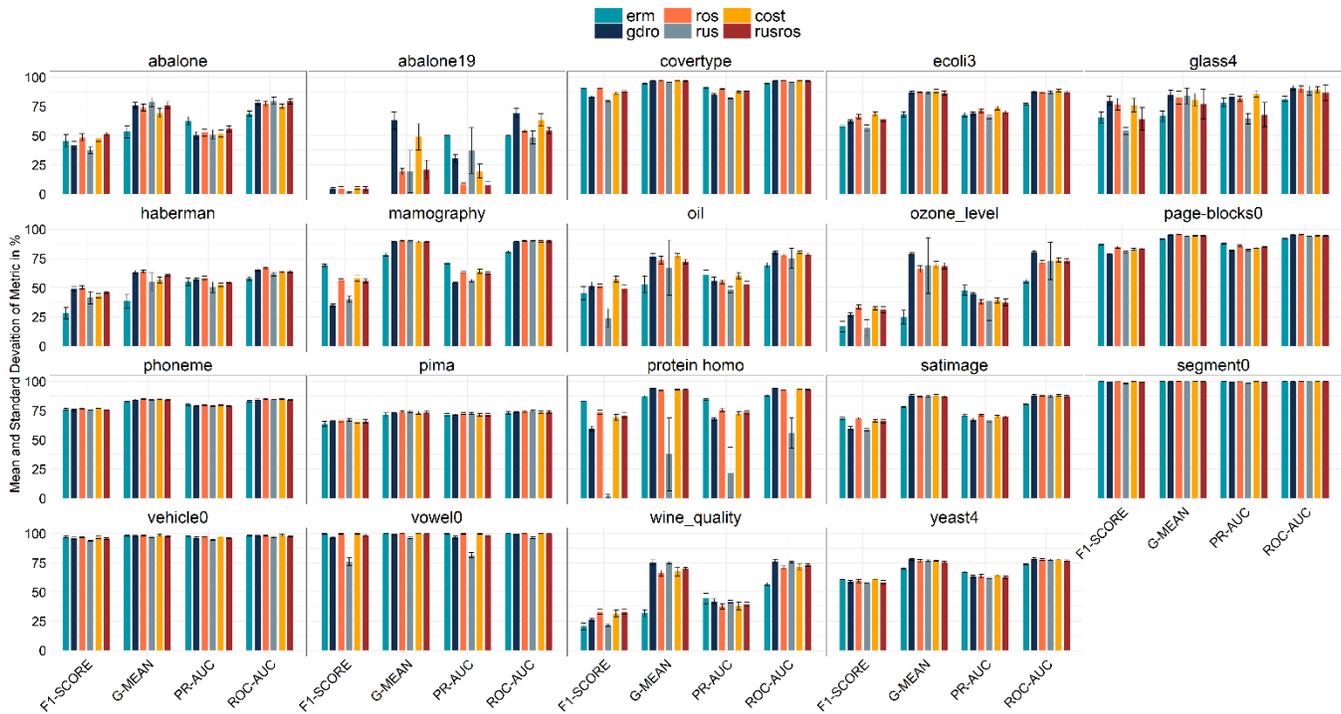

Fig. 2. Mean ( $\pm$ standard deviation) results of comparative methods

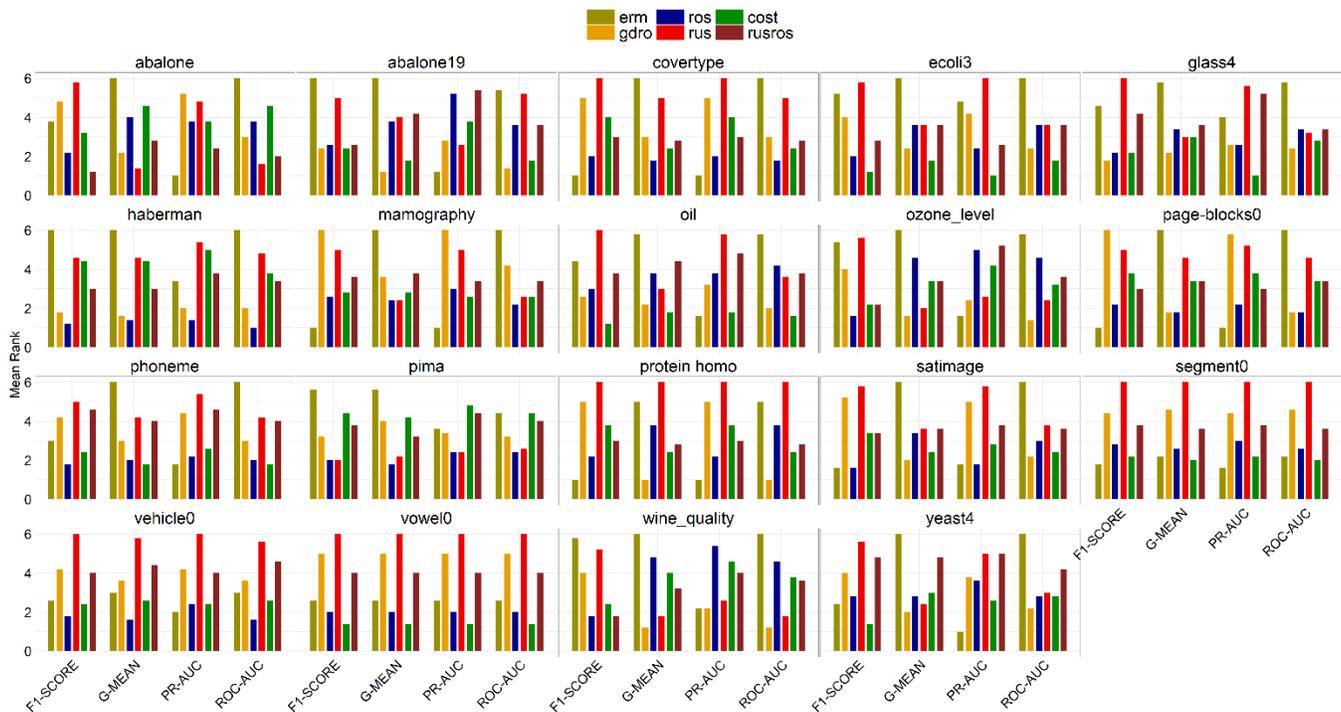

Fig. 3. Mean ranking of the experimental results (lower the better)

### A. Results based on F1-Score

As, depicted in Fig. 2, the performance of gDRO in comparison to ERM regarding the top six imbalanced benchmarks (IR of 129.44 to 21.85) shows that gDRO mostly produces better average f1-score for those with overlapping classes (abalone19, ozone level, wine\_quality and oil) i.e.,

gDRO identifies minority samples better on complex imbalanced datasets- whereas ERM performed better on those with better class separability (protein\_homo and mamography). The general f1-score on the abalone19 benchmark is notably very poor across the compared methods, a likely explanation for this is lack of data/information (given a meagre minority sample size of 32) worsened by class overlap.

Likewise, the superior performance of gDRO over ERM on this benchmark suggests the suitability of the former in extreme imbalance cases where data is lacking. As for the remaining datasets in decreasing order of imbalance ratio, ERM produced better average f1-score than gDRO in all but glass4, ecoli3 and haberman datasets; the three smallest datasets in the benchmarks and of varying degree of overlap. In comparison to the classical imbalance methods, while mostly outperforming RUS on mammography, page-block0 and pima, gDRO mostly produced lower average f1-score than, at least, one of ROS, COST or RUSROS except on abalone19 and glass4 datasets where gDRO outperformed other methods. As shown in Table II, ROS produced the best average overall f1-score across the benchmarks, producing the best score seven times in the process. On the other hand, RUS produced the lowest overall f1-score and only managed to produce the best score once (which was jointly with ROS on the least imbalance dataset, pima).

### B. Results based on G-Mean

As shown in Fig. 2, gDRO produced better average g-mean scores than ERM across all but the segment0, vehicle0 and vowel0 datasets where they both performed similarly or marginally better performance by ERM. It should be noted that the performance of the model on these datasets is generally better than the remaining datasets. In comparison to the selected imbalance methods in terms of the top six imbalanced datasets (abalone19, protein homo, mammography ozone level, wine\_quality and oil), gDRO yielded the best average g-mean on all but the mammography and oil datasets where ROS and RUS as well as COST respectively produced better performance. On the remaining datasets, as the imbalance ratio reduces and the minority to majority ratio increases, the performance of the classical imbalance methods generally become more comparable to gDRO which was only able to produce the best average g-mean on the glass4, satimage, page-block0 and yeast4 datasets. Table II shows that gDRO produced the best average overall g-mean of 84.28% across the benchmarks, while achieving the best score 8 times in the process. The implication of the impressive performance of gDRO in terms of g-mean is that it detects the minority samples with lower false positive and false negative rates. On the other hand, an overall average g-mean score of 67.74% achieved by ERM makes it the least performing method in this regard.

### C. Results based on PR-AUC

As shown in Fig. 2, ERM outperforms gDRO and other classical imbalance methods based on average pr-auc on all but the ecoli3, glass4, haberman and pima datasets. Three of these datasets (ecoli3, glass4 and haberman) have the least number of samples while the relatively larger pima dataset is the least imbalance amongst the considered benchmarks. Despite achieving better average pr-auc than ERM on these datasets, the performance of gDRO still remains inferior to at least one of ROS, RUS, COST or RUSROS. Table II further shows that ERM produced the best overall average pr-auc of 73.07%, achieving the best performance 14 times across the different benchmarks. In contrast, RUS showed the lowest performance in this regard despite producing the best result once (jointly with ROS on the pima dataset).

TABLE II. AVERAGE PERFORMANCE ACROSS ALL DATASETS (AND THE NUMBER OF TIMES EACH METHOD RANKS FIRST)

Metric	ERM	GDRO	ROS	RUS	COST	ROSRUS
F1-SCORE	61.85 (6)	60.57 (2)	65.07 (7)	51.54 (1)	64.37 (5)	63.19 (2)
G-MEAN	67.74 (0)	84.28 (8)	80.36 (6)	77.23 (2)	81.68 (5)	80.12 (0)
PR-AUC	73.07 (14)	68.16 (1)	68.41 (3)	62.83 (1)	68.95 (3)	66.92 (0)
ROC-AUC	77.86 (0)	85.55 (8)	83.80 (4)	81.10 (0)	84.28 (0)	83.58 (1)

### D. Results based on ROC-AUC

The performance of gDRO as illustrated in Fig. 2 relative to ERM in terms of average roc-auc is similar to findings based on average g-mean as gDRO shows better average roc-auc scores than ERM across all but the segment0, vehicle0 and vowel0 datasets where they both performed similarly or ERM is marginally better. Comparison based on the top six imbalanced benchmarks also shows similar trend as gDRO produced the best average roc-auc on all but the mammography (where ROS, RUS, COST and RUSROS were better) and oil (where COST was better) datasets. Datasets with lower IR produced improved results that are comparable or relatively better than gDRO with these methods. However, gDRO produced the best average roc-auc on the glass4, satimage, page-block0 and yeast4 datasets. Further, Table II shows that gDRO produced the highest overall average roc-auc (85.55%), producing the results eight times across the datasets. On the other hand, ERM produced the lowest overall average performance based on ROC-AUC.

### E. Statistical Analysis

The Friedman's test results presented in Table III shows that the null hypothesis, namely, the imbalance methods produce similar performance across the different datasets is rejected. Hence, pairwise posthoc analysis using Wilcoxon signed-rank test is carried out to rank each method across the evaluation metrics as illustrated in Fig. 4. The figure shows a critical difference diagram of the imbalance methods for each evaluation metric where a thick horizontal line indicates group of imbalance methods (a clique) for which the difference in their performance is not statistically significant. For each metric, the mean performance of each method across the dataset is used for the statistical test. The figure shows that although for f1-score, g-mean, pr-auc and roc-auc, ROS, gDRO, ERM and gDRO respectively rank highest, each of these methods is not significantly better than at least two other methods. For instance, in terms of f1-score, ROS is not statistically different from COST and ERM whereas in term of pr-auc, no statistically significant difference exists between ERM, ROS, COST and gDRO.

TABLE III. RESULT OF FRIEDMAN'S TEST

Metric	p-value
F1-Score	0.00000
G-Mean	0.00000
PR-AUC	0.00000
ROC-AUC	0.00000

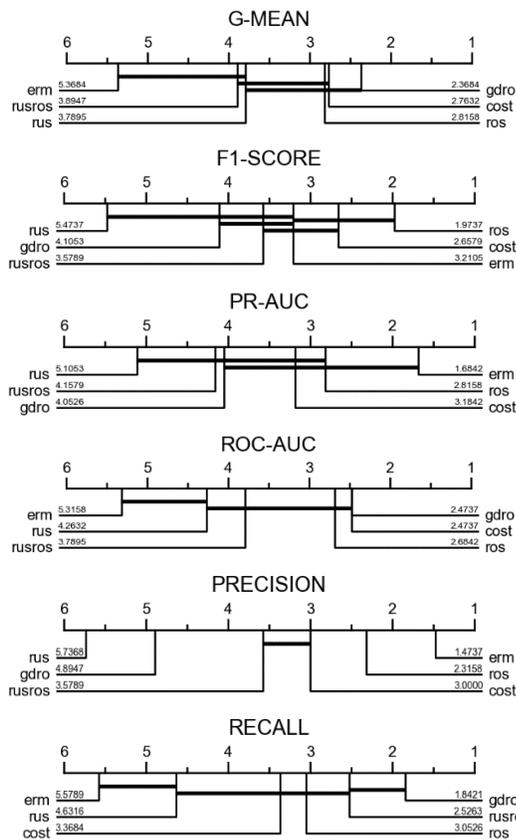

Fig. 4. Critical difference diagram of pairwise statistical difference comparison between imbalance methods

## V. DISCUSSION

The importance of this study cannot be overemphasized as it investigates gDRO for learning imbalance tabular data in DNN as against ERM which is the main learning objective in both balanced and imbalanced deep learning research. The empirical results of this study show that in terms of ROC-AUC which reflects a balanced assessment of the performance of the DNN models on both majority and minority samples across different thresholds, gDRO mostly outperforms ERM and most of the compared imbalance methods on benchmark datasets of varying imbalance ratios, sizes and complexities. This implies that deep imbalance learning via minimization of worst-case loss across classes can produce models that are more robust to both majority and minority class samples than ERM. Hence, gDRO is an ideal training objective in cases where both majority and minority classes of the imbalance data are equally important as it is known for its robustness to distributional shifts [32].

Following the generally held notion that ERM biases DNN models to the majority class when learning imbalance data [55], it would be expected that ERM perform poorly on the minority samples. However, it can be observed that ERM mostly outperform gDRO and other compared imbalance methods across the studied benchmarks in terms of pr-auc which mainly focuses on the performance of the DNN model on the minority samples under a range of thresholds. One likely explanation for this is that while ERM produced the best

overall result on the minority samples over different thresholds, this does not necessarily mean it produced the best performance for a specific threshold value [56]. This explains why ERM is unable to replicate similar feat on metrics like f1-score and g-mean that are computed for specific threshold value.

Additionally, since pr-auc measures the area under the plot of precision against recall for different thresholds, another possible explanation could be that the pr-auc of ERM is dominated by precision. As hinted in Section E of IV, precision quantifies the number of correct positive (minority) predictions by dividing the number of correctly classified positive samples by the total number of correctly classified positive samples and negative (majority) samples that are incorrectly classified as positive. Compared to recall which quantifies the number of correct positive predictions from all positive samples, only a model that is bias to the majority samples is less likely to misclassify a majority sample as minority than misclassify a minority sample. In other words, ERM could produce the best pr-auc while being bias to the majority class samples if pr-auc is dominated by precision. The critical difference diagrams for precision and recall have been included in Fig. 4 to further elucidate this line of thought. See Fig. 5 and Fig. 6 of the appendix for more details of each method on each dataset in terms of precision and recall.

In relation to the classical imbalance methods, COST and ROS tend to perform similarly and better than RUS in most cases with COST showing superior performance in highly imbalance cases. However, the performance gains in terms of minority sample detection for these methods tend to come at the expense of some majority class samples [20]. On the other hand, RUSROS does not appear to have any major advantage that its constituent methods have not exhibited. Generally, the inferior performance of the imbalance methods on the highly imbalance benchmarks with some degree of class overlap like abalone19 and ozone\_level compared to similarly imbalance ones like protein\_homo and mamography with more minority samples and better class separability underlines the impact of size and complexity of data in imbalance learning. Decreasing imbalance ratio tend to result in improved performance across the metrics.

It should however be noted that the adopted experimental design could have impacted the empirical results of this study. Particularly, in relation to reporting the mean scores of several repetitions of the experiments as against a single round as common in most DNN-based imbalance research [5]. Nevertheless, the adopted design has obvious benefits amongst which is an objective measure of the true model performance.

In sum, the choice of method for handling class imbalance in DNN models depends on several factors, including the severity of class imbalance, the size and complexity of the dataset, and the specific evaluation metric of interest. In some cases, ERM may be sufficient to achieve good performance on imbalanced datasets, while in other cases, gDRO or other methods may be necessary.

## VI. CONCLUSION

Deep imbalance learning has mainly focused on imbalance in computer vision related tasks. Likewise, empirical risk minimization (ERM) which entails minimizing the average per sample training loss over the entire training data has been shown in pertinent works to bias DNNs to the majority class when learning from imbalance data [31]. An alternative learning objective, group distributionally robust optimization (gDRO) is investigated in this study for imbalance learning with a focus on tabular data. The performance of gDRO in comparison with ERM and four classical imbalance resolution methods on several benchmark imbalance datasets of varying imbalance ratios are examined using four common metrics for evaluating class imbalance. Experimental findings show that while gDRO outperform other methods in terms of g-mean and ROC-AUC, whereas ERM and ROS rank highest in terms of pr-auc and f1-score respectively. Future research efforts will focus on the impact of pretraining on deep imbalance learning as well as gDRO for multiclass imbalance tabular data.

College of Information Engineering, Tangshan Polytechnic College, Tangshan, 063299, China<sup>2</sup>

**Abstract**—Visual tracking in uncrewed aerial vehicles is challenging because of the target appearance. Various research has been fulfilled to overcome appearance variations and unpredictable moving target issues. Visual saliency-based approaches have been widely studied in biologically inspired algorithms to detect moving targets based on attentional regions (ARs) extraction. This paper proposes a novel visual tracking method to deal with these issues. It consists of two main phases: spatiotemporal saliency-based appearance modeling (SSAM) and sample feature-based target detection (SFTD). The proposed method is based on a tracking-by-detection approach to provide a robust visual tracking system under appearance variation and unpredictable moving target conditions. Correspondingly, a semi-automatic trigger-based algorithm is proposed to handle the phases' operation, and a discriminative-based method is utilized for appearance modeling. In the SSAM phase, temporal saliency extracts the ARs and coarse segmentation. Spatial saliency is utilized for the object's appearance modeling and spatial saliency detection. Because the spatial saliency detection process is time-consuming for multiple target tracking conditions, an automatic algorithm is proposed to detect the region saliences in a multithreading implementation that leads to low processing time. Consequently, the temporal and spatial saliencies are integrated to generate the final saliency and sample features. The generated sample features are transferred to the sample feature-based target detection (SFTD) phase to detect the target in different images based on samples. Experimental results demonstrate that the proposed method is effective and presents promising results compared to other existing methods.

**Keywords**—Visual tracking; biologically inspired; visual saliency detection; appearance modeling; attention region; spatiotemporal

## I. INTRODUCTION

Visual tracking is mainly investigated as an active research topic according to its wide range of applications, including smart surveillance systems, intelligent remote sensing technologies, action recognition, and robotic and human-computer interaction [1]. Particularly, visual target tracking is broadly studied on uncrewed aerial vehicles (UAV) to detect and track targets on aerial images. As opposed to applications with fixed cameras, for example, traffic monitoring, aerial videos have the favorable circumstances of higher portability and superior reconnaissance and surveillance [2]. However, visual tracking systems are still suffered from various challenges and difficulties. Target appearance variations and

tracking the target under uncontrollable and unpredictable conditions are as main challenges of these systems [3, 4]. In this regard, online learning-based tracking methods that can incrementally update feature representations have received more attention for achieving a reliable and robust visual tracking algorithm [5]. Therefore, an online target feature representation is crucial for preserving an efficient appearance model to describe and identify the target from background [3, 6].

Recently, biologically inspired and cognition-based approaches have become a topic of interest by many researchers [7]. These approaches are inspired by human biological mechanisms, meaningfully indicating that human perception is sensitive to attentional regions (ARs) [5, 8]. By adopting biologically inspired approaches, visual saliency detection methods have been presented to detect attentional regions based on spatial and temporal information, resulting in the design of a significant number of saliency-based object detection methods [2]. Hence, a fascinating question is how we can exploit and take advantage of these approaches to develop a more powerful visual tracking algorithm [9]. Current visual saliency detection approaches can be categorized as task-driven attention (top-down) and data-driven attention (bottom-up) [10-13]. The top-down approach is a result of long-term visual simulation with prior knowledge [10]. The top-down approaches focused on high-level information investigation, such as the sky, faces, and humans [14]. This approach's drawback is a hard generalization because it is not simply obtained from images [15].

Furthermore, they are slow and computationally expensive [10]. On the other hand, the bottom-up approaches are based on low-level visual features simulating the formation of short-term visual attention [16]. In contrast to the top-down method, the bottom-up-approaches are rapid [14, 17]. As promising results indicated on bottom-up based approaches, this study focuses on the bottom-up approach.

## II. RELATED WORKS

In this section, existing related works discuss two categories, visual saliency-based, and appearance modeling-based methods.

### A. Visual Saliency-Based Approach

As discussed previously, saliency-based methods are categorized as bottom-up and top-down methods. The bottom-

up methods are categorized into temporal, spatial, and combined-based approaches [2]. The details of each approach discuss to address the advantages and disadvantages.

1) *Temporal saliency*: Detection of salient regions is highly dependent on the recognition of moving objects since motions attract more attention [18]. For moving object detection from a video, moving object detection methods are mainly based on temporal information, such as background subtraction [19, 20], frame difference [21, 22], and optical flow [23].

Background subtraction is based on background modeling. It is widely used for moving object detection. It segments foreground objects from the image background to detect objects that are not moving [24]. However, the background subtraction method suffers from some limitations. These methods are sensitive to the fixed background, and the object extraction fails when the background has changed [10].

Optical flow is also used for moving object detection, even under moving camera conditions. However, optical flow is computationally expensive and sensitive to noise. Thus, optical flow algorithms are not robust in real-time visual tracking systems [2, 25].

Frame differencing as a practical approach for moving object detection is based on pixel-wise difference extraction among the image frames. The frame difference does not require background modeling and is not sensitive to fixed background-like background subtraction methods. Frame differencing is adaptive to dynamic backgrounds and has a low computational cost [2]. However, one of the major drawbacks of frame differencing is moving the objects during the frame capturing process. Because a target may have unpredictable motions, such as stop-and-go periods, the frame difference method is not robust under uncontrollable and unpredictable target movement conditions [26]. Therefore, it is required to propose a temporal saliency detection method to overcome the mentioned challenges [25].

2) *Spatial saliency*: Spatial saliency detection is based on low-level feature representation and focuses on salient region extraction from images. These features are investigated to describe and identify the region of interest as salient regions [2,40]. Several spatial-based methods have been developed, such as region low rank matrix recovery [27], region covariance [28, 29], color-based [41], contrast-based [30], frequency domain [31] and graph [32] methods. As mentioned earlier, visual object tracking in aerial has difficulties in target appearance variations and background changes. To deal with difficulties, spatial saliency detection can extract the salient regions that are moving targets. This method is not sensitive to background changes and abrupt motion.

3) *Spatiotemporal saliency*: Spatiotemporal saliency detection methods calculate the temporal and spatial saliencies [10] separately. They used motion cues investigation for moving object detection. Generally, the results only based on motion cues are not undesirable because of the lack of spatial distribution [2]. Therefore, it is required to integrate the

temporal and spatial features to detect the salient regions more accurately [9, 10,46].

### B. Appearance Modeling-based Approach

Appearance modeling approaches are normally used to deal with appearance variations challenges. These approaches are categorized into generative and discriminative-based methods [5].

1) *Generative-based methods*: Generative-based methods are used to generate a model of an object during appearance changes in scenes. The generated model exploits the discriminative features to handle the target's appearance variations. The mechanism of appearance model generation is frequently updated online to describe the appearance variations. Some generative-based methods are as follows. Lee and Kriegman [33] proposed a generative-based algorithm to update a model for target detection dynamically. Wu and Wang [34] proposed a real-time generative method integrated with an incrementally updating covariance modeling approach for visual tracking. Tianxiang and Li [35] presented an appearance modeling approach based on a generative method and structured sparse representation for tracking an object in a video. However, even though various generative-based methods have been proposed, these methods still have not fully exploited spatial identification within the images efficiently.

2) *Discriminative-based methods*: The discriminative-based method has also been utilized to overcome the challenges related to appearance changes during visual tracking. The discriminative method are called tracking-by-detection. The mechanism for discriminative-based methods is a separate set of features that are extracted such that they distinguish the target from the background image. A binary separation approach is used for target identification from the background in successive frames. Various studies have been conducted based on discriminative-based methods, such as the discriminative learning method based on graph embedding proposed by Zhang et al. [37]. Fan et al. [38] presented an approach of discriminative region attention that describes the target from the background in terms of spatial features. Their proposed method aimed to overcome the spatial distraction in the visual appearance changes challenging. Tang et al. [39] proposed a robust visual tracking method, DRLTracker, based on a discriminative ranking list approach. DRLTracker utilizes the ranking lists and two-scale features to generate a model of the target and recognize it from the background based on the ranking lists of generated patches. However, the proposed method is limited to two-scales DRLTracker and suffers from high processing time.

This study investigates an enhanced discriminative-based appearance modeling approach to overcome the noise shortcoming and appearance variations difficulty. This study uses appearance modeling instead of discriminative-based appearance modeling term in this paper. The appearance

modeling approach details are discussed in the Material and Methods section.

Finally, the core of this paper is the proposal of visual object tracking based on a combination of spatiotemporal saliency appearance modeling and sample feature-based approaches. The proposed method is based on a tracking-by-detection approach to provide a robust visual tracking system in appearance variation conditions. Correspondingly, a semi-automatic trigger-based algorithm is proposed to handle the phases' operation. Furthermore, an automatic algorithm is proposed to detect the region saliencies in a parallel implementation that leads to low processing time. Consequently, the temporal and spatial saliencies are integrated to generate the final saliency and sample features. Our contributions can be summarized as follows,

- A visual tracking method based on spatiotemporal saliency-based appearance modeling (SSAM) and sample feature-based target detection (SFTD) to preserve the visual target tracking robustly under appearance variation conditions, unpredictable motion, and low processing time. The proposed method is efficient in both camera and target moving platforms.
- Develop a novel algorithm for switching automatically between phases to handle their operation based on trigger activation.
- An algorithm is proposed for multiple target detection based on dynamic multithreading implementation of SLIC segmentation algorithm.

The remainder of this paper is organized as follows. Material and Methods section discusses the proposed framework and details of the material and methods. The results and discussion section presents our experimental and performance analysis. Finally, the conclusion section concludes this study.

### III. MATERIAL AND METHODS

This section presents an overview and the details of the proposed approach. The underlying goal of the proposed approach is to take advantage of saliency values and appearance modeling in an efficient manner for target detection.

In this study, the proposed method consists of two main phases, spatiotemporal saliency appearance modeling (SSAM) and sample feature-based target detection (SFTD). To handle the phases' operation, a semi-automatic trigger-based algorithm is proposed to switch between the two phases; a phase operation is started when that phase receives a trigger activation. For example, when the saliency-slot time is reached, the SSAM phase activates a trigger to switch to the SFTD phase. The proposed method defines the saliency slot to activate the trigger. The SFTD phase activates a trigger when it cannot detect any objects. The overall architecture of the proposed framework is shown in Fig. 1. The details of the proposed approach are presented in the following sections.

#### A. Spatiotemporal Saliency Appearance Modeling (SSAM) Phase

This phase involves three stages, temporal saliency and localization detection, spatial and final saliency detection, and, finally, sample feature generation and target detection stages.

1) *Temporal saliency and localization detection (TSLD) stage:* This stage consists of temporal saliency detection and localization modules. In order to extract the moving target, salient regions are extracted using motion cues detection. For motion cue detection, temporal saliency is investigated with the following details.

2) *Temporal saliency detection module:* The purpose of temporal saliency is for attention region (ARs) extraction and coarse segmentation. The extracted attentional regions are called Candidate Motion Regions (CMRs). To extract the CMRs, we propose the following steps,

Frame differencing is used for temporal saliency detection. Frame differencing is utilized to identify moving objects in consecutive frames. This technique employs the image subtraction operator, which takes two images (or frames) as input and produces the output [42].

Image Enhancement. Morphological operations are generally applied for image enhancement [43]. This proposed method uses these operators, which are dilation, erosion, and opening and closing; the morphological operators are inspired by [44, 45] with adapted structuring elements parameters.

3) *Localization module:* Once the temporal saliency detects the moving target region and enhances the CMRs, a localization module is applied to localize the extracted CMRs based on connected components and blob identification methods [47]. This module involves the following steps.

Thresholding. Thresholding assists us in reducing the number of false positives and avoiding missed valid objects. The thresholding is based on the variation of intensity consideration between the object pixels and the background pixels, as inspired by [48]. Setting a determined value to identify those pixels to implement the thresholding. In this matter, THRESH\_OTSU is used to determine the optimal threshold value using Otsu's algorithm [49].

Edge segmentation. Canny edge segmentation is then run on the binarized image for further improvement of the extracted region.

*Blob Identification.* After all the region's edges are extracted, we need to detect the blobs (connected components). To identify the blobs, active contour features, such as the one proposed by [50], are utilized to detect regions of interest and localize them. In this paper, we also use active contour features to detect the contours of regions. The detected contour features from CMRs regions are used for connected component detection, blob area, and bounding box determination. Moreover, removing unwanted blobs with a pixel area smaller than  $A_{low}$  or a bounding box with dimensions larger than  $B_{max}$ .

Candidate Mask Generation. In this step, geometrical features are extracted from the regions to recognize their location in each frame. Extracting  $X_{pos}$ ,  $Y_{pos}$  as the centroid of

each object based on moment features, as described in the spatial saliency detection module section later. Furthermore, we experimentally found the appropriate width and height values to generate the candidate mask (CM), extracting the regions based on the region of interest (ROI) function. Fig. 2 shows the generated candidate mask by the proposed temporal saliency and localization stage.

4) *Spatial saliency detection (SSD) stage*: The result of the TSLD stage is one or multiple CM regions, which are ARs. However, as shown in Fig. 2, some regions are incorrectly extracted that are unrelated to a target object or include useless regions. The spatial saliency detection (SSD) is used to overcome this fault detection. Furthermore, because candidate masks are compact and informative, we also investigate SSD to extract the saliency over them to provide further information and generate sample features. Our proposed SSD algorithm is based on integrating the proposed methods in [2, 29] with several modifications in feature extraction, feature representation, and spatial distribution measurement to improve the efficiency of spatial saliency extraction.

In brief, the input image is first decomposed into perceptually homogeneous segments as patches based on a SLIC superpixel algorithm presented in [51]. Second, we extract visual features, including color and moment, to measure the uniqueness and compactness of the spatial distribution. Finally, the temporal and spatial information are integrated to generate a final saliency map named spatiotemporal saliency.

However, since the SLIC is time-consuming for spatial saliency, we implement spatial saliency detection via parallel processing based on multi-threading programming. The use of multi-threading assists us in processing all CM regions in parallel. It can impressively decrease the overall processing time of the SSD stage. In this regard, each thread captures a candidate mask and performs the following processes to determine the spatial saliency and sample feature generation. For instance, if the result of the TSLD stage includes four objects, we assign each object to a thread, totaling four. OpenMP multi-threading is used as a tool to implement our spatial saliency detection algorithm. The steps for the SSD stage are as follows.

5) *Patch generation module*: Super-pixels segmentation as an effective region-based analysis algorithm is increasingly investigated by many researchers in computer vision communities [36,52]. As proposed in [51], this study uses a SLIC algorithm to segment the CM regions into homogeneous regions. Fig. 3 shows patch generation for a moving object using the SLIC superpixel algorithm.

6) *Spatial saliency module*: In this study, we use spatial uniqueness and compactness to compute the spatial saliency detection inspired by Perazzi et al. [53]. Moreover, we take advantage of other features, such as image moments and different metrics, to improve efficiency. In our method, we investigate pixel intensity for dissimilarity measurement of a patch compared to other regions. Compactness spatial distribution also contributes to detecting salient objects based

on image moments for uniqueness measurement. Details of the proposed spatial saliency detection are explained in the following.

Spatial uniqueness measurement. Similar to [54], each region's color similarity with other regions is measured. However, in [54], they implemented the color feature in a static image. In contrast, we investigate saliency detection in a dynamic environment. Furthermore, as reported in [55], Earth Mover's Distance (EMD) yielded excellent retrieval performance for the small sample size; we also use the EMD distance metric instead of Euclidean.

Spatial compactness measurement. Because the salient patches are spatially compact, the pixels with high saliency values are also expected to be spatially close [56]. Spatial moments are efficient and powerful in describing spatial distribution and compactness. In this study, we investigate spatial moments to estimate spatial compactness. Our work employs first- and second-order spatial moments.

7) *Final saliency map generation*: Generally, it is necessary to collaborate the temporal and spatial saliencies in a meaningful way to produce the final spatiotemporal saliency maps [10]. Therefore, the temporal and spatial information are integrated to generate a final saliency map named spatiotemporal saliency.

8) *Sample generation and target detection (SGDT) stage*: As shown in Fig. 1, the sample feature generation and target detection stage involve feature extraction, sample feature generation, and target detection. According to the feature extraction step and the result of the SSD stage, we collect appropriate features, such as color contrast and region compactness. As mentioned previously, these features are dynamically updated per frame and normalized, generating the sample features. Based on the sample features, we can detect the target.

#### B. Sample Feature-based Target Detection (SFTD) Phase

A trigger is activated upon the sample features being generated, and the sample features are transferred from the SSAM phase to this phase. The advantage of this phase is that it covers both moving and non-moving object detection conditions to detect objects with uncontrollable and unpredictable target movement conditions and overcome the difficulty of frame difference. The steps for this phase are mostly similar to the previous operation's steps, i.e., frame differencing, Image Enhancement, Feature Matching, Object Segmentation, and, finally, Target Detection.

## IV. RESULTS AND DISCUSSION

This section presents the implementation details and experimental results. Additionally, we compare the results with existing methods based on qualitative and quantitative performance evaluations to test and evaluate the proposed method. The qualitative analysis presents the image results from the proposed and other methods. In contrast, quantitative analysis involves precision and recall calculation and processing time. To validate the efficacy of the proposed method, the experiment was conducted on the VIVID public

dataset [57]. The VIVID dataset was collected at Eglin during DARPA VIVID and involves aerial images in video sequences. Several videos have been collected in VIVID, of which we use the EgTest01 and EgTest02 videos. The EgTest01 video involves moving cars that pass each other, with an image size of 640\*480 pixels and 1800 frames, whereas the EgTest02 video involves 1300 frames with two sets of three civilian vehicles passing each other on a runway.

A. Qualitative Analysis

Qualitative analysis is implemented to demonstrate the result of each phase and compare the proposed method with others. Fig. 4 shows the results of the qualitative analysis. The saliency-based methods considered for comparison are Itti [58], MD [21], GBVS [59], and SD [2]. Fig. 5 shows the comparison of the proposed method with other existing methods. The first row is the original raw images (Raw), the second, third and fourth are the results for the TSLD, SSD, and MOED phases, respectively, and the final row represents the feature-based object detection phase.

In the following sections, quantitative analysis for precision, recall, and f-measure calculation is discussed.

B. Precision and Recall Measurement

Similar to Refs. [2, 31, 60], precision and recall measures are used to evaluate the performance of the proposed method. In our evaluation, the target is the exciting object, whether moving or not. To measure the precision, recall, and f-measure, we need to define the following terms,

- True Positive: Detected salient regions that correspond to a target.
- False Positive: Detected salient regions that do not correspond to a target.
- False Negative: No detection of salient regions where there is, in fact, a target,

$$\text{Precision} = \left( \sum_{i=1}^n \frac{TP}{TP + FP} \right) \times 100 \%$$

$$\text{Recall} = \left( \sum_{i=1}^n \frac{TP}{TP + FN} \right) \times 100 \%$$

$$F_1 - \text{score} = 2 \times \left( \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \right)$$

Details of the measurements for TP, FP, FN, precision, recall, and F1-score are presented for the proposed method in Table I.

The precision and recall rates of different numbers of frames are illustrated in Fig. 6. As shown in Fig. 6 and 7, precision and recall rates are increased when the number of frames is increased.

Furthermore, to validate the proposed method, we compare our model with state-of-the-art visual object tracking methods, such as the FMD [2], DMM [60], HSC [10], RD [2], and SD [2]. The comparison was conducted based on precision, recall (PR), and F1-score. Table II and Fig. 8 show the comparison results. Based on the obtained experimental results, we show that the proposed approach can be effectively employed for the extraction of moving objects.

C. Processing Time

Our experiment was implemented in Visual Studio and performed on a Windows 8 platform with an Intel 2.6 GHz CPU and 4 GB of Memory. The processing time is measured based on wall-clock time computation because, when measuring the performance of parallel programs, the wall-clock time needs to be considered, then using the tick\_count class, which is located in `tbb/tick_count.h`. A tick\_count is an absolute timestamp. The average processing time for the proposed method is approximately 78 and 24 milliseconds for SSAM and SFTD, respectively, which is suitable for near-real-time visual tracking applications.

## V. CONCLUSION

This paper addresses the significant problems facing visual tracking, such as appearance variations and unpredictable moving targets, for aerial images. The proposed method uses spatial and temporal saliencies to address these challenges by adopting biologically inspired approaches to detect the attentional regions (ARs). Furthermore, a biologically inspired approach integrated with an appearance modeling-based approach is investigated to overcome visual tracking challenges. In this regard, the proposed method consists of two main phases, spatiotemporal saliency-based appearance modeling (SSAM) and sample feature-based target detection (SFTD). The proposed method uses a tracking-by-detection approach to provide a robust visual tracking system under appearance variation conditions. Correspondingly, a semi-automatic trigger-based algorithm is proposed to handle the phases' operation, and a discriminative-based method is utilized for appearance modeling. In the spatiotemporal saliency phase, temporal saliency is used to extract the attentional regions (ARs) and coarse segmentation. Spatial saliency is utilized to obtain the object's appearance details in ARs regions. By combining temporal and spatial saliencies, we can obtain refined detection results and track the target. During

the spatial saliency detection, prominent features are collected, and a sample feature is generated to describe the target.

Consequently, a target detection process is performed to recognize the target in images. Experiments were conducted on the VIVID dataset. Moreover, the proposed method compared with other state-of-the-art methods. The analyses demonstrate that the proposed method is superior to most state-of-the-art methods and presents an effective visual tracking method which is robust in appearance variation difficulties.

Future works can be conducted to address other difficulties and challenges in visual tracking, such as when complicated backgrounds or backgrounds with partial and/or full occlusion are present.

## ACKNOWLEDGMENT

The authors would like to appreciate Assoc. Prof. Dr. Anton Satria Prabuwono, Dr. Ang Mei Choo, and Teck Loon Lim for helpful advice and suggestions. We also thank all the anonymous reviewers for their comments which assisted us in improving the quality of this paper.

# A Study on Distance Personalized English Teaching Based on Deep Directed Graph Knowledge Tracking Model

Lianmei Deng

Department of Economics and Trade, Chongqing College of Finance and Economics, Chongqing, 402160, China

**Abstract**—Despite the continuous development of online education models, the effectiveness of online distance education has never been able to meet people's expectations due to individual difference of learners. How to personalize teaching in a targeted manner and stimulate learners' independent learning ability has become a key issue. In this study, the multidimensional features of the learning process are mined with the help of the BORUTA feature selection model, and the DKVMN-BORUTA model incorporating multidimensional features is established. This optimized deep knowledge tracking method is combined with graph structure rules. Then, an intelligent knowledge recommendation algorithm based on reinforcement learning is used to construct a fusion approach-based model for distanced personalized teaching and learning of English. The results show that the research proposed fused deep-directed graph knowledge tracking with graph structure rules for remote personalized English teaching model has the lowest AUC value of 0.893 and the highest AUC value of 0.921 on each dataset. The prediction accuracy of the research model is 94.3% and the F1 score is 0.92, which is the highest among the studied models, indicating that the proposed model has a strong performance. The fusion model proposed in the study has a higher accuracy rate of knowledge personalization recommendation than the traditional deep knowledge tracking model, and it can help learners save revision time effectively and improve their overall English performance.

**Keywords**—Distanced personalized English teaching model; knowledge tracking; deep learning; graph structure rules; DKVMN

## I. INTRODUCTION

With the booming development of internet information technology, online educational resources are shared and disseminated nationwide [1]. Online distanced English teaching is particularly outstanding in terms of resource sharing and students are very fond of being taught by foreign teachers via online interactive communication. However, as the online teaching method is quite different from the traditional face-to-face teaching method, it put forwards higher requirements for students' independent learning ability and self-motivation. Therefore, a more scientific and effective way is required to track students' status in the classroom, attract students' attention, achieve knowledge tracking, and improve the quality of distanced English learning [2-3]. In previous studies, some scholars have proposed to apply deep learning to the prediction of knowledge and to build Deep Knowledge Tracing (DKT) models by combining Long Short-Term Networks (LSTM) with history department sequences [4-5].

However, the DKT model is not very accurate in analyzing students' learning data and predicting knowledge, and its performance is weakly stable. At present, the improvement of distance personalized teaching quality mainly depends on the knowledge tracking of learners. To accurately analyze the knowledge state of learners, many technologies have been applied in the field of knowledge tracking. Among them, the most advanced and widely used ones mainly include two types, namely, the knowledge tracking method based on probability graph and the knowledge tracking method based on deep learning. However, the knowledge tracking method based on probability graph lacks the consideration of the relationship between learner forgetting factors and knowledge, so its accuracy is low. However, the knowledge tracking method based on deep learning is difficult to obtain the specific information of learners' knowledge state. For this reason, the study optimizes the DKT model based on data mining and improves the DKT model in terms of multidimensional features of the learning process and feature fusion. The optimized model is combined with graph structure rules, and then the distanced personalized English teaching model based on deep directed graph knowledge tracking is proposed. This paper first reviews the application of deep learning model in teaching, and then summarizes the existing defects of current methods through the study of previous methods. Then, the research methods are elaborated, and the deep learning knowledge tracking model is proposed, which is applied to English distance personalized education. Secondly, in the part of result analysis, the research algorithm is compared with the current more advanced knowledge tracking algorithm, and the effectiveness and accuracy of the research algorithm are verified. Finally, in the conclusion part, the advantages and disadvantages of the research algorithm are summarized, and the future research direction is proposed. It aims to precisely locate the learning status of learners and their mastery of knowledge points so as to achieve good results of distanced personalized English teaching.

With the rapid development of deep learning and neural network algorithms, the role of computer technology in the teaching and learning process has been explored, and scholars have begun to focus on related topics, and substantial progress has been achieved. GERVETT et al. applied deep learning DKT models to knowledge tracking and analyzed the conditions under which their deep models can make the most accurate predictions [6]. SAPOUNTZIA et al. analyzed the Bayesian Knowledge Tracing (BKT) model, the DKT model,

and the Dynamic Key-Value Memory Network (DKVMN) model from a technical and educational perspective and compared the modeling techniques, evaluation, and performance in terms of optimization of the three models, and the results showed superior performance of the DKVMN model [7]. Hassan et al. focused on student dropout risk prediction by using deep long and short-term memory models. Multidimensional data can help teachers predict students' learning status, and comparative testing results on real datasets show superior application performance of the model over logistic regression and artificial neural networks [8]. Mubarak et al. analyzed the role of video clickstream data in prediction of online learners' learning performance, and deep neural network algorithms incorporating implicit features were found to have excellent performance in real-world applications, which outperformed super vector machines and logistic regression methods [9]. Kaser et al. proposed a dynamic Bayesian knowledge tracing (DBKT) model that uses DBNs to combine multiple knowledge tracing (KC) in one model, and the results showed that the model had validity and strong contractual performance [10].

DEONOVICB et al. proposed a method to improve the prediction accuracy of knowledge tracking by combining probability maps and cognitive diagnostic techniques in order to improve the performance of knowledge tracking, and the experimental results showed that the method effectively improved the performance and prediction accuracy of knowledge tracking [11]. Yang et al. optimized the deep knowledge tracking technique in tracking students' knowledge states. They enriched the original deep knowledge tracking model by adding heterogeneous feature implicatures to determine the probability of students' correct answers in the exercises. The study evaluated the optimized model using two different education-related datasets, and the evaluation results indicated the superior performance of the model in the relevant domain [12]. Wang et al. designed the DKTS method using the feature relationship between topics and the linkage of knowledge points, and the experimental results showed that the method is effective in improving the service performance of the knowledge tracking method [13]. Vie et al. concluded that tracking the evolution of students' knowledge can help teachers' instructional optimization, and factor decomposer can be used as a regression and classification model. The findings show that the model can handle multi-feature high-dimensional student learning data in a large number of real datasets, and it has significant superiority over existing models [14]. This is the first work to integrate competency-based tracking into MOOC course recommendations. Extensive experiments on real-world datasets demonstrate that capacity tracking-enhanced course recommendations improve the effectiveness and interpretability of MOOCs. Tian et al. made an attempt to integrate capacity tracking into course recommendations for MOOCs. Experiments on a large amount of real-world data demonstrate that deep knowledge tracking can improve the validity and interpretability of MOOCs [15].

In summary, deep learning and neural network algorithms have been widely used in education and a large number of research findings have enriched current educational approaches, where deep knowledge tracking has also been widely used to track student knowledge evolution. However, there has been no reports investigating directed graphs as an input data source. Therefore, the research will focus on the construction of graph attention neural networks on this basis to obtain a student knowledge tracking model with better performance.

## II. DEEP DIRECTED GRAPH KNOWLEDGE TRACKING MODEL BASED ON PERSONALIZED ENGLISH DISTANCE TEACHING

### A. Design of a Deep Learning Knowledge Tracking Model based on Multidimensional Feature Fusion

Knowledge tracking automatically tracks changes in the state of knowledge of learners based on their historical learning trajectories and predicts learners' mastery of knowledge in the future process [16]. The study describes a learner's answer

interaction as  $R_i = \{s_i, q_i, r_i, b_i\}$ , where  $b_i$  is a sequence of learning behaviors. Considering the large number of feature dimensions and the need for knowledge tracking methods to mine the historical learning data collected by the learning platform, this research proposes a knowledge tracking method incorporating multidimensional features of the learning process, as shown in Fig. 1.

As shown in Fig. 1, the knowledge tracking framework consists of data composition, knowledge tracking optimization, and knowledge tracking model. Among them, the answer history and other data constitute the data framework, and the knowledge tracking optimization includes data mining and improvement methods for the deep knowledge tracking model to optimize the model and improve the prediction accuracy and interpretability of the model. Since deep knowledge tracking and other learning models have the problem of weak interpretability, some studies have pointed out that the interpretability can be divided into Ante-hoc and Post-hoc perspectives. Based on Post-hoc as the perspective for global interpretation, the multidimensional features that affect the learning results are explored from many features of the learning process, and then redundant features are removed to complete the input composition of the model, i.e., the BORUTA feature selection method [17]. Moreover, the knowledge tracking model mainly utilizes the Dynamic Key-Value Memory Networks (DKVMN) model to ensure the performance and interpretability of the method [18]. Since DKVMN has a strong expansion performance, the core of the research is the optimization of the deep knowledge tracking model incorporating multidimensional features, as shown in Fig. 2.

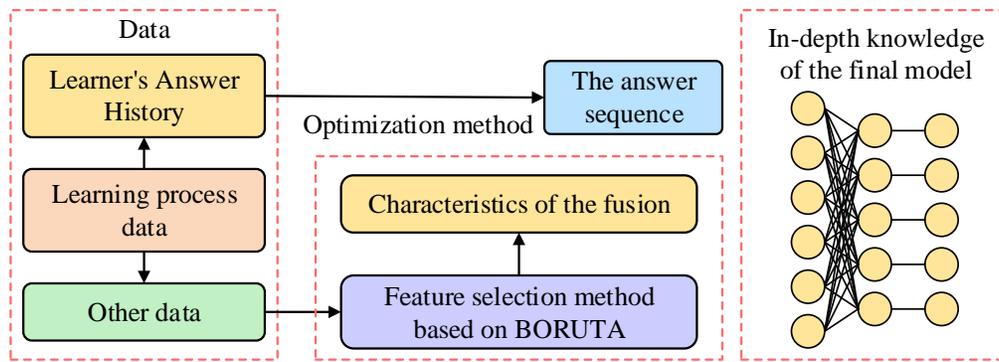

Fig. 1. Knowledge tracking framework based on learning process characteristics.

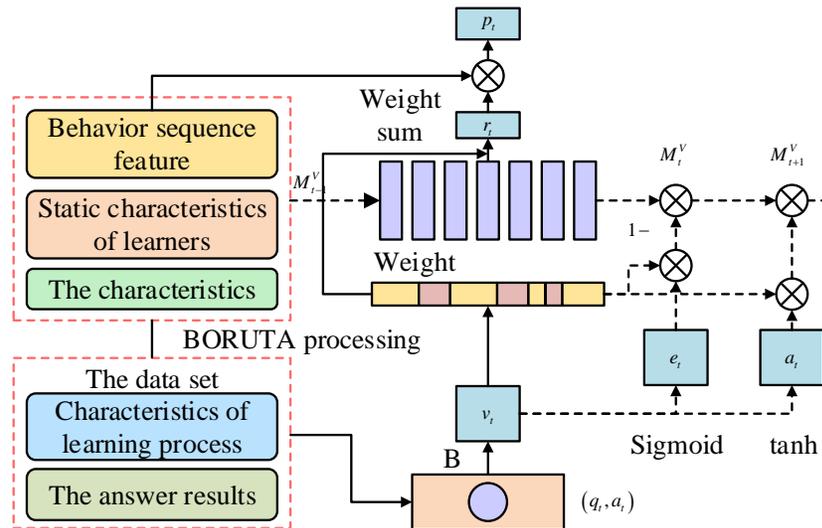

Fig. 2. Depth knowledge tracking model with multi-dimensional features.

As shown in Fig. 2, the processed data is used as the input of the model, and three networks, namely learning behavior sequence features, learner static features, and topic features, are built at the output location of this model, and then the optimization method is incorporated into the DKVMN framework, i.e., the deep knowledge tracking optimization method DKVMN-BORUTA is obtained. The study obtains the Embedding matrix of the topic by constructing its vector representation as in equation (1) for the knowledge concept weights[19].

$$w_t(i) = \text{soft max}(M_i^k g k_t) \quad (1)$$

Where, the problem  $q$  encountered by the learner at the moment  $t$  is first multiplied by the embedding matrix  $A$  that has been trained to obtain the embedding vector  $k_t$ . Then  $k_t$  is computed by  $\text{soft max}$  to obtain the attention weight vector  $w_t$ . The ease of expansion of DKVMN creates the conditions for the incorporation of multidimensional features in the learning process. Specifically, the DKVMN model receives learning records that will have some impact on the learner's feature vector  $f_t$ . Since  $f_t$  is obtained by fusing the read

vector  $r_t$  with the embedding vector  $k_t$ , it contains both information about the state of the learner's knowledge of the topic  $q_t$  and the embedding information of  $q_t$ . By processing the Fourier transform through the neural network, it is possible to infer the learner's ability on  $q_t$ . And the difficulty level of  $q_t$  can be obtained by passing  $k_t$  to the neural network.

Equation (2) is the formula for the read vector of  $r_t$

$$r_t = \sum_{i=1}^N w_t(i) M_i^v \quad (2)$$

Where,  $M_t^v$  represents the read value memory. The BORUTA features are processed through the embedding matrix to obtain the vector representation and then the embedding matrix is spliced with the topic content feature vector  $v_t$ . Eq. (3) is the formula for calculating the probability of a learner correctly answering the question  $q_t p_t$ .

$$p_t = \mathcal{O}\left(\tanh\left(W_o^T [r_t, m_t, l_t, v_t]\right) + b_{it}\right) \quad (3)$$

Where,  $l_t$  denotes the learner static features,  $m_t$  denotes the topic feature limit.  $b_{it}$  represents the conditioning factor, and  $\mathcal{O}$  is the Sigmoid activation function. Where  $b_{it} = \text{Sigmoid}|b_{it}|$ ,  $b_{it}$  is calculated by first mining the effective learning behavior through the learning behavior sequence feature vector. If the learner first watched the video and then discussed in the discussion forum and watched the learning video to answer the question, the learning behavior sequence of this learner is  $b_{it} = (2, 1)$ . The overall vector is a fusion of the BORUTA feature set with the current topic content features and the learner's knowledge state. The knowledge state matrix of the deep knowledge tracking optimization model is updated by inputting answer records  $(q_t, a_t)$  and  $w_t$  to collaboratively update  $M_t^v$ , and by erasing weights  $E$  and adding weights  $D$ , respectively, so as to obtain the memory erasure vector  $e$  and the memory addition vector  $a$ . The memory erasure vector is calculated by equation (4).

$$e_t = \text{Sigmoid}(W_e v + t) \quad (4)$$

Where,  $W_e$  represents the erasure weights and  $t$  represents the discretized value of the learner's time to deal with the problem. The memory addition vector is calculated by Eq. (5).

$$a_t = \tanh(W_a v_t + t) \quad (5)$$

Where,  $W_a$  stands for adding weights. The process of dynamic update of the learner's knowledge state is expressed by Eq. (6).

$$M_{t+1}^v = M_t^v [1 - w(i)e_t] [1 + w(i)a_t] \quad (6)$$

Where  $x_t = (q_t, a_t)$  represents the learner's answering behavior after the  $t$  moment and the value of the dynamic matrix  $M$ , which is transformed from  $M_t^v$  to  $M_{t+1}^v$ . The goal of model optimization is to minimize the difference between  $p_t$  and  $a_t$  with the minimum spread loss function. The model optimization is conducted using the momentum gradient descent method, as shown in equation (7).

$$L = -\sum_i [a_i \log p_i + (1 + a_i) \log (1 - p_i)] \quad (7)$$

In this study, the BORUTA feature selection model is used to explore the multi-dimensional features in the online learning process. Based on DKVMN model, the multi-dimensional feature network is constructed. Secondly, the deep knowledge tracking model with multi-dimensional learning features is designed. Finally, a deep knowledge tracking optimization model is constructed.

#### B. A Model Design for Distanced Personalized English Learning incorporating Deep Knowledge Tracking and Graph Structure Rules

In the design process of this research model, the deep knowledge tracking model was first introduced, allowing the construction of a directed graph of knowledge concepts for the probability values of the outcomes, and then directed graph was fed into the deep learning neural network as a data source, which in turn formed the attention neural network [20]. The probability value of the association relationship between concepts is actually the weight value of the network nodes. The structure of the deep directed knowledge tracking model is shown in Fig. 3.

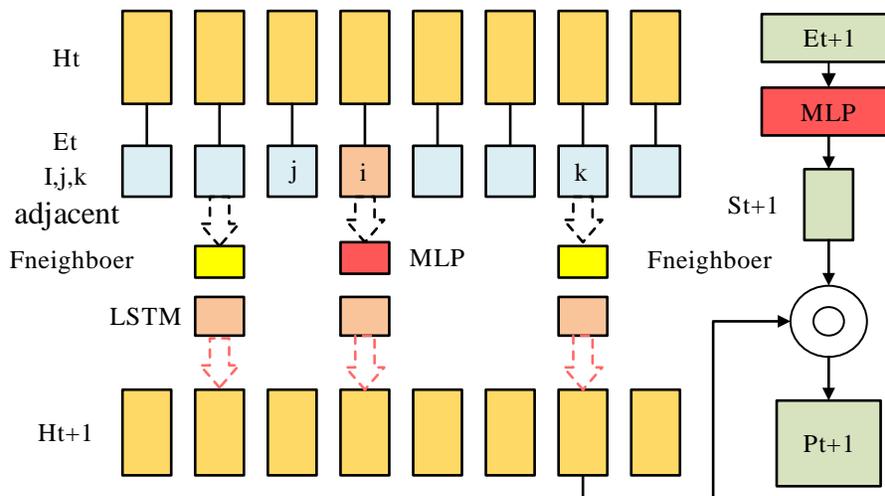

Fig. 3. Overall structure of knowledge tracking model integrating depth directed graph.

As shown in Fig. 3, the model first undergoes a Manifold Embedding popular embedding, setting up the memory linear matrix  $H$ , which holds mainly the basic state of the knowledge concept, and the corresponding  $N$  vector values of relatively independent concepts related to the problem. For the vectors,  $N d$  are used to represent their dimensions. The memory values in the matrix  $H$  at the time of  $t$  are  $H_t$ , and  $E$  is used to identify a matrix of processing result values after popular embedding. In the model processing, the extremely strong answer to the question at the  $t$  moment is processed as a one-bit valid code of length  $2N x_t$ , and the code is processed using the embedding matrix of  $2N * e$  to downscale the dimensionality to a vector of length  $e$ . For example, equation (8) is the vector matrix of.  $N * e$

$$E_k^t = \begin{cases} xtEx(k=i) \\ Ec(k)(k \neq i) \end{cases} \quad (8)$$

Where  $x_t$  represents the heat code and  $e_x$  represents the vector value. From Fig. 3, it can be seen that the model input value at the moment of  $t$  is  $(q_t, a_t)$ , and after that knowledge concept is defined as  $i$ , the directed graph connecting the adjacent nodes of  $i, j, k$  and the vector corresponding to  $i, j, k$  in the matrix of synchronous negative memory concepts  $h$  is established, as shown in Eq. (9).

$$H_t = [H_t, E_t] \quad (9)$$

Where the vector  $h_t^i$  is spliced with the vector  $e_t^i$ , processed by a fully connected neural network containing hidden and input layers, and then fed into the LSTM network to obtain the newly generated memory matrix, where the  $i$ -th vector expression is shown in Eq. (10)[21].

$$H_k^{t+1} = \begin{cases} RNN(f_{MLP}(h_k^t)) \\ RNN(f_{neighbor}(h_i^t, h_k^t)) \end{cases} \quad (10)$$

Where  $RNN$  represents the fully connected recurrent neural network,  $h_k^t$  represents the vector values at the moment, and  $f_{MLP}$  is the LSTM network. The process focuses on the nearest neighbor function of vector  $j$  and vector  $k$ , and this attention algorithm is formulated in Eq. (11).

$$f_{neighbor}(h_i^t, h_k^t) = \frac{1}{K} \sum_{k \in K} a_{ij}^k f_k(h_i^t, h_k^t) \quad (11)$$

Where  $a_{i,j}^k$  represents the threshold value for simplifying the graph structure. The study uses a deep knowledge tracing model to obtain vector graphs, which are acyclic structural graphs with positive-valued full connectivity between the nodes of the graph, and a threshold parameter will be introduced to simplify the graph structure. When the topic concept at the moment  $t$  is  $K$ , only the vector  $i$  adjacent to it needs to be considered, and the graph model is defined using the connection relations between directed graphs. Finally, the model needs to encode the knowledge concepts. The knowledge concept sailing in at  $t+1$  is set to  $e_{t+1}$ , and forward neural network processing is performed to obtain  $S_{t+1}$ . This encoding long queue is  $d$ , which is calculated by equation (12).

$$S_{t+1} = \sigma(W_1 \cdot \sigma(W_o \cdot e_{t+1} + b_o) + b_1) \quad (12)$$

Where the forgetting gate in the structure of the feedforward neural network is represented with the previous memory gate input parameter [22]. At the moment of  $t+1$ , the memory matrix vector  $H$  is multiplied by the vector points of the knowledge encoding  $S$  to obtain the true mastery probability value for moment  $P_{t+1}$ . The study developed a methodological model of reinforcement learning by mimicking the teacher's learning behavior towards the students and using a deep knowledge tracking model process sample training. In the process of using the knowledge tracking model, the recommended questions are first selected and then the input of the questions is completed. The predicted answers are obtained and the concept of knowledge is encoded, and this encoding is used as the input learning state vector value for training the reinforcement learning method. The model structure is shown in Fig. 4.

As shown in Fig. 4, when the algorithm is executed, a random state vector of fixed length is first initialized and the basic level of knowledge point concept mastered by the student is identified, where each element of the vector is labeled as the degree of learning to the knowledge value. On this basis, a convolutional neural network is built. Then, the process of learning action selection is executed, where three outputs exist in this process. When the return value is 1, then the learning is sufficient and no subsequent selection of knowledge-related topics is required. When the return value is 0, the old and new states, actions and their corresponding reward values need to be combined and saved to the experience pool according to the fixed collocation principle as the basis for subsequent learning and optimization. Continuous action selection for the immediate moment is performed, and the deep knowledge tracking model is trained for deep reinforcement learning after several iterations of the loop. The reinforcement learning method designed for this research uses the Nature DQN (Deep Q Network, DQN) network structure [23]. Two neural networks with the same number of layers and nodes were set up to address the correlation between the data samples and the

network before training. One of the  $Q$  networks is used as the training network with the input value of the state value of the environment mention training and the output corresponding to it is the recommended action. The second  $Q$  network is used as the target network to reduce the overfitting of the neural network, so that this network serves as the final target value for reinforcement learning, thus enabling an optimal update of the corresponding network parameters. The study evaluates the model in terms of average accuracy, average completeness and accuracy, where the average completeness ( $AP$ ) is calculated by equation (13).

$$AP = \sum_{u=1}^r P(u) \quad (13)$$

Where  $r$  denotes the number of categories and  $u$  denotes the category labels. The average finding rate ( $AR$ ) is expressed by Eq. (14).

$$AR = \sum_{u=1}^r R(u) \quad (14)$$

The accuracy of ( $ACC$ ) is calculated by Eq. (15) [24].

$$ACC = \frac{(TP + TN)}{(TP + FN + FP + TN)} \quad (15)$$

Where  $TP, FP$  denote the number of positive classes and the number of negative classes for positive class prediction, respectively.  $FN, TN$  denote the number of positive classes and the number of negative classes for negative class prediction, respectively. In addition, the study determines the performance of the model by comparing the Area Under Curve (AUC) of each dataset completion curve.

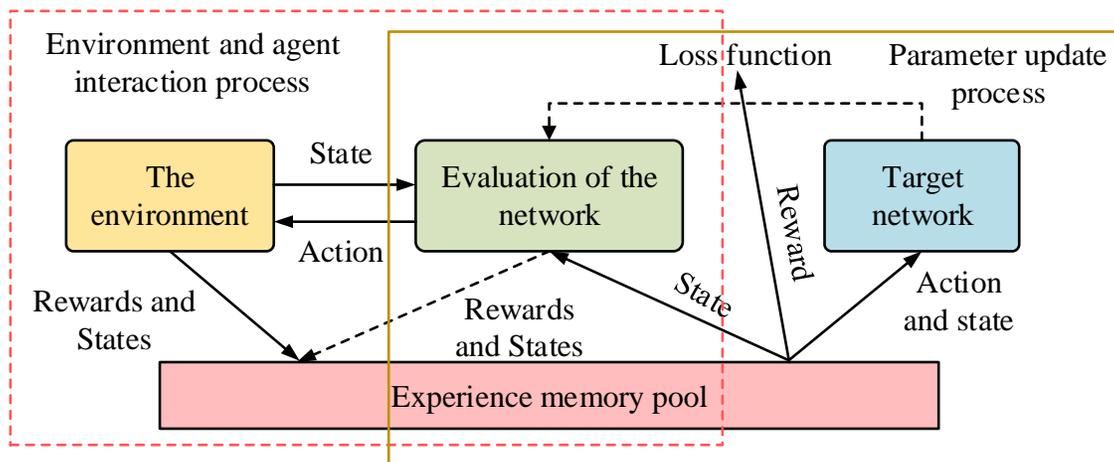

Fig. 4. Structure diagram of training reinforcement learning method model.

### III. ANALYSIS OF EXPERIMENTAL RESULTS OF A DEEP DIRECTED GRAPH KNOWLEDGE-TRACKING-BASED MODEL FOR DISTANCED PERSONALIZED ENGLISH TEACHING

#### A. Analysis of the Effectiveness of a Deep Learning Knowledge Tracking Model based on Multidimensional Feature Fusion

The validity, interpretability analysis of the deep knowledge tracking model incorporating multidimensional features was conducted. In this experiment, the Adam optimizer was used to train the model, and all datasets were sliced 7:3 to test set and training set with 10 training times. Based on tensor flow and keras, the methods in Table I were completed in NVIDIA 1080 Ti GPU environment. At present, knowledge tracing methods widely used include BKT (Bayesian knowledge tracing), DKT (Deep knowledge tracing), and DKVMN (Dynamic key tracing) value memory networks) these three knowledge tracking methods. BKT can construct the knowledge state of learners as a set of binary variables, but its prediction accuracy depends on the experience of the teacher, and the degree of automation is low. DKT is the

current mainstream knowledge tracking method without a lot of teaching experience and manual labeling, but it is difficult to obtain more specific knowledge state of learners. DKVMN can solve the problems existing in BKT and DKT with high prediction accuracy, but it ignores the factors and characteristics existing in the learning process of learners. AUC (Area Under Curve) ranges from 0.5 to 1.0. The closer the AUC is to 1.0, the higher the authenticity of the detection method. Table I shows the AUC values of multiple algorithms on 6 datasets.

As can be seen from Table I, the DKVMN-BORUTA model proposed in the study has an AUC value of around 0.83, which is higher than that of other three models, indicating the superior performance of the studied model. Since the model incorporates multidimensional features in the learning process, it can to some extent solve the problem of traditional knowledge tracking models for modeling simple mathematical logic in learning and achieve better simulation of the real state of the learner as well as better assessment of the learner's knowledge state.

TABLE I. AUC VALUES OF FOUR METHODS ON DATASETS

Data set	Number of students	Knowledge tag	AUC			
			BKT	DKT	DKTVMN	DKVMN-BORUTA
ASSIST2014	4208	112	0.632	0.806±0.02	0.815±0.01	0.832±0.01
ASSIST2015	19850	110	0.646	0.726±0.01	0.748±0.01	0.804±0.02
Statics2011	334	158	0.71	0.803±0.02	0.799±0.02	0.832±0.01
Synthetic	2000	6	0.761	0.804±0.01	0.806±0.01	0.841±0.02
Khan Academy	17825	108	0.689	0.802±0.02	0.814±0.02	0.822±0.01
KDD Cup	3996	180	0.743	0.783±0.01	0.811±0.01	0.831±0.02

The study collected data from the first half semester of a university’s personalized English course instruction in 2021 and organized that data into a dataset, which was used to train the DKVMN-BORUTA model. The questions were set with good differentiation and moderate difficulty, and if the mastery rate of the knowledge point under this question set was less than 40%, it indicates that the learners did not master the knowledge point. To verify the reliability of the proposed method, a random sample of learners was selected for the topic mastery statistics, and the changes in the knowledge state of the learners are shown in Fig. 5(a). Also, to verify whether the proposed method can achieve the goal of personalized instruction, the randomly selected learners were divided into three groups. No knowledge state information was provided for group A, knowledge state information but no precise instructional support service was provided for group B, and knowledge state information with precise instructional support service was provided for group C. Then, the learning performance and learning review time of the learners in the three groups were recorded, as shown in Fig. 5(b).

As can be seen from Fig. 5(a), the overall trend of learners’ mastery of the knowledge points was on the rise, indicating that this learner’s learning status became gradually become after being taught by the proposed method, indicating that the proposed knowledge tracking method has better readability. As shown in Fig. 5(b), the average test scores of Group C and Group B were higher than that of Group A, and the average review time of both groups was less than that of Group A. This

indicates that the deep learning knowledge tracking model based on multidimensional feature fusion proposed by the study is effective and can find learners’ weak points for learning knowledge more precisely. The average score of group C is 2.5 points higher than group B, and the average revision time is 4h less than group B. This indicates that the deep knowledge tracking model has better interpretability and can fully combine the multidimensional features of learners’ learning process to reach accuracy teaching and improve the English learning efficiency.

*B. Analysis of the Effectiveness of a Distanced Personalized English Teaching Model F incorporating Deep Directed Graph Knowledge Tracing and Graph Structure Rules*

After verifying the effectiveness of the deep learning knowledge tracking model based on multidimensional feature fusion, an experimental analysis of this deep learning knowledge tracking model combined with graph structure rules for distanced personalized English teaching and learning was conducted. The same dataset as before was used in this experimental phase and its basic situation is shown in Table II.

As can be seen from Table II, the lowest AUC value of the proposed model is 0.893 and the highest is 0.921, which shows the effectiveness and superior performance of the proposed model. Then, the performance of the proposed model was compared with other three knowledge tracking models in terms of prediction effectiveness by measuring the AUC of each dataset and its variation with the number of training sessions, and the results of the comparison are shown in Fig. 6(a).

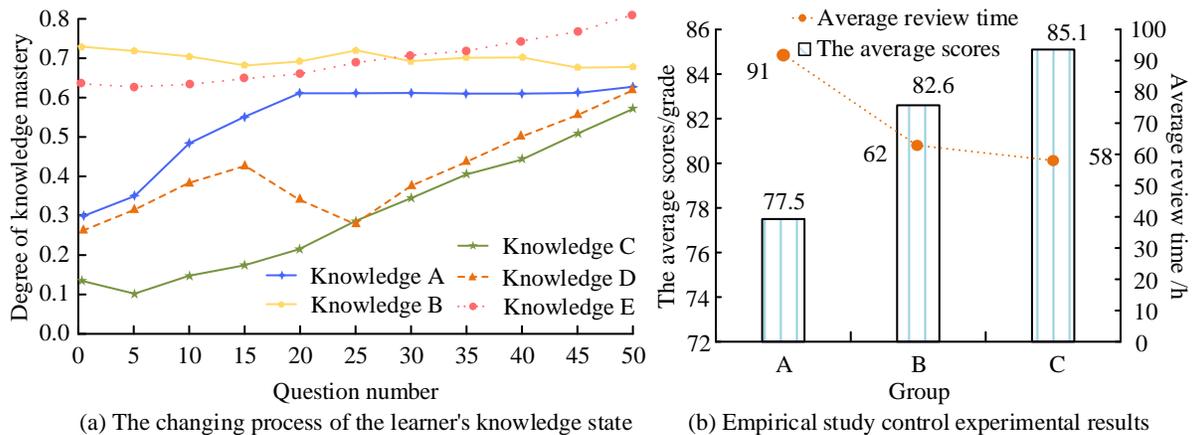

Fig. 5. The changes of learners’ knowledge state and the results of the empirical study.

TABLE II. AUC VALUES OF SIX PUBLIC DATA SETS AND FOUR MODELS

Data set	Number of students	Knowledge tag	Number of interactions	Number of valid result records	The AUC of the study model
ASSIST2014	4296	120	325682	314126	0.914±0.1
ASSIST2015	18246	116	598521	565247	0.893±0.2
Statics2011	400	188	3548	3264	0.912±0.1
Synthetic	2100	10	14621	13346	0.911±0.1
Khan Academy	18364	127	236489	216721	0.921±0.1
KDD Cup	4010	186	11000	10834	0.898±0.2

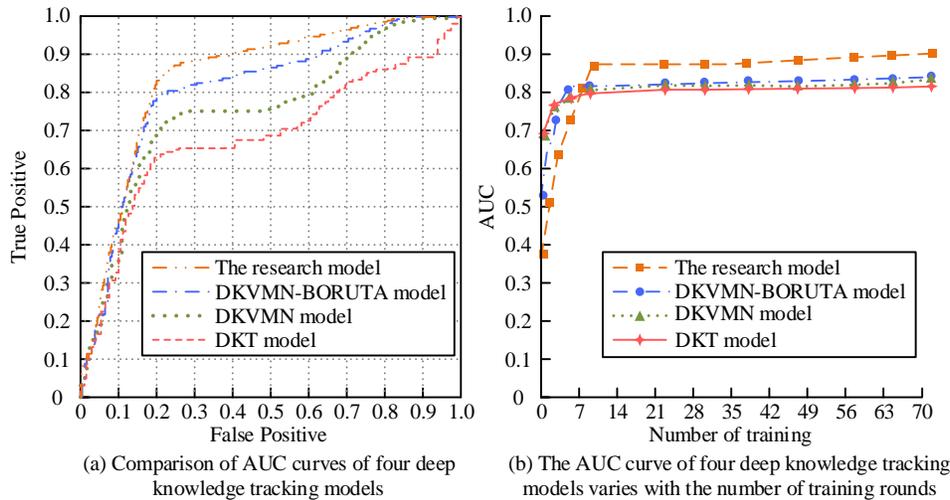

Fig. 6. AUC curves of four deep knowledge learning models.

From Fig. 6(a), it can be seen that the model proposed in the study had an average AUC value of 0.92 in various datasets, while the AUC value of the DKT model was only 0.73. Through comparing the boundary baseline on the KDD dataset, the model proposed in this study improved the gain by a factor of about four. As can be seen from Fig. 6(b), it can be found that the proposed model tended to be stable after the 9th training session, and the AUC value of the proposed model was consistently higher than that of the other three models after the 9th training session, indicating the superiority of the proposed model. The study collected the learners' mastery degree of each knowledge point in the personalized English instruction course, and the collected data were processed to obtain the empirical findings, as shown in Table III.

As shown in Table III, the prediction accuracy of the proposed method was 94.3%, which was 4.9%-26.0% higher than that of the other models. The mean square error of the proposed model was 0.1623, which was the smallest among the tested models. In addition, the F1 score of the proposed model was 0.92, which was the highest among the tested models. The

research data indicated that the proposed method had strong performance. Finally, the study tested the variation of the reward value and the number of training sessions, as shown in Fig. 7(a). The comparison of the overall English scores of the learners in each group and the time spent on revision is shown in Fig. 7(b).

From Fig. 7(a), it can be seen that the overall accuracy of the intelligent personalized recommendation algorithm based on reinforcement learning proposed in this study tended to increase with the increase of training times, and the difference between it and the random recommendation algorithm was gradually increasing, with the difference in the range of 6%-9%. This result indicates that the proposed method had more accurate recommendation capability, which can meet the demand of distanced personalized English teaching. It can be seen from Fig. 7(b) that the comprehensive score of the study group using the study method was 97.3, and the average daily review time of the students in this group was 63min. Research shows the proposed method can effectively improve learners' overall English performance and save learning time.

TABLE III. EMPIRICAL RESEARCH RESULTS

Model type	AP (%)	ACC (%)	F1-score	MSE
BKT	87.3	68.3	0.73	0.2491

#### IV. CONCLUSION

The rapid development of Internet information technology has led to the continuous innovation and progress of English online education models. This study proposes a distanced personalized English teaching model incorporating deep directed graph knowledge tracking. Firstly, with the help of BORUTA feature selection model, the multidimensional features of the learning process are mined and a deep knowledge-tracking model of the multidimensional features of the learning process is fused. This optimized deep knowledge tracking method is then combined with graph structure rules to construct a fused approach-based model for distanced personalized English teaching and learning. The results show that the proposed model has the lowest AUC value of 0.893 and the highest of 0.921 on each dataset, indicating its effectiveness and superior performance. The prediction accuracy of the proposed model is 94.3% and its mean square error is 0.1623, which is the smallest among the models. The F1 score of the proposed model is 0.92, which is the highest among the models indicating that the model has strong performance. Moreover, the overall accuracy of the proposed method shows an increasing trend and is higher than that of the random recommendation algorithm. The optimized deep knowledge tracking method based on the multi-dimensional features of the learning process has practical teaching application value. The fusion model has higher recommendation accuracy and better recommendation effect than the traditional method. And it can meet the needs of personalized remote English teaching and targeted recommendation teaching, so as to improve the quality of English teaching. This study provides a practical theoretical basis and reference direction for online teaching methods in the future. However, there is still room for improvement in the interpretability of the model, and future study will focus on the improvement and enhancement of the performance of the model.

**Abstract**—The task of saliency detection is to identify the most important and informative part of a scene. Saliency detection is broadly applied to numerous vision problems, including image segmentation, object recognition, image compression, content-based image retrieval, and moving object detection. Existing saliency detection methods suffer a low accuracy rate because of missing components of saliency regions. This study proposes a visual saliency detection method for the target representation to represent targets more accurately. The proposed method consists of five modules. In the first module, the salient region is extracted through manifold ranking on a graph, which incorporates local grouping cues and boundary priors. Secondly, using a region of interest (ROI) algorithm and the subtraction of the salient region from the original image, other parts of the image, either related or nonrelated to the interested target, are segmented. Lastly, those related and non-related regions are classified and distinguished using our proposed algorithm. Experimental result shows that proposed salient region accurately represent the interested target which can be used for object detection and tracking applications.

**Keywords**—Saliency detection; target representation; vision system; object detection

## I. INTRODUCTION

Saliency detection methods can be categorized into fixation prediction-based and salient object detection methods. Fixation prediction-based methods are strongly related to biological models. Their processes simulate how human fix locate an image. On the other hand, object-oriented approaches generate maps such that salient regions uniformly cover the whole objects [1].

Fixation prediction methods are inspired by biological principles. Itti et al. [2] proposed the seminal bottom-up saliency model derived from the human visual selective attention mechanism. It obtains saliency maps in different feature channels with a center-around operation and combines them linearly. Hou and Zhang [3] presented a saliency model counting for the Fourier envelope and the differential spectral components, called the spectrum residual, to extract salient regions. Garcia-Diaz et al. [4, 5] propose an adaptive approach achieved by decorrelation and contrast normalization. These fixation prediction-based methods usually overemphasize local contrast and difference from the neighborhood. They are more likely to produce spotlight saliency maps with low resolution and high saliency values on the object boundaries.

On the other hand, Achanta et al. [6] compute the saliency likelihood of each pixel based on its color contrast to the entire image. Ming et al. [7] consider the global region contrast concerning image and spatial relationships across the regions to extract a saliency map. In [8], Goferman et al. simultaneously model local low-level clues, global considerations, visual organization rules, and high-level features to highlight salient objects with their contexts. Such methods using local contrast tend to produce higher saliency values near edges instead of uniformly highlighting salient objects.

This paper proposes a new method for saliency detection for target appearance representation in images. It incorporates visual features and spatial information with the guidance of prior saliency knowledge. To provide more accurate visual cues, region descriptors are introduced for image segments by computing two saliency measures, feature distinctiveness, and spatial distribution. In contrast to previous models, which linearly combine basic features for visual cues, we provide nonlinear integration of the features. In addition, by taking the advantage of the prior saliency distribution obtained from a convex hull of salient points, we heighten the contrast of foreground and background [1].

In [9], a bottom-up method is proposed to detect salient regions in images through manifold ranking on a graph, which incorporates local grouping cues and boundary priors. This method adopts a two-stage approach with the background and foreground queries for ranking to generate the saliency maps. This method is taken advantage of node construction for saliency map identification. Fig. 1 shows the node construction in the GMR method.

Although various saliency detection methods are proposed and present promising results, current methods are not feasible and effective when an object is composed of several parts [1]. For example, as shown in Fig. 2, our model fails to detect the wheels since they are discriminated from the main part of the car. Therefore, current saliency detection methods are not effectively able to represent an object, which makes fail object appearance representation in moving object detection systems. Therefore, it is required to investigate an effective approach to deal with this issue. Fig. 3 shows the saliency fail detection in current methods.

## II. PROPOSED METHOD

In dealing with the mentioned problem in the previous step, a saliency detection method is proposed to recognize saliency components for a salient region. This component of saliency recognition aims to represent the accurate region because sometimes they consist of several parts, as shown in Fig. 4, and they are required to recognize. The proposed method is structured by five modules, salient region detection, salient region localization, region of interest extraction, particle region segmentation, and belonging ratio (BRM) measurement. The proposed method for multi-part saliency recognition is shown in Fig. 4. The detail of each step is discussed in the following sub-sections.

### A. Salient region Detection

There are numerous region saliency detection methods. This study adopted a graph-based manifold ranking (GMR) method for salient region detection [17]. As reported in [13], the GMR methods presented promising results for salient region detection [9]. The source code of the GMR method is

available from the author's website<sup>1</sup>. The source code collects a saliency map of the GMR method. For example, Fig. 5 shows the saliency map (saliency result) using the GMR method. The original image (Fig. 5(a)) was taken from the MSTR-1000 dataset, which is available from the author's website.

### B. Salient region Localization

After salient region detection, the localization of the salient region is performed using centroid finding and region size identification [18]. The purpose of localization is to locate the region saliency on the original image. This localization is also used to generate an expanded region to cover different parts of an interested target.

1) *Saliency map binarization:* To do the localization, the saliency map image is firstly converted to zero 0 and 1 pixels (binarization) using thresholding. The Otsu operator uses for thresholding and binarization. Fig. 6 shows the binarization of the saliency map image.

<sup>1</sup> [http://ivrlwww.epfl.ch/supplementary\\_material/RK\\_CVPR09](http://ivrlwww.epfl.ch/supplementary_material/RK_CVPR09)

2) *Centroid identification*: In this step, the centroid of the binary saliency map is identified. The connected component function is used to extract white pixels as a blob. Blob properties are used to recognize the center of the shape. A geometric decomposition algorithm [14, 15] is used to find the centroid identification. In geometric decomposition algorithm, the centroid of a blob figure as  $X$  can be computed by decomposing it into certain number of parts as,  $X_1, X_1, X_1, \dots, X_n$ , therefore, the centroid and area  $A_i$  of each part, and then the coordination of  $C_x$  and  $C_y$  can be computed as equations (1),

$$C_x = \frac{\sum C_{ix}A_i}{\sum A_i}, C_y = \frac{\sum C_{iy}A_i}{\sum A_i} \quad (1)$$

Using above equation, the centroid of salient region can be obtained. The centroid is represented by a coordination that can be used for further process.

3) *Region size identification*: Bed on the output of the previous step, which was the identified centroid, we can access the centroid coordination of the salient region. Other geometry properties such as the height and width parameters can be specified by this coordination. In this regard, considering  $S_{cp}(C_x, C_y)$ , where  $S_{cp}$  is the center point of salient region,  $C_x, C_y$  are the values for  $X$  and  $Y$  axis. Using the center point and identified height and width, an expanded region with  $H'$  and  $W'$  are calculated by following equation,

$$W' = W + 1/n (W) \quad (2)$$

$$H' = H + 1/n (H)$$

where the  $W'$  and  $H'$  are the expanded values by the  $n$  variable,  $n$  is a variable for expanding factor which is set 5 in this experimental. The expanding factor was obtained based on different experiments, assume as  $n = 6$ . Fig. 7 shows expanded height and weight of salient region with corresponding center point,  $W, H, W'$  and  $H'$ .

4) *Region of interest extraction*: The output from the previous step includes information such as expanded region details and salient region center points. This information is used to extract and generate a region of interest (ROI) from a binary saliency map. The extracted region of interest of the binary saliency map is defined as the ROI of the binary saliency map. Moreover, according to ROI, a binary saliency map can be extracted from the saliency map and original image using mapping of the extracted binary saliency map. The extracted new regions from the saliency map and original image are defined as the ROI of the saliency map and the ROI of the original image, respectively. Fig. 8 shows the region of interest extraction for the original, saliency map, and binary saliency map images.

5) *Particle region segmentation*: In this step, the ROI is segmented into different regions called particles. The purpose of particle region extraction is to extract different regions, including regular and symmetric shapes, from the ROI of the original image. The extracted particles are then transferred to the next step to check whether the particle belonged to the target (the detected salient region) or not. To segment different

particles, the following steps are considered; edge segmentation, image enhancement, filling blobs, and applying the proposed shape descriptor. Fig. 9 shows the steps of particle region segmentation.

### C. Thresholding and Edge Segmentation

Edges are significant properties of each region. The edges are used to detect region boundaries and segment the region. The segmented region using edges, can be used in more processes, such as region analysis and recognition. In this study, the edges are also used to segment different regions on the ROI of the original image and then generate particles. The particles are defined as different regions that are generated after edge segmentation.

1) *Region enhancement and filling blobs*: The detected edges from previous steps are contained many disconnected regions. Image enhancement is required to close the regions and remove some noises [19]. Therefore, noise removal [20], mathematical morphology operator [21], lightweight operators including dilation and closing [22], are applied to enhance the result of the edge detection process. Then filling function is applied, to fill the connected blobs in the enhanced image. Fig. 9(c) shows the image result from the image enchantment step.

2) *Interested region shape extraction*: As shown in Fig. 9(c), the result of image enhancement is still contained many noises, which are required to remove. The noises are involved different types of shapes. To remove these noises, the proposed shape descriptor is applied in this image. Additionally, regular [23] and symmetry [24] regions called interesting shapes (such as wheels) are extracted based on the proposed shape descriptor. With the proposed shape descriptor, the particle regions with regular and symmetry shapes are detected. Since, the final target (the salient region) that we are looking for (such as vehicles) are involved regular components. Fig. 9(d) shows the particle regions result after the interested shape extraction process.

3) *Saliency components recognition*: As discussed in the previous step, the result of the interest shape extraction step is contained regular and symmetry region shapes, which can be belonged to a salient. The belonged regions define as saliency components. To recognize the saliency components, an algorithm is proposed, which is shown in Table I. In the proposed algorithm, two input images are required. The first input image is a set of particles, including the segmented particles shown in Fig. 10. The other input is a saliency mask. The interior regions of a binary saliency map are filled with this saliency mask. Fig. 11 shows the saliency mask image. The saliency mask is considered because the exterior parts of the salient region are required to be recognized.

The details of proposed algorithm describe as follows.

### D. Particle Properties Identification

In this step, the properties of each particle are identified. To do this identification, the edges for particle regions and salient mask are detected, and their region is extracted. The Sobel

edge detector is used for edge segmentation. Fig. 12 shows the edge segmentation of the salient mask. The segmented regions are then integrated into one image. Fig. 13 shows a man-made image, including the integration of a salient mask and some particles regions.

To identify the properties of the particles, the centroid of particle is firstly extracted by taking the particle area and dividing it up into differential areas. The arbitrary shape has an area denoted by  $A$ . Differential area  $dA$  that exists some distance  $x$  and  $y$  from the origin. The total area is denoted as  $\int dA$ , which is the first moment of area in each direction from the following Eq. [16]:

$$Q_x = \int_A y dA \quad (3)$$

$$Q_y = \int_A x dA$$

The first moment of area is the integral of a length over an area. It is important because it helps us to locate the centroid of the particle. According to the obtained area, the centroid is defined as the "average  $x$  (or  $y$ ) position of the area"

$$\bar{x} = \frac{Q_y}{A} = \frac{\sum_i \bar{x}_i \bar{A}_i}{\sum_i \bar{A}_i} \quad (4)$$

$$\bar{y} = \frac{Q_x}{A} = \frac{\sum_i \bar{y}_i \bar{A}_i}{\sum_i \bar{A}_i}$$

Fig. 5 to 15 shows the centroid of the particles using calculation of centroid moments. Using the identified center point, diameter for particle is identified, as shown in Fig. 14.

#### E. Particle Mask Generation

In this step, a mask is generated according to the shape of the particle inspired from [25]. The purpose of this mask is to determine the range for exploring the area. The exploring area (ExA) is a search range to check whether the particle belongs to the target (salient region) or not. The diameter of the mask depends on particle diameter. It calculates by  $D_{mask} = 2 * D_{particle}$ . Fig. 15 shows the generated particle masks. Furthermore, Fig. 16 shows ExA on integrated salient and particles image.

#### F. Confluence Lines (CL) Generation

Confluence lines (CL) are the lines to find intersection points in different regions. These regions are the particles and the salient region. The CL lines are started from the particle center point and end up on the mask. Therefore, it is required to identify the endpoints on the mask to draw these lines. Having the area value of the mask to find the endpoint on the mask or particle is required. The area of the particle mask is considered that can be calculated using Eq. (3).

$$A = \int_0^\theta \int_0^r dS = \int_0^\theta \int_0^r \tilde{r} d\tilde{r} d\tilde{\theta} = \int_0^\theta \frac{1}{2} r^2 d\tilde{\theta} = \frac{r^2 \theta}{2} \quad (5)$$

where  $\theta$  is denoted as an angle between two individual points on the mask region, the radius of the mask,  $S$  is the region mask, and  $A$  is the area of the mask. Using the identified area, a mask can be divided into equal sectors. In this regard, several sectors and angles between sectors, are required. The equation is used to address the angle between each sector.

$$\varphi = \frac{2\pi}{n} \quad (6)$$

where  $n$  is number of sectors, and  $\theta$  denotes the angle between CL lines (sectors). According to our experiment, with 20 sectors, we can get promising results. Therefore, the mask contains 20 points (since there are 20 equal sectors on a mask). These points are considered endpoints for CL lines in which the angle between the CL lines is as,  $\theta = \frac{\pi}{10}$ . The angle between each pair CL is 18. Fig.17 shows a circle division demonstration inspired by trigonometry constants on real radicals<sup>2</sup>. Fig. 18 illustrates the sectors and confluence lines (CL) in a mask.

#### G. Particle and Salient Region Distance Measurement

Using the CL lines, the intersection points from the salient region and particles with CL can be extracted. The points form a salient region, and particles are collected; and composed of a pair of two points used for distance measurement. Fig. 19 shows the point on the salient region as  $P_s$  and particles as  $P_p$ . Euclidean distance (Equation (5)) is used for distance measurement. Then, Fig. 20 shows the result of Euclidean distance for distance measurement between  $P_s$  and  $P_p$ .

$$D_i = \sqrt{\sum_{i=1}^n (P_s - P_p)^2} \quad (7)$$

where, the  $P_p$  and  $P_s$  are defined as,

$P_p (x_p, y_p) \rightarrow$  intersection point for CL and particle, and

$P_s (x_s, y_s) \rightarrow$  intersection point for CL and salient region

The obtained distances for each pair of  $P_s$  and  $P_p$  called  $D_i$  are compared. The purpose of this comparison is to identify a number of equal lines and non-lines distances. For identification number of equal and equal distances, we consider conditions as shown in Eq. (6),

$$\text{For each } D_i \text{ and } (D_i - 1), \text{ if } \begin{cases} D_i - (D_{ps} - 1) > \varepsilon \rightarrow N_{eq} = N_{eq} + 1 \\ D_i - (D_{ps} - 1) < \varepsilon \rightarrow N_{non-eq} = N_{non-eq} + 1 \end{cases} \quad (8)$$

#### H. Possession Ratio Measurement

In this step, a ratio is introduced to decide whether the particle is belonged to the silent region (target) or not. The ratio is called the possession ratio (or belonging ratio) ( $\mu_{BR}$ ). Eq. (7) is defined in this study to measure the  $\mu_{BR}$  for each particle. A condition rule then is defined to decide the particle is belonged, which is based on a threshold denoted as  $\delta$ .

$$\mu_{BR} = 1/n(\sum_{i=1}^n N_{eq}) \quad (9)$$

where  $N_{eq}$  is a counter variable to count the equal distances and  $n$  number of lines. Based on obtained value from Eq. (7), a condition defines as shown in Eq. (10), to decide whether the particle is belonged to the target (salient region) or not as,

$$\begin{cases} \mu_{BR} = 1 & \text{then } P_i \leftarrow T \\ \mu_{BR} > \delta \text{ and } \mu < \delta + 0.1 & \text{then } P_i \leftarrow T \\ \mu_{BR} < \delta & \text{then } P_i \leftarrow N \end{cases} \quad (10)$$

According to calculated  $\mu_{BR}$  and asses the condition, the particle is labeled as True ( $T$ ) or Negative ( $N$ ). Lastly,

<sup>2</sup>[https://commons.wikimedia.org/wiki/File:Unit\\_circle\\_angles\\_color.svg](https://commons.wikimedia.org/wiki/File:Unit_circle_angles_color.svg)

according to  $T$  and  $N$  labels, the corresponding particles are recognized as the saliency components.

TABLE I. COMPONENTS SALIENCY RECOGNITION

**Saliency Components Detection Algorithm**

Input: A set of particles and salient mask.

Extract the edges for all regions and identify the particle properties such as centroid called as  $P_c$  and diameter as  $P_d$ .

Particle mask generation with these parameters: Diameter:  $2P_d$ , Origin: particle center ( $P_c$ )

Generate confluence lines finder (CL) from  $P_c$  to confluence the mask circumference (length of lines are equal to  $2P_d$ )

Measure the distance between points on particle to concern point on salient region touch, using Equation (2).

Count number of equal lines using Equation (3)

Measure the belonging ratio using Equation (4) and identify the particle is belonged to target or not.

Output: a saliency map with its related parts

### III. EXPERIMENTAL RESULTS

In this section, experimental results are presented for the proposed saliency detection method. The proposed method consists of five steps, salient region detection, salient region localization, region of interest extraction, particle segmentation, and multi-part saliency recognition. The salient region detects using the GMR method for an input image. The detected salient region localizes, and the region extract corresponding salient region, is extracted using region of interest extraction. The localization and region of extraction are integrated into one process, because, they are roughly related to each other. The extracted target segments using the segmentation process as explained earlier consist of, an extracted salient region from the original image, there holding and edge segmentation, filling blobs, and shape recognition.

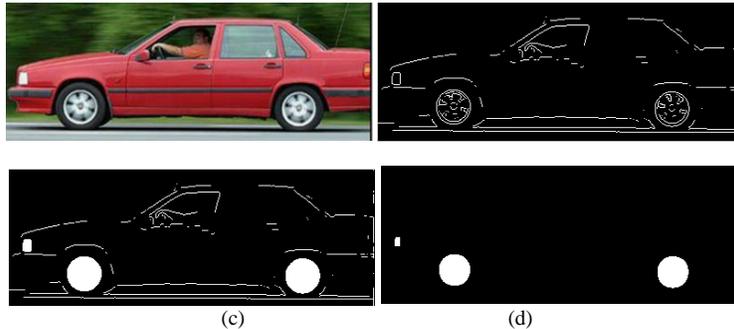

Fig. 21 shows the segmentation process for the salient particle segmentation step.

In the last step of the method, associated particles to the salient region detect using the proposed multi-part saline detection. For these steps, segmented particles (as shown in Fig. 21(a)) from particle segmentation steps are evaluated to check whether they belong to the detected salient region or not. This belonging assessment is based on checking distance measurement between the out-bounding of the segmented particle region and binary salient mask. Finally, those segmented particles belong to salient region are added to the saliency map as shown in Fig. 22(c).

According to the proposed saliency detection method, some image results are illustrated as shown in Fig. 23.

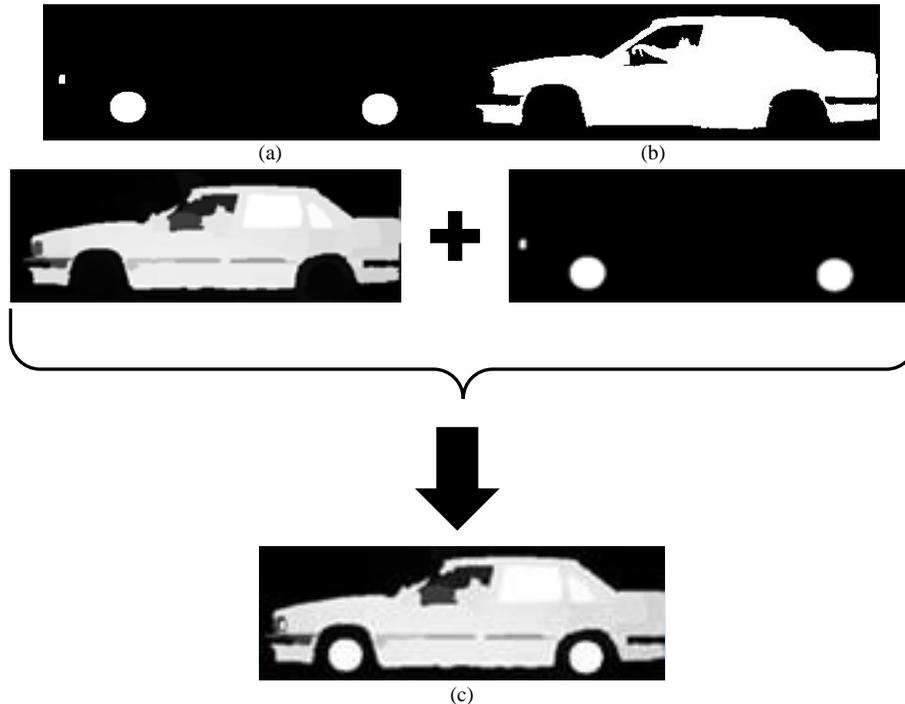

Fig. 22. Multi-part saliency recognition step. (a) segmented particles, (b) binary salient mask

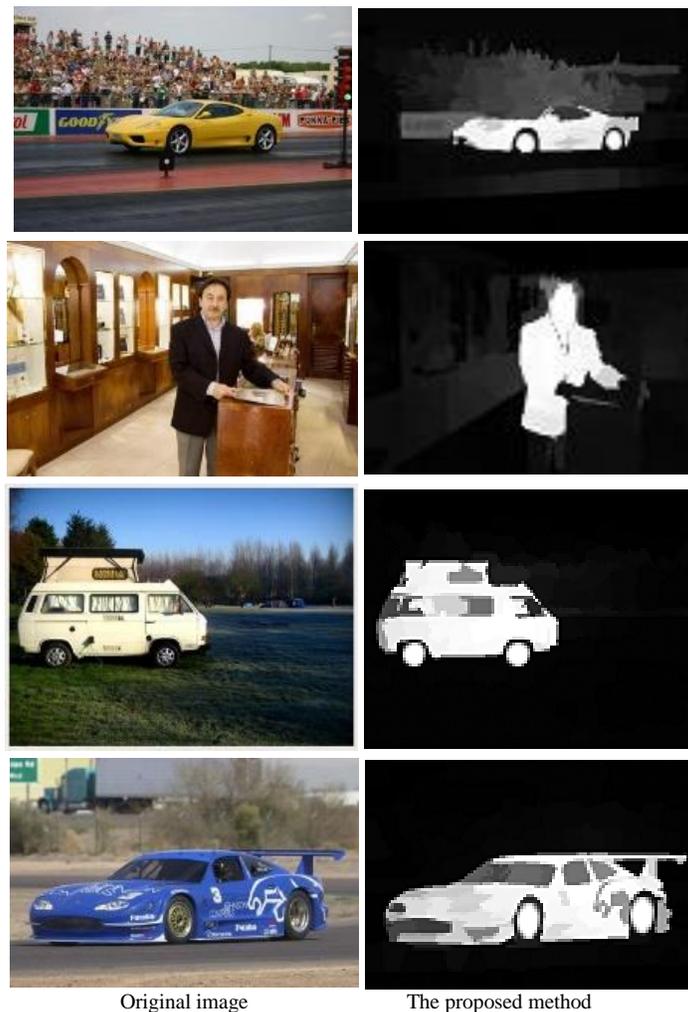

Fig. 23. Experimental result for the proposed saliency detection method

#### IV. CONCLUSION

In this study a new saliency detection method is proposed based on component saliency recognition for a salient region. This component of saliency recognition aims to represent the salient region more accurately because sometimes the salient regions involve several parts. To deal with component saliency recognition for a salient region, the proposed method is structured by five modules, salient region detection, salient region localization, region of interest extraction, particle region segmentation, and possession ratio measurement. In brief, the proposed method is first applied to a graph-based manifold ranking (GMR) method for salient region detection in an image. The detected salient region is localized using centroid finding and region size identification. The localized region is then extracted and called ROI. In ROI, some processes are performed to segment different regions and generate the particles. The BRM is the main module in our saliency detection method. Finally, as experimental results show, the proposed components' saliency recognition for a salient region can represent accurately and efficiently the target appearance representation. For directions of future study, modern advanced methods such as deep learning frameworks can be explored for further improvement of object representation in visual tracking

applications. Moreover, the proposed method can be extended for real time applications.

# Building a Machine Learning Powered Chatbot for KSU Blackboard Users

Qubayl Alqahtani, Omer Alrwais

Information Systems, King Saud University, Riyadh, Saudi Arabia

**Abstract**—Chatbots have attracted the interest of many entities within the public and private sectors locally within Saudi Arabia and also globally. Chatbots have many implementations in the education field and can range from enhancing the e-learning experience to answer students' inquiries about course schedules and grades, tracking prerequisites information and elective courses. This work aim is to develop a chatbot engine that helps with frequently asked questions about the Blackboard system, which could be embedded into the Blackboard website. It contains a machine-learning model trained on Arabic datasets. The engine accepts both Arabic textual content as well as English textual content if needed; for commonly used English terminologies. Rasa framework was chosen as the main tool for developing the Blackboard chatbot. The dataset to serve the current need (i.e. Blackboard system) was requested from Blackboard support staff to build the initial dataset and get a sense of the frequently asked questions by KSU Blackboard student users. The dataset is designed to account for as many as possible of KSU Blackboard related inquiries to provide the appropriate answers and reduce the workload of Blackboard system support staff. Testing and evaluating the model was a continuous process before and after the model deployment. The model post-tuning metrics were 93.4%, 92.5%, 92.49% for test accuracy, f1-score and precision, respectively. The average reported accuracy in similar studies were near 90% on average as opposed to results reported here.

**Keywords**—Chatbot; RASA; conversational agents; machine learning

## I. INTRODUCTION

A chatbot is an artificial intelligence (AI) software that can simulate a conversation (or a chat) with a user in natural language through messaging applications, websites, mobile apps or through the telephone [5]. It's an environment that receives questions from users in natural language, relates these questions with a knowledge base, and then answer based on pre-defined answers. Chatbots are more formally referred to in the literature as conversational agents or conversational assistants. The core principle of every conversational agent is to interact with humans using text messages and act as it were able to understand the user and replay with the appropriate message. The origin of computers talking to humans goes back to the start of the computer science field itself. Alan Turing defined a simple test referred to now as the Turing test back in 1950 where a human judge would have to predict if the entity they are communicating with via text is a computer program or not [6]. However, this test's scope is way greater than the case of chatbots, the main difference being that the domain knowledge of a chatbot is narrow compared to the Turing test.

Turing test assumes one can talk about any topic in mind with the agent.

Conversational agent environment consists of five different main parts [7]. Starting with user messages: they are a dynamic input received by the agent to process and replay. They contain a string representation of the actual text sent by the user, and a metadata that contains additional information like a reference to the session the conversation belongs to, and possibly the date and time the message was sent to the agent, on which platform the message was sent from if the agent is linked to more than one message, etc. The agent receives the message along with the information it contains in a read- only mode only with no possible means of making changes to it. The backend is one of the significant parts of the environment that the agent has access to. It contains additional information about the agent users and the database's states to store the user messages, their metadata, and keep track of the conversation events. The agent can view and update certain aspects of the backend. The chatbot can also obtain new information from the user if necessary, by asking the user to provide it.

RASA is a modular design framework proposed by [1] that consists of two main components, Rasa Core for dialog management and Rasa NLU for natural language understanding. Those are open- sourced python libraries for building machine-learning based conversational agents. They provide dialog management and NLU capabilities in an easy manner. By nature, a modular by design architecture allows for easier integration of modules with other systems and services. For instance, Rasa NLU can be used as a service in a different system other than rasa by exposing HTTP APIs for external requests and vice versa for Rasa Core. The code can be found by visiting: <https://github.com/RasaHQ>.

Although chatbots have been present for a long time, 2016, before the spring, was the true start of this technology. There are two main reasons for the renewed interest in chatbots (1) massive advances in artificial intelligence (AI) and (2) a major usage shift from online social networks to mobile applications such as WhatsApp, Telegram, Slack, and many more advances in AI holds a promise that intelligent chatbots are in fact, can be within reach. The increased usage of mobile applications attracts service providers to reach users through them. However, in spite of these advances, chatbot applications entail many challenges that need to be overcome in order to reach desired goals. Chatbots not only imply changes in the interface between users and technology; they imply changing user dynamics and usage patterns. A recent study indicated that 56% of chatbot users were interested in ordering meals from

restaurants using chatbots, while 34% had already ordered at least one meal [2]. Chatbots are considered to be beneficial for retailers in terms of customer service (about 95%), sales/marketing (about 55%), and order processing (about 48%) [3]. Generation Z and Millennials are more interested in using chatbots: 25% of a global sample aged 18 to 34 opted for a personal shopping chatbot [4], and the students using Blackboard system fall under this age range.

King Saud University (KSU) is the largest public university in Saudi Arabia and at any time encompass thousands of students whom some of them use and struggle with the online course and learning management system (blackboard), as such the customer support staff (which is not more than three employees) at KSU is overwhelmed with enquiries which can cause great user dissatisfaction and affect the adaptation of Blackboard system by KSU students. The goal of this work is to build a Minimum Viable Product (MVP) for an Arabic Chatbot which is intended to serve users of Blackboard system from King Saud University students by answering their frequently asked questions about the Blackboard system to reduce the load of answering repeated, one answered questions and allow customer service staff to focus on more dynamic issues that require human intervention.

## II. RELATED WORK

A revision for several chatbot related papers that highlights the usage of chatbots in the education field was conducted, along with other chatbot usages in different areas such as retail and government entities. A review and summarization of those implementations are discussed in the next paragraphs.

### A. Chatbots in Education

A chatbot named EASElective that was built to advise students on what to choose as an elective course was proposed in [22]. EASElective is a conversational agent that was built to supplement existing academic advising systems. It has an interactive, online interface that supports basic official course information to informal students' opinions about that course. Its major components included intent detection, conversational management routines, dialogue design, course information management, and a collection of analyzed students' peers' opinions. In this study, a survey was conducted to capture students' perceptions of the chatbot. The subjects were briefed about the chatbot's purpose and instructed on how to use it and were given up to a half-hour to interact with it and then fill the surveys. The survey results showed that many students preferred to either ask their friends for course information. Around 22% preferred to ask the program leader or use the official university website instead of the chatbot. There were a number of limitations, including the chatbot not having enough interactions to learn from before going live. And also, the chatbot patterns usages are neither recorded nor pre-defined in advance to prepare the appropriate responses.

Another chatbot implementation to enhance the LMS experience was proposed by [23]. This model classifies the main keywords that could be asked by students using R programming language, and this classification is then used in an Artificial Intelligent Markup language (AIML) script as a query. If this query was unsuccessful, it would run against SQL

lite. If neither AIML nor SQL lite worked, then the student query will be transferred to a human agent to take over and answer the query. Although the implementation of AIML scripting language is easy and also free to use as a scripting language, this model is a rule-based model and is less tolerant to changes in users' input and, thus, harder to capture the user intent.

Another study for developing a chatbot for university inquiries was put forward by [24]. This study discussed the development of a deep-learning based chatbot using RASA framework. RASA has many connectors to be used in integrating it with communication platforms. One of them is for Facebook. This chatbot is integrated with FB as the majority population is using FB as their main social media channel. This chatbot uses Long Short-Term Memory (LSTM), which is a recurrent neural network architecture that is used in deep learning. This architecture is included in RASA framework. Although the chatbot performed well in terms of intent classification and provided the appropriate replays, there was a platform limitation as they had to perform platform-specific steps to run the chatbot on Facebook, which can result in some limitations to the interaction with the chatbot.

A chatbot for instantly answering students' questions to reduce teacher's workload was proposed in [25]. It supports multiple common social platforms, including Telegram, Facebook Messenger, and Line. The chatbot can reply to commands and natural language questions. Once the instructors transfer the course-related data to an internet database, the chatbot can reply to questions about the course materials and logistics (e.g., course plan). It also supports student login to provide profile-based answers such as the schedule of student registered courses.

### B. Chatbots in other Fields

Chatbots also have many usages in other fields besides education. Some of those applications are in healthcare, such as self-diagnoses based on symptoms, using chatbots as a communication means in e-commerce websites, providing account data and paying bills in banking, etc. Below are some of the related works of chatbots.

A text-to-text chatbot engages patient's medical issues were proposed by [26]. It's a medical chatbot that diagnoses diseases using AI. This chatbot was built to reduce medical costs and improve patient's accessibility to medical knowledge. In this chatbot, a series of questions about the patient's symptoms are asked to give suggestions that help in clarifying the disease. The accurate disease is found based on the user reply to those series of questions, and in case of major diseases, a doctor is suggested to be consulted. The patient's past responses are recorded, and in order to reach an accurate diagnosis, the patient is asked more specific questions. There are three main components of the system, which are (1) user validation and symptoms extraction from the conversation, (2) mapping of extracted, potentially ambiguous symptoms to their corresponding database codes, and (3) personalized diagnosis and referring the patient to a specialized doctor if required. The sole focus of this system is extracting symptoms by analyzing natural language using NLG components, which in term makes it easier and less technical for the end-user.

Another example of chatbot usage in e-commerce to support customers in their website journey is called “SuperAgent” [27]. This chatbot scrapes public e-commerce websites' content of products description, user questions and answers, and product reviews and feeds them to its knowledge base. It uses NLP techniques to understand users' text and machine learning techniques to predict responses to it, including opinion mining for product reviews, fact QA for product information, and FAQ search for customer reviews and chit-chat for greetings and goodbyes.

ChatPy is one of the chatbot implementations in the wholesale business [28]. “Mundirepuestos” is a wholesaler

automotive spare company. This company is an SME company that started operating in 1992 that specialized in the distribution and sales of Volkswagen, Skoda, and Audi automotive parts. ChatPy is a conversational agent built mainly using a tool called Dialogflow. This tool makes use of intents, actions with parameters, entities, voice-to-text, and text-to-speech with automatic learning. A major reason for choosing this tool was its compatibility with the most known messaging platforms. A summary of chatbot related works in different fields is shown in Table I.

TABLE I. SUMMARY OF RELATED RESEARCH

Title	Field	Method	Limitations
Developing a Chatbot for College Student Programme Advisement [22]	Education	Intent detection, conversational management routines, dialogue design, course information management.	Minimal interactions to learn from before going live. Patterns usages are neither recorded nor pre-defined in advance to prepare the appropriate responses.
Enhancing LMS Experience through AIML Base and Retrieval Base Chatbot using R Language [23]	Education	Artificial Intelligent Markup language (AIML) script as a query, SQLite.	Using a rule-based model only.
Developing FB Chatbot Based on Deep Learning Using RASA Framework for University Enquiries [24]	Education	Long Short Term Memory (LSTM) a recurrent neural network architecture included in RASA framework.	Facebook-specific implementation to run the chatbot which limits customization.
Using a Multiplatform Chatbot as an Online Tutor in a University Course [25]	Education	DialogFlow's ML engine and knowledge base.	Low number of participants for evaluating the model.
A Self-Diagnosis Medical Chatbot Using Artificial Intelligence [26]	Healthcare	Symptom recognition, String Searching Algorithm.	No fallback policy for unknown symptoms.
SuperAgent: A Customer Service Chatbot for E-commerce Websites [27]	E-commerce	Opinion mining for product reviews, fact QA for product information, and FAQ search for customer reviews and chit-chat conversations.	No intent detection.
ChatPy: Conversational agent for SMEs: A case study [28]	Business	DialogFlow's ML engine and knowledge base.	Facebook-specific implementation to run the chatbot which limits customization.

To avoid issues in [22], the system needs to be internally deployed and used by diverse students' backgrounds while recording their usage patterns and interactions which is recorded by default in Rasa framework. Rule-based chatbots like the one presented in study [23] cannot learn which is not the case for Rasa as it has interactive learning capabilities which allows it to learn and refrain from making the same mistake in the future. Unlike the cases presented in study [24] and [28], this work is going to use Rasa API to communicate with the chatbot which remove the platform specific limitations and allows for more customizations. There needs to be a fit number of participants to fairly evaluate the chatbot to overcome the limitation in study [25]. As opposed to the case presented in study [26], Rasa provides a fallback policy that can be triggered when the prediction of the action to be taken is below a specified threshold; this fallback could be used to ask the user to rephrase or show some buttons for the user to choose from. Knowing the user intent can help greatly in providing the right answer to the user question and also helps in performing actions based on the user intent; Rasa uses deep learning embeddings to detect user intention which is not the case in study [27].

III. SYSTEM DESIGN

Fig. 1 below gives an overview of Rasa open-source architecture that consists of two main components which are the Rasa NLU and Dialog management (Core). Rasa NLU is

responsible for predicting intents, extracting entities and retrieving responses. It uses the saved model in the filesystem. The Core component is responsible for choosing the appropriate next action with regards to the conversation context and uses Tracker store to store the conversation states, messages and metadata.

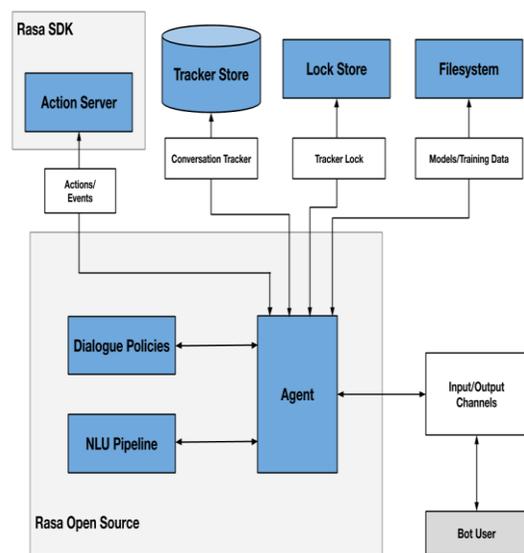

Fig. 1. System architecture overview.

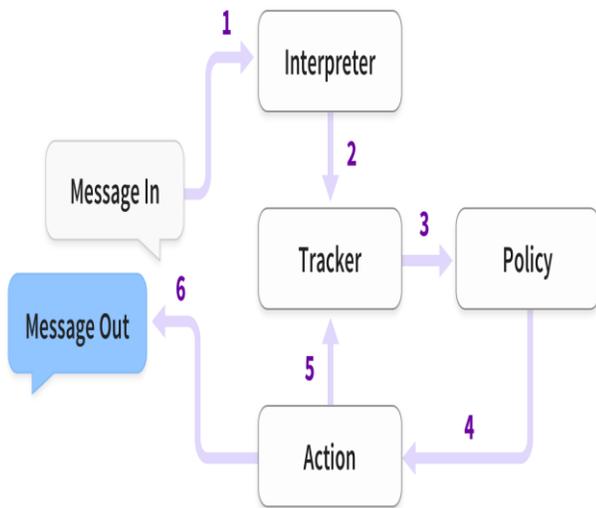

Fig. 2. Rasa architecture.

Rasa ensures that messages are being processed in the right order using the lock store. Actions are running on the Action Server and executed when called by the Core component. Fig. 2 shows the message flow and how Rasa architecture works.

The user first types in a message; this message is then passed to the interpreter in which NLU is used to extract user intention, intent for short, and any entities contained in the text. The conversation state is then saved in a Tracker object, and an event is created, i.e., new message arrival. The state is then received by the policy, and the next action is chosen by the policy to be taken. The action is also logged into the Tracker and then implemented, which could be a response that is based on an external API call or a simple text response that is sent back to the user.

#### A. Data Collection

To gather the required data for training the chatbot to answer most frequent questions asked by students, the LMS Blackboard team admin was contacted to provide this data. This data is in the form of a Word document format and will be used to manually generate the training data and build chatbot stories to train the chatbot. It contains 17 of the frequently asked questions by the Blackboard users. Examples are shown in Appendix 1.

There are two datasets to be built, one for the NLU model which contains examples for each user intent along with labeled entities. The data for this project are in MSA, Modern Standard Arabic and some common English words. The second dataset is for the Core model or the Dialog Management model, it has all the possible flows for the conversation (intents with their corresponding actions). The latter might not be needed when using mapping policy which maps each intent to an action or a template. The dataset to serve the current need (i.e., Blackboard system) was requested from Blackboard support staff to build the initial dataset, and get a sense of the frequently asked questions by KSU Blackboard student users. This data will be then increased by synthesizing text that could

be asked by the chatbot users to increase the chances of understanding students' questions about the Blackboard system. For chatbots systems, the datasets should be continuously updated after deployment for continuous enhancement. The data formats for both NLU and Core are written in a user-friendly format to make it easier to build, revise and edit. For the NLU model, examples for each intent along with labeled entities are created. There are two available formats for building the dataset, either as a json or a markdown format. Markdown formats are the most used as it can be rendered by most text editors.

#### B. Building NLU Corpus

The main goal of building this corpus is to make the chatbot see many examples of what the user might say regarding a specific intention of the user. There are two available formats for building the dataset, either as a json or a markdown format. Markdown formats are the most used one as it can be rendered by most text editors. Below is an example of markdown NLU dataset record.

```
1. ## intent: FAQ_login_issue
2. -(system)[نظام إدارة التعلم] لا أستطيع الدخول على
```

The other format is the json format; it's not sensitive for whitespaces and better in exchanging data among applications. The actual NLU corpus can be found in Appendix 2.

```
1. {
2. "text": " لا أستطيع الدخول على نظام إدارة التعلم",
3. "intent": "FAQ_login_issue",
4. "entities": [{
5. "start": 19,
6. "end": 33,
7. "value": "نظام إدارة التعلم",
8. "entity": "system"
9. }]}
```

#### C. Building Stories

Stories are a type of data that is used in order to teach the chatbot the possible messaging flow with user. Markdowns are used to specify the conversation paths i.e., stories. Below is an example for Dialog management model training data.

```
1. ## story_84854865
2. * greet
3. - utter_ask_howcanhelp
4. - utter_ask_issue
5. * inform("system":"نظام إدارة التعلم")
6. - action_replay_issue
```

The naming convention for stories is to start with two hashes, followed by the story name. Actions are events that start with a dash. The actual Core model corpus can be found in Appendix 3.

#### D. Implementation

Rasa environment requires a list of hard and software requirements for running Rasa on Docker. Although there are minimum hardware requirements on Rasa official website, the hardware requirements depend on the size of the model and training data as the training time and the size of the NLU data are positively correlated. Those requirements need to be met to

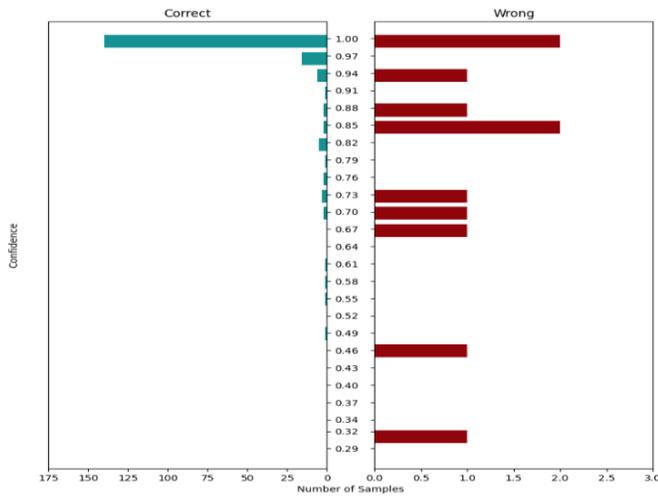

Fig. 5. NLU intent confidence histogram.

From Table III, we can see that all actions were predicted correctly with a value near to 1 for F1-score, precision, and accuracy. The reason for such high results is that the dialog management model is classifying actions based on the results of the intent classifier. If there are no errors in predicting the intention of the user, the prediction of the next action becomes easier and hence, result in a high hit rate.

TABLE III. DIALOG MANAGEMENT RESULTS

Metric	Score
Correct	335/338
F1-score	0.991
Precision	0.992
Accuracy	0.991

As mentioned earlier, we will try to optimize the NLU model by adding more examples and removing examples that might mislead the model into falsely predicting intents. We will also change some of the NLU model configurations to see if those changes yield better results (Table IV).

TABLE IV. PRE-TUNING VS. POST-TUNING METRICS

Metric	Pre-Tuning Score	Post-Tuning Score
Train Accuracy	1	1
Train F1-score	1	1
Train Precision	1	1
Test Accuracy	0.924	0.934
Test F1-score	0.911	0.925
Test Precision	0.922	0.925

Although those are minor changes, they do have an effect and it means that it's possible to further optimize the model by adding more data and tuning the model parameters to find the ones that best fit the data. The average reported accuracy in similar case studies mentioned in [22], [24], [27] is near 90% as opposed to our results which is slightly higher.

## V. CONCLUSION

This work intended to develop a chatbot engine that helps with frequently asked questions about Blackboard system, which could be embedded into Blackboard website. It contains a machine-learning model trained on Arabic datasets. The engine accepts both Arabic textual content as well as English textual content if needed; for commonly used English terminologies. The interactions with the chatbot, as well as the users' evaluations, are stored and used for optimizing the chatbot model to improve future interactions. Chatbot systems development entails many challenges in terms of preparing the training dataset in a way that incorporate as much as possible of users' inquiries without confusion, preprocessing it before feeding it to the NLU model to try to normalize the data and remove unnecessary words and symbols that could confuse the model, and deploy and maintain the model to be used. Rasa framework was chosen to as the main tool for developing the Blackboard chatbot.

The actual chatbot implementation started by preparing the datasets required for Rasa NLU and Core models. The dataset is designed to account for as many as possible of KSU Blackboard- related inquires to provide the appropriate answers and reduce the workload of Blackboard system support staff. When the data was ready, the model training and tuning began along with a number of experimentations to find the best model pipelines that fits the data. The chatbot is built using a combination of tools such as Python for programming, YAML as the markup language.

For future work, the chatbot should be deployed using Docker and Docker-compose for running the chatbot service. The chatbot can also be deployed in a distributed cluster either on cloud or on- premise to handle the workload and make the chatbot system scalable.

# WEB-based Collaborative Platform for College English Teaching

Yuwan Zhang

Henan Polytechnic Institute, School of Culture, Tourism and International Education, Nanyang, 473000, China

**Abstract**—At present, colleges and universities are trying to apply online education. The online college English course teaching cooperation platform is an important part of college English teaching. At present, teachers' scoring method for students' online examination on this kind of platform is mainly human scoring, which has a low efficiency. In view of this, based on the characteristics of web, this paper constructs an English test paper scoring algorithm based on text matching degree algorithm and improved KNN algorithm. The data analysis type of the algorithm is mainly prescriptive analysis that is, judging whether to give points according to the characteristics of the data. The automation and high efficiency of the algorithm can save a lot of human costs in the field of online education. The experimental results show that the recall rate of the improved KNN scoring algorithm for specific semantic topics is up to 0.9, and only 7.3% of students report that the algorithm misjudges their grades. The results indicate that the algorithm has the potential to be applied to the Web-based college English course teaching collaboration platform and reduce the workload of teachers and improve their efficiency.

**Keywords**—Web; text similarity; KNN algorithm; vocabulary matching; network teaching

## I INTRODUCTION

With the development of network and information technology, online teaching mode is gradually adopted by major universities. This mode is different from traditional teaching, and teaching methods are more diversified and convenient for students [1]. English is a required course for most majors in colleges and universities, and the number of users of its web-based teaching collaboration platform has been very large. Therefore, it often takes more time for English teachers to correct students' test papers online, which increases labor costs and reduces efficiency [2]. The reason why the English test paper correction of the web network teaching collaboration platform cannot be fully automated is that it is difficult to judge the compliance of students' answers with the standard answers through algorithms [3]. Among related technologies, text similarity detection is a technology to calculate the same degree of two texts, and k-nearest neighbor (KNN) algorithm is a mature classification algorithm [4]. In order to solve the automation problem of online English test paper marking, this paper studies the scoring algorithm of English test paper on the WEB online teaching platform based on these two technologies. The goal of the algorithm is to provide an automatic marking method, which can complete the marking of objective and subjective questions with high accuracy.

The article is divided into five parts. The second part is related works, which describes the latest progress in research related fields and shows the basis of research. The third part is the method, which describes the construction and related settings of the algorithm. The fourth part is the experiment, which describes the performance test of the algorithm. The fifth part is conclusion, which summarizes the whole research and proposes the future direction of the research.

## II RELATED WORKS

In recent years, relevant literature and research results have been sorted out. The fields involved are mainly the latest development of online education research, as well as the application of KNN and text similarity technology. Some studies have explored the web-based online teaching platform and related technologies. Poultsakis led his team to study the application of digital learning and related tools in Greece and found that the popularity of digital learning is very low [5]. This is largely due to the backwardness of digital learning-related technologies in the region, which leads teachers to believe that the teaching effect of digital learning is poor and do not trust digital learning. Stamatios Papadakis et al. studied the situation of students using mobile phones to access a learning management system [6]. According to the survey results, there are differences in the use of the learning management system by students through mobile phones. Due to the limitations of reliability and practicality, the system is more used by students as a document library than a learning tool. Panagiotakopoulos and his team proposed a structured approach to develop an outreach plan aimed at improving the coding ability of pre-service and in-service teachers [7]. The project is a successful online teaching plan, with the actual number of classroom logins and completion rate of 70.84%. Researchers believe that this is because the design of the project is easy to use. Christianson designed a remote online voting system to help students enhance their sense of participation. The students said they had a positive experience in this way of participation [8]. Karakose and his partners studied the psychological state and Internet addiction of school administrators and teachers under the background of the epidemic, and the results showed that Internet addiction indirectly affected teachers' loneliness and happiness [9]. The research expenditure on teachers' mental health also needs attention, and it is one of the feasible schemes to reduce teachers' workload through innovative algorithms. Lavidas K et al. studied the online teaching of preschool teachers during the epidemic, and pointed out that preschool teachers use less online teaching, and they prefer real communication framework and teaching process [10]. Katsaris and his partner

analyzed 42 papers related to online teaching from 2015 to 2020, introduced the theoretical and technical background of adaptive e-learning system, and emphasized the importance and efficiency of using learning style in adaptive learning process [11]. From the conclusion of this article, we can see that there is little research on automatic algorithms for marking test papers in online English teaching. From the research in the field of online education, we can see that the research of auxiliary technology for teacher's examination paper marking has received little attention and there is still a lot of research space.

Some researchers have also made corresponding explorations in KNN and text similarity detection. Zardari Za et al. have developed a detection and prevention algorithm to deal with network attacks. The algorithm is based on KNN and can distinguish abnormal nodes from normal nodes according to their behavior differences. Experiments show that the algorithm can effectively reduce latency and increase network throughput [12]. Wang and his team proposed a weighted KNN algorithm, which is calculated based on signal similarity and spatial location. They applied it to fingerprint location. The evaluation results show that the algorithm can improve the accuracy of fingerprint location [13]. In order to solve the problem of abnormal bridge health monitoring data, Lei Z and his research team proposed a KNN based bridge health monitoring algorithm. The algorithm measures the pattern distance between time subsequences according to the similarity of time series, and then selects abnormal patterns. The experimental results show that the model has certain reference value [14]. Pang and his collaborators put forward a Chinese text similarity detection method based on the semantics of feature phrases, which obtains feature phrases by replacing concepts and calculates text similarity. Experiments show that the output results are reliable [15]. Yang et al. proposed a news topic text detection method based on capsule semantic graph, which has lower time complexity than traditional detection, and the experimental data show that it has high accuracy and recall [16]. Franclinton and his research team proposed an extensible code similarity detection model with online architecture rather than local spikes. The experimental results show that the model can better maintain the academic integrity in programming [17].

Through combing the research trends in related fields, it is found that the web-based online teaching platform has been widely practiced and applied, but there is a lack of research on automatic scoring of English test papers. On the other hand, KNN and text similarity detection technology have also been applied in many fields. The research combines these two technologies in order to make contributions to the research of automatic scoring technology in the web online teaching platform.

### III CONSTRUCTION OF SCORING ALGORITHM FOR TEST PAPER OF WEB-BASED COLLABORATIVE TEACHING PLATFORM FOR COLLEGE ENGLISH COURSE

#### A. Web Architecture Selection and Vocabulary Matching Algorithm Construction

The WEB-based College English course network teaching cooperation platform uses B/S architecture to send documents. The structural diagram of B/S architecture is shown in Fig. 1. This architecture has very low requirements on the equipment of the client layer. Only a normal WEB browser is required to participate in College Online English courses. Due to the great differences in the electronic equipment used by college students, it is inevitable to make mistakes when the client mode. Therefore, the B/S architecture is the most secure [18]. In addition, the architecture has good reusability and scalability, which is conducive to the long-term use and version update of the English course online education collaboration platform [19].

After the framework of the platform is determined, the corresponding algorithm can be built. The test paper questions adopted by the WEB-based College English course network teaching and writing platform can be divided into objective questions and subjective questions. Due to the existence of standard answers to objective questions, students need to be completely consistent with the standard answers to score. Therefore, the idea of complete vocabulary matching can be used to build an objective question scoring algorithm. The judgment formula is shown in formula (1).

$$S = \frac{S_t N}{N_t} \quad (1)$$

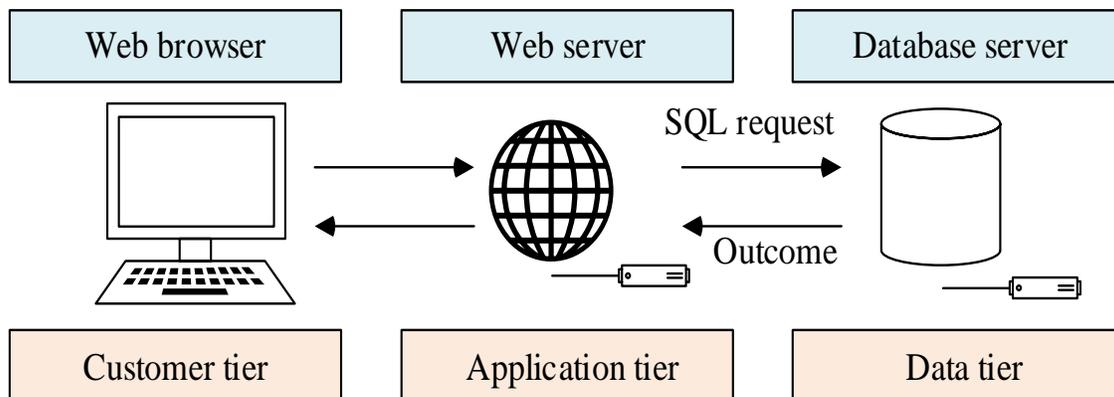

Fig. 1. B/S framework principle.

In formula (1),  $S$  represents the student's score on the question, and  $N$  represents the number of matching keywords with the standard answer, while  $S_t$  and  $N_t$  respectively represent the total score of the question and the number of all keywords. Compared with the scoring of objective questions, the algorithm of subjective questions is more complex. The reason is that both the reference answers of subjective questions and the answers of students are presented in the form of paragraphs. At the same time, the logic adopted by the two texts is not necessarily the same. There will also be differences in the keywords used by the two. It is common for the reference answers and the keywords used by students to be synonyms or superior and subordinate words (Liu M et al. 2021) [20]. The method that teachers use for manual marking of subjective questions is usually judged according to the coincidence degree of key words and reference answers in students' texts, as well as their writing logic and the purity of the overall content (Khan I u et al. 2021) [21]. The scoring algorithm design of English subjective questions on the web online teaching platform refers to the logical design of teachers' scoring, and it uses the method of prescriptive analysis to evaluate the score. Its process is shown in Fig. 2.

According to Fig. 1, the scoring logic of the algorithm is an imitation of the teacher's human scoring. On the one hand, the evaluation matches the keyword of the standard answer with the text of the student's answer, and gives the score according to the proportion of the number of successful matches in the total number. On the other hand, the text similarity between the standard answer and the student's answer is calculated, and the score is given according to the degree of fit between the two texts, and then the two scores are combined according to a certain weight to obtain the final score. In this model, the word matching algorithm adopts a two-way matching algorithm.

This algorithm is an optimization of the ordinary single item matching algorithm. It can distinguish keywords from the forward and reverse directions. In this algorithm, the matching degree between a keyword and the keyword in the student's answer is calculated by the common formula (2).

$$\alpha(K_i, D_i) = \frac{\text{Max}(K_i, K_j)}{m_i} \quad (2)$$

In equation (2),  $\alpha(K_i, D_i)$  is the ratio of a keyword to the number of characters of the current keyword. When the value is greater than the given threshold, the keyword matching is considered successful, otherwise, the matching is considered

failed.  $K_i$  and  $K_j$  are respectively the number of characters of keywords in the student text when the forward

matching and reverse matching are successful, while  $m_i$  is the number of characters of keywords in the reference answer. This algorithm effectively avoids the recognition failure due to the difference between the students' words and the reference answer. After the keyword matching condition is obtained, the keyword score of the question can be calculated. The calculation logic of the score of the subjective question is similar to that of the objective question. It is judged by the ratio of the total number of identified successful keywords to the total number of keywords in the reference answer. The calculation process is shown in formula (3).

$$S = S_t \frac{\sum_{i=1}^{N_t} \alpha(K_i, D_i)}{N_t} \quad (3)$$

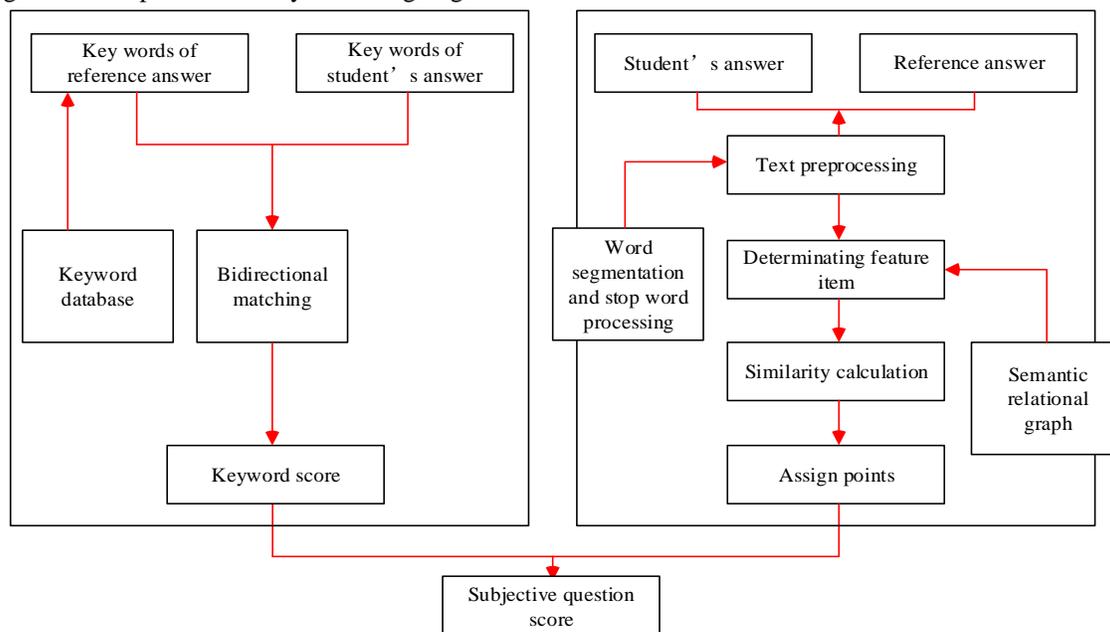

Fig. 2. Flow chart of subjective question scoring algorithm.

**B. Text Similarity Detection Algorithm**

According to the flow chart of subjective question scoring algorithm, the flow of text similarity detection algorithm is to preprocess student answers and reference answers, match feature vectors by combining semantic association, then calculate similarity, and finally calculate scores according to the closeness of answers. Text preprocessing mainly includes two steps: word segmentation and stop word filtering. The word segmentation tool uses THULAC as the word separator. The tool has high word segmentation accuracy and good recognition ability for professional terms. At the same time, it has good adaptability to the web [22]. Stop word filtering is the operation of filtering words such as “very” and “do” that have little effect on the actual meaning of the text, which can effectively reduce the workload of subsequent recognition and matching, save computing resources and improve speed [23]. In the subsequent feature item determination steps, the traditional feature item weight calculation does not consider the semantic problem, but the proposed vector space model takes the semantics into account when selecting feature items, so it is necessary to build a semantic association diagram. In this study, the semantic association diagram is made based on the How Net semantic knowledge dictionary, and its principle is shown in Fig. 3.

In Fig. 2,  $T_1, T_2, T_3$  and other items are semantic topic nodes. These items are a large number of semantic hypernyms, but these items do not have hypernyms. “Sports”, “biology” and other words can be used as semantic topics, while  $t_4, t_5, t_6$  and other items are called non semantic topic nodes. These nodes belong to the hyponymy of one or more semantic topics,

and may have their own hypernymic or hyponymic words, “Basketball” is the non-semantic topic node of “Sports”. Based on the upper and lower semantic relations of the semantic association graph, the upper semantic relations of the semantic association graph can be expressed in mathematical form, and the expression is shown in formula (4).

$$\begin{cases} L_U(t_i) = L(t_i), U = 1 \\ L_U(t_i) = \cup_{t_k \in L_{U-1}(t_i)} L(t_k), U > 1 \end{cases} \quad (4)$$

In formula (4),  $L_U(t_i)$  represents the set of semantics starting from  $t_i$  and going up the  $U$  layer, besides  $t_k$  and  $t_i$  respectively represent different semantic nodes. Based on this formula, the union of all the superscript nodes of any node can be obtained, that is, the set of the node. The expression for finding the set is shown in formula (5).

$$L_U(t_i) = L1(t_i) \cup L2(t_i) \cup L3(t_i) \cup \dots \quad (5)$$

After the definition of semantic association graph is completed, it is necessary to build a semantic space vector model. The model is set as  $R$ , its dimension is set as  $D$ , and the feature vector is  $\vec{t}$ . Then the expression of the model and semantic feature vector is shown in equation (6).

$$\begin{cases} R = T_{\geq 0}^D \\ \vec{t} = (t_1, t_2, \dots, t_n) \end{cases} \quad (6)$$

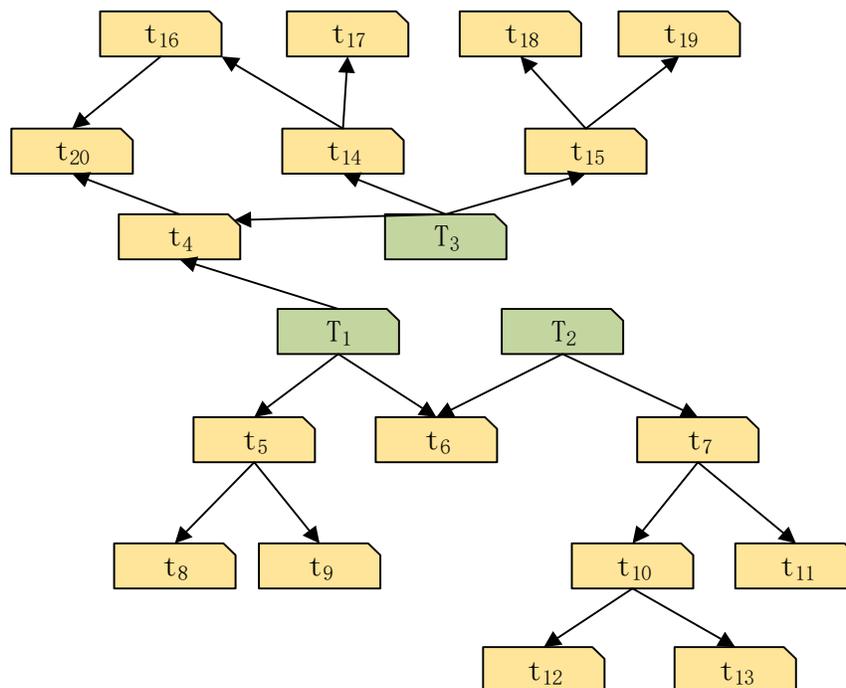

Fig. 3. Schematic diagram of semantic association.

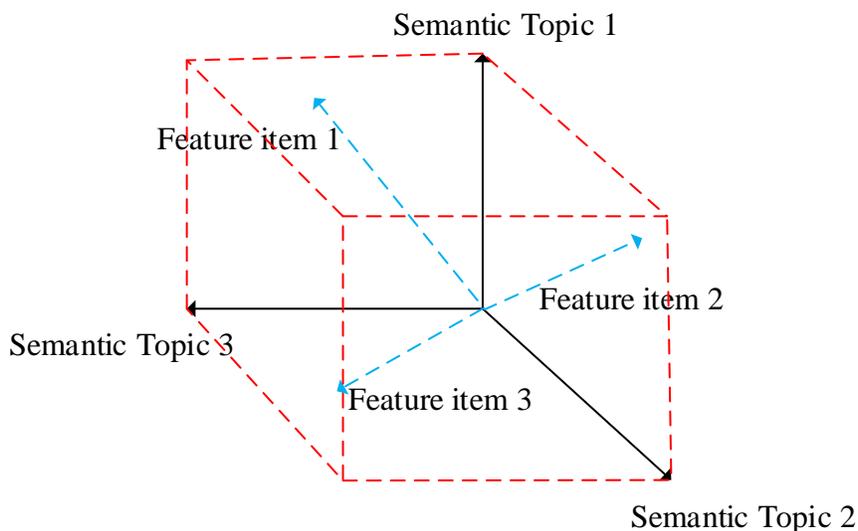

Fig. 4. Schematic diagram of feature item and semantic topic space.

The number of  $t_i$  in equation (6) is determined by the dimension, that is,  $i \in \{1, 2, \dots, D\}$ , and  $t_i \in [0, 1]$ . According to this formula, the schematic diagram of the semantic space vector model is shown in Fig. 4. Each coordinate axis in the figure represents a semantic topic. The more a feature item matches a semantic topic, the greater its value on the coordinate axis of the topic. If a feature item is related to a plurality of semantic topics, its vector will be between the two fields. The correlation between each feature item and each semantic topic depends on the weight of each vector. The higher the correlation with a topic, the higher the weight of its corresponding component.

After defining the semantic space vector model, it is necessary to quantify and express the semantic feature vector in an appropriate way. Quantification is to meet the needs of text similarity calculation, and the appropriate expression can simplify the calculation and improve the efficiency of the algorithm. In terms of quantification, the following rules are designed. First, the weight of the feature item ranges from 0 to 1. The larger the value, the better the feature item reflects the semantics. When the weight is close to 1, the feature item is considered to be basically equivalent to the semantic topic. When the weight is close to 0, the feature item is considered to be basically irrelevant to the semantic topic. Secondly, in terms of the angle of feature items, it is stipulated that the angle between synonyms and feature items not in any semantic field is 0, the angle between synonyms and hyponyms should be close to 0, and the vector angle between feature items in different fields is 90 degrees. In the aspect of feature vector representation, the occurrence times of feature items in the text and their weights in the semantic space vector model are used as variables to represent the feature vector, and the expression is shown in formula (7).

$$|\alpha| = \left| \sum_{i=1}^n F(t_i) \vec{t}_i \right| \quad (7)$$

In formula (7),  $|\alpha|$  is the feature item vector after normalization,  $F(t_i)$  is the number of times the feature item appears in the text, and  $\vec{t}_i$  is its corresponding vector in the semantic space. After the feature vector is properly expressed, the text similarity between the student answer and the reference answer can be detected. Here, the vector cosine method is used for detection, and its expression is shown in formula (8).

$$SIM = \frac{\sum_{t=1}^N \omega_{it} \cdot \omega_{kt}}{\sqrt{\left(\sum_{t=1}^N \omega_{it}^2\right) \cdot \left(\sum_{t=1}^N \omega_{kt}^2\right)}} \quad (8)$$

In formula (8),  $SIM$  refers to the text similarity of student answers and reference answers.  $\omega_{it}$  and  $\omega_{kt}$  respectively represent the weight of student answers and reference answers in the  $t$  feature item.  $N$  is the total number of feature items. It can be seen that the smaller  $SIM$ , the smaller the text similarity, and vice versa. Finally, after the keyword matching degree and text similarity are obtained, the subjective questions can be scored according to their respective weights. The scoring calculation process is shown in formula (9).

$$S = (A \times S_k + B \times SIM) \times S_t, \quad A + B = 1 \quad (9)$$

In formula (9),  $S$  is the final score of students,  $S_k$  refers to the score of students in keyword matching,  $A$  and  $B$  are the weights of keyword matching and text matching respectively, and  $S_t$  is the total score of the topic.

C. Subjective Item Scoring Algorithm Based on Nonlinear Classifier KNN

As a compulsory course for most majors, College English courses attract a large number of students every year, which leads to a large number of examination papers on the WEB English teaching platform [24]. In order to further improve the efficiency of subjective question marking, KNN algorithm is introduced into the test paper scoring algorithm. The data scored by word matching and text similarity algorithm is used as the training set to train the KNN algorithm. The successfully trained KNN algorithm will be able to evaluate other test papers with high efficiency. The judgment principle of KNN Algorithm in subjective question scoring situation is shown in Fig. 5. For the red circular judgment object in the figure, KNN algorithm will calculate the samples of orange Pentagram and black triangle, that is, the distance between the training sample and the judgment object, take the first k distances with the shortest distance, and then analyze the category of the corresponding K samples. The category with the largest number of samples is considered as the category of the judgment object.

Although KNN algorithm has the advantages of fast operation and no need to retrain when adding new samples, when there is difference in the number of samples or uneven density distribution, it will also lead to great error in the output results [25]. Fig. 6(a) is a schematic diagram of the output error of the algorithm result caused by the error of the sample number. As shown in the figure, when the value of K is large, although the object to be determined is closer to Y, it may still be determined as X, because the number of X is much higher than Y. Fig. 6(b) is a schematic diagram of misjudgment caused by too large difference in sample density. It can be seen

that under this condition, the object to be judged is closer to Y, but the X distribution in a K finger is too dense, resulting in the number of X greater than Y.

In view of this situation, the KNN local weight correction algorithm is used to improve. The principle of the algorithm is to give a lower weight to the samples with too many and too large density compared with other training samples within the range of K value. On the contrary, a higher weight is given to smooth out the error. To describe the correction algorithm, a weight correction parameter needs to be defined, and its expression is shown in equation (10).

$$\left\{ \begin{aligned} \omega(c) &= \frac{\log(\frac{AvgNum}{Num(c)} + \beta)}{\log(\beta + 1)} \\ \beta &= \left\lfloor \frac{MaxNum}{AvgNum} \right\rfloor \end{aligned} \right. \quad (10)$$

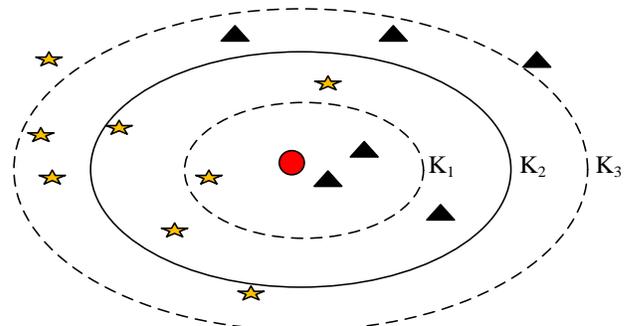

Fig. 5. Principle of KNN algorithm applied to test paper scoring.

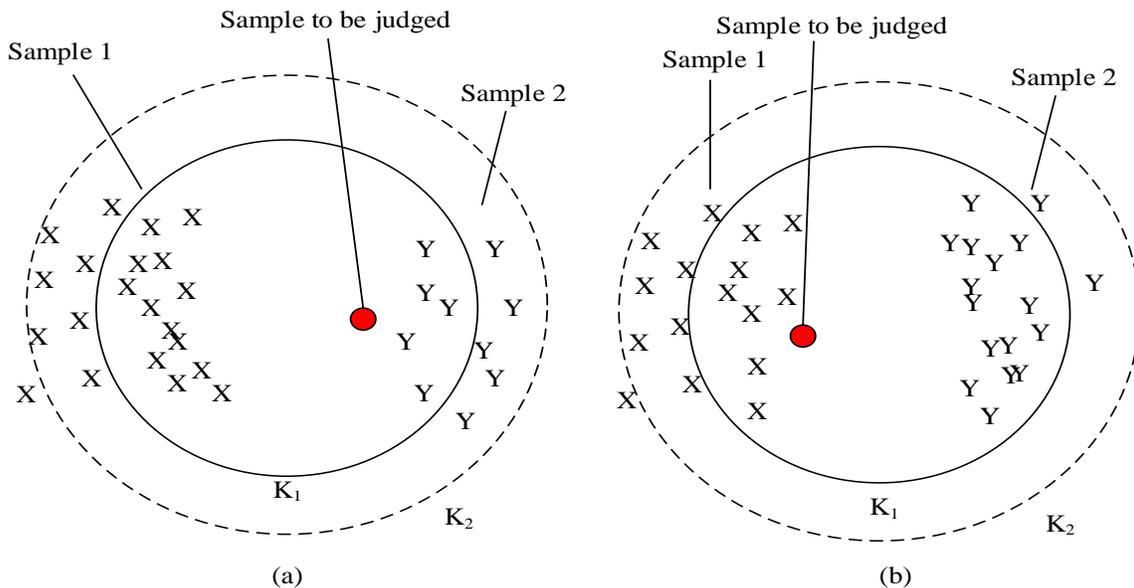

Fig. 6. Misjudgment principle of KNN Algorithm in subjective question scoring.

In equation (10),  $\omega(c)$  is the weight correction parameter of the object category,  $\beta$  is the adjustable parameter,  $MaxNum$  and  $avgNum$  are the maximum number of samples and the average number of samples of each category respectively, and  $Num(c)$  is the number of samples of the object category. The weight correction parameter can give different values according to the number and density of the actual training sets to smooth out this difference. The training samples with large differences in the number of samples can also enable KNN to output correct results. Finally, score one by one based on the weight correction parameters, and the expression of the final score is shown in equation (11).

$$S = \frac{\sum_{i=1}^k \omega(c) \cdot SIM}{k} \quad (11)$$

In equation (11),  $k$  is the nearest number,  $SIM$  represents the text similarity between the student's answer and the nearest sample, and  $S$  is the final score of the student's answer. Due to the existence of weight correction parameters, the weight of each type of sample is no longer unified as 1. Therefore, theoretically, the probability of outputting wrong results due to the difference in the number and density of samples will be greatly reduced.

#### IV PERFORMANCE ANALYSIS OF TEST PAPER SCORING ALGORITHM FOR WEB-BASED ENGLISH TEACHING PLATFORM

The performance analysis of the test paper scoring algorithm of the web network teaching platform mainly includes the judgment ability of the improved KNN algorithm, the differences between the scoring algorithm and manual scoring, and the scoring time. For KNN algorithm, the selection of K value has a great impact on its performance. Therefore, the algorithm is tested under different K values. The results are shown in Fig. 7.

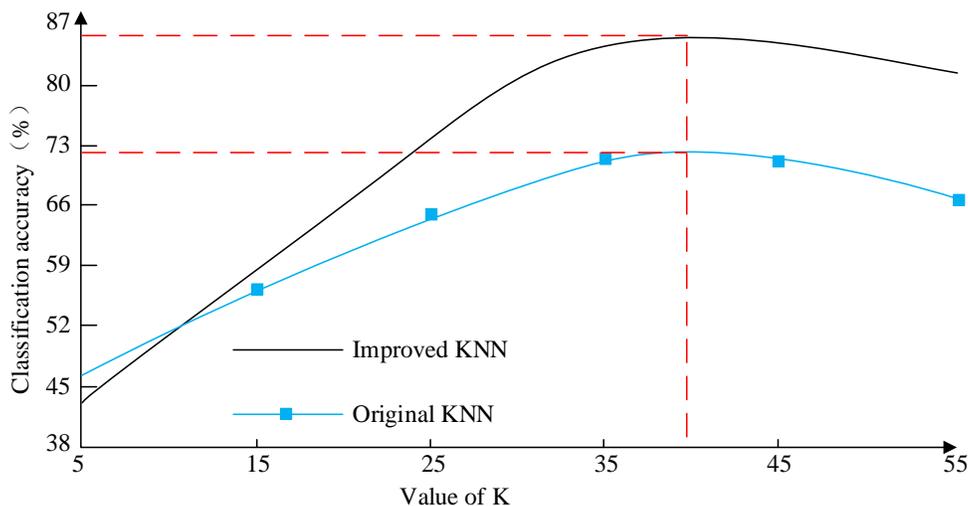

Fig. 7. Algorithm performance under different K values.

When the value of K is 39, the accuracy of both the improved KNN algorithm and the original KNN algorithm reaches the maximum, and then the accuracy of both algorithms begins to decline slowly. However, when K is 39, the accuracy of the improved KNN algorithm is 13% higher than that of the traditional algorithm, which shows that the weight correction parameters can significantly improve the accuracy of the KNN algorithm under the appropriate K value. Therefore, the value of K in this experiment is 39. The experiment was conducted on a WEB teaching platform based on Windows 10, which uses MySQL 5.1 database and Tomcat 6.0.33 server. In the process of correcting the actual test paper, different semantic topics may have an impact on the accuracy of the algorithm. Therefore, the common semantic topic data sets in six English tests are used to test the performance of the algorithm under different semantic topics. The performance is shown in Fig. 8.

Fig. 8(a) shows the test results of algorithm accuracy, Fig. 8(b) shows the test results of recall, and Fig. 8(c) shows the test results of F value. Under different semantic topics, the performance of the improved KNN algorithm and the original KNN algorithm shows obvious fluctuations. The improved KNN algorithm can achieve a recognition accuracy of 100% at most, while the lowest is only 34%. The highest recall rate is 0.90, and the lowest is only 0.50. However, compared with the two algorithms, the accuracy of the improved KNN algorithm is always higher than the original KNN algorithm, and the maximum difference between the two is 0.50. Except for the sixth semantic topic, the recall rate of the improved KNN algorithm is also higher than the original KNN algorithm. The results show that different semantic topics may have a significant impact on the performance of the algorithm. The web-based test paper scoring algorithm is constructed by imitating the mechanism of teacher manpower scoring. Therefore, comparing the scoring results with the teacher manpower scoring results can better evaluate its performance. The comparison results are shown in Fig. 9.

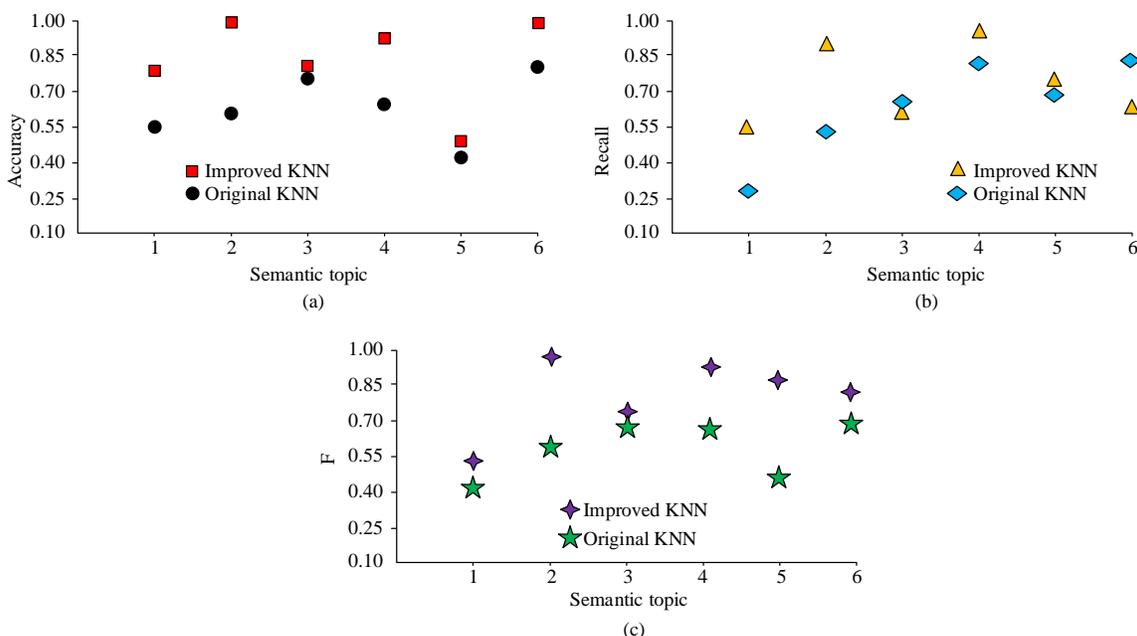

Fig. 8. Performance of the algorithm under different semantic topics.

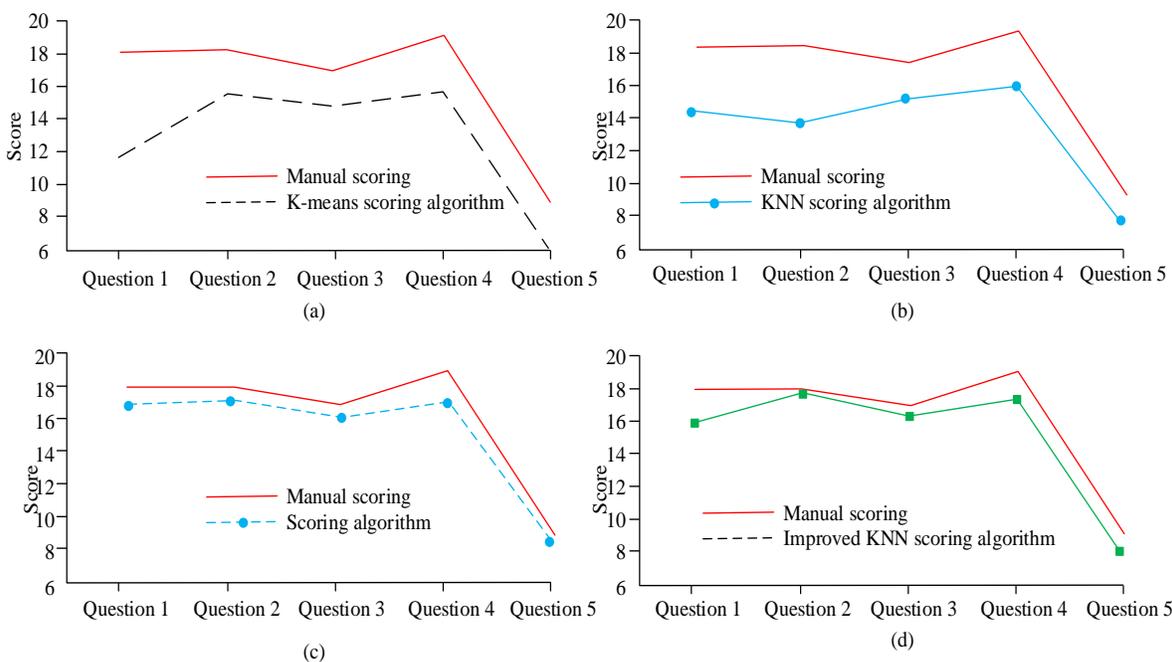

Fig. 9. Comparison of different algorithms and manpower scoring.

Fig. 9(a), Fig. 9(b), Fig. 9(c) and Fig. 9(d) are the comparison results of human scoring and K-means clustering algorithm, original KNN algorithm, test paper scoring algorithm without KNN and improved KNN algorithm respectively. Three machine learning algorithms are trained based on test paper scoring algorithm. It can be seen that the change trend of the scores of the four algorithms is basically consistent with the human scoring, which means that the four algorithms have successfully imitated the mechanism of teachers' human scoring to a certain extent, but the distance

between the broken line of K-means clustering algorithm and the original KNN algorithm and the broken line of human scoring is significantly greater than that of the test paper scoring algorithm and the improved KNN algorithm, which means that the test paper scoring algorithm and the improved KNN algorithm have a better effect on the imitation of human scoring. In order to further study the performance differences of several algorithms, the difference between them and the human score is described with pictures, as shown in Fig. 9.

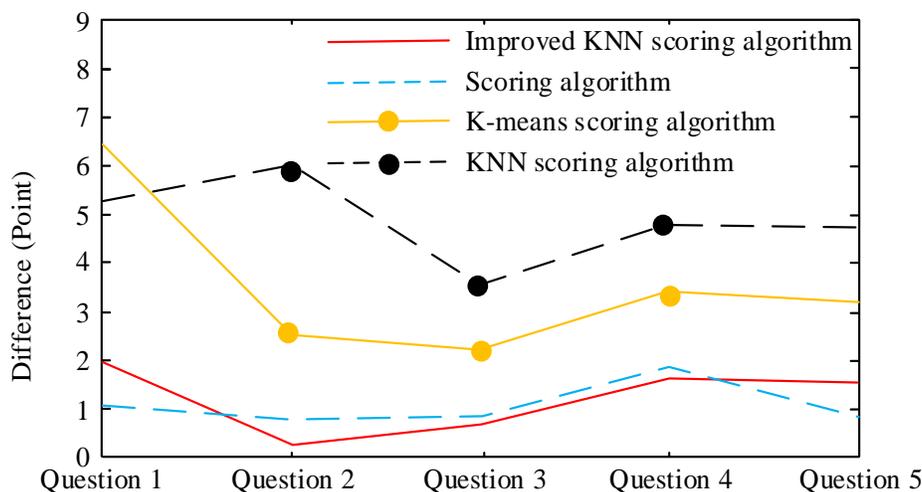

Fig. 10. Difference between different algorithms and manpower scores.

It can be seen from Fig. 10 that the difference between the scoring algorithm and the improved KNN algorithm and the manpower score is very low, ranging from 0 to 2 points, and the difference between the two is also small, less than 1 point. The difference between the other two algorithms is significantly greater, and the difference with the manpower score fluctuates between 2 and 6.5 points, which indicates that the scoring algorithm has a good imitation effect on the manpower score, while the improved KNN algorithm has a good learning effect on the scoring algorithm, and the learning effect of the original KNN and K-means clustering algorithm is inferior to the improved KNN algorithm. In addition to teachers, students often evaluate the fairness and accuracy of the automatic scoring algorithm. With the student feedback system of the Web English teaching platform, we studied and collected the proportion of misjudgments reported by students in multiple test papers through the platform under several scoring algorithms, and evaluated the performance of the algorithm from this angle. The results are shown in Fig. 11.

By comparing several algorithms, it is found that the proportion of students' reported misjudgment under the original KNN algorithm is the highest in each test paper, the highest is 12.5%, and the lowest is 7.8%. The student report misjudgment ratio of the scoring algorithm and the improved KNN algorithm is always lower than that of the original KNN algorithm, of which the highest is 10.8% and the lowest is 7.3%. According to the data statistics of the web platform, the average student report misjudgment ratio of teachers' manual correction is 5.7%. The algorithm is very close to this standard, which means that the evaluation accuracy of the algorithm is also high from the perspective of the evaluated students. Finally, the time consumed by different algorithms for the same test set is studied and counted. Since the original intention of the scoring algorithm is to improve the efficiency of the Web English teaching platform, the algorithm time is an important evaluation item. The results of time-consuming evaluation are shown in Table I.

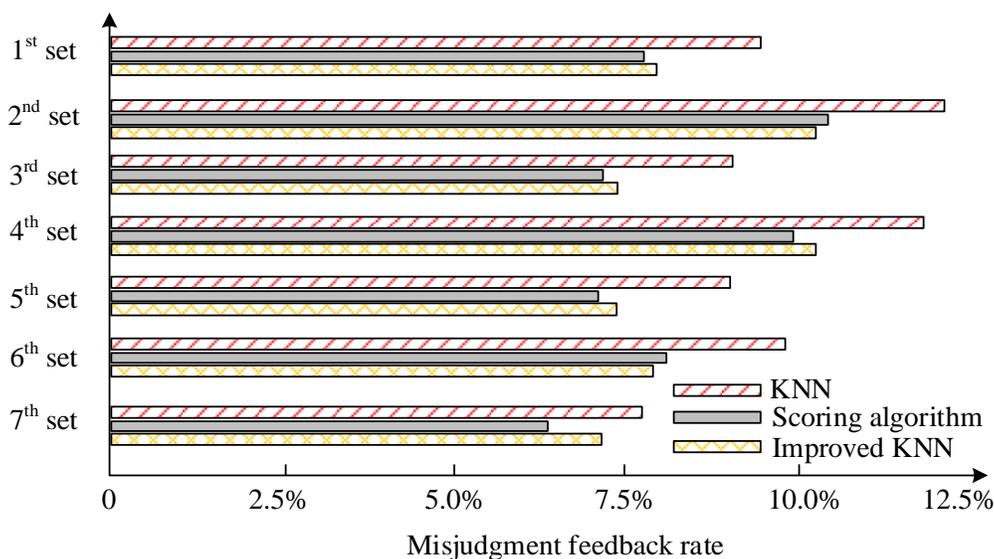

Fig. 11. Proportion of students' report misjudgment under different algorithm.

TABLE I. ALGORITHM TIME-CONSUMING DETECTION

		Scoring algorithm	Improved KNN	KNN
Time consuming (s)	Set 1	177	124	137
	Set 2	130	105	100
	Set 3	212	108	114
	Set 4	97	63	59
	Set 5	133	93	91

Table I describes the time-consuming of scoring three algorithms in five different sets of test papers. The time-consuming of the original KNN algorithm and the improved KNN algorithm is always less than that of the scoring algorithm for each set of test papers. The difference between the time-consuming of the improved KNN algorithm and the scoring algorithm is up to 104 seconds, indicating that the machine learning algorithm is stable in judging speed than the scoring algorithm without machine learning. Comparing the original KNN algorithm with the improved KNN algorithm, it is found that the time-consuming of the two algorithms is relatively close, and they have their own advantages and disadvantages in different test papers, which shows that the improved KNN algorithm is similar to the original KNN Algorithm in terms of calculation speed.

## V DISCUSSION

The English grading algorithm based on KNN and text similarity is constructed. The algorithm is divided into two parts: objective question scoring and subjective question scoring. Due to the inconsistency between students' answers and reference answers, it has been difficult to use automatic algorithms to completely replace teachers' manual scoring in the subjective scoring of English test papers. The algorithm's ability to judge the text similarity of different semantic topics has been tested. The results show that the proposed algorithm can achieve the highest recognition accuracy of 100%, and the highest recall rate is 0.90. Even for the performance of the method itself, the improved KNN structure in the algorithm is obviously superior to the ordinary KNN model. In the test of actual English test paper data, the algorithm is used to compare with the teacher's manual grading. Compared with other similar algorithms, the score given by the proposed algorithm is significantly closer to the score of the teacher's manual score, and the maximum difference between the scores is no more than two points. Further research on the misjudgment rate reported by students, shows that the proposed algorithm has the lowest misjudgment rate, which is the closest to the misjudgment rate of teachers' manual grading. In the current subjective question scoring algorithm applied in the online learning platform, the collected data of false judgment rate is often more than 13%. Therefore, the research believes that the proposed algorithm has higher scoring performance in comparison, and can be applied to the English test paper scoring on the WEB online learning platform.

## VI CONCLUSION

The WEB-based College English course network teaching cooperation platform has broadened the channels of College

English teaching, so that students and teachers can carry out English teaching activities more conveniently and efficiently. In the online examination of the WEB College English teaching platform, the scores of test papers, especially the subjective questions, are often scored by teachers' manpower, which is no different from the efficiency of traditional offline teaching. Therefore, this research designs a test paper scoring algorithm based on the College English teaching platform combined with the improved KNN algorithm. The performance test results show that the algorithm performs well in the similarity between the scores and the scores of teachers' manpower, The lowest score difference between it and the teacher manpower score is only 0.4 points, and the highest is only 2 points. In addition, the algorithm has outstanding performance in the classification accuracy of different semantic topics. The accuracy of some semantic topics reaches 100%, and the accuracy of all semantic topics is higher than the traditional KNN algorithm. In terms of the time-consuming of the algorithm, the minimum time-consuming of the algorithm in the experiment is only 63 seconds, which is significantly faster than the human scoring speed. According to the test results, the algorithm can correct the objective and subjective questions of the online English teaching test paper with the accuracy close to that of human marking. Its application can effectively reduce the workload of teachers and improve efficiency. At the same time, the algorithm has the potential to be applied to other subjects. The imperfection of this study lies in the calculation speed. The improved KNN algorithm is not much different from the traditional algorithm. Therefore, on the basis of this study, how to improve the speed is the next research direction.

# Predictions of Cybersecurity Experts on Future Cyber-Attacks and Related Cybersecurity Measures

Ahmad Mtair AL-Hawamleh  
Department of Electronic Training,  
Institute of Public Administration, Riyadh, Saudi Arabia

**Abstract**—The Internet interconnections' exponential growth has resulted in an increase in cyber-attack occurrences with mostly devastating consequences. Malware is a common tool for performing these attacks in cyberspace. The malefactors would either exploit the present weaknesses or employ the distinctive characteristics of the developing technologies. The cybersecurity community should increase their knowledge on the types and arsenals of cyber-attacks, and security measures against cyber-attacks should be in place as well. Also, advanced and effective malware defense mechanisms should be established. Hence, this study reviews cyber-attack types, measures and security precautions, and professional extrapolations on cyber-attacks future and the associated security measures. Semi-structured interviews were performed, involving five IT managers and nine Cybersecurity Consultants, to obtain the data. The study findings demonstrate prevention as key for data breach risk prevention. Knowledge of common attack methods and the use of cybersecurity software can facilitate individuals and organizations in thwarting hackers and in preserving their data privacy. Two-factor authorization by consumers and new back-end security protocols and security methods, including Artificial intelligence (AI) application, will encumber hacking attempts.

**Keywords**—Cybersecurity; cybercriminals; cyber-attacks; cyber-security techniques; security precautions

## I. INTRODUCTION

The last 20 years have seen the emergence of the Internet as key to global communication, making the Internet today an important part of the life of people globally. Worldwide, [1] reported that there were more than 3 billion internet users, and such number of users has been greatly factored by the ubiquity and low cost of the Internet. Through the immense global network made possible by the Internet, billions of dollars have been generated each year, adding to the global economy [2, 3]. Today, interactions and many other activities of various types are being carried out in cyberspace [3,4], like financial transactions between business parties and casual communication between individuals [5,6]. The cyberspace controls, manages and exploits vital and sensitive infrastructures and systems, but the cyberspace can also be made up of such infrastructures and systems [7].

The cyberspace is where varied aspects of citizens' lives are interconnected, and so, as indicated by [8], the conditions of the cyberspace will directly affect the lives of the citizens [8]. Today, cyberspace has presented new security challenges to governments. As reported by [9], cyber-attacks and their effects have been the subject of concern among analysts since the last decade. Cyber-attacks undeniably lead to damages, physical and/or economic, and there have been cases where the damages were so widespread and severe, as can be exemplified

by virus attacks on stock market of a country, resulting in a crash or a loss of colossal amount of money, or virus attacks on a power plant system leading to a massive explosion loss of lives and properties, just to name a few [10, 11].

The advent of the Internet and the current digital transformation have made cybersecurity a serious matter to experts and all other involved parties. Today, people are increasingly dependent on computer systems, the Internet, and wireless networks (e.g., Bluetooth and WiFi) [12], as can be observed by the increasingly common dependence of people towards smart devices like smartphones and the Internet of Things. In other words, people today are more at risk of being victims to cyber-attacks. Meanwhile, as reported by [13], the discovery of malicious activities on the network has been too common. In general, detection of intrusion has been reactive in nature, and the reaction is only to certain patterns or observed anomalies. However, scholars including [3] and [14] mentioned the need to employ a proactive approach instead, that is, to react to these intrusions before they manage to cause any harm. Somehow, it appears that work and advancement in predictions, measures and security precautions concerning cyber security remain obscure, but, recently, the efforts seem to be gradually gaining momentum [3, 14, 15].

Cyber-attacks are becoming more complex and severe as time passes [16]. Currently, only little is understood pertaining to the different types of cyber-attacks, how these attacks spread, and the current security precautions against them. As such, many organizations/countries have fallen victim to these attacks. Meanwhile, security measure development needs comprehensive understanding of these attacks, and so, a complete listing and classification of cyber-attacks is a crucial element of cyber security initiatives. The present study seeks to describe the different kinds of cyber-attacks, measures and security defenses against them, while also predicting future cyber-attacks. Some security measures are proposed, to facilitate programmers in their development of security devices and mechanisms according to the mode of attack.

## II. RELATED WORKS

### A. Cybersecurity

Cybersecurity entails a bulk of practices, technologies, and processes specifically developed to safeguard the data, networks, programs, and devices of people and enterprises from attacks [3], [14]–[18]. Meanwhile, financial, corporate, government, military, and medical organizations generally gather, process, and store data in substantial amounts on computers and other devices. Some of these gathered data

can be sensitive data like personal data, financial data, and intellectual property, and so, access to such data requires authorization because negative consequences could result when these data are accessed by unauthorized parties [15, 19, 20]. Therefore, for these organizations, cybersecurity is a crucial matter [19]–[22].

In business transactions, sensitive data is transferred to other devices across networks. Appositely, cybersecurity encompasses the discipline for safeguarding the information and the applied systems in its process or storage [23]–[26]. In this regard, firms that are responsible to protect the information on financial records, health, and national security are obliged to take measures to safeguard their sensitive business and personnel information, especially now that cyber-attacks have increased in terms of volume and superiority [23]–[26].

Through a solid cybersecurity strategy, an appropriate security mechanism can be achieved, and this mechanism could effectively deter malicious attacks that generally would attempt to access, modify, erase, extinguish or extort the systems and sensitive data of persons or organizations [27]–[29]. Additionally, cybersecurity could deter attacks that could incapacitate or mess up the operations of a device or system [27]–[29].

### B. Cybercriminals

Cybercrime relates to criminal activity involving a computer, networked device or a network [30]–[34]. In general, cybercrimes are executed by cybercriminals for the purpose of making personal gain [30]–[34]. However, there are cybercrimes performed for the purpose of damaging or disabling computers. There are also those who utilize computers or networks for the purpose of disseminating malware, and also for dispersing prohibited information, images or other materials [30]–[34].

Cybercrime was defined by the Council of Europe Convention on Cybercrime as a vast gamut of malicious activities, and among these activities are unlawful data interception, copyright infringements, and system intrusions, that impair the integrity and availability of the network [35, 36]. The USA is a signatory to this council [35, 36].

The internet connectivity is a common availability today as it is a requirement to various daily undertakings. However, such availability has caused cybercrime activities to thrive as the culprit could commit the crime without having to be physically present [37]. Fraud, money laundering, cyberbullying and cyber stalking are among the examples of commonly committed cybercrimes, and these crimes are further facilitated by the speed and convenience of the internet, and the anonymity and borderless reachability that the Internet is offering [23, 28, 36, 37].

Cybercrimes may be executed by persons or groups with fairly little technical skills. Equally, the crimes may be committed by extremely structured global criminal groups involving skilled developers and other experts. Also, it is common to see cybercriminals operating in countries that have no or weak cybercrime laws so that they could not be easily detected or prosecuted [38, 39].

### C. Cyber Attacks

A cyber-attack is an intentional and malicious effort made by a person or an organization to break the information system of others [40]. The attack is usually economically driven, but there are also attacks that involve data or information stealing, modifying or destruction. In other words, among the goals of attack include to break the system, or to steal, modify or destroy the data or information of others [3, 15, 39, 40].

Cyber-attacks are more and more common these days. Furthermore, the Cisco Annual Cybersecurity Report [41] has relevantly indicated that the advent of network-based ransomware worms has allowed attackers to launch campaigns without the need for human involvement. Also, security events nowadays have become more intricate and more copious [41]. Moreover, businesses today face cyber-attacks on a daily basis; it was mentioned by the then CEO of Cisco (Mr. Chambers) that businesses can be classed into two groups; One comprises those that have been hacked, and the other comprises those that are still unaware of the fact that they have been hacked [42].

Cyber-attacks generally occur in six forms namely: Malware, Phishing, Denial of Service (DoS), Man-in-the-Middle (MitM), Password Spraying, and Cross-site Scripting (XSS) [40]–[49]. Each of these attack types is described as follows:

1) *Malware*: Malware encompasses malicious code or malicious software, and it is essentially a program that is covertly implanted inside a system with the purpose of disrupting the data so that the data would lose their integrity, confidentiality, or accessibility [50]. Malware is regarded as a major external threat to systems as it can affect the systems' operation [40, 43, 50]. Malware can cause widespread damage and disruption, and significant efforts would be required to fix this malware problem. Malware comes in various forms including Trojans, virus, worms, spyware and ransomware [40, 43, 50]. The details are as follows:

- Trojans: This type of malware is also known as Trojan horse, and encompasses a seemingly legitimate and safe file, program, or piece of code (but indeed a malware) [43, 51]. Usually, Trojans are bundled and transported within an authentic software, and are created for spying on or for stealing data from victims. Trojans display themselves as genuine files, and so, victims would be misled to click, open, or install these Trojans (without knowing). Upon installation, many Trojans will download other malware to spy on the victim or cause other types of harm.
- Viruses: Viruses generally will attach themselves to the order of initialization, and these viruses would replicate themselves to infect other codes within the computer system [40, 51, 52]. They also could attach themselves to executable code or link themselves with a file through forming a virus file with a similar name but with an extension [51, 52]. This file is a decoy that transports the virus [40, 51, 52].
- Worms: Worms encompass self-contained programs spreading across networks and computers [43, 51, 53]. Frequently installed via email attachments, worms would dispatch a copy of themselves to all contacts

in the affected computer email list [53]. Usually, worms are used by perpetrators to overload an email server and generate a denial-of-service attack. However, worms don't attack the host like viruses do [40,53].

- **Spyware:** This type of malware entails a program that attackers use to gather information relating to users, their systems or browsing routines, sending the data to a remote user [54]. The obtained information can be used by the attacker to blackmail the user. Also, the attacker could download and install other malicious programs from the web [40, 43, 51, 54].
- **Ransomware:** Ransomware is a very common attack method with the ability to inhibit or restrict the access of users to their system [55]. It also may instruct users to pay a certain amount of ransom using online payment methods [56], which generally would involve the use of virtual currencies like bitcoins, before they could re-access their system or data. Ransomware gets into computer networks; through the use of public-key encryption, ransomware encrypts the files, and this encryption key remains with the server of the cybercriminal [56]. Encryption is used by cyber criminals to detain the data, and the data owner has to pay a certain amount of ransom to get the private key [40, 43, 55, 56].

2) *Phishing:* Phishing is an activity of transmitting deceitful communications through seemingly reputable emails [45,47]. It is common to see these emails demonstrating legitimacy but they actually link the receiver to a malicious script or file [45]. Through this script or file, the attackers could gain access to the device of the victim and gain control over it. Consequently, the attacker could also insert malicious scripts/files, and extract sensitive data like user information, financial data, and so forth [45,46]. Essentially, phishing is done to steal confidential data such as the victim's login information and credit card details.

3) *Denial of service (DoS) and distributed denial-of-service (DDoS):* DOS attacks involve flooding the systems, servers, and/or networks with traffic for the purpose of overloading the resources and bandwidth, resulting in failure of the system in meeting valid requests [48]. DoS attacks can be simultaneously executed by various computers at one specific time and this is called Distributed Denial-of-Service (DDoS) attack [34, 48]. Dealing with DDoS attacks can be very challenging because attackers can come from various IP addresses globally, making it very difficult for network administrators to determine the attack source [30, 48].

4) *Man-in-the-middle (MitM):* Man-in-the-Middle (MitM) attack which is also called eavesdropping attack, involves hijacks by an attacker during a session between a trusted client and network server [47]. During the attack, the attacker's computer switches the IP address of a trusted client while the session is resumed by the server as the server thinks that it is still in communication with the client, not knowing that the client has been replaced with the attacker's computer [36, 47]. As an illustration: a client is in connection with a server when the computer of the attacker gains control over the client. The computer of the attacker then disconnects the client from the

server. This is followed by the replacement of the client's IP address with that of the attacker's computer. The sequence numbers of the client are spoofed. The communication between the network server and the client resumes but the server does not know that it is no longer communicating with the client, but with the attacker's computer instead.

5) *Brute-force and password spraying:* Brute-force attacks generally involve attacks on a single account, whereby the attacker would test various passwords in the attempt of gaining access to an account [44]. This leads to recurrent failed logins [44, 57]. However, in general, modern cybersecurity protocols are able to identify such activity and will lock out an account following several failed login attempts within a short period of time [57].

However, the use of password spraying by attackers can overturn the standard protocols of cybersecurity [58]. Hence, the attacker would try to log on to several user accounts with the use of various passwords that are commonly used. Using a single password on several accounts before using another password on the exact accounts would prevent the standard lockout protocols from being activated. This way, the attacker could continue trying out more and more different passwords on the target account [44, 57, 58].

Owing to the failure of many users in adhering to best practices of password usage, the method of password spraying attacks are often successful. As reported in 2019, recognizable number arrangements like "12345", typical names of females like Jennifer, and the word "password" are among the most commonly used passwords among users [59, 60]. These, and other reported 200 easily guessed passwords have contributed to data breaches [59, 60]. Hence, attackers targeting a reasonably large number of usernames and utilizing a sufficiently large array of common passwords are likely to succeed in gaining access to some accounts [40, 43, 44, 59, 60].

6) *Cross-site scripting (XSS):* Cross-site scripting or XSS refers to a weakness of web security, allowing attackers to compromise the interactions of users with weak applications [49, 61]. The weakness of the user's system allows attackers to evade the exact origin policy that distinguishes websites [62]. The attacker could disguise as the user and perform any actions of the user and access all data of the user. Hence, the attacker may have complete functionality control over the application belonging to the user if the user has privileged access within the application [49, 61].

#### D. Cybersecurity Tools and Techniques

Today, the number of illegal attempts to gain access to private data has increased. These attempts are generally for stealing the data or for forcing users into information blackmailing. Such a situation has increased the importance of cybersecurity [3, 14, 15, 17, 18]. There are various methods being used in achieving cybersecurity. Among them include anti-virus, firewall, authentication, encryption and digital signatures. The details of each are as follows:

- **Anti-Virus:** A computer virus is generally an unwanted short program that prompts undesirable commands without user consent. An antivirus generally performs two tasks [15, 63]. The first task is to prevent the

installation of a virus in a system, and the second task is to scan the system to find out if there are viruses existing in a system [15, 63]. Most viruses are created to attack Windows operating systems because most users prefer to use Windows as their computing platform. However, there are also viruses created to attack Apple and Linux operating systems [63, 64].

- **Firewall:** Firewalls are created to provide an effective deterrent towards hackers' attempts to illegally access a computer upon its connection to the internet or to other network connections [65, 66]. Most operating systems are equipped with a firewall and the firewall is turned on by default. In addition to the default firewall, users could also install commercial firewalls if the default firewall does not provide sufficient protection or if it interferes with the user's legitimate network activities [65, 66].
- **Authentication:** Authentication is regarded as the basic method of cybersecurity. It provides a verification to user identity according to the records saved in the system's security domain [67]. Password technology is the most common security control method, but there are also other methods including SIM cards that are inserted into the cell phone of the user [67]–[69]. A SIM card has unique ID numbers, and during identification of certain cell phones, these numbers are transmitted over a secure communication line. During the process of authentication of a message, there may be eavesdropping attempts made by unauthorized parties, and it may be very difficult to counter these attempts. The transmission of password through an insecure medium may cause the password to be intercepted by fraudulent individuals disguising as the original user. Encryption can be used in dealing with this problem [67]–[69].
- **Encryption:** Encryption makes data incomprehensible and the right key is required to unlock it [70]. Resolving an encryption requires a resolution of intricate mathematical problems (e.g., factoring large primes) which is highly resource and time consuming [70, 71]. In the encoding and decoding of a message, a similar key is used in symmetric encryption, with security level similar to that of the key. Possible security risks are included alongside the key distribution. For asymmetric encryption, the public key is used in message encryption, while the private key is used in message decryption. For key distribution in today's security protocols, most employ asymmetric encryption [71].
- **Digital signatures:** Digital signatures can be formed from similar mathematical algorithms applied in asymmetric encryption [72]. Utilizing some information encoded with it, the user could perform a test to see if the key that he is in possession of, is private. Similar decryption can be obtained by the user through the attainment of a public key that will verify his (user) credentials [72, 73]. In general, this process is identical to that of public key encryption, and it operates based on the assumption that the authorized user is the only party in possession of private key [72, 73].

### III. METHODOLOGY

The study data were obtained by way of semi-structured interviews. The interviews took 45 minutes, and the interviewees comprised five IT managers and nine cybersecurity Consultants. The interviewees were reached through email and they took part in the interviews willingly. They were asked about the types of cyber-attacks and the measures and security precautions to be taken to counter these attacks. The interviewees were also asked to make predictions concerning the future of cyber-attacks and relevant security measures. All interviews would be stripped off of the identifying details. The authors would discuss the extracted data until an agreement was reached.

### IV. FINDINGS AND DISCUSSIONS

The conducted interviews resulted in the understanding of cyber-attacks in terms of types and weapons. Also, the interviews provide the researcher with understanding of the measures and security precautions to counter cyber-attacks. Additionally, the interviewees made predictions concerning the future of cyber-attacks and the associated security measures. Accordingly, all interviews would be stripped off of identifying details. Any disagreements or concerns about the extracted data were discussed among the authors until a consensus was reached.

#### A. Types and Weapons of Cyber Attacks

There is an increasing number of people working from a distance or online since the year 2019 [74]. Consequently, as reported by the FBI, the number of cyber-attacks have increased by fourfold towards online activities [74]. Also, studies have shown an increase in the impact of successful cyber-attacks on organizations and their users each year [57, 74, 75].

As reported, about 197 million records became exposed in 2017 because of data breaches, and the number of exposed records rose to 37 billion in 2020 albeit the decrease in the overall number of data breaches [76, 77]. In countries such as the USA, IBM reported that organizations have to incur increasing cost when facing these attacks. As reported, the average cost of a data breach has risen to \$8.64M in 2020 from \$7.91M in 2018 [76, 77].

A lot of times, the success of cybercriminals in breaching organizations, also depending on the methods used, is facilitated or made possible by human error [3, 15, 17, 18]. For instance, the use of phishing may not be successful if the target victim did not click on the link provided. Also, some types of cyber-attacks exploit the gaps in user's efforts in data security, allowing these cybercriminals to gain access to sensitive data [3, 15, 17, 18].

In the interviews, the participants were asked on the types and weapons of cyber-attacks. One participant stated the following:

*“Up to now, we are still facing some of the most common cyber-attacks, for example, Password Spraying Attacks, Ransomware, Denial of Service, and Malware Attacks too. Fortunately, there was no serious damage because we had been prepared – we invested a lot to build strategies against cyber-attacks. Still, we are not saying that we were unharmed at*

all. The damage was there, of course. As precautions, we are consistent with our Advanced Persistent Threats (APT) audits. Also, we would always check our risky points.”

Concerning the topic of ransomware, another interview participant stated the following:

*“It appears that ransomware is not just a security incident. It has changed. Also, it is obvious that the present-day cybercriminals want to breach our data, and for that, they are teaming up with organized cybercrime groups to steal the data. Then, they encrypt on corporate servers. As a company, our focus is to regain our data. At the same time, we worry about which public is sharing the data. Cybercriminals use ransomware when they are under extreme pressure, and their targeted victim could be any party – individual, company, or government.”*

The interviewees were asked about Phishing techniques. The response of one interviewee is as follows:

*“Phishing techniques involve emailing – the attacker would email thousands of deceitful messages to target victims. For instance, the victims would receive an email on receiving a handsome amount of money. Out of thousands of emails sent, certain fractions of target victims would fall for the scam. To increase the success rate, the attackers would use certain techniques, like mimicking the actual emails from a spoofed organization. For instance, PayPal. So, they would use similar phrasing, typefaces, logos, and signatures as PayPal’s. So, the messages will look legitimate that the victim is less aware that they are being scammed or attacked.”*

One more interviewee offered an opinion regarding phishing, by stating the following: *“It is an increasingly common cyber threat today. As you can see, it is common to receive emails from what seems like a reputable source when it is really not the case. These criminals - they just want to steal sensitive data like your login and credit card information. They also want to install malware on your computer.”*

The interviewees were asked on the subject of Distributed Denial of Service techniques used by cybercriminals. An interviewee responded by saying:

*“Usually, a DDoS attack is done by a group of malware-infected host machines. The attacker controls these machines. We call these attacks the Distributed Denial of Service. This is because the attacks prevent the affected site from providing the user with the service it is supposed to provide, and therefore, the user cannot gain access to the site. The attack causes the victimized site to become flooded with illegal requests, and since the site has to answer to each request, its resources become all used up that it cannot serve users. A shutdown may happen to the site.”*

Research has confirmed that the attacks are essentially actions aimed at impairing a system or disturbing the normal operations of a system through the exploitation of the system’s weaknesses through the use of different techniques and tools. Attacks are performed by attackers for different reasons like for gaining certain rewards or simply for personal satisfaction. The most commonly performed cyber-attacks on organizations today include Phishing, Password Spraying, Malware, Ransomware, Man-in-the-Middle (MitM), Denial of Service (DoS), and Cross-site Scripting (XSS).

## B. Measures and Security Precautions against Cyber Attacks

Individuals and businesses could benefit from the use of cybersecurity measures as it could provide basic protection to both individuals and businesses from the most common cybersecurity risks. The tools and processes of cybersecurity measures are rather easy to follow. They include usage of strong passwords, a firewall, control of access, security software, intrusion monitoring, and increased awareness.

Most global data breaches (86%) are financially driven [78]. It is thus highly crucial for both individuals and businesses to be proactive in preserving their cybersecurity, considering that a cyber-attack can cost the company millions of dollars [78].

In order that their business data, cash flow and customers are safe online, businesses should employ various types of cybersecurity measures, so that risks from various sources could be averted. Among these sources include internet attacks, user faults, system or software defects and weaknesses, and subvert system or software features [79].

The interview participants were asked concerning their applied measures and security precautions in countering cyber-attacks. According to one of the participants:

*“My organization uses two types of security measures and precautions – the traditional ones and the modern ones. The traditional ones include the common methods like IPS and IDS antivirus. They are used in different platforms. For modern measures, my organization uses anti-malware, DLP solutions and sandbox solutions.”*

On the same question, another interview participant responded by stating the following:

*“In our organization, the main focus is to standardize and adapt all the used measures. The human factor is important as well. We believe that in modern cybersecurity measures, human capital is the most vital element. That is why our organization regularly trains the employees on how to avoid recurrent cyber-attacks.”*

The third participant offered his viewpoint as well. He said:

*“I think that training programs are useful when you want to increase the awareness of personnel towards cybersecurity risks and cyber-attacks. Also, my organization is using security software and programs from different companies. This is to reduce the risks of cyber-attacks. For example, the antivirus and firewall software that my organization is using, was created by different companies. We feel that the risks and threats of cyber-attacks can be reduced this way.”*

For individuals, among the tips that they can follow in preserving their cybersecurity include creating a unique password for each account that they have and updating the password every three months, aside from constantly updating their software to prevent software flaws and to keep their software up to date. According to one participant:

*“It is important that social media users make their account private. Also, they should not reveal their sensitive information in their posts. In fact, I think that social media users need to have knowledge about how to properly use the internet.”*

For protecting business data, among the tips for organizations to follow include the use of secure hardware, data backup and encryption, cybersecurity insurance, security-focused culture, and strong cybersecurity software. One participant accordingly reacted to these tips by saying: *“These steps will help in decreasing the risk and the business can operate in a smooth manner.”*

Prevention is key to reducing the risk of a data breach. Through the use of cybersecurity software, and through having the knowledge of the common attack methods, both individuals and organizations could preserve the privacy of their data and inhibit hackers.

### C. The Future of Cyber Attacks and Related Security Measures

In today’s technology, cybersecurity is an integral element, amounting to approximately \$250 billion in market value [80]. Like the general tech industry, there is a market for cybersecurity in nearly all industries, especially now that the amount of company information being stored online is increasing, and so is the demand for cybersecurity solutions to assure its security.

Leaks and hacks on a large scale have occurred in the last several years, and they have cost companies their customer’s information and also their reputation [76]. For consumers, such occurrences have impaired their sense of safety and their security, and it could even disrupt their lives. Hackers seek leaked information as such information allows them to steal money and sensitive information from people.

In order to get access to lists of user accounts, hackers will go to major websites. However, hackers may face hurdles in their attempts to steal personal information of users from those sites. As stated by one participant of the interview:

*“Our prediction is that cyber-criminals will learn new and innovative ways to attack people, their homes and devices, in their efforts of finding a path to your trustworthy corporate network.”*

Then, another participant added to the discussion by stating: *“Two-factor authorization is now commonly practiced by consumers. There are also new back-end security protocols and security methods. AI is one good example, and I am confident that AI has the ability to disable hacking attempts. Still, we should not say that everything is secure because we all know that hackers will keep finding ways around security structures. Hence, cybersecurity professionals must always be one step ahead.”*

In discussing the topic of Ransomware, a participant said: *“Criminals have been making good profit through Ransomware these past several years. They would block users from using their computers and networks using some malicious software. These users are forced to pay large amounts of money or ransom to these criminals to regain their computer or network use. Unfortunately, we can expect that ransomware attacks will increase.”*

It has been reported that the damages caused by ransomware had amounted to USD \$11.5 billion in 2019 and the amount was expected to increase to USD \$20 billion by 2022 [81].

On phishing attacks, a participant reacted by saying: *“Phishing attacks are increasing and it is increasingly more difficult to detect them. A good example is the MailChimp phishing campaign case. Hackers made use of affected accounts in MailChimp to distribute malicious emails with malware, and considering that MailChimp is a trusted and well-established email marketing provider, the emails were likely to bypass the spam filters and enter the inbox of the unwary receiver.”*

Some experts agreed with the prediction that cybercrimes would cause financial damages amounting to \$6 trillion by the end of 2022 [82]–[84]. Also, a cyber-attack would be expected to occur in every 11 seconds, as compared to one attack in every 19 seconds reported in 2019. Comparatively, in 2016, one cyber-attack occurred every 40 seconds [82]–[84].

The COVID 19 outbreak has forced many to work remotely. On this matter, a participant stated the following:

*“COVID 19 has sped up the digital transformation of organizations and many employees have shifted to working from home. The problem with this situation is that, when working from home or remotely, employees are not safeguarded by corporate firewalls. Hackers could exploit the vulnerabilities that they discover in the gaps between people, their devices, and the corporate network. We can see that many employees are required to establish workloads in Cloud, and so, cloud-based security techniques are crucial in curbing the failing cybersecurity landscape. It is now necessary to work with cloud-native Identity and Access Management (IAM).”*

As stated by another participant: *“For those who maintain cloud-based security, they have to have adequate ability in managing the infrastructure with the use of structured programs. We know that networks and application tiers are short-lived, and so, for any organization, their most crucial asset is probably their own data and the data of their customers. Therefore, I think that data-security on the cloud will be a main theme in the future.”*

One participant viewed: *“cybersecurity as a highly viable career path.”* In fact, it was predicted that the number of vacant cybersecurity jobs would increase by 35%, considering the increase in cyber-attacks and the shifts in tactics used by cybercriminals [85, 86]. In other words, cybersecurity is likely to become a sound career choice in the long run.

In terms of AI application, all interviewees agreed that it can effectively improve the security of cyberspace. Also, the options of AI systems should be fully used so that the most optimal level of cybersecurity could be achieved. One participant indicated that: *“the use of AI can allow the discovery of new and refined transformations in attack flexibility.”* Notably, the old technology concentrates on the past and is mostly focusing on identified attackers and attacks. This can lead to the formation of blind spots in the detection of uncommon behavior in new attacks. For instance, privileged activity in an intranet can be monitored, and any discernible alteration in privileged access operations can signify a likely internal threat. For successful detection, the machine will strengthen the validity of the actions and increase its sensitivity for the detection of equivalent patterns in the future.

According to one participant: *“AI facilitates machine*

learning. It also helps the machine in detecting irregularities more effectively, and also in increasing the accurateness of operations. AI is particularly useful in dealing with more sophisticated cyber-attacks because the approaches used by hackers are increasingly more innovative these days.”

One participant indicated that: “the use of AI can increase network security, particularly through the ability of AI in detecting attacks and in responding to breaches.” For security groups, they could be overwhelmed by the amount of security alerts that they receive on a daily basis. Hence, the automatic detection and response towards threats can decrease their workload significantly. Also, they could more effectively detect the threats with the use of AI.

The formation and transmission of colossal amounts of security data on a daily basis would gradually impair the ability of security experts in quickly and reliably tracking and identifying the attack factors [87]. With the use of AI, the monitoring and detection of doubtful behavior could be expanded. This allows the network security personnel to effectively and promptly react to new situations.

The majority of participants agreed with the fact that in improving its response to threats, AI security systems have the ability to learn over time. Utilizing AI will facilitate the detection of threats following the application behavior and the entire network activity. The AI security system studies the standard network traffic and behavior, and over time, AI creates a reference point on what constitutes a normal pattern, and any divergences from the norm can be identified to determine attacks.

Considering the viewpoints of the participants in the interviews, it is clear that cybersecurity experts have to be consistently ahead of the cybercriminals. Also, the use of AI techniques can effectively improve cyberspace security. The options of AI systems should be fully utilized in order to achieve the most optimal level of cybersecurity. Lastly, remote working requirements owing to the COVID 19 outbreak have resulted in the value of cloud-based security techniques in protecting and improving the cybersecurity landscape.

## V. CONCLUSION AND FUTURE WORK

This paper reviews the topic of cyber-attacks focusing on the types and weapons of cyber-attacks, measures and security precautions against cyber-attacks, and the projections of experts on the future of cyber-attacks and the associated security measures.

Interviews were carried with several study participants, delving into the subjects of cybersecurity and cyber-attacks. The information obtained from the participants shows dramatic development of information technology within the past several years. It was found that albeit the presence of precautionary tools, cyber attackers are still successful in breaking the fire-wall systems, resulting in physical and non-physical damages. Victims of cyber-attacks, especially firms, could lose their reputation as well. Notably, cyber-attack risks and threats appear to increase in tandem with information technology development.

Taking into consideration the present situation of data breaches, ransomware attacks, in addition to the concerns

towards the impact of new technologies like AI, and the constantly evolving threats; it is a critical duty of cybersecurity experts to consistently provide the most updated best practices and tools of cybersecurity so that users could consistently avert cyber threats. Equally, employee awareness and expertise on cybersecurity issues need to be encouraged and cultivated via continuous training programs.

Further, scientific research should focus more on security adjustments and measures required by different business sectors and corporations towards remote work that tends to become a necessity today; especially with the spread of Corona pandemic. More focus on individual safety characteristics such as awareness, attitude, behavior and compliance is called for, and research is required to quantify these primary quality indicators. Based on past findings, the human factor appears the key to the progress of information security, but has not been adequately explored.

**Abstract**—Databases are commonly used to store complex and distinct information. With the advancement of the database system, non-relational databases have been used to store a vast amount of data as traditional databases are not sufficient for making queries on a wide range of massive data. However, storing data in a database is always challenging for non-expert users. We propose a conversion technique that enables non-expert users to access and filter data as close to human language as possible from the NoSQL database. Researchers have already explored a variety of technologies in order to develop more precise conversion procedures. This paper proposed a generic NoSQL query conversion learning method to generate a Non-Structured Query Language from natural language. The proposed system includes natural language processing-based text preprocessing and the Levenshtein distance algorithm to extract the collection and attributes if there were any spelling errors. The analysis of the result shows that our suggested approach is more efficient and accurate than other state-of-the-art methods in terms of bilingual understudy scoring with the WikiSQL dataset. Additionally, the proposed method outperforms the existing approaches because our method utilizes a bidirectional encoder representation from a transformer multi-text classifier. The classifier process extracts database operations that might increase the accuracy. The model achieves state-of-the-art performance on WikiSQL, obtaining 88.76% average accuracy.

**Keywords**—Natural language processing; NoSQL query; BERT model; Levenshtein distance algorithm; artificial neural network

## I. INTRODUCTION

In today's digital age, non-relational databases are utilized in almost every industry to store information. Non-Structured Query Language (NoSQL) databases [1], [2] are increasingly being used for large-scale data sets, search engines, and real-time web applications [3]. Nowadays, NoSQL databases work as an alternative to relational databases [4] and other conventional databases [5].

With the growth of technology, NoSQL databases stores a large amount of data in document stores, key-value data stores, wide-column stores, and Graph stores. As opposed to relational databases, MongoDB, CouchDB, Cassandra, etc are designed on the architecture of distributed systems to store massive data [6]. Many organizations are gradually looking into approaches to understand and analyze this enormous unstructured data. The current approaches to data management, organization, and storage are being changed by "Big Data" [7]. In particular, "Big Data," an open source framework used to store vast amounts of structured, unstructured, and semi-structured data [8]. So, Normal users require knowledge of the query syntax and table schema to access and store a large amount of data. However, finding a reliable approach to generate the NoSQL

query from Natural Language (English) is challenging. Using NoSQL approach, amateur users can interact with the database system. The model facilitates communication between humans and computers without recalling the query syntax method for the non-relational databases. Natural Language Processing (NLP) [9], [10], [11] is a branch of linguistics, information engineering, computer science, and artificial intelligence that studies how computers and humans interact with Natural Language [12]. Traditional machine translation is applied to translate the text from one language to another by NLP [13].

This research aims to develop a feasible tool for searching databases where natural language can be used without needing complex database queries that are developed by expertise. Generating NoSQL from natural language has wide range of applications. Tools with AI knowledge [14] such as Google Assistant or Alexa use the NLIDB system for non-technical users. Filling out a lengthy online form can be tedious and users might need to navigate through the screen, scroll, look up values in the scroll box, and so on whereas with NLIDB, the users need to type a question similar to a sentence. Consequently, such a tool has a wide range of usage and applications. NoSQL approach has been researched both in academia as well as in industry [15]. In this paper, we implement a Neural Machine translation model which consists of four steps. First, we have used a Natural Language Tool-Kit for performing text preprocessing. Secondly, attributes are collected and extracted using Levenshtein Distance (LD) [16], [17] algorithm. Thirdly, we have used a bidirectional encoder representations from BERT Transformers Model-based multi-text classification [18] to extract the operations including find, insert, update and remove. The last step of the proposed approach is generating query.

Many research works have used WIKISQL dataset for conversation Natural Language to Structured Query Language. The BERT Model generates the NoSQL operational command from the WIKISQL task. The contribution of this research paper can be summarized as follows:

- Designing several algorithms to come up with a standard machine translation model for converting Natural Language into NoSQL queries.
- To resolve the syntax errors for primitive users using Levenshtein Distance algorithm that can extract the collection and attributes from the text even if any users make spelling mistakes or utilize synonyms.
- To employ the latest contextual word representation BERT transformer model to extract the operations with a higher accuracy rate.

The remainder of the paper is organized as follows: Related works conducting with the same and different technologies by other researchers are illustrates in Section II. Section III describes the proposed methodology and work flow. Section IV shows experiment evaluation and result of the proposed system. Conclusions with the future expansion are detailed in Section V.

## II. RELATED WORK

Research in Natural Language for non-relational databases has started as far back as the twenty century. Since the interest in Natural Language Processing has continued tremendously. In the early 1970's LUNAR [19], the first Natural Language Interface for the relational database (NLIDB) has introduced to the researcher. LUNAR was a Question Answering (QA) system connected with the moon rock sample database. The information of rock samples brought back from the moon was used to make the LUNAR database. NLP to NoSQL query conversion field has very little research on it. This section discusses various works on Natural Language to query conversion.

In 2021, Minhazul et al. [20] suggested a machine learning-based NLP2SQL translation system. They used the Naive Bayes algorithm for command extraction and decision tree regression for condition extraction. Their proposed method lack accuracy because of using the bag of words technique in the derivation of condition from SQL. An advance deep learning solution can mitigate this problem. On the other hand, they can use the neural translation technique for this machine translation approach. The system can use the statistical translation method also.

Mallikarjun et al. [21] proposed an automated NLP-based text processing approach. Their approach can successfully convert an excel datasheet into a DBMS. Their system has a user authentication system that prevents unwanted users. The system has a limitation of 16,384 columns and 1,048,576 rows for an excel worksheet. This data may be massive for average purposes but not enough for big data.

An Intelligent processing system in a document-based NoSQL database had proposed by Benymol et al. [22] in 2021. They used state-of-the-art algorithms and technologies to convert text into NoSQL. They used different types of TF-IDF schemes for information retrieval, machine learning algorithm for modeling, and hyper parameter tuning for model selection. The system may have vulnerability in stream and batch data on the Big Data processing platform. The proposed model also has a problem with dynamic processing strategies. In this stage, the system fails to find any possible solution.

Fatma et al. [23] proposed an automatic UML/OCL model for the NoSQL database converter. Their system mainly focuses on the big data platform. Because there is wide use of NoSQL database in the big data platform. After creating the NoSQL database, the system automatically checks the OCL constraints of the model. There are different types of NoSQL databases and a maximum of them have a problem with integrity constraint checking. For this, it is the most challenging task in the system.

In [24] M. T. Majeed et al. have designed a fully automated framework that, using an AI technique, can recognize

keywords, symbols, attributes, values, and relationships among various types of queries. Additionally, they proposed a graphical user interface where users could enter NL queries and have a NoSQL query created from those queries. For complex queries, the proposed framework didn't offer a solution.

S. Mondal et al. [25] introduced a query-response model that can respond to a variety of queries, including assertive, interrogative, imperative, compound, and complicated forms. This NoSQL system's primary task is to retrieve knowledge data from the default MongoDB database. This paper didn't give any solution of time-related query such as "What is the age of x after 10 years".

T. Pradeep et al. [26] presented a Deep Learning based approach that converts English questions to MongoDB queries. They applied an encoder-Decoder machine-translation method for this conversion. The encoder turns the NLQ text input into a vector and sends it to the decoder. The decoder uses a deep neural network to predict NoSQL queries. Their system uses ten different deep learning models to handle ten types of MongoDB queries. One solution is the best possible answer for this problem.

Sebastian Blank et al. [27] suggested an end-to-end Question Answering (QA) system. It allows a user to ask a question in natural language on the Elasticsearch database. They solve the homogeneous operation problem of the database by using policy-based reinforcement learning. For that, they used Facebook's bAbI Movie Dialog dataset. They also design a KBQueryBot, an agent of translating a natural language query into the domain-specific query language based on a sequence-to-sequence model [28]. It gives every single answer with the help of an external knowledge base.

Some classic NLIDB systems can solve the spelling corrections of misspelled words automatically [29]. The module gives the interface between computer and user by the database query language. Consequently, they discuss the overall system architecture of the NLIDB, some implementation details, and experimental results. The proposed work only focuses on automatic spelling and grammar correction.

Z. Farooqui et al. [30] recommended the conversion of English to SQL. For example, their system converts English questions or text queries into SQL queries. Later it will be operated on databases. Their suggested technique and method are generic and smooth. It can handle both small and large applications for generic NLIDB systems. There are four types of input NLQ text Normal, Linear Disjoint, Linear Coincident, and Non-Linear Model. It focuses on simple SQL query clauses such as SELECT, FROM, WHERE, and JOIN. Their system can handle complex queries resulting from ambiguous NL queries.

Tanzim Mahmud et al. [31] proposed a system based on Context-Free-Grammar (CFG). Any input token of appropriate terminals found in the input NLQ will replace the corresponding attribute in the relational table or applicable operators of SQL. The interface can configure easily and automatically by the user. It relies on the Metadata set and Semantic sets for tables and attributes. It can handle ambiguities in the input NLQ. For example, the system can solve the same attribute name clashing problem within a table. The limitation of the

proposed CFG system can only convert limited queries. Other than that, the system is dependent on a specific language.

Xiaojun Xu et al. proposed SQLNet [32], an NLP to SQL conversion approach which is order-independent and alternative to the traditional sketch based program synthesis approaches [33]. Failing an order input NLQ text is not a problem in that case. It uses a sequence-to-set model, which is a column attention mechanism that generates SQL queries. It represents pseudo-tasks with the help of a function of relevance and works on the WikiSQL task.

Victor Zhong et al. [34] thought about the availability of the query ground truth (intermediate labels) and database response. They proposed Seq2SQL, a modular approach that translates NLQ into SQL queries. Their suggested system also generalizes across different table schemas. There are three modules in Seq2SQL. The first module tries to identify an aggregator function like MIN() or MAX(). The second module extracts column names from NLQ and uses them as a select operator. Both modules worked on question-answer pairs. The third module extracts condition or where-clause from NLQ. There is a possibility to swap between arguments in the WHERE clause. This ambiguity problem could solve by policy-based reinforcement learning [35] in question-answer pairs.

### III. PROPOSED METHODOLOGY

The main concept behind this method is to transform Natural Language (NL) into Non-Structured Query Language (NSQL) using Natural Language Tool Kit (NLTK) and Deep Learning Model. The concept and its description are formalized in the following sections. The proposed architecture is shown in Fig. 1.

#### A. Input Natural Language Query (NLQ)

NLQ consists of only the normal terms of user's language, without any special format or syntax. Natural language query (NLQ) in English is given as input. This input text will be processed for getting information and later converted into NoSQL queries.

1) *Text preprocessing*: Since the inventory of individual words, text can take many forms, ranging from sentences to many paragraphs with special letters. In NLP the text preprocessing is an important task and the first step in the preprocessing to building a model. It is a data mining technique that transforms plain text into a machine-readable format. Real-world data is frequently inadequate, inconsistent, or deficient in specific behaviors and is likely to contain various errors. This step is needed for transferring input text from human language to machine-readable format for further processing.

In this paper, we have used NLTK for text preprocessing. The NLTK is the most widely used and well-known of the NLP libraries in the Python ecosystem. It is used for all sorts of tasks from lowercase conversion to tokenization, removing escape words, part of speech tagging, and beyond. Input text will be processed for getting information from Natural language Query input. From the processed text, the system will extract collection, attribute, and operation for making a NoSQL query.

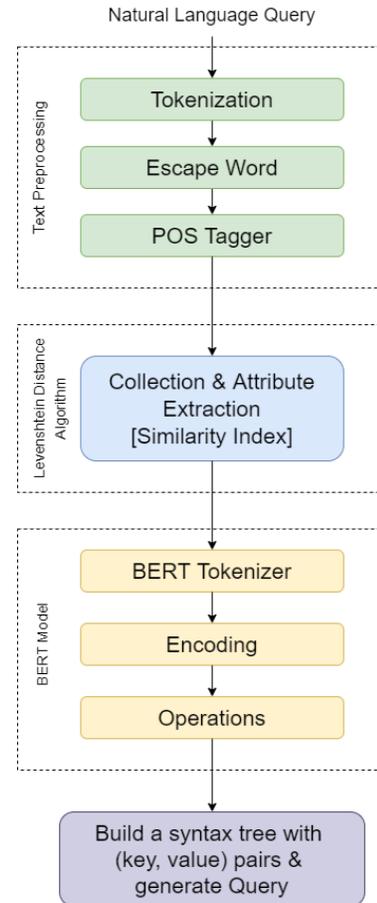

Fig. 1. Proposed methodology

2) *Lowercase conversion*: Lowercase conversion is the first step of text preprocessing. In this step, the input NLQ is converted into a lower case format. Although the uppercase or lowercase forms of words are supposed to have no difference, all the uppercase characters usually changed into lowercase forms before the classification.

3) *Tokenization*: Tokenization splits the natural language query, phrase, string, or entire text document into smaller units such as individual words or tokens. The former Sentence Boundary Disambiguation (SBD) is often used to form a list of individual sentences. It depends on a pre-trained, language-specific algorithm similar to the Punkt Models from NLTK. The text divides into a list of words using an unsupervised algorithm to form a model for abbreviated words. For the English language, a pre-trained Punkt tokenizer includes in the NLTK data package.

4) *Removing escape words*: Escape or extra words are the words that are frequently appeared within the text without having more information or content. So, the escape words are removed because they are not needed in the analysis of the query. For the purpose of building queries, several sets of escape words have been developed. In this paper, we proposed a new set of escape words. Auxiliary verbs and prepositions are mainly used in this context as escape words such as 'a', 'an', 'the', 'is', 'of', 'with', 'to', 'for', 'and', 'all', etc.

TABLE I. ESCAPE WORDS

Escape Words	With Escape Words	Without Escape Words
all, the	Find all the students	Find students
is, the, of, all	What is the name of all student?	What name student
the, and	Insert the student name x and age 20	Insert student name x age 20

Beside Table I, this step eliminates punctuation from the input natural query. The detailed process of eliminating escape words is illustrated in Algorithm 1.

**Algorithm 1: Removing Extra Words**

**Input:** I = Input words and; E = List of Extra Words  
**Output:** L: List of words after removing extra words  
 $c_w = \text{CountWord}(I)$   
**for**  $c_w \in C_W$  **do**  
     $I = I[c]$  **TOKENS** = Tokenization(I)  
    **for**  $l \in \text{TOKENS}$  **do**  
        **TOKEN** = EMPTY  
        **if**  $l \notin E$  **then**  
            |  $\text{PUSH}(\text{TOKEN}, t)$   
        **end**  
    **end**

**end**  
**return** L

Removing escape words is a simple but essential aspect of many text mining applications cause it reduces memory overhead. It can reduce noise and false positives. This method can potentially improve the power of prediction in any text mining application.

5) *Parts of Speech (PoS) tagger:* PoS tagging helps in text-to-speech conversion, information retrieval, and word sense disambiguation. It's used for the classification of words in their PoSs and labeling them according to the tagset. The collection of tags used for PoS tagging is tagset. PoS tagging is also referred to as word classes or lexical categories. However, all PoS tags aren't necessary to analyze. All PoS tagging attributes are provided by the NLTK toolkit. The PoSs must be defined as the following:

- Noun Tags = ['NN', 'NNS', 'NNP', 'NNPS']
- Adjective Tags = ['JJ', 'JJS', 'JJR']
- Verb Tags = ['VB', 'VBP', 'VBD', 'VBG', 'VBZ']
- Adverb Tags = ['RB', 'RBR', 'RBS']

Adverb and adjective tags do not have much significance in generating NoSQL queries. Only noun and verb tags are considered for the next steps of PoS tagging. Because verb & noun tags may indicate command and attributes or table name respectively. Algorithm 2 illustrates the process.

**B. Collection and Attribute Extraction**

Levenshtein distance (LD) algorithm is used in a specific solution to extract collections and attributes from natural

**Algorithm 2: Keeping Necessary Tags**

**Input:** W = All the words after removing stop words;  
**Output:** T = Necessary Tag's with appropriate word  
 $c = \text{CountWord}(W)$   
**for**  $c \in C$  **do**  
     $w = W[c]$  **TAGS** = Tagging(w)  
    **for**  $t \in \text{TAGS}$  **do**  
        **TAG** = EMPTY  
        **if**  $t \in \text{VERB}$  **then**  
            |  $\text{PUSH}(\text{TAG}, t)$   
        **end**  
        **if**  $t \in \text{NOUN}$  **then**  
            |  $\text{PUSH}(\text{TAG}, t)$   
        **end**  
    **end**  
     $\text{PUSH}(T, \text{TAG})$   
**end**  
**return** T

language queries. The approach starts by counting how many words in the list are similar to one another. Afterward, it compares every single similar word with every attribute from the WordNet by the LD and synonym list plays a crucial role in extracting attribute and collection names. This method keeps a list of words that are synonyms for each noun tag. Using WordNet, a list of noun tag synonyms is generated. The aim of making a synonym list is to find a specific collection and attribute from an input query. Every user formulates their query in a different way. They also use different words to describe the attribute or collection names. So, this approach checks synonyms of the words from the user query in the WordNet library. we give some analogies in Table II:

TABLE II. ANALOGY BETWEEN TEXT AND INTRUSION DETECTION WHEN APPLYING THE LD ALGORITHM

Text	Intrusion Detection
Find the name of all <b>student</b>	Collection( <b>all_student</b> )
What is the <b>accommodation</b> of student id 01	Attribute( <b>address</b> )
Find the <b>Fastname</b> of the students	Attribute( <b>name</b> )

In this paper, the LD algorithm works as a threshold. Sentence word is compared with the collection name if the value is greater than the threshold then it saves the collection and attributes with the appropriate name in a list. Finally, this approach gives an output figure of the match collection and attribute. The designed algorithm for collection and attribute extraction is described in Algorithm 3

Levenshtein Distance formula is used to measure the distance between the two strings  $a$  and  $b$  with length  $|a|$  and  $|b|$ , respectively.

$$LD_{a,b}(m, n) = \begin{cases} \max(m, n) \\ \min \begin{cases} LD_{a,b}(m-1, n) + 1 \\ LD_{a,b}(m, n-1) + 1 \\ LD_{a,b}(m-1, n-1) + 1_{(a_m \neq b_n)} \end{cases} \end{cases}$$

Here  $(a_m \neq b_n)$  is the indicator function that is equal to 0 when  $(a_m \neq b_n)$ , otherwise 1, and  $LD_{a,b}(m, n)$  is the distance

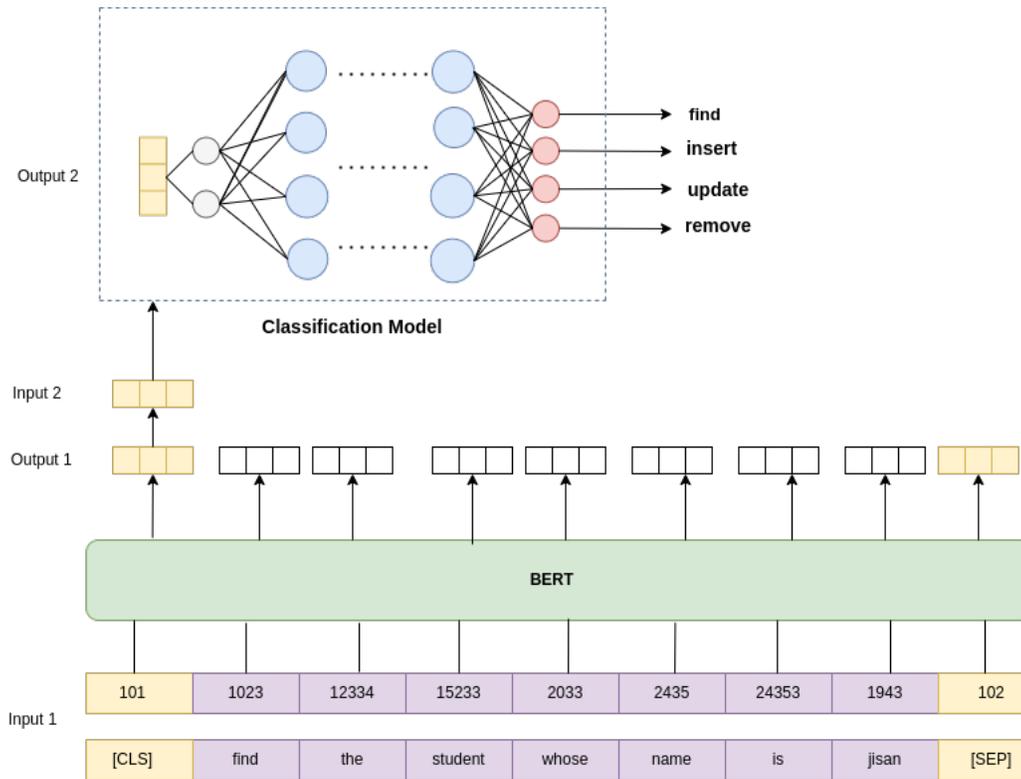

Fig. 2. Operation extraction using BERT model

**Algorithm 3: Attribute Extraction**

```

Input: W = List of Attributes from Database; C =
List of Collection name from Database; S = Set of
Similar Words
Output: A = Attributes Name; B = Table Name
t = CountWord(T)
for i ← 1 to t do
  for j ∈ S do
    LD - THRESHOLD = 1
    THRESHOLD = LD-Algorithm(S[j], W[j])
    if LD - THRESHOLD > THRESHOLD
      then
        PUSH (A[i], W[j])
        PUSH (B[i], C[i])
      end
    end
  end
end

```

between the first m characters of a and the first n characters of b.

*C. Operation Extraction*

Operation extraction is a particular solution that uses BERT Model to extract operations from natural language queries. In this approach, we use BERT Model for classifying the specific operation. In machine learning, classification is the set of categories that analysis belongs to the basis of a training set of

data containing (or instances) whose categorical membership is known [36]. A classification model tries to make some inferences from the observed data. To predict one or more outcomes from the dataset, provide one or more data as inputs to the categorization model.

In the dataset, BERT employs a novel technique known as Masked Language Model (MLM), in which it masks words in the sentence at random and then attempts to predict them. It doesn't use common sequence left-to-right or right-to-left language models. Instead, it uses the bidirectionally trained sequence with a deeper sense of language context and the model. The pre-train BERT applying two unsupervised tasks:

- Pre-training the BERT to understand language.
- Fine-tuning the BERT to learn specific task.

BERT depends on a Transformer (the self-attention mechanism to learn contextual relationships between words in a text). A simple Transformer consists of an encoder that reads text input and a decoder to generates a task prediction. Since the BERT model only requires the encoder part for generating a language representation model. There are two main models of BERT:

- **BERT base** has 12 transformer blocks, 768 hidden layers, 12 attention heads, and 110M parameters.
- **BERT large** has 24 transformer blocks, 1024 hidden layers, 16 attention heads, and 340M parameters.

In this paper, we used the BERT base model that has enough pre-trained data to help bridge the gap in data. The

model for operation extraction shows in Fig. 2. Given the input text, the Model that tokenizes the text using BERT tokenizer then generates the input masks with input IDs of the sentence. The input mask uses WordPiece [37] for tokenizing that splits the token like “going” to “go” and “ing.” It is mainly to cover a broad spectrum of Out-Of-Vocabulary (OOV) words. After tokenization, the output class goes as input in the classification model. we used a neural network for classification to get the highest accuracy. After classifying, we get the output of the operation. Here we work on four types of operations, in consideration- **FIND, INSERT, UPDATE, REMOVE**.

#### D. Build Syntax Tree & Generate Query

After Tokenization, collection, attribute, and operation are extracted from the sentence, we map the syntax tree with key-value pairs to build the query sequentially with the logical expression. If there are no logical expression in the sentence, it will be Nulled. Fig. 3 shows the syntax tree.

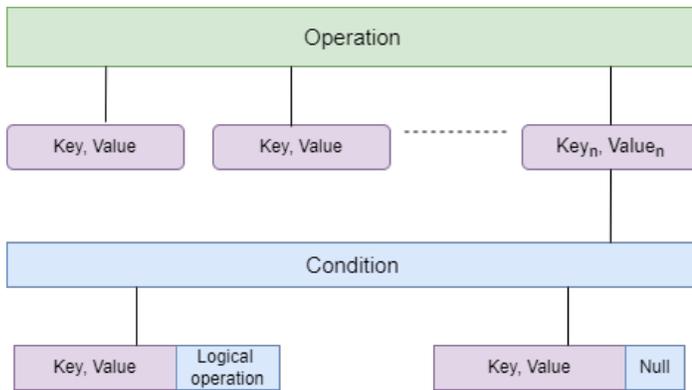

Fig. 3. Mapping syntax tree

Finally, we concatenate the whole step part-by-part and generate a NoSQL query. Fig. 4 shows the architecture of NoSQL query and given the output of the result.

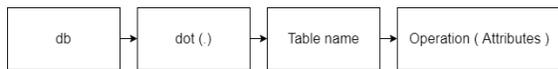

Fig. 4. Architecture of query generation

## IV. EXPERIMENTAL ANALYSIS AND RESULT

In this section, we evaluate our proposed model with the dataset. Firstly, we present the analysis of our dataset, then set up the evaluation. In the end, we compare our proposed model with the existing works and mention the differences, weak and strong points of our proposed model.

#### A. Dataset

We reshuffle the WIKISQL dataset for a better understanding of our model performance. WIKISQL is a massive crowd sourced dataset for creating NLIDB. The model is retrained periodically by reflecting the latest dataset. Our proposed model has used two types of data: (1) Natural Language

Query column which represent the natural language query and (2) Operations column. The description of the datasets is illustrated in Table III.

TABLE III. DESCRIPTION OF DATASET

Dataset	WIKISQL
Language	NLQ
Total number of cases	80,654
Length of the text (average)	61.09
Word count of the text (average)	11.66
Granularity of text description	line
Number of validation text	8,421
Number of test cases (total)	15,878
Number of train cases (total)	56,355

To avoid overfitting, we split the dataset into the training set and the testing set. we train our model on 70:30, 60:40, and 80:20 ratios and get the optimal result from the 80:20 ratio on our dataset. The data fields are the same among all splits. WikiSQL is a collection of hand-annotated SQL table, question, and query examples from Amazon Mechanical Turk crowd workers. It is orders of magnitude larger than current datasets, with 87000 samples as of this writing. The number of validation queries is 8,421. We build queries for the table and then ask crowd workers to paraphrase them. Each paraphrase is then double-checked by independent personnel to ensure that it does not alter the meaning of the original inquiry. We anticipate that making WikiSQL available will aid the community in developing the next generation of natural language interfaces (Fig. 5).

The Fig. 6 illustrates a blue histogram which shows the word and text distribution of dataset. It is hand-annotated semantic parsing dataset that contains logical and normal forms, respectively. In the dataset, the data is extracted from the web.

#### B. Text Pre-Processing

Text pre-processing is the first step of our proposed system. This step involves removing noise from our dataset. we apply several pre-processing steps to the data to convert words into numerical features. An example of tokenization is:

Input: ‘find the name of all student’  
Output: [‘find’, ‘the’, ‘name’, ‘of’, ‘all’, ‘student’]

#### C. Collection and Attribute Extraction from WordNet

We used NLTK WordNet to find find synonyms and antonyms of words. A WordNet is a lexical database that contains semantic relationships between words and their meanings. Our proposed model can successfully extract collection and attributes from WordNet library if there were any spelling errors occur or synonyms used. The bar diagram 5 shows how extract collection and attribute from WordNet using Levenshtein distance. For example:

Collection extraction: ‘all\_student’: [‘student’, ‘students’]  
Attribute extraction: ‘name’: [‘name’, ‘title’, ‘label’]

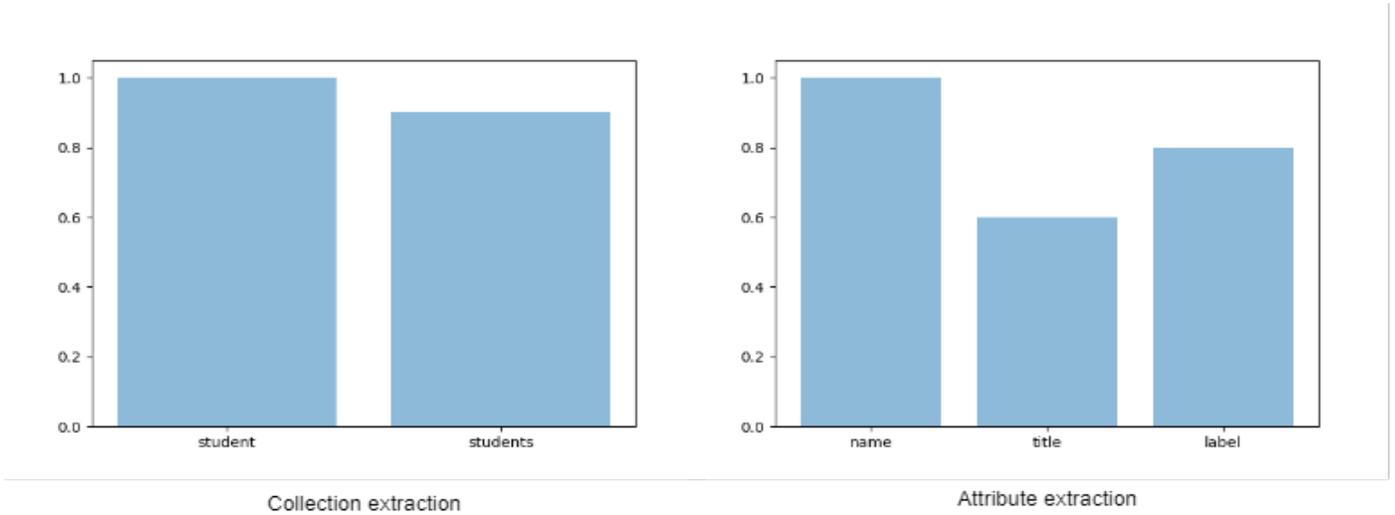

Fig. 5. Collection and attribute extraction

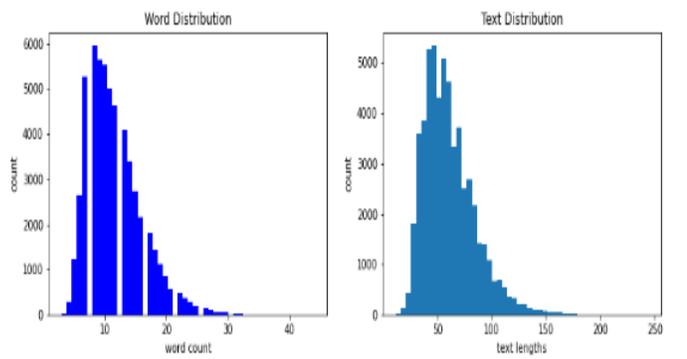

Fig. 6. Word and text distribution

#### D. BERT Tokenizer

In operation extraction our proposed system starts with BERT Tokenizer step. It gives sinusoidal positional encoding, the model itself learns the positional embedding during the training phase. Using the word-piece tokenizer concept that break some words into sub-words.

It helps many times to break unknown words into some known words and tokenize our text into tokens that correspond to BERT’s vocabulary. An example of BERT Tokenization is:

Input: ‘find the name of all student’  
Output 1: [101, 1023, 12334, 15233, 2033, 2435, 24353, 102]  
Output 2: [‘[CLS]’, ‘find’, ‘the’, ‘name’, ‘of’, ‘all’, ‘student’, ‘[SEP]’]

Output 1 is indices of the input tokens from the vocab file and output 2 is the reverse, a human-readable token of the input\_ids. Apart from the input tokens we also got 2 special tokens ‘[CLS]’ and ‘[SEP]’. BERT model is designed in such a way that the sentence has to start with the [CLS] token and end with the [SEP] token.

#### E. Split Data for Training and Testing

The training phase is the first step for the BERT Model. This model is a transformer design based on an encoder stack. We trained the WIKISQL dataset using this model. The Model uses the Semi-Supervised Learning approach for translating natural language query into operation. The training sub-dataset contains all of the features required to turn a natural language query into an operational query. To partition the WIKISQL dataset into two sub-datasets, we use the scikit-learn library’s “train test split” method. The suggested system is built using the dataset’s training sub-dataset. The training dataset is a fraction (80%) of the whole data set. The rest (20%) is considered as test data. This information is imported as a.csv file. Table IV shows a portion of the training data set.

TABLE IV. A SAMPLE OF TRAINING DATASET

Line No.	Natural Language Query	Operations
1	What’s Dorain Anneck’s pick number?	find
2	Find the student whose name is x.	find
3	Insert the arrival time of greenbat.	insert
4	Put the status of the trains at location Museum	insert
5	Update the record for september 15, 1985.	update
6	Re-equip the student	update
7	Remove the brighton cast for jerry cruncher	remove
8	Delete the all student	remove

#### F. Model Building

BERT is an architecture that uses a transformer encoder to process each token of input text in the context of all other tokens. After splitting the dataset, we start with the pre-trained BERT Model to classify the find, insert, update and remove operations. In our model we use 12 layers of Transformer encoder. After run the operation we get two variables: First

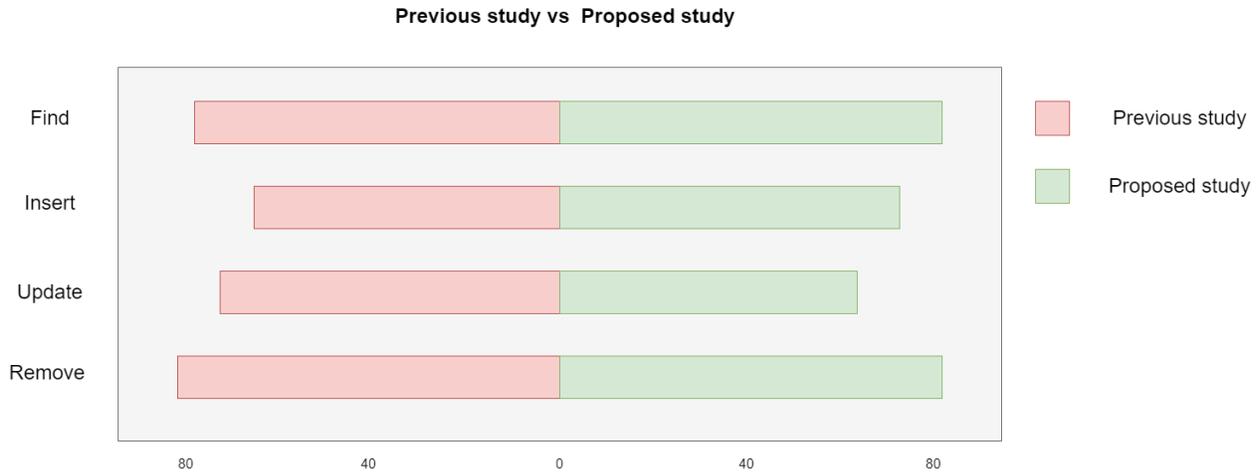

Fig. 7. Comparison of four types operations

variable contains the embedding vectors of all of the tokens in a sequence and second variable contains the embedding vector of [CLS] token. We then pass the variable into a linear layer with ReLU activation function. We have a vector of size 4 at the end of the linear layer, each of which corresponds to a category of our labels (find, insert, update, and remove). We use Adam as the optimizer and train the model for 10 epochs. Because we're dealing with multi-class classification, we'll need to use categorical cross entropy as our loss function. Fig. 8 depicted the operation.

For example:

Input: 'find the name of all student'  
Output: 'find'

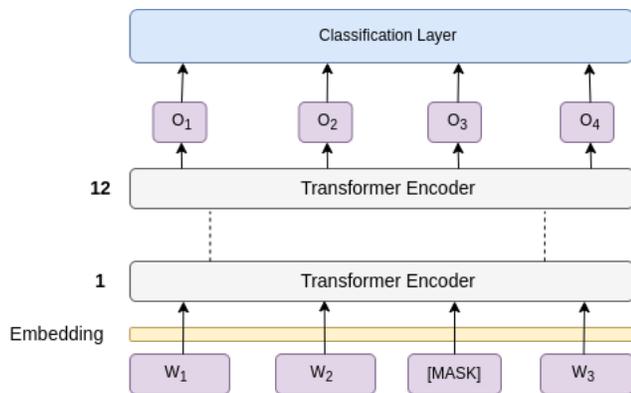

Fig. 8. Model building

The model enhances the accuracy rate for classification than the previous model. For the classification task, the model can classify 81.45% average class detection from previous research. One of the reasons is BERT uses a pre-trained model which is based on transfer learning. It can tune the data on a specific NoSQL language. Fig. 7 illustrates the accuracy rate of four types of operations separately.

### G. Model Accuracy

Accuracy evaluates how well our model forecasts compare them with the original values. With a low rigor yet a high blunder, the model would make huge mistakes in the data. Both blunder and rigor lowness indicates that with most data, the model produces smaller errors. However, it produces huge mistakes in some systems if they are both high. The ideal scenario of any model would be high rigor and little blunder. Fig. 9 illustrate the accuracy of the proposed model.

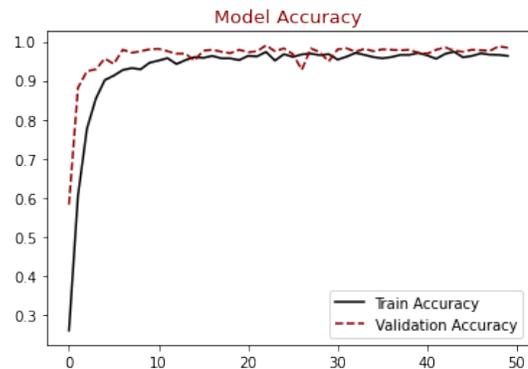

Fig. 9. Model accuracy

### H. Model Loss

Loss is the total of our model errors. It evaluates how well our model does (or how badly it does). When there are a lot of mistakes, the loss is high and the model doesn't work properly. The better our model works, the lower it is. However, the greatest conclusion we can make from it is whether the loss is big or low. If we plot losses over time, we can evaluate if and how quickly our model is learning. This is because the loss function is utilized by the model for learning. This takes the shape of approaches like gradient descent, which modify parameters of the model using information on the loss outcome. Fig. 10 illustrate the loss of the proposed model.

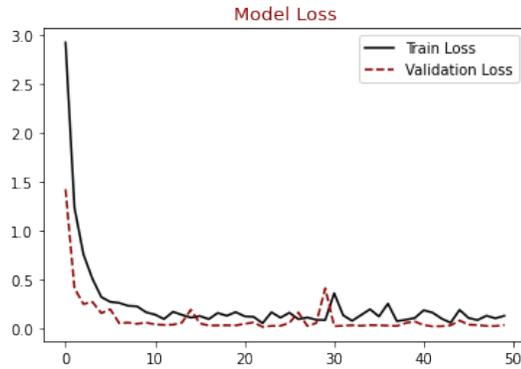

Fig. 10. Model loss

### I. Output

In output, we get the collection and attribute name, such as **all\_student** and **name**. From the operation extraction, get the **find** operation, then concatenate all the extractions output part-by-part to generate a NoSQL query. For example:

```
db.all_student.find({}, {'name':True})
```

We have classified the wrong output into two categories: (a) sometimes, the query contained incomplete logical expression in condition part (b) the query is incorrect. Analysis of the conversion results reveals the following:

- Observing all the NoSQL output, we can notice suggested model can work with natural language queries of different lengths. After a successful NoSQL query output, the number of input and output tokens might be distinct. The accuracy of the proposed model did not depend on the length of the query.
- The BERT Model successfully predicts the operation using a pre-trained model. It also tunes the NoSQL command from a distinctive size of input text.
- The BERT model can process a large amount of data. The WIKISQL dataset covered different types of query statements. So there is no problem for the BERT model to work with the WIKISQL dataset.
- The Bert model understands the semantic relationship between natural language and NoSQL queries. As a result, the decoder output is logically correct for the maximum query.
- The model can generate “contextualized” word embeddings but it is compute-intensive at inference time and need to calculate compute vectors every time.
- In collection and attribute extraction, we use the Levenshtein Distance algorithm. The algorithm can extract attributes from natural language queries furthermore check the spelling error. The run time complexity of this algorithm is lower than  $O(n^2)$ .

Test results show in Table V that have been translated into the NoSQL syntax. The test data contains the natural

language query as well as appropriate. The output contains each converted NoSQL query with original query and test query, along with the percentage of converted NoSQL query.

### J. Evaluation Setup

In this dissertation, we evaluate the result on our dataset that have three notation to evaluate the query synthesis accuracy.

- **Normal form accuracy** is the form of a NoSQL query that has no attribute. We analyze the synthesized NoSQL query with the ground truth to verify whether they match each other.
- **Logical form accuracy** is the accuracy of a NoSQL query that has attributes or any logical expression of the query.
- **Query match** is the comparison accuracy with the original query match for find, insert, update and remove operations query. We use a canonical representation of the synthesized NoSQL query and the ground truth to determine whether two NoSQL queries are identical.

We also find out the F1 score for operation extraction that measures the precision and recall value. Finally, we present the comparison of our model with previous work on NoSQL conversion tasks. The implementation of our model using python [38].

The F1-score measures the accuracy of the operation (find, insert, update, remove) by applying the precision and recall values of the test. This test looks at whether the system can process the sentences entered by the user so that it can be measured the operation accurately with the F1-score method. Table VI shows the accuracy values. The equation of the F1-score, precision, recall, and accuracy have given below:

- **Precision:** It is the true positive relevance rate that defined as the ratio  $\frac{tp}{tp+fp}$ , where  $fp$  indicates the number of false positives;
- **Recall:** It is the true positive rate that defined as the ratio  $\frac{tp}{tp+fn}$ , where  $tp$  and  $fn$  are the number of true positives and false negatives, respectively;
- **F1-score:** F1-score is a function of Precision and Recall that is the harmonic mean between Precision and Recall, defined the ratio as  $\frac{2*(precision*recall)}{precision+recall}$ ;

Next, we find out the accuracy of normal and logical forms. Let  $X$  is the total number of queries in our dataset and  $X_{ex}$  is the execution query. we evaluate the every clause (find, insert, update and remove) query using accuracy metric for normal form  $Acc_{nf} = \frac{X_{ex}}{X}$  and for logical form  $Acc_{lf} = \frac{X_{ex}}{X}$ . Table VII shows the accuracy of normal and logical queries. After that the overall result is evaluated by the BLEU (Bilingual Evaluation Understudy) that was developed to evaluate the machine translation system.

### K. Result

The article presents an efficient approach to transform the natural language query into a NoSQL query effectively.

TABLE V. THE ACCURACY FOR CONVERTING NATURAL LANGUAGE INTO NON STRUCTURED QUERY LANGUAGE

Input Text	Original query	Test query	Accuracy(%)
Find all the students	db.all_student.find()	db.all_student.find()	100
What is the name of all student?	db.all_student.find({name:True})	db.all_student.find({name:True})	100
Find the student whose age greater than 70	db.all_student.find({ age: { \$gt: 70 } })	db.all_student.find({ age: { 70 } })	75.0
Insert the student whose name is x	db.all_student.insert ({name:'x'})	db.all_student.insert ({name:'x'})	100
Insert student whose name is x, age 22	db.all_student.insert ({name:'x',{age:22}})	db.all_student.insert ({name:'x',{age:22}})	83.33
Update the name y who is x in student table	db.all_student.update ({name:'x'},{set:{name:'y'}})	db.all_student.update ({name:'x'},{set:{name:'y'}})	100
Update name z and age 40, whoes name is x	db.all_student.update ({name:'x'},{set:{name:'y'}})	db.all_student.update ({name:'x'},{set:{name:'x'}})	65.5
Remove all the students	db.all_student.drop()	db.all_student.drop()	100
Delete student whose name is x and age 20	db.all_student.removeMany ({name:'x', age: 20})	db.all_student.remove ({name:'x', age: 20})	75.0

This model achieves a competitive result on our dataset. The following tables represent the experiment result of each classifier.

TABLE VI. EXPERIMENTAL RESULTS OF EACH CLASSIFIER

F1-score	0.808
Precision	0.892
Recall	0.74

Bilingual Evaluation Understudy (BLEU) is a score for comparing a candidate translation of the NoSQL query to one or more reference translations. To predict the accuracy of automatic machine translation systems, Kishore Papineni, et al. [39] proposed this score in 2002. We used the BLEU score to determine the output.

BLEU is not entirely effective but offers several interesting benefits like quick, easy to calculate, language-independent, highly interactive with human interpretation, and widely used.

$$P = \frac{m}{w_t} \quad (1)$$

where,  $m$  is the estimate of tokens from the candidate source code that are found in the reference text, and  $w_t$  is the total estimate of words in the candidate query. The accuracy is calculated using the equation 2.

$$Accuracy = P \times 100\% \quad (2)$$

The performance analysis of our model is given in Table VII.

TABLE VII. PERFORMANCE ANALYSIS OF OUR MODEL.  $Acc_{nf}$  AND  $Acc_{lf}$  INDICATE THE NORMAL FORM AND LOGICAL FORM QUERY ACCURACY, AND  $Acc_{qm}$  INDICATES THE ACCURACY OF QUERY MATCH

Operation clause	$Acc_{nf}(\%)$	$Acc_{lf}(\%)$
Find	100	87.5
Insert	-	91.67
Update	-	82.75
Remove	100	75.0

Accounting to Concepts Identification errors and domain dictionary errors, the average accuracy achieved by our system is 88.76% respectively. We define the error rate as:

$$ErrorRate = (100 - AccuracyRate)\% \quad (3)$$

TABLE VIII. ANALOGY OF DIFFERENT TYPES OF MODEL

Model	Accuracy (%)	Error Rate (%)
Encoder-Decoder Model	71.5	28.5
REINFORCE-algorithm Model	84.2	15.8
Proposed Model	88.76	11.24

Table VIII represents BLEU portion of efficiency for forecasting correct NoSQL query. Using the WikiSQL reshape dataset the proposed model is passed down for comparing with the existing other models. Fig. 11 illustrates the three models' estimated efficiency and error rates. It demonstrates the accuracy of other measure rates of converting the natural language query into the non-structured query language (that scored 88.76%) is better or at least competitive than the earlier results.

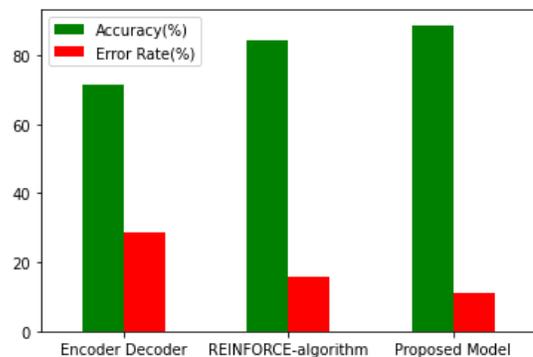

Fig. 11. Performance factor between previous and our proposed model

## V. CONCLUSION

In the age of digitalization, internet users have been increasing continuously. So a large amount of data needs to be stored in a database. Relational databases faced some challenges in search engines and social networking services. Here, the NoSQL database helps maintain a broad range of hierarchical data models. The proposed model deals with the NLP

to non-relational query conversion. Initially, preprocessing the text (English) by NLTK, then used LD algorithm for collection, attribute extraction and BERT model for operation extraction and finally, query generation. Our model can generate queries for Find, Insert, Update, Remove clause with an average accuracy of 88.76%. In the future, we intend to improve more complex NoSQL queries such as logical function queries, using other incentive mechanisms for better performance.

**Abstract**—In the big data era, machine learning has developed prominently and is widely used in real-world systems. Yet, machine learning raises fairness concerns, which incurs discrimination against groups determined by sensitive attributes such as gender and race. Many researchers have focused on developing fairness audit technique of machine learning model that enable users to protect themselves from discrimination. Existing solutions, however, rely on additional external trust assumptions, either on third-party entities or external components, that significantly lower the security. In this study, we propose a trustless verifiable fairness audit framework that assesses the fairness of ML algorithms while addressing potential security issues such as data privacy, model secrecy, and trustworthiness. With succinctness and non-interactive of zero knowledge proof, our framework not only guarantees audit integrity, but also clearly enhance security, enabling fair ML models to be publicly auditable and any client to verify audit results without extra trust assumption. Our evaluation on various machine learning models and real-world datasets shows that our framework achieves practical performance.

**Keywords**—Security and privacy; machine learning; fairness; cryptography; zero knowledge proof

## I. INTRODUCTION

Machine Learning has seen great success in decision-making and decision-support tasks in recent years [1] [2] [3], being deployed in various applications and products in practice, such as loans and hiring decisions. However, concerns are rising that algorithms amplify bias and discrimination from the training data, and fairness is becoming an essential metric for evaluating machine learning models [4]–[8]. Consequently, fairness has become a roadblock to widespread machine learning applications. To address this formally, many works towards considering how algorithm fairness can be assessed by proposing various measures and how discrimination in machine learning systems can be mitigated by pre-processing [9], [10], inter-processing [11], [12], and post-processing methods [5] [13].

In practice, there is a need for guarantees that the result of fairness audit are correctly calculated with respect to specific fairness metrics, which is referred to as the *audit integrity* of fairness. One of the basic ideas to ensure that users are protected from discrimination is to ensure the integrity of the audit. In order to get a fair model, the server usually requires the user's sensitive data, such as gender and race, to train the machine learning model. However, this requirement is often contrary to the interests of the user. First, users are usually reluctant to share their data, even if it is a reasonable aim,

because it would expand their exposure to privacy risks. In addition, the collection of sensitive user data is subject to legal restrictions. For example, the EU's General Data Protection Regulation (GDPR) highlights the minimal prerequisites for collecting sensitive data [14]. If the model itself is not a secret, anyone can potentially run tests on it to establish its purported fairness without exposing its data. However, this approach may be contrary to the benefits of the model owner due to intellectual property. Although there are fair learning approaches [15], [16], training fair models without the sensitive data have been proposed, it is still required to have the sensitive data for assessing the fairness of the trained model [17]. We call this problem as *sensitive data availability*.

To overcome sensitive data availability issues in providing audit integrity, Veale and Binns [14] introduce a trusted third party with sensitive data to certify the fairness of a machine learning model. Although this model works well, it requires a strong trust relationship between the third party and the model owner. Either the third party has access to the ML model, or the model owner has access to the sensitive data, which may be against their interests. To audit the model publicly while protecting sensitive data's privacy and keeping the model confidentiality, Kilbertus et al. [18] and Segal et al. [19] proposed to utilize multi-party computation (MPC) approach. Those approaches enable a public fairness audit under the assumption of a semi-honest security model and are extended by Pentylala et al. [20] to a malicious security model. Park et al. [17] propose a framework to enable secure fairness audit by leveraging confidential computing based on hardware enclave under the malicious security model.

**The problem.** While previous work have been work well, existing solutions still suffer from extra trust assumption. This is problematic for two reasons. First, the additional trust assumptions mean the third party determines the audit integrity. Second, relying on a third party can lead to single-point failures. Specifically, the MPC-based approach assumes that the server and the third party are running all required steps in a protocol. Moreover, the hardware-based approach introduces additional hardware security assumptions and also suffers from hardware vulnerabilities [21] [22]. Furthermore, when we are in a situation where we want to audit the model used for several different domains, we need to establish credible relationships with more third parties or hardware enclaves.

To get secure and robust service, we need a much more robust security guarantee: each party only trusts itself. This raises our question: *Can we design a framework for auditing the fairness of machine learning models under no trusted party existing scenario? Or can we guarantee security for audit*

<sup>2</sup>Corresponding Author.

integrity without external trust assumptions? For example, we want to support fairness audits as a service in the model market to achieve fairness integrity.

We answer the question above positively in this paper by proposing a fair audit framework, which enables a publicly verifiable fairness audit of the ML model without disclosing model parameters and guarantees audit integrity of the fair audit. The main idea is to leverage the progress of zero knowledge succinct non-interactive arguments of knowledge (zk-SNARKs) [23]–[29] recently. A zk-SNARK enables the third party to efficiently convince the verifier that the computation of fairness audit is correctly calculated. We solve the critical challenge of adapting zk-SNARK to this work under the malicious threat model. In summary, the contributions of this work are:

- We provide a generic framework to audit the fairness of machine learning model under the trustless condition. We can support generic machine learning models with arbitrary fairness metrics.
- We formally define security requirements and instantiate the framework described above. We have solved performance challenging problems in the instantiation process.
- We implement our framework and evaluate its performance on several real-world datasets. The experimental results show that our framework achieves practical performance.

## II. LITERATURE REVIEW

### A. Fairness Audit

Despite training a machine learning model is a fundamental problem, bringing the model to reality is also important. A fundamental question is how to ensure that the model used is non-discriminatory. There is a line of work to discuss this problem. Veale and Binns [14] introduced highly trusted third parties selectively storing data and performing discrimination auditing to achieve fairness in machine learning. However, they assume the modeler must disclose their model to a third party or trust it in order to obtain the model prediction on test data, which may be incompatible with modeler's intellectual property. To resolve these problems, other privacy-preserving approaches such as multi-party computation or trusted execute environment can be applied. Kibertus et al. [18] and Segal et al. [19] proposed privacy-preserving fair certification and inference of ML model that protect sensitive attributes and model confidentiality by using MPC. However, they assume that two honest-but-curious server and require high communication. The following work PrivFair [20] extend their security model to active security threat models in 2- or 3-server setups. Park et al. [17] provided a generic fairness audit framework that relies on hardware enclaves and explores more potential threats and attacks in the fairness certification process. Although their approach has a small computational overhead, their require additional hardware and trustworthiness to TEE, which is not our goal. And TEE also face many unknown vulnerability [21]. All of these work require additional trusts, and does not provide public verifiable. Their computation integrity rely on their trust on third party. In this study, we explore a publicly

verifiable security audit protocol based on zero knowledge proof with lower level of trust. Also [19] and [17] explore the auditing dataset are publicly known during model training, which makes the model certification harder by allowing the modeler can adaptive training their model on the audit data. We are also using this approach to improve the reliability and robustness of fairness audits, which is seen as a promising direction for fairness certification.

### B. Zero Knowledge Proof

Zero knowledge proofs were introduced by Goldwasser [30] and generic constructions based on probabilistically checkable proofs were proposed in the seminal works of Kilian [31] and Micali [32]. In recent years there has been significant progress in efficient ZKP protocols and systems. A radically different approach in zero-knowledge proof, categorized by their underlying techniques and assumptions, there are pairing-based schemes [24], [25], [27], discrete- log-based schemes [33], interactive-proof [34], [35], interactive oracle proofs (IOP) [26], [36], and so on. They provide different trade-offs between prover runtime, proof size and verifier runtime and so on. Please refer to [37] for more details on the performance and comparisons of different ZKP schemes. Zero knowledge proof has been widely used in blockchains and cryptocurrencies to achieve privacy [38] and scalability. More recently, it also found new applications in zero-knowledge machine learning [39], [40], zero-knowledge middlebox [41], and so on.

## III. PRELIMINARIES

In this section, we introduce the fairness notions in machine learning and the cryptographic primitives used in our framework.

**Notions.** We use  $\lambda$  to denote the security parameter. Let  $[n]$  denote the set  $\{0, 1, \dots, n - 1\}$ ; a vector be denoted by a boldface letter, e.g.,  $\mathbf{x}$ . And  $x \leftarrow \mathcal{X}$  denote that  $x$  is sampled from a distribution  $\mathcal{X}$ .

### A. Fairness Notions in Machine Learning

There is plenty of fairness definitions [42] such as group fairness, causal discrimination, and counterfactual fairness. In this study, we mainly focus on statistical fairness definitions that require protected data, such as demographic parity (or statistical parity) [43], equalized odds [5], equal of opportunity [5], and disparate impact [44]. Demographic parity means that both protected and unprotected groups have an equal probability of being assigned to the positive predicted class. Equalized odds enforces both equal bias and equal accuracy in all demographics. Equal of opportunity is a relaxation of equalized odds, which only focus the positive predication outcome. Disparate impact implies that the decision outcomes disproportionately benefit or hurt members of certain sensitive attribute value groups.

Let  $M$  be a trained machine learning model for a classification task. Suppose possible inputs  $\mathcal{X}$ , sensitive or protected attribute  $\mathcal{G}$  (relevant for fairness, e.g., ethnic or sex), the true class label  $y$  and the predication  $\hat{y} = M(x, g)$ , where  $x \in \mathcal{X}, g \in \mathcal{G}$ . And we use tuple  $(M, \mathcal{X}, \mathcal{Y}, \mathcal{G})$  represent the audit sample  $D$ . Consider  $g = 0$  designates the unprotected

group and  $g = 1$  designates the protected group. We recall these fairness definition below.

- Demographic parity (DP):  $P(\hat{y} = 1|g = 0) = P(\hat{y} = 1|g = 1)$
- Equalized odds (EO):  $P(\hat{y} = 1|y, g = 0) = P(\hat{y} = 1|y, g = 1), \forall y \in \mathcal{Y}$
- Equal opportunity:  $P(\hat{y} = 1|y = 1, g = 0) = P(\hat{y} = 1|y = 1, g = 1)$
- Disparate impact (DI):  $P(\hat{y} = 1|g) \neq P(\hat{y} = 1), \forall g \in \mathcal{G}$

The fairness of the ML model is assessed by means of the empirical fairness gap, as described in [19]. The fairness notion must be expressed in the formulation in order to audit ML models. Without loss of generality, we can consider the demographic parity:

$$l_{g,y}(M) = \mathbb{E}_{(x,g',y')} [\mathbb{I}\{M(x) = y\} | g' = g]$$

where  $\mathbb{I}$  is an indicator function. Then define the estimated group risk as  $l_{g,y}(M, T) = \frac{1}{m} \sum_{i=1}^{m_g} \mathbb{I}\{M(x_i) = y_i \wedge g_i = g\}$ , where  $T = \{(x_1, g_1, y_1), \dots, (x_m, g_m, y_m)\}$  is independent sample set and  $m_g$  is the number of samples in  $T$  from group  $g$ . Define the fairness gap of ML model as

$$\max_{g_0, g_1 \in \mathcal{G}, y \in \mathcal{Y}} |l_{g_0,y}(M) - l_{g_1,y}(M)|$$

Also define empirical fairness gap (EFG) using the empirical approximation as follows:

$$EFG = \max_{g_0, g_1 \in \mathcal{G}, y \in \mathcal{Y}} |l_{g_0,y}(M, T) - l_{g_1,y}(M, T)|$$

We call model  $M$   $(\epsilon, \delta)$ -fair on  $(\mathcal{G}, \mathcal{T})$  with respect to a fairness measurement if:

$$\Pr \left[ \max_{g_0, g_1 \in \mathcal{G}, y \in \mathcal{Y}} |l_{g_0,y}(M) - l_{g_1,y}(M)| > \epsilon \right] \leq \delta$$

The EFG can naturally extend to the other fairness notion and yield the corresponding  $(\epsilon, \delta)$ -fairness definitions.

## B. Cryptography Primitives

**Bilinear Groups.** A bilinear group is given by a description  $GK = (p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T)$  such that

- $\mathbb{G}_1, \mathbb{G}_2$  are cyclic groups of prime order  $p$  and generators are  $g \in \mathbb{G}_1$  and  $h \in \mathbb{G}_2$
- Bilinear map  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$ , that is,  $e(g^a, h^b) = e(g, h)^{ab}$ , where  $a, b \in \mathbb{Z}_p$
- $e(g, h)$  generates  $\mathbb{G}_T$

**Commitment Scheme.** A commitment scheme allows a committee to commit a secret value and later open the commitment and reveal the value to the verifier. We recall the commitment scheme definition.

*Definition 1:* A commitment scheme is a tuple of algorithms  $\text{Com} = (\text{Setup}, \text{Commit}, \text{VerifyCommit})$  that works as follows.

- $\text{Setup}(1^\lambda) \rightarrow \text{ck}$  takes as input the security parameter  $\lambda$  and outputs a commitment key  $\text{ck}$ .

- $\text{Commit}(\text{ck}, m) \rightarrow (c, o)$  takes as input the commitment key  $\text{ck}$  and a secret value  $m$ , and output a commitment  $c_m$  and an opening  $o$ .
- $\text{VerCom}(\text{ck}, c_m, m, o) \rightarrow b$  takes as input a commitment  $c_m$ , a value  $m$  and an opening  $o$ , and output accept ( $b = 1$ ) or reject ( $b = 0$ ).

The commitment scheme is required to be both binding and hiding. In the study, we will be using Pedersen-like commitment scheme [27] which is statistically hiding and computationally binding under suit assumptions.

**zkSNARKs.** Zero knowledge proof enables a *prover* to prove to a *verifier* the result  $y$  of a computation  $\mathcal{C}$  satisfying  $y = C(x, w)$ , where  $x$  is public input and  $w$  is secret witness of prover. The popular zero knowledge proof notions used in practice are zero-knowledge succinct non-interactive arguments of knowledge (zkSNARKs, for short) [23]–[25]. Here we recall the definition of zkSNARKs as follows:

*Definition 2:* A zk-SNARK for a relation  $R$  is a tuple of algorithms  $\Sigma = (\text{KeyGen}, \text{Prove}, \text{Verify}, \text{Sim})$  as follows:

- $\text{Setup}(1^\lambda, R) \rightarrow \text{CRS} = ((ek, vk), \tau)$ : The setup algorithm takes a relation  $R \in R_\lambda$  and security parameter as input, and returns a common reference string CRS and a simulation trapdoor  $\tau$ .
- $\text{Prove}(ek, x, w) \rightarrow \pi$  The prove algorithm takes an evaluation key  $ek$  from CRS, and  $(x, w) \in R$  as inputs, and generates a proof  $\pi$ .
- $\text{Verify}(vk, x, \pi) \rightarrow b \in \{0, 1\}$  The verify algorithm takes a verification key  $vk$  from CRS, public input  $x$ , and proof  $\pi$ , and outputs 0(reject) or 1 (accept).
- $\text{Sim}(\text{CRS}, \tau, R)$  The Sim algorithm takes a CRS, a simulation trapdoor  $\tau$ , and a relation  $R$  as input, and returns a proof  $\pi$ .

A zkSNARKs scheme should satisfy the following properties:

- **Completeness:** For any pair  $(x, w) \in R$ , the verifier always accepts the corresponding proof.
- **Knowledge Soundness:** it holds if the prover must know a witness and such knowledge can be efficiently extracted from the prover by using a knowledge extractor.
- **Zero knowledge:** An argument is zero-knowledge if it does not leak any information other than the truth of the statement. There are exist a simulator without secrets can generate valid proofs.
- **Succinctness:** The size of a proof is  $|\pi| \leq \text{poly}(k) \text{polylog}(|x| + |w|)$

**Commit-and-prove SNARK.** Commit-and-prove SNARK is a SNARK(cp-SNARK, for short) [27] that can prove knowledge of  $(x, w)$  such that  $R(x, w) = 1$  holds w.r.t. a witness  $w = (u, w)$  and  $u$  opens a commitment  $c_u$  as follow:

*Definition 3:* We denote a cp-SNARK as a triple of algorithm  $\text{CP} = (\text{KeyGen}, \text{Prove}, \text{VerProof})$ .

- $\text{KeyGen}(ck, R) \rightarrow \text{CRS} = (ek, vk)$  generates the common reference string(CRS).
- $\text{Prove}(ek, x, (c_j)_{j \in [l]}, (u_j)_{j \in [l]}, (o_j)_{j \in [l]}, w) \rightarrow \pi$  outputs the proof of correct commitment.
- $\text{VerProof}(vk, x, (c_j)_{j \in [l]}) \rightarrow b \in \{0, 1\}$  reject or accept the proofs.

The above definition has *perfect completeness*, *computational knowledge soundness* and *zero knowledge* in the random oracle model. Please refer to [27] for more details on the formal definition.

#### IV. PROBLEM STATEMENT

##### A. System Model

As shown in Fig. 1, our framework involves four entities: *server*, *regulators*, *client*, and *bulletin board*. With the involvement of the entities, we consider such a scenario problem: the server in possession of a trained model seeks to convince any later-coming client that the model satisfies a set of fairness metrics typically defined by a group of specialist regulators, while not revealing the model parameters. We note that we consider multiple specialist regulators who hold different fairness metrics dependent on the policy, law regulation, and environment of their domains, so as to ensure an all-around fairness assessment of a trained model. To address the above scenario problem, our framework contains three phases, including the query phase, the auditing phase, and the verification phase, with the following basic workflow:

- The sever commits to the model that will be evaluated, and meanwhile, the regulators commits to their test data that are used for evaluating model fairness.
- Any one regulator can send the test data to the server, and the model is evaluated on the data, thereby obtaining the corresponding evaluation result. Also, the commitment on the evaluation result and the proof regarding evaluation correctness are submitted to the bulletin board. Here refers to the query phase.
- A regulator can audit the model fairness with the evaluation result he obtains, according to the fairness metric he holds. As a result, the regulator submits the auditing result and a proof on correct auditing to the bulletin board. It refers to the auditing phase.
- Any later-coming client who questions the model fairness is able to browse the fairness auditing results and assert the truth with the proofs from the bulletin board. Here refers to the verification phase.

**Remarks.** We remark that the server provides a black-box query inference towards the regulators, without exposing the model parameters.

##### B. Threat Assumptions

We consider either the server or the regulators have the motivation to cheat the client with respect to the model fairness in our scenario problem. We now clarify our concrete threat assumptions on the involved entities.

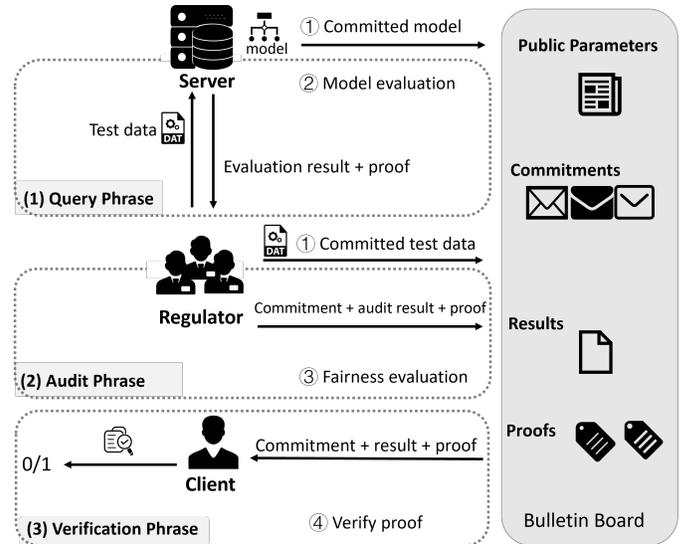

Fig. 1. System overview

**Server:** The server is considered to be *malicious*, which may arbitrarily deviate from the evaluation of model fairness. Specifically, 1) it may give incorrect model predication on test data, such as random values or predication not on the committed model or test data; 2) it also may use an unfair model to interact with the regulator, trying to trick the regulator. We note the server has access to the regulator’s test dataset in plaintext in our scenario. First, given that the source and amount of data is limited, there is a tendency to audit model fairness on publicly available datasets [19] to obtain richer test data. Second, in scenarios where privacy is required for the test dataset, since each of the regulator’s test data only contains sensitive attributes and an identifier as stated in work [14], this represents a lesser privacy risk.

**Regulator:** We consider regulator as *malicious*. The regulator might give wrong fairness audit results, such as auditing an unfair model as fair or vice versa, due to conflict of interest or just machine failure. The regulator also might use test datasets that differs from the previously committed data.

**Client:** We assume client is *honest*. The client can know the algorithms for model prediction and fairness evaluation, but does not have access to the model parameters. The commitments, audit result, and proofs are always available to client.

**Bulletin Board:** We assume that integrity and availability hold for bulletin board. The bulletin board can be instantiated by using a blockchain system, such as Bitcoin or Ethereum. We make the assumption like existing work [45]. We also assume the existence of a secure communication channel between any two entities.

**Remarks.** Note that we do not consider how to train a fair machine learning model and we do not discuss some machine learning attack, such as model extraction, model inversion, and evasion attacks [46] [47]. These studies are outside the scope of this work.

### C. Security Goals

We aim to propose a framework for model fairness auditing in trustless setting, which departs from previous works. The framework establishes an evidence on the server-side model fairness, such that an off-line or later-coming client can be faithfully convinced of the truth respective to model fairness. To be specific, we should achieve the following security goals.

**Trustless Verifiable Model Fairness:** We require that the truth of model fairness can be efficiently verified by any one non-designated client. Concretely, a client of interest as a verifier can verify the public proofs posted by the server and the regulators, so as to determine if the server's model indeed reaches the fairness degree of the regulators over specific test data.

**Model Privacy:** We require that neither evaluation results, auditing results or proofs reveals the private information of the model against any one verifier.

**Audit Integrity:** We can provide the publicly verifiable audit integrity to convince that any later-coming client.

**Accountability:** We require that a verifier can account the misbehavior of the server or the regulator, if evaluation proof or audit proof cannot be verified. This property cannot be provided by MPC-based works.

## V. TECHNICAL CHALLENGE

Above scenario allows the server to know the regulator's test data for evaluating his model, and the regulators to obtain the corresponding evaluation results for auditing model fairness. When any a later-coming client gets the auditing results, we do not desire the client to learn any private information of the server's model, the regulator's test data and the evaluation results. We therefore need to achieve that any client (as non-designated verifier) can check the correctness of model evaluation and fairness auditing without private information of the model, test data and evaluation results.

Zero-knowledge proof technique can be used to address the above scenario problem without leaking private information. As Fig. 1 demonstrated, a regulator can firstly commit to test data (the server also commits to the model). The server then conducts the model evaluation with the test data, yielding the corresponding evaluation results. It also commits to the evaluation results, and generates a proof  $\pi_1$  that the model is indeed evaluated over the test data, with the committed evaluation results as output. After that, the regulator executes the computations of fairness auditing, and generates a proof  $\pi_2$  regarding the execution correctness. Lastly, a verifier checks the validity of both  $\pi_1$  and  $\pi_2$  without knowing the previously mentioned model, test data and evaluation results. Despite the easy-following technical roadmap, we encounter the following two challenges for efficiency:

### A. Supporting Lightweight Verification

Our work adopts the state-of-the-art zkSNARK scheme constructed by Groth [25] (refer to Groth16) due to its short proof size (three group elements) and efficient verification. Despite the optimal performance of the scheme, the direct adoption without any modification cannot satisfy our scenario

requirements. Specifically, to test model fairness and ensure the result reliability require sufficiently large test data, e.g., 6800 test inputs per regulator, as mentioned in [19]. Based on the scenario, the overall proof size will increase linearly with the amount of data, although the single proof of the Groth16 scheme is succinct. But a verifier is considered a thin device with restricted resources, and thus the result proof as described above easily becomes a computational and storage burden on the lightweight verifier. Furthermore, this situation becomes even worse when we want to verify the results of the fairness audit of multiple regulators with different test data and different fairness metrics. Therefore, the challenge is implementing more efficient verification when the model fairness is audited by large test data from multiple regulators.

### B. Improving Proving Performance

Recall that the proof generation process based on an zk-SNARK scheme involves compiling a computation (e.g., model fairness auditing) into a circuit, such as arithmetic circuit and Boolean circuit, and then expressing the circuit with rank-1 constraint system (R1CS) used for generating proof. The involved arithmetic and Boolean operations generally determine the efficiency of the zkSNARK scheme used in practical. For example, the overhead of the Groth16 scheme is friendly for arithmetic operations in the finite field but unfriendly for Boolean operations (due to the radical blow-up in the circuit size required to compile Boolean operations into the arithmetic circuit). Such technical feature, however, is in conflict with the concrete computation of our scenario, since model fairness auditing involves many Boolean-efficient operations such as comparison. Our challenge thus is efficiently handling Boolean operations in proof generation.

## VI. CONCRETE DESIGN

We now present our framework that enables the fairness audit for an ML model while keep model confidentiality in an efficient publicly verifiable manner, enabling each one to assess model fairness individually and thus minimize trust dependency between server, regulator and client. It builds on Groth16 zk-SNARK scheme, Pedersen commitment and signature scheme. As mentioned above, our framework consists of three phase: *query phase*, *audit phase*, and *verification phase*. (1) In the query phase, the regulator query the server's model using the committed test dataset. Then the server evaluate model on test data and generate a proof for correct evaluation, and sends the evaluation results and the evaluation proof to the regulator. (2) The regulator verifies the evaluation proof and evaluate fairness metrics of model. And then the regulator generate auditing proof. And release auditing result and auditing proof to the bulletin board. (3) The client verifies the evaluation proof, audit proof and determines the fairness of the server's model.

### A. Query Phase

1) *Model evaluation.*: In this phase, the main goal of regulator is to obtain the evaluation of the server's model on test data that can be used to audit the model's fairness. Firstly, the regulator collects sufficient test dataset  $\mathcal{X} = \{x_0, \dots, x_{n-1}\}$  (in a legally compliant way or directly extracted from public audit datasets [19]) and commits it to  $\text{cm}_x$  using the Pedersen

commitment scheme. The server also commits its ML model parameter to  $\mathbf{cm}_m$  using the same commitment scheme. Then both parties posting their commitments  $\mathbf{cm}_x$  and  $\mathbf{cm}_m$  to the Bulletin board respectively. Noted that the ML model structure is known to the verifier, we only protect the model parameter privacy, e.g. weight information. Secondly, the regulator transmits test data  $\mathcal{X} = \{x_0, \dots, x_{n-1}\}$  to the server, then the server computes the evaluations of model on the test data  $\hat{\mathcal{Y}} = \{y_0, \dots, y_{n-1}\}$  and generates the evaluation proof  $\pi_e$ . Moreover, the server commit the evaluation of model to  $\mathbf{cm}_y$  and publish it and the evaluation proof  $\pi_e$  to the Bulletin board, and the server sends the model evaluations  $\hat{\mathcal{Y}}$  to the regulator.

2) *Proof generation.*: Our framework conducts the commit-and-prove paradigms [27] so that we can support zero-knowledge evaluation for both secret input and secret models in a straightforward way. Specially, in our scenario, we allow the server get the test data in plaintext, and the regulator obtains the evaluation results for audit the model. However, from the client's perspective, the privacy of the model, test data, and the evaluation result all is preserved.

The claim from [19] stated that an ML model  $M$  is  $\epsilon$ -fair with confidence  $1 - \delta$  if:

$$EFG < \epsilon \wedge \min_{g \in \mathcal{G}} \geq \frac{2}{(\epsilon - EFG)^2} \ln \frac{2|\mathcal{G}||\mathcal{Y}|}{\delta}$$

where  $m_g$  denotes the number of occurrences of  $g$  in  $T$ . Takes  $EFG = 0.05, \epsilon = 0.1, \delta = 0.2$  and  $|\mathcal{G}| = 100$  as example, we need sample number  $m_g \approx 6800$ . In this scenario, although the individual evaluation proof are small, thousands of test data make verifying multiple evaluation proofs expensive. As stated above, however, our goal is to keep the succinctness of proof due to we want to support a lightweight client who has limited memory and computation resources. There are two common techniques to keep succinctness of multiple proofs in literature, one is SNARK recursion [48] [49], and other is proof aggregation [50] [51]. The SNARK recursion can prove the proof is correct, and we can compress a sequence of proofs into one proof. Specially, we can aggregate proofs via recursive composition that create another SNARK for the circuit that contains  $n$  copies of the Groth16 verifier circuit [48]. But the SNARK recursion incur significant practical overhead due to we need to compile the verify algorithm into a circuit, and this is the bottleneck of recursion SNARK efficiency. For example, computing a pairing on the BLS12-377 curve require  $\sim 15000$  constraints [48].

3) *Proof aggregation.*: In our work, we adopt proof aggregation technique. Inspired by SnarkPack [50] [51], we resort to utilize special structure of proof to aggregate multiple proof. SnarkPack propose an approach to reduce the overhead in communication and verification time for verify multiple proofs without the need of further larger trusted setup ceremonies. The SnarkPack allows to aggregate  $n$  Groth16 zk-SNARKs proofs with  $O(\log n)$  proof size and verifier time and can be constructed from two different existing ceremonies (e.g., the "power of tau" for Zcash [38] and Filecoin [52]).

We explain the aggregation protocol used in SnarkPack and how it can adapt to our CP-SNARK scenario below. First, we recall the verification process used in Groth16. A detailed description of Groth16 SNARK protocol can be found in [25].

The proof  $\pi$  in Groth16 consists of three group element  $\pi = (A, B, C) \in \mathbb{G}_1 \times \mathbb{G}_2 \times \mathbb{G}_1$ . For the verification algorithm, we need the verification key vk:

$$vk := \left( g^\alpha, h^\beta, \left\{ S_j = g^{\frac{\beta_j(s) + \alpha w_j(s) + y_j(s)}{\gamma}} \right\}_{j=0}^t, h^\gamma, h^\delta \right)$$

The verifier need check that pairing equations is satisfy:  $e(A, B) = e(g^\alpha, h^\beta) \cdot e(\sum_{j=0}^t S_j^{\alpha_j}, h^\gamma) \cdot e(C, h^\delta)$ , where  $[a]$  is public input.

The high level idea of Groth16 aggregation is straightforward: instead of checking that  $n$  different pairing equations are simultaneously satisfied, it is sufficient to prove that only one inner pairing product of a random linear combination of these equations defined by a verifier's random challenge  $r \in \mathbb{Z}_p$  holds. The same idea is heavily exploited in polynomial commitment, SNARK batch, SNARK recursive [48]. Specially, consider  $n$  proof  $[\pi_i]_{i=0}^{n-1} = \{A_i, B_i, C_i\}_{i=0}^{n-1}$ , the verifier need to check  $n$  equations of  $e(A_i, B_i) = Y_i \cdot e(C_i, h^\delta)$ , where

$$Y_i = e(g^\alpha, h^\beta)^n \cdot e\left(\prod_{i=0}^{n-1} S_i^{\sum_{j=0}^{n-1} a_{i,j} \cdot r^j}, h^\gamma\right)$$

The aggregation will instead check a single randomized equation:

$$\prod_{i=0}^{n-1} e(A_i, B_i)^{r^i} = \prod_{i=0}^{n-1} Y_i^{r^i} \cdot e\left(\prod_{i=0}^{n-1} C_i^{r^i}, h^\delta\right)$$

And we rewritten above equation as:

$$Z_{AB} = Y'_{prod} \cdot e(Z_C, h^\delta)$$

where  $Z_{AB} = \prod_{i=0}^{n-1} e(A_i, B_i)^{r^i}$ ,  $Z_C = \prod_{i=0}^{n-1} C_i^{r^i}$  and  $Y'_{prod} = \prod_{i=0}^{n-1} Y_i^{r^i}$ . And then we will check that  $Z_{AB}, Z_C$  are consistent with the initial proof triples. Here we use two notions: the target inner pairing product (TIPP) and the multi-exponentiation inner product (MIPP) (detail can see [50]).

- TIPP: takes some committed vector  $\mathbf{A} \in \mathbb{G}_1^n, \mathbf{B} \in \mathbb{G}_2^n$  and shows that  $Z_{AB} = \prod_{i=0}^{n-1} e(A_i, B_i)$ ;
- MIPP: takes a committed vector  $\mathbf{C} \in \mathbb{G}_1^n$  and a vector  $\mathbf{r} \in \mathbb{Z}_p^n$  and shows that  $Z_C = \prod_{i=0}^{n-1} C_i^{r^i}$

After that we can use TIPP and MIPP to generate the aggregated proof  $\pi = (\pi_t, \pi_m, T_{AB}, U_{AB}, T_C, U_C, Z_{AB}, Z_C)$ , where the last two elements are required to verify the Groth16 equation, the first two elements used to verify the TIPP and MIPP arguments, and other elements are required for the verifier derive randomness  $r$  in Fiat-Shamir transformation [53]. After verify TIPP and MIPP proof, the regulator use  $Z_{AB}, Z_C$  as the linear combination of the proofs. Then the regulator verify the Groth16 equation using the aggregated proof  $Z_{AB}, Z_C$  and decides whether to move to the next stage.

In the case of CP-SNARK, we need additional element  $D$  of the proof that contains a commitment to the data and to create a CPlink to link  $D$  to the external commitment. Also we need some additional element in CRS to create  $D$  and the CPlink. Nevertheless, the special structure of the proof does

TABLE I. CONFUSION MATRIX

	Actual-Positive	Actual-Negative
Evaluation-Positive	True Positive (TP) $TPR = \frac{TP}{TP+FN}$ $PPV = \frac{TP}{TP+FP}$	False Positive (FP) $FPR = \frac{FP}{FP+TN}$
Evaluation-Negative	False Negative (FN) $FNR = \frac{FN}{TP+FN}$	True Negative (TN) $TNR = \frac{TN}{TN+FP}$

not change. In order to verify the proof, we only need verify equation of the structure:  $e(A, B) = Y \cdot e(C, h^\delta)$ . Thus, we can obtain the aggregated proof in the same way.

### B. Auditing Phase

In this phase, multiple regulators aim to evaluate particular fairness metrics depending on the environment, policy, and industry to determine the fairness of the ML model.

1) *Fairness audit*: Following the common approach in [42], we can use a confusion matrix (see Table I) to compute statistical metrics of ML model, which is what most statistical measures of fairness rely on. The basic notion in confusion matrix as follow:

- True positive (TN): a case when the predicted and actual evaluation are both in the positive class.
- False positive (FP): a case predicted to be in the positive class when the actual outcome belongs to the negative class.
- False negative (FN): a case predicted to be in the negative class when the actual outcome belongs to the positive class.
- True negative (TN): a case when the predicted and actual evaluation are both in the negative class.

Based on these basic concepts, we calculate the fairness metrics. Specifically, the fairness notion we took in this work is as follows: Demographic parity (DP), Equalize odds (EO), Equal opportunity, and Disparate impact (DI). Use these formulation, following the basic paradigm in zk-SNARKs, we can express the whole fairness computation as arithmetic circuit and then generate proof.

2) *Technical observation*: As mentioned earlier, the challenge in generating proof is that we must handle many non-linear operations because we adopt group-based fairness notions, e.g., divides, comparison, sorting, and so on. To resolve the challenge, our framework uses the observation that for a prover to convince a verifier that it knows the output of some non-linear operation, the prover does not actually need to execute the non-linear operation in the circuit. Instead, the prover just needs to prove that the output of the non-linear operations is correct. For example, suppose the prover wants to prove  $z = x/y$  to the verifier. In that case, the prover does not need to straight to compiler divide to a circuit but simply provides a divided result  $z$  as an "advice" and then prove multiplication operation  $x = z \times y$ . Note that the multiplication operation only contain one multiplication gate, so it much more efficient than naive encoding the divide operation to

a circuit (e.g., compute inverse use Fermat's little theorem,  $a \cdot a^{p-2} = 1$ ). The observation is broadly used in literature [24], [39], [54], [55]. Next, we will show how to bring this idea into our framework to help model audit.

3) *Handle non-linear operations*: At a high level, we can split the computation in the audit phase into two-component: one is to evaluate fairness metrics, and the other is to compute the empirical fairness gap. First, we summarize the typical non-linear operation in the auditing process below and then design a protocol to prompt efficiency. The typical operations in statistical fairness evaluate as follow: 1) divides; 2) absolute value; 3) comparison; and 4) maximum or minimum value. To clarify the research methodology, we consider the following examples. First, the regulator needs to compute the basic metrics: TP, FP, TN, and FN. And then calculate fairness metrics like TPR and FRP. Finally, the regulator computes the EFG corresponding fairness notion, such as DP.

For division operations, we have solved as above. For comparison operation, e.g.  $x \geq 0$ , we ask the prover to provide the bit decomposition  $(a_0, \dots, a_k)$  of  $x$  as a witness ( $a_k$  denote sign bit, e.g. positive(1) or negative(0)). Then we can check that: 1) each  $a_i$  is binary:  $a_i(a_i - 1) = 0, \forall i \in [k]$ ; 2) The correctness of bit-decomposition of  $x$ :  $a_k(x - \sum_{i=0}^{k-1} a_i 2^i) + (1 - a_k)(x + \sum_{i=0}^{k-1} a_i 2^i) = 0$ .

In calculating the EFG, we need to find the maximum metrics gap between different group. Naive computation is not feasible because it requires us to make a two-by-two difference between all the elements in the group and then select the maximum gap value. A more thoughtful way is to sort the array and then use the maximum value minus the minimum value to get EFG. Nevertheless, directly representing a sorting algorithm such as QuickSort as a circuit requires a comparison that contains  $O(n \log n)$ , which is expensive. Following the above observation, we asked the prover to provide some "advice" as a witness to improve efficiency, and we can combine absolute and maximum value into one relation. Concretely, assume that we have  $(x_0, \dots, x_{n-1})$  denote the fairness metrics on  $n$  test data and want to compute  $\max |x_i - x_j|$  between different group. The prover is required to provide the maximum  $x_{max}$  and the minimum value  $x_{min}$  in list as an auxiliary witness. Then we can check that  $x_{max}$  is actually the maximum number as follows:

- 1)  $x_{max} - x_j \geq 0 \forall j \in [n]$ .
- 2)  $\exists j \in [n]$  such that  $x_{max} - x_j = 0$ . This condition is equivalent to  $x_{max} \cdot \prod_{j=0}^{n-1} (x_{max} - x_j) = 0$ .

The first condition can be checked by bit-decomposing of  $x_{max} - x_j$  and then checks are exactly the same as the comparison operation. Similarly, the check of  $x_{min}$  is exactly the same as  $x_{max}$  above.

Overall, comparing to straight compute maximize value above, the prover only additionally provides bit-decomposing of maximize and minimize value, and the protocol checks two additional bit decomposition. After all of computation done, the regulator publish all of the commitments, proofs, and audit result with associated signature on bullet board.

TABLE II. EVALUATION PROOF TIME OF FLR MODEL

Dataset	preprocess time(s)	prover time(s)	verifier time(s)
German	2.139	0.736	0.0159
Bank	110.853	34.9684	0.0293
Adult	82.272	26.921	0.0403

### C. Verification Phase

Depending on the application area, regulator is selected to verify the correctness of the audit results. After get the audit result from  $y$ , the client request committed values for the ML models  $cm_m$ , test data  $cm_x$ , and evaluation results  $cm_y$ . The client then request evaluation proof  $\pi_e$  and auditing proof  $\pi_a$  from the bulletin board.

Upon reception of all of message, the client verifies the signature using the public key of the selected regulators and server for the authenticity of commitment, proof and results. If satisfied, client then verifies the evaluation proof  $\pi_e$  and audit proof  $\pi_a$  using the verification key and commitment. If all these verification pass, then the client will be convinced by the regulator's auditing results and thus determinate the fairness of the model.

If the client verify failure then one can identify the misbehaving party and take penalize it, in the form of reputation evaluation, incentives, etc. Then the party responsible for the misleading behavior is deterred and restart a new auditing process. After all checks are successful, the client can determine the correctness of the ML model auditing results.

## VII. EVALUATION

We implemented our fairness audit framework and we present the experiment result in this section.

### A. Setup

We have implemented the fairness audit framework in C++ using the libsnark [56] library. We run all of the experiments on 4-core Intel i7-5600k (2.6 GHZ, 8 physical cores) and 48 GB of RAM with Ubuntu18.04. Note that we run our experiments on Docker container. Our current implementation is only use a single CPU core. We report the time in seconds and take the average of 10 runs per experiment as the result.

We used three real-world datasets from various domains: German credit dataset (German), Bank marketing dataset (Bank), and Adult income dataset (Adult) [57]. The datasets vary in size and disparity of minority groups and as such some can be used to create fair or unfair models. In this experiment, we train fair logistic regression (FLR)<sup>1</sup>. Note that due to zk-SNARK systems only support group elements, we use a generic 8-bit unsigned quantization technique to transform float into integers.

<sup>1</sup>The implementation of fair machine learning model is based on the repository <https://github.com/mbilalzafar/fair-classification>.

### B. Performance of Model Query

In this section, we report the performance of the query phase of the model. First, we use FLR model to measure the time to generate evaluation proofs for all three datasets. Since matrix multiplication is involved in all three models, a representative FLR is selected to measure the performance. Table II shows the results of evaluation proof in model query phase. The FLR model needs matrix-vector multiplication between the weight vector and input matrix of test data, where the sizes of input matrix are  $1000 \times 20$  and  $45550 \times 20$ , and  $48880 \times 15$ . As a result, the input test data and the number of samples affect the circuit constraints and thus the performance.

After that we measure the overhead incurred by aggregating the proofs. Due to the different sizes of the three datasets to ensure the fairness of the model, we set different fairness gaps and confidence levels just like in [19]. We performed our test on the mentioned datasets with  $\delta = 0.05$  and  $\epsilon = 0.1$ . Our evaluation result can see in Fig. 2. The results show that aggregated proofs of thousands of proofs are relatively small in size and can be verified in a few seconds. Although the proofs take more time, this is not impractical. In practice, aggregation operations can be performed offline without affecting the online use of the model after deployment.

### C. Performance of Fairness Audit

After query phase, the regulator calculates fairness metrics based on the evaluation results from the server. Thus, we measure computation times of fairness metrics in three datasets. Naturally, we split the data into a training and test subset. The sizes of the three datasets are 200, 9100 and 9000, respectively. In Bank dataset, we use the marital status feature as binary sensitive attribute and income for labels. We considered gender as a binary sensitive variable in Adult and German. Table III shows the evaluation results of fairness audit. The experimental results prove the usefulness of our framework, which takes only a few milliseconds to verify the correctness of the fairness audit results, making it easy for anyone to ensure that they are protected from discrimination. In addition, both preprocessing and prove times are within acceptable bounds.

## VIII. DISCUSSION AND FUTURE WORK

One problem with the Groth16 system used in the framework instantiation, despite its state-of-the-art proof scale, is that it requires a trusted third party to generate the CRS used to construct the proofs. While it is possible to use MPC to generate reliable CRS [58], a transparent zkp system [28] could be used instead to avoid trusted party, which is left for future exploration. We expect that better ZK systems will emerge to replace the ZKP schemes we use and thus improve the efficiency of proposed framework. In order to achieve optimal ZK systems in all aspects, such as proof size, proofing time, etc., one promising direction is proof composition [37], [59]. Also, we can naturally extend our work to support confidential model prediction and model accuracy assessment [39], [40].

For future work, we want to explore further protecting the privacy of test data on the server. Especially since there are no publicly available test data and the user data is susceptible in some scenarios. A promising direction is the use of verifiable

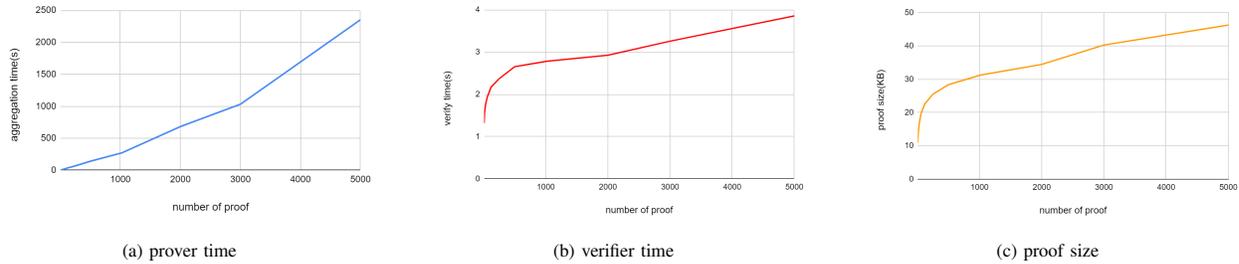

Fig. 2. Performance of Aggregation

TABLE III. FAIRNESS AUDIT PERFORMANCE OF FLR MODEL ON THREE DATASETS

Dataset	preprocess time(s)				prover time(s)				verifier time(s)			
	DP	EO	EOP	DI	DP	EO	EOP	DI	DP	EO	EOP	DI

encryption techniques [60] to ensure integrity and confidentiality. Finally, it is also interesting to explore other fairness definitions beyond group-based as a research direction.

## IX. CONCLUSION

This work proposes a framework to prompt publicly fair audits for a machine learning model. Unlike previous work, our construction only assumes the third-party collection test data and does not rely on the third party. We minimize the trust between the server, the regulator, and the client. Also, our framework can support multiple regulators to provide more strength and border fairness without additional trust assumptions. Our experimental evaluation confirms that our framework is practical for fairness auditing ML models with real datasets.

## ACKNOWLEDGMENT

The authors would like to thank Dr. Jiasi Weng for valuable and helpful discussions on this work. Wuzheng Tan was supported by National Natural Science Foundation of China (Grant Nos. 62272199).

**Abstract**—The digitization of receipts and invoices, and the recording of expenses in industry and accounting have begun to be used in the field of finance tracking. However, 100% success in character recognition for document digitization has not yet been achieved. In this study, a new Optical Character Recognition (OCR) engine called Nacsoft OCR was developed on Turkish receipt data by using artificial intelligence methods. The proposed OCR engine has been compared to widely used engines, Easy OCR, Tesseract OCR, and the Google Vision API. The benchmarking was made on English and Turkish receipts, and the accuracies of OCR engines in terms of character recognition and their speeds are presented. It is known that OCR character recognition engines perform better at word recognition when provided word position information. Therefore, the performance of the Nacsoft OCR engine in determining the word position was also compared with the performance of the other OCR engines, and the results were presented.

**Keywords**—Optical Character Recognition (OCR); image processing; deep learning; benchmarking; receipt

## I. INTRODUCTION

With the introduction of computers into our lives, important documents for the user began to be stored in the computer environment. Although most documents are stored electronically, there are still printed-paper documents that we frequently use in daily life. Invoices and receipts which are among such documents printed on nondurable paper contains information that needs to be saved. When it comes to saving and storing a paper document, the first thing that comes to mind is to scan the document and store the document image in electronic environment. With this method, documents can be stored properly by gaining space. Nevertheless, operations such as listing, sorting and processing these document images are carried out by people, which means a loss of time and resources, especially for companies. In order to meet this need, Optical Character Recognition (OCR) engines have been developed to automate the processing of document images. OCR engines have been developed to read the images containing the text and convert them into processable text outputs.

The most obvious examples of digitized printed documents are receipts and invoices. Receipts and invoices carry data on them that may be important to the user, such as amount, tax, date. The user may wish to store or process this information. Applications have been developed to meet these needs of the user. The common purpose of these applications is to enable the user to track his or her or someone else's spending, store and rank their spending. These applications may encounter many problems when reading the receipt data. Since receipts

and invoices are made of paper, they are nondurable, so they wrinkle very quickly, wear out in a short time and the writing on them can be easily erased. In addition, factors such as different fonts, images, shapes, presentation of information in the form of tables, background of the receipt image, and oblique withdrawal of the receipt make the situation more difficult. These factors are examples of problems that make it difficult to read a receipt. In the applications mentioned, it is necessary to use the OCR engine, which gives the best result despite these problems. The field of OCR is a field that attracts a lot of attention and is competitive. For this reason, there are many OCR engines produced. Since OCR engines are mostly useful for large companies, most OCR engines produced are for commercial purposes and the methods used are not shared. The most well-known of the commercially produced OCR engines are Amazon Textract and Google Vision Api. Unlike commercially produced OCR engines, there are also a small number of open source OCR engines. Examples of open source OCR engines are Tesseract [1], Easy OCR [2] and OCRopus [3].

The aim of this study is to develop an open source OCR engine using artificial intelligence methods. The developed OCR engine is trained using receipt data. The receipt dataset is difficult to find because the receipt images contain personal information belonging to the user. For this reason, we need to create the dataset to be used for training ourselves. Since all of the data obtained by us consisted of Turkish receipts, Turkish receipt images were used for the training. The success of the developed OCR engine is compared to other existing OCR engines. For comparison, both Turkish receipt dataset and English receipt dataset were used. Since the training dataset consists of Turkish receipt images, the comparison of the achievements of OCR engines was also made on Turkish receipts. As mentioned earlier, these receipts contain the personal information of the owner on them. For this reason, the Turkish dataset and the results of the comparison cannot be shared. Both for the sharing of the comparison results and to measure the success of the developed OCR engine in different datasets, the comparison is also made on the English receipt data. Test images from the ICDAR-2019 SROIE [4] competition were used for the English receipt dataset.

Although this study focuses on only one document type, the methods used can be applied to other document types. The method used in the study consists of three main headings. These; pre-preparation, word detection and word reading. In the preliminary preparation stage, the receipt areas are determined in the visual by passing through the visual masking and

segmentation model that comes first. Then, the corner detection algorithm is operated on the obtained mask and the perspective process is applied by detecting the four corners of the receipt. Thus, the receipt image is freed from unnecessary background and more focus is provided on the regions containing text. In the next step, the object detection algorithm is applied to the image obtained and the locations of the words in the receipt are determined. In the final stage, the words detected are passed through the Convolutional Recurrent Neural Network (C-RNN) [5] model and the reading process is performed. In this way, the incoming receipt image is OCR'd and the text output is produced. The success of the OCR engine developed in this study is compared to Tesseract, Easy OCR and Google Vision Api. When making the comparison, the test dataset consisting of Turkish receipt images selected by us and not used during the training phase and also English receipt data from the ICDAR2019-SROIE competition is used. Comparisons are evaluated on the basis of speed and accuracy, and the results from each dataset are shown in separate tables.

The flow in this article can be summarized as follows. In the following part of the study, the OCR engine developed will be explained. The method and dataset used in this regard will be detailed. In Section III, the success of the proposed OCR engine will be detailed from the dataset used to compare it with other commonly used OCR engines and the benchmark metrics used. Section IV contains the results from the comparison, interpretations and analyses of these results. Section V briefly summarizes our work and talks about the work to be done in the future.

## II. RELATED WORK

OCR engines have been a topic of interest for a long time. Even though studies have been carried out for a long time, the OCR problem is still not a solved problem. However, there are OCR engines that can achieve high success compared to others. Applications such as Amazon Textract and Google Vision Api, which are among these OCR engines, are chargeable to use. Since OCR engines are generally produced for commercial purposes, very few open source OCR engines are available. The most well-known open source OCR engine in the literature is Tesseract. Tesseract OCR engine differs from our study in terms of the methods it uses. While deep learning methods are used for OCR in our study, Tesseract performs OCR with pixel operations. The Tesseract OCR engine first determines the text areas in the image by performing page layout analysis. Blobs are obtained by applying connected component analysis in the specified text fields. The detected blobs are then separated into lines and words. After the words are divided into characters with two different methods, the text recognition process is performed using the two-pass adaptive classifier.

Apart from the Tesseract OCR engine, there is another open source OCR engine called OCRopus. This OCR engine, first determines the text fields by page layout analysis like Tesseract. Then the text fields determined by the page layout are sent to the Text Line Recognition stage, and the language of the text and the writing direction of the text (right to left, left to right) are determined. It uses dynamic programming algorithm for character detection and multi-layer perceptrons (MLPs) for character recognition. There is also a study [6], which uses slightly more modern methods and whose text

recognition stage is similar to our work. In the text detection phase, all contours are detected with the Canny algorithm and then lines are determined using these contours. Then, preprocessing operations such as Noise removal, perspective correction, baseline correction are applied to improve the reading process before the text recognition stage. The lines detected in the text detection stage are divided into smaller pieces by the sliding window method for the reading process. The image pieces obtained from the lines are then sent to the text recognition model. First, features are obtained by passing the incoming image pieces through the encoder consisting of Convolution layers. Then, these features are passed through the Bidirectional Long-Short Term Memory (Bi-LSTM) and Connectionist Temporal Classification (CTC) layer, which is the decoder part of the model, and text outputs are produced.

Unlike these [1], [3], [6] studies, [7] study describes a new method for reading clipped words from document data. In this method, the incoming word image is first passed through an encoder called the Gated Recurrent Convolution Neural Network (GRCNN). The features obtained in the encoder section are then sent to the decoder consisting of Bi-LSTM and CTC layers, and text outputs are produced. The aforementioned [1], [3], [6], [7] studies were developed using document data, similar to our study. In the OCR field, there is also OCR in Natural Scene data, in addition to document data. Although the OCR issue in Natural Scene data is similar to the OCR issue in document data, it is a much more difficult problem. While some studies on Natural Scene data focused only on text recognition [8], [9], [10], some others [11], [12], [13], [14] tried to solve the text detection and recognition issue together.

## III. METHODOLOGY

In this section, all stages of the developed OCR engine are examined in detail. The OCR engine mentioned in this study was developed through three basic processes. In the preliminary preparation stage, which is the first stage; the incoming receipt image is subjected to multiple processes for the detection of text fields. In the second stage, word positions are determined on the full-screen receipt image, which is the output of the first stage. In the final stage, the detected words are clipped and sent to the "word reading model" and the reading process is performed. The diagram given in Fig. 1 summarizes the process mentioned. The details of the processes are given in the following subheadings.

### A. Preliminary Preparation

Receipt images sent to the OCR engine and expected to be read often come with background images and taken from different angles. The input image can also contain a background image, as shown in Fig. 2. In such a case, the detection of text fields is even more difficult. Factors such as the constant change of the background, the position of the receipt in the image, the obliquity of the receipt are just some of the reasons that will make it difficult to determine the text field. For this reason, the receipt image is passed through the preliminary preparation stage before the text fields on it are detected. The purpose of the preliminary stage is to obtain a full-screen and vertical image of the receipt in the image, free from the background image, and to send the clean receipt image to the text detection stage.

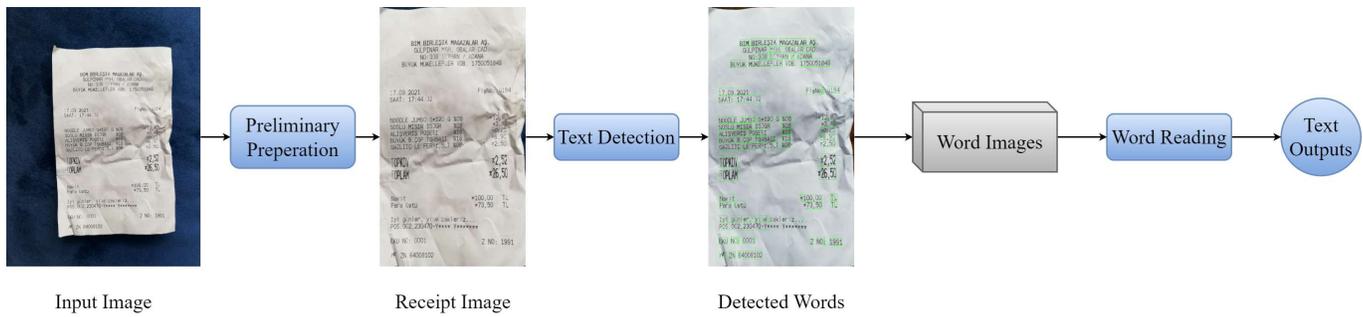

Fig. 1. The diagram that shows all the stages and outputs of the OCR model

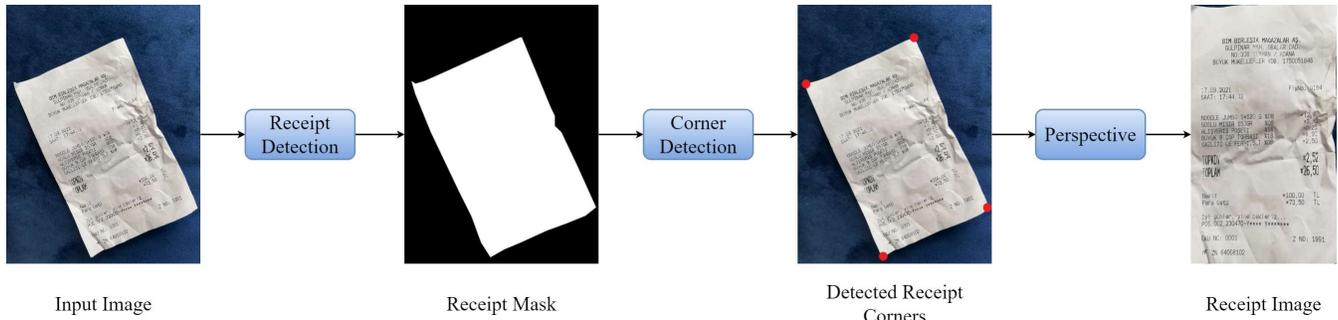

Fig. 2. The processes and outputs of the preliminary stage

Fig. 2 also appears to detail the inside of the box called Pre-processing in Fig. 1. The preliminary preparation phase consists of three steps. These can be listed as (i) determination of the receipt area (receipt mask formation), (ii) determination of receipt corners, and (iii) application of the perspective process. Masking model is used to determine the receipt area. The purpose of the masking model is to produce a mask of the objects in the visual and labeled in the training data. In the training of the masking model, the input visual for the input and the mask of the same resolution as the expected output are required. An example of an input image is the Input Image in Fig. 2. While the mask of this image is produced, the receipt field in the image is labeled with the help of a tool called LabelMe [15]. The tagged receipt field has a value of 1, while the background without a receipt is 0. When this matrix is converted to a image, the Receipt Mask given in Fig. 2 is obtained. This is how the dataset for the training of the masking model is prepared.

The masking model is based on the Convolutional Encoder-Decoder method. The resolution of the model input is reduced as the layers progress. This part is known as the Encoder and is the part where the Model draws information from the image. Then, in the Decoder stage, the image that is reduced in the Encoder stage is restored again. Finally, the mask of the input image is produced by passing through the classification layer. Depending on the number of classes in the training dataset, the activation function of this classification layer can be Sigmoid or Softmax. Since the OCR engine mentioned in this study has a single class of receipt field, the last layer of the masking model used is passed through the Sigmoid activation function. As an output, a matrix consisting of numbers between 0 and 1 in the input image resolution is obtained. In this matrix, pixels

that are close to zero are considered as backgrounds, while pixels with a value closer to one are considered as receipt areas. The receipt area in the receipt image is thus estimated.

There are multiple Encoder-Decoder methods for the masking model. As the masking model used in this study, the most appropriate Encoder-Decoder method was selected among the methods presented in the segmentation\_models [16] library by trying. Among the methods available in this library, only the achievements of Unet [17] and Linknet [18] Encoder-Decoder methods are compared. After selecting the Encoder-Decoder method for the masking model, it is necessary to select a Backbone for the Encoder. As skeletal model, VGG16 [19] and Resnet34 [20] models with similar parameter numbers are compared. A mobilenetv2 [21] model with a lower number of parameters has also been added to the comparison. As a result, the most appropriate masking model was selected by comparing two different Encoder-Decoder methods and three different Skeletons. The results obtained are shown in Table I.

When comparing, dataset and training parameters were kept constant. The dataset used in the comparison consists of the same data as the dataset of the masking model used in the OCR engine mentioned in this study. The dataset contains a

TABLE I. COMPARISON OF COMPARING THE SUCCESSES OF MASKING MODELS. (BATCH SIZE: 8, EPOCHS: 50, METRICS: IOU, SAVEBESTVAL\_IOU\_ACC, INPUT RESOLUTION: 512,512)

Model	Mobilenetv2 Unet	VGG16 Unet	Resnet34 Unet	Mobilenetv2 Linknet	VGG16 Linknet	Resnet34 Linknet
Duration (Sec)	0.0926	0.1070	0.0908	0.0880	0.1004	<b>0.0870</b>
IoU%	98.28	98.42	98.40	98.17	<b>98.44</b>	98.31

total of 1352 background receipt images. 10 percent of this data is reserved for testing. The results given in Table I were obtained using this training and testing dataset. In training, bce\_jaccard\_loss was used as a loss function. The remaining parameters are found in the description of Table I. Each model is trained by up to 50 epochs and the best Val\_IoU values are used for success comparison. Then the average elapsed time for a receipt estimate was used to compare the model speed. Test data were used for duration and success measurement. When the results given in Table I are examined, it is understood that there is not much difference between them. However, if it is necessary to choose the most suitable model, the Resnet34 Unet should be chosen due to its proximity to the highest success and lowest speed. In this study, Resnet34 is used as Skeleton and Unet is used as Encoder-Decoder method in the masking model.

Using the masking model, the receipt areas in the incoming receipt image are determined. This process alone is not enough. The detected receipt area needs to be separated from the unnecessary background. Perspective process is used in this study both to get rid of unnecessary background and to correct oblique receipt images. The perspective process converts images that are oblique, such as the input image given in Fig. 2, into full-screen images such as the Receipt Image in Fig. 2. For this, the four corners of the region to be applied to the perspective process (in this case, the receipt area in the image) must be determined correctly. The receipt mask obtained from the Masking model is used for corner determination. The edges of the receipt image are determined using the Canny function in the OpenCV library on the receipt mask. Then, the output consisting of black and white images with edges is sent to the findContours function and the corner points in the receipt mask are determined. Using the positions of the obtained corner points, the best four corners to represent the receipt mask are selected. Finally, the positions of these four designated verticals are sent to the getPerspectiveTransform. The output of this function is sent to the warpPerspective function and the Receipt Image in Fig. 2 with perspective applied is generated.

**B. Text Detection**

At this stage, the receipt visual, which is the output of the preliminary preparation stage, is taken as input. In order to read the incoming receipt image, the text fields must first be determined. In this study, object detection algorithm is used for the detection of text fields. Object detection algorithms are used to determine the position of pre-labeled objects in the image or video. In this study, the task of the object detection algorithm is to detect the text fields on the receipt image that comes as a full screen. The dataset used for the object detection algorithm is labeled using a tool called LabelMe. The data used in the dataset are the receipt images from the preliminary preparation stage. When this data is labeled, each word in the receipt image is labeled as belonging to the same object class. The dataset consists entirely of Turkish receipt images and consists of 552 data in total. 10 percent of this dataset is reserved for test data.

In this study, You Only Look Once (YOLO) model is used due to its speed and success. For word detection, YOLO V3 [22] and YOLO V4 [23] models were compared and the most appropriate model was selected. For the training, a dataset

Fig. 3. The Words Detected by YOLO Models on the Sample Turkish Receipt (Blue Boxes), the Output of the YOLO V3 (Left), the Output of the YOLO V4 (Right)

consisting of Turkish receipt data used in Text Detection was used. For success comparison, 10 percent of the dataset was used as a test dataset. Accuracy was taken into account as a benchmark. In comparison, the batch size and model resolution are kept the same. Average Precision, IoU, F1 Score are used as comparison metrics. The darknet [24] library, which is also used in YOLO training, was used to calculate the mentioned metrics of YOLO models. The results from the comparison are shared in Table II. In Fig. 3, the words detected by both YOLO models in the sample Turkish receipt image are seen. Although the difference in success is not clearly seen in Fig. 3, when Table II is examined, it is seen that the YOLO V4 model gives the best result in all categories. For this reason, YOLO V4 model is used in the word detection model.

**C. Word Reading**

The word reading stage is reached with the word positions determined during the text detection phase. At this stage, words are clipped from the receipt image using word positions. The cropped words are read by means of the reading model. C-RNN is used as a word reading model in this study. The dataset used for the training of the model consists of words clipped from Turkish receipt images. Words are manually tagged. Although Turkish data are used in the training dataset, the words are labeled according to the Latin alphabet. The reason for this is that there are letters in Turkish that are very similar to each other (ç-c, ö-o, i-ı ...). These letters create ambiguity due to their similarities, and labeling them as a single class increases success by eliminating uncertainty. For this reason, the training dataset is labeled according to the characters in the Latin alphabet. The dataset consists of 68,000 Turkish words

TABLE II. COMPARISON OF THE ACHIEVEMENTS OF YOLO MODELS

Model	Average Precision	IoU	F1 Score
YOLO V3	84.31	59.50	0.80
YOLO V4	<b>86.61</b>	<b>65.5</b>	<b>0.83</b>

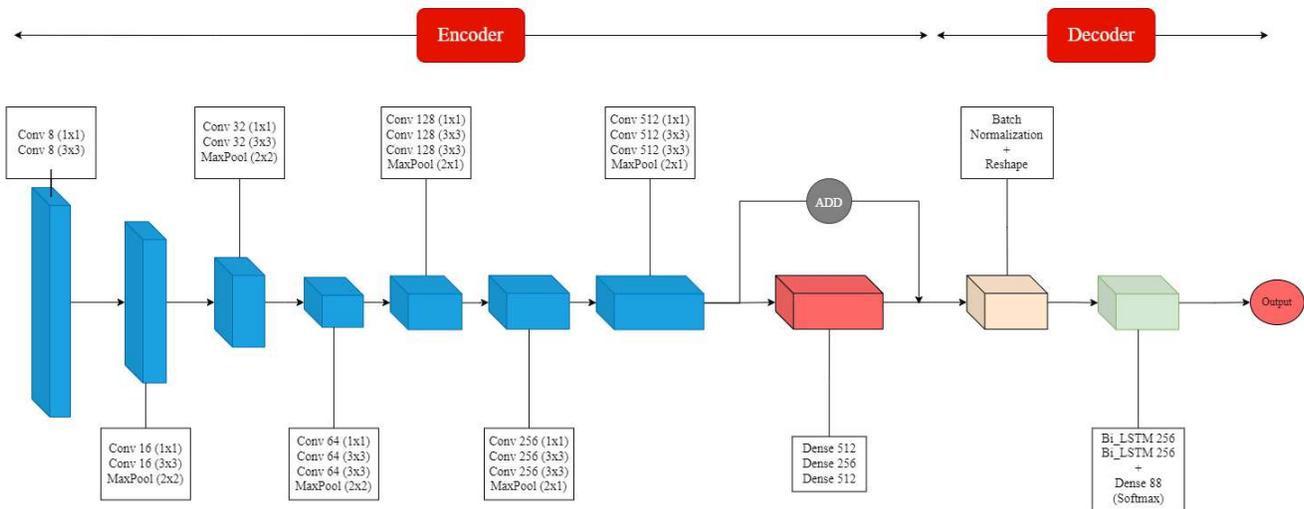

Fig. 4. The C-RNN model scheme used as a word reading model

that are clipped and labeled from approximately 1,100 receipt images. 10 percent of this Turkish data is reserved for the test dataset.

The C-RNN model used for the word reading model is based on the principle of Convolutional Encoder and Recurrent Decoder. As seen in Fig. 4, the incoming word image is first passed through the Convolutional layers. In this section, the information of the letters in the word is obtained. Then, wordprintouts are produced by looking at this information in the Bi-LSTM layer. CTC-Loss is used as the loss function in the model. The model takes words with resolution (256,64,1) as input. During the model prediction, word predictions are produced by passing the word outputs through the ctc\_decode function in the [25] Keras library. After this stage, the words on the receipt and the positions of these words are known. Using this information, the lines are determined. Thus, the text output with specified lines that are the output of the OCR engine is produced.

The word reading model consists of two parts: Encoder and Decoder. While creating the word reading model seen in Fig. 4, various methods were tried on the Encoder and Decoder layers. If we need to talk about the methods used in the Encoder section, some of them can be listed as follows: (i) The stride value was made 2 by using the Convolution layer instead of the pooling layer. (ii) If there are three consecutive Convolution layers, the first layer output is summed up with the third layer output. (iii) The number of Convolution layers before the pooling layer was reduced to one in order to create a simpler model and to increase success. (iv) The activation function used and the output dimension were changed. (v) A feed forward layer has been added to the end of the convolution layer, as shown in Fig. 4. Multiple encoder models were developed using such methods, and the most successful Encoder model seen in Fig. 4 was selected among them. When changing the encoder model, the parameters used in the training and the Decoder model were kept completely constant.

After the encoder model is selected, the Decoder model should be selected as the most successful. The methods used

for this can be listed as follows: (i) The activation function and output dimension used were changed. (ii) Instead of using bidirectional LSTM, two forward directional and two backward directional LSTMs were used and their outputs were combined. (iii) It was attempted to transfer the LSTM hidden state to the next LSTM layer, but this method was not used because it reduced the success as expected. (iv) LSTM outputs were collected with each other. (v) A feed forward layer has been added after the LSTM output. While trying these methods, the training parameters and the encoder model were kept constant. Among the methods tried, the Decoder model in Fig. 4 was selected that gave the most successful result.

## IV. EVALUATIONS

### A. Comparison Dataset

While the success of the OCR engine mentioned in this study was measured, the accuracy of the outputs obtained on the same dataset was compared with other OCR engines. The comparison was performed both in the dataset consisting of Turkish receipts and in the dataset consisting of English receipts. For the success comparison, the production of the OCR engine mentioned in this study requires a dataset that is not used in the preliminary preparation, text detection or word reading stages. A test dataset consisting of Turkish receipts was created for comparison. This dataset consists of 66 Turkish receipt images. These receipt data are labeled on a per-word basis. In Fig. 4, a sample image from the Turkish test dataset is given. When the receipt image is examined, there are Turkish letters such as "İ, Ş, Ü, Ç" in it. Since the OCR engine developed could only read the Latin alphabet, these Turkish letters were converted to similar letters in the Latin alphabet ("I, S, U, C") and tagged. For the sake of equality in comparison, the outputs of all compared OCR engines are also translated into the Latin alphabet. This process was applied only in the Turkish dataset.

As mentioned before, the Turkish dataset used in the comparison cannot be shared because it contains personal information. For this reason, in addition to the Turkish dataset,

the ICDAR2019-SROIE dataset, which consists of English receipt data, is also used. Since the OCR engines were also compared in the receipt dataset in the ICDAR2019-SROIE competition, test images of the same dataset were used to compare the OCR engine produced in this study with other OCR engines. Since the text positions are given on a word-by-word basis in the outputs of the compared OCR engines, the dataset to be compared must also be labeled as words. Since the ICDAR2019-SROIE dataset where the comparison will be made is labeled on a sentence-by-sentence basis, these tags need to be broken down and converted into word tags. When performing this operation, if there are spaces in the labeled text in the dataset, this text is divided into more words than the number of spaces. The process of shredding this tagged text was carried out by us. This English dataset is labeled by the contest holders with all letters capitalized. For this reason, the comparison was made after the outputs of all OCR engines were converted to capital letters. This process was applied to the English dataset only.

The application called LabelMe was used when labeling words. Thanks to the LabelMe application, words and word positions are saved in a file by manually labeling the data. Each word saved in the file is saved in the (LeftTopCornerX LeftTopCornerY RightLowerCornerX RightLowerCornerY Word) format. Only a single word is stored in each line of the file and only the words in a receipt are stored in each file. The order in which words are labeled is not important because then each tagged word is matched to the words read by OCR engines.

### B. Comparison Method

The comparison of OCR engines is based on speed and accuracy. The accuracy category includes two main issues. These are the success of Word Reading and Word Position Detection. These categories are the same as task 1 and task 2 in the ICDAR2019-SROIE study. The first task in the competition measures how accurately the contestants determine the positions of the words on the receipt. In the second task of the competition, it is measured how accurately the competitors read the text in the receipt image. In the ICDAR2019-SROIE competition, they used Precision, Recall and F1-Score to measure success in both tasks. These metrics are not enough to measure the success of an OCR engine. For this reason, while comparing OCR engines in this study, in addition to these metrics, Character Error Rate (CER) metric was used in word reading success and IoU metric was used in word position determination. As mentioned in the Comparison Dataset section of the article each receipt is labeled mixed on a word basis. Since the words and positions obtained by reading the receipt image with the OCR engine are also mixed, it is necessary to match the labeled data with the data read by the OCR engine to measure the success of the OCR engine.

When matching words, it is necessary to match them correctly. OCR engines may have guessed more or less than the words tagged. In order to prevent this situation, it is aimed to achieve the highest success in matching. Compared the tagged words with all the predicted words and recorded CER achievements. The achievements are recorded in the list and converted into a table in the size of (Number of Tagged Word X Number of Words Read). Then, starting from the first row of the table, the word with the highest achievement in the row

is determined. If this word also has the highest achievement in the column and is higher than the specified threshold value, the labeled word in the index of the row it is in is matched to the read word in the index of the column in which it is located. To prevent the matched words from being re-matched, the achievement values in the table where CER achievements are recorded are equalized to zero. Calculations are made after all the words are matched to each other. When performing calculations, the paired words are taken as True Positive ( $TP$ ), while the predicted but unmatched words are taken as False Positive. In addition, words that are not predicted but are labeled are considered False Negative ( $FN$ ). The total number of words matched in a receipt is shown as  $TP_n$ . With these definitions, formulas to be used in success comparison are produced. The formulas used are shown as Eq. (1) and Eq. (2).

## V. RESULTS

Two different categories are taken into account when comparing OCR engines. These are Speed and Accuracy. The accuracy category is similar to the ICDAR2019-SROIE competition and is divided into two as Word Position Detection Success and Word Reading Success. The speed of OCR engines depends on the system being tested. In particular, offline OCR engines such as Easy OCR and Tesseract OCR depend on the power of the system. For this reason, all OCR engines were tested from the same computer and success measurements were made. The processor of the system in which the tests are carried out is Intel i5-11400H 2.7 GHz, the amount of Ram is 16GB, the Graphics Card is NVIDIA RTX 3050TI (Mobile) and CUDA Version 11.7.

### A. Speed Achievement

For companies that use the OCR engine in a product, the document reading speed of the OCR engine is important. The use of a slow OCR engine in a project involving the use of the OCR engine leads to the accumulation of work, thus wasting time for the customer, the project user, and therefore dissatisfaction. For this reason, the speeds of OCR engines are compared in this section. When measuring the speed of the OCR engine, the reading speeds of all the receipts in the dataset used were measured. The sum of these speeds is then averaged by dividing them by the total number of receipts. This results in the average time spent by the OCR engine on a receipt. While the speed of Easy OCR, Tesseract OCR and Nacsoft OCR depends on the system specifications, the speed cannot be measured on the computer where the test results are obtained because the Google Vision Api does not work on the local computer. For this reason, Google Vision Api is not included in the speed measurement. The results obtained in Table III are given.

TABLE III. COMPARISON OF THE DURATION ACHIEVEMENTS OF OCR ENGINES IN THE ENGLISH DATASET

OCR Engine	Easy OCR	Tesseract OCR	Nacsoft OCR
Mean of Time (sec)	0.89	1.88	<b>0.45</b>

TABLE IV. COMPARISON OF THE WORD READING ACHIEVEMENTS OF OCR ENGINES IN THE TURKISH DATASET

OCR Engine	Easy OCR	Tesseract OCR	Vision Api	Nacsoft OCR
Word Reading Success (CER)	79.49	85.10	91.48	<b>93.89</b>
Precision	71.57	82.67	84.12	<b>88.04</b>
Recall	78.26	39.88	<b>92.71</b>	90.07
F1 Score	74.66	52.68	88.15	<b>89.01</b>

TABLE V. COMPARISON OF THE WORD READING ACHIEVEMENTS OF OCR ENGINES IN THE ENGLISH DATASET

OCR Engine	Easy OCR	Tesseract OCR	Vision Api	Nacsoft OCR
Word Reading Success (CER)	88.50	92.90	<b>94.63</b>	90.77
Precision	84.90	<b>92.58</b>	86.30	83.92
Recall	83.11	75.80	<b>92.41</b>	80.91
F1 Score	83.75	82.72	<b>89.13</b>	81.88

### B. Word Reading Success

Another important metric of OCR engines is Word Reading Success. The accuracy of the information contained in the document read by the OCR engine directly depends on the success of reading words. The success of reading words also affects the success in extracting information from the text read. Although there is no OCR engine that reads all documents correctly, it is desired to choose the OCR engine that gives the highest success possible. In this section, the success of reading the words on the receipts is compared. When measuring reading success, the word matching method mentioned in the Method section was used and then the CER value was measured among the matched words. The achievements are added together and divided by the total number of matched words ( $TP_n$ ). Thus, the Word Reading Success of a receipt as defined in Eq. (1) is measured. The achievements of these receipts are then summed up and divided by the number of receipts in the dataset. As a result, the Word Reading Success of the dataset is obtained. Table IV shows the success results in the Turkish receipt dataset, while Table V shows the success results obtained from the English receipt dataset.

$$\frac{\sum_{i=1}^{TP_n} CER_i}{TP_n} \quad (1)$$

When Table IV and Table V are examined, Tesseract OCR has high precision and low recall accuracy. This means that the Tesseract OCR engine predicts a small fraction of the words it needs to guess, but the words it predicts are mostly the words that are on the receipt. This difference between the precision and recall categories is only visible in the Tesseract OCR engine. When the results in Table IV are examined, it is seen that the Nacsoft OCR engine, whose methods are described in this study, has the best accuracy rate in almost all categories. When Table V is examined, it is seen that Nacsoft OCR engine gives close results to other OCR engines. Judging by the results of the Vision api in Table IV and Table V, it is seen that it gives the best success in the dataset consisting of English receipts, and in the Turkish dataset, it comes after the Nacsoft OCR engine with a close difference.

TABLE VI. COMPARISON OF THE WORD POSITION DETECTION ACHIEVEMENTS OF OCR ENGINES IN THE TURKISH DATASET

OCR Engine	Easy OCR	Tesseract OCR	Vision Api	Nacsoft OCR
Word Position Detection Success (IoU)	65.34	77.04	<b>84.03</b>	78.75
Precision	85.55	80.02	88.82	<b>92.68</b>
Recall	93.37	38.85	<b>97.90</b>	94.79
F1 Score	89.16	51.26	93.08	<b>93.69</b>

TABLE VII. COMPARISON OF THE WORD POSITION DETECTION ACHIEVEMENTS OF OCR ENGINES IN THE ENGLISH DATASET

OCR Engine	Easy OCR	Tesseract OCR	Vision Api	Nacsoft OCR
Word Position Detection Success (IoU)	66.87	<b>77.73</b>	75.94	76.86
Precision	92.10	<b>93.13</b>	90.01	90.74
Recall	89.92	76.44	<b>96.38</b>	86.88
F1 Score	90.72	83.40	<b>92.96</b>	88.16

### C. Word Position Detection Success

Determining the position of the word is important in extracting information from the text. IoU is used when calculating the success of word positioning. IoU is measured between the matched words in the word matching section mentioned in the method section. By adding up the achievements and dividing them by the total number of matched words, the Word Position Determination success of a receipt data as defined in Eq. (2) is measured. In this way, the IoU success of all receipts in the dataset is measured and the results obtained are collected. Then, the total value obtained is divided by the number of receipts in the dataset, measuring the Word Position Detection Success of the OCR engine in the dataset. Table VI shows the success results in the Turkish receipt dataset, while Table VII shows the success results obtained from the English receipt dataset.

$$\frac{\sum_{i=1}^{TP_n} IoU_i}{TP_n} \quad (2)$$

An examination of the results of the Tesseract OCR engine in Table VI and Table VII shows high precision and low recall as mentioned earlier. When the results of the Easy OCR engine are examined, Table VI and Table VII have the lowest accuracy of word position detection success. The Vision Api has the best success in both Turkish and English datasets. A review of the results of the Nacsoft OCR engine in Table VI shows that it has the best F1-Score accuracy compared to other OCR engines, but it surpasses the Vision Api in word position detection achievement.

## VI. CONCLUSION

In the study, OCR engine was developed on Turkish receipt data by using artificial intelligence methods. The success of the developed Nacsoft OCR engine was compared with the success of Tesseract OCR, Easy OCR and Google Vision Api on English and Turkish receipt data. When the results obtained are examined, Nacsoft OCR gives better results in Turkish receipt data than other open source OCR engines, but cannot

reach the same result in English receipt data. This may be due to the fact that the training dataset consists only of Turkish receipts. In addition, the low number of data used in the training of the Nacsoft OCR engine may also adversely affect success. According to this situation, success can be increased by increasing the number of data used in the training of the Nacsoft OCR engine and adding English data to the training dataset. In the training of the Nacsoft OCR engine in future studies, other document types besides the receipt data can be included in the training.

#### ACKNOWLEDGMENTS

We would like to thank Nacsoft for providing their anonymous receipt data.

#### DATA AVAILABILITY

The Turkish datasets used in this study to train the models cannot be shared due to they contain personal data. English receipt dataset that used for comparison in our study and also in ICDAR-2019-SROIE competition can be found here.

#### CONFLICT OF INTEREST

We have no conflicts of interest to disclose.

#### FUNDING DECLARATION

This work is supported by Turkey's National Small and Medium Enterprises Development Organization (KOSGEB). The project's title is "The development of machine learning software enabling the reading, analysis, and administration of invoices and receipts".

# A Survey on Blockchain Technology Concepts, Applications and Security

Asma Mubark Alqahtani<sup>1</sup>, Abdulmohsen Algarni<sup>2</sup>  
College of Computer Science, King Khalid University  
Abha, Asir, Saudi Arabia<sup>1,2</sup>

**Abstract**—In the past decade, blockchain technology has become increasingly prevalent in our daily lives. This technology consists of a chain of blocks that contains the history of transactions and information about its users. Distributed digital ledgers are used in blockchain. A transparent environment is created by using this technology, allowing encrypted secure transactions to be verified and approved by all users. As a powerful tool, blockchain can be utilized for a wide range of useful purposes in everyday life including cryptocurrency, Internet-of-Things (IoT), finance, reputation system, and healthcare. This paper aims to provide an overview of blockchain technology and its security issues for users and researchers. In particular, those who conduct their business using blockchain technology. This paper includes a comparison of consensus algorithms and a description of cryptography. Further, most applications used in blockchain are focused on in this paper also analyzing real attacks and then summarizing security measures in blockchain. Even though Blockchain holds a promising scope of development in several sectors, it is prone to several security and vulnerability issues that arise from different types of blockchain networks which represent a challenge to deal with blockchain. Finally, as a research community, we encourage future research challenges that can be addressed to improve security in blockchain systems.

**Keywords**—Blockchain; cryptography; cryptocurrency; consensus algorithms; blockchain security

## I. INTRODUCTION

Blockchain is based on a decentralized, unchangeable database that makes it simpler to record assets and keep track of transactions in a corporate network. An asset may be tangible or intangible. On a blockchain network, virtually anything of value may be stored and traded, reducing risk and improving efficiency for all users. Generally, a blockchain is a digital ledger of transactions that are being recorded. It is decentralized and is not controlled by any individual, group, or company [1].

As a structured technology, blockchain can be very difficult to change without the approval of the people who use it. Blockchain stores data as a decentralized ledger. Participants in this network can read, write, and verify transactions. Transactions cannot be modified or deleted. To support and secure the blockchain system, digital signatures, hash functions, and other cryptographic functions are used. These primitives ensure that transactions recorded in the ledger are integrity-protected and authenticated. This technology is called blockchain because new blocks are linked to older ones to form a chain. The first appearance of this term was a publication written by S. Haber and W.S. Stornetta in 1991 [2]. In general, blockchain technology is credited to Satoshi Nakamoto, who developed

the theory and implemented the technology in 2008 and 2009, respectively in the cryptocurrency Bitcoin, the most well-known blockchain application. Blockchain technology in recent years has attracted significant attention from academics and industries because of its advanced features. It can be applied to a variety of applications beyond cryptocurrencies. Blockchain technology has become a leading technology of internet interaction systems, including the Internet of Things (IoT) [3].

Our motivation in this paper is to inform and assist someone to become familiar with blockchain technology and its security issues, particularly for those who carry out transactions using blockchain technology and for researchers interested in developing blockchain technology and evaluating its security issues. To search publications and information on the Internet, the first step is to identify keywords such as blockchain, consensus algorithm, cryptography, cryptocurrency, and blockchain security. A second approach is to review papers that have been published in top conferences and journals that deal with blockchain. In this paper, we provide the following main contributions:

- A detailed survey was conducted on blockchain technology.
- A systematic survey of Blockchain applications is conducted in this paper. 10 application areas are considered.
- Security and privacy issues were also addressed.

Therefore, we encourage further efforts to survey and develop blockchain technology for widespread adoption.

The rest of this paper consists of the following sections: In Section II, we provide an overview of the history of blockchain technology. A typical consensus algorithm used in the blockchain is described in Section III. In Section IV, we focused on blockchain applications. In Section V, we summarize the technical risks, attacks, and challenges of security in this area, and in Section VI, we conclude this paper.

## II. HISTORY OF BLOCKCHAIN

Chaum's Ph.D. thesis, published in 1982, was the first to suggest a blockchain as a protocol. A paper by Haber and Stornetta published in 1991 titled "How to Time-Stamp a Digital Document" detailed the concept of time stamping digital data cryptographically [3].

In 1998, Nick Szabo proposed the creation of Bit Gold, an early attempt at the creation of a decentralized virtual currency.

However, Szabo’s attempt to implement Bit Gold is generally regarded as the basis for Satoshi Nakamoto’s bitcoin protocol, even though the project was never implemented [4].

Modern day blockchain technology is widely believed to have been first implemented by Satoshi Nakamoto in 2008. He hypothesized a direct online payment between parties without the use of a third-party intermediary. Rather than relying on trust, that paper presented a cryptographic proof-based electronic payment system [5].

Blockchain was introduced by Ethereum in 2013 as a technology for executing smart contracts on a decentralized platform. With Ethereum, it is possible for developers to create markets, store transactions, and move funds according to written instructions, all without the involvement of middlemen. Unlike Bitcoin, Ethereum is a ledger technology that is being used by companies to develop new programs, which are being expanded beyond the realm of currencies for the first time [6]. With the launch of the Ethereum platform in 2015, blockchain could be used for storing and processing loans and contacts. Using an algorithm known as a smart contract, this technology ensures the implementation of an action between two parties. Due to Ethereum’s ability to provide a faster, safer, and more efficient environment, it became extremely popular. Instead of all the different blockchain projects, Ethereum enables communication via untrusted distributed applications on its own blockchain, thus creating a new concept called Ethereum 2.0 [7].

Hyperledger is open source software for blockchains that was announced by the Linux Foundation in 2015. The Hyperledger blockchain framework aims to build enterprise blockchains, which are different from Bitcoin and Ethereum. Blockchain attracted interest with its capability to enable anonymity, but the real appeal lies in its capability to enable complete privacy. As will be discussed in the fourth section, there have been many applications for blockchain technology that have been discovered across a wide range of industries.

The following Fig. 1 summarizes the history of blockchain technology. Since everyone can participate in Bitcoin and Ethereum’s blockchain networks, they are considered public blockchains. Due to their need to verify participants before joining the network, the Hyperledger blockchain networks are considered private blockchains, also known as permissioned blockchains. The following Table I summarizes the differences between Hyperledger and Ethereum, two popular blockchain platforms and networks.

TABLE I. HYPERLEDGER AND ETHEREUM

Feature	Ethereum	Hyperledger
Purpose	run smart contracts	Businesses
Confidentiality	public network	limited access
Governance	Ethereum developers	Linux Foundation
Participation	permission-free	Only authorized members
Smart contracts	Yes	Yes using chaincode
Programming Language	Solidity	JavaScript, Java, etc
Consensus Mechanism	Yes, PoW,PoS, etc	No
Speed of Transactions	Low	High
Use	Public Applications	Private applications

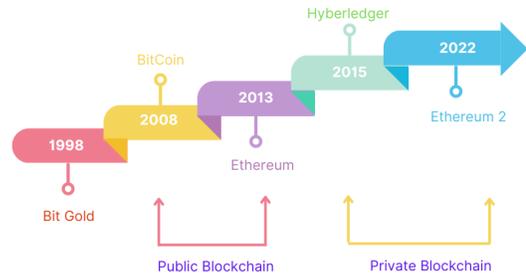

Fig. 1. History of blockchain.

### III. BLOCKCHAIN TECHNOLOGY

#### A. Blockchain Layers

According to Melanie Swan, blockchain technology has passed through two stages. The first stage is blockchain 1.0 represented by Bitcoin, and the second stage is blockchain 2.0 represented by Ethereum. In general, blockchain-based technologies include Bitcoin, Ethereum, Hyperledger, etc [8]. Even though the implementations are varied, there are some similarities in the basic architecture.

Blockchain environments can be classified into five layers, as shown in Table II application, network, contract, consensus, and data layers.

TABLE II. BLOCKCHAIN LAYERS

Layers	Bitcoin	Ethereum	Hyperledger
Application layer	Bitcoin trading	Ethereum trading	Enterprise blockchain
Network layer	TCP	TCP	HTTP
Contract layer	Script	Script	Java
Consensus layer	PoW	PoW/PoS	PBFT/SBFT
Data layer	Merkle tree	Merkle patricia tree	Merkle Bocket tree

Consensus mechanisms are the main component of the consensus layer. In the contract layer, smart contracts are included. Various protocols for data transmission and verification are included in the network layer. In addition, it is pertinent to note that the blockchain is a typical peer-to-peer network. There is no central node and all nodes are connected through a planar topology [9]. It is possible to transact between any two nodes. Each node within the network is free to leave or join anytime. A number of applications are included in the application layer, such as Bitcoin, Ethereum, and Hyperledger.

#### B. Consensus Algorithms

Among the many desirable characteristics of blockchain technology, it is possible to verify the honesty of anonymous users when they enter transactions into the ledger. This is done by validating each transaction to ensure that it is legal

before adding it to a block. Consensus algorithms are used to determine whether new blocks will be added to the blockchain and to ensure trust between parties involved in the blockchain system and to store transactions. As a result, consensus algorithms are the core of all blockchain transactions [10]. Every participant must follow a consensus protocol. There have been several consensus mechanisms developed for blockchains. This includes Proof of State, Delegated Proof of State, Proof of Work, Proof of Elapsed Time, Directed Acyclic Graph, and so on. We will take a look at the most common algorithms shown in Table III.

**Proof of Work (PoW):** The objective of this algorithm is to determine a problem that must be solved through guessing. Bitcoin and Ethereum employ PoW as the algorithm for their consensus. As a result of PoW requiring lots of electricity and time, it is not widely used [11].

**Proof of Stake (PoS):** It ranks second in popularity as a consensus algorithm, and it involves fewer computations than PoW. It minimizes the time and energy waste issues that PoW has. This consensus algorithm replaces the current method for reaching consensus in a distributed system, instead of solving a Proof-of-Work. BlackCoin was the first cryptocurrency to use a PoS [12].

**Proof of Elapsed Time (PoET):** It is a consensus algorithm for blockchain networks that keeps the process more efficient by avoiding over-utilization of resources and high-energy consumption. The PoET method resembles the proof of work method (PoW), but requires less power due to its ability to allow the processor to switch to other tasks after a period of time, which increases efficiency [13].

**Byzantine Fault Tolerance (BFT):** It is aimed at solving problems where there are untrustworthy parties, but they need to achieve consensus. PBFT is designed to improve BFT. With PBFT, if hostile nodes represent fewer than thirty percent of all nodes, then the current state of the blockchain will be agreed upon by all participants. Blockchain systems are more secure when there are more nodes involved. Currently, Hyperledger Fabric is based on PBFT [14].

**Direct Acyclic Graph (DAG):** It consists of vertices and edges, which differentiates it from various consensus algorithms. Transactions are represented by the vertices of the structure. A block is not referred to in this algorithm, nor do we need to use a mining process to add transactions. Each transaction is built upon the previous one rather than being grouped into a block. Several applications of DAG technology can be found in fields that require high speed and no fees, like Internet of Things (IoT) [15].

TABLE III. CONSENSUS ALGORITHMS

Algorithms	Speed	setup	Example of use
PoW	Low	Public/private	Bitcoin, Ethereum
PoS	High	Public/private	NXT
DPoS	High	Public/private	EOS, BitShares
DBFT	Very high	Public/private	NEO, TON
PBFT	High	Private	Hyperledger, Chain

### C. Smart Contract

The smart contract also called chaincode is an essential feature of blockchain because it not only offers a distributed, immutable completion of all activities, but is also capable of allowing for the creation of a computer program that is non-subjective and specifies how the process will be implemented. In this contract, an important activity is addressed. More than two parties don't need to be involved in this contract. The Ethereum smart contract was designed to overcome some of the limitations of Bitcoin [16].

Enterprise blockchain applications are based on smart contracts, which will revolutionize the way businesses operate. Smart contracts can be developed by anyone without the need for an intermediary. Because of a smart contract, the process is autonomous, accurate, and cost-effective.

### D. Cryptography of Blockchain

Blockchains enable confidential and secure transactions between anonymous parties. This trust is established through cryptography, thus eliminating the necessity for centralized institutions. By using cryptography, blockchain data is kept on the ledger. Cryptography building blocks are used in blockchain technology as follows [17]:

- **Public Key Cryptography:** Designed to create digital signatures and encrypt data.
- **Zero-Knowledge Proof:** Show that you know a secret without divulging it.
- **Hash Functions:** A mathematical function that generates pseudo-random numbers.

*1) Public key cryptography:* A transaction can be proven to have been created by the right user by this method. Using a private key, a user can sign a message, known as a digital signature. Digital signatures are used in Hyperledger and Ethereum transactions to verify the authenticity of the sender and that the information has not been changed since it was signed. The algorithm (ECDSA) is widely used to generate a combined set of private and public keys.

*2) Zero-knowledge proofs:* These are primarily used when users request to transfer money to other users. Before committing a transaction, the blockchain must verify that the participant who is transferring funds has enough to complete the transaction. However, the blockchain does not care about how much money he has in total or who is spending it so it has no idea who the user is or how much money he owns.

*3) Hash functions:* Hash Functions: Hash functions form an essential part of blockchain technology. There are five properties of a hash function that are critical for cryptography [18]:

**Fixed size:** The hash function can accept any input and create the output of a fixed size. In order to provide digital signatures, blockchains employ hash functions to condense messages.

**Preimage resistance:** When given a set of inputs, it is not challenging to produce a hash result. Despite this, reverse engineering the original input is mathematically impossible

based on the hash output. The only way to achieve the same result is to randomly select data that should be entered into the hash algorithm.

2nd preimage resistance: Obtaining a secondary input that provides the same hash result is impossible given an input and its hash result.

**Collision resistance:** The same hash output cannot be produced from two distinct inputs.

**Big change:** An entirely different hash output will be produced if any single bit is changed in the input.

#### IV. BLOCKCHAIN APPLICATIONS

According to the survey, blockchain applications include cryptocurrency, Internet-of-Things (IoT), finance, reputation system, healthcare, security and privacy, advertising, copyright protection, society application, energy, mobile applications, defense, digital records, supply chain, digital ownership management, automotive, intrusion detection, agricultural sector, voting, identity management, education, law and enforcement, property title registries, asset tracking, and so on [19]. An illustration of the spiraling applications of blockchain can be found in Fig. 2.

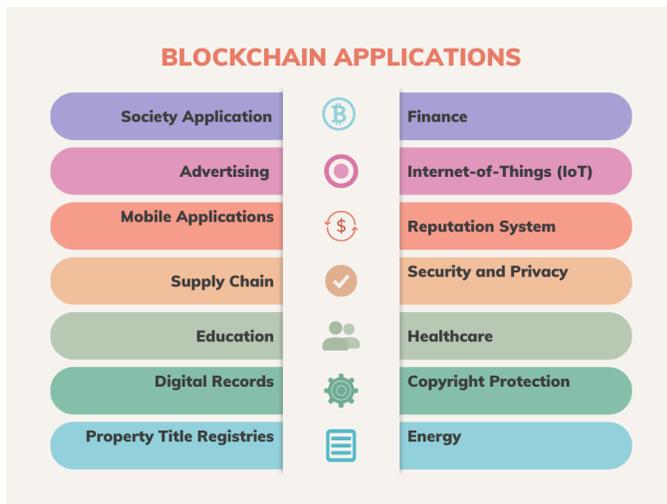

Fig. 2. Application of blockchain.

More applications of blockchain systems are predicted to be developed in the future. To provide further information, we have selected the following 10 blockchain-based applications:

##### A. Healthcare

Prescription medications are being tracked and traced throughout supply chains using blockchain technology. The tool enables the easy and rapid prevention and regulation of counterfeit pharmaceutical distribution as well as the recall of ineffective and unsafe medications. Security of customer data is a primary goal in healthcare, as is the exchange of data between hospitals, governments, and research institutes, which facilitates the improvement of healthcare services. As part of this project, Nokia has used wearable devices to track daily steps and hours of sleep and stored the data on the Blockchain [20].

##### B. IoT

People, places, and products can be connected via the Internet of Things (IoT), providing new opportunities for the generation of value in products and business processes. On the other hand, implementing this technology on a large scale is fraught with security concerns. Combining blockchain and IoT offers the following benefits: To detect data manipulation quickly and accurately, blockchain technology can provide a robust framework for faster detection. Due to the size of IoT networks, it can be difficult to detect failure patterns. Each IoT endpoint is assigned a unique key by blockchain technology, which facilitates the identification of inconsistencies. By combining IoT with smart contracts, it becomes possible to authorize automated responses. Decentralization enhances security: Blockchain technology is decentralized, making it impossible for cybercriminals to hack and corrupt a single server. Additionally, the use of blockchain technology allows tracking of user actions to provide information on who, when, and how users have used a particular device [21].

##### C. Government

Blockchain technology can be used in the public sector to improve the quality and quantity of services. It can also be used to improve transparency and accessibility, as well as to share information between different organizations. In addition to being secure against online attacks, the blockchain is publicly available. Transactions are not editable or deletable once they have been added. This makes data transactions safe, secure, and accessible to anyone [22].

##### D. Power Grid

The development of blockchain-based smart grids is aimed at improving energy distribution on a large scale. There is a significant amount of inefficiency in electricity distribution at the retail level. The use of blockchain technology and Internet-of-Things (IoT) devices for these types of services can reduce electricity bills by bypassing retailers and directly connecting consumers to wholesale distributors. Consumers connected to the smart grid can also shop around for the highest rates from a variety of providers. This leveled the playing field in an industry that has traditionally been dominated by a single provider. Several projects are leading the way in this area, including Grid + and Energy Web Token [23].

##### E. Copyright and Royalties

Music, films, and other creative mediums are subject to copyright and royalties. These are artistic mediums and do not appear to be linked to Blockchain in any way. In the creative industries, however, this technology is quite critical in terms of ensuring security and transparency. It is common for music, films, art, etc., to be plagiarized without proper credit being given to the original creators. A detailed ledger of artist rights can be maintained on the Blockchain to rectify this issue. The use of blockchain technology can also provide a secure record of artist royalties and deals with large production companies, in addition to being transparent. Digital currencies, such as Bitcoin, can also be used to manage the payment of royalties [24].

### F. Cryptocurrencies

In 2008, it was announced that Bitcoin would be the first cryptocurrency. It was launched in 2009. It is estimated that there are 21 million bitcoins in use today. The miner receives a transaction fee once he finds a value that matches the difficulty. Currently, about 90% of BTC is mined.

Ethereum (ETH) is regarded as the second largest cryptocurrency based on market capitalization after Bitcoin (BTC). According to Cryptoslate, [25] there are 2403 top cryptocurrencies ranked by market capitalization. Table IV below shows seven popular cryptocurrencies.

TABLE IV. TOP CRYPTOCURRENCIES

No	cryptocurrency	Market cap
1	Bitcoin (BTC)	322.5 billion
2	Ethereum (ETH)	162.8 billion
3	Tether (USDT)	66.3 billion
4	Binance Coin (BNB)	44.0 billion
5	U.S. Dollar Coin (USDC)	43.9 billion
6	XRP (XRP)	17.66 billion
7	Binance USD (BUSD)	16.3 billion

Blockchain technology can be applied to the use of cryptocurrencies, thus taking full advantage of the features of this technology including:

- There is no intermediary involved in the payment process.
- Processing fees are low.
- Money can be sent at any time without delay or restriction.

A few disadvantages of cryptocurrencies include:

- Black money may be incurred due to a lack of control.
- Digital assets may be lost as a result of a security attack, which we will discuss in more detail later.
- Some commentators claim that investing in cryptocurrencies is highly speculative and risky. Tesla, for instance, advised investors to be aware of Bitcoin's volatility.

### G. Dubai Blockchain Office

Strategy of Dubai Blockchain is the result of a collaboration between the Dubai Future Foundation and the Digital Dubai Office. The purpose of this initiative is to continuously explore and evaluate the latest technological innovations that can be used to enhance the quality of life in cities through seamless, efficient, safe, and impactful solutions [26].

The strategy represents a powerful and innovative tool to influence the future of the Internet through the provision of safe and simple transactions. This will help to achieve the vision of making Dubai the world's first blockchain-powered city. When this strategy is successful, Dubai will contribute substantially to the future economy.

### H. Cloud Computing

Cloud computing has had a major impact on the software technology industry due to its impressive benefits. There are many uses for cloud computing among businesses worldwide, including data storage and backup, software development and testing, disaster recovery, and more. Many industries are using cloud computing to build innovative solutions, including healthcare, automotive, and retail. Even with the advantages of cloud computing, it has its limitations. Blockchain can help overcome these limitations. Due to its transparency, security, and decentralized nature, blockchain technology is being used by millions of businesses for a variety of industrial applications. The use of blockchain and cloud technology together, however, can further revolutionize industries. Even though blockchain technology provides better network security, privacy, and decentralization, cloud computing provides high scalability and elasticity. Therefore, cloud technology and blockchain technology can be combined to produce innovative solutions [27].

### I. e-Commerce

Constant evolution is taking place in the e-commerce industry due to the development of new technologies and the creation of new ways to buy and sell products and services. Using blockchain technology, it is possible to create a decentralized database for storing information about products and customers. By doing so, customers would be able to obtain information about products, such as their origin and supplier, which would also reduce the possibility of fraud. A blockchain-based payment system can also ensure enhanced security and reduce the risk of fraudulent payments. As a distributed database, blockchain technology provides secure, transparent, and tamper-proof transactions. It is anticipated that this technology will revolutionize the e-commerce industry by improving the security of transactions and simplifying the fulfillment process. The system also enhances buyer-seller trust and transparency. Blockchain technology allows e-commerce businesses to track the history of orders and transactions to improve the customer experience. The customer would be able to track their orders easier and find information about previous purchases. Additionally, blockchain can reduce the risk of fraud and facilitate the tracking and verification of transactions more reliably and securely. The implementation of this technology could prove to be a game changer for the e-commerce industry, which is currently plagued by issues of fake reviews, fraudulent transactions, and other security risks. Businesses that use blockchain technology can reduce costs associated with processing transactions and shipping products, as well as improve the speed at which new products are introduced to the market [28].

### J. Advertising

A blockchain advertising application is a type of distributed ledger technology that promotes decentralization with the highest level of security and transparency. On the blockchain, digital records are immutable, which means that individuals have access to read but cannot amend the records. Blockchain can allow advertisers to track their advertising expenditures in real time since it stores information and transactions. It provides a level of transparency that cannot be achieved with

existing systems. Transparency is not the only advantage. In advertising, speed is crucial, as it is difficult to track inventory and ensure high-quality products. Blockchain technology has the capability of keeping up with these challenges [29].

## V. ATTACKS AND SECURITY MEASURE ON BLOCKCHAIN

### A. Attacks on Blockchains

Blockchains are distributed so it makes sense to conduct research on their security. In this section, we will discuss the security risks associated with this technology. In order to gain a deeper understanding of blockchain security, it is essential to first understand the differences between private and public blockchain security, particularly regarding data access and participation capabilities, as we mentioned above.

The following are the top security issues associated with blockchains [30]:

1) *Sybil attack*: In this attack, several fake network nodes are generated by hackers. Through the use of these nodes, it will be able to gain majority agreement and interrupt transactions.

2) *Endpoint vulnerabilities*: Another vital concern in the security of blockchain is the vulnerability of endpoints. Electronic devices such as mobile phones and computers are used to interact with the blockchain network. Observing the behavior of users and targeting their devices will allow hackers to steal the user's key. Perhaps this is one of the most prominent security issues associated with blockchain technology.

3) *51% attack*: An attack of 51% occurs when one user or institution controls half of the hash rate and takes control of the entire system. Transactions can be modified by hackers and prevent them from being confirmed. They will even reverse transactions that have already been completed, leading to double spending.

4) *Phishing attacks*: Phishing attacks are designed to steal user credentials. An email will be sent to the wallet key owner that appears to be legitimate. A fake hyperlink is attached to the email that requires the user to enter their login details. By gaining access to a user's credentials and private information, it is possible to cause damage to the user and the blockchain network as a whole.

5) *Routing attacks*: In this attack, participants are usually unaware of the threat because the transmission of data and the conduct of operations continue as usual. A potential danger is that such attacks could reveal sensitive information or generate revenue without the user's permission. There is a critical reliance on the movement in real time of enormous amounts of information in a blockchain application and network. Due to the anonymity of an account, hackers may be able to intercept information transmitted to Internet service providers by using it.

6) *Private keys*: You will need a private key in order to access your funds. A hacker can easily guess the private key if it is weak. Your funds could be accessed as a result. Keeping your private key secret is extremely critical, and it should be strong enough not to be guessed easily.

7) *Malicious nodes*: Additional security problems related to blockchain technology include the threat of malicious nodes. An attempt to disrupt the network will occur once a dishonest actor has joined the network. In order to accomplish this, they will attempt to reverse transactions or flood the network with transactions.

### B. Security Measures of Blockchain

To ensure the security of blockchain applications, security must be considered at all layers, including permission management through several security measures [31]. The following are some of the security measures of blockchain:

1) *Blockchain governance*: Determining how existing organizations or users leave or join the network, and providing mechanisms to prevent malicious actors, manage errors, secure data, and address issues between parties.

2) *Data security*: While data compression is generally regarded as the most effective method for identifying what data should be kept on-chain, additional privacy measures should be implemented to hash data, cloud storage, and data in transit.

3) *Security of blockchain network*: Blockchain is a distributed system, which requires network connections from various participants beyond a single organization to interact. All of these factors have the potential to introduce security exploits or flaws. Part of governance, therefore, includes reviewing security protocols for users [32].

4) *Blockchain application security*: Security applications are vulnerable points and should be protected with effective user identification and endpoint security measures. For private blockchains, where access and use are limited to authorized participants, it may be necessary to provide different levels of authorization that may change with time.

5) *Smart Contracts Security*: Smart contracts consist of a set of codes within the blockchain, triggered by a set of programmed conditions. This presents another point of vulnerability as their reliability determines whether the operation and the results can be trusted.

6) *Use of trusted third-parties*: Security evaluations, penetration checks, and reviews of the source code of smart contracts and blockchain implementations should be performed only by trusted individuals. Use these to protect against new security threats, such as unauthorized access to cryptographic algorithms [33].

## VI. CONCLUSION

During the past few years, blockchain technology has attracted a great deal of attention due to its advanced characteristics of decentralization, autonomy, integrity, immutability, verification, and fault tolerance. In terms of the future scope, the primary priority will be addressing the security concerns arising from the various types of blockchain networks. Furthermore, consensus algorithms such as PoW implemented on blockchain have several drawbacks. Thus, the development of a consensus algorithm that is more efficient will result in more cost-effective blockchain networks. This survey introduces an in-depth overview of blockchain technology. A brief historical overview of blockchain was presented, followed by

a comparison of the most widely used consensus algorithms. It has been discussed in detail how public key cryptography and hash functions applied to blockchains can be used for security, identification, and non-repudiation purposes. In addition, it provides detailed information and comparisons of some cryptocurrencies used in blockchain. Also, we focus on various categories of top security risks associated with blockchain technology. Finally, by making this effort, we hope that someone will gain a deeper understanding of blockchain technology. We also hope that individuals will give more focus to the safety of the blockchain

# An Autonomous Role and Consideration of Electronic Health Systems with Access Control in Developed Countries: A Review

Mohd Rafiz Salji<sup>1</sup>, Nur Izura Udzir<sup>2</sup>

Faculty of Information Management, Universiti Teknologi MARA,  
Malaysia<sup>1</sup>

Faculty of Computer Science and Information Technology, Universiti Putra  
Malaysia<sup>2</sup>

**Abstract**—The electronic healthcare system (EHS) nowadays is essential to access, maintain, store, and share the electronic health records (EHR) of patients. It should provide safer, more efficient, and cost-effective healthcare. There are several challenges with EHS, notably in terms of security and privacy. Nonetheless, many approaches can be utilized to tackle it, and one of them is access control. Even though numerous access control models were presented, traditional methods of access control, such as role-based access control (RBAC), were extensively employed and are still in use today. Currently, the number of EHS equipped with access control keeps growing, and some previous works utilize RBAC only or an autonomous role. However, relying only on a role in today's advanced technology may jeopardize security and privacy. The previous work also has flaws because of using an ineffective instrument that is costly to maintain and will burden organizations, particularly in developed countries. In this paper, the background and emphasis on the challenges associated with an autonomous role in the EHS are discussed. Following that, this paper provides recommendations and analytical discussion on existing EHSs with access control mechanisms for securing and protecting EHR in developed countries. Finally, instrument information in the form of a SWOT analysis is recommended to replace the present instrument utilized by the previous work for a notion to the organizations in the developed countries to select the best environment for their future or upgrade EHS.

**Keywords**—Access control; security; privacy; electronic health-care system; electronic health record; developed countries

## I. INTRODUCTION

Recently, developments in information technology have made significant progress in the field of medical information. This information nowadays is managed in a system called EHS. Advanced EHS is required to manage massive volumes of EHR clearly and cost-effectively. EHR is a non-printed form that electronically stores all of a patient's medical information. EHS is now developed and administered by numerous medical institution systems that allow sharing of EHR among various healthcare practitioners and organizations, rather than by a single healthcare organization. Due to that, a sophisticated system must be put in place to secure and preserve EHR.

Many approaches have been utilized to address security and privacy protection, but the most commonly used is access control. In general, access control is important in securing systems and protecting the privacy of authorized users, especially when providing health services. Today, many types of EHS

combined with access control have been proposed, however, there are still issues that impede the development of EHS with access control.

This study discusses the issue of the utilization of access control mechanisms in EHS. The current EHS [1] has been established to secure and preserve EHR in developed countries. With regards to security and privacy, the previous system was in the initial stage of discussing the plan to use some instruments to secure their system, and the EHR in this system was protected using RBAC, which uses role or job function to allow or deny access to resources. Subsequently, another previous system [2], also used the RBAC model to secure the storage server in the cloud environment. Based on these previous works [1], [2], an autonomous role was utilized in these systems. It is indisputable that this traditional access control model is still applicable today; however, the problem is that employing an autonomous role to secure systems and preserve privacy in today's advances of ICT is not acceptable and unsafe, especially in a healthcare environment, due to various drawbacks of this scheme observed by previous works. Details about RBAC are discussed in Section II. The previous work [1] also suffers from the problem of utilizing the wrong choice of instrument, since they utilize a centralized database that has been claimed to have issues such as timely, frequent errors, and costly [3], [4].

This article review's main contributions are grouped into four categories. First, based on the problems of the previous works [1], [2], this paper provides background information on the RBAC model, including a description of the model's history, followed by examining the scheme's benefits and drawbacks based on previous works, and finally, discussions on the current EHSs employing autonomous RBAC. Second, this article examines and suggests previous literature reviews related to current EHS with access control models by discovering the environment and mechanisms used by previous systems instead of relying solely on an anonymous role. The aim is as a notion or an opportunity for the clinics and hospitals in developed countries to enhance their EHS with appropriate mechanisms in a specific environment in the future. It also aids researchers in swiftly grasping each function of the mechanisms employed by prior systems. The current EHS with access control models is examined in three categories: EHS with access controls aimed at securing the system, existing systems aimed at protecting the EHR, and finally,

existing systems capable of securing the system and protecting the EHR. Third, based on previous literature reviews, this article provides an analytical discussion in terms of the issues or problems of previous works, findings, or results of the previous works, and finally, comments or suggestions based on previous works. This discussion aimed to help identify how many issues or problems were faced by previous works and group them in the same categories. This discussion also helps clinics and hospitals in developed countries in obtaining information about the problems that happen in EHS and the way to solve them and have a notion to develop or upgrade EHS. It also helps the researcher in understanding difficulties and the ideas of previous works in solving problems, and comments or suggestions can be used to find opportunities for future work. Finally, because of previous work employed the wrong instrument, this paper provides critical instrument selection information in the form of a SWOT analysis that can assist clinics and hospitals in developed countries choose an acceptable and cost-effective instrument.

The rest of this paper is organized as follows: Section II provides the background of the RBAC model, while consideration of EHS with access control is discussed in Section III. In Section IV, the SWOT analysis is presented, and finally, Section V concludes the work.

## II. ROLE-BASED ACCESS CONTROL (RBAC)

Role-Based Access Control (RBAC) means to allow or deny client data from being accessed by the user based on role, i.e., job function or position, however, this decision depends on organizational policy [5]. This model has been introduced for over twenty years, primarily in UNIX, and centralized computer conditions, yet this model needs standardization because every framework utilizes its restrictive elements [6]. Therefore, the National Institute of Standards and Technology (NIST) began a task in 1992 to bound together with the principles of RBAC by incorporating the current models [6]. Although RBAC has since quite a while ago existed and is viewed as traditional access control, this model is still being used and stays pertinent right up until today.

In a positive sense, there are quite a few points why RBAC has become well known and can be utilized by current systems. The advantages of RBAC are as follows:

- 1) Simplifies access management and user permission review [7], where it is easy to categorize roles and a group of users for each role [8] and it aids in determining which permissions are permitted for which users in a large enterprise system [9].
- 2) RBAC policies adhere to the need-to-know security concept and fulfil the notion of least-access privileges [10]. This model also may be well-known for managing complicated role hierarchies in organizations [11].
- 3) This model may not need to be concerned about users being added or deleted from the system because this architecture is ideally suited to a large organization [12].
- 4) It can be considered an acceptable model in a healthcare cloud, as it has key strengths such as efficient management of large-scale user permissions, enforcement of need-to-know access controls, simplified

auditing for regulatory compliance, and scalability [8].

Even though RBAC offers advantages, this model likewise experiences a few limitations. The following are RBAC drawbacks:

- 1) This model is incompatible with an open system in which the user is almost likely unknown, and the system recognizes a user solely by roles without knowing the identity and purpose of access —[13].
- 2) Previous works [14], [15] have highlighted that RBAC can lead to privacy disclosure, especially sensitive attributes to unauthorized and untrusted users because of the insufficient and inefficient of this model.
- 3) RBAC is less flexible and responsive because of its static role. As a result, RBAC cannot define granular control over users in certain roles in accessing certain individual objects, which is generally not sufficient for organizations with complex organizational structures, such as collaborative E-healthcare environments [9], [16], [17].
- 4) In a healthcare environment, installing an emergency access mechanism on a static role can pose a high security threat [18], for example, if unauthorized users can have illegal access rights under RBAC, they can easily compromise health records using the emergency access control window because there are no additional control variables to authenticate attacker access.
- 5) Although a previous study [12] has shown that RBAC is suitable for large organizations, however, RBAC is experiencing a role explosion or lack of scalability due to the increasing number of different roles. Furthermore, maintaining all these roles to provide appropriate access rights can be a difficult task [19]. Therefore, RBAC is not advised to be used in cloud computing or in a large system due to the lack of scalability [20], [21], [4].

In light of the previous passages, the aim of featuring the advantages and the drawbacks is to indicate the performance of this model. Despite the fact that the relevance of using RBAC until now was highlighted, nonetheless, this model also has many limitations. Therefore, proposing access control with an autonomous role, in the current context, i.e., in a collaborative system, is extremely hazardous.

Currently, several EHSs utilizing an autonomous role have been proposed. First, previous work [1] proposes a notion of early implementation of the EHS design model in the clinics and hospitals in developed countries, so that they do not miss out on the benefits of building this system rather than paper-based. A typical hospital workflow was defined and utilized in the design process. This study offers a prototype of an EHR web-based system that secures and protects privacy by utilizing RBAC. However, relying solely on RBAC without supporting other features may cause a security and privacy risk. This system also suffers weaknesses when using RBAC, such as static in nature and inflexibility [9], [16], [18], [17], which pose a difficulty if the user needs to treat patients during an emergency situation. A centralized database is an instrument

used in this system to allow access, maintain and store EHR. However, this instrument is not suitable to be utilized in developed countries since it contradicts the goals of generating cost-effective EHS. Next, Li et al. [22] also propose EHS with RBAC model to protect cloud-based outsourced EHRs. They claimed that this model provides an efficient and secure RBAC strategy for securing EHR stored on a storage server, even if the storage server is administered by an untrustworthy third party. This system offers a distinct and more efficient form of fine-grained access control that does not rely on attribute-based encryption (ABE). Only users with roles that adhere to the access policy are permitted to decapsulate. However, in the current circumstances, adopting an autonomous role may put the system in danger.

To summarize, employing an autonomous role to secure and maintain privacy in an internal, external, or collaborative system setting is not viable in today's tough environment. It is agreed that RBAC is still relevant nowadays since it has numerous benefits, however, this model needs support or a hybrid with other features. In the next section, the recommended current EHSs with access control utilizing with or without roles to secure and preserve the EHR is highlighted.

### III. CONSIDERATION OF EHS WITH ACCESS CONTROL MODEL

This section provides information on current EHSs with access control as a reference or notion for organizations in developed countries to developing efficient and effective EHS. The main aim is to highlight and compare the environment and mechanisms applied in the previous works. This section is divided into three sections: 1) The EHS with access control approaches seeks to secure the system, 2) The EHS with access control mechanisms intends to protect the EHR, and 3) The EHS with access control models to secure and protect EHR. This section also provides an analytical discussion of all collections of previous works in terms of the problems or issues, finding or results, and comments or suggestions.

#### A. Security

There are eight EHSs with access control in a cloud environment, and in this section, these systems are discussed.

First, in the cloud-fog computing environment, a searchable personal health records (PHR) framework with fine-grained access control was proposed. PHR is also EHR, however, PHR is controlled, shared, or maintained by patients themselves to support their personal care [23]. This framework was proposed to address the need for local information for a terminal device and the weaknesses of cloud computing [24]. To provide a keyword search function and fine-grained access control, the proposed framework integrates attribute-based encryption (ABE) technology and search encryption (SE) technology. When the keyword index and trapdoor match are successful, the cloud server provider only delivers relevant search results to the user, resulting in a more accurate search. Experiments with simulations demonstrate that the proposed method works well in a cloud-fog scenario. However, the keyword sets are obtained from the actual encrypted file on the cloud, introducing the prospect of a chosen-ciphertext attack. Besides, a novel, fine-grained, and flexible PHRs data access control system for

cloud computing based on encryption was proposed to address the problem of repeated processes in data encryption [2]. The scheme consists of the symmetric key and the ABE layer. The system supports multi-privilege access control for PHRs from multiple patients in the ABE layer. To resolve the problem of repetitive processes, the scheme combines data encryption from different patients, where data is under a single access policy, to reduce encryption and decryption costs. Through implementation and simulation, the proposed scheme shows efficient in terms of time. Moreover, the proposed scheme proved that it was secured based on the security of the CP-ABE scheme. This system ensures data privacy, but, due to computational complexity and scalability concerns, it is unsuitable for health records. Next, the previous work [25] also utilized a CP-ABE based access control for a smart medical system with policy-hiding capabilities that is secure and efficient to overcome the problem of Zhang et al. [26] approach that fails to offer efficient large data storage with leakage resistance. The access control uses hidden access policies to satisfy the medical user's attribute values. A comparison of performance analysis reveals that the suggested system is more efficient than the current scheme. A Secure Healthcare Framework (SecHS) in the cloud using CP-ABE was proposed to provide secure access to health and medical information [27]. Patient data is encrypted under a symmetric encryption scheme and the access policy in CP-ABE is embedded with the ciphertext. The proposed framework was compared with current CP-ABE frameworks, and it demonstrates that SecHS offers greater features for data security. Next, the User Usage Based Encryption (UUBE) diversified access control framework, which usually builds on the searchable encryption technique to secure outsourced data was proposed [28]. In this method, the owner or patient will outsource data to the cloud data center. Data will be encrypted with a multiuser setting and will be stored in the form of ciphertext and finally stored in the database. To search PHR, the user needs to be authenticated by their category of user and institution. After receiving a request from a user, the data center computes the matching encrypted keyword search and returns the relevant outcome. Usage-based encryption is designed for user access and revoke after a specified time. This approach ensures a high level of security for data sharing. If there is misconduct in data access and various attacks by the revocation of the user, the suggested approach proved efficient. However, granular data access cannot be achieved using standard CP-ABE techniques, instead, a multi message CP-ABE is required. Subsequently, to secure cloud storage, a novel system using a hybrid encryption algorithm using Improved Key Scheme of RSA (IKGSR) and Blowfish was proposed [10]. To efficiently retrieve the encrypted data, steganography-based access control was utilized for key sharing via substring indexing and keyword search mechanisms. The findings clearly show that the proposed technique delivers superior security while also retrieving data more efficiently. An expressive and efficient access control method with attribute/user revocation based on the ordered binary decision diagram (OBDD) access structure was proposed to overcome the previous CP-ABE schemes relying on access structures that are either restrictive or cumbersome, resulting in less expressive and efficient [29]. The proposed work establishes attribute groups, which are made up of users who have specific attributes. Each attribute group has its own group key. Version numbers are assigned to user secret keys and ciphertexts to avoid cooperation between

revoked and non-revoked users. When a user's attribute is revoked, a new attribute group key is produced and disseminated to all group members except the revoked user. When there is a change in the attribute group key following an attribute/user revocation, the version number is incremented. The proposed approach was analyzed regarding security and efficiency, and shows that it is secure, expressive, and efficient. Finally, due to the inflexibility of the RBAC, a cloud-based EHR architecture to implement ABAC that employs extensible access control markup language (XACML) was presented [30]. The proposed approach has two stages, after conducting access control on patient records, encryption and digital signatures are applied as an additional security precaution utilizing XML encryption and XML digital signatures to provide more flexible and fine-grained control and minimize the chances of revealing patient private records. A comparison of the security criteria to those utilized in other relevant research was applied and found that the suggested technique was more secure than previous methods. However, encryption in XML requests and responses, on the other hand, is highly expensive for data sharing. Requests and responses are explicitly communicated between legal parties in the first phase and are thus vulnerable to attack.

Subsequently, the previous discussion of EHS with access control models aimed to secure the system is summarized in the form of a comparative analysis. The explanation is shown in Table I.

## B. Privacy

In this section, eight EHSs with access control models that seek to protect EHR are discussed.

First, a privacy-aware relationship semantics-based extensible access control markup language (XACML) access control model was proposed that uses XACML to execute hybrid relationship and ABAC in the hybrid cloud [4]. To enhance multipurpose EHR utilization, the proposed approach offers fine-grained relation-based access control (Rel BAC) with an anonymization technique called Anatomy as it provides quality data utilization. The proposed model delivers and maintains efficient privacy vs utility trade-off. The proposed model was explicitly validated to assess its efficacy regarding privacy-aware electronic health data access and multi-functional usage. The experimental findings demonstrate that access policies based on relationships and EHR anonymization may perform well in terms of access policy response time, and space storage in the proposed model. Next, due to the patient's reluctance to share sensitive data, organizations rely on cloud solutions that employ machine learning models. This article offers a Euclidean L3P-based Multi-Objective Successive Approximation (EMSA) algorithm, efficient measure of privacy in a cloud [31]. Each EHR is divided into common and privacy-related attributes. Privacy-related attributes, such as sensitive information, are subjected to a cryptographic mechanism to produce a key for storage in a cloud environment. Role-based encryption keys are provided here as the fundamental foundation for the storage of sensitive data in cloud environments. In terms of performance, the proposed EMSA was compared with Bat, PUBAT, TPNGS, WOA, and CIC-WOA algorithms based on performance metrics, such as fitness, privacy, and utility.

According to the simulation, the suggested EMSA model has greater privacy values.

A new framework for access control was proposed that protects the privacy of PHR data while a patient is in an emergency [32]. The system proposed uses smart contracts that may limit PHR access permissions in a state of emergency. The smart contract also enables the PHR owner to assign the rules to an employee (a certified medical practitioner) who has the authorization to access the actual data from the PHR, considering the time restriction. The system suggested provides historical audit records that store the history of transactions in an emergency. The proposed framework, based on the experiment, is improved regarding accessibility, privacy, emergency access control, and data auditing in health care systems. A PHR-based blockchain model was proposed to solve the limitation of the blockchain [33]. The proposed model is constructed to provide a tamper-resistant feature utilizing blockchain technology. To protect privacy, proxy re-encryption, and other cryptographic methods are applied. A comprehensive safety analysis reveals that the proposed model can protect the privacy and tamper resistance. The performance study reveals superior overall performance in the proposed model compared to the current literature approach. This work extended [34] by analyzing the system on a variety of user counts and PHR data sizes in a real-world situation.

Permission to access the EHR requires agreement from the patient (data owner), and additional access authorization to be granted by the patient to the healthcare professional is required. A newly built Health Information System (HIS) access decisions flow, guaranteed by RBAC, incorporating patient-centered control was designed [35]. Colored Petri-Networks (CPN) is used as a mimic for RBAC to demonstrate security policy conflicts or restrictions during the access control authorization process. To provide explicit permission for a patient to access their data in a non-offensive access flow, a discretionary access control (DAC) feature was added. Mutual exclusive was designed to consider patient needs for them to permit healthcare providers to access EHR data. Additional information was added to the permission Access Control matrix to ensure privacy is protected and subject to DAC. When compared to prior CPN simulations, a minor modification is proposed to integrate RBAC-aware systems with no significant drawbacks. Subsequently, a novel healthcare access control model named Solution de Gestion Automatisée du Consentement / automated consent management solution (SGAC) was proposed to manage patient consent for accessing their EHR [36]. Because patient preferences and rules may conflict, the SGAC provides a mechanism to handle this issue based on priority, specificity, and modality. Four sorts of characteristics were examined to safeguard patient privacy while providing effective care in life-threatening situations: accessibility, availability, contextuality, and rule effectivity. The verification of SGAC access control rules utilizing two first-order logic model controls, Alloy, and ProB, based on distinct technologies. The results show that SGAC performs better than XACML and that ProB outperforms Alloy by two orders of magnitude thanks to its programmable approach to constraint solving. A formal specification of the system based on the legislation that defines it was proposed to improve the confidence level of the patient towards the system in privacy preservation [37]. This work concentrated on the control and access features

TABLE I. EHS WITH ACCESS CONTROL MODELS IN THE CLOUD ENVIRONMENT AIMS TO SECURE THE SYSTEM

of patients' health information. The method used relies on the correct-by-construction Event-B to prove the control and access properties of the system. Finally, traditional approaches like k-anonymity and its derivations frequently overgeneralize, resulting in lower data accuracy. To address this problem, the Semantic Linkage K-Anonymity (SLKA) method was offered, which allows for continuing record linkages [38]. This work demonstrates how SLKA strikes a balance between privacy and utility preservation by detecting risky combinations hidden in data releases.

Subsequently, the previous discussion of EHSs with access control aims to protect privacy is summarized in the form of comparative analysis. The explanation is shown in Table II.

### C. Security and Privacy

In this section, information about recent works on EHSs with access control to secure the system and protect EHR is highlighted.

A secure sharing architecture based on MA-ABE with anonymous authentication outsourcing was proposed to protect the patients' privacy and guarantee that patients may control their PHRs [39]. Before outsourcing, all PHRs are protected using MA-ABE, which overcomes the key hosting problem and achieves fine-grained access control to PHRs. Furthermore, anonymous authentication between the cloud and the user is recommended in order to secure data integrity on the cloud without revealing the user's identity during authentication. The proposed authentication is based on a novel attribute-based online-offline signature. In comparison to previous studies, the suggested approach not only retains encrypted PHRs resistant to collusion assaults and not forged throughout the sharing time, but it also accomplishes privacy preservation, which improves patients' control over their PHRs. Next, some health institutions in the Republic of South Africa have problems protecting HIV patient data because they still use traditional approaches, e.g., paper-based. This work aims to build a cloud-based access control model to share in nine (9) provinces in the South African Republic [40]. This study is based on the acceptance and use of the RBAC model for permission access based on job function, the Access Control List (ACL) contained a list of access control entries (ACE) to identify

trustees and specify access privileges, and Motive Based Access Control (MBAC) models related to data object and motives of seeking them. However, this framework proposes a static model which is not suitable for emergency conditions. Subsequently, CP-ABE also was employed in the proposed scheme to enhance the retrieval capabilities of data based on disease and to solve the inefficiency of RBAC [41]. The proposed scheme can retrieve encrypted EHR based on a specific disease. Furthermore, the scheme ensures user access control and the anonymity of the user or data owner during data retrieval. Moreover, the scheme is resistant to collusion between unauthorized retrievers to access the data. Based on the results of the analysis, the suggested method accomplishes data confidentiality, user anonymity, and collusion resistance. A unique privacy-preserving access control (PPAC) method for electronic health records (EHR) was proposed based on the attribute-based signcryption (ABSC) scheme and the cuckoo filter [42] to solve the issue of security and privacy in sharing EHR. The ciphertext-policy attribute-based signcryption (CP-ABSC) is proposed to ensure fine-grained access control of the EHR data, utilize a cuckoo filter to hide the access policy, and preserve the privacy of EHR owners. Security analysis reveals that the proposed scheme is provably secure. In addition, the performance study reveals that, compared to previous schemes, the suggested scheme achieves low communication and calculation costs, while maintaining the privacy of its owner. However, hiding the AC policy may result in a loss of efficiency. A multi-layer access control (MLAC) model was proposed for building a secure and privacy-preserving EHR system that allows patients to exchange data with stakeholders [43]. In this article, a dual-layer access control model called pseudo-role attribute-based access control (PR-ABAC) was utilized that incorporates attributes with roles for secure sharing of EHR across many contributors. To protect the integrity of patient data, the proposed system also employs the notion of provenance. PASH, a privacy-aware s-health access control system, was introduced based on a large universe CP-ABE with partially concealed access restrictions to solve the problems of conventional CP-ABE [41]. In PASH, access policy attribute values are concealed in encrypted s-health records (SHRs), and only attribute names are exposed. In reality, attribute values contain far more sensitive data than general attribute names.

TABLE II. EHS WITH ACCESS CONTROL MODELS AIMS TO PROTECT PRIVACY

PASH, in particular, implements an efficient SHR decryption test that requires a limited number of bilinear pairings. The attribute universe can be exponentially huge, whereas public parameters are modest and constant in size. According to security analysis, PASH is completely secure in the standard model. PASH is more efficient and expressive than prior systems, based on performance comparisons and experimental data. However, this system lacks revocation. A sensitive and energetic access control (SEAC) was proposed for managing cloud-hosted EHRs and enabling fine-grained access control even in the critical environment to solve problems of the security of the prior system that have threatened the patient’s privacy [44]. The system suggested guarantees that data from a patient are confidential where only authorized users may be permitted to modify or review particular data from the patient. Before submitting to cloud storage, each EHR data is encrypted by the managing authority. The requesting user can receive rights that change permission dynamically based on authentication and context attributes. The security analysis shows that the SEAC mechanism is secure and prevents unwanted access. The findings indicate outstanding compatibility and performance with various configurations and settings. However, keyword searches on encrypted data are not possible using the encryption methods employed. The encryption technique employs bilinear mapping, which has a high computational cost and is impractical for lightweight applications. A hybrid framework called MediTrust was proposed which combines two systems, namely RBAC and ABE, and operates in a semantic database, guaranteeing that patient data are accessible to various access controls [19]. On the provider side, patient data is encrypted before it is outsourced to the cloud server. After download, it is decrypted again at the user. The patient’s general PHR and medical reports are stored separately on another cloud server. CAPTCHA provides the second stage of security control, particularly for security checks, which allows users to connect to MediTrust. The third step of safety control additionally provides for sharing one key with the registered cell phone number of the user and sharing another key with the user’s e-mail id. In MediTrust, the PHR must be decrypted with the combination of the two keys. Furthermore, Amazon AWS EC2 CA was used to validate ABE policies and access control security mechanisms for privacy preservation on PHR. The

results of performance evaluations demonstrate that regarding time complexity and computational overhead, the proposed MediTrust is superior than the prior projects.

A system was proposed by using a technique known as channelling integrated with a smart contract logic script within the network to ensure interoperability of EHR and access control only through the authorization of the patient [45]. The goal of this approach is to provide the entire privacy, integrity, and access control of distributed EHR. Simulated findings show that the proposed solution uses the blockchain to provide absolute transparency and perfect privacy inside a distributed network of sharing EHRs in the medical setting. Next, a blockchain-based architecture was proposed to secure, interoperable and efficient access to patients’ medical records, while protecting the privacy of sensitive data of patients [46]. The proposed framework, named Ancile, uses smart contracts on an Ethereum-based blockchain for enhanced access control, and data obfuscation, as well as advanced cryptographic methods for additional security. However, this work uses six different forms of smart contracts for a proxy re-encryption approach that may incur high computational costs. Finally, Smart Contract-based Attribute-based Searchable Encryption (SC-ABSE) was proposed to solve the issue of security, privacy, and searchability in PHR [47]. This work bridges the gap between PHRs and blockchain technology by downloading extensive medical data into the IPFS and building a compulsory cryptography authorization and access control system for outsourced encrypted medical data. This system expands CP-ABE and searchable symmetric encryption (SSE), as well as using smart contract technologies, to accomplish the following: 1) efficient and secure fine-grained access control of outsourced encrypted data, 2) confidentiality of data by eliminating trusted private key generators, and 3) multi keyword searchable mechanism. The rigorous security indistinguishability analysis, based on decisional bilinear Diffie–Hellman hardness assumptions (DBDH) and dismulti-keywordhm (DL) issues, reveals that SC-ABSE is secure against the chosen-keyword attack (CKA) and keyword secrecy (KS) in the standard model. User collusion assaults are prevented, and data tamper-proof resistance is assured. Furthermore, security validation is validated by simulating a formal verification scenario with Automated Validation of Internet Security Protocols and

Applications (AVISPA), revealing that SC-ABSE is immune to man-in-the-middle (MIM) and replay attacks. Simulation findings demonstrate that SC-ABSE has high performance and low latency and that network life are ultimately increased in comparison with conventional medical systems.

Subsequently, the previous discussion of EHS with access control models aim to secure the system and protect privacy are summarized in the form of a comparative analysis. The explanation is shown in Table III.

Finally, all previous literature will be discussed in the form of an analytical discussion. The discussion is depicted in Table IV.

#### IV. SWOT ANALYSIS OF INSTRUMENTS CONSIDERABLE IN DEVELOPED COUNTRIES

In view of past work [1], an affordable EHS was developed and it was targeted to be utilized by the organizations in the developed countries. The instrument used to maintain and store EHR is by using a centralized database system. However, this storage is timely, frequent error, and costly [3], [4] to use and maintain, and it is against the aims of creating an affordable EHS in developed countries. As indicated in the preceding sections, blockchain system and cloud computing were the dominant instruments to be used for accessing, maintaining, and storing EHR. These instruments can also be used as one of the solutions for securing and protecting privacy. However, organizations in developed countries should have the knowledge to choose the right instruments for their new or upgraded EHS. Therefore, information about blockchain systems and cloud computing is provided in this paper in the form of strength, weakness, opportunity, and threat (SWOT) analysis to allow organizations doing instrument selection either to use only one or hybrid instruments. This analysis is essential planning that can take enormous amounts of information inside these four domains and sort out them into explicit concerns [48], [49]. Because of its successful and simple forms of analysis, hospitals may use this method, and it is ideal for use in strategic planning in healthcare systems or medical advances.

First, the Blockchain is discussed in the form of a SWOT analysis. The description of the analysis is discussed as follows and summarized in the form of a list in Table V.

##### 1) Strengths

Benefits were classified into two groups: patient-related benefits and organizational-related benefits.

For patient-related benefits, they include the followings:

- a) Users may only register their identity on the blockchain network once so they do not need to re-register their identification for the future [50].
- b) Allows healthcare professionals to embrace the concept of a shared database capable of producing sharable individualized healthcare plans for patients [50].
- c) The traceability feature enables tracking of the patient since every Bitcoin transaction is logged with a timestamp that is validated and

maintained by all computer nodes participating in the blockchain network [50].

- d) Enable effective patient monitoring, especially for critically sick patients, because this technology assists physicians in making appropriate medical-related treatment decisions. To do this, patients' wearable gadgets such as smartwatches, smartphones, and smart glasses must be linked to the healthcare blockchain network [50].
- e) Improve privacy protection for citizens and governments by giving individuals more control over their personal data. They can use blockchain technology to control who has access to their data, for what purpose, and for how long [51].

The organizational-related benefits are:

- a) To enable the secure sharing of patient information between healthcare organizations [50].
- b) To make clinical trial management easier because the study contains extremely sensitive patient-related information [50].
- c) The traceability function is crucial in controlling the pharmaceutical supply chain. In particular, can identify the origin of data, which can help pharmaceutical firms track the supply of products [50].
- d) Ability to manage medical insurance [50].
- e) Decentralized authority allows for the reduction of time, errors, and costs in the performance of processes, with the goal of building and updating a predictive model that supports medical care and risk management [3].
- f) The cryptographic system, the immutability of the data transmitted throughout the network, and the decentralized authority all contribute to increased confidence in the system [3].
- g) Every member can confirm the activities that happen in the organization as they have a duplicate of the entire blockchain on their gadget and this makes the process transparent [3].
- h) In Bitcoin, it is possible to identify any alteration to transaction records after they have been verified by solving a cryptographic problem [51].

##### 2) Weaknesses

- a) A verified transaction might be reversed after a government or group of persons in control of a blockchain [51].
- b) With the possibility for additional records to be produced natively on chain via smart contracts, legal admissibility must be considered. Laws and regulations regulating the admission and weight to be given to such evidence vary by jurisdiction, making it difficult to generalize how such evidence could be regarded by courts [51].

TABLE III. EHS WITH ACCESS CONTROL MODELS AIMS TO SECURE THE SYSTEM AND PROTECT PRIVACY

- c) Blockchain records are intended to be immutable rather than changeable. This highlights the larger issue of how to remove or dispose of records from blockchain, which is also an issue to address when adopting data retention regulations or correcting mistakes in the record [51].
  - d) The topic of how to maintain blockchain records, in the long run, remains unanswered [51].
  - 3) Opportunities
    - a) As more companies see the advantages of blockchain-based recordkeeping, they will need a trusted adviser to assist them [51].
    - b) Through its usage, information professionals may reinvent their methods. For example, the UK National Archives is investigating smart contracts, to automatically execute data publishing [51].
  - 4) Threats
    - a) The sharing of whole copies of the blockchain under a model in which sensitive data on a single patient is shared would raise several issues related to privacy regulations, especially if entities other than public healthcare corporations participated in the network [52].
    - b) Scalability has become a major challenge for public blockchain applications, such as linking wearable devices because there is no control over the number of people joining the network [50].
    - c) Vulnerable to cyber-attacks where the attacker gains control of the blockchain network, which can lead to disaster if the attacker disrupts, stops or even reverses previously verified transactions within the network [50].
    - d) The high energy consumption has been noted since it pertains to the usage of the blockchain (public blockchain) based on proof of work, which is a mining process that uses a lot of electricity and it has gotten worse as more users have joined it and the number of transactions made per second has risen [50].
    - e) Absence of guidelines given by legitimate experts for blockchain advances [50].
    - f) Interoperability was considered as one of the significant difficulties for blockchain innovation reception in medical services because of the absence of trust between medical care organizations [50].
    - g) Lack of adequate technical skills and capabilities while carrying out blockchain advancements might prompt tragic results [50].
    - h) Data centers require a high cost of financing to maintain and require a large quantity of electricity [52].
    - i) One of the challenges is to train stakeholders on how to use this complex new system [52].
- Next, this paper describes the SWOT analysis of cloud computing. A detailed list of cloud analysis is indicated in Table VI.
- 1) Strengths
    - a) It has been recognized that cloud computing reduces the price of IT infrastructure, and the lower cost of IT infrastructure will open the road for certain businesses to embrace the technology [53].
    - b) Cloud computing allows companies to concentrate their efforts on their core competencies while also providing them with a scalability scenario, both in terms of services and infrastructure, that becomes “unlimited” [54].
    - c) Cloud resources can be anything: database services, virtual servers or machines, full service processes, or complex setups of distributed computing systems such as clusters [54].
    - d) It does not require hardware and software updates as it is managed by the cloud provider [55].
  - 2) Weaknesses
    - a) Concerns raised regarding the integrity, privacy, and security of services for users and their data [54].
    - b) Raises legal difficulties such as trademark infringement, security concerns, and the sharing of proprietary data resources [54].

- c) There is a lack of consistency in service legal agreement (SLA) terminology. Performance and availability are essential SLA goals, but additional variables like security, data (ownership, location, access, and portability), dispute mediation, disaster recovery, and exit strategy negotiation are also crucial [54].
- 3) Opportunities
  - a) Assist developed countries in reaping the advantages of cloud without the large upfront costs that have hindered previous attempts [54].
  - b) Many innovative services are produced in the cloud, such as educational applications for African or developed country schools [54].
  - c) Many vendors provide affordable cloud computing services [56].
  - d) Cloud computing research is still in its initial phases, particularly in the health industry [56].
  - e) The network, server, and security issues associated with locally installed, outdated systems are eliminated by adopting cloud computing [57].
- 4) Threats
  - a) Problem in terms of data security, IT audit policies [54].
  - b) Raises privacy problems since the service provider may access the data on the cloud at any moment, notwithstanding their own encryption claim. They may inadvertently or purposefully change or destroy data [54].
  - c) The problem is with the legal ownership of the data. Many Terms of Service agreements do not address ownership issues [54].
  - d) Lack of trust in cloud services [55].

## V. CONCLUSION

This paper discusses the EHS with access control to secure and preserve EHR. The issue addressed in this paper is about the EHS with the RBAC model. In general, RBAC is a prevalent model in access control, and it may still be used in current EHS research, despite the fact that it is considered a conventional access control model. The problem highlighted in this paper is that using EHS with RBAC only to secure and preserve an EHR may cause a huge risk to the system. Therefore, several of the current studies on EHS utilizing access control have been suggested and examined their mechanisms and environment for a notion to the organizations in developed countries to develop their EHS instead of using an autonomous role. Analytical discussion in the form of a table has also been provided to identify the issues or problems, findings or results, and comments or suggestions related to previous works. Finally, due to problems with the instrument used by the previous work, information on instrument selection was provided in the form of a SWOT analysis as it is hoped that this information can be useful for organizations in developed countries in obtaining ideas for building their new or upgraded EHS in the right environment.

In the future, further developments need to be considered. First, many different types of access control models were employed, such as trust, purpose, and attributes. Therefore, this is an opportunity for researchers to develop EHS with a variety of access control models instead of an anonymous role to secure the system and protect privacy. Second, instead of developing EHS in a blockchain and cloud environment, maybe developing EHS in another environment needs to be considered for example mobile or IoT environment.

No.	Ref.	Problems / Issues										Findings / Results	Comments / Suggestions		
		Data Access	Data Sharing	Patient Consent	Patient Control	Emergency Cases	Data Protection	Security Issues	CP-ABE Problems	Lack of RBAC	Other Problems				
16.	Lu, 2018													No experimental analysis	-
17.	Zhang, 2020		/		/									Comparison = Accomplishes privacy preservation	-
18.	Azeez, 2018		/											Show preliminary framework	Static
19.	Zarezadeh, 2020												/	Accomplishes data confidentiality, user anonymity, and collusion resistance.	-
20.	Ming, 2018		/											a) Security analysis = Secure b) Performance = Low cost, while maintaining the privacy	Hiding the AC policy may sacrifice efficiency.
21.	Chentthara, 2019		/											No experimental analysis	-
22.	Zhang, 2018											/		a) Security analysis = Secure b) Performance = Efficient and expressive than prior	Lack of revocation
23.	Riad, 2019											/		a) Security analysis = Secure and prevents unwanted access. b) Outstanding compatibility and performance.	Encryption schemes = Has a huge computational cost and inefficient for lightweight applications.
24.	Tembhare, 2019	/												Performance = Superior than prior	-
25.	Nortey, 2019											/		Transparency and privacy	No experimental analysis
26.	Dagher, 2018					/				/				No experimental analysis	High computational cost
27.	Hussien, 2021									/				a) Proved secured b) AVISPA = Immune to man-in-the-middle-attack and replay attack c) High performance	-

TABLE V. SWOT OF BLOCKCHAIN TECHNOLOGY

Strengths	Weaknesses
Patient-related: - Register once - Shared database - Traceability - Patient monitoring - Privacy protection  Organizational-related: - Secure sharing - Clinical trials - Pharmaceutical supply chain - Manage medical insurance - Reduce time, error, cost - Confidence - Transparent - Alteration detection	- Controlled by the top management - Legal admissibility - Disposition records - Maintain records
Opportunities	Threats
- Trusted advisor - Professional reinvention	- Sharing sensitive data - Scalability - Cyber-attack - High-energy consumption - Absence of guidelines - Inter-operability - Technical skills - Financial cost - Training

TABLE VI. SWOT OF CLOUD COMPUTING

Strengths	Weaknesses
- Reduce price - Scalability - Multi-purpose - Updated by the cloud provider	- Integrity, privacy, and security issues. - Legal issues - SLA inconsistency
Opportunities	Threats
- Assist developed countries - Produce innovative services - Services affordable - Research - Equipment and installation are removed	- Data security and audit - Privacy problem - Data legal ownership - Trust issues

**Abstract**—Financial fraud is a complex problem faced by financial institutions, and existing fraud detection systems are often insufficient, resulting in significant financial losses. Researchers have proposed various machine learning-based techniques to enhance the performance of these systems. In this work, we present a semi-supervised approach to detect fraudulent transactions. First, we extract and select features, followed by the training of a binary classification model. Secondly, we apply a clustering algorithm to the fraudulent transactions and use the binary classification model with the SHAP framework to analyze the clusters and associate them with a particular fraud type. Finally, we present an algorithm to detect and assign a fraud type by leveraging a multi-fraud classification model. To minimize the mounting cost of the model, we propose an algorithm to choose an optimal threshold that can detect fraudulent transactions. We work with experts to adapt a risk cost matrix to estimate the mounting cost of the model. This risk cost matrix takes into account the cost of missing fraudulent transactions and the cost of incorrectly flagging a legitimate transaction as fraudulent. In our experiments on a real dataset, our approach achieved high accuracy in detecting fraudulent transactions, with the added benefit of identifying the fraud type, which can help financial institutions better understand and combat fraudulent activities. Overall, our approach offers a comprehensive and efficient solution to financial fraud detection, and our results demonstrate its effectiveness in reducing financial losses for financial institutions.

**Keywords**—Machine learning; semi-supervised learning; fraud; finance; cost analysis

## I. INTRODUCTION

Financial institutions face multiple challenges in fighting money laundering activities. Jensen [1] defines it as *the disguise of the origin of illegally obtained funds to make them appear legitimate. The goal of money laundering is to convert cash into another form.* Financial institutions must fight fraudulent activities by analyzing their customers' transactions. Transactions exchanged between financial institutions use SWIFT (Society for Worldwide Interbank Financial Telecommunication). This provides an interbank network offering different services, such as money transfers between bank accounts. More than 11,000 banking organizations across nearly 200 countries use SWIFT to transfer money [2]. SWIFT transactions are international and may have multiple intermediaries between the transaction's originator and beneficiary. However, among these transactions, anomalies may be linked

to financial fraud. Thus, the analysis of interbank transactions is a crucial issue for financial institutions [3]. The current systems have four limitations outlined by SWIFT<sup>1</sup>: 1) **systems and processes inefficiency**, originally designed for retail banking, is based on rules and risks. In this context, a critical problem is the high alert volume generated by them, and 90 percent of them are false alerts. Therefore, a manual investigation by experts is required. 2) Due to **mounting costs**, financial institutions lose a considerable amount of money fighting against money laundering—either by being fined for their weak compliance systems, maintaining these, or paying experts to review the alerts. 3) **Indirect structure**: Some domestic and regional banks act as aggregators for smaller banks. It is hard to follow and monitor the payment activity effectively in such instances. 4) **Information sharing**: Banks do not share information with their customers due to confidentiality clauses. In addition, due to these limitations, fraudulent transactions' detection is a complex task. It's also difficult to identify the fraud types [4]. For these reasons, our work aims to respond to the first three challenges by answering the following questions: How can fraudulent transactions be detected with their frauds types while minimizing the mounting costs? The article is structured as follows: in Section II, we review the most recent developments in the field of machine learning for detecting financial fraud and identifying different types of fraud. Then, in Section III, we present our method, which aims to detect fraudulent transactions within the SWIFT network and identify fraud types, while minimizing the associated costs. In Section IV, we apply our methodology to a real-world dataset and report on the experimental results, demonstrating the effectiveness of our approach. Finally, in Section VI, we summarize our findings and outline potential avenues for future research.

## II. RELATED WORK

Most of the detection systems are based on rules. These systems, based on predefined rules pertaining to amounts, countries, or customer behaviors, are identified by fraudsters. In turn, they adapt their behaviors to bypass these rules and manage to launder their money through illegal activities. For these reasons, they generate a high false alerts rate and detect few fraudulent transactions. Most of the literature on

<sup>1</sup><https://www.swift.com/fr/node/166756>

financial fraud detection techniques are based on machine learning. These techniques “offer numerical power and functional flexibility needed to identify complex patterns” [5]. Machine learning techniques for detecting financial fraud follow a process that can be divided into four steps: 1) **data acquisition**, which can be a complicated task for specific fields, such as finance or medicine, in instances where the data is confidential. Synthetic data can be used to validate experiments. 2) **Features extraction** involves calculating new information from existing features and reducing the number of dimensions while storing the information in the initial features. The 3) choice of **algorithms and their hyperparameters** depends on the number of dimensions, the volume, and the nature of the data. 4) The last step is the model **evaluation**. The predictive models are evaluated with metrics based on correct and wrong predictions.

This section is structured as follows: we present the machine learning process used for fraudulent transaction detection. Then we present a fraud types identification work. Finally, we synthesize the related work and introduce our approach.

#### A. Machine Learning Process

1) *Data acquisition*: A financial dataset is transactions with fields such as the amount, the date, the beneficiary [6], [7], [8]. They are confidential, and the lack of public data hinders experiments, particularly for their validation and comparison. There are different data formats depending on the data source (retail bank [9], agricultural bank [10]). The data volume in various experiments is heterogeneous, ranging from thousands [11] to millions [12] transactions. Validation of fraud detection approaches requires labeled datasets with legitimate and fraudulent transactions. A common aspect of financial fraud datasets is the class imbalance between fraudulent and legitimate transactions, with a fraudulent ratio usually around 0.1% [13]. In this context, researchers are interested on synthetic financial data generation. Lopez and al. [14] developed *PaySim* a mobile payment simulator tool with fraudulent transactions.

Most of the studied approaches don't explain the data generation process [15], [10]. Michalak and al. [16] detail in their study how they generated transactions. They use Gaussian distribution to generate a transactions networks between employees of companies. LV and al. [17] use real data coupled with artificially generated fraudulent data. Some approaches use the *kaggle* public dataset<sup>2</sup> to validate anti-money laundering methods [18], [7], [19]. This dataset comprises transactions conducted with credit cards involved in fraud. It includes the following three known attributes: the date, the amount, the transaction class (fraudulent or legitimate), and 28 remaining attributes with unknown meanings.

2) *Features extraction*: The data must be processed before training the models with algorithms. There are many types of processing, namely standardization, features addition, or dimensions reduction. Features from the transaction attributes are extracted to represent customers' behaviors based on their transaction history. The transactions are aggregated with different periods (weekly, monthly, and yearly) to compute several features, such as the transactions' average amounts made by customers and their frequency (number of transactions

done in a period). There are few works based on SWIFT transactions [20] or international transactions fields (countries or currencies) [21] to extract features. When the features number is too high, a dimensions reduction step is used to train the models faster or for visualization purposes. Bestami et al. [19] use the PCA (Principal Component Analysis) algorithm to reduce dimensions number to train a model with the K nearest neighbors algorithm. Paula et al. [22] use auto-encoders (deep learning technique) to reduce dataset dimensions number and complete the training 20 times faster. As mentioned, financial fraud datasets are imbalanced. The class imbalance problem can be less constraining using over or under-sampling techniques. Oversampling techniques generate synthetic new instances from the minority class, whereas under-sampling is used to reduce the number of instances from the majority class. SMOTE [23] is a popular oversampling algorithm in the literature that generate additional fraudulent transactions from the existing ones in the dataset. Badal et al. [24] prove this technique effective in financial fraud detection by obtaining better results using the SMOTE algorithm.

3) *Algorithms and hyperparameters*: Fraud analysts use fraud detection rules. These rules are used to detect fraudulent scenarios that occur frequently. However, rules can become quickly obsolete and must be reviewed. Nowadays, machine learning can be combined with a rules-based system. Classification (supervised learning) and clustering (unsupervised learning) help in fraud prevention and detection by classifying transactions as fraudulent or legitimate. The choice between supervised and unsupervised learning depends on the datasets. Supervised learning aims to learn the relationship between the data and its label. In unsupervised learning, the goal is to retrieve exploratory information, by grouping similar data or detecting hidden patterns [5]. Ryman-Tubb et al. [25] conduct a survey on card fraud detection methods for using financial transactions. This survey shows that only eight methods can be deployed on real data. Al-Hashedi et al. [26] expanded the work of Albashrawi [27] and present a survey from 2009 to 2019 conducted on financial fraud classified by fraud types.

a) *Supervised methods*: These compare algorithms to deduce which is pertinent to the data and their volume [28], [29], [19]. Mehbodniya et al. [30] propose financial fraud detection in healthcare based on machine learning and deep learning techniques and showed that the KNN algorithm generates better results than other approaches. Ensemble methods such as random forest [31] or boosting algorithms [32], [33], which combine multiple models, also proved their effectiveness in imbalanced datasets by using local decisions taken in areas where the imbalance is less prominent.

b) *Unsupervised methods*: These are used for financial fraud detection. Porwal et al. [7] use K-means algorithm to create fraudulent and legitimate transaction clusters. Simultaneously, other works propose new distance measurements to detect outliers [34]. Guo et al. [35] use autoencoders to have a deep representation of their data; they combined it with a KNN-based outlier detection method [36].

c) *Semi-supervised methods*: This combines supervised and unsupervised learning. Some approaches [37], [38], [8], [39] apply unsupervised algorithms to label their data, then they use supervised algorithms to classify their transactions. These approaches don't need an expert to verify each abnormal

<sup>2</sup><https://www.kaggle.com/mlg-ulb/creditcardfraud>

transaction from the unsupervised model, they verify clusters and fraudulent transactions from the supervised model.

4) *Evaluation and metrics:* The trained models are evaluated to check their effectiveness. Many metrics for evaluation, such as precision, recall, or F1-Score, exist. These metrics are used for model validation and comparison. In the evaluation process, data volume and fraudulent class rate are important. The evaluation should be done on the minority class.

In the case of unlabeled datasets, the evaluation is more complex. The verification of prediction results can be a long and imprecise operation. Furthermore, in the financial domain, Bahnsen et al. [40] propose a cost-risk matrix (Table I) to estimate the model mounting cost for a financial institution fighting against credit card fraud. It estimates model mounting costs depending on its predictions: it has an administration cost  $C_a$  for transactions predicted fraudulent, representing the estimated price for a transaction investigated by an expert.  $Amt_i$  is a fraudulent transaction cost, the fraudulent transaction amount predicted as legitimate by the model. They sum up all the transaction costs used in the evaluation phase to compute the model mounting costs.

TABLE I. BAHNSEN [40] RISK-COST MATRIX

		Reality ( $t_i$ )	
		Fraud	Legit
Prediction ( $t_i$ )	Fraud	$C_a$	$C_a$
	Legit	$Amt_i$	0

### B. Fraud Types Identification

Desrousseau et al. [41] present an approach to profile money laundering activities. They use the SOM (Self-Organizing Map) algorithm from an unlabeled transaction dataset to map its transactions into a two-dimensions matrix. SOM algorithm [42] is used as an unsupervised algorithm to cluster and visualize data with a two-dimensional map. The algorithm assign a new representation for each transaction. It uses the map node value associated to the transaction. Desrousseau et al. use this node and its neighborhood as a new transaction representation. With it, they train a neural network called Fuzzy ART, which forms clusters with transactions. Finally, they combine these clusters with the map from the SOM algorithm, resulting in a map with different regions depending on the value of the node associated with a cluster. To interpret results, they use two methods: 1) They use the Fuzzy Art model weighted vector for each money laundering type and features distribution to retrieve the features with the highest weight. 2) They group transactions with the same type and use features distribution. This approach is interesting because no literature interprets fraud types in financial datasets. The choice of algorithms might be questionable because there are numerous clustering algorithms, such as k-means or BIRCH. The interpretation through the comparison of maps can be very complicated depending on the number of dataset features. Moreover, this approach relies on unlabeled datasets. It does not address the banks' concern of identifying the fraudulent patterns on their labeled dataset and the fraud types identification. While their interpretation of feature distribution is interesting, a new tool in the literature has been designed to interpret models, which could be helpful. In our work, we aim

TABLE II. EXAMPLE OF SWIFT MESSAGES OF THE DATASET

Originator	Intermediary	Beneficiary	Date	Currency	Amount	Class
BIC0FR01	BIC0IT01	BIC0FR02	210625	EUR	15006	L
BIC0US03	-	BIC0GB01	210625	GBP	33065	L
BIC0FR04	BIC0FR06	BIC0FR05	210626	EUR	100325	F

to extend this work, propose a method to detect fraudulent transactions with a reduced features number, and interpret the fraud types with interpretable tools.

### C. Synthesis

We studied the related works of fraudulent transactions detection and types identification. This problem has not been considered yet on the SWIFT transactions. As mentioned, SWIFT executes financial transactions between banks worldwide. These transactions have fields such as: country, currency and intermediary. SWIFT fraudulent transactions detection model is obtained through a comparative study of the supervised and unsupervised algorithms and their evaluation.

Desrousseau et al. [41] present interesting results to identify the fraud types inside our datasets. However, this approach could be improved by considering labeled datasets and using model interpretation (SHAP). We aim to reduce our model mounting costs by using and expanding the risk-cost matrix from [40].

## III. METHODOLOGY

In this section, we present our proposed approach for labeled transactions (fraudulent and legitimate). Our approach has three goals:

- 1) Detect fraudulent transactions
- 2) Identify and analyze the fraud types in the dataset
- 3) Minimize the mounting costs

To achieve these goals, we present our semi-supervised approach in Fig. 1. First, we extract features from a SWIFT transaction set. Second, we select the relevant features for detecting fraudulent transactions from the legitimate by training a binary classification model. Afterward, we create a fraudulent transaction subset, from which we apply an unsupervised algorithm to form clusters based on the fraud types. We also use the binary classification model to interpret the cluster to identify the fraud type. Moreover, we label fraudulent transactions based on the fraud types and train a multi-class classification model. We propose the *Multi-Fraud Detection* algorithm (MFD) to classify a transaction as legitimate or classes associated to fraud types. Then we propose a second algorithm to minimize the model mounting cost.

This section is structured as follows: (A) we present the dataset and the fields, (B) we list the extracted features, (C) we train a binary classification model and evaluate it, (D) we apply a clustering algorithm on the fraudulent transactions and identify the fraud type, (E) we train a multi-class classification model, and (F) we minimize the model mounting costs.

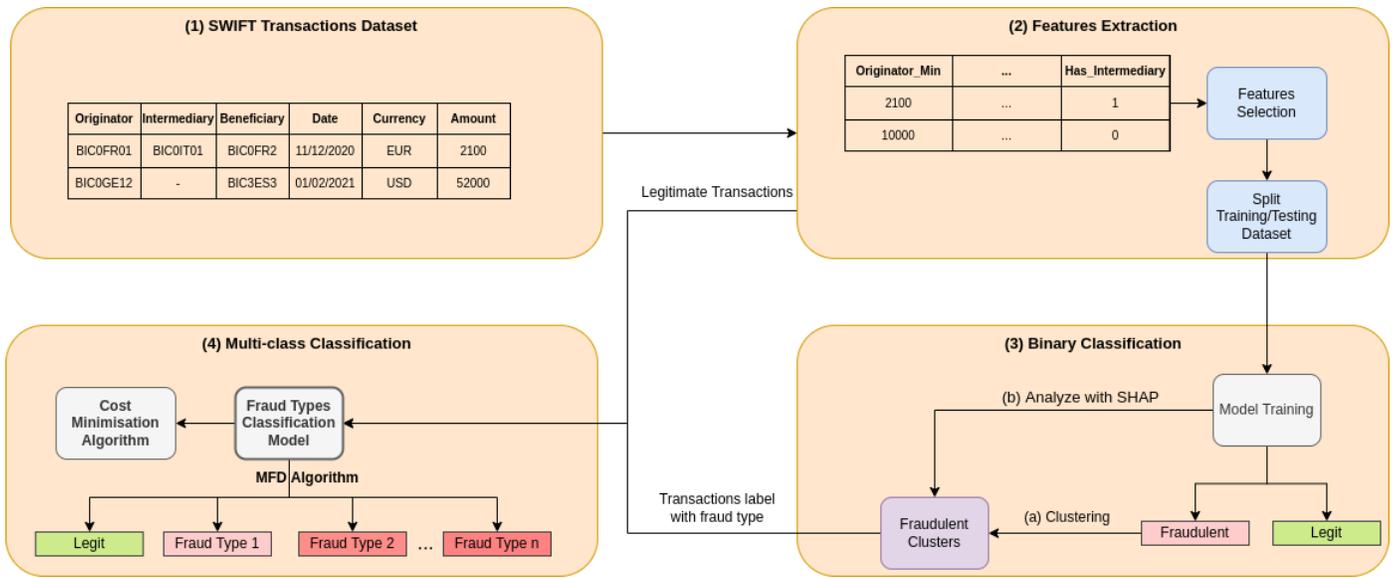

Fig. 1. Methodology architecture schema

### A. Dataset Presentation

In Table II, we present the SWIFT transactions fields. These transactions contain three actors: the originator, the intermediary, and the beneficiary. The transaction corresponds to the transfer of a money **amount** in a **currency** operated on a **date** between an **originator** and a **beneficiary**. SWIFT transactions path depends on the relationship between the **originator** bank and the **beneficiary** bank. If they have no direct relationship, then the transaction involves an **intermediary** connecting the two banks. Otherwise, the path only includes the originator and the beneficiary. An actor is identified with a BIC code, which contains the financial institution country. The transaction class indicates if the transaction is fraudulent (F) or legitimate (L). We formalize transactions as the following:

We have a set  $T$  of transactions  $t_i$ , where  $i$  ranges from 1 to  $n$ , the total number of transactions. To compute features for each transaction  $t_i$ , we form transactions subset with a similar field (e.g. originator), with specific time window, (e.g. last 15 days). For example, for a transaction  $t_1$ , we have subset  $T^{15D}(\text{originator})$  containing all transactions with the same originator for the last 15 days.

### B. Detection of Fraudulent Transactions

We need to extract features from the dataset to separate legitimate and fraudulent transactions. The computed features must enlighten the fraud associated with SWIFT transactions. In a transaction, we have one numerical field: the amount. Features are computed on different period with the date field. Hence, we use the amount and the date to compute features associated with the other fields: the originator, the intermediary, the beneficiary and their countries, and the currency. With a financial expert, we define a list of features with their formalization in Table III.

We also define other features relative to the transaction path. In this context, by path, we mean the countries implied

in the transaction and the presence of an intermediary. We list the features in Table IV.

Finally, we add temporal features relative to the day, the week, the year. We select a reduced features number. Some features might be irrelevant to the separate legitimate and fraudulent transactions in the features computed. A feature selection algorithm assigns an importance value to each feature. We select the top  $n$  features depending on the feature number required to interpret the fraud type. With the additional features, we train a binary classification model, evaluated with the metrics presented in Section III-C.

### C. Model Training and Evaluation

In the related works, researchers trained a model with different classifiers and then selected the classifier with the best evaluation results. A good evaluation is crucial to ensure that the extracted features can distinguish between legitimate and fraudulent transactions. To do this, we use a confusion matrix presented in Table V.  $TP$  is the number of true positives.  $FN$  is the number of false negatives.  $FP$  is the number of false positives. Finally,  $TN$  is the number of true negatives.

From the confusion matrix, we can evaluate our approach with the classical metrics:

$$Precision = \frac{TP}{TP + FP}; \quad (1)$$

$$Recall = \frac{TP}{TP + FN}; \quad (2)$$

$$F1 = \frac{2 * TP}{2 * TP + FP + FN}; \quad (3)$$

### D. Clustering of Fraudulent Transaction

Unsupervised algorithms are effective at discovering new patterns and hidden relations in datasets. Thus, we create

TABLE III. FIELDS BASED FEATURES

Formalization	Description
$ T(field) $	Transactions number in the set
$\max_{0 < i < n} T(field amount)$	Maximum amount
$\min_{0 < i < n} T(field amount)$	Minimum amount
$\sum_{i=0}^t T(field amount)$	Sum of transactions
$\frac{\sum_{i=0}^t T(field amount)}{ T(field) }$	Average transactions amounts
Latency	Seconds since the last transaction
$ T(field) \cap T(Originator) $	Count of transactions with the same Originator
$ T(field) \cap T(Intermediary) $	Count of transactions with the same Intermediary
$ T(field) \cap T(Beneficiary) $	Count of transactions with the same Beneficiary
$ T(field) \cap T(Currency) $	Count of transactions with the same Currency
$ T(field) \cap T(OriginatorCountry) $	Count of transactions with the same Originator Country
$ T(field) \cap T(IntermediaryCountry) $	Count of transactions with the same Intermediary Country
$ T(field) \cap T(BeneficiaryCountry) $	Count of transactions with the same Beneficiary Country
$ \{T(field) \cap T(Originator)\} $	Distinct count of transactions with the same Originator
$ \{T(field) \cap T(Intermediary)\} $	Distinct count of transactions with the same Intermediary
$ \{T(field) \cap T(Beneficiary)\} $	Distinct count of transactions with the same Beneficiary
$ \{T(field) \cap T(Currency)\} $	Distinct count of transactions with the same Currency
$ \{T(field) \cap T(OriginatorCountry)\} $	Distinct count of transactions with the same Originator Country
$ \{T(field) \cap T(IntermediaryCountry)\} $	Distinct count of transactions with the same Intermediary Country
$ \{T(field) \cap T(BeneficiaryCountry)\} $	Distinct count of transactions with the same Beneficiary Distinct country

TABLE IV. PATH FEATURES

Features	Description
Intermediary	Boolean value to specify if there is an intermediary
Originator path	The count of the originator using the intermediary and beneficiary countries to make a transaction
Intermediary path	The count of the originator using the originator and beneficiary countries to make a transaction
Beneficiary path	The count of the originator using the originator and intermediary countries to make a transaction
Distinct originator Path	The count of a distinct path with an intermediary and beneficiary countries
Distinct intermediary Path	The count of a distinct path with an originator and a beneficiary countries
Distinct beneficiary path	The count of a distinct path with an originator and an intermediary countries

TABLE V. CONFUSION MATRIX

	Predicted : Positive	Predicted : Negative

Actual : Negative	$FP$	$TN$

fraudulent transactions clusters, each of which will be associated with a fraud type. Cluster analysis allows experts to identify which fraud types clusters are associated based on their fraud knowledge. We use the SHAP framework [43] to facilitate cluster analysis and interpret model predictions. It assigns importance to each feature (Shapley values) for a prediction, depending on the feature’s value. By leveraging this framework, we use visualization tools: *heatmap* and *beeswarm* for each cluster.

### E. Multi-Class Model

After identifying the fraud types, we train a new model to predict the transactions class between legitimate and fraud types. Class numbers rely on the fraud types’ numbers on the dataset. The new model attributes a probability to each

class; however, the frauds’ probability is split into different classes. Some fraudulent transactions’ probability is divided into different fraudulent classes. The legitimate class could, in turn, take over them. For these reasons, we sum the fraudulent classes’ probability  $p_i$  ( $1 < i < n$ ,  $n$  number of fraudulent classes), we start at 1 because  $i = 0$  represents the legitimate class. The transaction is considered fraudulent if the sum of  $p_i$  is above a defined threshold. The transaction’s class will be the fraudulent with the highest probability. We resumed this on our *MFD* algorithm presented in the Algorithm 1.

### F. Mounting Costs Minimization

To estimate the model mounting costs, we used the matrix of Bahnsen et al. [40], where we added a cost  $C_d$  for the legitimate transaction predicted as fraudulent, which estimates the dissatisfaction price of a customer whose transaction has been blocked. Indeed, Bahnsen et al. did not consider the wrong prediction cost for a fraudulent transaction. If a transaction is incorrectly blocked for a customer, then this one could be unsatisfied and result in losses for the financial institution.

We minimize the model’s risk cost with our new risk–cost

**Algorithm 1** MFD : Multi-Fraud Detection

SKAIZen Group<sup>3</sup> company. We split the data into a training dataset composed of 294136 transactions with 10722 fraudulent transactions and a testing dataset composed of 735359 transactions with 2645 fraudulent transactions. Thereafter, we used the Jupyter<sup>4</sup> platform to develop the experimentation. We trained our models with the Scikit-Learn library.

A. Features Extraction

We compute the features for the fields listed in Table VII.

Then, we compute the features related to transactions paths. Features are extracted for each transaction on a time window of one year, one month, and three days before the transaction date. We obtain 267 features, and we reduce this number using the *SelectFromModel* algorithm, a meta-transformer with a model trained with a classifier to assign an importance score to each feature. We use CatBoost as the classifier for its performance and capacity to deal with categorical features. The features number is an algorithm parameter, we choose 10 features based on SWIFT experts' knowledge (Table VIII).

The algorithm selects features related to the relationship between the intermediary and the beneficiary. For the transactions' history, no features related to the month were retained, except the last three days ('3D' suffix) and the last year. We apply a value transformation between 0 and 1 with the *Quantile Transformer* algorithm, which transforms according to a uniform distribution to reduce the outlier transaction impact. A very high amount of transactions could misrepresent other transactions during the visualization step (section IV-C).

B. Algorithms Comparison

We compare the classifiers from the literature to observe the best algorithm for our data. The results are presented in Table IX. Results show that CatBoost is the best algorithm for our data with a f1-score of 0.89.

Cluster	Count of transactions	Average
0	4970	107999
1	4652	771069
2	3745	1279286

Our features are relevant enough to distinguish legitimate and fraudulent transactions. Our future experiment models will be trained with CatBoost.

C. Clustering of Fraudulent Transactions

After algorithms comparison, k-means [44] unsupervised algorithm is applied on the fraudulent transactions subset. We test different cluster numbers on our 13367 fraudulent transactions. We used the elbow method [45] to select the optimal  $k$  Fig. 2. The optimal cluster number is 3 because the curve linearly decreases at this number. Table X presents transactions distribution for each cluster and the average of transactions amount. The 3 clusters have an equivalent transactions number; however, the average of the transactions amount is different. The first cluster has a low average, the second one has a medium average, and the third has a high average.

In order to assign a fraud type to each cluster, we present fraud types in Table XI identified by our experts and the literature [46].

TABLE XI. FRAUD TYPES

Fraud Types	Description
Payment diversion	unauthorized redirection of payment instructions
Large amount	unauthorized initiation of high-value transactions
Smurf	illegal money laundering using money mules
Dormant account	unauthorized use of inactive bank accounts
False demand draft	creation and use of fake financial instruments to withdraw money.

D. Clusters Analyses and Fraud Types Identification

To analyze clusters, we used the SHAP framework [43] with the binary classification model trained on section IV-B on the transactions of each cluster. We compute the Shapley values with SHAP. For the interpretation, we use two visualization types: i) *beeswarm* for global cluster visualizations with features' importance and their value, ii) *heatmap* for cluster local visualizations with features impact on each transaction prediction.

1) *Cluster 0*: From the *heatmap* (Fig. 3), we split the map in two parts with the first five features : (i) on the left side, the first three features have a high impact. The *beeswarm* (Fig. 4) indicates that these values are low. For the last two features, their impact is lower, and their values are medium. (ii) The right side indicates the high impact of the first and fourth features with low values and a negative impact of the feature *value* (Amount field) with low values. This fraud type comprises customers making a few transactions with low and medium amounts.

Experts analyzed it as either to new customers doing few transactions (low frequency) of low amount (left side), or either to customers doing medium amount transaction after a long time (right side). This cluster is assigned to the “dormant account” fraud type (DAF).

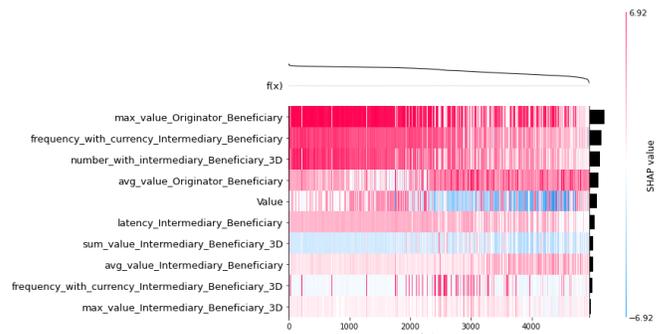

Fig. 3. Heatmap cluster 0

2) *Cluster 1*: According to the *heatmap* (Fig. 5), we split the map in two parts: (i) the right side shows that the amount

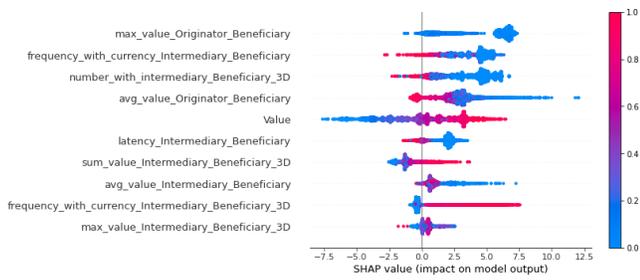

Fig. 4. Beeswarm cluster 0

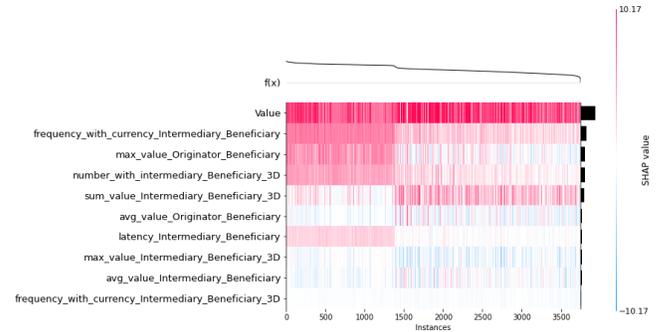

Fig. 7. Heatmap cluster 2

has a high impact with high value, as shown in the *beeswarm* (Fig. 6). (ii) the *heatmap*'s left side has a high impact on the second and third features with high values according to the *beeswarm*. The amount has an average impact corresponding to a medium value for these impacts.

Experts associated this fraud type with customers realizing many transactions (high frequency) in a short time (three days) and with an average amount. This cluster is assigned to the “smurf” fraud type (SF).

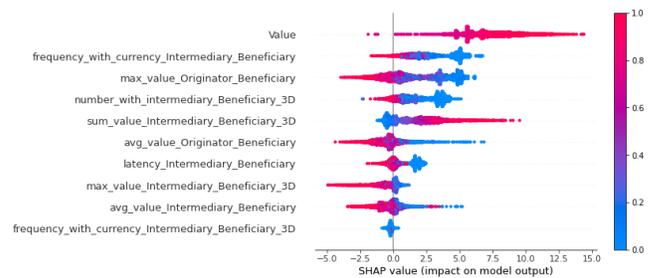

Fig. 8. Beeswarm cluster 2

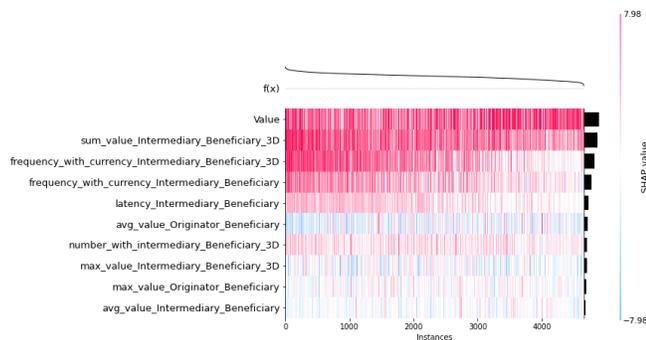

Fig. 5. Heatmap cluster 1

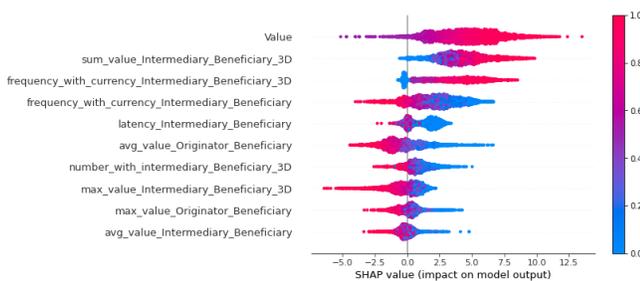

Fig. 6. Beeswarm cluster 1

3) *Cluster 2*: According to the *heatmap* (Fig. 7), the feature *value* (Amount field) greatly impacts the whole cluster. Furthermore, the *beeswarm* (Fig. 8) indicates that its value is high, and if we revert to Table X, the average amount of this cluster is very high. Experts associate this fraud type with customers realizing a high amount of transactions. This cluster is assigned to the “large amount” fraud type (LAF).

We identified three fraud types by leveraging the binary classification model in combination with the SHAP framework and *k-means* algorithm. The next step is training a multi-fraud

classification model to classify frauds in their fraud types. we update the fraudulent transaction label with their fraud type.

### E. Multi-Fraud Classification and Mounting Cost Minimization

We train a multi-Fraud classification model with the same transactions in the training and testing set. Once our model is trained, we choose a threshold for the *MFD* algorithm presented in Section III-E.

we used our cost minimization algorithm to select the optimal threshold. The administrative cost  $C_a$  is set to 100, and the dissatisfaction cost  $C_d$  set to 50.

Fig. 9 shows the model mounting cost, and its f1-score is represented by two curves for each threshold. The mounting cost is low when the threshold is low because transactions probability to belong to fraudulent class are above 0.1. There is no cost impact on the model with fraudulent transaction amounts. However, the model generates many false alerts, for this reason, it's important to maintain a good f1-score. When the threshold is above 0.1, the model has the highest f1-score (0.85). Using our cost minimization algorithm, we retrieve 0.19 as the optimal threshold that minimizes the model mounting cost while maintaining a good f1-score (0.85). We reduce the f1-score of the hundredth order, which is insignificant.

We detail the model's evaluation results with the threshold in Table XII and in the confusion matrix in Table XIII. Our model has a good precision and a weaker recall. It results in a f1-score of 0.74, which is lower than 0.85 with the binary classification. *MFD* algorithm sums the probability of 3 fraud types. The transaction is fraudulent if the sum is above a threshold and its class is the fraud type with

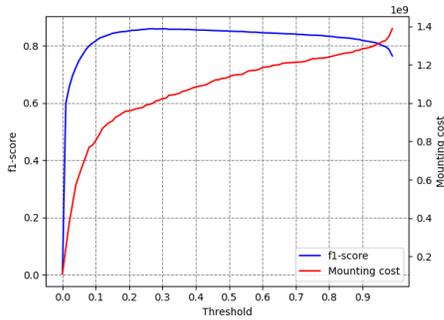

Fig. 9. Mounting costs and f1-score curves

TABLE XII. MULTI-CLASS MODEL

	Fraud Type	Precision	Recall	f1-score
Multi-Class	Legit	0.99	0.99	0.99
	SF	0.91	0.43	0.58
	DAF	0.93	0.50	0.65
	LAF	0.92	0.60	0.73
	Macro avg	0.94	0.63	<b>0.74</b>
Binary (DAF+SF+LAF)	Legit	0.99	0.99	0.99
	Fraud	0.92	0.57	0.70
	Macro avg	0.96	0.78	<b>0.85</b>

the highest probability. In conclusion, our multi-class model detects fraudulent transactions as a binary model, and the fraud type assignment reduces the f1-score of just 0.09 but give additional information to experts about frauds.

V. LIMITS AND DISCUSSIONS

In this section, we completed the 3 goals outlined in section III through experimentation. First, we detect fraudulent transactions by extracting relevant features and using the *CatBoost* algorithm. This resulted in a f1-score of 0.89. However, due to data privacy limitations, we can't compare these results with other datasets. Second, we identify our dataset's fraud types based on the *CatBoost* model, *k-means* algorithm and SHAP framework. A multi-class classification model is trained using the *MFD* algorithm to detect fraudulent transactions and assign them a fraud type. Finally, we select a threshold to detect fraudulent transactions in order to achieve the highest f1-score while minimizing costs. Our multi-class model obtain 0.74 as f1-score (Table XII), which is lower than the 0.89 from the first step. However, if we consider a transaction as fraudulent when it's part on one the 3 fraud types, there is a f1-score of 0.85 (binary row). It means that fraudulent transactions are still detected on this model, however the fraud type assignment is decreasing the f1-score. It can be explained by possible close boundaries between clusters.

TABLE XIII. CONFUSION MATRIX

		Predicted			
		Legitimate	DAF	SF	LAF
Actual	Legitimate	732605	18	2	89
	DAF	317	243	2	2
	SF	55	2	59	0
	LAF	779	2	0	1184

VI. CONCLUSION

We presented in this work the context of financial transactions between banks through the SWIFT network. We studied financial fraud detection literature. Machine learning techniques are valuable for identifying the fraudulent pattern provided during the training phase. We proposed a detection and identification frauds approach based on Desrousseau et al. method. We can summarize our approach as: First, we extracted features from the transaction base fields and on the actors, currencies, countries, and transactions path. Second, we applied a supervised algorithm on our labeled dataset and reduced the features number to retain the relevant one. Third, we used the unsupervised algorithm to cluster fraudulent transactions to identify the fraud types by leveraging the SHAP framework and the supervised model. Then, we trained a multi-fraud classification model to assign a class to a transaction with the three identified fraud types: dormant account fraud, smurf fraud, and large amount fraud. To handle this model prediction, we proposed the *MFD* algorithm to classify a transaction as fraudulent or fraudulent with its type. Finally, we proposed another algorithm to minimize the model mounting cost by choosing a threshold from which a transaction is considered fraudulent.

Our semi-supervised methodology is used by financial institutions to understand their dataset. Cluster interpretation needs experts feedback based on visualization tools (Fig. 3-8).

In conclusion, our contributions with the proposed approach are : detecting fraudulent transactions, identifying fraud types and minimizing the mounting cost.

In future work, we plan to explore additional fraud types on different datasets. We also plan to automatize identifying fraud type with semantic analyses based on financial fraud ontology.

ACKNOWLEDGMENT

The authors would like to thank the University of Burgundy and more particularly the laboratory LIB for the scientific help. We also thank SKAIZen Group company for providing the dataset and experts. Finally, we thank the ANRT for supporting this project.

**Abstract**—Recently liver diseases are becoming most lethal disorder in a number of countries. The count of patients with liver disorder has been going up because of alcohol intake, breathing of harmful gases, and consumption of food which is spoiled and drugs. Liver patient data sets are being studied for the purpose of developing classification models to predict liver disorder. This data set was used to implement prediction and classification algorithms which in turn reduces the workload on doctors. In this work, we proposed apply machine learning algorithms to check the entire patient's liver disorder. Chronic liver disorder is defined as a liver disorder that lasts for at least six months. As a result, we will use the percentage of patients who contract the disease as both positive and negative information. We are processing Liver disease percentages with classifiers, and the results are displayed as a confusion matrix. We proposed several classification schemes that can effectively improve classification performance when a training data set is available. Then, using a machine learning classifier, good and bad values are classified. Thus, the outputs of the proposed classification model show accuracy in predicting the result.

**Keywords**—Machine learning algorithms; classification model; classifier; liver disease

## I. INTRODUCTION

The liver is the most imperative structure in a human build. Insulin is broken down by the liver. The liver breaks bilirubin with glucuronidation, which further helps its defecation into bile [1]. It is also accountable for the breaking down and excretion of many unwanted products. It shows a noteworthy role in altering toxic materials. It shows a noteworthy role in collapsing medicinal products. It's named Drug metabolism. The weight would be 1.3 kg. The liver consists of 2 immense portions namely the privileged portion, and the left estimate. The gallbladder is located below the liver, near the pancreas. The Liver along with these organs helps to consume and give nutrition. Its job is to help the flow of the wounding materials in the stream of blood from the stomach, before passing it to whatsoever is left of the body. Liver sicknesses are triggered when the working of the liver is affected or any injury has happened to it [2].

The development of liver disorders [3] is complicated and varied in character, influenced by a number of variables that determine disease susceptibility. Sex, ethnicity, genetics, environmental exposures (viruses, alcohol, nutrition, and chemicals), body mass index (BMI), and coexisting diseases like diabetes are among them. A high mortality rate is associated with liver problems, which are life-threatening diseases. The usual urine and blood tests are the first step in the prognosis of liver disorders. A LFT (liver functions test) is recommended for the patient based on the symptoms seen [4].

Liver disease is a significant health issue affecting millions of people globally. Early detection and accurate classification of liver diseases can lead to better patient outcomes and reduce the burden on the healthcare system. One-third of adults and an increasing proportion of youngsters in affluent nations suffer from non-alcoholic fatty liver disease (NAFLD) [5], a growing health issue. The abnormal buildup of triglycerides in the liver, which in some people causes an inflammatory reaction that can lead to cirrhosis and liver cancer, is the first sign of the condition. While there is a significant correlation between obesity, insulin resistance, and non-alcoholic fatty liver disease (NAFLD), the pathophysiology of NAFLD remains poorly understood, and treatment options are limited. However, machine learning techniques have demonstrated encouraging results in predicting and categorizing liver diseases based on patient data. By utilizing sophisticated algorithms to analyze and learn from large datasets, these techniques can identify patterns and anticipate outcomes. The employment of machine learning techniques in liver disease prediction and classification is a dynamic area of research, with continual advancements being made to enhance accuracy and decrease healthcare costs.

### A. Overview of Liver Disease

Liver disease refers to an abnormality in the liver's function, resulting in illness [4]. The liver is responsible for many vital functions within the body, and if it becomes damaged or infected, the loss of these functions can have a significant impact on overall health. Hepatic disorder is another term used to describe liver disease [6]. This umbrella term encompasses a range of possible complications that prevent the liver from performing its assigned roles. Even if only a quarter of the liver is still functioning and the rest is damaged, this organ's efficiency will be greatly reduced. The liver is the biggest hard structure in the human build and is well thought-out as a gland because, amid its many roles, it creates and secretes bile. The liver is stood at the upright part of the abdomen and the rib cage shelters it. It has two core lobes that are thru with small lobules. The liver cells have two dissimilar bases of a blood source. The hepatic artery transfers heart-driven blood abundant in oxygen, while the portal vein provides nutrients from the intestines. Generally, the vein's job is to bring the blood from all other organs to the heart, but the portal vein permits nutrients from the digestive region to go into the liver for treating and purifying the former to flow into the general circulation. The portal vein proficiently transports the chemicals that liver cells require to yield the proteins, cholesterol, and glycogen needed for usual body actions.

## B. Causes of Liver Disease

There are numerous activities that prompt liver maladies [7]. The classifications are:

1) *Infection*: The liver can become infected by parasites and viruses, which can lead to inflammation or edoema and compromise liver function. The virus that typically results in liver damage is spread through blood or sperm and is primarily brought on by tainted food, contaminated water, or contact with an infected person. Hepatitis A, C, and B are liver infections that can affect people.

2) *Immune system abnormality*: The body's immune system is administered by certain ailments, to attack other body parts. The liver is also affected. These diseases could be Autoimmune hepatitis. In addition, it could be Primary biliary cholangitis, and Primary sclerosing cholangitis.

3) *Inheritance*: A rare gene genetically inherited from either of your parents can cause a buildup of various compounds in the liver, which can cause liver damage. Wilson's disease, Hemochromatosis, and alpha-1 antitrypsin deficiency are three examples of genetic liver illnesses.

4) *Cancer and other progressions*: Cancers that have may reason liver diseases are Liver adenoma, Bile duct cancer, and Liver cancer.

5) *Others*: The general reasons are prolonged alcohol abuse, fat buildup in the liver (NAFLD), certain drugs or over-the-counter treatments, and certain herbal mixes.

6) *Risk aspects*: Factors that might raise the risk of liver diseases are excessive usage of liquor, being overweight, diabetes of type, tattoos, piercings of the body, drug injection with used needles, transfusion of blood, exposure to foreign blood, unprotected intercourse, exposure to chemicals, and inheritance.

## C. Chemicals Compounds in Liver

Chemicals such as Bilirubin, Albumin, Alkaline phosphatase, Aspartate aminotransferase, and globulin are existent in the liver and perform a vital role in the daily operations of the healthy liver.

1) *Bilirubin*: Bilirubin is a yellowish complex that arises in the usual catabolic trail that breaks down heme in vertebrates. Bile and urine emit it. Raised volumes of bilirubin in the body cause diseases. The bilirubin is accountable for the yellow shade of cuts and the yellow staining in jaundice disease. Its following breakdown products, like stercobilin, are accountable for the brown color of feces. Another breakdown product, urobilin, is the key constituent of the straw-yellow color of urine.

2) *Alkaline phosphatase*: In beings, alkaline phosphatase is existent in all tissues all over the body but is mainly focused in the liver, intestinal mucosa, bile duct, bone, kidney, and placenta. In the serum, two kinds of alkaline phosphatase isozymes prevail skeletal and liver. In childhood, most of the alkaline phosphatase is of the skeletal source. Most of the mammals including humans have these types of alkaline phosphatases:

- ALPI: It is intestinal having a molecular mass of 150 kDa.
- ALPL: It is tissue-nonspecific mainly present in the liver, kidney, and bone.
- ALPP: It is placental and is also known as Regan isozyme.
- GCAP: It is a germ cell.

3) *Aspartate aminotransferase*: AST is a kind of enzyme. AST levels are higher in the heart and liver. AST is found in the kidneys and muscles, although in less amounts. It is very low in human blood. When muscle or liver cells are injured, the AST is released into the bloodstream. The AST test will therefore be useful for tracking or identifying liver damage or dysfunction.

4) *Albumin*: They're globular proteins. Serum albumins are common and are the most imperative protein of blood. It binds thyroxine (T4), water, cations like Ca<sup>2+</sup> and Na<sup>+</sup>, hormones, fatty acids, bilirubin, and pharmaceuticals. Its core part is to govern and normalize the oncotic pressure of the blood. It binds several fatty acids, cations, and bilirubin.

5) *Globulin*: They are protein globules. They are heavier than albumin at the molecular level. It will not dissolve in pure water but will solvate in dilute salt solutions. The liver produces some globulins. Globulin absorption in fit human blood is around 2.6-3.5 g/dL. There are several different types of globulins, including beta, alpha 1, alpha 2, and gamma globulins. Any unfitting amounts of these chemicals produced in the kidney can reason an imbalance and cause liver diseases. These are considered features. There are  $n$  number of kinds of liver illnesses and these are grounded based on the proportion of these chemicals stashed.

## II. MACHINE LEARNING AND LIVER DISEASE

Classification algorithms are often defined to be used for forecasting the liver disease as they can help predict whether a patient has the disease or not based on certain features or characteristics. Based on the existing solutions, it was found that the F-Tree algorithm shows the highest accuracy among the algorithms tested, making it a suitable choice for forecasting liver disease. Feature selection along with the fuzzy K-means classification methods are commonly used in the classification of liver diseases. These methods can help identify important features that can be used to distinguish between different types of liver disorders. As the same attribute values may be present in different liver disorders, using fuzzy-based classification can help improve the performance of the classification process by taking into account the degree of similarity between instances [8], several classification algorithms, including J48, SVM, RF, and MLP, were used to classify liver diseases. The study evaluated the performance of these state-of-the-art algorithms using metrics such as data accuracy, data effectiveness, and correction rate, and compared the results. The findings indicated that the multilayer perceptron algorithm achieved the highest accuracy compared to the other algorithms examined in the research. In this work [9], researchers employed Bayesian classification to distinguish between various liver diseases, including cirrhosis, hepatitis, and non-liver diseases. They used both Naive Bayes and FT

tree techniques to categorize the liver patient dataset into different illness subtypes, and evaluated the performance of these methods in terms of accuracy and execution time. Their analysis revealed that Naive Bayes algorithm outperformed the FT tree algorithm in terms of execution time.

In this work [10], authors explored the effectiveness of several classification methods in diagnosing liver diseases. These methods included Naive Bayes, Decision Tree, Multilayer Perceptron, K-Nearest Neighbors, Random Forest, and Logistic Regression. To evaluate their performance, the authors used metrics such as precision, recall, sensitivity, and specificity. The results showed that Naive Bayes achieved the highest precision compared to the other algorithms examined. Additionally, the Logistic Regression and Random Forest algorithms were found to have good results when recall was considered.

In [11], to create a model for analysing liver illness, the WEKA tool was employed. To create their suggested model, the Naive Bayes, Decision Tree (DT), and *J48* algorithms were employed. The algorithms' accuracy and execution time were measured, and the results were compared to those of the available options. The findings demonstrated that the *J48* and DT algorithms outperformed the Naive Bayes algorithm in terms of accuracy.

In [12], uses a dataset of Indian patients with liver disease and implements it using various classification algorithms, including LR, K-NN, and SVM. Additionally, confusion matrix was used to evaluate the algorithms against one another. Based on their correctness, the experimental analysis of these algorithms was examined and evaluated. According to the findings, LR and KNN techniques can both achieve a sizable degree of accuracy, although LR has a high sensitivity. With this, it can be inferred that LR is an appropriate strategy for disease prediction. A novel feature model with the classification methods Random Forest, SVM, *J48*, Bayesian Net, and MLP was proposed in [13], [14], [15].

Three distinct procedures are used to examine and implement a comparative study for the prediction of liver disease. On the dataset containing records of liver diseases, the normalisation method min-max was examined and tested in the initial phase. The second step uses the PSO feature selection approach to choose the dataset's necessary components for predicting liver illness. The implementation of the classification algorithms and an accuracy-based performance evaluation of the methods were done in the third phase. The experimental study leads to the conclusion that the *J48* method outperformed when PSO feature selection was used. In this work [16], aimed to balance the dataset for accurate prediction of liver diseases by using a combination of sampling and oversampling techniques. Several classification algorithms were used, including *J48*, Multilayer perceptron, Random Forest, Multiple linear regression, Support Vector Machines, and Genetic programming. The Random Forest algorithm with oversampling at higher rates demonstrated the best performance in predicting liver diseases. Similarly, In this work [17] utilized various classification algorithms such as Naive Bayes, FT tree, *J48*, SVM, RF, MLP, K-NN, LR, and *C4.5* to classify liver diseases. Different techniques such as feature selection, fuzzy K-means classification, normalization, PSO feature selection, oversampling, and undersampling were

also employed to enhance the performance of these algorithms. The performance of these algorithms was evaluated based on different factors such as accuracy, execution time, precision, recall, sensitivity, specificity, and F-measures. The results of these studies indicate that different algorithms perform differently depending on the dataset and application [18]. Therefore, it is crucial to evaluate the performance of multiple algorithms and techniques to identify the best approach for a specific dataset and application. Although the outcomes have been found to differ depending on the dataset employed and the specific algorithm used, some algorithms such as Multilayer perceptron, Random Forest, Support Vector Machines, and Artificial Neural Network generally perform better than others in predicting liver diseases.

ML has a multiplied widespread routine in the modern ages. Using ML as a means of aid in therapeutic and pharmacological diagnostics is increasing. However, the common thing is rapidly increasing access to huge amounts of data. The following content gives a thorough summary of the major defies and prevalent resolutions to ML challenges [19] in medicine. Feature selection is to decrease the struggle by selecting a subsection of the useful features in the input and disposing of the residual features.

It is clear from the above statement that various studies have been conducted using different machine learning algorithms to predict liver diseases and evaluate their performance. Different algorithms such as Naive Bayes, Decision Trees, Random Forest, Logistic Regression, K-NN, SVM, Artificial Neural Networks, and *C4.5* have been used in these studies. The performance of these algorithms has been evaluated based on factors such as accuracy, precision, recall, F1-score, specificity, and execution time. It is also noted that different studies have different conclusion on which algorithm performs best, it depends on the dataset and evaluation metrics used.

#### A. Logistic Regression

Its new name is the Logit model [20]. It is used to simulate the likelihood of a specific class or event prevailing, such as pass/fail, healthy/sick, alive/dead, or win/lose. It's a mathematical model. In its most basic form, it employs a logistic strategy to advance a binary dependent variable, while several complicated expansions exist. A binary logistic model [21] will include a variable that is dependent and has two possible values, such as pass/fail, which represents an indicator variable, and the two values are regarded as 0 and 1.

#### B. Support Vector Machine

It targets to find an ideal hyperplane that splits the data into diverse classes. A way of implementing SVM [22] in python is by making use of the scikit-learn package. The data is sorted out and is disjointed into test data and training sets. The testing data is set as twenty out of every hundred. The set for algorithm preparation is fixed as one hundred and sixty out of every two hundred. An SVM forms either a set of hyperplanes. It is built in an immeasurable-extension space. A hyperplane that has the farthest distance to the nearest data point of any class achieves a good separation, called a functional margin. In essence, a wider margin implies a smaller simplification defect for the classifier.

### C. Convolutional Neural Networks

CNN is a portion of DNN [23]. It is broadly purposed for the exploration of imageries. They are also known as shift invariant ANN or space invariant ANN. They have a mutual-bulks architecture. Here, the network develops a mathematical process termed convolution. They are solely, neural networks that practice convolution as a replacement for general matrix multiplication in a minimum of one of their layers.

### D. MLP Classifier

MLP [24] is a portion of (ANN). Also called, feed-forward ANN. An MLP encompasses the bottom of three sheets of nodes. The three sheets are the first input, the mid-hidden, and the final output layers. Further, each other node is doubled as a neuron that makes use of a nonlinear activation, with an exception of the input node. MLP practices an administered learning system that is known as backpropagation, for training. MLP [25] can be distinguished from linear perceptron because of its manifold layers and non-linear instigation.

### E. Random Forest

The random forest [26] creates decision trees on data mockups and gains the prediction from all the formed decision trees. Finally, it elects the best elucidation by voting means. The data is sorted out and is disjointed into test data and training sets. The testing data is set as twenty out of every hundred. The set for algorithm preparation is fixed as one hundred and sixty out of every two hundred. The program fragments the data into many groups and subgroups. If an individual draws lines between data points in a subgroup, lines connecting subgroups into a group, and so on. The erection appears to be tree-like. The hyperplane that maximizes the distance to the nearest data point in the training set provides a reliable separation between classes.

## III. LITERATURE REVIEW

### A. Liver Disease Biopsies using Deep Learning and CNN

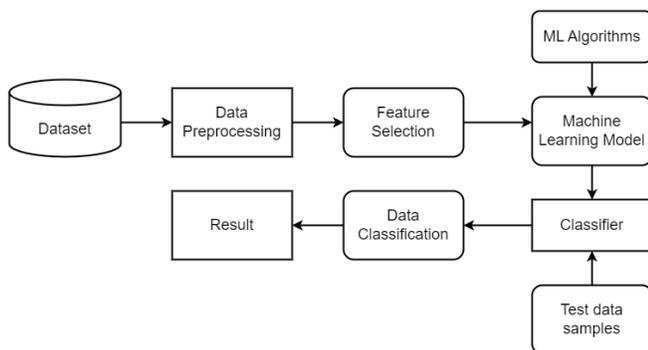

Fig. 1. Processing of ML algorithms

The author sought to implement a completely involuntary tool for diagnosing liver disease by using liver biopsy images. The author considered using biopsy images because there is a respectable chance of differentiating an unhealthy and healthy liver using these images. The projected tactic is to

use image study and deep learning and further determine an efficient CNN [27] architecture and further execution. NAFLD is common. An investigation stated that almost forty percent of all liver illnesses around the globe are caused by NAFLD. The existence of NAFLD in the liver can be found by the sign of hepatic steatosis, and also other reasons for fat build-up, such as major consumption of alcohol, lasting use of steatogenic medicines, and genetic problems. In this proposed method, the biopsy images of the liver are taken and the hepatic structures existent in these are analyzed with the aid of two CNN [28] which have the same architecture. They want to develop a 4-class detection system, which detects sinusoids, ballooned hepatocytes, veins, and fat droplets initially. In the concluding phase, this detection system is united with each other to complete the methodology. It then calculates the fat and ballooning ratio. The found ratio will aid in concluding the patient's condition. They made use of seven hundred and twenty liver biopsy images. Six hundred and twenty of these images are used for testing the algorithm, sixty are used for validation and the rest of the forty images are used for testing. These images originally are of 10,000 \* 10,000 pixels or above. The area in which the tissue is extant is hauled out from each image and the resultant images are 64 \* 64 pixels.

### B. Predicting the Accuracy of Liver Disease using Machine Learning

Utilizing and modeling medicinal data sets are now considered by specialists across the globe. The main plan here is to shorten the time gap in the middle of testing the liver, and generating the report and final result. They used some Machine Learning algorithms [29] like decision tree, naive Bayes, ANN, and random forest. Then, the Pearson correlation [30] to find the anomalies such as TP (true positives), FN (false negatives), FP (false positives), and TN (true negatives) is applied. This is done to find the precision, specificity, and affectability of the algorithms used. The produced words are used to compute the sensitivity, affectability, specificity, and accuracy using pre-defined equations. The author intended to create an interface in which the user could enter the patient's report as input. The algorithms are then skill-trained using the allocated data set, and the output of the user input information is determined. The output will be a single number that is either a zero or a one, with the binary one indicating that the patient's liver is sickly and the binary zero indicating that the patient's liver is healthy. The user-given input data will be logged and this data will further train the algorithm again. These additional tabulated values will train and skill the algorithm to progress with precision. UCI machine is the site from where the authors obtained the data set. The outcoming results of these respective algorithms are charted. These grids show outcomes, which are encouraging Accuracy not cited. They made use of ML algorithms- ANN, Naïve Bayes, and Decision tree to make the model. There are numerous types of liver ailments, the authors considered the general liver diseases to ease the process and get a precise result.

### C. Segmentation of Liver using CT Scan and Finding Disease

The authors lit up an idea by making the use of Abdominal CT, liver disease can be perceived. Some organs cannot be perceived through standard X-Ray equipment. These are the

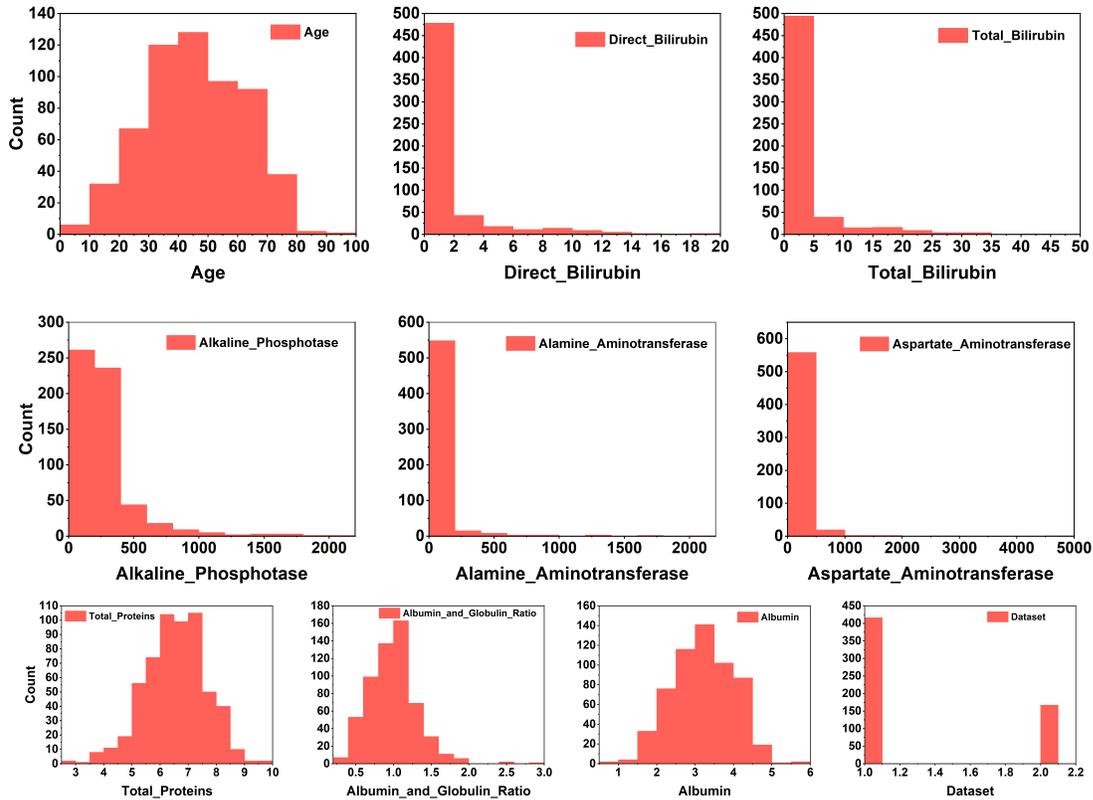

Fig. 2. Histogram for frequency distributions of various patients based on attribute

ML Models	Accuracy
Logistic Regression	0.76
Support Vector Machine	0.72
Nearest Neighborhood	0.80
Random Forest	0.88

conditions that strengthen the motives to use CT Scans as they can show the structures better than an X-Ray. These CT scan-produced images will have an accurate resolution. They proposed to use WTA to segment the Scan image, identify the liver placement, and differentiate it from the background. In the ending step, the percentage of the area affected is calculated. With the intention of perceiving the progress or sternness of the liver disease, one should use a highly precise technique, that is CT Scan. This CT Scan is extensively used in this medical field to attain info about the humanoid build. In the initial step, the imageries are scrutinized to find different parts. In the following step, the images are handled using the Erode and Dilate algorithm. Viewing point values are adjusted here. Further, they are processed with WTA to segment the liver area. The WTA gives two outputs namely the liver area and the non-liver area. The output yielded is referred to as cropping. Then the gathered copy is adapted into a binary where this organ is white and the rest is black. Then median filtering is done to reduce the noise and smoothens the texture. Then the damaged region of the liver is tallied using a formula. The authors affirm that the typical precision of image breakdown

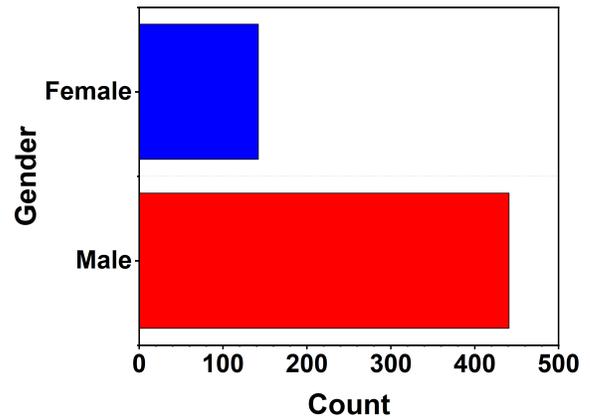

Fig. 3. Comparison with the frequency of males and females

is around eighty-one percent and the typical precision of liver breakdown is around 92 percent. The author used the WTA to distinguish the liver. Another method suggested is to use the binary threshold to isolate the liver area and the diseased area. The closing process in this paper is to measure the fraction of diseased spaces in the liver.

#### D. Liver Disease Prediction using Classification Algorithms

The proposed process by the authors shows that machine learning can not only predict the disease but also can recognize hidden patterns for diagnosis and decision-making. The everyday growing cases of liver disorders are considered to be a common problem around the world. The goal of this thesis is to provide competent findings in identifying liver disease using classification algorithms [31]. Logistic Regression, K-Nearest Neighbor, and Support Vector Machines are the algorithms utilized for this type of job. The algorithms called Classification

algorithms [32] are predominantly being used in predicting diseases among machine learning algorithms. ML techniques are now very helpful in the healthcare sector for the prediction of diseases from medical databases. In almost every continent there are researchers and scientists who are rigorously using machine learning models [33] with classification algorithms to strategically enhance medical diagnostics and are showing better results. Logistic Regression, K-Nearest Neighbor, and Support Vector Machines are used in this paper to predict liver disease. We all know that the liver is the body’s largest internal organ, performing vital functions such as producing blood clotting factors and proteins, producing triglycerides and

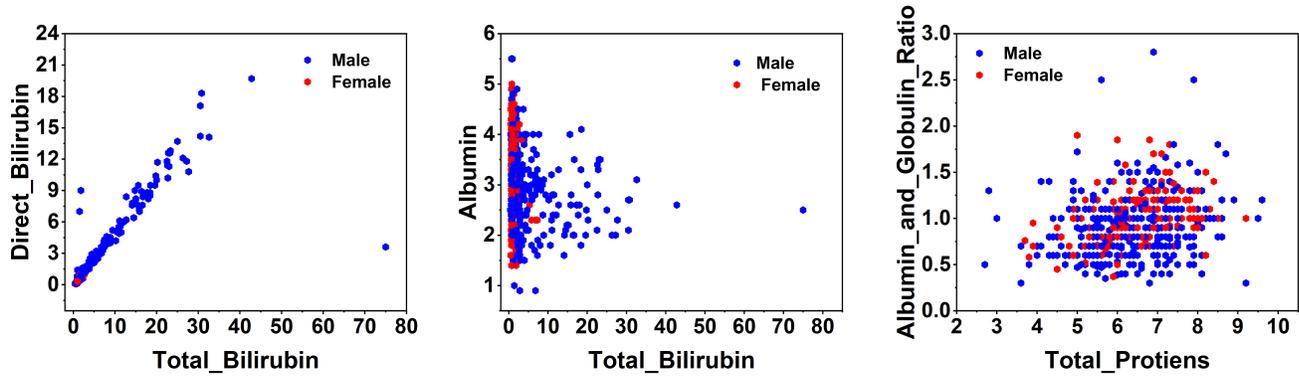

Fig. 7. Scatter plots for Direct\_Bilirubin vs Total\_Bilirubin, Albumin vs Total\_Bilirubin, Albumin\_and\_Globulin\_Ratio vs Total\_Proteins

cholesterol, glycogen synthesis, and bile production. In most cases, a decrease in function must affect much more than 75% of the liver tissue. So it's crucial to notice at an untimely stage at which the disease can be treated before it progresses to the severe stage

#### IV. PROPOSED SYSTEM

In the proposed system, we have to import the liver patient dataset (.csv). Then the dataset is pre-processed and the anomalies and full-up empty cells in the dataset are removed, so that we can further improve the effective liver disease prediction. Then we construct a Confusion matrix for accomplishing an enhanced lucidity of the no of correct/incorrect predictions. Formerly, several classification and prediction procedures and if possible, combinations of different algorithms are implemented and check the accuracy. Our objective is to develop a code that delivers an exactitude of 90%. The advantages are improved classification, early prediction of risks, and improved accuracy. The block diagram of the overall system is shown in Fig. 1.

#### V. RESULTS

Using various methods, we begin our study in this part with the data-processing stage and go on to feature extraction, classification, and prediction analysis. The attributes used in the dataset are Age, Direct Bilirubin, Total Bilirubin, Alkaline Phosphate, Alamine Aminotransferase, Aspartate Aminotransferase, Total Proteins, Albumin, and Globulin Ratio, Albumin, Dataset (where data set is the class label). Each histogram tells us about the frequency distributions for various patients in that particular attribute, shown in Fig. 2.

We represented attributes count or frequency of the patients based on the age, direct\_bilirubin, total\_bilirubin, alkaline\_phosphotase, alamine\_aminotransferase, aspartate\_aminotransferase, total\_proteins, albumin\_and\_globulin\_ratio, albumin, and data set. The Fig 4 shows the correlation between each attribute used in data set are plotted. The lighter the color between two attributes in the graph the higher the values of one attribute are dependent or correlated on the second attribute. From the Fig. 4 we can say that direct\_bilirubin and total\_bilirubin are highly correlated.

The Fig. 3 the frequency of males used in the dataset is compared with frequency of females. The Data set contains a total of 441 males and 142 females. The accuracy of each model is obtained by training the model with the dataset values and testing it by predicting the dataset value. The number of correct predictions done by the model gives us accuracy. From Fig. 5, we can say that Random Forest has the highest accuracy compared to other models. The box plot is plotted which tells us about the outliers present in that attribute. The box plot identifies the outliers using IQR (Inter Quartile Range) method. From Fig. 6, we can see only two values are greater than 450 and far from other values. Hence they are outliers. From Fig. 7 scatter plots for Direct\_Bilirubin vs Total Bilirubin, Albumin vs Total\_Bilirubin, Albumin and Globulin Ratio vs Total Proteins are plotted. Scatter plots are a valuable tool for visualizing the relationship between variables, with dots representing the data points. They are commonly employed to illustrate the associations between variables and how changes in one variable impact another. From the Fig. 7, we can see for Direct\_Bilirubin vs Total Bilirubin the scatter plot is like a straight line which indicates they are highly related. Table I shows the accuracy of the ML method results. The random forest method gives good accuracy than LR, SVM, and nearest neighborhood.

#### VI. CONCLUSION

The liver patient data set was used to implement prediction and classification algorithms, which in turn reduces the workload on doctors. We suggested employing machine learning techniques to examine the patient's total liver condition. A liver condition that has persisted for at least six months is considered chronic. We will thus utilise the proportion of people who get the condition as both positive and negative data. A confusion matrix is used to represent the outcomes of classifier processing of percentages of liver disease. When a training data set is available, our proposed classification schemes can significantly enhance classification performance. Then, using a machine learning classifier, good and bad values are classified. Thus, the outputs of the proposed classification model show accuracy in predicting the result.

The extent of our work is that we will apply deep learning techniques to predict liver disease. Some of the future directions are improve the accuracy of liver disease prediction

and classification models is to include more diverse data sources, improving liver disease prediction and classification is to combine multiple machine learning techniques, machine learning models can be trained to predict the likelihood of liver disease in individuals based on their unique characteristics. Another important direction in liver disease prediction and classification using machine learning is to develop models that are explainable. This means that the models should provide clear and interpretable insights into the factors that contribute to liver disease. Explainable models can help healthcare professionals to make better decisions and provide better care for patients.

**Abstract**—The image super-resolution is utilized for the image transformation from low resolution to higher resolution to obtain more detailed information to identify the targets. The super-resolution has potential applications in various domains, such as medical image processing, crime investigation, remote sensing, and other image-processing application domains. The goal of the super-resolution is to obtain the image with minimal mean square error with improved perceptual quality. Therefore, this study introduces the perceptual loss minimization technique through efficient learning criteria. The proposed image reconstruction technique uses the image super-resolution generative adversarial network (ISRGAN), in which the learning of the discriminator in the ISRGAN is performed using the EfficientNet-v2 to obtain a better image quality. The proposed ISRGAN with the EfficientNet-v2 achieved a minimal loss of 0.02, 0.1, and 0.015 at the generator, discriminator, and self-supervised learning, respectively, with a batch size of 32. The minimal mean square error and mean absolute error are 0.001025 and 0.00225, and the maximal peak signal-to-noise ratio and structural similarity index measure obtained are 45.56985 and 0.9997, respectively.

**Keywords**—Single image super-resolution (SISR); generative adversarial networks (GAN); convolutional neural networks (CNN); EfficientNetv2

## I. INTRODUCTION

With the rapid development of information technology (IT) along with the boom of Internet technology, information processing based on image and signal is widely utilized by an enormous population, in which image processing is a crucial component of information processing. Here, the role of image super-resolution (SR) is significant when considering image processing-based applications [1], [2]. Image SR is the image transformation from low resolution (LR) to high resolution (HR) for obtaining an enhanced quality image. Medicine, agriculture, industry, and military applications utilize the SR technique due to its high practicability [3], [4]. While considering artificial intelligence, the role of SR is crucial for performing various processes [5], like public security, remote sensing imaging, medical imaging, image compression, and so on using the single image SR criteria [6], [7]. The image resolution enhancement using the up-sampling process lacks texture details. The image transformed into the HR provides enormous information with finer details [8]. For example, the crime scene image offers plenty of evidence for investigating crime. Likewise, an image acquired from the satellite image undergoes various processing, like resource detection, object detection, and several other processing using the HR image [9]. While considering the medical application domain, the disease diagnosis is employed based on Magnetic Resonance Imaging

(MRI) and Computed Tomography (CT) Scan images with better resolution for providing accurate medication. Thus, the role of SR is crucial in image-processing application domains.

The SR of the image is obtained from the LR image using three various categories: 1) learning-based approach, 2) reconstruction approach, and 3) interpolation approach [10]. Image resolution enhancement using interpolation is the earliest method most researchers utilized and is easy to implement. Some of the interpolation techniques used to enhance the image's quality are non-uniform sampling interpolation, Bicubic Interpolation, Bilinear Interpolation, and Nearest Neighbor Interpolation. In these approaches, the higher frequency details can be reconstructed through the linear characteristics of the approaches. The image SR using the interpolation approach provides a better outcome; still, the performance degrades with the scaling factor's elevation [11]. Reconstruction based SR approach transforms the LR image by gathering the non-redundant details. The approaches with non-negativity, energy boundedness, support boundedness, and smoothness-based hypothetical constraints using the Projection onto Convex Set are one of the methods utilized for SR reconstruction. The slower convergence rate is the limitation of the reconstruction-based criteria and has many solutions [12], [13]. In addition, the reconstruction solution acquired at the final stage hang-on on the initial evaluation. Also, the performance is limited while considering reliable robustness and real-time modeling due to the inefficiency in handling the noise level reconstruction [14]. Finally, the third approach is the learning-based image transformation approach that enhances the quality of the image using machine learning and deep learning algorithms [15]. Nowadays, learning-based image quality enhancement is the widely utilized approach by researchers [16] due to better image perception.

The learning of the network is employed in the learning-based approach of image SR for providing a high-quality reconstructed image. Here, for network learning, the high representation of the samples is utilized with variation in data for generalizing [17]. Thus, enormous data is acquired from various sources to obtain the required solution. While considering the image taken from the remote sensing domain, the information collection is a challenging task due to the variations of image based on the factors like different sensors and locations along with the difference in the objects [18], [19], [20]. Thus, the network learned with the limited samples affects the model's performance due to the poor generalization capability. Nowadays, the advent of deep learning models based on non-linear operation in artificial intelligence accumulates enormous

samples that can be utilized for several computer vision-based applications [21]. Hence, the generalization capability of the deep learning models is elevated through the enormous learning of data samples. The convolutional neural network (CNN) based image resolution enhancement technique was first suggested by Dong et al. [22]. The method acquired a better signal-to-noise ratio (SNR) with a high sampling rate, but the information about the image is lost due to the too smoothness of the reconstructed image [23], [24]. In the deep learning approaches, the error concerning the mean squared error (MSE) reduction of 2.98 and the elevation of the peak signal-to-noise ratio (PSNR) value of 21.15dB are obtained through the optimization target for acquiring the high-quality image from the ill-posed nature. The variation between the reconstructed and the original image based on the perception is not photorealistic by some existing approaches. Generative adversarial network (GAN) based methods are also designed by several researchers to overcome the issue concerning information loss in image reconstruction, in which the CNN is replaced with the GAN network [3]. The GAN-based image SR techniques gather the non-linear high-dimensional features from enormous data [25], [26] and make the generalization more effective for providing a better outcome.

This study aims to reconstruct the SR image from the LR image by minimizing the perceptual loss to obtain a perceptually good image with detailed information that gratifies the human eye. This study proposes ISRGAN with EfficientNet-v2 to enhance reconstruction accuracy with minimal distortions. The ISRGAN is designed for image reconstruction by minimizing the perceptual loss comprising of content and adversarial loss with EfficientNet-v2 is utilized for learning the discriminator of the ISRGAN, in which the perceptual loss concerning the image is minimized for the acquisition of a better quality image.

The significant contributions of the research are:

- Design of ISRGAN: Image Super-Resolution Generative Adversarial Network (ISRGAN) is designed for image reconstruction by minimizing the perceptual loss comprising of content and adversarial loss.
- EfficientNet-v2: EfficientNet-v2 is utilized for learning the discriminator of the ISRGAN, in which the perceptual loss concerning the image is minimized for the acquisition of a better quality image through the fast learning criteria.

The manuscript is organized as follows: The primary methods review is enclosed in Section II with its problem definition. The detailed proposed ISRGAN based on EfficientNet-v2 is portrayed in Section IV, Section V for implementation, and Section VI discusses the results and analysis of the study. Finally, Section VII concludes the work.

## II. RELATED WORK

The primary methods concerning the image SR are detailed in this section. The image SR using the GAN concerning the quality loss was devised by Zhu et al. [27] to solve the issue of instability of the GAN in image reconstruction. The method addressed the loss issue by optimizing the pre-trained network. The gradient magnitude similarity deviation was utilized for

the discriminator training to obtain a better performance. In addition, batch normalization, computation overhead, and memory reduction make learning more efficient and obtain better visual appeal. Image SR using GAN with the fused attentive network to extract global features was designed by Jiang et al. [28] using the scanning time reduction technique. In this study, the attributes at various scales are taken out based on the attention criteria to acquire the most relevant attributes and enhance reconstruction accuracy. In addition, the stability of the learning is accomplished through the spectral normalization approach. The analysis based on the distance measure and the similarity index offered a better outcome.

Shahidi [29] designed the wide attention-based GAN to stabilize the learning process using the Wasserstein with a Gradient penalty. Two different normalizations, such as weight and batch normalization, elevate the similarity index of the image by considering the texture and color restoration. Besides, the inclusion of the self-attention layers and the residual blocks assures a high-quality image by learning past information. The self-attention layer is utilized in the discriminator to extract the attributes from the image patches to correct the generator more effectively. The loss function was evaluated using the VGG-19 network. An enlightened GAN was developed by Gong [30] using the self-supervised hierarchical perception loss to acquire enhanced image reconstruction performance through network induced convergence. The enlighten blocks were introduced to accomplish a better gradient using the improved generalization capability. Besides, the occurrence of seam lines in the reconstructed image was eliminated through the clipping and merging approach-based learning criteria using the batch internal inconsistency loss. The image quality assessment of the method provided a superior outcome by solving the merging issue that depicts the realistic criteria of the developed method. GAN with cascading residual network was designed by hybridizing the neural network (NN) with the GAN by Ahn et al. [31] to acquire the network's short connection and multi-level representation for improving the reconstruction performance. The balanced distortion and the perception criteria of the designed method are made using the multi-scale discriminator and GAN-based learning. Here, the usage of the multi-scale discriminator gathers fine information from the image concerning the resolution to reduce the losses in the network. The visual outcome of the method provided a realistic and sharp image.

Residual-in-Residual Dense Block-based GAN was devised by Song et al. [32], in which the optimal network with transfer learning was employed to acquire a high-quality image with better perception and low distortion. The slow convergence rate and the unstable learning capability were enhanced through the inclusion of the dense block with enhanced perception and minimal distortion in the reconstructed image. In addition, the feature reuse and propagation were improved along with the vanishing gradient issue solution, which was accomplished through the dense connection establishment with minimal parameters. A conditional GAN-based image reconstruction was presented by Sun et al. [33], in which the color space transformation was initially employed based on the variance and mean of the channel for the channel normalization. The better visual representation of the image was accomplished through the colorization training criteria, which converge faster than the traditional image reconstruction approach. In addition,

curriculum learning was utilized to solve the issue of large resolution differences in the learning phase. Color normalization through self-supervised learning offers better generalization capability to obtain better performance by eliminating color variance. A weighted Multi-Scale Residual Block-based image reconstruction strategy was introduced by Li et al. [34] for image reconstruction through the weighted feature representation approach. In this, the low-level attributes were taken out from the image. Then, using the global residual learning, the high-frequency information from the features is mapped using the non-linear mapping criteria. The reconstruction of the image was accomplished from the reconstruction subnet of the network. The benefits and the challenges of the reviewed techniques is depicted in Table I.

### A. Research Gap

The acquisition of high resolution image from the low resolution input image is the image super resolution technique. The learning based methods of image super resolution are widely utilized for reconstructing the image to accomplish the better performance through the non-linear learning capability. The goal behind the image reconstruction is to obtain the better perceptual image to identify the target solution in medical imaging and satellite imaging applications. Many of the prior researchers devised the GAN based image reconstruction technique for obtaining better performance. Still, the loss function estimation and the network training with minimal loss is a challenging task in most of the methods based on the GAN. In addition, the un-pleased image reconstruction with higher distortions and the over-smoothing of the image degrades the better reconstruction. Hence in order to overcome the above mentioned challenges, an ISRGAN is introduced for learning the discriminator with higher learning speed with minimal information loss, which enhances the generalization capability of the network and obtains the better image.

## III. METHODOLOGY

The ISRGAN is designed by modifying the loss function of the traditional GAN to enhance the image quality that is more pleasant to the human eyes and to improve the accuracy of image reconstruction. The GAN for the super image resolution of the single image is termed ISRGAN for transforming the LR image into the SR image. The ISRGAN comprises of discriminator and generator, which denotes  $A_{\theta_A}$  the discriminator model. The min-max issue of the ISRGAN is solved by optimizing  $Q_{\theta_Q}$  alternatively and  $A_{\theta_A}$ . The formulation for the min-max issue is expressed as,

$$\min_{\theta_{\infty}} \max_{\theta_1} E_{S^R \sim p-\text{train}}(S^R) [\log A_{\theta_A}(S^R)] + E_{S^L \sim p-G}(S^L) | [\log (1 - A_{\theta_A}(D_{\theta_D}(S^R)))] \quad (1)$$

where, the high-resolution image is notated as  $S^R$ , the low-resolution image is indicated as  $S^L$ , the discriminator is notated as  $A$ , and the generator is indicated as  $Q$ . Here, the role of the generator is to mislead the discriminator, in which the discriminator module of the ISRGAN is learned to identify the difference between the real image and the SR image. Similarly,

TABLE I. REVIEWED TECHNIQUES: BENEFITS AND CHALLENGES

Technique	Benefits	Challenges
GAN [27]	The enhanced adversarial learning along with the loss function estimation using the image quality assessment provided a high quality image.	The failure case of the method was higher and provides an unsatisfactory result. Besides, the imperfection of the network portrayed diagonal lines in the blocks of the outcome.
Fused Attentive GAN [28]	The assessment with various GAN-based image super-resolution acquired better performance in terms of signal-to-noise ratio using various datasets. Besides, the reconstructed image is near to the real image with high resolution.	The reduction of the loss function with a higher number of iterations elevates the computation overhead.
Wide-Attention GAN [29]	Two normalizations like weights and batch normalization along with the self-attention layer provide the method a small range of gradient clipping that elevates the accuracy of image reconstruction.	The analysis without the pre-processing step limits the performance of the model.
Enlighten-GAN [30]	The convergence stabilization along with the network intensification provided a better outcome with an artifact-free reconstructed image by maintaining the hue and shape.	The outcome accomplished using the method still has the issue of an unclear outline due to the object fusing technique. Hence, for the complex image, the developed method provided poor performance.
Cascading Residual Network-GAN [31]	The improved performance is accomplished for the image translation technique by balancing distortion and perception.	The complexity analysis based on the execution time depicts the minimal time complexity compared to some baseline techniques; still, acquired poor performance due to the memory fragmentation criteria that limit the parallelism of the approach.
Residual-in-Residual Dense Block-GAN [32]	The visual outcome of the method was better and was applicable for the applications that don't require the details concerning the place and obtained better running time.	The signal-to-noise ratio evaluated by the method was not pleasant to the human eye.
Weighted Multi-Scale Residual Block [33]	The weight-based image reconstruction obtained better performance using the high-frequency attributes acquired from the low-resolution image.	The method failed to analyze the accuracy.
Conditional GAN with color normalization [34]	The augmentation of the features helps to acquire various degradations degrees, which assures the capability of learning from the de-blurred image that enhances the convergence rate and boosts the performance of the method.	For the images with severe information loss, the method offered an unsatisfactory outcome.

the generator module is trained to produce the SR image close to the real image, making the discriminator's detection capability a tedious task. As mentioned above, the generator and the discriminator processes provide a more appropriate perceptual solution. The maximization issue is solved using the discriminator with minimal MSE. The architecture of the ISRGAN is portrayed in Fig. 1.

## IV. PROPOSED WORK

The proposed ISRGAN with EfficientNet-v2 incorporates the EfficientNet-v2 to evaluate the loss function and train the discriminator based on the loss to enhance the quality of image reconstruction. The evaluation of the loss function and the

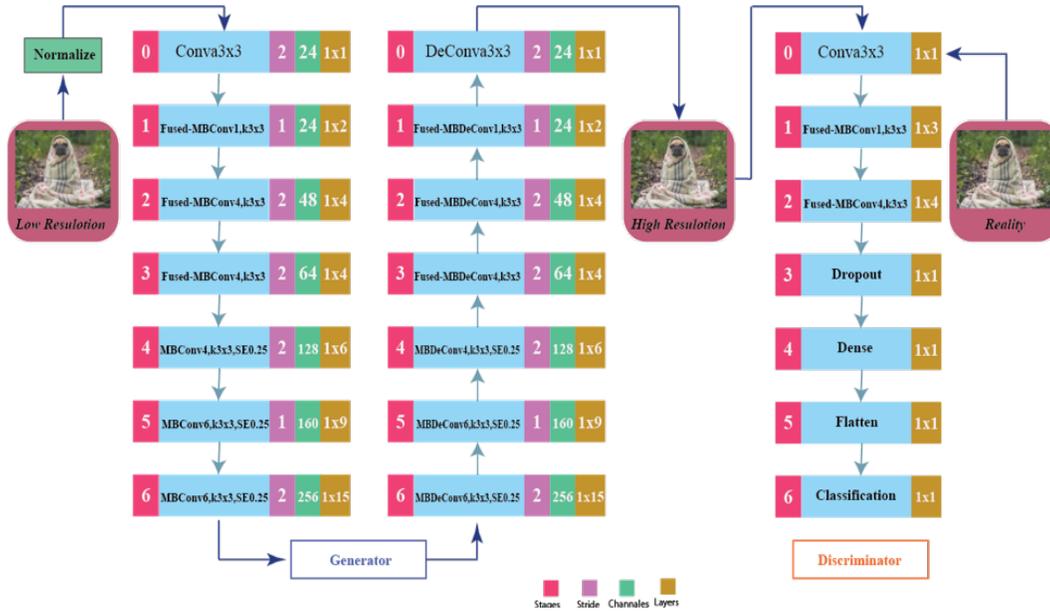

Fig. 1. The architecture of ISRGAN

learning based on the loss function using the EfficientNet-v2 is detailed below.

#### A. Loss Function

1) *Perceptual loss* : The perceptual loss function of the ISRGAN is considered a crucial factor that elevates the perceptual characteristics of the image based on the loss function [4]. The adversarial and content loss function of the ISRGAN constitutes the perceptual loss function and is formulated as,

$$h^H = h_B^H + 10^{-3}h_G^H \quad (2)$$

where, the adversarial loss of the ISRGAN is referred to as  $10^{-3}h_G^H$ , the content loss of the ISRGAN is indicated as  $h_B^H$  and the perceptual loss evaluated by the VGG-based network is indicated as  $h^H$ .

2) *Content loss*: Here, the goal of the ISRGAN is to replace the perceptual loss using the VGG feature map of the network. The loss function of the pixel-wise MSE, evaluated by VGG, is formulated as,

$$h_E^H = \frac{1}{s^2KN} \sum_{m=1}^{sK} \sum_{n=1}^{sN} (S_{m,n}^R - Q_{\theta Q}(S^L)_{m,n})^2 \quad (3)$$

where, the MSE error estimated by the VGG is indicated as  $h_E^H$ , and the height and width of the low-resolution image are indicated as  $N$  and  $K$ , respectively. For the image points  $(m, n)$ , the gray level value is indicated as  $(S^L)_{m,n}$ . Then, the characteristic loss of the VGG network is formulated as,

$$h_{VGG/u,v}^H = \frac{1}{K_{u,v}N_{u,v}} \sum_{m=1}^{K_{u,v}} \sum_{n=1}^{N_{u,v}} (\alpha_{u,v}(S^R)_{m,n} - \alpha_{u,v}(Q_{\theta Q}(S^L))_{m,n})^2 \quad (4)$$

where,  $H$  refers to the image SR,  $R$  refers to the high-resolution image,  $h_{VGG/u,v}^H$  refers to the low-resolution image,  $L$  refers to the characteristic loss for the VGG network, the reference image is indicated as  $(S^R)$ , and the reconstructed image is indicated as  $Q_{\theta Q}$ .  $u^t h$  Max-pooling layer with  $v^t h$  convolution corresponding to the feature map is indicated as  $\alpha_{u,v}$ . The dimensions of the feature maps are indicated as  $N_{u,v}$  and  $K_{u,v}$ , respectively. Here, the characteristics loss function is evaluated based on the activation function of VGG loss, which is nothing but the Euclidean distance between the reference and reconstructed image. The combination of the characteristic loss and the MSE error constitutes the content loss of the ISRGAN.

3) *Adversarial loss*: The loss generated by the generative component of the ISRGAN for providing the most appropriate solutions by tricking the discriminator of the network is termed Adversarial loss, which is formulated as,

$$h_G^H = \sum_{c=1}^C -\log A_{\theta A}(Q_{\theta Q}(S^L)) \quad (5)$$

where, the natural high-resolution image is indicated as  $Q_{\theta Q}(S^L)$ , and the reconstructed image's probability is notated as  $A_{\theta A}(Q_{\theta Q}(S^L))$ . Here, the adversarial loss function needs to be minimized for the acquisition of better gradient behavior.

### B. EfficientNet-v2 based Perceptual Loss Function

The proposed improved ISRGAN utilizes EfficientNet-v2 to estimate the loss function to enhance the quality of the reconstructed image perceptually. The ISRGAN has the issue of gradient disappearance that makes information losses due to poor generalization capability. Thus, the EfficientNet-2 is utilized for learning the discriminator based on the perceptual loss function through the higher learning rate and the parameter efficiency. Here, the role of the EfficientNet-v2 is to detect the difference between the ground truth and the reconstructed image for measuring the loss function to train the discriminator to make the reconstruction more effective. The loss functions like content loss and the adversarial losses that constitute the perceptual loss are evaluated using the EfficientNet-v2 to enhance the efficiency of the image SR.

EfficientNet-v2 for estimating the loss function utilizes smaller kernel sizes with minimal memory access overhead. Besides, the last stride-1 is eliminated to reduce the memory access overhead and size of the parameter. The runtime overhead is minimized through network capacity elevation, and the training overhead, along with higher memory, is minimized by restricting the interference of the image. The learning capability of the EfficientNet-v2 is higher by making the original interference size for learning, which depicts the scaling characteristics of the loss function estimator. The building blocks of the EfficientNet-v2 are Fused MBCConv along with the mobile inverted bottleneck MBCConv and are portrayed in Fig. 2.

### C. ISRGAN Architecture

The ISRGAN comprises two different modules: the discriminator and the generator for producing the perceptually quality image.

1) *Generator*: The transformation of the input image to obtain the SR image is employed in the generator module of the proposed ISRGAN. Initially, the encoding of the input image is performed to acquire the high-dimensional information. Then, the decoding is employed in the hidden layer of the generator to provide high-resolution images. Here, the image dimensions are scaled using the scaling algorithm to acquire the feature resolution, which is performed as convolutional and deconvolutional operations in the generator. Thus, the CNN is utilized in the generator module of the ISRGAN to extract the relevant features with a single dimension, which leads to the failure in acquiring the granular patterns of the image. Thus, the compound scaling factor is introduced in the ISRGAN to obtain the image's finer granular patterns. Hence, the generator module is designed with 42 layers of convolutional and deconvolutional, along with the Leaky rectified linear unit (Leaky ReLU) activation function and batch normalization. Besides, training aware Neural Architecture Search (NAS) and scaling are utilized for designing the generator module.

2) *Discriminator*: The difference between the high-resolution image generated by the generator module and the real image is identified by the discriminator module using the EfficientNet-v2. Here also, finer granular patterns are extracted from the image. Seven Fused-MBCConv, one convolutional layer, and eight hidden layers constitute the discriminator module along with the EfficientNet-v2. The sigmoid function

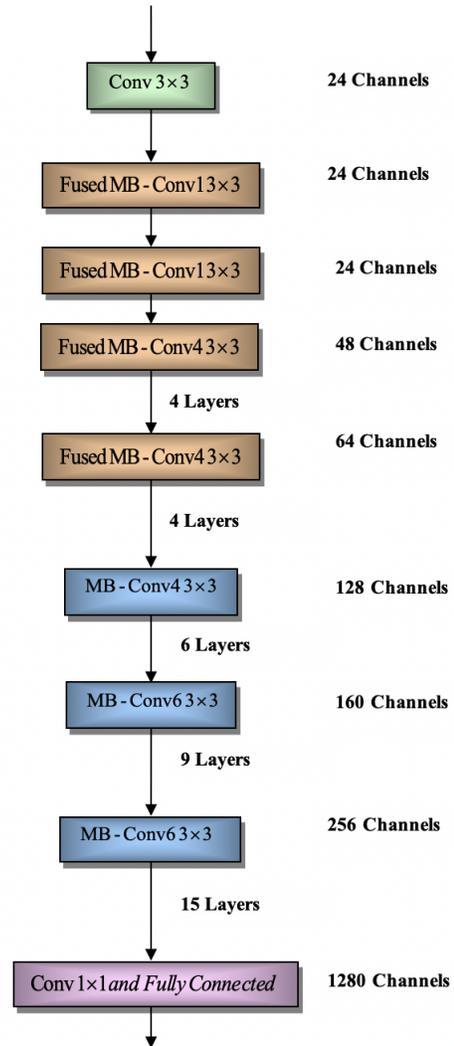

Fig. 2. Architecture of efficientNetv2

is utilized to determine the likelihood of SR images by considering the fake and real images. The perceptual loss function training is employed alternatively in both the discriminator and generator to obtain perceptually better image SR.

## V. IMPLEMENTATION

The experimentation setup along with the interpretation of the introduced ISRGAN is detailed in this section.

### A. Experimental Setup

The implementation of the proposed method is employed in Google Colaboratory (Colab) Notebooks tool. The total number of iterations performed is 100, with batch sizes of 8 and 32.

1) *Image dataset*: The dataset utilized for the analysis of the proposed ISRGAN is the CIFAR-10 dataset [35] comprises 10000 test images and 50,000 training images with 10 different classes. Thus, a total of 60,000 images with the size of is utilized. The type of image utilized for the evaluation is synthesis.

2) *Network learning*: The generator module of the ISRGAN is learned with the loss function, expressed as,

$$\text{Loss}_Q = h^H + \text{Loss}_{\text{texture}} \quad (6)$$

where,  $\text{Loss}_Q$  refers to the loss utilized to learn the generator,  $h^H$  notates the perceptual loss, which comprises adversarial loss and content loss and the texture loss is indicated as  $\text{Loss}_{\text{texture}}$ . Here, the Adam optimizer is utilized to solve the optimization issue, and the learning rate of  $1e^{-4}$  is initially utilized. EfficientNet-v2 is utilized for extracting the finer granular patterns from the image.

3) *Loss function*: The empirical risk of the proposed ISRGAN in reconstructing the HR image is evaluated based on the loss function and is enunciated as,

$$\text{Loss} = \frac{1}{W} \sum_{i=1}^W (O_i - \hat{O}_i)^2 \quad (7)$$

where, the total reconstructed samples is indicated as  $W$ , the HR reconstructed image by the proposed ISRGAN is  $O_i$  and the targeted outcome is indicated as  $\hat{O}_i$ .

4) *Network parameter setting*: The setting for the network parameters of the Generator and Discriminator in the ISRGAN architecture are displayed in Table II.

TABLE II. ISRGAN PARAMETER SETTINGS

Parameters	Values
Generator	
Dense Layer	256x4x4
Conv-1	128 filters, 3x3 kernel, 2x2 stride
Conv-2	128 filters, 3x3 kernel, 2x2 stride
Conv-3	128 filters, 3x3 kernel, 2x2 stride
Conv-4	3 filters, 3x3 kernel
Discriminator	
Input Layer	32x32x3
Conv-2	64 filters, 3x3 kernel, 2x2 stride
Conv-3	128 filters, 3x3 kernel, 2x2 stride
Conv-4	128 filters, 3x3 kernel, 2x2 stride
Conv-5	256 filters, 3x3 kernel, 2x2 stride

## VI. RESULTS AND ANALYSIS

### A. Qualitative Analysis

The experimental outcome concerning the input LR image and the output HR image is shown in Fig. 3.

The outcome acquired by the introduced ISRGAN shown in Fig. 3(b) is visually pleasing to the human eye by reconstructing the LR image 3(a). The discriminator learning based on the perception loss estimated by the generator using the EfficientNet-v2 elevates the accuracy of image reconstruction by minimizing the MSE.

### B. Quantitative Analysis

The quantitative analysis based on the loss function evaluated by the proposed method and the error analysis is detailed in this section.

Fig. 3. Outcome of ISRGAN: (a) input LR image and (b) output HR image

1) *Analysis based on loss function*: The quantitative analysis of the introduced ISRGAN is analyzed based on the loss function measure and is portrayed in Fig. 4. The Table III presents the batch sizes, number of iterations, and outcomes of generator, discriminator, and the self-supervised. From the table, we can observe that the increase in batch size and iteration minimizes the loss. Here, the increase in the batch size of the method reduces the noise in the gradients, which assures enhanced accuracy in image reconstruction and reduces the loss. Similarly, the increase in iteration helps the algorithm obtain a closer solution to the target solution, which reduces the loss and enhances image reconstruction accuracy. The ISRGAN with the EfficientNet-v2 acquires minimal loss and can be applied for the media, medical, and surveillance-related application domains by detecting various objects in the image. Besides, the loss function evaluation based on the perceptual similarity loss assists in capturing the high-level information that provides a more accurate solution.

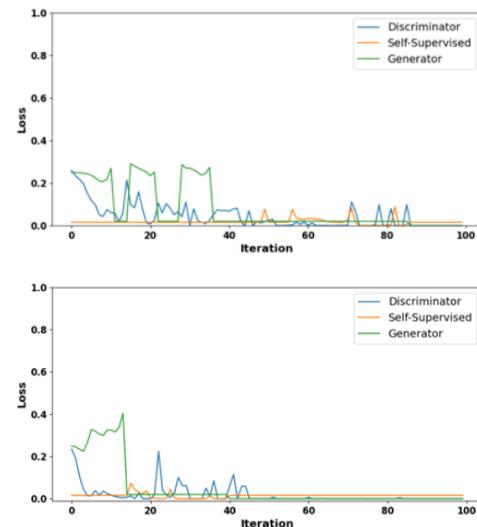

Fig. 4. Analysis based on loss function with batch size 8 (top) and batch size 32 (bottom)

TABLE III. LOSS FUNCTION ANALYSIS

Batch size	Iteration	Generator	Discriminator	Self supervised
8	20	0.251	0.012	0.0154
32	20	0.02	0.000057	0.037
8	100	3.778	3.916	0.0154
32	100	0	9.130	0.015

2) *Error and similarity analysis:* The analysis is executed based on MSE, PSNR, structural similarity index measure (SSIM), and mean absolute error (MAE).

**MSE:** The analysis of the risk function concerning the target solution in reconstructing the image is measured through the MSE and is formulated as,

$$ISRGAN_{MSE} = \frac{1}{T_{samples}} \sum_{i=1}^{T_{samples}} (I_{outcome} - I_{Target})^2 \quad (8)$$

Here, the targeted outcome is indicated as  $I_{Target}$ , the outcome acquired by the proposed ISRGAN is indicated as  $I_{outcome}$ , the total number of samples is indicated as  $T_{samples}$  and the MSE is notated as  $ISRGAN_{MSE}$ . The MSE evaluated by the proposed ISRGAN and the comparative methods like Wide-Attention GAN [29], Enlighten GAN [30], and Fused Attentive GAN [28] is portrayed in Fig. 5. The MSE evaluated by the introduced ISRGAN with the EfficientNet-v2 is minimal compared to the other conventional methods.

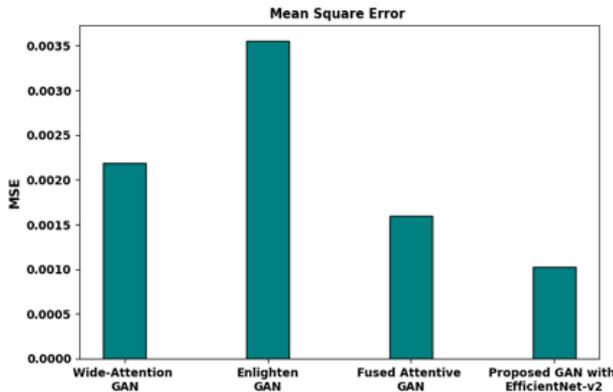

Fig. 5. Analysis based on MSE

**MAE:** The absolute difference between the obtained and the targeted outcome of the super image resolution is measured through the MAE and is formulated as,

$$ISRGAN_{MAE} = \frac{1}{T_{samples}} \sum_{i=1}^{T_{samples}} |I_{outcome} - I_{Target}| \quad (9)$$

where, the MAE measure is indicated as  $ISRGAN_{MAE}$ . The outcome of the proposed ISRGAN, along with the comparative methods, is portrayed in Fig. 6. The MAE evaluated by the proposed method is minimal compared to the other state-of-the-art techniques.

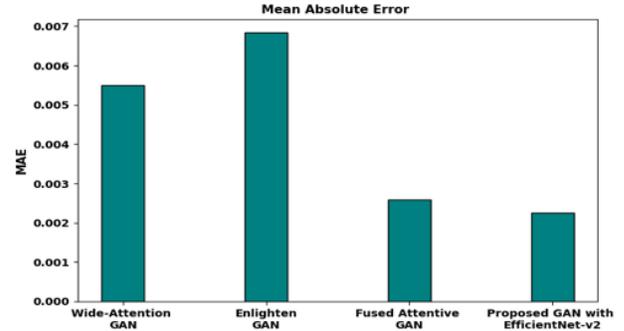

Fig. 6. Analysis based on MAE

**PSNR:** The quality of the image reconstructed from the low-resolution image is measured through the PSNR. The greater value of PSNR depicts better reconstruction. The formulation of the PSNR of the reconstructed image is expressed as,

$$ISRGAN_{PSNR} = 10 \log_{10} \left( \frac{R^2}{ISRGAN_{MSE}} \right) \quad (10)$$

where, the PSNR measure is indicated as  $ISRGAN_{PSNR}$ , and the fluctuation of the reconstructed image compared to the original image is denoted as  $R$ . The PSNR estimated by the proposed and the comparative methods is portrayed in Fig. 7. The PSNR acquired by the introduced method is higher and depicts a better image reconstruction quality.

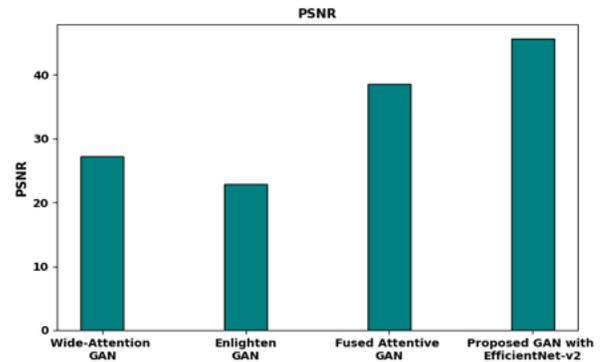

Fig. 7. Analysis based on PSNR

**SSIM:** The similarity between the reconstructed and the original image is measured through the SSIM that depicts the perceptual quality of the image. The mathematical formulation of the SSIM is expressed as,

$$ISRGAN_{SSIM} = \frac{(2\mu_p\mu_q + s_1)(2\sigma_{pq} + s_2)}{(\mu_p^2 + \mu_q^2 + s_1)(\sigma_p^2 + \sigma_q^2 + s_2)} \quad (11)$$

where, the SSIM is indicated as  $ISRGAN_{SSIM}$ . The mean and the variance of the reconstructed image are indicated

as  $\mu_p$  and  $\sigma_p^2$ , and the mean and variance of the original image are indicated as  $\mu_q$  and  $\sigma_q^2$ . The covariance between the original and reconstructed image is notated as  $\sigma_{pq}$ , and the variable utilized for the stabilization is indicated as  $s_1$  and  $s_2$ , respectively.

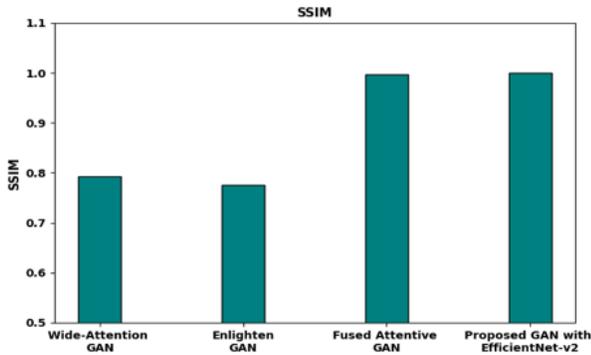

Fig. 8. Analysis based on SSIM

The outcome of the proposed method, along with its comparative methods, is portrayed in Fig. 8. The higher SSIM evaluated by the proposed method depicts the similarity of the reconstructed super resolution image with the original image.

3) *Comparative discussion:* The comparative analysis of the proposed method, along with the conventional image reconstruction techniques, is portrayed in Table IV. The MSE acquired by the proposed method is 0.001025, which is 52.93%, 70.99%, and 35.54% minimum compared to the traditional Wide-Attention GAN, Enlighten GAN, and Fused Attentive GAN methods. Similarly, the proposed method accomplished the minimal MAE of 0.00259, which is 59.09%, 67.08%, and 13.13% minimum compared to the traditional Wide-Attention GAN, Enlighten GAN, and Fused Attentive GAN methods. In contrast, the proposed method acquired the maximal PSNR of 45.5698, which is 40.26%, 49.89%, and 15.34% better compared to conventional Wide-Attention GAN, Enlighten GAN, and Fused Attentive GAN methods. Likewise, the maximal SSIM measured by the proposed method is 0.9997, which is 20.62%, 22.32%, and 0.18% superior compared to state-of-the-art Wide-Attention GAN [29], Enlighten GAN [30], and Fused Attentive GAN [28] methods.

TABLE IV. COMPARATIVE ANALYSIS

Method	MSE	PSNR	SSIM	MAE
Wide-Attention GAN [29]	0.002188	27.2254	0.7936	0.0055
Enlighten-GAN [30]	0.00355	22.834	0.77656	0.006835
Fused Attentive GAN [28]	0.001598	38.58	0.9979	0.00259
Proposed Method	0.001025	45.56985	0.9997	0.00225

The proposed method incorporates the EfficientNet-v2 with the traditional GAN for enhancing the image super resolution quality by minimizing the perceptual loss. For this, the EfficientNet-v2 is utilized at the discriminator that minimizes the information loss with fast learning rate. Thus

The Fused GAN was devised by integrating the attention module in the traditional GAN for enhancing the performance of the image super resolution technique. The quality assessment based on the similarity measure was closer to the proposed method; still, the higher time complexity and failure in maintaining the system parallelism mechanism limits the method. Thus, the existing Fused GAN acquired little minimal performance compared to the proposed GAN with EfficientNet-v2. Followed by, Wide Attention GAN devised by integrating the self-attention module. Due to the inclusion of the attention mechanism, the introduced Wide Attention GAN also suffered with higher time complexity. Finally, the Enlighten-GAN that was designed by incorporating enlighten blocks into the traditional GAN. Here, the introduced method accomplished better quality image as outcome by solving the unstable convergence issue through the enlighten block. However, method is inefficient in processing the image with complex background. Thus, the analysis based on the error estimation and the similarity analysis shows that the proposed method accomplished better performance than other super image resolution methods. The training of the discriminator using the EfficientNet-v2 provides fast learning and the least loss function based on the perception enhancing the image's visual quality.

## VII. CONCLUSION

The SR image reconstruction from the LR image for the acquisition of fine-grained information from the image, along with the visual quality, is attained using ISRGAN with EfficientNet-v2 in this paper. The proposed image reconstruction technique elevates the quality of the image by minimizing the perception loss present in the GAN network. The information loss is minimized through the efficient learning of the discriminator using the EfficientNet-v2, which has the probability of a fast learning rate with more accurate learning based on the perception loss generated by the generator module of the ISRGAN. The learning capability of the EfficientNet-v2 is higher by making the original interference size for learning that depicts the scaling characteristics of the loss function estimator. Thus, the proposed method provides a promising outcome based on the error analysis and acquires the minimal values of loss of 0.02 at the generator, 0.1 at the discriminator, and 0.015 at the self-supervised learning, respectively, with a batch size of 32. Besides, the minimal MSE and MAE accomplished by the proposed method are 0.001025 and 0.00225, respectively. Likewise, the maximal PSNR and SSIM acquired by the proposed method are 45.56985 and 0.9997, respectively. However, the loss of the method further needs to be reduced for real-time processing.

In the future, we plan to introduce a novel hybrid meta-heuristic optimization-based deep learning approach to overcome the challenges the proposed model encountered in this study.

**Abstract**—Text simplification is a fundamental unsolved problem for Natural Language Understanding (NLU) models, which is deemed a hard-to-solve task. Recently, this hard task has aimed to simplify texts with complex linguistic structures and improve their readability, not only for human readers but also for boosting the performance of many natural language processing (NLP) applications. Towards tackling this hard task for the low-resource Arabic NLP, this paper presents a text split-and-rephrase strategy for simplifying complex texts, which depends principally on a sequence-to-sequence Transformer-based architecture (which we call TSimAr). For evaluation, we created a new benchmarking corpus for Arabic text simplification (so-called ATSC) containing 500 articles besides their corresponding simplifications. Through our automatic and manual analyses, experimental results report that our TSimAr evidently outperforms all the publicly accessible state-of-the-art text-to-text generation models for the Arabic language as it achieved the best score on SARI, BLEU, and METEOR metrics of about 0.73, 0.65, and 0.68, respectively.

**Keywords**—Text simplification; sequence-to-sequence; split-and-rephrase; natural language understanding; NLP; TSimAr; ATSC

## I. INTRODUCTION

Texts with complex linguistic structures often pose a difficulty in interpreting and understanding the indented meanings, particularly the meanings between the lines. Such difficulty is not only encountered by human readers but also by intelligent applications that demand text comprehension at some point. Consequently, text simplification methodologies have come to help various readers (mainly readers with low-literacy skills [1], such as children or non-native readers) as well as to boost the performance of many natural language processing (NLP) applications (e.g., automated text parsing [2], summarizations [3], and translations).

Given a linguistically complex text as input, automated text simplifications (ATS) work around generating candidate texts as output that are essentially uncomplicated in structure and easy to understand without losing the purposed meaning [4]. In broad, the relatively common two steps involved in many ATS approaches are 1) splitting complex texts into simple sentences [5], [6] and 2) text rephrasing [7], [8], [9], [10], [11] using more straightforward common words (well-known in some approaches as lexical paraphrasing). In this paper, we

focus on these two steps and introduce a novel text split-and-rephrase solution for Arabic ATS.

Unlike the highly supported Indo-European languages (such as English), the recent ATS literature [4], [12], [13], [14] indicates that quite a few works are dedicated to supporting the Arabic language. To our knowledge, a few text splitting (e.g. [5]) and/or text-to-text rephrasing (e.g. [15], [16], [17], [18], [19]) techniques exist in Arabic NLP literature for tasks not related to simplification problems. Thus, in this paper, we seek to combine these techniques to support Arabic ATS in general. To illustrate the originality of our proposal, in the next section, we review in some detail these techniques besides exploring the existing non-Arabic split-and-rephrase models [7], [20], [10], [9]. Until then, we briefly outline the originality and main contributions of this paper as follows:

- We introduce a text split-and-rephrase strategy for simplifying complex Arabic texts, which depends principally on a sequence-to-sequence Transformer-based architecture. In the splitting part, we integrate our suggested solution with a punctuation detector for text segmentation (PDTs) built on top of a pre-trained multilingual masked-language model (mBERT). This PDTs attempts to generate the shortest set of simple independent-clause sentences from a given lengthy complex text. While in the rephrasing part, we propose a modified attention-free Transformer model, depending on a fast Fourier-Transform (FNet-based), which rephrases the concatenated simple sentences into a more readable version. The significant (original) work introduced in this paper focuses on the latter part.
- We create a new Arabic corpus for benchmarking text simplification approaches and make it publicly available<sup>1</sup>. Besides, we make the details of our experimental evaluations and implementations (i.e., including codes and scripts) publicly accessible<sup>2</sup> to the interested researchers for replicating our experiments.

The remainder of this paper structurally unfolds as follows. First, we present the closely related work and the state-of-the-art NLP pre-trained models, including a brief review of gaps in the literature concerning the Arabic text simplification prob-

<sup>1</sup><https://github.com/AMahfodh/ArSummarizer/tree/main/TSimAr/resources>

<sup>2</sup><https://github.com/AMahfodh/ArSummarizer/tree/main/TSimAr>

lem. Next, we introduce our text split-and-rephrase approach and discuss the subsequent experimental analysis and results. Concluding the paper and outlining the potential forthcoming avenues of investigation are presented afterward.

## II. REVIEW OF RELATED LITERATURE

This section provides a synopsis of Text Simplification (TS) methods, broadly categorized into extractive and abstractive approaches. In principle, text simplification approaches (illustrated in Figure 1) are abstractly analogous to text summarization approaches, as they both strive to simplify texts. However, the dissimilarity between them is fundamental. Text summarization attempts to shorten text without losing the key meanings, while simplification attempts to improve text readability by reducing linguistic complexity constrained by preserving the key meanings. Before delving into TS approaches, we position the novelty of our contribution in the context of related literature by stating the following:

- no split-and-rephrase model has been suggested yet for simplifying complex Arabic texts to the extent of the authors' knowledge; and
- for text-to-text rephrasing, we explore, for the first time, the effect of the modified attention-free Transformer model [21](i.e., depends on a fast Fourier-Transform) for the Arabic language.

### A. Extractive Approaches

The core idea of the extractive approach is to extract the main sentences of the text through text summarization. In other words, the simplification here is performed using summarization. However, summarization does not necessarily lead to simplification. Therefore, this approach is not recommended. One of the examples of text simplification through summarization is the TF-IDF [14]. Preprocessing is a normal requirement of this approach. The preprocessing includes converting text into lower-case, removing punctuation, special characters, and stop words, and stemming to return complex words to their language base.

### B. Abstractive Approaches

The previous approach is not a real simplification, it is just a summarization, but in the abstractive approach, the output text is a real simplified text. In this approach, there are two main categories of simplifications. The first is Lexical Simplification (LS), and the second is Text Generation (TG).

1) *Lexical simplification*: The simplification in the LS category is performed through the replacement of complex/hard words with simple/easy words. Therefore, it is called lexical simplification. LS algorithms work at the sentence level. The structure of sentences is not changed, and the grammar is simplified. Only word replacement is included in the simplification. As so, this type of simplification is not effective enough. The hard words may be replaced with easy ones, but the sentence structure and grammar may still be hard to understand. Examples of lexical simplification are the following.

- Rules-based LS
- Parallel corpora extracted-rules LS
- Word embedding LS

- Pre-trained language models LS

Rule-based LS [22], [23] depends on a linguistic database, like WordNet, to get the simplest synonym of a word, which can be based on its frequency or its length. In parallel corpora, extracted-rules TS [24], [25], [26], the rules are extracted automatically from a parallel aligned corpus. While Word Embedding TS [27], [28], [29] has the advantage that there is no need for lexical resources. The appearance of pre-trained models had a huge benefit for all NLP tasks; one of these tasks is text simplification. Some systems use pre-trained models like BERT to find and generate easy words for complex ones. Therefore, the class of pre-trained language models TS systems [30], [31] has proved its effectiveness compared to other techniques.

2) *Text generation*: The second category of the abstractive approach is Text Generation (TG). In TG, a new simplified text is generated. The new text may have a different structure or a different number of sentences. TG's approach includes sentence splitting, text addition, and deletion. TG can only be considered a true simplification, while the previous methods can be seen as good trials for the simplification, but not real simplification because real simplification means digestion of the original text and generating a new simplified one with new simple words, structures, and grammar. The recent text generation-based TS is data-driven, considering the advantage of the complex structures in data. The text generation techniques can be classified as follows:

- Syntactic simplification
- Statistical Machine Translation (SMT)
- Deep Learning Techniques

In the next paragraphs, we explain each approach.

a) *Syntactic simplification*: In syntactic simplification, the hard/complex words are replaced by easy/simple ones, and the grammatically complex sentences are identified and rewritten in simple sentences. The process of simplification includes splitting long sentences, changing passive sentences to active ones, and resolving ambiguities. Examples of syntactic simplification research are mentioned in [32], [33].

In [34], the authors proposed a model called: TriS: Their approach was to break down a long statement into numerous shorter ones. When a sentence is written in the subject-verb-object order, it is called simple (SVO). A dataset of 854 sentences taken from the New York Times and Wikipedia, manual simplification is performed for the evaluation. The authors assess 100 unseen sentences and compare them to Heilman and Smith's rule-based method [35]. Their approach gets higher ROUGE [36] and Flesch-Kincaid Grade Level scores. Another method is grammar induction, where simplification is considered by converting the tree1 to tree2 problem, where tree1 is for the source, and tree2 is for the target. The process includes extracting tree transformation rules using a corpus, then learning how to select the adequate rule(s) to be applied to simplify unseen sentences. In [37], authors modeled the syntactic and lexical simplification using tree transduction rules. The evaluation of their proposal was performed using the Simple Wikipedia corpus and it showed good results. The authors highlighted the need for a mechanism to eliminate useless transformation rules.

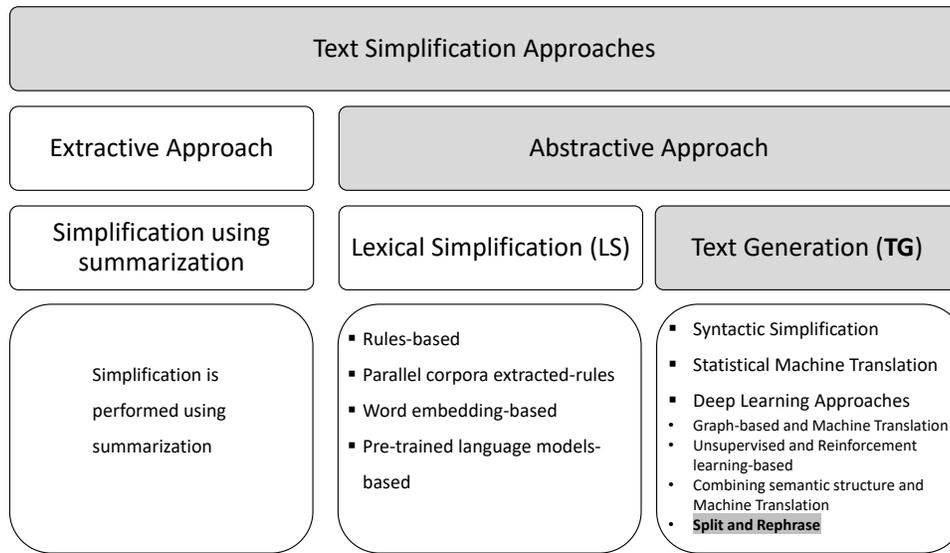

Fig. 1. Text simplification approaches

b) Statistical machine translation (SMT): Machine translation (MT) is the process of translating a text written in language A (source) to language B (target), where the two languages are different. Due to the massive amount of available data nowadays, MT has achieved many success stories. MT is applied successfully to the TS by considering that language B (target) is a simplified version of language A (source), where both represent the same language. Now the problem of simplification can be seen as the generation of monolingual text-to-text or monolingual translation. Some research used phrase-based statistical MT and applied it to TS. The task obviously is simpler than the source, and the target languages are the same; only the target is simpler than the source. Examples of SMT used for TS includes [38], [39], [40], [41], [42].

c) Deep learning techniques: In the era of big data, powerful computers, and GPUs, deep learning took the lead in AI, especially data-driven AI. Deep learning proved to be effective when used with SMT, where RNN Encoder-Decoder is used in MT [43]. This motivated researchers to employ DL in TS using the monolingual translation approach. In [44], the researchers successfully used RNN-based Neural Machine Translation (NMT) for TS; other authors in [45] used LSTM Encoder-Decoder in the simplification process. The authors in [46] developed a model called R-PBMT, Phrase-Based Machine Translation, augmented with a re-Ranking heuristic based on dissimilarity. The model is trained and tested using the PWKP dataset; they compare their work with three models, Word-Substitution Baseline models, that replace a word in a sentence with synonyms retrieved from WordNet. In another research [47], the authors performed four rewriting operations, replacing, splitting, reordering, and deletion; their work is also depending on DL. In [48], the authors proposed a system that is based on quasi-synchronous grammar. Results showed the general superiority of their model using the human evaluation and the automatic evaluation using the metrics BLEU and Flesch-Kincaid grade level. There exist many other DL-based approaches for TS. These approaches include graph-based

approaches [49], reinforcement learning-based TS [50], NMT [51], combining semantic structure and NMT [52], phrase-based unsupervised TS [53], unsupervised neural TS [54], and split-and-rephrasing techniques [8], [9], [7], [10], [20]. In this paper, we conceptually consider the latter technique (i.e., split-and-rephrasing technique) for the Arabic language for the first time. In addition, Table I summarizes the recent existing approaches which indicate the originality of our proposal.

### III. METHODOLOGY

Figure 2 presents an overview of our proposed TSimAr in five steps with illustrative input-output examples. In principle, we integrate a punctuation detector for text segmentation (PDTs [5], see step 3) with a modified attention-free Transformer architecture for rephrasing and simplifying complex Arabic text, step 4. The former (i.e., PDTs) attempts to split a given input text into the shortest set of simple independent-clause sentences. The latter (i.e. the focus of this paper) aims to rephrase the concatenated simple sentences to generate a more readable version. For example, given a textual document  $X$  containing complex sentences, TSimAr attempts to break it down into ( $Y$ ) uncomplicated sentences with rephrasing, such that  $Y \leftarrow TSimAr(X)$  and  $Y = \{y_1, y_2, \dots, y_{|n|}\}$ , where  $n$  is the number of generated simple sentences.

As usual with most NLP applications, TSimAr is set off with straightforward text preprocessing (see step 2), which includes noise/diacritizations removal and soft normalization. This preprocessing step cleans the input texts without breaking sentence structures, and more importantly, it preserves the overall meaning to an extent. For implementing this step, we consider two Python-based toolkits: NLTK<sup>3</sup> and CAMEL<sup>4</sup>. Once the preprocessing step is performed, TSimAr segments and then rephrases the cleaned input text, shown in steps 3 and 4 of Figure 2. In the following subsections, we focus on these

<sup>3</sup>NLTK Tool: <https://www.nltk.org/>

<sup>4</sup>CAMEL is an Arabic natural language processing tool: <https://camel-tools.readthedocs.io/>

TABLE I. A BRIEF SUMMARY OF REVIEWED TEXT SIMPLIFICATION APPROACHES THAT APPLY SPLIT-AND-REPHRASING TECHNIQUES

	Approach	Language	Split Technique	Rephrase Technique	Transformer Architecture

two main steps (i.e. the segmentation and rephrase steps) in a little more detail.

### A. Text Segmentation

We base our proposed TSimAr on top of PDTS [5] (i.e. an Arabic text splitting tool that employs a pre-trained multilingual BERT [55] model for detecting missing punctuations) for segmenting input texts into a set of potentially independent-clauses. More in detail, PDTS queries mBERT<sup>5</sup>  $|X|$  times to predict proper punctuations between words on which they can be used as text split delimiters:

$$p(pu_i^m | t_i^m; pun, \theta) = PDTS \circ mBERT(X'_i), \quad (1)$$

$$X'_i \leftarrow insertMaskToken(X, i), \forall i \in X \quad (2)$$

where  $pu_i^m$  represents the valid mBERT's output for a given white-space at index  $i$ ;  $t_i^m$  is the actual mBERT's output;  $pun$  and  $\theta$  are model parameters set by the user to filter out  $t_i^m$ ; and  $X'_i$  is the input  $X$  with the inserted  $[MASK]$  token at index  $i$ . PDTS then validates the predicted set of punctuations  $pu^m \forall i \in \{1, 2, \dots, |X|\}$  using four generic linguistic rules in a greedy-like strategy. In this paper, we have set  $pun$  with only the main splitting punctuations, including full-stop, comma, semicolon, and colon.

### B. Rephrase Generation

Motivated by Transformers-based encoder-decoder architecture [56] that has achieved outstanding improvements in complicated NLP tasks, we consider one of its optimized sequence-to-sequence models. In particular, we utilize (FNet) an efficient version that substitutes complex self-attention layers with linear Fourier Transforms-based layers, introduced originally in [21]. Here, FNet is efficiently lighter and much faster than the standard Transformer model with complicated attention layers. Besides, it closely matches the performance of the standard Transformer model. Considering the right part of Figure 2, it describes the core part of standard Transformer architecture that is modified by adding fast Fourier Transforms layers. Broadly speaking, *Transformer* blocks are stacked with a size of  $N_x$ , where each block consists of a two residual

gateless layers that adds additional weight matrix with *Skip Connection*, Eq. (3):

$$y := \epsilon f(x) + x \quad (3)$$

where  $\epsilon$  is the regularization parameter. In the standard Transformer architecture, the multi-head attention (i.e. concatenate a number of self-attention layers) allows to learn the structural and morphological correlation between different input-tokens impressively, using Eq. (4):

$$attention(Q_i, K_i, V_i) = \sigma \left( \frac{Q_i K_i^T}{\sqrt{d_k}} \right) V_i, \quad \text{for } i = 1, \dots, h \text{ (head)}. \quad (4)$$

where **query**, **key**, and **value** vectors are computed as  $Q_i = W_q^i x$ ,  $K_i = W_k^i x$ ,  $V_i = W_v^i x$ ; and  $\sigma$  is the softmax activation function. Nevertheless, it is memory intensive and has an exponential (quadratic) time complexity concerning the size of the input sequence [56]. Thus, to avoid such scalability issues, we employ fast Fourier Transform layers as an alternative to attention sublayers, expressed in Eq. (5):

$$W_{ij} = \left( \frac{e^{-i \frac{2\pi}{N} i \times j}}{\sqrt{N}} \right) \quad (5)$$

where  $i, j = 0, \dots, N - 1$ . Recent experiments [21] demonstrated that the Fourier Transform-based model (so-called FNet) can significantly reduce the training time and space complexity while providing an excellent performance that is exceptionally comparable to the performance offered by the standard Transformer-based encoder-decoder model. The architecture of our implemented FNet sequence-to-sequence model for rephrasing Arabic texts is presented explicitly in Figure 3.

## IV. EXPERIMENTS AND RESULTS

We conduct experiments to assess the performance of TSimAr and analogize its rephrasing part with the existing Arabic pre-trained text-to-text generation models. We introduce ATSC (a new Arabic corpus for text simplification) and use it in our evaluation protocols. As a quality benchmark of generated simplifications, we report various automatic text

<sup>5</sup><https://github.com/google-research/bert/blob/master/multilingual.md>

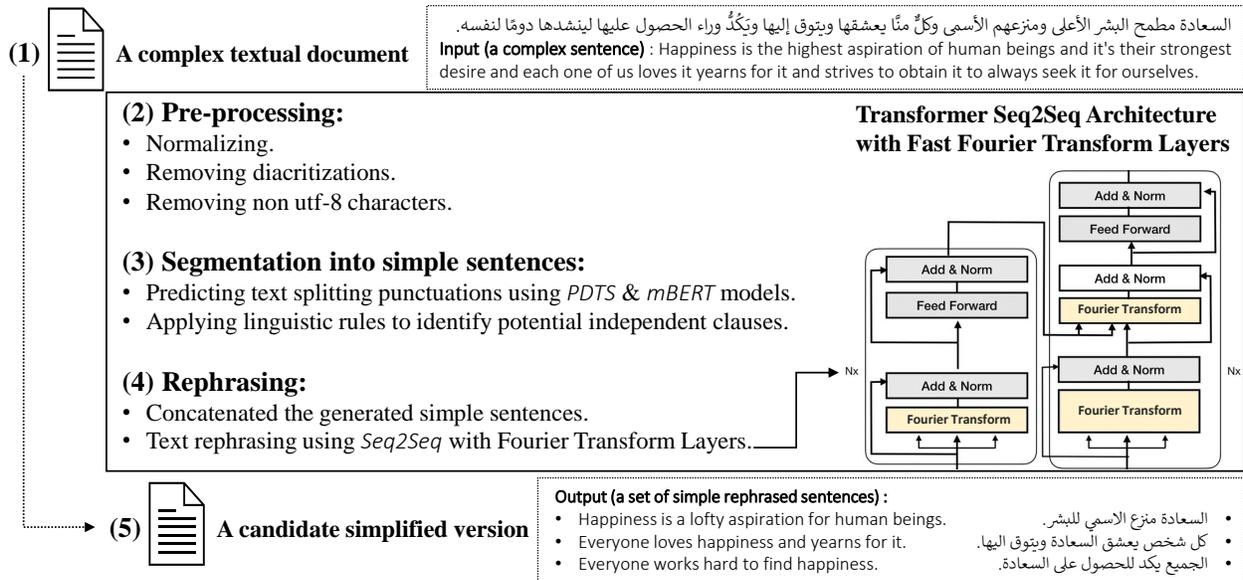

Fig. 2. The overview flow of the proposed TSimAr with an illustrative input-output example

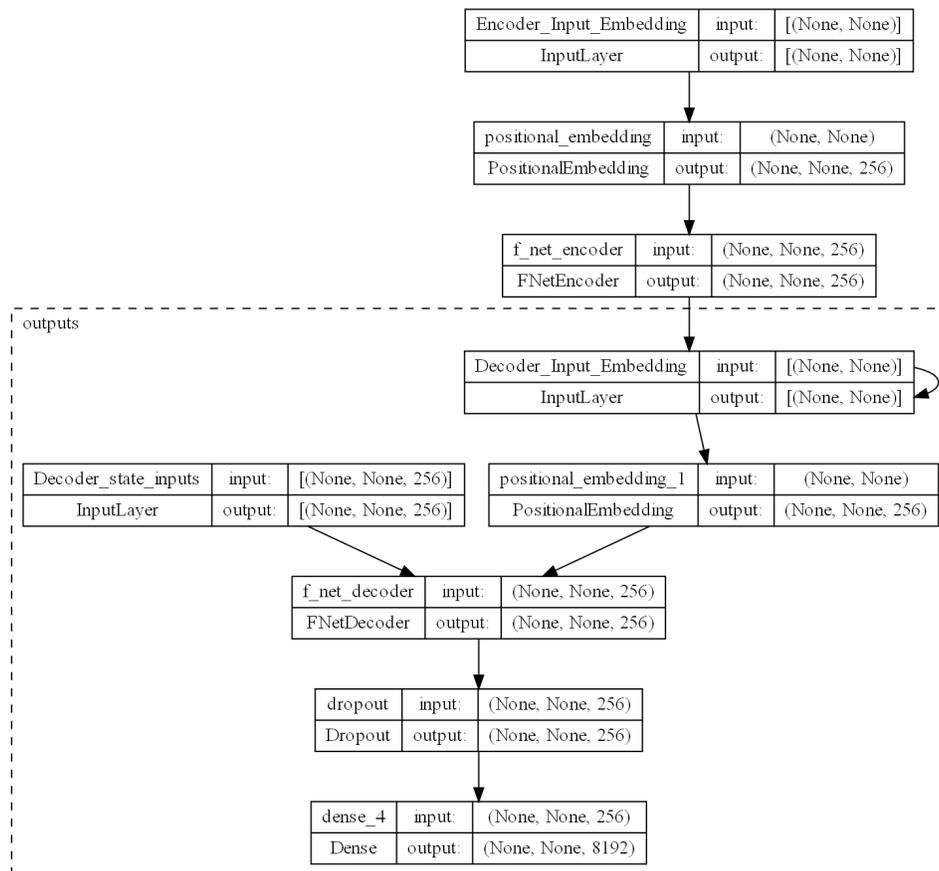

Fig. 3. The architecture of our implemented FNet sequence-to-sequence model for Arabic texts rephrasing. The total trainable parameters are 11,055,616

matching metrics, including SARI (the primary metric for text simplification and rephrasing), besides presenting the findings from the conducted manual (human-based) assessment.

#### A. Corpus and Experimental Setup

a) Arabic text simplification corpus (ATSC):: To the extent of our knowledge, there is no specific Arabic corpus for

text simplification. Thus, we create a small benchmark corpus containing 500 pairs of a small-to-large complex text (source) and a gold-standard simplified (i.e. splitted and rephrased) text. The gold-standard reference simplifications are written and carefully reviewed by human experts. In a little more detail, our corpus ATSC has been constructed from selective Arabic articles that contain appropriate text to simplify. We collected these articles from different public sources (i.e., Wikipedia, newspapers, and news agencies), which cover various domains, including history, geography, health, education, and technology. For constructing the simplified versions from the collected articles (i.e., form the gold-standard human-based references), we have applied two simplification methods: *syntactic simplification* (i.e. just an extractive text summarization method that drops/selects the key sub-sentences without generating new words) as well as *linguistic simplification* (i.e. almost similar to the abstractive summarization method that attempts to replace complicated words with conceivably simpler synonym words), depending on their contexts and overall meaning. Table II shows some general statistical descriptions of our ATSC.

TABLE II. STATISTICAL DESCRIPTIONS OF OUR EVALUATION CORPUS (ATSC)

	Original complex texts	Simplified Rewrites
# No. Documents	500	500
# No. Sentences	546	1243
# No. Words (distinct)	17069 (6046)	17564 (5479)
# No. Vocabularies (for both complex and simplified texts)	6737	

*b) Baselines::* We compare the text rephrasing part in our TSimAr (i.e. FNet model) against the state-of-the-art pre-trained Arabic monolingual (Arabic-T5-small [16], Arabic-T5 [15], UBC-AraT5 [17]) and general multilingual (MT5-base [19], mBART-large-50 [18]) models for text generation tasks. These text-to-text generation models are architecturally extended from T5 encoder-decoder transformer blocks[57], except mBART that is a multilingual Sequence-to-Sequence model used generally for translation tasks:

*c) Automatic metrics::* Given a source text  $st$  and a gold-reference  $gr$  (i.e. a typical simplification version written by human experts), we evaluate the efficiency of the produced simplification  $y$  (i.e.  $Y \leftarrow TSimAr(st)$ ) using a variety of automatic metrics as follows:

- SARI [58] (*System output against References and against the Input sentence*) is a standard evaluation metric for text simplification, which compares the generated candidate simplifications  $y$  against both (1) the source input  $st$  and (2) the gold-reference  $gr$ . It uses precision and F1 scores of  $n$ -grams ( $n \in 1, 2, 3, 4$ ) to measure the goodness of added, deleted, and preserved tokens by the simplifier model (i.e. TSimAr).
- BLEU [59] (Bilingual Evaluation Understudy) is a popular evaluation metric for text quality, commonly used in machine-translated tasks. It compares  $y$  against  $gr$  only and approximates recall and precision metrics using the best match ( $n$ -gram) length and modified  $n$ -gram precision, respectively.
- METEOR [60] (*Metric for Evaluation for Translation with Explicit Ordering*) is similar to BLEU but replaces the best match ( $n$ -gram) length and modified  $n$ -gram

precision with a weighted F-score metric that depends on unigram mapping.

- TER [61] (Translation Edit Rate) which estimates the number of edits required (e.g., adding, deleting, or shifting a word token) to improve  $y$  as matched with  $gr$ .
- ROUGE [36] (Recall-Oriented Understudy for Gisting Evaluation) gives different ROUGE- $n$  metrics, where  $n$  represents the number of overlapping  $n$ -grams between  $y$  and  $gr$ . It uses the standard statistical metrics (precision, recall, and F-measure) for its measurements. In our experiments, we consider ROUGE-1 (unigram overlapping), ROUGE-2 (bi-grams overlapping), and ROUGE-L (the longest identical subsequence overlapping between  $y$  and  $gr$ ).

Concerning SARI, BLEU, METEOR, and ROUGE, higher scores indicate better quality correlated to rational human judgments. In contrast, a lower TER metric (i.e. lower editing scores) indicates better performance.

*d) Implementation details:* To train and configure the text rephrasing part in our TSimAr (presented in Figure 3), we applied a 50—20—30 random split on our ATSC corpus to create train, dev, and test sets, respectively. Besides, we used the Adam optimization algorithm for training with a learning rate of 0.001. The training loop lasts 5k epochs with a batch size of 64 and a maximum sequence length of 256. Moreover, the text-to-text generation models, considered in this paper as baselines, are publicly available at the Hugging Face<sup>6</sup>, under the model (card) names: ‘google/mt5-base’, ‘facebook/mbart-large-50’, ‘flax-community/arabic-t5-small’, ‘UBC-NLP/AraT5-base-title-generation’, and ‘malmarjeh/t5-arabic-text-summarization’. We have constructed these models using PyTorch<sup>7</sup> framework besides utilizing some NLP toolkits for text preprocessing, including NLTK<sup>8</sup> and CAMEL<sup>9</sup>. All experiments have been conducted using a gaming PC equipped with Intel i9-CPU, 64G-RAM, and a single NVIDIA GeForce RTX3070 GPU.

## B. Performance Evaluation

In Table III, we show the performance of our TSimAr with FNet against different text rephrasing models (i.e. depending on text-to-text generation models) using the validation portion from ATSC. Performance results are also visualized in Figure 4. Besides that, we break down the performance details and simplification quality for one input instance in Table IV. As can be observed, TSimAr evidently outperforms all the existing state of the art text-to-text generation models for the Arabic language. It achieves the best score on all standard metrics (particularly SARI) and gives the second to the best score on TER and ROUGE-1. The last column on the right of Table III shows the execution time in second, visualized in Figure 5. Here, our TSimAr gives foreseen poor-to-ordinary time performance as its FNet architecture is quite heavy (consisting of more than 11M trainable parameters).

In addition, giving insight into the text simplifications produced by the competitors’ models, presented in Table IV

mBART [18]	0.44	0.15	1.10	0.57	0.51	0.28	0.50
UBC-AraT5 [17]	0.27	0.00	1.00	0.01	0.04	0.00	0.04
Our TSimAr	0.90 *	0.79 *	0.19	0.81 *	0.92 *	0.87 *	0.92 *

and Table V, one can observe that mid-to-high automatic metrics results may not necessarily reflect valid candidate

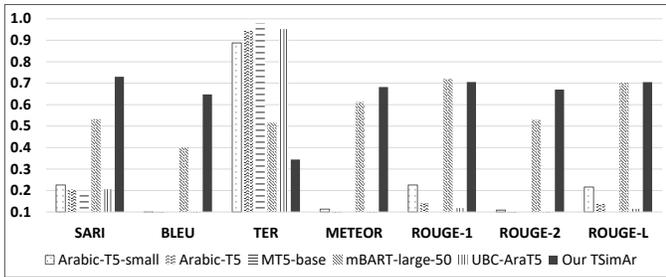

Fig. 4. Performance of TSimAr with FNet against competitors' text rephrasing models (i.e. depending on text-to-text generation models)

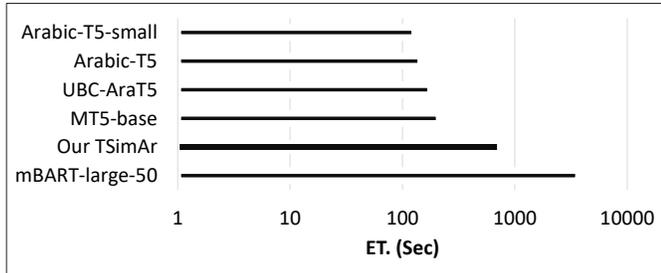

Fig. 5. Performance (w.r.t execution time in second) of TSimAr with FNet against competitors' text rephrasing models

simplification. To clarify more, we observe that mBART [18] often produces outputs almost identical to the input without simplifying or rephrasing, and in turn, it inaccurately archives more than 0.4 SARI score. While, UBC-AraT5 [17] simplifies input text in much better quality, it achieves around 0.27 SARI. Accordingly, it was essential to solidify the evaluation of our proposed TSimAr using manual insight by eliciting human judgments.

### C. Manual Evaluation

To get an additional in-depth evaluation of our TSimAr, we conducted a qualitative analysis by eliciting a humanistic viewpoint on 36 sampled text documents selected randomly from the ATSC validation set. We invited two expert consultants in Arabic linguistics (not authors of this paper) to evaluate these documents (each expert is given 18 documents) on the following three standards using a five-star-point Likert scale (1-5):

- Adequacy (preservation of the source meaning),
- Contextual soundness (quality of rephrased and simplified texts), and
- Grammaticality (to what extent the generated text is free from grammatical errors).

Experts are asked to compare the generated simplifications TSimAr by (i.e. depending on Arabic-T5-small, Arabic-T5, MT5-base, mBART, UBC-AraT5, and our FNet) against the gold-standard references (i.e. text simplification versions written by human experts). With a glancing over into Table VI, the results of our manual evaluation look almost compatible with the automatic evaluation results (shown in Table III) for only the first and the third standards (i.e. *Adequacy* or *Grammaticality*). Nevertheless, *Contextual soundness* standard

TABLE VI. HUMAN EVALUATION RESULTS FOR THE THREE CRITERIA: ADEQUACY, CONTEXTUAL SOUNDNESS, AND GRAMMATICALITY. BASE PRE-TRAINED TEXT-TO-TEXT GENERATION MODELS WITH \* ARE SIGNIFICANTLY DIFFERENT FROM TSIMAR'S BASE MODEL †, DEPENDING ON A TWO-TAILED INDEPENDENT T-TEST, WHERE  $p < .05$ . FOR ARABIC-T5, THE DIFFERENCE IS SIGNIFICANT AT ( $p < .1$ )

Text generation models	A	C	G	Avg.	p-value	t-value
Arabic-T5-small [16]	1.5	2	3	2.17	.010585 *	4.52904
Arabic-T5 [15]	3	3.5	4.5	3.67	.080472 *	1.71791
MT5-base [19]	0	0	1	0.33	.000694 *	9.47046
mBART [18]	5	0	4	3.00	.366645	1.01705
UBC-AraT5 [17]	3.5	4.75	5	4.42	.778051	0.30151
Our TSimAr depending on FNet	4	4.75	5	4.58	†	

reveals the quality differences more precisely, which also confirms that our TSimAr with FNet (indicated by †) can produce a highly competitive performance (see, 4.58 the best average ratings obtained by TSimAr).

Furthermore, the manual experimental results indicated that UBC-AraT5 is a feasible pre-trained text rephrasing model to adopt (i.e. an alternative model to FNet) as it achieves the second highest average score of about 4.42. This indication can also be statistically noticed by its insignificant p-value (i.e. the obtained .78 with UBC-AraT5). In contrast, however, the worst performances observed were with MT5-base and mBART, which unexpectedly gave zero simplification quality. Here, the performance of mBART contradicts the insignificant p-value (i.e. .367) as this heavy model offers an illusive high score in *Adequacy* and *Grammaticality* standards, which is a consequence of generating texts exactly similar to the input texts with no simplification.

### D. Discussion and Potential Threats to Validity

In this section, we discuss the potential threats to the empirical validity of the proposed TSimAr. The main threats may include the creation of our corpus (ATSC) for evaluation as well as the benchmarking against the state-of-the-art text rephrasing models. As mentioned earlier in this section, there is no specific Arabic corpus for text simplification available to date. Therefore, we had to make an effort to (1) collect professionally written corpus from online sources (mainly from newspaper articles) and (2) simplify them precisely (i.e. split with rephrasing) by linguistic experts in Arabic, elaborated in ATSC. One may argue that ATSC is relatively small (containing only 500 pairs of texts), and more importantly, it may be insufficient to train a heavy model like FNet. These thoughts are valid to a reasonable extent. However, recent studies demonstrated that training a language understanding model on a larger corpora/dataset might not necessarily imply improving its performance [62], [63]. Besides, our intention here is not to use ATSC to train a language understating model but rather to use it as a benchmarking corpus for testing the generalization of a pre-trained test-to-text generation model. We make our ATSC available for researchers to exploit in this regard.

Concerning the chosen text rephrasing baseline models, we attempted to counter this concern by using all publicly available Arabic monolingual sequence-to-sequence models (we have encountered only Arabic-T5, Arabic-T5-small, and UBC-AraT5) as well as using the state-of-the-art multilingual models

(i.e. MT5 and mBART). For a fair comparison between these pre-trained models, we confirmed that their large vocabulary contains all the distinct 6737 words extracted from ATSC.

## V. CONCLUSION

Approaching towards breaking down a given complex Arabic text into a simple and meaning-preserving version, we have presented a text split-and-rephrase solution (so-called TSimAr), which depends principally on a sequence-to-sequence Transformer-based architecture. For the splitting, we have integrated TSimAr with a punctuation detector for text segmentation (PDTS) built on top of a pre-trained multilingual masked-language model (mBERT). This PDTS attempts to generate the shortest set of simple independent-clause sentences from a given lengthy complex text. While in the rephrasing phase, we have proposed an attention-free Transformer model, depending on a fast Fourier-Transform (FNet-based), which rephrases the concatenated simple sentences into a more readable version.

In addition, we have created a new corpus (ATSC) to train and evaluate the rephrasing part in our TSimAr. Automated and manual analyses demonstrated that with the support of PDTS, our TSimAr evidently outperforms all the existing state-of-the-art text-to-text generation models for the Arabic language as it achieved the best score on SARI, BLEU, and METEOR metrics. Nevertheless, a trivial limitation noted in TSimAr lies in the execution time compared with competitors' lighter models, such as Arabic-T5-small. Hence, for the generality, we imagine a remarkable extension of this ongoing work in two directions:

- (1) evaluating TSimAr on a comprehensively benchmarking dataset that we plan to create, and
- (2) optimizing our FNet architecture for enhancing its execution performance.

For the latter direction, we will investigate the feasibility of applying a knowledge distillation technique to compress our FNet into a smaller version to help us reduce its space complexity while achieving higher inference speed and accuracy.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation at the Ministry of Education in the Kingdom of Saudi Arabia for funding this research work through project number (19/20).

**Abstract**—Presently, sample social applications have emerged, and each one is trying to knock down the other. They expand their game by bringing novelty to the market, being ingenious and providing advanced level of security in the form of encryption. It has become significant to manage the network traffic and analyze it; hence we are performing a network traffic binary classification on one of the globally used application – WhatsApp. Also, this will be helpful to evaluate the sender-receiver system of the application alongside stipulate the properties of the network traces. By analyzing the behavior of network traces, we can scrutinize the type and nature of traffic for future maintenance of the network. In this study, we have carried out three different objectives. First, we have classified between the WhatsApp network packets and other applications using different ML classifiers, secondly, we have segmented the WhatsApp application files into image and text and third, we have incorporated a deep learning module with the same ML classifiers to understand and boost the performance of the previous experiments. Following the experiments, we have also highlighted the difference in the performance of both tree-based and vector-based classifiers of Machine Learning. Based on our findings, XGBoost classifier is a pre-eminent algorithm in the identification of WhatsApp network traces from the dataset. Whereas in the experiment of WhatsApp media segmentation, Random Forest has outperformed the other ML algorithms. Similarly, SVM when clubbed with a Deep Learning Auto encoder boosts the performance of this vector-based classifier in the binary classification task.

**Keywords**—Network traffic; encrypted network traffic; tree based classifiers; SVM

## I. INTRODUCTION

All network applications need encryption as it provides authenticity, confidentiality and integrity to the users. In unencrypted network traffic, an intruder; whether spiteful (attacker), or not (e.g. network administrator tracking infrastructure) can read network packets and can view their contents. This leads to the intrusion of privacy and misuse of user's data. Whereas, in case of WhatsApp application, the data is end-to-end encrypted from the sender to receiver. Such applications do not leave room for any kind of violation of privacy. In widespread, encryption has a giant effect on detection and analysis of network traffic, because it conceals all payload statistics. As a result, new methodologies and frameworks are required to understand the complexity of Network traces without the need for decryption.

With an efficient and accurate Network Traffic Classification (TC), we can attain the cognizance of the nature and type of packets without the need of decryption. This is a secure way for Network traffic analysers to understand about the complex features of data packet. This could benefit the Network Traffic analysers in wide area of applications including advertising, allocating more bandwidth, understanding network patterns and its alterations etc. without the need of decryption. However, the rising strength of encryption requires efficient frameworks which can sustain the complexity of different and novel features of the data packets and can yield accurate results. In this study, we have used multiple Machine learning classifiers for performing binary TC. In accordance with that, we have also incorporated Deep Learning Auto encoder and PCA with ML classifiers to see their influence on the previous results. Over the last few studies, researchers have demonstrated how the inclusion of Deep Learning in the classification frameworks has improvised the results. This extra module of DL thus takes care of the packet's features and extracts them for the classifier. With an extracted set of features, the complexity for the classifier reduces and as a result it performs better. The results in this paper indicate the same and give a clear understanding of the performance of different models taken into consideration. The model which we proposed is to make the features learned from the deep learning algorithm such as auto encoder, PCA and those features will be feeded to train the machine learning model such as SVM, XGBoost, and Random forest. The performance analysis is done to verify whether the auto encoder or PCA helps the machine learning model to improve the classification in network traffic data.

### A. Key Contributions

Our major contributions in this paper are:

- The available dataset [1] [2] does not includes WhatsApp network traffic traces. In this work we collected WhatsApp network traffic and integrate into the existing dataset.
- Implementing auto encoder, PCA with machine learning models for network traffic classification.
- Comparative study on the performance of tree based classifiers and large margin classifier for encrypted network traffic classification.

### B. Introduction of WhatsApp Application Data in the Dataset

The WhatsApp Network traces are captured using the Port Mirroring Technique in a supervised environment over a secure connection. This enables us to club this captured data with open-source datasets available and use this combined dataset to train our proposed models.

### C. Comparison of Tree-Based and Vector-Based ML Classifiers for Traffic Classification

A contrast is highlighted between Tree-based and Vector-based algorithms of Machine Learning and the results are thoroughly explained using precision and F-1 scores. At the end of this study, a claim is also made in favour of Tree-based algorithms for their excellent performance.

### D. Feature Learning using Deep Learning and Comparison of Proposed Cross-Frameworks

An extra step is implemented to distribute the workload of Traffic Classification over different modules of the proposed framework. During the feature extraction and learning, Auto encoder and PCA come into action and pass the set of learned features to the classifier. This not only performs the TC but also boosts the performance of the model.

## II. RELATED WORK

The rising demand for Network Traffic Classification (TC) [3] [4] has led to many studies in the recent years. TC has use in wide areas of applications and holds a huge demand among the Network Analysers. A lot of studies have also demonstrated hybrid models that are known to have better accuracy in identifying large variety of applications.

In [5], T.T. Nguyen and others put forth the execution of ML techniques to IP traffic classification. They claim that the algorithms have demonstrated varied accuracy, even up to 99 percent, for a wide range of web application traffic. In [6], A. Dainotti and others have provided a wide range of worthy recommendations for traffic classification. According to one of their recommendations, the blend of traffic classification and algorithms should include a thorough analysis of efficiency and performance. Weibo Liu and others in [7] bestow the combination of Auto encoder, convolutional neural networks, deep belief network, and restricted Boltzmann machine. Using this combination, they indicate that we can now use unsupervised learning algorithms to process the unlabelled data. In [1], Hongtao Shi and others propose an approach that insists on dimensional reduction in feature space and overcomes the multi-class imbalance. Giuseppe Aceto and others in [2] put forward Deep Learning to build traffic classifiers based on auto-extracted features and reflect their traffic patterns. Finally, they have dissected existing DL algorithms in standard traffic classification. In [8], Chuan Guo and others put forth the calibration prospect of the ML algorithms. Their findings signify the effectiveness of temperature scaling on datasets. Arthur Callado and others in [9] propose techniques like signature-matching, sampling, and inheritance, known in the field of IP traffic analysis, and focuses on application detection. In [10], Wei Wang and others present a new perspective of traffic classification using AI. They achieved good accuracy using a traffic classifier, which can learn features automatically

(used CNN). Meanwhile, [11] and [12] are concerned with the privacy involved in network traffic analysis in applications present on the smartphone. They propose methods to secure end-to-end encryption as well as show the threats an eavesdropper can bid.

A similar approach is also investigated in [13] where the author proposes high performance multi class classification architecture capable of enhancing the classification results by up to +9.5 percent. The popularity and efficacy of DL based hybrid model is also evident in [14]. In [14], [15], [16] a pure DL framework with a series of Neural Network is proposed. The focus here lies on addressing a novel and updated experimental setup for an umbrella of TC tasks which are encrypted. In addition to this, sustainable frameworks are designed by researchers to use it for multi-classification tasks. In [17], a single architecture is proposed which can perform two tasks simultaneously. Task one being the characterization of the network traces based on F2P and P2P. The second task being the identification of applications [18]. With this single Deep Learning framework [19], the author has been able to further distinguish the packets into VPN and Non-VPN [20] traces followed by TC. The need of standard framework in network traffic analysis is discussed in [21].

Our research is greatly influenced by the concept of hybrid models and their multi-classification purpose. With that in mind, we have deduced different models and selected the most promising among them.

In this work the feature learning process is automated through the auto encoder, PCA. The proposed model trains the machine learning model [5] with the features learned using the auto encoder, PCA. A comparative study is done between the performance of the tree based classifiers and SVM. From the results it shows the performance of random forest improved much better with auto encoder.

## III. DATASET COLLECTION

Fig. 1 demonstrates the experimental setup involved in the data collection process. This setup consists of a router, a viable internet connection, a port mirroring switch, communicating devices and software for the purpose of analysis. The Wireshark software is used on the controlling unit which displays the features and network traces in a series of timeline. However, this raw data obtained from this setup is in the .pcap format. CIC Flowmeter tool is used to convert this extension in a usable format of .csv extension for our model to be trained. Once the data is converted, it passes through the pre-processing stage. Here, the CIC Flowmeter tool extracts more features from the raw data by performing mathematical calculations using statistics at the backend. These are called the derived features. Based on the previous studies, the relevant features for our model are considered and the others are omitted. These features include both the backward BWD and forward FWD transmission flow. Once the data is pre-processed, it is combined with an open-source network traffic dataset (ISCXVPN2016) to train our proposed model. As a result, this combined dataset includes WhatsApp network traces along with Other Applications. This experimental setup is carried out in a supervised environment and is one our major contributions in this paper.

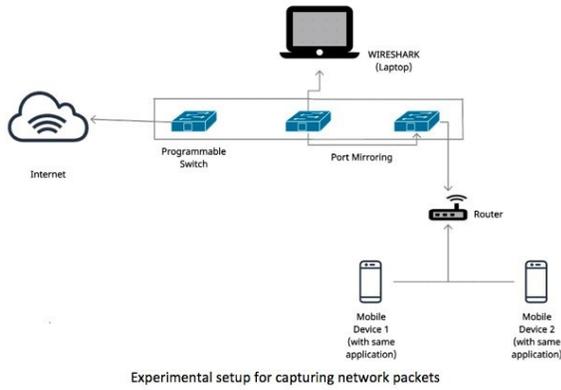

Fig. 1. Experimental setup for capturing network packets

### A. Dataset

The dataset used in the experiment includes VPN [22] traffic data from the Canada Institute for Cybersecurity. Since VPN data are encrypted it is combined with WhatsApp traffic data. Total VPN data is 16395 which includes 'vpn\_email', 'vpn\_facebook', 'vpn\_hangouts', 'vpn\_spotify', 'vpn\_youtube' and the WhatsApp data is about 17997. For experiments on classifying WhatsApp data as image, text the number of image data is 12546 and number of text data is 26258

## IV. PROPOSED METHODOLOGY

Although a simple Machine Learning Classifier is capable of distinguishing between two types of data packets and segmenting them into classes, however with the rising complexity and security of social media applications, these traditional classifiers namely SVM, Random Forest, XGBoost etc. under perform.

Our proposed model in Fig. 2 is a dual stage framework with each stage performing an independent task in the TC. This not only boosts the efficiency of the model but also yields improvised results as compared to pure Machine Learning models. Stage 1 provides a pipeline where the data is captured and pre-processed before it is passed onto the classifiers. In this stage, MinMax scaler is implemented to normalize the data entries and convert them in the range of [0,1]. ML classifiers like SVM, XGBoost and Random Forest are tested on our self-gathered dataset. Also, a contrast between Tree-based (XGBoost and Random Forest) and Vector-based (SVM) algorithms is made at the end of each stage.

In order to improve the results obtained in stage 1, stage 2 is introduced with an extra module of Deep Learning. Stage 2 provides a fusion of Machine Learning and Deep Learning to form a Hybrid System. This system comes into action after the data passes through the pre-processing pipeline. For the purpose of comparison, Auto encoders and PCA are used with each classifier implemented in stage 1. Once the data is passed through the Auto encoders or PCA, it extracts the complex features from the dataset and provides a reduced set of relevant features which are then traversed back to stage 1. Here the normal flow of data is then followed by Machine Learning.

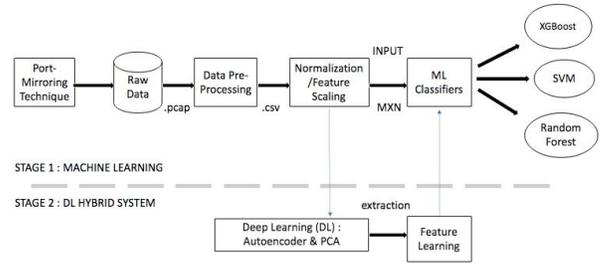

Fig. 2. A dual-stage hybrid architecture

This simple yet effective system has proved to enhance the outcome of classification obtained from stage 1.

The Random Forest algorithm is a tree-based algorithm suitable for selecting relevant features to perform classification. In the above algorithm, the tree starts at a single root node. At each node of the tree, a subset from the feature set is taken which is then split into different nodes. Each node denotes an attribute relevant for the classification of the Network Packets.  $f$  denotes the subset of features taken for each node, where  $f$  is much smaller than  $F$ . The decision to split a particular node is a computationally expensive process. By restricting each split in the tree, the rate of learning becomes faster.

### Algorithm 1 Algorithm for Feature Learning with Auto Encoder

**Input:**[X1,X2,X3,...]

- 1: Feature in  $X1=X1,X2,...,Xn$
- 2: **for each** X **do**
- 3:      $y=f(x)=se(w*x+bh)$
- 4:      $se(x) = \text{sigmoid}(x)=1 / (1+e^{-x})$
- 5:      $g(y)=sd(w*y+bf)$
- 6:      $sd = \text{tanh}(x)(e^x-e^{-x}) / (e^x+e^{-x})$
- 7:     Optimize  $\theta=[W,bh,b'r]$
- 8:     **while**  $D_i = [x_1, x_2, x_3, \dots, x_n]$  **do**
- 9:          $JAE(\theta)=\sum R(x,r) \quad x \in D_i$
- 10:     **end while**
- 11: **end for**
- 12: Train\_Feature =
- 13: Test\_Feature=
- 14: **for each** Train\_X in  $Se(X)$  **do**
- 15:     Train\_Feature = X
- 16: **end for**
- 17: **for each** Test\_X in  $Se(X)$  **do**
- 18:     Test\_Feature = X
- 19: **end for**
- 20: se – Encoder Function
- 21: sd – Decoder Function

In Algorithm 1, where  $R$  denotes the reconstruction error,  $w'$  the weights given to the inputs of the hidden layer, and  $b'$  the biasness of the inputs given to the hidden layer.  $Train_X$ ,  $Test_X$  denotes the number of training and testing samples. The  $Train_{Feature}$ ,  $Test_{Feature}$  are used to train the machine learning models. Encoder encodes the input  $X_i$  to hidden representation  $h_i$ . It does with the function  $h(X)=G(W*X+B)$ .  $W$  is the set of weights,  $B$  is bias and  $G()$  is a nonlinear

function. The work of the decoder is to reconstruct the input from the hidden representation. Initially the weights and bias are randomly assigned and the values are optimized with every iteration. The loss function is used to calculate how much the hidden values are deviated from the original data. The network traffic data with dimensions of 21 features are given as input to the encoder. The encoder with sigmoid activation function produces a hidden representation of data with 10 dimensions. The loss function used for the decoder is binary cross entropy. The Adam optimizer is used for getting the right set of values for W and B. After the encoder optimizes the values, the features are transformed to train the machine learning models. The machine learning model such as SVM, XGBoost, and Random Forest are trained and tested with the features from auto encoder, PCA.

## V. RESULTS AND DISCUSSION

TABLE I. COMPARISON OF ML CLASSIFIERS FOR WHATSAPP AND OTHER APPLICATIONS

Model	Precision	Recall	F1 Score
Random Forest	0.84	0.99	0.91
XGBoost	0.98	0.97	0.98
SVM	1.00	0.90	0.94

In this experiment, we aim to classify the WhatsApp network packets from other applications. Evaluation of this experiment is conducted using a self-gathered dataset. The dataset consists of encrypted traffic [23] flow which is gathered using a port-mirroring switch and a network router. The raw data consists of more than 35 features which are eventually narrowed down to 21 features after doing a considerable amount of data analysis. The influence of original (non-normalized) and normalized data has been studied in this experiment. The encrypted data is then normalized using MinMax Scaler for our distance based algorithms to yield correct and accurate results.

Towards the end of this experiment, we propose a comparison between vector based and tree-based machine learning classifiers. The normalized traffic flow data is fetched into three machine learning algorithms, namely, SVM, XGBoost and Random Forest algorithm. The comparison between these three classifiers is illustrated in Table I. It demonstrates the effectiveness and performance of tree-based algorithms over the vector-based classifiers. With a F-1 score of 0.92 (for WhatsApp) and 0.98 (for others), XGBoost succeeds the other classifiers in this experiment. With the analysis of the F-1 scores derived above, we conclude that tree-based algorithms perform better than vector-based algorithms in the classification of network packets.

In the second experiment we have presented the comparison between different machine learning classifiers in the classification of image and text files of WhatsApp Network packets. The network packets obtained using the Port mirroring switch consists of a combination of different file transmissions. Due to their encrypted nature, it becomes challenging to classify them into different classes based on the nature of these files. As a result, tree- based and vector-based classifiers in machine learning are used for this purpose. To have a better

understanding, the author has denoted the media files as class 1 and text files as class 0. For each class, precision, recall and F-1 score is calculated to measure and analyze the performance of these classifiers. Table II gives the performance metrics for each class and its classifier. In Table II, Random Forest and XGBoost are the tree-based classifier which follows the approach of branching for classification tasks. On the other hand, SVM follows a vector- based approach to classify the packets. Upon comparison, it is found that Random Forest overcomes the performance of XGBoost and SVM. With an F-1 score of 0.91 (class 0) and 0.80 (class 1) for image files and text files classification, Random Forest has been the best classifier among the other two algorithms. Followed by Random Forest, it is noticed that XGBoost is closer to Random Forest in terms of performance with an F-1 score of 0.86 (class 0) and 0.67 (class 1). From this experiment, we conclude that tree-based algorithms perform better than vector-based classifiers and Random Forest has achieved better results than XGBoost and SVM in the classification of image and text files of WhatsApp packets.

TABLE II. CLASSIFICATION OF WHATSAPP FILES INTO TEXT AND IMAGE USING ML CLASSIFIERS

Model	Precision	Recall	F1 Score
Random Forest	0.88	0.95	0.91
XGBoost	0.83	0.90	0.86
SVM	0.72	0.91	0.80

TABLE III. COMPARISON OF PROPOSED HYBRID SYSTEMS FOR WHATSAPP CONTENT CLASSIFICATION

Model	Precision	Recall	F1	Accuracy
Auto Encoder + SVM	0.80	0.80	0.84	0.90
Auto Encoder +XGBoost	0.83	0.88	0.85	0.91
Auto Encoder +Random Forest	0.85	0.84	0.84	0.88
PCA + SVM	0.68	0.98	0.80	0.85
PCA + XGBoost	0.73	0.66	0.69	0.78
PCA + Random Forest	0.70	0.95	0.81	0.84

In the last experiment, we present a method and a framework for efficient and effective feature extraction followed by ML classification. This architecture consists of deep learning modules and machine learning classifiers in order to fulfill the objective of our experiment i.e. classification of WhatsApp network packets into text and image. During this experiment, we show that our implementation of the framework can extract the features of the network packets which are encrypted and unlabelled. For the purpose of comparison, Auto encoders and PCA are taken into consideration for feature extraction.

As we move forward in this architecture, tree-based and vector-based machine learning classifiers are implemented to classify the packets based on the features extracted. For each feature extraction module, three classifiers are tested, namely, SVM, XGBoost and Random Forest. Table III highlights the results obtained after testing all the algorithms. SVM when implemented alone performed the lowest among XGBoost and Random Forest as observed in experiment 2. However, in contrast to this, it is seen that auto encoders are improvising the results of SVM in experiment 3. With the use of Auto encoders, the F-1 scores of SVM have drastically improved

whereas it has been nearly same for the other two classifiers. From the chart shown in Fig. 3 and 4, it is clear that PCA has failed to show any improvement in the classification task, the results suggest that feature extraction through auto encoders has contributed towards a positive learning curve. In conclusion, the deep learning module – auto encoders has provided a better result when clubbed with SVM in comparison to when SVM is implemented alone. Fig. 5 and 6 shows how the precision and recall value varies between the different models with respect to auto encoder, PCA usage.

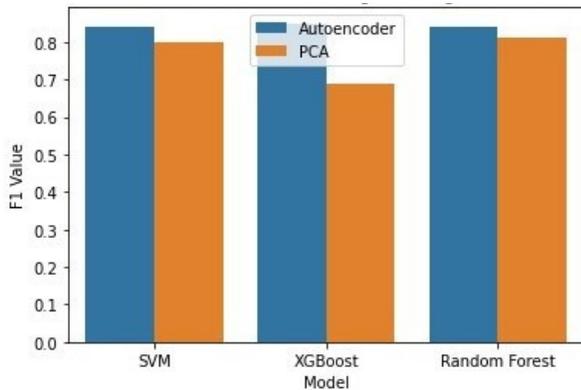

Fig. 3. Comparison of auto encoder and PCA with machine learning model in classifying WhatsApp image from text

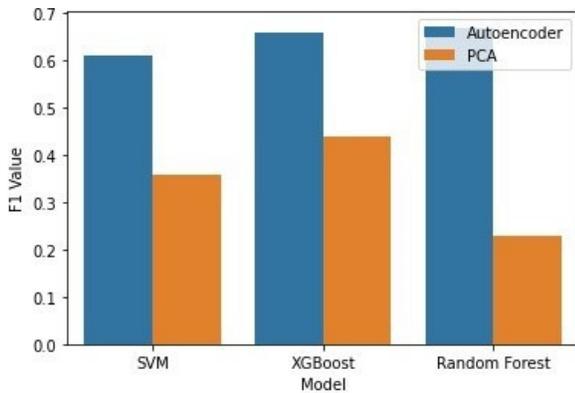

Fig. 4. Comparison of auto encoder and PCA with machine learning model in classifying WhatsApp text from image

## VI. CONCLUSION AND FUTURE WORK

Every tactical model performed differently under our experimental environment. This is also attributed to the dataset as well as the computational complexity of the algorithms. Thus, the model yielding the best results should also be efficient enough to perform TC on large datasets. It should also be noted that the efficiency of the model is directly related to its performance in real time TC. The computational complexity of each algorithm is closely scrutinized. The vector-based classifier SVM has a computational complexity of  $O(n^3)$ , wherein  $n$  is the training data's strength. While the computational complexity of Tree based algorithms highly depends upon the number of attributes taken into consideration which is 45

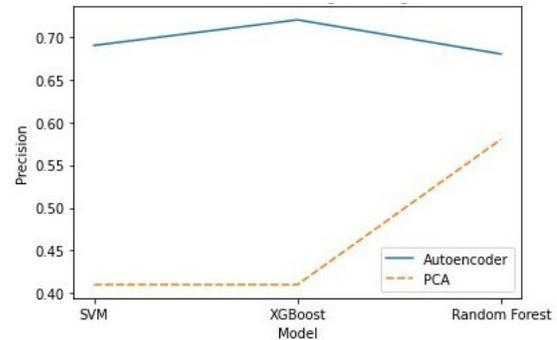

Fig. 5. Comparison of auto encoder and PCA with machine learning model in classifying WhatsApp image from text in terms of precision

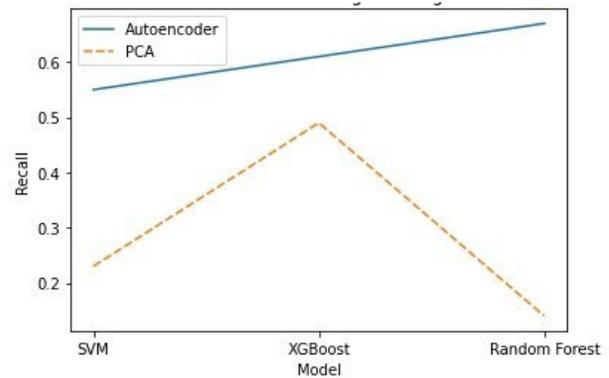

Fig. 6. Comparison of auto encoder and PCA with machine learning model in classifying WhatsApp image from text in terms of recall

features in our case. Thus, the feature count becomes directly proportional to the number of subtrees formed in the model. As a result, the computational complexity of XGBoost for learning each tree becomes  $O(n \log n)$ . In the case of Random Forest algorithm, the computational complexity is  $O(TD)$ , where  $T$  is the size of random forest and  $D$  is the maximum depth. In case of Random Forest, the subtree balance and  $D$  highly influence the results. Different tactical models and hybrid systems are tested in our paper and a conclusion is drawn in favour of the Tree-based classifiers. Upon testing all the classifiers upon our self-gathered dataset, it is concluded that Tree-based classifiers (XGBoost and Random Forest) outperforms the Vector-based classifier (SVM) and yields a better accuracy and F-1 score in Network TC. Therefore, from experiment 1, Performance (XGBoost) is greater than the Performance of Random Forest and SVM. Similarly, in experiment 2, the performance of Random Forest and XGBoost are interchanged whereas SVM remains the last in comparison. This clearly indicates that Tree-based classifiers are better in performance than Vector-based classifiers. Also, the use of Deep Learning for feature extraction has given a boost to the results of SVM. Thus, auto encoder reduces the complexity of the features and supports the classifiers in the classification process.

Certain cases are expected to be covered in the future work for making this proposed architecture a state-of-the-art system. This includes the segmentation of other media files including file transfer, voice message and location sharing.

Apart from this, other Deep Learning models like CNN, Deep Neural Networks, RNN, etc. are yet to be tested upon this dataset. Thus, a further investigation is required with other Deep Learning modules. In future the work can be extended to other WhatsApp data such as text, voice, etc. The development of an intrusion detection system for encrypted data such as WhatsApp, Telegram.

# Indoor Pollutant Classification Modeling using Relevant Sensors under Thermodynamic Conditions with Multilayer Perceptron Hyperparameter Tuning

Percival J. Forcadilla

Department of Computer Science, College of Science  
University of the Philippines Cebu  
Lahug, Cebu City, Philippines

**Abstract**—Air pollutants that are generated from indoor sources such as cigarettes, cleaning products, air fresheners, etc. impact human health. These sources are usually safe but exposure beyond the recommended standards could be hazardous to health. Due to this fact, people started to use technology to monitor indoor air quality (IAQ) but have no capability of recognizing pollutant sources. This research is an improvement in building a classification model for recognizing pollutant sources using the multilayer perceptron. The current research model receives four data parameters under warm & humid and cool & dry conditions compared to nine parameters of the previous literature in detecting five pollutant sources. The classification model was optimized using GridSearchCV to obtain the best combination of hyperparameters while giving the best-fit model accuracy, loss, and computational time. The tuned classification model gives an accuracy of 98.9% and a loss function value of 0.0986 under the number of epochs equal to 50. In comparison with the previous research, the accuracy was 100% with the number of epochs equal to 1000. Computational time was greatly reduced at the same time giving the best-fit accuracy and loss function values without incurring the problem of overfitting.

**Keywords**—Indoor air pollutants; pollutant sources; indoor air quality; IAQ; sensors; multilayer perceptron; classification modeling; gridSearchCV; hyperparameter tuning

## I. INTRODUCTION

In the last several years, scientific evidence has been produced regarding indoor air being more harmful than the air outdoors. That is why, people at homes, offices, and schools desire to have indoor air to be fresh and pleasant, not harmful to health to promote productivity. Air pollutants are one of the contributory factors in harming indoor air which comes from different sources and significantly impacts the health of the people in the long run. With this threat present, relevant organizations develop Indoor Air Quality (IAQ) standards and guidelines to eliminate or prevent people from the potential health risk of these indoor pollutants. These organizations gave threshold values for concentration levels and exposure time in maintaining the optimal IAQ level.

Aside from the IAQ standards and guidelines made by different organizations around the world, the research community contributed a lot to the development of advanced technologies that will help monitor and keep IAQ at the optimum level. Research themes like performance assessments on industry and consumer sensors and devices, factors affecting indoor air pollution in residential and commercial spaces,

machine learning algorithms, strategies, and techniques were also included giving new contributions to the existing body of knowledge. But with all these research trends, it was found that limited contribution was given to IAQ research on pattern recognition techniques. This gave the researcher motivation to further study the topic revolving around machine learning using pattern recognition techniques.

One of the studies that were considered was from Saad Shaharil Mad et al. [19]. In the study, nine parameters were used to develop pollutant recognition based on pattern recognition techniques. With the motivation of exploring the topic of pattern recognition techniques, the researcher formulated a research question to further explore the topic. The question was - How effective is an algorithm if the dataset parameters are reduced from nine to targeted parameters in classifying indoor air pollution sources in terms of model accuracy and loss? The research question was then supported with another study which gives this research a starting point for further investigation. That study was from Demanega Ingrid et al. [19] and was all about assessing the performance of low-cost monitors and not classifying indoor pollutants. The result of the study shows positive detection outcomes for all sensors and devices using particulate matter (PM), carbon dioxide (CO<sub>2</sub>), total volatile organic compounds (TVOC), indoor air temperature, and relative humidity as the parametric specifications considered in the research. Most of the low-cost sensors in the study responded to the simulated indoor pollutant sources with varying parametric readings. Also, the pollutant sources in the study of Demanega Ingrid et al. [11] and Saad Shaharil Mad et al. [19] shows to have relatively the same sources used as indoor pollutants. On that note, a hypothesis was then created to predict that selecting key parameters out of the nine parameters that were considered in the study of Saad Shaharil Mad et al. [19] can still be able to recognize or classify indoor air pollutants. With this study, the sensors to use were purely dependent on consumer-grade monitors available in the market which has no ability to recognize sources. The selected parameter that was considered were PM, CO<sub>2</sub>, TVOC, and formaldehyde (HCHO). These parameters were collected in a controlled room setup where indoor air temperature and relative humidity were set as one parameter while generating an environment simulation commonly encountered in many indoor climates around the world. These indoor climates are set as two thermodynamic conditions, warm & humid and cool & dry conditions which were adopted in the research

of Demanega Ingrid et al. [11]. The multilayer perceptron classification model algorithm was used as the only algorithm for this study since it performs to have the highest classification accuracy in the previous study. Lastly, to further improve the previous work and set an additional contribution, optimization was done through hyperparameter tuning.

This paper starts by introducing what Indoor Air Quality is followed by the significance of the study, and the different research trends that bring motivation to implementing this research. Validation of the research question was done through the review of the literature followed by a brief description of the methodology. The methodology starts with data collection of the target parameters under two thermodynamic conditions, processing the data through a pattern recognition technique (Multilayer Perceptron) leading to the classification of pollutant sources. Afterward, a preliminary analysis was done to show the parameter's categorical correlation followed by the model's accuracy and loss results. Finally, an optimization process through hyperparameter tuning was also performed.

## II. LITERATURE REVIEW

### A. Indoor Air Quality: Description, Sources and Effects to Human Health

The quality of air inside a building or structure like homes, schools, and offices which promotes good health and comfort for occupants is called indoor air quality (IAQ). It is also the extent to which human requirements in terms of indoor air are met. In this case, it is the desire which air should be fresh and pleasant, have no harmful effect on health, promotes good working conditions in the context of building offices or homes, and productivity in terms of learning at schools [1]. IAQ has been recognized as an important factor in people's health and comfort in indoor environments because 90% of people's time is spent indoors [2]. Also, studies have shown that the occupants are 100 times more exposed to indoor air pollutants than outdoor air pollutants and the concentration of air pollution indoor is seen to be 2 to 4 times higher than that of outdoor [3].

When indoor air quality is not taken into consideration for buildings and structures, possible health concerns due to high indoor pollutant exposure may be experienced. According to United State Environmental Protection Agency (EPA), there are many sources of indoor air pollution. Sources like fuel-burning combustion appliances, tobacco products, products for home cleaning and maintenance, building materials, furnishings, a product like air fresheners, and many more [4]. Over the years, these sources have been producing gaseous pollutants which are chemicals tagged as hazardous. These include radon, ozone, nitric oxides, sulfur dioxide, carbon monoxide, diatomic carbon, and VOCs [5]. Aside from these sources, particulate matter from combustion and cleaning activities, heavy metals from fuel consumption and building materials, airborne particles, pest control chemicals, and biological contaminants are recognized as air pollutants harmful to human health [6].

With the threat of pollutant exposure leading to significant risks to human health, relevant organizations developed different IAQ standards and guidelines. Among these organizations are the World Health Organization (WHO) and the United

States Environmental Protection Agency (USEPA) which contributed to the making of indoor air quality standards and guidelines. The guidelines serve as a database reference to eliminate or prevent people from too much exposure to indoor air pollution and the potential health risks that may be brought to the human population [7]. Aside from WHO and USEPA, other recognized organizations like ASHRAE [22], National Health & Medical Research Council in Australia, and many more around the world have set guidelines and threshold values to maintain an optimal IAQ [8].

### B. IAQ Current Research Trends

With the standards and guidelines set by the different organizations and the development of sensor technologies in a network and systems, different research trends have been developed through time. Most of this literature fall under advanced technologies for monitoring, performance assessments of cheap and high-end monitoring device or systems, factors affecting indoor air pollution in residential and commercial spaces, forecasting, and pattern recognition techniques.

1) *Advanced technologies for monitoring IAQ:* The development of mobile technologies and the internet of things (IoT) has brought great capability toward improving IAQ monitoring systems. Air quality monitoring nowadays can easily be done through smartphones by simply accessing the web. In the study of M. Tastan et al. the research proposed an IoT-based real-time e-nose measuring system using low-cost electronic sensors [9]. The system includes sensors such as MH-Z14A for Carbon Dioxide, MICS-4514 for Nitrogen Oxide and Carbon Monoxide sensor, GP2Y1010AU as a dust sensor, and DHT22 for Temperature and Humidity sensor together with an ESP32 microcontroller with built-in Wi-fi, used to process the information provided by the sensors. Pollutant concentration data is thrown into the Blynk cloud, and an android-based mobile user interface was developed for users to access the data in a form of digital or graphical monitoring.

In another study by Giacomo Chiesa et al. [10], a system was developed based on several sensor data to model the IAQ which serves as input in controlling the ventilation system. The system is connected to an app that features management of the device, real-time data visualization, and statistical data [10]. Device management allows the user to create a list of installed devices and set desired ventilation time to report indoor conditions in threshold value for each device. Real-time data visualization includes the quality level of indoor air and each of the parameters because of the sensor devices, and lastly, statistical data which gives users daily or weekly graphs for each sensor. The parameters that were considered for this research were carbon dioxide, TVOC, pressure, humidity, and temperature. Raspberry Pi serves as the backend platform where it handles device management, sensor-to-microcontroller interface, sensor data communication, control algorithms, data storage, and aggregation. The research data platform used for IoT needs was MongoDB. It is a source-available cross-platform document-oriented database program.

2) *Performance assessment on IAQ monitoring device and systems:* Another research trend from the existing body of knowledge revolves around an IAQ theme that was based on IAQ monitoring devices and system performance assessment

and evaluation. Performance assessment is needed since there are different sensor devices and systems in the market and these sensors can either be low-cost or industry-grade sensors that influence the sensor reading's accuracy. Sensor devices and systems were tested to know their performance reliability or prove if these devices can competently measure a target parameter. In the study of Ingrid Demanega et al. consumer environmental monitors available in the market together with low-cost single variable sensors were assessed to know their reading reliability in thermodynamic conditions [11]. Different sources were introduced inside a room chamber like candle burning, mosquito coil burning, wood lacquer drying, room deodorant injection, essential oil heating, carpet vacuuming, popcorn cooking, and carbon dioxide injection. The parameters to be evaluated were the particulate matter (1.0, 2.5, and 10), carbon dioxide, and TVOC. Particulate Matter Monitor miniWRAS, LI-COR 850 Bioscience gas analyzer for carbon dioxide, and GrayWolf AdvancedSense Pro as TVOC monitor were all used as the industry-grade reference monitor to evaluate the consumer-grade monitors and sensors.

In another research, Zhiqiang Wang et al. [12] tested the performance of low-cost IAQ monitors for PM 2.5 and 10 [12]. The low-cost monitors are Air Quality Egg 2018 version, IQAir Airvisual Pro, Awair 2nd Edition, Kaiterra Laser Egg 2, PurpleAir Indoor, and Ikaair with reference measurement systems together with professional-grade particulate monitors. The test chamber used in this research is a room of 120m<sup>3</sup> with three external walls, two doors, and raised ceiling. Several sources were used in multiple experiments, sometimes with variations that include measuring indoor concentrations of infiltrated outdoor PM<sub>2.5</sub> were collected to evaluate the performance of the low-cost devices.

3) *Factors influencing indoor air pollution:* There are different factors that contribute to the level of indoor air pollution inside buildings and structures. Several researchers have spent time and effort discovering such factors with the aim to improve air quality inside buildings and structures. In the study of Wonho Yang et al. [13], the IAQ level was investigated in different schools in Korea with the intention to know the correlation with respect to the age of the buildings [13]. Air samples were taken indoors and outdoors with parameters to consider such as carbon monoxide, carbon dioxide, particulate matter (PM<sub>10</sub>), total microbial count, total volatile organic compounds, and formaldehyde. Results show that the factors which contributed to indoor air pollution in schools are unsatisfactory ventilation and chemical emissions from building materials or furnishings. Significant high concentrations of carbon dioxide, TVOCs, and HCHO were also found at schools constructed within one year.

A relevant factor that influences the variation of indoor pollutants inside the buildings and structures points to the different seasons. In the study of Corinne Mandin et al. [14], a European project OFFICAIR was made to gain more knowledge with regard to IAQ in modern office buildings. It was found that significantly higher concentrations of formaldehyde and ozone were measured in summer whereas benzene,  $\alpha$ -pinene, D-limonene, and nitrogen dioxide were significantly high during winter. Another study focused on the variation in the concentration of pollutants at different locations in India. The study of Arindam Datta et al. [15] focuses on

the indoor air quality of non-residential buildings which is scarce in India [15]. It was found that among different non-residential buildings, a lower concentration of pollutants was recorded in the educational building compared to the two office buildings. A ductless air-conditioning system with poor air circulation and active air filtration contributed to the higher concentration of PM<sub>2.5</sub>. In Doha, Qatar, another study was carried out to investigate the level of PM<sub>2.5</sub> and PM<sub>10</sub> in office environments [16]. It was found that the cause for significant concentrations of particulate matter inside the office is ventilation, faulty envelopes, and windows.

Different factors influencing indoor air quality have been a trend in the research community. Aside from the identified factors and themes that were done by the researchers above, the study of Mehzabenn Mannan et al. [8] summarizes some of the factors that were gathered by the researcher's related literature which influenced indoor air pollution. The research identified factors like different indoor building materials and few surface finishes and appliances, nearby construction activity, indoor movement, tobacco smoke, and computer operation, high benzene concentration was observed in the lower-level classrooms and school carpet was seen to be responsible for higher PM. Another factor indicated to be the source of air pollution was the concrete additive in an office while comparing two office settings (Beijing and Stockholm) and the contribution of indoor air pollution with respect to newly built and refurbished office buildings. Factors like occupant behavior, the role of humans, respiratory emissions from human beings, and the reaction of ozone to skin lipids are seen to be giving a contribution to indoor air pollution.

4) *Machine learning and statistical modeling in IAQ:* Building a system that can forecast the concentration level of pollutants to characterize indoor air quality has been a long important topic in the community and domain of indoor environment and health science [17]. In real-occupied environments, statistical modeling has great potential to explore and predict indoor air pollution concentration levels [18]. Statistical modeling on IAQ can use forecasting techniques to predict the level of IAQ and pattern recognition techniques which allow the system to recognize certain types of smell [19].

In the study of Wenjuan Wei et al. [18], a summary of common machine learning and statistical modeling methods was collected through a literature review. Methods were compared based on strengths and weaknesses while discussing how and where the methods have been used in the field of IAQ. A summary of machine learning algorithms used in IAQ are based on either supervised or unsupervised learning with a different type of response variable and linearity of the model.

a) *Forecasting techniques:* A study about forecasting indoor concentration levels in an office space using machine learning was made by Johanna Kallio et al. [20]. The research contribution gives the body of knowledge a comprehensive dataset covering a full year with the applicability of four machine learning methods which include ridge regression, decision tree, random forest, and multilayer perceptron. Accuracy was evaluated with respect to the different methods of prediction, history window time frames, and the impact of multiple sensor modalities. In another study, Shisheng Chen et al. [23] use a machine learning approach to predict CO<sub>2</sub>, TVOC, and HCHO. Five Classrooms at the National University

of Singapore were used to perform the continuous parametric collection of data. The dataset was trained and tested using Support Vector Machine, Gaussian Processes, M5P, and a backpropagation neural network. According to Wenjuan Wei et al. [18], an artificial neural network (ANN) is the most popular method for the prediction of IAQ based on the researcher's findings. Dwellings, offices, schools, and subway stations are the different sites where ANN modeling was used to predict several IAQ parameters [18].

*b) IAQ pattern recognition techniques:* Forecasting techniques prove to be relevant and saturated in the field of indoor air quality. In the case of pattern recognition techniques, little literature has been found to have a relevant contribution to the IAQ research community. One of which was a study that uses pattern recognition techniques to recognize specific types of pollutants by Saad Shaharil Mad et al. The authors of this topic publish two papers in 2015 and 2017. The first paper classifies pollutant sources with the use of one pattern recognition technique, ANN. The other study was an enhancement to the previous paper which utilizes different supervised machine learning algorithms like multilayer perceptron, k-nearest neighbors, and linear discrimination analysis. Nine (9) parameters were used to classify five (5) different pollutant sources. These parameters were nitrogen oxide, carbon dioxide, ozone, carbon monoxide, oxygen, VOCs, particulate matter, temperature, and humidity [19].

### C. IAQ Parameter and Sensors

The research topic regarding indoor air quality was narrowed down to the context of classifying pollutant sources using pattern recognition techniques. To classify indoor air pollutant sources, sensors must collect different parametric data to generate the IAQ dataset. Choosing the target parameters with the corresponding sensors serves as one of the important points to make this research a success.

*1) Relevant IAQ parameter consideration:* In the study of Saad Shaharil Mad et al. [19], sensors were used to target the different parameters like CDM4161 for carbon dioxide, TGS5342 for carbon monoxide, TGS2602 for VOC, MiCS2610 for Ozone, MiCS2710 for nitrogen dioxide, KE25 for oxygen, HSM20G for Temperature and Humidity, and GP2Y1010AUOF for Particulate Matter (PM10). These sensors were used to respond to the five indoor pollution sources, such as the ambient air, combustion activity, chemical presence, fragrance product, and food & beverages [19].

In another study, H. Zhang et al. [21] developed a low-cost IAQ multi-pollutant monitoring system using raspberry pi. Different sensors with specifications from different manufacturers together with their prices were carefully considered to be included in the Low-Cost Air Quality System or LCAQS. Sensors that measure Relative Humidity, Temperature, Particulate Matter (PM<sub>2.5/10</sub>), Nitrogen Dioxide, Sulfur Dioxide, Carbon Dioxide, Carbon Monoxide, Ozone, and Total Volatile Organic Compound (TVOCs) was used to develop the system [21].

To measure the indoor air quality level, parameters were divided into categories: physical condition, chemical contaminants, biological contaminants, and other common IAQ parameters. Using these categories, the study of Saad Shaharil

Mad et al. divided the sensors into three types: gas sensor, particle sensor, and thermal sensor [19]. The two studies above both have common thermal and particle parameters (Temperature, Relative Humidity, and Particulate Matter) with different IAQ research themes. Both studies above utilize nine (9) parameters, and most of the gas parameters were common to both studies except for oxygen and sulfur dioxide. In the study of Demanega Ingrid et al. [11], four parameters were only utilized to assess low-cost environmental monitors and single sensors which were used to respond to different indoor pollution sources. These parameters were temperature, relative humidity, carbon dioxide, and particulate matter [11].

Also, it can be seen in the study of Demanega Ingrid et al. [11] that the results of using the different simulated activities for indoor pollution sources show positive detection outcomes for all sensors and devices used in the study. Different particle sensor responds to indoor pollution sources such as candle burning, mosquito oil burning, and popcorn cooking. This reflects that the current study has the basis to use only target parameters to classify pollutant sources.

*2) Thermodynamic conditions:* To simulate an environment that is commonly encountered indoors in many climates around the world, thermodynamic conditions should be considered which helps assess the performance based on the standard thermal comfort zone [11,22]. This methodology was also adopted in this research in using thermodynamic conditions – warm & humid (26 +/- 1 C, 70 +/- 5%) and cool & dry (20 +/- 1 C, 30 +/- 5%)[11].

### D. IAQ Research Motivation and Summary

The exhaustive search done on the internet through online research databases proves that the topic of indoor air quality revolves mostly around advanced technologies for monitoring, performance assessments of cheap and high-end monitoring devices or systems, factors affecting indoor air pollution in residential and commercial spaces, and research about machine learning specifically forecasting techniques. On that note, a limited contribution was found regarding pattern recognition techniques in IAQ research, thus, this research takes that route related to pattern recognition. One of the pattern recognition studies that were reviewed came from Saad Shaharil Mad et al. which became the major motivation for doing the current research. The research done by Saad Shaharil Mad et al. considers nine parameters to classify pollutant sources. This pique the interest of the researcher to formulate a research question in optimizing the previous strategy. A strategy to select a few parameters out of the nine, to classify pollutant sources. In selecting parameters to be included in the classification process, the study of Demanega et al. shows results that were relevant in choosing the parameter of this research. To add another layer of parameter, the thermodynamic condition was also adopted to simulate two indoor climates commonly encountered.

## III. METHODOLOGY

This chapter discusses the key design choices, concepts, and procedures in attaining the classification of Indoor Air Pollutant Sources using targeted Pollutant Parameters based on Machine Learning's Pattern Recognition Techniques for Indoor

Air Quality (IAQ) Systems. Fig. 1 below shows the outline of the methodological process on how to attain the research objectives.

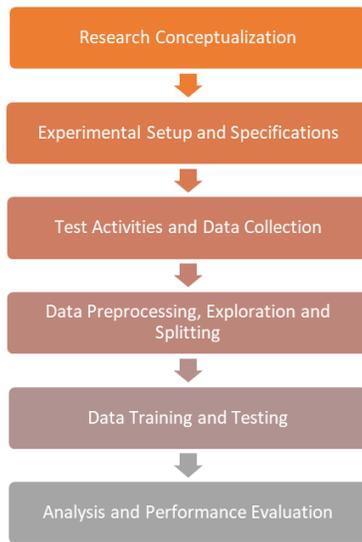

Fig. 1. Research framework flowchart

After establishing the research novelty, relevance, and feasibility through the review of related literature, the development procedure of this research starts with the implementation stage through research conceptualization. This defines the research considerations regarding the approach, initial strategies, the participants involved, and the research setting. Experimental setup and specifications were the next procedure which provides details regarding the room setup, thermodynamic conditions, sources of indoor air pollutants to consider, IAQ parameters, and what device monitor to use. When the different setup and conditions were met in the second stage, test activities and data collection follows. This procedure provides details as to how the data was collected in the room setup, the simulation activity for the source of pollutants, and the timeframe needed for the device to collect data. When all the necessary data under different conditions were collected, the raw data undergoes the stage of preprocessing and data splitting. Raw data was secured to be clean, and normalized, making the data classification-ready, and undergoes data splitting for the training proper. After the previous procedure, data training follows using a pattern recognition technique identified in this study. The trained data was then validated based on its accuracy and performance evaluation was done through the given statistical methods involved in this research.

#### A. Research Conceptualization

The ground theory of the previous literature builds the foundation of this research. The literature of this study revolves around (1) the significance of why IAQ is needed and the possible health impact on humans, (2) the indoor air quality research trends, giving details to literature who were well-studied, researched, and studies with limited resource contribution, (3) IAQ parameters to consider using the sensor results and readings under different thermodynamic conditions,

and (4) different pattern recognition techniques based on the machine learning research trends.

In the last several years, indoor air quality has been a well-studied area in the environmental research community. Different environmental organizations have taken steps to establish standards and guidelines to address issues and potential risks to human health. Technological advancements are also given attention to the research community and IAQ industry on intelligent systems, IoT, machine learning, etc. During the literature review, limited research contribution was seen in the area of indoor air quality which involves pattern recognition techniques. This identified gap motivated the researcher to conduct further study on the topic. The study of Saad Shaharil Mad et al. [19], was the main literature that gave motivation to this research. This study is an improvement to the study of Saad Shaharil Mad et al. [19] by taking into consideration the use of targeted parameters under different thermodynamic conditions.

1) *Research approach and initial strategies:* The study's general objective was to classify five (5) indoor air pollutants using thermal, particle, and gas parameters under two (2) thermodynamic conditions using multilayer perceptron pattern recognition technique. Thus, the research approach should be quantitative. Another consideration in selecting what research approach to use was based on the typical approach used by the related literature in this research. Also, the nature of the research objectives should clearly define what strategy to utilize. Since the research is about the classification process in machine learning then the strategy to pursue should be the predictive strategy.

2) *Participants and setting:* The usual strategy for the collection of data regarding air quality uses environmental chambers and other controlled room setups. In the study of Shisheng, Chen et al. [23] regarding time series prediction of CO<sub>2</sub>, TVOC, and HCHO, they made use of the rooms with the air-conditioning unit (ACU) inside the campus of the National University of Singapore (NUS) as the location for the air quality data collection [23]. In the same way, this research used the facility of the University of the Philippines – Cebu as the location for collecting air parameters in classifying pollutant sources. Specifically, this research was conducted in the Department of Computer Science Conference Room, 3rd floor, Room 313 of the Arts and Sciences (AS) building University of the Philippines - Cebu.

#### B. Experimental Setup and Specifications

Before acquiring the data for preprocessing and data training, needed preparations were done to achieve organized procedures regarding the simulated test activities. This subpart talks about the setup and conditions inside the room, pollutant sources and parameters to consider, and the IAQ device monitor to use.

1) *Room setup and conditions:* Fig. 2 below shows the room's details, fixtures, and specifications. The figure was the floorplan venue for the collection of indoor air parameters. The room has the dimension of 5.33m x 3.10m x 3.05m, it has one door, three windows, one window-type air-conditioning unit (ACU), and fixtures like couches (small and big), a conference table with office chairs, and small cabinet.

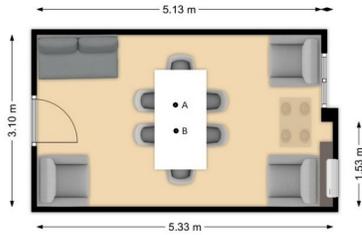

Fig. 2. Room specifications using floorplanner.com

2) *Sources of indoor air pollutants:* The research also adopted one of the indoor air pollutants activities being used in the study of Demanega, Ingrid, et al. [11] which was candle burning for combustion activity. Other source pollutants adopted came for the study of Saad, Shaharil Mad et al. [19] such as cleaning agents like “Lysol”, rotten cooked fish, and the ambient condition. This research also included rubbing alcohol as one of the sources which is currently a big contributor to indoor air pollutants because of the pandemic. Table I shows the summary of the source pollutants included in this research with the activity description, data collection interval, and span. Each pollutant undergoes two thermodynamic conditions cool & dry and warm & humid. Data was then collected every 1-minute interval and a collection span of 16 hours or 960 samples will be collected across each of the source pollutants considering the thermodynamic condition. An 8-hour day plan was decided in consideration of the university’s working hours. Gathering samples for the 5 single source pollutants for each thermodynamic condition gives us a total of 9600 samples or 160 hours of collection time. Given an 8-hour day plan, 160 hours is equal to 20 days collection process.

TABLE I. ACTIVITY DESCRIPTION, DATA COLLECTION INTERVAL OF THE SOURCE POLLUTANTS

Source Pollutants	Thermodynamic Condition	Activity Description	Data Collection Interval
Ambient	Cool and Dry	Observe the ambient condition reading of the surrogate sensors and device reference.	Collect data every 1 minute. A total of 960 samples should be collected.
	Warm and Humid		
Combustion	Cool and Dry	Light up two candles in the room.	
	Warm and Humid		
Chemical	Cool and Dry	Place half full glass of isopropyl alcohol in the middle of the room.	
	Warm and Humid		
Fragrance	Cool and Dry	Automatic Spray using Lysol for every 18 minutes in the room.	
	Warm and Humid		
Rotten Food	Cool and Dry	5 days old rotten food(leftovers) will be placed in the middle of the room	
	Warm and Humid		

3) *Indoor air quality parameter and device monitor:* In the study of Saad Shaharil Mad et al. [19], nine parameters were used to develop a pollutant recognition based on pattern recognition techniques, but the study of Demanega Ingrid et al. [11] paved way to consider only using a few target parameters in classifying indoor pollutants. That same

study gave results showing positive detection outcomes for all sensors and devices. Most of the sensors responded to the simulated indoor pollutant sources which gave way to adopting the previous studies’ parameters. The pollutant parameters that were considered were air temperature and relative humidity for thermal parameters, particulate matter (PM2.5/10) for particle parameters, and carbon dioxide as a gas parameter. Thus, this study considers the parameters that were studied in the previous related work.

The study of Demanega Ingrid et al. [11], provides an assessment of low-cost monitors, research, and professional-grade IAQ systems used as reference monitors. These systems are expensive, yet the reading accuracy is top-notch with respect to the different IAQ parameters. Not just expensive, most of these systems detect a single parameter only unlike the consumer-grade IAQ monitors which are available in the market. But in that same study, some of the consumer-grade monitors were assessed and exhibited good performance grading in detecting the different parametric values for pollutant sources. On that note, the IAQ monitor that was used in this study was low-cost and consumer-grade monitors targeting the relevant parameters that were considered in the previous study. Two IAQ handheld devices were considered in implementing this research. Temptop M2000 2nd Generation was used to collect CO2 and particulate matter. BR-SMART-123SE was used to collect TVOC and HCHO. These devices were then positioned in the middle of the room, specifically on the top of the table.

4) *Working with thermodynamic conditions:* According to the study of Xiangguo et al. [24], conventional all-air central air-conditioning (AC) systems can control the temperature and humidity through cooling, reheating, and humidifying equipment but AC systems which were commonly seen in small and medium-sized buildings have no specific dehumidifying equipment to deal with moisture. In the Philippines, relative humidity is high because of the surrounding body of water. It is said on the PAGASA website that the average monthly relative humidity varies between 71 percent in March and 85 percent in September. In a requirement to have fresh air indoors, good ventilation by opening the windows can help but will greatly influence the moisture level. In working with thermodynamic conditions and achieving the cool & dry and warm & humid room setup, doors and windows were sealed to avoid moisture air influencing the indoor humidity and temperature. Also, dehumidifiers and humidifier equipment were placed inside to control the humidity level of the room while an AC unit was used to control the room temperature with a significant contribution to the relative humidity. The dehumidifier and humidifier equipment has automatic control which directly reacts with the varying humidity levels in the room.

### C. Data Collection and Test Activities

Before the collection procedure, the two thermodynamic conditions should be first met. In the case of cool and dry, the ACU was turned on together with the dehumidifier for some time until the conditions were met for an activity to happen. For relative humidity control, only the dehumidifier was turned on since the room space was not completely sealed. A humidity level of 30% was never achieved in consideration with the study of Demanega Ingrid et al. [11]. Only 45% +/- 5% was

achieved in this research. Both the ACU and dehumidifier have a control device that shuts off when a certain temperature or humidity value is reached. For warm and humid, ACU will be turned off and both the dehumidifier and humidifier were turn on to control the humidity level of the room. In the same way, the ACU, dehumidifier, and humidifier were connected to a control device that establishes the right thermodynamic condition. When the conditions were set, different source pollutants were injected. Also, the device monitors which were placed in the middle of the room were turned on at least 1 hour before each activity allowing the sensors to have enough time to stabilize and the collection procedure commences as soon as the desired thermodynamic conditions were met.

Table I shows the order in collecting the source pollutants data with the desired activity description. A warm and humid condition will be implemented first to be followed by a cool and dry condition. The start and end of the collection procedure will be manually timestamped to map the desired data activity. PM2.5, CO2, TVOC and HCHO was collected while considering thermodynamic conditions. Thus, giving this research a total of 5 parameters.

#### D. Data Preprocessing, Exploration and Splitting

The raw dataset that was then generated from the device monitor and was extracted through USB in excel format. The manual timestamp was defined and divided into different data based on the thermodynamic conditions and different pollutant sources. After organizing the dataset, data cleaning was followed. This was where incorrect data type or format, missing values, and data duplication in the dataset were either modified, replaced, or deleted before the data normalizatin/standardization process and choosing other data preprocessing techniques. Preprocessing is important because it may aid in the success of pattern recognition performance [19].

After the procedures above, data exploratory analysis follows. This process will investigate the data values and explore meaningful insights. One process for data exploration is through descriptive statistics which gives this research the first insight for interpretation or an overview of what the clean raw data look like. This process will also give insight into the potential outlier readings inside the dataset which can be deleted. After doing descriptive statistics, this research will explore some of the questions identified below.

1. What are the relationships between the collected parameters?
2. Are the collected values different considering two thermodynamic conditions?

Answering these questions through the process of data exploratory analysis gives the researcher an initial understanding of what the dataset looks like. The initial analysis taken through the dataset was then generated using visual representation. Data exploratory analysis use python software to generate the visual results.

After the data exploratory analysis, data splitting was followed by dividing the cleaned and explored raw data into a training dataset and a testing dataset. The training dataset was used for the classification training and the testing dataset was used to check how the current generated model was working.

If the model was not performing well, an iterative process of training to develop a pattern recognition model followed by testing dataset checking occurs. The testing dataset will be used to evaluate the classification model's performance. 60% of the data will be taken for training and 40% will be taken for the testing procedure.

#### E. Data Training and Testing

According to the study of Saad Shaharil Mad et al. [19], an artificial neural network (ANN) was more suitable to be embedded in an IAQ system. The algorithm does not need large storage space unlike the other counterparts and is easy to embed because it requires a less complicated formula. ANN are parallel information processing approaches that are applied for data processing, process analysis, control, fault detection, pattern recognition, defining the complex and non-linear relationship, and employing a number of input-output training patterns from the experimental data [25]. The commonly used neural network architecture is the multilayer feed-forward neural network known as Multilayer Perceptrons or MLP networks which are based on a backpropagation algorithm and comprise multiple hidden layers and neurons. Adding one or more hidden layers creates another set of synaptic connections and more neural interactions which leads to the improvement of the network's accuracy. Fig. 3 shows the general architecture of the multilayer feed-forward neural network for prediction.

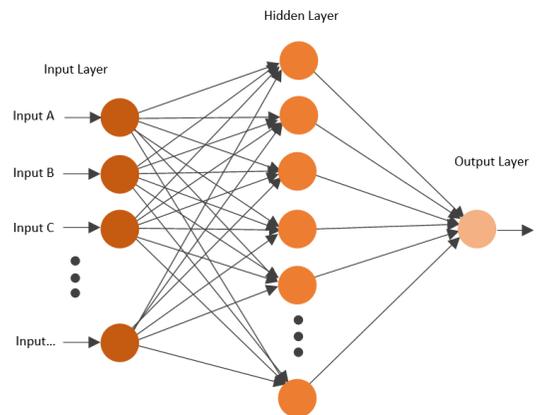

Fig. 3. Sample multilayer perceptron network architecture

Hyperparameters in the study of Saad Shaharil Mad et al. [19] were adopted in this study. One hidden layer was used with three (3) neurons. Vector array normalization was used as feature scaling and an assumption of using stochastic gradient descent was used as the optimizer algorithm since there was no mention in the previous study. Other hyperparameters like the input layer, batch size, kernel initializer, activation function in the last layer, etc. are all defined based on the nature of the classification problem. Using the hyperparameters, training of the dataset will follow to generate the multilayer perceptron model accuracy and loss function. Optimization was then carried out to improve the model with the consideration of overfitting and underfitting. GridSearchCV was then used to find the values of the optimal hyperparameters.

F. Performance Evaluation and Software Details

Evaluation of the performance of the classification model was done through model training and validation metric of accuracy while the loss function was through categorical cross-entropy.

The high-level programming language that was used to implement the methods regarding data cleaning, exploration, normalization, splitting, training, testing, and evaluation was done through Python language. This research utilized the integrated development environment (IDE), Spyder, as the open-source platform for scientific programming in the python language. During the implementation using the platform, software libraries imported such as pandas, sci-kit-learn, Keras, and TensorFlow, etc.

IV. RESULTS AND DISCUSSION

In this study, the IAQ handheld devices were set up in the middle of the room to collect PM2.5, CO2, HCHO, and TVOC. Secondly, temperature and humidity equipment were prepared to achieve two thermodynamic conditions commonly encountered in many climates around the world. During the preparation of the experimental room setup, a specific limitation was found before the implementation of the data collection process. Before injecting a source pollutant, the two thermodynamic conditions must be met first. In the case of the cool and dry condition, room temperature should be at 20C +/- 1C and humidity of 30% +/- 5%. It was found that the room condition can reach the required temperature for the cool and dry condition but can never reach the humidity value of 30% +/- 5%. This limitation was brought about by the experimental room setup which was not completely sealed. This setup simulates the regular room setup where pollutant sources can be found. The final humidity value of 45% +/- 5% was set for cool and dry condition. Finally, adding the limitation above, the simulation of different indoor air pollutants was administered while collecting the data values generated by the devices. This section reports the results and findings in relation to the research question and hypothesis of this study while providing meaning, importance, and relevance of the result.

A. Preliminary Analysis

Initially, data cleaning was performed to the collected raw dataset to ensure correctness and improve data quality. The cleaned raw dataset was processed through preliminary analysis by describing key features of the data. Each parameter for all categorical conditions was correlated to provide insights into the parameter's relationship. Table II shows the individual categorical correlation.

Examining the table above shows that for ambient conditions, it was observable that HCHO has a very high positive correlation with respect to the thermodynamic condition and has a value of 0.92. For combustion conditions, PM2.5 and TVOC has negative high relationship with respect to thermodynamic conditions. For chemical conditions, HCHO has a very high positive correlation with the thermodynamic condition

TABLE II. CATEGORICAL PEARSON CORRELATION

Class 0	Ambient Condition				Class 1	Combustion Condition					
	PM2.5	CO2	HCHO	TVOC		PM2.5	CO2	HCHO	TVOC		
PM2.5	1.000				PM2.5	1.000					
CO2	0.400	1.000			CO2	0.310	1.000				
HCHO	0.087	0.560	1.000		CO2	-0.170	0.055	1.000			
TVOC	0.220	0.480	0.340	1.000	CO2	0.450	0.200	0.300	1.000		
CD/WH	-0.023	0.480	0.920	0.049	1.000	CO2	-0.790	-0.077	0.220	-0.710	1.000
Class 2	Chemical Condition				Class 3	Fragrance Condition					
	PM2.5	CO2	HCHO	TVOC		PM2.5	CO2	HCHO	TVOC	CD/WH	
PM2.5	1.000				PM2.5	1.000					
CO2	0.062	1.000			CO2	0.600	1.000				
HCHO	0.370	0.079	1.000		CO2	0.590	0.690	1.000			
TVOC	0.390	0.320	0.670	1.000	CO2	0.200	0.429	0.680	1.000		
CD/WH	0.390	0.084	0.930	0.590	1.000	CO2	0.430	0.670	0.800	0.830	1.000
Class 4	Rotten Food Condition										
	PM2.5	CO2	HCHO	TVOC	CD/WH						
PM2.5	1.000										
CO2	0.410	1.000									
HCHO	-0.130	0.020	1.000								
TVOC	0.110	0.190	0.960	1.000							
CD/WH	-0.200	-0.059	0.960	0.910	1.000						

and a moderate correlation value of 0.59 with respect to TVOC. For the fragrance conditions, most of the parameters has a moderate to very high positive correlation with respect to each other. Lastly for rotten food conditions, HCHO and TVOC has a high positive correlation with thermodynamic conditions.

The categorical dataset was then merged to provide insight to have the overall Pearson correlation of the dataset's parameters including the categorical conditions. Fig. 4 shows the heatmap generated through seaborn in python.

Fig. 4. Overall correlation heatmap

Firstly, the figure above shows that PM2.5 has a high positive correlation value with respect to CO2 which measures a positive correlation of 0.77 which verifies the result in most of the IAP conditions having a significant correlation value. The same positive correlational value was also observed for HCHO and TVOC parameters. Strong correlation was found for HCHO and TVOC since HCHO was part of the parameters to be collected in TVOC device. Secondly, CO2 has negligible correlational value with respect to the thermodynamic condition and has a very minimal negative correlation with respect to TVOC and HCHO with the value of 0.37 and 0.2 respectively. The result of CO2 is also verified using the correlation table of the individual IAP condition. Thirdly, the thermodynamic condition has a low correlational value to HCHO of positive 0.32 which verifies as well in the individual IAP condition correlation table. Lastly, the overall correlation of the IAP conditions has a very low negative correlation with respect to PM2.5 and CO2 with negligible correlation to other variables.

**B. Accuracy and Loss Comparison between Distinct Scaling Technique and Optimizer Algorithm**

After the preliminary analysis, model training was initiated. The study of Saad Shaharil Mad et al. [19] model training algorithm motivates this study in adopting multilayer perceptron as the only machine learning algorithm and adopted some of the hyperparameters used in the previous study. Table III shows the adopted hyperparameters and using additional hyperparameters to carry out this study.

TABLE III. MULTILAYER PERCEPTRON HYPERPARAMETERS

Adopted Hyperparameters	
Hidden Layer	1
Neurons	3
Output Layer	5
Learning Rate	0.01
Momentum Constant	0.5
Epochs	1000
Additional Hyperparameters	
New Input Layer	5
Batch Size	64 (based on a paper)
Feature Scaling	VAN, Standardization
Optimizer Algorithm	SGD, Adam
Hidden Layer Activation	Relu (default on Keras)
Kernel Initializer	glorot_uniform (default on Keras)
Output Layer Activation	Softmax
Metric	Accuracy
Loss Function	Categorical Cross Entropy

This study addresses the hypothesis by using only 5 IAQ parameters in predicting the different classes of indoor air pollution, thus, setting the input layer equal to 5. The hidden layer, neurons, output layer, learning rate, and momentum constant were directly adopted in generating the model accuracy and loss. Additional hyperparameters were set to successfully train the data using Multilayer Perceptron. This study uses a fixed batch size of 64, in reference to the recommendation of the study of Kandel, Ibrahim et al [26]. For feature scaling, Vector Array Normalization was seen to be the best performer in the previous research, and standardization was not included for comparison. This study has drawn insights into the difference in results between using VAN and Standardization (STD) technique. Optimizer Algorithm was never mentioned in the previous research; thus, this study assumes and adopted the use of stochastic gradient descent (SGD) as the optimizer for this research. Also, this study has explored the Adam optimizer since this optimizer is always compared with SGD in many papers. For this comparison setup, this study has used 'relu' for the hidden layer activation, 'glorot\_uniform' for the kernel initializer, and 'softmax' for the output layer activation function. The two former variables were considered as default hyperparameter of Keras for model training. 'Softmax' was used as the output layer activation function since this is an example of a multiclass classification problem.

After setting up the hyperparameters, model training starts. Accuracy and loss function results was compared using the combination of two feature scaling and two optimizer algorithms.

Given Fig. 5, in using VAN as the feature scaling and SGD as the optimizer, it can be observe that the accuracy output

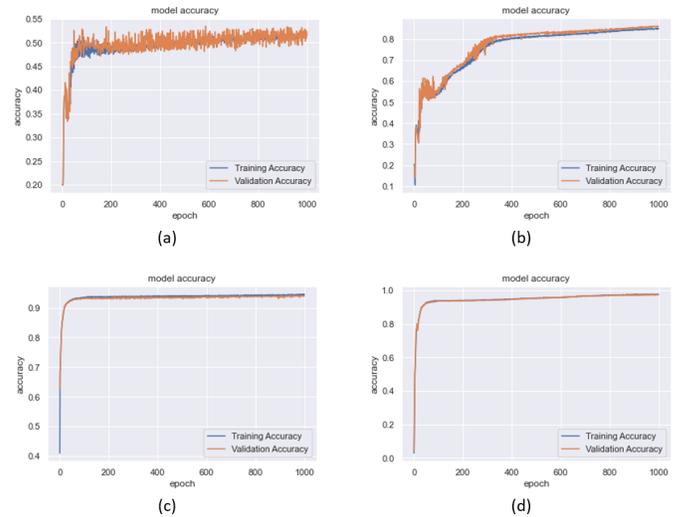

Fig. 5. Model training and validation accuracy (a) VAN-SGD (b) VAN-Adam (c) STD-SGD (d) STD-Adam

was noisy, and the training process was slow reaching to a validation accuracy of 52% for 1000 epochs. Using the same feature scaling while changing SGD to Adam optimizer, the accuracy results are less noisy, and the validation accuracy improves reaching 86% for 1000 epoch. Using standardization (STD) as the feature scaling while varying the optimizer, the result greatly improves. With SGD as the optimizer, the validation accuracy incurs a value of 93.8% compared to Adam optimizer with a value of 97% for 1000 epochs.

Fig. 6 shows the model loss comparison. Model loss in VAN feature scaling was observed to be bigger compared to the feature scaling of standardization after 1000 epochs. VAN-Adam has better loss value compared to VAN-SGD with 0.34 and 0.99 validation loss respectively. Both optimizers using STD as the feature scaling reaches a loss value of less than 0.2 in 1000 epochs. STD-SGD incur a validation loss of 0.16 compared to STD-Adam with a validation of 0.07.

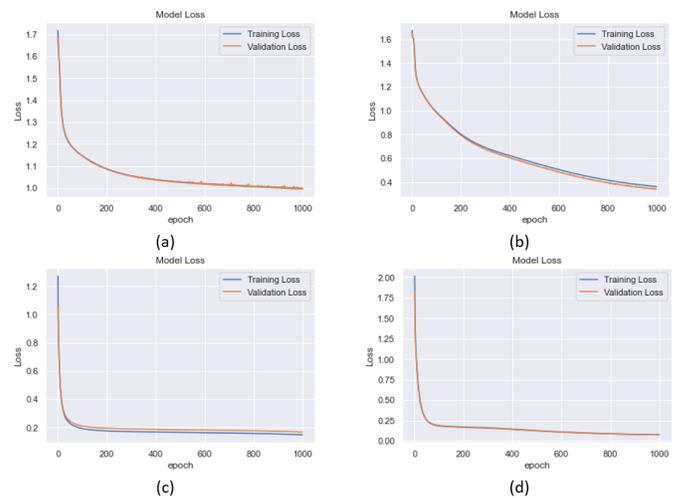

Fig. 6. Model training and validation loss (a) VAN-SGD (b) VAN-Adam (c) STD-SGD (d) STD-Adam

### C. Hyperparameter Tuning

Referring to the comparison results in the above section, the accuracy in using STD and Adam can be seen as good fit already. Even if the result was good, it can be observed that some of the hyperparameters was not tuned with the hypothesis of gaining the optimized accuracy and loss value. To further improve the results, tuning of different hyperparameters was investigated. Hyperparameters like number of input layers, number of hidden layers, number of neurons, number of output layers, output layer activation function, metrics and loss function were preset because of the nature of the dataset. The result in the previous section in using standardization as the feature scaling and Adam as the optimizer algorithm was also included as a preset value for the tuning process. Momentum was excluded in this process because of the new optimizer. It was also observed that in using STD as feature scaling, 1000 epochs was too much of a training period and eventually just limits the number of epochs to 50. Table IV shows the validation accuracy and loss function for the different epochs. The table shows that the use of standardization (STD) feature scaling is superior compared to vector array normalization (VAN) in this dataset. It is observable that even if the epoch was 50, using standardization still exhibits a good accuracy and loss value.

TABLE IV. VALIDATION RESULT PER EPOCHS

	Validation Result					
	1000 epochs		100 epochs		50 epochs	
	Accuracy	Loss	Accuracy	Loss	Accuracy	Loss
VAN-SGD	0.5216	0.9952	0.4794	1.1598	0.4711	1.2210
VAN-Adam	0.8617	0.3420	0.5706	1.0109	0.4599	1.1576
STD-SGD	0.9383	0.1169	0.9284	0.2206	0.9102	0.2902
STD-Adam	0.9711	0.0750	0.9362	0.1837	0.9255	0.2475

Taking into consideration the execution time of model training, hyperparameters like learning rate and batch size was varied. Other hyperparameters like hidden layer activation and kernel initializer was also varied to find the best possible combination of hyperparameters. Table V shows the summary of hyperparameters.

TABLE V. NEW SET OF HYPERPARAMETERS

Hyperparameters	
Input Layer	5
Hidden Layer	1
Neurons	3
Output Layer	5
Learning Rate	0.1, 0.01, 0.001
Epochs	50
Batch Size	32, 64, 128
Feature Scaling	Standardization (STD)
Optimizer Algorithm	Adam
Hidden Layer Activation	Tanh, Relu, Sigmoid
Kernel Initializer	glorot_uniform, uniform, he_uniform
Output Layer Activation	Softmax
Metric	Accuracy
Loss Function	Categorical Cross Entropy

Given all the hyperparameters above, model training was initiated and using python's gridsearchCV to exhaustively

search for the best fit combination of hyperparameters. Cross validation (CV) for this process was set to 5.

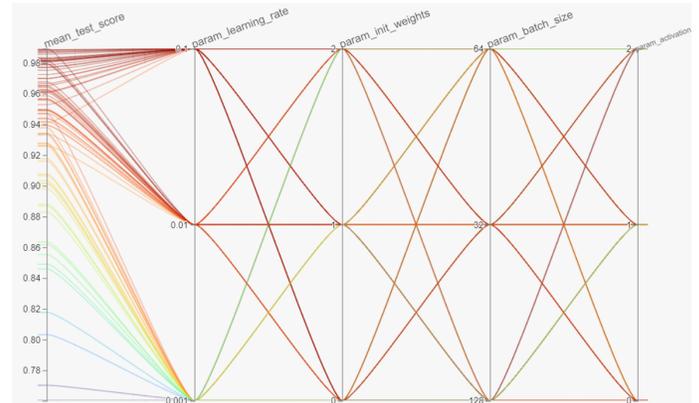

Fig. 7. GridSearchCV hyperparameter combinations

Fig. 7 shows the different hyperparameter combinations with the mean test score value where mean test score is the mean accuracy of the classification. Using STD and Adam optimizer as the new hyperparameter, it is shown that all hyperparameter combination exhibits the value of mean test score greater than 70%. It also shows that there are hyperparameter combinations that reaches more than 99% of mean test score.

Table VI shows top 10 performing hyperparameter combinations with respect to the mean test score with mean fit time

TABLE VI. TOP PERFORMING HYPERPARAMETER COMBINATION BASED-ON MEAN TEST SCORE

Activation	Batch Size	Initial Weights	Learning Rate	Mean Test Score	Mean Fit Time
Relu	32	be_uniform	0.01	0.98924	15.98910
Sigmoid	64	glorot_uniform	0.1	0.98854	8.60077
Relu	64	Uniform	0.1	0.98819	8.35799
Sigmoid	32	glorot_uniform	0.1	0.98901	15.08160
Sigmoid	32	be_uniform	0.1	0.98698	14.59695
Sigmoid	32	Uniform	0.1	0.98681	15.14623
Tanh	128	glorot_uniform	0.1	0.98559	4.98741
Relu	128	glorot_uniform	0.1	0.98333	4.68067
Sigmoid	128	glorot_uniform	0.1	0.98264	4.75186
Relu	128	be_uniform	0.1	0.98264	4.82595

It was observable that rank 1 combination garnered a mean test score of 98.9 percent while having a mean fit time of 15.878 seconds. Succeeding combinations have good mean test score values but has longer mean fit time. The mean fit time is the average time of training between cross validation folds. The correlation figure below shows the relationship between mean test score and mean fit time with the varying hyperparameters.

TABLE VII. CORRELATION OF VARYING HYPERPARAMETERS WITH MEAN TEST SCORE AND MEAN FIT TIME

	Activation	Batch Size	Initial Weights	Learning Rate
Mean Test Score	-0.1963	-0.2720	0.0035	0.5749
Mean Fit Time	0.0212	-0.9222	0.0194	-0.0091

Table VII shows the correlation of varying hyperparameter results. Batch size can be seen to have a high negative correlation with respect to the mean fit time which gives an idea that training period is greatly influence by the value of batch size. The bigger the batch size, the lesser the mean fit time and the lower the batch size, the bigger the mean fit time. Negligible relationship can be seen through learning rate, activation function and initial weights with respect to the mean fit time. Moderate positive correlation value was found from mean test score with respect to learning rate and very low to negligible relationship can be seen from mean test score with respect to hidden layer activation and batch size and initial weight.

#### D. Accuracy and Loss using the Optimal Hyperparameter based on Mean Test Score

Using the optimal value of hyperparameters based on mean test score, model training was again initiated to get the accuracy and loss function. Fig. 8 shows the model training and validation results.

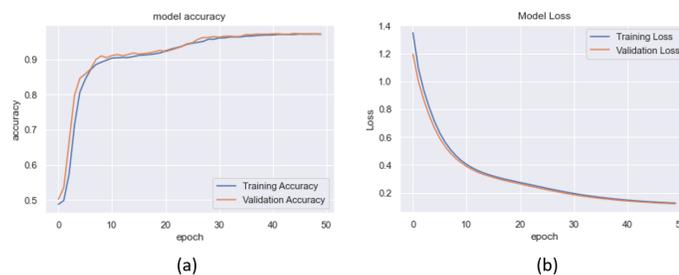

Fig. 8. Model training and validation using the optimal hyperparameter(a) accuracy (b) loss

Taking into consideration Table IV and Fig. 8, it is observable that the accuracy and loss function in 50 epochs greatly improves using the tuned hyperparameters in comparison to old hyperparameters. Accuracy of the old hyperparameters in 50 epochs was 92.55% while the new hyperparameter incurred a value 98.9%. Loss function for old hyperparameter in 50 epochs was 0.2475 in comparison of the new hyperparameter with a value of 0.0986.

#### V. CONCLUSION

This research presents the process of classifying indoor air pollutant sources using relevant parameters under two thermodynamic conditions. The research question that was formulated at the start of this study was finally addressed using this research. Model accuracy and loss function values were seen to be in good fit which is comparable to the previous study. From nine parameters, this research streamlines the number of parameters into five considering CO<sub>2</sub>, PM<sub>2.5</sub>, TVOC, HCHO, and Thermodynamic Conditions. Using the dataset generated in this study feature scaling was compared using normalization and standardization. Standardization scaling was shown to be superior in relation to the vector array normalization scaling which was used in the previous study. The hyperparameters

used in the previous study were also taken into consideration for this research to have the optimal values of hyperparameters. It can be observed that hyperparameters should be tuned to gain optimal result value. Computational time was greatly reduced at the same time giving the best-fit accuracy and loss function values without incurring the problem of overfitting.

The current study classifies indoor pollutants with a minimal number of sensors but can only classify one pollutant source at a time. The previous study collected a dataset on a single source and tested the acquired model on mixed pollutant sources but relatively gains poor performance. Considering this limitation, further dataset gathering and investigation on mixed pollutant sources should be examined while taking into consideration hyperparameter tuning.

#### ACKNOWLEDGMENT

The researcher would like to thank Central Visayas Studies Center (CVSC) of University of the Phillipines Cebu for funding this research. Also, special thanks to Lovelie and Elle for being an inspiration.
