Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

An Ontology-driven DBpedia Quality Enhancement to Support Entity Annotation for Arabic Text

Adham Kahlawi
Department of Statistics, Computer Science Applications, University of Florence, Florence, Italy

***Abstract*—Improving NLP outputs by extracting structured data from unstructured data is crucial, and several tools are available for the English language to achieve this objective. However, little attention has been paid to the Arabic language. This research aims to address this issue by enhancing the quality of DBpedia data. One limitation of DBpedia is that each resource can belong to multiple types and may not represent the intended concept. Additionally, some resources may be assigned incorrect types. To overcome these limitations, this study proposes creating a new ontology to represent Arabic data using the DBpedia ontology, followed by an algorithm to verify type assignments using the resource's title metadata and similarity between resources' descriptions. Finally, the research builds an entity annotation tool for Arabic using the verified dataset.**

Keywords—Entity annotation; semantics annotation; DBpedia; Arabic language; ontology; semantic web; linked open data

I. Introduction

The volume of unstructured text data increases daily, which increases the need for methodologies to help understand and classify this information. Since such data is not structured, the best way to understand it is by adding a metadata to it; consequently, it can be converted to semi-structured data. Part of Speech (POS) tagging, morphological annotation, structural annotation, pragmatic annotation, syntactic annotation, semantic annotation, pragmatic annotation, and stylistic annotation are several methodologies used in Natural Language Processing (NLP) to improve the results of the text analyze. One of the biggest sources of text data that is edited collaboratively from different users is Wikipedia [1]; furthermore, it covers a large number of topics, and it is a free information source. As a consequence, a specific type of semantic annotation has been involved based on Wikipedia called wikification [2]. Thus, Wikipedia has become training data for multiple models and not just a source of information. DBpedia is a project to convert Wikipedia data into structured data and make this data not only available on the web but also machine-readable [3]. DBpedia is available in different languages with cross-language being available to identify the same concept. In other words, the semantic structure of DBpedia allows the connection between more than one label written in more than one language with the same concept. One of these languages is Arabic, which makes DBpedia a good choice to be the information source to build entity annotation for Arabic text. Nonetheless, the transformation process that DBpedia underwent caused some problems, such as the use of the Wikipedia category system does not form a complete topical classification because there exist cycles between the categories, sometimes representing a loose connection between the Wikipedia articles [4]. Consequently, DBpedia data is not high quality. These problems can be summarized into two main categories. The first category, the types to which the DBpedia resources[1] belong to were extrapolated from the DBpedia ontology, but this ontology contains a large number of classes and subclasses. Thus, the single resource can belong to more than one type; meanwhile, these types do not necessarily refer to the same concept. In the second category, the process of assigning types to resources was not accurate enough; therefore, can find some resources which were assigned a type that does not correspond to their concept, or some resources which were assigned more than one type but at least one of these types does not correspond to their concept.

To build an efficient tool, the quality of the data taken from DBpedia has to be improved by building a methodology from several steps. The methodology begins from building a new ontology inspired by the DBpedia ontology, up to validating the information through the content of the text itself or by using the measurement of similarity between texts.

The rest of this paper is structured as follows; Section II discusses the related work. Section III shows what DBpedia is and how it is built. Section IV explains how to obtain data from DBpedia. Section V describes the data collected. Section VI explains the methodology that was followed in this article. Section VII evaluates the methodology. Finally, Section VIII concludes the paper.

II. Related Work

The ability to give metadata to text data has been established as a strategic task for understanding and analyzing texts. Cucerzan [5] seeks through his large-scale system for the recognition and semantic disambiguation to name entity by using data extracted from Wikipedia. Through a link between a single information presented in Wikipedia with the document in which presented and with the category tags of this document. This system passes through three stages. The first stage is to surface from entity mappings, which use the information of the titles of entity pages, the titles of redirecting pages, the disambiguation pages, and the references to entity pages in other Wikipedia articles. The second stage is category information, which takes advantage of the classifications built by Wikipedia contributors. The third stage is contexts, which use the information present in the entity page and other pages

[1] A resource is a basic object encapsulating a "real" thing like a text, image or whatever. This object is accessible within the server according to its Uniform Resource Identifier (URI) because each URI is unique at the global level. All the information that describes the resource itself is stored using the Resource Description Framework (RDF).

that explicitly refer to the same entity. Mihalcea and Csomai [6] integrate two algorithms into one system called Wikify, where the first algorithm identifies and extract the important words in the input text, and the second algorithm assigns each word of the output of the first algorithm with the correct page of Wikipedia. According to Milne and Witten [2], the Wikify system will make mistakes because of its dependence on a probabilistic value of word link that is calculated by the number of a link of the same word in different articles on Wikipedia with a specific article. For these reasons, they developed a new system that takes into consideration not only the word but also the context surrounding this word.

On the other hand, Kulkarni and others [7] proposed a new system that is not directly human interpretable, but downstream indexing, search, and mining. This system is an optimization of the previous one through investigating practical solutions based on local hill-climbing, rounding integer linear programs, and pre-clustering entities followed by local optimization within clusters. TAGME is a software system proposed by Ferragina and Scailla [8] which addresses the problem of cross-referencing text fragments with Wikipedia pages. In particular, TAGME took advantage of previous work and assigned it to small texts such as tweets. Makris et al. [9] proposed techniques that enhanced the TAGME to be applied to different approaches for Wikipedia disambiguation. These techniques improve the quality of Wikipedia by auxiliary information provided by more formal knowledge resources like WordNet [10], which is a large lexical network where concepts/senses are represented by so called synsets. In addition, these techniques employed the PageRank of the Wikipedia pages as an extra factor for disambiguation. Wikifier is a semantic annotation approach presented by Brank and others [11], which supports different languages that are available in Wikipedia; furthermore, it is suitable for parallel processing and supports various minor heuristics. Wikifier refinements is an effort to improve the performance of other approaches; indeed, it uses Wikipedia class membership to ignore certain types of concepts and use the indicator of word frequency to ignore the common words. Consequently, Wikifier reduces the noise in the annotation output. WEXEA, a Wikipedia EXhaustive Entity Annotation system [12] proposed by Strobl and others. the approach aims to create an annotated text corpus include all mentions in Wikipedia instead of simply depend on already existing links between Wikipedia pages; as a consequence, that can be more useful in downstream tasks and can introduce unnecessary errors. There have been several attempts to build tools for the Arabic language. In the following, we will list the most important of these attempts. In 2008 Benajiba et al. [13] used contextual, lexical, part-of-speech, and other features to train a Named Entity Recognition model using an SVM-based approach. The model can recognize four (Person, Location, Organization, and Miscellaneous). Next, in 2012 Al-Jumaily et al. [14] built a real-time named entity recognition system using the data from DBPedia and other sources. The system can recognize three entities only (Person, Location and Organization); the system can also extract the linguistic roots (nouns and verbs). Then, in 2014 Yosef et al. [15] used the Wikipedia Arabic version to create a Named entity disambiguation framework. The framework structure contains four principal concepts entity repository, name entity dictionary, entity description and entity-entity relation. Meanwhile, the framework uses the connection between the Arabic version and the English one of Wikipedia to control the data quality. To test the framework, the authors chose ten news Arabic articles and manually annotated them. After that, in 2015, Al-Yahya et al. [16] presented a lexical semantic annotation based on an ontology that contains six classes that build a three-level hierarchical structure. The higher level is Linguistic Concepts, and the lower level is Words. Consequently, in 2016, Al-Qawasmeh et al. [17] created a similar tool based on DBPedia, where they made an ontology consisting of three classes and filled it in the DBPedia's individuals that belong to these three classes. The authors use a similar algorism to optimize the performance where the algorism finds the nearest entity from the dataset to the input entity. Finally, in 2018, Albukhitan et al. [18] built a tool using deep learning to recognise three entities (Food, Nutrition and Health). The tool will assign the closest ontological class to the input text as a named entity using the weighted candidate vectors and word2vec model. Jarrar et al. [29] introduce Wojood, a corpus for nested Named Entity Recognition in Arabic, consisting of 550K tokens manually annotated with 21 entity types, including nested entities, with a strong inter-annotator agreement. The corpus was used to train a nested NER model achieving a micro F1-score of 0.884, and all resources are publicly available. Al-Thubaity et al. [30] present the COVID-19 Arabic Named Entities Recognition (CAraNER) dataset, consisting of 55,389 tokens from Saudi Arabian newspaper articles labelled with five named-entity tags. The paper also evaluates the dataset using four BERT-based Arabic language models, with AraBERTv0.2-large achieving the highest F1 macro measure of 0.86.

III. Baseline: Dbpedia

Wikipedia is one of the large knowledge sources, and is created by the contribution of thousands of users through writing the articles using natural languages. On the other hand, Wikipedia contains info box, images, geo-coordinates, and categorization information which can be considered as structured information. Moreover, this structure information has been presented by different languages [19]. The structured information of Wikipedia was the basis for building the DBpedia through an open-source extraction framework; as a consequence, DBpedia has been considered as a multilingual and multidomain knowledge base. Each concept of DBpedia is described by a corresponding Wikipedia page and is identified by a Uniform Resource Identifier (URI) [20]. The use of URI and the Resource Description Framework (RDF) has made the DBpedia relatively stable, machines readable, and commonly used ontology. The DBpedia ontology can be used in the integration of different languages and the organization of extracted data [21]. Lehmann and others [22] illustrated the process of data extraction from Wikipedia through Fig. 1. The data extraction process passes through several stages that start from the inputs which are Wikipedia pages; secondly, it moves to the parsing stage that transforms the pages into an Abstract Syntax Tree; thirdly, the extraction stage which converts different parts of pages to RDF by following the next steps:

- the creation of DBpedia ontology terms like the data property through the mapping of infobox structure manually;
- mapping the information in the infobox to RDF taking into consideration the DBpedia ontology;
- extracting a single feature from pages such as a label or geographic coordinates;
- extracting aggregated data from all pages like word counts as further description.

Furthermore, to improve the DBpedia by adding the Arabic language, Ismail et al. [23][23] [23] made special data extraction for Arabic Wikipedia pages through the mapping of infoboxes to the DBpedia ontology by different mapping extractors.

The data extraction based on infoboxes was of great importance in the automation of extraction; on the other hand, it causes some quality issues. Consequently, several papers have been published discussing these issues. For instance, the quality problems resulting from incorrect or missing information like incorrect values, data types, and links were discussed by Zaveri et al. [24], several automatic quality tests were provided by Kontostas et al. [25] to be applied to Linked Open Data (LOD) dataset of DBpedia, the DBpedia accessibility quality was tested by a Linked Data Quality Model that was developed by Radulović et al. [26], and the use of machine learning was proposed by Rico et al. [27] for the detection of incorrect mappings. Lakshen et al. [28] focused on identifying the quality of Arabic DBpedia since it contains problems different from the problems of other languages like the presentation of characters as symbols, the use of Hindu numerals that can create wrong values in numerical data, and occurrence of different names for the same attribute.

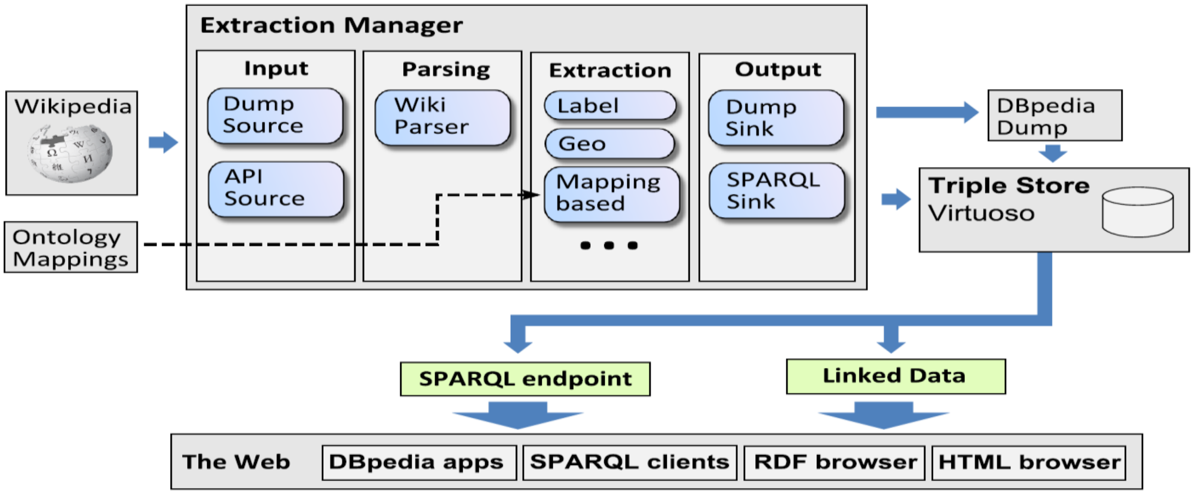

Fig. 1. Overview of DBpedia extraction framework [15].

IV. Data Collection

The latest releases of core data from en.wikipedia.org have been published by the DBpedia protect on the first of July 2020; also the collection URI is https://databus.dbpedia.org/dbpedia/collections/latest-core. However, the collection does not contain downloadable files for the Arabic language; for this reason, the data has been acquired by applying SPARQL Query at a DBpedia public SPARQL endpoint “http://dbpedia.org/sparql” using python function.

```
        def apply_query(query):
            sparql=
SPARQLWrapper("http://dbpedia.org/sparql")
            sparql.setQuery(query)
            sparql.setReturnFormat(JSON)
            results = sparql.query().convert()
            df=
pd.json_normalize(results["results"]["bindings"])
            return df
```

public SPARQL endpoint has a limit as the following[31] :
“ *ResultSetMaxRows = 10000*
MaxQueryExecutionTime = 120 (seconds)
MaxQueryCostEstimationTime = 1500 (seconds)
Connection limi = 50 (parallel connections per IP address)
maximum request rate = 100 (requests per second per IP address, with an initial burst of 120 requests)”

As a consequence, the data was collected following the steps below:

a) identify the types of all the instances.

The DBpedia collection offers a special file that contains the type of all instances.

b) building the DBpedia Arabic dataset.

At this point, a dataset containing instances URI, label, description, and type will be obtained by sending a SPARQL query to DBpedia SPARQL endpoint through a specific Python code. The SPARQL query has been built and has been sent for each type obtained in the previous step.

where_text = """ ?uri rdfs:label ?label;

```
                              rdf:type   ?type.
                        optional{}
                       filter(lang(?label)="ar")
                     filter(?type in(<{}>))
    """
optional_text = """{
                       ?uri rdfs:comment ?descrption.
                      filter(lang(?descrption)="ar")
                     }"""
for i in range(0,len(type_list)):
  arabic_dataset_query = f"""PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
  PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
  SELECT distinct ?uri ?label  ?descrption ?type WHERE {'{'}
  {where_text.format(optional_text,type_list[i])}
  {'}'}
  """
  arabic_label_df=
arabic_label_df.append(apply_query(arabic_datset_query))
```

V. Data Description

In this chapter, we will discuss the validity of the dataset from two different points of view. Firstly, the dataset description and the affiliations of each resource; secondly, the formal and grammatical structure of the resources' label.

A. Description of the Dataset obtained from DBpedia

As shown in Fig. 2, the number of URI of the resources without repetition within the dataset is greater than the number of resources label without repetition. As a consequence, this information indicates the problem of the existence of a group of resources within the dataset that have the same name but have more than one URI.

On the other hand, the total data in the dataset is greater than the number of resources label without repetition. For this reason, there is a problem of the presence of some resources that belong to more than one type; in fact, Fig 3 shows that resources may belong to more than one type at the same time and the max is seven types for example: this URI http://dbpedia.org/page/Pomegranate_soup refer to Pomegranate soup resource that has two different types, the first one is dbo:Food but the second one is dbo:GivenName that usually use to indicate a person name. However, it is not necessary that these different types refer to different concepts; nonetheless, they may refer to the same concept with different names or refer to the sub-concepts of the same concept.

B. The Formal and Grammatical Structure

Arabic labels contain additional information placed in brackets to clarify the meaning of the label; on the other hand, this method of adding additional information is not considered as one of the common methods used in the Arabic language to attend this goal. For example, the URI http://dbpedia.org/resource/Pato has the Arabic label written in this way "باتو(رياضة)" which means Pato (sport); however, the English label is written with only the word Pato. The dataset contains 63747 Arabic labels contain additional information placed in brackets.

As for the linguistic rules, the rules of definite or indefinite articles in the Arabic language is different from other languages like English. The English language uses the articles that are placed before the noun, indicating whether the word is definite or indefinite. In contrast, the Arabic language adds two letters to the word at the beginning to differentiate between definite or indefinite nouns; consequently, the natural language processing will consider the definite word different from the same word in the indefinite form.

For instance, the URI that has Cartilage as English label, this label can be written inside any English text as "a cartilage" or "the cartilage"; in contrast, the Arabic label of this URI is غضروف that can be written inside any Arabic text as "غضروف" or "الغضروف".

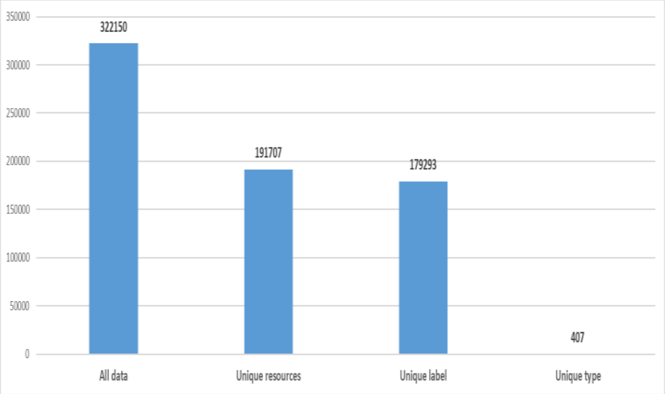

Fig. 2. Dataset description.

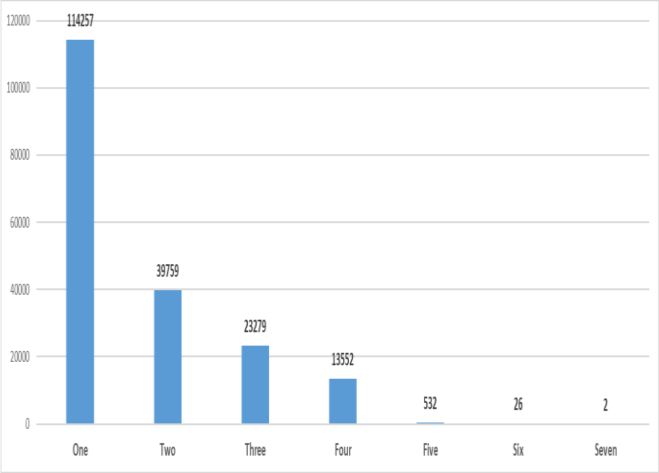

Fig. 3. Frequency of resources depending on the number of types.

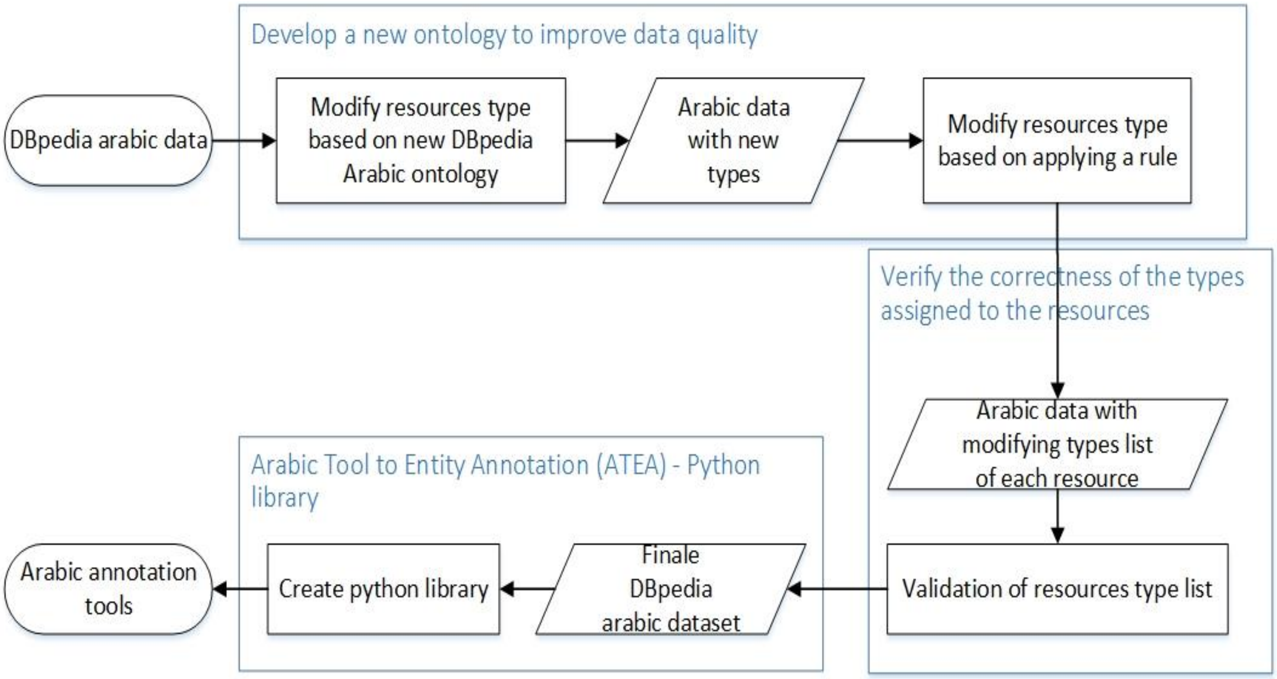
VI. Methodology

The methodology seeks to reduce the number of types that some resources can belong to; in addition, seeks to verify the validity of the types that have been assigned to the resources. Finally, the data obtained from achieving the two previous goals will be used to build a tool to annotate the Arabic text. Fig. 4 shows that the methodology depends on the implementation of a set of successive steps to achieve its objective, which are described as follows:

A. Develop a New Ontology to Improve Data Quality

Each resource in the data belongs to one or more types as shown in Fig. 3; indeed, these types belong to DBpedia ontology. By referring to DBpedia ontology, it can be seen that the group of types to which the resource belongs does not necessarily belong to different concepts. However, these types may belong to the same general concept; consequently, it represents one of the oldest data quality problems faced by machine learning technologies [32]. Therefore, this study proposes to create a new ontology inspired by the DBpedia ontology and correspond to the types of Arabic dataset in order to improve the quality of data and reduce the number of types to which belongs every resource [33][34]. Afterward, the basic types to which the data belong were transformed into individuals belonging to the classes of new ontology that represent the general concept of it. We must point out that building the new ontology depends on human experience; therefore, it will be a manual process, while the process of individual transformation for it will be automatic. Fig. 5 represents the DBpedia Arabic resources ontology, while Table I represents its metrics.



Develop a new ontology to improve data quality
DBpedia arabic data
Modify resources type based on new DBpedia Arabic ontology
Arabic data with new types
Modify resources type based on applying a rule
Verify the correctness of the types assigned to the resources

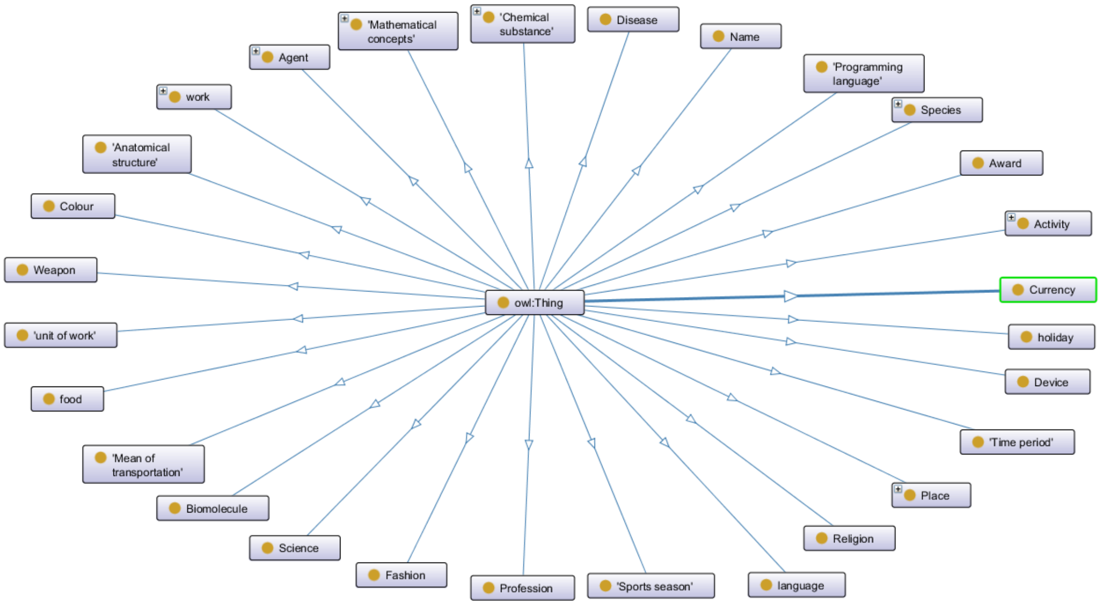

Fig. 5. DBpedia Arabic resources ontology.

TABLE I. DBPEDIA ARABIC RESOURCES ONTOLOGY METRICS

Ontology metrics	description
Metrics	
Axiom	240
Logical axiom count	106
Declaration axioms count	134
Class count	134
Class axioms	
SubClassOf	**106**

As a consequence of applying the previous mapping process to the data, each element belongs to a new type or group of types. Based on the new ontology, the following rule was applied to reduce the number of the types to which each source belongs.

Rule:

If there are two types one of which is a subclass of the other in the group of types to which a resource belongs; consequently, the type that represents a subclass is retained and the other is deleted from the group of types to which this resource belongs.

B. Verify the Correctness of the Types Assigned to the Resources

The DBpedia data is considered as structure data that was built through a process of mapping from Wikipedia; nonetheless, this process caused some errors in assigning the correct type to some resources. For this reason, this study proposed an algorithm to verify the validity of the type assigned to each resource and correct it in the event that an error is discovered. This algorithm is shown in Fig. 6 based on thirteen actions that are described as follows:

- Action 1 - Create URI_Type dictionary: A subset will be extracted from the dataset which contains the URI of each resource and its type or their types.
- Action 2 - Create URI_label dictionary: A subset will be extracted from the dataset which contains the URI of each resource and its Arabic label.
- Action 3 - Extract words in parentheses: The words written between parentheses in some labels of resource will be extracted.
- Action 4 - Associate words with the type they refer to: The list of words that result from the previous action will be checked manually if it refers to a specific type; then, a dataset of words and the types that refer to will be built.
- Action 5 - Assign to the resource URI the extracted word from parentheses presented in its label: Will build a dataset of URI of each resource and the extracted word written between parentheses in the label of resources, or the value of Null if the label does not include words between parentheses.
- Action 6 - Assign the word's type to the URI: The sources whose label contains an explanatory word and this word refer to a specific type. In this action, this type will be assigned to the resource URI.
- Action 7 - Create URI_Description dictionary: A subset will be extracted from the dataset which contains the URI of each resource and its English description.
- Action 8 - Calculate the similarity between the descriptions: The similarity will be calculated using the Latent Semantic Indexing (LSI) model. LSI is an indexing and retrieval technique. LSI is a text mining that is able to calculate the similarity between the text data by projecting it into space with latent semantic dimensions. In other words, the similarity is calculated by the co-occurrence of each word and every single word in the documents. The measure ranges from 0 to 1 (the greater the more similar)[35, 36]. LSI model was trained by using the English description of each resource to calculate the percentage of similarity between the resources, and then this dataset was constructed by linking each resource with the best five resources similar to it.
- Action 9 - Get for each URI the type of the best five similar URI: The type of five most similar resources of each resource will be gotten; indeed, the type of similar resources will be gotten from two sources. The first "verified URI_type dictionary" will be used if a similar resource is one of the resources whose type has been verified in the action 6. The second "URI_type dictionary" will be used if a similar resource is one of the resources that have not been verified its type yet.
- Action 10 - Get the type list for each URI: the type list of each resource will be gotten.
- Action 11 - Calculate the intersection between the two list: The intersection value between the two lists resulted in action 9 and action 10 will be calculated.
- Action 12 - Assign the intersection values as type to the URI: The intersection value will be assigned to the resource URI as a type for it.
- Action 13 - Human verification to the URI type: All resources that were the results of the calculated intersection in the action 11 are Null, its type will be verified manually. Manual verification faces two cases. The first case, the type that was assigned to the resource is correct, so no action will be taken. The second case, the type that was assigned to the resource is not appropriate for it, so the type will be changed to a type that corresponds to the nature of the resource.

C. *Arabic Tool to Entity Annotation (ATEA) - Python Library*

Fig. 7 illustrates the mechanism of ATEA library's work as it takes short text lake input; in contrast, its output contains different types of data. The first one represents the DBpedia Arabic resource ontology's types that belong to each entity detected in the text. The second type represents the DBpedia URI and DBpedia types that belong to each entity detected in the text. The last type represents the interpretation of the label of each entity detected in the text to different languages available in DBpedia.

ATEA includes four data set:

- URI_Label dataset: This dataset contains the entire Arabic resources label after applying two adjustments. First, all additional information attached to the primary label has been deleted; second, all the labels have been stemmed.
- Verified URI_Type dataset: This dataset contains all the resources types; indeed, these types follow the DBpedia Arabic resources ontology.
- URI_Type dataset: This dataset contains all the resources types obtained directly from DBpedia.
- This dataset contains the English label of all resources included in URI_Label dataset.

ATEA performed seven actions as following:

- Action 1 - Split text: This action is divided into two steps; first one is splitting the text based on the punctuation marks. The second step is tokenizing each subtext to all possible n gram word where n is between one and the number of words of the longest label in DBpedia Arabic resources.
- Action 2 - Find all entities: The intersection between the label list of DBpedia Arabic resources and the tokenization list will be calculated.
- Action 3 - Get the DBpedia Arabic resource ontology's type of each entity: Each element in the intersection list will be assigned to its type of the DBpedia Arabic resource ontology.

- Action 4 - Get the DBpedia URI and types of each entity: Each element in the intersection list will be assigned to its type and URI of the DBpedia.
- Action 5 - Interpret each entity to English language: Will be assigned to each element in the intersection list the English label of its represented resource in DBpedia.
- Action 6 - Integration of the three categories of data: The results of each item in the intersection list will be combined and organized into a dictionary that will represent the output of ATEA.

VII. Evaluation

Arabic resources collected from DBpedia had 407 different types and the resource may have up to seven types; consequently, each resource belongs to 1.68 types on average. The use of our developed DBpedia Arabic resources ontology reduced the number of types that the resources could belong to; as a result, DBpedia Arabic resources ontology grouped the types that belong to one concept together; thus, the number of types was reduced from 407 to 106. Indeed, Fig. 8 shows that the max number of types that any resource could belong to is five, and each resource belongs to 1.33 types on average. On the other hand, the use of DBpedia Arabic resources ontology left 739 resources without type, because these resources were related to the "Thing" type such as the resource of Whale that has the URI "http://dbpedia.org/resource/Whale". In addition, the implementation of the rule resulted in the max number of types that any resource could belong to reduce to three and each resource belongs to 1.08 types on average. At the end of the first step of the methodology, it is noted the optimization in the number of types that one resource can belong to; in fact, about 92% of the resources belong to one type.

In the second step of the methodology, firstly, 1688 words indicating specific types were extracted from information contained in parentheses in Arabic labels. Examples of these words are Novel, Book, Journal, Writer, Poet, Rocket, Tank, TV series, wrestling, Scientist, king, Restaurant, Church, programming language, Plant and bird. These words were used to verify the validity of the types to which the resources belong; indeed, if the Arabic label of any resource contains a word indicating a specific type and this type does not correspond to the resource type, the source type is modified to the type to which the word refers, as shown in Table II.

Secondly, the similarity between the descriptions of the resources was used. If the resource type corresponds to at least one of the five types of sources that are most similar to it; consequently, the resource type is considered correct. Otherwise, it will be manually verified. Table III shows some resources that have been verified manually.

As a result of the second step of the methodology, the max number of types that any resource could belong to is three types, but each resource belongs to 1.01 types on average. Moreover, about 99% of the resources belong to one type.

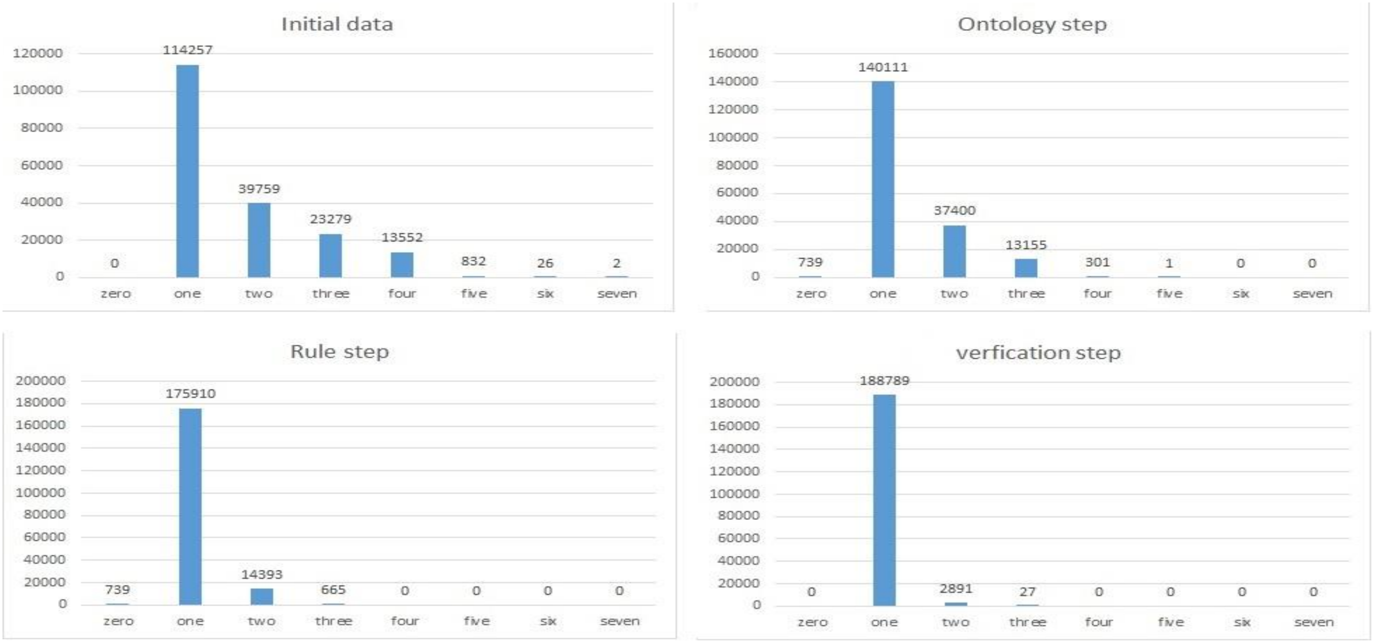

Fig. 8. Frequency of resources depending on the number of types that belong to for each methodology's step.

TABLE II. Examples of Text Verification Results

Resource URI	Arabic label	English label	DBpedia type	verify type
http://dbpedia.org/resource/Anthony_Wong_(Hong_Kong_actor)	أنتوني وونغ (ممثل هونغ كونغي)	Anthony Wong (Hong Kong actor)	Artist, Film	Artist
http://dbpedia.org/resource/Antalya_Province	أنطاليا (محافظة)	Antalya Province	PopulatedPlace, Athlete	PopulatedPlace
http://dbpedia.org/resource/Bell_AH-1Z_Viper	فايبر (مروحية)	Bell AH-1Z Viper	MeanOfTransportation	Weapon
http://dbpedia.org/resource/George_Hamilton_(actor)	جورج هاميلتون (ممثل)	George Hamilton (actor)	Film	Artist
http://dbpedia.org/resource/Ballade_(classical_music)	بالاد (موسيقى كلاسيكية)	Ballade (classical music)	Thing	MusicalWork

TABLE III. EXAMPLES OF HUMAN VERIFICATION RESULTS

Resource URI	**Arabic label**	**English label**	**DBpedia type**	**verify type**
http://dbpedia.org/resource /Orient_News	أورينت نيوز	Orient News	Band, Company	Media
http://dbpedia.org/resource/König-class_battleship	بارجة فئة كونيغ	König-class battleship	Band, MeanOfTransportation	Weapon
http://dbpedia.org/resource/ Sovereign_Military_Order_of_Malta	فرسان مالطة	Sovereign Military Order of Malta	EducationalInstitution, PopulatedPlace	MilitaryUnit
http://dbpedia.org/resource/Gezer	تل الجزر	Gezer	Event, MilitaryConflict	HistoricPlace
http://dbpedia.org/resource/ Burgundians	برغنديون	Burgundians	Language, Name	EthnicGroup
http://dbpedia.org/resource/Sabines	سابينيون	سابينيون	Language, Animal	EthnicGroup
http://dbpedia.org/resource/ Amr_Sobhy	عمرو صبحي	Amr Sobhy	Award, Writer	Writer
http://dbpedia.org/resource/Whale	حوت	Whale	Thing	Animal
http://dbpedia.org/resource/Narcotic	ناركوتي	Narcotic	Thing	Drug
http://dbpedia.org/resource/ Tank	دبابة	Tank	Thing	Weapon
http://dbpedia.org/resource/ Beef	لحم بقر	Beef	Thing	Food
http://dbpedia.org/resource/ Operetta	أوبريت	Operetta	Thing	Play
http://dbpedia.org/resource/ Train	قطار	Train	Thing	MeanOfTransportation

In the third step of the methodology, ATEA is built which takes short text as its input and then performs the following steps:

Firstly, the length of the text is measured, if the length of the text is equal or greater than 17 words, the text will be divided into n_ gram where n = 17; because of the max length Arabic label present in the data equal to 17. On the other hand, if the length of the text is less than 17 then the text will be divided into n_ gram where n equal to the length of the text.

Secondly, all n_gram obtained from the previous step are searched for; afterward, if any of them was found in the database. First of all, it will be annotated then it will be deleted from the text; last of all, if n equal to one, the finale results will be returned to the user; in contrast, if n greater than one, the previous steps will be repeated. This is the application of your method to an example. The example talks about Syria.

“ سورية دولة عربية يبلغ عدد سكانها ما يقارب 23 مليون منهم 93% عرب و 5% كرد و 2% أعراق أخرى مثل أرمن و تركمان. يعتنق السوريون أكثر من ديانة فنجد أن 90% إسلام و 7% مسيحية و 3% طوائف أخرى. يتكلم غالبية السكان لغة عربية. . تعاقبن على سوريا حضارات ممتالية ومن أشهرها إبلا وكانت هذه الحضارة العريقة والقوية قد ازدهرت في منتصف الألف الثالث قبل الميلاد و التي تم إكتشافها من قبل بعثة أثرية من جامعة روما سابينزا برئاسة باولو ماتييه. ”

“Syria is an Arab country with a population of approximately 23 million, of which 93% Arabs, 5% Kurds, and 2% other ethnicities such as Armenians and Turkmen. Syrians have more than one religion; indeed, we find that 90% Islam, 7% Christian, and 3% other sects. The majority of the population speaks Arabic. Successive civilizations took place in Syria, the most famous of which is Ebla. This ancient and powerful civilization had flourished in the middle of the third millennium BC, which was discovered by an archaeological mission from the University of Rome Sapienza headed by Paolo Mattei.”

The automatic entity annotation results are in JSON format as the following:

The Arabic language suffers from the scarcity of databases that can be used to evaluate the performance of such tools. In order to evaluate the performance of this tool, we will use the ANERcorp dataset [37, 38] that includes five entities (Person, Location, Organization, Miscellaneous, and others). It is necessary to point out some of the difficulties facing the evaluation process, including:

The tool provided by this work is able to distinguish more than 100 entities; therefore, we must perform a manual comparison process between the type predicted by the tool and the real type.

The database contains single words. In some cases, this single word is a part of a name of an organization or a location; thus, the assigned entity will be the same entity of the full name even if the single name refers to another entity. According to the way the proposed tool works “as shown in the previous example", the entity that the tool will predict will correspond to the nature of the single word and not the full name.

Since we will do the evaluation process manually, we have selected a sample of 2000 words from the ANERcorp dataset to complete the evaluation process. Consequently, the proposed tool could annotate words belonging to more than fifty entities, but only fifty entities contain at least three words.

We measured the annotation accuracy for each entity separately; therefore, we can say that the annotation accuracy was between 75% and 100%. It should be noted here that the entities with 100% accuracy are entities that contain less than six words.

In conclusion, we can say that the tool presented by this research is comparable in its accuracy to other tools that do the same work, but it surpasses them in its ability to annotate more entities. Thus, giving a more accurate description.

VIII. Conclusion

This research aimed to reach an automatic entity annotation tools for Arabic texts. This tool uses the DBpedia database as an information source; afterwards, work was done to improve its quality in terms of the number of types that a single resource could belong to. In addition, the research focused on verifying the validity of the attribution that was made for each resource; in other words, whether the type to which the resource belongs matches the concept that this resource represents. This is with the aim of obtaining structured data from unstructured data; thus, improving the quality of the output that can be obtained through applying NLP models. The contributions made by this research were:

First, devise a new ontology from the DBpedia ontology that represents the resources with Arabic label; besides, the new ontology aims to improve the quality of automatic entity annotation by unifying the resources that belong to similar concepts within the same type;

Second, build an algorithm to verify the validity of the types that were given to the resources;

Third, build an ATEA that provides the user with the final results in a format that enables him to use them in a different field.

This tool can be developed by increasing the size of its database in two ways, the first is to use the existing resources in DBpedia but have not an Arabic label after translating their English label to the Arabic language. The second is to use a new database and expanding the classes included in the DBpedia Arabic resources ontology. Thus, it will increase the efficiency of the output of this tool; then, the possibility of using their output as inputs for classification models and cluster models.

In future works, we will develop the tool to build semantic relationships to convert text into a RDF triple store. We will use different datasets after performing all data quality checks to achieve this goal. In addition, we aim to expand languages that can be automatically annotated; consequently, this will allow the use of different texts written in different languages as an input of different NLP models like similarity model without the need for translation by the use of the information of the words annotated.

HPCC Systems LexisNexis Risk Solutions, Alpharetta, USA[5, 6]

***Abstract*—A key motivator for the usage of cryptocurrency such as bitcoin in illicit activity is the degree of anonymity provided by the alphanumeric addresses used in transactions. This however does not mean that anonymity is built into the system as the transactions being made are still subject to the human element. Additionally, there is around 400 Gigabytes of raw data available in the bitcoin blockchain, making it a big data problem. HPCC Systems is used in this research, which is a data intensive, open source, big data platform. This paper attempts to use timing data produced by taking the time intervals between consecutive transactions performed by an address and make an identification of the nature of the address (illegal or legal). With the use of three different goodness of fit run tests namely Kolmogorov–Smirnov test, Anderson-Darling test and Cramér–von Mises criterion, two addresses are compared to find if they are from the same source. The BABD-13 dataset was used as a source of illegal addresses, which provided both references and test data points. The research shows that time-series data can be used to represent transactional behaviour of a user and the algorithm proposed is able to identify different addresses originating from the same user or users engaging in similar activity.**

***Keywords*—Bitcoin; time-series analysis; HPCC systems; random time interval; illicit activity detection**

I. Introduction

The rapid growth of Cryptocurrencies has proved to be a major regulatory challenge. They are used in various illegal activities including illegal trade of drugs, hacks, thefts, illicit pornography and other major crimes. According to the 2022 Crypto Crime report by Chainalysis [1], a total of $14 billion was involved in Cryptocurrency based illicit activities in the year 2021. Although it represents only 0.15% of the total volume of crypto transactions, digital currencies and trading of these assets is becoming increasingly mainstream. The tracked volume of illicit activity is likely to rise in the future as more bad actors are identified. Bitcoin is the first and the most established cryptocurrencies in the world. Bitcoin provides pseudo-anonymity in the form of a 26-35 length alphanumeric addresses. This makes the identification of users difficult. However, it is possible to link transactions to users due to the public nature of the Bitcoin blockchain. After linking the addresses to users, it is further possible to identify which of these users were involved in activities that are of criminal nature [2].

Consider a user who has a dedicated set of Bitcoin addresses which they use to perform some kind of illegal activity. Over time, as they perform their transactions, the timestamps are available publicly and can be used to reveal the identity of the user. Behavioral biometrics rely usually on a rich stream of information to identify a user. RTI is one such biometric which can be considered as any sequence of time intervals between successive events. As we have the timestamps from the bitcoin blockchain we can obtain the RTI of transactions by taking the difference between the timestamp of the current transaction and the previous transaction for the sequence of transactions made by the user. This work uses the random time-interval (RTI) biometric [3].

This paper presents a method to recognise individual users from their behavioral metrics which is the time-series data and is publicly available on the bitcoin blockchain. A review of the related work is presented on the next section. In Section III, we present the methodology used which encompasses the methods and components involved in the research. Finally, the results and discussion of the three goodness-of-fit tests are presented in Section IV followed by conclusion in Section V.

II. Related Work

The most important datapoint that is generated by a bitcoin address for this technique of fraud detection is the RTI or Random Time Interval data which was first made use of in the paper by Laskaris, Zafeiriou, and Garefa [4]. Subjects were given a button to press randomly and it was shown that the time series produced could be used as a biometric signature of a person's cognitive thought process. Monaco [3] made use of 12 total time signatures unique to any address and used Takens's theorem for phase space reconstruction followed by the approximate multivariate wald-wolfowitz test to check whether the two samples originated from the same sources. The best identification rate was 76.

Other types of biometric identification have been attempted such as signature verification using template matching [5]. In this a novel variation of the DTW algorithm is used which produced verification errors of as low as 1.34% at a very rapid speed. Another application of timing data for biometric identification is in gait analysis. Mekruksavanich and Jitpattanakul [6] were able to use the timing data of 22 subjects from portable devices and create a CNN model which achieved an identification accuracy of as high as 93.9%.

Dynamic Time Warping (DTW) [7] is used to align two different time series data to recognize the origin of data. The only fundamental difference between various time series analysis and bitcoin time series analysis is that the measurement is event driven versus being measured continuously by sensors. Often transactions also occur over various weeks or even months whereas with a specific application such as gait analysis data can be continuously captured over a period of day or two. Another difference is the accuracy of the time stamps being used, with sensor data the data is quite precise, but since transaction level timestamps are not available in the blockchain, block level time stamps are used which reduces accuracy.

Many techniques have been developed for bitcoin fraud detection apart from the usage of timestamp data such as clustering [8], various techniques such as trimmed k-means, DBSCAN etc. are tested to this end. Various network analysis techniques have also been analyzed [9] such as use of LOF (local outlier factor). The difference between these and time series analysis is that network analysis attempts to find anomalies in behavior globally whereas time series attempts to show that two addresses originate from the same user with no mention of the nature of the transactions being made.

III. Methodology

Bitcoin is the oldest and most widely adopted cryptocurrency to date. It becomes the natural choice for study given the amount of transactional data available publicly. Having 389 Gigabytes of raw data to work with immediately makes this a big data problem as bare metal resources cannot handle this much data. Hence, HPCC Systems is used. Another reason to choose HPCC is its ROXIE delivery engine which let us query new addresses quickly.

A. Bitcoin

On October 28th, 2008 Satoshi Nakamoto made public his research on a trustless peer to peer electronic cash system called bitcoin [10]. The system has its origins in the growing distrust around centralized financial institutions [11]. It relies on the proof of work model where the longest chain is the one that is trusted first amongst all the miners. Bitcoin also makes its transaction history easily accessible to the public making it easy to perform analysis.

The two most relevant data points on the chain to this particular research effort are the bitcoin addresses and bitcoin transactions. Every bitcoin user has access to a private key and a public key. The bitcoin address is derived from the public key by the use of one-way cryptographic hashing [12]. It represents the origin and destination of bitcoin in transactions. RTI data will be aggregated

Bitcoin transactions represent a transfer of bitcoin from one address to another. The transactions are then added to a mempool and miners race to add it to their blocks and obtain the block reward. The transactions are contained in blocks which are chained together.

B. HPCC Platform

As of April 2022, the amount of raw blk data a bitcoin client would download is 389 Gigabytes and if the solution is expanded to other crypto such as ethereum it can take as much as 658 Gigabytes of data. This makes the problem of fraud detection a big data problem where regular computational resources will struggle to keep up with the demands of scaling data. HPCC (High-Performance Computing Cluster) is a big data platform developed by LexisNexis Risk Solutions. It supports both parallelized batch computing and online querying using a declarative and data centric programming language called ECL (Enterprise Control Language) [13].

The HPCC platform has three main components as shown in Fig. 1, namely THOR, Roxie and ECL. The THOR cluster is used for batch processing, while ROXIE is used to run multiple online queries. ECL is the language used to interact with these two clusters. There is a plethora of other components used for housekeeping and maintenance of logical files and work units such as Dali, Sasha etc. The clusters themselves can be made up of commodity hardware to supercomputers as nodes. Thus, HPCC provides for scalability.

C. Goodness-of-Fit Tests

These statistical tests check whether a given set of observations were drawn from the same distribution. Generally, these tests check whether the observations were drawn from the normal distribution. For our purposes, a two-sample variation of the tests is used, to compare the underlying continuous distributions of two sets of independent observations.

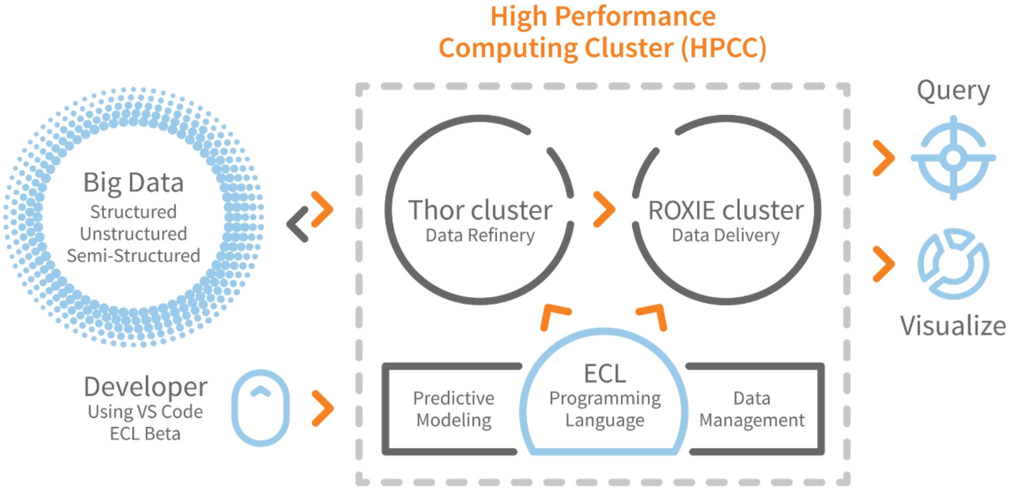

Fig. 1. HPCC systems architecture.

The three tests chosen show a varying degree of bias in different situations and have varying statistical power measures. Various studies have been conducted which include a series of goodness of fit tests and compare its statistical powers on different distributions. The Kolmogorov-Smirnov test has more statistical power against the distributions with n<100. The Anderson Darling test shows a better power against the distributions with higher sample sizes. The Cramer-von-Mises test performs similar to the KS test but for certain distributions with n>50, this test outperforms the Kolmogorov-Smirnov test [14].

1) Kolmogorov-smirnov test: A variation of the one sample test is used which compares a set of two observations [15]. It creates a cumulative distribution for both of the sets of observations after sorting them. The difference between the two distributions is obtained and the maximum of these differences is compared against the critical value. Should the Kolmogorov test statistic be less than critical value, the null hypothesis that both the observations originate from the same distribution will be rejected. In this paper the scipy implementation of this test is used [16]. We use the 'two-sided' option for the alternative parameter which states that the alternative hypothesis is that two distributions are not identical, F(x) is not equal to G(x) for all x; and the statistic is given by the maximum absolute difference between the empirical distribution functions of the samples. The method parameter is set to 'auto' option which means that for small arrays, it uses the exact distribution of test statistic; and for large arrays, it uses asymptotic distribution of test statistic.

2) Anderson-darling test: The Anderson Darling test is another test to check for data coming from a particular distribution. K-sample Anderson-Darling test is a modification that tests the null hypothesis that k-samples are drawn from the same population without any specification of the distribution function of that population [17]. The critical values depend on the number of samples. In this paper the scipy implementation of the k-sample Anderson-Darling test is used, taking the value of k as 2 [18]. The *midrank* parameter is set to *True* which computes the test using the midrank empirical distribution function applicable to continuous and discrete data.

3) Cramér–von mises criterion: Cramér–von Mises is another goodness of fit test. The two-sample Cramér-von Mises test is a test where the null hypothesis is that the samples are from the same, unspecified continuous distribution [19]. The scipy implementation of the Cramér-von Mises test is used in this paper [20]. The only parameter is *method* which is set to '*auto'* option working similar to the parameter in the Kolmogorov-Smirnov test.

D. Dataset

The Bitcoin Address Behavior Dataset [21] contains 13 categories of bitcoin addresses, each containing a list of addresses from a different type of crime. The reference illegal addresses have been picked from these. Specifically, to make the task of obtaining RTI simpler, 1500 addresses were randomly picked from labels 0, 10 and 11 and their RTI data was obtained by using a simple python script using the JSON-RPC interface to fetch all the information about transactions made by that address. The BABD-13 is used as it is a robust dataset which addresses not only the crime that the address was involved in, but also provides the degree of certainty that the illegal activity has occurred. Not only does this allow for the selection of illegal activities of interest, but it also enables the selection of only those addresses that are labeled as illegal with a high degree of certainty.

The other dataset in use is the one generated by the parser described later on, it has been obtained by parsing the binary data to CSV. There are many more data points that can be extracted from the raw blk data such as Merkle root, block hash etc. but have been ignored as the crucial data point for the research is the timing data.

E. Methods

The main idea was to retrieve all the bitcoin raw data using bitcoin core followed by the usage of a parser to retain the data in CSV format. This is followed by the generation of Random Time Interval data. This data is also generated for the addresses extracted from the BABD-13 dataset which will be part of both reference and test dataset. Each sample in the test dataset is then run using all three goodness of fit tests against each of the reference addresses. The statistic values are then averaged and if the average is greater than 0.5, the test returns a positive hit for suspicious activity from the tested address. The workflow is shown in Fig. 2.

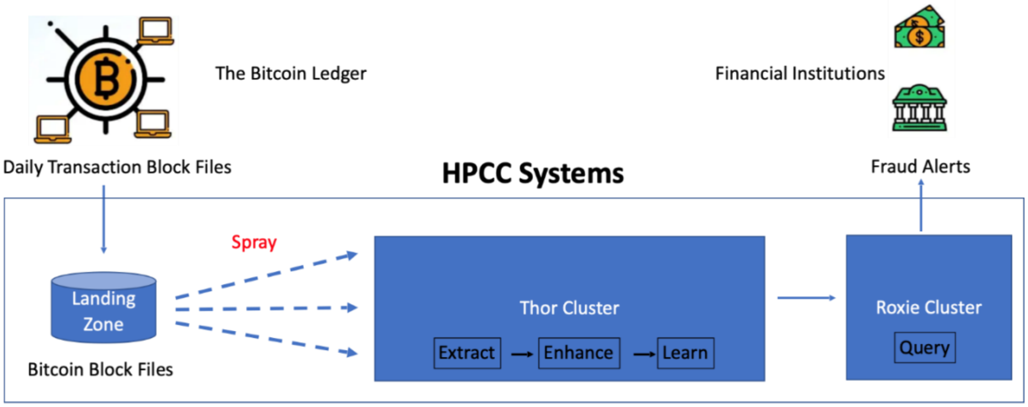

Fig. 2. Algorithm methodology.

The bitcoin data is obtained by initializing a bitcoin core node which downloads the data in the form of blk.dat files which are then sprayed onto the thor cluster for processing after passing through the landing zone. Here it goes through various ETL operations after which financial institutions will be able to submit queries of particular addresses to check for fraud on Roxie.

1) Parser: A bitcoin core node was set up to fetch the bitcoin blockchain raw data. The blockchain has been broken down into multiple blk.dat files (3185 as of writing this paper). The blk files consist of multiple blocks and are limited to 128 MiB. This data is all in binary form and a parser must be used to convert to CSV, JSON or some other structured format.

A modified Bitcoin parser [22] written in python is implemented using the HPCC Systems platform. The parser is embedded into ECL to take advantage of the parallel architecture available on the platform. This embedded python parser showed a significant improvement over a single node parser. For a set of 50 random blk.dat files, the HPCC parser ran at 5% of the time of a single node parser for 41 minutes.

This first phase of the parser extracted the following data points

a) Transaction Hash

b) Input Index

c) Input Transaction Hash

d) Output Index

e) Output Address

f) Output Value

g) Timestamp

The only missing data here is the input address, this data is obtained by using ECL. The blockchain stores the input transaction hash and the corresponding output index to refer to the inputs of a transaction. Thus, to find the actual input address ECL's self-join operation is used. Here the transaction in question and the previous transaction are joined, the corresponding output address of the previous transaction is the input address of the current transaction. This is shown in Fig. 3. This process leads to all the data being collected as required by the various algorithms used in this paper.

2) RTI Generation: Random Time Interval (RTI) data [4] can be generated from the timestamp data obtained from the blockchain. The data is generally precise and captured by sensors in cases such as gait analysis [7], this is where bitcoin presents a slight hurdle. Transaction level timestamps are not recorded and the closest substitute is the block level timestamp. Even with this rougher granularity however, some promising results do arise as will be seen later on.

The RTI data is calculated by taking consecutive timestamps in UNIX time of transactions made by a given address and subtracting them from their successor. Thus, if an address has made n transactions it will have an RTI of length n-1. RTI generation was done by making use of ECL's ITERATE function.

3) Algorithm: A set of reference addresses are taken which can contain legal and illegal addresses. A test query is then taken and one of the three aforementioned run tests is used to evaluate the test address against each and every reference address. If the reference address is illegal and returns a p value greater than the threshold or if the reference address is legal and the test returns a p value less than the threshold it is added to the total number of hits. Finally, if the fraction of hits is greater than a threshold value, the query will return as illegal.

This threshold on the fraction can be thought of as a level of risk tolerance, where a lower threshold means that financial institutions would want to investigate addresses even with a small fraction of hits and vice versa.

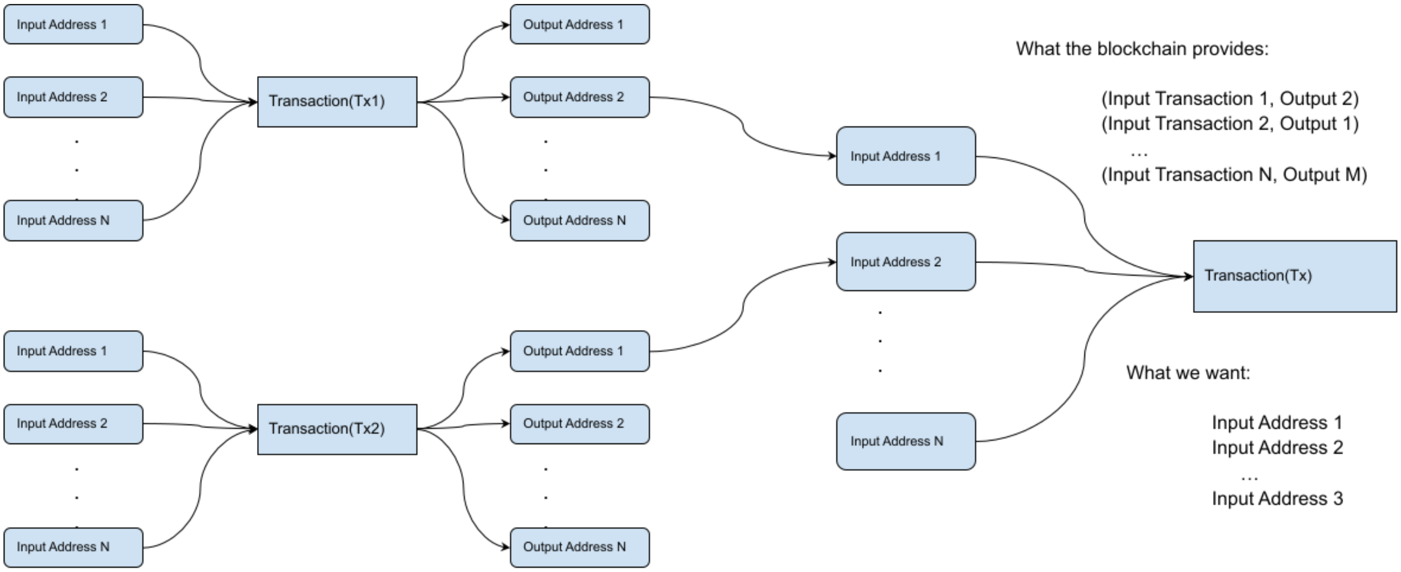

Fig. 3. Input to output address relation.

These illegal reference addresses are taken from the Bitcoin Address Behavior Dataset (BABD) [21] and the legal addresses are addresses which have been randomly taken with the assumption that 1% of bitcoin addresses are illegal. There is very high variability in the consideration of percentage of illegal activity in bitcoin [2][23]. The implementation of this querying will eventually be done on ROXIE for financial institutions to use.

IV. Results and Discussion

Before there are three run tests that have been used to evaluate distributional similarities between the RTI data of two addresses. They are:

- Kolmogorov–Smirnov test
- Anderson–Darling test
- Cramér–von Mises criterion

Based on the composition of the reference and test query dataset, three evaluations were made,

- Illegal only test vs illegal only reference
- Illegal only test vs illegal and legal reference
- Illegal and legal test vs illegal only reference

The results obtained were evaluated based on precision, accuracy, f1-score and recall and only those addresses with at least 25 transactions were considered in both reference and query sets.

A. *Method 1*

In this method the test dataset consisted of only known illegal addresses and the references also consisted of only known illegal addresses. The size of the reference set was 263 and the size of the query set was 66. Table I summarizes these findings.

TABLE I. Illegal Only Test Vs Illegal Only Reference

Algorithms	Precision	Recall	f1-score	Accuracy
Kolmogorov–Smirnov test	1.00	0.85	0.92	0.85
Anderson–Darling test	1.00	0.77	0.87	0.77
Cramér–von Mises criterion	1.00	0.80	0.89	0.80

B. *Method 2*

In this method the test dataset consisted of only known illegal addresses but the references consisted of both known illegal addresses and random addresses which were considered legal. The size of the reference set was 304 and the size of the query set was 66. Table II summarizes these findings.

TABLE II. Illegal Only Test Vs Illegal and Legal References

Algorithms	Precision	Recall	f1-score	Accuracy
Kolmogorov–Smirnov test	1.00	0.85	0.92	0.85
Anderson–Darling test	1.00	0.79	0.88	0.79
Cramér–von Mises criterion	1.00	0.80	0.89	0.80

C. *Method 3*

In this method the test dataset consisted of known illegal addresses and legal addressee and the references consisted of only known illegal addresses. The size of the reference set was 263 and the size of the query set was 107. Table III summarizes these findings.

The following observations can be made from the above data. The Kolmogorov–Smirnov test consistently across all three methods either outperforms or is at par with the other two run tests in terms of accuracy. However, the f1-score is lower in general.

Given the f1-score is lower a further look into the recall and precision of the methods is called for. In the use case of detecting illegal addresses for financial institutions with virtually unlimited resources, it is possible to look into false positives and so a higher recall would be preferable. Here as well, the Kolmogorov–Smirnov test gives the highest recall except in the detection of legal addresses in method 3 where the Anderson –Darling test does better with 33%.

From method 3 we see a sharp contrast in detection between legal and illegal addresses. The f1 is consistently over double for all three run tests. This is due to the initial assumption that only 1% of addresses being involved in illegal activity is wrong and random selection of addresses has led to addresses that are not legal to be included making the query and test dataset impure. It is also because the activity that legal addresses are involved in and thereby the time series patterns generated vary too widely for a small sampling to represent them. This can cause legal addresses to be misclassified as illegal, leading to lower overall detection rates for legal addresses.

TABLE III. Illegal and Legal Test, Illegal Only Reference

Algorithms	Kolmogorov–Smirnov test					Anderson–Darling test					Cramér–von Mises criterion				
	class		*accuracy*	*macro avg*	*weighted avg*	*class*		*accuracy*	*macro avg*	*weighted avg*	*class*		*accuracy*	*macro avg*	*weighted avg*
	0	*1*				*0*	*1*				*0*	*1*			
Precision	0.47	0.64		0.56	0.57	0.46	0.65		0.55	0.58	0.41	0.62		0.52	0.54
Recall	0.22	0.85		0.53	0.61	0.32	0.77		0.54	0.6	0.22	0.8		0.51	0.58
f1-score	0.3	0.73	0.61	0.51	0.56	0.38	0.7	0.62	0.54	0.58	0.29	0.7	0.58	0.49	0.54
Support	41	66	107	107	107	41	66	107	107	107	41	66	107	107	107

The number of addresses with more than 25 transactions is a smaller fraction of the number of data points collected. This also points to other transactional behavior where bitcoin addresses are not reused as much or that bitcoin is often unused and parked in addresses. The limited number of addresses with more than 25 transactions suggests that the behavior of bitcoin addresses may vary widely and may not be accurately represented in the dataset.

The lack of data on illegal transactions and addresses limits the certainty of identifying illegal addresses. Therefore, the accuracy of the results may be affected, and false positives may occur.

V. Conclusion

The work supports the original hypothesis that bitcoin transaction behavior is nonrandom. The paper presents strong evidence that users engaging in illegal activity can be detected by use of previously known illegal addresses.

The simple use of timing data has proven to be quite effective. Paired with external information about the owner of an address or even network information available on the blockchain such as the amount being sent, the effectiveness could go higher.

One problem with any bitcoin illegal detection approach is the lack of data on illegal transactions and addresses. The dataset used in this paper does provide illegal addresses but only with a limited degree of certainty. Legal addresses are also seen to have a lower overall detection rate. This is likely due to the assumption of a percent of addresses being illegal being off while picking random addresses. While the Kolmogorov-Smirnov test may outperform the other run tests in terms of accuracy, the limitations of the dataset and assumptions made in the paper must be considered when interpreting the results. Further research and more comprehensive datasets are needed to improve the accuracy and reliability of illegal address detection in bitcoin transactions.

The method is only dependent on one feature which is the time interval data being generated, and since this is not a feature specific to bitcoin it can very easily be extended to other cryptocurrencies such as Ethereum, Luna etc. Similarly, it can be extended to other applications such as credit card fraud detection which have the added advantage of having precise transaction timestamp information and easy access to a person's history.

Strategic Monitoring for Efficient Detection of Simultaneous APT Attacks with Limited Resources

Fan Shen, Zhiyuan Liu, Levi Perigo
Department of Computer Science, University of Colorado Boulder
Boulder, Colorado 80309

***Abstract*—Advanced Persistent Threats (APT) are a type of sophisticated multistage cyber attack, and the defense against APT is challenging. Existing studies apply signature-based or behavior-based methods to analyze monitoring data to detect APT, but little research has been dedicated to the important problem of addressing APT detection with limited resources. In order to maintain the primary functionality of a system, the resources allocated for security purposes, for example logging and examining the behavior of a system, are usually constrained. Therefore, when facing multiple simultaneous powerful cyber attacks like APT, the allocation of limited security resources becomes critical. The research in this paper focuses on the threat model where multiple simultaneous APT attacks exist in the defender's system, but the defender does not have sufficient monitoring resources to check every running process. To capture the footprint of multistage activities including APT attacks and benign activities, this work leverages the provenance graph which is constructed based on dependencies of processes. Furthermore, this work studies the monitoring strategy to efficiently detect APT attacks from incomplete information of paths on the provenance graph, by considering both the "exploitation" effect and the "exploration" effect. The contributions of this work are two-fold. First, it extends the classic UCB algorithm in the domain of the multi-armed bandit problem to solve cyber security problems, and proposes to use the malevolence value of a path, which is generated by a novel LSTM neural network as the exploitation term. Second, the consideration of "exploration" is innovative in the detection of APT attacks with limited monitoring resources. The experimental results show that the use of the LSTM neural network is beneficial to enforce the exploitation effect as it satisfies the same property as the exploitation term in the classic UCB algorithm and that by using the proposed monitoring strategy, multiple simultaneous APT attacks are detected more efficiently than using the random strategy and the greedy strategy, regarding the time needed to detect same number of APT attacks.**

Keywords*—*Advanced persistent threats; intrusion detection; LSTM; multi-armed bandit

I. Introduction

Multiple malicious activities can happen simultaneously on a host or system, especially when it performs mission-critical tasks [1]. If the monitoring capacity (also referred to as monitoring resources throughout this paper) is limited, without thoughtful allocation of these resources, it is possible that some malicious activities will not be captured and identified. A generic way of allocating limited resources is to assign the monitoring resources to the most important or suspicious objects, which is also called a greedy strategy. One dilemma of the greedy strategy, however, is that, if the early perceptions about objects are not reliable, benign objects might consume more monitoring resources than malicious objects. Unfortunately, unreliable early detection of Advanced Persistent Threats is common, because such advanced attacks are stealthy and it is possible that an APT attack in its earlier stages is less suspicious than a benign activity. When using a greedy strategy to allocate resources, the Matthew Effect can cause some of the attacks to be undetected, because less monitoring resources are assigned to them. Therefore, an enhanced method to allocate monitoring resources, compared with the greedy strategy, is needed for the detection of simultaneous long-term attacks with limited resources, because this threat model has not been extensively addressed by existing works in the area of anomaly detection.

The research in this paper focuses on the detection of a sophisticated cyber attack, APT[2], and proposes a strategy to allocate limited security resources for monitoring, in order to efficiently detect APT activities when multiple APT activities are ongoing concurrently in a system.

II. Related Work

APT has attracted the attention of industry and academia since the 2010s, when several unseen yet powerful APT malware were discovered including Stuxnet, Duqu, Flame and Gauss. Although it is a multistage, complicated attack, the typical stages and behavioral patterns of APT are extracted by existing studies. For example, attack chain models based on Cyber Kill Chain [3] and the attack pyramid model [4] are proposed to characterize multiple APT stages and their relations. MITRE ATT&CK [5] constantly publish common tactics, techniques, and procedures (TTP) of APT attacks. Then according to the characteristics of APT, researchers use different methods to effectively detect it from illegitimate system access, suspicious network traffic patterns, and abnormal system resource utilization. Based on the categories of methods, APT detection studies are mainly divided into two categories: signature-based and behavior-based.

Signature-based detection methods match system behaviors with known attack patterns, once a match is found, pre-configured actions will be taken. Snort [6] is an example of signature-based intrusion detection system, which generates explicit rules from known attacks, if any rule is matched, it will trigger actions such as SNMP traps, event logging, and allow/deny traffic. The author [7] leverages the Intrusion Kill Chain [8] model defining rules to identify each APT stage by its attack mechanisms from multiple sources of logs and build the kill chain by comparing the timestamps of found APT stages. HOLMES [9] defines explicit rules to map a low-level system event to an abstracted APT TTP of MITRE ATT&CK and use the rules to identify each APT stage. As Command and Control (C2) communication is common in an APT campaign, network packet inspection or network flow analysis is used in some works to identify the C2 communication. The authors of [10] found consistent patterns in the network traffic between the APT malware of interest and the C2 server, and used protocol-aware rules, special strings in a URL, and malformed images to effectively detect C2 communication. Signature-based detection methods are effective to attacks whose characteristics are known and can be well-represented by a set of matching rules, and when compared with behavior-based methods, signature-based methods are less complicated and easier to implement. However, the performance of signature-based methods can degrade quickly when dealing with variants of known attacks and novel or zero-day attacks.

Behavior-based detection methods do not rely on known patterns, and they profile behaviors, either benign or malicious, using statistical or machine learning methods [11]. The advantage of such detection methods is being able to accommodate variations and uncertainties of behaviors and characterize behaviors that can not be represented by explicit matching rules. To identify suspicious hosts that might be involved in C&C communications, the authors in [12] characterized each host periodically using features extracted from network flows, then assigned a risk score to each host based on the deviation from its historical positions, distances from other hosts, and magnitude of increment in the feature space. The authors [13][14] focus on detection of spear phishing emails that are used for initial penetration in APT. The authors of [13] extract static and dynamic features of PDF files attached in emails, and propose a classification model using Support Vector Machine, to detect malicious PDF files. Active learning is also integrated in their model to cope with unseen PDF files. The researchers in [14] used Naïve Bayes theorem to detect spam emails containing links that redirect the victim to malicious websites, which could help APT attacker establish backdoors inside the victim's system. The study [15] proposes an ensemble RNN-based model to detect different APT steps by analyzing network traffic data. Host-level system logs are analyzed in [16] to identify different APT phases. The authors of [16] first translated system log sequences into abstracted states by using the hidden Markov model, then fed high-level state sequences to three multi-classification models: LSTM, one-dimensional CNN, and SVM, to predict the APT phase. Since the detection of a single APT stage does not necessarily indicate a multistage APT activity, some works [4][17][18][19] detect APT by correlating detection results of different APT stages based on models that describe dependencies between stages.

In existing studies on APT detection, the resource allocation problem is rarely addressed; whereas, it is a popular topic in game-theoretic studies [20][21] on APT prevention. Resource constraints, however, do exist in APT detection, either only a portion of CPU and memory can be used for monitoring activities in a system, or only limited insights can be obtained from enormous monitoring data in a timely manner. In a worse-case scenario, if multiple attacks concurrently exist in a system, and monitoring resources are not enough to cover all attacks, it is critical that the system operator allocate limited resources efficiently so that the most attacks possible are detected. Therefore, this work focuses on multistage APT attacks, and proposes a novel strategy that allocates monitoring resources, not only based on the current malevolence of activities, but also introducing an exploration mechanism to eliminate the side effect of a greedy strategy when the malevolence calculation based on early stage information of APT is not reliable.

III. Threat Model

In this work, simultaneous and continuous APT attack activities exist in the defender's system. For each multistage APT attack, each of its stages can be detected if relevant behavior is monitored. It is assumed that a whole-system provenance graph is used to obtain all paths including non-APT paths and APT paths. However, to reflect a real-world scenario, the monitoring capability of the defender's system is limited, so that only the activity on some, but not all, paths can be monitored and analyzed at each timestamp. Every monitoring timestamp provides a classification result indicating that the monitored activity is benign or one of APT stages. Therefore, for each path on the provenance graph, the defender has a sequence of temporal but incomplete detection results about the activities on the path. Thus, the goal of the defender is to efficiently detect as many simultaneous APT attacks as possible, while utilizing limited resources.

IV. Problem Setting

To capture the footprint of system activities, this work leverages the provenance graph which is constructed based on the dependencies of processes. It is assumed that the provenance graph is complete and not compromised in this paper. Therefore, the movement of a multistage APT attack is represented by one of the paths on the provenance graph, and in the threat model of this paper, the defender needs to detect those attack paths efficiently with limited resources. In addition, to decide the identity of a path, benign or APT, monitoring and investigation is used to check the state of nodes on a path. At each timestamp, however, not all running nodes can be checked because the monitoring resources are limited. Therefore, the research question addressed in this paper is, how to allocate limited monitoring resources, (i.e. select which running nodes should be evaluated at each timestamp), so APT attacks are detected effectively in terms of the number of detected attacks, and efficiently in terms of time needed? And a strategic monitoring model which considers both the estimated malevolence of system activities and the uncertainty of that estimation is proposed to solve the problem.

The problem setting of this paper is described as follows. There are n processes running on a host, which correspond to n paths on the provenance graph, but at each timestamp, only k ($k < n$) processes can be monitored and investigated to get the current state of the corresponding path. In this paper, when a process is chosen to be monitored, its local structure is fed into the detection engine developed by [11] which outputs a classification result. Mathematically, for each path i ($i \in [1, n]$), at time j, if the process corresponding to path i is monitored, the current state of path s_{ij} is obtained from the detection engine and $s_{ij} = \{0, 1, 2, 3, 4, 5, 6\}$; if the process corresponding to path i is not monitored, the current state of path s_{ij} is unknown and is represented by $s_{ij} = -1$. In this paper, the defender decides which k processes are selected to be monitored at each timestamp, based on historical and temporal state information of each path.

V. Strategic Monitoring Model

In this paper, a scoring mechanism is proposed to decide which k processes to monitor at each timestamp, in other words, to solve a sequential decision making problem to identify all simultaneous APT attacks as early as possible. The proposed scoring rule is derived from a classic multi-armed bandit algorithm Upper Confidence Bound (UCB) [22]. The purpose of a multi-armed bandit problem is to maximize the cumulative reward by sequentially selecting arms to pull, by assuming the existence of uncertainties in the reward of each arm [23]. The UCB algorithm integrate both the exploitation effect (observed mean reward of each arm so far) and the exploration effect (number of times each arm has been pulled) when prioritizing arms. The index of arm i at time t is calculated as follows:

$$I_i(t) = \bar{\theta}_i(t) + \sqrt{2\frac{\log t}{\tau_i(t)}} \tag{1}$$

where $\bar{\theta}_i(t)$ is the sample mean reward of arm i, which is the exploitation factor meaning that arms with higher historical reward are prioritized; $\tau_i(t)$ is the number of times arm i has been pulled, which is the exploration factor meaning that the less pulled arms are prioritized.

It is appropriate to apply UCB to solve the monitoring strategy in the threat model of this paper, because the detection of multistage APT relies on sequential decisions of monitoring to obtain temporal state of each system behavior path. Therefore, the proposed scoring mechanism is a variation of the UCB algorithm, replacing the sample mean reward with the current malevolence value of a path. One novelty of this paper is that, it extends the UCB algorithm to the multistage APT detection scenario by proposing to use a long short-term memory (LSTM) based malevolence value as the exploitation driver, and showing that this modification to the UCB algorithm is reasonable. The proposed scoring rule is formulated as follows:

$$I_i(t) = \alpha \cdot f_i([s_{i1}, s_{i2}, ..., s_{it}]) + (1-\alpha) \cdot \sqrt{2\frac{\log t}{\tau_i(t)}} \tag{2}$$

where $I_i(t)$ is the index or score of path i at time t which is a weighted sum of an exploitation term and an exploration term; $f(\cdot)$ is a neural network that takes the temporal state information of path i as input and outputs the current malevolence value the path i; the exploration term is the same as in Equation 1; and α is a constant in $[0, 1]$.

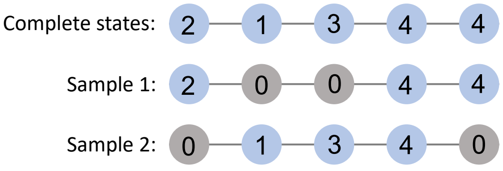

Fig. 1. Different samples generated from a sequence of complete states of a system behavior path.

A LSTM neural network is used to assign a malevolence value to a system behavior path based on its temporal states information. Samples of paths with various temporal states are used to train the neural network. In this paper, these samples are generated from complete state sequences of both benign behavior paths and APT behavior paths, by randomly selecting some states and making them unknown. For example, as shown in Fig. 1, the top row indicates that the state of an "APT attack" path at every timestamp is known, thus the sequence of states is complete (1 represents the state is benign, 2-4 represent different APT stages). To generate samples e.g. "Sample 1" and "Sample 2" resulted from incomplete monitoring in a scenario where resource constraints exist, some timestamps of the complete sequence are masked with value 0 representing that the state information at those timestamps become unknown. Note that, the class of "Sample 1" and "Sample 2" is still "APT attack". By choosing different values for the number of timestamps that are masked, samples with different incompleteness are generated, and together with their classes they are used to train the LSTM model which outputs how likely a sequence of states is an APT attack. There are two classes in the data: "1" for APT attack behavior paths; "0" for benign behavior paths. The LSTM neural network is trained to output a value in $[0, 1]$. A higher LSTM output value indicates a more suspicious behavior path, and this value is used as the exploitation factor in Equation 2: the more suspicious the behavior path is, the more likely it would be monitored next time. The second term in Equation 2 is the exploration factor, meaning that the less frequently the behavior path was monitored, the more likely it would be monitored next time.

VI. Experiments

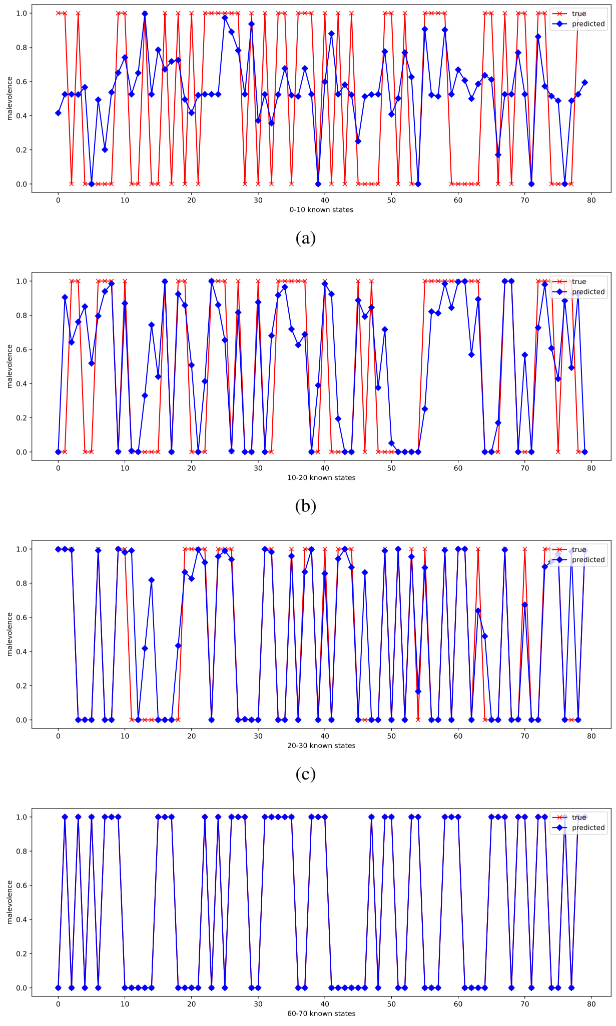
To evaluate the performance of the proposed monitoring strategy developed in this research, synthetic behavior paths with temporal states for both benign scenario and APT attack scenario are generated and implemented. Two principles are followed when generating the synthetic data: (1) all states at a timestamp ($\{1$: "benign"; 2: "APT stage 1"; 3: "APT stage 2"; 4: "APT stage 3"; 5: "APT stage 4"; 6: "APT stage 5"; 7: "APT stage 6"$\}$) can appear on a behavior path of benign scenario and APT attack scenario; (2) the temporal order of states is differentiated on a behavior path of benign scenario and on a behavior path of APT attack scenario. More specifically, the states corresponding to APT stages on the behavior path of a benign scenario are uncorrelated; however, the states corresponding to APT stages on the behavior path of an APT attack scenario are correlated in the sense that, without interruption an APT attacker gradually moves from lower APT stages to higher stages because the attacker does not have incentive to move from higher APT stages to lower stages. In addition, a random number of benign states appear between APT related states on behavior paths of both benign scenarios and APT attack scenarios. By following these principles, 100 attack paths and 100 benign paths with 80 complete temporal states are generated. Then, each complete path generates 79 incomplete paths by randomly hiding i ($i \in [1, 79]$) states. Eventually, 8000 APT attack paths and 8000 benign paths with various degrees of incompleteness are generated and used to train and test the LSTM model in this paper.

The first part of the experiment is to demonstrate that using the output of a novel LSTM neural network as the exploitation term in the proposed model is effective, in other words, the trained neural network should satisfy the same property as the exploitation term defined in the classic UCB algorithm. In the classic UCB algorithm, the property of the exploitation term is that, as an arm is pulled more often, the estimation to its reward becomes more accurate. Therefore, the proposed LSTM neural network is tested on behavior paths of which the defender has different degrees of information incompleteness. If the LSTM neural network is effective, it is desired that its estimation to the malevolence of paths is more accurate as the defender's information incompleteness of paths decreases.

The second part of the experiment is to demonstrate the performance of the proposed monitoring strategy. Before evaluation, 20 behavior paths are randomly selected from the data set, including four APT attack paths and 16 benign paths. Then, the the proposed monitoring strategy, a random strategy and a greedy strategy are evaluated respectively, in terms of when the attack paths are detected and the number of false positives. In the experiment setting, only five paths can be monitored at each timestamp, a random strategy means that the five monitored paths are randomly selected; a greedy strategy means that the paths with five highest malevolence scores are selected, in other words, only the exploitation effect in the proposed strategy is considered; the proposed strategy selects the 5 paths with the highest scores where the score is defined as the weighed sum of the exploitation factor and the exploration factor are selected. In addition, two termination conditions are applied when implementing the proposed strategy: (1) when the malevolence score of a path is greater than β, the path is determined as an APT attack and will no longer be a candidate of being monitored; (2) when the malevolence score of a path is smaller than γ, the path is determined as a benign scenario and will no longer be a candidate to be monitored. By testing different sets of parameter values, the best parameter values of the proposed strategy are used to compare the proposed strategy with other strategies, including the weight parameter α in Equation 2 ($\alpha = 0.82$), and two threshold parameters β ($\beta = 0.9$) and γ ($\gamma = 0.05$).

VII. Results and Analysis

Fig. 2 shows the performance of the LSTM neural network in the proposed strategic monitoring model. From Fig. 2(a) to Fig. 2(d), the number of known states of paths increases, in other words, the defender's information incompleteness of paths decreases. The red line represents the true malevolence of paths, and the blue line represents the predicted malevolence of paths by the LSTM neural network. It can be seen that the difference between the true malevolence values and predicted malevolence values by the LSTM neural network becomes smaller, when the number of known states increases. Therefore, the estimation of the LSTM neural network to the malevolence of a behavior path becomes more accurate along the path that is monitored more frequently, making the output of the LSTM neural network an effective exploitation term in the proposed monitoring strategy model.



(a)

(b)

(c)

(d)

Fig. 2. Comparison of true and predicted malevolence of paths with various number of known states.

To demonstrate the performance of the proposed monitoring strategy, it is compared with a random strategy and a greedy strategy, and the results of the three strategies including the paths monitored at each timestamp as well as when attacks are detected are visualized in Fig. 3, Fig. 4, Fig. 5 respectively. Note that, in Fig. 3 to 5, each row i represents a behavior path and the rows with light red shade means that the row represents an APT path. Each column j represents a timestamp, and at each time j, the defender can pick $\max(5, u_j)$ paths to monitor where u_j is the number of undetermined paths at time j. For a position (i, j) where $i \in [1, 20]$ and $j \in [1, 80]$, if it is in blue, it means path i is monitored at timestamp j; if it is in red, it means path i is classified as an APT attack scenario at timestamp j and it will no longer be monitored which is represented by marking its future states as grey; if it is in green, it means path i is classified as a benign scenario at timestamp j and it will no longer be monitored which is represented by marking its future states as grey. Therefore, the number of undetermined paths u_j is the number of paths that are not in grey at time j.

Fig. 3 shows the results of using a random strategy, which means that the defender randomly picks paths to monitor at each timestamp. The four APT attacks paths are detected at timestamp 57, 50, 49 and 41. In addition, the number of false positives is 2.

Fig. 4 shows the result of using a greedy strategy, which

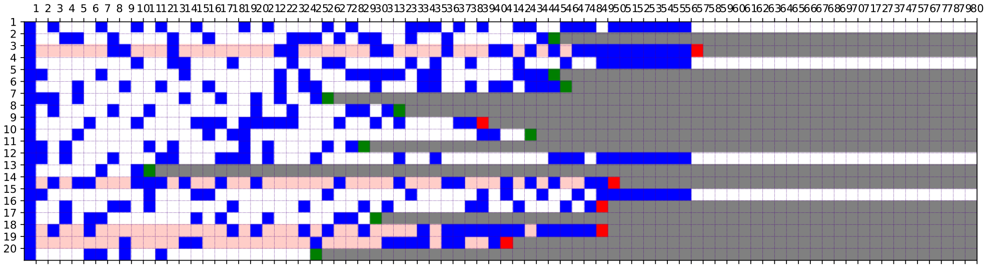


Fig. 3. Performance of the random monitoring strategy.

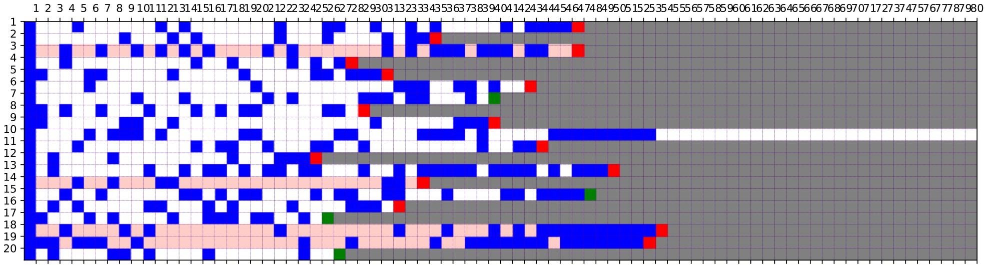

Fig. 4. Performance of the greedy monitoring strategy.

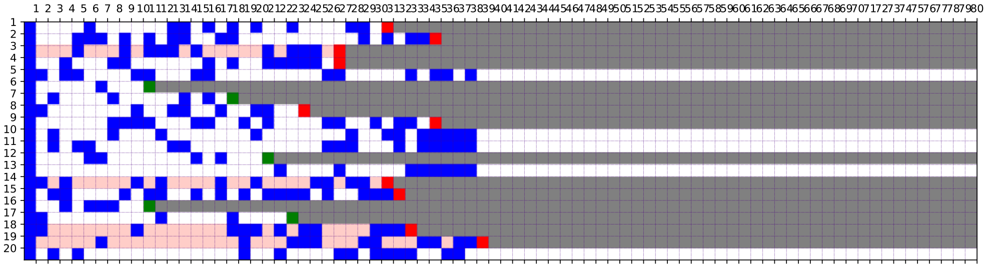

Fig. 5. Performance of the proposed monitoring strategy.

means that the defender picks paths with the highest malevolence values predicted by the LSTM neural network. The 4 APT attacks paths are detected at timestamp 47, 34, 54 and 53. In addition, the number of false positives is 11.

Fig. 5 shows the result of using the strategy developed by this paper, which means the defender considers both exploitation and exploration then picks paths with the highest values calculated by Equation 2. The 4 APT attacks paths are detected at timestamp 27, 31, 33 and 39. In addition, the number of false positives is 6.

Compared with the other two strategies, the monitoring strategy proposed in this paper detects all 4 APT attacks significantly earlier, specifically nearly 17 timestamps earlier than the random strategy, and 15 timestamps earlier than the greedy strategy. The key to the efficiency of the proposed strategy is that by considering exploration when the malevolence estimation is not as accurate in early timestamps, the defender is able to identify some benign paths quickly, which reduces the number of competitors of limited monitoring resources. However, the random strategy treats benign paths and attacks paths equally and the greedy strategy can be misled by inaccurate malevolence in earlier stamps, thus they are less efficient in the detection of simultaneous APT attacks.

When facing advanced attacks like APT, false positive is more acceptable compared to false negative, because missing an APT attack is more devastating than looking into a benign activity which is falsely classified as attack. Regarding the number of false positives in the experiments, the proposed strategy is better than the greedy strategy, but is worse than the random strategy. This is as expected, because from Fig. 3, it takes longer and relies on more information for the defender to determine the identity of a path when using the random strategy. With more information, the malevolence estimation to a path is more accurate at shown in Fig. 2, however, the random strategy is the least efficient regarding the time needed to detect simultaneous APT attacks. Therefore, overall the proposed strategy outperforms the other two strategies regarding the metric of efficient detection of simultaneous APT attacks with limited resources. And the improvement on other metrics is left as a future extension.

VIII. Conclusion

The work in this paper addresses the issue of resource constraints in the detection of multiple simultaneous APT attacks. It proposes a monitoring strategy to efficiently detect APT attacks with incomplete information about activities in a system. The key of the proposed strategy is that it considers both the “exploitation” effect and the “exploration” effect in resource allocation, which is beneficial for finding the optimal strategy in circumstances with high uncertainties. The novel contributions of this work to address the research question are as follows.

First, differing from existing works that allocate security resources based on the estimated malevolence of system activities only, this work emphasizes the importance of “exploration” in APT detection, because the perception to advanced and stealthy attacks based on its earlier stage information is usually not accurate. This work is the seminal paper to consider both the “exploitation” effect and the “exploration” effect in monitoring resource allocation, and apply the classic multi-armed bandit algorithm, UCB, to solve optimal resource allocation problems in APT defense.

Second, this work proposes a novel LSTM neural network to measure the malevolence of a path on the provenance graph based on its incomplete temporal information, and replaces the exploitation term in the classic UCB algorithm with this malevolence value. The experimental results show that by using the proposed monitoring strategy, multiple simultaneous APT attacks are detected more efficiently than using a random strategy and a greedy strategy, regarding the time needed to detect same number of attacks.

Although the proposed model shows the advantage of detecting simultaneous APT attacks efficiently with limited resources, a future extension to this work is to enhance the model in terms of more metrics, for example, reducing false positives by exploring more features of APT to differentiate it from benign activities more effectively.

***Abstract*—With the continuous improvement of technology, modern sports training is gradually developing towards precision and efficiency, which requires more accurate identification of athletes' sports stances. The study first establishes a classification structure of basketball stance, then designs a hardware module to collect different stance data by using inertial sensors, thus extracting multidimensional motion stance features. Then the traditional convolutional neural network (CNN) is improved by principal component analysis (PCA) to form the PCA+CNN algorithm. Finally, the algorithm is simulated and tested. The outcomes demonstrated that the average discrimination error rate of the improved PCA+CNN algorithm in the Human 3.6M dataset was 3.15%, which was a low error rate. In recognition of basketball sports pose, the wearable based on the improved algorithm had the highest accuracy of 99.4% and took the quietest time of 18s, which was better than the other three methods. It demonstrated that the method had high discrimination precision and recognition efficiency, which could provide a reliable technical means to improve the science of basketball sports training plan and training effect.**

I. Introduction

When basketball players training and contesting program is to be devised then developing a scientific and rational training program based on individual circumstances is the basis for improving their skills[1]. Considering player's actual ability, traditional training methods use experience and theory as a reference for the development of the program. However, this model is highly subjective and requires much time to analyze athletes' gestures, which is hard to meet the requirements of modern sports training. When coaches control the various postures of different athletes accurately, the training effect will be greatly raised, so it is important to collect and analyze posture data to achieve accurate identification. Basketball posture is one of the human postures, and today's human posture recognition is based on image acquisition and inertial sensor-based posture recognition [2]. The image acquisition stance recognition is achieved through camera image, video acquisition or different classifiers, whose technical maturity is high. But it has drawbacks that it needs a large amount of equipment and it is difficult to be applied widely. On the other hand, inertial sensor recognition is achieved by wearing a data acquisition sensor, which transmits the collected data in real time. Finally, the processing terminal completes the recognition. Its high recognition efficiency and low requirements for the use of the environment have become a research hotspot in this field [3]. In addition, with the increasing penetration of deep learning in various fields, the CNN, it contains, is used in discrimination widely. Therefore, in order to improve the recognition accuracy of the deep learning algorithm in basketball posture, wearable devices are applied in basketball training. This paper studies the recognition of basketball posture based on inertial sensors and convolution neural network. At the same time, the convolution neural network is improved by principal component to provide more high-performance auxiliary training technology for basketball.

II. Related Works

Deep learning algorithms are highly capable of learning, cover a wide range of areas, and can exhibit greater stability as more data is available. Through deep learning algorithms, the recognition of motion gestures has attracted huge attention from many professionals recently. And a series of forward-looking and practical research outcomes have been achieved. Hu B et al. developed a gesture recognition system based on UAV control for dynamic gesture recognition instead of human-machine interaction. This system used 8-layers CNN, 5-layers fully connected network and 2-layers fully connected network that could convert 4-D spatio-temporal data into 1-D and 2-D matrices to model the data of gesture sequences. The experimental outcomes demonstrated an average accuracy of 89.1% in the unscaled dataset [4]. Azad R's team designed a multi-level temporal sampling method based on depth sequence key frames for gesture recognition in computer vision. And they combined it with weighted depth motion maps to extract spatio-temporal information in the sequences by accumulating weighted absolute differences in successive frames. The outcomes demonstrated that the method had great precision [5]. Sun Y et al. made a posture discrimination processing framework based on a radar system with a shallow CNN whose input is a feature cube. And it could feed gesture contours into the CNN through lower latency. Experimental outcomes demonstrated that the framework achieved 92.08% accuracy in performing real-time classification of 12 gestures [6]. Zhang Y's team addressed the human-computer interaction in wearable devices. A benchmark dataset called EgoGesture was proposed to address the problem of human-computer interaction in wearable devices. In static and dynamic gesture recognition of different scenarios, it performed well with sufficient variability and realism when training deep neural networks [7]. The outcomes demonstrated that the method could achieve the discrimination of different body movements in basketball with a high accuracy rate [8]. Pan T Y et al. developed a gesture discrimination way based on multiple inertial measurement unit transducers, which could record the rotation information and acceleration of hand joints. And the average precision in the discrimination of basketball referee signals was 90.02% [9].

Zhao Y et al. designed a 3D position estimation method with an integrated ankle sensing device consisting of a magnetometer, accelerometer, gyroscope and barometer. And they added vertical variables to the adaptive multimodal stride in combination with it. Experimental outcomes demonstrated that it raised the applicability and precision of pedestrian horizontal position estimation [10]. Neethu P S's team applied a convolutional neural network classification method to human hand gesture detection and recognition, which extracted fingertip features in hand images by a connected component analysis algorithm. The outcomes demonstrated that the method had good operational performance [11]. Zhang W et al. applied deep learning networks to gesture recognition for human-computer interaction in hand gestures. It learned short-term and long-term features in the video input and feeded into a CNN for feature extraction. Experiments on the Jester and Nvidia datasets demonstrated its high accuracy [12]. Lian C et al. designed an IoT wristband to facilitate quantitative shooting action guidance for basketball players, which used a miniature inertial measurement unit sensor and was capable of collecting. The outcomes demonstrated that it was able to achieve 98.0% accuracy for layups, free throws, positioning shots and jump shots. And the overall accuracy was nearly 97.5% for 18 out of 18 shooting motions [13]. Kamel A's team developed a way for discriminating depth maps and pose data through convolutional neural networks, which used two inputs to describe the action representation. That is, a depth motion image that accumulates human movements and a motion joint descriptor that represents body joints over time. And the action prediction outcomes are generated from three CNN channels, which are experimentally demonstrated to be around 6.84% higher than general recognition methods [14]. Adithya V et al. applied CNN in deep learning to solve the problem of automatic sign language recognition by capturing gesture images and deriving complex feature descriptors. The outcomes demonstrate that it has good recognition accuracy on the hand gesture dataset [15].

To sum up, most researchers had proposed corresponding recognition methods for motion, gesture and human posture recognition. And these methods had improved the convolutional neural network in deep learning, which had achieved good application results. However, few people combined convolution neural network with inertial sensors, and there was a lack of research on the application of wearable devices in basketball motion recognition. And there was little research on the recognition of basketball posture. Therefore, the research first improves the action recognition effect of convolutional neural network, and combines it with wearable devices to apply it in basketball training, so as to improve the level of basketball training.

III. Basketball Pose Recognition based on Deep Learning Algorithms

A. *Basketball Posture Recognition Model and Wearable Device Design*

There are very complex and variable body movements during basketball. To carry out effective and accurate posture recognition, it is necessary to establish a scientific and comprehensive posture classification [16]. Based on the various limb states of the basketball player, the first two categories are static and athletic [17]. The athletic state is athletes' performance of different basketball actions, where the limbs remain in motion. While the resting state is the state in which the athlete's limbs do not perform any action and are strictly static. To effectively discern sporting gestures, the study has implemented a progression of two levels. In the first level, there are two types of movement gestures, namely transient and continuous, based on whether they are cyclical or not. And in the second level, it is further divided into seven stances, namely running, jumping, shooting, catching, passing, walking and dribbling, according to whether the movement state is lower or upper limb. The recognition of basketball movement stance actually becomes a recognition of the movement stance proposed by the automatic recognition. The classification of basketball sports stance is demonstrated in Fig. 1.

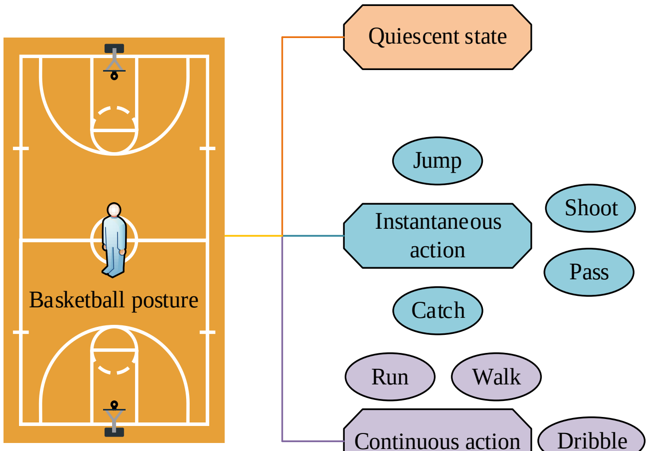

Fig. 1. Classification structure of basketball posture.

After determining the individual basketball postures, the wearable device is optimized. Timely and accurate gesture data acquisition is essential for accurate identification, so the research designs a basketball gesture data acquisition module based on inertial sensors in the wearable device. The data is first collected by using angular velocity, magnetic and acceleration sensors fixed to the basketball player. Then it is transmitted to the terminal device using wireless sensors for gesture discrimination. The hardware of the data acquisition includes data acquisition and transmission, containing a base station for data transmission and four nodes for information collection. Together form the data acquisition points which contains the acceleration and palstance information of the human body, the tri-axial accelerometer, tri-axial gyroscope MPU3050 and magnetometer LSM303DLH are collected. The wireless transceiver nRF24L01 is the core component of the data transmitting site and is for receiving information from the nodes and transmitting this data to the data terminals via the wireless network. For the information collection module, the microcontroller STM32F103 is for the core processing functions. At the same time, a 3.7V lithium-ion battery completes the energy supply for this module, the hardware structure is shown in Fig. 2.

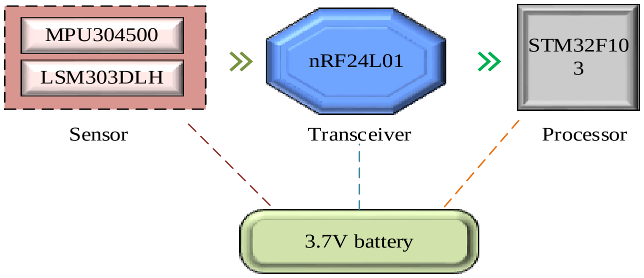

Fig. 2. Hardware structure diagram of basketball player posture data acquisition module.

In the data acquisition module, the signal transmission is carried out containing two parts. Firstly, the information conveying site receives the human posture data from the sensor nodes. Secondly, it is transmitted to the processing terminal. This part needs to minimize data collision rates and retain data to prevent large amounts of data loss, thus improving the accuracy of the collected data. The star topology network is the basis for the signal conveying between the processing terminal and the information conveying station, which is carried out via a time division multiplexing protocol. And the calibration of the clock deviations of the different nodes to maintain time uniformity is key to this. In conjunction with the classification of the basketball stance, four sensor nodes are set up in the legs and arms to obtain accurate data on the legs and arms of the athlete to collect magnetic field strength, acceleration and palstance data. The acceleration vector addition and the palstance vector addition for the n sampling point are calculated as demonstrated in equation (1).

$$\begin{cases} a_n = \sqrt{(a_n^x)^2 + (a_n^y)^2 + (a_n^z)^2} \\ p_n = \sqrt{(p_n^x)^2 + (p_n^y)^2 + (p_n^z)^2} \end{cases} \tag{1}$$

In Eq. (1), a_n^x, a_n^y and a_n^z correspond to the axial accelerations of x, y and z at the first n point, respectively, while p_n^x, p_n^y and p_n^z represent the corresponding angular velocities. a_n and p_n are the combined motion of the accelerations and palstance, respectively. The vector sums and three vectors of acceleration and angular velocity are then combined to form an 8-dimensional feature matrix. When the sampling point is N, each sample owns a feature matrix of $N \times 8$. The mean and variance are the time domain characteristics identified, and the mean and variance of each point is calculated as demonstrated in Eq. (2).

$$\begin{cases} \delta^2 = \frac{1}{N}\sum_{n=1}^{N}(a_n - \mu_a)^2 \\ \mu_a = \frac{1}{N}\sum_{n=1}^{N} a_n \end{cases} \tag{2}$$

In equation (2), δ^2 represents the mean value and μ_a is the variance. The time domain data is then transformed into the frequency domain data by the Fourier transform, which is calculated as demonstrated in Eq. (3).

$$S(n) = \sum_{i=0}^{N-1} a_i e^{-j\frac{2\pi}{N^n}} \tag{3}$$

In Eq. (3), $S(n)$ represents the value of adoption point n, where the frequency domain is located. The time domain features required for basketball gesture discrimination is actually the peaks of the Fourier transform, as demonstrated in equation (4).

$$f = \frac{Kf_s}{N} \tag{4}$$

In equation (4), K represents the quantity of frequency domain sampling point and f_s represents the sampling frequency. After the motion stance features are extracted, a 32-dimensional feature parameter set is obtained. For these parameters as a whole, there are some features with low or even no correlation with basketball motion pose. And there are also some features with redundant information between them, which seriously affect the classification efficiency and performance. Therefore, the study needs to make feature dimensionality further being reduced to achieve better recognition outcomes.

B. Motion Pose Recognition based on Convolutional Neural Networks

After obtaining the basketball pose data features, a CNN is used to downscale and identify the features. A CNN includes convolutional layers, pooling layers, activation functions and fully connected layers [18]. In general, the upper layers are convolutional layers, and then one or more fully connected layers are cascaded. All fully connected and convolutional layers are followed by an activation function, which is used as a non-linear transform. At the same time, pooling layer is after convolutional layer, which serves to reduce the amount of data contained in the intermediate outcomes. In a convolutional neural network, the convolutional layer is the most basic unit [19]. Under the action of mapping, a well-trained convolutional layer automatically and efficiently extracts features from the data and transfers the original data to the hidden feature space. The fully connected layer is the classifier in CNN, which maps the learned features to the sample data labeling space. At the same time, the essence of the operation in this layer is the multiplication of vectors and matrices. If it is transformed into vector form after the straightening operation, only the convolutional layer feature map can be input to the fully connected layer [20]. The pooling layer differs significantly from the fully connected and convolutional layers. Because it has no bias or weight parameters and is mostly used to lowering feature map. Thereby, the redundancy is eliminated significantly in the feature map. Among the pooling approaches, maximum and average pooling are more widely used. Similar to the convolutional layer, the pooling mode slides through a box n_1 high and n_2 wide, over all the input channels of the feature map. And it finds the maximum or average value in this box and the size of the box are usually consistent with the step size of the slide. The activation function acts as the key step in the convolutional neural network to complete the non-linear mapping. And almost all fully connected and convolutional layers must go through it. The missing activation function will cause the stack of fully connected layers and multiple volume layers. It is equivalent to the multiplication of multiple matrices to finally get a matrix, resulting in the original data not being activated to obtain a strong fit. The basic structure of CNN is demonstrated in Fig. 3.

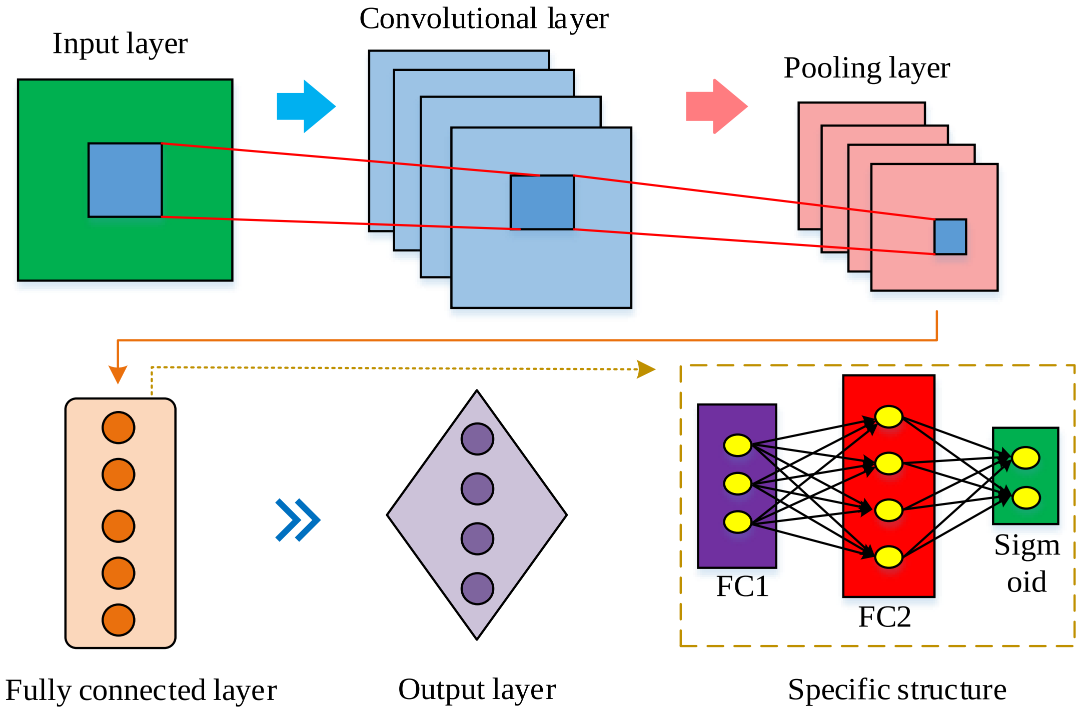

Fig. 3. Basic structure of convolutional neural network.

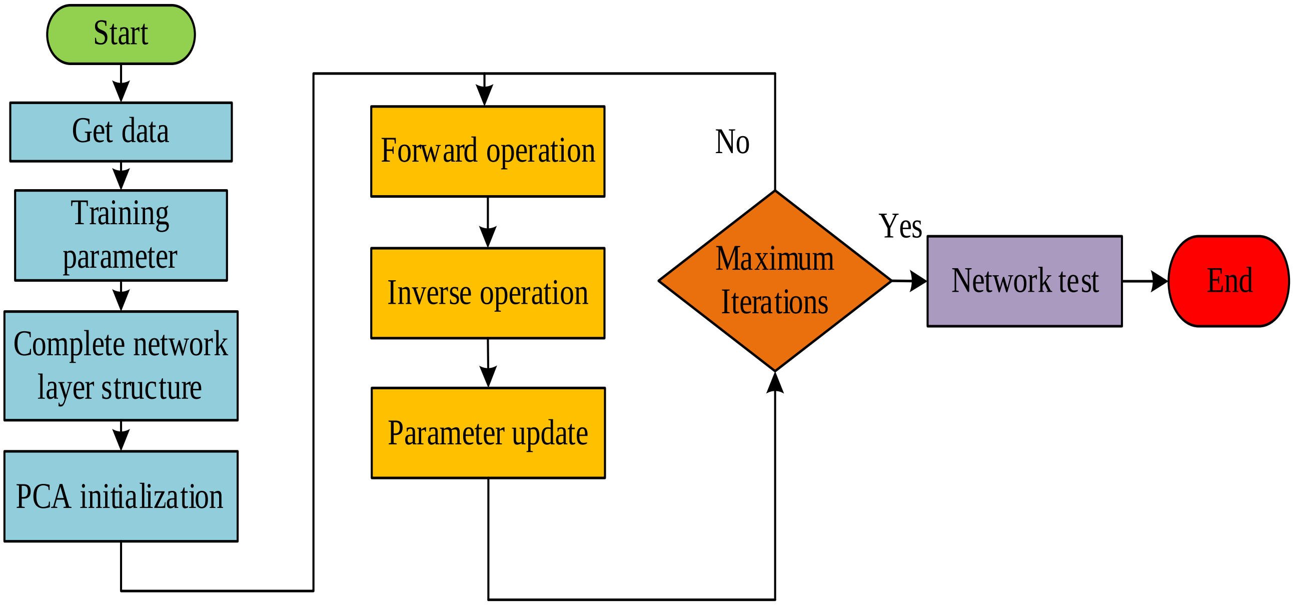

Fig. 4. Algorithm flow of CNN with principal component analysis.

The multi-layer perceptron is the basic structure of a fully connected layer in CNN, including input and output layer, with a weight matrix connecting the layer to the layer [21]. The input layer is formed by the upper layer feature map after vectorization. After the inner product of the input vector and the weight matrix, and mapped by the activation function, the outcome is obtained for the output layer. The calculation is demonstrated in Eq. (5).

$$y_{pj}^{l} = f\left(\sum_{i=0}^{N^{l-1}} X_{pj}^{l-1} \cdot b_{j}^{l} + w_{ji}^{l}\right) \tag{5}$$

In Eq. (5), f represents activation function, N is the quantity of neurons, b represents the neuron bias, w is the weights. l is the convolutional layer sequence, j is the feature map sequence, and p is the training sample sequence. As the number of layers in the network increases, the extracted features become more abstract and discriminative, and these features facilitate the classification of basketball poses. At the same time, the features give feedback to the extraction of shallow features [22]. The main problem with convolutional neural networks is the network parameters training and updating. To raise the ability of basketball posture recognition, principal component analysis is introduced to integrate with convolutional neural networks. Principal component analysis is a statistically based feature extraction method that can filter features with a high correlation, i.e. selecting the optimal sign. At the same time, the principal component analysis method has a high similarity with the learning outcomes of self-coding neural networks. Therefore, the study uses this method to perform multiple calculations on all convolutional kernel sets in layers. The convolutional kernel parameters are initialized to optimize the convolutional neural network performance. The optimized algorithm is demonstrated in Fig. 4.

In Fig. 4, the improved convolutional neural network first completes all network layer structures based on training and test data, then the training parameters can be defined. From there, the initialized network parameters are analyzed by principal component analysis, followed by forward and backward operations for network training. Then parameter updates are implemented. Finally the network is tested and concluded by determining whether iterations has been reached to complete the network. The principal component analysis method calculates the input layer feature vector set V and then orients the first L of the vector set. These can be used as the principal component feature vector of the input sample data set, thus forming the convolutional kernel set $V1$ of the $C1$ layer, as demonstrated in Eq. (6).

$$\begin{cases} \min \left\| Y - V_1 V_1^T Y \right\|_F^2 \\ V_1^T V_1 = I \end{cases} \tag{6}$$

In Eq. (6), I represents the unit matrix and V_1 represents the training data fed into the convolutional neural network. In the convolutional layer $C2$, the same method is used to treat the feature maps from the previous layer as the sample set for the principal component analysis. So it outcomes in the convolutional group $V2$ of the $C2$ layer. According to the convolution and size, and used as the initialization values for the corresponding layer's convolution kernel, all the column vectors contained in all the computed feature vectors are arranged, which finally completes the convolution kernel initialization. The optimized convolutional neural network model is in Fig. 5.

Finally, the optimized convolutional neural network is applied to the wearable device classifier to obtain different basketball motion pose types, thus completing the output of the recognition outcomes.

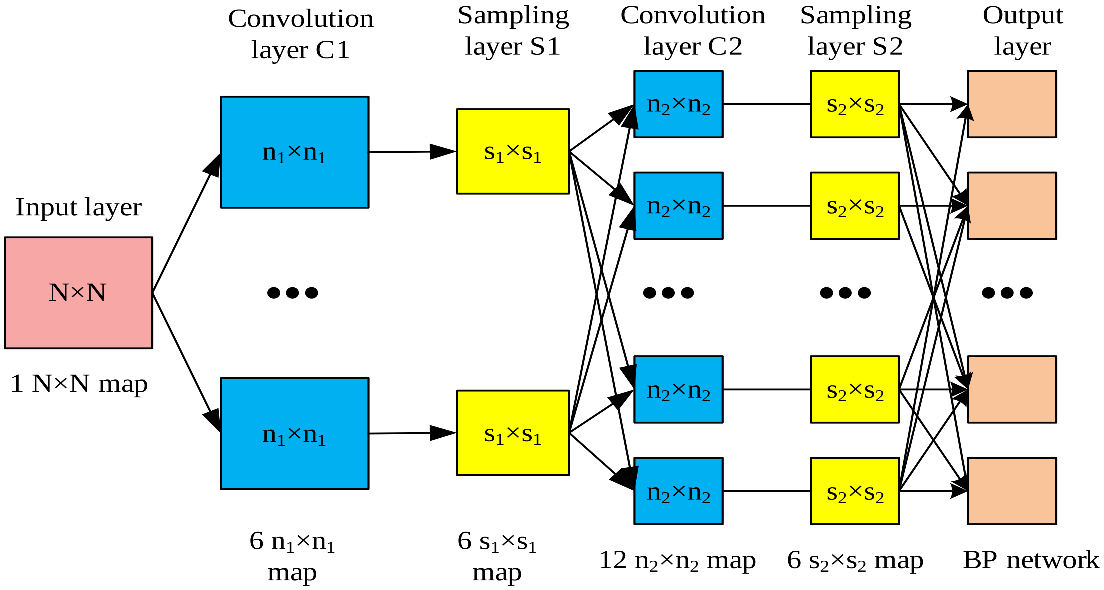

Fig. 5. CNN optimized by introducing principal component analysis.

IV. Analysis of Basketball Posture Recognition Outcomes based on Improved CNN

The function of the PCA-improved CNN is first examined. The simulation environment is a discrete graphics card GeForce MX150, 7th generation Intel i5 processor, Matlab (R2016b), 2 GB GDDR5, 256 GB PCIe SSD, memory 8 GB DDR4, Deep Learning-Toolbox. The PCA+CNN is compared with the classical CNN algorithm and the selected dataset is Human3.6M dataset. This dataset is a large public dataset for 3D human pose estimation, containing 3.6 million human poses and corresponding images. A comparison of the outcomes of the two algorithms is in Table I.

Table I demonstrates the comparison outcomes of the error rate and time between CNN algorithm and PCA+CNN for five runs on the Human3.6M dataset. In Table I, in terms of running time, the average time of the PCA+CNN and the classical CNN over the five experiments was 291.60s and 289.11s respectively, which shows a small difference. In terms of error rate, the average error rate of PCA+CNN algorithm and classical CNN were 3.15% and 4.68% respectively. The former had a lower error rate and the error rate of each experiment was lower than that of the traditional CNN. Then the number of iterations with mean square error outcomes were taken from one of the five experiments. And the outcomes of the other four experiments were graphically similar to the selected experimental outcomes. The comparison of the two algorithms was demonstrated in Fig. 6.

In Fig. 6, the red line was the experimental run of the classical CNN algorithm, while blue line represented the run of PCA+CNN. The horizontal coordinate was 6000 samples after 5 iterations with 50 training samples input each time. And the vertical coordinate was the mean square error for each input training sample number of 50. From Fig. 6, in the initial period of iteration, the mean square error obtained by the CNN algorithm was greater than that produced by PCA+CNN. The difference was most significant when the number of iterations was between 145 and 1000. While after the number of iterations exceeds 1000, the mean square error of both algorithms changes less. But the error convergence curve of PCA+CNN always stayed below the CNN experimental outcomes. At the same time, when the mean square error was 0.0479, iterations of PCA+CNN was only 4261. While the number of iterations of conventional CNN was 5893, which is 1632 times higher than the former. So the error rate obtained by PCA+CNN algorithm was smaller than that of the classical CNN algorithm. The two algorithms were then simulated for the MPII Human Pose dataset, evaluated by loss function curves and accuracy curves. 410 human activities were included in the MPII Human Pose dataset, and each image was clearly labelled with an activity, making it a dataset for human pose recognition. For the accuracy metric, it was the ratio of the number of correctly recognised poses to the total. The loss function was an important metric for evaluating how well the deep learning training was done. Here, the loss function was mainly for the test set and was judged on the basis that the loss functions of both the test and training sets converge and the difference was small. The loss function and precision curves are in Fig. 7.

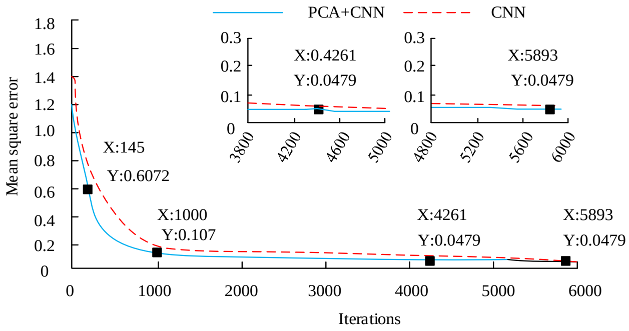

Fig. 6. Error convergence curve outcomes of CNN algorithm and PCA+CNN algorithm.

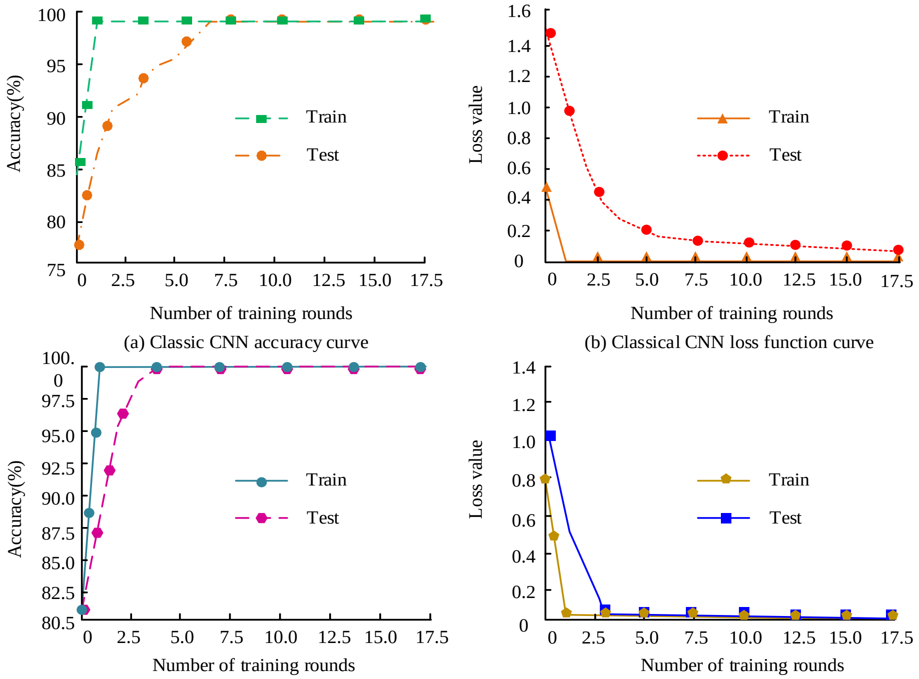
TABLE I. Comparison of Running Outcomes of PCA+CNN and Classical CNN Algorithms on Human 3.6M Dataset

Algorithm	Number of experiments	Running time/s	Error rate/%
PCA+CNN	1	291.53	3.04
	2	290.14	3.22
	3	293.52	3.13
	4	292.37	3.28
	5	290.45	3.10
CNN	1	289.12	4.35
	2	287.56	4.47
	3	289.73	4.92
	4	290.51	5.01
	5	288.64	4.63



(a) Classic CNN accuracy curve

(b) Classical CNN loss function curve

(c) PCA+CNN accuracy curve

(d) PCA+CNN loss function curve

Fig. 7. Loss function and accuracy curve outcomes of CNN and PCA+CNN algorithms.

Fig. 7(a) and Fig. 7(b) demonstrated the accuracy curve and loss function curve of the classical CNN algorithm, respectively, while Fig. 7(c) and Fig. 7(d) demonstrated the precision and loss-function curve of the PCA+CNN algorithm. From Fig. 7(a), the classical CNN achieved a fit at round 7, where the accuracy was 99%. In Fig. 7(b), the loss function curve starts to smooth out and converge to 0 in round 8. In Fig. 7(c) and Fig. 7(d), the PCA+CNN converged near round 5 with 100% accuracy, which was faster and more accurate than the CNN algorithm, and the loss function also converged faster than the CNN algorithm, which has better performance. Finally, for example validation, sample data was collected from 10 athletes in eight stances: dribbling, walking, shooting, no movement, jumping, passing, catching and running. 80 sets of repeated data were collected for each movement, and a total of 6400 data samples can be obtained. The data was collected by performing a series of pre-determined basketball stances in conjunction with the participant's own exercise habits. All postures included both upper and lower limb movements, and the lower and upper limb movements were also analyzed separately for identification purposes. For checking the validity of the posed way, Support Vector Machine (SVM) and Random Forest (RF) were for comparison in the example validation. The outcomes of the four methods for the recognition of upper limb basketball postures are demonstrated in Fig. 8.

Fig. 8(a) and Fig. 8(b) the upper limb recognition accuracy and recognition time outcomes for the four algorithms respectively, with the horizontal coordinates all representing the types of upper limb basketball sports poses, i.e. shooting, catching, passing and dribbling. From Fig. 8(a), it can be seen that among the four types of upper limb sports pose recognition, RF, SVM and CNN are stable between 88~94%, 86~89% and 89~93% respectively, while the accuracy of PCA+CNN is above 97% for all of them, and the recognition accuracy for passing is as high as 99%. From Fig. 8(b), among the four methods, the PCA+CNN algorithm recognized the four types of upper limb movement poses in 20s, 19s, 21s and 18s, respectively, all of which were faster than the other three methods, with a maximum lead of 10s and high operational efficiency. The recognition outcomes of the four methods for the three lower limb motion postures of jumping, walking and running are demonstrated in Fig. 9.

Fig. 9(a) and Fig. 9(b) represent the accuracy and time outcomes of the four methods for lower limb motion pose recognition, respectively, and the horizontal coordinates represent the four algorithms compared. From Fig. 9(a), the accuracy of the proposed PCA+CNN among the four methods is as high as 99.4% in the recognition of jumping, and the accuracy of 97.7% and 97.3% for running and walking respectively, which is higher than the other three methods. From Fig. 9(b), the recognition time of the Random Forest algorithm was above 28s, which was the worst performance among the four methods. In contrast, the PCA+CNN algorithm was stable at around 20s, which was more efficient than the other three methods and had better recognition performance. To sum up, the method proposed in the study can identify the basketball posture with high accuracy and maintain high recognition efficiency, which can provide more scientific and effective methods for basketball training.

V. Conclusion

Traditional basketball training is based on the coach's personal training experience and theory, making it difficult to evaluate the training effect objectively. With the continuous improvement of deep learning algorithms, neural networks are increasingly widely used in data reduction and classification processing. The study proposes a scientific sports stance classification structure for basketball's complex and variable stance characteristics and thus establishes a data information collection module based on inertial sensors. The convolutional neural network is then improved using principal component analysis, and finally, the improved algorithm is applied to the recognition of basketball postures. Experimental outcomes demonstrate that the proposed PCA+CNN algorithm has an average recognition error rate of 3.15% in the Human3.6M dataset. Compared to 4.68% of the traditional CNN, the difference is 1.53%, and the error convergence curve of PCA+CNN is consistently below the CNN outcomes. In the MPII Human Pose dataset, the PCA+CNN converged in only the 5th round achieved 100% accuracy with better performance. In recognition of the upper limb pose for basketball, the method performed above 97% accuracy for all four types of dribbling, passing, catching, and shooting. Its running time is 10s faster and the accuracy for the lower limb motion pose is 99.4%. It has higher running efficiency and accuracy. However, the performance of CNN algorithm in the case of increased learning rate has not been analyzed in the study, and the power consumption caused by wearable devices has not been optimized. Therefore, it is necessary to further reduce the power consumption and increase the learning rate to achieve better results.

***Abstract*—The distributed nature of fog computing is designed to alleviate bottleneck traffic congestion which happens when a massive number of devices try to connect to more powerful computing resources simultaneously. Fog computing focuses on bringing data processing geographically closer to data source utilizing existing computing resources such as routers and switches. This heterogeneity nature of fog computing is an important feature and a challenge at the same time. To enhance fog computing availability with such nature, several studies have been conducted using different methods such as placement policies and scheduling algorithms. This paper proposes a fog computing model that includes an extra layer of duplex management system. This layer is designated for operating fog managers and warm spares to ensure higher availability for such a geographically disseminated paradigm. A Markov chain is utilized to calculate the probabilities of each possible state in the proposed model along with availability analysis. By utilizing the standby system, we were able to increase the availability to 93%.**

Keywords—Fog computing; fault tolerance; Markov chain; hardware redundancy

I. INTRODUCTION

The main idea that led researchers to introduce fog computing was to increase systems availability and delivered quality of service to overcoming cloud computing limitations. Fog computing focuses on distributing data processing instead of relying on centralized computing resources which is cloud data centers. It was introduced in 2012 by Cisco and defined as "an extremely virtualized environment that delivers networking, storage, and compute resources between outdated cloud computing information centers, usually, but not entirely situated at the network edge [1]." The reference structure of fog computing was introduced later in 2017. The structure consists of three layers. Highest layer is for cloud data centers, lowest layer is where end users reside, and between these two layers, a layer designed for fog node devices [2]. Fog nodes are computing devices with limited capabilities compared to data centers. These nodes can be routers, switches, access points, vehicles, or personal computers. On the other hand, end users can be mobile devices, sensors, actuators, or vehicles. The name fog reflects that fog in weather is closer to the ground than clouds. Fog computing brings the computation process closer to the end user by leveraging all available computing resources at the periphery of the network. The decentralised nature of fog computing reduces the amount of data that needs to be sent to the cloud. Thus, higher quality of service (QoS) can be achieved. Given the nature of fog computing which includes heterogeneity and end users mobility, numerous studies were conducted by researchers to explore the potential of this new computing paradigm aiming to support users mobility and design context aware fog computing paradigms. However, fog systems availability did not receive much attention in cases of faults occurrence. fog computing systems availability must be properly addressed to mitigate service disruption impact since such interruption can be very financially expensive and, in some cases, can lead to fatalities.

Availability of fog computing paradigm is concerned with ensuring that the system is reachable to end users as much as possible. In such highly heterogeneous paradigm, system availability is divided into two main parts. The first part is related to the availability of cloud layer, which is the sustainability of cloud data centers and their networking. This part has been investigated by scholars over the years as surveyed in [3], [4], and [5]. Different mechanisms were incorporated to improve the availability of cloud computing such as hot migration, load balancing, resource management, and traffic management. The second part is concerned with fog nodes and their communication. Researchers have done some work related to enhance the overall performance of fog computing by resource management mechanisms, load balancing algorithms, designing mobility, energy, and context aware fog environment, reviewing different fog architectures, and only a few incorporated fault tolerance techniques into fog computing.

Fault tolerance FT concept is defined as systems survival attribute in which it can operate with the existence of faults in any part of it. FT is a mechanism used to achieve high availability, scalability, resilience, and reliability and can be found in many fields including aviation, military, telecommunication, and space missions. Faults can be results of several factors - some are external factors and other internal ones like incorrect algorithms. Various Fault Tolerance Techniques FTT have been introduced to minimize faults manifestation in computing systems such as checkpointing, watchdog, and redundancy [6]. Fig. 1 summarizes fault tolerance techniques which include software and hardware techniques.

Aiming to increase fog computing availability, two fault tolerance techniques FTT are used. First, a management layer as a software FTT. This layer should be able to function independently from main cloud where contacting main cloud in the proposed work should be minimal. Main cloud communication is allowed to perform certain tasks such as long-term storage, history analysis, or complex computation. The efficiency of this layer is discussed in detail in [7]. Second, a standby system deployed at management layer as a hardware FTT since the management layer is considered as a backbone in the proposed model.

The remaining of the paper is structured as follows: Section II discusses related studies. Section III briefly, describes the software FTT in the proposed model followed by a duplex management system as a hardware FTT. Section IV provides a quantitative analysis for the proposed model using an example followed by an availability analysis in Section V. The comparison of proposed model with other models is given in Section VI and Section VII concludes the paper and highlights future work.

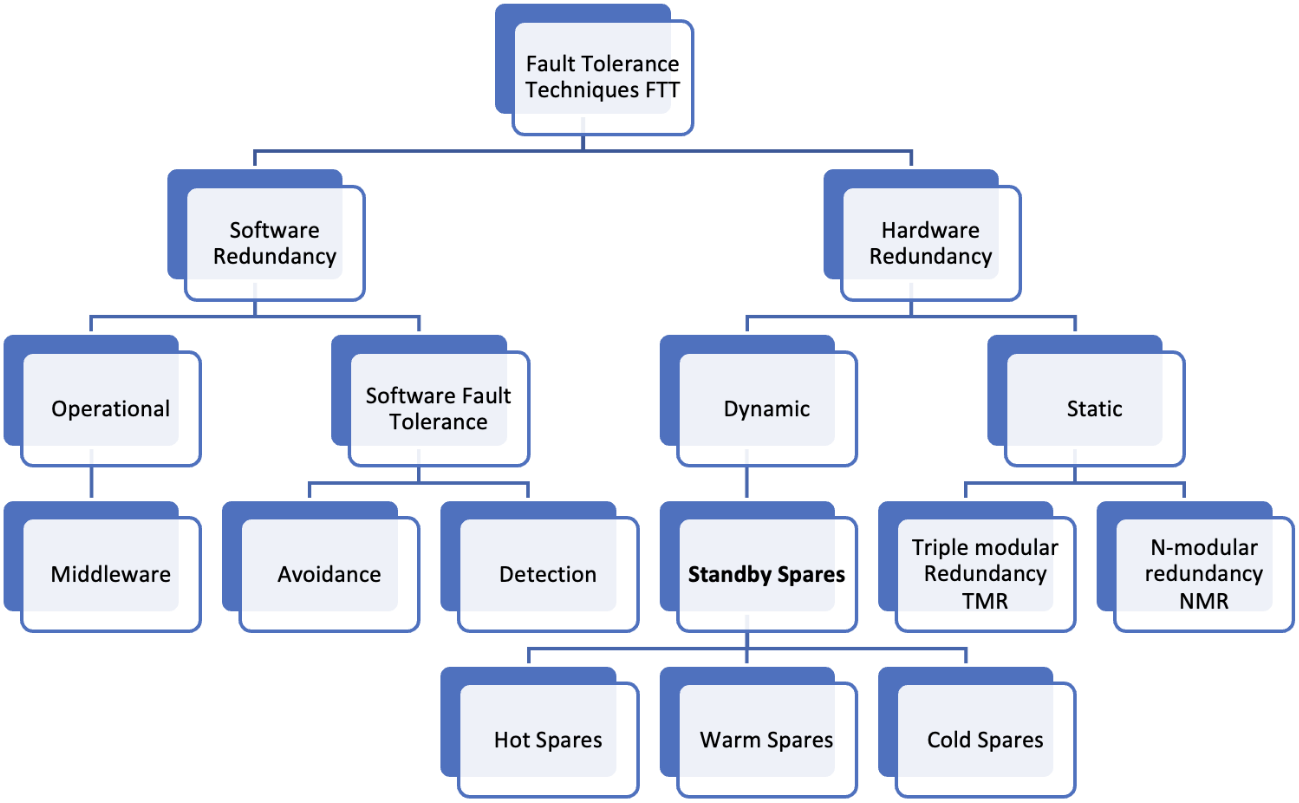

Fig. 1. Fault tolerance techniques FTT.

II. Literature Review

Fog computing is becoming popular since it provides a computing experience with low latency at low cost, and it is applicable to be deployed in various domains like healthcare, industries, and smart cities. To reach its potentials, researchers have been exploring several aspects of this new computing paradigm including: first, placement policies as in [8], [9], and [10]. Placement polices are responsible for deciding the most suitable computing node to process each single request. These policies can be context aware, energy aware or mobility aware. Second, several studies have been conducted on fog computing architecture as in [11], [12], [13], [14], and [15]. Some researchers increased the number of layers to reach six layers aiming to enhance the performance and robustness of fog computing. Third, scholars have been investing in fog resources management. Because of the heterogeneous nature of fog computing, balancing resources utilization and achieving the required quality of service must be addressed. Hence, authors in [16] propose load balancing algorithm to maximize resource utilization. However, searching for studies that focus on fault tolerance in fog computing, showed that service replication was the only FTT investigated by researchers. The main idea of service replication is to create replicas of data at the edge of the hierarchy. These replicas can be used in cases of fault occurrence. Authors in [17], propose a multi-tiers fog model, in which data replicas are generated at the same tier. The proposed model includes mobile agents that can roam all tiers to investigate failures when occurred, facilities communication between devices in different tiers and most importantly, fetch jobs with high priorities to be assigned. Simulating this model showed better performance and fault tolerance. Additionally, Javed et al. in [18], propose a fault tolerant architecture for edge applications which can save data when connection to cloud is lost. This architecture consists of three layers which are: application isolation, data transport, and management layer.

They tested the performance of the proposed architecture on surveillance cameras and found that the model was able to tolerate losing two nodes out of five. Furthermore, Authors in [19] developed a service replication scheme that can sense what services need to be replicated and chooses the most suitable node to perform and store the replica.

After reviewing all the listed studies, we found out that hardware redundancy did not receive much attention. One of the reasons behind this goes to the fact that hardware redundancy involves extra cost. Also, incorporating hardware redundancy increase the level of complexity of any system. However, integrating extra hardware ensures higher availability and higher fault tolerance level because faults are inevitable whether internal or external ones. Accordingly, the idea of the proposed model in this paper arose, which addresses heterogeneity and resource management in fog computing and improve system availability using hardware FTT as the next section illustrates.

III. Proposed Model Design

Fog computing architecture mainly consists of three layers as mentioned before. In this paper, one more layer is added to the hierarchy that resides between fog node layer and cloud layer. The purpose of this layer is to governs fog nodes and their communications among each other and with cloud data centres. It consists of fog nodes that are called fog managers. Each fog manager has three modules: processing module, tracking module, and allocating module. It also, has a sending and receiving units for communication purposes as depicted in Fig. 2 [7].

Since this management layer is considered the backbone of the proposed hierarchy, any fault that occurs at this layer will lead to expensive consequences. Therefore, a standby system for this layer is designed. Generally, standby systems were designed for extremely high availability systems such as aircraft where service disruptions are not acceptable. Standby systems consist of three components: active node, standby node, and a switching unit as illustrated in Fig. 3. Techniques to implement a standby system fall into three categories: hot, warm, and cold. Tradeoffs between cost, energy consumption, and availability rate must be considered during design stage. When switching time is critical as the case in aircrafts, hot standby is the most suitable technique. In this technique, a completely fired up node is always ready to take over the failing node. Energy consumption for this technique is very high, yet higher availability is guaranteed. On the other hand, cold standby requires higher switchover time, consumes less energy since the standby node is not fully functioning and in sometimes is not fired up, and provides less availability than hot standby. It is suitable for industrial use and weapon systems. Lastly, warm standby which falls between hot and cold standby technique [20]. In this paper, a standby system is designed at management layer to increase availability in fog computing environment. To the best of our knowledge, designing a highly available fog computing environment using this fault tolerance technique was not investigated yet.

Accordingly, at management layer in the proposed model, a group of fog nodes reside in charge of managing fog nodes connected to it. Each cluster of fog nodes in a relatively small area is managed by a single fog node. In this proposed model, a number of standby nodes is added to optimize the availability as described in Fig. 4.

The proposed model is an active/passive standby system which denotes that only one node is in control. Passive/standby node steps into failover the active node. The switching technique between nodes is the common switching policy as illustrated in Fig. 5.

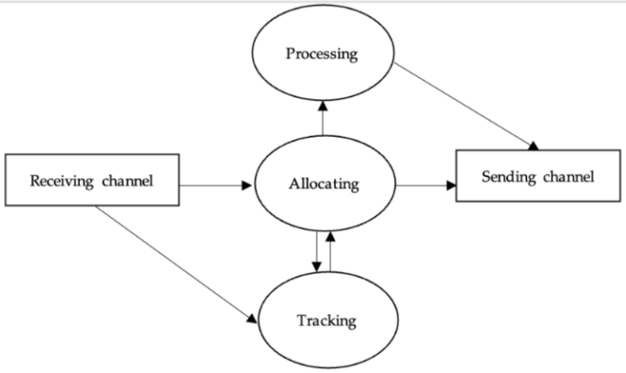

Fig. 2. Fog manager components.

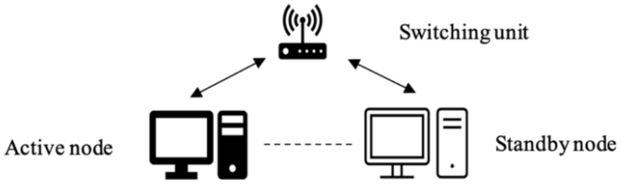

Fig. 3. Standby systems components.

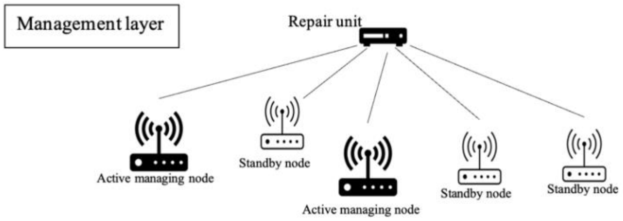

Fig. 4. Proposed standby system at management layer.

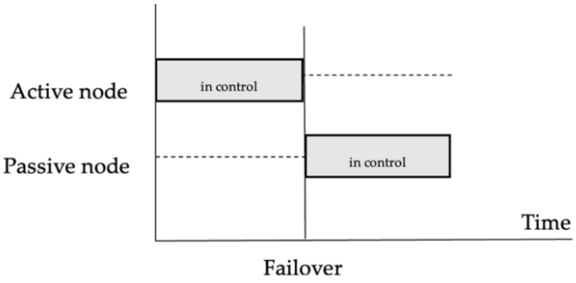

Fig. 5. Common switching policy for standby systems.

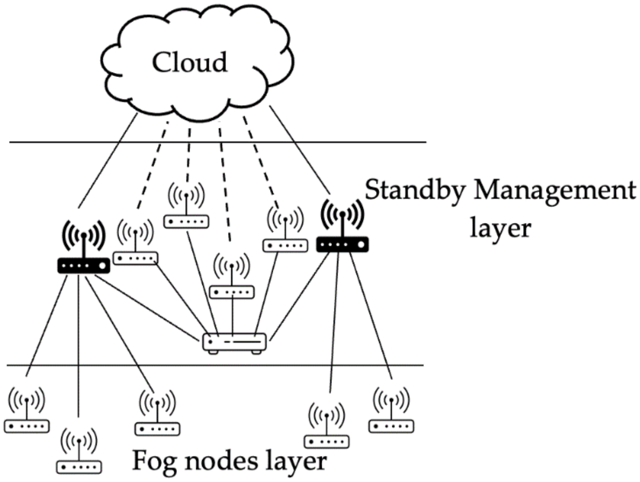

Fig. 6. Network connectivity in the proposed model.

Both the active/operating manager O_m and warm manager W_m are identical hardware components but differ in the failure rate. The failure rate of O_m is λ_o while $\lambda_o > 0$, and the W_m failure rate is λ_w where $0 < \lambda_w < \lambda_o$. Each standby manager has a unit with a Boolean value either up or down. When the unit value is up (one) the manager can be in an active mode or idle mode. A down or (zero) value indicates that the manager is not operating. Network connectivity assumptions for the proposed standby system are depicted in Fig. 6 as follows:

- Both active managers and standby mangers are securely connected the repair unit.
- Active managers are securely connected to cloud data centers.
- Standby managers have an established connection to cloud centers which will activated once the standby manager status switched to active.
- Active fog managers are connected to fog nodes at the next lower level of the models.
- Fog managers can establish secure connections among each other for higher resource utilization.

To illustrate and evaluate the switching mechanism between active and standby managers at the management layer, a Colored Petri net is designed. Petri nets PN are used to evaluate and analyze embedded systems performance, and they consist of places, transitions, and arcs. Places, which are in a circle, represent the states of a system; transitions, symbolized as rectangles, exist between places; and arcs demonstrate the workflow [21]. Usually, some places contain tokens that demonstrates the dynamics of the system. Even though Petri nets were invented at an earlier time, it is still used for its proficiency in designing sophisticated distributed computing systems as in [22]. Fig. 7 describes how the proposed standby system works in case an active manager fails. The red places represent failed managers and blue places signifies the completion of a process. Additionally, green transitions indicate the start of the moving process.

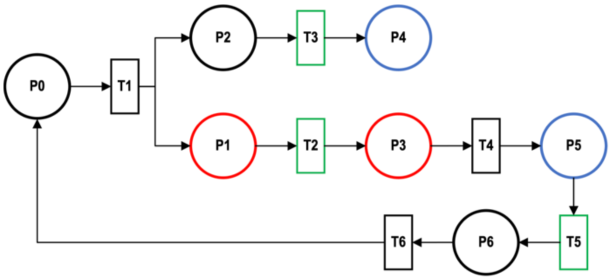

Fig. 7. PN design of the proposed standby system.

<u>PN notations_1:</u> There are six states for the proposed system components as follow:

P0: initial state

P1: failed fog manager moving to repair unit

P2: setting W_m in full operating mode with failure rate of λ_o instead of λ_w

P3: failed managers are moving to repair unit

P4: fog manager is active with a failure rate of λ_o

P5: failed managers are being fixed and restored as new components

P6: the manager is ready to use as a warm standby manager

<u>PN notations_2:</u>

T1: is enabled when an active manager has failed

T3: start moving the activated manager into fully operating manager

T2: start moving the failed manager to the repair unit

T4: end moving the failed manager to the repair unit

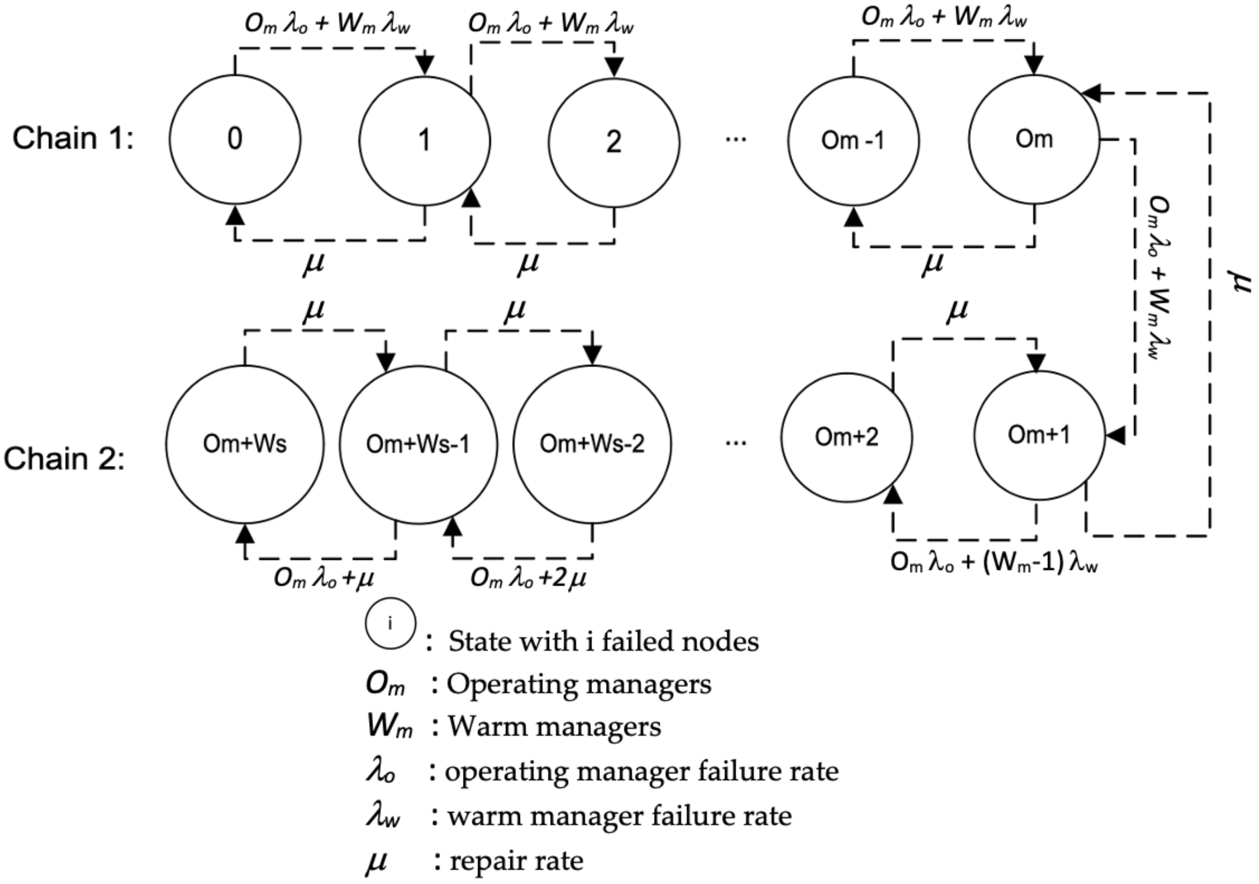
T5: enabled when the failed manager has been fixed

T6: start using fixed manager as a warm standby manager with failure rate of λ_w which takes the system to its initial state.

The initial state of the proposed model is represented by P0 where the active manager is in a fully functioning state with a failure rate of λ_o and the standby manager in warm state and with a failure rate of λ_w. When the active manager fails, which is represented by T1, the system performs two steps. First, it moves the failed manager to the repair unit (P1) and sends an order to the standby manager to be fully operating (P2). P3 represents the system state during moving the failed manager to the repair unit, and in P4, standby manager is now fully active with failure rate of λ_o and referred to as the active manager. States P3 and P4 happen at the same time as well as P1 and P2. Next, P5 represents the system state when the failed manager is being fixed or replaced depending on its condition. When P5 is completed, T5 is enabled. T5 transits the system to P6, in which the failed manager is fixed and ready to be active again. Subsequently, T6 is activated by P6 which takes the system back to its initial state.

IV. Qualitative Analysis of the Proposed Model

The proposed model consists of cloud data centers, operating fog manager O_m, warm fog managers W_m, fog manager, and one repair unit. In the next lower layer, fog nodes reside to provide the required services to end users. Operating fog managers manage the fog nodes with a failure rate of λo, and warm fog managers are in standby mode with a failure rate of λw. There are two chains of circles representing all possible states as illustrated in Fig. 8. Each circle has a number inside of it representing the number of failed managers in that state. The values on the arcs flowing in and out is associated with the status of the devices (failed/fixed) that changes the system state. Two chains of states coded as 1 and 2 to represent the possible state transitions for operating managers O_m and warm managers W_m where μ is the repair rate of the repair unit. Chain 1 represents the system states with 0, 1, …, O_m failed operating managers, and chain 2 represents the system states with failed warm managers starting from O_m+1 until $O_m + W_m$, which represents the total number of managers T.



Chain 1:
0

Om+1
μ
μ
μ
$O_m \lambda_o + \mu$
$O_m \lambda_o + 2\mu$
$O_m \lambda_o + (W_m\text{-}1) \lambda_w$
i : State with i failed nodes
O_m : Operating managers
W_m : Warm managers
λ_o : operating manager failure rate
λ_w : warm manager failure rate
μ : repair rate

Fig. 8. Markov chain of the proposed model.

Let T represent the total number of fog managers, and the states i, i$\in$ [0, T], represents the number of failed devices in a state. In the initial state P(0), there is a state with zero failed devices, and P(i) represents the probability of i failed devices. The states probability can be derived from the following equation:

Chain (1): $0 \le i \le O_m$

i = 0 (initial state): $O_m \lambda_o + W_m \lambda_w P(0) = \mu P(1)$

i = 1: $(O_m \lambda_o + W_m \lambda_w + \mu) P(1) = (O_m \lambda_o + W_m \lambda_w) P(0) + \mu P(2)$

i = 2: $(O_m \lambda_o + W_m \lambda_w + \mu) P(2) = (O_m \lambda_o + W_m \lambda_w) P(1) + \mu P(3)$

i = O_m -1 : $(O_m \lambda_o + W_m \lambda_w + \mu) P(O_m -1) = (O_m \lambda_o + W_m \lambda_w) P(O_m -2) + \mu P(O_m)$

i = O_m : $(O_m \lambda_o + W_m \lambda_w + \mu) P(O_m) = (O_m \lambda_o + W_m \lambda_w) P(O_m -1) + \mu P(O_m +1)$

A general expression for P(i) in chain 1 can be calculated by:

$$(O_m \lambda_o + W_m \lambda_w + \mu) P(i) = (O_m \lambda_o + W_m \lambda_w) P(i-1) + \mu P(i+1) \quad (1)$$

where i $\in$ [1, O_m]

Chain (2): $(O_m + 1) \le i \le (O_m + W_m)$

i = O_m + 1 : $[O_m \lambda_o + (W_m\text{-}1) \lambda_w + \mu] P(O_m + 1) = [O_m \lambda_o + (W_m\text{-}1) \lambda_w] P(O_m) + \mu P(O_m +2)$

i = O_m + 2 : $[O_m \lambda_o + (W_m\text{-}2) \lambda_w + \mu] P(O_m + 2) = [O_m \lambda_o + (W_m\text{-}2) \lambda_w] P(O_m+1) + \mu P(O_m +3)$

i = $(O_m + W_m - 1)$: $[O_m \lambda_o + \lambda_w + \mu] P(O_m + W_m - 1) =$

$$[O_m \lambda_o + 2\lambda_w] P(O_m + W_m - 2) + \mu P(O_m + W_m)$$

$$i = O_m + W_m : [O_m \lambda_o + \mu] P(O_m + W_m) = [O_m \lambda_o + \mu] P(O_m + W_m)$$

A general expression for P(i) in chain 1 can be calculated by:

$$i = O_m + W_m : [O_m \lambda_o + \mu] P(O_m + W_m) = [O_m \lambda_o + \mu] P(O_m W_m - 1) + \mu P(O_m + W_m + 1) \quad (2)$$

$$[O_m \lambda_o + (O_m + W_m - i) \lambda_w + \mu] P(i) = [O_m \lambda_o + ((O_m - W_m - i) +1) \lambda_w P(i-1) + \mu P(i+1)$$

$$\text{where } i \in [(O_m + 1) , (O_m + W_m)] \quad (3)$$

Given the fact that $O_m + W_m$ is equal to T and based on equation (2), the final state of the system is given by:

$$i = T \text{ (final state)} : [O_m \lambda_o + \mu] P(T) = [O_m \lambda_o + \mu] P(T - 1) + \mu P(T+1) \quad (4)$$

Consequently, the utilization of operating managers and warm managers can be denoted as ρ_o and ρ_w respectively. The utilization parameter can be calculated by dividing the failure rate by the repair rate. By solving Eqs. (1) to (4) P(i) can be calculated as follows:

$$\text{Chain 1} : P(i) (Om + Wm) i \; P(0) , 0 \leq i \leq Om) \quad (5)$$

$$\text{Chain 2} : P(i) (Om + Wm) om \; x \prod_{j=om}^{i-1} [Om \rho o + (T - j) \rho w] P(0) \; , Om \leq i \leq T \quad (6)$$

V. Availability Analysis for the Proposed Model

Since the proposed model is designed to enhance availability in fog computing, it is crucial to construct related metrics such as expected number of failed operating and warm fog managers, which is the focus of this paper. Generally, systems availability can be defined as the system probability of being in a functioning state at any time. Fog computing availability includes two parts: the availability of cloud data centers and the availability of fog nodes. Cloud computing availability has been receiving a decent amount of attention from scholars compared to fog computing. The following characteristics has been defined for the proposed model:

L = represents the expected number of failed managers

E[O] = the expected number of failed operating managers O_m

E[W] = the expected number of warm managers W_m

A = the availability of standby management layer

From Eq. (5) to (6), the following expressions can be driven:

$$L = \sum_{i=0}^{T} i \times P(i) \quad (7)$$

$$E[O] = \sum_{i=1}^{Om} (T - i) \times P(i) \quad (8)$$

$$E[W] = \sum_{i=(Om+1)}^{T} (T - i) \times P(i) \quad (9)$$

$$A = \frac{T - L}{T} = 1 - \frac{L}{T} \quad (10)$$

In order to illustrate the theoretical implication of the proposed model, an example with comprehensive calculation is provided. In this example, there are two operating managers with failure rate λ_o of 0.1, three warm managers with failure rate λ_w of 0.024, and one repair unit with repair rate μ of 0.8. Accordingly, ρ_o and ρ_w are equal to 0.125 and 0.03 respectively.

Based on Eq. (5) and the given values of:

$$O_m = 2, \rho_o = 0.125, W_m = 3, \rho_w = 0.03, \text{ and } \mu = 0.8$$

chain 1 yields to:

$$\text{Chain 1: } P(i) = (O_m \rho_o + W_m \rho_w)^i P(0), 0 \leq i \leq O_m \quad (5)$$

$$i = 1, P(1) = (O_m \rho_o + W_m \rho_w) P(0) = (0.25 + 0.09) P(0) = 0.34 P(0)$$

$$i = 2, P(2) = (O_m \rho_o + W_m \rho_w)^2 P(0) = (0.25 + 0.09)^2 = (0.34)^2 P(0) = 0.1P(0)$$

And chain 2 based on Eqs. 6 leads to

$$\text{Chain 2} : P(i) (O_m + W_m)^{om} x \prod_{j=om}^{i-1} [Om \rho o + (T - j) \rho w] P(0) \; , O_m \leq i \leq T \quad (6)$$

$$i = 3, P(3) = (0.34)^2 x \prod_2^2 [0.25 + (5 - j) 0.03] P(0)$$

$$\Rightarrow (0.34)^2 x [0.25 + (5-2) 0.03]$$

$$P(3) = 0.1 \times 0.34 P(0) = 0.034 P(0)$$

$$i = 4, P(4) = (0.34)^2 \times \prod_2^3 [0.25 + (5 - j) 0.03] P(0)$$

$$\Rightarrow (0.34)^2 x \{ [0.25 + (5-2) 0.03] x [0.25 + (5-3) 0.03]\}$$

$$P(4) = 0.1 \times 0.1 P(0) = 0.01P(0)$$

$$i = 5, P(5) = (0.7)^2 \times \prod_2^4 [0.25 + (5 - j) 0.03] P(0)$$

$$\Rightarrow (0.34)^2 x \{ [0.25 + (5-2) 0.03] x [0.25 + (5-3) 0.03] x [0.25 + (5-4) 0.03\}$$

$$P(5) = 0.1 \times 0.03 P(0) = 0.003 P(0)$$

The five state probabilities expressed in terms of P(0) are as follows:

$$[P(1), P(2), P(3), P(4), P(5)] P(0) = [0.34, 0.1, 0.034, 0.01 \; 0.003] P(0) \Rightarrow 0.49 P(0)$$

To calculate the value of P(0), the following normalization condition is used,

$$\sum_{i=0}^{T} P(i) = 1$$

$$\sum_{i=0}^{5} P(0) + P(1) + P(2) + P(3) + P(4) + P(5) = 1$$

$$\Rightarrow 0 .51 + P(0) = 1 \Rightarrow \therefore P(0) = 0.51$$

All the values above were calculated with respect to P(0). After calculating P(0), P(i) values are as follows:

$$P(1) = 0.17,\ P(2) = 0.05,\ P(3) = 0.017,\ P(4) = 0.005,\ \text{and}\ P(5) = 0.0015$$

Accordingly, solving Eq. (7) to (10) to calculate the proposed model metrics as follows:

$$L = \sum_{i=0}^{5} i \times P(i) = [P(1) + 2\ (P2) + 3\ (P3) + 4\ P(4) + 5\ P(5)] \Rightarrow$$

$$= (0.34 + 0.2 + 0.1 + + 0.04 + 0.015) = 0.7 \times 0.51 = 0.357$$

$$E[O] = \sum_{i=1}^{2}(5 - i) \times P(i) = 4\ P(1) + 3\ P(2) \Rightarrow (1.36 + 0.3) \times 0.51 \quad = 0.85$$

$$E[W] = \sum_{i=3}^{5}(5 - i) \times P(i) = 2\ P(3) + P(4) \Rightarrow (0.7 + 0.01) \times 0.51 \quad = 0.36$$

$$A = 1 - \frac{L}{T} = 1 - \frac{0.36}{5} \Rightarrow 93\%$$

Fig. 9 illustrates the probabilities of a fog management system of two operating managers and three warm managers with failure rates of 0.1 and 0.024 respectively and a repair rate of 0.8. The vertical axis represents the steady state probability, and the horizontal axis denotes the number of failed managers. The curve starts with the probability of losing one operating manager with a probability of 0.17. As the number of failed managers increases, the failure probability decreases until it reaches 0.0015. With the mentioned failure and repair rates, the model was able to reach 93% availability and the relevant measures such as E[O] and E[W] are 0.7 and 1.5 independently.

Additionally, Fig. 10 depicts the improvement in availability percentage of the proposed model using redundancy. The figure compares availability percentages of two models. First, the redundant model consists of two operating mangers, three warm mangers, and a repair unit. Second, the non-redundant model consists of only two operating managers. Failure rates are identical in both models. As the figure shows, the redundant model availability is 93% while the non-redundant model availability is 87%. Accordingly, the redundant model increases availability by 6% compared to a non-redundant model.

Further experiments were conducted to increase the proposed model availability over 98%. These experiments included changing the failure and repair rates. However, increasing the repair rate and decreasing failure rate can be very expensive. A different experiment was conducted which focused on the ratio of operating managers to warm managers.

As Fig. 11 represents, availability percentage increases as the number of warm managers increase. The figure depicts different configurations with correlations of operating managers O_m to warm managers W_m as follows:

A: $W_m = O_m$

(The number of W_m equals to the number of O_m e.g., O_m = 2 and W_m = 2).

B: $W_m = O_m^{\,2}$

(The number of W_m equals to the number of O_m to the power of 2 e.g., O_m = 2 and W_m = 4).

C: $W_m = O_m^{\,3}$

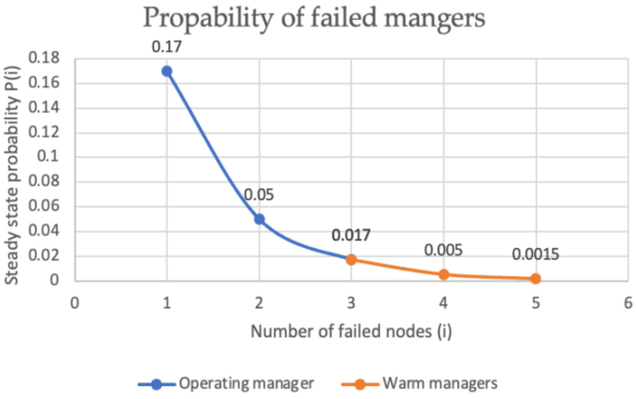

Fig. 9. Probabilities of failed managers in fog management system.

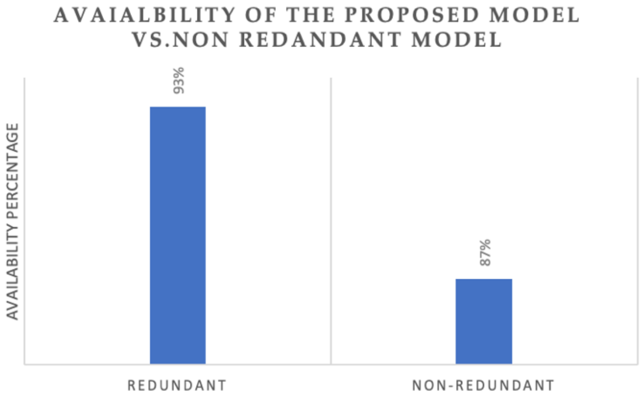

Fig. 10. Availability of the proposed model compared to a non-redundant model.

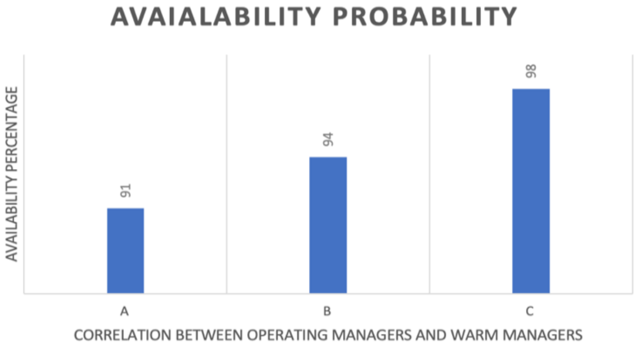

Fig. 11. Availability probability for different numbers of operating/warm nodes.

(The number of W_m equals to the number of O_m to the power of 3 e.g., O_m = 2 and W_m = 8).

Failure and repair rates are fixed for all models. As the figure shows, an availability rate of 98% can be reached when using configuration C, which is a high rate and defiantly it comes with expenses. In the case of configuration C, the extra cost is in the form of extra hardware which is more practical than unreasonable repair and failure rates.

VI. Comparison of the Proposed Model with other Models

The proposed model in this paper is a standby system consisting of operating nodes and warm nodes. The system is designed to reside in a separate layer between fog nodes and cloud data centers, which is called the management layer. This layer is discussed in detail in [7]. The mechanism used in this model is hardware redundancy. As mentioned in Section II, the main fault tolerance technique that have been incorporated into fog computing is data/application replication as in [18] and [19]. Availability probability was not calculated in these studies. The research in [18], did not include any evaluation metrics for the proposed software, On the other hand, authors in [19] presented a proactive scheme for service replication in IoT computing. The evaluation process of the scheme included service drop rate, response time, and service completion time. Even though this study covered aspect of availability, it was designed for qusai adhoc scenarios in general which may include fog computing. Also, it did not include hardware redundancy to be suitable for comparison with the presented model in this paper. Further research can be conducted to explore other models or techniques to improve availability in fog computing.

VII. Conclusion and Future Works

To enhance performance and availability in fog computing, researchers have been focusing on several aspects of fog computing such as resource management, load balancing algorithms, placement policies, and service replication. However, deployment in fault tolerance techniques has not received much attention. In this paper, a fog model is proposed with a standby management layer. The model is designed to tolerate losing fog managers at the management layer. Qualitative analysis of the proposed model is presented using a Markov chain. For further studies, we aim to study the limitations of the proposed model and enable periodic switching for the duplex system to avoid exhausting fog nodes. Furthermore, a cost effectiveness study along with extensive comparison of the proposed model with other models designed to improve availability in fog computing can be conducted.

Eye Contact as a New Modality for Man-machine Interface

Syusuke Kobayashi[1], Pitoyo Hartono[2]
Graduate School of Engineering, Chukyo University, Nagoya, Japan[1]
School of Engineering, Chukyo University, Nagoya, Japan[2]

***Abstract*—In daily life, people use many appliances, where different machines and tools should be operated with their specialized interfaces. These specialized interfaces are often not intuitive and thus require considerable time and effort to master. On the other hand, human communications are rich in modalities and mostly intuitive. One of them is eye contact. This study proposes eye contact for enriching modalities for human-machine interface. The proposed interface modality, based on a neural network for object detection, allows humans to initiate machine operations by looking at them. In this paper, the hardware framework for building this interface is elaborated and the results of usability assessment through users' experiments are reported.**

Keywords—Eye contact; man-machine interface; non-verbal communication; object detection; neural network

I. Introduction

Machines and tools have been invented for centuries to support humans to efficiently work and to make life comfortable. However, most machines, for example, home appliances, require specialized interfaces that are not necessarily intuitive for humans. The situation is more serious in industrial settings where many types of machinery need to be operated under specialized rules. Sometimes it takes considerable time for humans to be proficient in the interface while misoperation may cause serious accidents. Therefore, it is desirable to develop interfaces that minimize human errors and allows users to instantly understand and be proficient in using them. The intuitiveness of an interface is influenced by various factors since the user's subjective senses are important. For example, in psychology, there is a concept of Organization of Memory [1, 2]. Since there is a limit to the capacity of human memory, it is important to represent information and skills in simple forms that can be easily remembered or executable by humans. One of the important aspects of the simplicity of the representation is familiarity. From these considerations, interfaces will be more intuitive if they are based on familiar experiences [3]. Hence, enclosing familiarity is a good strategy for building an intuitive human-machine interface.

While most machines need fixed and specialized interfaces, humans flexibly utilize various modalities for communicating with each other. In human interactions, verbal communication is the most frequently used interface. However, humans also utilize rich nonverbal modalities for communication, such as gestures, facial expressions, gaze, and eye contact.

Recently, interfaces based on voice and natural language recognition have been widely used in households. They enable humans to verbally interact with machines. While verbal interfaces are effective in household settings, they are not necessarily useful in other settings, such as factories, busy streets, public spaces, and public transportation. In such situations, humans complement verbal communication with nonverbal modalities [4] to seamlessly interact with each other. Hence, it is also beneficial for human-machine interfaces to complement verbal-based modality with nonverbal modalities, for example, eye contact.

In recent years, the advance in technology allows the proposal for many nonverbal interfaces between humans and machines. For example, gaze-based interactions between humans and computers have been developed to assist people who are unable to perform some physical movements due to spinal cord injury or other causes, but also for helping healthy users efficiently operate computers. For example, some studies have been conducted on the use of eye gaze for cursor manipulation in Graphical User Interface (GUI) [5, 6]. When operating a GUI using a mouse or touch screen, the user's gaze is directed to a button on the screen before making a selection. While it is natural and reasonable to use eye movement as a pointer, there is a so-called Midas Touch Problem [7], in which the system cannot determine the intention of a user, in that it is difficult to distinguish whether the user is looking at the screen or has an intention for clicking a button on the screen. Furthermore, it has been reported that clicking by staring or blinking has some latencies compared to clicking a mouse [8]. A system has also been developed to move a wheelchair in the direction of the user's gaze [9]. Here, the discomfort of having to look down the road when operating the wheelchair has been reported in the experiment in simply linking gaze input to a particular movement of a machine is not natural and not intuitive. Additionally, eye gaze is information that can be used to extract human unconscious interests and attention. One of the gaze-based systems [10] generates e-commerce recommendations based on gaze information. While conventional recommendation systems require past shopping characteristics of a user, to determine what to recommend, this system can estimate the user's preferences with high accuracy based on his/her gaze movements. In addition, there is also a study that detects drivers' distractions using gaze tracking as Advanced Drive Assistance System (ADAS) [11]. By dealing with gaze, a human can interact with machines intuitively, naturally, and efficiently. The intuitiveness of gaze information motivates this study.

This study attempts to propose a means for adding a new modality for nonverbal interaction between humans and machines. Here, the basic concept is to allow eye contact between humans and machines. Eye contact has four roles in human communication [12-14]. The one that is highly relevant to this study is the cognitive role of displaying attention to other people and conveying an intention for starting to communicate. In this study, eye contact is expanded to establish intuitive interactions between humans and machines.

There were existing interfaces that attempt to utilize eye contact. For example, the smart speaker "Tama" [15] can be activated using mutual gaze for starting an interaction. It is reported that the usability and the sense of dialogue improved. Other systems include the construction of an IoT system that combines eye gazing and gestures for human appliances [16]. It realized intuitive interaction between humans with home appliances through gaze and gesture via a so-called "Watch module". Our study shares some similarities with these past studies, in that they realize natural and intuitive interaction by using eyes [15-17]. However, the proposed study differs in that it offers direct interactions with the objects without requiring any other intermediate media and hence increases the naturalness and intuitiveness of the interaction. The proposed system also established a flexible relationship that was not limited to smart speakers and home appliances, but also any type or number of objects.

In the past, a basic framework was developed for this system [18]. This paper reports on the preliminary experiments' results on the performance of the proposed systems and the user's assessments. It is important to mention that it is not our intention to compete with the existing systems' efficiency. Here our objective is to investigate the usability of the proposed eye-contact system and to assess its potential for enriching the user interface modalities. In this paper, the proposed system's characteristics are assessed through statistical tests on users' experiment data.

The rest of the paper is organized as follows. Section II explains the hardware and software configurations of the proposed Gaze Switch. Section III explains the experiments, while the final section explains the conclusions and future work for this study.

II. Outline of Gaze Switch

Gaze Switch developed in this research is an interface that enables humans to activate or deactivate a machine by looking at it. This interaction is comparable to eye contact. Fig. 1 illustrates the process of establishing inter-human and human-machine through eye contact.

Eye contact between two humans starts when they gaze at each other and in the process, each party needs to perceive the gaze. In this study, for human machine-interaction, it is assumed that the machines are always gazing at humans, and so when a human visually perceives the machines, eye contact is established. Here, a neural network is utilized for determining the target object. Fig. 2 shows an overview of the Gaze Switch system developed in this research.

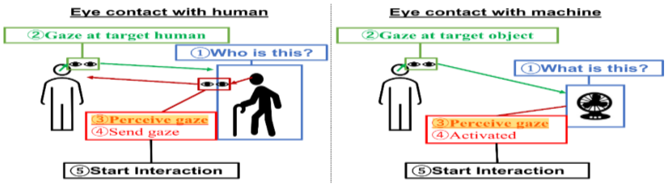

Fig. 1. Eye contact.

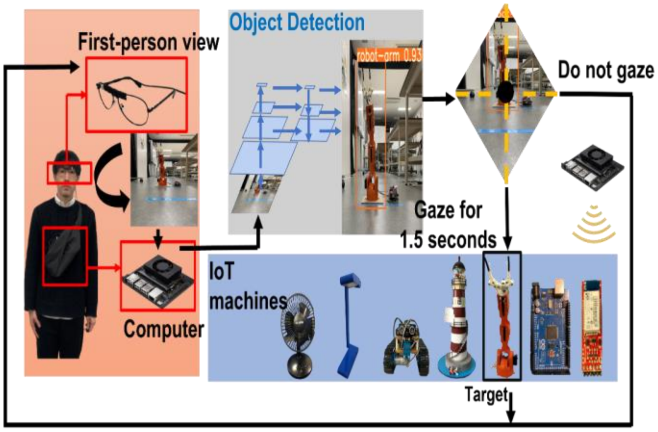

Fig. 2. Outline of the proposed system.

Here, a small camera is attached to the eyeglasses worn by a user. This camera captures and sends the image to a computer to be further processed by a neural network running on the computer for object detection. Here, the objects to be detected must be pre-specified for training the neural network, although the type and number of the objects are not constrained. YOLOv5 [19, 20] is utilized for the neural network's easy implementation and fast response. Fig. 3 shows the five machines as targets in this study.

The input to YOLOv5 is the image perceived by a human through the attached camera, and the output is bounding boxes, the center normalized coordinate of objects in the images, their heights and widths, and their IDs, as shown in Fig. 4.

To train the neural network, 3427 images for training data and 773 images for test data consisting of the five machines in various postures and distances were generated and labeled. The learning results are presented in the next section.

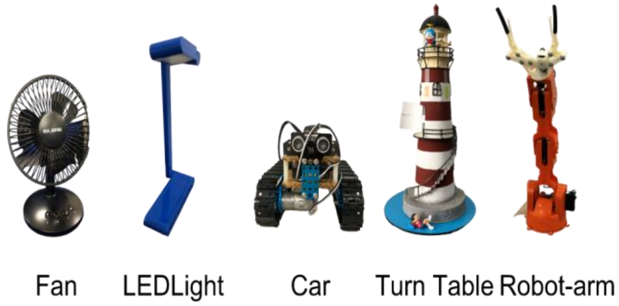

Fig. 3. Appearances of five machines.

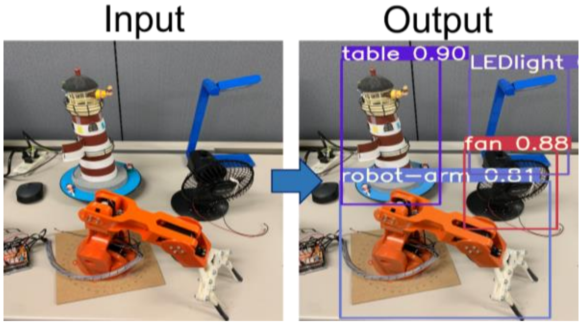

Fig. 4. The output of YOLOv5.

After detecting an object with YOLOv5, the system checks whether the human gaze is focused on that object. Here, in establishing eye contact, it is assumed that the human always put the intended object at the center of his/her field of view. Thus, the center of the coordinate of the obtained images is treated as the focus of the gaze. The system checks that the eye contact object is within the gaze focus for 1.5 seconds. Subsequently, the system refers to the object ID and sends a signal to the target machine. Here, each target machine is connected to a control PC wirelessly via Bluetooth.

By executing the above process in real time, the proposed Gaze Switch system is realized.

III. Experiments

The viability of the proposed Gaze Switch is assessed through user experiments. Before the user experiments, some preliminary experiments were run for verifying the basic operability of the proposed system.

The preliminary experiments were run on Windows 10 Pro Intel® Core™ i7-9700k CPU @3.60GHz to 4.90GHz 16.00GB and Nvidia® GTX750Ti GPU @1020MHz to 1085MHz, while the user experiments were run on Jetson Xavier NX [21], operated by Jetson Pack 4.5.1 for improving the system's compactness and processing speed. The neural networks for both experiments were the same.

A. Preliminary Experiments

In the preliminary experiment, the detection range of the neural network was assessed. The necessity of this assessment is due to the existence of a natural range of eye contact and whether the proposed system adheres to this natural range [22]. In particular, the mean Average Precision (mAP) against validation data was evaluated as shown in Fig. 5.

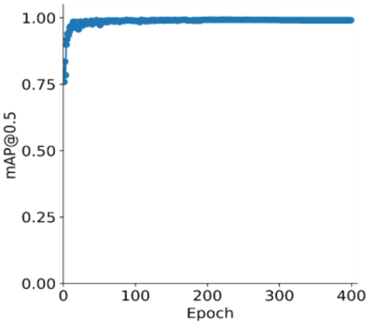

Fig. 5. Learning precision.

From Fig. 5, it can be observed that the mAP exceeds 0.9 after the training process, indicating that the neural network can learn the object detection task.

Next, validation data were created for evaluating the neural network's detection accuracy. Here, 700 labeled images of the seven objects at various distances are generated and checked for their detection accuracies. Fig. 6 shows the results of the accuracy test regarding the distance of the object (with the example of the robotic arm).

This figure shows that the accuracy does not significantly decrease until 5 meters. This indicates that the operating range of the system is around 5 meters which is similar to the human's natural range for eye contact.

The preliminary experiments indicate that the proposed system is viable for establishing eye contact intuitively and naturally.

After assessing the neural network's learning and detection capabilities, two experiments with nine human subjects were conducted. The main purpose was to verify the basic usability and operability of the Gaze Switch. Before the experiments, the subjects were explained the objective of the proposed interface.

After that, the subjects practiced using the interface for about five minutes. In the experiment, a monitor in front of the subject randomly showed an object that the subject must operate. Here, the subject should try to operate the specified machine by looking at it. The interface was evaluated in whether the human subject could operate the object within a specific time range. In the experiment, the subjects were instructed ten times in random order to operate each target twice.

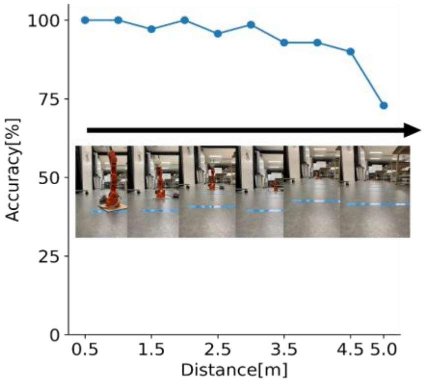

Fig. 6. Accuracy across distances.

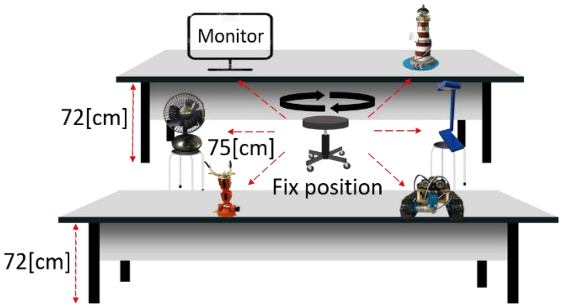

Fig. 7. Settings for preliminary experiment 1.

In this experiment, the target objects were randomly positioned but fixed to their respective position. During the experiment, the subjects were instructed to sit in a fixed position and use a swivel chair to turn their bodies to establish eye contact with the objects (see Fig. 7).

The human subjects were instructed to operate an object that randomly appears on the monitor within 10 seconds, and then return his/her gaze to the monitor. If the subject fails to operate the object within 10 seconds, the experiment continues, but the task is considered a failure. Fig. 8 shows the average accuracy for operating the instructed object.

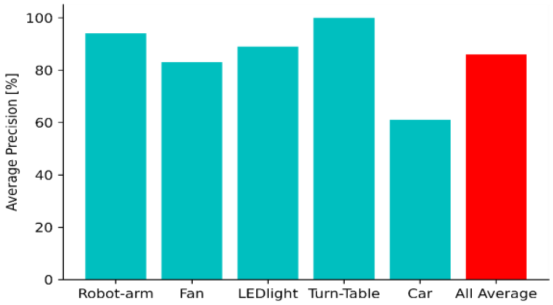

Fig. 8. The result of preliminary experiment 1.

The overall average accuracy was 88% which indicates the subjects were able to operate the specified targets. However, the accuracy rate for the object "Car" is low. This low accuracy is due to "Car" moving away from its fixed position. This indicates that it may be difficult for a human to operate moving objects from a fixed position using this interface.

Next, Preliminary Experiment 2 was conducted with the setup shown in Fig. 9.

The same task was applied to this experiment as in Preliminary Experiment 1. However, in this experiment the subject was allowed to freely move rather than operate from a fixed position. This experiment aims to evaluate the operability of this system in an environment that is more similar to a general living space. Fig. 10 shows the average accuracy in Preliminary Experiment 2.

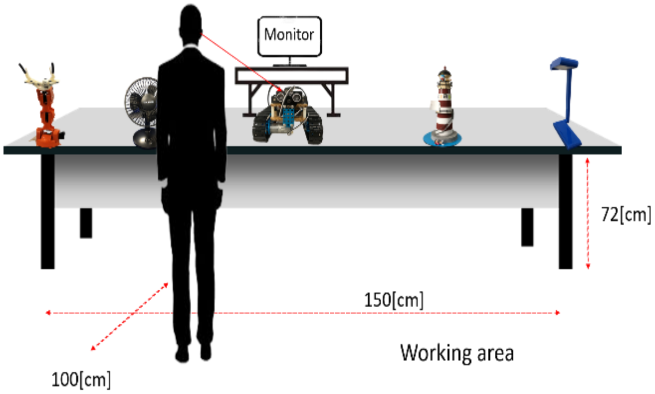

Fig. 9. Settings for preliminary experiment 2.

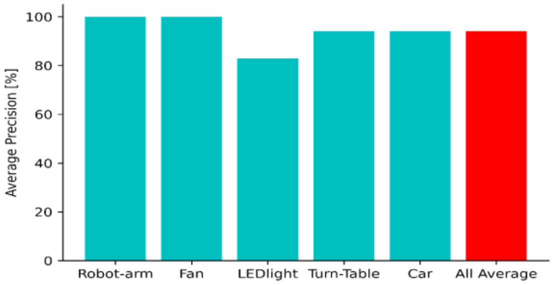

Fig. 10. The result of preliminary experiment 2.

The results in Preliminary Experiment 2 are better than those in Preliminary Experiment 1. In particular, the average accuracy for the object Car is significantly improved. This accuracy is because each subject can move his/her body in a way that makes it easier to follow the object when necessary.

From these experiments, the operability range and usage of the proposed system can be learned. The insights gained from the preliminary experiments are then utilized for users' assessment tests.

B. User Assessment Experiment

User assessment experiments were conducted to investigate the usability of the proposed eye-contact system and to assess its potential for its usage of interface modality. As an evaluation index, usability defined in ISO 9240-11 [23] was used. This criterion encompasses efficiency, effectiveness, and user satisfaction when a user executes a specific task to achieve a goal. This section explains the experiment method and the analytical results. A short demo movie for this experiment can be accessed from https://youtu.be/rKBbP2aLcxY.

A conventional remote-control switch was utilized as a benchmark against the proposed Gaze Switch. The outline of a remote-control switch is shown in Fig. 11.

Here, a target machine can be activated/deactivated by pushing a correlated button in the remote controller (RC) like selecting a TV channel.

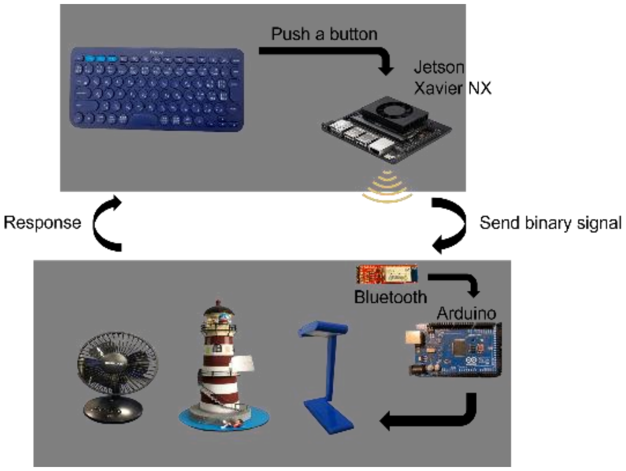

Fig. 11. Outline of the remote-control switch.

Naturally, as many subjects have already been familiar with RC for a long time, it is easy to predict that RC yields higher usability measures. Therefore, the objective of this experiment is not to directly compare the usability measure of the proposed Gaze Switch with RC but to compare the improvement of the usability over some repeated experiments. Here, it is enough to argue that if the users experience improvements in their familiarity and operability of the Gaze Switch over some repeated experiments, then the validity of the Gaze Switch as a new modality can be confirmed. It is also important to show that the improvements' signatures are similar to those of RC. Here, the number of repeated experiments was four with an interval of one week before the next experiment.

In the experiment, the task is based on a scenario where a user activates a household appliance while reading a book at home. This scenario is applied based on the results of the preliminary experiments where the fixed position of users yields worse results so that the rigorousness of the test is guaranteed. Fig. 12 illustrates the experimental environment.

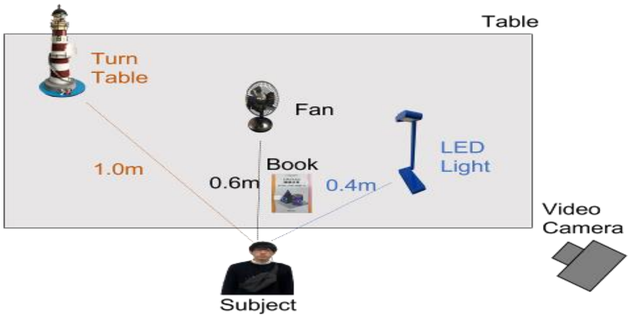

Fig. 12. The setting for the user assessment experiments.

The procedure was as follows.

Step 1. The subject sits and reads a book.

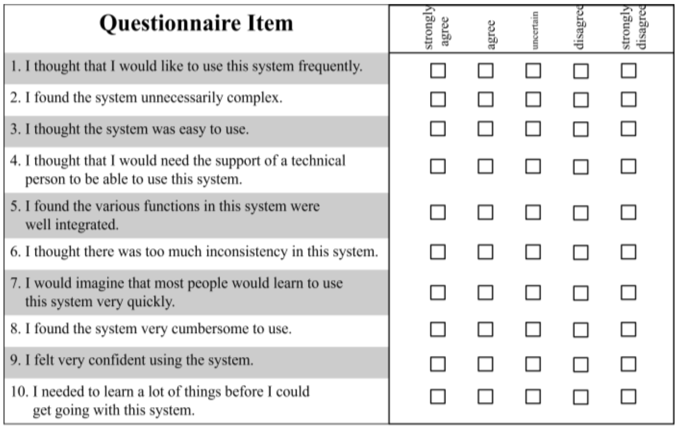
Step 2. A control PC instructs the subject to activate or deactivate one of three designated machines: Fan, LED Light, or Turn Table, in a random manner.

Step 3. The subject stops reading and activates/deactivates the machine with an interface at hand.

Step 4. The subject resumes reading upon confirming the activation or deactivation.

Go to Step 1 until the terminal condition is met.

During the experiment, the reaction time from the instruction to the activation/deactivation of the specified machine and the accuracy of the interaction were evaluated. Additionally, the users were asked to complete the questionnaire for measuring their satisfaction based on System Usability Scale (SUS) [24] on a 5-point Likert scale as shown in Fig. 13. The result of SUS is standardized in the range of 0 to 100. A null hypothesis test regarding the significant difference between the interfaces' characteristics and the familiarity factor due to the repeated usage of these usability-quantitative data was run. Here, the significance of the difference is assessed through a p-value with a 0.05 threshold. Here, the null hypothesis is that the evaluated factors are identical regarding the usage of RC and Gaze Switch.



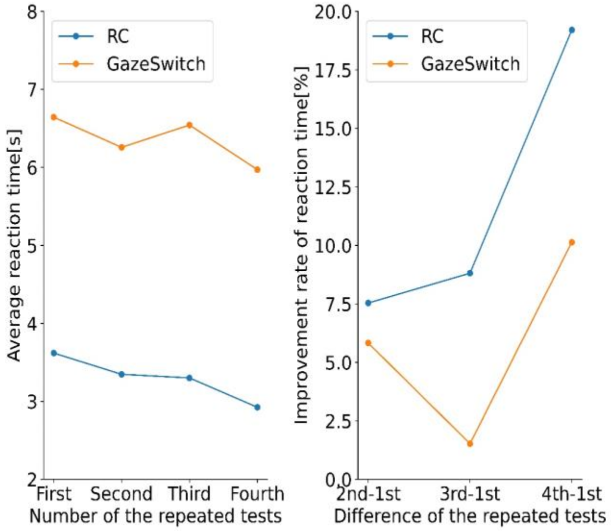
Questionnaire Item	strongly agree	agree	uncertain	disagree	strongly disagree
1. I thought that I would like to use this system frequently.	□	□	□	□	□
2. I found the system unnecessarily complex.	□	□	□	□	□
3. I thought the system was easy to use.	□	□	□	□	□
4. I thought that I would need the support of a technical person to be able to use this system.	□	□	□	□	□
5. I found the various functions in this system were well integrated.	□	□	□	□	□
6. I thought there was too much inconsistency in this system.	□	□	□	□	□
7. I would imagine that most people would learn to use this system very quickly.	□	□	□	□	□
8. I found the system very cumbersome to use.	□	□	□	□	□
9. I felt very confident using the system.	□	□	□	□	□
10. I needed to learn a lot of things before I could get going with this system.	□	□	□	□	□

Fig. 13. Question items of the system usability scale.

Eq. (1) shows the improvement rate, $IR_{i,j}$ of the j-th factor in the i-th repeated test, where $R_{i,j}$ is the score of factor j in the i-th experiment where $j \in \{\text{Reaction time, Accuracy, SUS score}\}$ and $i \in \{\text{Second, Third, Fourth}\}$. This experiment was conducted with 12 subjects.

$$IR_{i,j} = \frac{R_{i,j} - R_{First,j}}{R_{First,j}} \times 100\# \qquad (1)$$

First, the average reaction time needed for operating the specified object with RC and Gaze Switch for the respective test is shown in Fig. 14(a) and the IRs are shown in Fig. 14(b).



(a) Average. (b) Improvement rates.

Fig. 14. Reaction time.

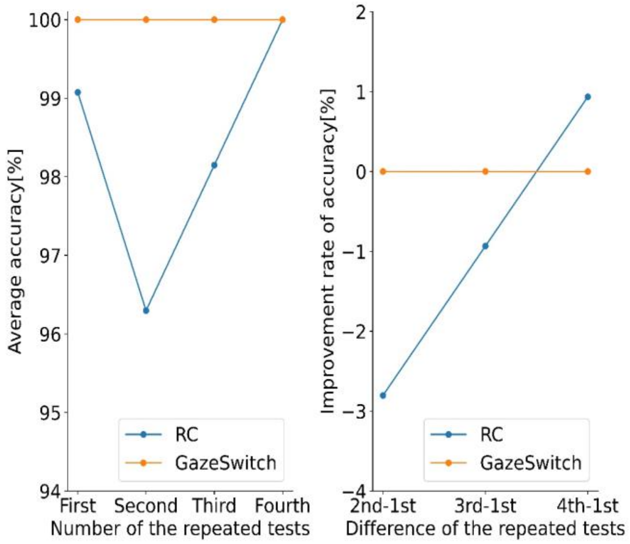
RC is superior to Gaze Switch with regard to the reaction time as can be learned from Fig. 14(a). To check whether the difference is significant, a Wilcoxon signed rank test was conducted that showed a significant difference (p<0.001). In addition, a Friedman test on the familiarity factor of RC and Gaze Switch was conducted. The result showed significant differences between the repeated tests on RC (p=0.002) but no significant differences on Gaze Switch (p=0.376). Fig. 14(b) shows that the gap in the reaction time between RC and Gaze

Switch does not decrease with the number of tests, and this trend can be predicted to stay true. Hence, it can be argued that the difference regarding the reaction time does not depend on familiarity due to the repeated usage of the two interfaces but depends on the basic characteristics of the two interfaces. Table I shows the average reaction time of each machine in the experiment on the respective test.

During the experiments, Gaze Switch allows the subjects to interact with the machines by perceiving them for 1.5 seconds but the latency compared to RC's reaction time was about 3.0 seconds. This latency is due to a discrepancy between the human's field of view and that of the camera, but not the system's operating range.

Next, the average accuracies (the correctness of activating/deactivating the instructed object) using RC and Gaze Switch for the respective test are shown in Fig. 15(a) and IRs are shown in Fig. 15(b).

It is obvious from Fig. 15(a) that the subjects did not need a long time to get familiar to use the Gaze Switch, indicating its good intuitiveness. The intuitiveness of the Gaze Switch is further emphasized in Fig. 15(b). Regarding the difference, the result of a Wilcoxon signed rank test on the interface factor showed a significant difference (p=0.008) between the accuracy of Gaze Switch and RC. In addition, a Friedman test on the familiarity factor in RC was conducted with no significant differences in RC (p=0.137). The significance test results show that RC is not necessarily stable in its intuitiveness. This is because the users occasionally misoperate the machines with RC due to the failure to memorize the relation between the buttons in the RC and the machines. By contrast, with the proposed Gaze Switch, the user can operate an intended machine by looking at it, so it does not need any memorization. From this experiment, it can be argued that the intuitiveness of the proposed interface contributes to its accuracy. Table II shows the accuracy of the respective machines.



(a) Average (b) Improvement rates

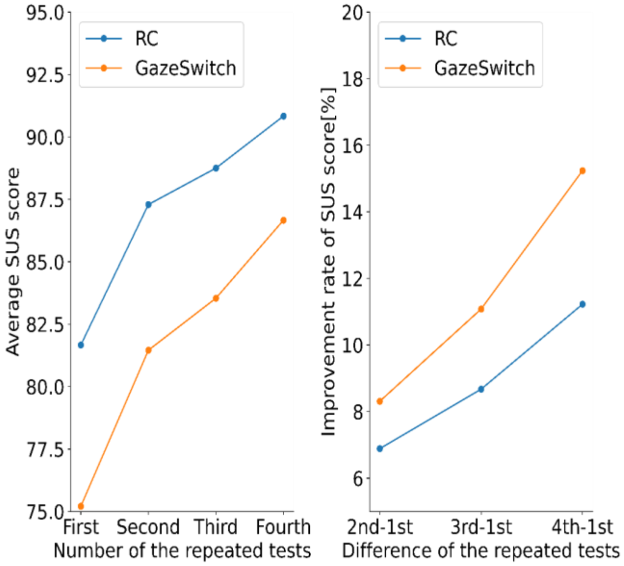
Fig. 15. Accuracy.

TABLE I. AVERAGE REACTION TIME

	RC Average Reaction Time (s)			**Gaze Switch Average Reaction Time (s)**		
Trials	***Fan***	***TurnTable***	***LEDlight***	***Fan***	***TurnTable***	***LEDlight***
First	3.81	3.54	3.51	6.39	6.93	6.61
Second	3.44	3.27	3.33	5.73	6.70	6.34
Third	3.33	3.54	3.03	6.44	6.89	6.30
Fourth	2.93	2.81	3.03	6.04	5.94	5.93
All	3.38	3.29	3.29	6.15	6.62	6.30

TABLE II. AVERAGE ACCURACY

	RC Average Accuracy (%)			**Gaze Switch Average Accuracy (%)**		
Trials	***Fan***	***TurnTable***	***LEDlight***	***Fan***	***TurnTable***	***LEDlight***
First	100	97.2	100	100	100	100
Second	97.2	94.4	97.2	100	100	100
Third	97.2	97.2	100	100	100	100
Fourth	100	100	100	100	100	100
All	98.6	97.2	99.3	100	100	100



(a) Average (b) Improvement rates

Fig. 16. SUS score.

Finally, the average SUS scores of RC and Gaze Switch are shown in Fig. 16(a) and the IRs are shown in Fig. 16(b).

Regarding the SUS score, RC is inferior to Gaze Switch as indicated in Fig. 16(a). The value for Cronbach’s Alpha (0≦a ≦1) to measure whether each item of the questionnaire is reliably able to measure the identical concept (here, satisfaction) by confirming the average covariance between pairs of the items, and the variance of the total score, was a = 0.83. These results indicate the result of the questionnaire is reliable because the value is 0.8 or more. Meanwhile, a Wilcoxon signed rank test to the result on the interface factor showed a significant difference (p=0.014). Likewise, A Friedman test on the familiarity factor in each RC and Gaze Switch showed significant differences in RC (p=0.027) and Gaze Switch (p<0.001). A Wilcoxon signed-rank test on the familiarity factor in RC and Gaze Switch was also conducted. The result showed a significant difference between the First and Forth of the repeated tests in Gaze Switch (p=0.004 after Bonferroni correction for the multiple comparisons problems). Fig. 16(b) shows that the difference in questionnaire scores and the number of repeated tests is getting wider.

It is restressed here that the objective of the experiments is not to directly compare the performance of the RC against the proposed Gaze Switch. The primary objective is to investigate the characteristics of the Gaze Switch in its usage as an interface modality using RC as a baseline. The experiments indicate that the Gaze Switch shows good user intuitiveness. Regarding the reaction time and the user SUS, the Gaze Switch shows good familiarity growth, meaning repeated usage will yield better experiences. The growth trends are also similar to that of a more established interface of RC, which shows the appropriateness of the proposed Gaze Switch as a new modality in the human-machine interface.

IV. Conclusion

In this study, we developed a hardware framework for expanding an intuitive and familiar communication modality, eye contact, for human-machine interaction. The proposed system allows humans to intuitively operate machines through eye contact. Unlike the existing gaze interfaces that often depend on specialized tools, the system allows direct interaction with various machines, thus offering better flexibility and intuitiveness. The users’ assessment tests in this study demonstrate that familiarity with eye contact in human daily communications translates into intuitiveness and robustness of the system. Through this study, it can be argued that eye contact is a reasonable modality in the human-machine interface.

The authors are aware of some technical drawbacks of the proposed system. For example, the relatively long reaction time decreases the usability of the proposed system. This is due to the discrepancy between the human field of view and the field of view captured by the camera. In the near future, this problem can be alleviated by better calibration of the camera or using a multi-camera system to align the view better.

Like the rich modalities in human interactions, in the future, the proposed Gaze Switch is not intended for single usage but in combination with other modalities, for example, verbal and nonverbal interfaces. The combinations of various interfaces will improve the precision of human-machine interactions and remove the difference between inter-human interactions and human-machine interactions. The seamless integration of machines into human interactions in daily life is one of the most important aspects in the coming era of AI technology, Metaverse, and XR, and hence the proposed eye-contact system has good potential for enriching the existing modalities for human-machine interfaces.

Abstract—**Pancreatic cancer, a fatal type of cancer, has a very poor prognosis. To monitor, forecast, and categorise cancer presence, automated pancreatic cancer segmentation and classification utilising Computer-Aided Diagnostic (CAD) model can be used. Furthermore, deep learning algorithms can provide in-depth diagnostic knowledge and precise image analysis for therapeutic usage. In this context, our study aims to develop an Antlion Optimization-Convolutional Neural Network-Gated Recurrent Unit (ALO-CNN-GRU) model for pancreatic tumor segmentation and classification based on deep learning and CT scans. The ALO-CNN-GRU technique's objective is to segment and categorize the presence of cancer tissues. This technique consists of pre-processing, segmentation and feature extraction and classification phases. The images go through a pre-processing stage to reduce noise from the dataset that was obtained. A hybrid Gaussian and median filter is applied for the pre-processing phase. To identify the pancreatic area that is affected, the segmentation is processed utilizing the Antlion optimization method. Then, the categorization of pancreatic cancer as benign or malignant is done by employing the classifiers of the Convolutional neural network and Gated Recurrent Unit networks. The suggested model offers improved precision and a better rate of pancreatic cancer diagnosis with an accuracy of 99.92%.**

Keywords—Pancreatic cancer; Antlion optimization; deep learning; convolutional neural network

I. Introduction

The pancreas is a vital organ in the human body that secretes both internally and externally and is prone to several illnesses. Deeper within the belly, the pancreas is a glandular organ [1]. It is made up of the endocrine and exocrine tissues, which, separately, are essential to digestion and glucose metabolism. Endocrine and exocrine pancreatic illnesses are divided into categories based on the tissue most frequently impacted by pathologies. Chronic pancreatitis, pancreatic cancer, and acute pancreatitis are exocrine pancreas diseases. There is an increasing realization that these three conditions exist on some kind of continuous sequence [2]. Pancreatic endocrine malfunction, a key factor connecting the various kinds of diabetes mellitus, characterizes disorders of the endocrine pancreas. Diabetes of the exocrine pancreas, type 1 DM and type 2 DM, make up the bulk of the spectrum in terms of prevalence in adults [3]. There are other forms of DM as well. Consequently, disorders of the endocrine and exocrine pancreas place enormous socioeconomic and health costs on people across the world.

Pancreatic cancer has a relatively high mortality rate that closely resembles its incidence rates. The fourth most frequent cause of cancer mortality and the twelfth most frequent cause of cancer overall is pancreatic cancer [4]. 62,210 new cases of pancreatic cancer are anticipated to be discovered in the USA in 2022 with a percentage of 3.2% of all cancer cases. Pancreatic cancer patients typically have vague symptoms, such as loss of weight and abdominal discomfort, which can delay detection. Usually, pancreatic cancer patients experience no symptoms up to an established stage of the illness. A standardized approach for monitoring individuals who are at risk of pancreatic cancer does not exist, yet [5]. Pancreatic intraepithelial neoplasias, which are tiny, non-invasive epidermal proliferations inside the pancreatic ducts, are the primary causes of most pancreatic malignancies. The exceedingly dismal outcome for pancreatic cancer is underlined by the strong correlation between disease occurrence and death. In USA, the five-year survival rate for those with pancreatic cancer is still as low as 7%. The terminal stage at which the majority individuals are identified is among the causes of the lower survival rate and is arguably the most significant one. Prior to the illness progressing to an advanced phase, the majority of pancreatic cancer patients have no symptoms [6].

Numerous techniques based on deep learning and machine learning have recently been proposed to identify pancreatic cancer because of the invention of Computer-Aided Diagnosis (CAD). Accurate segmentation of the pancreatic and reliable categorization are often necessary for an automated and elevated pancreas cancer diagnostic model [7]. In everyday practice, pancreatic disorders are diagnosed and monitored using cutting-edge cross-sectional imaging techniques such as computed tomography, magnetic resonance cholangiopancreatography, magnetic resonance imaging, and endoscopic ultrasonography (EUS). Through these techniques, the complete pancreas may be seen in connection to the adjacent anatomy [8]. The most frequently employed imaging technique for the first assessment of suspicious pancreatic cancer is computed tomography. It is chosen over Magnetic Resonance Imaging (MRI) as the initial line modalities because it is less expensive and more widely accessible than MRI. A more accurate assessment of the pancreatic parenchyma and calcifications can be made using computed tomography. Structural information may be obtained from Computerized Tomography (CT) scans. The preferred imaging technique for diagnosing pancreatic illness nowadays is contrast-enhanced CT, which may also have the best standard specifications rates for pancreatic cancer. In various fields, the segmentation of the pancreas in CT images can help clinical processes, such as pancreatic cancer detection, treatment, and surgical support [9]. Therefore, it is worthwhile to investigate a reliable, accurate, and automated segmentation approach for the pancreas.

In abdominal computed tomography images, segmenting organs including the liver, spleen, and pancreas is essential for computer-aided diagnosis, quantitative and qualitative studies, and surgical support. In CAD systems that do quantitative image analysis of people with diabetes or pancreatic diagnostic tools, pancreas segmentation in particular is a crucial component. Because of its size, shape, and position in the abdomen on computed tomography scans, the pancreas is extremely difficult to segment [10]. In the area of organs segmentation, the network architectures of UNet, SegNet and FCN are especially well-liked, and all these techniques have been successfully used in the segmentation of big organs, such the heart, kidneys, and lungs. The segmentation of minor organs might still use different approach. Particularly challenging in terms of form learning are the extremely intricate anatomical components of the pancreatic. Second, there is a dearth of annotated medical imaging data [11]. As a result, the segmentation is unable to achieve a high level of precision. Additionally, the pancreas' location in the abdominal wall differs from patient to patient, and the border contrast is influenced by the amount of visceral fat that surrounds the pancreas. These additional elements are combined to make pancreatic segmentation difficult and susceptible to both over and under-segmentation. To address these issues, we aim to develop a powerful pancreatic segmentation approach that will improve the precision and robustness of pancreatic segmentation.

Because the pancreas is more varied in size and shape than other organs and is challenging to categorize with neighboring organs, segmenting it is a challenging process. The manual segmentation of the pancreas by radiologists requires a lot of time and effort. Additionally, there are variations in the manual results produced by radiologists. Even though advanced machine learning technology, techniques were put forth to separate the pancreas after extracting specific properties utilizing prior information [12]. Numerous deep learning-based studies have been recently completed as hardware efficiency and deep learning technologies have advanced. The results have outperformed earlier approaches in a variety of applications. The convolutional neural network, one of several deep learning methods, performs well for the segmentation and classification challenge and may be efficiently used to segment the pancreas [13].

The research’s main contributions are as follows:

- A significant number of patients' CT images are first gathered, and the CT datasets are analysed in the system.
- Furthermore, the recovered CT pancreatic images contain unwanted noises, which are filtered utilizing an advanced Gaussian and median filter.
- An upgraded Antlion Optimization model has been used for the segmentation process.
- Gray Level Co-occurrence Matrix was used for feature extraction.
- The ALO-CNN-GRU classifies the affected regions as benign and malignant.
- The efficacy of the suggested technique is demonstrated by validating its performance and comparing it to current methodologies.

The paper is structured as follows. Several related works are covered in Section II. The suggested ALO-CNN-GRU architectures are explored in depth in Section III. In Section IV, experiment findings are shown, evaluated, and a thorough assessment of the suggested strategy in comparison to current best practices is made. In Section V, the final portion of the document, the work is concluded.

II. Related Works

In order to improve the segmentation of pancreatic cancer, Jun Li et al. suggested a dual meta-learning approach based on idle data [14]. For clinical treatment and detection of pancreatic cancer, automated segmentation is essential. The segmentation performance is however constrained by the tiny size and hardly perceptible borders. Researchers gather pancreatic cancer unused multi-parametric Magnetic resonance imaging from numerous researches to build a significantly larger dataset for improving the Computed tomography pancreatic cancer segmentation in order to resolve the issue brought on by the small-scale dataset. So, for pancreatic cancer, researchers suggest a deep learning segmentation technique with a dual meta-learning structure. Elevated characteristics become more discriminatory as a result of its ability to combine salient information from CT images. In order to flawlessly satisfy the gaps in visual appeal as well as provide rich intermediate depictions for the ensuing meta-learning scheme, the arbitrary transitional methods between CT and MRIs are generated. Researchers then use prototype meta-learning based on transitional modes to identify and transmit similarities. The distraction caused by internal variations is finally reduced by using a meta-optimizer to flexibly understand the relevant characteristics inside CT data. The suggested approach is a robust pancreatic cancer segmentation approach that is simple to implement into existing segmentation networks and has promise as a viable model for addressing the problems of data scarcity with idle data but its accuracy is very low when compared to the other existing models.

A Deep Learning-Enabled Automated Medical Decision-Making System for Pancreatic Tumor Diagnosis on Computed Tomography was proposed by Thavavel Vaiyapuri et al. [15]. The computer-aided diagnostic model can automatically identify and categorize pancreatic cancers. Deep learning and Machine learning models that have lately been created can be utilized to automatically and quickly diagnose pancreatic cancer. The study introduces an innovative deep-learning-enabled medical decision-making system for classifying pancreatic tumors from CT scans. The IDLDMS-PTC technique's primary goal is to assess the CT images for the presence of pancreatic tumors. An emperor's penguin optimizer with multilayer thresholding approach is derived using the IDLDMS-PTC model for segmenting pancreatic tumors. Furthermore, the MobileNet algorithm is used as an optimum feature extractor for classifying pancreatic tumors. The multileader optimization approach is employed to alter the bias and weight parameters of the AE approach in the best possible way. The innovative features are demonstrated by the EPO algorithm's design for selecting the best threshold and by the MLO algorithm's design for parameter adjustment. Numerous simulations were run on data sets, and the results showed that the IDLDMS-PTC model performed well compared to other techniques but the model still needs improvements.

The Anatomy-Aware Transformers were addressed by Yingda Xia et al. for the efficient pancreatic cancer screening [16]. The most fatal malignancy, pancreatic cancer is quite infrequent. It is not advised to screen the entire asymptomatic populace because to the possibility that a sizable proportion of false positive people may have unneeded imaging tests, considerably increasing health care expenditures with no discernible patient benefits. In the study, researchers explore the viability of detecting respectable pancreatic masses utilizing a single-phase non-contrast CT scan and classifying the detected masses as pancreatic ductal adenocarcinoma, other anomalies, or healthy pancreas. The majority of the time, regular radiologist or perhaps even pancreatic experts perform the duty ineffectively. Researchers suggest a novel deep classification method with an anatomy transformer employing pathology verified mass kinds and transfer of knowledge from contrast-enhanced Computed tomography to non-contrast Computerized Tomography as supervision. The research identifies a possible new instrument with considerably higher accuracy and reduced computational risk and cost for widespread pancreatic screening and treatment. However, the proposed instrument is not able to analyze vast amounts of data.

Xiaoyu Yang et al. used Interpolation neural network with local linear embedding for cancer progression segmentation [17]. The thick Computed tomography with its low resolution and wide spacing increases the risk of misinterpretation and makes it extremely difficult to automatically separate organs and tumors. Because of the technology limitations, particularly in automated pancreatic tumor segmentation, there is poor consistency among segments of the 3D CT image containing few tumors per image. In addition, tumor characteristics, such as size, form, localization, and severity, vary greatly between instances. The segmentation process is very unclear due to the hazy borders of tiny tumors. Researchers integrate the LLE-based interpolation neural network into the pancreatic tumor segmentation challenge in an effort to address these issues, which primarily incorporates the following enhancements. To represent the connection between nearby segments and the interpolated segment, researchers use local linear embedding. It adjusts the organ's geometric transition between segments. The LLE module and neural network work together to greatly improve image quality, resulting in more consistent and sharper images being produced for each sequence. The system utilizes a multiscale cascading technique to lessen the impact of sudden changes in tumor size on segmentation outcomes. Furthermore, to improve accuracy, the mechanism must be improved.

Vahid Asadpour et al. analyzed pancreatic cancer tumors in Computed tomography images using a patch-based multi-resolution convolutional neural network. In the article, researchers suggested a cascaded framework for extracting the volumetric form of the tumor and pancreas in adenocarcinoma patients. The method combines an elastic atlas that can fit on 3D volumetric shape retrieved from Computed tomography slices, a convolutional network with multiple forward pathways to recognize the fragments of images with particles to good resolutions using a multi-resolution structure. Geometrical characteristics that were altered both globally and per organ were employed to value the atlas organs. A multiresolution CNN was utilized for the categorization of image patches. By using an edge detection technique, the pancreas and tumor were finally segmented. The completely cascaded technique that has been developed outperformed all other methods in comparison. However, it takes a lengthy time to analyze data compared to other approaches [18].

The Preoperative Estimation of Pancreatic Survival Rates and Operational Margins utilizing Contrast-Enhanced CT Imaging were described by Jiawen Yao et al. [19]. One of the deadliest fatal malignancies, pancreatic ductal adenocarcinoma, has a poor prognosis. For individuals who are qualified for first treatment of PDAC, surgery continues to provide the highest chance of a possible cure. Nevertheless, even among resected individuals who were at the similar stage and got identical therapies, results might differ dramatically. In the study, researchers introduce a unique deep neural network called 3D CE-ConvLSTM, which can extract the tumor regression characteristics or features from CE-CT imaging techniques, for the survival prediction of PDAC victims. Researchers describe a multi-task CNN that can predict margins and outcomes, and which gains from understanding variables associated with tumor resection margins to enhance survival prediction. Comparing the suggested framework to current cutting-edge techniques to survival analysis, prediction performances must be improved.

An Effective Deep Learning-Based Pancreatic Cancer and Non cancer Categorization Model Utilizing CT scans were proposed by Maha M. Althobaiti et al. [20]. The prognosis for pancreatic tumors, which are a fatal kind of tumor, is quite dismal. To monitor, anticipate, and categorize the presence of pancreatic tumors, an automated pancreatic tumor categorization employing a computer-aided diagnostic model is required. Artificial intelligence can provide in-depth diagnostic knowledge and precise picture interpretations during treatment. The work develops an ODL-PTNTC model for optimum deep learning-based pancreatic tumor and nontumor categorization utilizing CT images. The ODL-PTNTC method's objective is to identify and categorize pancreatic tumors and non-tumors. Adaptive window filtering is a method included in the suggested ODL-PTNTC approach to eliminate noise. Additionally, the image segmentation procedure uses the Sailfish Optimizer based Kapur's Thresholding approach. A collection of feature vectors is also produced through feature extraction utilizing the Capsule Network. For categorization reasons, Political Optimizer with CFNN is also used. The performance of the classifier of the ODL-PTNTC approach can be enhanced by DL-based segmentation methods.

III. Proposed Methodology

In the beginning, pancreatic cancer images from Computerized Tomography (CT) are gathered. After that, the images are employed for testing and training. Pre-processing of pancreas-dependent CT images involves the removal of extraneous noise using a combined Gaussian and median filter. In this study, the nodules associated with pancreatic cancer are found and segmented using the Antlion optimization method. The Grey Level Co-occurrence Matrix is then used to extract the features. The suggested ALO-CNN-GRU method is utilized to categorize the aggressiveness of pancreatic cancer nodules. Fig. 1 represents the proposed method's framework.

A. Dataset Description

From the General Hospital of the Shenyang Military Area Command, 80 patients' CT data were analyzed. A total of 1700 images in Digital form are included in every pair of CT imaging sequence. Each CT picture is 512 x 512 pixels in resolution. There are 40 patients who have pancreatic cancer, while the others are well. Both malignant and benign pancreatic cancer images can also be found in the CT imaging. Three nuclear medicine specialists choose the descriptions for the images. Researchers perform segmentation tests using the NIH pancreatic segmentation dataset, which comprises 82 abdominal contrast-enhanced 3-Dimensional CT images, to fairly compare our segmentation approach to others. The surface pancreatic segmentation masks have indeed been submitted by a med student and have been reviewed by a radiologist. 1782 CT data are present, of which 863 serve as the training datasets and 919 serve as the testing datasets.

B. Pre-Processing

The initial stage in the identification of pancreatic cancer is pre-processing. It is employed to remove extraneous data and fill in dataset shortages. The evaluation of the sample images is slowed down by unrelated and unexpected sounds that affect the computed tomography images. The speckle noises that are brought on by internal and external causes mostly impact the CT images. Therefore, a hybrid filter using a mixture of Gaussian and median is applied in this research to minimize noise in CT pancreatic images. The Gaussian filter is applied to minimize the noise in the CT scans as well as the residual variations of geographical intensities. The Gaussian filter is utilized to replace the noisy pixels in the images with the Gaussian-distributed average value of the surrounding pixels. The median filter, on the other hand, may effectively remove spiky noises while maintaining the image's crisp edges and will also restore each pixel's grey level. In order to segment the images of pancreatic cancer, the noise-reduced images are employed in the ALO-CNN-GRU model.

The equation for the Gaussian filter is:

$$G(r) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{r^2}{2\pi\sigma^2}}) \tag{1}$$

Where σ is the standard deviation of the distribution. The distribution's mean is considered to be zero.

The equation for the median filter is:

$$\hat{g}(m,n) = median_{(s,t)\in T_{mn}}\{f(s,t)\} \tag{2}$$

Here $f(s,t)$ residual pixel following removal.

The improved equation for the pre-processing of CT images is:

$$\hat{g}(m,n) = median_{(s,t)\in T_{mn}}\{G(r)\} \tag{3}$$

Here *r* is the pixel dimension of every image. Every image is denoted by *m*.

C. Segmentation

The segmentation process is primarily employed to segment the affected region in the visualizations of CT images. The performance of image processing depends on how well the segmentation process works. Image segmentation is widely used to pinpoint an image's influenced areas as well as the constraints imposed by its curves and lines. The process of image segmentation divides each collection of pixels in the images into its own group of labels. In medical image processing, image segmentation's primary goal is to locate the cancer-affected regions and provide sufficient information for further identification. The identification of morphological characters and the detection of pancreatic cancer typically involve pancreas segmentation. Nevertheless, due to the significant anatomical heterogeneity of the pancreas, precise segmentation remains difficult. For this purpose, we segment the pancreas utilizing Antlion Optimization (ALO).

1) Antlion optimization: The Ant Lion (called Antlion) optimization algorithm imitates an antlion's natural hunting strategy. While antlions primarily hunt as larvae, the adult period is used for reproducing. A larval antlion moves in a circle while ejecting sand with its muscular jaws to create a cone-shaped opening in the sand. Following the construction of the traps, the larvae conceal underneath the base of the cone and waits for insect species ants—to enter the hole and become entangled. When the antlion discovers that there is prey in the trap, it tries to catch its victim. Although they try to get away from the trap, insects are often not immediately caught. In this case, antlions cunningly throw grains along the edge of the opening to assist the prey in slipping towards the bottom of the pit. A prey that is captured in the jaws is dragged under the ground and eaten. Antlions discard the remaining prey outside of the hole after eating it and prepare the pit for the subsequent hunt. Another noteworthy aspect of antlions' way of life is the relationship between the dimensions of the traps, one's personal level of hunger, and the form of the moon.

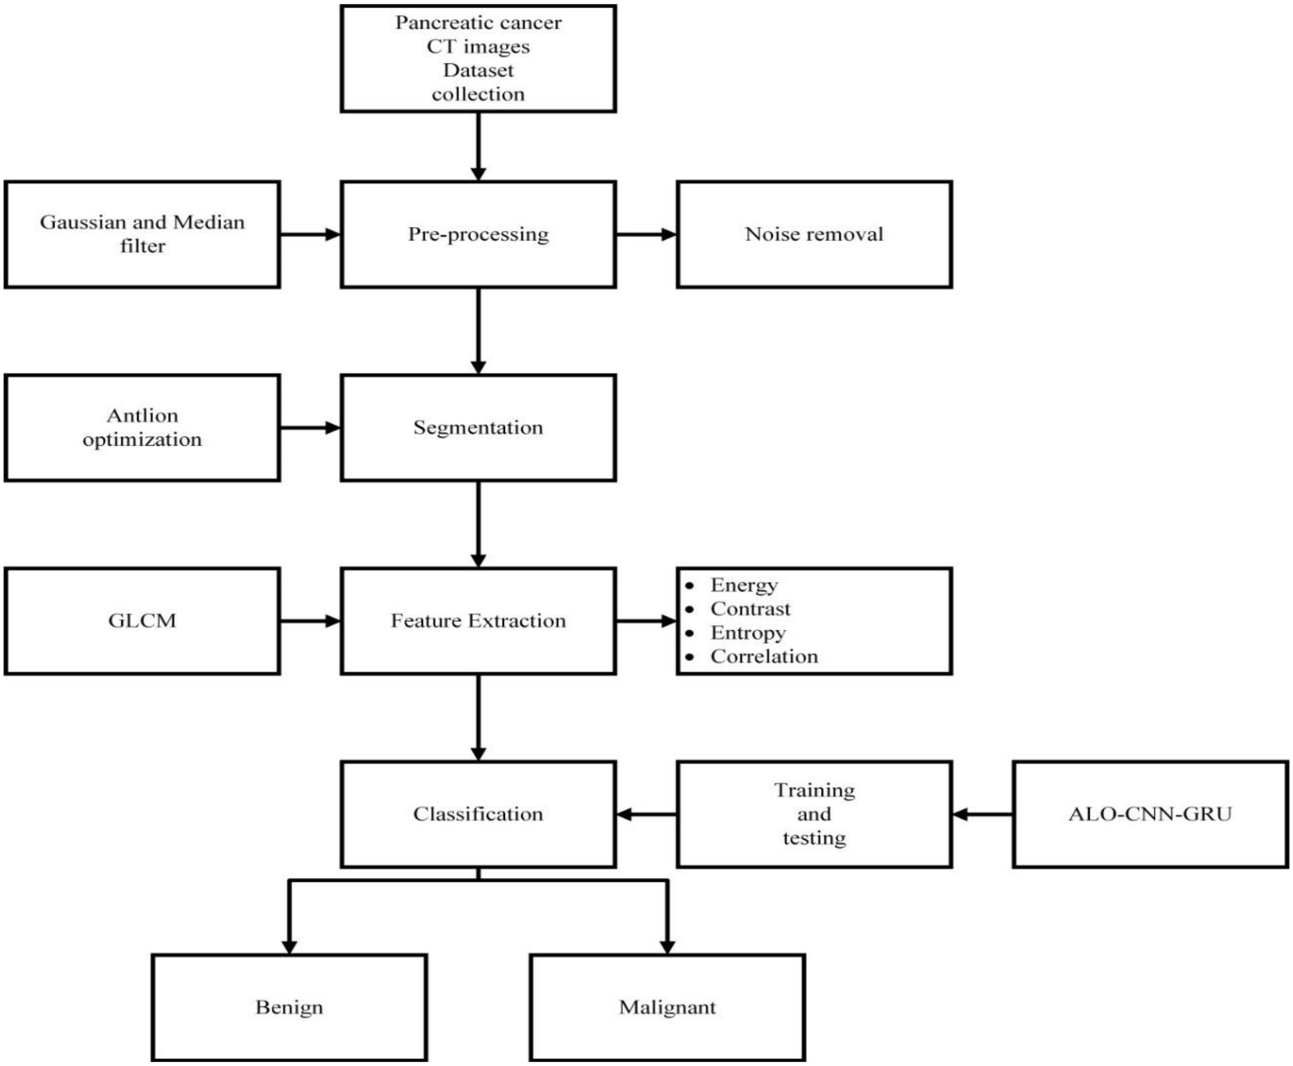

Fig. 1. Proposed method’s framework.

2) ALO algorithm operators: The ALO algorithm simulates ant behaviour in nature, including how they create trap and goes on the hunts. Ants taking lengthy walks at random. The ant moves arbitrarily throughout the search area in accordance with equation (4).

$$X_i^t = \frac{(X_i^t - b_i)\times(h_i - G_i^t)}{(h_i - b_i)} + G_i \tag{4}$$

where b_i is the random walk's i-th variable's minimum value, G_i^t is the i-th variable's minimal value at the t-th iteration, and h_i reflects the highest value for variable *i* at iteration *t*. The ant random walk is normalized to the maximum or minimum values of the search area if it occurs outside the search area.

3) Trapping in antlions pits: The antlion traps have an impact on the ants' random travels. It is demonstrated that a variety of variables govern the ants' random travels (g, h). Where g is the lowest consistent factor for i-th ant and h is the highest consistent factor for i-th ant.

$$g_i^t = Antlion_j^t + G^t$$

$$h_i^t = Antlion_j^t + h^t \tag{5}$$

4) Building trap: The ability of an antlion to hunt was modelled using a roulette wheel. The person operating the roulette wheel chooses the antlion based on its fitness because only one antlion is allowed to capture every ant. The likelihood of catching ants increases with an antlion's fitness.

5) Ants moving toward the antlion: The antlion begins to spray sand outward from the center of the trap once it understands there's an ant in the conic hole. Flexible reduction of the ant's random journey range is calculated as follows:

$$g^t = \frac{g^t}{I}$$

$$h^t = \frac{h^t}{I} \tag{6}$$

where g^t the smallest of all the variable at the t-th iterations, and h^t shows the vectors that contains the most variable at the t-th iterations.

6) Prey capture and trap construction: Subsequently, the antlion captures the ant and consumes its body when the ant grows stronger than it. To improve its chances of a new hunt, the antlion changes its location to match that of the hunted ant. The suggested equation is shown below.

$$Antlion_j^t = Ant_i^t, \ if \ f(Ant_i^t) > f(Antlion_j^t) \qquad (7)$$

The antlion known as the Elite-Antlion is the one that consistently provides the best answer across all iteration and searches domains. Every iteration compares the elite-antlion to the antlion only with best fitness. By using the ant's randomness algorithm throughout the roulette wheel (R_B^t) and the unplanned excursion of Elite-Antlion (R_P^t), the elite-antlion strategy affects how the ants wander randomly around the antlion.

$$Ant_i^t = \frac{R_B^t + R_P^t}{2} \qquad (8)$$

The complete flow chart of the working process is given below in Fig. 2.

```
Algorithm 1: ALO-CNN-GRU mechanism
Input: Computerized Tomography Images
Output: Benign, malignant
Import input CT image data
Let I be the input data that is taken for analysis
$I = \{I_1, I_2, I_3 \ldots.\}$
Pre-processing of images          //Gaussian and median filter
Segmentation of images            //Antlion Optimization
Create a population of n ants and n antlions at random starting sites
Determine each ant's and antlion's fitness
Locate the elite antlion;
t=0
While (t ≤ T)
    Foreach $ant_i$ do
        Use the roulette wheel to choose an antlion
        Entice ants to approach the antlion
        Construct a random walk to $ant_i$ and normalize
    End
    Compute each ant's level of fitness
    To become fitter, swap an antlion for the equivalent ant
    If an antlion gets more fit than the elite, upgrade the elite
    end if
    Feature extraction            //GLCM
    Classification                //CNN-GRU classifier
    Classifying as benign, malignant
    end if
end while
```

D. Feature Extraction

The feature extraction process entails transforming unstructured data into numerical qualities that may be used to protect the data included in the original set of information. These characteristics, which are obtained from every one of the CT images that were taken, represent how each patient interprets CT scans individually. During testing, the images' dimensionality is enhanced. However, in order to identify pancreatic cancer, the dimensionality of the images must be decreased. To fix this problem, the feature extraction process was being used.

In the feature extraction, the Gray Level Co-occurrence Matrix (GLCM) is utilized. By calculating the pairings of pixels with specific values, it may calculate the structure of the images. The GLCM analyses the image's grayscale to determine the pixels' brightness. Energy, Correlation, homogeneity, entropy, contrast, and other properties of the second-order representations are evaluated for the purpose of deleting the statistical texture characteristic.

1) *Energy:* Energy is described as the insertion of a square in images when the concentration levels are unequal, and the grey levels are often greater. Eq. (9) is used to determine the energy of the input data.

$$E = \sum_j \sum_k \{V(j,k)\}^2 \qquad (9)$$

where an image is indicated as V and grey level squares are denoted as (j, k).

2) *Contrast:* When an image's local contrast is evaluated, attributes are used, and when the concentration is even, a low value is calculated. The original images contrast and total number of grey levels are projected in eqn. (10)

$$C = \sum_{m-0}^{\mathrm{Pq}} \mathrm{m} \ \{ \sum_{j-1}^{\mathrm{Pq}} \sum_{k-1}^{\mathrm{Pq}} V\ (j,k)\} \qquad (10)$$

where P denote the grey level of the images, V denotes the images, and (j, k) denotes the grey level square of the images.

3) *Correlation:* The correlation characteristics could be utilized to account for both the linear dependency of the grey levels on the pixels and the numerical correlations between the variables. In eq. (11), the qualities are revealed.

$$\mathrm{C} = \frac{\sum_j \sum_k (j,k) V\ (j,k) - \mu\mathrm{m}\ \mu\mathrm{n}}{\sigma_m\ \sigma_n} \qquad (11)$$

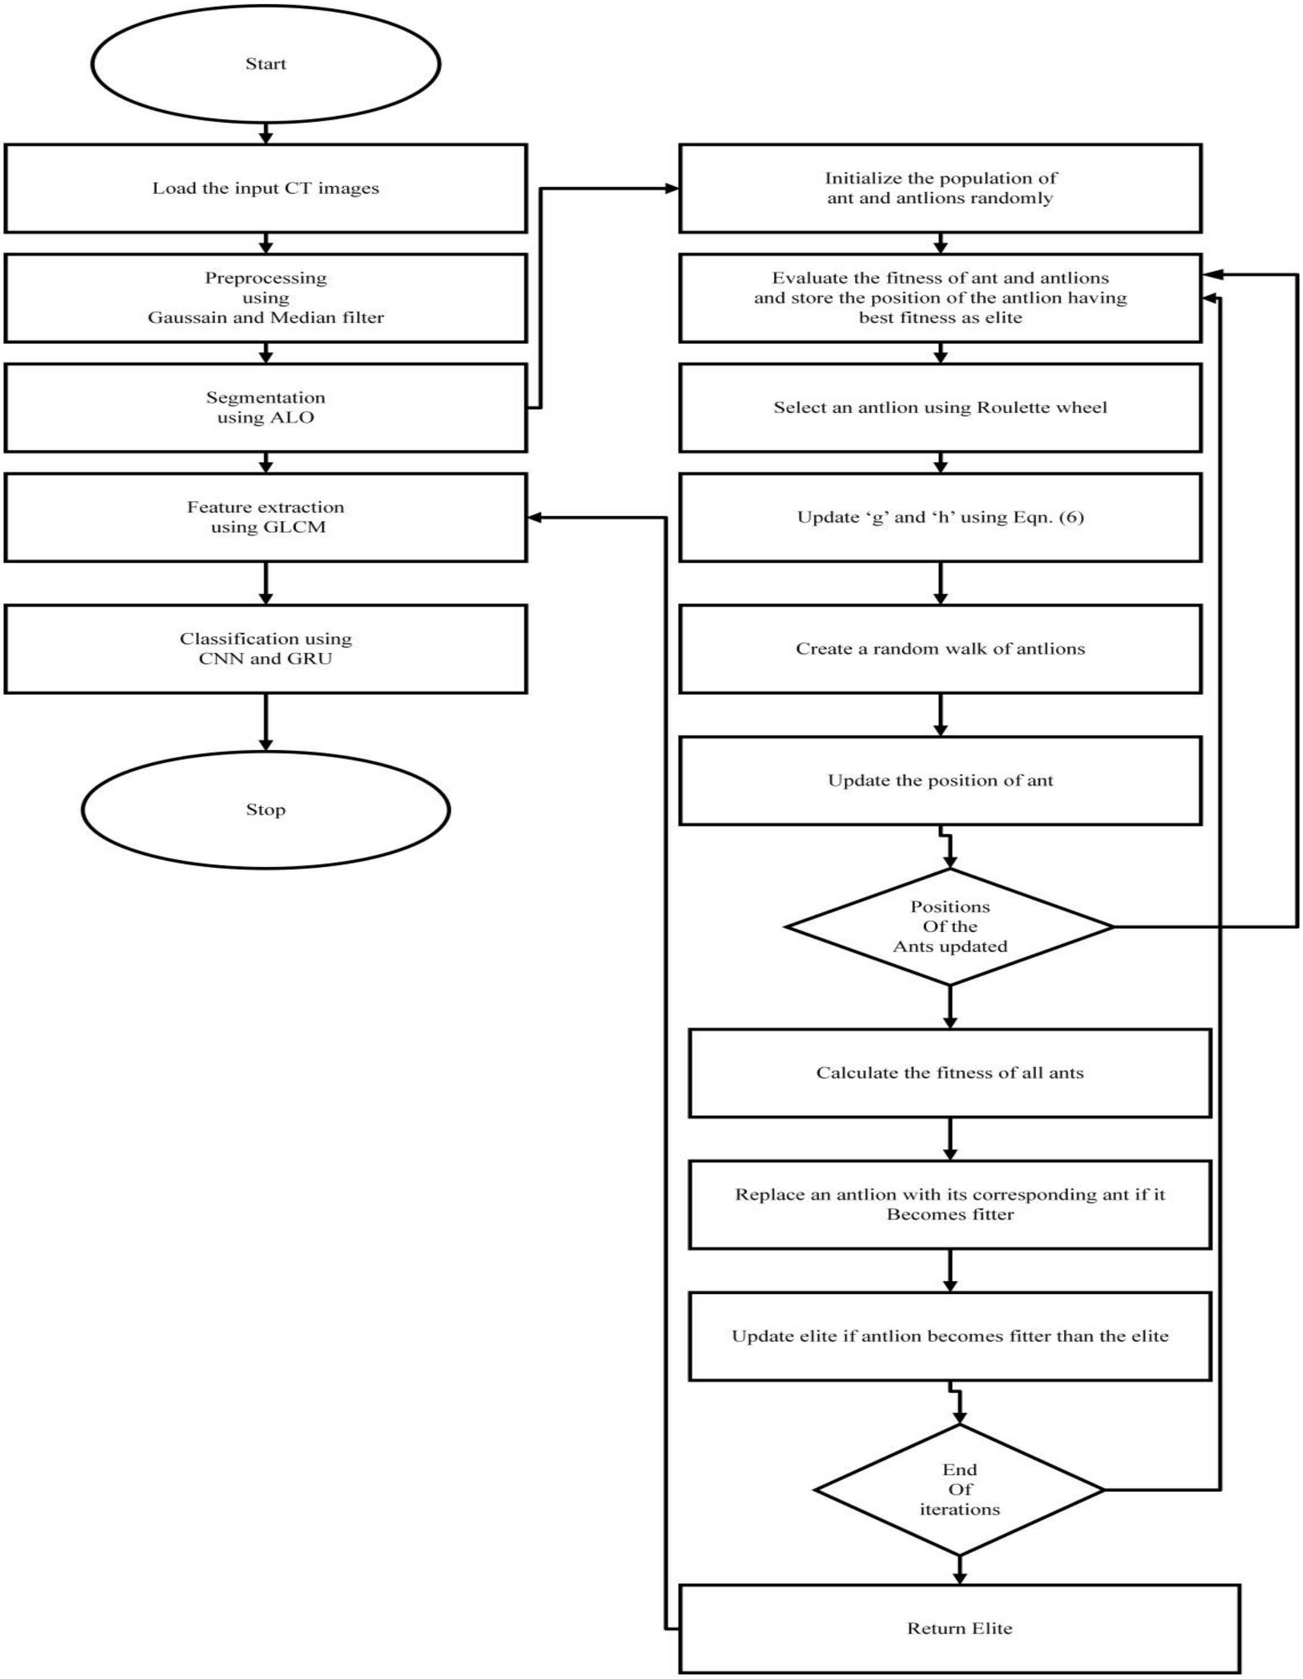
The mean and standard deviation values, in the images, are μ_{m}, μ_{n} , $\sigma_{m,}\ \sigma_n$ which are defined as row and column, respectively.

4) *Entropy:* The expected significant amount of the unpredictability of the distribution of the grey level, which is indicated in eq. (12), is referred to as entropy.

$$En = -\sum_j \sum_k V(j,k) \log(V(j,k)) \qquad (12)$$

E. Classification using CNN and GRU

1) *Convolutional neural network:* Utilizing many CNN front layers, which are used to uncover patterns in images, convolutional neural networks are able to recognize lines and corners.



Start
Load the input CT images
Preprocessing using Gaussain and Median filter
Segmentation using ALO
Feature extraction using GLCM
Classification using CNN and GRU
Stop
Initialize the population of ant and antlions randomly
Evaluate the fitness of ant and antlions and store the position of the antlion having best fitness as elite
Select an antlion using Roulette wheel
Update 'g' and 'h' using Eqn. (6)
Create a random walk of antlions
Update the position of ant
Positions Of the Ants updated
Calculate the fitness of all ants
Replace an antlion with its corresponding ant if it Becomes fitter
Update elite if antlion becomes fitter than the elite
End Of iterations
Return Elite

Fig. 2. ALO-CNN-GRU technique flow chart.

However, when they get farther into the neural network, they may transfer these patterns there and attempt to find more distinguishing properties. For extracting image features, the CNN model is incredibly effective. Furthermore, the suggested CNNs model, according to the researchers, successfully distinguishes pancreatic CT scans. The pooling, convolutional layer (CLs), and fully connected layers make up the CNN's three major layers (FCs). Calculating the results of neurons connected to local sites is the responsibility of the CLs. By taking into account the region's and weights' dot product, it is decided. The common filters in the instance of the input images are made up of small area pixels. These filters can examine the images by swiping a window over them while automatically regulating any recurring patterns that show up in any image location. The stride is the separation in a series of filters. In the event that the initial parameter set is less than any one of the filter dimensions, they expand the convolution to incorporate screens that overlap. Each image's equation from the training set is given in Eq. (13)

$$p(c,q)=\frac{o(c,q)-\mu}{\sigma} \qquad (13)$$

a) Convolutional layer: The convolutional layer uses every layer to examine every image's complexity after collecting a range of input images. It is connected directly to the characteristics needed in the given image. It is expressed in Eq. (14)

$$f_i^n = x(\sum_{j\in N_i} f_j^{n-1} * p_{ji}^n + t_i^n) \qquad (14)$$

N_i – It stands for an input choice. The output is a bias that is additive. The kernel used for the map i, which if the map t and map s both sums over map i.

b) Max pooling layer: This layer is included in the down sampling layer to minimize fitting and the quantity of the neurons utilized. In addition to controlling overfitting, the pooling layer minimizes the size of the feature map, number of parameters, pace of computation, and the training time. It is calculated by using eqn. (15)

$$x_{mab} = max_{(c,d)\in} f_{ncd} \qquad (15)$$

Map, f_{ncd} is the element as (c, d) within the pooling region pts which represents a local neighbourhood around the place (t, s).

c) Fully connected layer: Fully Connected Layer has been employed for the representation classification context. Convolutional layers are put first, then FC layers. The output and input illustrations are mapped using the Fully Connected layer. The last layers of the network are completely coupled layers. The output of the max pooling layer serves as the input for the fully connected layer.

d) Softmax layer: The Softmax layer converts the values into a standardized proportion distribution. The classifier receives the output as an input. The Softmax classifier is a standard contribution classifier that applies the Softmax layer's structure to pancreatic cancer nodules. It is shown in Eq. (16)

$$\sigma(\vec{X})_a = \frac{e^{x_a}}{\sum_{i=1}^{n} e^{x_i}} \qquad (16)$$

2) Gated recurrent unit network: In order to solve the gradient vanishing problem, the GRU model was most frequently used in recurrent neural networks (RNN). GRU is more effective than LSTM since it has an internal cell state and three primary gates. The data is kept in a secure location within the GRU. The update gate offers both past and forward information, whereas the reset gate offers previous knowledge. The needed data from the former condition of the system is preserved and kept by the present memory gate using the reset gate. The input modulation gate allows for the introduction of nonlinearity while simultaneously giving the input zero-mean properties. The mathematical formulation of the basic GRU of rest and updated gates is, as defined by the following,

$$A_t = \sigma\,(Y_t.Z_{ya} + F_{t-1}.Z_{ha} + d_a) \qquad (17)$$

$$B_t = \sigma\,(Y_t.Z_{yb} + F_{t-1}.Z_{hb} + d_b) \qquad (18)$$

where Z_{ya} and Z_{yb} present weight parameters, while the d_a , $d_b$are biased. Fig. 3 represents the fundamental design of the GRU model.

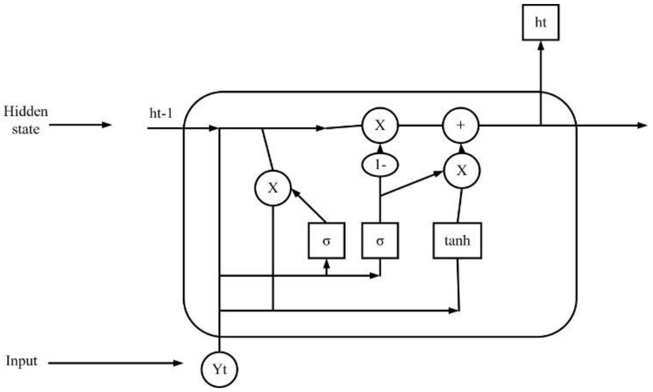


Fig. 3. The fundamental design of the GRU model.

3) Combined CNN-GRU: Four convolution layer (CL) layers, three max-pooling layers, and three fully linked layers made up the CNN-GRU model (FC). The activation function was included since it might not stimulate every neuron at once, which improves performance and speeds up learning. The raw image data were initially provided with the dimensions in CLs. Features must be extracted for the CNN-GRU model by going through Convolutional Layers. To reduce the nonlinearity dimension, ReLUs were combined with Convolutional Layers. The parameter for the training dataset is likewise decreased by the pooling layer. After the pooling layer, the training variables were transferred over from the hidden layer to avoid overfitting issues in the system. Fig. 4 represents the overall structure of the CNN-GRU model.

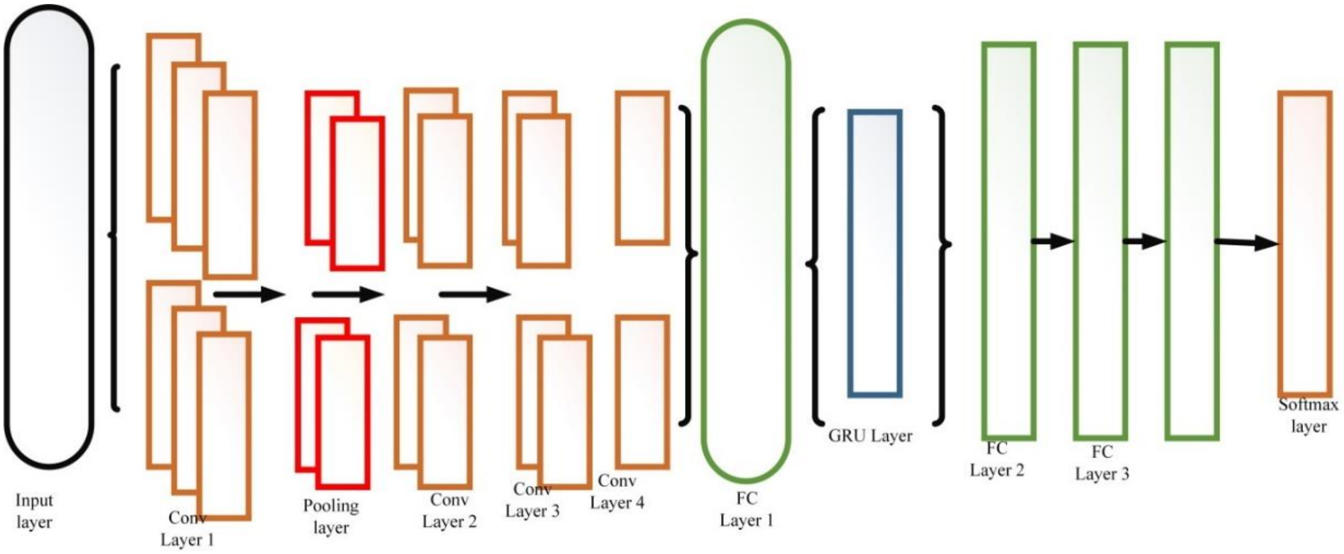

Fig. 4. Overall structure of the CNN-GRU model.

IV. Results and Discussion

A dataset of images from computerized tomography is used to evaluate the suggested strategy. The 1782 CT images were pre-processed utilizing a hybrid Gaussian and median filter. CT image pre-processing is essential for enhancing the image's visual appeal before additional processing. The images in the collection often contain noise; the noise is removed by pre-processing. After that, the segmentation process is completed using the Antlion optimization method. The areas of pancreatic cancer are identified and separated throughout this procedure. The Gray Level Co-occurrence Matrix then does the feature extraction. The combined CNN-GRU performs the classification after that. The effectiveness of the offered technique is assessed using performance indicators such as Recall, Accuracy, F-measure, and Precision.

A. Accuracy

The model of the system accuracy is a measure of how precisely it functions across all classes. Generally, it is the statement that all observations are accurately expected observations. Accuracy is expressed in Eq. (19),

$$Accuracy = \frac{Tpos+Tneg}{Tpos+Tneg+Fpos+Fneg} \quad (19)$$

TABLE I. Comparison of Accuracy

Methods	Accuracy (%)
IDLDMS	99.35
Multi resolution CNN	89.67
CE-ConvLSTM	73.6
ODL-PTNTC	98.82
Proposed ALO-CNN-GRU	99.92

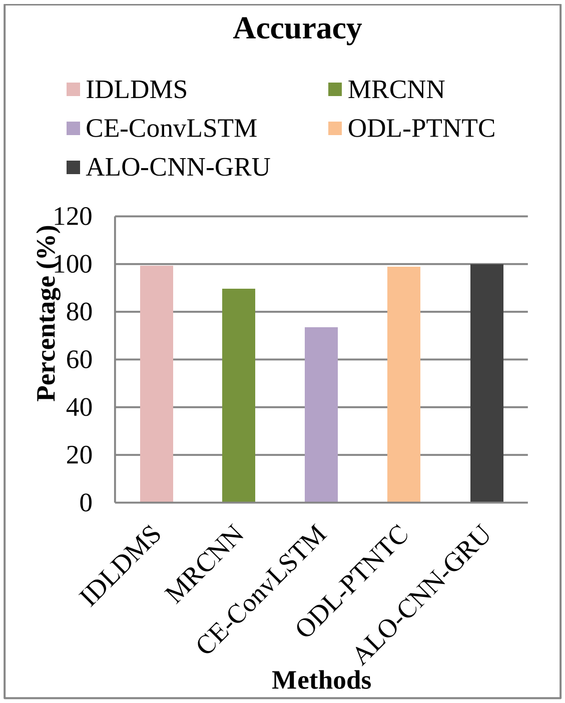

Fig. 5. Comparison of accuracy.

When compared to the current Pancreatic cancer segmentation and classification techniques like IDLDMS, MRCNN, CE-ConvLSTM, ODL-PTNTC, which are shown in Table I, the projected methodology ALO-CNN-GRU obtains superior accuracy. The accuracy of ALO-CNN-GRU and other approaches is compared in Fig. 5.

B. Precision

Precision is determined by counting the precise positive ratings that differ from the total positive evaluations. By using eqn. (20), it is possible to determine the accurate identification of cancer nodules in the afflicted area.

$$P = \frac{Tpos}{Tpos+Fpos} \qquad (20)$$

TABLE II. COMPARISON OF PRECISION

Methods	Precision (%)
IDLDMS	99.35
Multi resolution CNN	91.37
CE-ConvLSTM	81.3
ODL-PTNTC	98.73
Proposed ALO-CNN-GRU	99.64
AAT	95.2
LLE	96.55

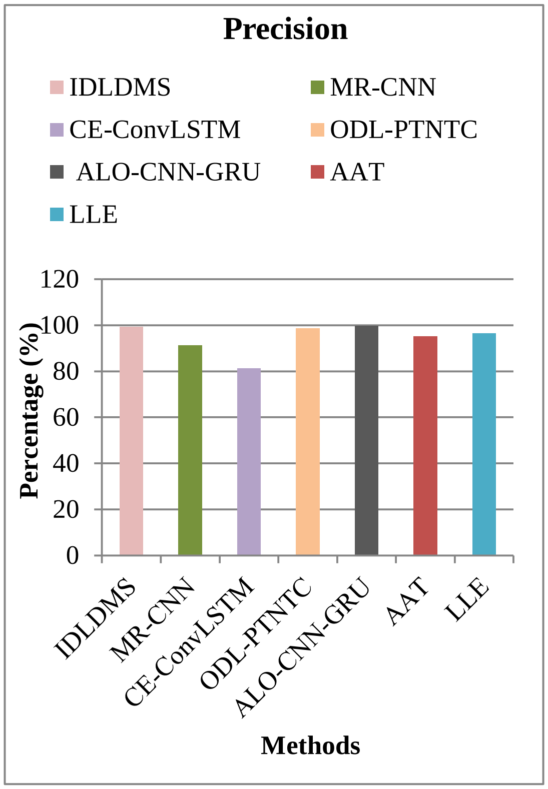

Fig. 6. Comparison of precision.

The precision comparison between ALO-CNN-GRU and other methods is shown in Fig. 6. Table II shows that the proposed Antlion Optimization-Convolutional Neural Network-Gated Recurrent Unit strategy outperforms previous pancreatic cancer segmentation and classification methods including IDLDMS, MR-CNN, CE-ConvLSTM, ODL-PTNTC, AAT, and LLE with a greater precision of 99.64%.

C. Recall

The recall is the ratio of the total amount of positive sample to the number of actual positives that were accurately classified as positives. It displays the percentage of prediction about the identification of tumor nodules indicated by Eq. (21) were correct.

$$R = \frac{Tpos}{Tpos+Fneg} \qquad (21)$$

TABLE III. COMPARISON OF RECALL

Methods	Recall (%)
IDLDMS	98.84
Multi resolution CNN	93.63
CE-ConvLSTM	65.9
ODL-PTNTC	98.73
Proposed ALO-CNN-GRU	99.53
AAT	95.8

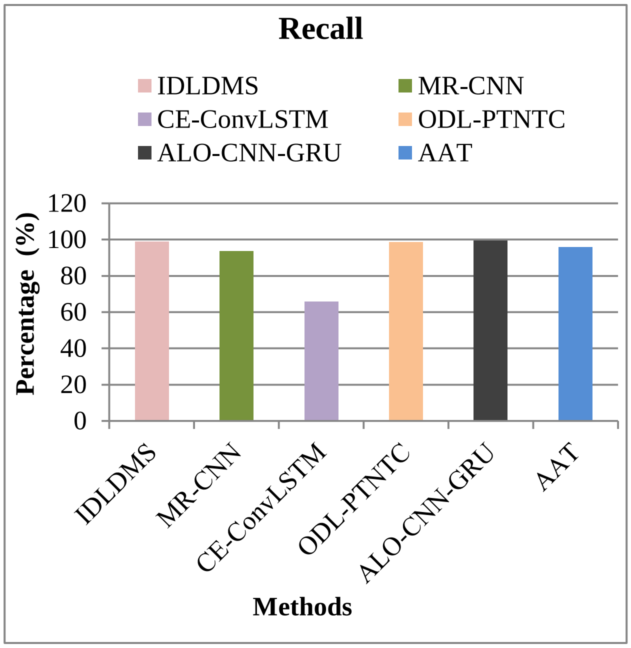

Fig. 7. Comparison of recall.

The suggested methodology ALO-CNN-GRU greatly improves recall comparing to the current Pancreatic cancer segmentation and classification techniques such IDLDMS, MR-CNN, CE-ConvLSTM, ODL-PTNTC, and AAT, as shown in Table III. Fig. 7 displays the recall comparison between ALO-CNN-GRU and other methods.

D. F1-Score

Recall and precision are combined in the F1-Score computation. The F1-Score is computed using recall and precision that is represented in Eq. (22),

$$F1 - score = \frac{2\times precision \times recall}{precision\times recall} \qquad (22)$$

TABLE IV. COMPARISON OF F1-SCORE

Methods	F1-Score (%)
IDLDMS	99.48
Multi resolution CNN	84.97
CE-ConvLSTM	70.5
ODL-PTNTC	98.82
Proposed ALO-CNN-GRU	99.72

Fig. 8 illustrates a comparison of the ALO-CNN-GRU and other methodologies' F1-Scores. Table IV demonstrates that the proposed methodology, Antlion Optimization-Convolutional Neural Network-Gated Recurrent Unit technique, achieves a superior F1-Score in comparison to the current pancreatic cancer segmentation and classification approaches, such as IDLDMS, MR-CNN, CE-ConvLSTM, and ODL-PTNTC.

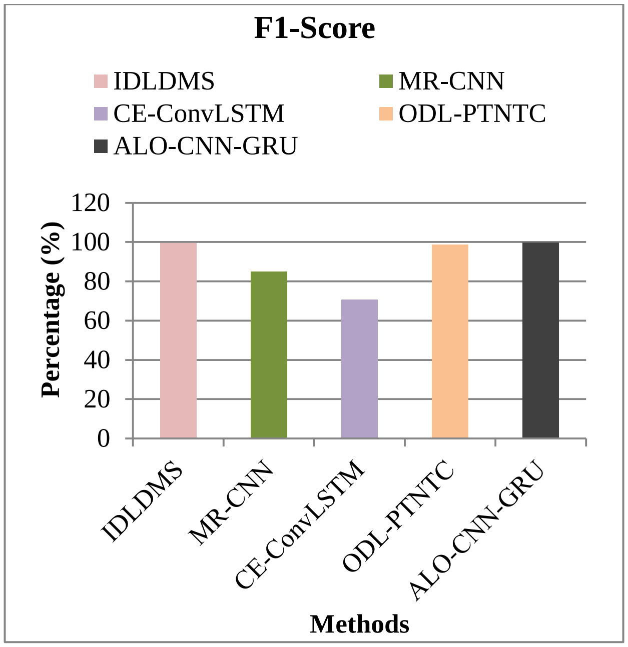

Fig. 8. Comparison of F1-score.

V. CONCLUSION

An essential part of the human body, the pancreas performs both internal and exterior secretion duties and is prone to a number of illnesses. Pancreatic malignancies, which are deadly in nature, currently have very poor prognoses. Computerized pancreatic cancer segmentation and classification utilizing a computer-aided diagnostic model is needed to monitor, identify, and categorize the incidence of cancer. Accurate image interpretation can be provided throughout deep learning algorithms for therapeutic application. To achieve this goal, the study created an ALO-CNN-GRU model for CT images and deep learning-based pancreatic tumor segmentation and classification. To remove noise from the acquired dataset, the images go through pre-processing. For the pre-processing, a hybrid Gaussian and median filter is being used. The segmentation is performed using the Antlion optimization algorithm to determine the impacted pancreatic region. Next, the classifiers of the Convolutional neural network and Gated Recurrent Unit networks are used to categorize pancreatic cancer as benign and malignant. We examined recall, accuracy, precision, and F1-score as performance indicators. Better performance metrics are produced by the suggested ALO-CNN-GRU technique. The experimental results back up the claim that the suggested strategy works better than approaches already in use. In order to accurately detect and categorize the pancreatic cancer locations, future versions of the methods will employ LSTM with additional deep learning mechanisms and combine sophisticated optimization with classification algorithms.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Saudi Electronic University for logistic support for this work through the 2nd Interdisciplinary Scientific Research Hackathon, project no. (SRH005T1).

A New Task Scheduling Framework for Internet of Things based on Agile VNFs On-demand Service Model and Deep Reinforcement Learning Method

Li YANG
Department of Electronic Information Engineering, Leshan Vocational and Technical College,
Leshan 614099, Sichuan, China

***Abstract*—Recent innovations in the Internet of Things (IoT) have given rise to IoT applications that require quick response times and low latency. Fog computing has proven to be an effective platform for handling IoT applications. It is a significant challenge to deploy fog computing resources effectively because of the heterogeneity of IoT tasks and their delay sensitivity. To take advantage of idle resources in IoT devices, this paper presents an edge computing concept that offloads edge tasks to nearby IoT devices. The IoT-assisted edge computing should meet two conditions, edge services should exploit the computing resources of IoT devices effectively and edge tasks offloaded to IoT devices do not interfere with local IoT tasks. Two main phases are included in the proposed method: virtualization of edge nodes, and task scheduling based on deep reinforcement learning. The first phase offers a layered edge framework. In the second phase, we applied deep reinforcement learning (DRL) to schedule tasks taking into account the diversity of tasks and the heterogeneity of available resources. According to simulation results, our proposed task scheduling method achieves higher levels of task satisfaction and success than existing methods.**

Keywords*—*Internet of things; task scheduling; edge computing; resource allocation

I. Introduction

The recent rapid development of artificial intelligence [1, 2], machine learning [3], optical networks [4, 5], smart grids [6], cloud computing [7, 8], 5G connectivity [9], Blockchain, and Internet of Things (IoT) [10, 11] is leading to an exponential growth in data usage across a wide range of engineering and commerce disciplines. Over the last decade, the IoT has been recognized for its remarkable potential in computer science. It brings out an environment in which many intelligent objects with limited resources can interact with each other through different technologies [12]. The IoT tries to link the physical and virtual worlds by equipping physical devices with processing, networking, detection, and identification functions. The IoT objects are employed in different applications, such as vehicle networks, energy management, traffic control, medical treatment, and healthcare, aiming to gather information about the physical world [13, 14]. In this regard, to obtain valuable information and fulfil the assigned tasks, a massive amount of data is produced that brings challenging problems for efficient information processing, especially for the specific scenarios requiring real-time data handling. Considering edge computing capability in real-time processing, the computing IoT tasks can be offloaded to edge devices for implementation [15, 16].

Moreover, since the IoT services and applications are increasing daily, a practical approach to serving the growing needs in different application domains becomes vital [17, 18]. To address the mentioned problems, achieve high resource utilization, reduce communication costs, and improve the lifetime of IoT networks, task scheduling methods can have significant impacts [19, 20]. These methods aim to schedule the existing tasks in a suitable sequence to accomplish tasks under problem-specific constraints, such as communication costs among IoT objects, resource utilization, and the operational lifetime of sensor nodes [21].

Nowadays, Network Function Virtualization (NFV) is known as a superior technology in telecommunication networks. It refers to centralizing and virtualizing network functions that can be run in data centres on standard and commercial off-the-shelf (COTS) hardware instead of distributed and proprietary hardware [22]. Using NFV, network device purchases and related maintenance costs can be reduced effectively. As a logical consequence of NFV, Virtual Network Functions (VNFs) take advantage of middleware to virtualize network functions. The deployment of VNFs on commodity hardware reduces the need for dedicated hardware devices to perform individual network functions. Our main objective is to improve edge computing operational efficiency by implementing the agile VNF on-demand model and the deep reinforcement learning-based task scheduling method. The proposed method includes two main phases, virtualization of edge nodes and task scheduling based on the deep reinforcement learning method. In the first step, a layered edge framework is presented. In the second step, we employed deep reinforcement learning (DRL) to solve task scheduling problems considering the tasks' diversity and the heterogeneity of available resources. This article makes the following major contribution.

- We analyze the optimization of time scheduling and the assignment of virtual machines in edge computing using model-free DRL-based task scheduling. VM availability, task characteristics, and queue dynamics are considered in the formulation of the problem as an MDP problem.

- In this case, the action is represented as a pair of VMs and tasks, whose dimension may be extremely large. In the MDP formulation, a new mechanism is designed to decouple the scheduling time step from the real-time step. With this mechanism, the action space remains linear with the product of the number of VMs and the queue size, and multiple tasks can be scheduled simultaneously.

The rest of the paper in organized as follows. Related works are reviewed in Section II. The proposed task scheduling method is described in Section III. Section IV reports the simulation results. Finally, the conclusion is presented in Section V.

II. Related Work

Al-Habob, Dobre [23] considers offloading multiple tasks concurrently to several mobile edge computing servers. Offloading latency and failure probability are minimized by scheduling interdependent subtasks for servers. Models based on conflict graphs and genetic algorithms are used to solve scheduling problems. Experimental findings demonstrate that these algorithms approach optimal solutions found by exhaustive searches. In addition, even though parallel offloading employs orthogonal channels, sequential offloading is more likely to fail than parallel offloading. In contrast, parallel offloading provides lower latency. Latency gaps between parallel and sequential schemes decrease as the dependency between sub-tasks increases.

Chen, Guo [24] examine the business processes of edge cloud task scheduling. The authors propose an algorithm to optimize resource-constrained task scheduling using the construction of profit matrices, classification, and clustering preprocessing. Tasks with similar characteristics are grouped and categorized using clustering preprocessing. On the basis of the constructed profit matrix, a resource-constrained task scheduling strategy is derived. In the second step, edge cloud components such as virtual machines, user requests, tasks, and resources are constructed using Petri nets. As a final step, the suggested mechanism is evaluated through several experiments. According to simulations, the algorithm maximizes profit while managing tasks efficiently, reliably, and with a high load balance.

A mathematical formulation of the fog node task scheduling problem is presented by Azizi, Shojafar [25] to reduce fog node energy consumption while maintaining IoT QoS requirements. The goal of their model was to reduce deadline violation time. The authors proposed two partially greedy algorithms, semi-greedy with priority awareness and multi-start semi-greedy with priority awareness, to map IoT tasks to fog nodes efficiently. The proposed approaches were evaluated in terms of system lifespan, latency, energy, and the IoT task completion rate. In comparison with existing algorithms, tests indicate that the introduced algorithms improve task deadline compliance and reduce the total time spent violating deadlines.

Kanbar and Faraj [26] developed the Region Aware Dynamic Scheduling (RADISH) model, which consists of five consecutive processes. To reduce latency in scheduling, they implemented a bi-class neural network based on task nature to classify incoming tasks based on their nature, taking into account login credentials, emails, passwords, types of services, and quality of service parameters. In the second process, the improved moth flame optimization is used to schedule classified tasks considering workload, deadline, priority, and energy. Third, load balancing is accomplished by clustering potential fields. With the aim of balancing server load and improving efficiency, three repository systems have been implemented. The final step involves introducing the Hopcroft-Karp algorithm that takes into account the VM state and minimizes allocation times and enhances the quality of service.

Hybrid Flamingo Search with a Genetic Algorithm (HFSGA) is implemented by Hussain and Begh [27] to optimize task scheduling for cost minimization. HFSGA and other well-known optimization algorithms are compared on seven essential benchmark optimization functions. Furthermore, Friedman Rank Tests are conducted to ascertain the results' significance. Implementing the model produces better results regarding task completion percentages, makespan, and costs. This work shows better results than existing algorithms such as round-robin, genetic, PSO, and ACO.

In order to secure the allocation of tasks on cloud and fog nodes, Najafizadeh, Salajegheh [28] proposed a multi-objective simulated annealing algorithm. A compromise solution is found by applying the goal-programming approach. In addition, a new goal called client-driven access level and schedule is created in regard to distributing tasks among fog and cloud nodes. The proposed algorithm was found to be 50% more efficient regarding deadlines, 88% more efficient regarding control levels, and 10% more efficient regarding service delays in comparison to moth-flame optimization, tabu search, and PSO algorithms.

Task scheduling in edge computing requires the consideration of two special problems: time scheduling and resource allocation. The task execution order is determined by time scheduling, while resource allocation is responsible for allocating tasks to suitable virtual machines (VMs) for execution. In the field of edge computing, a number of scheduling issues have been explored [29-33]. However, the majority of existing works focus on resource allocation, while time scheduling has received little attention. Tan, Han [34] proposed a general model to minimize task response times when tasks are offloaded to edge servers. Zhang, Du [35] proposed a scheduling algorithm based on Lyapunov optimization in order to minimize the communication delay and the computing delay. Chen, Thomas [36] developed a dual-scheduling framework to accommodate the unstable capacity of servers and task arrival rates in heterogeneous vehicular edge computing. In [37], a mixed integer nonlinear programming (MINLP) algorithm was employed for data-parallel offloading and scheduling of computationally-intensive data-parallel tasks in order to minimize the average completion time. According to [38], tasks with the lowest delay are scheduled first using the shortest-job-first (SJF) scheduling method.

Alameddine, Sharafeddine [39] explored the use of device-to-device collaboration for task offloading by taking into consideration the mobility of humans in order to optimize the task assignment and power management. The issue of energy-efficient task scheduling for IoT edge computing has been addressed in [20] by a heuristic algorithm. In these methods, ideal mathematical models are used and optimization is achieved through mixed-integer nonlinear programming (MINLP) or heuristic algorithms. In spite of the fact that these model-oriented algorithms can produce excellent results, they are not well suited to dynamic environments in which task arrival rates and popularity are unknown in advance. It is also important to note that the model-based task scheduling algorithms are largely concerned with optimizing one-step instead of pursuing long-term objectives. In these algorithms, the availability of resources is assumed to be fixed during the scheduling period.

III. Proposed Task Scheduling Method

In our proposed mechanism, each gateway node serves as a connection point for several IoT nodes connected to the gateway node based on their shortest distance. Our main aim is to propose an edge computing service model based on gateways to maximize IoT resource utilization, accelerate the processing of users' service requests, and enhance edge computing efficiency. The proposed model involves user requests passing through the edge gateway, which determines whether to process tasks. To decrease data processing time, the controller forwards service requests to the cloud if the edge gateway is unable to process them. The edge computing service model contains three main components, lightweight VNF configuration, scheduler, and resource estimation. According to the proposed model, when a request for a service is received, it is checked whether or not an adequate amount of computing resources is available to fulfil such demand. In this regard, one of the following events may occur. Depending on the outcome of the task scheduling algorithm, the edge gateway processes the requests through the scheduler and queues them in the system. On the other hand, requests are transferred directly to the cloud if the edge gateway lacks the resources.

Improving edge gateway operational efficiency is the main aim of task scheduling methods. Since the service requests are different from each other, a task scheduling algorithm determines how to meet the demands of each request. A scheduling method reduces time spent on tackling high-demand tasks as a primary objective. Our main objective is implementing on-demand models for agile VNFs and deep reinforcement learning-based task scheduling methods to enhance edge computing efficiency. The proposed method includes two main phases, virtualization of edge nodes and task scheduling based on the deep reinforcement learning method.

In order to simplify the task scheduling process, we will only focus on computational resources. In order to make scheduling decisions, the scheduler monitors the status information of incoming tasks and virtual machines (VMs), including the task sizes, the expected completion time, the computing speed (in million instructions per second (MIPS)), and the waiting time. The scheduler determines when to schedule (e.g., the scheduling order and the start time for each task) and where to schedule (e.g., which VM is assigned to each task) based on the observations. In order to schedule the tasks, they are divided into two sets: a waiting set and a backlog queue. A task in the waiting set occupies a waiting slot that can be observed fully, whereas the scheduler can only observe the number of tasks in the backlog queue. In each scheduling time step, the scheduler selects at most one task from the waiting slot for scheduling. In this study, we examine the scheduling of tasks in edge computing when only one edge server is deployed. It is the objective to maximize the long-term task satisfaction of all tasks, which is achieved by:

$$\boldsymbol{max}\sum_{\boldsymbol{t=1}}^{\boldsymbol{T}}\sum_{\boldsymbol{i\in J,j\in V}}\boldsymbol{g_{i,j}} \qquad (1)$$

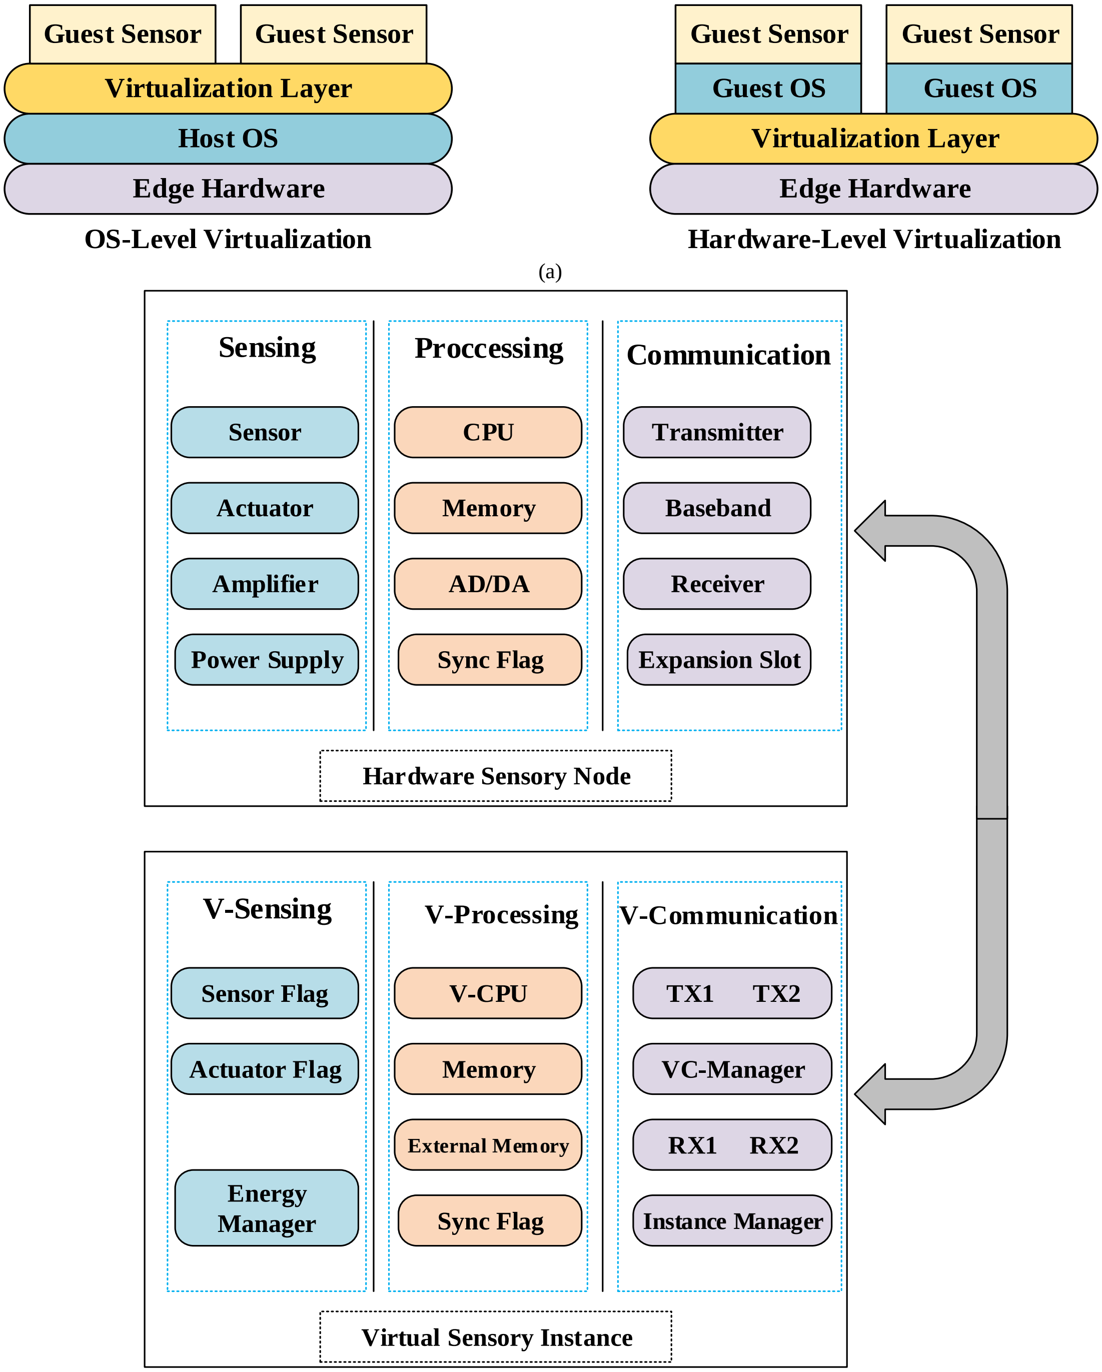
where $g_{i,j}$ is the task satisfaction of the task i scheduled to VM j.

A. *First Phase: Virtualization of Edge Nodes*

This step proposes a virtualized edge framework to support Cloud-to-Things applications at all layers. The virtualization process involves three stages: virtualizing objects, network functions, and services. The implementation of object virtualization allows physical sensors to gain IP capability without compromising their unique functionalities. In order to represent heterogeneous physical entities, we need to create a unified software Virtual Object (VO) on edge nodes. An abstract VO is capable of interacting over the Internet with various hosts.

Additionally, it can act as a close neighbour to physical objects through wireless or wired connections available at the edge. VOs provide semantic descriptions of actual objects. Although physical objects have heterogeneous functions, they generally have limited memory and components such as communication modules, sensing modules, and power supply units. These components can be expanded and installed on edge devices for real physical objects as virtual software instances.

As illustrated in Fig. 1(a), two critical streams of object virtualization are taken into account to illustrate VO-hosting solutions: hardware-level and OS-level virtualization. VOs are compatible with established operating systems. Edge players, such as providers, developers, and end users, can develop dedicated hosting platforms with advanced features, such as memory, hardware interface, and CPU, in order to achieve better performance. Fig. 1(b) provides more details about the sensor virtualization framework. Both virtual sensor instructions and physical sensor data are stored in the "Sync Flag". Version numbers are used to synchronize actual and virtual objects. "Energy Manager" indicates the battery life of physical sensors and turns them on. Compared to physical sensors, virtual sensors are composed of V-communication, V-processing, and V-sensing components. In the left column, "Actuator Flag" contains the instructions given to the physical sensor, and "Sensor Flag" holds the sensor's collected data. V-processing is the equivalent of physical sensor processing. A predefined local or network storage device can be used as an external memory.



(a)

(b)

Fig. 1. Object virtualization scheme.

To manage virtual and physical nodes as well as VNFs in the proposed method, an Object Virtualization Manager (OVM) is required. As depicted in Fig. 2, the OVM manages and orchestrates physical and virtual entities. Initially, the OVM deploys and programs the corresponding VOs, monitors and coordinates their operation, discovers and registers them, and creates and terminates them. In this regard, the OVM stores the configuration files of VOs editable by remote or local users. In order to perform automatic self-configuration for service deployment, the OVM downloads the configuration profiles of registered VOs. A VO will be migrated to a more resourceful container if its container is overloaded. VNFs, as software instances, contain several portions of VMs that run network functions on standard hardware. In order to decompose the VNF into reusable components, which can be designed as executable microservices and optimized, upgraded, and configured independently, network functions typically involve several approaches, including verification, computing, media access control, coding, and signaling. These components combine to form VNFs in micro containers.

B. *Second Phase: Task Scheduling based on Deep Reinforcement Learning*

Scheduling tasks in edge computing involves two main concerns, allocation of resources and schedule. Resource allocation involves assigning tasks to the appropriate virtual machines, and time scheduling determines the order of task execution. To maximize the quality of experience, our task scheduling strategy considers the expected delay requirement for heterogeneous virtual machine resources. The level of task satisfaction acts as a reward in the deep reinforcement learning algorithm. Network edge servers handle computationally-intensive tasks owing to the difficulty of performing them on local devices. The edge servers are configured with various virtual machines that differ in terms of computational capacity and execution time. The scheduler is responsible for monitoring the status of virtual machines and incoming tasks. The waiting time, the speed of computing, the expected completion time, and task size are significant factors in scheduling decision-making. Observations confirm that the scheduler decides the scheduling order and the start time of each task, determining suitable virtual machines. Fig. 3 shows the general layout of the proposed task-scheduling framework.

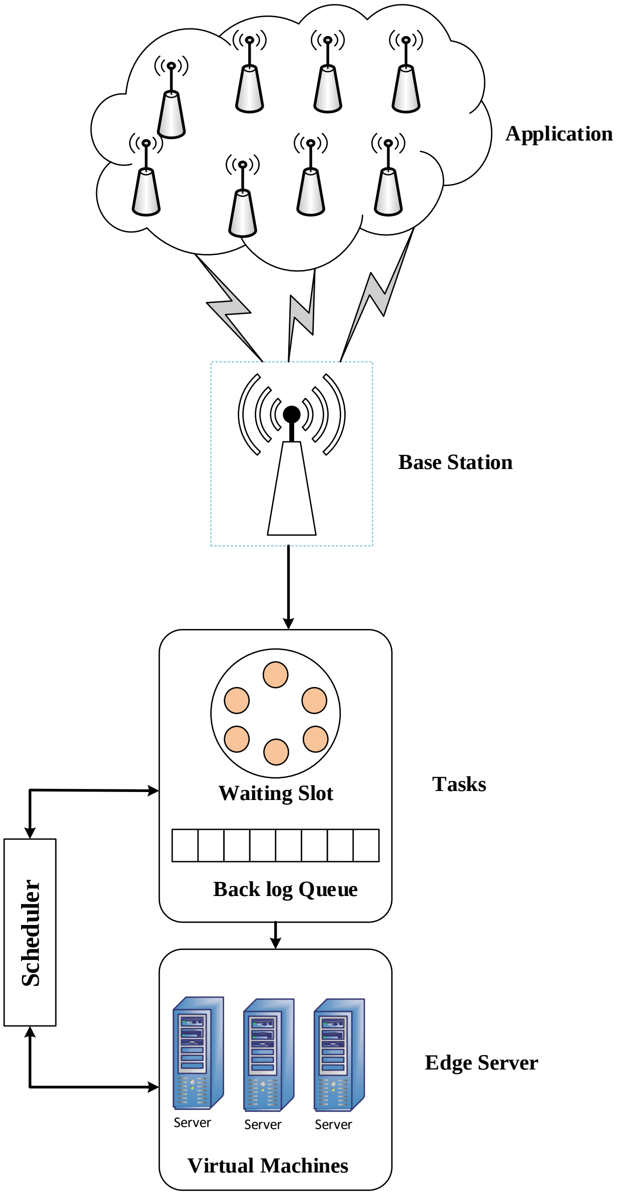

Fig. 3. Proposed task scheduling framework.

IV. Experimental Results

A numerical evaluation of the proposed task scheduling mechanism is presented in this section. Pytorch running on Python 3 produced all simulation results. A comparison was made between the proposed mechanism and two baselines. We implemented the task scheduling policy using a four-layer DNN structure. Each hidden layer encompasses 64 neurons with a rectified linear unit (ReLU) as an activation function. The output layer consists of (M+1)×O neurons, where M refers to the number of VMs and O denotes the maximum tasks in the waiting slot. In training, we set the discount factor to 0.99, which indicates that the current decision is affected by future steps. The learning rate is set to 10−4, and gradient descent is performed using the Adam optimizer. The paper focuses on scheduling tasks in the edge system by considering only computational resources. VM resources and task characteristics are the only environment parameters considered in calculating residual computation delay. IoT devices generate tasks and send them to the base station for transmission. The edge server receives these tasks periodically. Latency is expected to range from 5 to 10 seconds, with transmission delays ranging from 1 to 5 seconds. Task sizes range from 500 to 4000 MI. Virtual machines have a processing capacity ranging from 1000 to 2000 MIPS. Waiting slots are set to O=5 and backlog queues to |b|=5.

The effects of task popularity skewness, task arrival rate, and virtual machine count on task satisfaction and success ratio were studied. Fig. 4 and Fig. 5 illustrate the excremental outcomes. As illustrated in Fig. 4, the number of virtual machines and the task arrival rate are associated with the cumulative degree of task satisfaction. With the popularity skewness set at 0.3, the task arrival rate ranges from 3 to 7, and the number of virtual machines increases from 3 to 5. According to Fig. 5, the cumulative task satisfaction degree decreases as the task arrival rate increases. A higher arrival rate means that more tasks are waiting for scheduling in the edge system simultaneously, which lengthens their waiting time. As the number of VMs increases, the average task satisfaction degree also increases. Tasks can be scheduled across multiple virtual machines, resulting in shorter waiting times. Fig. 5 shows the skewness of task popularity versus task satisfaction degree. Task popularity skewness ranges from 0.1 to 0.9 with three virtual machines. A higher cumulative task satisfaction is associated with greater skewness in task popularity. Each type of task has a different popularity skewness. As task popularity skewness increases, smaller tasks become more popular while larger tasks become less popular, thus reducing the overall waiting time.

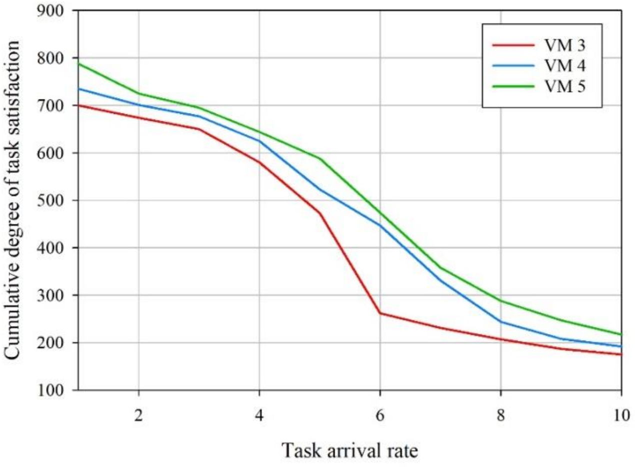

Fig. 4. Task satisfaction degree vs. task arrival rate.

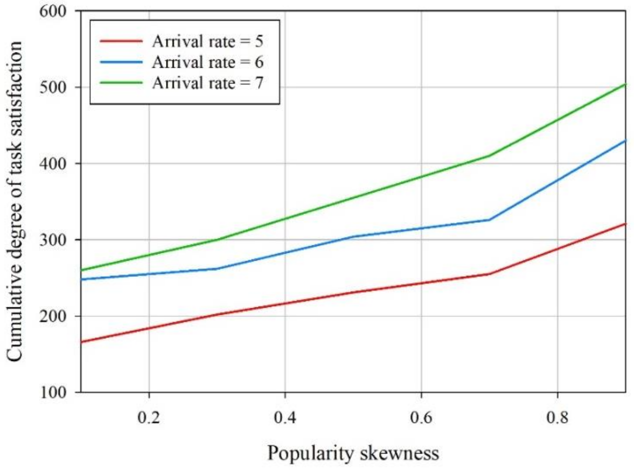

Fig. 5. Task satisfaction degree vs. popularity skewness.

Shortest Job First (SJF) [38] and First Come First Service (FCFS) [37] algorithms are chosen as benchmarks for evaluating the performance of the proposed task scheduling mechanism. SJF and FCFS assign the scheduled task to virtual machines with the highest instant reward. This leads to the scheduling of tasks in a greedy manner. These benchmarks can therefore be categorized into greedy-FCFS and greedy-SFJ. A comparison was made between our proposed method and these benchmarks in terms of task success rate and task satisfaction rate. Total task satisfaction is affected by the average task satisfaction degree, which makes it possible to evaluate the algorithm's overall quality. The task is considered complete when the response time is less than the expected delay. According to Eq. (1), the task success ratio can be obtained by dividing the number of satisfied tasks by the number of tasks in total.

$$\boldsymbol{\varepsilon_s} = \frac{\boldsymbol{N_s}}{\sum_{j\epsilon J} \boldsymbol{N_T}}. \tag{1}$$

Fig. 6 and Fig. 7 show how performance is affected by varying task arrival rates. In all algorithms, the average task success ratio and level of task satisfaction decrease as task arrival rates rise. Our method is significantly more efficient than the greedy-FCFS and greedy-SJF scheduling algorithms. In particular, the suggested method can increase average task satisfaction degrees by around 50% and 25% over greedy-FCFS and greedy-SJF. As FCFS schedules earlier-arriving tasks first, subsequent tasks may be delayed when the earlier-arriving tasks demand a lot of CPU power. For long tasks, greedy SFJ prioritizes shorter tasks over longer ones. The expected delay demand is not taken into account by greedy-FCFS or greedy-SJF algorithms.

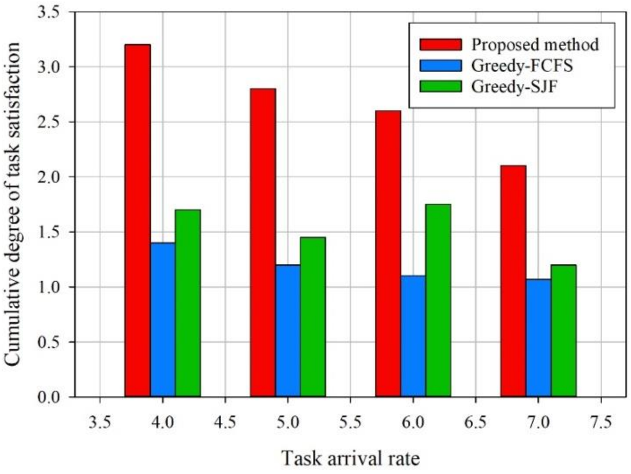

Fig. 6. Task satisfaction degree vs. task arrival rate.

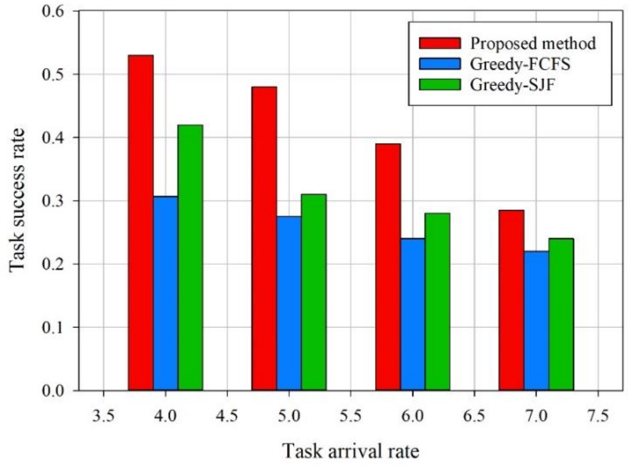

Fig. 7. Task success rate vs. task arrival rate.

Fig. 8 and Fig. 9 compare our task scheduling mechanism with the baselines in terms of task popularity. A higher skewness factor results in a higher degree of task satisfaction and a higher success ratio. The proposed algorithm can significantly improve task satisfaction, as shown in Fig. 8. The gap widens with increasing popularity factor values compared to greedy-SJF and greedy-FCFS algorithms. The greedy-SJF algorithm suffers from performance degradation due to a larger proportion of small tasks being assigned as popularity increases. The higher skewness factor allows for more accurate predictions of task lengths, leading to more efficient scheduling. This leads to better results for popularity-based algorithms compared to greedy-SJF and greedy-FCFS algorithms. The improved task satisfaction and success ratio observed in Fig. 8 are a direct result of this improved scheduling efficiency.

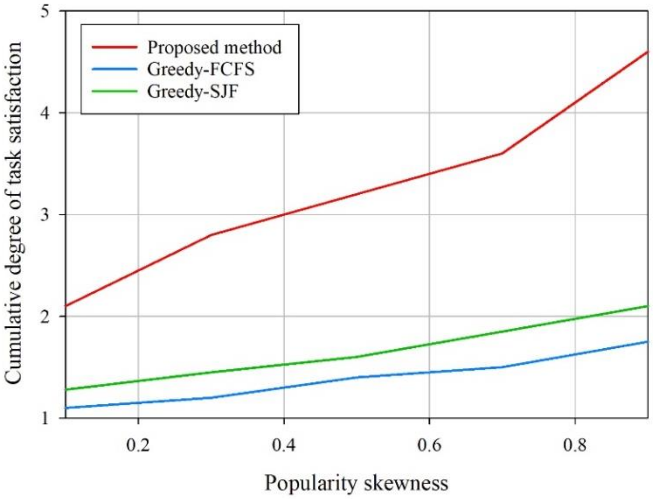

Fig. 8. Task satisfaction degree vs. populariry skewness.

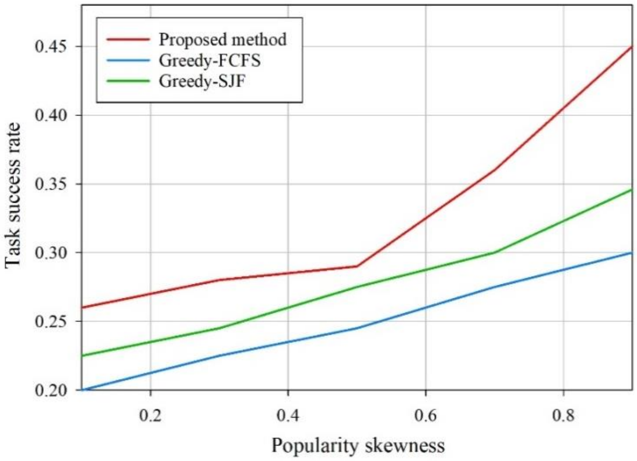

Fig. 9. Task success rate vs. popularity skewness.

V. Conclusion

With the rapid growth of IoT applications, edge and IoT devices have expanded their services in recent years. Fog computing offers a latency sensitivity advantage over cloud computing for IoT-enabled smart applications. Task scheduling effectively reduces application computation time and latency while improving quality of service. This paper's proposed task scheduling framework comprises two main phases: virtualization of edge nodes and task scheduling based on deep reinforcement learning. The first phase offers a layered edge framework. In the second phase, we applied DRL to schedule tasks taking into account the diversity of tasks and the heterogeneity of available resources. Simulations indicate that our proposed task scheduling method leads to greater levels of task satisfaction and success than existing approaches.

A Blockchain-based Three-factor Mutual Authentication System for IoT using PUFs and Group Signatures

Meriam Fariss, Ahmed Toumanari
Laboratory of Applied Mathematics and Intelligent Systems Engineering (MAISI)
National School of Applied Sciences (ENSA), Agadir, Morocco[1]

Abstract—**The widespread adoption of Internet of Things has brought many benefits to society, such as increased efficiency and convenience in various aspects of daily life. However, this has also led to a rise in security threats. Moreover, resource-constrained feature of IoT devices makes them vulnerable to various attacks that compromise the user's privacy and sensitive information confidentiality. It is therefore essential to address the security concerns of IoT devices to ensure their reliable and secure operation. This paper proposes a blockchain-based three-factor mutual authentication system for IoT using Elliptic Curve Cryptography, physical unclonable functions and group signatures. The main purpose is to achieve a secure mutual authentication among different involved entities while providing anonymous group member authentication and reliable auditing. The AVISPA tool is utilized in the paper to formally prove that the proposed system satisfies the security and privacy requirements.**

Keywords—Internet of Things; blockchain; mutual authentication; physical unclonable functions; biometrics; group signatures; elliptic curve cryptography

I. Introduction

Internet of Things (IoT) is a rapidly developing technology that has gained significant traction in various fields such as healthcare, military, smart cities and houses [1]–[4]. It involves smart devices that collect thousands of gigabytes of data and use this collected data to make instant decisions that are immediately shared with remote users and servers. Nonetheless, the absence of inherent security measures renders the IoT-based architectures susceptible to many security breaches and privacy violations [5]. Many surveys and researches have been conducted to show the security challenges in IoT [6]–[8].

Authors in [9] indicate that there were 50 billion connected devices by the end of 2020 and this number is expected to increase to 14.7 billion by 2023. As the number of connected devices in IoT continues to increase, there are numerous challenges and issues that arise, particularly in regards to security and privacy. To overcome these challenges, new and emerging technologies such as fog computing and blockchain are integrated with IoT.

Blockchain has gained significant attention from researchers due to its ability to protect IoT devices and security-critical data [10]–[12]. By incorporating blockchain technology into IoT devices, it can provide an effective solution to the security and privacy challenges facing IoT devices. Blockchain can ensure the integrity and authenticity of data, and provide a secure platform for sharing data between devices. Additionally, blockchain can help to create a decentralized and trustless network, which is essential for secure communication and transactions between IoT devices. Blockchain's security stems from its use of cryptographic techniques, such as hash functions, digital signatures, and encryption, to ensure the integrity and confidentiality of data stored on the blockchain.

Besides blockchain, fog computing is an emerging technology that brings important enhancement to the security of IoT devices [13]. The limited resources of these latter leave them vulnerable to security threats. To address this issue, fog computing can enhance their capabilities by offering localized compute, storage, and networking for a cluster of IoT devices. By performing processing and storage tasks closer to IoT devices at the fog node instead of moving the data to a cloud server, fog computing reduces latency and increases network efficiency due to its high-quality services and quick response time. This can help address security concerns by reducing the amount of data that needs to be transmitted to the cloud, which in turn reduces the attack surface for cyber criminals. Additionally, fog computing can provide an additional layer of security by enabling real-time threat detection and response. This can help detect and mitigate security threats more quickly, reducing the potential damage that can be caused by such attacks.

A. Our Contribution

To address the aforementioned security threats while taking into consideration the resource constrained feature in IoT environment, we propose in this paper a blockchain-based secure mutual authentication system for IoT using Physical Unclonable Functions (PUFs) and group signatures providing the following advantages:

1) Permissioned blockchain: to achieve more control, privacy and high transparency over the network, we use a permissioned blockchain where only selected nodes are allowed to participate in consensus.

2) Group signature scheme with two authorities: In our proposed scheme, we distinguish between the group manager and the opening manager roles. The former is in charge of assigning private signing keys to group members, while the latter can open signatures. This enhanced security, as both have their own secret key, mitigates the risk of untrustworthy authorities.

3) Three-factor authentication: the proposed authentication protocol requires the user to provide three types of credentials: the first factor is something the user knows (password), the second factor is something the user has (hardware token) and the third factor is something the user is (biometric characteristic like a fingerprint, iris scan or facial recognition). Hence, the security of the system is strengthened, as it is much more difficult for an attacker to obtain all three types of credentials.

4) PUFs: they are used to generate a unique private key for every token, which can be used for cryptographic operations such as signing and encryption. The private key is generated by applying a one-way function to the PUF's response, which ensures that the private key cannot be reverse-engineered from the response. The private key is securely stored in the hardware token and can only be accessed by authorized users with the appropriate credentials.

5) Fog computing: provides a trusted entity with more computing and storage resources that supervises a group of IoT devices, controls access and manages communication between devices and remote users. This improves security by providing a local point of control, reducing data transmission, and improving network efficiency, reliability and scalability.

B. Organization

The remainder of this paper is organized as follows. In section II, we present an overview of the related work. Section III is dedicated to the basic concepts of blockchain namely smart contracts and the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm. The cryptographic primitives adopted in this paper are presented in Section IV. The description of our proposed blockchain-based protocol is presented in Section V. We dedicate Section VI to the informal security analysis of our proposed protocol and the formal security analysis using the widely used AVISPA Tool. Finally, we draw our conclusions and present our future work in Section VII.

II. Related Work

Every year, numerous studies are conducted to secure exchanged data over the unattended IoT area. These studies suggested reliable architectures and frameworks to overcome the challenges and security threats in order to achieve secure mutual authentication between all involved parties in the IoT environment. Among these security solutions, blockchain technology brings many solutions for tackling security and privacy concerns in the context of IoT. In 2022, researchers in [14] developed a secure and efficient authentication mechanism for fog computing using blockchain technology. The proposed approach aims to overcome the limitations of traditional authentication methods while maintaining high levels of security and performance. Another secure IoT system was proposed in 2022 [15]. This paper presented a new approach to managing device identities in IoT systems based on blockchain technology. The approach enhanced data security through two methods: a lightweight time-based identification protocol that validates data using hub identification, and a blockchain application that provides secure data storage and sharing among multiple parties with easy access and immutability. In [16], researchers proposed a blockchain-based scheme where certificateless cryptography, Elliptic Curve Cryptography (ECC), and pseudonym-based cryptography (PBC) are employed. The goal is to achieve users' privacy and to hide the true identity of IoT devices using pseudonym-based cryptography. In 2020, Huang et al. [17] presented in their paper a blockchain-based authentication framework for IoT networks to achieve fast decentralized authentication while preserving privacy. The framework satisfied various security requirements such as strong key protection, identity anonymity, single registry, and traceability. In 2017, Cha et al. [18] suggested a blockchain-connected gateway design that is claimed to ensure security and user privacy. However, in 2020, Yavari et al. [19] revealed that [18] is vulnerable to various attacks, including secret disclosure, replay, traceability, and token reuse attacks. They proposed an improved blockchain-based authentication protocol that provides secure access management and anonymity. The paper in [20] proposed a solution to address security risks in IoT, particularly in decentralized authentication by providing a secure framework using blockchain technology which supported certificate issuance, update, revocation, and audit functions through the use of a smart contract. Authors in [21] presented a multi-layer security model for IoT devices operating in multi-hop cellular networks that utilized blockchain's distributed technology. The proposed model offered a viable approach to deploying decentralized blockchain technology for securing cellular-enabled IoT networks. After analyzing the limitations of traditional IoT authentication and security mechanisms, authors in [22] proposed a blockchain-based model to address these issues namely the single-point-failure issue.

III. Blockchain

Blockchain is a secure and transparent digital ledger that records transactions across a decentralized network. Nodes in the network must reach a consensus before new blocks of transactions can be added. The ledger includes various types of transactions, and each block contains a header with the previous block hash, timestamp, version, nonce, difficulty target, and Merkle root [23]. Blockchain can be divided into three types: public, permissioned, and private. Public blockchains like Bitcoin and Ethereum are open to anyone, transactions are validated by consensus mechanisms, and no central trusted authority is required. In contrast, only trusted participants are allowed in private and permissioned blockchains, but there are significant differences between them. In private blockchains, a single private entity controls the network, while in permissioned blockchains, a consortium of organizations adds an access control layer and allows multiple organizations to validate transactions, making it more decentralized than private blockchains.

A. PBFT

Introduced in the late 90s, Practical Byzantine Fault Tolerance (PBFT) [24] is a consensus algorithm used in permissioned blockchain networks to ensure secure and consistent agreement on the network's state even in the presence of malicious nodes. The network security is ensured by the PBFT algorithm as long as the number of faulty nodes is under a predefined threshold *$f=(n-1)/3$* where *n* is the total number of nodes. In the PBFT consensus, eligible nodes can switch from primary or leader nodes (during a period of time called view) to secondary nodes to reach a consensus on the state of the system. When the leader node is non faulty, the PBFT consensus works as follows:

- Client requests: The client initiates a request and sends it to the network.
- Pre-prepare message: The leader verifies the request message and broadcasts the pre-prepare message to all other replica nodes, containing the client's request and a sequence number.
- Prepare messages: Upon receiving the pre-prepare message, each replica node verifies its legitimacy and broadcasts a Prepare message.
- Commit messages: When no less than two-thirds of the total consensus nodes have sent Pepare messages, the leader node broadcasts a commit message to all other nodes (ie. a consensus has been reached on the client's request).
- Reply message: When at least two third of the received commit messages are valid, nodes return a reply message to the client containing the result of the request transaction.
- State Update: the ledger state is then updated in every consensus node.

If the system encounters a verification failure or network interruption case, then the View change protocol is executed to select another primary node in the network, that is responsible for carrying out the consensus process from the prepare phase through the following steps:

- View_Change_Request: after detecting an exception message, every node in the network broadcasts a view change request to all other participating nodes.
- New_View_Prep: after verifying the View_Change_Request and broadcasting an acknowledgment (no less than ⅔ of the total nodes), the nodes collaborate to prepare a new chosen primary node to substitute the previous one.
- New_View: through a voting process, nodes must reach a consensus to select the new primary node. This latter will take the responsibility of processing requests and generating new blocks.

B. *Smart Contract*

To address the trust problem in a decentralized environment, smart contracts are programs where required conditions are implemented using a Turing complete language (like go language in Hyperledger Fabric, Solidity in Ethereum). The smart contract byte code is stored in the blockchain platform with a unique address and automatically executed when predefined conditions are verified. It is replicated across all the blockchain consensus nodes. Hence, no third trusted party is needed to make decisions. The main benefits of smart contracts are speed, efficiency, trust and transparency. It also benefits from the security immutability features offered by the blockchain.

IV. Cryptographic Primitives

A. *Group Signatures*

Group signature is a type of digital signature scheme that was first proposed by Chaum and Van Heyst [25], and then many other contributions on group signature schemes were made in order to allow group members to anonymously sign messages while being traceable by a designated authority. In 2015, [26] proposed a novel short group signature scheme along with two group membership revocation methods that only disclose revocation information to verifiers. This section briefly presents the digital signature scheme by [26] which is adopted in our proposed protocol.

- System Setup phase

In this phase, the system parameters are initialized. The input is a security parameter λ and the output is (*PP*, *sk*, *gpk*, *trace*). Public parameters *$PP=(q,G_1,G_2,G_T,e,P_1,P_2,h())$*, where G_1, G_2 and G_T are three cyclic groups of λ-bit prime order q and $e{:}G_1 x G_2 \rightarrow G_T$ is a bilinear map. P_1 and P_2 are the generator points of G_1 and G_2 respectively, and $h{:}\{0,1\}^* \rightarrow Z_q$ is a secure hash function.

The Group Manager chooses randomly two secret parameters *d* and *s* in Z_q^* where *(d,s)* represents its private key *sk*. The group public key is *$gpk = (D, S, U)$* where *$D = d.P_1$*, *$S = s.P_2$* and *$U = u.P_1$*. The secret parameter *u* represents the private tracing key *$trace=u$* only known by the openening manager that uses it in *GTrace* algorithm to find the member's real identity.

- Enroll

In this phase group members are enrolled by the group manager. The input is *(PP, sk)* and the output is a private key *$gsk_i=(x_i , Z_i)$* is generated for each group member GM_i by the group manager who chooses randomly a distinct x_i for each member and sets $Z_i = z_i.P_1$ where $z_i = (d- x_i) (sx_i)^{-1} \in Z_q^*$. After that, the group manager computes *$tag_i = x_i.Z_i$* and maps it with the relevant group member's identity in a members table. This table also contains $status_i$ that shows if the member is allowed to access the network or is revoked.

- GSign

During this phase, a group member can sign his/her messages. The input is *(PP, gpk, gsk_i, message)* and the output is the signature *$\sigma = (C_1, C_2, c, w)$*. Each group member can sign his/her messages using his/her private key *gsk_i* as follows: choose $k \in Z_q^*$ randomly, computes *$C_1=k.P_1$,$C_2=x_i.Z_i+k.U$* and *$Q=e(U,S)^k$*, computes *$c=h(message,C_1,C_2,Q)$* and *$w=kc+x_i$*.

- GVerify

This is the signature verification phase. The input is *(message, σ, gpk)* and the output is the verification result if the message has been signed by a group member or not. The verifier computes:

$$Q' = \frac{e(C_2,S).e(P_1,P_2)^w}{e(cC_1+D,P_2)} \quad (1)$$

and checks if *c = h(message, C_1, C_2, Q')* to confirm or not the validity of the signature.

- MRev

This is the group membership revocation algorithm. The group manager publishes a Revocation List (RL) that contains $tag_i = x_i.Z_i$ for revoked members. The revocation algorithm MRev operated by the verifier takes as input the signature *σ=(C_1, C_2, c, w)* for each member in the RL and the output is: for each member in RL, verifiers can test whether the value of $tag_i = x_i.Z_i$ belongs to a revoked member as follows: compute $e(C_2 - tag_i , S)$ and compare it to Q'. If the equality holds, then the signature σ belongs to a revoked member. Hence, the signature is rejected.

- GTrace

This is the tracing algorithm that takes as input *(trace, message, σ)* and outputs the signer identity using the tracing key *trace = u*. The group opener computes $tag_i = x_i.Z_i = C_2 - u.C_1$, then it searches in the table mapping each tag_i with the corresponding member identity.

B. Fuzzy Commitment Scheme

Fuzzy commitment scheme F is a cryptographic primitive that allows a party to commit to a message without revealing the message itself. It was first introduced in 1999 by Juels and Wattenberg [27]. It is performed in two phases. The commitment phase where the committer creates a commitment by applying a one-way function to a random secret value and the message, which prevents the receiver from determining the message from the commitment. The opening phase where the committer discloses the secret value and committed message. The receiver can verify the commitment by applying the same one-way function to both values.

Fuzzy commitment enhances privacy and security in biometric based authentication systems, by generating a commitment value based on biometric data, such as a fingerprint or face scan, and a secret key.

C. Physical Unclonable Functions

A Physical Unclonable Function (PUF) [28] is a hardware security primitive that is designed to generate a unique signature for a physical device, based on its manufacturing process and the physical variations that occur during the manufacturing process. The mathematical model of a PUF is based on a challenge-response mechanism, where a unique response is generated for every challenge. A PUF can be represented as: R = P(C). The challenge-response pair (CRP) is unique to each PUF. The PUF takes a challenge C as input and produces a response, which is a unique digital fingerprint that can be used for device identification. The response R is generated based on the physical characteristics of the device, such as the pattern of its silicon crystal lattice or the precise positions of transistors in the circuit.

V. The Proposed BC-Auth Scheme

In this section, we discuss the details of our proposed system which is based on blockchain technology, group signatures, Elliptic Curve Cryptography, Physical Unclonable Functions, the Message Authentication Code (MAC) and biometrics. In this BC-Auth, we adopt the permissioned blockchain type, where only legitimate nodes are allowed to access the blockchain, in order to achieve high privacy protection. This blockchain is managed and maintained by permissioned nodes on the basis of the Practical Byzantine Fault Tolerance consensus (PBFT) (see Section III A). These consensus nodes have enough computational, communication and storage resources to operate hundreds of thousands transactions within seconds.

Similar to the Bitcoin block structure, the block in our design is composed of the previous block hash, block version, timestamp, block size, the Merkle root, transaction counter and the recorded transactions in this block.

A. BC-Auth Model

We describe, in this section, the BC-Auth scheme model. The participants involved in this model are:

- Group manager: a trusted entity that enrolls new legitimate group members and generates their private keys and the group public key. It also revokes malicious users and maintains the Revocation List.
- Opening manager: the group manager cannot trace group members. The entity responsible for members' tracing is the opening manager using a secret parameter *trace*.
- Group members: the remote users that are allowed to access the IoT devices remotely.
- Consensus nodes: in our model, we work with the permissioned blockchain where the participating nodes are chosen and authorized to maintain the blockchain under the PBFT consensus mechanism.
- Fog node: a trusted entity with additional computing and storage resources that oversees a group of IoT devices and manages access to them. It also ensures the communication between these devices and the remote users.
- Devices: IoT devices are resource-constrained devices. Each IoT device corresponds to a single fog node. They collect data from the physical world to control and manage the industrial processes.

B. Smart Contract and PBFT in BC-Auth

In our proposed design, each logged in user interacts with the smart contract to broadcast his/her request transactions where *status=0*. These pending transactions are firstly verified by consensus nodes via GVerify_{gpk} to confirm that they're signed by a group member. If the verification fails, the transaction is discarded. Secondly, the opening manager monitors the smart contract to retrieve new verified group members transactions and sends allowed transactions (*status=1*) to the blockchain after verifying that the signer does not belong to the RL. These latter are verified by consensus nodes via $\text{Verify}_{\text{pko}}$. Finally, the fog node monitors the smart contract to find new valid transactions. When a sufficient number of consensus nodes agree that the transaction is valid (i.e. successfully verified by $\text{GVerify}_{\text{gpk}}$ and $\text{Verify}_{\text{pko}}$), it can then be chained in the blockchain.

A new block is added to the PBFT-based blockchain by a designed primary node PN_i of the current consensus round as follows:

- PN_i collects all the valid transactions of the current round and appends them to a new candidate block $Block_i$;
- PN_i broadcasts $Block_i$ to all consensus nodes;
- Upon receiving $Block_i$, each node verifies its validity based on many parameters such as the Block header, the block generator digital signature, the list of transactions contained in the block,
- If $Block_i$ passes this verification successfully, then each node broadcasts a prepare message along with hash ($Block_i$) to all other participating nodes.
- If the number of received messages is no less than two third of the total nodes, then each node adds the candidate block to its local copy of the ledger.

Hence, the consensus is reached and $Block_i$ is added to the blockchain. If the consensus is not reached, then View-Change protocol is executed (see Section III A).

C. *BC-Auth Protocol*

Our proposed protocol consists of four phases: initialization phase, member enrollment, login and mutual authentication, and member revocation phase. In this section, we describe these steps in detail.

1) System initialization phase: The initialization phase must be performed before the execution of the protocol. This phase takes as input a security parameter λ and outputs the public parameters $PP=(q,G_1,G_2,G_T,e,P_1,P_2,h())$. Using the Elliptic Curve Integrated Encryption Scheme (ECIES) [29], the group manager chooses randomly two secret parameters d and s in Z_q^*, where (d,s) represents its private key sk. The opening manager generates a random secret parameter $u \in Z_q^*$ that represents its tracing key $trace \leftarrow u$. It also has its private/public key pair (sk_o, pk_o). The group public key is equal to $gpk = (D,S,U)$ where $D = d.P_1$, $S = s.P_2$ and $U = u.P_1$. In the other side, the fog node generates a random secret parameter $sk_{fn} \in Z_q^*$ that represents its private key, and computes the corresponding public key $pk_{fn}=sk_{fn}.P_1$. We assume that each smart device has its private/public key pair (d_j, D_j) where $d_j \in Z_q^*$ and $D_j=d_j.P_1$.

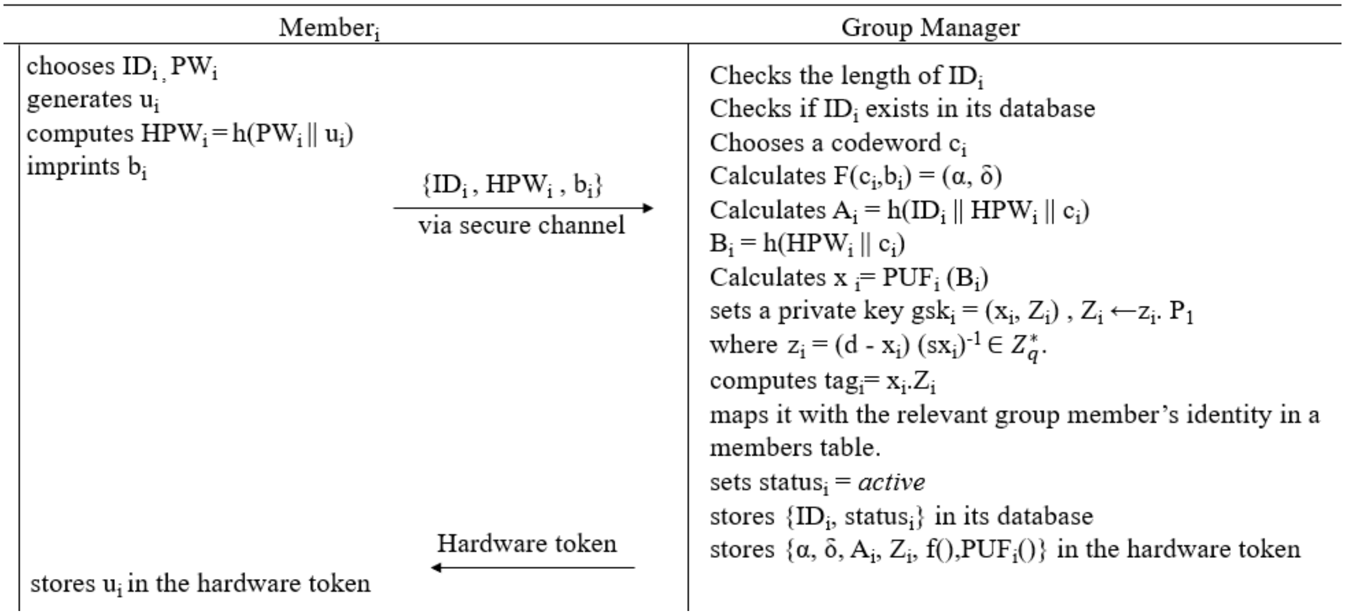
2) Member enrollment phase: This phase is initiated by the user who sends, via a secure channel, an enrollment request containing its chosen ID_i, HPW_i and biometric b_i to the Group Manager. This phase outputs the group members private keys $gsk_i=(x_i, Z_i)$ and the hardware token that stores $\{\alpha, \delta, u_i, A_i, Z_i, f(),PUF_i()\}$. These private keys are uniquely generated using PUFs functions and will be used by group members to anonymously sign their transactions before being sent to the blockchain network. Fig. 1 shows the details of the member enrollment phase.

3) Login and mutual authentication: This phase is performed every time a remote group member needs to access or control a smart device. Fig. 2 shows the login and mutual authentication phase.

- Login: To achieve a secure mutual authentication between the fog node and the group member, the latter needs to successfully login by inserting the correct ID_i, PW_i and b_i. This login phase is performed locally via the hardware token.
- Request transaction: Once the group member is logged in, his/her private key is computed using the physical unclonable function characteristics. A one-time private/public key pair (m_i, M_i) is generated where $m \in Z_q^*$ is a random secret and $M_i=m_i.P_1$. The transaction is structured as follows: Computes the message $Msg = txnumber||to||M_i||D_j||request$, where $txnumber$ is the transaction number and to is the address of the smart contract. Then it computes $E_{msg}=Enc_{pkfn}(Msg)$ where Enc is an AES Encryption, and sends the transaction $Tx= \{data, GSign_{gski}(data)\}$ where $data=(to,E_{msg}, TS_i, status)$ to the blockchain. TS_i is the current timestamp. The status=0 which means that it is a pending transaction. The smart contract is invoked and the consensus nodes verify the signed transaction using the GVerify algorithm. If the verification fails, i.e. the signer is not a group member, then the transaction is discarded. Else, the opening manager monitors the blockchain to find the pending transactions. It verifies then if the signer is a revoked member, i.e. the corresponding $tag_i \in RL$ by computing $tag_i=x_i.Z=C_2-u.C_1$. The revoked transaction is discarded from the blockchain. The allowed transaction Tx' status is set to 1 and is sent to the blockchain. The consensus nodes verify the validity of this transaction by operating the Elliptic Curve Digital Signature Algorithm (ECDSA) [29] Verify using the opening manager public key pk_o.
- Transaction chaining: The transaction is considered valid when at least two-third of total consensus nodes verify the transaction successfully through $\text{GVerify}_{\text{gpk}}$ (for Tx) and $\text{Verify}_{\text{pko}}$ (for Tx'). All valid transactions recorded through a predefined period of time are chained into a pending block that can be chained into the blockchain when the PBFT consensus is reached among more than two-third of total consensus nodes.
- Response delivery: The Fog node monitors the blockchain to retrieve the new valid transactions and decrypts the message $Msg = Dec_{skfn}(E_{msg})$, where Dec is an AES Decryption, and computes the signature $R=Sign_{skfn}(M_i \mid\mid request)$ using its private key and sends $\{M_i, request, R\}$ to the targeted IoT device. After successfully verifying the received request, the device encrypts the response using the one time group member's public key M_i, and signs it with its private

key d_j. If the response passes the signature verification Verify_{Dj} (RES, E_{res},), then the fog node computes MAC = MAC_{SK} (E_{res}) using the secret session key SK and sends {E_{res}, MAC} to the group member. The latter compares the $MAC'=MAC_{SK'}(E_{res})$ to the received MAC. If the equality holds, this means that the secure mutual authentication is successfully established between the fog node and the group member, who can then decrypt the response using its one-time private key.

4) Member revocation: The group manager maintains the RL that contains $tag_i=x_i.Z_i$ of revoked users. If the behavior of a group member is malicious, or if he does not belong to the group anymore, the group manager can then revoke its membership and add the corresponding tag_i in the public RL. This revocation list is shared only between the group manager and the opening manager.



Member_i
Group Manager
chooses ID_i , PW_i
generates u_i
computes $HPW_i = h(PW_i \| u_i)$
imprints b_i
$\{ID_i , HPW_i , b_i\}$
via secure channel
Checks the length of ID_i
Checks if ID_i exists in its database
Chooses a codeword c_i
Calculates $F(c_i,b_i) = (\alpha, \delta)$
Calculates $A_i = h(ID_i \| HPW_i \| c_i)$
$B_i = h(HPW_i \| c_i)$
Calculates $x_i = PUF_i (B_i)$
sets a private key $gsk_i = (x_i, Z_i)$, $Z_i \leftarrow z_i. P_1$
where $z_i = (d - x_i) (sx_i)^{-1} \in Z_q^*$.
computes $tag_i = x_i.Z_i$
maps it with the relevant group member's identity in a members table.
sets $status_i = active$
stores $\{ID_i, status_i\}$ in its database
stores $\{\alpha, \delta, A_i, Z_i, f(), PUF_i()\}$ in the hardware token
Hardware token
stores u_i in the hardware token

VI. Security Analysis

A. Informal Security Analysis

In this section, we provide an informal overview of the security aspects of our protocol, highlighting its robustness against various security threats and its important security features. Furthermore, we present a comparison of the proposed BC-Auth scheme with other competing schemes in terms of functionality and security features. The results of this comparison are summarized in Table I.

1) Mutual authentication: First, the consensus nodes and the opening manager authenticate the user by verifying the request transactions via group signature scheme. Then, the IoT device authenticates the fog node by verifying its digital signature (ECDSA), confirming that the fog node is authorized to access the device's data. Finally, mutual authentication is achieved between the fog node and group members through the use of MAC that provides a way to verify the authenticity and integrity of messages exchanged between the two parties. By using MAC, the fog node can authenticate the group members and vice versa, ensuring that only authorized parties can access the system.

2) Single registration: The process of single registration involves the issuance of private keys to each group member by the group manager, which is based on a unique identifier (PUF). Even when some members are revoked by the group manager, legitimate members can continue to use their private keys for signing transactions, which eliminates the need for multiple registrations and minimizes the risk associated with key management.

3) Suitable for IoT: The proposed protocol is designed to be compatible with the constraints and requirements of IoT devices, which typically have limited processing power, memory, and energy resources. To address these constraints, the proposed protocol leverages the fog node as an intermediary between IoT devices and the blockchain network, allowing IoT devices to offload some of the computation and communication tasks to the fog node. This approach reduces the computational burden on IoT devices and enables them to participate in the blockchain network securely and efficiently. Additionally, the fog node can act as a gateway for IoT devices that are not directly connected to the internet, providing them with secure and reliable access to the blockchain network. Therefore, the proposed protocol is suitable for IoT applications that require secure and efficient communication with the blockchain network.

TABLE I. Security Requirements Comparison

Security requirement	[30]	[31]	[32]	Our protocol
Anonymity	No	Yes	No	Yes
Traceability	Yes	No	Yes	Yes
Confidentiality	No	Yes	Yes	Yes
Revocation	No	Yes	No	Yes
Mutual Authentication	Yes	Yes	No	Yes
Timely Tempo detection	No	No	No	Yes

4) Resistance to cloning and counterfeiting: The proposed system uses PUF to generate members' private keys, which are then securely stored in a hardware token. PUF is a technique that leverages the inherent randomness of physical systems to generate unique and unclonable keys. By utilizing PUF, the system can ensure that the private keys of group members cannot be cloned or counterfeited, which provides a higher level of security. Even if an attacker gains access to the hardware token, they will not be able to clone or counterfeit the private key, as it is generated using PUF, which is a unique physical characteristic of the device. This resistance to cloning and counterfeiting is important because it ensures that the private keys of group members cannot be compromised, which would otherwise compromise the entire system.

5) Resistance to man in the middle attack: In the proposed protocol, a MAC is used to verify the authenticity and integrity of the exchanged messages between the communicating parties. MAC is generated by computing a cryptographic hash function over a shared secret key and the message. This shared secret key is only known to the legitimate parties, ensuring that any changes made to the message by an attacker will be detected by the receiving party. This ensures that the messages cannot be tampered with or intercepted by a malicious party without detection, preventing man-in-the-middle attacks.

6) Resistance to stolen hardware token: In the proposed system, the private keys of group members are securely generated and stored in hardware tokens using PUF. Additionally, biometric authentication is used to ensure that only the legitimate owner of the hardware token can access the private key. In the event of a hardware token being stolen, the group manager can revoke the token, rendering the private key unusable. This approach provides resistance to stolen hardware tokens and protects the system against attacks that attempt to use a stolen token to impersonate a legitimate group member.

7) Session key agreement and resistance to replay attacks: In the proposed system, session key agreement is used to establish secure communication between the fog node and the user. In every session, a fresh private/public key pair is generated for every user. This ensures that each session has a unique session key, which is used to encrypt responses and to generate a session MAC between the fog node and the user. By using a fresh private/public key pair for every session, the system resists replay attacks. If the same key is used in every session, an attacker could use a previously intercepted session key to forge or replay messages, which would compromise the security of the system. However, by using a fresh private/public key pair for every session, the system ensures that each session has a unique session key, which makes it much more difficult for an attacker to replay messages.

8) Timely tempo detection: In the proposed system, there is a login phase that locally checks the user credentials before granting access to the system. This means that the system can quickly detect and reject unauthorized users who try to access the system without valid credentials. By doing so, the system can prevent potential security breaches and minimize the communication and computation costs. Therefore, the timely tempo detection helps to enhance the security of the system and protect it from unauthorized access.

9) Traceability: In the proposed system, group signatures are utilized to provide traceability for suspicious transactions. Only the opening manager has the ability to trace these transactions through a mechanism called GTrace. Other parties who wish to trace suspicious transactions must compromise the ElGamal encryption, which is infeasible under the current security assumptions. Thus, the use of group signatures in the system allows for traceability by authorized parties while preserving the anonymity of group members for regular transactions.

10)User anonymity: User anonymity in this context refers to the fact that the proposed system ensures that users can sign transactions without revealing their real identities. The system utilizes a group signature scheme, where a member's identity is not disclosed, and only the opening manager knows the true identity of the member who signed the transaction. Additionally, for each new transaction, a one-time public key is used, which further obscures the identity of the signer.

The comparison results in Table I show that our proposed protocol provides anonymity, traceability, confidentiality, revocation, mutual authentication, and timely tempo detection, making it a more comprehensive and robust solution for securing IoT systems than protocols [30], [31], and [32]. The lack of these features in the other protocols makes them vulnerable to security breaches, privacy violations, and man-in-the-middle attacks.

B. Formal Security Analysis using AVISPA Tool

In this section, we provide a formal security analysis of our protocol, Fig. 3, based on the widely used Automated Validation of Internet Security Protocols and Applications (AVISPA) Tool [33]. This latter takes in input a formal model of a security protocol and verifies its robustness against a set of security properties. AVISPA tool can also be used to perform security analysis on blockchain protocols. It is capable of analyzing smart contracts and consensus protocols. Avispa supports four backends for analysis: OFMC (On the fly Model Checker), CL-AtSe (Constraint-Logic-based Attack Searcher), SATMC (SAT-based Model-Checker) and TA4SP (Tree Automata based on Automatic Approximations for the Analysis of Security Protocols). Each backend has its own strengths and weaknesses.

In our analysis we adopt the OFMC and CL-AtSe backends and we use the syntax provided by the High-Level Protocol Specification Language (HLPSL) supported by AVISPA. In this HLPSL specification, we define the principal roles representing our model: group manager, group opener, group member, consensus node, fog node and IoT device. In addition, there are two composed roles, session and environment, and a goals section where the security goals are specified. As you can see in Fig. 3, the obtained analysis results show that our proposed protocol is safe under the OFMC and CL-AtSe backends.

VII. CONCLUSION

In this paper, we proposed a blockchain-based secure mutual authentication system for IoT using PUFs and group signatures. The proposed BC-Auth scheme provides several advantages, including the use of permissioned blockchain for more control and privacy, a group signature scheme with two authorities for enhanced security, three-factor authentication for stronger user verification, PUFs for unique private key generation, and fog computing for improved security and efficiency. The proposed system aims to strengthen IoT security and efficiency by mitigating risks and making it more difficult for attackers to obtain user credentials.

We also proved the security of our protocol informally and formally using the AVISPA tool and provided a security comparison with other blockchain based authentication protocols.

In our future work, we are working on:

1) The practical implementation of the proposed BC-Auth protocol using the Hyperledger Fabric which is a permissioned blockchain platform designed for enterprise use cases with modular architecture and privacy features,

2) The practical simulation of the proposed BC-Auth protocol to prove its performance in terms of computational and communication costs.

3) Evolving our protocol by proposing a blockchain based multiple managers' group signature scheme to avoid the risks related to the single authority in the case of one group manager model.

***Abstract*—This paper discusses the importance of virtual machine (VM) scheduling strategies in cloud computing environments for handling the increasing number of tasks due to virtualization and cloud computing technology adoption. The paper evaluates legacy methods and specific VM scheduling algorithms for the Eucalyptus cloud environment and compare existing algorithms using QoS. The paper also presents a self-adapting security monitoring system for cloud infrastructure that takes into account the specific monitoring requirements of each tenant. The system uses Master Adaptation Drivers to convert tenant requirements into configuration settings and the Adaptation Manager to coordinate the adaptation process. The framework ensures security, cost efficiency, and responsiveness to dynamic events in the cloud environment. The paper also presents the need for improvement in the current security monitoring platform to support more types of monitoring devices and cover the consequences of multi-tenant setups. Future work includes incorporating log collectors and aggregators and addressing the needs of a super-tenant in the security monitoring architecture. The equitable sharing of monitoring resources between tenants and the provider should be established with an adjustable threshold mentioned in the SLA. The results of experiments show that Enhanced Round-Robin uses less energy compared to other methods, and the Fusion Method outperforms other techniques by reducing the number of Physical Machines turned on and increasing power efficiency.**

***Keywords*—Component; VM scheduling; cloud computing; Eucalyptus; virtualization; power efficiency; self-adapting security monitoring system; tenant-driven customization; dynamic events; adaptation manager; master adaptation drivers**

I. Introduction

Cloud computing is a technology that provides on-demand access to a pool of resources (such as networks, servers, storage, applications, and services) through networks. It is offered by companies like Google, Amazon, and SalesForce and eliminates the need for users to handle administration and IT maintenance [1]. Resource scheduling and allocation can be challenging for cloud providers due to the dynamic behavior of services and multiple types of cloud systems available [2]. Cloud computing is a form of computing as a service rather than a product, providing customers with access to software, resources, and information as a utility. It is cost-effective, with lower upfront costs and a pay-per-use model [3]. Virtualization technology is used by cloud providers to improve cost-efficiency and energy efficiency. Cloud computing is used in various applications such as website hosting, scientific methods, customer relationship management, and high-performance computing [4].

Server virtualization allows for the allocation of computer resources (such as CPU and RAM) on demand through a pay-as-you-go model, where clients (tenants) only pay for what they use. Infrastructure as a Service (IaaS) is a popular cloud model using virtual machines (VMs) and virtual networks to provide tenants access to compute, storage, and network resources. By outsourcing some information systems through the virtual infrastructure on the cloud provider's physical infrastructure, businesses can enjoy automated management, flexible resource allocation, and the illusion of unlimited computing and networking capabilities, as outlined in the Service Level Agreement signed by tenants and the cloud provider.

Despite the potential cost and efficiency benefits of cloud adoption, security remains a major concern. Multi-tenancy, an essential aspect of cloud architecture, enables the coexistence of trustworthy and hostile virtual machines, making the cloud vulnerable to attacks from both inside and outside the environment [5]. A successful attack could lead to alteration of data stored in the cloud, including login credentials, and even complete control of the cloud infrastructure for illicit purposes. Traditional security solutions like traffic filtering and inspection are insufficient against sophisticated threats targeting virtual infrastructures. To ensure cloud security, an automated self-contained security architecture incorporating multiple protection and monitoring technologies is necessary [6].

In Infrastructure as a Service (IaaS) cloud architecture, tenants are responsible for managing their virtual information systems while the provider manages the physical infrastructure. Tenants have concerns about security monitoring of their virtualized infrastructure and need a solution that considers their specific security requirements and can respond to dynamic events in the cloud environment. This research aims to create a self-adaptable security monitoring framework to address these concerns and ensure adequate security monitoring for tenants' virtual infrastructures. The research work focuses on creating a self-adaptive security monitoring framework for cloud infrastructure. The framework should respond to dynamic events in the cloud and adjust its components accordingly, while maintaining a balance between security, performance, and cost. It should incorporate tenant-driven customization and meet tenant-defined thresholds and security requirements. The framework should not create new vulnerabilities and should not significantly impact performance or regular cloud operations. The research work also assesses existing cloud computing approaches and scheduling methodologies, and explores Eucalyptus cloud scheduling methods. Two independent Eucalyptus virtual machine scheduling techniques are proposed and evaluated, which aim to improve energy efficiency in cloud data centers.

Cloud computing is becoming increasingly prevalent in various industries, and efficient resource allocation and security are critical for maintaining acceptable throughput and revenue. Therefore, it is important to evaluate and compare existing VM scheduling algorithms and develop a comprehensive self-adapting security monitoring system that meets the specific needs of each tenant in a cloud environment. While there are many existing virtual machine scheduling algorithms for cloud computing environments, the specific context of the Eucalyptus cloud environment has not been extensively studied. Therefore, this paper aims to evaluate and compare existing VM scheduling algorithms in the Eucalyptus cloud environment, with a focus on energy efficiency. The paper addresses are the lack of a comprehensive self-adapting security monitoring system that takes into account the specific requirements of each tenant in a cloud environment. The paper proposes a framework for such a system that combines precise security monitoring with self-adaptation.

This paper is organized as follows: Section II presents a literature review and an overview of related works in this field. Section III presents the design and methodology used in the study. Section IV presents the discussion on the study and results. Finally, Section V draws a conclusion and proposes future research.

II. Literature Review

A. New Approach to Cloud Computing

Cloud computing is a software-based network infrastructure that enables users to access and store data on demand. It allows for flexible, elastic and cost-effective use of IT resources without the need for new hardware or software. The five core properties of cloud computing include independence, resource pooling, on-demand self-provisioning, rapid adaptation, and a consistent network as shown in Fig. 1. Cloud computing also includes three delivery options: Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS). There are four deployment strategies for cloud computing: public, private, communal, and hybrid clouds [7].

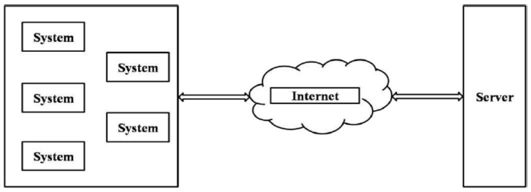

Fig. 1. Basic architecture of cloud.

B. Cloud Computing Models based on Services

The Cloud Security Alliance has identified security and privacy concerns as major obstacles to trusted cloud computing. Different security levels are needed for public and private clouds and Service-Level Agreements (SLAs) define customer and cloud provider responsibilities. Key safeguards include data integrity, vendor trust, consumer confidentiality, individual users and user groups. There are three delivery methods for cloud computing: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS). IaaS provides a layer of middleware and OS services, while PaaS offers a web-based platform to run apps as shown in Fig. 2. SaaS is the pinnacle of cloud computing technology, provided as a service and accessed online [8]. PaaS has the advantage of cost-effectiveness, but there is a risk of lock-in if it uses proprietary interfaces or programming languages.

C. Cloud Computing Security Issues and Challenges

Cloud computing is a rapidly growing field in IT that provides benefits such as improved infrastructure and cost-efficient access to services. However, it also presents risks such as security threats, privacy concerns, and reliability issues [9]. To address these, there is a move towards open standards, better compatibility, and compliance resources from cloud service providers. When considering cloud computing, it is important to also consider its long-term viability. There are challenges to cloud computing solutions such as lack of interoperability, compatibility with existing programs, difficulty in meeting regulations, and insufficient security. Lack of standardization and proprietary applications can lead to complexity and high costs, as well as security concerns with shared infrastructure not providing enough security [10].

D. Resource Allocation

Network resources or shared resources can include files, the challenge in sharing resources such as data, audio and video, and hardware in a cloud environment can be addressed through resource management. This involves coordinating IT resources by controlling templates, managing virtual IT resources, performing load balancing, resource replication and failover, and monitoring the operational conditions of IT resources [11]. The cloud provider or user accesses these functionalities through a cloud resource administrator, and the virtual machine image repository is located in the Virtual Infrastructure Manager (VIM) as shown in Fig. 3.

E. Primary IaaS Systems

The OpenStack platform is a popular open-source cloud management system that is used by tenants to access, build, and manage their resources through a web interface or command line clients [12]. The system is designed to be modular, with a central controller node and compute nodes that report on the status of deployed virtual machines as shown in Fig. 4. The cloud infrastructure is dynamic, and changes may occur at various levels including services, topologies, and traffic. There are four types of cloud deployment models - private, public, community, and hybrid clouds. In a cloud environment, tenants can easily deploy virtual machines and create services that are accessible to others [13]. The cloud infrastructure is dynamic and changes happen frequently, including topology-related events caused by virtual machine life cycle commands, and traffic-related events due to changes in network demand.

F. Virtualization

The three main architectural layers in an IaaS system are the physical layer, the hypervisor, and the virtual machine layer. The security monitoring architecture focuses on the virtual machine layer. There are four main server virtualization strategies: emulation, full virtualization, par virtualization, and OS-level virtualization. OS-level virtualization uses containers and is a popular option for minimal overhead. Network virtualization is crucial for IaaS cloud architecture and manages IP addresses and communication. Network virtualization is achieved through MPLS, VLANs, Flat Networking, and GRE encapsulation, and is simplified by Software Defined Networking (SDN), with OpenFlow being the most popular example. The SDN architecture separates the control and data planes and allows for centralized control of the network [14][15] as shown in Fig. 5.

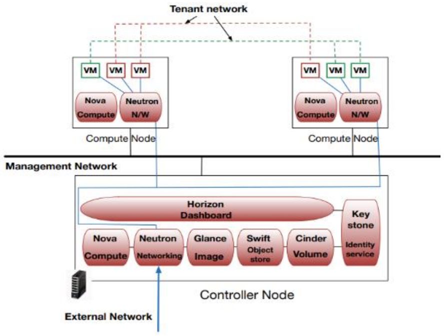

Fig. 4. The modular architecture of openstack.

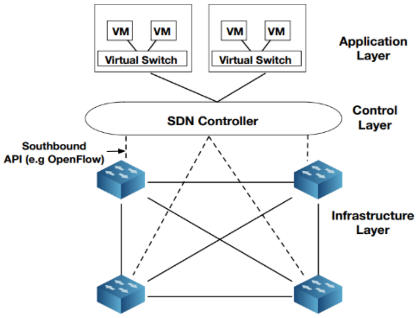

Fig. 5. The architecture of SDN.

SDN (Software Defined Networking) is a network management concept that allows for programmatic control and administration of the network through a programmatic interface. Examples of SDN controllers include OpenDaylight and Floodlight. Network virtualization in IaaS (Infrastructure as a Service) clouds allows for programmatic creation, modification, and deletion of network objects (such as networks, subnets, ports, etc.) without affecting the underlying hardware infrastructure [16]. The Neutron component of OpenStack is responsible for managing tenant networks and providing VMs with networking capabilities, with the ML2 plugin creating virtual bridges to connect VMs to networks with either GRE encapsulation or VLAN tagging to differentiate network traffic among tenants. In a typical cloud implementation, three types of networks are created: management network, tenant networks, and external network.

G. Security Threats

Different types of security threats to information systems, including the application level, network level, operating system level, and cloud environment. Threats can include SQL injection attacks, cross-site scripting, buffer overflows, impersonation, denial of service attacks, man-in-the-middle attacks, and exploitation tactics. In cloud environments, both tenants and providers face security risks such as risks from other tenants, the provider's infrastructure, and the API. Multi-tenancy can also create new security threats, such as side channel attacks and exploitation of shared resources. The security of virtual machines in a cloud environment is dependent on the stability of the hypervisor, which can be a target for security vulnerabilities and malware attacks. A successful attack on the control interface can result in full compromise of the account and stored information [17].

H. Security Monitoring

Information systems are continuously threatened at several layers of their infrastructure. To prevent significant damage, it's crucial to have a security monitoring system in place, such as an Intrusion Detection System (IDS). IDSs are the main component of a security monitoring framework and they detect security holes by collecting, processing and reporting data. There are two types of IDSs: signature-based and anomaly-based. Signature-based IDSs use string comparison to match observed events to known attack patterns, while anomaly-based IDSs compare observed events to a normal profile of activity to detect potential security breaches. Additionally, there are two types of IDSs based on location: network-based and host-based. Network-based IDSs monitor network traffic, while host-based IDSs monitor a single host for suspicious activity [18]. In cloud environments, security monitoring must be automatic to adjust to changing events. Different cloud security monitoring strategies focus on either the tenant's data system or the provider's infrastructure. Provider infrastructure monitoring includes hypervisor or kernel-based IDSs as shown in Fig. 6. The trend in hypervisor security is to lower the Trusted Code Base, but this does not guarantee the complete integrity of the system.

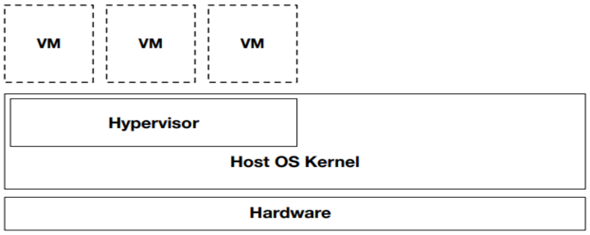

Fig. 6. The kernels of the host and hypervisor.

In the context of security monitoring in cloud environments, there are two main areas of focus: the provider's infrastructure and the tenant's information system. The provider's infrastructure is monitored by hypervisor or kernel-based intrusion detection systems (IDSs), which focus on securing the integrity of the hypervisor and kernel [19]. However, these systems may not adapt to changes in the programs running in the monitored system. On the other hand, the tenant's information system can be monitored through virtual machine introspection, which allows for real-time monitoring of the health of the underlying operating system and active processes in deployed virtual machines. However, designing cloud-tailored intrusion detection systems for the tenant's information system can be challenging due to the complexity and variety of the cloud environment and the conflicting security requirements of tenants.

It is evident from the literature review that there are still several areas that require further research, including the development of standardized SLAs, the development of cloud computing architectures for a wider range of applications, the effectiveness of cloud computing security measures, and the environmental impact of cloud computing.

III. Design and Methodologies

Eucalyptus is an open-source software platform used to create an IaaS (Infrastructure as a Service) for private or hybrid cloud settings. It is scalable and distributed, with each component serving a small number of users, making it suitable for enterprises of all sizes. The platform offers virtualized cloud resources like infrastructure, network, and storage as a service. The name "Eucalyptus" stands for Elastic Utility Computing Architecture for Linking Your Programs to Useful Systems.

A. Setting up Eucalyptus Cloud

Eucalyptus cloud setup consists of the Cloud Controller (CLC) and Walrus, which manage various clusters of real computers that host virtual instances. Each cluster has a Cluster Controller (CC), a Storage Controller (SC), and multiple physical machines known as Nodes [20]. The Node Controller regulates the hypervisor on each node to manage virtual instances. In the study mentioned, all components were co-located on the same system except the NC, with one machine hosting CLC, Walrus, CC, and SC, and five machines hosting NC as shown in Fig. 7.

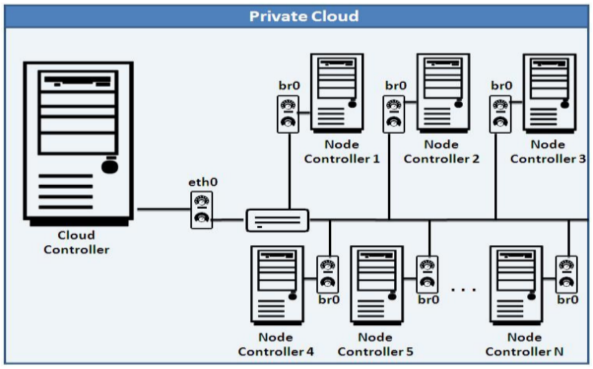

Fig. 7. The NC service is hosted by the domain-0 kernel in the xen setup.

B. IaaS Clouds based Self-Adaptable Framework for Monitoring Security

We consider an IaaS cloud environment with a global cloud Tenants have control over a networked group of virtual machines (VMs) and can specify unique monitoring requirements through a Service Level Agreement (SLA) or API. The cloud controller provides networking capabilities and the tenant receives both an external and internal IP address. The study focuses on software attacks from inside or outside the cloud infrastructure and the potential for an attacker to exploit a deployed VM and compromise the victim's infrastructure [21]. Trust is placed in the cloud provider's infrastructure being physically safe and not affected by malicious viruses. Attacks that weaken the cloud management system are not taken into account.

C. Goals Designed

The objective of the research is to develop a self-adaptive security monitoring platform for virtualized information systems of tenants that meets several requirements including self-adaptation, tenant-driven customization, security and accuracy, and cost savings. The framework should be able to update its components automatically in response to changes in the cloud environment and to allow for customization based on tenant needs [22]. It should minimize security risks and costs for both the provider and the tenants. The framework should consider the different sources of adaptation, including changes in services, topology, monitoring load, and tenant requirements. The framework should ensure that reconfigurations do not compromise security or monitoring accuracy, while minimizing resource use and performance impact on tenant applications.

D. Methods

The research presents a self-adaptive security monitoring framework for IaaS cloud with a three-tier architecture including a controller, two computing nodes, network IDS, edge firewall, local firewalls, and a log aggregator. The three tiers are the tenant, adaptability, and monitoring devices with the monitoring devices consisting of log collectors, aggregators, and probes as shown in Fig. 8.

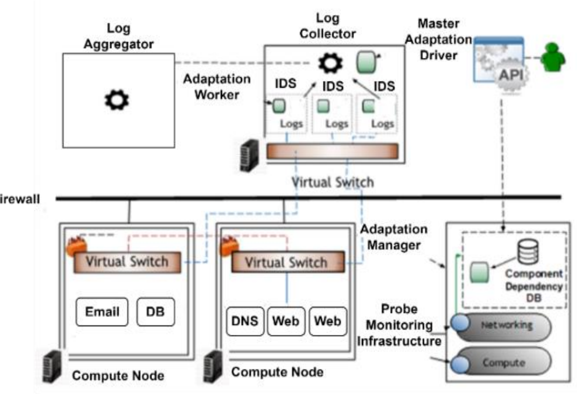

Fig. 8. The framework's architecture [23].

The research presents a self-adaptive security monitoring framework for IaaS cloud with three main tiers: tenant, adaptability, and monitoring devices. The adaptation level is responsible for planning and enforcing the adaptation process and is made up of the Adaptation Manager in the cloud controller, Master Adaptation Drivers in the nodes, and a dependency database. The Adaptation Worker in each monitoring device enforces the reconfiguration settings and the Infrastructure Monitoring Probes discover topology changes. The tenant API provides access to all monitoring features as shown in Fig. 9.

The research presents a self-adaptive security monitoring framework for IaaS cloud with a controller, two computing nodes, network IDS, edge firewall, local firewalls, and log aggregator. The framework has three main tiers: tenant, adaptability, and monitoring devices. The tenant tier has access to a tenant API, which allows tenants to express their monitoring requirements in a high-level language. The API is broken down into two parts: the tenant-exposed part and the translation part. The tenant-exposed part allows tenants to access the list of monitoring services, add or remove a monitoring service, and alter monitoring metrics. The translation part translates the high-level tenant requirements into framework-specific information, which is used by the framework to make adaption decisions.

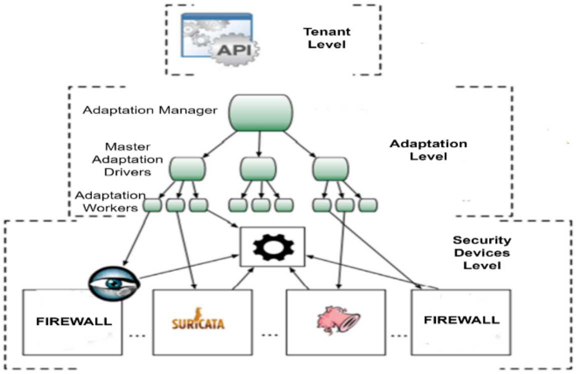

Fig. 9. The framework’s various levels [23].

Example scenario: Consider the following instance as an illustration: On various compute nodes, there are two unique VMs installed, each of which belongs to a different tenant. An ssh server and an Apache server with SQL support are hosted by the first VM with ID 24 that is installed on node A. Although its private IP address is 192.168.1.3, the virtual machine's public IP address is 182.12.34.201. A port with the name "qvo1432" is used to link the VM to the compute node's virtual switch. On node P-20, the second VM, ID 63, is configured and is only used to host an ssh server as a service. The VM's secret IP address is 192.168.1.3, whereas its public IP address is 182.12.34.199. In this condensed example, we solely use firewalls and network-based IDSs as monitoring tools.

The security of a cloud computing infrastructure is monitored by security devices such as firewalls, vulnerability scanners, antivirus programs, and others. These devices are able to create log files that are managed by log collectors and aggregated by the framework administrator for searching for specific patterns. The Adaptation Manager is a key component of the monitoring framework that is responsible for selecting the adaptations to the monitoring tools, maintaining an acceptable degree of monitoring, and managing dynamic events within the cloud architecture. The Adaptation Manager performs algorithms in Algorithm 1 in response to dynamic events and makes decisions on whether to adapt based on the topological and functional overviews of the monitoring framework.

Algorithm 1 The choice algorithm for adaptation

```
1: procedure ADAPTATIONS (dynamic activity)
2:     services list ← MAP (dynamic activity.VMid, vm info file)
3:     affected equipments, agents ← MAP (dynamic activity.VMid)
4:     for j in affected equipments do
5:         reconfiguration needed ← DECIDE (j, services list)
6:     PROPAGATE DECISION (agents, reconfiguration needed)
```

- Connect the ID of the VM that is affected by the modification to the list of services that are currently executing within the VM (line 2 in Algorithm 1). To do this, the data in the file that the API generated is parsed.
- Determine the monitoring systems in charge of the impacted VM. These will be the monitoring tools that are modified. Utilizing data from the Component Dependency Database, this is accomplished. The vm information file is a single file that contains both the list of monitoring devices that will be updated and the list of active services.
- Select the necessary reconfiguration type (line 5 in Algorithm 1). Different reconfiguration kinds may be required depending on the monitoring device type and incident category.
- Distribute the reconfiguration parameters to the personnel in charge of upholding the adaption choice (line 6 in Algorithm 1).

E. *Infrastructure Monitoring Probes*

IMPs (Instance Monitoring Processes) are components of the cloud engine that monitor topology changes, such as placement and VM lifecycle alterations. They collect VM-related data from the cloud engine and provide information to the adaptation manager, which then decides which adaptation to deploy. IMPs do not affect normal cloud operations when adjusted.

F. *Component Dependency Database*

The article discusses the challenges of security issues in complex security monitoring frameworks composed of various components. The methodology states that a decision taken in response to a dynamic event can impact both an active and passive monitoring device, requiring both to be changed. The Dependency Database, a component of the cloud controller, lists all security devices for each monitored VM and gives the Application Manager both functional and topological viewpoints. The VM information table can be used by the Adaptation Manager as a key to access the list of monitoring tools in charge of a VM, making it easier to identify impacted devices during an adaptation. The VM information table for the VMs in the previously discussed scenario is found in Table I.

For example, the VM with ID 24 can see a host IDS, a network IDS, and two firewalls: one inside the local switch called f-p-20 and one on the edge called f-ext1. Multiple IDS types can monitor a single VM (host- and network-based).

TABLE I. THE VM INFO TABLE

VM ID	Network IDS	Host IDS	External-firewall	Switch-firewall
24	S-79	24	Mar24	f-p-20
14	S-99	14	Aprs14	f-p-63

TABLE II. THE EQUIPMENT INFO TABLE

Equipment Name	Location	Equipment Type
S-65	182.12.34.201	signature based

Device-specific information is kept in the equipment info table. The Adaptation Manager gathers the following data using each device name: both the device's location and its type Table II contains the S-65 IDS equipment information table. This instance demonstrates that the signature-based NIDS suricata65 is situated on a node with the IP address 182.12.34.201. The Dependency Database's information is used by the AM to compile a complete list of all devices that are impacted by a dynamic event. The AM updates the two tables with a corresponding entry for every new monitoring device that is created, including all the relevant data.

G. *Self-Adaptable System for Intrusion Detection in IaaS Cloud*

A self-adaptable intrusion detection system has been proposed for IaaS cloud environments. This system offers features such as self-adaptation, customization, scalability and security, and correctness. The system allows for adaptation to changing conditions in the cloud, enables tenants to modify monitored events, and adjusts the number of IDS systems based on network traffic and infrastructure size. The system ensures proper level of detection during adaptation to maintain security and correctness.

1) Proposed framework: Detailed design of a proposed framework, including its components and the system and threat model used. It starts with a general overview of the framework, followed by a detailed explanation of how each component works.

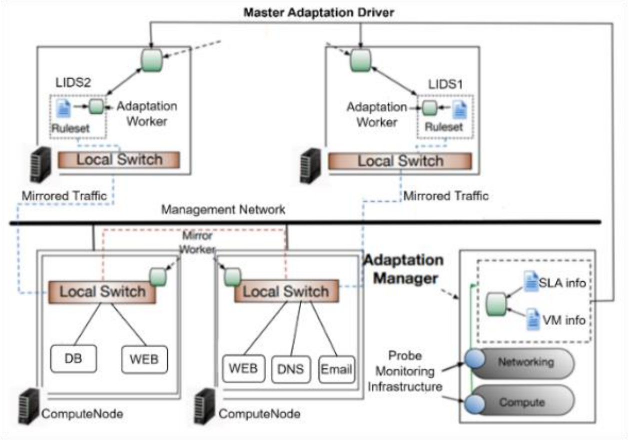

Fig. 10. The proposed framework for self-adaptable system.

The framework described in Fig. 10 is composed of four main parts: Adaptation Worker (AW), Local Intrusion Detection Sensors (LID), Mirror Worker (MW) and Master Adaptation Driver (MAD). LIDs are deployed on separate nodes and are used to collect and analyze network packets, either using anomaly-based or signature-based techniques. The AW updates the applicable ruleset, monitors the performance of the LID, and updates the MAD after a successful reconfiguration [24]. The MAD handles the reconfiguration of multiple LIDs, manages their lifecycle, and collects performance metrics. The MW ensures accurate mirroring of traffic to the matching LID node and constructs a mirroring endpoint if needed. A safety mechanism on each compute node ensures that VMs don't become active before the accompanying LID has been reconfigured.

The proposed framework for security in cloud computing has both potential weaknesses in its architecture and contributions to the service provider's infrastructure. A vulnerability in the framework is the configuration files that translate adaptation arguments into rule names, which are simple text or XML files and could be manipulated by attackers to produce fake adaptation arguments. The framework includes parsers for these files. The power utilization model evaluates the power usage of physical machines and is based on power meters built into the physical machines [25]. Research has shown that power consumption is inversely correlated with the number of fully utilized cores. The migration model describes the methods and costs of relocating virtual machines as shown in Fig. 11.

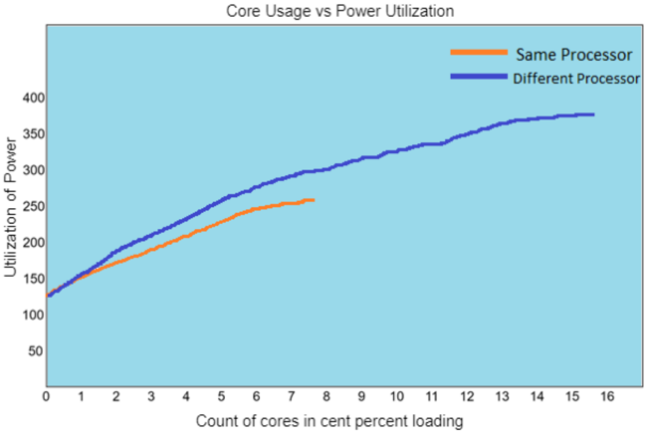

Fig. 11. Power utilization demonstration with various processor loads.

The Top power (Tp) is the maximum power used by a PM (Processing Module) when all 16 cores are fully loaded. The Inactive power (Ip) is the power consumption when none of the cores are loaded. The Top power is about half of the Inactive power. The linear power model is used to fairly assess the power utilization (PU) of PM.

$$PU = \left[\frac{C_v}{C_p}(1-\beta)+\beta\right]T_p \qquad (1)$$

Where β displays the ratio of dormant to active power. Consider Fig. 11 above, β is set to half, Cv is the total number of cores required by resident VMs, and Cp is the total number of cores required by PM.

The Migratory technique uses live migration to allow a server administrator to move an active virtual machine (VM) to a different PM without affecting its performance. Although live migration does not affect the execution time of the VM, it does increase energy consumption during the transfer due to increased load on the receiving PM [26]. The energy consumption during relocation has been quantified based on experimental data.

$$U_E = U_S + U_D \qquad (2)$$

$$U_S = \left[\frac{C_v}{C_p}(1-\beta)+\beta\right]T_p M_t \qquad (3)$$

$$U_D = \left\{\left[\frac{C_v'}{C_p}+L\right](1-\beta)+\beta\right\}T_p M_t \qquad (4)$$

The U_E is the percentage load of the sending and receiving machines. Cv is the number of cores required to migrate a VM, and Cv/Cp and Cv'/Cp are the percentage load of the sending and receiving machines. The migration time (Mt) and additional burden (L) imposed by the migration procedure must be considered when deploying VMs with various hardware requirements on PMs with specific hardware limitations. The First-Fit approach may be used to address the fusing problem, though it is more challenging. It seeks to deploy a VM to the first PM that has space for it and can be simple to apply, but may not be the best solution.

This study investigates a more challenging VM fusing problem where each VM has resource requirements, Time of Execution and Time of Arrival restrictions, and a limited availability window during its execution. The idle cores used by a VM after it has ceased to function can lead to the need for additional PMs. The Eucalyptus architecture provides two scheduling options, Enhanced Round-Robin (ERR) and a Fusion mechanism, to lower the number of PMs needed and save power consumption. The ERR approach uses two criteria to aid in VM fusion: retiring PMs cannot have additional VMs added to them, and retiring PMs that cannot complete all VMs before the deadline must transfer and shut down. The Fusion method combines the ERR and First-Fit approaches, depending on the rate of incoming VMs, to save more energy. The biggest challenge in implementation is choosing a reasonable Limit of Resigning (LR), calculated by adding migration time and time left for the VM to execute. The Fusion method with LR calculation can result in energy savings by transferring VMs during non-peak hours.

$$U_S = \left[\frac{C_v}{C_p}(1-\beta)+\beta\right]T_p R_t \qquad (5)$$

$$U_D = \left[\frac{C_v'}{C_p}(1-\beta)+\beta\right]+T_p R_t \qquad (6)$$

Where U_E and U_D are, respectively, the energy expenses associated with sending and receiving PMs when the VM is not being migrated. Instead of deciding to relocate every VM by its remaining time for execution after the PM resigned, Rt, that's a mystery, the limit α below is the resignation limit.

$$\alpha = (1-L)M_t + \frac{L}{\beta} \qquad (7)$$

Assuming a VM with Rt smaller than indicates that not migrating saves more energy, and the VM will eventually finish before PM starts moving VMs. On the other hand, in the unlikely event that Rt greater than α, VMs will be transferred after the resigning limit is exceeded, indicating that moving is the better option. Execution time that is left over Rt While using the ERR approach, it is not essential. The limit α has been established and fixed. After a brief pause, α., a resigning VM will be shut down. Regardless of how much time is left for execution, each incomplete VM would be transferred.

2) Self-Adaptable framework for monitoring security: The proposed framework consists of four main components: Adaptation Worker, Local Intrusion Detection Sensors, Mirror Worker, and Master Adaptation Driver. The Adaptation Manager, a part of the proposed framework, is implemented using a multi-threaded model in Python, using Open-Stack as the cloud management system [27] and Open vSwitch for network traffic mirroring. The AM receives notifications of topology changes from the Infrastructure Monitoring Probes and creates a worker thread to manage the potential adaptation event as shown in Listing 1. The worker thread reads information about the impacted guest VM from a vm information file and retrieves the list of active services and tenant-specific security requirements using the VM ID as an identifier.

Listing 1 Adaptation during VM migration

```
procedure ADAPTATION (VM network information)
    SPAWN ADAPTATION THREAD
    services list ← INFORMATION PARSER (VM network info.VM id, vm information file)
    affected equipments, locations ← INFORMATION PARSER (VM network info.VMid, VM network info.source node,VM network info.destination node, topology.txt)
    for p,qj in affected devices, locations do
    args.txt ← DECIDE (services list, p)
    IDS CONN (q, args.txt, +/-)
```

The parameters (such as what types of rules will be activated/deactivated, what is the acceptable tenant drop rate, etc.) are put to a specific file called args.txt when the AM decides to adapt. A separate file (topology.txt) that contains the topological and functional views required by the AM is extracted by the worker to obtain the names, kinds, and locations of the impacted security probes.

One NIDS is used on each computing node in the monitoring technique shown in this section. The single node hosts all of the deployed NIDSs. Following a VM migration, the master thread receives network-related information from the IMP, for example for the VM with ID 24.

The worker thread parses the topology.txt and vm information file.xml files as soon as it receives this information to extract the services that are currently running in the migrated VM (sshd, apache2, sqld), any additional tenant-defined monitoring requirements (worm), tenant-specific monitoring metrics, and finally the names of the NIDS responsible for monitoring the traffic in the source and destination nodes (S-9 and S-65, respectively), as well as their host IP. Adaptation is necessary for these two NIDS. The adaptation parameters are then written by the worker thread to adaptation args.txt. Listing 2 displays the findings of the NIDS monitoring traffic to and from the destination. Listing 2 shows the file holding an NIDS's adaption arguments.

Listing 2

```
signature based
S-65
apache 2
sql
ssh 192.168.1.1, 192.168.1.3
worm
5
```

- Using a secure connection, the worker thread sends the dedicated file to a MAD in the node(s) holding the affected security devices. The name and IP address of the node housing the security device are used to create a connection by the ids conn function.
- The file containing the adaptation arguments must additionally contain a specialised operator if the adaptation calls for the activation or deactivation of monitoring parameters (such as + or -), as stated by the AM. In our illustration, a + denotes that the monitoring parameters need to be activated by the operator that was sent with the file in Listing 2. To allow for the concurrent transmission of the adaptation file, a separate thread is created for each security component that will be touched by the adaptation choice.

H. *Self-Adaptable System for Intrusion Detection*

A private cloud framework prototype was created using OpenStack and Open vSwitch as a virtual switch. The framework uses GRE tunnels to separate VMs into tenant networks and mirrors traffic using signature-based LID nodes in Docker containers [28]. An Adaptation Worker was developed to manage the LID nodes and communicates with the Master Adaptation Driver (MAD) using a shared folder. MAD uses a multithreaded method to manage and reconfigure the LID nodes and includes configuration files to convert adaptation parameters into rules for the IDS. The plug vifs function was used to delay the creation of virtual interfaces until the LID reconfiguration is finished to ensure network access for the VMs. [15].

IV. Experimental Results and Discussions

The experiment was performed on an eight-node cluster, each with a quad-core CPU and a power model that uses half of peak power in idle mode. The cost of migration was calculated as 0.025 * 1/8 * 0.2. Data for VM arrival and execution times, and whether they were small or large-scale, was used in the test. The arrival and execution times were estimated using a normal distribution of two to ten hours. Small-scale tests were conducted to study power and migration models using the Xen hypervisor on each node. The power usage was measured using the proposed power model and actual power consumption and an average power usage was calculated. The results of the proposed ERR strategy were compared to the First-Fit power-saving strategy and showed little variance between the estimated and measured power. Thus, different scheduling techniques can be evaluated using the results of the recommended model as shown in Table III.

A simulation was conducted to evaluate the performance and energy consumption of a system with 500 octa-core servers and 3000 virtual machines. The impact of different resigning limitations (10, 20, 30) was tested, and the results of energy usage were compared between the ERR method and the RR and First-Fit methods. The results showed that power usage decreases as the resignation limit decreases and are represented in a graphical form in Fig. 12, with First-Fit as the baseline.

TABLE III. Power Utilization ERR and First-Fit Power Save Results

	Estimated Power (W)	Power Meters Provide Actual Power
ERR	744.53	695.20
Save with First-Fit Power	698.30	659.28
Improvements were made.	46.23	35.92

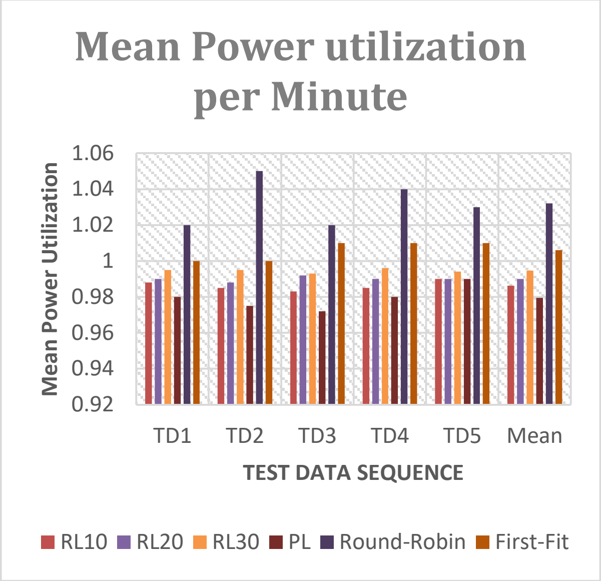

Fig. 12. Using ERR to calculate mean power utilization under different limits of resigning.

This simulation compares five different energy-saving solutions (Best-Fit, RR, First-Fit, ERR, and Fusion Method) by considering metrics like mean power use, mean PM count, and migration count. During busy hours, the Fusion Methodology is used. A graphical analysis is shown in Fig. 13 which demonstrates that the Fusion Methodology performs better in terms of energy conservation compared to the other approaches, as it uses PM loads as the resignation limit.

The paper compares the performance of five different algorithms for VM Scheduling in Eucalyptus cloud: RR, Greedy, PowerSave (similar to First-Fit), ERR and Fusion Method. The analysis compares the number of powered-on PMs and power consumption for each of these algorithms, with the results presented in Fig. 14 and 15. The paper shows that the use of the recommended strategies (ERR and Fusion Method) leads to a significant reduction in the number of powered-on PMs and power usage compared to the three basic Eucalyptus scheduling algorithms (RR, Greedy, and PowerSave).

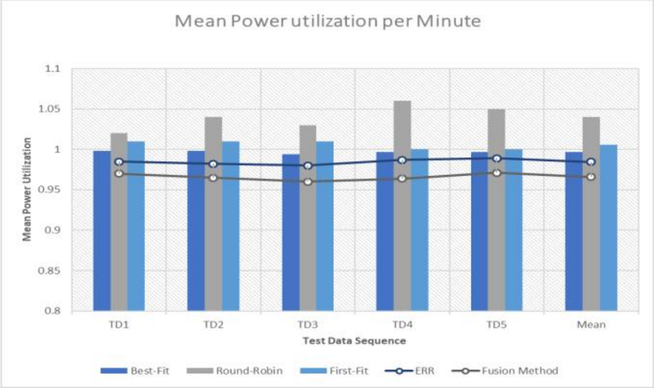

Fig. 13. Comparing the proposed technique's mean power utilization to that of other techniques.

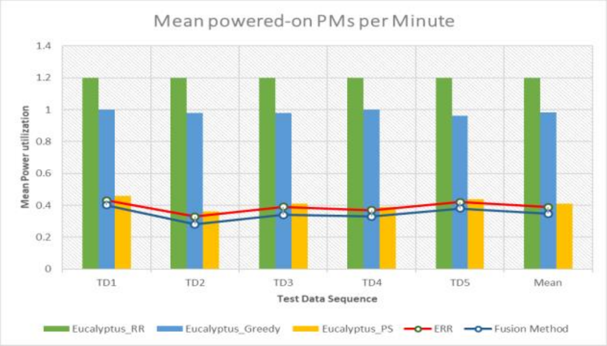

Fig. 14. Usage of RR base to analyze mean powered-on PMS.

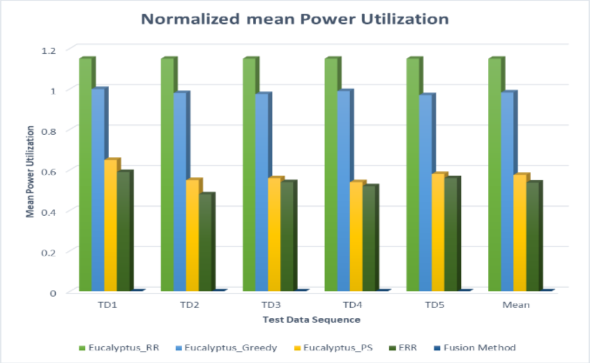

Fig. 15. The usage of RR base to analyse the normalised mean power utilisation.

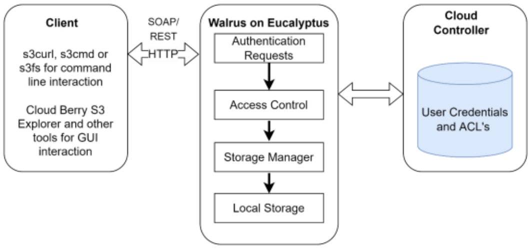
A. *Eucalyptus with Walrus*

This section discusses the private cloud patterns controlled by Eucalyptus and the use of WALRUS, a data storage service for customer data. The Eucalyptus web interface supports "admin" and "user" accounts, and after registration, customers receive X509 certificates, secret key, and Query Id. The client credentials, including RSA private and public keys and X509 certificates, are stored in a file called "eucarc". WALRUS can be accessed through SOAP or REST via HTTP with the help of various utilities and is managed by ACLs and client credentials [10] [29] as shown in Fig. 16.

WALRUS is a data storage service used in Eucalyptus and can be accessed using tools like s3cmd, s3curl, s3fs, cloud berry s3 via SOAP or REST via HTTP. Access to data stored in WALRUS is managed by Access Control Lists and client credentials and secured using the MD5 hashing method. This section also mentions potential security attacks on private cloud systems powered by Eucalyptus that target cloud databases.



Client
s3curl, s3cmd or s3fs for command line interaction
Cloud Berry S3 Explorer and other tools for GUI interaction
SOAP/ REST HTTP
Walrus on Eucalyptus
Authentication Requests
Access Control
Storage Manager
Local Storage
Cloud Controller
User Credentials and ACL's

Fig. 16. Architectural demonstration of Eucalyptus-WALRUS.

1) Attacks related to buckets: The Eucalyptus private cloud system can be vulnerable to security attacks targeting cloud databases. Fig. 17 shows the credentials used for querying user interface names, such as EC2_SECRET_KEY and EC2_ACCESS_KEY, which are stored in the AUTH USERS table with attributes AUTH_USER_SECRETKEY, AUTH_USER_QUERY_ID, and AUTH_USER_NAME, respectively. One specific attack is the use of the file "eucarc," which is obtained from the eucalyptus auth.script catalogue. As shown in Fig. 18, an attacker must upload a new file called "eucarc" along with an S3 URL set that includes the IP address of the cloud controller and the values of EC2_SECRET_KEY and EC2_ACCESS_KEY, which are represented by AUTH_USER_SECRETKEY and AUTH_USER_QUERY_ID, respectively.

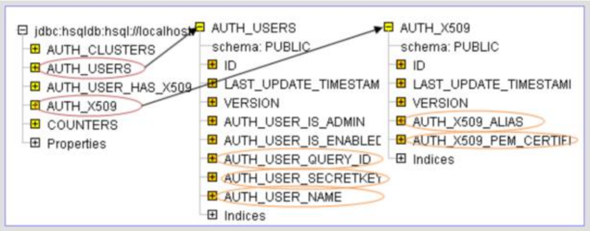


Fig. 17. Illustrations from the table script for Eucalyptus_auth.

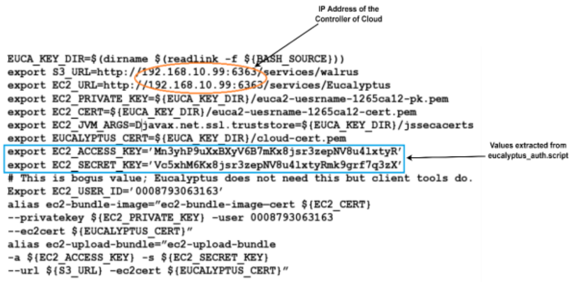

```

Fig. 18. The “eucarc”: credentials compressed file constituent.

The remaining parts of the "eucarc" paper might be omitted because they are not necessary for attacks involving buckets. The attacker essentially needs to obtain the most recent version of the eucarc document after it has been prepared and use the command s3curl to create a bucket that impersonates the client whose login details are used, or to gain access to a significant number of buckets that the client has reserved.

2) Attacks related to objects: Before launching attacks on an object, an intruder must be aware of the precise name of the bucket containing the target object. The eucalyptus-walrus can be used in two distinct ways to determine the precise name of a bucket. One possibility is the script catalogue. Fig. 19 shows how the names of the parent bucket, the individual objects, and the bucket owner are all shown in the OBJECTS table of this catalogue under the attributes OBJECT KEY, BUCKET NAME, and OWNER ID.

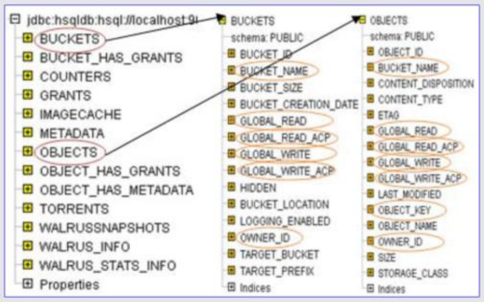

Fig. 19. Eucalyptus-walrus.script table illustrations.

The attacker must use the victim's interface certificates to create a new eucarc document and use s3curl to insert an object into the victim's bucket. The attacker must determine the object's size, MD5 checksum, and last update time and decide whether to read or delete the object. However, these actions require the owner to be an "administrator."

3) Attacks related to ACLs: In Eucalyptus, every WALRUS object and bucket has an associated Access Control List (ACL) in the form of a sub-resource. To launch ACL attacks, the attacker must first have access to ACL-related subresources. The ACL can be obtained using the s3curl command, and can be modified or a new one can be created with desired access control privileges. Attackers can also exploit the distribution of access control privileges to all cloud-registered users. The attacker can change the ACL file to grant access to all users by setting attributes in the eucalyptus walrus.script catalogue.

4) Attacks related to log file: Customers in Eucalyptus can create access logs for their buckets and decide where to send the logs. The logs can be treated like other objects, with the ability to list, remove, and read them. The logging data is stored in the eucalyptus walrus.script catalogue's properties TARGET PREFIX, TARGET BUCKET, and LOGGING ENABLED. If LOGGING ENABLED is set to TRUE, the TARGET PREFIX will add the client-specified prefix to the end of the log file names, and the TARGET BUCKET will be the client-selected bucket where the access log files will be saved. An attacker who gains access to the bucket containing the log entries can use the log entries as they see fit.

B. Analysis of Self-Adaptable System for Intrusion Detection

A data center with five physical nodes (1 controller, 1 network node, 2 compute nodes, and 1 LID host node) running Ubuntu Server 14.04 connected by a 1Gb/s network was set up on the Grid5000 platform for testing. Experiments were conducted using a memory-intensive workload with a 1024MB working set and 10 executions of the LMBench benchmark suite. The proposed framework's overhead during VM migration was tested with two new rule types related to ssh traffic.

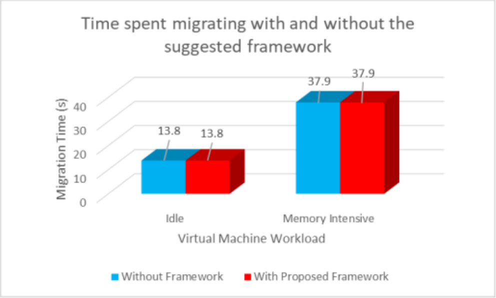

Fig. 20. Time spent migrating with and without the suggested framework.

The outcomes are displayed in Fig. 20. Our initial expectation that the proposed framework imposes minimal overhead on ordinary cloud operations is confirmed by the fact that the imposed overhead in both scenarios of an idle virtual machine and 0.0s represents a virtual machine with a memory-intensive workload. Fig. 21 and Fig. 22 display a breakdown of the two separate adaptation instances (new LIDS with traffic distribution and ruleset reconfiguration only) per phase.

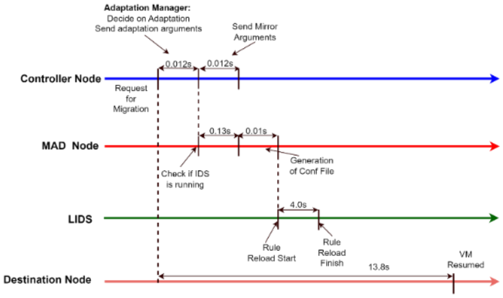

Fig. 21. Breakdown of the adaptation time when the proposed framework only modifies the imposed inside the LIDS ruleset.

Both instances involve the safety mechanism being in operation, however, when the plug vifs is called, the LIDS reconfiguration is finished significantly more quickly (4.14s and 0.97s respectively while the plug vifs function is called always after the 10th second).

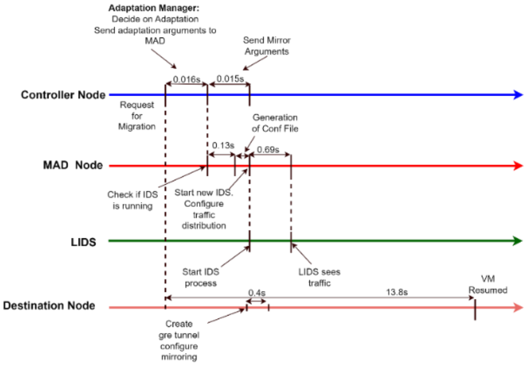

Fig. 22. A breakdown of how long it takes framework to build a mirroring tunnel, distribute traffic, and start a new LIDS.

The proposed framework reduces waiting time when restarting a virtual machine (VM) and completes a full adaptation cycle faster than migration. It takes 4.14 seconds to reconfigure the imposed ruleset in the first scenario and 0.97 seconds to access traffic in the second scenario when a new LID needs to be created. The total time needed by the framework is less than migration and creating a new IDS is easier than changing an old one.

Multiple LIDSs and MADs: A specialized script is created to replicate migration events by creating precise inputs from the Infrastructure Monitoring Probe for the Adaptation Manager. This allows for concurrent production of multiple adaptation events. During experimentation, a single instance of the Master Adaptation Driver (MAD) is configured to handle multiple LID instances, with the maximum number theoretically handled by a single MAD instance shown in Fig. 23.

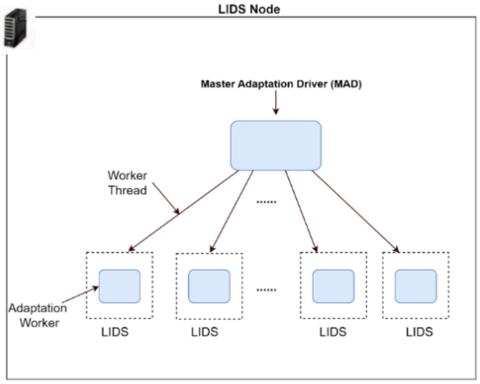

Fig. 23. Setup for MAD scalability.

Our findings demonstrate that up to 50 LIDS can be supported by a single MAD instance running on a dedicated node with 24GB RAM. Fig. 24 displays the MAD agent's typical response time under various LIDS loads.

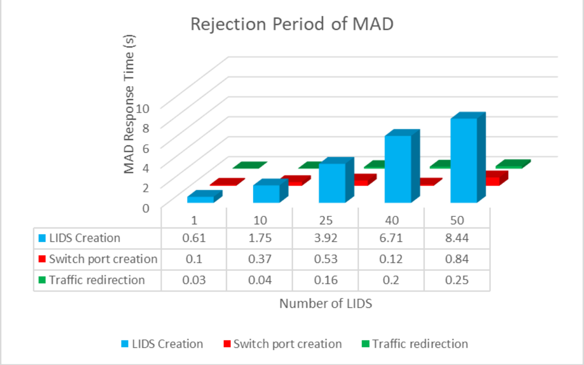

Fig. 24. MAD reaction periods.

The results show that the longest creation time for a new LID container requires interaction with the Docker daemon. The proposed framework can handle 50 simultaneous LID launching requests and still has a faster reaction time than the average migration time for an idle VM. The framework does not include the time for building the new LID configuration file or testing its functionality due to their low impact on the overall duration. Each LID is typically assigned one core in a production setting to maintain performance. The framework was tested with 10 concurrent adaptation requests to simulate a commercial setting. The maximum number of LID's that a single Master Adaptation Driver instance can manage simultaneously was determined, and there is room for nearly 100 worker threads for the Adaptation Manager. One AM instance is configured to control multiple MADs in Fig. 25.

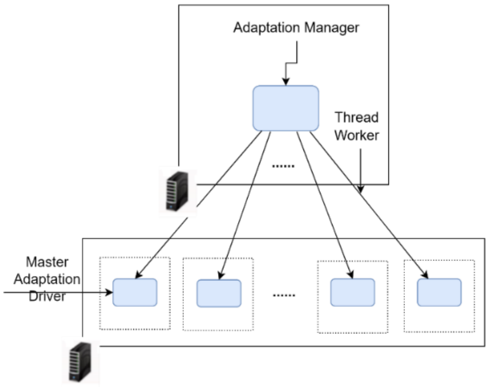

Fig. 25. AM scaling configuration.

The chosen monitoring mechanism for a single VM is a single LID. The framework was tested by simulating 50 dynamic events for 50 different VMs, providing adaptation requirements for 50 LID of each thread. A worker thread relocates all of its virtual machines to the same destination node to target the LID under the same MAD instance it is handling. The worker thread parses the vm info.xml file containing all the VM-related data to obtain settings for each of the 50 VMs it is responsible for. The minimum number of VM entries in the vm info.xml file required is calculated as maximum AM worker threads multiplied by the number of VMs per thread (in this case 100 AM worker threads and 50 VMs per thread, requiring 5000 entries). Justifications for each LID adaptation are recorded in a separate file. The worker thread delivers 50 files, one for each LID, to the MAD in charge of those 50 LID after establishing a secure connection. Only one file is required in the experiment as all virtual machines for a single worker thread are moved to the same compute node. The experiment aims to understand how the AM scales with the quantity of MADs, not the number of compute nodes.

	1	15	30	50	70	100
■ Adaptation Decision	0.14	0.14	0.14	0.14	0.14	0.14
■ Node Connection of LIDS	0.16	0.18	0.18	0.19	0.2	0.21
■ Send adaptation args	0.34	0.34	0.34	0.34	0.34	0.34
■ Node Connection Destination	0.17	0.19	0.19	0.2	0.21	0.22
■ Send Mirror args	0.015	0.014	0.014	0.014	0.013	0.014

Fig. 26. AM response time.

Fig. 26 presents the outcomes. As the data show, the formation of the secure connection is the phase that is most impacted by raising the MADs' load for the AM. This is due to the fact that each MAD has its own IP address and is kept in a distinct container, necessitating the use of a separate secure connection. On the AM side, we track the time it takes to send the adaption arguments. No network contention-related delay is seen in the outcome since we don't wait for each instance to validate that it has received the files. However, because each MAD instance is essentially run on a separate container on the same node, there may be many processes running on the node that are causing severe ssh connection formation delays. Since each MAD instance would operate in a distinct, less-loaded node in a real-world scenario, the findings of our experiment are unsatisfactory. The adaption decision time is not greatly shortened by the multi-threading method because all VM-related data is retained in a single file.

Up to 5000 LIDS instances can be managed by a single AM instance and still respond to thread requests in under one second, according to the results. The testbed's memory capacity is the single factor limiting the number of LIDS instances that can be employed for our research. If framework is implemented in a different configuration with production nodes having memory capacities that are substantially a minimum of 24 GB of RAM per node, the number of instances could rise.

The pidstat programme from the sysstat suite, a utility used to measure the resource utilisation of a given job running in an OS, is utilized to compute the resource consumption of an AM in terms of CPU and memory handling multiple MADs. Each experiment asks the first worker thread to run pidstat as soon as the adaption parameters are received, and the monitoring is stopped after the last worker thread has finished its task. This method ensures that during the adaptation process, we will only calculate the resource usage of each worker thread. No other framework-related processes use resources since the worker thread in charge of that adaptation request handles all the adaptation-related duties in that request. One second was chosen as the monitoring interval. The results are shown in Table IV. The Graphical illustration of resources consumption by AM is analysed in the Fig. 27.

The CPU use grows as the number of AM worker threads rise since there is a one-time CPU cost for starting a new ssh session. For each worker thread, the measurements compute the worst-case situation, which is to create a new connection. When the framework has to modify an existing LIDS, it can transfer the file containing the adaption arguments using an already established connection as a result of the anticipated decrease in CPU usage.

TABLE IV. CONSUMPTION OF RESOURCES BY THE AM COMPONENT

Number of MADs	Usr%	Sys%	CPU%	Memory (MB)
15	18.15	2.35	20.35	189.66
30	24.30	3.39	27.08	189.83
50	25.19	3.71	30.12	189.74
70	27.63	3.82	31.98	189.61
100	29.4	3.98	33.45	189.89

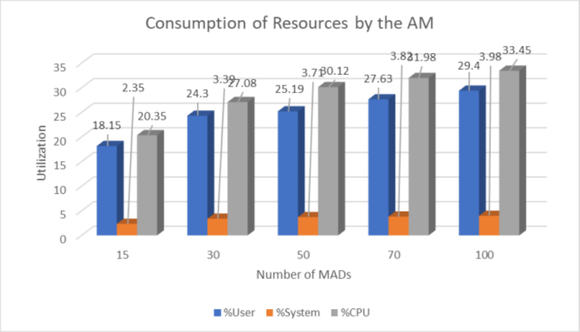

Fig. 27. Graphical illustration of resources consumption by AM.

The proposed framework for self-adapting security monitoring in cloud infrastructure is better than previous approaches for several reasons as below

1) Customization for each tenant: The framework takes into account the specific security monitoring requirements of each tenant, allowing for customized security monitoring configurations. This is an improvement over previous approaches that had a one-size-fits-all security monitoring approach that may not have been optimal for all tenants.

2) Self-adaptation: The framework includes an Adaptation Manager that can adapt to changing conditions in the cloud infrastructure and serve as a coordinator of the adaptation process. This allows the framework to respond dynamically to events in the cloud environment and adjust security monitoring configurations as needed. This is an improvement over previous approaches that did not have a self-adapting mechanism and required manual adjustments.

3) Cost efficiency: The framework aims to achieve cost efficiency by sharing monitoring resources between the tenants and the provider. The equitable sharing of monitoring resources is established with an adjustable threshold mentioned in the SLA. This is an improvement over previous approaches that may have been resource-intensive and costly.

4) Comprehensive solution: The framework provides a comprehensive solution that combines precise security monitoring with self-adaptation. The design of the framework ensures that it does not introduce new security weaknesses or affect the performance of the infrastructure. This is an improvement over previous approaches that may have been limited in scope or may have introduced new security weaknesses.

Overall, the proposed framework is an improvement over previous approaches because it is customized for each tenant, includes a self-adapting mechanism, achieves cost efficiency, and provides a comprehensive solution for security monitoring in cloud infrastructure.

V. Conclusion and Future Works

In this paper, the increasing number of tasks in clouds due to virtualization and cloud computing technology adoption is discussed. VM scheduling strategies are important for determining the allocation of cloud resources to handle these tasks for maintaining acceptable throughput and revenue. The paper evaluates the current knowledge on legacy methods and specific virtual machine scheduling algorithms for the Eucalyptus cloud environment and compares some existing algorithms using specific measures for a better understanding.

The Eucalyptus cloud uses two methods for scheduling VMs: Fusion Method and Enhanced Round-Robin. The experiment showed that Enhanced Round-Robin uses less energy compared to other methods and that using Physical Machine load as a limit of resigning saves the most energy. The Fusion Method outperforms other techniques by reducing the number of Physical Machines turned on and increasing power efficiency. The authors also developed a self-adapting security monitoring system with goals of security, cost savings, tenant-driven customization, and self-adaptation. The Adaptation Manager is the main element that can adapt to changing conditions in the cloud infrastructure and serves as a coordinator of the adaptation process.

This paper presents a self-adapting security monitoring system for cloud infrastructure that takes into account the specific monitoring requirements of each tenant. The system uses Master Adaptation Drivers to convert the tenant requirements into configuration settings and the Adaptation Manager to coordinate the adaptation process. The framework ensures security, cost efficiency, and responsiveness to dynamic events in the cloud environment. The design of the framework is such that it does not introduce new security weaknesses or affect the performance of the infrastructure. The system provides a comprehensive solution that combines precise security monitoring with self-adaptation.

The current security monitoring platform needs improvement to support more types of monitoring devices such as network traffic analysis and inside-the-host activity monitoring. The platform is also limited to supporting firewall functionality and doesn't cover the consequences of multi-tenant setups. The future work includes incorporating log collectors and aggregators and addressing the needs of a super-tenant (the provider) in the security monitoring architecture. The equitable sharing of monitoring resources between the tenants and the provider should be established with an adjustable threshold mentioned in the SLA.

Acknowledgment

The authors would like to thank Malaysia University of Science and Technology, for the support and encouragement to carry out this study.

***Abstract*—Rice is one of the most extensively cultivated crops in India. Leaf diseases can have a significant impact on the productivity and quality of a rice crop. Since it has a direct impact on the economy and food security, the detection of rice leaf diseases is the most important factor. The most prevalent diseases affecting rice leaves are leaf blast, brown spots, and hispa. To address this issue, this research builds a new classification model for rice leaf diseases. The model begins with a preprocessing step that employs the Median Filter (MF) process. Improved BIRCH is then utilized for picture segmentation. Features such as LBP, GLCM, color, shape, and modified Median Binary Pattern (MBP) are retrieved from segmented images. Then, an ensemble of three classification models, including Bi-GRU, Convolutional Neural Network (CNN), and Deep Maxout (DMN) is utilized. By adjusting the model weights, the suggested Opposition Learning Integrated Hybrid Feedback Artificial and Butterfly algorithm (OLIHFA-BA) will train the model to improve the performance of the proposed work.**

Keywords—Rice leaf; modified MBP; Bi-GRU; improved BIRCH; OLIHFA-BA Algorithm

I. Introduction

Agriculture is more important to the Indian economy than other industries. Rice production is a significant aspect of agriculture [1] [2] [3] [4]. 20% of India's GDP is contributed by rice agriculture [5] [6] [7] [8]. Rice is cultivated in most Indian states (Odessa, Uttar Pradesh, Punjab, West Bengal, Assam, Tamil Nadu, Bihar, etc.) [9] [10] [11] [12]. Due to the several diseases that can impact rice plants, rice productivity is currently falling. Farmers have only a limited comprehension of the disease. This crisis diminishes the efficiency of rice production, hence reducing the agricultural income [13] [14] [15].

Not only are rice leaf diseases prevalent in India, but they are also prevalent in other countries. There are several types of leaf diseases, such as brown spot, tungro, bacterial blight, blast, etc. Farmers have no control over these infections. Consequently, visual examination or laboratory tests are used to detect illnesses on leaves [16] [17] [18]. Visual analysis of this issue is time-consuming for a specialist. In addition, when chemical reagents are necessary, the experimental procedure becomes more difficult.

Certain strategies are employed to simplify these matters. The Deep Learning (DL) algorithm is applicable to agricultural problems such as root segment, fruit count, seed selection, disease classification, etc. [19] [20] [21]. DL algorithms are sophisticated versions of ML for detecting crop infections. With this method, the inputs were automatically learned, and the output was generated based on the decision criteria. CNN technology was utilized during the development of the visual image. In addition, "Rice Doctor" and "Rice Xpert" smart phone applications for farmers were introduced using the internet and mobile technology. The "Rice Doctor" app serves as a questionnaire for farmers [22] [23] [24] [25].

This study considered the most prevalent rice leaf diseases, including brown spot, leaf blast, and bacterial blight. The CNN model was calibrated to improve its accuracy. It is exceptionally accurate. Only the disorders were treated with the tuned model. We have to implement advanced DL algorithms [26] [27] [28] [29] due to the need to identify different forms of rice leaf disease and raise the degree of accuracy.

The contributions are detailed as follows:

- Proposed a new classification model for rice diseases with enhanced BIRCH-based segmentation.
- Utilizes an ensemble model based on OLIHFA-BA with a defined feature set consisting of enhanced MBP features, Local Binary Pattern (LBP), Gray Scale Co-Occurrence Matrix (GLCM), color, and shape features.

The structure of the paper is as follows: Section II describes standard works. Section III describes the adopted phases of the suggested classification strategy, whereas Section IV describes characteristics. Section V displays optimised ensemble classifiers, while Section VI depicts an assisted OLIHFA-BA optimization algorithm. Results and conclusions are provided in Sections VII and VIII.

II. Literature Review

A. Related Works

In 2021, Krishnamoorthy N et al. [1] conducted study on rice leaf disease classification. Moreover, fifty percent of the world's population consumes rice. Therefore, rice is the world's principal source of energy. Rice plant diseases, which are caused by viruses, bacteria, fertile soil, pests, temperature fluctuations, and so on, are the most significant obstacles in rice cultivation. Finding and treating rice plant illnesses is a challenging undertaking for farmers. In this investigation, sickness identification was performed using a DL approach. CNNs were used for object segmentation, image classification, and image analysis in Deep Learning. The

*Corresponding Author.

recommended model achieved the highest accuracy, 95.67 percent.

Kumar Sethy et al. [2] looked at how to find diseases on rice leaves in 2020. This study talks about the four diseases that can hurt rice leaves: bacteria blight, blast, tungro, and brown spot. DL technology is used to find out if someone is sick. In this study, TL with CNN models, deep features, and SVM were used to figure out how to group things. Two conclusions were similar, but the deeper features of SVM performed much better.

Chen et al. [3] conducted rice plant disease detection research in 2021. Using CNN models constructed with the DL approach presented various technical challenges, such as picture identification and classification. In this work, however, MobileNet-V2 was employed, and numerous techniques were employed to assess the significance of spatial sites for input characteristics and inter-channel interaction. Using DL-based CNN approaches, most of the technical challenges associated with picture recognition and classification have been resolved. Transfer learning and the enhanced loss function were repeated on two separate occasions. The public dataset [48] utilized for this investigation was 99.67% accurate. In difficult research environments, the accuracy of rice plant disease diagnosis was determined to be 98.48%. Therefore, the suggested method was more efficient at identifying rice plant diseases.

Madhavi and M.A. Saleem [4] studied the identification of rice leaf diseases in 2021. To preserve the growth of the agricultural sector, the first step of plant disease identification was taken. The comparison between automatic and manual plant monitoring is required and beneficial. CNN is frequently used for this kind of categorization. It does a good job of classifying and diagnosing plant diseases by utilizing highly accurate data collected from a range of sources.

Jjang et al. [5] studied the leaf diseases of wheat and rice plants in 2021. To reduce plant growth loss, this issue would be diagnosed quickly and precisely. In this study, the Image NET pre-training model, alternating learning, and the VGG16 implementation were used to facilitate multitask learning, TL, and recognition. This model's accuracy for rice plants was 98% and for wheat plants it was 99%. This model has proved the excellent performance of the VGG16 model and the multi-task TL, which is accurate in recognizing plant diseases.

Jiang et al. [6] conducted a study on image-based disease diagnosis in rice leaf images using Support Vector Machine (SVM) and DL in 2020. Combining these two approaches has helped to effectively address the issue while also improving precision. The authors of this study have utilized CNN to derive the images of the relevant leaf. During the last round of the evaluation, the classic Back Propagation Neural Network (BPNN) models were compared to the more accurate SVM models.

Zhang et al. [7] conducted study in 2020 utilizing spectral image technology to identify leaf illnesses in rice crops. This method was utilized to determine the severity of rice leaf explosions. In this work, a hyperspectral imaging method was used to distinguish between images of afflicted and healthy leaves. The data was then reconstructed using the SRR method. This model's precision was approximately 98%.

In 2021, Bakade et al. [8] conducted a study on preventing bacterial illness in rice leaves. Xoo is the primary cause of this problem. This investigation revealed the interconnected actions of genes and plant immune pathways, which could be leveraged to develop resistant rice cultivars.

B. Review

Once, the only means for diagnosing a disease was a manual analysis of the leaf. This was accomplished manually by examining plant leaves or consulting a book to identify the disease [5]. This method has three major drawbacks: it is imprecise, it cannot study every leaf, and it is time-consuming. Several approaches for effectively identifying these ailments have been created because of the advancement of science and technology. Image processing and deep learning are methodologies. Image processing includes a range of techniques, including filtering, clustering, histogram analysis, and image processing algorithms, to discover damaged areas and diagnose diseases. In contrast, DLNN are used to identify diseases. There are two principal causes of plant diseases. The first is a bacterial or fungal attack, and the second is an unanticipated shift in the weather [6].

When addressing rice infections, we must consider a few critical elements. Collecting samples from a damaged rice plant is one of the crucial and critical duties. To do this, multimedia sensors may be deployed across the farm. This permits routine monitoring of rice plants. Additionally, the effects of climate change on rice plants can be monitored and studied. This approach has several disadvantages, including the necessity for frequent system maintenance and low precision due to shadows in the gathered photos. It is crucial to accurately identify rice infections in order to avert the disease's devastating effects on crop productivity. However, the present methods for diagnosing illnesses in rice are neither exact nor effective, necessitating the need of supplementary equipment.

III. Adopted Phases in Proposed Classification Approach

The following are the adopted phases of the proposed rice leaf disease classification:

- In the very first phase, the input image is submitted to MF for the aim of pre-processing. Then, Improved BIRCH is implemented to segment the images.
- The LBP, GLCM, colour, and improved MBP-based feature set is derived from segmented images. Then, ensemble model-based classification is performed with three classifiers, including Bi-GRU, CNN, and DMN as shown in Fig. 1.
- The final classification results are determined by the combined averaged outcome.

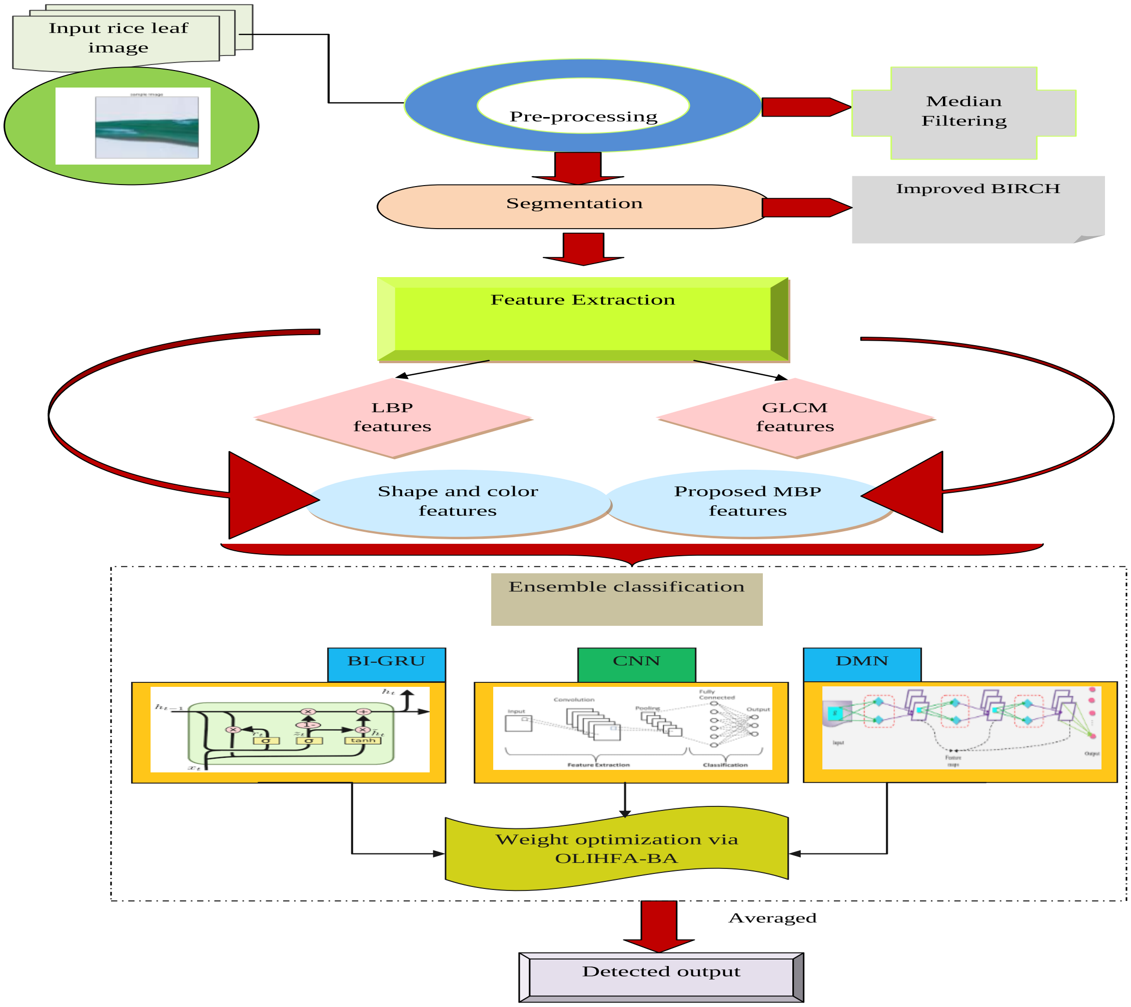

Fig. 1. A diagram of the rice disease classification model that was used.

A. *Pre-processing*

In this research, median filtering is utilised to pre-process the image input.

MF [30]: The median filter is a common non-linear digital filtering technique used to remove noise from a picture or signal. This type of noise reduction is a typical pre-processing technique used to improve the results of future processing (edge recognition in image). MF is widely utilised in the processing of digital photos, and in certain instances it preserves edges while lowering noise.

The MF oriented pre-processed image is designated as $\left(ig^{mf}\right)$.

Following image processing, improved BIRCH is utilized for image segmentation.

B. *Modified BIRCH Model*

Clustered features [31] store the information necessary for data grouping and provide a concise description of a set of points in feature space. Consider the set of points in the dimension [31].

Conservatively, the size, of a set is described as the average distance between two points, as shown in Eq. (1).

$$Di=\sqrt{\frac{\sum_{i=1}^{M}\left\|s_i-t_i\right\|_2^2}{M(M-1)}} \tag{1}$$

As per improved BIRCH, Di is modeled as shown in Eq. (2).

$$Di(s_i,t_i)=\sqrt{\frac{\sum_{i=1}^{M}(s_i-t_i)^2}{\sum_{i=1}^{M}(s_i)^2+\sum_{i=1}^{M}(t_j)^2-\sum_{i=1}^{M}s_it_j}} \tag{2}$$

The representation of clustering feature, cf, of set X is specified in Eq. (3).

$$cf=(M,L,x) \tag{3}$$

Here, M points out points in X, $L=\sum_{i=1}^{M}s_i$ refers to summation of every points in X and the scalar $x=\sum_{i=1}^{M}\left\|s_i\right\|_2^2$ refers to summation of square of every element of every points in X. Thus, an individual point is indicated by a cluster feature. A cluster feature represented the set X, and retained data to calculate the centroid, s_c, of X, the size Di of set, and the distance, $d(X_1, X_2)$, among 2 sets. Conservatively, these can be expressed as in Eq. (4).

$$s_c = \frac{L}{M} \tag{4}$$

As per enhanced BIRCH, s_c is computed as exposed in Eq. (5), in which, $corr$ points out correlation that is modeled as in Eq. (6).

$$s_c = \frac{L}{M} * corr \tag{5}$$

$$corr = 1 - \left(\frac{\sum_{i=1}^{M} (s_i - \bar{s})(t_i - \bar{t})}{\sqrt{\sum_{i=1}^{M} (s_i - \bar{s})^2} \sqrt{\sum_{i=1}^{M} (t_i - \bar{t})^2}} \right)^2 \tag{6}$$

The improved BIRCH image is denoted as ig^{IBIRCH}.

IV. Extracting LBP, GLCM, Color, Shape and Improved MBP Features

From ig^{IBIRCH}, the feature set including LBP, GLCM, color, shape and improved MBP are extracted.

A. Shape Features

The primary source of information used for object identification is shape [32]. Without shape, a visual item cannot be effectively recognised. Without understanding shape, an image is incomplete. Although the two items cannot have the exact same shape, we may identify comparable shapes by utilising a variety of techniques. Triangle, Circle, Rectangle, Square, Oval, and Diamond are some of the available shapes. The features of the extracted shapes are indicated by fs^{Sh}.

B. Colour Features

Colour space characterizes colour in the type of intensity value [32]. By employing the colour space approach, we can define, see, and produce colour. The colour histogram shows the image from various angles. The colour histogram used to describe the frequency distribution of colours in the image counts and stores related pixels. Every statistical colour frequency in an image is examined using the colour histogram. The colour histogram not only focuses on specific areas of an image, but also solves difficulties with translation, rotation, and angle of view changes. The local colour histogram is simple to calculate and robust to minute image fluctuations, making it crucial for the retrieval and indexing of image databases.

C. GLCM Features

GLCM is employed to evaluate the spatial association among the pixel [33]. The constraints in GLCM are given in Table I.

TABLE I. GLCM Features

S. No.	Features	Arithmetical term
1.	Energy	$E = \sum_{\omega}\sum_{\xi} \upsilon_{\omega\xi}^2$ here $\upsilon_{\omega\xi}$ is the $(\omega,\xi)^{th}$ entry in GLCM
2.	Entropy	$Et = -\sum_{\omega}\sum_{\xi} \upsilon_{\omega\xi} \log_2 \upsilon_{\omega\xi}$
3.	Variance	$Var = \sum_{\omega}\sum_{\xi} (\omega - \mu)^2 \upsilon_{\omega\xi}$, where μ specifies the mean of $\upsilon_{\omega\xi}$
4.	Contrast	$Con = \sum_{\omega}\sum_{\xi} (\omega - \xi)^2 \upsilon_{\omega\xi}$
5.	Correlation	$Cor = \frac{\sum_{\omega}\sum_{\xi} (\omega\xi)\upsilon_{\omega\xi} - \mu_x\mu_y}{\sigma_x\sigma_y}$, where σ_x, σ_y, μ_x, μ_y are the std deviations and mean of υ_x, υ_y
6.	Sum Average	$SA = \sum_{\omega=2}^{2N_\upsilon} \omega.\upsilon_{x+y}(\omega)$, where N_υ indicates the varied gray levels in image.
7.	Homogeneity	$Hom = \sum_{\omega}\sum_{\omega} \frac{1}{1 + (\omega - \xi)^2} \upsilon_{\omega\xi}$
8.	Sum Variance	$SV = \sum_{\omega=2}^{2N_\upsilon} (\omega - SE)^2 s_{x+y}(\omega)$
9.	Sum Entropy	$SE = \sum_{\omega=2}^{2N_\upsilon} \upsilon_{x+y}(\omega) \log\{\upsilon_{x+y}(\omega)\}$
10.	Difference Variance	$DV =$ variance of $\upsilon_{\omega x-y}$
11.	MCC	$MCC = \sum_{k} \frac{g(\omega,k)g(b,k)}{g_x(\omega)g_y(k)}$
12.	Difference Entropy	$DE = \sum_{\omega=0}^{N_\upsilon - 1} \upsilon_{x-y}(\omega) \log\{\upsilon_{x-y}(\omega)\}$
13.	IMC 1	$IMC1 = \frac{hxy - hxy1}{\max\{hx, hy\}}$
14.	IMC 2	$IMC2 = \sqrt{(1 - \exp[-2.0[hxy1 - hxy]])}$ $hxy = -\sum_{\omega}\sum_{\xi} \upsilon_{\omega\xi} \log_2 \upsilon_{\omega\xi}$, where $hxy1 = -\sum_{\omega}\sum_{\xi} \upsilon_{\omega\xi} \log_2 \{\upsilon_x(\omega)\upsilon_y(\xi)\}$,,

D. Modified MBP Features

The MBP [34] attempts to determine the LBP by thresholding pixels with a median value above the threshold. In this level of filtering, the centre pixel is evaluated, providing 29 potential structures. MBP is conventionally represented using Eq. (7).

$$MBP = \sum_{i=1}^{J} f(b_i) \times 2^i \tag{7}$$

As per modified MBP, it is modelled as in Eq. (8). Here, we point out weight function that is evaluated by means of cubic chaotic map.

$$MBP = \sum_{i=1}^{J} f(b_i) \times 2^i * we \tag{8}$$

Conventionally, $f(b_i)$ is modeled based upon median as in Eq. (9).

$$f(b_i) = \begin{cases} 1; & if\ b_i \geq med \\ 0; & otherwise \end{cases} \tag{9}$$

As per modified MBP, $f(b_i)$ is modeled based upon median absolute deviation (MAD) as in Eq. (10) and Eq. (11).

$$f(b_i) = \begin{cases} 1; & if\ b_i \geq MAD \\ 0; & otherwise \end{cases} \tag{10}$$

$$MAD = Median\left|b_i - \bar{b}\right| \tag{11}$$

E. LBP Features

In a variety of comparison analyses, the patterns of LBP [35] are provided with a high level of discrimination and simplicity. The fundamental LBP is used to derive the differential features between a certain reference pixel and its neighbours with radius. The resultant LBP for a pixel is given by Eq. (12), where is the geometric mean of nearby pixels and represents the grey values of the middle pixel and surrounding pixels with radius.

$$LBP_{P,R}(q_e, r_e) = \sum_{P=0}^{P-1} s * 2^P \tag{12}$$

The derived LBP, GLCM, color, shape and modified MBP are totally implied by fs, i.e., $fs^{Sh} + fs^{Cl} + fs^{glcm} + fs^{IMBP} + fs^{LBP} = fs$.

V. Optimized Bi-GRU, CNN and DMN Models

The derived fs is then given as input to three classifiers such as Bi-GRU, CNN and DMN.

A. Bi-GRU

It [36] is a sort of Recurrent Neural Network (RNN) that facilitates the handling of data from successive and previous time steps in order to provide output predictions based on the present state. Eq. (13) to (16) expose the BI-GRU calculation by displaying the sigmoid function, hidden, and input vectors as, and respectively. The reset data is represented as, weight, time interval, and the condition of the cell at the previous time stamp.

$$F_t = \left(WG_i * \left[v_t, hi_{t-1},\right]\right)\sigma \tag{13}$$

$$r_t = \left(WG_i * \left[v_t, hi_{t-1}\right]\right)\sigma \tag{14}$$

$$hi_t = \left(WG_c * \left[r_t . v_t, hi_{t-1}\right]\right)\tanh \tag{15}$$

$$hi_t = .C_{t-1}\left(1 - F_t\right) + hi_t F_t \tag{16}$$

B. CNN

The features of CNN [37] are depicted in Eq. (17).

$$D_{r,t,w}^{l} = \varpi_w^{l\ T} PA_{r,t}^{l} + B_w^{l} \tag{17}$$

In Eq. (17), ϖ_w^l → weight tuned optimally by means of OLIHFA-BA model, B_w^l →bias. At core location (r,t) of l^{th} layer, the input patch is signified as $PA_{r,t}^l$, $D_{r,t,w}^l$ → convolution features and $\left(act_{r,t,w}^l\right)$ → activation value.

$$act_{r,t,w}^l = act\left(D_{r,t,w}^l\right) \tag{18}$$

Pooling layer: CNN loss PL is given in Eq. (20), here, θ → term linked with W_w^l and B_w^l . The output, the labels and h^{th} input feature is termed as $F^{(h)}$, $H^{(h)}$ and $PA^{(h)}$ and $nn_{r,t}$ signifies (r,t) near neighbor position.

$$H_{r,t,w}^l = pool\left(act_{m,h,w}^l\right), \forall (m.h) \in nn_{r,t} \tag{19}$$

$$PL = \frac{1}{wn} \sum_{h=1}^{wn} l\left(\theta; H^{(h)}, F^{(h)}\right) \tag{20}$$

C. DMN Classifier

DMN [38], a form of NN, is utilized well in a few applications. A NN contains candidate components in each neuron. It is intended to use an extendable maximum value component for neuron activation [39]. Mark as the node of the hiding layer and each of its components. Eq. (21) and Eq. (22) demonstrate their relationship to one another:

$$J_m^i = \max_{j \in 1,2,\ldots,u} O_m^{ij} \tag{21}$$

By forwarded propagation, O_m^{ij} is modeled as in Eq. (22).

$$O_m = W^{*G}_{m-1} J_{m-1} + f_m \tag{22}$$

Here, $O_1 \in L^O$ refers to l^{th} layer vector

$J_{m-1} \in L^{H}$ and $W^{*}{}_{m-1} \in L^{H\times O}$ refers to max out activation vector and weight matrix of $m-1$ layer.

$f_m \in L^{O}$ refers to bias vector of m^{th} layer.

The Bi-GRU, CNN and DMN outputs are averaged to get final result.

VI. OLIHFA-BA Assisted Algorithm for Optimization

Objective: The objective is to diminish error as in Eq. (23).

$$Objective = \min(Error) \tag{23}$$

Solution Encoding: The weights of BI-GRU (WG), CNN (ϖ) and DMN (k) are elected optimally by OLIHFA-BA scheme as given in Fig. 2.

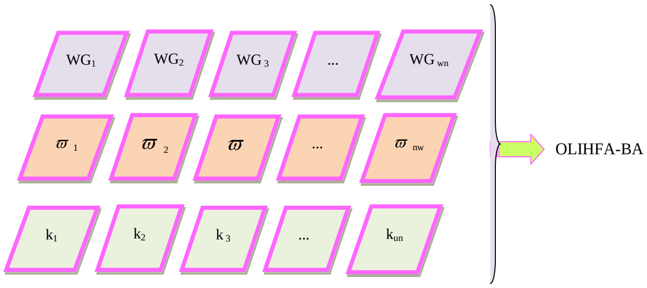

Fig. 2. Solution encoding.

Existing Butterfly Optimization Algorithm (BOA) [39] recognizes the best options, however it is not precise. FAT [40] is merged with BOA [39] to develop OLIHFA-BA, which addresses the shortcomings of original BOA [39] [41] [42] [43] [44]. The concepts of hybridization show considerable potential for advancing with improved outcomes [41] [42] [43] [44].

The butterfly mating and feeding behaviors inspired BOA. The distinctive characteristic of BOA represented by Eq. (24) is the fragrances with diverse aromas in butterflies, where the power exponent (between 0 and 1) relates to the index of sensor modality and indicates stimulus magnitude.

$$q = sl^{\theta} \tag{24}$$

Butterflies are capable of accurately locating scent sources and share this knowledge with one another. There were three stages of OLIHFA-BA, and they were as follows:

1) Initialization: The constraints and objectives would all be initialized. Additionally, chaotic-based OBL is produced according to the model in Eq. (25), which α refers to chaotic map function that uses a tent map.

$$\bar{y}_i = a + b - y_i * \alpha \tag{25}$$

2) Iteration: Both local and international searches were performed.

The traditional numerical depiction for butterfly global search movement is in Eq. (26), herein, t points out iteration, y_i^t points out i^{th} butterfly position at t, q_i points out scent of i^{th} butterfly and G_{best} points out finest position of global butterfly.

$$y_i^{t+1} = y_i^t + \left(ra^2 \times G_{best} - y_i^t\right) \times q_i \tag{26}$$

In OLIHFA-BA model, it is formulated depending upon FAT's branch update as in Eq. (27), in which, d points out smaller constant, (d = 0.382) and $rand(0,1)$ points out random numeral. Moreover, we use FAT based crossover operation to generate new branches.

$$y_i^{t+1} = y_i^t + \begin{pmatrix} rand(0,1) * y_{best} \\ -rand(0,1) * y_i \end{pmatrix} * d + levy(\beta) \tag{27}$$

Numerous typical events might hinder butterfly movement and fragrance dispersal. Local search is simulated by the butterfly positions according to Eq. (28).

$$y_i^{t+1} = y_i^t + \left(ra^{2} \times y_j^t - y_k^t\right) \times q_i \tag{28}$$

3) Termination: OLIHFA-BA terminates once the utmost iterations were arrived. The OLIHFA-BA model is shown in Algorithm 1.

Algorithm 1: OLIHFA-BA model

```

VII. Results and Discussion

A. Simulation Set Up

Matlab was used to create the proposed Ensemble Classifiers (EC) (Bi-GRU, CNN, and DMN) + OLIHFA-BA focused classification for rice illness. On numerous measures, EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA was compared against Improved Crossover Monarch Butterfly Optimization (ICRMBOS) [45], Transfer Learning based Deep CNN (TL-DCNN) [46], LMBWO [47], Deep Belief Network (DBN), Recurrent Neural Network (RNN), Quantum Neural Networks (QNN), SVM, RF, and Long Short Term Memory (LSTM), EC + DHO, EC + SMO (Spider Monkey Optimization), EC + CMBO (Cat and Mouse Optimization), EC + BMO (Blue Monkey Optimization), and EC + MFO (Mouth Flame Optimization). Fig. 3 displays the illustration of the sample image.

B. Performance Analysis

The performances of the proposed EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA over existing met heuristic models are calculated and displayed in Fig. 4 to 6 for various measures. The EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA model is compared to the EC + DHO, EC + SMO, EC + CMBO, EC + BMO, and EC + MFO models for several LPs. Table II compares EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA with existing classifiers such as DBN, RNN, QNN, SVM, RF, LSTM, ICRMBOS [45], TL-DCNN [46], and LMBWO [47]. The proposed EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA model has produced superior results compared to differentiated approaches for optimization and classification models. The improved prediction rate should result in slight negative results and bigger positive values. As seen in Fig. 4, the outputs of the EC model for all positive metrics grow, whilst the outputs for negative metrics decrease. Specifically for current and prospective schemes, the 50th LP yielded the best results. The proposed system at the 50th LP achieved the highest accuracy values (0.96), whereas other schemes achieved low precision levels. This improvement in classifier analysis and optimization analysis by EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA is mostly due to the incorporation of enhancements in features, segmentation, and classifiers.

C. Convergence Study

Fig. 7 shows the completed cost analysis. EC (CNN, Bi-GRU, and DMN) is evaluated over EC + DHO, EC + SMO, EC + CMBO, EC + BMO, and EC + MFO. In view of Fig. 7, the cost of EC (Bi-GRU, CNN, and DMN) has increased little. From iterations 0 through 5, the CMBO model achieves a high cost of 1.095. In addition, between iterations 0 and 5, the cost of EC (Bi-GRU, CNN, and DMN) is approximately 1.084%. Thus, EC (Bi-GRU, CNN, and DMN) was able to obtain BIRCH at a reduced cost and with expanded features.

D. Conventional VS. Proposed Analysis

Table III compares the adopted EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA scheme to EC without OLIHFA-BA, EC with traditional BIRCH, and EC with traditional MBP. Observing the Table, the recommended EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA had superior values than the EC without OLIHFA-BA, the EC with conventional BIRCH, and the EC with conventional MBP. This demonstrates the effect of BIRCH enhancements and hybrid optimization.

E. Analysis on DICE and Jaccard Scores

Table IV provides a study of dice scores and Jaccard scores. The dice and Jaccard scores for suggested BIRCH are greater than those for FCM, K-mean, and conventional BIRCH.

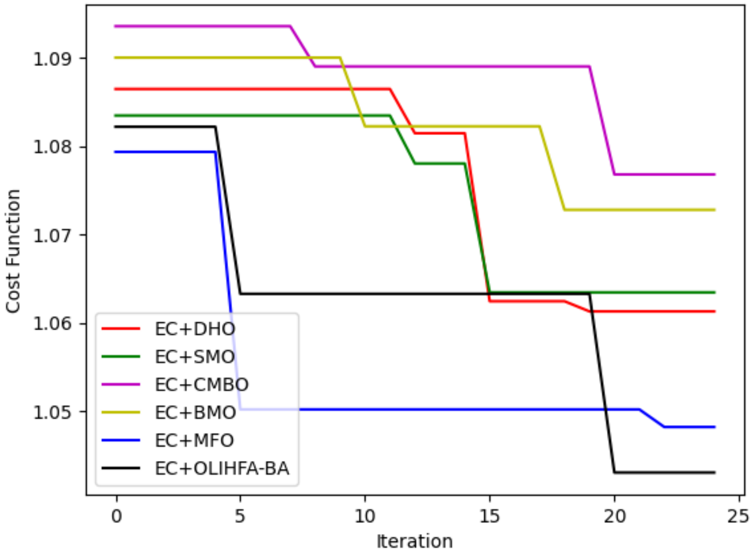

Fig. 7. Convergence study.

TABLE III. ANALYSIS ON PROPOSED AND EXISTING VARIANTS

VIII. Conclusion

We have developed a novel classification technique for rice leaf diseases in which the image was preprocessed using MF. The image was then segmented using BIRCH with enhancements. LBP, GLCM, colour, shape, and enhanced MBP-based features were recovered from segmented images. The data was then classified using three classifiers: Bi-GRU, CNN, and DMN. The results of the Bi-GRU, CNN, and DMN systems were averaged to determine the results. In addition, the Bi-GRU, CNN, and DMN schemes' weights were determined optimally using the OLIHFA-BA method. The 50th LP proposal produced the highest accuracy values (0.96), but other systems achieved low precision levels. This improvement in classifier analysis and optimization analysis employing EC (Bi-GRU, CNN, and DMN) + OLIHFA-BA is mostly attributable to the incorporation of enhanced features, segmentation, and classifiers. In the future, illness types should be analyzed.

Acknowledgment

I would like to express my deep gratitude to Professor Dr. K Kiran Kumar, my research supervisor, for his patient guidance, enthusiastic encouragement and useful critiques of this research work. I'd also want to thank the technicians at department's laboratory for their assistance in providing me with the resources I needed to run the application.

***Abstract*—Adding spectral indices to Sentinel-2 spectral bands to improve land-cover (LC) classification with limited sample size can affect the accuracy due to the curse of dimensionality. In this study, we compared the performance metrics of Random Forest (RF) classifier with three different combinations of features for land cover classification in an urban arid area. The first combination used the ten Sentinel-2 bands with 10 and 20 m spatial resolution. The second combination consisted of the first combination in addition to five common spectral indices (15 features). The third combination represented the best output of features in terms of performance metrics after applying recursive feature elimination (RFE) for the second combination. The results showed that applying RFE reduced the number of features in combination 2 from 15 to 8 and the average F_1-score indicator increased by nearly 8 and 6 percent in comparison with using the other two combinations respectively. The findings of this study confirmed the importance of feature selection in improving LC classification accuracy in arid areas through removing the redundant variable when using limited sample size and using spectral indices with spectral bands, respectively.**

***Keywords*—Feature selection; land cover; sentinel-2; arid areas; random forest; accuracy**

I. Introduction

Extracted information from satellite imagery regarding LC and its changes are essential in many applications. They are used as inputs for many models as hydrological models [1], ecosystem modelling [2] and land surface modelling [3]. Thus, the accuracy of LC is critical for these products, as it affects the final results of these models [4].

Adding auxiliary features to improve the classification of LC is a common practice in remote sensing community such as in Landsat imagery data [5], [6]. These auxiliary features include different spectral indices, topographic data, texture, and biophysical parameters [7], [8]. Using too many features to improve LC classification requires increasing the training samples size [9] to overcome the curse of dimensionality which negatively affects the classification accuracy and increases processing time [10]. In most cases, increasing training samples is not cost-effective, and this should be met by selecting only the most relevant features to achieve the optimal classification accuracy. Feature selection is very important in LC classification to overcome the high-dimensional data to increase class separation and compensate for the limited samples used for training classification models [9]. Moreover, feature selection removes the irrelevant and redundant variables which eventually helps in reducing the training data, decreasing the processing time and decrease the requirements of the data storage [11], [12]. In addition, feature selection documented to improve prediction performance and making data more interpretable [10].

According to [13], choosing a feature selection method subjects to various consideration such as stability, simplicity, requirements of computation, accuracy and the number of reduced features. In remote sensing applications, various feature selection methods were used in different spatial areas and for different purposes. Over a global LC classification, Relieff and max-min-associated methods were useful in decreasing computation time [14]. With sentinel-2 imagery, a comparative study among various feature selection methods concluded that similarity-based methods are the best in terms of F_1-score and the optimal features number for mapping landscapes infested by the Parthenium weed in South Africa, while wrapper methods were more accurate but with larger number of the selected features [15]. In northern Germany, grouped forward feature selection helped in data interpretation and reduced processing time in crop mapping. In spite of the several methods which were developed for selecting features, Reference [16] recommended using RFE, a wrapper method, in combination with RF for feature selection due to its stability and ability to improve classification. This method also proved to be efficient in improving accuracy in both the regression and classification processes by selecting the most relevant features [17], [18].

Arid regions are different from other spatial environments as they are dominant with less precipitation, dry climate, and scattered vegetation. Thus, ecosystems in urban arid areas are fragile [19]. These systems are not stable, and their change is rapid [20]. All these conditions are being captured by satellite sensors and translated into image pixels; therefore, need special attentions since these tend to affect the accuracy of LC classification to be produced later.

Since Sentinel-2 imagery was released in 2015, it has been widely used in producing LC maps due to its high spatial resolution, its temporal resolution (5 days), and its spectral wavelength ranging from visible to near-infrared, which helped to map and distinguishing LC classes [21].

*Corresponding Author.

In urban arid areas, there is no LC classification model based on the Sentinel-2 imagery for the selected study area in the Arabian arid Peninsula. Therefore, the objective of this study was to develop an optimal LC classification model for this area with cost-effective samples. This will include using RFE with RF classifier to choose the optimal relevant features from the combination of spectral bands and the most common indices. In addition, the effect of feature selection on processing time during training the model and prediction was investigated.

The paper is organised as follows: Section II describes the study area, data, and the methodology. In Sections III and IV, results and discussion are presented, respectively. Finally, Section V represents the conclusion of this study.

II. Materials and Methods

A. Study Site and Data

The study area was chosen as part of the tile number T38RPN (Fig. 1) from sentinel-2 satellite imagery which covers the metropolitan city of Riyadh, the capital of Kingdom of Saudia Arabia as a urban arid area. The image was selected on 4 July 2022 with ID: L1C_T38RPN_A027817_ 20220704T073152 when the cloud is minimum, and the selected part was considered to represent the variations in LC classes. While Sentinel-2 has 13 bands as shown in, only 10 bands were used in this study and the 60-meter spatial resolution bands related to atmospheric and cloud detection were dropped.

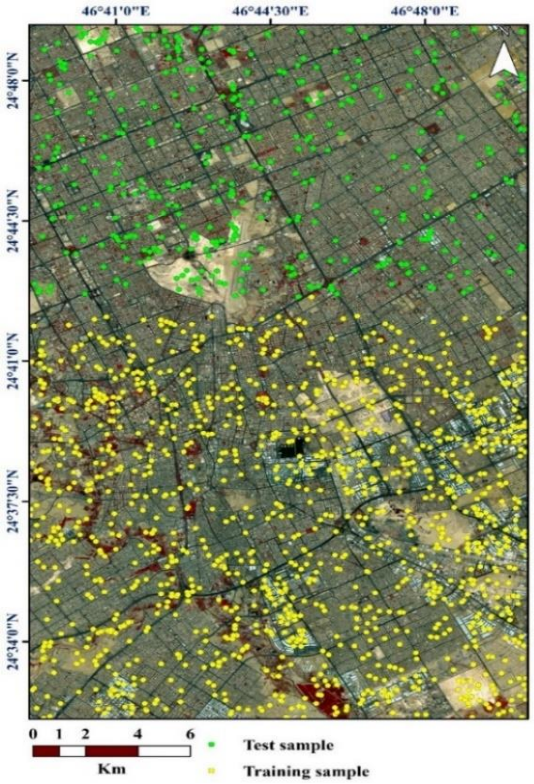

Fig. 1. Location of the study area.

B. Data Preprocessing and Preparation

In order to achieve the optimal accuracy, three steps have been performed on the raw image before clipping to the study area. First, atmospheric and topographic correction were carried out to convert the digital numbers to surface reflectance values using the FORCE algorithm [20] and to remove the effects of shadow, respectively. This preprocess step is initial and proved to contribute in improving LC accuracy. The SRTM digital elevation model (DEM) from EarthExplorer was used for topographic correction. Second, downscaling the 20-meter spatial resolution bands to 10 metre using nearest neighbor technique, which proved to be more accurate than other techniques in terms of producing LC classification accuracy [21]. After that, the image was cropped to the study area shapefile using QGIS software, version 3.

C. Classification System and Sampling

The selection of LC classes was based on the basis that confirms the inclusion of the main land types in the study area with reference to previous studies [22], [23]. In this study, the urban class has been divided into three categories: roads, industrial and building where spectral differences are unique. Table I shows the classes with their representative numbers in the selected study area.

The stratified random sampling method was used to collect training and testing samples. All samples were collected based on the per-pixel as a classification unit to avoid spatial-autocorrelation and reduce redundant data. The choice of samples was based on visual interpretation on the high spatial resolution Google Earth maps with intensive field work for validation. The number of training samples was determined to be in the range of 10–30 times the number of bands used for classification [24]. The test samples were 30% of the total samples and independent of the training samples. Fig. 1 and Table I show the distribution of training, testing samples, and their numbers in the study area, respectively.

D. Spectral Indices

In this urban arid study area, the effect of adding the following spectral indices on accuracy was investigated:

- The normalized difference vegetation index (NDVI) which is used as a monitoring and measuring index for vegetation cover from satellite imagery.
- The normalised difference built-up index (NDBI) is used to distinguish built surfaces, which receive positive values, from bare soils.
- The modified normalised difference water index (MNDWI) was proposed to detect superficial water. However, due to the relation between SWIR and wetness in soils, it can be also used to detect water in surfaces of vegetation or soil.
- The bare soil index (BSI) was proposed to enhance differentiation between bare and built-up lands.
- The soil adjusted vegetation index (SAVI): this index way to fit NDVI index to background average reflectance and minimises shadow effects.

TABLE I. LAND COVER CLASSES WITH THEIR TRAINING AND TESTING NUMBER AND DESCRIPTION

Classes	Sampling	
	Training (70%)	***Testing (30%)***
Vegetation	452	138
Roads	478	144
Bare land	474	142
Built-up	534	164
Industrial	530	160
Water	146	44
Total	2614	792

E. Classification Process and Evaluation

In order to investigate the effect of dimensionality reduction on LC classification accuracy in this study, we compared the performance of RF with three different combinations of features. The first combination consisted of the original ten spectral bands. The second combination consisted of the same features of the first combination in addition to the fifth spectral indices already mentioned in the previous subsection 2.5. The third combination represented the subset of the features which achieved the best performance metrics after applying the RFE selection method on the second combination. We referred to these combinations as model-1, model-2 and model-3 in the whole paper.

In each model, RF was used for classification due to its accurate results with less time, less sensitivity to overfitting, and because it requires few internal parameters to be tuned. RF is one of the most supervised ML algorithms widely used in both regression and classification and it can work with continuous and categorical data [26]. It belongs to the family of ensemble learning classifiers which depends on the bagging mechanism. The ntree and mtry are the most two internal parameters in the RF classifier. Each tree in FR model acts as a decision in the classification or regression process and the number of these decision trees is known as ntree and determined by the selected features from the user. In this study, the ntree was set to 500 as recommended by [27]. The mtry parameter refers to the predictors number that are randomly sampled when creating the trees at each split. In this study, mtry was set to the number of square root of the variables used as inputs for classification in each model [28].

The validation process for each model was carried out, using a 10-fold cross validation technique to avoid bias in results and conclusions. In this technique, data set is divided into 10 subsets. Next, a model is trained using a subset formed by combining these nine subsets and tested using the remaining subset. This is done 10 times each using a different subset as a test set and calculating the test set error.

The evaluation for all models was based on the performance metrics represented by the overall accuracy (OA), the user's (UA), and producer's (PA) accuracies, which were calculated from the confusion matrix. In addition, F_1-score was calculated as a balance accuracy measurement [29] and used in this study as the main index for comparing the models.

In order to explore the contribution of each feature to the improvement of the LC accuracy for all models, the built-in variable importance property of the RF classifier (randomForest package) was analysed. Thus, a useful reference can be provided to choose the appropriate features as input variables in other studies in the selected study area.

The last step of evaluation was the computational time analysis which included comparing the average processing time for the three models with their different number of features. The average of 10 running times was used in this study for processing time of the models during training and when the models were used to predict the whole image of the study area. All analyses were carried out using R programming language (version 3.6.1). We used a laptop with Intel® Core™ i7-7700HQ CPU @ 2.80GHz × 8 and 32 GiB memory in Ubuntu 20.04.5 LTS operating system.

III. RESULTS

A. Model Evaluation by Overall, User's, Producer's Accuracy Matrices and Variable Importance

1) Model-1: Table II shows the confusion matrix when the classification model used only the original 10 spectral bands. The overall accuracy of the model was 81%. Generally speaking, the greatest misclassification has occurred between vegetation and built-up classes, on the one hand, and between industrial and bare classes, on the other hand.

In this model and as shown in Fig. 2, the PA and UA are variated in values among the classes. The PA for the built-up class was the maximum with 98.8 percent, while the water class had the minimum value with 22.7 percent. Regarding the UA, the industrial and built-up classes were the highest and lowest values with 95.8 and 70.4 respectively.

Fig. 3 shows the importance of the features and their contributions in the accuracy. It is clearly that b3, b4, b12, b8 and b2 are the first five bands that contributed to achieving most of classification accuracy improvement while b6 was the less important regarding contribution in classification accuracy.

2) Model-2: Table III shows the confusion matrix when the classification model used the tenth spectral bands with the five spectral indices. The overall accuracy of this model increased by nearly 2 % compared to the previous model.

TABLE II. CONFUSION MATRIX OF MODEL-1

Classes		Predicted Values						Total
Actual values	Vegetation	82	10	2	42	0	2	138
	Roads	2	136	0	6	0	0	144
	Bare land	0	5	134	0	3	0	142
	Built-up	0	2	0	162	0	0	164
	Industrial	0	0	42	4	114	0	160
	Water	6	10	0	16	2	10	44
	Total	90	163	178	230	119	12	792
Overall accuracy 80.56 %								

TABLE III. CONFUSION MATRIX OF MODEL-2

Classes		Predicted values						Total
Actual values	Vegetation	90	7	3	38	0	0	138
	Roads	0	134	0	10	0	0	144
	Bare land	0	4	136	0	2	0	142
	Built-up	0	2	2	160	0	0	164
	Industrial	0	0	32	2	126	0	160
	Water	4	11	0	19	0	10	44
	Total	94	158	173	229	128	10	792
Overall accuracy 82.83 %								

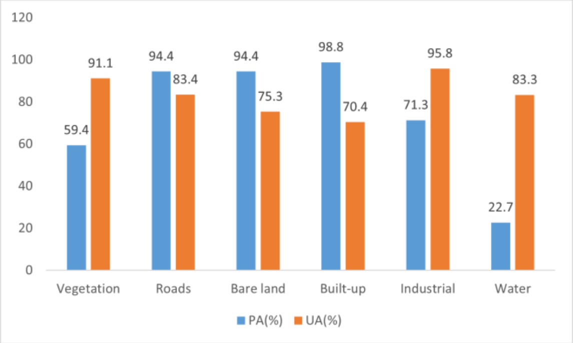

Fig. 2. Producer's and User's accuracy in model-1.

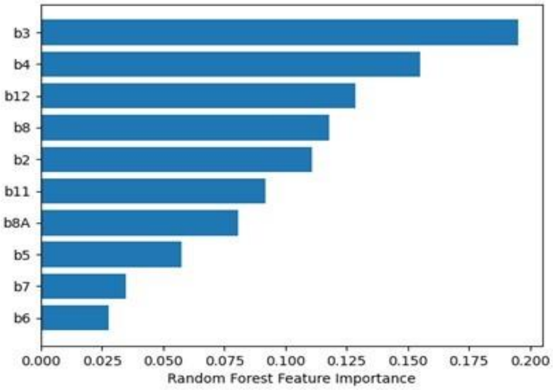

Fig. 3. Variable importance in model-1.

This improvement in overall accuracy can be interpreted by the contribution of the indices in improving the per-class accuracy.

As shown in Fig. 4, the PA and UA accuracy in this model are variated. The highest and lowest PA values were registered for the built-up and water classes, respectively, while the highest and lowest UA values were registered for water and industrial classes, respectively.

The variable importance in this model is shown in Fig. 5. From the first five features, two spectral indices: SAVI and BSI are the most important in classification accuracy. It is noticeable that NDVI has a medium importance in improving accuracy, while MNDWI and NDBI have less importance in improving classification accuracy.

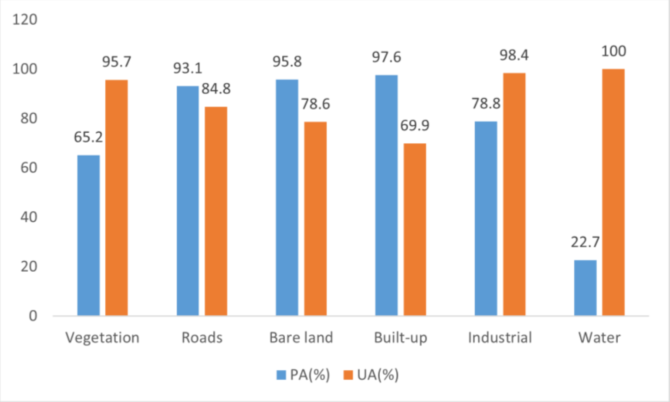

Fig. 4. Producer's and User's accuracy in model-2.

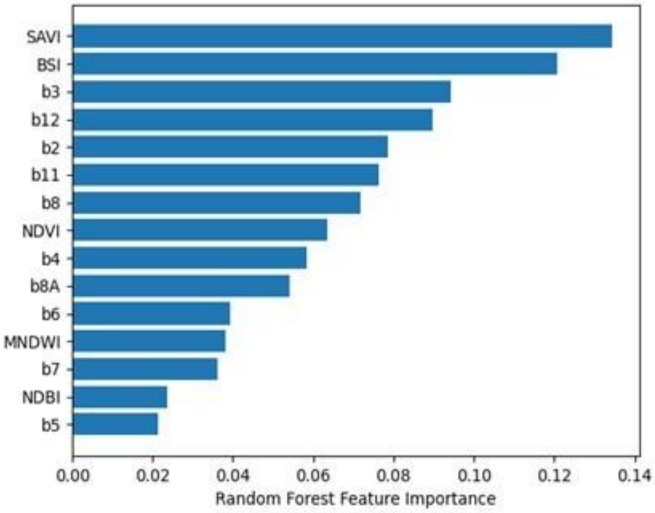

Fig. 5. Variable importance in model-2.

3) Model-3: The confusion matrix after applying the RFE to subset the feature with the best accuracy is shown in Table IV. The best accuracy derived from this model was 85.98 % using only eight features: six spectral bands and two spectral indices.

Comparing the previous two models, the accuracy in this model increased by nearly 5 and 3 percent, respectively. Most of the accuracy improvement was in both vegetation, industrial and water classes where the number of the correct instances increased by 8, 4 and 9 respectively in comparison with the same classes in the previous model.

In this model, the PA ranged between 43.2 % for the water class and 97.6 % for the built-up class. In terms of UA, the water class ranked the best, while the built-up class ranked the lowest (Fig. 6).

The first five feature importance in this model included four spectral bands: b3, b12, b2, and b8 and only one spectral index: BSI as shown in Fig. 7. After applying RFE, the feature numbers decreased nearly to half in comparison with the previous model.

TABLE IV. CONFUSION MATRIX OF MODEL-3

Classes		Predicted values						Total
Actual values	Vegetation	98	7	5	28	0	0	138
	Roads	0	137	5	2	0	0	144
	Bare land	0	3	137	0	2	0	142
	Built-up	2	2	0	160	0	0	164
	Industrial	0	0	23	7	130	0	160
	Water	3	8	0	14	0	19	44
	Total	103	158	169	213	133	19	792
Overall accuracy 85.98 %								

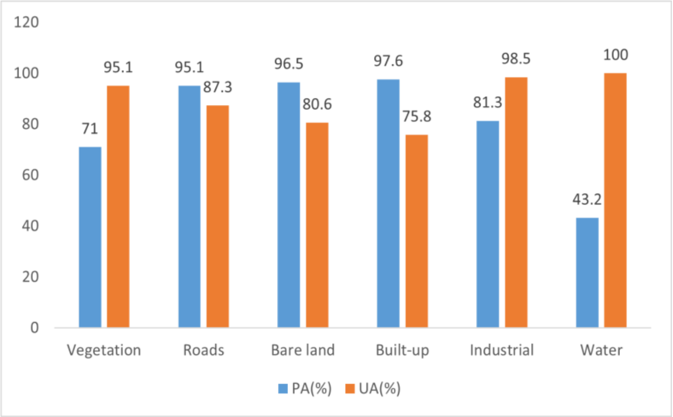

Fig. 6. Producer's and User's accuracy in model-3.

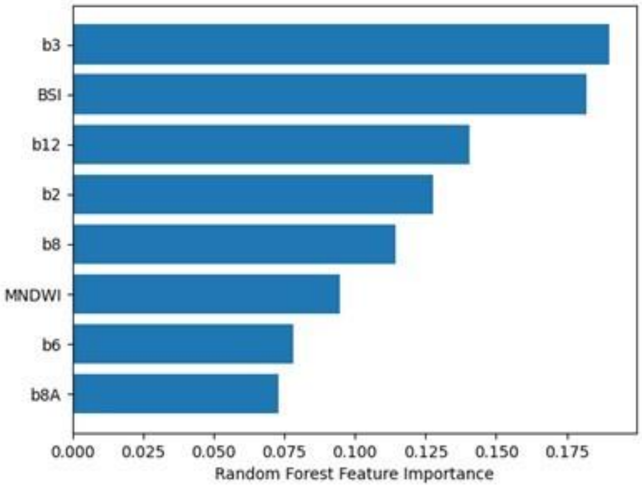

Fig. 7. Variable importance in model-3.

B. Model Evaluation by F_1-score Accuracy Metric

Fig. 8 shows the value of F_1-score accuracy for the three models compared in this study. It is very clear that the F_1-score value for most of the classes was increased from model-1 to model-3. This increase was noticeable in most of the classes after adding the spectral indices in model-2 with reference to the initial model-1 where spectral bands were only used. For instance, F_1-score in vegetation and industrial classes increased by nearly 6 % in model-2 when compared with model-1.

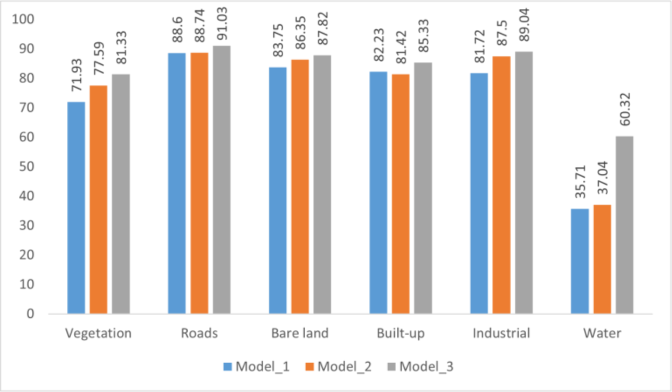

Fig. 8. F_1-score accuracy in the three models.

After applying the RFE to choose the optimal features, the F_1-score increased with different percentage between classes when compared to the values in model-2. The water class achieved the highest increase by 23 %, while the bare land class achieved the lowest increase by 1.67 %.

C. Computation Time Evaluation

Fig. 9 compares the average processing time spent for training and predict in each model aligned with the number of features used. The model-3 achieved the best rank in terms of the training and prediction processing time, where its average reached 1.56 and 1.83 mins respectively. This model used the lowest number of features (6 spectral bands plus 2 spectral indices). On the other hand, the highest training and prediction processing time was associated with model-2, which has the largest number of features (10 spectral bands plus 5 spectral indices).

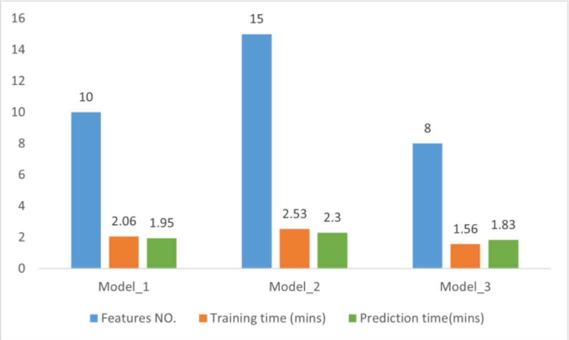

Fig. 9. Feature number, training, and prediction time in the models.

IV. DISCUSSION

This study aimed to explore the effect of feature selection on LC classification accuracy and processing time in arid areas aligned with limited sample size. In terms of the overall accuracy, average PA, UA and F_1-score as shown in Fig. 10, there was an increase in accuracy after adding the spectral indices to the spectral bands. In addition, there is a noticeable increase in the accuracy of all these metrics in model-3 after applying the RFE feature selection technique.

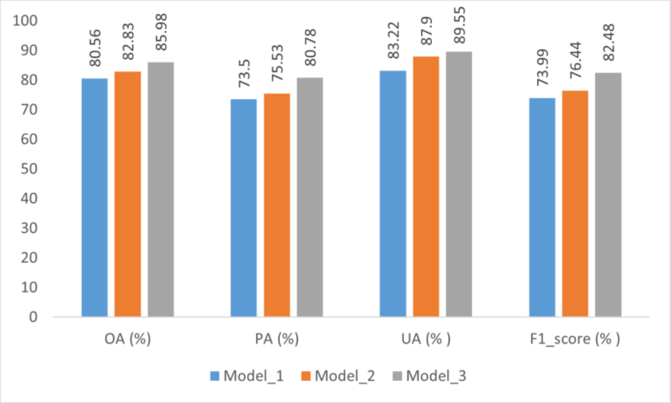

Fig. 10. Average of accuracy indicators for the three models.

Adding spectral indices proved to be effective in improving LC classification accuracy in model-2 in this study by increasing the separability between the individual classes in comparison with model-1. In this study, the SAVI and BSI indices were the two most important features in terms of improving classification accuracy in model-2. The fact of improving accuracy through adding indices is a common practice in many other studies such as in [25]–[27].

Despite the added value of indices in improving LC classification accuracy in model-2, the application of feature selection in model-3 proved to be more effective in improving all the performance metrics in model-3 and in decreasing the processing time without the need for increasing sample size. This could be interpreted by the importance of applying feature selection technique in removing redundant features which affect both the accuracy and processing time [28]. Many studies in terms of improving LC classification recommended applying feature selection methods to select the optimal relevant features and reduce the processing time [29].

The low accuracy of model-2 in comparison with model-3 indicates that the curse of dimensionality can affect the classification accuracy. Previous studies showed that increasing the number of features can lead to complexity by increasing the processing time and decreasing the potential accuracy of the model [30].

The application of RFE in combination with the property of RF variable importance in this study helped in determining the input features and their contribution in producing the optimal classification accuracy in the study area. This subset of the relevant features is a common appropriate approach for building robust learning models [31].

V. Conclusion

With a limited sample size for LC classification, adding spectral indices to improve the classification accuracy is not an ideal solution, as shown in this study. The feature selection techniques proved to overcome the limited size of samples by choosing the relevant features that increase the classes separability. In urban arid areas, the RFE technique decreased the features from 15 to 8 with best F_1-score average accuracy (82.48%) in comparison with the case when only spectral features were used in model-1 (73.99%) or when the spectral bands and indices were used in model-2 (76.44%). Furthermore, less training and prediction processing time was achieved after applying RFE (1.56 and 1.83 min) when comparing with values of model-1 (2.06 and 1.95 min) and with values in model-2 (2.53 and 2.3 min). The combination of the spectral bands: b2, b3, b6, b8, b8a, and b12 with the spectral indices: BSI and MNDWI represent the optimal variables for LC classification in terms of accuracy and computation time in this geographic study area.

The results of this study showed that feature selection is useful in reducing the dimensionality of spectral bands of Sentinel-2 and the spectral indices as well. This refers that not all indices can contribute to improving classification accuracy when sample size is limited.

Other feature selection techniques are recommended to be explored and compared in alignment with the other machine learning classifiers in urban arid areas. In addition, more multitemporal images for different seasons can be investigated to overcome the single image used in this study.

Abstract—**Machine Learning has been potentially contributing towards smart diagnosis in the medical domain for more than a decade with a target towards achieving higher accuracy in detection and classification. However, from the perspective of medical image processing, the contribution of machine learning towards segmentation is not been much to find in recent times. The proposed study considers a use case of Tuberculosis detection and classification from chest x-rays where a unique machine learning approach of Convolution Neural Network is adopted for segmentation of lung images from CXR. A computational framework is developed that performs segmentation, feature extraction, detection, and classification. The proposed system's study outcome is analyzed with and without segmentation over existing machine learning models to exhibit 99.85% accuracy, which is the highest score to date in contrast to existing approaches found in the literature. The study outcome based on the comparative analysis exhibits the effectiveness of the proposed system.**

Keywords—Chest X-Ray; machine learning; convolution neural network; segmentation; detection; classification

I. Introduction

Tuberculosis (TB) is a disease caused due to the bacteria Mycobacterium tuberculosis [1]. Most often, this affects the lungs and causes tissue damage in them, while its common symptom is found to be cough. These bacteria can spread through the air; hence they will spread from person to person when the infected person coughs, sneezes, or spits [2]. According to WHO, one-fourth of the world's population is already infected with these bacteria, but they are not ill and cannot transmit it further [3]. People infected with TB have a 5-10% lifetime risk of falling ill due to it. When the person falls ill due to TB, it shows immediate symptoms like cough, blood in the cough, high fever, chest pain, and in some cases, mental illness. In order to treat this, finding out the extent of damage caused to the lungs is most important. Early diagnosis is crucial for treatment.

TB is also most commonly confused with lung cancer due to all similar symptoms. When doctors have such confusion, they will go for a TB skin test and blood test; however, such a test doesn't exhibit the criticality of lung damage. Hence, Chest X-Ray (CXR) is commonly adopted for the identification of stages of the criticality of TB [4]. This is where the domain of medical image processing comes into play, where various algorithms and mechanisms are constructed in order to find all the indicative symptoms of abnormalities in the lung region when the subject is infected by TB. Some of the possible problems in this stage of acquisition of CXR image are that there are higher possibilities of artifacts in that acquired CXR image [5]. This could be due to lower or fluctuating illumination conditions, absence of some significant region of lungs, movement of the subject during taking X-rays, etc. The conclusive remarks to state that a subject is confirmed of TB completely depends upon a manual analysis of the doctor. Because of this manual assessment, it's humanly impossible for any doctor to diagnose the disease for a large number of patients per day. Therefore, there is a serious need to make this identification system smarter and more intelligent, which can diagnose the disease without human intervention, which is manually not possible for humans. This is where artificial intelligence and machine learning come into the picture [6]. Currently, much research is being carried out toward adopting machine learning in diagnosing critical diseases [7]-[9]. There are also some significant studies where common diseases and diseases associated with COVID-19 have been assessed in recent times [10].

However, there are not many recent studies investigating TB. It has also been noticed that detection and classification completely depend upon the efficiency of processing input and extracted features. One such technique is known as segmentation, which differentiates the background image from the foreground image, offering more clearance to the system or a physician to make a conclusive decision about the diagnosis.

This paper introduces a novel computational model to perform segmentation and thereby contribute towards detecting and classifying CXR in TB patients. The contribution of the study is i) an augmented U-Net model is presented to carry out segmentation, ii) a computationally efficient training model is introduced, iii) a simplified preprocessing is carried out to leverage accuracy, and iv) accomplishing higher accuracy of classification till date. The organization of the manuscript is as follows: Discussion of existing literature where Machine learning is used for identification and classification is carried out in Section II followed by exclusive highlights of the research problem in Section III; Section IV showcases the research methodology, while Section V discusses system implementation. Section VI discusses the results obtained from the study. Finally, Section VII makes conclusive remarks about the study's contribution.

II. Related Work

This Section discusses the different mechanisms carried out in the existing system toward analyzing CXR images. The prime emphasis is given to the latest publication with different techniques of detection and classification of CXR. Although the proposed study targets the detection and classification of Tuberculosis, this section mainly studies all potential approaches toward screening any form of significant deformities in CXR. This is meant to assist more information that could be assistive towards the detection and classification of Tuberculosis too.

The recent work carried out by Lin et al. [11] has presented a detection of COVID-19 symptoms right from CXR images using an adaptive attention network using ResNet. Although this work aims to extract contextual information for lesion detection in CXR, its limitation is that it is quite an iterative process in the course of learning the network. Another recent work by Wu et al. [12] has used a unique classification technique using the fractional order of convolution approach. The method also makes use of a radial Bayesian network in order to identify complex structures. However, the limitation of the model is that it involves a higher number of layered operations to perform classification. A study towards segmentation has been reported by Eslami et al. [13] that uses an adversarial network with conditional generative attributes where a network is constructed for all the pixels. Although the model claims support for multitasking applications, its limitation remains in complex architecture design over many pixels. A study towards adopting an adversarial network is also witnessed in work carried out by An et al. [14]. The study has developed a multi-appearance model for carrying out the extraction of significant features associated with COVID-19.

Further, the model uses a design of an adaptive network for a multi-scale adversarial domain for targeting better accuracy. The study's limitation is using a complex structure of an adaptive network irrespective of an accuracy of 98.83%. Londono et al. [15] present a unique evaluation-based model where a Convolution Neural Network (CNN) is used for training the dataset of CXR with COVID-19 symptoms. The study also performs preprocessing of data to deal with variability issues during analysis. The limitation of the study is lowered accuracy score of 91.5% while ignoring the process of masking the images. The problems associated with detecting lesion in CXR is carried out by Li et al. [16] where an amplitude modulation scheme has been presented to extract deformation features within CXR with deformable convolution. The study also uses the loss function of regression in order to carry out optimization; however, a lowered precision score of 0.914 is obtained as a limitation. A unique form of machine learning approach called a deep zoom neural network is presented by Wang et al. [17] that targets optimizing the training process using CXR images for thoracic diseases. The study has used U-Net in order to carry out segmentation followed by using attention heatmap, the regions of lesions are extracted. The limitation of the study is that it is more inclined toward detection and possesses fewer conditional constraints for supporting classification. The study of tuberculosis detection is presented by Rahman et al. [18] using deep CNN for classification. The study's limitation is its accuracy of 98.6% without much emphasis on the masking process. Further study towards segmentation of CXR images is carried out by Munawar et al. [19], focusing on using the generative adversarial network. This study carries out segmentation masking while the model training is carried out using multiple discriminators. The limitation of the study is its lower accuracy, irrespective of using the sophisticated adversarial network. It is also observed that most of the existing system focuses more or less on detection or classification; however, not much emphasis is offered to outlier detection, which is essential to confirm its accuracy. A study in such a direction is carried out by Kim et al. [20] using artificial intelligence. The study also uses a Recurrent Neural network to perform learning operations. The limitation of the model is the inclusion of higher convolution layers; still, extraction of potential features doesn't carry any objective function.

Paluru et al. [21] have presented a study of chest CT images, especially focusing on the segmentation process using a unique form of CNN called as Anam-Net. The study claims to include lower parameters to show its lightweight features. The limitation of the model is that it still has a dependency on high-end resources in order to make it functional. Synthesis is one of the essential operations for analyzing CXR, while a study in this direction is carried out by Salehinejad et al. [22]. The study has used CNN, whose outcome shows the supportability of five classes of CXR. The limitation of this model is that it lacks potential preprocessing and planning while taking input for real- images. Catala et al. [23] have investigated CXR images for the identification of Pneumonia with more emphasis on the dataset. Work carried out by Zhang et al. [24] has carried out a segmentation process for CXR using deep learning, which is capable of generating information about infection over the lungs. The limitation of the study is its lowered accuracy score of 95.9%. The work carried out by Zhou et al. [25] used ResNet and Support Vector Machine (SVM) in order to detect abnormalities in CXR images. The study also uses image regrouping, where encoders of deep networks extract the features. The limitation of the study is its lowered accuracy of 93% only. The work carried out by Zaidi et al. [26] has used a tailored make CNN model to perform lung segmentation. The limitation of the study is its inclusion of a higher number of iterations in order to achieve below-average accuracy. Similarly, there are various other works in the same problem domain carried out by Wu et al. [27], Yan et al. [28], Fan et al. [29], and Lian et al. [30]. Therefore, various detection and classification mechanisms exist in current times towards CXR images with reported claims of accuracy outcome and limitation. The next section highlights identified research problems.

III. RESEARCH PROBLEM

After reviewing the existing system to analyze CXR images, the following are the open-end research problems being identified:

- Existing models for the detection of lung abnormalities have mainly found lung anatomy, which is preferentially applicable to low-level image processing. However, such methods often produce inferior segmentation when certain areas of the lung are malformed or missing from CXR.

- Machine learning techniques are mainly used for classification, mainly for feature extraction. CNN is one such dominant machine learning model. However, existing studies using this technique were generally found to be computationally slow and expensive due to higher iterations and resource involvement. It also does not help extract information on proper thresholding, which could be a potential problem during training operations. Other than that, there is not much emphasis on consistency and scalability since the uncertainty increases when the segmented regions change to different resolutions. Beyond that, not many techniques have been used to classify specific regions of the lung and its connected organs. From this perspective, research on segmentation is rather sparse.

- Existing studies have adopted the distortion model for the investigation of CXR. They were primarily used for the segmentation of lung fields in CXR; however, their performance is not up to the mark for large networks or high numbers of training images. There is less evidence to be verified at the same time, which reduces applicability in a practical world scenario. Furthermore, the mechanism to initialize the lung model during Tuberculosis has also been found to be manual and error-prone.

- There is no denying the fact that adopting CNN or other machine learning approaches gives good classification performance. However, the participation of machine learning approaches to perform autonomous segmentation is much lower than in existing systems. Without a proper segmentation considering all possible constraints of the CXR images, an improved form of identification and classification cannot be made. Furthermore, most machine learning approaches applied to CXR images have achieved low accuracy scores, while there is still scope to optimize them. Therefore, existing studies are found to be more inclined to implement complex architectures on machine learning rather than trying simplified modeling of it.

Therefore, the problem statement of the proposed study is "Optimized usage of machine learning towards identification of abnormalities in CXR images with more focus on segmentation approach is quite a challenging task".

IV. Proposed System

The research work reported in this paper aims to develop an efficient and robust computational model that can accurately identify and classify TB disease using chest X-ray (CXR) images. As it has been identified based on review of literature that there is wide adoption of CNN for medical image analysis such as detecting tuberculosis from chest X-ray images. However, due to the complexity of CXR images, which include detailed information about the shoulder bones, rib cage, and outer body of the person, direct usage of CNN on these images may not yield very accurate results. In this regard, the proposed work presents a highly integrated system with more optimized computing operation in automating the task of TB diagnosis. The schematic architecture of the proposed system is illustrated in Fig. 1.

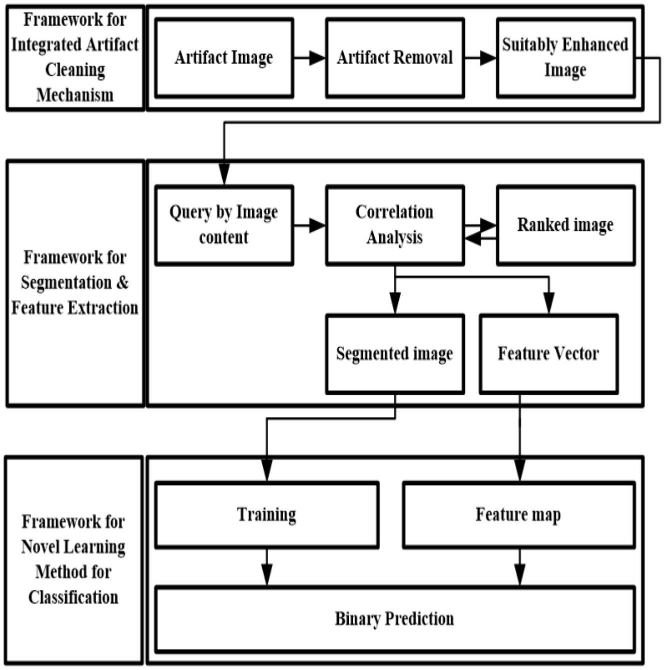

Fig. 1. Block based Architecture of the propsoed system.

The proposed system aims to accurately diagnose TB by using a combination of exploratory data analysis, image segmentation, and machine learning. Firstly, the system executes exploratory data analysis to understand the data and determine the preprocessing requirements to make the input data suitable for learning models. This includes data cleaning, artifact removal normalization, and feature engineering.

Secondly, the system performs image segmentation to extract the region of interest from the input CXR image. This is done using a customized and enhanced version of the UNet Model, which accurately locates the lungs and masks out residual regions. This segmentation process reduces the surface of computational complexity, improves the feature extraction process, and increases accuracy by extracting only the region of interest. The generated masks from the proposed UNet learning model accurately represent the boundaries of the relevant structures in the images.

Finally, the generated masks serve as input to a CNN classifier to diagnose or classify TB. The CNN is trained on a large and diverse dataset of CXR images with and without TB, and is designed to accurately classify the input image as TB positive or TB negative.

Overall, this system has the potential to significantly improve the accuracy and efficiency of TB diagnosis, which is crucial for effective treatment and management of the disease. The performance of proposed system will be thoroughly evaluated on various metrics, and compared with existing methods in the literature.

A. Introduction to CXR based Diagnosis of TB

To understand the research flow, it is essential to comprehend the working mechanism of chest X-ray (CXR) and how it can be used to diagnose tuberculosis (TB). It is important to note that there are several techniques available to diagnose TB in patients, which range from invasive to non-invasive methods. Radiological diagnosis is considered a non-invasive method as it does not require any surgical tools to be inserted inside the patient's body, thereby posing a lower risk. However, CXR diagnosis is not always reliable as it requires an expert pulmonologist to interpret the results accurately. Fig. 2 to 4 illustrate how an expert pulmonologist makes a diagnosis using CXR.

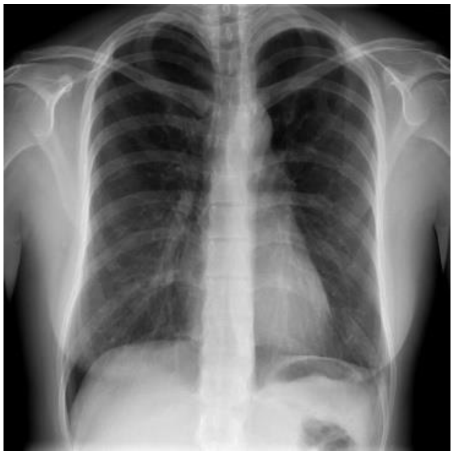

Fig. 2. Illustration of normal lungs.

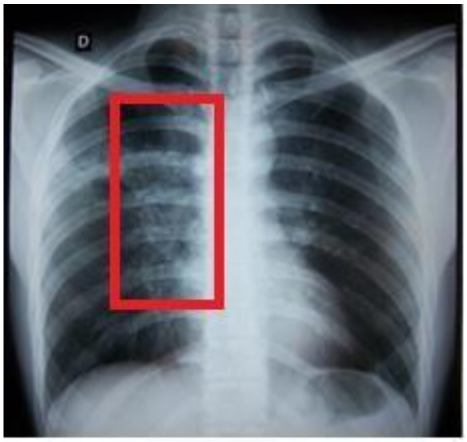

Fig. 3. Illustration of TB lungs.

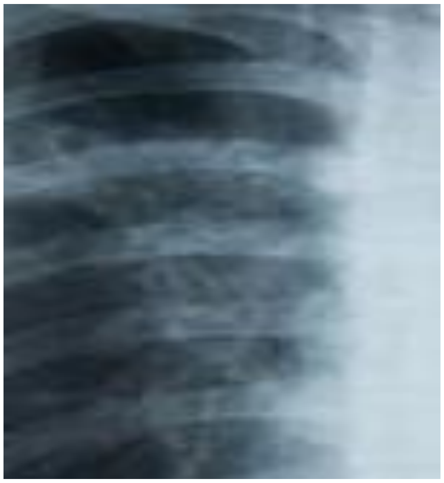

Fig. 4. Illustration of damaged lung tissues due to TB.

In CXR, an image of the chest is captured using an X-ray machine, which produces a black and white image of the chest cavity. The image contains detailed information about the structures inside the chest, including the lungs, heart, and ribs. A trained pulmonologist can use this image to identify abnormalities such as nodules, masses, and infiltrates that may indicate the presence of TB. The process of CXR diagnosis involves a thorough examination of the image by an expert pulmonologist who looks for specific patterns and abnormalities that may indicate TB.

The presence of TB in the lungs can cause damage to lung tissue, as shown in Fig. 3. However, it can be difficult for a layperson to distinguish tissue damage caused by TB from damage to the muscles of the lungs. To diagnose TB, doctors typically perform a TB skin test or a TB blood test. The TB skin test involves injecting a small amount of tuberculin under the skin and observing whether a blister forms at the injection site after 72 hours. However, this test is painful and only indicates the presence of TB bacteria on the skin. Similarly, the TB blood test only indicates the presence of TB bacteria in the blood. Neither of these tests can reveal the extent of lung damage caused by TB, which is critical for accurate diagnosis. The most definitive way to assess lung damage is through a lung biopsy, but this invasive procedure carries a risk of secondary lung infections. To avoid this risk, expert doctors rely on two non-invasive methods: listening to the sound of the lymph glands with a stethoscope while the patient breathes, or using chest X-rays to diagnose tissue damage in the lungs.

The manual process requires specialized knowledge and experience, which can make it challenging to diagnose TB accurately. Therefore, an effective computational model is developed that can accurately diagnose TB using CXR images.

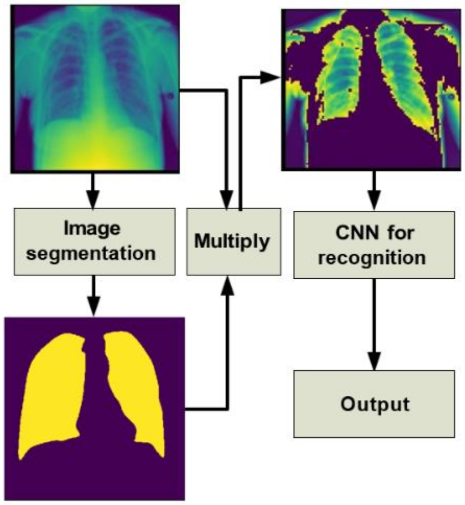

Fig. 5. Outline of the proposed computational model for TB diagnosis.

The illustration of computational model is shown in Fig. 5, which uses image processing techniques and machine learning algorithms to automate the process and improve the accuracy of TB diagnosis. The proposed computational model, as illustrated in Fig. 5, consists of three main components: a CXR image, its segmentation using a customized UNet model, and TB recognition using a CNN with the obtained mask. The target accuracy for proposed system is a minimum of 90%, because an accuracy of 90% is the bare minimum in the medical system to be acceptable to the reliability of a biopsy. Additionally, our proposed method is non-invasive, providing a desirable alternative to invasive biopsy for TB diagnosis. One of the major advantages of our model is the adoption of novel segmentation techniques using machine learning, which makes the entire process autonomous and independent of human intervention. This feature not only reduces the possibility of errors due to human intervention but also saves time and resources.

V. System Implementation

As mentioned in the previous section, the proposed system aims at identifying and classifying tuberculosis from chest radiographs (CXR). This section discusses the implementation procedure adopted in the proposed system design system. The entire discussion is carried out in systematic manner following preprocessing operation and Add on CNN based TB detection. Here Add on means applying proposed customized UNet model for precise mask generation for supervised learning.

A. Pre-processing

The first step of the research methodology is to collect a large dataset of CXR images that includes both normal and TB-infected images. The dataset considered is diverse enough to cover normal and TB infections images. In the next step, the CXR dataset is then subjected to extensive preprocessing operation to enhance the image quality and remove any artifacts. This implementation of preprocessing phase includes checking size of image and converting to grayscale, resizing, and removing any artifacts or noise, and then splits them into training and testing datasets using an 80:20 ratio. The preprocessing over input CXR images is done using a Python library OpenCV's function. For example, the signature used for resizing image to 512×512 is shown as follows:

$$\text{Resized\_CXR} = \text{cv2.resize}(\text{CXR}, (512, 512)).$$

The enhancement of the each CXR images in the dataset are carried out using adaptive histogram-based equalization approach. The implementation step is discussed as follows:

1) Let an input CXR image be denoted by $I(x,y)$, where x and y represent the spatial coordinates of the image.

2) Divide the input image $I(x,y)$ into non-overlapping tiles of size $N\ x\ N$.

3) For each tile, compute the histogram $H(i,j,k)$, where i and j represent the pixel coordinates within the tile and k represents the intensity levels ranging in 0 to $L-1$, where L is the number of gray levels.

4) Apply the Contrast Enhancement Function (CEF) on each tile, which maps the original pixel values to new enhanced values, denoted by $E(x,y)$. The CEF is numerically expressed as follows:

$$E(i,j) = \frac{fr((CDF(I(i,j))-CDFmin)}{(1-CDFmin) \times (L-1))} \quad (1)$$

where CDF is the Cumulative Distribution Function, CDFmin is the minimum CDF value in the tile, and round function rounds the values to nearest integer.

5) Replace the pixels within each tile with the enhanced values $\mathrm{E(x,y)}$.

6) Reconstruct the output image by combining the enhanced tiles.

The output image is denoted by $\mathrm{I'(x,y)}$, as enhanced version of the input CXR image $I(x,y)$. Similar operation is executed for ∀ CXR ∈ Dataset. Afterwards, dataset is split into training and testing sets with an 80:20 ratio using Python's train_test_split ( ) function from the scikit-learn library. Overall, this phase applies a basic pre-processing scheme to make CXR images suitable for segmentation process.

B. Segmentation and Mask Generation

In this phase, a customized UNet model (i.e., UNet with bi-ConvGRU model) is developed and trained to segment the lung region from the input CXR images. Once the lung region is segmented, a mask of the region of interest (ROI) is generated to focus on the segmented lungs only. The output of the proposed UNet model is a binary mask that shows the segmented lung region.

The customization in UNET is done by integrating it with bi-ConvGRU layer to each of the encoder and decoder blocks in the UNET model. Basically, the convolutional layers in the encoder and decoder are replaced with bi-ConvGRU which consist of a set of updates and reset gates that control the flow of information through the network, and a hidden state that stores the current state of the network. The bi-convGRU layers learn to selectively update and forget information based on the input image and the previous state of the network. This layers also have attention mechanisms that allow the network to focus on specific parts of the input image when making predictions. The attention mechanisms use learned weights to selectively weight the input image features at different spatial locations. The mathematical model for the U-Net architecture with bi-ConvGRU can be described as follows:

Input: An enhanced image of size $W \times H \times C$, where W is width, H is height, and C is the number of channels.

Output: A segmentation map or a mask of size $W \times H$, where each pixel represents the class of the corresponding pixel in the input image.

Encoder: The input image is passed through a series of convolutional layers with filters of increasing size. Here, the encoder takes the input X and generates a set of feature maps E such that:

$$E = \{E1, E2, E3, E4, E5\} \quad (2)$$

Each convolutional layer is followed by batch normalization and activation function (ReLU). The output feature maps are downsampled using max-pooling such that:

$$\mathrm{E_i} = \mathrm{Pool(ReLU(Conv(E\_\{i-1\})))} \quad (3)$$

The output of the ith encoder block is denoted as U_i, where i denotes the depth of the block. The output feature map U_i has a spatial size of $W_i \times H_i$ and contains C_i channels.

Decoder: The decoder upsamples the feature maps from the encoder, restoring the original image size. The ith decoder block takes the output from the ith encoder block and concatenates it with the feature map from the corresponding level of the encoder, which helps to capture more detailed information. The output of the ith decoder block is denoted as D_i, where i denotes the depth of the block. The output feature map D_i has a spatial size of $W_i \times H_i$ and contains C_i channels.

Bi-ConvGRU: The bi-ConvGRU processes the feature maps from the encoder and decoder. It enhances the network's ability to capture long-range dependencies. The bi-ConvGRU is implemented as follows:

- A convolutional layer with 1x1 kernel size is applied to the feature maps from the encoder and decoder to reduce the number of channels.
- The output feature maps are then passed through two layers of bi-directional ConvGRU, which processes the feature maps in both forward and backward directions.
- The output of the bi-ConvGRU is then upsampled to the original image size.

The output of the bi-ConvGRU is denoted as G and has a spatial size of W x H and a single channel.

Final layer: The output of the bi-ConvGRU is passed through a convolutional layer with 1x1 kernel size to obtain the final segmentation map. Fig. 6 shows schematic architecture of the implemented customized UNet model.

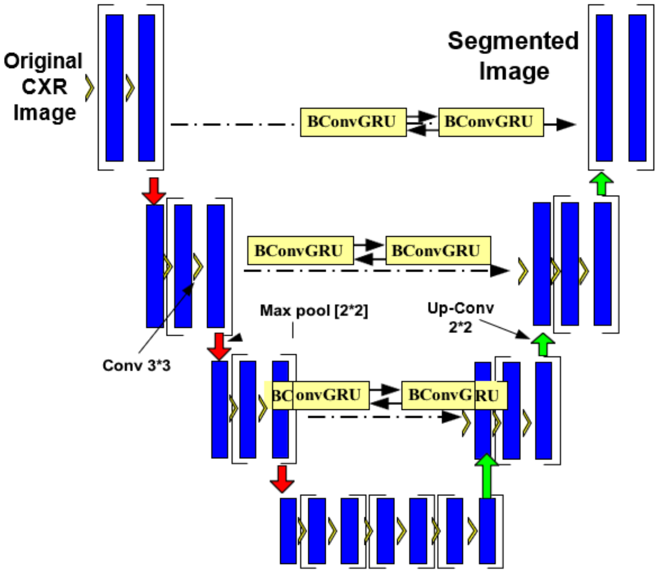

Fig. 6. Proposed customized U-Net model for segmentation and mask generation.

For ∀ pixel at location (i,j) in the feature map at layer l, the encoding process applies a convolution operation to the corresponding receptive field in the previous feature map at layer $l-1$, adds a bias term, and applies an activation function to obtain the output feature map at layer l. This process is repeated for all pixels in the feature map to obtain the full output feature map at layer l, expressed as follows:

$$h_{i,j}^{l} = f(W_l \times h_{i,j}^{l-1} + b_l) \quad (4)$$

where:

- $h_{i,j}^{l-1}$ represents the feature map at layer $l-1$ of the previous convolutional layer,
- $h_{i,j}^{l}$ represents the feature map at layer l,
- W_l is the weight matrix for the convolutional operation at layer l,
- b_l is the bias vector at layer l, and
- $f(\,)$ is the activation function applied element-wise to the output of the convolution operation.

Specifically, the customized UNet is used to learn the mapping between the input image and the output segmentation masks. The learned model parameters can then be used to minimize the energy function, which consists of a data fitting term and a regularizing term, to generate the optimized segmentation. Eq. (5) represents the image segmentation function with the addition of transform domain analysis to enhance its performance. It includes a term that measures the curvature of the segmentation contours in the transform domain, which helps to improve the smoothness of the segmentation.

$$argmin_{u,}|k| + \mu \int_{c} |\Delta u|^{2}\, dx + \int (u-f)^{2}\, dx \quad (5)$$

In Eq. (5), the variable f represents the original image pixel values, u represents the average pixel strength in a segment, Δu represents the variance of pixel intensities in a segment, and k represents a constant that is optimized by Bi-Conv-GRU.

C. CNN based TB Diagnosis

In the previous section, the image segmentation is performed using a customized UNet model, which generates a binary mask of the regions of interest (ROI) in the input image. The trained UNet model is then used to generate masks from other CXR datasets by processing the input CXR images through the trained UNet model. The output of the UNet model is a binary mask that shows the segmented lung region. The generated mask is then used to train a CNN model for TB detection. The input to the CNN model is the generated mask, and the output is the binary classification of TB or non-TB. The CNN model is trained using the preprocessed training dataset, and its performance is evaluated using the preprocessed validation dataset. The TB diagnosis model involved implementation of the CNN architecture which includes convolutional layers, pooling layers, and fully connected layers with activation functions such as ReLU and sigmoid. The loss function used could be binary cross-entropy, and the optimization algorithm is used as Adam optimizer. Mathematically, this process can be represented as follows:

Let I be the input CXR image, and M be the binary mask generated by the UNet model. The trained UNet model can be represented as a function F, which takes the input image I and generates the binary mask M such that:

$$M = F(I) \quad (6)$$

The binary mask M is then fed into a CNN model, which takes it as input and generates a binary classification output, indicating whether the image contains TB or not. The CNN model can be represented as a function G, which takes the binary mask M as input and generates the binary classification output y:

$$y = G(M) \tag{7}$$

Thus, the entire process of image segmentation and mask generation using UNet, and TB detection using a CNN can be represented as a composite function H, which is the composition of F and G, given as follows:

$$H(I) = G(F(I)) \tag{8}$$

To train the CNN model, we use the binary mask M generated by the UNet model as the input, and its corresponding label (0 or 1, indicating whether the image contains TB or not) as the output. The CNN model is trained using a binary cross-entropy loss function, given as follows:

$$L(y_{true}, y_{pred}) = -\alpha + (\beta \times \gamma) \tag{9}$$

where:

$$\alpha = (y_{\text{true}} \times \log(y_{\text{pred}})$$

$$\beta = (1 - \text{y\_true})$$

$$\gamma = \log(1 - \text{y\_pred})$$

In Eq. (9), the variable y_{true} is the true label, y_{pred} is the predicted output from the CNN model, and log represents the natural logarithm. The training process involves minimizing the loss function over a set of training images and their corresponding labels, using an optimizer, Adam. The negative sign in the beginning of the right-hand side of the equation is used to indicate that we want to minimize the loss function. During training, the objective is to minimize the difference between the true labels and the predicted labels. By adding a negative sign to the equation, we can use optimization algorithms that are designed to minimize a function, rather than maximize it. In other words, by minimizing the negative of the log likelihood loss, we are maximizing the likelihood of the predicted labels given the true labels. Once the CNN model is trained, it can be used to classify new CXR images as either TB positive or negative, by first generating the binary mask using the UNet model and then passing it through the CNN model. The proposed learning model can be used as a tool for early diagnosis of damage caused by TB in the lungs. To be more specific, this device will help in the detection of tuberculous pneumonia or tuberculous pneumothorax.

VI. Experimental Analysis

The design and development of the proposed system is done using Python executed in Anaconda distribution. The proposed work encompasses two main contributions Viz. i) development of novel customized UNet learning model which is trained to generate binary mask as segmented lung region from the given chest X-ray image; ii) implementing and training CNN with generated mask to diagnose Tuberculosis from the given mask generated. Both models are integrated and their response are synchronized to carry out detection of Tuberculosis. This section presents the outcome and performance analysis of the proposed learning models.

A. Performance Analysis of Segmentaion Model

The dataset used to train the proposed customized UNet model for image segmentation is highlighted in Table I.

TABLE I. Dataset Used for Training UNet for Image Segmentation

Dataset	Total images	Training images	Testing ratio
Lung image segmentation [31]	704	563	141

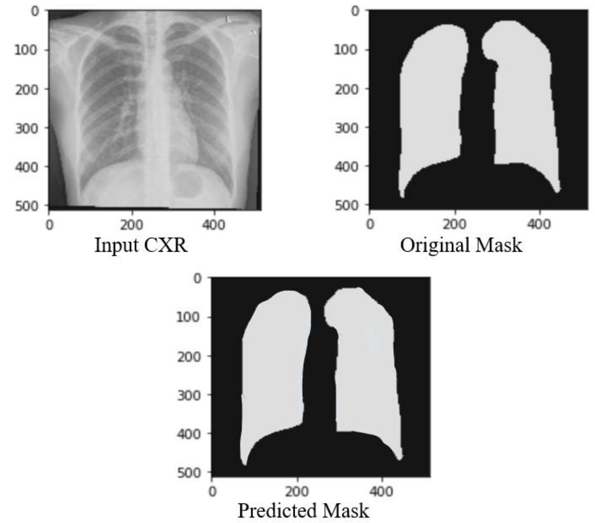
As shown in Table I, the dataset obtained from Kaggle which consists of total 704 chest X-rays with corresponding masks. The dataset is further split in training and testing set with a ratio of 80:20. The parameters used to train the models is also highlighted in Table II.

TABLE II. Training Parameters Used for Image Segmentation

No. Epochs	Batch size	Loss function	Optimizer
50	32	Binary crossentropy	Adam

The training of the proposed augmented UNet model for generating mask in form of segmented image is carried out with total 563 images. The model is trained for 50 epochs, followed by batch size equals 32. In addition, binary cross entropy and Adam is used as loss function and optimized to calibrate learning of the model. The trained UNet model is further applied to different chest-Xray to generate mask.

The interpretation of the Fig. 7 reveals that the predicted mask is mostly the same as the original mask with only minor differences, it indicates that the UNET-based segmentation model is performing well on the given CXR image. The smooth edge border in the predicted mask could be due to the model's ability to capture fine details and edges in the image. A good performance is achieved by the customized based segmentation model indicating that it is able to accurately generate mask with lung areas. This would be useful in a TB detection system, as it can provide a good scope for an accurate localization of the disease for further analysis and diagnosis.



Input CXR

Original Mask

Predicted Mask

Fig. 7. Depiction of mask predicted by the proposed customized U-Net model with input CXR and original mask.

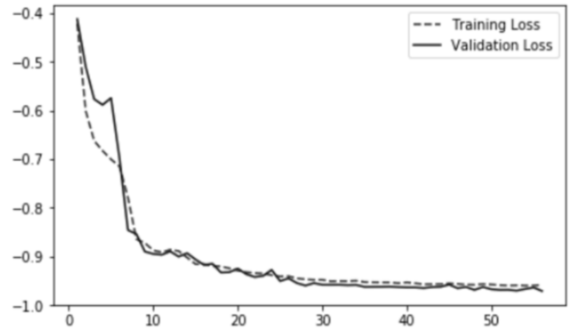


Fig. 8. Model training and validation loss curve analysis.

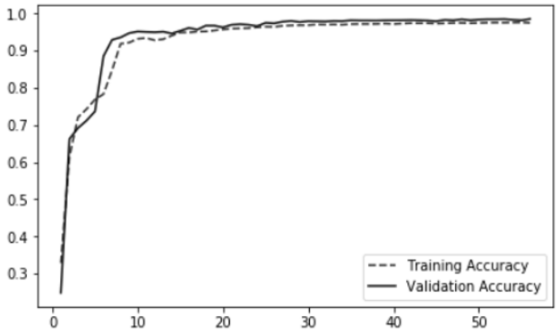

Fig. 9. Model training and validation accuracy curve analysis.

The training and validation loss curve in Fig. 8 shows the evolution of the loss (or cost) function over time as the model is trained on the training data. It can be seen from the graph trend that the loss decreases over time or epochs as the model learns to make better predictions. Similarly, the graph trend of training and validation accuracy curve shown in Fig. 9 accuracy curves follow a stable and linear trend towards 0.9696 accuracy on 50 epochs suggests that the model has converged and is performing well on the given task. Although, there is initial fluctuations in the training and validation accuracy curves which are common and can be attributed to the random initialization of weights in the model and the stochastic nature of the optimization algorithm. As the training progresses, the model learns more features from the data and the accuracy of the model on both the training and validation data gets improved. This also indicates that the model is not overfitting to the training data and generalizes well to new, unseen data.

B. *Performance Analysis of CNN based TB Detection*

The dataset used for generating mask using trained UNet model and training CNN model for detecting TB is highlighted in Table III.

A synthetic dataset is used in the phase of disease (TB) detection. Many chest X-rays images including normal and Tuberculosis are collected from different sources to build a dataset. The dataset consists of 7000 images, where 3500 images are belongs to normal CXR and reaming 3500 CXR images belongs to TB. The images are processed with the trained UNet model to generate a mask for all the input images towards performing efficient supervised learning for disease detection. After generating mask, dataset is split into training and testing set with ratio of 80:20. Table IV shows the training parameters used for training the CNN for TB detection.

The classification model is trained over 5600 masks for 50 epoch, and batch size considered equals to 32. Binary cross entropy loss function and Adam optimizer is used to improve the learning of the CNN learning model. The performance of trained CNN is assessed with testing dataset. The analysis is conducted using confusion matrix and classification performance indicators such as accuracy, precision, recall rate and F1-score. The accuracy is a general metric that measures the overall performance of the model, while precision and recall are more specific metrics that measure the model's ability to correctly classify positive samples. The F1-score is a balanced metric that considers both precision and recall. The confusion matrix for TB detection model is shown in Figure 10.

The confusion matrix shown in Fig. 10 reveals that the trained CNN model using the generated masks from the proposed customized UNet model has performed well in detecting both normal and TB images. The confusion matrix shows that out of 700 normal images, 693 have been correctly predicted as normal, which gives a precision of 1.00 and a recall of 0.99. Similarly, out of 700 TB images, all have been correctly predicted as TB, giving a precision of 0.99, recall and F1-score of 1.00 as shown in Table V.

TABLE III. DATASET USED FOR GENERATING MASK AND TRAINING CNN FOR TB DETECTION

Dataset	Total images	Training images	Testing ratio
TB lungs classificationdataset	7000	5600	1400

TABLE IV. TRAINING PARAMETERS FOR TB DETECTION USING CNN

No. Epochs	Batch size	Loss function	Optimizer
50	32	Binary crossentropy	Adam

TABLE V. QUANTIFIED OUTCOMES FOR TB DETECTION

	Precision	Recall	F1-score	Support
Normal Lung	0.99	0.99	0.99	700
TB Lung	1.00	1.00	1.00	700
micro avg	0.99	0.99	0.99	1400
macro avg	1.00	0.99	0.99	1400
weighted avg	1.00	0.99	0.99	1400

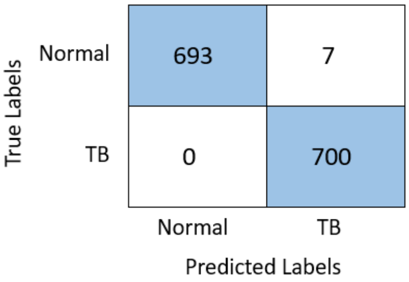

Fig. 10. Confusion plot for assessing performance of trained CNN for TB detection.

The quantified values shown in Table V represent the performance metrics of a binary classification model for the classes "Normal" and "TB". The precision for "Normal CXR" is 1.00, meaning that all the samples predicted as "Normal" were correctly classified, and for "TB" it is 0.99, indicating that out of all samples predicted as "TB", 99% were actually "TB". The recall for "Normal" is 0.99, meaning that out of all the actual "Normal" samples, the model correctly identified 99%, and for "TB" it is 1.00, indicating that the model correctly identified all the actual "TB" samples.

The micro avg. represents the performance metrics computed globally by counting the total true positives, false negatives, and false positives, and the macro avg represents the average of the performance metrics calculated for each class. The weighted avg. takes the weighted average of the performance metrics, where the weights are the number of samples in each class. Overall, the model has high precision, recall, and F1-score for both classes, indicating a good performance in the binary classification task.

C. Extensive Analysis with Different Versions of CNN

This section presents an extensive analysis of the proposed work by evaluation proposed system with different version of existing CNN models. Moreover, entire analysis is carried in two scenarios viz. i) performance analysis with proposed segmentation scheme using customized UNet and ii) performance analysis without segmentation (i.e., models are trained directly on the input images with any pre-processing and segmentation).

For an effective analysis, the proposed system is subjected to a comparative analysis. However, this is a different form of comparative analysis, where the outcome of proposed system (performance parameters with segmentation) is further subjected to 7 version of neural network viz. Resnet 18 [32], Resnet 50 [33], Resnet101 [34], VGG19 [35], Densenet201 [36], Squeezenet [37], and Mobilenet [38].

The prime justification behind this mode of comparative analysis is to assess whether the performance of proposed classification model with segmentation using augmented U-Net model can be further improved upon using above mentioned seven variants of CNN model with different layers, The idea is to perform an assessment with respect to standard performance parameters of Accuracy, Precision, Sensitivity, F1-Score, and Specificity using dual combination of with proposed system (i.e., with segmentation) and without proposed system (i.e., without segmentation).

As shown in Fig. 11, the accuracy of learning models with proposed segmentation scheme ranges between 99-100, whereas that of without segmentation ranges between 95-97 for different types of CNNs architecture or model. Nearly similar trend is also observed for precision (Fig. 12), sensitivity (Fig. 13), F1 score (Fig. 14) and specificity (Fig. 15).

The F1 score with segmentation is found in range of 97-98 whereas that of without segmentation is found between 95 and 96 mainly. Out of different variants of CNN, the outcome is found to be better for Squeezenet and Mobilenet for accuracy followed by Resnet 18 in Fig. 11. The outcome of precision from Fig. 12 showcases Resnet50, Resnet101, and Squeezenet to be performing well compared to other variants of CNN model. The outcome of sensitivity from Fig. 13 highlights better performance of Densenet201 followed by Mobilenet and Resnet101. Similar performance trend can be also seen with respect to higher F1 score from Fig. 14 compared to others versions of CNN. The performance of Resnet50, Resnet101, Densenet201, and Squeezenet offers nearly similar performance for specificity shown in Fig. 15.

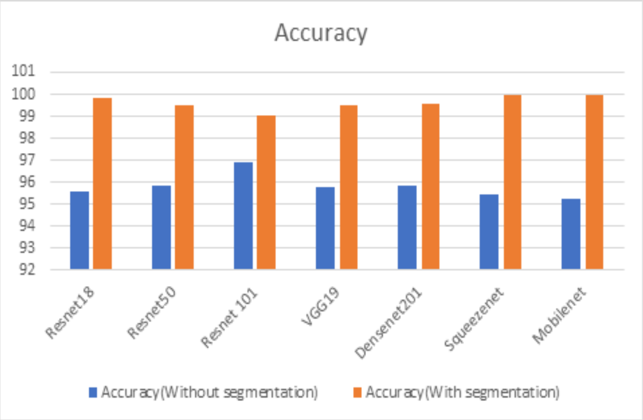

Fig. 11. Comparative analysis of accuracy (%).

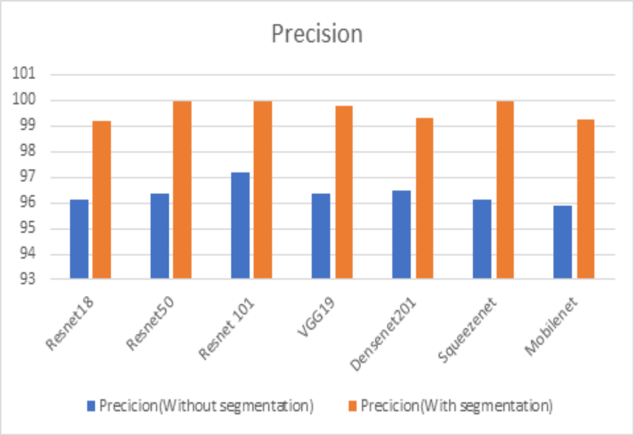

Fig. 12. Comparative analysis of precision (%).

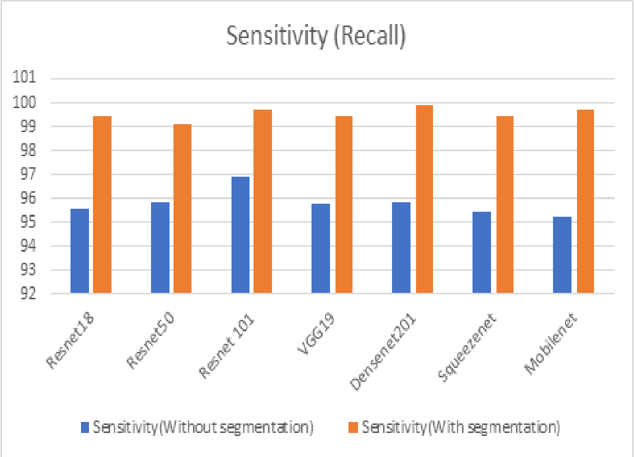

Fig. 13. Comparative analysis of sensitivity (%).

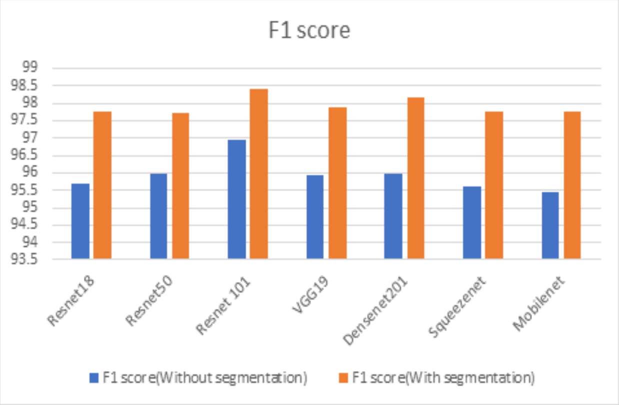

Fig. 14. Comparative analysis of f1 score (%).

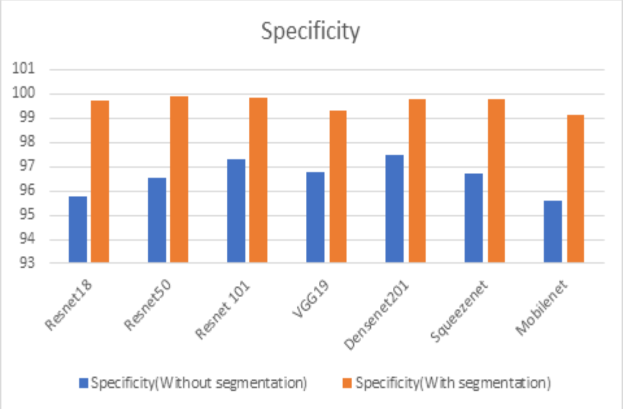

Fig. 15. Comparative analysis of specificity (%).

Based on the analysis and performance statistics, it can be concluded that the proposed scheme has provided a better performance with strong potential in TB diagnosis. The customized UNet model is able to accurately capture the important features in the input CXR images and generate precise masks, which are then used to train the CNN model. This results in a more robust and accurate CNN model, which is able to accurately classify the CXR images as normal or TB. Therefore, the customized UNet model acts as an important pre-processing step, which enhances the performance of the CNN model. Overall, the combination of exploratory data analysis, image segmentation, and appropriate training of CNN provided a more accurate and efficient approach to TB diagnosis, which is crucial for effective treatment and management of the disease.

VII. Conclusion

In this paper, the research work has suggested a novel automated disease diagnosis scheme based on the Add-on CNN learning model which benefited using augmented U-Net based segmentation algorithm. The implementation of the proposed system follows a systematic procedure which included exploratory data analysis, image segmentation, and CNN to accurately diagnose TB. The proposed system effectively preprocesses the input data, locates the lungs, and extracts the region of interest from the CXR images, using customized UNet model which is augmented with Bi-Conv-GRU layers to carry out precise and optimized form of segmentation. This procedure greatly improves the accuracy and efficiency of the subsequent classification process. The generated masks from the proposed UNet Model accurately represent the boundaries of the relevant structures in the images, which improves the feature extraction process and increases the accuracy of the CNN classifier. Our evaluation on various metrics with extensive analysis demonstrates the effectiveness and potential of the proposed system in TB diagnosis. In the future, we plan to further improve the proposed system using self-exploration like reinforcement learning and apply it to larger datasets and different types of medical images. Also, the future study focuses on security aspect of medical imaging in telemedicine application.

Umm Al-Qura University, Mecca 24382, Saudi Arabia

***Abstract*—For enhanced adaptability to poor light enhancement whilst achieving high image contrast, a new method for color image correction based on the advantages of non-linear function in grey transformation and histogram equalization techniques is proposed in this work. Firstly, the original red, green and blue (RGB) image is converted into the HSV color space, and the V channel is used for enhancement. An adaptive gamma generator is proposed to adaptively calculate gamma parameters in accordance with dark, medium, or bright image conditions. The computed gamma parameters are used to propose a cumulative distribution function that produces an optimized curve for illumination values. Next, a second modified equalization is performed to evenly correct the offset of the illumination curve values on the basis of the equal probability of the available values only. Finally, the processed V channel replaces the original V channel, and the new HSV model returns to the RGB color space. Experiments show that the proposed method can significantly improve the low contrast and poor illumination of the color image whilst preserving the color and details of the original image. Results from benchmark data sets and measurements indicate that the proposed method outperforms other state-of-the-art methods.**

Keywords—Color image; gamma correction; histogram equalization; image contrast; image enhancement

I. INTRODUCTION

These days, digital images are used widely because of the rapid development in capturing machines and computer vision technology. Usually, we deal with low-quality images with low contrast and poor illumination caused by various capturing conditions [1]–[3]. Low-quality visual images pose challenges to human perception, as well as image processing and computer vision applications [2], [4], [5]. Therefore, the quality of images should be improved before they are used to make images highly appropriate to the human visual perception and be analyzed easily by machines and improve computer vision applications [1]–[3], [6], [7].

Although no standards exist for correct levels of illumination and contrast, any images captured in condition lighting that does not correspond to normal levels of light are often poor images [2], [8], [9]. In accordance with reviews in previous studies, low contrast and poor illumination are classic challenges in image processing, computer vision and other applications, such as medical technologies, military applications, satellite imaging, video monitoring, traffic technologies, industrial production and underwater image enhancement [2]–[4], [10], [11].

In reality, color images are commonly used, and research is concerned about improving the quality of images [4], [10], [12]. In general, the visual quality of images is enhanced by improving their illumination and contrast. The main enhancement techniques are histogram equalization (HE) [3], grey transformation (GT) [13], defogging model [14], image fusion [8], Retinex theory [15], frequency-domain [11] and machine learning [16].

HE methods remap the histogram of pixel values to corresponding new values to improve the poor contrast of images [2], [3]. They are widely used for their simplicity, swiftness, and effectiveness. However, the output quality varies with the characteristics of the input image, which may cause uneven brightness, lost details and color degradation. GT methods calculate new values of pixels by using linear/non-linear mathematical functions [2], [17]. They are simple, but they could require manual input parameters. This leads to unsatisfactory results, and some details may be lost in the enhanced images.

Image defogging methods remove atmospheric dispersion, such as fog, from images to restore the contrast [2], [5]. Defogging methods show good performance. Nevertheless, they have complex computation, require prior knowledge of the scene and show the over-enhancement problem. Image fusion methods use multiple images of the same scene under different conditions to extract information for improving the image quality [2], [8]. They are difficult to use in many applications, and the process time is long.

Retinex theory-based methods deal with illumination conditions that vary spatially with color and intensity [2], [18], [19]. Retinex methods are simple and enhance contrast, brightness, and colors. However, they may damage edges and produce over-enhancement and uneven brightness levels. Frequency-domain methods use a Fourier transform of an image to be multiplied by a high-frequency modulation filter and then perform inverse transformation to produce an enhanced image [2], [20], [21]. Such methods can improve image details and noise but require complex calculations and manual input parameters. Recently, machine learning methods have been a trend in image enhancement for their excellent performance [22]–[27]. Nonetheless, they require large data sets for training, benchmark data sets on poor contrast and illumination are still lacking and the complexity of the models increases the cost in time and hardware required.

Almost all the above-mentioned techniques still have low contrast within weak illumination images, as well as missing detail in enhanced images. The available methods also suffer from various drawbacks. However, GT and HE methods are mostly used for their simplicity and fewer disadvantages.

The objective of this paper is to propose a novel global enhancement method to overcome the disadvantages of previous methods by combining the advantages of HE and GT methodologies in one method. The proposed method is simple and fast, and it offers excellent performance to improve low contrast and poor illumination in color images. It does not cause color distortion and increases information preservation as much as possible compared with existing methods. A set of experiments is conducted using many measurements on several benchmark data set images. The results show that the proposed method significantly improves the contrast and illumination, as well as preserves the colors and details of the benchmark data sets better than existing methods.

The rest of this paper is organized as follows. In Section II, the state of the art is presented. Section III describes the proposed method in detail. Section IV shows the experiments, results and discussion. Section V presents the conclusion.

II. Related Work

In accordance with literature reviews provided over the years, several methods for improving images' contrast and illumination have been proposed. Previous survey studies, such [2]–[4], [6], [7], [10], [11], [17], [20], [28]–[31], reported that HE and GT are the most involved techniques in proposed contrast and illumination enhancement methods given their simplicity, fast processing time and high performance.

Many GT methods use linear functions to calculate current values of pixels. However, bright regions may become saturated after values are reset, causing lost details in processed images. These methods also require manual intervention and some experience from the user to find optimal enhancement [32]–[35]. To avoid this problem, GT methods then adopt non-linear functions to perform the enhancement. For instance, authors of [1] proposed an enhancement method for color images of the retina. This method improves the detail by using a bilateral filter. Next, non-linear gamma and logarithmic functions are used to correct the illumination. Finally, the corrected grey values replace the V channel in the HSV color space. This method has achieved great performance, but it shows over-enhancement in some cases. In [8], an enhancement method for low-light images based on a pair of complementary gamma functions through image fusion is introduced. Experiments show that this method can enhance the detail and improve the contrast of low-light images. Nevertheless, it exhibits over-enhancement and loses details in some cases.

In [9], a method based on Retinex theory for improving image illumination is proposed. This method uses a recursive filter to estimate layers and a 2D visual gamma transform function to remap pixels. The results show that this method improves visibility in local areas, but it loses detail in images. Authors of [13] recommended a non-linear transformation with a bat optimization algorithm. The bat algorithm is employed to solve the problem of manual selection of control parameters. It is used for automated selection of control parameters in non-linear transformation, but this method presents slow time processing.

In [36], a method to enhance low-light color images based on the fusion strategy is proposed, Gaussian function, and non-linear function parameters. This method improves brightness and contrast. However, it is slow, so it cannot be used to improve video images. Authors of [37] introduced a method that uses a grey-value histogram to adaptively obtain a non-linear function to enhance dark regions whilst preventing bright regions. Nonetheless, the performance is strongly limited. Authors of [38] proposed a contrast and brightness enhancement method based on adaptive gamma correction non-linear function to enhance dimmed regions. This method can enhance low-brightness images and is only effective for such images.

Previous GT methods mainly used logarithmic or gamma as transformation functions, and GT was adopted widely as a step in other image enhancement methods, especially in low-light images. The use of non-linear functions may require complex calculations, in addition to the traditional problems of over-enhancement and unsatisfactory results.

HE is another common technique to improve illumination and contrast and prevent saturation. It has become a popular technique for its high ability to enhance contrast, and several improvements, such as improving the brightness, have been proposed to overcome its limitations. The basic HE was proposed in [39]; this method used a PDF for different CDFs to calculate the new distributions of values. In [40], the output by applying preprocessing steps to the original is improved. However, the method produces unwanted side effects in a wide type of images.

To reduce the side effects of using grey values of the entire image to estimate the optimal enhancement for local different areas in the image, many methods have adopted the local approach, which divides the histogram or image into independent parts to be enhanced individually [41]–[42]. In general, the results of these methods were better than those of the global approach. Nevertheless, these methods are complex and slow, as well as produce noise and over-enhancement challenges.

The mean and variance-based sub-image HE method [43] was proposed to enhance the contrast and preserve the illumination of images. This method exhibits high performance in many types of images. However, it may lose some details from images with a narrow range of grey values. Authors of [42] suggested an HE method for color images. In this method, a clipped histogram based on the HSV color space is separated into two parts by a thresholding method, then the parts are equalized independently. The result of this method has many problems.

Some methods have adopted different techniques instead of the usual equalization to find corresponding new pixel values. Authors of [44] used the min, max, mean and median of a histogram to clip extreme values. Then, several methods were applied to remap new histograms. Authors of [21] utilized a set of filters and the binary tree structure to remap histogram values. In [45], a region-based thresholding method and the entropy of grey level is adopted to reshape histograms. These methods are complex to apply and depend on the accuracy of the set of involved methods. In addition, results are unsatisfactory in many cases. Previous HE methods could effectively enhance light, improve contrast, and increase the visibility of image details. Nonetheless, HE methods may produce noise, lose information, and destroy color fidelity.

In sum, GT mainly deals with illumination issues but does not improve contrast. It may produce problems on contrast in many cases. Meanwhile, HE methods mainly enhance the contrast between pixel values in images, but they do not improve the illumination perfectly or even produce a potential challenge in low illumination levels.

To utilize both advantages of HE and GT, some proposed algorithms combine HE and GT as steps in one method. For example, authors of [12] proposed a method for improving image contrast, adaptive gamma correction with weighted histogram distribution are used, and then the gamma function in the illumination channel of the HSI color space. This method improves contrast and preserves the color of images. However, noise is created for the outputs. In [46], a method for improving the contrast of images via HE and the gamma function is introduced. This method improves images, but the results are unsatisfactory. In [47], a method to improve dark images is proposed. This method uses both the non-linear gamma function and the local HE method as steps in the algorithm. It enhances dark images; nevertheless, its output is a contrast that depends on the state of the images.

Methods that combine the advantages of both GT and HE technologies should be proposed, especially for large sets of images that suffer from low contrast and poor illumination, such as underwater and medical images. Moreover, the traditional challenges mentioned before must be addressed. Wang et al. [2] claimed that research on image enhancement should focus on the following issues: reduction of processing time and complexity to meet practical application needs and improvement of the effectiveness and adaptive capabilities of proposed methods.

III. Proposed Method

The objective of this work is to propose a method for improving poor illumination and low contrast, as well as preserving the natural color and details of original color images. The flow chart of the proposed method is shown in Fig. 1, whilst each step is described in detail below.

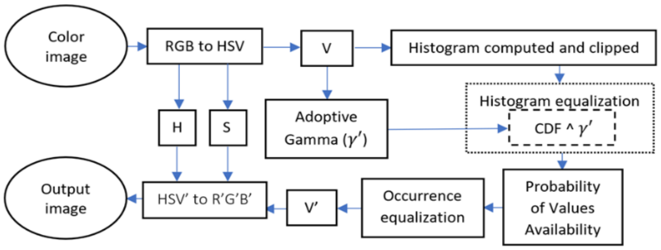

Fig. 1. The flowchart of proposed method.

A. Color Space Conversion

In human eyes, cones consist of three different photopigments that enable color perception under normal lighting conditions. When light levels drop to darkness, the human eye becomes highly sensitive to light and loses the ability to distinguish color. Therefore, illumination correction is of critical importance for enhancing images obtained under inaccurate lighting conditions. In general, RGB is not the most intuitive color model for humans; it is tied on screen hardware to display colors. By contrast, humans usually introduce illumination and color as two different related things. Several color space systems present color and illumination similar to the human visual system. HSV is one of the easy-to-use systems to identify colors and illumination and closest to how humans perceive and compare colors.

The hue (H), saturation (S) and brightness (V) in the HSV color space are independent of one another. Hue (H) is the rainbow side of color, showing where a particular color is in the visible light spectrum. Saturation (S) describes how pure a color is. Value (V) is the brightness; it is the amount of light that comes from the color. The H and S channels are both related to color. Any modification will distort the color, such that both are ignored. Enhancement of the value of brightness (V) does not affect the color information of images. The channel (V) that presents the obtained brightness matrix of an image (Fig. 2 (d)) is separated from the two channels, hue (H) and saturation (S), to be used in the proposed method individually.

The expression for converting RGB space to HSV space is as follows:

$$H = \begin{cases} 60 \times (G - B)/(V - \ min(R,G,B)) & if\ V = R \\ 120 + 60 \times (B - R)/(V - \ min(R,G,B)) & if\ V = G. \\ 240 + 60 \times (R - G)/(V - \ min(R,G,B)) & if\ V = B \end{cases} \quad (1)$$

$$S = 1 - min(R,G,B)/V \quad (2)$$

$$V = max(R,G,B) \quad (3)$$

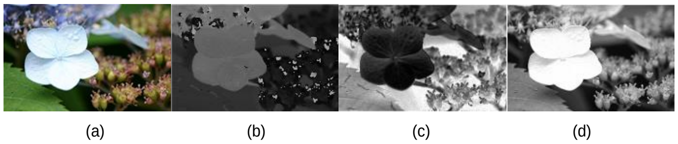

Fig. 2. (a) Original images in RGB format, (b) H channel, (c) S channel, and (d) V channel (brightness matrix) of HSV.

B. Adaptive Gamma

To effectively enhance the illumination of images, the range of low-level values should be increased significantly, the moderate-level values should be increased slightly, and the high-level values should be maintained. To achieve that, a non-linear function is adopted in this work to transform the brightness level values. The gamma function is a common non-linear transformation for illumination level curve and is expressed as:

$$G(x,y) = N(x,y)^{\gamma} \qquad (4)$$

where N refers to the normalized pixel illumination values in the range [0,1]; G(x, y) denotes the new illumination values of x, y pixels; and γ is a constant of the gamma correction parameter.

Different transformation curves can be obtained by changing the constant parameter γ . When $\gamma > 1$, the transformation will stretch to low illumination values, making images look darker. Conversely, when $\gamma < 1$, the transformation will extend to high illumination values to make images look brighter. Meanwhile, when y = 1, no transformation occurs. Despite the advantages of gamma transformation, it does not consider the global grey distribution of images, and its adaptability is poor.

To overcome these disadvantages, an adaptive gamma generator, in which the gamma parameter is acquired adaptively in accordance with the global illumination condition of an image (dark, medium or bright image), is proposed. Firstly, the mean of values in the brightness matrix (V) is calculated (Eq. (5)) to compute the brightness level of the image. Larger values indicate brighter images, whereas smaller values indicate darker images.

$$Mean = \frac{1}{X \times Y} \sum_{x,y=0}^{x,y=X-1,Y-1} V(x,y) \quad (5)$$

where X and Y refer to the size of the brightness matrix (V), and V(x, y) is the value at x, y points. Then, the adaptive gamma parameter (γ') value is calculated using the following proposed equation:

$$\gamma' = \frac{Mean}{L \times 0.33} + C \qquad (6)$$

where L is the maximum grey level of the images; here, $L = 255$, and it is multiplied by 0.33 to adapt γ' value to one of the three global states, which are dark, medium or bright, for the images. C is a bias constant to overcome the problem of $\gamma' = 0$; here, $C = 0.1$. The extracted gamma parameters produce a high transformation to brightness, which is required to unify the characteristics of different images, regardless of their original state (dark, medium, or bright), and the subsequent steps in this work.

C. Histogram Computation and Clipping

A histogram is a cumulative representation of the distribution of brightness values and displays the frequency of each value in V. Some values have higher frequency than others (Fig. 3 (c)), which produces the over-enhancement problem after HE process. To prevent over-enhancement, the histogram is clipped to reduce the high enhancement rate of higher-frequency values by using an adaptive threshold value based on the mean of histogram values. Any value that exceeds the threshold will regard the threshold as a new value, as shown in Fig. 3 (d). The calculation is performed using the following equations:

$$T_{clip} = \frac{1}{L} \sum_{l=0}^{l=L} H(l) \qquad (7)$$

$$H_{clip}(l) = T_{clip}: for\ H(l) > T_{clip} \quad (8)$$

where T_{clip} is the threshold value, H_{clip} is the clipped histogram, and l is a point in the histogram from 0 to 255.

D. Equalization Process

In this stage, HE with a proposed significant modification is performed to improve image contrast and prepare the illumination for subsequent stages. A proposed CDF function is also used to greatly improve the illumination. Firstly, the PDF of the clipped histogram is computed as follows:

$$pdf(l) = \frac{H_{clip}(l)}{\sum H_{clip}(l)} \qquad (9)$$

The computed PDF is used to calculate the CDF by using the following equation:

$$cdf(l) = \sum_{l=0}^{l=L} pdf(l) \qquad (10)$$

However, the CDF displays a curve wherein its values are within [0, 1], as shown in Fig. 3 (e); they can be assumed as normalized pixel values. This condition can be exploited to turn the CDF curve into an illuminated curve of the images. The CDF curve can be further transformed to clarify the details and improve the illumination of the images. To do this, a proposed CDF (cdf') is used to produce a new curve (Fig. 3 (f)) by using the proposed adaptive gamma parameter of Eq. (11) via the following equation:

$$cdf'(l) = \left(\sum_{l=0}^{l=L} pdf(l)\right)^{\gamma'} \qquad (11)$$

This proposed CDF function aims to improve the illumination and contrast adaptively to unify the visual properties of any image, ranging from considerably light to dark. The subsequent steps affected by any type of illumination problem are then unified. Next, the HE processes is performed. New values of brightness matrix are calculated using the following transformation function:

$$V_{MID}(x,y) = cdf'(V(x,y)) \times 255 \qquad (12)$$

where V_{MID} is the new brightness matrix that will be used in the last enhancement stage. V_{MID} has an improved contrast but has extreme high displacement towards high-brightness values, as shown in Fig. 3 (g), and new histograms, as shown in Fig. 3 (h). The histogram values shift to high-brightness regions for all image types compared with the original histograms shown in Fig. 3 (c). Therefore, the next step is required to solve this displacement.

E. Probability of Value Availability

After V_{MID} matrix is calculated, a second equalization process, which aims to modify the displacement of values equally, is applied. Here, an equal probability of density is applied instead of a normal pdf. The equal probability is calculated based on the available values only by using the following equation:

$$V_{\text{available}}\ (l) = \begin{cases} 1:\ V_{MID} \neq 0 \\ 0:\ V_{MID} = 0 \end{cases} \qquad (13)$$

$$pdf_{available}\ (l) = \frac{V_{available}}{\sum V_{\text{available}}} \qquad (14)$$

where $V_{\text{available}}$ is a list of size (L=255). Each cell has 1 if the index value is available in V_{MID}; $else, it\ has$ 0, as shown in Figure 4 (a). $pdf_{\text{available}}$ is the equal probability of each available value in V_{MID} matrix.

F. Value Equalization

Subsequently, the distribution of displaced values of V_{MID} matrix is corrected by rearranging equally to correct the illumination levels and the contrast of the processed images. Therefore, the cdf of $pdf_{available}(l)$ is calculated using Eq. (15), as shown in Fig. 4 (b), and equalized using the transformation function of Eq. (16).

$$cdf_{available}(l) = \sum_{l=0}^{l=L} pdf_{available}(l) \qquad (15)$$

$$V'(x,y) = cdf_{available}(V_{MID}(x,y)) \times 255 \quad (16)$$

From Fig. 4 (c), the result is a processed brightness matrix (V') that presents improved contrast and illumination properties of the original V channel (Fig. 3 (b)). Their new histograms in Fig. 4 (e) show balanced and arranged distribution of values that are better than the original histograms (Fig. 3 (c)).

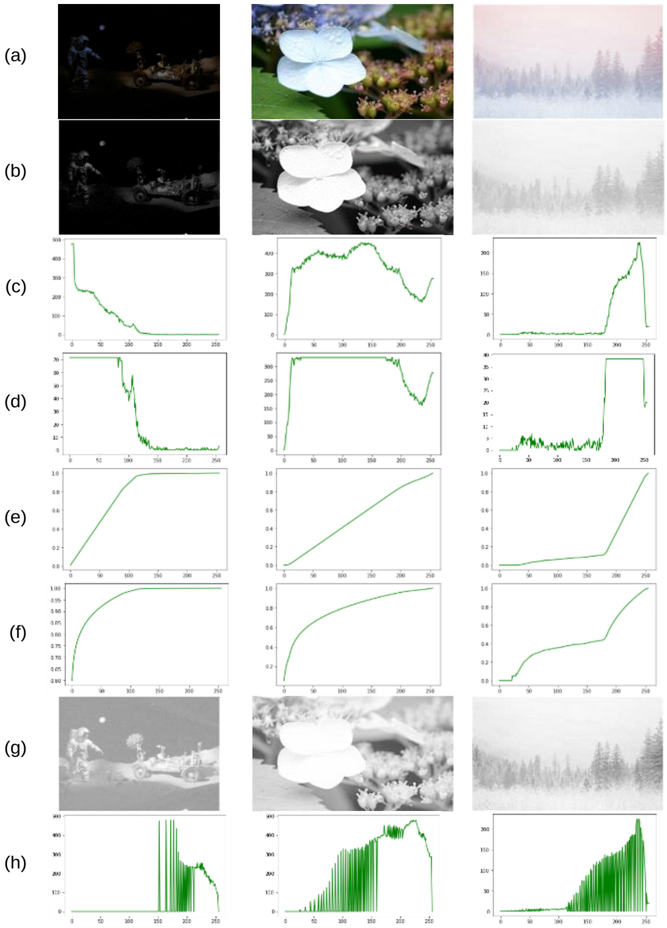

Fig. 3. (a) Original images in RGB format: dark (left), normal (middle) and overly bright (right); (b) V channel of HSV (the brightness matrix); (c) brightness matrix histogram of each image; (d) histogram of brightness matrix values; (d) clipped histogram; (e) CDF of each histogram; (f) proposed CDF (cdf') of each associated histogram; (g) new brightness matrix (V_{MID}) of each image; and (f) histogram distribution of each new brightness matrix (V_{MID}).

G. HSV Modification and Conversion into RGB

After the contrast and illumination of V' matrix have been improved in the previous stages, it is used to produce brilliant color images. V' matrix is the processed V channel, which will replace the original V channel and be recombined with the H and S channels of the original image. The new HSV' model is then returned to the RGB color space. The conversion from HSV to RGB is shown using the following formats.

$$A = V' \times S \qquad (17)$$

$$m = V' - C \qquad (18)$$

$$X = A \times (1 - \left|\left(\frac{H}{60^{\circ}}\right) mod2 - 1\right|) \qquad (19)$$

$$(r, g, b) \begin{cases} (A,X,0), & 0 \le H < 60 \\ (X,A,0), & 60 \le H < 120 \\ (0,A,X), & 120 \le H < 180 \\ (0,X,A), & 180 \le H < 240 \\ (X,0,A), & 240 \le H < 300 \\ (A,0,X), & 300 \le H, < 360 \end{cases}, \qquad (20)$$

$$R' = (r \times m) \times 255, G' = (g \times m) \times 255, B' = (b \times m) \times 255. \qquad (21)$$

where $R'G'B'$ denotes the equivalent red, green and blue channels of HSV' for each pixel in the modified image. The values of S and V' illumination-corrected channels range within (0 to 1), whilst 0º ≤ H < 360º. The results present a fine colorful image with improved illumination and contrast properties.

IV. Experiments and Results

In this section, two types of experiments are performed to evaluate the proposed method: visual and statistical experiments. A comparative analysis is also conducted with a set of well-known recent methods. In accordance with the state of the art, the bio-inspired multi-exposure (BIME) method [48], multi-scale Retinex with color restoration (MSRCR) [49], naturalness preserved enhancement (NPE) algorithm [50], simultaneous reflection and illumination estimation (SRIE) [51], multi-deviation fusion (MF) method [52], low-light image enhancement (LIME) [52] and a fusion-based enhancement method for weakly illuminated images (Dong) [53] are chosen to evaluate the performance of the proposed method.

To obtain significant results showing valid performance of each of the contributing methods, approximately 180 color images from many benchmark data sets for poor illumination and contrast challenges are used for the experiments. Specifically, the DICM data set contains **69 color** indoor and outdoor images in varying degrees of dark to high-brightness lighting conditions captured from commercial digital cameras[54]. The LIME-data data set contains **10** indoor and outdoor low-light color images[55]. The MEF data set contains **17** high-quality dark indoor and outdoor color images, including natural scene [56]. The NPE [50] data set contains **85** low-light outdoor images collected from the Internet [50]. They present outdoor natural scenes, including cloudy, daytime, daybreak, nightfall, and night-time scenes.

A. Visual Experiments

Visual experiments measure image quality based on the subjective perception of human vision. These experiments can only qualitatively assess image quality, which provide a clear idea of the image quality for humans. They are conducted on selected images from the above data sets. The most interesting cases are selected and presented in Fig. 5 to 9. The results show that all selected images are visually enhanced differently depending on the method used. In general, all images become better than original images, which is expected because the involved methods are some of the most interesting in accordance with the state of the art.

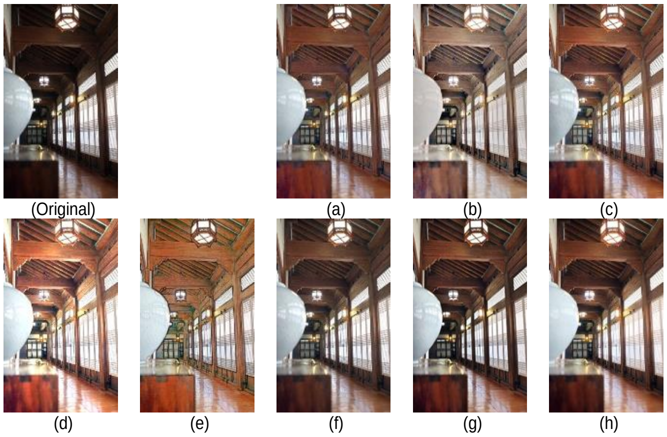

Fig. 5. Experimental results of image (59) from DICM dataset, where the original image, and its results by (a) NPE, (b) MSRCR, (c) MF, (d) LIME, (e) Dong, (f) BIME, (g) SRIE and (h) Proposed methods.

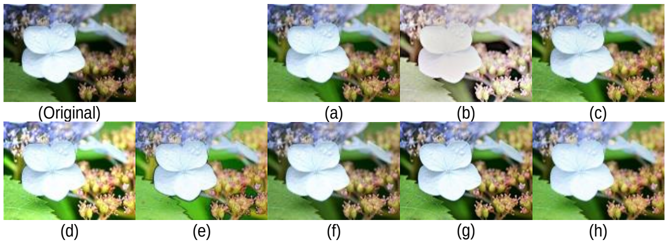

Fig. 6. Experimental results of image (50) from DICM dataset, where the original image, and its results by (a) NPE, (b) MSRCR, (c) MF, (d) LIME, (e) Dong, (f) BIME, (g) SRIE and (h) Proposed methods.

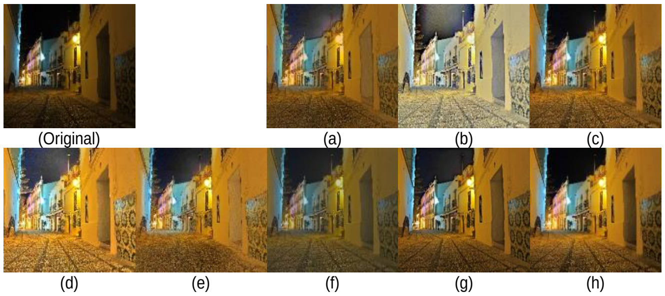

Fig. 7. Experimental results of image (5) from LIME dataset, where the original image, and its results by (a) NPE, (b) MSRCR, (c) MF, (d) LIME, (e) Dong, (f) BIME, (g) SRIE and (h) Proposed methods.

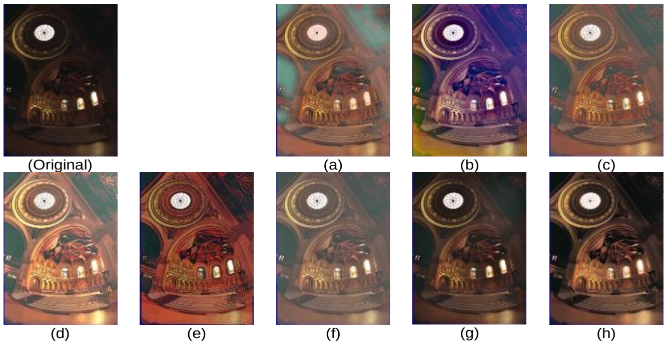

Fig. 8. Experimental results of image (Memorial) from MEF dataset, where the original image, and its results by (a) NPE, (b) MSRCR, (c) MF, (d) LIME, (e) Dong, (f) BIME, (g) SRIE and (h) Proposed methods.

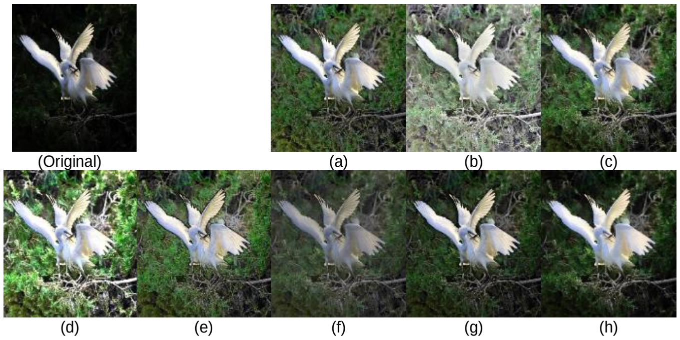

Fig. 9. Experimental results of image (birds) from NPE dataset, where the original image, and its results by (a) NPE, (b) MSRCR, (c) MF, (d) LIME, (e) Dong, (f) BIME, (g) SRIE and (h) Proposed methods.

In detail, the MSRCR [49], LIME [52] and Dong [53] methods produce images with high brightness levels. The MSRCR [49], Dong [53] and NPE [50] methods show excessive levels of enhancement, and edges appear aggressive. MSRCR [49] and LIME [52] present color fading and uneven brightness levels in some cases. The Dong [53] method produces low contrast levels caused by the effect of oil paintings on images. The BIME [48] method exhibits low brightness and contrast levels. It is the worst method in case of brightness. The SRIE [51], MF [52] and proposed methods preserve the colors of original images, but MF [52] shows faded colors in some cases. The SRIE [51] and proposed methods produce constant brightness levels with all cases of images. They preserve color effects for all involved images. In conclusion, the LIME [52] method achieves higher brightness with accepted preservation for color and details, but SIRI and the proposed method achieve higher performance in the perception of human vision.

B. Statistical Experiments

The visual experiment methodology is simple and evaluates the visual quality of images in an understandable way for humans. However, this type of assessment lacks stability and observed properties of image structures and details. In addition, visual experiments are influenced by the background, visual capability, and visual properties of images; experimental conditions; and the emotional state and motivation of observers.

To overcome the disadvantages of visual experiments, analytical statistical evaluation methods, which use objective criteria that rely on benchmark measures, are adopted. The measurement methods used in this work are mean value (MV), the standard deviation (STD) for contrast, entropy, peak signal-to-noise ratio (PSNR), structural similarity index metric (SSIM), absolute mean brightness error (AMBE) and contrast-to-noise ratio (CNR).

- **Mean** of grey values of images expresses their brightness. Larger values indicate brighter images, whereas smaller values indicate darker images.

$$Mean = \frac{1}{X\times Y}\sum_{x,y=0}^{x,y=X-1,Y-1} I(x,y) \quad (22)$$

where *X* and *Y* refer to the size of image *I*, and *I(x, y)* is the value at x, y points.

- **STD,** in greyscale values of images, measures the contrast of images. Larger values show more information and better visual properties in images

$$STD = \sqrt{\frac{\sum_{x,y=0}^{x,y=X-1,Y-1} I(x,y)-(I(x,y)-Mean)}{X\times Y}} \quad (23)$$

- **AMBE** is a common method for detecting brightness change. It evaluates the similarity between the brightness of original and processed images. It presents the absolute delta between the MVs of original and processed images. Smaller values indicate that the brightness of the processed image is closer to that of the original image.

$$AMBE = |Original_{\ Mean} - Processed_{Mean}| \quad (24)$$

- **SSIM** is popular for assessing image quality because it simulates human visual perception about the structure of images. SSIM analyses the correlations between pixels by comparing luminance, contrast and structure between original and processed images. A value closer to 1 indicates more similarity between the two images.

$$SIM(x,y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \quad (25)$$

where L is the dynamic range of the pixel values; and μ_x, μ_y are the means of x and y, respectively. σ_x^2, σ_y^2 are the variances of x and y, respectively; and σ_{xy} is the covariance of x and y.

- **CNR** simulates human perception to evaluate contrast resolution in images. It shows a visual quantitative evaluation of the detectability of defects. Smaller values are better.

$$CRN = \frac{|S_A - S_B|}{\sigma_n} \quad (26)$$

where S_A and S_B are the signal intensities (MVs) of A and B regions of interest, respectively; and σ_n is the STD of the background image noise.

- **PSNR** is a common method to measure the effect of denoising on an image. Larger values show a smaller difference between the original and processed images.

$$PSNR = 10\, log_{10}\left(\frac{255^2}{MSE}\right) \quad (27)$$

$$MSE = \frac{1}{(X \times Y)} \sum_{x,y=0}^{x,y=X-1,Y-1} (Org_{image}(x,y) - Pro_{image}(x,y))^2 \quad (28)$$

- **Entropy** is used in evaluating image quality by measuring the amount of information in images. A larger value shows more details in an image.

$$Entropy = \sum_{V=0}^{V=255} e(V) = -\sum_{V=0}^{V=255} p(V)\, log_2 p(V) (29)$$

where $p(V)$ is the probability of the grey value V in the image.

Here, the result of each measurement method could not be meaningful individually. For example, high mean and AMBE show high levels of brightness. Nonetheless, they may lead to missing information in the processed image if the accompanying STD, SSIM or PSNR values are small. Considerable difference between original and processed images and entropy indicates great effect, but they are not good with high CNR. With much side effects, excessive noise and unwanted details are produced in processed images. Therefore, all previous measurements should not be used individually to estimate the quality of output images. The relationships and interactions between all measurement values must be analyzed to evaluate performance.

Tables I to IV show the evaluation results of the involved methods. The analytical observation indicates that the SRIE [51] and proposed methods are more stable than the other methods, regardless of the type of data sets. The other methods show a large variation in their performance in accordance with the data set used. The SRIE [51] and proposed methods are the most adaptive methods for different types of images. However, the proposed method produces enhanced images that have higher brightness levels, better contrast and better preservation for color and details than the SRIE [51] method.

C. Analysis and Discussion

The objective of the conducted experiments is to evaluate the performance of the respective methods in accordance with their ability to enhance image quality by improving contrast and brightness, as well as preserving the details and color of processed images similar to the original ones. From the literature review, SRIE [51], NPE [50], MSCRR, MF [52], LIME [52], Dong [53] and BIME [48] are popular methods that deal with many challenges of low contrast and brightness. Therefore, high performance is expected using these methods to compare with the proposed method. On the basis of the results, the following conclusions are drawn:

- The **MSRCR** [49] method shows the highest levels of brightness by recording the highest mean and AMBE values. However, it destroys the contrast in many cases, which is evident because its STD values are lower than those of the original images in the DICM and NPE data sets (Tables I to IV). In addition, it shows worse SSIM and CNR results than the other methods. It also presents worse MVs of PSNR (specifically, it is the worst in the DICM data set) and the farthest entropy value of the original images. The results of SSIM, CNR, PSNR and entropy show that this method is the worst for preserving the color and natural details of processed images.

- The **LIME** [52] method has the second-highest mean and AMBE values after the MSRCR method. It increases brightness more than the methods mentioned. This correlates with the highest STD values compared with the other methods. It is one of the best methods to improve the contrast of enhanced images. Nevertheless, its SSIM, CNR and entropy are the worst after the MSRCR method, in addition to the varying PSNR values in accordance with the applied data set. This method is unstable based on the applied images, and it is one of the worst methods used to preserve the details of the processed images.

- The **Dong** [53] method shows average brightness levels by scoring average mean and AMBE values. However, this method reduces the contrast of images in many cases with STD values that are lower than those of the original images in some data sets. Moreover, it shows some of the worst results for SSIM, CNR, PSNR and entropy compared with other methods. The results indicate that the performance of this method varies in accordance with input images, and it is not good at preserving the color and natural details of processed images.

- The **BIME** [48] method shows average brightness levels by scoring average mean and AMBE values. Nonetheless, it significantly reduces the contrast of images. It shows the lowest STD values, and its STD is smaller than that of the original images in most cases. This method scores an average value for SSIM, CNR, PSNR and entropy compared with other methods. Therefore, its ability to preserve colors and details is intermediate amongst the participating methods.

- The **MF** [52] method shows average brightness with average values of mean and AMBE, but it reduces the contrast of processed images compared with that of the original ones. It shows the lowest STD in most cases. The ability of this method to preserve colors and details is intermediate but unstable amongst the involved methods by scoring varying average values for SSIM, CNR, PSNR and entropy.

- The **NPE** [50] method gives average values of mean and AMBE and average brightness levels in processed images. However, its STD values are less than those of the original images in most cases. It reduces the contrast of processed images. It scores an average value for SSIM, CNR, PSNR and entropy. Therefore, its ability to preserve colors and details is intermediate amongst the involved methods.

- The **SRIE** [51] method shows average but the lowest brightness levels compared with the involved methods by scoring the lowest mean and AMBE values in all data sets. Nevertheless, it improves the contrast of resulting images by scoring higher STD values than those of the original images in all image cases. In addition, the **SRIE** [51] method exhibits the best SSIM and CNR results in all data sets, as well as better-than-average PSNR and entropy. Therefore, it is one of the best methods to preserve colors and details of processed images.

- The **proposed** method shows average brightness levels by scoring average values in mean and AMBE. The STD shows that it is the best method to improve the contrast of outputs. The proposed method scores higher STD in two data sets and presents the best performance amongst the involved methods overall. Moreover, the proposed method shows the second-best SSIM and CNR results in all data sets, next to the SRIE [51] method. It scores the best or better-than-average PSNR values in all data sets. Therefore, it is one of the best methods to preserve colors and details of processed images. In case of entropy, it achieves the closest values to the original images, which means its results are the closest to the original images.

Based on the above observations, the performance of the methods varies between the brightness levels and the accuracy of preserving the properties of the resulting images. The LIME [52] and MSRCR [49] methods achieve higher brightness levels amongst the respective methods but fail to preserve the color and information of the original images. Whilst MSRCR performs the worst, the LIME [52] method can be accepted for human vision applications. However, it loses considerable information, which makes it inefficient for computer vision applications.

On the contrary, the performance of the remaining methods, such as SRIE [51], NPE [50], MF [52], LIME [52], Dong [53], BIME [48] and the proposed method, varies in brightness from average to better than average. Nonetheless, many of these methods reduce the contrast and fail to preserve the color and detail of the images, such as the NPE [50], MF [52], LIME [53], Dong [53] and BIME [48] methods. They show variance and over-enhancement performance for many image situations. Therefore, they can be useful in specific cases of images. However, in general, they cannot adapt to all situations of human vision and computer vision applications.

In cases of preserving image properties, such as color, contrast and detail, only the SRIE [51] and proposed methods achieve the best performance. In addition to stable performance in enhancing brightness levels, they improve contrast, produce fewer side effects and show better color and detail preservation similar to original images. SRIE [51] and the proposed method are the most suitable in computer vision applications. Nevertheless, comparison of the two methods shows that the proposed method is better at improving contrast and keeping details closer to the original images. In conclusion, the proposed method is the most adaptive and stable regardless of the type of image applied. In future work, we aim to conserve details in images with extremely varied levels to highlight all the details in the image and prevent any loss of information.

V. Conclusion

In this work, a new method for color image brightness and contrast correction based on the advantages of non-linear function in gray transformation and histogram equalization techniques is proposed. The proposed method consists of set stages: the original red, green and blue (RGB) image is converted into the HSV color space, and the V channel is used for enhancement. Next, an adaptive gamma generator is proposed to calculate gamma parameters in accordance to dark, medium, or bright image conditions. This parameter is used to propose a cumulative distribution function that produces an optimized curve for illumination values. Then, a second modified equalization is performed to evenly correct the offset of the illumination curve values based on the equal probability of the available values only. Finally, the processed V channel replaces the original V channel, and the new HSV model returns to the RGB color space. The experiments show that the proposed method significantly improves the low contrast and poor illumination of the color image while preserving the color and details of the original image. It is the most adaptive and stable method, regardless of the type of image applied, compared to other state-of-the-art methods.

A Study on Institution Improvement Plans for the National Supercomputing Joint Utilization System in South Korea

Hyungwook Shim, Myungju Ko, Yungeun Choe, Jaegyoon Hahm*
National Supercomputer Department, Korea Institute of Science and Technology Information,
Daejeon, Republic of Korea

***Abstract*—The purpose of this paper is to discover institutional gaps in the supercomputing joint utilization system that the government is actively promoting as an alternative to the problem of shortage of domestic supercomputing resources. The institutional gaps were discovered by examining the current status of laws, top-level plans, and operating guidelines related to the current joint utilization system and matching them with problems or issues that need to be resolved socially. The improvement plan for the institutional gaps was derived at a level that can be reflected in the operating guidelines of the Specialized Center and Unit Center so that the performing subject constituting the joint utilization system can directly participate and solve it. In the future, for the effective operation of the joint utilization system, we plan to promote the domestic market through the diffusion of research results and secure external technological competitiveness by reflecting the contents of institution improvement.**

Keywords*—Component; supercomputer; joint utilization system; institutional gap; national supercomputing center; specialized center

I. Introduction

Looking at major policies and technology development trends of major supercomputer countries, there is a tendency to integrate and link resources for efficient construction and utilization of computing resources. Leading countries such as XSEDE and ACCESS in the U.S., EuroHPC JU and PRACE in Europe, and Flagship 2020 strategy in Japan collect and intensively support supercomputer resources for key strategic areas at the national level, and also provide large-scale resources to various academic and industrial users as needed. In South Korea, as demand for AI-based supercomputer calculations is gradually increasing, the need and urgency for a joint utilization system for efficient use of resources has increased. Therefore, the government is making efforts to prepare a joint utilization system as an alternative to securing insufficient supercomputing resources. The joint utilization system refers to a system that is jointly utilized at the national level by linking domestic supercomputer resources, and converts from the existing governance system of a single national center to an ecosystem composed of national-specialized-unit centers. In 2021, with the designation of the 1st specialized center (7 fields, 7 institutions) and the beginning of the establishment of the joint utilization system in Korea, institutional support for smooth system establishment and non-discriminatory and fair participation of companies is essential. In particular, considering the nature of the structure of the supercomputer industry, where small and medium-sized venture companies participate and the number of experts is limited, influx of new companies and mid- to long-term development are important. Therefore, this paper analyzes the current status of the joint utilization system, support system that has been overhauled, focuses on participating organizations, discovers blank areas related to issues that are currently socially required to be resolved, and proposes institutional improvement measures [1-3].

This paper consists of a total of six sections. In the introduction of Section I, it was explained by presenting the background and necessity of the research, and the purpose. The Section II and III introduce the supercomputer joint utilization system, explain its functions and compositional system. Also, previous studies related to supercomputing joint utilization system are investigated, and academic values such as differentiation and novelty from this paper are reviewed. Section IV analyzes the current institutional status of the joint utilization system in Korea and discovers gaps. Section V analyzes the causes of the institutional vacuum and presents improvement plans. In the conclusion of Section VI, the analysis results were summarized and implications and future utilization plans were mentioned.

II. Theoretical Background

The supercomputing joint utilization system refers to a system in which the supercomputing resources installed in the domestic government, companies, research institutes, and schools in accordance with Article 17 of the (Supercomputer Act) is interlocked with joint utilization resources and used as needed at the national level. The main body of the joint utilization system is composed of a National Center, a Specialized Center, and a Unit Center according to the (Supercomputer Innovation Strategy) (referred to as Innovation Strategy). Currently, KISTI as the National Center and seven institutions, Korea Meteorological Administration, GIST (Gwangju Institute of Science and Technology) as the Specialized Center, has been selected. In the future, Specialized Centers and Unit Centers will continue to expand considering the needs of each field and computing demand. Jointly utilized resources are used for research areas where there is no Specialized Center or research that has a Specialized

Center but requires other types of resources, and there are plans to flexibly respond to various demands such as emergency demand support such as COVID-19. In the joint utilization system, resource linkage and service provision are made through the joint utilization platform. The platform closely links common resources with different resource characteristics and operating environments and improves user accessibility by providing cloud-based integrated services. Therefore, the following ripple effects can be obtained for users who use common resources [4-5].

- Establish a system that can integrate and utilize jointly utilized resources by National Center, Specialized Centers, Unit Centers to expand national supercomputing service resources and utilization base
- Improved scalability so that users can utilize resources as much as they need by integrating by applying cloud technology without being tied to physical environment of specific facilities and specific public institutions
- Improved user accessibility and convenience so that first-time users and advanced users who require various specialized languages and execution environments can use supercomputing services without restrictions and inconveniences.

III. Literature Review

Lee (2018) performed an economic analysis on the effect of joint utilization of supercomputers. A cost-benefit analysis method was used as an economic feasibility analysis method, and the economic effect was analyzed by comparing the cost required for the establishment and operation of the existing centralized system. Economic effect means cost reduction effect. Hardware, software construction and purchase costs, operating manpower and maintenance costs were selected as cost reduction factors [6]. Kim (2015) analyzed trends on supercomputer innovation policies in the manufacturing sector and drew implications. Manufacturing innovation plans of advanced manufacturing powerhouses in the United States, Japan, and Germany were analyzed to investigate the use of supercomputers in manufacturing innovation plans and the promotion trends of related organizations and projects. In order to expand the use of supercomputers in the domestic manufacturing sector, it is concluded that participation of small and medium-sized venture companies is necessary, and efforts to prepare related policies are urged [7]. Nam (2016) introduces a plan to introduce and operate a supercomputer system led by a National Center and secure self-development capabilities as a way to secure national competitiveness of supercomputers. As the main contents, it describes the demand forecast of domestic resources, development goals and strategies for the introduction of supercomputers, and analyzes the operating environment for the establishment of a supercomputer ecosystem in the long term, and presents future plans and expected effects [8]. Huh (2021) suggested legal and institutional improvements to secure technological competitiveness in the future supercomputer market. Problems were identified through analysis of relevant legal systems and ecosystem conditions, and improvements were suggested, such as strengthening the role of the government, National Centers, and Specialized Centers, supporting industries, and promoting commercialization. As for the problems with the (supercomputer law), the highest law related to supercomputers, the factors that impede the linkage between national R&D achievements and industries, and the factors that are ineffective in enforcement were analyzed with an emphasis [9].

Summarizing the content of previous studies, it can be divided into studies that analyze economic effects on the subject of joint use of supercomputers, and studies that present legal and institutional improvements or plans for supercomputers. In the case of the supercomputer joint utilization system, since it is being promoted starting with the designation of a Specialized Center in 2021, there has been no research dealing with the legal and institutional aspects yet. Although many studies on supercomputers and related laws and top-level planning units have been published, there are no studies dealing with subsystems such as operating guidelines related to the joint utilization system. In addition, this paper derives legal and institutional improvements related to the joint utilization system, so it is novel compared to previous studies. As for the improvement plan, the status of problems and issues in the domestic supercomputer industry was investigated, and through the analysis of the OS matrix with the solution plan, inventiveness was secured and academic value was enhanced in presenting the improvement plan by focusing on the institutional gaps.

IV. Joint Utilization System Institutional Status Analysis

A. Identification of Problems and Issues

Institutional problems and issues of the joint utilization system were investigated through individual interviews with supercomputer forum members, etc., and a number of problems and issues presented were prioritized in order of frequency and selected. Problems and issues including the lack of supercomputer computational resources that can be used jointly, the absence of source technology related to supercomputer manufacturing, the insignificant participation of SMEs and the lack of professional manpower due to the ecosystem centered on government-funded research institutes, schools, and large corporations has been derived

B. Institutional Support Status

The status of institutional support for the derived problems and issues was derived based on the possibility of solving problems and issues and the level of association as an alternative, with reference to the legal system related to the joint utilization system. First, as a solution to the lack of infrastructure, two alternatives can be suggested: expansion of domestic supercomputer infrastructure and utilization of overseas infrastructure. The legal basis for the expansion of domestic infrastructure can be found in Articles 11 and 17 of the (Supercomputer Act), and it is stated that the government must provide support for infrastructure expansion. Second, as an alternative to the absence of source technology, direct technology development and introduction of foreign technology can be presented as alternatives, and institutional grounds exist for the expansion of investment in R&D projects and technology exchange through international cooperation. There are two alternatives to the problem of insignificant private participation: inducing participation of private companies and direct promotion. By law, the government must provide preferential support to technology-intensive SMEs related to supercomputing and the establishment of a joint utilization system in which companies, institutions, organizations, and universities participate. Lastly, there are alternatives to the lack of professional manpower, such as fostering professional manpower, developing training programs, and utilizing overseas professional manpower. In accordance with Articles 9 and 12 of the (Supercomputer Act), the government and the National Center must establish a plan for fostering and supplying specialized manpower, and make efforts to introduce advanced technology through attracting excellent foreign manpower and international cooperation.

As a result of the current status analysis shown in Table I, it can be considered that the response to industrial issues related to the joint utilization system is institutionally prepared at a certain level or higher. However, most of the institutional support specified is centering on the government and National Centers, and there are relatively few details on Specialized Centers and Unit Centers. Therefore, it is necessary to look at the support institution for the sub-participating organizations based on the performance system of the joint utilization system.

TABLE I. INSTITUTIONAL SUPPORT STATUS ANALYSIS RESULT

Problems and issues	Alternative solution	Relevant basis(Supercomputer Act)
Lack of infrastructure	Infrastructure expansion	Articles 11 and 17 of the Act
	Utilization of overseas infrastructure	-
Absence of source technology	Core/original technology development	Articles 10 and 16 of the Act
	Introduction of overseas core/original technology	Article 19 of the Act
Lack of private participation	Encourage participation of participating private companies (provision of incentives)	Article 17 of the Act
	Nurturing private companies	Article 18 of the Act, Enforcement decree of the Act 15-2
Lack of professional manpower	Enforcement Decree Establishment of curriculum (graduate school)	Article 12 of the Act, Enforcement decree of the Act 13
	Utilization of overseas experts	Article 19 of the Act
	Education training and program development	Article 9 of the Act

C. Discover Institutional Gaps

The analysis of the current status of institutional support in the joint utilization system was conducted targeting the Specialized Centers currently. As for the analysis method, a 2 by 2 matrix analysis method was used for the function of the Specialized Centers and the support for function execution. The function of the Specialized Center targets the main functions specified in the (Supercomputer Act). The contents of the support matched the contents of the “Innovation Strategy” the top-level supercomputer plan, and the “Operation Guidelines” of the Specialized Center, the subsystem, for budget, technology, and network, which are essential factors of the joint utilization system. First, the support contents of the “Innovation Strategy” and the joint utilization system of the “Operation Guidelines” were coded as Table II. In the “Innovation Strategy”, related institution specify services including service providers and users, educational programs, data management systems, etc., and “Operation Guidelines” support costs, technologies, and domestic and international networks for service operation and management.

TABLE II. CODING RESULT

[Innovation Strategy]	[Specialized Center Operation Guidelines]
AA - Designation and development of 10 Specialized Centers for 30 years AB - Training and dispatch to Specialized Centers, provision of technical education programs(strengthening manpower capacity) AC - Operation of a joint utilization consultative body(Establishment of resource distribution standards and establishment of an operating system) AD - Provides cloud-based platform service to link common resources and improve user accessibility AE - Establishment of Data Hub - Establishment of integrated data storage and preparation of data standard system AF - Expand integrated sharing of data in connection with domestic and foreign data centers (data dam: bio, material, transportation, disaster, environment, etc.) and platforms	BA - Linked technology support BB - Resource building budget BC - Providing opportunities to participate in R&D projects BD - Training and technical exchange support BE - Operating expenses BF - Network BG - International cooperation, technology exchange, etc.

The matrix analysis results are shown in Table III. In the function of the Specialized Center for building resources, institutional support was established in all factors of budget, technology, and network. The contents of support for operation and service provision and basic adaptation research are also presented in the “Innovation Strategy” and “Operation Guidelines”. In terms of data management and operation support and manpower training, the grounds for support are meticulously prepared without institutional gaps. On the other hand, in the part related to the dissemination of research results, the budget part belongs to the realm of the institutional gap. Dissemination of research results refers to all cases in which research results related to the joint utilization system are transferred to the private sector, schools, research institutes, etc. Support for the dissemination of research results refers to technology value evaluation costs, patent-related costs, standards-related costs, etc. under the “Act on Performance Evaluation and Performance Management of National R&D Projects”. In the case of other technology fields, various government-led financial support is provided. Therefore, although the current support institution for the joint utilization system is prepared at a compliant level, it can be analyzed as a situation where the financial support system is insufficient in terms of performance utilization.

TABLE III. MATRIX ANALYSIS

Specialized Center Functions	Support content		
	Budget	Technology	Network
Building resources	BB, AA	BA	AC
Operation and service provision	BE	BA	AC, AD
Basic and applied research	BC	BA, BC	BG
Dissemination of research results	-	BG	BD, BF
Data management and operation support	BE, AE	BA, AE, AF	AD, AF
manpower training	BD AB	BD, AB	BG

V. INSTITUTIONAL IMPROVEMENT PLAN

A. Cause Analysis

In order to prepare improvement plans for the joint utilization system support institution, it is necessary to analyze the cause of the gaps. For the analysis of causes, recent domestic supercomputer-related statistical data and reports were referred to, and the following four causes were derived by comprehensively considering the influence and solution potential among various causes.

1) Low participation of private enterprises: The budget for dissemination of research achievements is targeted at institutions that have research achievements. According to the National Center statistics, the utilization rate of national supercomputers by private companies in 2022 is very low at about 3.9% of the total. Given the computational capacity of the National Center, which supports about 140 institutions for a year, the number of private companies that commercialize research results is very small, considering the number of participating private companies. The participation of SMEs in the private sector is also very small. Even at KSC (Korea Supercomputing Conference), the largest conference in Korea, the committee is mostly composed of personnel from government-funded research institutes and schools, except for some employees of large foreign companies. Even in the case of representative research achievements of National Centers, all 26 are owned by schools or government-funded research institutes. Therefore, it is difficult to efficiently execute the budget as there is no beneficiary to support the spread of performance. The reasons for the limited participation of SMEs can be attributed to the investment cost and lack of professional manpower. Since supercomputers have high initial investment costs, SMEs have limitations in building and operating their own infrastructure. This is why the National Center is currently building infrastructure and providing services to SMEs. However, participation in services provided by National Centers is also limited. It is difficult to secure supercomputer experts, who are classified as relatively high-level workers, for the use of supercomputers, and there is a burden of labor costs for the experts.

2) Limitation of small market size: The global HPC market size is about $32 billion by 2021. However, in the case of South Korea, it is less than 980 million dollars, so effective economies of scale do not apply, and it is an unstable market in which some foreign companies may monopolize due to the absence of competitive domestic companies. Even if domestic companies commercialize technology, technical competition is impossible due to the technological gap with leading companies such as Intel, AMD, and NVIDIA, and it is difficult to respond in terms of price. In cases where institutions with excellent technologies, such as domestic conglomerates and government-funded research institutes, transfer technology and try to commercialize it, the results are sold back to large corporations and government-funded research institutes.

3) Inadequate start-up support system: In the field of supercomputers, there are few achievements in commercialization technology development for the dissemination of research achievements. In the statistical data of the National Center, more than 60% of creative research (usage, as of 2022), which is in the basic source stage, is higher than research related to application, development, and commercialization for start-ups. In other words, there are few research projects and achievements in the commercialization stage where start-ups can generate sales and invest in technology development and manpower recruitment. In addition, in the case of other fields, programs such as technology exchange, financial support, and environment creation are being prepared for corporate support. However, in the case of the supercomputer field, there is no program to support the growth and development of start-up companies, and there is a shortage of dedicated departments and manpower in charge of the government.

4) Few institutions that possess source technology and transfer cases: In the case of source technology related to supercomputers, major companies in some countries, such as the United States, China, and Japan, preoccupy it. As a result of a survey on the status of patent index by country for US registered patents, in South Korea, the patent impact index was 0.05, lower than that of the US (1.06), and the market security index was 1.75, lower than the US (2.63), leaving behind a lot in both technological competitiveness and quality. The lack of source technology and the need to promote commercialization and commercialization limited to applied technology also become an economic barrier for companies. In addition, because of few cases of technology transfer and success, it makes difficult for start-ups to enter the market.

B. Suggestions for Improvement

In order to prepare an effective and efficient budget support institution for the dissemination of research results, the following institutional improvement plans are proposed.

1) Establishment of a national center performance management organization utilizing the execution system and legal functions: First, the current National Center is designated as the KISTI, and the KISTI is designated as an institution dedicated to R&D performance management and distribution according to Article 33 of the Enforcement Decree of the (National R&D Innovation Act)". Based on the (Act on Performance Evaluation and Performance Management of National R&D Projects), etc., KISTI can receive support for all or part of the expenses necessary for the operation as a dedicated agency, and the dedicated agency can receive papers and patents from a number of research institutes to promote joint utilization by registering and depositing research results. Therefore, the National Center will be able to benchmark the existing research performance utilization and management system as a dedicated agency, establish its own research performance utilization and management system, and effectively operate the organizational system and professional manpower. Even in the transfer of achievements, the KISTI, in accordance with Article 11 of the (Act on the Promotion of Technology Transfer and Commercialization), transfers technology developed in public research institutes to the private sector. Since an organization dedicated to commercialization must be established, it is possible to quickly form an organization. In addition, since the NTIS (National Science & Technology Information Service) platform, which is a performance information integration service that enables performance status, statistical data, and performance search, is established, accessibility and diversity of performance information can be increased by providing services related to this platform. Therefore, it is possible to establish efficient governance for performance utilization through functional convergence and linkage with the organization of the National Center and the dedicated agency, and through this, it will be possible to lower the entry barrier for private companies and continuously secure excellence and transfer cases.

2) Support for the whole cycle of commercialization of SMEs using the venture center: One of the ways to grow the market is to nurture companies that directly participate in the market. Although costly, it is the most effective way to rapidly nurture companies and expand the market. In South Korea, there are excellent benchmarking cases. In the case of the green technology industry, a number of start-ups and SMEs are being introduced by setting up an Environmental Venture Center in an environmental research complex composed of a number of related government departments, research and policy institutions. Economic and technical support is provided to resident companies at a relatively low cost. It is supported with full-cycle demonstration facilities for commercialization, such as inspection and certification for sales, expert mentoring for technology transfer items from public institutions related to R&D, testing and analysis, and certification, performance test. To date, the Environmental Venture Center has generated about four trillion won in economic effects and created about 9,400 jobs for 15 years.

In the field of supercomputers, it is possible to build an efficient venture center through a joint utilization system. First, companies participating in the joint utilization system can be institutionally introduced by designating them as Specialized Centers and Unit Centers. In the case of Unit Centers, they will be expanded step by step after the designation of Specialized Centers, so relevant contents can be reflected when establishing guidelines for the operation of Unit Centers. In addition, Specialized Centers and Unit Centers are supported with all expenses necessary for infrastructure construction and operation. Therefore, when a Specialized Center and a Unit Center are integrated into a venture center, it is possible to effectively reduce infrastructure construction space and common operating costs. It is possible to develop various convergence technologies by physically gathering supercomputer companies by field, and companies, not the government, can discover jobs for future with high added value. Due to the nature of supercomputers, face-to-face training and mentoring are possible even for small businesses that have difficulties in accessing and using services, so the use of services in the private sector is expected to increase significantly. However, in the case of supercomputers, research results and technology transfer items are lacking. Unlike environmental venture centers, Specialized Centers and Unit Centers should prioritize technology development and self-implementation, and induce exchange of research results between centers.

3) Establishment of unit center certification system reflecting preferential treatment for small and medium-sized enterprises: The Specialized Center is currently designated by the Ministry of Science and ICT. Currently, seven institutions in seven fields have been designated, and there are plans to continuously expand Specialized Centers for each field through the development of supercomputer-related fields in the future. However, in the case of the Unit Center, the relevant information for designation is not institutionally prepared. Unit Centers are classified and designated by sector like Specialized Centers, and operation plans such as infrastructure establishment and technology development linked to Specialized Centers must be established in the form of sub-organizations of Specialized Centers. Therefore, the budget size and payment method should be specified institutionally so that the budgetary part can be considered in the operation plan establishment stage. In addition, it is necessary to determine the appropriate size of the Unit Center through a demand survey by field so that many start-ups and small and medium-sized enterprises can participate. Also regulations to receive preferential treatment in the designation examination must be prepared. There is a need for a recovery support system to alleviate the burden of failure. Considering the market environment where the commercialization success rate of SMEs does not exceed 21%, it is necessary to prepare a safety device that can continue the benefits as a Unit Center [10].

4) Support lowering the threshold for commercialization through the introduction of the preferential purchase institution: The institution that preferentially purchases the research results of companies participating in the joint utilization system, such as the public institution preferential purchase institution, is essential for startups and SMEs to cross the threshold of commercialization. In the case of related companies in the supercomputer field, the initial threshold is even higher. Based on the supercomputers built in South Korea, the domestic market share is very low. Therefore, voluntary market entry by domestic companies should be pursued from a long-term perspective, and the government should provide sufficient time and resources for companies to grow by first raising the total purchase ratio in consideration of the characteristics of the sector.

VI. Conclusion

At the beginning of the establishment of the supercomputer joint utilization system, institutional gaps were discovered and improvement plans were drawn. In order to effectively perform the functions of the Specialized Centers constituting the joint utilization system, most of the support items are included through government laws and plans, such as the （Supercomputer Law）, “Innovation Strategy” and “Operation Guidelines”, etc. However, it was confirmed that the support system for securing a budget for the dissemination of research results was insufficient. As improvement plans for this, establishment of a National Center performance management organization using the execution system and legal functions of an institution dedicated to research achievements, support for the entire life cycle of commercialization of SMEs using venture centers, and establishment of a Unit Center certification institution that reflects preferential treatment for SMEs. Finally, support for lowering the threshold for commercialization through the introduction of a preferential purchase institution was proposed.

The government plans to designate a total of 60 Unit Centers by 2030 and prepare “Operating Guidelines” within this year. Using the results of this study, a specific support plan will be prepared so that a number of private companies can participate in the competition for designating Unit Centers, and preferential treatment for SMEs to participate will be reflected in the evaluation plan. In addition, in consultation with related ministries, the plan for the preliminary feasibility study project will be promptly promoted so that sufficient budget can be secured in advance.

Efficient Handwritten Signatures Identification using Machine Learning

Ibraheem M. Alharbi
MIS Dept., College of Business, University of Jeddah, Jeddah,
Kingdom of Saudi Arabia (KSA)

***Abstract*—Any agreement or contract between two or more parties requires at least one party to employ a signature as evidence of the other parties' identities and as a means of establishing the parties' intent. As a result, more people are curious about Signature Recognition than other biometric methods like fingerprint scanning. Utilizing both Fourier Descriptors and histogram of oriented gradients (HOG) features, this paper presents an efficient algorithms for signature recognition. The use of Local binary patterns (LBP) features in a signature verification technique has been proposed. Using morphological techniques, the signature is encapsulated within a curve that is both symmetrical and a good match. Measured by the frequency with which incorrect patterns are confirmed by a given system, false acceptance rate (FAR) provides an indication of the effectiveness and precision of the proposed system. Using a local dataset of 60 test signature patterns, this investigation found that 10% were incorrectly accepted for FAR of 0.169. Experiments are conducted on signature photos from a local dataset. Verification of signatures has previously made use of KNN classifier. KNN classifier produced higher FARs and recognition accuracies than prior techniques.**

Keywords—K-nearest neighbor; histogram of oriented gradients; local binary patterns; false acceptance rate; Fourier descriptors

I. Introduction

Identifying and authenticating individuals has developed into a crucial step in the provision of services in commercial and government institutions, and is also an important aspect of maintaining law and order. Biometric data from the individual being verified. The two Greek words for life and measurement provide the basis of the English word "biometrics" (to measure). Because of their uniqueness, the biometric features listed in [1] can be used to confirm or authenticate an individual's identity. Because the distinguishing trait in question is intrinsic to the individual being identified, biometric identification is more fool proof. As a result, it's extremely difficult to give away, swap, or steal from another person.

Physiological features biometrics and behavioural characteristics biometrics are the two most common types of biometrics identification. Fingerprinting, retinal scans, and handprint scans are all examples of physiological biometrics. Checking a person's signature or voice is examples of behavioural biometrics. Biometric systems are "automatic methods of identifying or validating the identity of an individual based on physiological or behavioural features" [2]. A biometric system can function in verification mode or identification mode, depending on the requirements of the application. An individual claims their identity, and the system checks to see if that assertion is true. In order for a claim to be considered "genuine," there must be a significant degree of similarity between the user's input and the template of the claimed identity. If not, the user's claim will be denied and they will be labelled a "fraud." When performing Identification, the biometric system compares the user's input to all of the stored templates and returns the identification of the individual whose template is most similar to the user's input [3]. The system will typically return a refuse decision, indicating that the user presenting the input is not one of the enrolled users, if the highest similarity between the input and all the templates is less than a defined minimum level. Accordingly, the ratio of matches in an identifying system is 1 to N.

The need for a reliable method to verify and authenticate individual signatures arises from the widespread use of signatures in financial, economic, and legal operations. Static and dynamic digital handwritten signature authentications are the two most used methods. One of the most common types of static is a visual comparison between two scanned signatures or between a scanned signature and an ink signature [4]. The signer's signature is captured in the form of coordinate values from the signing device, which is subsequently used for dynamic digital handwritten signature authentication. One part of signature recognition and verification is determining whether or not the signature is authentic, and the other part is determining who the signature belongs to. Image processing and feature extraction methods are utilised throughout the static signature verification process [5].

In order to determine if an input signature is real or forged, matching relies on authentication (false signatures of an individual). Two stages make up this section: Verifying a person's identification using the first-signature part's database and other identifying information. Identification: Basically the input signature image for each subject is compared with entire of the database i.e. with samples from all subjects in the database. Verification: Which entails the comparing of the input signature image to samples of the same subject's signature. Confirming a person's identity is the primary focus of this procedure.

Signature authentication or verification approach may be writer dependent or writer independent. Following this process allows for a writer-independent approach. Mean distances between authentic and forgery classes, as well as forgery and known classes, are used to calculate prior parameter distributions for the respective means. Posterior class probabilities for the two classes, authentic and forged signatures for a given author, are calculated. Next, the probabilities of each group are compared and select the group with the higher probability based on a signature that is under scrutiny [6].

In case of writer dependent technique, an individual classifier is constructed for each user using his enrolment samples. During verification, only query signature samples are analysed by the classifier [7]. The success of these systems is obviously dependent on having a large enough sample size with which to train their classifiers.

A. Objective of the Research Work

By comparing the signature to other examples, the identity of the signer is determined. Learning-based signature recognition systems necessitate a sizable training set, ideally including examples from the vast majority of the intended users. Based on the published works, it is clear that several researchers have created their own databases to test the reliability of their signature verification or identification systems. Multiple static signature databases have also been made public for study. Signatures from a variety of countries and regions, including Malaysia, Spain, China, the Netherlands, Tunisia, etc., are used to test out the methodologies suggested in the literature. However, they don't accurately reflect the diversity of Arabic signatures. Also, most Arabic signatures are written in regional scripts other than English script, hence the approaches may not produce high recognition accuracy for these signatures. That's why it was important to create a regional database of signatures for the area and develop effective algorithms for checking the offline signatures so that they can be recognised with high precision.

II. Previous Work

Using global, directional, and grid aspects of signatures, authors [8, 9] suggested a solution for an off-line signature verification and identification system. The signatures were validated and categorised using a system called a Support Vector Machine (SVM). In [10], researchers analysed two popular Tablet PCs for use in signature verification tests. Using a database of 3000 signature photos, the authors report on experimental evaluations of authentication performance. Current best practises for authenticating digital signatures are summarised in [11]. With the help of Adaptive Feature Threshold, authors [12] have presented a person-dependent off-line technique for verifying signatures (AFT). This method improves on the practise of transforming a signature's basic feature into a binary feature vector in order to increase its representational resemblance to training signatures. They employed a hybrid of spatial pyramid and equi-mass sampling grids to enhance the representation of a signature dependent on gradient direction. They employed a DWT and a graph matching technique during the classification phase. Using graph matching to compare signatures and the Euclidean distance to determine how dissimilar they are, researchers. [13] present a Cross-Validation Technique for Graph Matching based Off-Line Signature Verification (CSMOSV). In [14], authors propose using image registration to identify and authenticate off-line Persian signatures.

As for the matching, they employed Euclidean distance and DWT to extract features. The approach, however, is language specific. In [15], authors offer an offline signature verification method that uses machine learning. Directional Gradient Density characteristics have been presented for competent forgery verification. A grid-based solution employing global characteristics for offline signature verification was reported by researchers in [16].

Authors [17] describe a system that requires fewer characteristics through the use of sub-pattern analysis, which in turn results in faster responses in real-time situations. A multilayer weighted fuzzy classifier that fuses match scores via selection priority has been developed to fully leverage the potential of two sets of characteristics. Multiple features for biometric recognition systems were proposed by researchers in [18]. Signature feature extraction, which takes in data from twelve various angles, was proposed using Rotated Complex Wavelet Filters (RCWF) and Dual Tree Complex Wavelet transform (DTCWT). In [19], authors proposed the issue of handwriting biometrics and presented a method for validating handwritten signatures with an ANN. In [20], researchers offer a scale- and rotation-invariant method for signature recognition based on the extraction of invariant rotation invariant texture features (sub-uniform local binary patterns) from each of an image's 12 blocks. Verification makes use of DCT coefficients. In [21], the state-of-the-art of offline signature recognition using Computer Vision is outlined. The authors go on some of the latest developments and areas for further study, including the creation of synthetic signatures, temporal drifting, identifying forgers and impostors, and dealing with scenarios involving more than one language. The Support Local Binary Pattern (SLBP) characteristics were proposed by authors in [22] for use in offline signature verification. Several writers use LBP variants in the context of signature verification.

To quickly and accurately verify signatures with minimal effort, authors demonstrate a technique that she has developed. For feature extraction, the Discrete Wavelet Transform (DWT) with Haar wavelets is primarily studied, both for global features and grid features, in [23]. Offline verification of signatures using a small number of basic geometric features was presented by authors in [24], the features Area, Euler's Number, Eccentricity, Standard deviation, Centroid, Skewness, Kurtosis, and orientation are employed. The artificial Immune Recognition System (AIRS) and ANN employed in the verification step are supported by a novel offline signature verification technique presented by researchers in [25].

From the reviewed literature, it is clear that many different approaches have been proposed for signature verification, and that experiments on both local datasets and standard datasets, such as MCYT have been used to provide verification results. It is important to note that many of the techniques described are language dependent, meaning that their effectiveness is limited to signatures written in those languages. Recognizing that offline signature verification is a challenging problem with room for further investigation, we have proposed the development of efficient verification systems that improve performance for signatures written in both local languages and other languages defined in a standard database of signature images [26].

It is well-documented that various feature extraction strategies have been developed for author-independent signature verification. Using a combination of multiple feature extraction, dichotomy transformation, and boosting feature selection, authors [27] present a writer-independent method. They used feature extraction methods that worked at various scales before applying the Dichotomy Transformation, which turned the problem into a two-class one. Finally, boosted feature selection is used to narrow down the training set to the most important features.

A writer-independent method for authenticating handwritten signatures was proposed by researchers in [28]. The primary segments' curvature was used to generate graphometric feature sets, and this was done virtually using Bezier curves. The robustness against forgeries was bolstered by employing an ensemble of classifiers.

Using the dichotomy transformation and an SVM writer-independent classifier, authors in [29] explored the usage of these deep convolution neural network (CNN) features for writer-independent offline signature verification. Experimental results on the Brazilian and GPDS datasets demonstrated that the proposed strategy outperformed its competitors [30-31].

III. The Proposed Work

If a separate model is trained for each user, the system is more robust in signature verification. Author-specific signature validations are more precise. During the training phase, authentic signatures from a given topic are considered positive examples, whereas signatures from other users are considered negative examples. Each user has their own binary classifier that they've been training. As the number of participants in the study grows, the complexity and cost of maintaining the system rises in tandem. Writer-independent signature verification techniques, on the other hand, can be used to categorise the signatures of any user in the dataset. When training a model in this setting, it is done so with all of the subjects combined into a single one. Offline and online automatic signature verification systems are available, depending on the preference of the author. Both cases involve training a classifier, in this case a supervised classifier, to verify signatures using a small subset of data drawn from a more complicated distribution than the whole. The classifier is taught using a dataset of authentic signatures that is large enough to be representative of all of the valid users that have registered for the verification service.

This paper proposes a method that allows writers to be creative while remaining untethered to any one particular platform. Extracting features involves estimating a continuous curve that best matches the signature based on Identification utilising Fourier Descriptors (FD). A closed boundary is drawn around the entire signature image, and then FDs are calculated as features of the boundary. KNN classifiers take these features as input and use them to determine whether or not a signature belongs to a certain person based on similarities between the input features and the features already stored in the database. Fig. 1 shows a general block diagram of the proposed method. The details of the method will be shown in the next subsections.

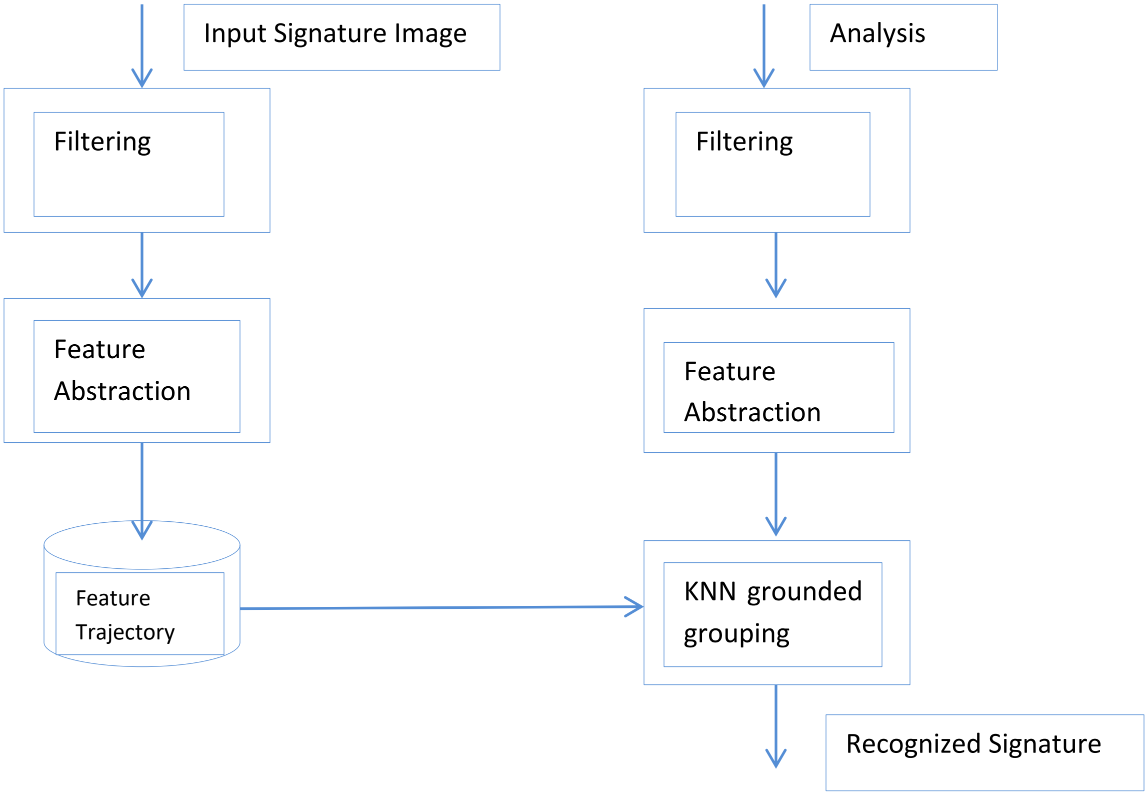

Fig. 1. The proposed block diagram.

A. Filtering

Some examples of pre-processing operations include noise reduction, binarization, rotation normalisation, resizing, and thinning. Scanning can create grey-scale signatures, although these may have unwanted extra dots. In order to get rid of the extraneous dots, median filters are applied to the gathered signature image (salt and pepper noise). Processing a grey-scale or colour image is more time-consuming than a binary one. The image is typically depicted in monochrome.

Pixels minimization is based on thresholding. Otsu's binarization strategy is suggested for use [31]. A signature's angular shifts over time are mitigated by rotation. The axes of inertia of all signatures are arranged horizontally. One approach to alignment involves finding the border of the signature with an edge detector, then thinning (or skeletonizing) it, applying the Radon transform, and determining the counter clockwise rotation angle. The signature's crookedness can be fixed by turning it around in a clockwise direction.

Signatures with a similar form but vastly different sizes have a low similarity score. This is because of the normalisation effect, which nullifies this. All normalised signatures provide comparison between reference (first-phase generated) and test samples (input signature picture classified as authentic or counterfeit). A bounding box is applied to the signature in order to normalise its proportions by erasing the surrounding space [32], [33].

The size of normalised images varies widely. Resolutions ranging from 40x40 to 200x300 were selected at random by the researchers. The width-to-height ratio (aspect ratio) is taken into account throughout the resizing process. The trademark image is reduced down to a single pixel in thickness. The operation remembers nothing beyond the bare minimum of the signature, even though this is by no means optional. It lessens the signature image should first have any unnecessary pixels removed before feature extraction can begin. The preliminary analysis is depicted in Fig. 2.

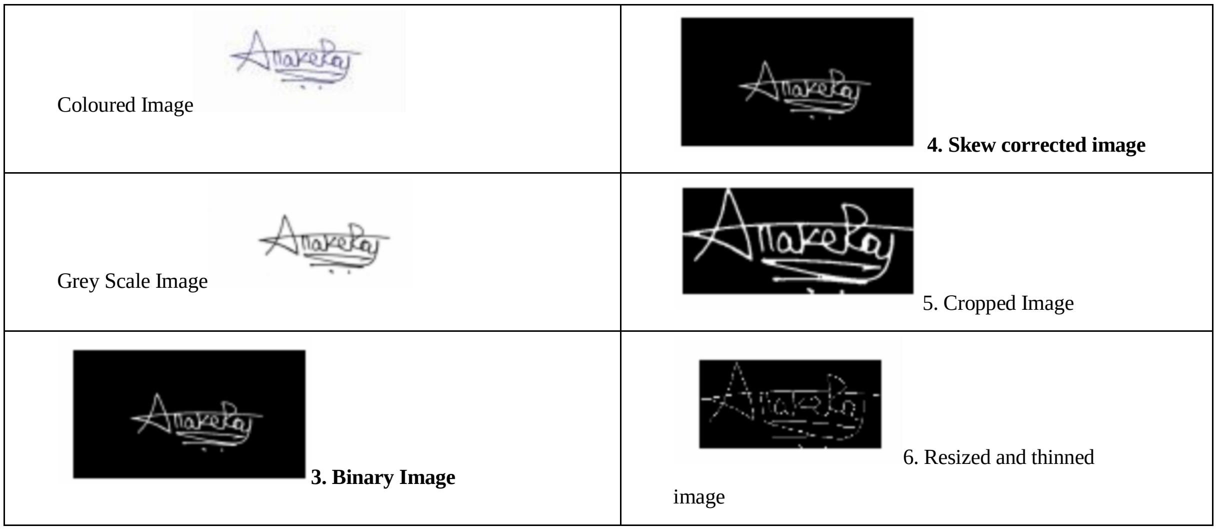

Fig. 2. Pre-processing of offline signature images.

B. Feature Abstraction

Shape analysis makes extensive use of Fourier Descriptors (FDs). Fourier descriptors of a shape are the coefficients of the Fourier transformation. The form of the object is reflected in these characterizations, which are expressed in terms of frequency. To begin, you'll need the N points that make up a region's boundary by sampling from the N pixels that make up the boundary. Just follow the perimeter around in a counter clockwise direction to get the job done. In the complex plane, the ordinate represents the imaginary axis and the abscissa represents the real axis, as seen in Fig. 3. Every point on the outline of the object has an x-coordinate pair of the form (Ak, Bk), where, 0 < k ≤ N-1.

The boundary is completely described by a set of coordinates. Coordinate series can then be used to describe the contour.

$$P(K) = [A(k), B(k)], \text{ for k=0, 1, 2…..N-1} \quad (1)$$

Where, $P(k) = A(k) + jB(k)$

The DFT of P(K) is given as:

$$X(u) = \frac{1}{N}\sum_{k=0}^{N-1} \quad P(k)e^{\frac{-j2\mu ku}{N}} \quad \text{for K= 0,1,2,….N-1} \quad (2)$$

The transform typically produces a large number of coefficients, but typically only a small subset of those coefficients are necessary to represent the essential properties of the shape. In this way, the FD's normalised magnitude can remove dependence on the size of the shape being examined. Information regarding the shape's finer intricacies can be found in the high frequency descriptors, while details about the shape's global or overall characteristics can be found in the low frequency descriptors. The size of the Fourier descriptors for these purposes must be increased accordingly.

Indexing forms have been drastically cut down. Since there are so many possible words, a figure out of the number of FD should be determined. Due to its position-only dependence, the DC component is useless for characterising shape and is therefore omitted. To normalise the scale, the second magnitude value is divided by each of the other descriptors' magnitude values.

In order to implement FD, the signature image will need to undergo a boundary tracing. Optimal FD for signature shape recognition are found through trial and error. Since a signature may include more than one part, we often encompass the whole thing within a closed curve that best represents it. The enclosed, closed curve is generated using morphological processes. The resulting curve is successfully computing FDs for form recognition, as they are signature-specific. Fig. 3 shows several example contour drawings.

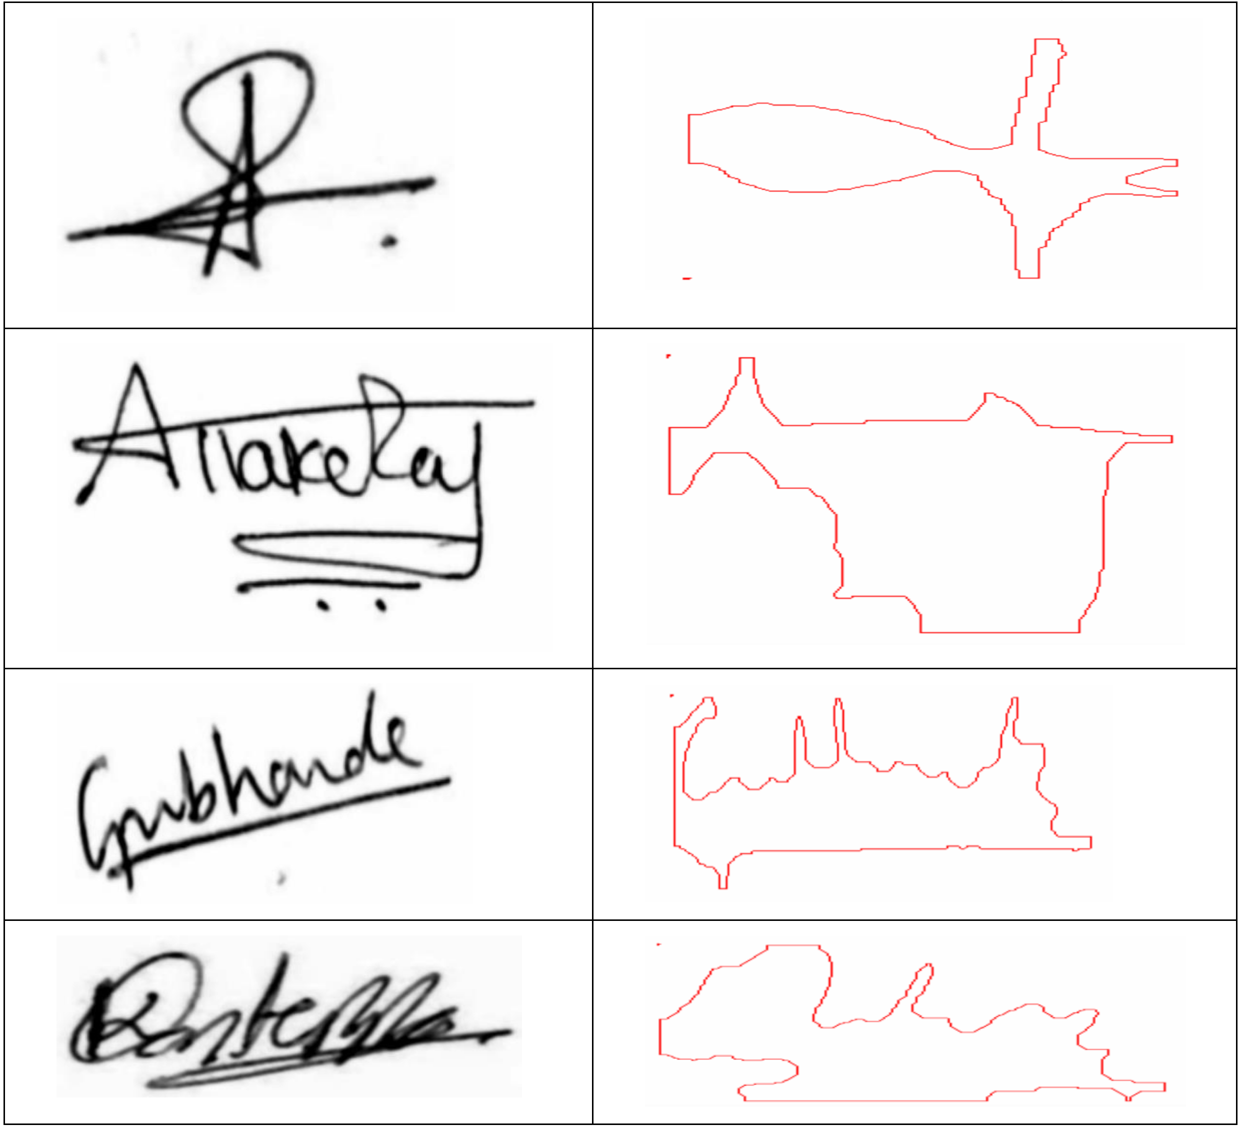

Fig. 3. Sample signature images and their enclosing curves.

C. Recognition

One common non-parametric classifier is the K-Nearest Neighbour (KNN) classifier. Classifier that uses the frequency of an unknown pattern's neighbours to estimate its posterior probability. When compared to other supervised statistical pattern recognition approaches, the KNN rule produces consistently good performance while making no a priori assumptions about the distributions from which the training examples are obtained.

To test FD's usefulness as feature vectors for signature image recognition, the KNN classifier has been selected. To do this, KNN classifier is used to compare the array of templates for the target signature to the arrays of all the other signatures in the database, with the goal of appropriately assigning the signature to a specific signature in the database based on the minimum distance attained. Specifically, the Euclidean distance is used for the calculation.

Following is a description of how to calculate the K-nearest neighbours.

Find the K value, which corresponds to the number of nearest neighbours. In most cases, an odd number (such as 1, 3, 5, etc.) is selected for K.

In order to do this, the distance between the query instance and all of the training samples is computed. A distance criterion, such as the Euclidean distance, can be used to calculate the distance between two points.

Find the closest neighbours by sorting the distances from closest to farthest.

Collect the neighbourhood's classification or tag. In most cases, labels are merely connected to the training sets.

In this method, the prediction value (label) of the query instance is determined by taking the simple majority of the category of the nearest neighbours.

IV. RESULT AND DISCUSSION

The goal here is to evaluate and contrast how various methods of approaching the problem fare. Method of identifying signatures is proposed. Ten participants from various occupations were selected at random. Variations, if any, in signatures were recorded by collecting them on white A4 paper at various intervals. Each participant signed 16 consent forms. A flatbed scanner is used to scan the signature pages at 300 dpi in grey-scale, and then a software is used to clip out each signer.

Profile work can be done in both the horizontal and vertical planes. From a total of 16, only 10 signatures were used for training and the remaining six were used for testing. This meant that there were 100 signatures in the training set and 60 in the test set. Training samples had 64-dimensional feature descriptors (FDs) generated for them and labelled with 10 topic labels for every 100 features.

Dimensions, each of which is a 64-dimensional vector of FDs. Label-free 64-dimensional FDs were calculated for each of the test samples. Using the generated FDs as features to describe the signature images, the training and test vectors were fed into a KNN classifier. To keep track of which feature vector xr from the signature picture corresponds to which reference signature Sr, a training phase is employed, when the system acquires its foundational knowledge. In recognition mode, the picture of the suspect signature Sq is displayed to the system, and the feature vector xq is fed into the KNN module alongside the reference set xr of signatures from users who have opted into the knowledge base.

In both cases, the outcomes are enhanced when K=1 is used. Using the MCYT database photos, the suggested technique performs better at K=1 than it does with images taken from the local dataset. The incorrect classification may be traced back to the fact that the enclosing boundary for that signature instance was different from the samples used for the rest of the image, which meant that the pre-processed image had gaps that weren't filled properly.

The classifier results are presented in Table I. The comparison of these subjects performance with different values of KNN classifier is plotted in Fig. 4.

TABLE I. RECOGNITION RESULTS USING KNN CLASSIFIER

Subjects	**No. of assessment**	**Recognition Local Database**		**MCYT Recognition**	
		K=1	**K=3**	**K=1**	**K=3**
1	10/6	6	6	6	5
2	10/6	6	5	5	6
3	10/6	5	6	6	5
4	10/6	6	6	5	5
5	10/6	5	5	5	5
6	10/6	5	4	5	6
7	10/6	4	2	4	5
8	10/6	5	4	5	5
9	10/6	4	5	6	5
10	10/6	6	6	6	6
Recognition accuracy in %		88.35	82.35	89.61	86.62

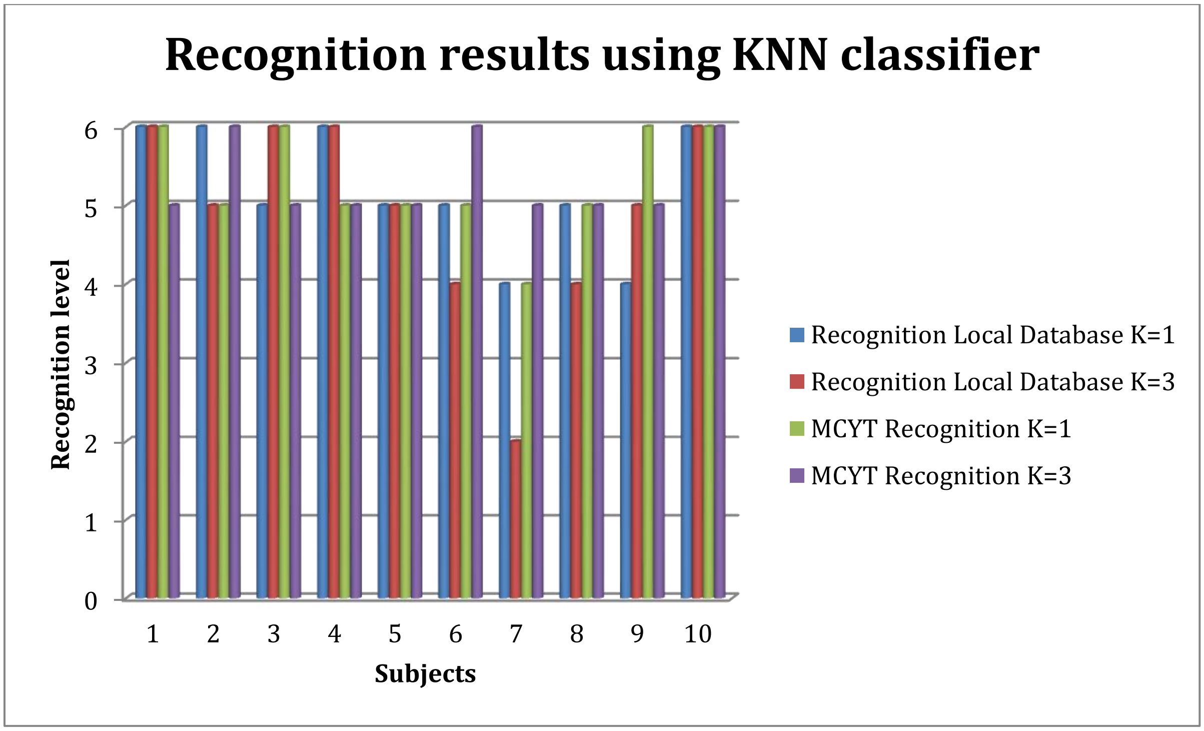

Fig. 4. Recognition results comparison using KNN classifier.

Form this comparison plot, we can conclude that KNN classifier with K=1 performs better and accuracy improved.

It is possible for a biometric security system to accept an access attempt from an unauthorised user; this possibility is quantified by the false acceptance rate (FAR). The false acceptance rate (FAR) of a system is sometimes described in terms of the fraction of identification efforts that result in a false positive.

$$false\ acceptance\ rate\ (FAR) = \frac{number\ of\ false\ acceptence}{number\ of\ identification\ attempts} \tag{3}$$

The accuracy and FAR for different data-set and for different value of K is presented and compared in Table II.

TABLE II. ACCURACY AND FAR VALUE OF CLASSIFIER

Data-set	Classifier	Accuracy	FAR
Local Data-set	KNN for K=1	88.35	0.1672
	KNN for K=3	82.35	0.2187
MCYT Data-set	KNN for K=1	89.61	0.1772
	KNN for K=3	86.62	0.2192

From this Table II, we can conclude that MCYT dataset and KNN classifier with K=1 perform best for signature identification.

V. CONCLUSION AND FUTURE SCOPE

A. Conclusion

The writer's characteristic patterns of behaviour during the signature-making process are retrieved as distinct features and then saved and compared in a Signature Recognition system. While signature verification seeks to confirm or reject a particular sample, signature recognition seeks to identify the author of that sample. Through the use of Fourier Descriptors and HOG features, we have presented efficient algorithms for signature recognition. Using LBP characteristics, a signature verification technique has been presented. An effective method for signature identification is given in this study. Features are extracted using FDs, and recognition is accomplished with KNN. The acquired findings validate the usefulness of the proposed method. In order to proceed with the recognition process, authentication must first take place. However, we found that there is a substantial class overlap in authentication when using the proposed technique, particularly between the confined boundaries of authentic signatures and forged ones are often confused. The challenge is deciding what level of confidence to assign to the recognised signature. Accuracy and false alarm rate (FAR) comparisons are shown with the experimental results. Functioning Area Ratio (FAR) is a tool for gauging and assessing the effectiveness reliability of a suggested system by counting the number of times incorrect patterns were confirmed using that system. Ten incorrectly accepted patterns out of 60 in the test signature dataset resulted in a FAR of 0.1672 and an accuracy of 88.35% for K=1.

B. Future Work

FDs and HOG characteristics, which are used in the signature identification method, broadened to include signature authentication. Signature images written in different Arabic and non-Arabic scripts can be studied using the methods provided in this experimental results have validated the effectiveness of the proposed system. While each of the proposed features may improve performance individually, they can be coupled for even greater gains. The performance can be enhanced by using an ensemble of classifiers.

***Abstract*—Cloud systems by virtue characterize ultimate resource utilization with ever evolving user requirements facilitating adaptivity. With a scope of enhancing the QoS needs of user applications, numerous factors are considered fortunning among which Task scheduling promises to grab focus. The Task Scheduling mechanism ascertains improvement by distributing the subtasks to specific set of resources pertaining to prevailing Quality models. The work emphasizes the need for effective task scheduling and optimizing resource allocation by modelling a modified AHP (Analytical Hierarchy Process) driven approach. The proposed method guarantees the functionality in two phases pertaining to Task ranking and pipelined with Optimized scheduling algorithms resulting in maximization of resource utilization. The former phase of task ranking is aided by improved AHP with substantial usage of fuzzy clustering followed by an enhanced CUCMCA (Chimp Updated and Cauchy Mutated Coot Algorithm) algorithm for optimal resource allocation of cloud applications. The contributed model promises leveraged performance of 32% for memory usage, 33.5% for execution time, 29% for makespan and 18% for communication cost over pre-existing conventional models considered.**

Keywords—Task scheduling; AHP; TS; QoS; optimization; CUCMCA

NOMENCLATURE

Abbreviation	Description
QoS	Quality of Service.
RM	Resource management.
CESS	Cross-Entropy based stochastic scheduling.
OP-MLB	Online VM Prediction based Multi-objective Load Balancing.
MESA	Migration enabled scheduling algorithm.
MINLP	Mixed integer non-linear programming.
LCS	Learning classifier systems.
SLA	Service level agreement.
VM	Virtual machine.
HASRA	Hotspot aware server relocation algorithm.
PM	Physical machine.
HAWDA	Hotspot adaptive workload deployment algorithm.
CSO	Cat swarm optimization.
RMFW	Resource Management Framework for multiple online Scientific workflows.
HGCSBAT	Hybrid cat swarm bat algorithm.
TS	Task scheduling.

I. INTRODUCTION

Cloud computing is a flexible strategy for exchanging distributed services and resources with the user wherever and anytime they require [1]. Because of its scalable user pool of services and resources, cloud computing has become more popular in recent years. This is because it allows users to freely control their consumption and only pay for the cloud resources they actually utilize [10] [28]. Google Compute Engine, Rackspace Cloud, and Amazon EC2 are just a few of the commercial cloud computing systems that have recently entered the market [2] [15]. Moreover, for hosting and delivering software solutions for many industrial applications, cloud computing has established itself as a dependable, affordable, and scalable service option [14] [12]. Still, a cloud must have sufficient capacity to meet peak user demand in order to uphold user expectations for QoS [19] [16].

Resource usage, server power consumption, and storage all play significant roles in the cloud environment, making resource management essential. While provisioning and allocating cloud resources, availability was frequently used as the determining factor without considering the other essential factors like resource utilization or the server's thermal properties [9]. A cloud system's ability to manage its resources autonomously and adaptively based on the workload changes is known as autonomous RM [20]. Elastic resource management encompasses a wide range of processes, including balanced virtual machine and application scheduling, server over/under-load control utilizing VM migration, etc. [3] [17]. One or more physical machine resources, including CPU, memory, I/O, and network bandwidth, may be overloaded due to the increased load of virtual machine operations [5] [8].

The scheduling solution was optimized in terms of each metric specified in the QoS model using a QoS-driven CESS method [4]. It has been suggested to use an OP-MLB system, which combines a number of algorithms that cooperate to provide effective resource management for cloud environments [6] [7]. With more effective storage and V/F scaling improvement, the EARU model significantly reduces LLC disappointments and thus more effectively utilizes asset. In terms of CPU utilization, preparation time, and energy output, it also achieves preferred execution to the board's current asset management plan [11]. Greedy method named MESA is recommended due to the high computing complexity of addressing the MINLP problem [18] in order to arrive at the best solution [13]. Also, advanced metaheuristic models are in need to proceed with optimal scheduling process.

This paper introduces a new optimization assisted task scheduling, and the main contributions are as follows:

- Initially, modified AHP process is introduced for ranking the task.
- A hybrid optimization model, namely, CUCMCA method for optimal scheduling of task with appropriate allocation of resources to execute the task.
- The proposed method is implemented using CloudSim simulator.

The work progresses initiating with intense literature review in Section II paving path for improvisation issues addressed with modified AHP based task ranking and hybrid optimal resource allocation provided in Section III followed by proposed CUCMCA Algorithm in Section IV formulates results and discussions in Section V Section VI contributes to conclusion of work with a wide overview of work.

II. Related Work

Several Researchers have contributed innumerable solutions addressing issues of scheduling and resource allocation. Despite, leaving few coins unturned that are addressed in our work with enhancements improvising performance.

In 2020, Mahdi Abbasi et al. [1] presented two approaches, XCS and BCM-XCS, depending on XCS - LCS, to manage the network's edge power consumption and lessen workload delay. The outcomes of this tests show that BCM-XCS is superior to the standard XCS-based approach. The workloads were distributed using the suggested approaches in a way that both the communication and processing delay among cloud and fog nodes were kept to a minimum. Additionally, the suggested approaches can recharge the reusable batteries utilized at the network's edge 18% faster than the existing technique.

In 2020, Yunliang Chen et al. [2] suggested a detailed QoS model to evaluate the performance level of data center clouds. To improve the cumulative QoS and sojourn time of all activities, an enhanced CESS algorithm was created. According to experimental findings, this approach outperforms the baseline algorithm in terms of accumulative QoS as well as sojourn duration by up to 56.1% and 25.4%, correspondingly. The algorithm's duration only increases linearly as more Cloud data centres and workloads are added. This technique constantly develops scheduling solutions with acceptable QoS without compromising sojourn time when the arrival rate as well as service rate ratio are kept constant.

In 2022, M. Hasan Jamal et al. [6] suggested a HAWDA and HASRA depending on thermal profiling considering outlet temperature detection. In order to reduce the peak output temperatures, HAWDA distributed workload on servers in a thermally efficient manner, while HASRA optimized server positioning in thermal hotspot areas. To evaluate the effectiveness of HAWDA against the TASA and GRANITE methods, performance comparison is done. Results showed that HAWDA, which reduces peak outlet temperature, achieved average peak server utilization comparable to GRANITE as well as TASA without adding additional load to the cooling system, with or without server relocation.

In 2022, M. Hasan Jamal et al. [6] suggested a HAWDA and HASRA depending on thermal profiling considering outlet temperature detection. In order to reduce the peak output temperatures, HAWDA distributed workload on servers in a thermally efficient manner, while HASRA optimized server positioning in thermal hotspot areas. To evaluate the effectiveness of HAWDA against the TASA and GRANITE methods, performance comparison is done. Results showed that HAWDA, which reduces peak outlet temperature, achieved average peak server utilization comparable to GRANITE as well as TASA without adding additional load to the cooling system, with or without server relocation.

In 2020, Ali Asghari et al. [7] developed a new architecture made up of many cooperating agents that took into account all aspects of TS and resource provisioning and managed the QoS offered to users. The integrated model that was suggested included all processes for TS and resource provisioning, and its many components help with managing user applications and making better use of cloud resources. This framework performs effectively with concurrent dependent activities, which have a challenging scheduling procedure due to the dependency of their subtasks.

In 2021, A. M. Senthil Kumar et al. [8] suggested a new task allocation method employing BAT and CSO method. The BAT algorithm aids the CSO algorithm in overcoming a pre convergence problem. The suggested HGCSBAT algorithm's performance was assessed and contrasted with that of the well-known CSO & BAT methods. In regards to availability & throughput, HGCSBAT performs better than that of the BAT, Cat Swarm Optimization, & Genetic algorithms. Traditional work scheduling algorithms features and limitations are given in Table I.

TABLE I. FEATURES AND LIMITATIONS OF TRADITIONAL TASK SCHEDULING ALGORITHMS

Author [citation]	**Methodology**	**Features**	**Limitations**
Mahdi Abbasi	XCS and BCM-XCS	Processing delay gets minimized	Workload latency is increased
Yunliang Chen	CESS method	Minimize waiting time	QoS is need to be upgraded for responsibilityexecution
Deepika Saxena	OP-MLB Method	Less power Consumption	Need for cloud data centre's performanceimprovement
Uma Tadakamalla	FogQN-AC	optimized cost average response time	Unplanned resources demand
Lei Yu	Stochastic Load Balancing approach	Migration cost is minimized	It is crucial to evaluate how different workload distributions affect load balancing performance.
M. Hasan Jamal	HAWDA and HASRA	Low memory usage	Fairer resource allocation needs a moreaccurate approach.
Ali Asghari	RMFW method	Reduced resource utilization	Higher computation cost
A. M. Senthil Kumar	HGCSBAT	Increased throughputand availability	Needs to consider balancing problem

In 2023 K.Pradeep, Sharma, and Jishnu[29] proposed an intense review on Task scheduling parameters which shed light on various strategies that make way for efficient scheduling with fault tolerant approaches in Fog computing. Their work emphasizes on tuning QoS parameters for improved results.

III. MODIFIED AHP BASED TASK RANKING AND HYBRID OPTIMAL SCHEDULING WITH APPROPRIATE RESOURCE ALLOCATION

Fig. 1 depicts the scenarios of Task Scheduling where user requests assemble at various virtual machines pertaining to a physical machine. These VMs promise improved performance by scheduling the tasks using our proposed approach. Scheduling of Tasks is performed in two phases i.e., Task ranking using FCM clustering followed by CUCMCA optimization for enhanced results.

A. System Model

Considering a data center with M servers include servers $A \in \{A_1, A_2, ..., A_M\}$, here, various VM types are purchased by Q users for executing the applications on U VM's includes $vm \in \{vm_1, vm_2, ..., vm_U\}$. Assume application R_Q pertaining to Q^{th} number of users depicted as $\{Tsk_1, Tsk_2, ..., Tsk_Z\} \in R_Q$, here Tsk_z represents the application task. The tasks are scheduled according to their resource requirements, which chooses the best VM for i^{th} task (Tsk_i^{res}) execution, where res defines resources such as memory, CPU, etc. as well as $vm_A^{res}, vm_Q^{res}, vm_L^{res}, vm_{XL}^{res}$ were small, medium, large as well as extra-large VM sets. The number of VM types available at a specific data center can be expanded. If need for resources of i^{th} task (Tsk_i^{res}) is equal or lesser to capacity of resource of vm_A, then smaller VM types were given to it. The proposed workload scheduling and resource management is progressed with two different steps:

1) *Task ranking:* This phase handles the process for ranking the tasks as per their priorities by first identifying priorities and generating Task queues pertaining to priority groups.

2) *Optimal scheduling:* Optimal scheduling phase deals with the assignment of corresponding resources according to the constraints resulting in better performance.

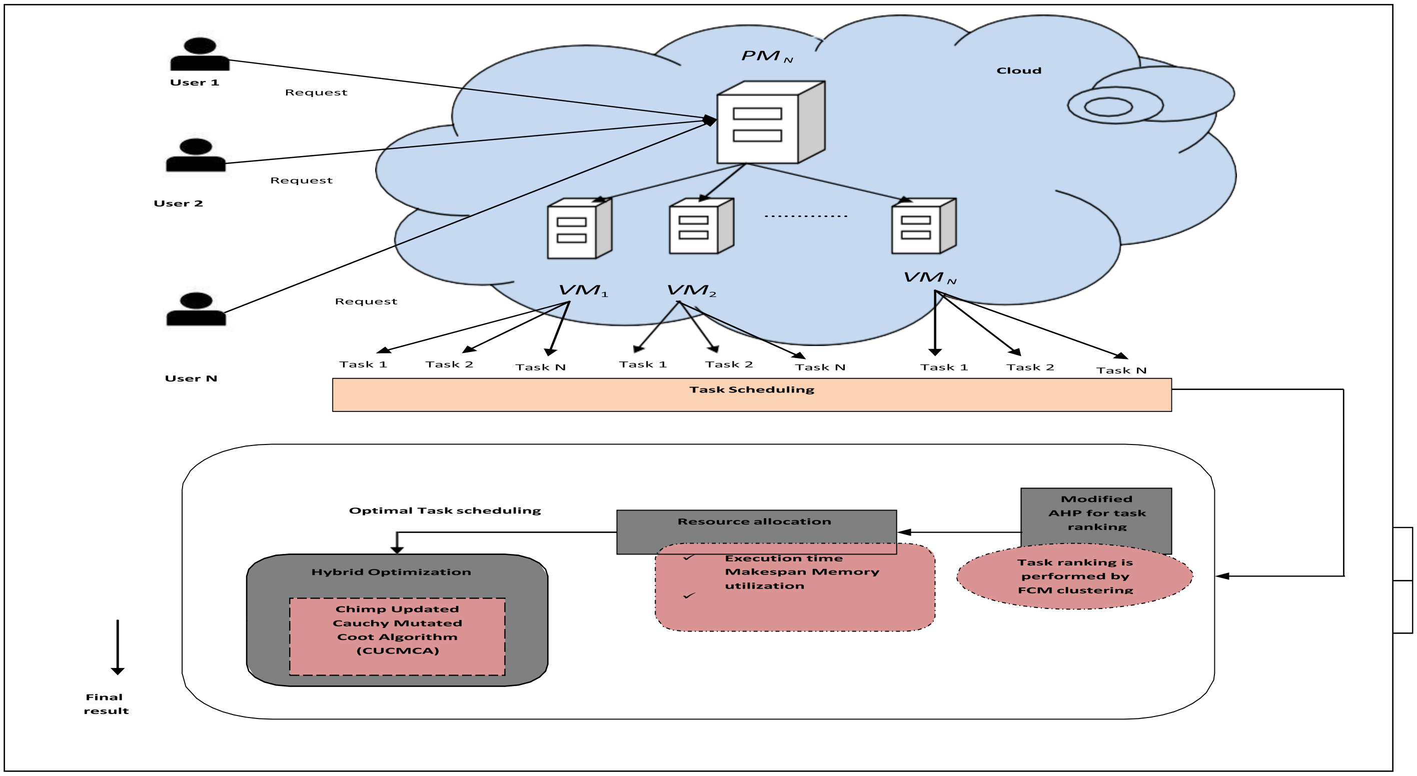

Fig. 1. Task scheduling in proposed approach.

B. *Task Ranking*

This is the first stage, where the ranking of task was done by using modified AHP (Analytical Hierarchy Process). Conventional AHP steps for ranking purpose are as follows:

- Implement the Saaty preference table [23]. Given below is Saaty preference table which offers point scale including descriptors (Table II).

TABLE II. SAATY TABLE

Points	Descriptor
1	Conditions were equally important
3	First condition is slightly more significant than second condition
5	First condition is rather more significant than second condition.
7	Obviously, the first condition is more significant than the second one.
9	The first condition is unquestionably more significant than the

- Afterwards each column summation and each column normalization and weighted sum is computed [24].
- Based on the Saaty preference table, AHP ranking is performed.

According to recommended concept, modified AHP process is followed for ranking purpose. Modified AHP steps are as follows:

- Instead of using the Saaty preference table, in modified AHP, FCM (Fuzzy c-Means Clustering) is followed on the basis of 1-9 clustering for implementing the table. A data collection is divided into N clusters using the FCM data clustering method, with each cluster having some of the data points in the dataset.
- Based on the FCM, AHP ranking is performed for task scheduling. Modified AHP based ranking is shown in Fig. 2.

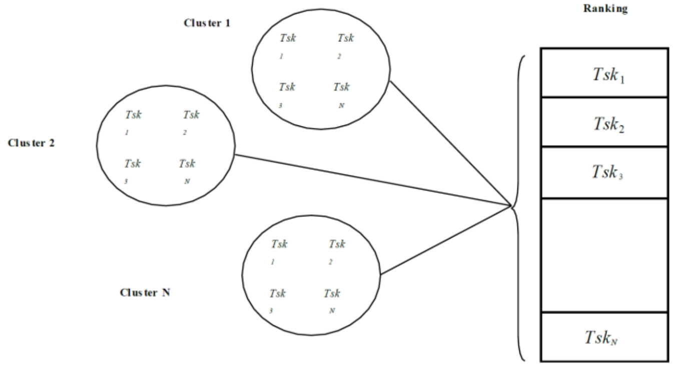

Fig. 2. Modified AHP based ranking paradigm.

C. *Optimal Task Scheduling and Resource Management*

In this step, the process of optimal scheduling is done by selecting the optimal PM and VM to execute the tasks. During this process, certain constraints are evaluated to ensure the scheduling in a precise manner. Also, the constrains involve in the assignment of corresponding resources ∇ to execute the tasks involved.

Constraints involved in this optimal scheduling process are as follows:

- Execution time
- Make span
- Memory utilization
- Communication cost

Optimal assignment of PM and VM for task scheduling: In this stage, optimal assignment of PM and VM for task scheduling is done by hybrid optimization combines Coot and Chimp optimization algorithms which is detailed in upcoming section. The factors used for optimal TS were:

- **Make span** ($F1$): Make span is described as the whole amount of time needed to complete the task. Make span is defined in eq. (1), where m denotes VM count, n denotes task count, Tsk denotes task, len denotes theTsk size in MI (Million Instructions), and $pesnum$ denotes PE (processing Element) in VM.

$$Makespan = Maxi_{1 \le i \le m}\{fTsk_i\} \quad (1)$$

- **Communication Cost** ($F2$): Here, communication cost among task i and task j are given to different VM's.

  Communication cost Com_Cost is calculated in eq. (2).

$$Com\_Cost = \sum_{Tsk_i=1}^{n} Com\_Cost(Tsk_i, i = 1,2, \dots n) \quad (2)$$

- **Execution time (** $F3$**):** The time duration needed by VM to finish each task is known as execution time.
- **Memory Utilization (** $F4$ **):** Memory Utilization is a measure of average memory usage that is calculated by averaging the percentage of memory space that is being used at any given time across the reporting interval. Memory Utilization is defined in eq. (3).

$$Mem - Util = \left(100^*(TotalMBytes - AvailMBytes/TotalMBytes)\right) \quad (3)$$

$$TotalMBytes \rightarrow vm(Mem)$$

Here,

$$AvailMem \rightarrow (VirtualMem - TaskMem)$$

Solution encoding: The selection process will be decided by the proposed optimization algorithm where the solution including both PM and VM set from which the model selected corresponding PM and VM to execute the respective task. Fig. 3 gives solution encoding ofproposed CUCMCA method.

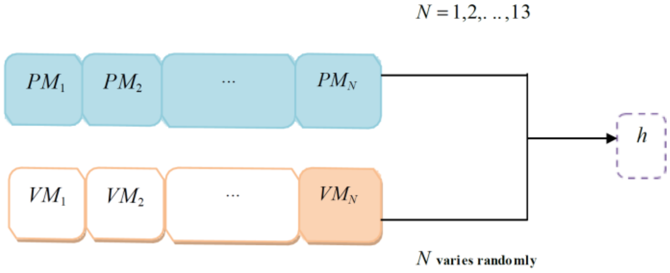

Fig. 3. Solution encoding of proposed CUCMCA method.

Weighted Objective Function: Minimization: The objective function obj defined in the model is given in eq. (4), where $w1$, $w2$, $w3$, $w4$ are the weights assigned to each parameter.

These weights are calculated using chaotic cubic map function.

$$obj = w1^*F1 + w2^*F2 + w3^*F3 + w4^*F4 \quad (4)$$

Cubic map: The cubic map is one of the maps that are most frequently used to generate chaotic sequences in many applications. In eq. (5), cubic map is defined.

$$L_{y+1} = 259 \times L_y\left(1 - L_y^2\right) \quad (5)$$

IV. Chimp Updated Cauchy Mutated Coot Algorithm (CUCMCA) Optimization

Hybrid optimizations are a new class of optimization methods that we develop to solve the optimization issue with more convergence efficiency. For hybrid optimizations, two or more algorithms must have been used for the same optimization. In this paper, we hybridized two algorithms named coot and chimp optimization. The solution update is done by this hybridized algorithm. Here the random number K^2 is estimated by using Tent map function. Also, Cauchy mutation is introduced in our proposed concept. Our proposed hybrid algorithm concept is given below:

Small water birds called Coots [21] were the rail family members. In coot optimization, with the formula (6), a small area is used to produce the population at random, where $Coot^{pos(i)}$ represents the coot position, g represents the variables count, and ub,lb represents the upper as well as lower bound of search space.

$$C^{pos(i)} = rnd(1, O)^*(ub - lb) + lb \quad (6)$$

Random motion to this direction and that direction: Different areas of the search space are explored by coot migration. This movement will let the algorithm escape the local optimal if it becomes stuck in the local optimal. Coot's new position is determined in eq. (7).

$$C^{pos(i)} = C^{pos(i)} + G \times K^2 \times \left(Z - C^{pos(i)}\right)$$

$$Z = rnd(1, O)^*(ub - lb) + lb \quad (7)$$

Where, K^2 represents the random number which is calculated using tent map function according to proposed model, $G = 1 - Y \times \left(\frac{I}{iter}\right)$ where Y represents the current iteration, $iter$ represents the maximum iteration.

Tent map: Tent chaotic map is also refereed as the logistic map represents particular chaotic effects. The following equation (8) gives the definition of this map:

$$q_{r+1} = \begin{cases} 2qr, qr < 0.5 \\ 2(1 - q_r), q_r \geq 0.5 \end{cases} \tag{8}$$

Chain movement: It is possible to construct chain movement by using the average position of 2 coots. The formula (9) is used to calculate the coot's new position, where $C^{Pos}(i-1)$ represents the second coot.

$$C^{Pos(i)} = 0.5 \times \left(C^{Pos}(i-1) + C^{Pos}(i)\right) \tag{9}$$

Adjusting position in accordance with the group leaders: To carry out this movement, a system is deployed based on the formula (10) to choose the leader, where i represents current coot index, D represents leader index, and lc represents the leader count.

$$D = 1 + (iMODlc) \tag{10}$$

Depending on leader O , $C^{Pos}(i)$ update its position. Formula (11) uses the chosen leader to determine the coot's subsequent position, where $C^{Pos}(i)$ represents new coot position, $L^{pos}(i)$ represents selected leader position, and *I1*, *I* represents the random number.

$$C^{Pos}(i) = L^{Pos}(O) + 2 \times I1 \times cos(2I\pi) \times \left(L^{Pos}(O) - C^{Pos}(i)\right) \tag{11}$$

According to proposed model, position update is done by hybridizing Coot and Chimp position [22] which is specified in eq. (12) to eq. (16).

Proposed update equation: $h_{chimp} = h_{prey}(t) - u.v$

Substitute $L^{Pos} = LP, h_{prey} = h, C^{Pos} = h$

$$h - u.v = LP(O) + 2\times I1\times\cos(2I\pi)\times LP(O) - C^{Pos}(i) \tag{12}$$

$$h - u.v = LP + 2I1\times\cos(2I\pi)\times(LP - h) \tag{13}$$

$$h - u.v = LP + 2I1\times\cos(2I\pi)\times LP - 2I1\times\cos(2I\pi)\times h \tag{14}$$

$$h - u.v = LP(1 + 2I1\times\cos(2I\pi) - 2I1\times\cos(2I\pi)\times h \tag{15}$$

$$h = LP(1 + 2I1\times\cos(2I\pi) + u.v - 2I1\times\cos(2I\pi)\times h \tag{16}$$

Leader movement: Leaders need to change their location with respect to the objective in order to move the group toward an objective (the ideal region). It is advised to update leader position using formula (17), where $OBest$ represents the best position, $J3$, $J4$ represents the random number.

$$L^{Pos(i)} = \begin{cases} S \times I3 \times cos(2I\pi) \times \begin{pmatrix} FBest - L^{Pos(i)} \\ +FBest,\ I4 < 0.5 \end{pmatrix} \\ S \times I3 \times cos(2I\pi) \times \begin{pmatrix} FBest - L^{Pos(i)} \\ -FBest,\ I4 \geq 0.5 \end{pmatrix} \end{cases} \tag{17}$$

Here, $S = 2 - R\left(\frac{1}{S_t}\right), S^t$ represents maximum iteration, and R represents the current iteration.

Cauchy mutation: Cauchy mutation is also employed in this algorithm to produce the solution. Due to its wider search range, Cauchy mutation has a significant ability to seek globally. This ensures the high convergence rate. Below Algorithm 1 gives the pseudocode of suggested CUCMCA model:

Algorithm 1: Pseudo code of Chimp Updated and Cauchy Mutated Coot (CUCMCA)

```
Input: Randomly initialize coot population (Tasks and VMs)
Output: Optimally mapped VMs and Tasks
Parameter initialization $\Pr = 0.5$, $Lc$, $Cnt_{coot}$ ( coot count)
$Cnt_{coot} = Cnt_{pop} - Cnt1$
Randomly select the leader of coot
Coot as well as leader fitness calculation
Identify best leader or coot as $FBest$
While end condition is not met
    Calculate $t, S$ parameter
    if $rnd < \Pr$
        $I, I1, I3$ were random numbers along the problem dimension
    Else
        $I, I1, I3$ were random number
    end if
    $I, I1, I3$ were random number
    for $i = 1$ to $Cnt_{coot}$
        Evaluate parameter of $D$
        if $rnd > 0.5$
            Position update using new evaluation given in eq. (16)
        Else
            if $rnd < 0.5i$ ~=1
                update coot position by eq. (7)
                In eq. (7), random number $K^2$ is calculated using the Tent map as per proposed model
            end if
        end if
        Evaluate fitness using eq. (4)
        if $C^{fitness} < L^{fitness}(O)$
            $temp = L(O)$
            $L(O) = coot$
```

```
$coot = temp$
end if
for leader count
Leader position update by eq. (17.1)
Else
Leader position update by eq. (17.2)
end for
if $L^{fitness} < FBest$
$temp = FBest$
$FBest = L$
$L = temp$
end if
end for
$S^t = S^t + 1$
Cauchy mutation is performed for global search
end while
```

V. Results and Discussion

A. Simulation Procedure

The proposed Chimp Updated and Cauchy Mutated Coot Algorithm (CUCMCA) method for task Scheduling and Resource Management was done in Cloudsim. The dataset considered for our work are extracted from internet sources i.e. google cluster traces 2019. The assessment was done on Bald Eagle Search (BES), Arithmetic Optimization Algorithm Method (AOAM) [26], Moth Flame Optimization (MFO), Hybrid Swarm Optimization (HSO) [27], Elephant Herding Optimization (EHO), Chimp and COOT, regarding Communication Cost, Execution Time, Fitness, Makespan and Memory Utilization. Also, it was examined by altering the number of virtual machines to 10, 20, 30, 40 and 50.

B. Dataset Description

This is a trace of the workloads running on eight Google Borg compute clusters for the month of May 2019 [25]. The trace describes every job submission, scheduling decision, and resource usage data for the jobs that ran in those clusters.

It builds on the May 2011 trace of one cluster, which has enabled a wide range of research on advancing the state-of-the-art for cluster schedulers and cloud computing, and has been used to generate hundreds of analyses and studies.

Since 2011, machines and software have evolved, workloads have changed, and the importance of workload variance has become even clearer. The new trace allows researchers to explore these changes.

The new dataset includes additional data, including:

- CPU usage information histograms for each 5 minute period, not just a point sample;
- Information about allow sets (shared resource reservations used by jobs); and
- Job-parent information for master/worker relationships such as MapReduce jobs.

Just like the last trace, these new ones focus on resource requests and usage, and contain no information about end users, their data, or access patterns to storage systems and other services."

C. Evaluation of Communication Cost

The proposed CUCMCA method is compared to extant systems in terms of communication cost. Fig. 4 depicts the study of communication cost. A variety of Virtual Machines, including 10, 20, 30, 40 and 50 are evaluated. A successful system should have minimal communication costs. On examining the communication cost, the values gained by recommended method are considerably lower than other models. That is, the communication cost of (~) 125 is obtained by adopted method at the 40th VM. In contrast, the compared models like BES, AOAM, MFO, HSO, EHO, Chimp and COOT has obtained relatively higher communication cost of 174, 176, 132, 177, 175, 163 and 164, respectively. While compared to other schemes such as BES, AOAM, MFO, HSO, EHO, Chimp and COOT, the communication cost achieved using suggested approach is the smallest in the 50th VM. Thus, the outcomes of the experiment reveal that the proposed CUCMCA method's communication cost score is preferable to the established approaches.

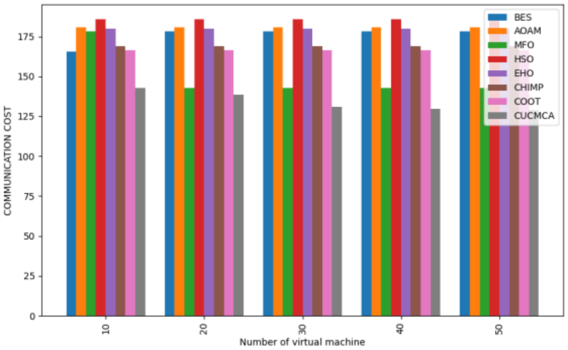

Fig. 4. Communication cost analysis: proposed CUCMCA method vs conventional models.

D. Evaluation on Execution Time

In this section, the analysis on Execution Time is examined for varied VMs. The analysis on developed CUCMCA method over BES, AOAM, MFO, HSO, EHO, Chimp and COOT for varied VMs is exposed in Fig. 5. In order to improve the system's performance, the execution time should be reduced. The developed approach holds minimal execution time of 8.24 at the VM 50; whereas, the traditional models holds the highest execution time for BES (39.53), AOAM (47.92), MFO (49.67), HSO (62.18), EHO (18.65), Chimp (48.85) and COOT (53.67), respectively. Moreover, it is observed that, the suggested method has accomplished better outcomes at 30th VM than at 10th and 20th VMs. As a result, the superiority of the suggested CUCMCA work is proved.

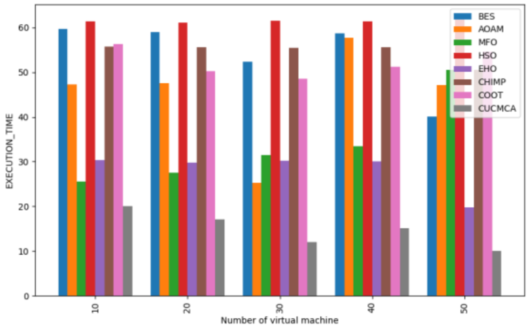

Fig. 5. Execution time analysis: proposed CUCMCA method vs conventional models.

E. Evaluation of Fitness

The Fitness analysis of the proposed CUCMCA classifier is computed over the existing classifiers and the graphical illustration is represented in Fig. 6. Further, the Fitness of the suggested model attains better outcomes than other conventional approaches. The models like BES, AOAM, MFO, HSO, EHO, Chimp and COOT acquired the highest fitness of (~) 28.69, 23.54, 20.71, 28.67, 17.46, 26.82 and 25.18, whilst the proposed strategy yielded the lowest fitness of 17.82, at the 30th VM. Likewise, the fitness of the adopted approach obtained the better value of (~) 14.28; however, the existing schemes like BES, AOAM, MFO, HSO, EHO, Chimp and COOT holds the lowest values for the VM 40. Hence, the improvement of the suggested CUCMCA model is established over others in terms of fitness.

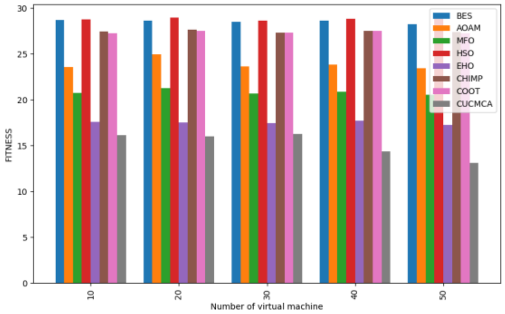

Fig. 6. Fitness analysis: proposed CUCMCA method vs conventional models.

F. Evaluation of Makespan Time

The Makespan using suggested CUCMCA method is analyzed over BES, AOAM, MFO, HSO, EHO, Chimp and COOT for varied VMs as shown in Fig. 7. Low makespan is required for enhanced system performance. The suggested method successfully achieves our goal, whose Makespan values exceed the traditional approaches. Moreover, the Makespan of the developed model attains lower value of 43.56, in the 20th VM than other existing classifiers like BES (82.67), AOAM (68.42), MFO (76.84), HSO (63.45), EHO (81.96), Chimp (80.87) and COOT (78.12), respectively. This analysis shows that the developed CUCMCA approach makes the system more robust at scheduling workloads and managing resource than the conventional approaches.

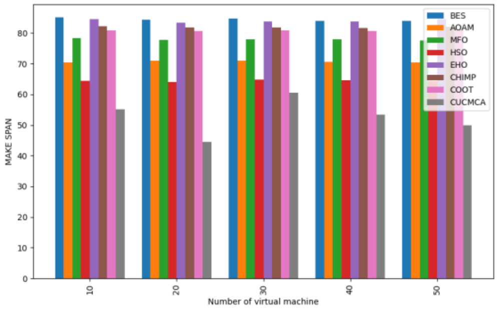

Fig. 7. Makespan analysis: proposed CUCMCA method vs conventional models.

G. Analysis on Memory Utilization

The performance of adopted CUCMCA model regarding Memory Utilization is displayed in the Fig. 8. The memory utilization should be minimal for better system performance. In this manner, it is observed that the adopted model achieves least memory utilization when compared to models like BES, AOAM, MFO, HSO, EHO, Chimp, and COOT, respectively. Particularly, incredible outcomes for both proposed and current approaches have been obtained for all measures at the 10th, 30th, and 50th VM. Nevertheless, the developed approach has delivered more determinative outcomes than distinct strategies for every VM. For instance, at 50th VM, the memory utilization of suggested approach is 0.04, which is better than the values obtained for existing schemes like BES is 0.05, AOAM is 0.06, EHO is 1.2, COOT is 1.1 and HSO is 0.07, respectively. As a consequence, this assessment proves that the proposed CUCMCA model is better to make an efficient workload scheduling when compared to other conventional models.

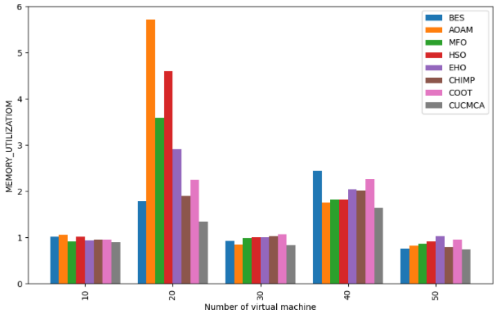

Fig. 8. Memory utilization analysis: proposed CUCMCA method vs conventional models.

H. Convergence Analysis

The convergence study of the proposed CUCMCA work is contrasted to the traditional methods like BES, AOAM, MFO, HSO, EHO, Chimp and COOT are shown in Fig. 9. In addition, it was examined by altering the iterations to 5, 10, 15, 20 and 25, respectively. When comparing the suggested method to other extant schemes, the findings show that the developed model has the lowest error rate. Here, the COOT algorithm has exhibited the worst performance in the initial (0th) iteration. From iteration 5 through iteration 25, the proposed approach and other current classifiers have lower error rates. Nevertheless, at the last 25th iteration, the adopted approach recorded the lowest error rate of (~) 1.0. Thus, recommended strategy resulted in a slightly lower error rate than BES, AOAM, MFO, HSO, EHO, Chimp and COOT. Therefore, the proposed CUCMCA strategy is appropriate for the workload scheduling and resource management. The improvisation in the performance of proposed logic shows the impact of proposed hybrid algorithm in enhancing the convergence rate and speed.

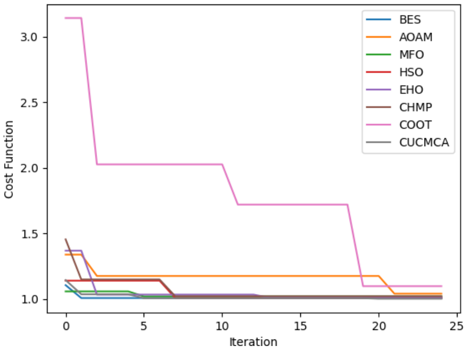

Fig. 9. Convergence analysis: proposed CUCMCA method vs conventional models.

I. Statistical Analysis

Table III represents the statistical analysis with respect to Fitness, Makespan, Communication Cost, Memory Utilization and Execution Time for the proposed CUCMCA method over the established models. Also, the analysis was carried out with five different case scenarios including Mean, Maximum, Standard Deviation, Minimum and Median. The optimization schemes are stochastic, and to substantiate the fair assessment, every model is examined several times. On examining the resultants, the suggested scheme has achieved minimal values for the majority of the scenarios. Based on the mean case scenario analysis, the proposed model obtains lower execution time of 12.06345 than other traditional models like AOAM is 44.99084, MFO is 33.69218, HSO is 61.50506, EHO is 28.04894, Chimp is 54.63884, COOT is 52.19459 respectively. According to the Median analysis, the Memory utilization of the suggested work is 0.892668, which is superior to the existing models like BES, AOAM, MFO, HSO, EHO, Chimp and COOT.

VI. Conclusion and Future Scope

Cloud system must be able to manage its resources autonomously and adaptively in response to the changes in workload needs with its vast computing power and flexibility for ever evolving challenges. Despite credibility features, it faces many challenges such as Scheduling, Security, and Energy Management etc. Among aforementioned issues the one of concern that owes to be improved is Task scheduling, intending the maximization of user-favoured application QoS parameters our proposed hybrid algorithm performs task scheduling and allocates resources efficiently in cloud computing environments. Our work considers Google cloud (May 2019) workload traces as input using modified AHP to rank the task via FCM. Furthermore, the optimal task scheduling and resource allocation are done by the developed Chimp Updated and Cauchy Mutated Coot Algorithm (CUCMCA). Deliberately the outcome promises improved results in comparison to the existing conventional BES, AOAM, MFO, HSO, EHO, Chimp, COOT models with respect to makespan time, execution time, communication cost and memory utilization gives improved results. As a scope for further enhancement classifying user tasks prior to scheduling promises improved results in terms of QoS metrics and extends scope for better resource allocation.

Abstract—**With the current developments in technology, not only has digital media become widely available, the editing and manipulation of digital media has become equally available to everyone without any prior experience. The need for detecting manipulated images has grown immensely as it can now cause false information in news media, forensics, and daily life of common users. In this work, a cascaded approach DMobile-ELA is presented to ensure an image's credibility and that the data it contains has not been compromised. DMobile-ELA integrates Error Level Analysis and MobileNet-based classification for tampering detection. It was able to achieve promising results compared to the state of the art on CASIAv2.0 dataset. DMobile-ELA has successfully reached a training accuracy of 99.79% and a validation accuracy of 98.48% in detecting image manipulation.**

Keywords—Tampering detection; MobileNet; error level analysis; CASIAv2.0

I. Introduction

Digital imaging use has recently prevailed in various domains, starting from social networks [1], through medical diagnostics [2] till reaching its use as digital forensics court evidence [3]. Coupled with its use in different critical fields, technology advancements has led to the ease of digital image manipulation and forgery[4].

Image tampering and forgery include a wide range of types such as copy-move, splicing, retouching and image morphing [5]. Copy-move forgery includes copying a piece of the same picture and moving it to cover another part of the image, while splicing involves copying a part of an image to place it in another image. Retouching often involves changes in shape, color and texture of image parts to improve its visual and technical quality, whereas image morphing perform images interpolation to create an image blend. Recently, Generative Adversial Networks (GANs) made it possible to create full face fake images and media using DeepFake technology[6].

The wide availability of editing and enhancement tools may encourage the malicious use of such tools in criminal acts. Such possibility raises public concern and demand for verifying the originality of the images. Hence, effective approaches are required for detecting image forgery [7]. Forgery detection revolves around the recognition of image manipulation and authenticity validation. Active techniques such as digital signatures and watermarking can be used, in addition to passive detection techniques [7].

In this study, a passive forgery detection approach DMobile-ELA is proposed to automatically detect copy-move and splicing image edits with high accuracy. A dilated modified MobileNet architecture is presented to determine whether an image is authentic or tampered. Error Level Analysis (ELA) is used to preprocess the investigated image at different compression levels before being input to the Dilated-MobileNet. The proposed approach has the advantages of encompassing a light weight architecture suitable for mobile device use. Also, the atrous modification allows the network to capture larger spatial context; which increases its ability to reconstruct more complex edge structures. In addition, the adopted ELA preprocessing enables the detection of the tampered areas easily, due their characteristic aspects in the ELA representation.

This paper is organized as follows: a background on deep learning is given in Section II covering two of the most popular architectures VGG16 and ResNet-50 to allow further comparison. In Section III , a briefing on the related studies will be provided before presenting DMobile-ELA forgery detection system in Section IV. The experimental setup and results will be discussed in Section V. Finally, the conclusions will be drawn in Section VI.

II. Background

A. Deep Neural Network

Deep learning or Deep neural network (DNN) belongs to the class of machine learning, which models high level abstractions in the data with multiple nonlinear transformations [8]. DNN is a subclass of neural networks requiring large volumes of data to increase the efficiency of the training processes. The term "deep" also known as hierarchical learning represents the large number of multiple hidden layers, which includes nonlinear processing units for the purpose of conversion and automatic feature extraction [8].

1) Convolution neural networks: Convolution Neural Networks (CNNs) can extract automatic discriminative features which have some invariance properties (e.g. translation invariance) [9]. It consists of three main layers which are convolution layers, pooling layers and fully connected layers [8].

The early convolution layers of the architecture are used for extracting local low-level features from the raw input while the deeper convolution layers of CNN are used for combining features together to generate global high-level features. The pooling layers are used to down sample the dimensionality of the extracted feature. The fully connected layers form an ANN network where each neuron in the previous layer is connected to all the neurons in the current layer. The total number of fully connected neurons in the final layer determines the number of classes [8].

The advantages of CNNs include that they are well suited for end-to-end learning that generates automatic features from the raw data without any a priori feature selection. Moreover, CNNs scale well to large datasets. The disadvantages of CNNs include the large amount of training data, the long training time compared to simpler models, and the large number of hyper parameters to be learned. Two of the most famous CNN are VGG-16 [10] and ResNet-50 [11], which will be described briefly below.

a) Visual graphic group net (VGG Net) model: This net was developed by the technicians at the Visual Graphics Group from the Oxford and is in pyramid shape. The model consists of the bottom layers which are wide and the top layers are deep. There are two versions of VGG which are VGG-16 and VGG-19. VGG-16 is a combination 13 convolutional layers and Three fully connected layers as shown in . The VGG-19 is a much deeper network with 16 convolutional layers and three fully connected layers.

b) depicts VGG16 layered architecture.

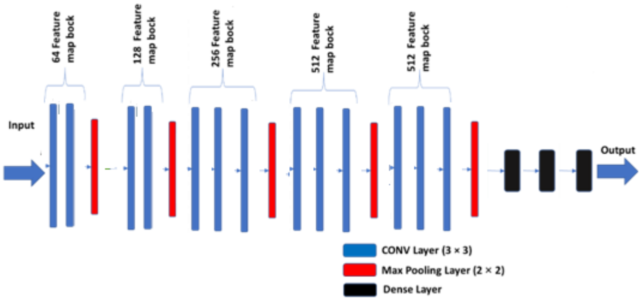

Fig. 1. VGG16 layered architecture.

c) ResNet model: It is a type of deep network based on residual learning. There are different versions of ResNet which are ResNet-18, ResNet-34, ResNet-50, ResNet-101 and ResNet-152. All of them have the same building units or residual blocks and formed by stacking the building residual blocks over each other. Any ResNet starts with block has a structure as shown in The residual blocks; are divided into two types which are Identity shortcut and Projection shortcut. The first block shown in Fig. 2 is the identity shortcut bottleneck block which is composed of a sequence of convolution layers of kernel size (1 × 1) and stride = 1 connected to a convolution layer with kernel (3 × 3) and stride = 1 followed by a convolution layer followed by kernel (1 × 1) and stride = 2. This block is used when the input and output of feature map are the same. The other block shown in Fig. 2 is the projection shortcut bottleneck block which has the same sequence of layers with a newly added convolution layer in the projection shortcut which has a kernel size of (1 × 1) with stride = 2. It is applied when shortcuts go across the feature map of two sizes. In the two blocks all the convolution layers are followed by batch normalization and RELU activation function. The difference between different ResNet versions are the number of stacked residual blocks. For example, ResNet-50 which has 16 residual blocks and ends with fully connected layer as shown in Fig. 2.

III. Related Work

Due to the recent advancements in computer vision and the growing need for forgery detection, resources for targeted algorithms are vastly diverse in their approaches and practices.

Originally, the leading method in identifying tampered and non-tampered images was Support Vector Machine (SVM), as seen in [12], [13] and [14]. Shen et al. [12] were able to achieve quite high accuracies using the datasets CASIAv1.0 and CASIAv2.0 reaching 98% and 97% respectively. TF-GLCM method was proposed, which combines textural features extraction with grey level co-occurrence matrices. This method was directed at spliced images in particular. They used calculated textural features as components in feature vectors in order to recognize genuine and spliced images employing SVM as the classifier.

Similarly, Han et al. [13] used SVM to classify spliced images but after extracting features using the Markov method. They presented three types of Markov feature vectors and achieved accuracies up to 97.86% for CASIA v1 and 97.33% for CASIA v2 even with a small range of features.

Recent approaches are now leaning towards more complex neural network architectures, especially the ones to be able to detect more than one type of tampering rather than only splicing which was previously the case. One prominent study by Rao et al. [17] introduces a new CNN designated for the detection of copy-move and splicing forgeries. It utilizes high-pass filters to calculate residual maps in a special rich model (SRM) to capture any subtle pattern that is produced when image manipulation happens. The used CNN extract features from the test images, and a feature fusion method is then applied to acquire the final key features that are fed to SVM for classification. This method was able to achieve 98.04% for CASIA v1 and 97.83% for CASIA v2.

An interesting approach was presented by Sudiatmika et al. [5] , who utilized the idea of error-level analysis (ELA) in conjunction with CNNs to create a more universal tool for detecting various types of forgery. Sudiatmika proposed normalizing the images before pursuing ELA calculation and feeding the resulting images to a VGG16 network. Sudiatmika et al. reached 92.2% accuracy on CASIA v2.0.

Kuznetsov [18] took a slightly different tactic in detecting forgeries using VGG network. The adopted method did not use the entire image for classification but rather small patches that are identified by either being forged on original expanding the training pool. He used a sliding window method to analyse each fragment of the image regarding its authenticity. This approach achieved very good results reaching 97.8% accuracy, 97.1% precision and 96.8% recall.

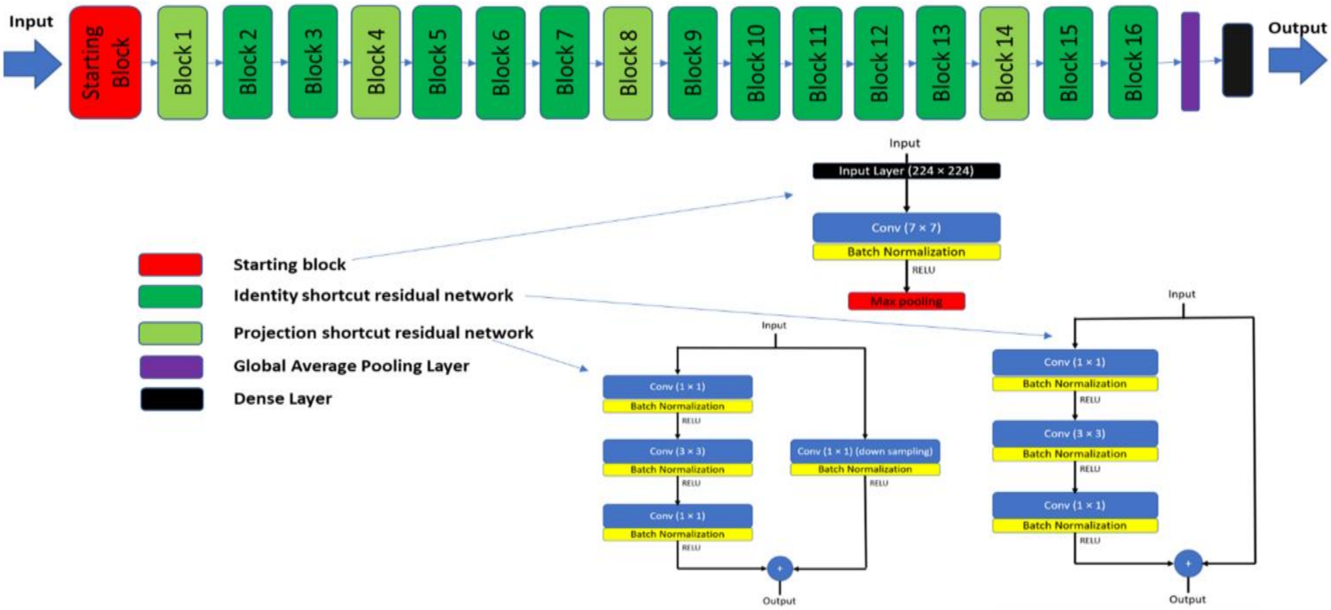

Fig. 2. ResNet layered architecture.

A modified ResNet architecture was used by Nath and Naskar [19] to automatically extract features, followed by a dense Artificial Neural network (ANN) for classification. The yielded results that exceeded 96% on sampled CASIA v2.0 to balance the classes.

Ding et al. [20] proposed a dual channel U-Net (DCU-Net), which accepts two inputs- the original tampered image and the residual tampered image. The residual image is generated by high pass filters to obtain the edges. The experimental results were shown on Casia2.0 and Columbia datasets, where the accuracy reached 97.93% and 97.27 % respectively.

The related work presents studies that either use traditional learning or deep learning approaches. With the increasing volumes of media and the advancements of editing technologies, traditional models will not provide adequate solution to the problem [21]. On the other hand, the used deep learning architectures are computationally intensive reducing their applicability on mobile real time applications [22]. In addition, further performance enhancement is needed to handle the problem.

IV. DMobile-ELA Proposed Model

A cascaded model is proposed to analyze whether images are tampered or authentic. The flow of the process model is shown in Fig. 3. The images are preprocessed applying ELA, then passed to a Dilated Mobile Net for classification.

A. *Error Level Analysis*

Error Level Analysis (ELA) is a concept that measures and visualizes the difference between an image and a re-compressed version of the same image which emphasizes certain parts that have been altered during previous edits. ELA measures the amount of error based on 8x8, relying on two main conditions applicable to JPEG images:

- A JPEG is said to be original if all 8x8 blocks have a similar error pattern. Therefore, the 8x8 pixel block can be said to have attained local minima.
- A JPEG is said to be manipulated if any 8x8 block has a higher error pattern and an 8x8 pixel block is not at its local minima.

In general, the computation of Error Level Images (ELIs) follows the formulation in Eq (1)....

$$\begin{gathered}\mathbf{I_o - I_{rc1} = ELI_1}\\ \mathbf{I_o - I_{rc2} = ELI_2}\\ \mathbf{I_o - I_{rc3} = ELI_3}\end{gathered} \tag{1}$$

where I_o denote the original image and I_{rc1} represent a recompressed image at a given rate of compression. ELI is generated through pixel-wise difference of the two images.

The resultant ELI conveys the different quality levels within an image through varying intensities. For example if the image is forged, the added regions will be compressed at a different rate than the remaining original image. Such variation will be reflected through a distinct error pattern as the forged regions will be quantized through a non-linear ratio. Thus, can be used to localize the tampered areas. In this study, three different levels of image compression were examined, namely 10%, 50%, and 90% compression.

Fig. 3 depicts the localized error pattern of the spliced person, when applying three level of compression. The images clarify the potential of ELA in locating tampered regions. As can be seen from Fig. 3, higher compression rates better localize the tampered region. A difference Error Level Image (ELI) is produced between compression rates 50% and 90% to eliminate details and detect changes. The resultant image is shown in Fig. 4. The difference image is input to the Dilated-Mobile Net.

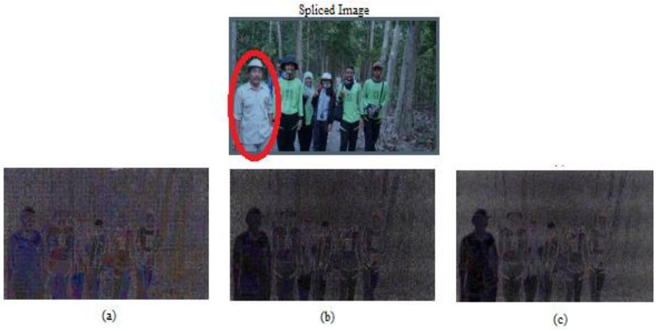

Fig. 3. ELIs at different compression rates (a) 10%, (b) 50% and (c) 90% emphasizing the spliced person (marked in red).

Fig. 4. Difference image generation from the available ELIs.

B. *Multiscale Dilated-MobileNet*

A dilated or atrous MobileNet deep learning architecture is developed for classifying images into authentic and tampered. A detailed description of the architecture will be given below.

1) Multiscale dilation : Multiple dilated filters are applied to the input differece ELI. The aim of applying filters with various dilation rates is to increase the receptive field of the filters. Expansion of the receptive field help in considering all the relevant regions in an image and and capturing all important information [23].

The dilation process inserts zeros depending on the dilation rate, hence increasing the receptive field of the filter while maintaining the number of parameters to be learnt. For example, with a dilation rate of 2 the receptive field of 3x3 filter is expanded to 5x5 convolution. Similarly, a dilation rate of three enlarges the filter to 7x7. The output of the multiscale dilation convolution is concatenated and input the first layer of of the MobileNet.

2) Light weight convolution : MobileNet is a light weight architecture known for its applicability on mobile devices [24]. It is characterized by fewer parameters, small convolution filters 3x3 and hence lower computation demand compared to other CNN architectures. MobileNet architecture employ Depthwise Separable Convolution (DSConv) Layer (shown in Fig. 5) instead of the standard convolution layer.

During depthwise separable convolution, each channel is convolved with each filter separately. The process is divided into depthwise convolution (3x3 depthwise convolution, batch normalization BN and RELU), followed by pointwise convolution (1x1 convolution, batch normalization BN and RELU). Splitting the convolution task into two steps speed up the computation task by a factor that reaches $\frac{1}{f^2}+\frac{1}{n}$, where f is the filter (kernel) size assuming squared dimensions and n is the number of filters (corresponding output channels). In addition, DSConv helps maintain a shallower network than traditional CNNs with competitive accuracies.

Despite the advantages of DSConv, the small sized convolution filters may reduce the goodness of the captured filters. Hence, the atrous filters with varying dilation rates offers a promising solution to this issue.

3) Fully connected classification: A dense layer of fully connected neurons is utilized to produce the final classification of whether the investigated image is authentic or tampered.

Overview of the network architecture is presented in Fig. 6, depicting the multiscale dilation and DSConv layers.

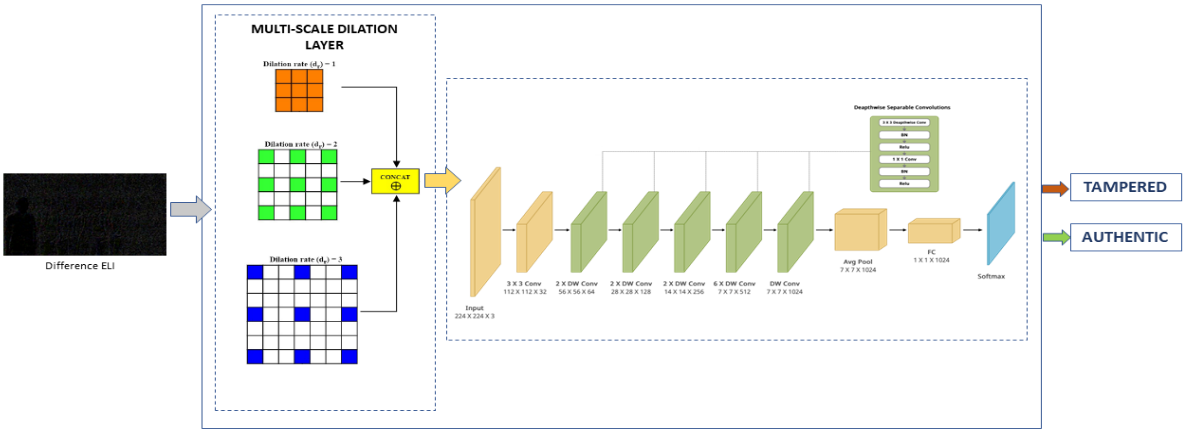

Fig. 6. Multiscale dilated MobileNet forgery classification on different ELI.

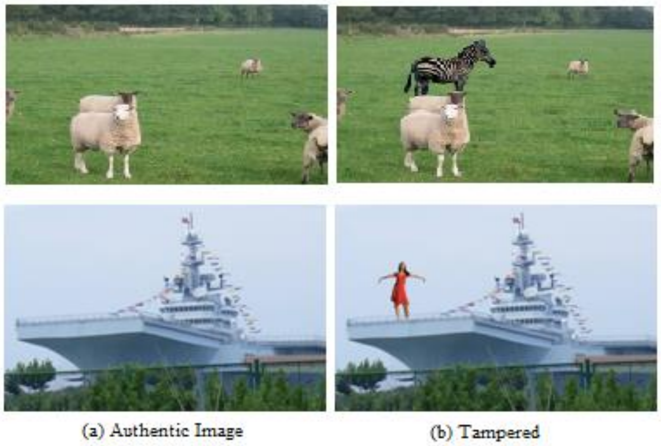
V. Results and Discussion

A briefing of the CASIAV2.0 dataset used in our experiments is given, followed by the performance measures applied to validate the performance of the proposed approach. The devised experimental setup is described for reproducibility of results. Then, the achieved results are presented and compared to recent forgery detection systems.

A. *Dataset Description*

CASIAv2.0.[25] dataset is used in the following experiments to validate the performance of DMobile-ELA. CASIAv2.0 is a benchmark dataset created by Dong et al. [25] at the Institute of Automation, the Chinese Academy of Sciences, with the purpose of aiding the research and development of image tampering detection methods. It contains 5123 tampered images and 7491 authentic images. Tampered images contain both copy-move and splicing altered images, at 3295 and 1828, respectively. This dataset is a successor of CASIAv1.0 which only included spliced images. Fig. 7 displays samples of authentic and tampered images from the dataset.



(a) Authentic Image
(b) Tampered

Fig. 7. Sample authentic and tampered images from CASIAV2.0 dataset.

B. *Performance Measures*

Four performance measures are used to evaluate DMobile-ELA and allow its comparison with recent studies. The used measures are Accuracy (Acc), Precision (P), Recall (R) and $F1_{score.}$ The computation of these measures relies on the confusion matrix given in Fig. 8.

		Predicted	
		Positive	Negative
Actual	Positive	TP	FN
	Negative	FP	TN

Fig. 8. Confusion matrix outlining true positive (TP), false negative (FN), false positive (FP) and true negative (TN).

The measures are calculated according to the following Eq. (2) to (5).

$$\boldsymbol{Acc} = \frac{\boldsymbol{TP+TN}}{\boldsymbol{TP+TN+FP+FN}} \tag{2}$$

$$\boldsymbol{P} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FP}} \tag{3}$$

$$\boldsymbol{R} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FN}} \tag{4}$$

$$\boldsymbol{F1} = \boldsymbol{2}\,\frac{\boldsymbol{P\times R}}{\boldsymbol{P+R}} \tag{5}$$

C. *Experimental Setup*

The performance of DMobile-ELA is analyzed and compared to variable counterparts systematically. First, the performance of DMobileNet structure is contrasted to VGG16, ResNet-50 and MobileNet standard architectures. Also, the impact of transfer (pretrained on ImageNet [26]) learning or retraining from scratch is investigated. In addition, the effect of ELA on performance is elucidated through a comparison between models' performance with and without ELA. Finally, DMobile-ELA performance is compared against recent related studies.

The resolution of input images was adapted to the largest quadratic value that the MobileNet network supported which was 224x224. The default settings we used for assessing each model are splitting into 80% training and 20% validation sets, running the training for 10 epochs, and using 0.0001 learning rate. The model utilized Adam-optimizer while maintaining a batch size of 16.

D. *DMobile-ELA Performance Results*

Forgery detection accuracy is measured for VGG16, ResNet-50, MobileNet and DMobileNet on the original image without ELA preprocessing. The results are shown in Fig. 9. Also, the performance of tuning pretrained models versus retraining of the models is tested. The results show that DMobile Net attains the highest accuracy, while VGG16 scores the lowest accuracy. Another observation is that retraining is better suited to the problem under study, as there is an evident performance gap that reaches around 15% in case of ResNet-50.

The accuracy of the models with ELA preprocessing is depicted in Fig. 10. From the shown accuracies, it can be seen that ELA aided the models to score higher accuracies than without ELA with differences ranging from 5% to7% in case of retrained models. For pre-trained ResNet-50, the improvement arrived at 13%. Retrained models still presents higher accuracies compared to pre-trained models. Overall, retrained DMobile-ELA records the highest accuracy of 98.48%. The difference in accuracy between DMobileNet and MobileNet is around 3%, which is a considerable difference given that the number of parameter to be learned is the same.

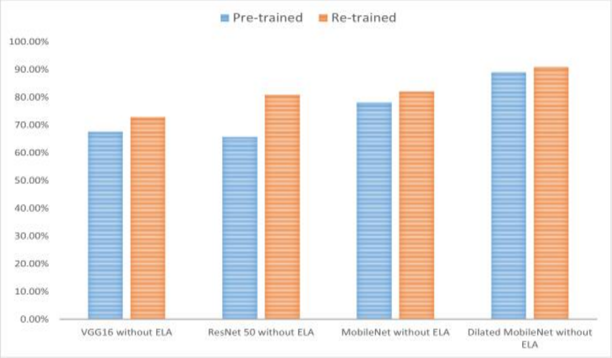


Fig. 9. Accuracy of CNN models without ELA preprocessing.

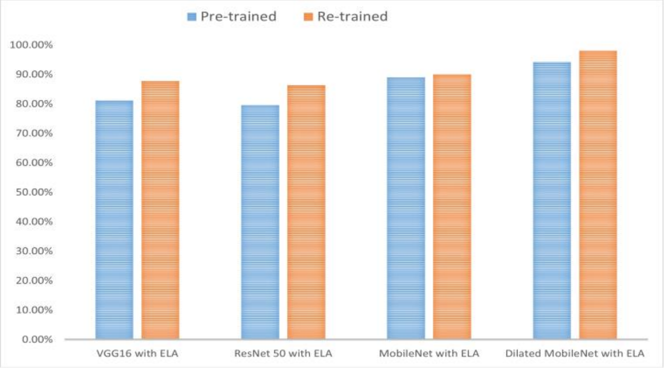

Fig. 10. Accuracy of CNN models with ELA preprocessing.

The training and validation accuracies learning curves for 10 epochs are shown in Fig. 11. The validation curve follows smoothly the training curve in the last three epochs diminishing the possibility of overfitting.

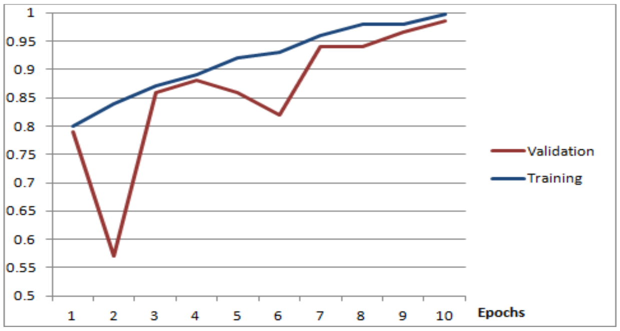

Fig. 11. **V**alidation and training accuracy learning curves of DMobile – ELA.

TABLE I. PERFORMANCE COMPARISON BETWEEN DMOBILE-ELA AND RECENT RELATED STUDIES

Approach	Performance Measures			
	Acc	*P*	*R*	*F1$_{score}$*
Alahmadi et al. [14]	0.9645	0.9669	0.9415	0.9540
Ding et al. [20]	0.9793	0.8772	0.8893	0.8667
Kanwal et al. [16]	0.9759	🟩	🟩	🟩
Niyishaka et al. [15]	0.9459	0.9000	0.9900	0.9300
A Kuznetsov [18]	0.9780	0.9710	0.9680	🟩
Proposed DMobile-ELA	0.9848	0.9781	0.9862	0.9821

TABLE II. NUMBER OF PARAMETERS COMPARISON BETWEEN DMOBILE-ELA AND RECENT RELATED STUDIES

Approach	Parameters
Ding et al. [20]	17.2M
A Kuznetsov [18]	138M
Proposed DMobile-ELA	3.4M

Table I details the measures for assessing DMobile-ELA against some of the recent studies. The metrics show that the proposed DMobile-ELA surpasses its counterparts. It presents superior P, R and F1$_{score}$ than Ding et al. [20] with a gap of around 0.1 in all these measures. Also, it scores higher accuracy, P and F1$_{score}$ compared to Niyishaka et al. [15] with differences of around 0.04, 0.07 and 0.05 respectively. Kanwal et al. [16] and Alahmadi et al. [14] offer solutions with comparable accuracy. Similarly, Kuznetsov [18] presents competitive performance in terms of all metrics. However, Kuznetsov used VGG16 for detection, which is a computationally demanding architecture. Table II outlines the number of parameters to be learned for each backbone architecture. The given numbers highlight the favorable low computation demand of DMobileNet as a light weight architecture.

VI. CONCLUSION

In this study, a forgery detection approach named DMobile-ELA is proposed. It integrates dilated MobileNet and Error Level Analysis (ELA), which leads to a lightweight high performing solution. The conducted experiments confirmed the success of DMobile-ELA in forgery detection, emphasizing the advantageous effect of ELA on performance. In addition, the experiments indicated the higher suitability of model retraining to the problem of forgery detection. Retrained DMobile-ELA performance reached Acc, P, R and F1$_{score}$ of 0.9848, 09781, 0.9862 and 0.9821 respectively on CASIAv2.0 dataset. Further improvements can be applied such as integrating different preprocessing procedures and merging textural features. Also, forgery types other than copy-move and splicing can be investigated to increase the applicability scope of the proposed approach.

A Comprehensive Study on Medical Image Segmentation using Deep Neural Networks

Loan Dao, Ngoc Quoc Ly
Dept. of Computer Vision and Cognitive Cybernetics
University of Science, VNUHCM, Ho Chi Minh, Vietnam
Viet Nam National University, Ho Chi Minh City, Vietnam

***Abstract*—Over the past decade, Medical Image Segmentation (MIS) using Deep Neural Networks (DNNs) has achieved significant performance improvements and holds great promise for future developments. This paper presents a comprehensive study on MIS based on DNNs. Intelligent Vision Systems are often evaluated based on their output levels, such as Data, Information, Knowledge, Intelligence, and Wisdom (DIKIW), and the state-of-the-art solutions in MIS at these levels are the focus of research. Additionally, Explainable Artificial Intelligence (XAI) has become an important research direction, as it aims to uncover the "black box" nature of previous DNN architectures to meet the requirements of transparency and ethics. The study emphasizes the importance of MIS in disease diagnosis and early detection, particularly for increasing the survival rate of cancer patients through timely diagnosis. XAI and early prediction are considered two important steps in the journey from "intelligence" to "wisdom." Additionally, the paper addresses existing challenges and proposes potential solutions to enhance the efficiency of implementing DNN-based MIS.**

Keywords*—Medical image segmentation (MIS); SOTA solutions in MIS; XAI; early disease diagnosis

I. Introduction

Computers store images as grids of pixels, each containing a color value. These digital images are considered unstructured data, and image segmentation is the process of partitioning pixels into separate regions that correspond to a single object or class. This is accomplished by labeling each pixel with its corresponding class.

Image segmentation provides a deeper understanding of the structure of an image and is a crucial processing step in many image and video applications. It serves as the foundation for other challenges, such as object detection, image classification, and image analysis.

In medical imaging, image segmentation involves separating organs, disease regions, tumors, or anomalies to assist in diagnosis, detect pathology, and monitor the progression of diseases. MIS is a challenging task because of the slow grayscale variation in medical images, making it difficult to distinguish objects.

Currently, AI applications have reached the "Intelligence" level in DIKIW [1], which stands for Data, Information, Knowledge, Intelligence, and Wisdom. In MIS, “Intelligence” is demonstrated through highly accurate segmentation results, even on low-contrast, blurry, noisy images [2]. Additionally, "Intelligence" in MIS is not only demonstrated through the ability to segment organs, but also through the ability to segment lesions [2].

"Wisdom", the highest level in the DIKIW hierarchy, represents humanity's ultimate goal. In MIS systems, the output not only provides segmented medical images but also offers an explanation for the segmentation results through eXplainable Artificial Intelligence (XAI). This helps to increase trust in the results among both doctors and patients, satisfying the demands for transparency and medical ethics, which is a critical aspect in realizing the practical application of AI-based disease diagnosis. Transparent segmentation results also contribute to early disease diagnosis, leading to improved treatment, monitoring, and healthcare processes. In healthcare systems, predicting future health conditions to plan appropriate care and potentially reducing the risk of death holds significant humanitarian significance. XAI and early prediction are two crucial steps towards bridging the "Intelligence-to-Wisdom" gap.

The following major contributions are presented:

- The state-of-the-art solutions in MIS focus on key factors such as network architecture, data, loss function, and evaluation metrics. The paper specifically explains the development process of the network architecture from the perspective of three levels of an intelligent vision system: the backbone, the typical network architecture, and applications of MIS.
- The paper focuses on the state-of-the-art solutions in MIS and highlights the current interest in XAI-based MIS to meet ethical and legal requirements.
- The paper presents a new perspective on MIS by incorporating the capability of making early predictions based on the results, which contributes to the improvement of community healthcare systems.

The rest of the paper is organized as follows: In Section II the state-of-the-art solutions for deep neural network-based medical image segmentation are presented. Section III focuses on the explanation of black-box models using eXplainable Artificial Intelligence (XAI) to increase trust among end-users. The paper analyzes early prediction techniques for disease progression in Section IV. The challenges and proposed solutions for improving the efficiency of future clinical applications are discussed in Section V. Finally, the conclusions of this comprehensive study and suggestions for future research are presented in Section VI.

II. State-of- the-Art Solutions in Medical Image Segmentation

This section presents state-of-the-art solutions in MIS, including network architectures, data, loss functions, and evaluation metrics. The specifics are depicted in Fig. 1.

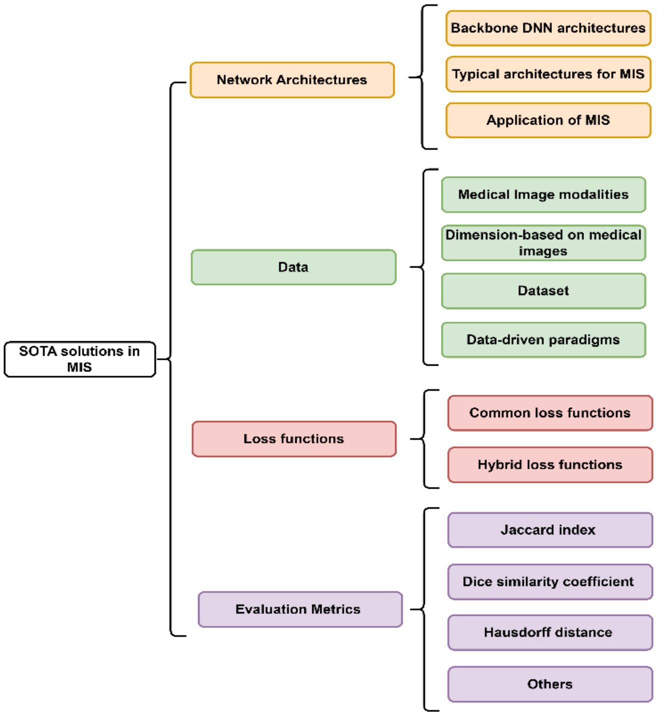

Fig. 1. The pipeline of SOTA solutions in MIS.

A. Network Architectures

This study conducts a survey of state-of-the-art solutions in MIS based on the standard framework of intelligent vision systems (IVS). An IVS encompasses three main levels.

Level 1 encompasses the backbone deep neural network (DNN) architectures used in image segmentation.

Level 2 builds on Level 1 to create specialized image segmentation models.

Level 3 leverages the knowledge from Levels 1 and 2 to develop typical applications for medical image segmentation.

This study thoroughly describes and explains the three levels in the IVS framework (TABLE I.)

In the following sections, typical modules and architectures for each level will be thoroughly examined.

Level 1: Background DNN architectures:

This section introduces typical background neural network architectures and state-of-the-art modules aimed at enhancing the efficiency of segmentation.

1) The typical background network architectures: The paper delves into several typical background architectures, including Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), Graph Neural Networks (GNNs), Generative Adversarial Networks (GANs), and Transformers.

- Convolutional neural network (CNN) (1982, [3]). Before gaining popularity, Convolutional Neural Networks (CNNs) have gone through several historical stages. The first foundation for convolution was laid by K. Fukushima et al. through a series of works, including "Cognitron: A self-organizing multilayered neural network" (1975), “Neural network model for a mechanism of pattern recognition unaffected by shift in position-Neocognitron” (1979), “Neocognitron: A new algorithm for pattern recognition tolerant of deformations and shifts in position” (1982). Since neighboring pixels in an image typically have strong inter-dependencies, K. Fukushima introduced the concept of "connectable areas" to extract features in "neighborhoods" instead of fully connecting the layers. This marked the first paradigm for unsupervised pattern recognition. The breakthrough of Convolutional Neural Networks (CNNs) lies in the use of two-dimensional filters, which are capable of extracting meaningful features from locally connected subsamples. These filters have smaller size, resulting in more optimal computing and storage capacity compared to earlier fully connected networks. The output from the filters is fed into an activation function, which adds non-linearity to the feature space and can be learned during training. Additionally, the non-linear activation function generates outputs that are typically monitored through subsampling. This allows for the aggregation of outputs, making the input insensitive to geometric deviations such as distortion, resizing, and repositioning of the sample input. CNNs have been successful in overcoming challenges in MIS, such as noise, blur, and low contrast. CNN architecture has several different backbones that are used in MIS, such as VGG (2014, [4]), ResNet (2015, [5]), DenseNet, DeepLabv3, MobileNets (2017, [6][7][8]), EfficientNet (2019, [9]).

- Recurrent Neural Networks (RNN) (1989, [10]) Barak A. Pearlmutter has explored various approaches to constructing the foundational concept of continuous time-recurrent networks. The Recurrent Neural Network (RNN) aims to mitigate the weight gradient to minimize the time-orbit error of the states in the continuous regression network. RNNs are particularly well-suited for continuous time domains such as signal, control, and speech processing. In medical image segmentation, RNN has been applied to model the time-dependence of image sequences (video). By leveraging the relationships between space-time information, RNNs can be combined with other architectures to improve the accuracy of image segmentation. RNNs can capture both local and global spatial features of the image by considering the context information [11].

TABLE I. THE COMMON FRAMEWORK OF INTELLIGENT VISION SYSTEMS (IVS) FOR MEDICAL IMAGE SEGMENTATION (MIS)

	Level of IVS	Explanation	Specific Solutions
1	**Backbone DNN Architectures**	Traditional segmentation methods, such as thresholding, edge detection, and region-based techniques, have limitations when dealing with noisy, fuzzy, and low-contrast medical images. Convolutional Neural Networks (CNNs) alleviate these drawbacks. Additionally, Graph Neural Networks (GNNs) and Transformers address the limitations of convolution kernels with regards to locality and invariance	**Background Networks Architectures:** ***CNN*** (1982, [3]), ***RNN*** (1989, [10]), ***GNN*** (2009, [12]), ***GAN*** (2014, [14]), ***Transformer*** (2017, [16]**).** **Backbone DNN**: VGG (2014, [4]), ResNet (2015, [5]), DenseNet, DeepLabv3, MobileNets (2017, [6][7][8]), EfficientNet (2019, [9]). **Some additional modules:** Inception (2015, [19]), Dilation convolution (2016, [21]), ASPP (2017, [7]), Attention (2015, [29]), Squeeze-and-excitation (2018, [33]), Residual (2015, [5]), Dense (2017, [6]), Residual Dense (2018, [37]).
2	**Specific DNN Architectures for MIS**	UNet is a widely used method in medical image segmentation. Its variants and hybrid network architectures have been developed to achieve higher accuracy in segmentation	***Unet*** (2015, [38]), ***V-net***, 3D U-Net (2016, [39], [40]), Mask R-CNN (2017, [41]), ***U-Net++*** (2018, [42]), UNet 3+, DRU-Net, DoubleU-net (2020, [43] – [45]), ***TransUNet,*** Swin Transformer (2021, [46], [47]), UNETR++, LE-UDA, ***TransUNet+*** (2022, [48], [49], [50]), SEP (2022, [51]), ESFPNet (2022, [52])
3	**Applications of MIS**	Medical image segmentation has evolved from single-organ segmentation to multi-organ segmentation and from organ segmentation to lesion segmentation. This has allowed for a more comprehensive and effective diagnosis of diseases, thereby improving human health care.	***Kidney Tumor Segmentation*** (F.Isensee et al., 2019, [53]), Brain Tumor Segmentation (S. Li et al. 2021, [54]), COVID-19 infection localization and severity grading from chest X-ray images (A. M. Tahir et al, 2021, [2][1]), ***Abdominal Multi-Organ Segmentation*** (F.Isensee, et al., 2022, [55]), and so on.

- Graph Neural Network (GNN) (2009, [12]) Scarselli et al. introduced the Graph Neural Network (GNN) architecture, which expands upon traditional neural network methods for processing data represented in graph regions. Geometric Deep Learning, also known as GNN, is a nascent field of study that extends deep neural modeling to non-Euclidean domains. The structures of medical images often have irregular and unordered patterns, making it challenging to represent them as matrices for CNNs. As a result, graph-based representations are becoming increasingly popular in MIS [13].

- Generative Adversarial Networks (GAN) (2014, [14]) The Generative Adversarial Network (GAN) architecture was introduced by Goodfellow et al. based on game theory. In this architecture, two players, a generator and a discriminator, play against each other to minimize their respective costs. The discriminator's cost encourages it to correctly classify data as real or fake, while the generator's cost encourages it to generate the most realistic fake samples that the discriminator finds difficult to distinguish. In medical image segmentation, GANs can be used to create synthetic medical images and their corresponding segmented masks, leading to improved segmentation accuracy thanks to GAN's powerful generation ability and ability to capture the data distribution [15][14].

- Transformer (2017, [16]): The Transformer architecture was originally designed for natural language processing (NLP) tasks, where it achieved remarkable improvements. Its success in NLP has drawn the attention of the computer vision community. The Transformer enables parallel processing of input sequences while supporting long-term dependencies between sequence elements, thus overcoming the explicit long-term dependency limitations of the Unet model [17]. Transformers, unlike CNNs, are designed with less inductive bias and can fit into any data structure as easily as established functions. Their fundamental structure also demonstrates great scalability, making them suitable for networks with high capacity and large data sets. This allows for multi-modal processing, including images, videos, text, and audio, using the same processing blocks. For medical imaging, organs that are frequently spread across a large receptive field can be efficiently encoded by modeling relationships between distant pixels. Therefore, the ability of Transformers to model the global context is crucial for accurate medical image segmentation, such as lung segmentation. Additionally, medical images are often blurred, noisy, and have low contrast, such as in ultrasound scans. Understanding the overall context between pixels against the background can help models avoid mis-segmentation [18].

2) SOTA modules for enhancing segmentation efficiency

- For aggregating features at multiple scales:
  - The Inception module (2015, [19]) which concatenates multiple parallel convolutional filter banks with varying kernel sizes to extract features at multiple scales. Example of the application of the Inception module in medical image segmentation can be found in [20].
  - The dilation convolution (or "atrous convolution") kernel, introduced in 2016 [21], increases the size of the kernel, and the corresponding receptive field without significantly increasing the number of pixels processed. This results in improved speed and accuracy. Example of the use of the dilation module in medical image segmentation networks can be found in [22].
  - The Atrous Spatial Pyramid Pooling (ASPP, [7]) module, introduced in 2017, utilizes dilated (or atrous) convolution to gather information at multiple scales. This helps to preserve local features while capturing multi-scale contextual information, leading to improved segmentation

efficiency. ASPP module is applied in medical image segmentation such as retinal segmentation [23], segmentation of abdominal organs from CT images [24], SAR-U-Net liver segmentation from CT images [25], U-Net-ASPP segmented COVID-19 [26], localized skin lesions [27]; spinal segments [28]

- Focusing on important features:
  - The attention mechanism (2015, [29]) focuses on spatially significant features. This mechanism is commonly applied in medical image segmentation problems such as [30] - [32]
  - Squeeze-and-excitation block (2018, [33]) focus on features based on channel-weighted adjustment. Medical image segmentation problems that apply this block like [34] - [36].
- Connecting to the previous layers and solving the vanishing gradient problem:
  - Residual block (2015, [5]), which adds the previous layer outputs to feature maps learned from the current layer;
  - Dense block (2017, [6]), which connects the outputs of all previous layers to the feature maps learned by the current layer;
  - Residual Dense block (2018, [37]), which allows full using the local and global features.

Level 2: Specific DNN Architecture for MIS.

Background network architectures at level 1 such as CNN, GNN, transformer, and so on can be used to implement various tasks such as detection, recognition, classification, and segmentation. This paper focuses on DNN architectures for **image segmentation.** TABLE II. compares three specific networks for the medical imaging segment, UNet (2015, [38]), UNet++ (2018, [42]), and TransUNet+ (2022, [50]) in terms of network architecture, pros, cons, and performance.

From the comparison results, it can be observed that network architectures are continuously improving in terms of performance. The current trend is the use of hybrid networks, such as TransUNet+ [50], to meet the increasing demand in healthcare systems.

TABLE II. COMPARES THREE SPECIFIC NETWORKS FOR THE MEDICAL IMAGING SEGMENT

	Unet (2015, [38])	**Unet++ (2018, [42])**	**TransUNet+ (2022, [50])**
Architectures	 Skip connection Encoder Decoder input image tile output segmentation map conv 3x3, ReLU copy and crop max pool 2x2 up-conv 2x2 conv 1x1 Unet includes **encoder** to extract features, **decoder** synthesize extracted features to segmentation results and **skip connection** copies low-resolution (encoder) to high-resolution (decoder) feature maps.	 $\mathcal{L}$ $X^{0,0}$ $X^{0,1}$ $X^{0,2}$ $X^{0,3}$ $X^{0,4}$ $X^{1,0}$ $X^{1,1}$ $X^{1,2}$ $X^{1,3}$ $X^{2,0}$ $X^{2,1}$ $X^{2,2}$ $X^{3,0}$ $X^{3,1}$ $X^{4,0}$ Backbone Down-sampling Up-sampling Skip connection $X^{i,j}$ Convolution Uses dense blocks to **Re-designed skip pathways** and use **Deep supervision**	 Enhancement Module Trans (d) TransUNet+ (Enhancment Skip Connection) Down-sampling Up-sampling Res Path Skip Connection **Encoder**: CNN and Trans**; decoder:** original decoder and the enhanced features; **skip connection:** enhancement module.
Pros	- Train with fewer annotated images (at most 35 annotated images) - Fast training time in 2015 (On a NVidia Titan GPU (6 GB), segmenting a 512x512 image takes less than a second.). - Easily applied to more tasks.	- Added redesigned skip pathways and deep supervision for ***more precise segmentation, model pruning, and increased speed.***	- Combining Transformer (***global self-attention mechanisms***) and CNN (enhance finer details by recovering ***localized spatial information***), Redesigning the skip connection to ***enhance features and improve the focus on the key patches***. In the decoder, cascaded up-sampler contains an up-sampling layer and a linear layer. - Performance in small organ segmentation.
Cons	- Limits on network depth and skip connection - Limitations on long-range information extraction	- Reduces the robustness of feature representation and increases the number of parameters.	- High computational cost and memory usage
Performances	 IoU: 76.62 (**<u>LiTS Challenge</u>**)	 **IoU: 82.90** **(<u>LiTS Challenge</u>)**	
		 DSC 76.09 (**<u>Synapse multi-organ CT dataset</u>**)	 **DSC: 81.57** **(<u>Synapse multi-organ CT dataset</u>)**

The paper not only compares three of the most specific network architectures for MIS, but it also tracks the latest MIS rankings on paperswithcode. According to the latest updates, the two top models, SEP (2022, [51]) and ESFPNet-L (2022, [52]), are at the forefront on two datasets, Kvasir-SEG and CVC-ClinicDB, respectively.

Spatially Exclusive Pasting (SEP) (2022, [51]) is an innovative data augmentation technique designed to tackle the issue of data scarcity in polyp segmentation, an important task in the diagnosis of intestinal diseases such as tumors and precancerous lesions.

Fig. 2 illustrates the procedure of SEP technique. The core concept of this technique is to copy the polyp region and paste it to other locations in order to generate a large number of new images. The augmentation process is divided into three modules: (1) a Potential Map Generation Module that generates a potential value for each coordinate, (2) a Pasting Module, and (3) an Update Module that updates the potential values for each coordinate.

According to the latest statistics on the rankings of paperswithcode.com (Fig. 3), SEP has achieved the highest mean Dice score (0.941) surpassing UNet (0.818), UNet++ (0.821), and FCBFormer (0.939).

The limitation of SEP is that it is only applicable to a limited number of data sources and is specifically designed for the task of polyp segmentation.

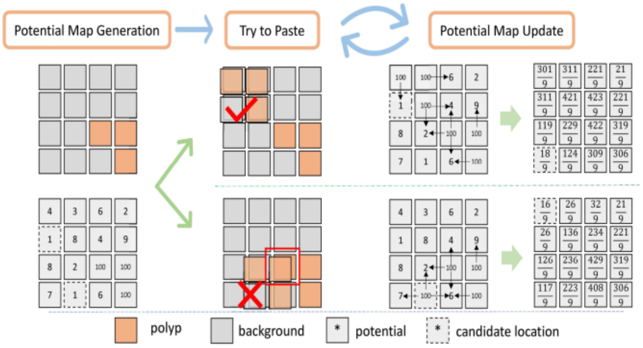

Fig. 2. The process of SEP [51].

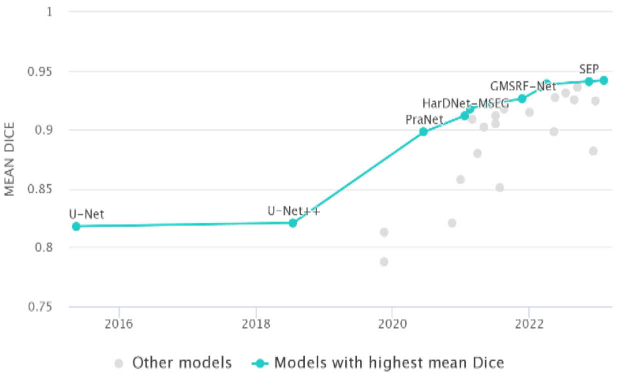

Fig. 3. Leaderboard the models with the highest mean Dice on the Kvasir-SEG.

ESFPNet (2022, [52]) is a deep learning architecture designed for real-time accurate segmentation and robust detection of bronchial lesions in autofluorescent bronchoscopy (AFB) video streams. Fig. 4 depicts the architecture of ESFPNet, which consists of a pre-trained Mix Transformer (MiT) encoder that leverages the encoder structure and an efficient Intelligent Phased Feature Pyramid (ESFP) decoder structure. ESFPNet-L produces superior results, with a mean Dice score of 0.949, compared to other recent architectures such as DuAT (0.948) and ColonFormer (0.947). Fig. 5 displays the rankings of the models with the highest mean Dice scores on the CVC-ClinicDB dataset. Additionally, with a processing speed of 27 frames per second, ESFPNet provides clinicians with a useful tool for confidently segmenting and detecting lesions in real-time during direct airway bronchoscopy. However, one drawback of ESFPNet is the high cost and difficulty in acquiring more live human video data.

Level 3: Applications of MIS

Level 3 is dedicated to the investigation of specific applications designed to perform medical image segmentation. This inherits and develops the background and backbone of the Deep Neural Network (DNN) architectures from Level 1 with a specific DNN architecture designed for image segmentation processing at Level 2.

According to the estimate of cancer cases in the United States in 2022, the most common types of cancer were prostate (268,490 cases in men) and breast (287,850 cases in women). The second most common cancers were lung and bronchus (117,910 cases in men and 118,830 cases in women) [56].

TABLE III. lists the number of papers with codes corresponding to each task, based on the latest statistics (as of November 2022) available on paperswithcode.com in the "Browse SoTA > Medical > Medical Image Segmentation" section.

Furthermore, the paper considers papers that have won first place in challenges at the International Conference on Medical Image Computing and Computer-Assisted Intervention (MICCAI)[1] in the past three years (2019 - 2022). TABLE IV. summarizes these challenges [57]

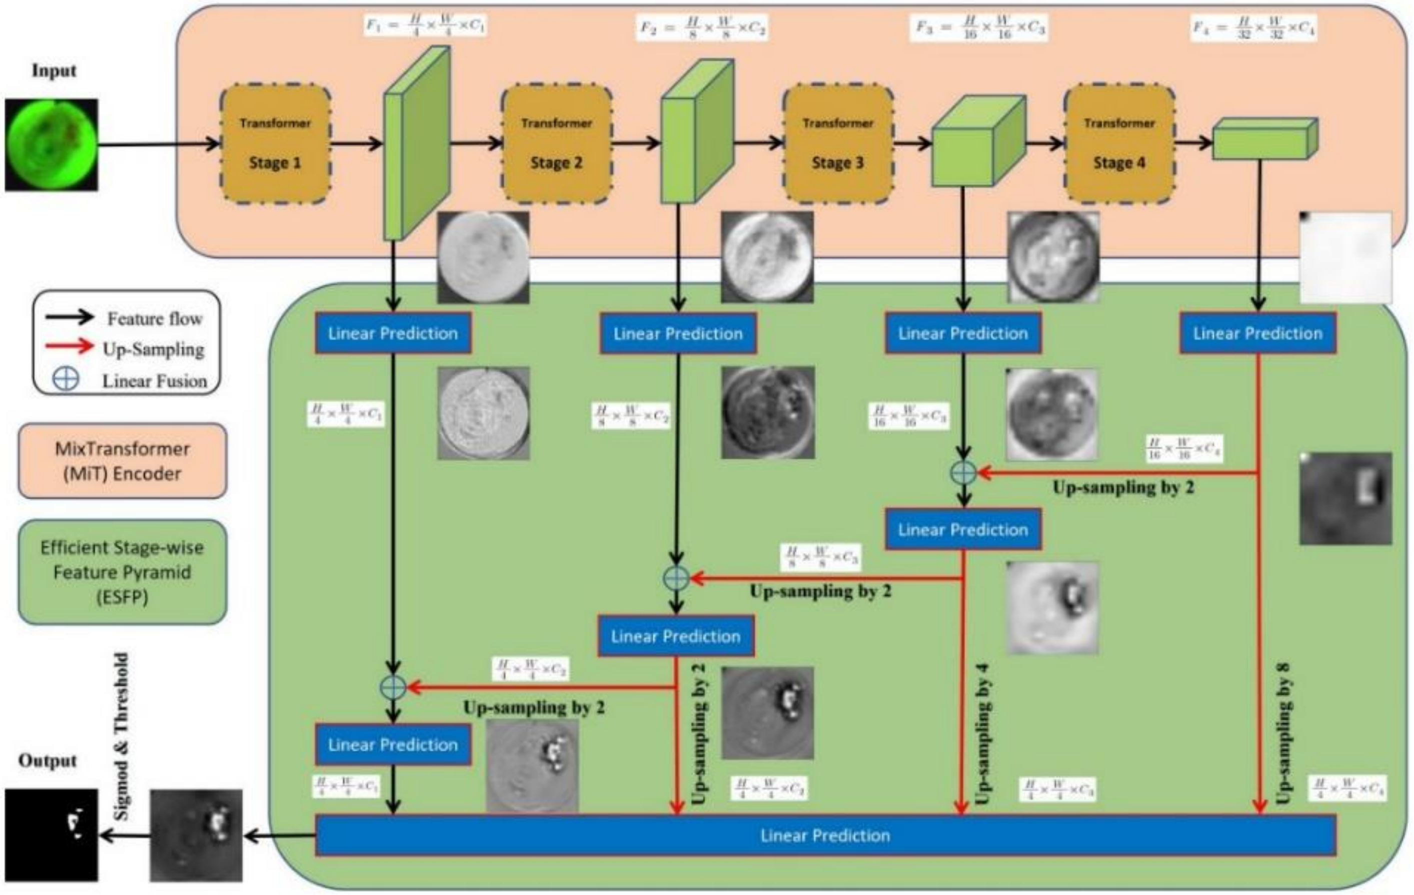
According to the research results, it is evident that state-of-the-art (SOTA) applications are focusing on improving segmentation performance, from single organ segmentation to multi-organ segmentation (abdomen, brain, genital organs, etc.), and from organ segmentation to tumor and infection area segmentation, to provide comprehensive care for human health.

B. Data

1) Medical image modalities: Data is a crucial component in the learning process. Medical imaging is a method and approach to create visual images of the interior of the body using non-invasive technologies [58]. It is used to aid in the diagnosis or treatment of various diseases. Some common

[1] https://miccai.org/

medical imaging techniques include X-rays, computed tomography (CT) scans, magnetic resonance imaging (MRI), ultrasound (US), positron emission tomography (PET), and single-photon emission computed tomography (SPECT), among others [59]. This paper explores the four most commonly used medical imaging modalities—X-ray, CT, MRI, and Ultrasound. TABLE V. compares these four imaging modalities in terms of their advantages, disadvantages, SOTA applications, and health effects [60].



Input
$F_1 = \frac{H}{4} \times \frac{W}{4} \times C_1$
$F_2 = \frac{H}{8} \times \frac{W}{8} \times C_2$
$F_3 = \frac{H}{16} \times \frac{W}{16} \times C_3$
$F_4 = \frac{H}{32} \times \frac{W}{32} \times C_4$

TABLE V. COMPARISON BETWEEN THE MEDICAL IMAGING MODALITIES

	X-ray	CT	MRI	US
Advantages	Low cost Fast imaging time.	Quick imaging Excellent spatial resolution It is possible to combine it with angiographic techniques.	There is no ionizing radiation. Exceptional spatial resolution Outstanding soft tissue contrast Dynamic angiographic imaging.	Low cost and real-time nature Fast imaging time No ionizing radiation, good spatial resolution More prevalent, portability.
Disadvantages	Ionizing radiation Low sensitivity.	Ionizing radiation Low sensitivity Limited soft tissue contrast.	High cost Long imaging time Contraindications in some patients	Operator dependent The difficulty of distinguishing imaging structures between tissue and gas Noise, shadow, speckle, low contrast, and blurred edges Limited penetration/sensitivity
Applications of MIS	Bone [61], Lung [2], [62], Caries lesion [63]	Lung [42], [64] - [66], Proximal femur segmentation [67], Kidney tumor segmentation [68], tooth and alveolar bone segmentation [69]	Brain [66], [70] - [72], Retinal Vessel [73] - [75], Cardiac [66], [76] – [78], prostate [66], [39], [78], Osteosarcoma [79]	Breast [80], kidney [81], prostate [82], multi-organs [83]
Health effects	Biological effect, need protection against unnecessary does.	High radiation, dangerous to health.	Less harmful effects, better for the fetus.	Safe, painless, non-invasive and non-ionized.

Some comments on medical imaging modalities:

- Regarding the segmentation problem: Due to challenges such as noise, shadow, speckling, low contrast, and blurred edges, US images pose more difficulties in segmentation compared to MRI and CT images
- Regarding health effects: X-ray and CT imaging have various negative impacts on human health.
- Regarding segmentation applications: Multiple medical imaging modalities can be utilized for various health care applications to provide comprehensive health care for individuals

2) MIS in different dimensionality of medical images: This section provides an overview of 2D, 3D, and 4D data types in medical imaging, as well as image segmentation issues in these three data types.

- Structured 2D images have a defined height and width and exist in a flat space. The most common type of medical image in this category is X-rays. This paper focuses on examining segmentation models, such as 2D CNNs, original UNets, and their variants, that are applicable to 2D image.
- Structured 3D images have a defined height, width, and depth, and can be considered as a collection of stacked 2D frames. This type of medical imaging, which utilizes spatial relationships, is commonly used in modalities such as CT and MRI scans. 3D imaging is widely used in clinical practice due to its ability to provide rich information about the imaged regions, which aid in the visualization and quantification of various tissues and organs. However, manual segmentation of 3D images is challenging and time-consuming, highlighting the importance of automated computer-aided segmentation models. or 3D medical image segmentation, CNN models often employ a 3D kernel to extract spatial features or utilize GNN or Transformer. Some of SOTA models in this field include 3D U-Net [40], V-Net [39], nnU-Net [84], HighRes3dNet [85], 3D-Res-Unet [86], DenseVNet [87], UNETR [88], SegResNet [89], Point-Unet [90], and others.
- Structured 4D images, which are comprised of height, width, depth, and temporal dimensions, are commonly referred to as dynamic volumes and represent moving data in real-time. In the medical field, 4D images are often used to measure various parameters such as heart rate [91], lung breathing [92], blood flow rate, fetal movement, and more. In the field of medicine, 4D imaging techniques include dynamic volume CT, 4D CT, MRI, and ultrasound. The segmentation of 4D medical images has great potential in uncovering disease progression and monitoring disease trajectory [93]. However, traditional image segmentation can be complex and costly without the aid of AI models. Commonly used models in 4D image segmentation include "balloon" models and deformable (time-varying) models, such as, LSTM, FCSLSTM [93], and XCAT [94].

Based on the characteristics of each medical imaging modality, as well as the statistics from the MICCAI 2023 and 2022 challenges, and the latest papers on paperswithcode, it appears that 3D medical imaging techniques, such as MRI and CT, are currently the most popular. The advantages of 3D medical images include the utilization of spatial relationships, the ability to obtain more information from image regions than can be obtained from 2D images, and a lower cost for processing and acquisition compared to 4D images.

3) Medical image dataset: Data is a crucial aspect of learning, and medical image segmentation datasets often contain sensitive information, making them highly privacy-sensitive. However, in order to evaluate the performance of image segmentation methods, the datasets must be made publicly available. To accomplish this, organizers gather and anonymize medical imaging datasets, and host various challenges to advance the field of medical imaging. There are several medical databases available for free use in research, including:

- World Health Organization (WHO): WHO is a United Nations agency that connects nations, partners, and people to promote health and ensure the safety of the world. Established in 1948, WHO serves the most vulnerable populations so that everyone, everywhere, can attain the best possible health. The World Health Data Hub of the WHO is a comprehensive digital platform for global health data that provides efficient solutions for collecting, storing, analyzing, and sharing timely, reliable, and actionable data. The WHO is responsible for managing and preserving a vast array of data collections related to global health and well-being, as mandated by its Member States.

- Medical ImageNet is a large-scale resource for machine learning based on medical images. The Stanford Center for Artificial Intelligence in Medicine and Imaging (AIMI Center) was established in 2018 with the primary objective of using AI to address clinically significant medical issues. The Stanford Medical ImageNet is a petabyte-scale searchable repository of annotated and de-identified clinical images (radiology and pathology) that are linked to genomic data and electronic medical records, providing a platform for the speedy development of computer vision systems.

- Kaggle: Kaggle offers a customizable Jupyter Notebook environment with no setup required. It provides free access to GPUs and a vast repository of community-submitted data and code. Within Kaggle, you will find all the necessary code and data to complete your data science projects. With over 50,000 public datasets and 400,000 public notebooks available, you can quickly complete any analysis. Currently, Kaggle has 930 medical datasets, including 210 medical image datasets.

- Paperswithcode: The mission of Papers with Code is to create a free and open resource for machine learning research, including papers, code, datasets, methods, and benchmarks. It lists 2029 results for medical image datasets. Simpson, Amber L., et al. released ten datasets for medical image segmentation for various tasks under the Medical Segmentation Decathlon.

- mridata.org is an open platform for researchers to share raw magnetic resonance imaging (MRI) datasets. The website was created through a collaboration between Professor Michael Lustig's group at UC Berkeley and Professor Shreyas Vasanawala's group at Stanford's Lucile Packard Children's Hospital. The datasets available on the website can be used for a variety of purposes.

- Medical image datasets for segmentation are collected by researchers from various sources, including scientific journals and conferences, and collaborations between health organizations and partnerships. These datasets can be found by searching Google Scholar and Google using keywords such as 'medical segmentation', 'medical image datasets for segmentation', etc.

4) Taxonomy of data-driven learning paradigms: Data-driven learning paradigms can be classified into four categories: supervised learning, unsupervised learning, semi-supervised learning, and weakly supervised learning.

- Supervised learning: The first type of machine learning that humans introduced was supervised learning. In this method, the learning model is trained by providing labeled data, where both the input data and the corresponding output labels are given. The model then uses this information to make predictions on new, unseen data based on what it has learned from the training data. Learning from a forest to predict a tree is an example of supervised learning. The first model to utilize this method was the perceptron. Most ML algorithms employ supervised learning. In the medical field, supervised learning is commonly used to estimate risk. With risk modeling, the computer not only replicates a doctor's expertise, but it can also uncover novel relationships that might not be noticeable to humans [95].

- Unsupervised learning: However, labeling data is often difficult, expensive, and time-consuming, requiring the assistance of specialists. Furthermore, as network architecture advances, models can learn from unlabeled data. This is known as unsupervised learning. The Deep Belief Network (DBN) was proposed by Hinton in 2006, which uses this unsupervised mechanism. Unsupervised learning is based on data structures for performing clustering and data classification. However, since the data is not labeled, the learning challenge will increase. The usefulness of the patterns identified through unsupervised learning needs to be assessed either by human inspection or through additional supervised learning tasks [96]. Studies using unsupervised learning for Medical Image Segmentation (MIS) include the following: breast cancer segmentation on MRI [97]; COVID segmentation on CT lung tissue [98]; brain segmentation on 3D MRI [99]; multi-modality segmentation, including 2D hand x-ray, 3D abdominal magnetic resonance (MR) image, and 3D cardiovascular MR images [100], as well as cardiac substructure segmentation and abdominal multi-organ segmentation between MRI and CT images [101], etc.

- Semi-supervised learning combines supervised and unsupervised learning paradigms to solve the problem of training an accurate classifier with less human effort and time. This framework leverages both a limited amount of labeled data and a large amount of unlabeled (undiagnosed) data to achieve this goal [102]. Studies using semi-supervised learning in the field of MIS can be found in the range of studies [103] to [105].

- Weakly supervised learning paradigms are used when raw data is not fully processed or processed inaccurately. The goal of weakly supervised learning is similar to that of supervised learning, but instead of using a carefully labeled and processed training set, weak supervision is provided through one or more weakly annotated examples. These examples may come from community sources, be the output of rule heuristics, the results of remote monitoring, or the output of other classifiers [106]. Numerous studies have employed weakly supervised learning for the segmentation of medical images, as demonstrated in researches [107] to [109].

One thing to remember about medical imaging data is that the amount of annotated (labeled) data is very small. TABLE VI. TABLE VI. compares the four paradigms discussed above in terms of labeling costs.

TABLE VI. COMPARISON OF LABELING COSTS OF DATA-DRIVEN LEARNING PARADIGMS

Methods	Data	Labeling Cost
Supervised Learning	Labeled data	High
Unsupervised Learning	Unlabeled data	No
Semi-supervised Learning	Labeled data + unlabeled data	Medium
Weakly supervised Learning	Labeled data (small) + noise data (incomplete and inaccurate labels) + unlabeled data	Low

The accuracy of data-driven learning models is directly proportional to the amount of annotated data and inversely proportional to the cost of labeling. To improve the accuracy of learning models while reducing the cost of labeling, two solutions that have been proposed are transfer learning and active learning.

Traditional machine learning methods assume that the training and test data come from the same domain, with the same input feature space and data distribution characteristics. However, this assumption is not always true in real-world machine learning scenario. In some cases, collecting and annotating training data can be expensive or difficult. Transfer learning addresses this issue by training models on labeled data from domains where data collection and annotation are easier. The knowledge gained from the training data is then transferred to the test data domain [110]. Many models today are pre-trained on the ImageNet dataset [111]. Transfer learning has been applied in the field of medical image analysis in works such as [112] and [113].

While the ImageNet dataset is large and well-labeled, medical image data has distinctive characteristics that set it apart from natural images in datasets like ImageNet. Active learning is a method of selecting a subset of data from a larger dataset, such as a data lake [114] for annotation. The goal of this method is to increase the amount of annotated data, reduce data annotation costs, and improve model performance. This paradigm has been used in papers ranging from [115] to [118]

C. Loss Functions

1) Common loss functions:

1) Common loss functions: The image segmentation labels each pixel with the corresponding class. Therefore, it is necessary to use a mechanism to calculate the loss weight for each pixel. The most commonly used loss functions in segmentation are cross entropy and its variants.

- Cross-Entropy loss is a fundamental function in medical image segmentation. It is derived from the Kullback-Leibler (KL) divergence, which measures the difference between two probability distributions, such as those provided by the training set. The minimum KL divergence is equivalent to the minimum Cross-Entropy. The Cross-Entropy is defined as follows:

$$L_{CE} = -\frac{1}{N}\sum_{c=1}^{C}\sum_{i=1}^{N} gt_i^c logms_i^s \qquad (1)$$

where gt_i^c is a binary indicator representing whether class label c is the correct classification for pixel i, and ms_i^s is the corresponding predicted probability.

- A variant of the Cross-Entropy loss is the Weighted Cross-Entropy loss (WCE). This loss function takes into account class imbalance by assigning weights to different classes. Another emerging variant of the Cross-Entropy loss is the Focal Loss, which adjusts the weights of well-classified training samples to reduce their impact.

$$L_{WCE} = -\frac{1}{N}\sum_{c=1}^{C}\sum_{i=1}^{N} w_c gt_i^c logms_i^s \qquad (2)$$

where w_c is the class weight assigned to penalize majority classes, w_c is typically set inversely proportional to the frequency of each class in the training set. In the experiments to follow, we will set the class weight w_c to be the reciprocal of class frequency in the training set.

Aside from cross-entropy, other standard loss functions used in image segmentation are the **Dice loss**, and the **Intersection over union (IoU) loss** - which is derived from the Jaccard index and measures the ratio of sample intersection to its union. Dice loss and IoU loss are often used to improve the corresponding evaluation metrics.

$$L_{Dice} = 1 - \frac{2\sum_{c=1}^{C}\sum_{i=1}^{N} gt_i^c ms_i^s}{\sum_{c=1}^{C}\sum_{i=1}^{N} gt_i^c + \sum_{c=1}^{C}\sum_{i=1}^{N} ms_i^c} \qquad (3)$$

$$L_{IoU} = 1 - \frac{\sum_{c=1}^{C}\sum_{i=1}^{N} gt_i^c ms_i^s}{\sum_{c=1}^{C}\sum_{i=1}^{N}(gt_i^c + ms_i^s - gt_i^c ms_i^s)} \qquad (4)$$

2) Hybrid loss functions: Jun Ma et al. presented an overview of loss functions in MIS sorted according to the following classification system: distribution-based, region-based, boundary-based, and association-based. At the same time, the authors also found the relationship (connection) between different loss functions (see Fig. 6), as well as the specific use case of loss functions in different applications of MIS [119]. These loss functions are installed on GitHub [4]

Loss function relationships: As shown in Fig. 6 there are strong connections between loss functions.

[4] https://github.com/JunMa11/SegLoss.

- Most distribution-based and region-based loss functions are variants of Cross entropy and Dice loss.
- Although boundary-based losses are designed to minimize the distance between two boundaries, they share some similarities with Dice loss because both are calculated using region-based methods.
- A compound loss is a combination of multiple loss functions.

Recommendations for selecting loss functions: It is impossible to determine which loss function is the best. The data balance can be used to select the appropriate loss function.

- Mild imbalance issues are well handled by Dice loss or General Dice loss (GD)
- For highly imbalanced segmentation tasks, the compound loss functions are more commonly used.

The Combo Loss function proposed by Saeid Asgari Taghanaki et al. [120] aims to improve multi-organ segmentation performance in cases where the input and output are imbalanced. This loss function has been shown to achieve higher Dice scores and reduce false negatives and false positives, and can be applied to 3D U-Net, 3D V-Net, and 3D Seg-Net architectures.

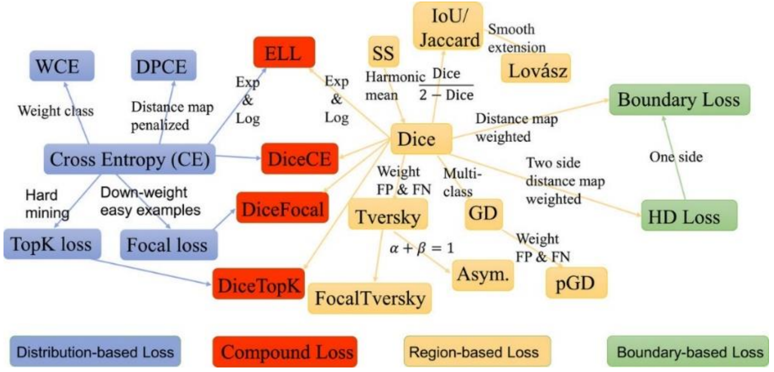

Fig. 6. An overview of 20 loss functions for MIS and their relationships [119].

D. Evaluation Metrics

Segmentation performance evaluation involves comparing the similarity between a manually generated and a DNN-generated segmentation. Many metrics are used for evaluation, but some of the most commonly used ones in medical imaging are presented below.

In MIS, the regions of interest (ROI) are often quite small compared to the overall image. This results in an imbalanced distribution of pixels between different classes. To address this issue, two common metrics used in MIS are the Dice Similarity Coefficient (DSC), also known as the F1 score, and the Intersection over Union (IoU), also known as the Jaccard index.

Explanation of some acronyms: GT: Ground Truth; MS: Machine Segmentation; TP: True positive; TN: True negative; FP: False positive; FN: False negative; these terms are illustrated in Fig. 7, which has been modified from source [121].

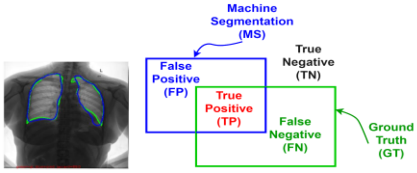

Fig. 7. Illustrate GT, MS, TP, TN, FP, and FN modified from the source [121].

1) Jaccard index (JAC - IoU) evaluates the overlap between GT and MS regions.

$$JAC = IoU = \frac{▨}{▨} = \frac{|GT \cap MS|}{|GT \cup MS|} = \frac{TP}{TP + FP + FN} \quad (5)$$

2) Dice similarity coefficient (DSC - F1 score) measures the similarity between GT and MS regions.

$$DSC = F1\ Score = \frac{2 * ▨}{□ + □} = \frac{2|GT \cap MS|}{|GT| + |MS|} \quad (6)$$

$$= \frac{2TP}{2TP + FP + FN} = \frac{2JAC}{1 + JAC}$$

The following are other metrics that are less commonly used in the evaluation of medical image segmentation due to their sensitivity to the size of the segment, meaning they penalize errors in small segments more heavily than in larger segments.

3) The Hausdorff distance (HD) between two GT and MS regions is defined as "the maximum of all minimum distances" (see Fig. 8) [122].

$$HD\ (GT, MS) = \ max\{\{d(gt, ms)\}\} \quad (7)$$

where gt and ms represent the pixels of regions GT and MS respectively, and d (gt, ms) is any metric between these pixels; for the sake of simplicity, take d (gt, ms) is taken as the Euclidean distance between gt and ms.

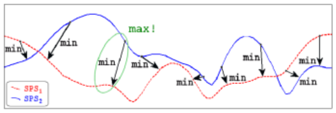

Fig. 8. Illustrate the Hausdorff distance [122].

4) Other evaluation metrics

- Sensitivity / Recall / True Positive Rate (TPR):

$$Sensitivity = Recall = TPR = \frac{TP}{TP+FN} \quad (8)$$

- Specificity or True Negative Rate (TNR):

$$Specificity = TNR = \frac{TN}{TN+FP} \quad (9)$$

- Accuracy (ACC):

$$Acc = \frac{TP+TN}{TP+FP+TN+FP} \quad (10)$$

- False Positive Rate (FPR)

$$FPR = \frac{FP}{FP+TN} = 1 - TNR \quad (11)$$

- False Negative Rate (FNR)

$$FNR = \frac{FN}{FN+TP} = 1 - TPR \quad (12)$$

- Precision or Positive Predictive Value (PPV):

$$Precision = PPV = \frac{TP}{TP+FP} \quad (13)$$

III. Explainable Artificial Intelligence in Medical Image Segmentation (XAI in MIS)

Recently, the use of AI in the medical field has led to impressive results, with machine learning models achieving over 99% accuracy. However, the practical application of these models remains limited due to their "black box" nature. XAI learns how models make decisions, investigates the inner workings of its layers, and provides visualizations of neural networks. Interpretability, which supports the reasoning behind a model's output, is crucial, particularly in precision medicine where experts require more in-depth information from a model beyond just a binary prediction to make an accurate diagnosis. In general, people are cautious about using techniques that are not transparent and can't be easily understood, due to the increasing emphasis on ethical AI, particularly in fields that have a direct impact on human lives [123]. To build trust among physicians, regulators, and patients, medical diagnostic systems must be transparent, easily understandable, and capable of providing explanations [123]. Moreover, by using XAI, model designers can uncover weaknesses in existing architecture and debug and fine-tune models to improve their performance.

If an image-based diagnostic system is enhanced with XAI, it will reach a level of Wisdom, which is higher than mere Intelligence. This is because, in addition to having high IQ, it also has high EQ or a sense of responsibility.

XAI can be divided into two categories: interpretability and explainability.

- "Interpretability" focuses on the underlying processes and events. It answers the "how" question by showing how the decision was made (based on the scoring criteria), but it does not explain "why" the criteria used are reasonable. The term "interpretability" addresses the "quantitative" aspects of the decision-making process.

- "Explainability" focuses on the inherent characteristics of events. It addresses the "why" question by explaining the reasoning behind the decision, rather than just the "how". The term "explainability" refers to the "qualitative" aspects of the decision-making process. Some commonly used methods for explainability include CAM [124], Grad-CAM [125], Grad-CAM++ [126], LIME [127], and SHAP [128]:
  - Bolei Zhou and colleagues introduced the Class Activation Maps (CAM) approach [124], which utilizes a global average pooling (GAP) layer at the end of the neural network. CAM provides an interpretation of the model and reveals the areas of the image that the network focuses on to make decisions. By producing heatmaps, CAM shows which regions of the image are most important for decision-making.
  - Building on the CAM approach, various variants have been developed for the XAI process, including the widely used Grad-CAM [125] and Grad-CAM++ [126].
  - Local Interpretable Model-agnostic Explanations (LIME) [127] were introduced by Marco Tulio Ribeiro and others as a method for creating an interpretable model that accurately reflects the classifier in a locally interpretable representation.
  - SHAP (SHapley Additive exPlanations) [128], developed by S. Lundberg and S.-I. Lee, is a method that assigns a significant value to each feature for a specific prediction. This approach is viewed as a comprehensive framework for interpreting predictions.

There are some XAI models that can only be interpretable, explainable or both.

1) Consider the linear regression model for disease diagnosis.

- It is considered "interpretable" because once the coefficients of the linear model are calculated, the new input can be used to determine how the predicted output was obtained. This process is clearly quantified.

- However, it is "unexplainable" because it does not provide an explanation for why there is a linear relationship between the independent and dependent variables, which is not clearly quantified.

- Both "interpretability" and "explainability" can be achieved if the statistical process includes a step for testing the linear hypothesis. This provides a way to determine the presence of a linear relationship and quantify the relationship between the independent and dependent variables, making the results both interpretable and explainable.

2) Example of a model that can only be explained: The lung infection segmentation model from X-ray images was trained using a Deep Convolutional Neural Network (DCNN) combined with Class Activation Maps (CAM) on data from two different scanners at two hospitals. It is possible to understand which areas of the lungs contribute to a positive outcome ("why"), but the reason why the sample test with the trained model at hospital 1 is positive but with the trained model at hospital 2 is negative is unclear ("how" to calculate it is not understood).

IV. Early Prediction with MIS

This section presents the role and typical applications of MIS in the field of early prediction.

Tumors often start as small, hard-to-detect nodules, which can lead to a high mortality rate among patients. However, if detected early and treated promptly, it can increase the patient's chances of survival and decrease the cost of treatment. This is the motivation behind researchers performing early prediction problems. The segmentation results can be used to anticipate disease progression and offer appropriate treatment. Early prediction has a critical role in reducing patient risk, which holds great humanitarian significance. Furthermore, it helps to elevate the level of the system from intelligence to wisdom.

A. Some Typical Applications

The Fuzzy C-means (FCM) intelligent segmentation algorithm [129] was developed for early detection of enlarged hematoma in patients with intracerebral hemorrhage (ICH) on CT images. The processing of cranial CT images using the FCM algorithm has high clinical value in predicting early hematoma in ICH patients.

Lung cancer is usually detected early when lesions appear in the bronchial epithelium of the airway wall. Autofluorescence bronchoscopy (AFB) [52] has been shown in recent studies to be particularly effective in detecting lesions, making it a potentially crucial approach for airway evaluation. Bronchoscopy is a commonly used method for detecting early-stage lung cancer. ESFPNet is a method for accurately segmenting and identifying bronchial lesions in AFB video streams.

There are also some other early prediction models based on segmentation results such as brain-related disease [130] - [132], evaluation of bone tumors [133], lung disease [134] - [136], breast cancer [137] - [138], tumor metastasis of ovarian cancer patients [139], stroke, ischemic coma [140] - [141], acute pancreatitis [142], and cancer radiation [143]- [144].

In addition, early segmentation is also applicable to cases with noisy and incomplete annotations [145].

V. Challenges and Solutions

A. Challenges with Dataset

1) Shortage of large-scale, annotated, and standardized datasets: High-quality and large amounts of data are crucial for deep neural network (DNN) models. However, obtaining data, especially sensitive information like medical images, can be difficult through crawling methods. Additionally, manual annotations on medical images can be time-consuming, costly, and require specialized knowledge.

Solutions to address the shortage of datasets include: (a) utilizing unsupervised learning techniques, such as semi-supervised learning, weak supervision, active learning, and transfer learning (as discussed in Section IV4); (b) utilizing open-source datasets, including those mentioned in previous sections, as well as others listed in "10 Open Repositories for the Medical Image Processing Community" by vin bigdata [146]; (c) creating simulated data using the Synthetic Minority Oversampling (SMOTE) technique, which generates new data points based on the closest data points of the minority class; (d) implementing data augmentation [51]; (e) and Deploying Pre-Trained DNN models [147].

2) Class Imbalance in Datasets: Medical datasets are often highly imbalanced with regards to class distribution, with some diseases having significantly more negative samples than positive samples, sometimes up to a 98% to 2% ratio. This level of imbalance can result in biased outcomes, and the prediction model may not be accurate for the minority class as it is frequently biased towards the majority class.

Solutions to class imbalance in medical datasets include adjusting the evaluation metric, under-sampling, over-sampling, collecting more data, incorporating model penalties, and using cross-validation.

In addition to class imbalance, medical image datasets can also face issues of sparse annotations and intensity inhomogeneities, which can affect model performance. There are specific solutions for each of these cases presented in the papers [148] and [149].

B. Challenges with DNN

1) Training time: Training a deep neural network (DNN) requires significant time and effort to extract the necessary features and enhance performance.

Solutions to improve the efficiency of DNN training include: (a) implementing batch normalization; (b) using pooling layers to reduce image size and the number of parameters, and employing the early stopping technique to minimize unnecessary training time and avoid overfitting.

2) Overfitting: Deep learning algorithms are susceptible to overfitting, where a model becomes too tailored to the training data and memorizes both meaningful patterns and random noise and fluctuations. This can result in poor generalization and low performance on unseen test data.

To prevent overfitting, various techniques can be utilized, as outlined in [150]. These include training with more data, implementing data augmentation, adding noise to input data, performing feature selection, utilizing cross-validation, simplifying data, applying regularization, using ensembling methods, employing early stopping, and incorporating dropout layers.

3) Gradient vanishing: Gradients tend to decrease in magnitude as back propagation be activated in a deep neural network (DNN). This means that the updates performed by Gradient Descent have limited impact on the weights of these layers, making convergence difficult and potentially leading to poor performance of the DNN. This phenomenon is referred to as the Vanishing Gradients problem.

To address the Vanishing Gradients problem, there are two main approaches: (a) Preprocessing, appropriate activation function selection, and proper weight initialization. (b) Using residual blocks and skip connections along the encoder-decoder path, as described in [151].

4) Computational complexity: Deep learning algorithms often involve complex calculations, and the training process is typically performed on high-performance hardware such as GPUs or supercomputers.

To address this, it is important to construct compact and portable models with a reduced number of parameters while still maintaining high performance for the intended task [152]. This can be achieved through various techniques such as regularization, model pruning, and efficient architectures

5) The "black box" nature of AI models: The "black box" nature of artificial intelligence raises important ethical, transparent, and explainability concerns in clinical medical applications. Despite numerous efforts in the field of XAI, this problem remains a significant challenge for researchers to address.

To address the challenges of explainability in AI, there are several solutions available, beyond those mentioned in Section III, such as CAM, LIME, and SHAP. Other measures include SAU-Net [153], saliency map, and others.

Building on the progress made by the XAI community, Seibold et al. [154] have proposed an indirect segmentation method that leverages Layer Relevancy Propagation (LRP) to extract binary segmentation maps at the pixel level. This approach demonstrates comparable results to UNet while only using image-level labeled data.

6) Early segmentation problems: This approach represents a new and promising opportunity for application in clinical settings. It has the potential to drive advancements in both medicine and AI, and ultimately contribute to better protection of human health. This is a significant breakthrough that holds great promise for the future.

Solutions:

In the early stages of tumor development, it can be difficult to detect small tumors due to their size. To address this challenge, it is important to build highly sensitive models that are capable of accurately segmenting small regions of interest, such as the TransUNet+ model described in [50].

To predict the progression of a disease in patients, one approach is to conduct a follow-up study that combines previous and current results to forecast future segmentation outcomes. In practical experience, malignant tumors often grow abnormally and out of control, making early and accurate detection and segmentation critical for reducing the risk of patient mortality. To achieve this goal, it is crucial to develop early and precise auto-segmentation technology. The use of past observations to predict future events is a key method for making informed decisions, as described in [155].

VI. Conclusions and Future Work

Over the past decade, AI-assisted automated medical image segmentation has gained significant attention from the computer vision community. This study provides a comprehensive overview of the state-of-the-art solutions in terms of network architecture, data, loss functions, and performance metrics. With a focus on network architecture, this research categorizes the solutions into three levels of intelligent vision systems. The study also considers the "intelligence" level of the DIKIW hierarchy.

The paper also highlights two issues that are currently gaining significant attention, which are Explainable AI (XAI) and Medical Image Segmentation (MIS)-based early prediction. Both of these topics are considered hot research areas due to their practical and humanistic values. By addressing XAI and early prediction, the level of the DIKIW hierarchy can be raised from "intelligence" to "wisdom". Despite some progress in these areas, there are still numerous challenges that remain for researchers to tackle.

The next step in the research direction of this paper is to develop a trusted XAI-based early diagnosis support system that can be used in hospitals by both patients and doctors.

The aim of the paper is to advance the use of AI in disease diagnosis to a level of wisdom and, as a result, improve the well-being of society.

An Ensemble Multi-layered Sentiment Analysis Model (EMLSA) for Classifying the Complex Datasets

Penubaka Balaji[1], D. Haritha[2]
Department of Computer Science & Engineering, K L University, Vaddeswaram, Andhra Pradesh, India

***Abstract*—Sentiment analysis is one domain that analyzes the feelings and emotions of the users based on their text messages. Sentiment analysis of short messages, reviews in online social media (OSM), and social networking sites (SNS) messages gives the analysis of given text data. Processing short text and SNS messages is a very tedious task because of the restricted detailed information generally contained. Solving this issue requires advanced techniques that are combined to give accurate results. This paper developed an Ensemble Multi-Layered Sentiment Analysis Model (EMLSA) that exploits the trust-based sentiment analysis on various real-time datasets. EMLA is the combined approach with VADER (Valence Aware Dictionary and sEntiment Reasoned) and Recurrent Neural Networks (RNNs). VADER is the lexicon and rule-based sentiment analysis model that predicts the sentiments extracted from input datasets and it is used for training. The feature extraction technique is term-frequency and inverse document frequency. Word-Level Embeddings (WLE) and Character-Level Embeddings (CLE) are the two models that increase the short text and single-word analysis. The proposed model was applied to four real-time datasets: Amazon, eBay, Trip-advisor, and IMDB Movie Reviews. The performance is analyzed using various parameters such as sensitivity, specificity, precision, accuracy, and F1-score.**

***Keywords*—Sentiment analysis; online social media; social networking sites; VADER; recurrent neural networks**

I. Introduction

Sentiment Analysis (SA) is the process of finding and dividing the opinions of the people expressed in text, voice, and videos. SA, also called opinion mining (OM), is natural language processing (NLP) that finds the emotions behind the body's text [1]. Opinions are expressed in various domains, such as movie reviews, e-commerce reviews, and Twitter reviews. Every day, many people and millions of reviews are generated by social media platforms regarding products, movies, and general topics [2]. An automated system is required to analyze the users' views, opinions, and sentiments. SA mainly focused on finding non-trivial, emotional information collected from various online sources belonging to social media [3]. Sentiment analysis can also be applied to multiple documents and phrases and analyzed single words. Finally, sentiment analysis divides the reviews into three types such as positive, negative, and neutral, based on the text data. Sentiment analysis helps e-commerce applications increase the sales of specific products [4] [5].

Natural language processing (NLP) is mainly focused on two aspects such as human language understanding and generation. It is a challenging task to analyze the natural language with the existing models. Several applications include speech recognition, text analysis, questioning and answering, synthesis of speech etc. [6]. NLP is divided into two significant areas such as sentiment analysis and recognition of emotions. Sometimes these two areas differ based on their aspects. "Emotion detection" is the domain that finds the feelings from the user's expressions like happiness, sadness, and depression. There is a significant connection between "sentiment analysis" and "emotion detection" [7]. From the emotions, the users express their feelings through text, video, and audio.

Sometimes sentiment analysis goes beyond people's opinions and views, such as sad, happy, angry, etc. [8]. Based on the feedback of the user or customer, sentiment analysis is required [9] [10] [11]. This paper describes various sentiment analyses belonging to several domains using deep learning algorithms with the integration of advanced fine-tuned models. The proposed approach focused on finding the sentiment analysis on multiple domains and analyzing the trust-based reviews in the input dataset. The proposed method also focused on aspect, Multilingual and emotion-based sentiment analysis.

II. Literature Survey

T. Gu et al. [12] proposed a novel sentiment analysis approach called MBGCV introduced to increase sentiment classification performance. MBGCV combined with various BiGRU, CNN, and VIB models. The proposed model obtained the high-level sentiment features from the given datasets. The real-time review dataset is used to analyze the performance of the proposed approach. M. K. Hayat et al. [13] introduced a DL model combined with the taxonomy-based approach to solving various issues in sentiment analytics. H. Liu [14] describes the comparative study among the lexicon, ML, and DL-based models that solve several accuracy issues. Various real-time datasets are used for experiments and analysis of sentiments. P. Gupta et al. [15] proposed the lexicon-based model that classifies the twitter data about COVID-19. The proposed model analysis the given Twitter data based on medicines, situations, and conditions faced by the users in lockdown time. This model aims to know the positive and negative opinions regarding the lockdown situation and the performance of the Indian government. Linear SVC is used to classify the data.

A. Elouardighi et al. [16] introduced the lexicon-based model combined with N-grams and TF-IDF model. The proposed approach is applied to comments in the Arabic language collected from Facebook. The data belongs to the Legislative Elections in Morocco in 2016. Several ML algorithms are used for performance evaluation, such as NB, RF, and SVM. Effective sentiment results were analyzed by using ML algorithms. P. Vyas et al. [17] introduced the framework that works on sentiment analysis regarding COVID-19. The proposed framework extracts the positive, negative, and neutral sentiments from the Twitter data and applies various ML algorithms present for classification. R. Khan et al. [18] introduced the deep LSTM model that predicts the sentiment polarity and emotions from the sentiment140 dataset. The accuracy of proposed model is 90.23%, this is very high compare with previous models. A. S. Imran et al. [19] introduced the LSTM model for detection of emotions and sentiments in terms of text messages collected from twitter. The main drawback of this model is lack of accuracy based on several emotions such as bad, good, anger. D. Antonakaki et al. [20] describe several DL models that work on sentiment analysis. The author mainly focused on three areas such as fake news, spam content, and threats messages given on Twitter. The proposed model analyzed the better sentiments based on the result analysis—the Twitter data used for performance evaluation. H. Strobelt et al. [21] proposed a model called as LSTMVIS that process the complex patterns present in various applications. S. Kumar et al. [22] proposed a hybrid recommended system that was applied to the movies dataset. The proposed model, combined with CF and CBF, provides a better recommendation system based on sentiment analysis. The proposed approach analyzed the present trends, people's sentiments, and users' responses. S. Bhatia [23] proposed a novel graph model that analyses duplicate phrases. The proposed approach focused on correcting the sentences by using graphs. To summarize the text and reduce the dimensions, PCA is used. The proposed method achieved better opinions mining based on sentiments.

S. Davis et al. [24] discussed various works on analyzing customer reviews based on E-commerce datasets. The comparative study shows the proposed approach applied to multiple user review datasets. M. A. Tayal et al. [25] submitted an integrated system based on several operations, such as pre-processing approach. Pre-processing is used to remove ambiguity from the given dataset. The proposed method mainly combines Semantic Sentence Similarity with n-gram co-occurrence relations belonging to specific sentences. Finally, the proposed model is applied to several benchmark datasets and analyzes the performances of existing and proposed models. E. Aslanian et al. [26] proposed the hybrid recommender system (HRS) that improves the high accuracy. The proposed approach, combined with the feature relationship matrix and collaborative filtering, was used to solve the cold-start problem. The proposed method achieves better accuracy compared with other existing algorithms. E. Cambria [27] proposed an automated approach for analyzing sentiments based on emotions. The proposed system combines emotions and reviews and gives better performance.

C. Du et al. [28] proposed a new classification approach that classifies the sentiment data using an advanced feature extraction technique. The softmax classifier is adopted to increase the proposed system's performance. The F1-score of the proposed approach shows the high values for two datasets. Maria Giatsoglou et al. [29] proposed a rapid and reliable model that finds the sentiments of different types of people's opinions from other languages. The ML approach combined with the proposed approach applied to text documents initialized by vectors and trained as a polarity classification model. The proposed model is analyzed using four datasets containing reviews in Greek and English.

III. PROPOSED METHODOLOGY

The proposed methodology is developed with various advanced models such as the pre-trained DL model stemming model for pre-processing, TF-IDF for feature extraction, Word-Level Embeddings (WLE) for text analysis, VADER for training and RNN for classification of text data. Fig. 1 shows the step by step process of implementation.

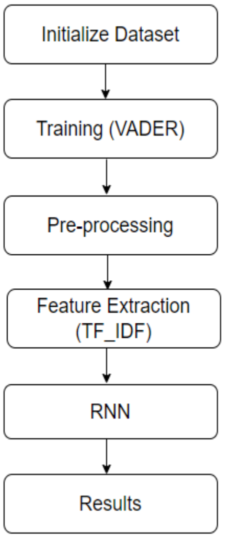

Fig. 1. System architecture.

IV. VADER

This paper uses VADER to train the given datasets to analyze the sentiments. It is the lexical database developed by using rule-based sentiment analysis. The lexicon collects the features (e.g., words) classified as positive or negative based on the sentiment polarity. VADER shows the positivity and negativity scores and also the strength of the positive and negative sentiments. The VADER is mainly based on a compound score measured by aggregation of valence scores of every word in the lexicon, find-tuned based on rules, and then normalized between -1 (high negative) and +1 (high positive). Thus this is considered the single uni-dimensional measure of sentiment for a given sentence.

$$x = \frac{x}{\sqrt{x^2 + \alpha}} \tag{1}$$

Where x = sum of valence scores of constituent words, and α = Normalization constant (default value is 15).

A. TF-IDF (Term Frequency- Inverse Document Frequency)

TF-IDF is a feature extraction approach that can extract highly reputed words in the given documents and reviews. TF mainly measures the frequently appeared mentions in the given input datasets. The term frequency refers to the total time that appeared in the given input datasets, while the document frequency refers to complete documents that contain the word. IDF counts the word from papers or reviews divided by the phrase "document frequency." Every word initialized the score by measuring the TF by its IDF. Here features mean repeated words from multiple reviews from multiple documents.

B. Word-Level Embeddings (WLE)

WLE's are encoded by using column vectors within the embedding matrix $W^{wrd} \in R^{d^{wrd} \times |V^{wrd}|}$. Every column belongs to WLE of kth word in the vocabulary. By using matrix-vector product, the word W transformed into WLE r^{wrd}.

$$r^{wrd} = W^{wrd} v^{w}) \qquad (2)$$

Where v^{w} is size of vector $|V^{wrd}|$ which is value 1 at index w and 0 in all other portions. W^{wrd} → matrix. That learns and WLE size is given as d^{wrd} is hyper-parameter which is selected by the user.

C. RNN

All these layers are fully connected and are not associated with each other. RNN [30] performs better on the text sentiments dataset, and all the tasks involve sequential inputs. RNN considers one piece of information at a time and maintains the hidden units of a "state vector" consisting of data regarding the previous history based on the sequence. The outputs of hidden units are considered at various discrete time steps if the results of several neurons in a deep multi-layer network, this becomes easy to implement back-propagation to train RNN. RNN is a dynamic approach, and it is mighty to prepare them and solves the issues in back-propagated gradients either grow or shrink at each step; several times, this process is typically terminated as shown in Fig. 2.

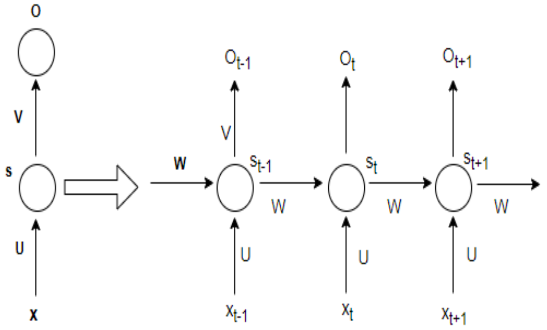

Fig. 2. Process of RNN.

The neurons in the hidden layers get the inputs from previous layers based on the time steps. Based on the above process, the RNN maps the input sequence elements represented as x_t, and the output sequence represents the elements with o_t, dependent on the previous x t′ (for t′ ≤ t). Similar metrics such as U, V, and W are utilized at every step. The back-propagation approach measures the unfolded network on the right and computes overall error based on general states s_t and all the metrics.

V. Dataset Description

1) Amazon dataset: The Amazon dataset consists of testing and training data. The training data contains 3Lakh, and testing data consists of 4Lakh data belonging to 568,000 customer's data. All these customers give reviews of the products. This is open source and free dataset collected from Kaggle: https://www.kaggle.com/datasets/bittlingmayer/amazonreviews?resource=download.

2) Ebay dataset: A data science Bootcamp project created the eBay dataset. This project aims to develop the best model for sentiment analysis. The author created this dataset using python web scraping scripts for the research work. This dataset consists of two files as ebay_reviews.csv file consists of four attributes: product category, title review, content review, and rating. The total instances are 44757. The rating attribute represents the integer value with one as the worst score and five gives the best score. The second file is a preprocessed file that consists of two attributes: rating, title review, and content review. The dataset available at: https://www.kaggle.com/data sets/wojtekbonicki/ebayreviews/discussion?select=ebay_reviews.csv.

3) Trip-advisor: This dataset consists of 20k reviews of various hotels given by customers. Trip-advisor extracts these reviews, and it is available on the Kaggle website. The dataset available at: https://www.kaggle.com/datasets/andrewmvd/tripadvisorhotel-reviews IMDB Movie Reviews Dataset: This dataset consists of 50k movie reviews and this contains 40k testing and 10 k training data. IMDB movie review dataset consists of 25k positive and 25k negative reviews and this data available at:

VI. Performance Metrics

The performance of the proposed model is analyzed by using a confusion matrix. The confusion matrix mainly measures the accurate values obtained from the proposed model. Based on the count of the importance, the performance is measured. The proposed approach focused on developing a model which can work on any dataset. The factors that show an impact on the performance of the proposed model are a true positive (TP), true negative (TN), false positive (FP), and false negative (FN).

TP: The predicted value is true, and it is true.

TN: The predicted values is no and it is false.

FP: The predicted values is yes, originally it is not true.

FN: The predicted values is no, but the values are true.

Precision: The total positives measured from the overall positives give precision.

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (3)$$

Accuracy: The model accuracy is identified.

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (4)$$

Recall: The overall TPs are identified.

$$\text{Recall} = \frac{\text{TP}}{\text{TP+ FN}} \quad (5)$$

Specificity: The overall false values are correctly identified.

$$\text{Specificity} = \frac{\text{No of TN}}{\text{No of TN+ No of FP}} \quad (6)$$

F1-Score: This measure the coherence mean of Precision and Recall achieved the better computation which is incorrectly classified cases than the Accuracy.

$$\text{F1} - \text{Score} = 2 * \frac{(\text{Precision}*\text{Recall})}{(\text{Precision}+\text{Recall})} \quad (7)$$

Result Analysis: From the results it is analyzed that the performance of various existing and proposed algorithms are given in Table I to IV. The comparative performance of RTA, IDER and EMLSA is implemented with four datasets. The proposed model EMLSA performed better on all the datasets by analyzing sentiments compared with existing models. The performance is measured by confusion matrix measures such as precision, accuracy, recall and specificity (see Fig. 3 to 6)

TABLE I. COMPARATIVE ANALYSIS OF EXISTING AND PROPOSED ALGORITHMS FOR AMAZON DATASET

Algorithms	**Precision**	**Accuracy**	**Recall**	**Specificity**	**F1-Score**

VII. CONCLUSION

Even though a conclusion may review the main results this paper describes the new DL model that can process complex datasets based on the reviews given by the users. The proposed approach was applied to four benchmark datasets that show the comparative performance in terms of sensitivity, specificity, accuracy, precision, and f1-score. The proposed DL model focused on extracting every aspect of the input reviews. The word embedding models TF-IDF, and Word2Vec combined with the DL model give high performance in terms of given input datasets. The proposed model achieved an accuracy of 98.45% for the amazon dataset, 97.78% for the TripAdvisor dataset, and 99.56% for the ebay dataset and for IMDB dataset the accuracy is 99.8%. Thus it is shown that the accuracy is more for the proposed model. In future, the multi-layered models are to be developed by improving the sentiments and emotion detection. Various combined and integrated models are required to increase the performance.

***Abstract*—In order to achieve a competitive edge in the market, one of the most essential components of effective operations management is aggregate production planning, abbreviated as APP. The sources of uncertainty discussed in the APP model include uncertainty in demand, uncertainty of production costs, and uncertainty of storage costs. The problem of APP usually involves many imprecise, conflicting and incommensurable objective functions. The application of APP in real conditions is often inaccurate, because some information is incomplete or cannot be obtained. The aim of this study is to develop APP model under uncertainty with a dynamic programming (DP) approach to meet consumer demand and minimize total costs during the planning period. The APP model includes several parameters including market demand, production costs, inventory costs, production levels and production capacity. After describing the problem, the optimal APP model is formulated using artificial neural network (ANN) techniques in the demand forecasting process and fuzzy logic (FL) in the DP framework. The ANN technique is used to forecast the input demand for APP and minimize the total cost during the planning period using the FL technique in the DP framework to accommodate uncertainties. The model input is historical data obtained through interviews. A case study was conducted on the the need for aluminum plates for the automotive industry. The results show that the ANN technique proposed for demand projection has a low error value in forecasting demand and FL in the DP framework is able to find minimal production costs in the APP model.**

***Keywords*—Aggregate production planning; artificial neural network; dynamic programming; fuzzy logic**

I. Introduction

A form of intermediate production planning known as aggregate production planning, or APP, has a time horizon of three to eighteen months and is used to establish the optimum solution level of production, stockpiles, and personnel management for each planning period within the form of limited factors of production and other constraints [1], [2]. The preferred APP strategy is capacity. Strategies for capacity choice include changing inventory levels[3]; varying the size of the workforce by hiring or firing[4]; varying production rates through overtime and idle time[5]; subcontract; using part time workers [6].

Aggregate planning is a complex issue mainly due to the need to coordinate the interacting variables so that the company can respond to requests in an effective manner [7]. The APP activity hierarchies is positioned somewhere in the between of long-term strategic alignment like new product development and short-term scheduling procedures on the factory floor [8]. The APP model is for operations managers with operations planning and sales teams.

Based on the number of objective functions, which are considered in the model, the APP model can be classified into two categories namely single objective function and multiple objective function [9]. The general purpose function in the APP model is to minimize the total system cost [7], [8], [10].

The nature of the data or input parameters in real-world APP issues, such as those involving demand, resources, costs, objective function coefficients, etc., is inherently imprecise due to the fact that some information cannot be retrieved or is unavailable in its whole [11]. In business practice, products usually have an uncertain demand and variable [12], customer preferences change, production capacity is limited [13], labor market conditions are unstable, subcontracting can incur higher costs[14], uncertainty of raw material supply [15], and an increase in backorders caused customer claim and led them to change the source of their purchases[8], [16]. This demonstrates the complex characteristics of APP and an appropriate APP model is needed.

The forecasts of future demand are the most important input for the creation of the APP strategy. A highly unpredictable demand results in frequent revisions of production planning from one planning period to the next [8], [15], [17]. This not only results in anxiety and nervousness within the production environment [4], but it is also one of the primary drivers of costs due to its adverse effects on labor and supply levels [5].

Artificial Neural Network (ANN) [18] algorithms have indeed been noticed to be effective methods for prediction due to their ability to facilitate non-linear data, to acquire delicate functional relationships among empirical data, even in cases where the underlying relationships are hard to explain or are unidentified. This is because ANN algorithms have the ability to accommodate non-linear data [19].

Conventional APP problem assumes market demand is crisp value [20], difficulty estimating crisp demand is overcome by using fuzzy demand which also increases estimation flexibility and results in better production plans that increase profits [13], [21].

Dynamic programming (DP) is a powerful optimization tool for dealing with complex problems involving sequential or multi-stage decision making in many fields [22].

As a result of the intrinsic subjectivity of people as well as the fuzziness with which they articulate their thoughts, there are a great deal of aspects that are imprecise and ambiguous. When applied in a context where there is uncertainty, doing an analysis of an issue involving multi-stage decision making using traditional DP can be challenging [23]. There are several reasons for this. DP is one of the earliest essential approaches in which fuzzy set theory is applied [24]. This is assuming that Zadeh's fuzzy set theory is the correct way to deal with uncertainty and imprecision in real-world issues [25], which leads to what is called fuzzy dynamic programming (FDP). One of the FDP applications has been used to find optimal routes with minimal costs on the problem of shipping goods from city one to city ten [26].

Key contribution of this paper are:

1) *Formulating the aggregate production planning (APP) problem as a Markov decision process (MDP) under uncertainty:* The authors developed a mathematical model to represent the APP problem in a stochastic environment. They formulated the problem as an MDP, which allowed them to take into account the uncertain variables that affect production planning decisions, such as demand and supply constraints.

2) *Applying a dynamic programming approach to solve the APP problem:* The authors used the value iteration algorithm to solve the MDP and determine the optimal production plan for each period. The dynamic programming approach allowed them to find the optimal solution for the APP problem by breaking it down into smaller subproblems and solving them recursively.

3) *Developing a scenario-based approach to model uncertainty:* The authors used a scenario-based approach to generate possible outcomes of uncertain variables, such as demand and supply constraints. This approach allowed them to create a set of scenarios that capture the uncertainty in the APP problem and formulate a stochastic optimization problem.

4) *Evaluating the proposed approach on a case study:* The authors evaluated the effectiveness of their proposed approach on a case study involving a manufacturing company. They compared the results of their approach with those obtained from a traditional linear programming model and found that the proposed approach was more effective in addressing uncertainty and generating optimal production plans.

Overall, the key contributions of the paper are the development of a dynamic programming approach to solve the APP problem under uncertainty and the application of a scenario-based approach to model uncertainty in the optimization problem. These contributions have the potential to improve production planning decisions for manufacturing companies facing uncertain demand and supply constraints.

Therefore, this study aims to formulate an optimal APP model with a DP framework that combines ANN and FL techniques. The ANN technique is used to forecast the input demand for APP and the preparation of APP using the FL technique in the DP framework.

This paper is divided into several sections that cover different aspects of the proposed approach: 1)Introduction: The introduction provides an overview of the problem of aggregate production planning (APP) under uncertainty and highlights the need for a dynamic programming approach to solve it. The authors introduce the concept of Markov decision processes (MDPs) and explain how they can be used to model the APP problem. 2) Methodology: The authors present the mathematical model that they developed to represent the APP problem as an MDP under uncertainty. They explain the variables and constraints that are included in the model and describe how it can be used to determine the optimal production plan for each period. 3) Result and Discussion. This section explains the value iteration algorithm that the authors used to solve the MDP and find the optimal production plan for each period. They describe the algorithm in detail and provide a step-by-step explanation of how it can be used to solve the APP problem. The authors introduce a scenario-based approach to model uncertainty in the APP problem. They explain how this approach can be used to generate possible outcomes of uncertain variables and describe how it can be used to formulate a stochastic optimization problem. The authors present a case study involving a manufacturing company to evaluate the effectiveness of their proposed approach. They compare the results obtained from their approach with those obtained from a traditional linear programming model and demonstrate the superiority of their approach in addressing uncertainty and generating optimal production plans. 4) Conclusion: The conclusion summarizes the key contributions of the paper and highlights the potential benefits of the proposed approach for manufacturing companies facing uncertain demand and supply constraints. The authors also suggest areas for future research and development in this field.

II. Methodology

A. Research Framework

The work step of this research is to first identify the affected factors in the APP system. Then build a demand forecasting model using the ANN technique which will be used as input to build the APP model. Finally, build the APP model using FL techniques within the DP framework. The research framework can be seen in Fig. 1.

B. Artificial Neural Networks (ANN)

The notion that underpins ANN is that the input, also known as the dependent variable, is passed through one or more hidden layers, each of which is composed of hidden units, or nodes, before it reaches the variable that is being measured as the output [27]. For the purposes of series data modeling and forecasting, the type of neural network model that sees the most widespread use is the single hidden layer feed - forward neural network [28].

Fig. 1. Research framework.

According to the standard concept, the connection between outputs (y_t) and inputs ($y_{t-1},...,y_{t-p}$) is as follows:

$$y_t = w_0 + \sum_{j=1}^{q} w_j \,.\, g\left(w_{0j} + \sum_{i=1}^{p} w_{ij} \,.\, y_{t-1}\right) + \varepsilon_t$$

Where:

$w_{i,j}$ (i = 0,1,2, ..., p, j = 1,2, ..., q) and w_j (j = 0,1,2, ..., q) are the parameter that represents the model weight;

p represents the number of input nodes, and

q represents the number of hidden nodes.

In other words, the recurrent neural network receives the values y left as input, and it also has a hidden layer that is comprised of size q nodes [29]. In point of fact, then, the model executes a nonlinear functional mapping from historical data to those of the future:

$$y_t = f\left(y_{t-1}, \ldots\ldots, y_{t-p}, w\right) + \varepsilon_t$$

This considers that w is a vector of all parameters and f () is a function defined by the network structure and the weights for the connection. The ANN applied in this study is the default single hidden layer model using the feed-forward backpropagation algorithm [30], where the extension of the nodes number in one layer is equal to the input nodes number plus 1 (Fig. 2). The quantity of grids that were put in place, each having a starting weight that was chosen at random, and then averaged as estimates are calculated [31]. ANN technique is used in the demand forecasting process using Matlab R2017b software.

C. Dynamic Programming

Dynamic Programming is a strong formal instrument that may be utilized for the purpose of addressing a wide variety of multi-stage decision-making issues [32]. Since its origin in the middle of the 1950s by Bellman 1957, DP has developed into a common tool in a variety of fields [26], including but not limited to operations research, systems analysis, engineering, data analysis, control, and computer science, amongst others [22], [2], [33]. The fact that one only needs to solve a little fraction of each subproblem in order to complete DP successfully is one of its strengths [34]. This is because of Bellman's concept of optimality, which explains the situation. According to this, regardless of the decisions that were made in the stage before it, if the decisions that are going to be made in stage n are going to be a part of the overall optimal solution, then the decisions that are going to be made at stage n have to be optimal for all of the stages that come after it [34].

At each stage, n in the DP there are state variables, x_n, and optimum decision variables, d_n.

In stage n, there is a value returned by the function for each of the values xn and dn, $r_n(x_n,d_n)$. The result of the procedure once it has reached step n is x_{n-1}, the status variable for the stage n-1. The stage transformation function is responsible for calculating this result, $x_{n-1} = x_n + d_n - D_n$ which means inventory plus production minus demand (D_n). The optimum value function, denoted as $fn(xn)$, is the combined total return beginning at step n in the state xn and proceeding to stage 1 in accordance with the best possible strategy.

In general, the most effective way to tackle problems with dynamic programming is to begin at the end of the process and work your way backwards to the beginning. This is referred to as recursion in reverse. The recursive connection that is presented here may be utilized in order to implement the concept of optimal solutions in the context of achieving the lowest possible total cost:

$$f_n(x_n) = \min_{d_n}\{r_n(x_n, d_n) + f_{n-1}(x_n + d_n - D_n)\}$$

Where $r_n(x_n, d_n)$ is the total production and storage costs for the stage / month n. Production costs are the cost of production per unit multiplied by the number of units produced (d_n). Storage cost is the ending inventory for the month multiplied by the unit cost of storage. Mathematically, it is written as follows:

$$r_n(x_n, d_n) = C_n d_n + H_n(x_n + d_n - D_n)$$

Since there is no provision for backordering, it must fulfill the needs of the customers. That is, for the month n:

$$x_n + d_n \geq D_n$$

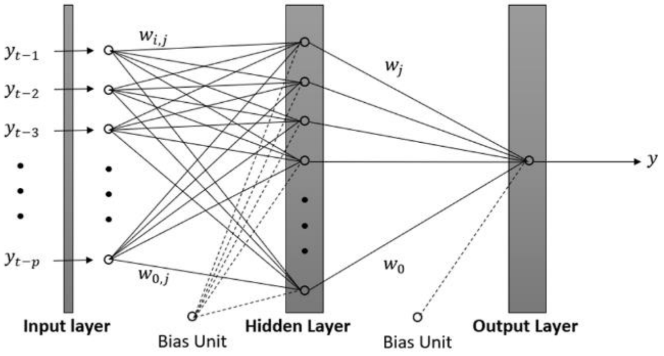

Fig. 2. Neural network structure.

Because there is a storage capacity limit of *Wn* at each and every stage *n*, the overall inventory at the conclusion of any given month cannot be greater than *Wn*. So that for every month it must be:

$$x_n + d_n - D_n \leq W_n, or$$

$$x_n + d_n \leq W_n + D_n$$

It is imperative that the quantity generated in any given month does not go over the capability of production for that month, or:

$$d_n \leq P_n$$

Beginning at stage 0 with the boundary conditions $f_0(x_0) = 0$, a problem can be solved by working backwards through the stages until reaching the final stage, *n*. It is assumed that there are no products stored in inventory at the beginning and end of the planning period.

D. Fuzzy Dynamic Programming

A fuzzy set may be identified by its one-of-a-kind membership function, which is responsible for mapping each component of the X discourse environment to the interval [0,1].

$$\tilde{A} = \{(x, \mu_{\tilde{A}}(x)); x \in X\}$$

A function related to the degree of membership A˜ determined by $\mu_{\tilde{A}}(x): X \rightarrow [0,1]$. In a fuzzy set $\tilde{A}$, $\mu_{\tilde{A}}(x)$ is the degree of membership $x \in X$.

A fuzzy set that is defined on the uniform real numbers is denoted by the symbol A, is said to be a Triangular Fuzzy Number (TFN) if there are three arguments with the value $\tilde{A}$ (a_1, a_2, a_3) determined by the following membership functions:

$$\mu_{\tilde{A}}(x) = \begin{cases} 0, & x < a_1 \\ \dfrac{x - a_1}{a_2 - a_1}, & a_1 \leq x \leq a_2 \\ \dfrac{a_3 - x}{a_3 - a_2}, & a_2 \leq x \leq a_3 \\ 0, & x > a_3 \end{cases}$$

TFN may also be expressed in the form of an interval: [d1,d2], where $d_1 = (a_2 - a_1)\alpha + a_1$ and $d_2 = -(a_3 - a_2)\,\alpha + a_3$ [35]. Fuzzy numbers can be processed mathematically fuzzy according to the method of representation. Representation in the interval for example $\tilde{A} = [d_1, d_2]$ and $\tilde{B} = [e_1, e_2]$ be a representation of two TFN numbers, the arithmetic operation is as follows:

1) $\tilde{A} + \tilde{B} = [d_1 + e_1, d_2 + e_2]$
2) $\tilde{A} \times \tilde{B} = [d_1 \times e_1, d_2 \times e_2]$
3) $c \times \tilde{A} = [c \times d_1, c \times d_2]$

Fuzzy aggregate production planning problems are related to the uncertainty of demand, production costs and storage costs with the aim of producing minimal total costs during the planning period. Suppose an industry must produce goods from one period to another with different production costs and storage costs in each period. So a plan is needed to determine the amount of production per period with the lowest cost that takes into account the demand for each period.

In order to address fuzzy APP issues utilizing the fuzzy dynamic programming approach, one must first follow the methods that are mentioned below. Step 1: Determine that there is an issue with hazy choice variables and then to state that the fuzzy objective function is going to be optimized using definite bounds. Step 2: The problem that has to be addressed is then broken down into smaller subproblems or stages. Classify the fuzzy condition variables at each level, and then create the transformation function such that it is a function of both the fuzzy condition variables at the previous stage and the fuzzy decision variables at the stage after that. Step 3: Then using generalized fuzzy recursive relationships we get the optimal decision for the problem. $\widetilde{f_n}(x_n, d_n)$ is the lowest possible sum of money spent on the previous *n* stages. $\widetilde{f_n^*}(x_n)$ is the optimal value (minimum cost) when the product is in the state x_n with *n* stage again to reach the final stage. The optimal value equation of $\widetilde{f_n}$ on condition x_n can be obtained by selecting the appropriate decision on the decision variable d_n that is:

$$\tilde{f}_n^*(x_n) = \min_{d_n}\{\tilde{r}_n(x_n, d_n) + \tilde{f}_{n-1}(x_{n-1})\}$$

Range d_n determined by x_n, but x_n defined by the events that took place in the stage before it. The return function will then assume its final shape in the subsequent stage:

$$\tilde{r}_n(x_n, d_n) = \tilde{C}_n d_n + \widetilde{H}_n\big(x_n + d_n - \widetilde{D}_n\big)$$

So that the fuzzy recursive equation is obtained as follows:

$$\tilde{f}_n^*(x_n) = \min_{d_n}\{(\tilde{C}_n d_n + \widetilde{H}_n\big(x_n + d_n - \widetilde{D}_n\big) + \tilde{f}_{n-1}(x_{n-1})\}$$

Step 4: Create a suitable table to show the importance of the return function at each stage. Step 5: Determine the overall optimal decision and its value.

The case study reported in this research is aluminum industry which processes aluminum plates for the automotive industry.

III. Results and Discussion

A. Demand Forecasting

Demand forecasting is done using the backpropagation feed-forward algorithm in the Matlab R2017b software. The input data used consisted of data on sales results, selling prices, total stock of goods, and prices for complementary products. The activation function in the hidden layer uses sigmoid and in the output layer uses linear (Fig. 3). The learning process uses a scaled conjugate gradient (trainscg) with parameters epochs 5000, sigma 5e-05, lambda 5e-07, goal 0.001 and the rest is default. From the training results obtained the mean squared error (MSE) of 0.00014347 at epoch 18 (Fig. 4) and the overall R value is 0.99074 (Fig. 5).

Demand forecasting stage with the backpropagation algorithm on ANN with input data obtained from historical data from 2016 to 2019 consisting of sales data (X1), selling price (X2), product stock (X3), and complementary product prices (X4) . Data normalization was carried out using the *X/Xmax* formula (Table I).

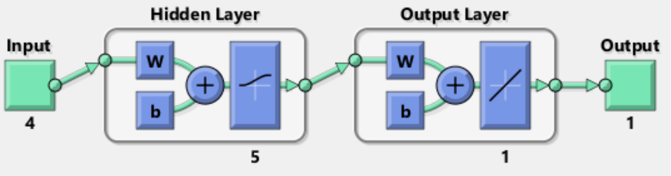

Fig. 3. Network structure.

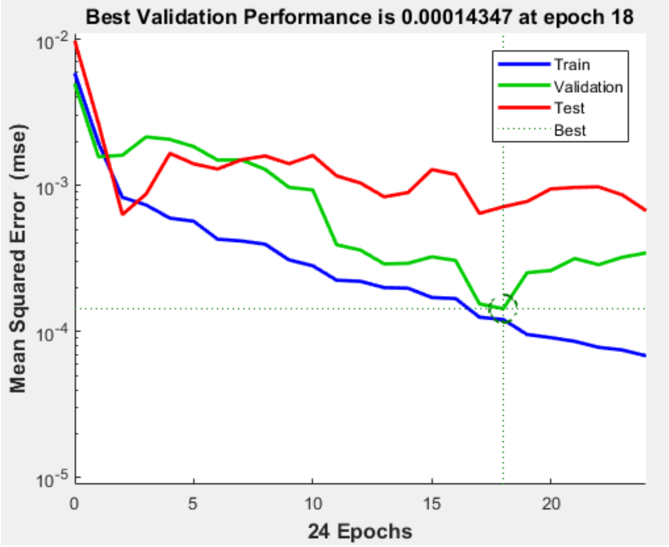

Fig. 4. MSE value.

TABLE I. DATA INPUT, TARGET, AND OUTPUT

Variable Data	
X1	... 0.63 0.64 0,67 0.60 0.64 0.75 0.67 0.64 0.67 0.70

Output	... 0.64 0.63 0.67 0.60 0.64 0.73 0.67 0.64 0.67 0.69

After the training and data testing were carried out, a simulation was carried out. This demand forecasting uses ANN backpropagation with a two-layer architecture consisting of one hidden layer with five neurons and one output layer, the sigmoid activation function (logsig) on the hidden layer and linear (purelin) on the output layer. The comparison of simulation results with actual data can be seen in Fig. 6. The comparison of simulation results and actual data shows that the simulation results by ANN backpropagation are close to the actual data, there is only a slight difference which is not too significant.

B. APP Model under Uncertainty

The simulation results of demand forecasting are used as input for the APP model. This paper sets out for a period of six months, from July to December which is completed by beginning at the end of the process and working one's way back to the beginning (backwards recursion). Stage 1 is December, stage 2 is November and beyond. Units are in tonnes and costs are in million rupiah. Production capacity (P_n) each month the same, namely 600 tons and storage capacity (W_n) each month is 900 tons. Demand data, production costs and storage costs in the TFN are shown in Table II and the fuzzy representation data in the confidence interval (α) is 0.5 in Table III.

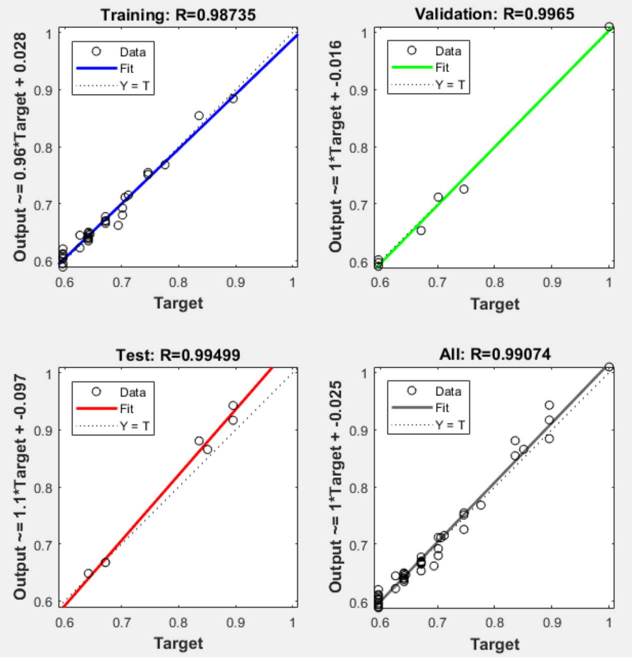

Fig. 5. R value.

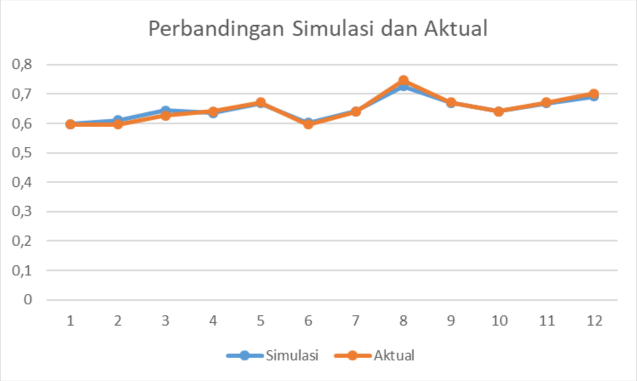

Fig. 6. Comparison of ANN backpropagation simulation results with actual data.

APP problem solving is divided into six stage according to a planning period of six months. Its objective function is to minimize total costs which include production costs and inventory storage costs during the planning period. The minimal costs at each stage are solved by equations:

$$\tilde{f}_n^*(x_n) = \min_{d_n}\{(\tilde{C}_n d_n + \tilde{H}_n(x_n + d_n - \tilde{D}_n) + \tilde{f}_{n-1}(x_{n-1})\}$$

$$\tilde{f}_1^*(x_1) = \min_{d_n}\{[5.227d_{1l} + 0.077x_{1l} - 34.76\,; 5.329d_{1u} + 0.079x_{1u} - 43.31]\}$$

$$\tilde{f}_2^*(x_2) = \min_{d_n}\{[5.43d_{2l} + 0.08x_{2l} - 28.09 + \ f_{1l}(x_{1l}); 5.532d_{2u} + 0.082x_{2u} - 36.79 + \ f_{1u}(x_{1u})]\}$$

$$\tilde{f}_3^*(x_3) = \min_{d_n}\{[5.024d_{3l} + 0.074x_{3l} - 25.99 + \ f_{2l}(x_{2l}); 5.126d_{3u} + 0.076x_{3u} - 34.09 + \ f_{2u}(x_{2u})]\}$$

$$\tilde{f}_4^*(x_4) = \min_{d_n}\{[5.126d_{4l} + 0.076x_{4l} - 26.51 + \ f_{3l}(x_{3l}); 5.227d_{4u} + 0.077x_{4u} - 34.76 + \ f_{3u}(x_{3u})]\}$$

$$\tilde{f}_5^*(x_5) = \min_{d_n}\{[5.532d_{5l} + 0.082x_{5l} - 36.79 + \ f_{4l}(x_{4l}); 5.633d_{5u} + 0.083x_{5u} - 45.79 + \ f_{4u}(x_{4u})]\}$$

$$\tilde{f}_6^*(x_6) = \min_{d_n}\{[5.126d_{6l} + 0.076x_{6l} - 26.51 + \ f_{5l}(x_{5l}); 5.227d_{6u} + 0.077x_{6u} - 34.76 + \ f_{5u}(x_{5u})]\}$$

The calculation for each stage from steps 1 to 6 is shown in Tables IV to IX.

IV. CONCLUSION

This paper presents an application of the use of backpropagation artificial neural network (ANN) to predict demand as input to an Aggregate Production Planning model that is compiled using a fuzzy dynamic programming (FDP) framework. Demand uncertainty, production costs, and storage costs are accommodated in the FDP framework. The prediction result of the number of requests using ANN backpropagation produces a prediction with an MSE value of 0.00014347, which means that the prediction generated by the ANN model is very close to the actual value.

The minimum total cost during the six months of the planning period calculated using the FDP framework is [11142.5; 14517.5] with a middle value of 12830 or twelve billion eight hundred and thirty million rupiah. The lowest production was in September, October and November with the amount between 300 and 400 tonnes. In July the production is between 350 and 450 tonnes. August and December with the same amount of production between 450 to 550 tons. Total product held in inventory was 50 tonnes each at the end of August, September and October.

***Abstract*—Agricultural productivity is a critical component of sustainable economic growth, particularly in developing countries. Morocco, with its vast agricultural potential, is in need of advanced technologies to optimize crop productivity. Precision farming is one such technology, which incorporates the use of artificial intelligence and machine learning to analyze data from various sources and make informed decisions about crop management. In this study, we propose a web-based crop recommendation system that leverages ML algorithms to predict the most suitable crop to harvest based on environmental factors such as soil nutrient levels, temperature, and precipitations. We evaluated the performance of five ML algorithms (Decision Tree, Naïve Bayes, Random Forest, Logistic Regression, and Support Vector Machine) and identified Random Forest as the best-performing algorithm. Despite the promising results, we faced several challenges, including limited availability of data and the need for field validation of the results. Nonetheless, our platform aims to provide free and open-source precision farming solutions to Moroccan farmers to improve agricultural productivity and contribute to sustainable economic growth in the country.**

Keywords—Precision agriculture; artificial intelligence; machine learning; crop recommendation; Morocco

I. Introduction

Agriculture is a crucial sector in Morocco, accounting for a significant portion of the country's GDP and employing a large percentage of the population. However, the sector faces several challenges, including water scarcity, unpredictable weather patterns, and a lack of access to information and resources [1]. Recently, an increasing interest has been observed for developing crop recommendation systems to address these challenges and improve agricultural productivity in the country [2].

Crop recommendation systems use predictive techniques to suggest the most suitable crops for a given location and set of conditions. These systems rely on data from various sources, such as satellite imagery, weather forecasts, soil analyses, and historical crop yields, to make accurate predictions [3]. By providing farmers with personalized recommendations, crop recommendation systems can help them make informed decisions about crop selection and improve their yields and profits [4].

The objective of this paper is to present a predictive approach to improving agricultural productivity in Morocco through crop recommendations. Specifically, we will develop a crop recommendation system that utilizes prediction techniques to suggest the most suitable crops for a given location and set of conditions.

In order to achieve this objective, we will initially examine the current body of literature related to crop recommendation systems as well as the difficulties encountered by the agricultural sector in Morocco. After this, we will outline the approach we employed to construct our system, which including the dataset, prediction techniques, and evaluation metrics. Following this, we will detail the outcomes of our study, including the precision of our forecasts and the efficacy of our crop recommendation system. Lastly, we will analyze the implications of our research on enhancing agricultural productivity in Morocco and suggest potential avenues for future research.

The structure of the paper is as follows. Firstly, an introduction is provided, followed by a succinct AI in precision agriculture summary, focusing primarily on Machine Learning (ML) as a component of Artificial Intelligence (AI). The paper also includes a concise literature review that highlights recent developments in the field. The research methodology is then presented, which involves an experimental evaluation of our research using various ML algorithms such as Decision Tree, Naïve Bayes, Random Forest, Logistic Regression, and Support Vector Machine. A discussion comes after this section. Finally, the key findings of the study are summed up as a conclusion of this paper.

II. Precision Farming Overview

Precision farming is an agricultural management approach that uses technology to optimize crop yields and reduce waste. Its objective is to provide farmers with real-time data and information on their farms and livestock, in order to take accurate actions that can result in maximized crop yields and limited losses.

AI helps in analyzing data from various sources and making informed decisions about crop management [5]. ML, a subfield of AI, has proven to be particularly useful in precision farming due to its ability to automatically learn patterns from large datasets and make predictions based on those patterns [6]. Fig. 1 presents the key component of precision farming.

Precision farming involves the use of a range of IoT sensors that gather various indicators associated with farming [7]. These indicators can include various environmental parameters such as soil moisture, nutrient levels, pH, temperature, humidity, light, and weather conditions. Other indicators may also relate to livestock, such as veterinary well-being, feed intake, and weight gain. These indicators can be used to optimize various aspects of crop and livestock management, including irrigation, fertilization, disease prevention, and pest control [8].

The data collected by these sensors is transmitted to the technical staff. Various data analytic methods are then applied to interpret and derive useful insights from the collected data. The resulting information is exploited to take accurate and timely actions. To provide a better understanding, Fig. 2 illustrates the various stages involved, including the automated collection of data and the processing operations by agribots according to the insights derived from the processed data.

One area where ML has been applied in precision farming is crop yield prediction. ML algorithms can analyze data from sensors, such as satellite imagery, weather stations, and soil sensors, to make accurate predictions about crop yields [9]. For example, a study [10] used ML to predict winter wheat yields in China based on satellite imagery and weather data.

Another application of ML in precision farming is crop disease detection. By analyzing images of crops, ML algorithms can identify signs of disease or stress and alert farmers to take action [11]. For example, a study [12] used ML to identify cassava disease in Tanzania based on images captured by drones. The authors found that their ML model was able to accurately identify diseased plants, even in cases where the symptoms were not visible to the human eye.

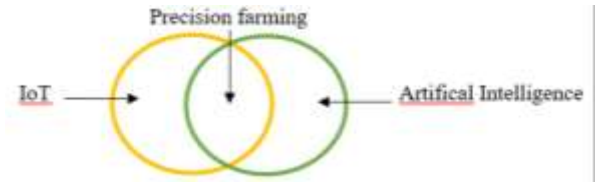

Fig. 1. Core components of precision agriculture.

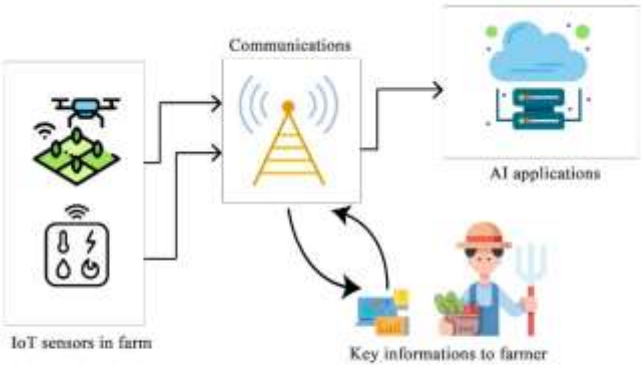

Fig. 2. Overview of the general process involved in precision agriculture.

ML can also be used to optimize crop management decisions, such as irrigation and fertilization. By analyzing data on soil moisture, nutrient levels, and weather patterns, ML algorithms can suggest the optimal amount of water to apply to a crop [13]. For example, a study by [14] demonstrates that the integration of active canopy sensing and machine learning improves the prediction accuracy of the corn nitrogen nutrition index by accounting for genetic, environmental, and management factors.

In conclusion, ML has significant potential in precision farming due to its ability to analyze large datasets and make accurate predictions. By applying ML to tasks such as crop yield prediction, disease detection, and crop management optimization, farmers can improve their yields and reduce waste.

III. Literature Review

Nowadays, as ML has been increasingly employed in precision agriculture, numerous studies have been conducted across various areas of farming. Therefore, to provide a clearer picture and distinguish this work from others, we present a summary of recent research in Table I.

TABLE I. Overview of the Latest Research and their Significant Contributions

Reference	Field	Techniques Used	Results
[15]	Crop yield prediction	Machine learning	Improved accuracy in crop yield prediction with the use of multiple data sources and ML
[16]	Disease detection	Transfer learning, Convolutional neural networks	Accurate detection of grapes and tomatoes leaf diseases using transfer learning and CNNs
[17]	Crop manageme nt	Machine learning	Accurate prediction of crop yield and nutrient deficiency using aerial images and ML
[18]	Soil mapping	Machine learning	Accurate mapping of soil properties using ML and sensor data
[19]	Pest detection	Deep convolutional neural networks	Accurate detection of tomato pests using deep learning and image analysis
[20]	Irrigation optimizati on	Reinforcement learning	Efficient water use and yield improvement in precision irrigation using reinforcement learning
[21]	Crop growth modeling	Deep learning	Accurate modeling of crop growth and development using deep learning with satellite and climate data
[22]	Crop yield prediction	Convolutional neural networks, gradient boosting	Accurate wheat yield prediction UAV-based multi-sensor data fusion approach and a machine learning algorithm
[23]	Nitrogen manageme nt	Machine learning algorithms	Accurate estimation of plant nitrogen status using machine learning and hyperspectral imaging
[24]	Crop health monitoring	Deep learning	Accurate monitoring of banana health using aerial images and deep learning

[25]	Seed selection	Deep learning, machine vision	Efficient maize kernel selection using deep learning and machine vision techniques
[26]	Crop yield prediction	Convolutional neural networks	Accurate wheat yield prediction using UAV images and ML algorithms
[27]	Weed detection	Convolutional neural networks	Accurate detection of weeds in rice using deep learning and image analysis
[28]	Crop manageme nt	Random forests, GIS approaches	Accurate prediction of nutrient deficiency using aerial images and ML
[29]	Disease detection	Convolutional neural networks	Accurate detection of potato diseases using deep learning and image analysis

Table I displays that numerous scientists have created Artificial Intelligence AI-based solutions suitable for different agriculture areas including crop selection and cultivation techniques. These solutions are often presented in the form of predictive systems and recommendation platforms, using state-of-the-art techniques. While these approaches have potential, they do not necessarily address the need for real solutions that can be implemented in the field at low cost and can help farmers and decision-makers optimize their resources and maximize profits.

It is interesting to note that few studies have focused on this issue in recent years, with most studies providing only theoretical overviews and practical implementations. The challenge is to find a way to make these solutions available for all, and make them more visible to a larger audience, such as farmers. Our study provides a step-by-step explanation of how to address these problems and offers examples of how to make these technologies available for free.

IV. Methods and Results

A. System Conception

To design our crop recommendation system, we initiated the first step by preparing a crop recommendation dataset. We used Moroccan climate, fertilizer and precipitations data [30] then preprocessed it in order to make extensive explorations. We worked with a dataset consisting of 1800 entries and eight variables. Next, we conducted an exploration of the data to understand its nature. Finally, we used ML techniques counting NB, DT, RF, SVM, and LR to extract the best features and build our ML models.

Fig. 3 provides a detailed illustration of the steps taken in designing the architecture and developing the crop recommendation system.

After completing the models building step, we proceeded to evaluate their performance. Once the evaluation was complete, we then moved on to deploy the model with highest performance as a web application, which forms a basis of our crop recommendation system.

After completing the evaluation, the next step was to deploy the best selected model as a web application, which serves as the foundation for our crop recommendation system.

B. Dataset Preparation and Feature Selection

The crop recommendation dataset we selected comprised several features, including content in soil of Phosphorus (P), Potassium (K) and Nitrogen (N), as well as soil pH value and moisture, precipitations, temperature and plant variety. The data collection consisted of 1800 entries, and an overview of the dataset statistics is presented in Table II.

In terms of the relationship between the input parameters and target, we observed that certain parameters, such as Potassium, phosphorus and Nitrogen exhibit strong correlations of 0.6. This is a promising sign prior to the commencement of the prediction. There were also some phew negative correlation values between the indicators. This shows that the dataset is rich in information.

From a biological perspective, the P K N levels play a vital role as important macro-nutrients that support plant growth. Potassium, is responsible for the plant's natural functioning, while phosphorus aids in the maturation of fruits. Nitrogen contributes mainly to the growth of leaves.

Fertilizer containing elements such as P K N and can be tailored to different crops based on their concentrations. These nutrients are essential for the growth and productivity of crops, and using fertilizer can make up for any deficiencies in the soil. By understanding the PKN ratios required for optimal plant development, farmers can manage fertilization and achieve better yields [31].

Other parameters in our data, including temperature, soil moisture and pH, and precipitations play important roles in crop selection. The pH value affects the existence of vital substances, while precipitations level is crucial in plant survival. Air temperature impacts photosynthesis, and soil moisture is essential for growth, but too much or too little can be detrimental. Our dataset includes several crop categories, such as apples, dates, corn, grape, pepper, orange, peach, potatoes, onions, tomatoes, olives, and watermelon, that can be predicted based on these features. The prediction of these crops yields is dependent on the parameters mentioned.

TABLE II. STATISTICAL DESCRIPTION OF THE DATASET

Parameters	P	K	N	Temperature	Soil Moisture	pH	Precipitations
Records	1800	1800	1800	1800	1800	1800	1800
Mean	53.36	48.14	50.55	25.61	71.48	6.47	103.50
Standard Deviation	32.98	150.64	36.9	5.06	22.26	0.77	54.95
Minimum	5.00	5.00	0.00	8.82	14.25	3.50	20.21
Maximum	145.00	205.00	140.00	43.67	99.98	9.93	298.56

C. Predictive Models Development

To develop our predictive ML models, we utilized the Python programming language. The data preprocessing stage involved importing the necessary libraries, including NumPy, Pandas, Scikit-learn, and Matplotlib.

To train and test the models, we split the dataset into training and testing datasets, with a ratio of 70:30. We then employed five ML models (DT, NB, LR, RF, and SVM).

To evaluate the accuracy of the models, we used precision, recall, F1 and accuracy metrics, which were calculated using the following formulas:

$$Precision \ = \frac{TP}{TP+FP} \quad (1)$$

$$Recall \ = \frac{TP}{TP+FN} \quad (2)$$

$$Accuracy \ = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

$$F1\ score \ = \ 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (4)$$

Where TP (true positive) is the number of correctly predicted positive values, FP (false positive) is the number of falsely predicted positive values, TN (true negative) is the number of correctly predicted negative values, and FN (false negative) is the number of falsely predicted negative values.

Additionally, we used k-fold cross-validation scores to evaluate the effectiveness of the different algorithms used in the predictive analysis, which provided a more robust assessment of the models' performance [32].

These scores helped us evaluate the effectiveness of the different algorithms used in the predictive analysis.

V. RESULTS AND DISCUSSION

A. Results of Prediction

This section presents a discussion of the experimental results obtained for the performance of the ML algorithms used in our study. Table III provides a detailed summary of the precision, recall, accuracy, and k-fold cross-validation score results.

Based on our results, the ML algorithms employed in our study exhibit varying levels of predictive capabilities in determining profitable crop based on inputs. Our analysis shows that RF has the highest performance in terms of accuracy, with a score of 97.18%. In comparison, other algorithms such as NB (96.36%), LR (95.62%), SVM (87.38%), and DT (86.64%) have lower accuracy scores.

Fig. 4 illustrates a comparison of the accuracy for all ML models adopted in our analysis.

The precision value assesses the ratio of accurate positive label predictions, indicates that NB and RF exhibit excellent performance. Conversely, DT has the lowest performance in this category. Regarding recall value, which assesses the ability of the ML models to correctly predict actual positives, RF once again outperforms the other models, while SVM and DT have the lowest scores.

Regarding the F1 score, which is the harmonic mean of precision and recall, RF attains the highest score of 97%, followed by NB at 96%, LR at 96%, SVM at 87%, and DT at 83%.

To estimate the overall performance of the models, we used K-fold cross-validation with a value of K=10. The results indicate that RF has the highest 10-fold cross-validation vale, while DT has the lowest performance. Although accuracy alone is not a reliable performance metric, considering other evaluation measures, it is apparent that RF surpasses the used ML techniques in forecasting the most appropriate crop.

TABLE III. PERFORMANCE METRICS SCORES FOR THE ML MODELS

Algorithm	Accuracy	F1	Recall	Precision	10-Fold Cross Validation
SVM	87.38%	87%	87%	87%	88.50%
NB	96.36%	96%	96%	97%	97%
RF	97.18%	97%	97%	97%	97.40%
LR	95.62%	96%	96%	96%	96.31%
DT	86.64%	83%	87%	82%	92%

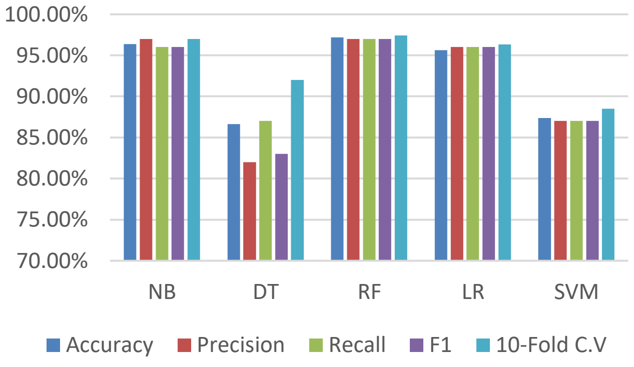

Fig. 4. Results comparison of the ML algorithms.

B. Crop Recommendation Solution

In our opinion, the market for precision agriculture solutions that are available at no cost and released under an open-source license is continuing to evolve, and considerable progress is needed for these solutions to compete with closed-source solutions. However, the involvement of a network of IT specialists and interested parties, including farmers, has aided expansion of open-source alternatives. These communities can address any issues or doubts related to technology integration with ease [33-35]. Bearing this in mind, our main objective was to propose and design a crop recommendation system.

Relying on the performance metrics mentioned earlier, RF demonstrated superior performance in comparison to the other ML models we used. Therefore, we plan to employ RF to predict the optimal crop based on the user's input parameters, such as P K N, soil moisture and pH, temperature, and precipitations. After selecting the best-performing model, we serialized/saved it Python’s built-in persistence model, namely pickle, for developing of the crop recommendation system. The various steps involved in designing and deploying the crop recommendation system are outlined in Fig. 5.

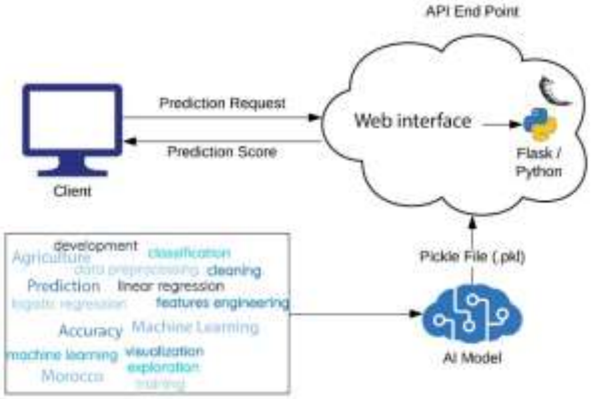

Fig. 5. Stages included in creating and launching the crop suggestion platform.

To create the system, we utilized Flask as a Python micro framework used in applications development, which enables programmers to conveniently build Application Programming Interfaces (APIs) in Python language. To create interactive web pages for users, we used HTML (Hypertext Markup Language) and designed them using CSS. After that, we implemented the platform Flask micro web framework. Fig. 6 depicts the fully functional recommendation platform hosted locally.

The working system along with the development environment are available on an uploaded directory online [36]. It consists of all code files used for the training and prediction, as well as the app code of the recommendation system and the frontend source code.

In Fig. 6(a), the collected field data is entered manually at the Front end.

In Fig. 6(b), the Result is displayed after processing the given data through the trained M.L Model.

Fig. 6. Implemented crop recommendation system.

VI. Discussion

After evaluating the performance results of the ML model training, we found that RF has the best performance among all the models. Despite the small training dataset of only 1800 entries, RF still outperforms other models in terms of recall, precision, and other performance criteria, apart from accuracy. Therefore, we chose RF as the ML technique to use in building the recommendation system.

Once the required inputs are submitted, the platform verifies for missing values and if the entries fall within acceptable thresholds before proceeding. The system then predicts the most appropriate crop to plant based on the input parameters. This enables farmers to make informed decisions for higher returns on investment and reduced wastage. This enables farmers to opt for knowledgeable choices that lead to increased profits and reduced waste.

During the development of our crop recommendation system, we postulated that users would utilize pre-existing meteorological data and the abundant IoT farming tools that are already deployed to obtain necessary information for submitting parameters to our platform. Since our platform is web-based, it is accessible from anywhere and from any device, providing a high level of convenience for the users.

However, we acknowledge that the dataset we used for developing the system is constituted of Moroccan data, and crop growth can vary based on the context and circumstances of different territories. To provide our system to farmers globally, more data from various geographic locations may be required. As our system continues to develop, it can have the capability to compile information from various geographical territories, allowing users to enter their position along with the relevant data to predict suitable crops for planting. This paper displays the potential of using ML to design smart techniques at the service of agriculture, and it may set the stage for emerging studies to develop predictive platforms in conjunction with robotic technology.

Investing in farming is critical for any economy, and selecting profitable crops is an important task that can guarantee the best production. Our proposed solution aims to help farmers select the best crop for their land and environmental context. With further improvements, like integrating IoT in automated data collection and using more parameters and key indicators from different locations, we can offer this technology to more farmers, especially those who want to implement technology-driven precision farming.

While many organizations and startups are designing precision farming solutions, most of them are subscription-based with high prices, free and open-source alternatives can be accessible for farmers to. It is crucial for farmers to be knowledgeable about these alternatives that can enable them to utilize technology at no cost, instead of making significant upfront investments.

VII. Conclusion and Perspectives

Agriculture is a vital industry that feeds billions of people worldwide, and the use of technology has transformed traditional farming practices, resulting in improved yields and a higher quality harvest while reducing manual labor. Precision farming, powered by AI, is becoming increasingly popular due to its ability to collect field data and to assist farmers in taking informed actions to manage their cultivated lands.

This study presents a web-based ML-driven crop recommendation system to assist users choose the most suitable crops to plant based on local environmental conditions. Although there are many commercial solutions available, alternatives also exist at freely and at no coast.

The study demonstrates the combination of ML and precision agriculture and outlines the architecture of a web-based platform. The platform could be improved by adding real-time monitoring capabilities by interfacing with existing data aggregation platforms from sensors and IoT. This would result in a more accurate and suitable prediction framework, making precision farming more accessible to farmers worldwide, ultimately helping to address the challenges of feeding the global population.

The Research on the Motion Control of the Sorting Manipulator based on Machine Vision

Kuandong Peng[1], Zufeng Wang[2]
School of Intelligent Manufacturing, Hangzhou Polytechnic, Hangzhou, Zhejiang 311402, China[1]
Information Technology Center, Zhejiang University City College, Hangzhou, Zhejiang 310015, China[2]

***Abstract*—With the development of production technology, manipulators are gradually introduced in advanced production manufacturing industries to complete some tasks such as picking and sorting. However, the traditional manipulator has a complicated sorting process and low production efficiency. In order to improve the accuracy of sorting and reduce the labor intensity of workers, this paper studied the motion control of the sorting manipulator with machine vision. After placing four kinds of objects of different shapes on the conveyor belt, experiments were conducted on the catching and sorting process of the manipulator under different experimental environments, different conveyor belt speeds, and with or without machine vision. It was found that the overall success rate of the sorting robotic arm using machine vision for catching objects of different shapes was as high as 96%, and the sorting accuracy was as high as 97.91%. Therefore, it is concluded that the manipulator can achieve high accuracy in catching and sorting objects with the guidance of machine vision, and the adoption of machine vision has a positive impact on the motion control of the sorting manipulator.**

***Keywords*—Machine vision; manipulator; motion control; camera calibration; item sorting**

I. Introduction

In today’s rapid development of the intelligent technology industry, industrial automation has become the development direction of the production manufacturing industry, and manipulators have been widely used in industrial operations [1], for example, manipulator sorting technology. Traditional robot sorting is mainly carried out by means of demonstration and can only work in a fixed environment, and the manipulator does not work efficiently because it cannot recognize and process objects without a vision system. The manipulator using machine vision system can take camera shots of the work site to collect images and obtain information such as the location and size of the object to realize catching and sorting. Therefore, the combination of machine vision and manipulators allows the arms to identify objects independently, which has important practical significance for improving efficiency and reducing labor costs. Radcliffe et al. found that the use of machine vision allowed small vehicle platform systems to navigate autonomously and reduce errors through laboratory field tests [2]. Min et al. found that a portable machine-based visual inspection system for track defects could replace manual labor to some extent after field experiments [3]. Liu proposed that robots equipped with machine vision-based manipulators could efficiently perform tasks such as logistics courier sorting and fruit picking in orchards [4]. Abad et al. found through field experiments that machine vision was able to achieve at least 95% accuracy in color discrimination of stacked colored objects [5]. Nair et al. found that the application of machine vision for image analysis helped in classifying flood zones and had an accuracy of 83.1% [6]. Mohamed et al. applied a real-time machine vision manipulator through Python software and found that the arm was very accurate in detecting external defects in agricultural products [7]. He et al. verified that a machine vision-based sorting method was feasible by obtaining the contours, features and dimensions of mechanical parts with a camera and filtering out defective products through image analysis [8]. The article first described the machine vision of the sorting manipulator through camera calibration and image processing methods; then, the inverse kinematic equation in the D-H parameters was used to solve different joint angles of the manipulator to achieve motion control. Finally, after placing four objects of different shapes onto the conveyor belt in turn, the experiments were conducted to investigate whether the application of machine vision is helpful for the motion control of the sorting manipulator by adjusting the experimental environment and the speed of the conveyor belt and using machine vision or not. This work provides a theoretical basis for future research on the motion control of the sorting manipulator using machine vision.

II. Machine Vision for Sorting Manipulators

Machine vision technology involves several disciplines, including image processing [9], artificial intelligence [10], pattern recognition [11], etc. Computers are used to simulate human visual ability, and their combinations with manipulator catching technology allow arms discriminate and grasp like humans. This paper established a manipulator vision system to realize the camera calibration of the machine vision part and carried out image pre-processing [12] and feature extraction to match and recognize objects. The system determined the catching coordinate position by the image edge contour information of objects, and then positioned, grasped, and sorted objects.

A. Camera Calibration

The purpose of camera calibration [13] is to correct the distorted image and construct a three-dimensional scene based on the obtained image. It is assumed that there is a point named P in the space [14]. Point P is converted into a camera image plane to obtain the image pixel coordinates to realize manipulator catching. The specific conversion process is as follows.

$$S\begin{bmatrix}u\\v\\1\end{bmatrix}=\begin{bmatrix}f_x & 0 & u_0\\0 & f_y & v_0\\0 & 0 & 1\end{bmatrix}\begin{bmatrix}R & T\\0 & 1\end{bmatrix}\begin{bmatrix}x_w\\y_w\\z_w\\1\end{bmatrix}, \quad (1)$$

where S is a scale factor, R is a 3*3 rotation matrix, T is a 3*1 translational transformation vector, $\mathrm{x_w}$, $\mathrm{y_w}$, and $\mathrm{z_w}$ are the homogeneous coordinates of a point in the space under the world coordinate system and camera coordinates, f_x and f_y are the focal lengths of the camera in the X/Y directions, respectively, and u_0 and v_0 are the position of the image coordinate system origin O in the pixel coordinate system.

$$M_1=\begin{bmatrix}f_x & 0 & u_0\\0 & f_y & v_0\\0 & 0 & 1\end{bmatrix}, \quad (2)$$

$$M_2=\begin{bmatrix}R & T\\0 & 1\end{bmatrix}, \quad (3)$$

where M_1 and M_2 represent the internal and external parameter matrices of the camera, respectively. The internal parameters of the camera include the internal information such as the focal length, optical axis, and focus position of the camera, while the external parameter of the camera is the conversion relationship between the world coordinate system and the camera coordinate system. The overall conversion relationship is as follows:

$$S\begin{bmatrix}u\\v\\1\end{bmatrix}=M_1M_2\begin{bmatrix}x_w\\y_w\\z_w\\1\end{bmatrix} \quad (4)$$

B. Image Pre-processing

1) Image filtering process: Median filtering [15] can eliminate isolated noise points in an image and effectively protect the boundary information of images, which will not cause severe blur to images like mean filter. The specific method is described below. First, sequence $\mathrm{f_1}$, $\mathrm{f_2}$,⋯, and $\mathrm{f_n}$ is defined, and the length of the window corresponding to the median filter is odd number L, L = 2n+1, where n is a positive integer. It is assumed that at a time point, $\mathrm{f_i}$ is the value of the signal sample located in the center of the window, and the signal sample inside the window is $\mathrm{f_{i-n}}$, ⋯, $\mathrm{f_i}$, ⋯, $\mathrm{f_{i+n}}$. These L signal sample values are ranked from large to small, and the i value in the middle is taken as the output value of median filtering:

$$X_i = med\{f_{i-n}, \cdots, f_i, \cdots,\ f_{i+n}\} \quad (5)$$

To obtain better image processing result, the two-dimensional median filtering is used:

$$\mathrm{g(x,y) = med\{f(x-k, y-l), (k,l) \in W\}} \quad (6)$$

where f(x,y) is the original image and g(x,y) is the image after median processing. W is a two-dimensional template, usually 3*3 or 5*5, and in this paper, a 3*3 two-dimensional region is chosen.

2) Image grayscale: Regarding image grayscale [16] in the RGB model, the value of R=G=B is called the grayscale value, and the grayscale range is [0,255]. When the gray scale is 255, it is the brightest (pure white); when the gray scale is 0, it is the darkest (pure black). There are two main implications of converting the captured sorter image to grayscale image, one is that the grayscale image takes up less memory and has faster computing speed compared to the color image; the second is that the contrast is more obvious visually after conversion to grayscale image, highlighting the object location. After grayscale processing of the image of the sorter captured by the camera as in Fig. 1, the next step of feature extraction operation can be performed.

Fig. 1. Comparison of before and after grayscale processing of the sorter.

3) Image segmentation: Image segmentation [17] is a key step from processing an image to analyzing it, and is an indispensable pre-processing for recognition images and computer vision. In the acquired image of the sorter, the identified object is found to be only a small part of the overall image, and the excess makes the system slow in processing the image, so the image is segmented to highlight the object. In this paper, Matlab code [18] will be used to segment the sorter images, using the functions shown in Table I.

TABLE I. MATLAB IMAGE SEGMENTATION FUNCTIONS AND THEIR FUNCTIONS

Function Name	Function
imshow	Show images
imfinfo	Read information about the image file
imhist	Calculate and display the histogram of an image
Imadjust	Contrast enhancement
edge	Detect image edges
imcrop	Cut image (x: the width of the cut image, y: the height of the cut image)

III. MANIPULATOR MOTION CONTROL

The manipulator is an artificial intelligence device, and its motion control is the basis for ensuring the stability of the arm's posture [19]. The kinematic analysis of the manipulator can be divided into forward kinematics and inverse kinematics. Forward kinematics means deducing the pose of the end-effector of the manipulator relative to the reference coordinate system when the geometric parameters of the connecting rod joint and the angular value of the joint angle have been known. Inverse kinematics means calculating the joint angle of the manipulator when the geometric parameters of the connecting rod joint have been known and the pose of the end-effector of the manipulator relative to the base coordinate system has been given. D-H parameters [20] determine the coordinate change relationship between adjacent joints by assigning a coordinate system to every joint of the manipulator (Fig. 2), then the joint transformation relationship are combined through a mathematical formula to determine the overall change relationship between the end-effector and the base to obtain the related kinematic equation. D-H parameters contain four basic parameters, as shown in Table II.

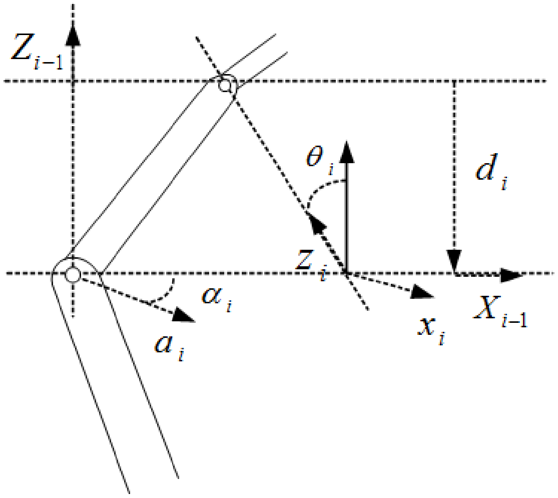

Fig. 2. Description of standard D-H parameters.

TABLE II. DESCRIPTION OF STANDARD D-H PARAMETERS

Name	Symbol	Meaning
joint angle (°)	α_i	The angle rotating from x_{i-1} to x_i around the z_{i-1} axis
connecting rod torsion angle (°)	θ_i	The angle rotating from Z_{i-1} to Z_i around the X_i axis
connecting rod length (mm)	a_i	The distance from Z_{i-1} to Z_i around the X_i axis
offset distance (mm)	d_i	The distance from X_{i-1} to X_i around the Z_{i-1} axis

In this paper, the equation of the inverse kinematics [21] is used: when the pose of the manipulator end coordinates has been known, joint variable θθ_i is calculated. The specific equation is:

$$ {}^0_iT = {}^0_1T(\alpha_1){}^1_2T(\alpha_2)\cdots{}^{i-1}_{\;\;\;i}T(\alpha_i) = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad (7)$$

where P is the translation vector used for determining the coordinates of the end of the manipulator in the space, n, o, and a denote the rotation vectors used for determining the attitude information of the end of the manipulator. The equation is solved by isolating the joint variables. Joint variable α_i can be obtained by left multiplication of the unknown inverse transformation of connecting rod and the two sides of (7).

IV. EXAMPLE ANALYSIS

A. Experimental Principle

The working principle of the sorting manipulator system used in this experiment is shown in Fig. 3. The image of an object is captured by an industrial-grade 3D smart camera [22]. The image data captured by the camera is transmitted to the input port of the image capture card. The image capture card transforms the analog video signal into a digital image. The computer program calculates the specific position of the object through the image and sends the position coordinates to the control system of the manipulator. Finally, the manipulator grasps and sorts the object.

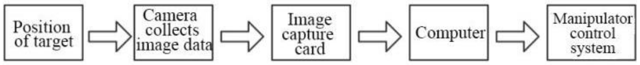

Fig. 3. Manipulator working principle diagram.

B. Experimental Design

The machine vision-based manipulator first scans the object with bilateral cameras, then pre-processes and recognizes the collected object image, and finally catches and sorts the object. Since the objects on the conveyor belt are dynamic and the background of the images captured by the cameras is variable, it is also important to study the manipulator's catching and sorting for dynamic objects under different experimental environments. The objects were placed under three different conditions, including different experimental environments, different object movement speeds, and with or without machine vision, 100 times each condition. Four objects of different shapes [23] were placed onto the conveyor belt in turn, and the conveyor belt and manipulator were turned on. The original environment of the experiment was an empty laboratory without any shade and with no shadow on the conveyor belt under the light. The main change of the experimental environment was to add large potted plants to the original environment and place them under the light to make their shadows cast the conveyor belt. The specific change before and after the experimental environment is shown in Fig. 4. The number of times the manipulator successfully caught and the number of times it correctly sorted under different experimental environments and movement speeds of the four objects were recorded, and the success rate was calculated. Finally, the catching and sorting results of the manipulator with and without machine vision were presented in the form of a table.

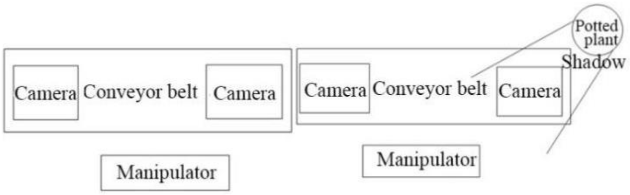

Fig. 4. Simple diagram before and after the change of experimental environment.

C. Experimental Results

Sorting accuracy formula: sorting accuracy = number of correct sporting/number of successful catch.

According to the experimental data displayed in Table III, it was seen that the manipulator completed the catching and sorting of objects of four shapes in the 100 times of catching and sorting under every condition. After calculation, the overall catching and sorting rates of the manipulator with machine vision were 96% and 97.91%, respectively, while the overall rates of the manipulator without machine vision were 84% and 57.99%, respectively. It was also found that the catching rates for the objects of four shapes showed decreasing trends, but the decreasing trend in the sorting rate was more significant than the catching rate. Thus, it was concluded that the manipulator with machine vision had a huge improvement for both object catching and sorting, i.e., machine vision had a positive influence on the motion control of the manipulator.

It was seen from Table IV that when the speed of the conveyor belt rose to 150 mm/s, the success rates of catching and sorting clothes, ball sports equipment and ring-pull cans gradually decreased, but the sorting success rate of the cardboard box remained at 100%. Overall it was seen that the sorting rate using the machine vision-based manipulator remained above 90%. This showed that although the number of successful catching and correct sorting decreased as the speed of the object moved faster, but the manipulator with machine vision could still effectively catch and sort objects. The results fully demonstrated that machine vision was beneficial to the motion control of the manipulator.

In order to compare the effect of the machine vision-based manipulator for object catching and sorting under different experimental environments, large potted plants were placed next to the conveyor belt to create a shadow influence. It was seen from the data in Table V that the catching and sorting rates of objects of four shapes in the complex environment decreased, and the catching rate of cardboard box decreased from 96% to 80%, which was the most significant. However, from an overall perspective, the manipulator with machine vision performed better than the manipulator without machine vision. This showed that the application of machine vision had a very significant impact on the sorting service of the manipulator and machine vision helped the manipulator to sort objects.

TABLE III. THE CATCHING AND SORTING RESULTS OF THE MANIPULATOR WITH AND WITHOUT MACHINE VISION AT THE SAME SPEED

	Clothes		**Ball Sports Equipment**		**Ring-pull Can**		**Cardboard Box**	
	Catching rate	***Sorting rate***	***Catching rate***	***Sorting rate***	***Catching rate***	***Sorting rate***	***Catching rate***	***Sorting rate***
with machine vision	92%	95.65%	96%	100%	100%	96%	96%	100%
without machine vision	84%	52.94%	80%	62.50%	80%	60%	92%	56.52%

TABLE IV. CATCHING AND SORTING TEST RESULTS OF THE MACHINE VISION-BASED MANIPULATOR AT DIFFERENT SPEEDS

	Clothes		**Ball Sports Equipment**		**Ring-pull Can**		**Cardboard Box**	
	Catching rate	***Sorting rate***	***Catching rate***	***Sorting rate***	***Catching rate***	***Sorting rate***	***Catching rate***	***Sorting rate***
100 mm/s	92%	95.65%	96%	100%	100%	96%	96%	100%
150 mm/s	84%	90.48%	92%	86.96%	80%	90%	96%	100%

complex environment	92%	86.96%	92%	82.61%	92%	82.61%	80%	90%

V. DISCUSSION

The manipulator plays an important role in the field of automation engineering as an important component of industrial systems [24]. A study has developed an improved machine vision system that is capable of identifying and classifying items with different geometric shapes and colors and manipulating and separating them using a computer-controlled manipulator [25]. The experimental parameters in this paper differed from those in existing studies in the following aspects: (1) existing experiments use three cameras, while this paper used two cameras; (2) the sorted objects in existing research are in a condition of rest, while the sorted objects in this paper are in a state of motion; (3) existing research on manipulators under machine vision is oriented to grasp and sort items according to different geometric shapes and colors, but this paper took into account not only the different geometric shapes of the items, but also the different running speeds of the items on the conveyor belt and the complexity of the environment in which the manipulator performs sorting. In this paper, by reviewing a large number of literature on machine vision and robotic arm, the authors further deepened the research on the use of machine vision-based sorting manipulator on the basis of existing research and achieve good experimental results. However, there is still room for further research.

1) This paper showed that the correct sorting rate of manipulators using machine vision decreased to a certain extent in the case of high speed motion of sorted items and in the case of complex sorting environment, and subsequent studies can be conducted to analyze these problems.

2) To improve the sorting speed of the manipulator using machine vision, speeding up the image acquisition or transmission process can be considered.

3) Whether classification algorithms can be added for sorting items, and whether classification algorithms can play a role in improving the correct rate of robotic arm sorting should be studied.

VI. Conclusion

This paper mainly introduced the machine vision and the motion control of the sorting manipulator. After putting four kinds of objects of different shapes on the conveyor belt in turn, the cameras on both sides scanned the objects, the collected images were fed back to the manipulator control system after processing, and the catching and sorting behaviors of the manipulator were tested by adjusting the experimental environment and the speed of the conveyor belt and applying machine vision or not. The experiment found that among the 300 catching and sorting tests, the overall catching and sorting success rates of the manipulator were 96% and 97.91%, respectively, while the manipulator without machine vision had an overall catching rate of 84% and an overall sorting success rate of 57.99%. The experiment verified that the manipulator guided by machine vision could improve the ability to perceive and recognize the external world and achieve high accuracy in catching and sorting objects. Therefore, the application of machine vision has a positive impact on the motion control of the sorting manipulator, laying a foundation for the future application of machine vision in sorting service in practice.

Frequency Domain Improvements to Texture Discrimination Algorithms

***Abstract*—As the production speeds of factories increase, it becomes more and more challenging to inspect products in real time. The goal of this article is to come up with a computationally efficient texture discrimination algorithm by first testing their ability to localize defects and then increase their efficiency by removing less effective parts of them. Therefore, abilities of the most popular texture classification algorithms such as the GLCM, the LBP and the SDH to localize defects are tested on different datasets. These tests reveal that, on small windows GLCM and SDH perform better. Frequency properties of the textures are used to fine-tune the parameters of these algorithms. Further experiments on three different datasets prove that the accuracy of the algorithms are increased almost twice while decreasing the processing time considerably.**

***Keywords*—Machine vision; ANN; SVM; pattern recognition; co-occurrence; texture feature extraction**

I. Introduction

Despite being old, based on the yearly citations they receive, Haralick’s grey level co-occurrence matrices (GLCM)[1], Unser’s sum and difference histograms (SDH)[2] and Local Binary Patterns (LBP)[3] are the most popular texture classifiers in the literature. As shown in Fig. 1, great majority of machine vision systems inspect a product simultaneously while it is being produced. Usually, imaging sensors are stationary and the product moves under them. This causes the viewing angle of the cameras to always be static with respect to the product. The lighting conditions in a factory are usually under some degree of control and do not change radically. When used for such purpose, these algorithms are usually applied to the texture towards the same alignment because in a factory the camera is usually at a fixed position with respect to the production line or the conveyor belt. Therefore, throughout the experiments performed in this article, texture alignment is fixed.

Another difference between the texture recognition and the discrimination is that the recognition applications process the entire image while the discrimination applications process smaller windows to localize where the defect is. Unfortunately, there are not many experimental studies in the literature that measures the effectiveness of algorithms on different (non-overlapping) window sizes. Texture segmentation [4] applications use sliding windows which makes them very slow.

Because of the rapid progress of technology, materials in factories are produced faster and faster. Flat surfaced products such as wood [5], fabric [6] and metal [7] require machine vision systems to detect production defects. Unfortunately, high-speed production of these goods combined with the availability of high-resolution cameras put great strain on the network and the computers that process those images in real time. A typical line-scan camera, employed in web inspection tasks for products such as film, paper and fabric, generates between 15 and 150 MB of data per second and half a dozen cameras are required to cover the entire width of the web, meaning that gigabytes of data must be reliably transferred and processed. One approach to this problem is to pre-process images inside the cameras and send the image data to the main computer only when the camera suspects that there might be a defect [8]. In this study, Brodatz texture set is experimented on with popular texture classification algorithms to see which one performs better on small windows. Based on these results, improvements to these existing algorithms are proposed. These modified algorithms are tested on three different datasets.

II. Related Work

GLCM are calculated by counting the relative pixel value occurrences that are away from each other (d) pixels. The result is a histogram matrix of size N×N. N is defined by the maximum number of gray levels in the image. Therefore, for greyscale images it is usually 256×256=64K elements. Haralick proposes 14 features that can be calculated from the GLCM, which requires processing of those 64K elements 14 times. This not only requires considerable amount of processing power but also consumes several 64 KB of memory. Considering the fact that the GLCM was invented in 1973, this was a problem for the computers back then. One solution to overcome this problem was to use 16 grey levels for the image. That solution reduces the matrix size to 16×16.

Unser proposed another optimization to this problem. He mathematically proved that almost the same results could be achieved by using the sum and difference histograms (SDH) of those pixel pairs. Instead of a matrix, his algorithm generates two vectors, one for the sum of the pixels and one for the difference for every given distance ‘d.’ An image with 256 gray levels produces two vectors with 512 elements. Calculating those 14 features that Haralick suggested becomes computationally simpler. This method's main advantage is the fact that it reduces the amount of memory. However, based on our experiments (see Section VIII) it increases the computational complexity compared to the GLCM if reduced number of gray levels are used. In the literature, SDH has been tested on many texture classification problems and it has been proved that it is a quite successful texture classifier.

Texture analysis has been the focus of numerous studies over the years and as a result, over two dozen algorithms have been invented to classify texture. In volume II of “Handbook of Computer Vision and Applications,” Wagner [9] experimented on seven different texture sets using 18 different texture classification algorithms. His experiments showed that Unser's SDH is not only the most successful among the 18 algorithms, but also the second fastest. Based on the measurements of that study, the only algorithm faster than the SDH is the Local Textural Features [10]. However, that algorithm had the second lowest success rate. Therefore, according to that study, SDH is computationally the most efficient texture classifier. However, it should be noted that the GLCM was probably calculated using the full 256 gray levels making it much slower compared to the SDH. The second most successful algorithm is Chen’s geometric features [11] which is the slowest among the 18 algorithms (30 times slower than the SDH). The third successful algorithm is the Gabor Filters [12], which is the second most popular algorithm used for fabric defect detection in the literature. Gabor Filters compare energy of the specific frequency bands on fabric images to detect defects. Our method to select pixel distance and the orientation is mathematically related to Gabor Filters. Another popular algorithm in the literature is Law's Masks [13]. Laws has suggested five 1-D convolution masks for feature extraction. From these masks 25 2-D filter masks can be constructed and features are calculated from them. According to Wagner [9], Law's Masks performed slightly worse than the SDH, but is eight times slower. Galloway’s Run-Length Matrices [14] should also be mentioned because of their speed. His technique calculates characteristic textural features from gray-level run lengths in different image directions and then calculates five features from them for each direction. However his algorithm did not score as high as the previously mentioned algorithms according to Wagner.

The literature still lacks a mathematical definition of the texture. Therefore, humans are the only referee when it comes to judging which texture is the same or different. That is why an interesting experiment conducted by Petrou [15], comparing human perception to the texture classification algorithms is so important. In this study, classification performance of numerous algorithms were compared to a group of humans. Variants of both the GLCM and the SDH, with different gray levels were experimented with. These experiments showed that direct use of GLCM or SDH as input to a classifier resembles to human perception much closer than using only the features derived from them. SDH was measured as one of the fastest. SDH using16 gray levels is closer to human perception than the GLCM as well. In his exhaustive experiments, Gonzales-Rufino [16] shows that GLCM and SDH perform better against the Local Binary Patterns, and the Neighboring Grey Level Dependence Statistics [17]. In the literature, there is abundant evidence that second order pixel statistics based texture classification is one of the most successful and the most efficient method. All this evidence suggests that, further improving SDH might give us computationally the most efficient texture discrimination method.

III. Performance Comparison on Small Windows

In the literature, mathematical definitions of the texture is very vague: “A region in an image has a constant texture if a set of local statistics or other local properties of the picture function are constant, slowly varying, or approximately periodic” [18]. Because of the fact that a texture is defined in terms of “statistics” and “periodicity,” a texture can exist only as a group of pixels, or in other words as a window. As mentioned before, texture discrimination requires localization of texture aberrance. Therefore, we need to measure the performance of texture classifiers on varying size of windows.

For this experiment, four different size windows were used on 13 different Brodatz textures. The size of the windows are 240×240, 120×120, 60×60 and 30×30. As shown in Fig. 2, the right half of the images are used for training and the left halves are used for testing. Overlapping blue squares represent training locations and green squares represent non-overlapping test locations. The ones at the top use 120x120 pixel windows and the ones at the bottom use 30x30 pixel windows. Green boxes indicate correctly classified windows and red ones indicate falsely classified windows. The numbers inside the red boxes indicate which of the 13 textures that window was misclassified as.

For this experiment, six different feature sets were used. The first two feature set is the four features obtained from the GLCM. In the literature GLCM is mostly used in either 256 color mode or 16 color mode. Therefore, both versions were tried. The third feature set is the 32 gray level histogram plus Unser’s difference histograms with 16 colors (H-32+DH-16). The final three feature sets are LBP with (r=1;P=8), (r=1,2;P=8) and (r,P)={(1,8);(2,8)};(3,12)}. Either Artificial Neural Networks (ANN) or Support Vector Machine (SVM) were used as classifiers. Table I shows that ANN is slightly more successful than the SVM. While LBP is more successful on larger windows, 16 color GLCM and (H-32+DH-16) are more successful on smaller windows. In other words, these algorithms are more suitable for defect localization or texture segmentation applications. However, readers must keep in mind that “window size” is a relative value, which depends on the image resolution. If the image of the texture is high resolution, than these window sizes must be increased. More detailed results of this experiment were shared in a conference article [19].

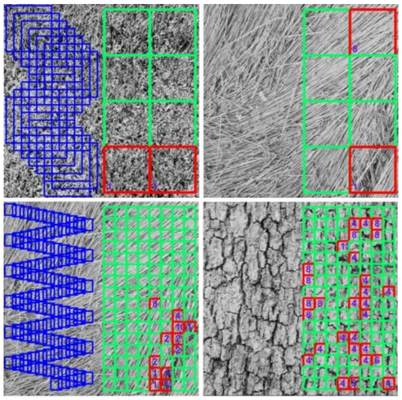

Fig. 2. Top: 120×120 pixel size window test. Bottom: 30×30 pixel size window test. Left half of the images are used for training. Overlapping blue boxes are training areas. Non-overlapping green windows on the right half of images are correctly classified windows.

IV. PROPOSED MODIFICATIONS

Despite the growing popularity of the LBP, the previous test shows that on smaller windows (patches), performance of GLCM and "histogram plus difference histograms" are superior. In his article, Unser proves that his sum and difference histograms (SDH) are mathematically equivalent of the GLCM. The reason why he proposes them is because SDH requires less memory and processing power. Since one of the main objectives of this study is to come up with a texture discrimination (defect detection) algorithm that can fit inside a camera, it is natural that we chose to continue with Unser's sum and difference algorithms. Unser also states that %99 of the texture information comes from the difference histogram rather than the sum histograms.

Another reason why difference histograms are used is that they are immune against illumination changes. Despite the fact that illumination conditions are under control in factory settings, we would still want our algorithm to be as robust as possible to illumination changes. This can be explained using the mathematical model of the light absorption. Let's assume that a light source is sending photons to a textured surface at an illumination strength of 200. Let the first area corresponding to the pixel-1 has a reflectivity of %90 and the second area corresponding to the pixel-2 has reflectivity of %50. Then the camera would detect the photons coming from these two areas at a strength of 180 and 100 respectively. The sum of these pixels would be 280, and their difference would be 80. If the illumination is increased by %20, then these pixels would be registered as gray levels of 240×0.9=216 and 240×0.5=120. Their sum would be 346 and their difference would be 96. The fluctuation for the difference histogram would be much lower because the increase in the intensities would cancel each other out. If we use 16 gray levels instead of 256, then the difference values for those two different illumination conditions would be 5 and 6. This is only one level shift for %20 change in the illumination, which means that for lower illumination changes or for pixels with less contrast difference, it would not be noticeable at all. Nevertheless, applying the histogram equalization would be enough for this algorithm to withstand any reasonable illumination fluctuations. On the other hand, even with the histogram equalization, sum vectors would be very sensitive to any illumination change.

A. Frequency Domain Fine Tuning

There are dozens of articles in the literature that present successful results of both Haralick's and Unser's method on texture classification and discrimination problems. As Haralick and Unser both did, almost every one of those studies set the pixel distance "d" to 1. There is no explanation in Haralick's paper why he used d=1. Using 1 for the pixel distance has become so common that some articles don't even mention what distance they used [20]. The rest of them either use 1 or use 1 along with some other pixel distance, such as 5s. For example, a fabric defect detection experiment done by Latif-Amet [21] also set pixel distance to 1. A defect detection study on aluminium surfaces conducted by Chondronasios [22] selects d=1 and Georgieva [23] uses two different pixel distances, d=1 and d=5 to classify the cork tiles.

Because the texture pixels are defined as "a region slowly varying, or approximately periodic" [6], we will build our mathematical model based on this. If we scan a texture through a straight line at any given angle, the one dimensional signal obtained should be:

$$f(x) = a_0 + \sum_{n=1}^{N} An\,cos\left(2\pi\frac{n}{k}+\theta_n\right) + \varphi(x) \qquad (1)$$

Where $\varphi(x)$ is the noise. Since we want to calculate histograms of pixels that are "d" pixels apart, and assuming that the texture has frequencies that are integer multiple of themselves, the values of the two pixels that are "d" pixels apart would be:

$$f(p_{x1}) = a_0 + \sum_{n=1}^{N} An\ cos\left(2\pi \frac{nx1}{k} + \theta_n\right) + \varphi(x1)(2)$$

$$f(p_{x2}) = a_0 + \sum_{n=1}^{N} An\ cos\left(2\pi \frac{n(x1+d)}{k} + \theta_n\right) + \varphi(x1 + d)\ (3)$$

If our eyes can detect obvious periodicity in a texture, such as the ones created by periodic weavings of a fabric, then we can assume that most of the cosine terms have frequencies that are integer multiple of the main repetition. This means that, when the pixel distance "d" is equal to exactly one period of the texture, the difference of these two pixels will cancel out all of the cosine terms:

$$f(p_{x1}) - f(p_{x2}) = \varphi(x_1) - \varphi(x_1 + d) \qquad (4)$$

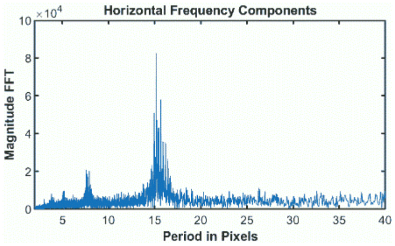
Naturally, we assume that the biases cancel each other out as well and all that remains are the two random variables. If the pixel distance does not equal to one period of the sinusoid, there will always be cosine terms in (4), meaning that the signal's variance would be much higher. High variance is not a desired property for a feature. This is the main reason why we use difference histograms (DH).

As shown in Fig. 3, if we scan through the texture image in four different orientations and calculate the magnitude of the Fourier Transform (FT) of that signal, the highest peaks in the magnitude of the FT will tell us which direction and distance must be used for the calculation of difference histogram.

We can use another method to verify our approach. If we have large number of defective samples (or areas), we can perform Fisher's Discriminant Analysis (FDA). The difference histogram vectors must be calculated on non-defective and defective windows for a range of "d" (let's say from 1 to 25) and for all of the orientations. Then the FDA of each element must be calculated and summed. The pixel distance and the orientation with the highest FDA sum should give us the optimum pixel distance "d". Fisher's Discriminant Ratio (FDR) is defined as:

$$FDR = \frac{(m_1 - m_2)^2}{\sigma_1^2 + \sigma_2^2}\ (5)$$

In this equation, m1 and m2 are the respective mean values, and σ_1 and σ_2 are the respective deviations associated with the values of a feature in defective and non-defective classes. Collectively these modifications will be referred to as "Diftogram." The following sections will show how this is done through a few examples.



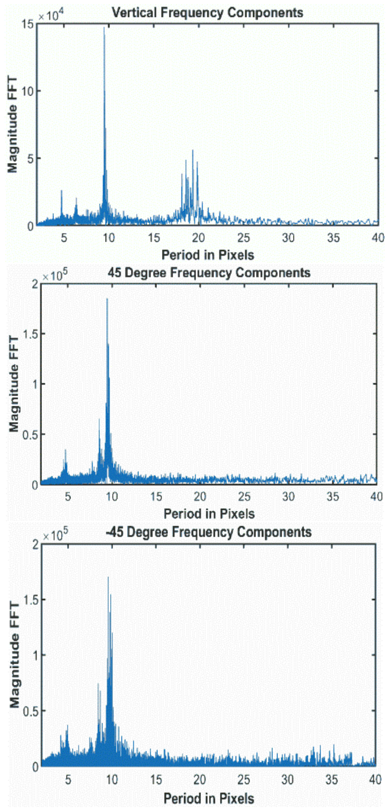


Fig. 3. Magnitude FFTs of the signals obtained by scanning the fabric image horizontally, vertically, at +45 and -45 degree angle.

V. Dataset-I

A typical fabric sample is used for the first experiment. Fabric defect detection is one of the areas of industrial machine vision where texture discrimination is widely used. In this experiment, 12 images with natural fabric defects such as broken thread, missing thread, stuck thread, weaving error, punctures, and lubricant oil stains are used. In order to compare the effects of modifications, the co-occurrence matrices are used as in the conventional way. In order to increase robustness against illumination changes, histogram equalization is applied to the area of interest. This can be noticed by the slight increase of contrast around the perimeter of the white boxes in all of the fabric images. GLCM are calculated for each of the 80×80 pixel windows on 1024×720 pixel images with pixel distance set as d=1. Co-occurrence matrices are calculated for orientations of 0, +45, +90 and -45 degrees using reduced gray levels of 16. Alongside the 14 features proposed by Haralick, the two features proposed by Clausi [24] and the three features proposed by Soh [25] are also calculated. This is necessary to prevent possible criticism that GLCM method is incomplete without the newly added features and that the results could have been better. In Section 3, the ANN performed better than the SVM. Therefore, a feed forward ANN with 25 neurons in hidden layer is used for all of the experiments.

Total of 19 features, 14 from Haralick, 2 from Clausi and 3 from Soh are calculated from every matrix. Since there is one matrix per each of the four directions, a total of 76 features are calculated to be used as input to the neural network. The training and the test sets are the same. The Neural Network toolbox of the Matlab software was used to train the ANN. The ANN training process is not a deterministic one. Every time a neural net is trained, even with the same training set and the parameters, results will be slightly different. Because of that, the experiment was conducted more than 30 times and the most successful ANN among them was selected. Results of this experiment are shown in Table II and Fig. 4. The white windows represent 80×80 pixel squares that are defined as "normal" by the ground truth and are also correctly classified as non-defective by the algorithm. The green boxes are drawn if both the ground truth and the algorithm classifies them as defective. In other words, correctly classified areas are marked as either white or green boxes. The black color window represents that the window was marked as defective but the algorithm failed to detect it. If the window is red, this means that a non-defective area was incorrectly classified by the algorithm as defective. Table II reveals that the GLCM algorithm using d=1 and using four orientations was able to detect 14 defects out of 42, and misclassified 1 or 2 areas as defective.

In order to see the effect of using Unser's difference matrices as direct input only, without applying the method to find the most effective pixel distance and orientation, the experiment was repeated using Unser's difference histograms with d=1 and in the four orientations. It was observed that the ANN had a very low margin to distinguish defective and normal areas. Because of this, two different outcomes were observed. In some of the trials, ANN recognized 37 of the 42 defective regions with 27 misclassification of normal areas whereas in the other trials it recognized 28 defective areas with 19 misclassification of non-defective areas. Both of these results are given in Table II.

To measure the success rate of the proposed method against other algorithms, the most effective pixel distance 'd' needs to be calculated. In order to achieve that, a fabric image without any defects must be scanned through four directions to obtain one dimensional signals. Afterwards, the magnitude of the Fourier transform of these signals should be calculated as shown in Fig. 3. Each signal has one dominant peak. The pixel period corresponding to those peaks should be used as the pixel distance.

To verify, or perhaps to get a second opinion, Fisher's Discriminant Analysis should also be used. As the first step, we calculate all of the DH for each of the 80×80 pixel windows for all of the twelve fabric images, using all possible pixel distances between one and twenty five. Afterwards we calculate the FDR value for each element in the difference vector using (5), and then sum these FDR values. The pixel distance and orientation with the highest FDR sum value is the one that should be used for texture discrimination. Below are the FDR sums for the elements of the vectors obtained for 25 different distances and four orientations. For 0-degree orientation:

1 2 3 4 5 6 7 8
FDR(Θ = 0)=[0.39 0.26 0.76 1.12 2.20 3.02 3.94 4.23

6.66
20 21 22 23 24 25
4.48 3.93 4.48 5.23 5.63 5.33]

The largest FDR sum values are for d=15 and d=16 for Θ equals 0 degrees (horizontal direction). When we look at the Fourier transform of the horizontal signals in Fig. 3, we see that the peak magnitude is exactly at d=16. Proceeding with the vertical direction,

1 2 3 **4** **5** 6 7 8
FDR (Θ = 90) = [2.76 4.65 5.43 **6.02** **5.51** 4.58 3.44 3.00
9 10 11 12 13 14 **15** **16** 17 18 19 20
21
3.21 3.51 3.53 2.47 2.70 3.75 **5.02** **5.66** 4.54 2.62 2.87 3.68
1.74 1.15 2.49 3.03 2.82]

FDR sum values reach their maximum at d=(4,5) and d=(15,16). As seen in the Fourier analysis of the vertical signal, there is a small peak at d=5 but the most important peak at d=10 has no effect on the FDR values and instead of the flat peak around d=19 we the values at d=15 and 16 of the FDR are higher. It is possible that the very narrow peak at d=10 is not detected and the defects have their own characteristics that is altering the values of the FDR. Because there are more than one significant cosine components in the vertical signal, the FDR values in the vertical direction are far smaller than that of the horizontal. This increases the variance of the signal and as a result, reduces the FDR values. For +45 orientation we get d=9, and for -45 degree orientation we get d=10.

1 2 3 4 5 6 7 8
FDR (Θ = + 45)=[2.70 4.28 5.48 6.00 5.70 5.52 5.47 5.78

3.29 1.47 1.68 3.45 4.12]

The FDR values for 0 degree orientation clearly indicate that difference histogram should be applied in the horizontal direction and the pixel distances should be set as d=15 and d=16. Using these parameters Diftogram's success rate is shown in Table II. The algorithm classified 37 defective areas out of 42 correctly and misclassified 6 areas as defective. That is almost 2.5 times (37/14=%264) higher defect recognition rate than the GLCM experiment.

As shown in Table II and Fig. 4, the results are considerably superior against the LBP. Some readers might be confused that the training and test sets are the same. The purpose of this study is not to measure the actual success rate of a single algorithm but to measure relative success rate of several algorithms with respect to each other. As long as the training conditions are the same, these results will give us which algorithm performs relatively better. This will be proven in Section VII (Dataset III) where we perform training on different training and test sets and the relative success rates remain similar.

White boxes are correctly classified normal areas and green ones are correctly discriminated defective ones. Black ones indicate the regions that the algorithm failed to discriminate and red ones are incorrectly classified defects.

VI. DATASET-II

A slightly more challenging fabric sample is selected for this experiment. The thread used for weaving this fabric has an alternating colour making the noise level of the texture extremely high. The lighting conditions were also altered. For this experiment, multiple light sources were used. The first three fabric samples in the set were taken under %20 higher illumination then the rest to demonstrate illumination change's effect. Another challenging part of this experiment is that the defects were artificially created to make them extra difficult to detect. The defects are so mild that even the human eye can barely notice them. In order to do so, 15 different images of the fabric were taken and then using the GNU Image Manipulation Software, GIMP (https://www.gimp.org), different kind of defects were created using blurring, Gaussian and salt and pepper noise, contrast altering, spatial compression, pixel smearing and etc.

Table III and Fig. 5 shows the results of the GLCM algorithm using 256 and 16 grey levels, four orientations and 19 features calculated from each orientation. Pixel distance was set to d=1, similar to almost every GLCM experiment published in the literature. The classifier is the same ANN used for the previous experiments, a feed forward network with 25 neurons in hidden layers. The training set and the test set are the same, the training was repeated more than a dozen times and the most successful one is shown here. This combination of algorithms classified 20 defects correctly out of 64. Zero or two normal areas were misclassified as defective.

GLCM-256 with 4 orientations d=1. LBPri DH d=1, 0 & 90 degrees

Fig. 5. Samples from dataset II. Above: A different kind of weaving was cut and paste on it as defect. Below: Added salt and pepper noise. Green boxes are correctly discriminated defective areas and black boxes are the ones that the algorithm failed. Images on the right shows zoomed defects.

Before proceeding to the second part of the experiment, the Fourier analysis of the fabric image must be performed. The absolute value of the FFT obtained by combining many lines from several images shows that there isn't any salient sinusoid in this signal. The FFT results are similar in other directions therefore they are not shown. Under such circumstances, the highest peak is usually obtained at zero frequency. This means that the FDR analysis should give us d=1. When we perform the FDR analysis that is exactly what we get:

FDR(Θ = 0)=[**5.97** 2.37 1.41 1.39 1.68 2.00 2.17 2.19 2.18 2.05 1.97 1.99 2.03 1.91 1.71 1.64 1.50 1.34 1.25 1.26 1.32 1.29 1.24 1.22 1.12]

FDR(Θ = 90)=[**5.50** 1.89 0.57 0.52 0.77 1.25 1.58 1.94 2.18 2.33 2.43 2.47 2.29 2.01 1.80 1.81 2.03 2.24 2.63 2.97 3.42 3.58 3.67 3.58 3.43]

Similar results are obtained for 45 and -45-degree orientations. It seems that selection of pixel distance as 1 is not a bad choice if the texture has a lot of noise or there are more than a few high amplitude periodic components in the texture.

For the next part of the experiment, Unser's difference histograms are directly used as the texture features. The grey levels are reduced to 16, pixel distance is set to one, and only two orientations, horizontal and vertical are selected. In the first part of the experiment where GLCM was used, same parameters were used except for the fact that, 45 and -45-degree orientations were also used with the GLCM. These two directions, 45 and -45 are skipped to demonstrate the power of the proposed method and also to make the algorithm twice as fast. The elements of the two difference vectors are directly fed to the same ANN used for the previous experiments. As shown in Table III, this algorithm recognized 59 defective regions out of 64 and misclassified one normal area as defective. Compared to the defect detection rate of the GLCM algorithm, this is almost %300 higher. Against the LBP variants, it is almost %200 more successful.

VII. Dataset-III

For the third experiment, a fabric sample with a patterned weaving is used. The fabric is weaved to display a repeating pattern, which creates a secondary pattern on top of the pattern created by the threads of the fabric. Lighting conditions were slightly altered for many of the 45 image samples of this fabric. The defects were created using the GIMP software, but this time with increased variety and larger surface area. These defects vary in strength; about half of them are easily noticeable by the human eye. The frequency analysis in Fig 6 shows that this fabric has a major component at a period of around 27 pixels in the horizontal direction. At 45 degrees, the major component is at 13 pixels (not shown) and for the vertical direction, there are three peaks at 9, 14 and 25 pixels. The FDR analysis show consistent results with these findings:

FDR(Θ = 0)=[3.63 2.11 1.60 0.56 2.12 0.46 1.55 0.76 0.54 1.03 0.79 1.35 2.07 1.79 1.66 1.13 1.09 0.43 0.6 0.53 0.30 1.24 1.29 0.86 1.12 2.18 **6.10** 4.92 1.89 0.95]

FDR(Θ = 45)=[3.75 2.57 2.60 0.75 0.51 1.51 2.66 0.75 0.47 0.55 1.32 1.97 **6.41** 4.25 1.21 1.55 1.17 0.74 0.69 0.90 0.56 0.3814 0.73 1.03 1.66 2.30 2.06 0.95 0.50 0.51]

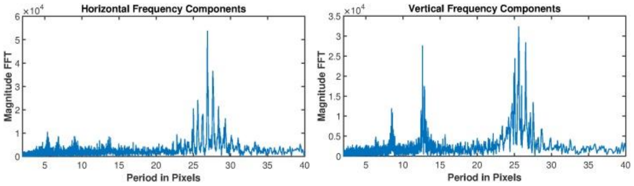

Fig. 6. Magnitude of the FFT of the signal obtained by scanning the fabric of dataset III, horizontally and vertically.

FDR(Θ = 90)=[**6.16** 2.65 1.21 0.86 0.82 1.08 1.18 1.57 1.85 1.56 1.40 1.19 1.07 1.54 2.01 1.91 1.68 1.18 0.87 0.72 0.64 1.15 2.11 3.14 3.87 2.83 1.52 0.78 0.76 1.17]

Because of the abundance of distinct frequency components in the vertical direction, (Θ = 90), the FDR analysis show that there is no advantageous pixel distance in the vertical direction other than d=1. For the 0-degree orientation, d=27 and for the 45-degree orientation d=13. Fig. 7 and Table IV shows the results of discrimination tests for the GLCM with d=1 in four directions, Diftogram with d=27 for the horizontal and d=one for the vertical orientations and the LBP. Diftogram is approximately %250 more successful than the GLCMs and %200 more successful than the LBPs. Notice also that the number of false positives are smaller than both the GLCMs and the LBPs. This result is slightly lower than the previous examples. The reason for that is because the fabric has two different patterns on it and the defects are stronger. Much higher results could be obtained by adding more orientations and pixel distances to the Diftogram if computational efficiency is not essential.

Because we are testing the reliability of different kind of features against each other, there is nothing wrong about using the same images for both training the ANN and testing it as long as the ANN is trained the same amount for each feature set and the ANN is not trained excessively to the point where it memorizes the samples. In other words, if the ANN has enough generalization capability, it will measure how well the features separate the defects from the background. The default parameters of the ANN trainer in Matlab has very good balance between memorizing and generalizing therefore, the experiments conducted so far has measured the reliability of the features quite well. Unfortunately, there might be people who do not trust such findings and demand that the training and the test sets should be different. For those people the third experiment is conducted again, this time using the odd numbered 23 images (1, 3, 5, ... 45) for training and the other 22 for testing. Table V shows that the Diftogram is still about two times more successful than both the GLCMs and the LBPs.

VIII. Complexity Measurements

In order to measure the computational complexity of each method, a C++ program was written. Measuring the processing time per one image is not possible on today's fast computers. To get an accurate measurement of how long each method takes to compute, 10 images were processed 500 times and then the total duration was divided to 5000. The computer was programmed to run a loop 5000 times, processing one of the 10 images in each iteration. This was done to prevent the CPU from copying an entire image in its cache. Processing the same image from the cache repeatedly would yield wrong results. Using The Microsoft Visual Studio compiler, with full optimization, measurements show that the calculation of the GLCM in one direction using 16 grey levels takes approximately the same amount of time with calculating the difference histogram in one direction with the same grey levels. Calculation of the difference histogram takes %98.5 of that of the GLCM. A few of the features that Haralick proposed were also implemented. The time required for their completion was negligible compared to the time required for the computation of a 16×16 GLCM. Over all, it seems that it takes %3-5 percent longer for the GLCM and its features to be calculated. However, for 256 grey levels, the GLCM becomes 256×256, making the calculation time for the features far longer. In Matlab, overall time for the calculation of 256 grey level GLCM takes 32 times longer compared to 16 grey level GLCM.

In order to compute the speed of LBP, a pure Matlab code is used. LBP (R=1, 2 p=8) took %43 longer to calculate than the GLCM-16 (Matlab code) in one direction. Therefore, it is computationally more efficient than the GLCM because it is more successful than the GLCM calculated in four directions. LBPri is % 419 slower than the GLCM-16 in one direction therefore it is only slightly more efficient than the GLCM. However, it should be noted that the LBP is cheating by using a gigantic; 16 MB look up table to speed up its calculations. It is essentially creating a processor inside the memory. Based on these numbers, Diftogram is computationally more efficient than both of the LBP algorithms are. According to a recent comparative study [26], among the LBP algorithms, LBPri is the fastest among all of them and it is only %15 less successful than the most successful variants such as the MRELBP [27]. Considering that the most successful ones are at least five times slower than the LBPri, (MRELBP is 9 times slower) it is seems that Diftogram is still computationally more efficient, even if it is not as reliable as the newest versions of the LBP.

In both of the previous experiments, GLCM was computed in four directions. On the other hand, based on our proposed method, the difference matrix (DM) was calculated in only two directions. Therefore, the proposed method is not only more successful at recognizing the defects, but also twice faster against GLCM-16.

IX. Results and Conclusion

In this article, two new approaches were proposed. The first one suggests that the use of Unser's difference histograms as input to a classifier yields better results at discriminating the texture than Haralick's method. Usually texture discrimination is a far more challenging problem then the texture classification; therefore, by using this method, similar superior results should be expected for classification as well. The second approach is that the orientation and the pixel distance to calculate the second order histograms must be selected based on the frequency properties of the texture. Two methods are proposed for the selection of these parameters. Another suggestion is the use of pixel average as an extra feature for more challenging patterns. Based on this design, three experiments are conducted.

Many of the defects used in the experiments are so faint that the human eye can barely notice them. In each of the experiments, the proposed set of methods performed approximately %250-%300 better at discriminating the texture, compared to the GLCM method with 19 features. The C++ implementation of the proposed algorithm, based on the parameters used for these experiments, should be approximately twice faster than the GLCM-16, which means, at least %500 improvement in efficiency. Against the LBP variants, the Diftogram is almost %200 more successful. The computational efficiency of the rotation variant plain LBP is comparable to that of the Diftogram while both the success rate and the efficiency of the LBPri is less.

Majority of the recent articles study rotation invariant texture recognition and discrimination algorithms. Therefore, the improvements discussed here might seem not very important for many academicians. However, engineering is performed to solve the problems of humanity, not the ones that we create in our own labs. Considering the fact that, every second, quality inspection is being performed on thousands of factories across the planet, hopefully, the improvements proposed in this article will find much greater use than many others published in the literature.

An Autonomous Multi-agent Framework using Quality of Service to Prevent Service Level Agreement Violations in Cloud Environment

Jaspal Singh*, Major Singh Goraya
Department of Computer Science and Engineering-Sant Longowal Institute of Engineering and Technology,
Deemed University, Longowal, Sangrur, Punjab, India

Abstract—Cloud is a specialized computing technology accommodating several million users to provide seamless services via the internet. The extension of this reverenced technology is growing abruptly with the increase in the number of users. One of the major issues with the cloud is that it receives a huge volume of workloads requesting resources to complete their executions. While executing these workloads, the cloud suffers from the issue of service level agreement (SLA) violations which impacts the performance and reputation of the cloud. Therefore, there is a requirement for an effective design that supports faster and optimal execution of workloads without any violation of SLA. To fill this gap, this article proposes an automatic multi-agent framework that ensures the minimization of the SLA violation rate in workload execution. The proposed framework includes seven major agents such as user agent, system agent, negotiator agent, coordinator agent, monitoring agent, arbitrator agent and the history agent. All these agents work cooperatively to enable the effective execution of workloads irrespective of their dynamic nature. With effective execution of workloads, the proposed model also resulted in an advantage of minimized energy consumption in data centres. The inclusion of a history agent within the framework enabled the model to predict future requirements based on the records of resource utilization. The proposed model followed the Poisson distribution to generate random numbers that are further used for evaluation purposes. The simulations of the model proved that model is more reliable in reducing SLA violations compared to the existing works. The proposed method resulted in an average SLA violation rate of 55.71% for 1200 workloads and resulted in an average energy consumption of 47.84kWh for 1500 workloads.

Keywords—Cloud computing; multi-agent framework; SLA violations; energy consumption; history agent; Poisson distribution

I. INTRODUCTION

Cloud computing is a well-established paradigm that offers computing resources and services in a pay-as-you-go fashion to all the users connected to it [1]. It also provides resources to users that can be fully controlled by the users themselves through the virtualization of resources [2]. The cloud paradigm can be generally categorized as a scalable architecture that supports the inheritance of a wide range of technologies including utility computing, service-oriented architecture (SOA), and virtualization [3]. This paradigm also provides a shared pool of resources that offers services to workloads belonging to diverse forms of applications. Virtualized IT resources offer services of three types including software as a service (SaaS), Platform as a service (PaaS), and infrastructure as a service (IaaS) [4, 5]. With deep-spread data centers, the cloud paradigm ensures seamless services to its end users. Most of the popular organizations and companies are currently rendering cloud services to their customers and some of them include Google, Amazon, and Microsoft [6, 7]. The main acceptance of this paradigm is due to the flexible services offered where the users are requested to pay only for the services they have used [8].

The daily needs of the general community are satisfied with the cloud computing service which stays at a basic level of the computing paradigm [9]. Such a computing facility is specifically introduced to provide quality of service (QoS) aware services to a market of users to meet their objectives and requirements [10]. Thus, the service level agreement (SLA) oriented resource management is a crucial need for the users that negotiate a pile of virtualized and inter-connected systems between the users and cloud service providers or between the resource providers and brokers [11]. Due to the widespread availability of business models, it becomes a highly complex issue to select the appropriate service provider that can fulfil the execution of an application by meeting its QoS requirements [12]. A system-centric resource management framework is usually employed by cloud providers to offer computing services and resources [13]. A market-oriented resource management framework is of utmost need to enable the supply and demand of resources thereby offering feedback to both providers and consumers in terms of economic incentives [14]. Also, based on the usage of resources and services, the service requests are distinguished through QoS-based resource allocation [15].

Currently, the cloud paradigm provides only limited support for dynamic SLA negotiations between the associated participants such as cloud service providers and consumers [16]. Also, there are no reliable mechanisms that can offer automatic resource allocation to multiple competing requests [17]. The existing frameworks are unable to completely support customer-driven service management with the requested service requirements and customer profiles [18]. The SLAs that are signed between the cloud customers and cloud service providers are required to be maintained on each call of request processing and executions. Generally, market-based resource management strategies are more focused on customer satisfaction and service provider profits [19, 20]. Therefore, the development of a framework that can satisfy both the service providers and customers is of utmost need [21]. In most of the research works conducted, it has been concluded that it is almost impossible to extract appropriate market-based resource management schemes that can encompass both computational risk management and user-driven service management to sustain the SLA-aware allocation of resources [22, 23].

The SLA-oriented schemes are required to offer personalized attention to customers to help them meet their SLA-aware objectives [24]. One of the most important factors to be considered while designing such a solution is that the demands of the users fluctuate with time for the changes encountered in the operating environment and business operations [25]. SLA can be defined as a formal agreement that provides information regarding the quality of every non-functional requirement (NFR) of a service [26]. A formal procedure is followed in cloud computing that if there is any SLA violation encountered in the workload execution process, then penalties are provided to the service providers [27]. When there are no violations of SLA for different workload executions, then rewards are provided either to the customers or service providers after evaluations [28]. One of the major problems arising here is with the dynamic execution of workloads where there are a huge number of workloads arriving in the cloud for executions. At this point, the QoS cannot be assured in every circumstance and there is a requirement for an automated system that can accurately monitor the violations occurring within the environment [29, 30]. Therefore, there is a leading requirement for an automatic system that can control and monitor the QoS of the workloads within the negotiated terms.

A. Motivation

There are several techniques encountered to automate the process of resource management via SLA negotiation. Generally, those methodologies integrate virtualization and market-based allocation policies for allocating the cloud resources to workloads to complete executions. Several efforts have been made to automate the process of SLA-aware resource allocation to the workloads. Some methods focused on framing SLA to workload execution through the negotiation process whereas others focused on automating the entire process. But, only a few methods explored the benefits of multiple agents in the cloud to enable the automatic management of resources to support SLA-aware workload execution. Therefore, there is a need for such a technique to be enforced to avoid SLA violations while executing the workloads. Therefore, this paper presents an automatic multi-agent framework that supports the execution of workloads without any violation of SLA. Moreover, the proposed framework also optimizes energy consumption in data centers to enhance overall performance.

B. Contribution

The major contributions of the proposed work include the following:

- A new and efficient multi-agent system is proposed in this work to enable seamless services to its users by satisfying their fluctuating demands and enabling SLA-aware executions of workloads.

- Presenting the agent-based cloud framework where each of the agents is incorporated to provide timely execution of workloads without disturbing the SLAs. Moreover, the framework is designed in a unique way to satisfy both the service providers and the customers involved.

- Introducing an additional history agent within the agent-based framework to keep track of the resources used and the requests processed. The aim of adding this agent is to enable the prediction of future demands so that the overall efficiency and reputation of the system can be enhanced.

- Introducing the Poisson distribution function (PDF) model to generate random numbers based on the input to form the dataset. The generated dataset is then provided to the proposed model to evaluate and compare the model extensively.

C. Organization

The remainder of the paper is structured as per the following: Section II presents the literary works established by other researchers working in the same field, Section III provides the proposed methodology with architectures and explanations, Section IV provides the results and discussion with comparative analysis and Section V concludes the paper with future scopes.

II. Background on Resource Provisioning in Cloud Computing and QoS Constraints

Some of the recent works established for controlling SLA violations in the cloud are reviewed below:

Cloud computing technology faces several challenges among which SLA violation is one of the most common and tiring problems affecting its overall performance. In the cloud-based e-commerce negotiation framework, the optimization of broker negotiation strategy is a cumbersome task. Generally, long-term or pre-request optimizations are followed to resolve the task. The pre-request strategies focus on the usage of various utility functions and are followed in most research works. The long-term strategies are less focused and most of them are unable to guarantee negotiation and state-of-art to minimize SLA. Such limitation was addressed by Rajavel and Thangarathanam [31] effectively through the stochastic behavioral learning negotiation (SBLN) technique. The main intention of the technique was to maximize the success rate and utility value to a maximum level. The increase in the desired values was attained by increasing the count of negotiation rounds. The performance of the method was implemented and compared with other techniques and the outcomes proved its efficacy.

The Multiple agent-based systems were developed by Azhagu and Gnanasekar [32] to deal with the SLA violations in the cloud computing infrastructure. Violations of SLA affect the business operations of both the cloud service providers and customers as compensation is required to be provided by the service providers (CSP) for their customers. The agent-based model enhanced the trust of every stakeholder through the automatic minimization of SLA violations. The framework included a total of six agents a user agent, a system agent, a negotiation agent, a coordinating agent, a monitoring agent, and an arbitrator agent. The monitoring agent was responsible to monitor the cloud environment and indicated SLA violations. The arbitrator agent observed and identified the cause of the violation and posted penalties or rewards based on the performance. After evaluations of the entire framework, the outcomes suggested that the method was effective in controlling SLA violations in the cloud with the maximization of performance in workload executions.

The Discovery of cloud services is a highly challenging issue due to the increase in complexities and network size. With the dynamic increase of these two factors, the effective discovery of services is hampered making it an NP-hard problem. The popular cloud service discovery method based on ant colony optimization (ACO) suffered from load balancing issues. To resolve the issue and enable effective usage of resources, Heidari and Navimipour [33] introduced the inverted ACO (IACO) method that promised load-aware service discovery to the cloud. In the inverted algorithm, the attractive behavior of pheromones was replaced with the repulsive behavior. The model was simulated using the Cloudsim tool and the numerical results of the model proved its efficiency over the other compared methods. Also, the model provided several other benefits including energy efficiency, response time mitigation, and control of SLA violations.

Cloud computing supports large-scale processing in a distributed fashion with higher flexibility. SLA violations in the cloud occur due to several facts and it is important to control these violations to attain performance improvement. VM allocation is one of the common and challenging problems in the cloud resulting in SLA violations. Other problems associated with VM allocation include problems in asset utilization and energy consumption. An SLA-aware strategy to allocate the VMs in the cloud using an intelligent algorithm was introduced by Samriya et al. [34]. To attain the objective, the method utilized the multi-objective emperor penguin optimization (EPO) algorithm that allocated the VMs in a heterogeneous cloud environment. Further, simulations were conducted to prove the performance of the method compared with other multi-objective metaheuristic optimization algorithms. The outcomes proved that the model effectively reduced SLA violations and energy consumption in the cloud environment.

Another strategy based on resource allocation was introduced by Belgacem et al. [35] based on the exploration of properties of multiple agents in the cloud. Cloud infrastructure face challenges in resource allocation due to its heterogeneous nature, volatile resource usage, and accommodation of VMs with diverse specifications. The method introduced the combination of an intelligent multi-agent system with the reinforcement learning method (IMARM) to attain the objective of optimal resource allocation. The Q-learning process was combined with the properties of multiple agents to gain performance enhancement in resource allocation accordingly. IMARM method responded well to the fluctuating customer demands through dynamic allocation and release of resources accordingly. Moreover, the VMs were moved to the best state concerning the current state environment through the learning model. Finally, simulations were conducted to prove the performance improvement attained by the model compared to previous models in terms of various metrics.

In both cloud and utility-based computing platforms, SLA emerge as a chief aspect while providing personalized services to the users. In order to offer flexible establishment of SLAs and to prevent SLA violations, Son and Jun [36] presented a proactive resource allocation (PRA) scheme. The presented scheme optimally selected a suitable datacenter among the available globally distributed datacenters to enhance resource allocation to the workloads. The method also provided time slots and price negotiations for flexible SLAs. The effectiveness of the method was proved through experiments.

TABLE I. COMPARATIVE ANALYSIS OF THE EXISTING LITERARY WORKS

Authors	Methods	Advantages	Drawbacks
Rajavel and Thangarathanam [31]	SBLN	Obtained drastic increase in success rate and utility value	The unwanted conflicts among the participants are required to be addressed
Azhagu and Gnanasekar [32]	Multi-agent system	Automatically controlled SLA violations in the cloud through continuous monitoring	More QoS parameters are required to be considered to attain optimal performance
Heidari and Navimipour [33]	IACO	Efficient discovery of cloud services with enhanced utilization of resources	The repulsive behavior of pheromones is required to be evaluated deeper to prove its advantages
Samaria et al. [34]	Multi-objective EPO	To enable effective VM allocation in the cloud with minimized SLA violation and energy consumption	Other important performance objectives such as wastage of resources are required to be focused
Belgacem et al. [35]	IMARM	Dynamic allocation and release of resources and providing better responses to the customers' changing demands	More metrics are required to be considered and more analyses are required to prove its reliability
Son and Jun [36]	PRA	The overall efficiency of negotiation and utility has been increased with the trade-off algorithm	Limited SLA options are provided by the framework based on enforced SLA strategies
Wu et al. [37]	PURS	Facilitated intelligent bilateral bargaining of SLAs and provided maximum profit for the brokers through enhanced customer satisfaction levels	The penalty for the failure of negotiation from the user's perspective is not considered

Another SLA negotiation framework was introduced by Wu et al. [37] to accomplish profit with higher customer satisfaction. The process of negotiation establishment becomes tough with the existence of multiple CSPs. The introduced framework considered SaaS broker as a one-stop-shop for the customers and negotiation was performed with multiple CSPs. The automated framework supported bilateral bargaining of SLAs and helped in maximizing the profit of brokers. Extensive evaluations with real CSP proved the efficacy of the method. Table I presents a comparative analysis of the existing literary works.

A. Problem Statement

On reviewing the existing works, it has been identified that the multi-agent system in the cloud is highly advantageous and helps to offer numerous reliable services to its customers. The Multi-agent-based framework is one of the effective methods to enable the execution of workloads without any violation of the SLA constraints. The existing methodologies are unable to completely enable the execution of workloads within the defined deadlines. Other agent-based frameworks are merely unstable as the failure of negotiation is not given importance or considered that may result in performance degradation. Moreover, the negotiations terms and conditions are not well-established in most of the existing works. Apart from these, the demands of the future workloads are unidentified which delays processing of workloads. Because of looking forward to attaining optimal resource provisioning using QoS in cloud computing and higher performance by satisfying the QoS constraints of users, a very few techniques are formulated based on the self-management of cloud services using multiple agents. Moreover, it is of utmost need to optimize the violations of SLA with the help of negotiation before the deployment of services in the cloud. To overcome the existing drawbacks and to fill the gaps, a new multi-agent-based framework is introduced based on the accommodation of multiple agents to monitor and complete the execution of workloads within the defined SLA. The proposed framework also utilizes an additional agent to back up the details regarding executions in order to identify the future demands for resources. By this way, the profit and rewards from both the ends can be considered and the effectiveness of negotiations can also be improved.

III. Proposed Methodology

Execution of cloud workloads within the defined deadlines is a complex task and requires appropriate algorithms and techniques. Efficient workload execution in cloud is highly crucial as it has wide range of applications supporting companies associated with it. The agent-based frameworks are faster in approaching the requests from users compared to other agentless frameworks. This helps to complete the workload execution within the deadlines. Moreover, these frameworks are capable of constantly monitoring the environment and collect data at real time. Due to these advantages, a new Autonomous Multi-agent-based framework based upon Probability and History (AMAPH) is designed in this work to prevent SLA violations and to attain higher performance in workload executions. The proposed multi-agent system monitors the cloud environment and checks for SLA violations. When there is no violation encountered in a workload execution, rewards are provided to the service provider or customer and when there is a violation, penalties are provided and the reason for the violation is determined. The proposed mechanism works deliberately to avoid any kind of SLA violation within the cloud environment and assures proper execution of workloads that are succeeded respectfully. Moreover, the History agent keeps a record of either successful or failed requests, respectfully. The overall architecture of the proposed work is displayed in Fig. 1.

The proposed multi-agent framework includes seven agents a user agent, a system agent, a negotiation agent, a history agent, a coordinating agent, a monitoring agent, and an arbitrator agent. The requests reach the user agent at the initial stage and then based on the type of request; it is forwarded to the system agent.

The type of service required for processing the request is determined and the request is forwarded to the negotiation agent where a negotiation process is initiated between the user agent and service provider. A service is selected for the request and the details are then forwarded to the coordinating agent. The history agent is responsible to track the services offered to the requests. SLA is established by the coordinator and the monitoring agent dynamically monitors the environment for any violation and each violation, an indication is sent to the arbitrator agent.

Finally, penalties are laid by the arbitrator to the service provider and the type and reasons for the violation are determined. The Poisson distribution function (PDF) component is included in the framework to test the performance of the proposed system (AMAPH) and assuring for the different number of workloads accordingly in comparison to the base paper [32], at a glance.

A. User Agent

The user agent is the initial agent of the proposed framework, and the role of the agent is to receive the requests provided by the associated cloud users. Thus, the cloud users directly request the services via the user agent to the cloud. This agent is responsible for dealing with the user registration processes for new users. Each user is linked with a single user agent to attain the cloud services.

For any kind of additional services requested by the user, multiple user agents are not created in the proposed work and the additional requested services are handled by the same agent. For registration of new users, the user agent gathers the required information such as the personal information of users via a registration form. In the case of service requests from the user side, the user agent determines the type of service being requested by the user. All the details regarding the service type requested are collected and analyzed and then the requests are forwarded to the system agent for further processing.

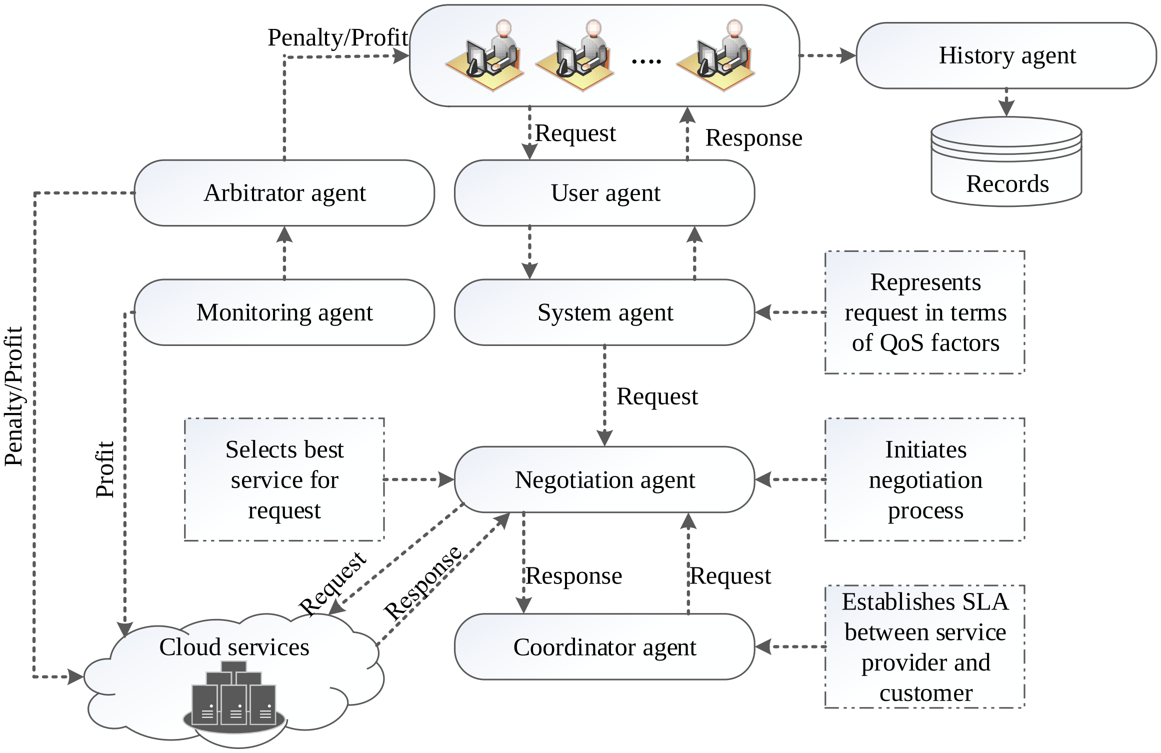

Fig. 1. Architecture of the proposed Multi-Agent framework (AMAPH).

B. *System Agent*

The system agent receives the requests from the user agent and determines the actions to be taken further. The details regarding the requests are obtained and then the requests are represented in technical terms including the quality of service (QoS) factors such as account type, number of accounts, contract length, solution time, and response time [32]. The system agent is responsible for verifying the quality factors of all the incoming requests and helps the framework to better process the requests. After representing the requests in terms of quality factors, the service type requested by the user is identified. Based on the requested service type, the system agent either forward it to the negotiation or the coordinator agent.

C. *Negotiation Agent*

This agent is responsible for initiating the negotiation process between the user agent and the service provider. The negotiation process is established based on diverse technical factors including nature of service, reliability, response time, monitoring, reporting of service, and responsibilities. Based on the technical factors and the service type being requested by the user, the negotiation agent communicates with the available service providers. The available service providers on the other side, place bids in the given view of processing the requests based on the available resources, resource capabilities, market circumstances, and business objectives. The main significance of the proposed framework is that the negotiation agent broadcasts the request details to all the service providers to provide the best service to the requests. The negotiation process ensures maintaining a more feasible SLA in workload executions. Based on the requested details available, the negotiation agent evaluates the received bids from service providers. Then, the attributes of service providers are compared with the resource requirements of the user and the appropriate service provider has selected that best suit the request. The details regarding the selected service and the service provider are then forwarded to the coordinator for further processing. Further, the history agent shall maintain the state-of-art in records wherein the id of the user, the CSP being selected by the negotiator as optimal resource provisioning process using QoS with respect to different data centres.

D. *Coordinator Agent*

The coordinator agent receives the request and selected service details from the negotiation agent and evaluates the request. The agents evaluate the received request for first-time access or request for service upgradation. After analyzing the type of request received, appropriate actions are taken further. The agent also formally establishes an SLA between the respective user and service provider and the message is forwarded to both parties. Apart from sending the message, it is also preserved by the agent for enforcement. Finally, the SLA is sent to the monitoring agent for further effective actions.

E. *Monitoring Agent*

The main responsibility of the monitoring agent is to continuously monitor for SLA violations within the cloud environment. Based on the established SLA details received from the coordinating agent, the monitoring process is regulated by the agent. When a violation is encountered in the environment, the agent immediately sends an indication to the arbitrator to take appropriate actions or to provide a penalty to the respective party. If there is no violation in the workload execution, then the monitoring agent sends an indication about providing a profit message to the respective party for the successful execution of the task. It recommends the arbitrator provide rewards to the concerned service provider.

F. Arbitrator Agent

This agent is responsible to analyze the type of violation that has occurred and the reasons behind the occurrence of such violation. Then, based on the analysis, penalties are enforced on the service providers or the respective customers concerning the defined SLAs.

G. History Agent

The history agent is one of the significant agents in the proposed work that keeps track of service usage and workload executions. This helps the system to predict future workload requests and the type of services that could be predicted by those requests. The history agent maintains records where the id of the user, the type of service requested, the service being selected by the negotiator as optimal resource provisioning, and the service provider allocated to process the requests are stored as files. Based on these details, the agent predicts future workload requests and the type of service needed to process the request. By predicting these parameters, the proposed system decides on faster workload executions with minimized SLA violations. The history agent keeps a record wherein the service provider allocated to the request and other constraints are stored as files.

H. Poisson Distribution for Random Number Generation

The Poisson distribution function (PDF) is followed in this work for random number generation and these numbers are then given to the model for evaluation purposes. This distribution has very minimum parameters and is very simple to implement. Therefore, this distribution is chosen in our work to reduce the complexities. Consider a discrete random variable χ and it is assumed to follow a Poisson distribution with parameter $\lambda > 0$ if and only if it follows the following probability mass function:

$$f(k;\lambda) = \Pr(\chi = k) = \frac{\lambda^k e^{-\lambda}}{k!} \quad (1)$$

where, k specifies the count of occurrences, e is the Euler number, λ specifies the positive real number which is equal to the expected value and variance of the random variable χ.

$$\lambda = \mathrm{E}(\chi) = \mathrm{var}(\chi) \quad (2)$$

This distribution can be generally followed in systems with a large number of rare but possible events and the count of such events within a fixed time interval can be specified as a random number with the Poisson distribution. Instead of knowing its value of λ it the system provides the value of the average rate δ, then λ is substituted by δt an Eq. (1) that can be adopted as follows:

$$\mathrm{P}(k \ events \ within \ \mathrm{int} \ t) = \frac{(\delta t)^k e^{-\delta t}}{k!} \quad (3)$$

IV. Results and Discussion

A detailed analysis of the results obtained through evaluations of the proposed framework is presented in this section. The entire simulations of the proposed work have been carried out using the CloudSim tool with the Java Agent Development Environment (JADE). The proposed system includes multiple active agents such as a user agent, system agent, negotiation agent, history agent, coordinator agent, monitoring agent, and arbitrator agent. The user agents receive the requests and provide a registration form if it is a new request or evaluates and forwards the details to the system agent. The system agent evaluates the requests and represents them in technical form and then forwards it to the negotiation agent where the negotiation process is initiated. The history agent is responsible to keep track of certain important records and the coordinator agent chooses the appropriate service to process the request based on the SLAs. The monitoring agent monitors the entire cloud environment for SLA violations and if there is any violation, then the agent sends an indication to the arbitrator for penalty enforcement or directly forwards a message for rewards if there is no violation. The proposed framework is autonomic and automatically monitors and controls the environment without the need for the intervention of a cloud engineer.

In the JADE environment and evaluations, the overall framework is implemented as agents and the random numbers are generated via the Probability Distribution Function for realistic datasets that are exchanged between agents for collaboration. Apart from the seven agents of the framework, the environment also accommodated a resource manager, cloud broker, VM manager, physical machine manager, and cloud registry. The entire simulations are carried out with a total of 05 data centers and 20 service providers. In the simulations, the requests arising from the VMs are forwarded to the service broker. The workloads are simulated based on the business workload traces provided by GWA-T-12 Bitbrains. The simulated dataset includes the performance values for different VMs running in datacenters and the data are recorded in .CSV files. The data values are generated for 5 datacenters to provide extensive evaluations and analysis. The generated dataset included performance values such as CPU usage, memory usage, network throughput, disk throughput, CPU capacity provisioned and memory capacity provisioned. A total of 1500 workloads are generated to evaluate the proposed system and each workload included the above-mentioned performance values. Moreover, the dataset consisted of no missing or duplicate values and this reduced the need for preprocessing. For comparison, the proposed method selected PRA [36], PURS [37], and a multi-agent system [32]. All these results are respectfully taken from the multi-agent system [32] for comparison; the results are undertaken by varying the number of workloads, resources, and execution times for optimal resource provisioning using QoS in cloud computing.

A. *Performance Metrics*

The proposed framework has been evaluated in terms of SLA violation rate and energy consumption [32]. The mathematical representations and descriptions of the metrics chosen are as follows:

SLA violation rate: SLA violation rate indicates the rate of violations occurring in the environment for different workload executions. The mathematical representation for the SLA violation rate can be given as follows:

$$S_{VR} = f_R * SLA_W \tag{4}$$

where, f_R is the failure rate and SLA_W is the weight of SLA. The failure rate can be measured using the following formulation:

$$f_R = \frac{W_{fR}}{W_{total}} \tag{5}$$

wherein, W_{fR} is the workloads' failure rate and W_{total} indicates the total count of workloads involved. The SLA violation rate is taken by varying the number of workloads, number of resources, and the number of execution times which is given by the following formulation:

$$E_T = \frac{W_{ct} - W_{st}}{W_{total}} \tag{6}$$

where, W_{ct} is the completion time of workload, and W_{st} is the submission time of workload.

Energy consumption: Energy consumption indicates the consumption of energy by the VM to complete the execution of a workload. The mathematical formulation is as follows:

$$E_C = (l * \max) + (1 - l) * \max E_{VM} \tag{7}$$

wherein, E_{VM} indicates the energy consumed by VM and l indicates the constant set to 0.5 in simulations.

B. *Performance Analysis*

The overall performance of the proposed framework is analyzed in this section. The simulations are performed with user-defined QoS constraints like CPU, RAM etc. All the results obtained are compared with the methods such as PRA [36], PURS [37], and multi-agent system [32]. The existing methodologies also follow the same configurations and parameter settings. The analysis of the obtained results is presented:

The results of the SLA violation rate for the different workloads are recorded. The performance of the proposed method is more optimal than the other methods. The addition of a history agent helped the model to accurately predict future workloads so that the SLA violation rates are reduced. The results are taken by varying the number of workloads from 0 to 1200. For all the workload input, the proposed model maintained higher performance compared to the other models. When the number of workloads is low, the violation rate is also low and when the workload is increased, the violation rate is scanty also and gradually increased. The performance comparison of SLA violation rate with respect to number of workloads is presented in Table II. A graphical representation of the results is presented in Fig. 2. The figure shows that there is only a minimal increase in violation rate for the proposed method showing its efficacy. The graph also shows that there is a huge impact on the overall performance of the framework when the number of workloads are varied. The proposed approach depicts a result of 19.5% violation rate when the number of workloads is 200 and resulted in 55.71% violation rate when the number of workloads is increased to 1200. Among the compared methods, the multi-agent system resulted in better performance compared to PRA and PURS and other details of QoS [32].

TABLE II. PERFORMANCE VALUES OF SLA VIOLATION RATE VS. NUMBER OF WORKLOADS

Methods	**Workloads**					
	200	**400**	**600**	**800**	**1000**	**1200**
PRA	41.81	46.88	47.11	57.99	69.06	79.35
PURS	32.52	37.2	42.46	50.44	62.28	69.48
Multi-agent system	23.35	28.3	36.64	45.38	56.52	59.47
Proposed	**19.5**	**26.79**	**32.03**	**38.41**	**46.21**	**55.71**

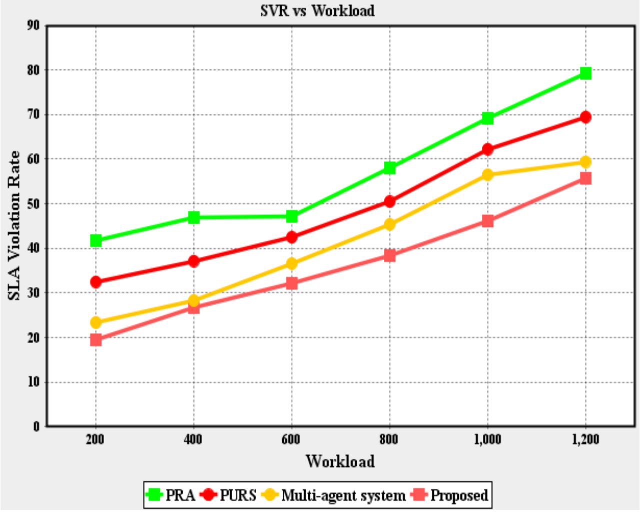

Fig. 2. Graphical representation of SLA violation rate vs number of workloads.

TABLE III. PERFORMANCE VALUES OF SLA VIOLATION RATE VS. NUMBER OF RESOURCES

Methods	**Resources**					
	50	**100**	**150**	**200**	**250**	**300**
PRA	90.91	166.51	195.22	235.41	310.05	354.07
PURS	81.34	145.45	157.89	220.1	282.3	309.09
Multi-agent system	64.72	113.08	140.76	197.22	269.85	290.35
Proposed	**48.29**	**91.27**	**110.91**	**134.88**	**164.11**	**199.77**

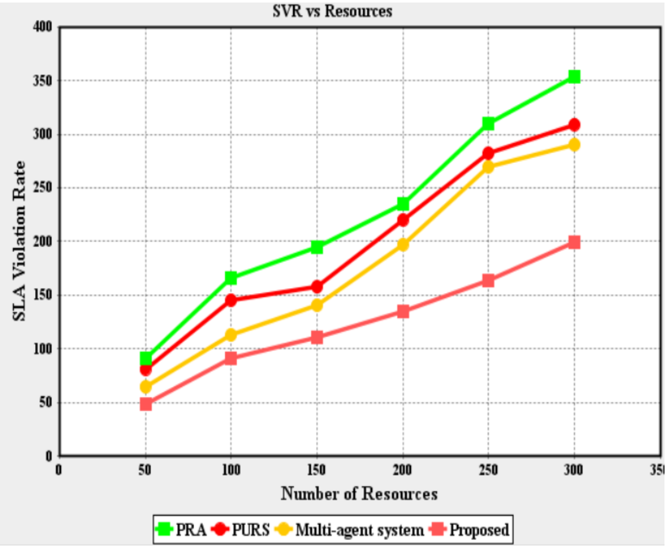

Fig. 3. Graphical representation of SLA violation rate vs number of resources.

The results of the SLA violation rate based on the number of resources are presented. The proposed technique is more optimal in resource provisioning using QoS than the existing methods in reducing SLA violations accordingly. The number of resources used for executing the workloads has a major impact on the variations in SLA violations. When the number of resources used in execution is less, the SLA violation rate is low significantly and when the resource is increased, the violation rate is also increased gradually in a scanty manner. This is because of the increase in the number of resources required to handle more workloads that results in increased SLA violations. This is also plotted in the graphical representation shown in Fig. 3. The values obtained on comparison of SLA violation rate with respect to number of resources are shown in Table III. The proposed method resulted in 48.29% of violations whereas for a total of 300 resources of violation rate could be affirmed accordingly. Among the compared techniques, the multi-agent system yielded better results.

The results of energy consumption for the different workloads are presented. The proposed method consumed less energy as compared to other methods in workload execution. When there is a minimum number of workloads, the energy consumption is less, and it increases gradually with the scanty increase in the number of workloads as per the provisioning of resources using QoS. This is also shown in the graphical representation presented in Fig. 4. The values obtained for energy consumption comparison are presented in Table IV. For 250 workloads, the energy consumed by the proposed method is 17.67kWh and for 1500 workloads, the energy consumed is 47.84kWh. Among the compared techniques, the multi-agent system consumed less energy to execute the workloads, and the other two methods consumed more energy for executions.

The results of the SLA violation rate for different execution times are recorded. The proposed method is more optimal than the existing methods. The values obtained on comparison of SLA violation rate with respect to execution time are shown in Table V. The graphical representation of the SLA violation rate based on execution times is shown in Fig. 5. The figure shows that the SLA violation rate is low for smaller execution times and gradually increases with the increase in execution times. Also, the proposed multi-agent system (AMAPH) produced better results as being compared to existing methods [32].

TABLE IV. PERFORMANCE VALUES OF ENERGY CONSUMPTION VS. NUMBER OF WORKLOADS

Methods	Workloads					
	250	500	750	1000	1250	1500
PRA	35.87	41.12	52.72	54.79	73.8	72.7
PURS	26.18	36.13	48.11	47.74	63.78	64.52
Multi-agent system	20.63	26.9	38.03	42.94	56.21	59.17
Proposed	**17.67**	**23.38**	**27.87**	**33.31**	**39.89**	**47.84**

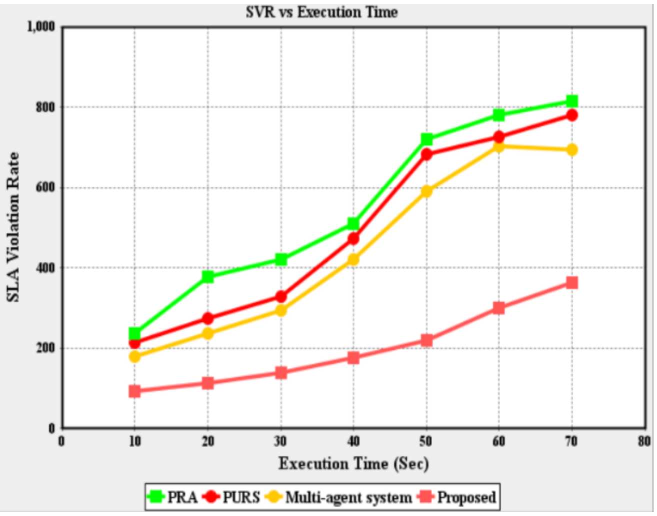

Fig. 5. Graphical representation of SLA violation rate vs execution time.

The overall simulations suggested that the proposed framework of resource provisioning using QoS is more optimal than the other compared techniques in reducing the SLA violations occurring in the cloud environment. As per the above results, the simulation build time has been considered accordingly but it may have a little change as in ground level of implications. The violation rate generally increases when the number of executions is increased. With the increase in the number of workload executions, the performance of the cloud network slows down due to higher energy consumption and increased violation rates as different case studies analyses for 05 different data centers. Therefore, the proposed framework is presented that is highly optimized for reducing the SLA violation rate and energy consumption in data centers. The performance of the framework is analyzed by varying the number of resources and workloads as these are the major factors influencing the performance. The results also proved that SLA violations increase when the number of executions needed is increased. While dealing with more workloads, the elasticity of the cloud and the resource availability is required to be regularly maintained to reduce SLA violations. The proposed framework of modelling and simulation measures the Quality of Service (QoS) and performance in Data-Center along with resource utilization policy. The analysis proved that the proposed model worked on reducing both the energy consumption in data centers and SLA violations in every dimension. The inclusion of a history agent within the architecture helped the model to forecast the arriving workloads and to predict the future requirement of resources. It kept track of the records of utilized resources and the available resources to maintain normal execution without any deviation in SLAs. The conjecture can be clarified for the response time as one of the major components of QoS factors based upon different workload's build time (Minimum is 21 sec and Maximum is 113 seconds). The method optimized the workload executions thereby reducing the overall violation rates and enhancing the overall cloud performance. Therefore, the proposed framework can be suggested as a promising tool to mitigate SLA violations and issues of higher energy consumption in cloud data centers and to achieve optimal performance for QoS as MOHFO and CGR analyses [15].

V. Conclusion

Cloud computing technology is one of the most popular computing technologies followed by most organizations throughout the world. This is because of its elastic and distributed nature that is capable of supporting faster network services with abundant provisioning of resources. In this work, a new and efficient framework is designed that supports the optimal execution of workloads with minimized SLA violations and energy consumption. The proposed framework includes multiple agents such as a user agent, system agent, negotiation agent, history agent, coordinator agent, monitoring agent, and arbitrator agent. The user agent obtains the request details from users and forwards them to the system agent where the technical terms of the requests are explored. The negotiation agent initiates the negotiation process between the service provider and the customer to avoid SLA violations. It selects the best service that can execute the current workload without SLA violation and with minimum consumption of energy. The history agent keeps track of workload executions to provide better forecasts of future executions. The coordinator agent receives the selected service details from the negotiator and establishes a formal SLA. The monitoring agent monitors the environment continuously for violations and sends an indication to the arbitrator if any violation is encountered. The arbitrator provides penalties or rewards to the service provider or customer and analyses the cause of the violation. The method is simulated and evaluated using a random number generated by Poisson distribution. The analysis proved that the method minimized the SLA violation rate and energy consumption in data centers much better compared to other existing techniques. Therefore, a resource provisioning framework using QoS attribute requirements to manage the resources of the Cloud while taking into account the Customer's Quality of Service as determined by the Service-Level Agreement (SLA) in the Cloud Computing environment has been incorporated successfully.

An Efficient Deep Learning based Hybrid Model for Image Caption Generation

Mehzabeen Kaur[1], Harpreet Kaur[2]
Ph.D Research Scholar, Department of Computer Science and Engineering, Punjabi University, Patiala[1]
Faculty, Department of Computer Science & Engineering, Punjabi University, Patiala[2]

***Abstract*—In the recent yeas, with the increase in the use of different social media platforms, image captioning approach play a major role in automatically describe the whole image into natural language sentence. Image captioning plays a significant role in computer-based society. Image captioning is the process of automatically generating the natural language textual description of the image using artificial intelligence techniques. Computer vision and natural language processing are the key aspect of the image processing system. Convolutional Neural Network (CNN) is a part of computer vision and used object detection and feature extraction and on the other side Natural Language Processing (NLP) techniques help in generating the textual caption of the image. Generating suitable image description by machine is challenging task as it is based upon object detection, location and their semantic relationships in a human understandable language such as English. In this paper our aim to develop an encoder-decoder based hybrid image captioning approach using VGG16, ResNet50 and YOLO. VGG16 and ResNet50 are the pre-trained feature extraction model which are trained on millions of images. YOLO is used for real time object detection. It first extracts the image features using VGG16, ResNet50 and YOLO and concatenate the result in to single file. At last LSTM and BiGRU are used for textual description of the image. Proposed model is evaluated by using BLEU, METEOR and RUGE score.**

Keywords*—*CNN; RNN; LSTM; YOLO

I. Introduction

In this www world, every day in our life, all have experienced with the huge number of images in a real world which are self-interpret by the individual human being by using their wisdom. Human are naturally programmed to convert the natural scene in to text but it is the complex task for the machine as they are not much efficient like human. Still, human generated captions are considered better as machine need human intervention and programmed accordingly for the better result. Due to the recent development in deep learning-based techniques, computers are capable to handle the challenges of image captioning like detection of object, attribute and their relationship, image feature extraction and generating syntactic and semantic image caption [1].

With the advancement of AI, so many new ideas have revolutionized in the areas of image processing and it has transformed the world in a surprising way. The image captioning Approach (Fig. 1) has wider application in the real world as it provides the better platform for human computer interaction. Due to the emerging application in image processing, image captioning becomes the topic of interest for the academician and researchers.

By seeing the Fig. 2, picture someone guess that two dogs are playing with toy and someone might say two dogs hauling in floating toy from the ocean or two dogs run through the water with rope in their mouths, so all of these captions are appropriate to describe this picture. Our brain is so much trained and advanced that it can describe a picture almost accurate but same was not the case with machines.

Hence, the main aim of the image captioning is first identified the different objects and their relationship present in the image using deep learning-based technique, generating the textual description using the natural language processing and evaluate the performance of the natural language-based description using different performance matrices. Object detection and segmentation are the part of the computer vision and done with the help of popular CNN and DNN and generating image description (Fig. 3) are the part of natural language processing which is done by RNN and LSTM. CNN works for understanding the objects of the image or scene and provide the answers the various questions about the objects in image like what, where, how, etc.

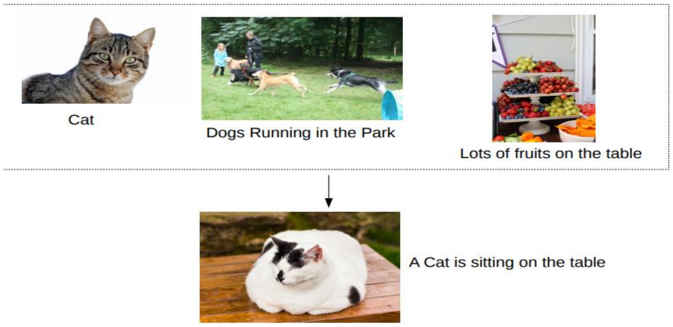

Fig. 1. Image captioning.

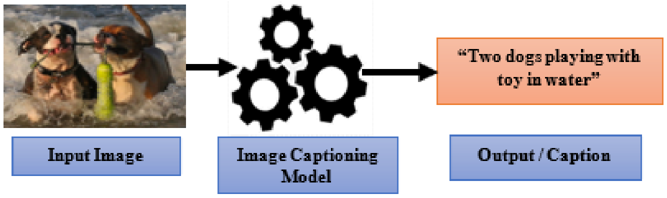

Fig. 2. Working of image captioning.

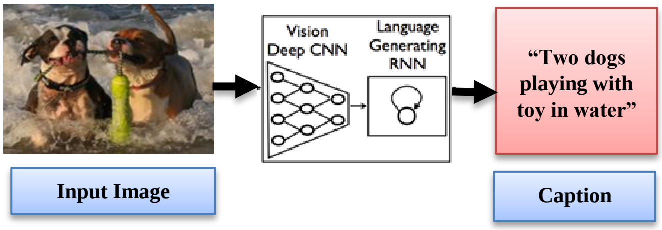

Fig. 3. Image captioning architecture.

For example, in Fig. 3, CNN identify the "dog", "toy", "water" and their relationship in the scene. Further RNN give the shape in textual form by using the keywords described by CNN by considering it in group of words. This one is also called the encoder-decoder architecture. Object detection is a part of computer vision which uses various algorithms, like YOLO, R-CNN, Mask R-CNN, MobileNet and SqueezeDet for detecting the different parts of the image efficiently.

II. Literature Survey

In this section, review of literature in image captioning is presented. Various state-of-the-art techniques and model have been published in previous years to generate the human like captions. Image captioning approaches [11], [14] and [17] broadly classified in to Template-based [18-21], Retrieval-based [22-26], and Encoder-decoder methods [27-30]. In paper [31] a content selection approach has been proposed for image description by using geometric, conceptual and visual features of image. All of these models work on CNN, first use encode the image and extract the feature and further use RNN or LSTM to make captions of the image. In paper [1] researchers presented an image captioning model with probabilistic distribution using successor and predecessor words and image captioning. Attention and visual based approach are very famous approach in image captioning. In [2,3] authors generate the captions using the attention mechanism. In most of the papers predefined models were used in bulk of papers like VGG16 papers [1], [3-7], YOLO [8], Inception V3 [9-10], AlexNet [5], [7], ResNet [4-5], [12] and Unet [13] are the famous encoder or CNN model used for image feature extraction. For image caption generation or decoding, LSTM [4], [8-10] and [15], BiLSTM [7], [13], RNN [16]. Image captions are also generated in various languages like Chinese, Japanese, Hindi, Punjabi and German, etc.

Template based approach uses predefined templates of objects, actions and attributes to identify the input image [18], the authors use visual elements like object, action and scene for predicting the caption of the image. In [19] author takes the advantages of Conditional Random Field (CRF) based technique extract the features of the image. The proposed model evaluated using BLUE and ROUGE score on PASCAL dataset. As it is based upon pre-defined template it is not able to generate the caption of image with variable lengths.

Retrieval based approach generate caption by capering the features of the image with the datasets. It tries to finds the caption for input image by discovering similar features in the dataset. In [22] authors proposed a model to extract feature of the query image by searching it through the dataset and in [32], the authors propose the caption by using the density estimation method. In [25], the authors used semantic and visual features for image caption generation.

In the original dataset we have five captions for each image and our goal is to train a particular model on this dataset. After the training phase model becomes efficient for extracting the features of the particular image, various predefined image classification models are available which uses state-of-the-art algorithms for classifying the thousands of different objects/images efficiently. These models come up with better accuracy with respect to image rate classification, like ResNet. These are very easy to implement.

Encoder-decoder based approach is a most widely used for machine translation and image caption generation which is based upon deep neural networks. A dual graph convolution network based is proposed in [33] and NIC (Neural Image Caption) model based on encoder-decoder architecture is in [27]. This one is a simple model where CNN is used as a encoder, and in the decoder end LSTM and RNN are used for image caption generation.

III. Research Methodology

Here, for extracting the visual feature of the image, CNN used as an encoder which have Convolution layer, Pooling layer, and fully connected layer. Earlier AlexNet was used for compute vision problems but nowadays, the transfer learning are in trends in where several pre-trained CNN based models are available like VGGNet, Inception V3, DenseNet, ResNet etc. which are available with different convolutional neural layers and used for saving the training time of the model. Further, decoder is used to generating the final captions which gets the input from the encoder. GRU, LSTM and RNN are the most commonly used decoder. RNN are suitable for short words sequence and LSTM is best for long sequence.

This section depicts the proposed hybrid research methodology. Our main objective of the proposed model is to achieve the higher Meteor value. Our model is based on an Encoder-Decoder approach where it used the concept of transfer learning. Here in the first phase, features of the image is extracted by using VGG16, ResNet50 and YOLO (You Only Look Once) separately. YOLO is an efficient object detection algorithm in real time with is developed in 2015 Joseph Redmon et al. whereas VGG16 (Visual Geometry Group) is an object detection and classification approach which is pretrained on ImageNet dataset. This is deep Convolutional Neural Network (CNN) architecture which uses 16 convolutional layers. ResNet50 is a deep CNN with 50 convolutional layers which is able to classify more than 1000 object category.

In second phase, concatenate of the features of image extracted by the VGG16, ResNet50 and YOLO and all the duplicate words are eliminated.

In third phase, captions are generated by using the BiGRU and LSTM. BiGRU (Bidirectional Gated Recurrent Units) is a Neural Network architecture used in NLP (Natural Language Processing). This architecture uses two GRUs for taking input in forward and backwards directions. LSTM (Long Short - Term Memory) is a type of recurrent neural network architecture which used feedback connections and capable of identifying the relation between objects. In the last phase, both the captions are compared with the Meteor performance evaluation metrices. Final caption has the higher meteor value.

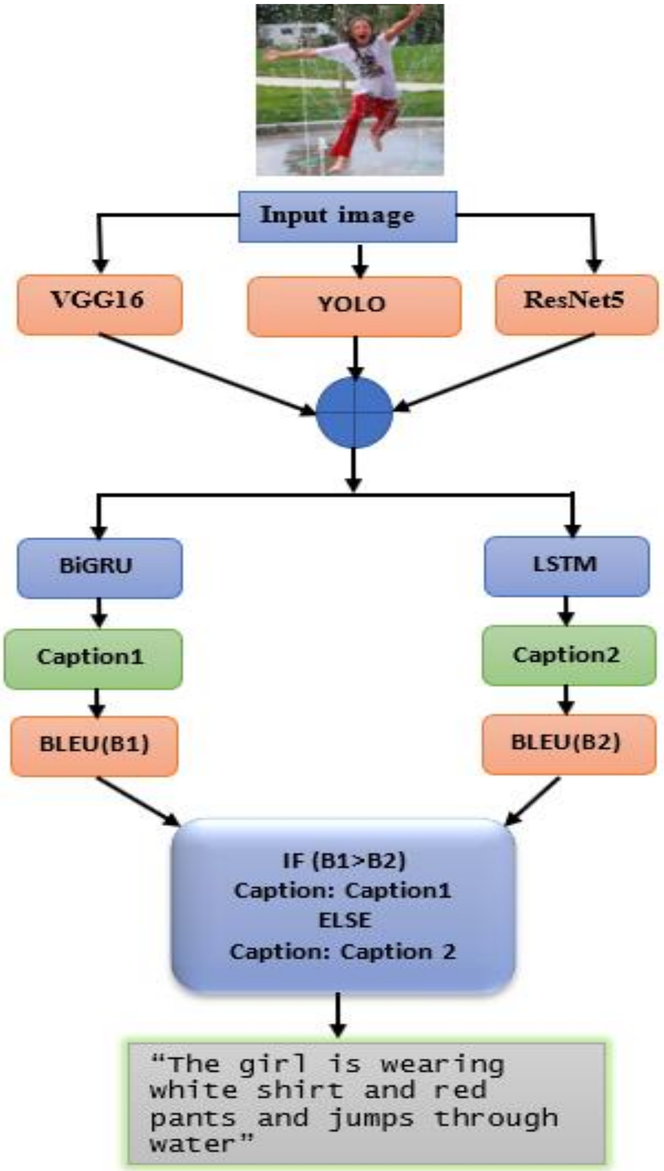

Fig. 4. Proposed image captioning architecture.

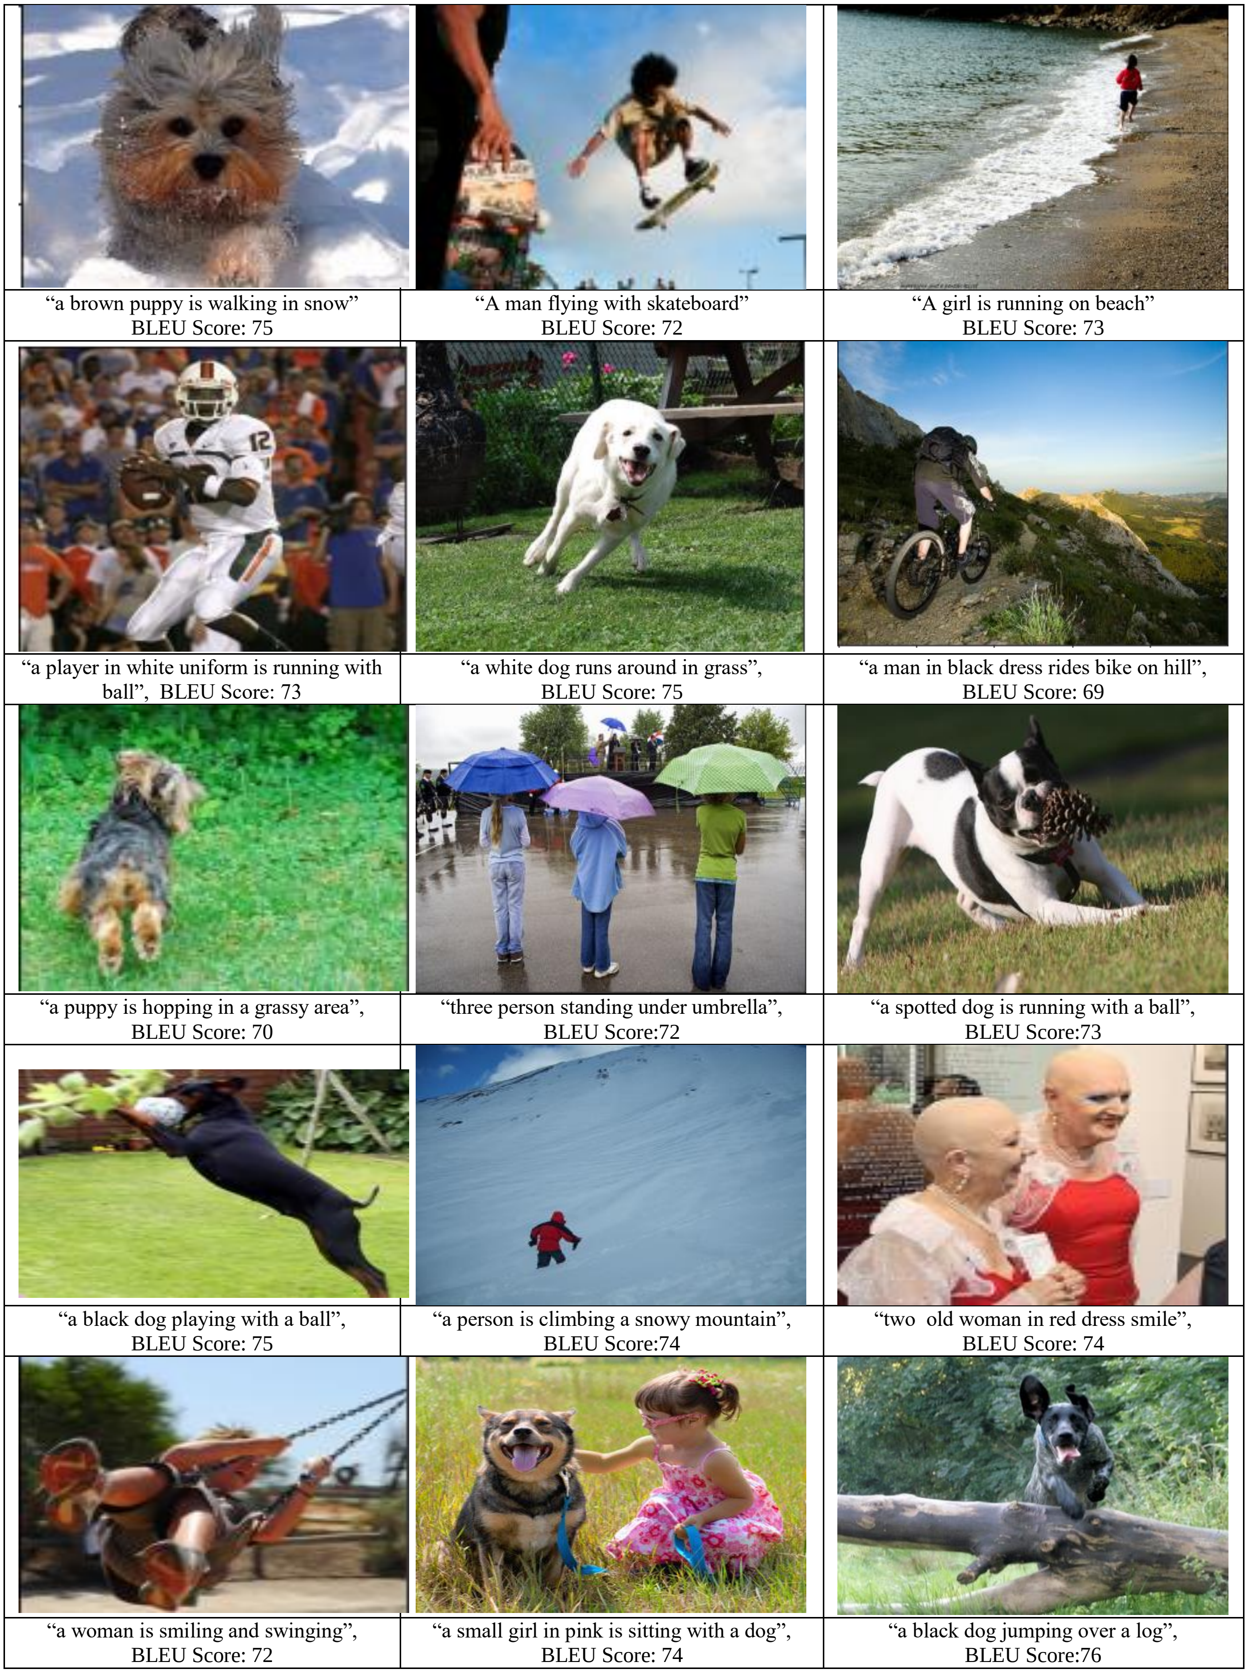
IV. Datasets

Data are the backbone of any AI based systems. Recently image captioning is blessed with rich datasets like MSCOCO, Flickr8k, Flickr30k, PASCAL etc. in the dataset, every image is described in related five reference sentences. Every description of the scene is described by using different algorithms and grammar. MSCOCO is a large dataset which was developed by Microsoft whose target to describe the image as a human being. It first understands the scene and complete the image recognition, segmentation and generating suitable caption of the image. It contains 82,783 images, with validation set 40,504 images, and the test set 40,775 images. Flickr30k dataset has 28000 training images, 1000 testing and 1000 validation images.

Here, in this paper a benchmark dataset Flickr8k for the training of the model. It contains 8000 images with 5 captions of each image which provides the clear descriptions of the silent objects. It has manually labelled captions for all the images in English language. The dataset is divided into two categories. First one is image directory which has 8k images with 5 captions. Out of 8000 images, 6000 are used for training and remaining 2k images are for training purpose. Images in Flickr8k dataset are in jpg format with resolution 256*500 to 500*500 and average length of sentence is 12 words.

V. Result and Analysis

Performance of the image captions are evaluated by using different evaluation BLEU, METEOR, ROUGE, CIDEr and SPICE metrics. When analyzing the proposed model and matching the predicted words to their original captions, the BLEU score is applied. Fig. 4 illustrates how the loss gradually decreased as the number of training epochs grew. it could train our datasets across more epochs to get better descriptions, and here it did so for 100 epochs to enable comparison study. The loss value is between 0.5 and 0.1 epochs. Maximum and minimum values are observed for 10 epochs with losses of 0.5+ and less than 0.1 epoch, respectively. In Fig. 5, the comparison of the predicted caption with five additional original captions using a graphic representation of the BLEU score is illustrated. From 5 to 10 epochs, a sharp increase is observed from 0.50 to 0.56 BLEU score, then the graph experiences slight ups and downs till 50 epochs. Another score called "match words" counts the words that match up with the produced text of a picture. As shown in the graphical representation, the match words undergo significant upswell with changes as time passes. Witnessed as 0.49 match words in the case of 50 epochs and 0.40 in the case of 5 epochs. When Match Word and BLEU Score were compared, it was found that both inclined before reaching the heights. In the instance of Match words, the score increased from 0.500 to 0.555 from 5 to 10 epochs. After that, this sample saw minor changes through 50 epoch, reaching a score of 0.575. When discussing the BLEU score, it had two distinct peaks at 0.450 and 0.470 score at the 15 and 30 epochs. At 35, the graph had a slight decline (0.460), and at 50, it finally hit the score (0.480).



"a brown puppy is walking in snow"
BLEU Score: 75

"A man flying with skateboard"
BLEU Score: 72

"A girl is running on beach"
BLEU Score: 73

"a player in white uniform is running with ball", BLEU Score: 73

"a white dog runs around in grass",
BLEU Score: 75

"a man in black dress rides bike on hill",
BLEU Score: 69

"a puppy is hopping in a grassy area",
BLEU Score: 70

"three person standing under umbrella",
BLEU Score:72

"a spotted dog is running with a ball",
BLEU Score:73

"a black dog playing with a ball",
BLEU Score: 75

"a person is climbing a snowy mountain",
BLEU Score:74

"two old woman in red dress smile",
BLEU Score: 74

"a woman is smiling and swinging",
BLEU Score: 72

"a small girl in pink is sitting with a dog",
BLEU Score: 74

"a black dog jumping over a log",
BLEU Score:76

Fig. 5. Image captions generated by proposed approach.

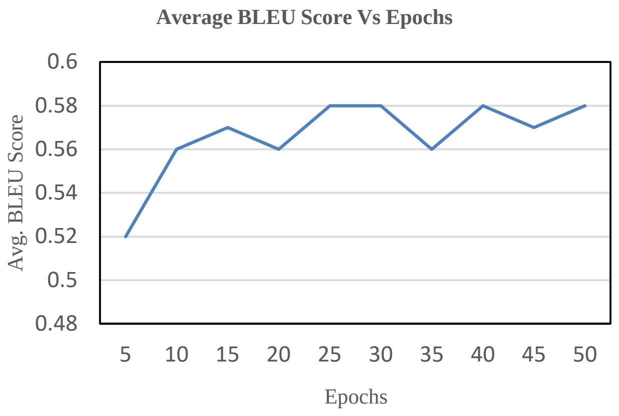


Fig. 6. Average BLEU Score vs Epochs.

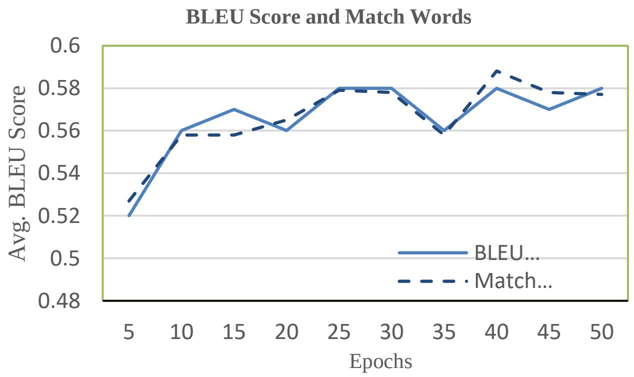

Fig. 7. BLEU Score vs Match words.

The graphical representation illustrates the model's recall changes with threshold values. Threshold values from 0.0 to 0.25 remained constant at 1. After then, a steady fall was observed from 0.25 to 0.75 and approached 0.0 value until a very little increase with around 0.1 recall value was noted too and final recalled value is accounted as 64.056. The graph that depicts the variation in accuracy with threshold values changes the shape of a sharp peak that is constant at 0.500 accuracy up until 0.0 to 0.25v threshold value, then a straight climb up to 0.675 accuracy, followed by a similar value fall up until 0.75 threshold value (Fig. 6). And resultant accuracy is 67.052. The graph shows model precision levels as well as variations in threshold settings. Although the precision value overall is 68.138, changes are seen from a 0.2 threshold value to a 0.75 with a simple increase in the precision values. Other starting and ending values were 1.0 from .075 to 0.25 and 0.5 from 0.0 to 0.25. Further in Fig. 7, BLEU score and Match score are compared which shows the compatible score. First average score of both are .52 on 5 Epochs. At 10 Epochs the values are increased to 0.56. it shows its best performance in 30 Epochs and decreases in 35 Epochs due the overfitting. In Fig. 8, 9 and 10 precision recall and accuracy are shown.

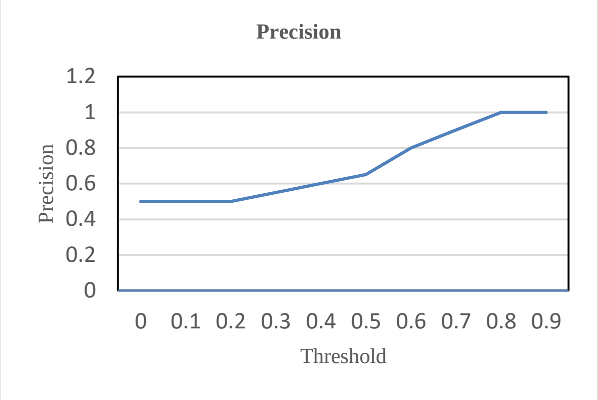

Fig. 8. Precision of proposed systems.

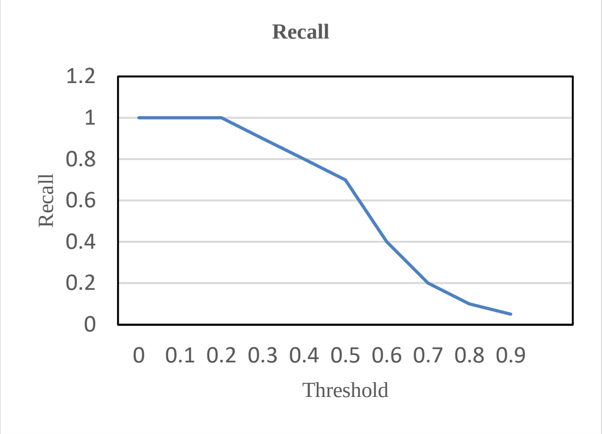

Fig. 9. Recall of proposed systems.

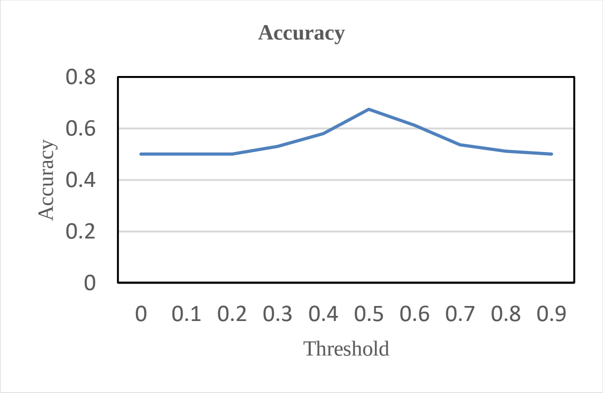

Fig. 10. Accuracy of proposed systems.

The represented graph illustrates the loss and the epochs. According to the provided scale, maximum values are attained by 1.0 on 0.0 epochs. The loss reached a value of 0.75 at 1.0 epochs. Moving further with a curved change value of loss and epochs graph, the loss stopped at 17.5 epochs when the value of loss was witnessed as 0.3.

TABLE I. COMPARATIVE ANALYSIS OF PROPOSED APPROACH WITH SINGLE MODEL

Model	BLEU-1	BLEU-2	BLEU-3	BLEU-4	ROUGE-L	METEOR
Inception V3	0.65	0.43	0.29	0.17	0.21	0.41
VGG16	0.66	0.38	0.30	0.16	0.23	0.22
Res Net50	0.56	0.31	0.18	0.12	0.27	0.51
VGG19	0.61	0.35	0.28	0.18	0.21	0.22
Proposed Hybrid Approach	0.67	0.46	0.35	0.26	0.31	0.54

TABLE II. COMPARATIVE ANALYSIS OF PROPOSED APPROACH WITH HYBRID MODEL

Model	BLEU-1	BLEU-2	BLEU-3	BLEU-4	ROUGE-L	METEOR
Densenet169 + LSTM [34]	63.73	45.00	30.87	21.13	46.41	19.95
Resnet101 + LSTM [35]	62.77	44.11	30.62	21.10	43.54	18.79
VGG-16 + LSTM [36]	60.56	41.98	28.66	19.51	44.82	19.04
Densenet121 + Attention + LSTM[34]	65.00	46.99	32.83	22.56	47.57	20.44
ResNet152 + Attention + LSTM [37]	65.26	47.55	33.72	23.67	47.54	20.94
VGG-16 + Attention + LSTM [36]	63.81	45.77	32.35	22.55	46.72	20.19
Proposed Hybrid Approach	0.67	0.46	0.35	0.26	0.31	0.54

The given Tables I and II are the results from an LSTM based decoder model using a signal encoder on the flickr8k dataset. There are five encoders (Inception V3, VGG16, Res Net50, VGG19, and Proposed Hybrid Approach) given each represents their own values of BLEU-1, BLEU-2, BLEU-3, BLEU-4, ROUGE-L, and METEOR in the table chart. The maximum value in terms of BLEU-1 data is 0.67 for the proposed Hybrid Approach Encoder. However, in BLEU-2, the minimum value is held by Res Net50. Considering the data in BLEU-3 and BLEU-4, the minimum is send in the case of ResNet50 as 0.18 and 0.12, whereas the maximum is witnessed in the case of the proposed Hybrid Approach Encoder. In ROUGE-L, data is numbered as 0.21, 0.23, 0.27, 0.21, and 0.31 for Inception V3, VGG16, Res Net50, VGG19, and Proposed Hybrid approach, respectively. On the other hand, 0.22 was the value which was similar to VGG16 and VGG19 in the case of METEOR.

VI. CONCLUSION

In this paper, a hybrid encoder-decoder based model to generate the effective caption of the image by using the Flickr8k dataset. During the encoding phase, the proposed model used transfer learning-based model like VGG16 and ResNet5o and YOLO for extracting the image features. A concatenate function is used to combine the feature and removes the duplicate one. For the decoding, BiGRu and LSTM are used to get the complete caption of the image. Further BLEU value is evaluated of both the captions generated by BiGRU and LSTM. Final caption is considered whose METEOR value is high. The proposed model is also evaluated by METEOR and ROUGE. The proposed model achieved score BLUE-1: 0.67, METEOR: 0.54 and ROUGE: 0.31 on Flickr8k dataset. The experimental results show the better results through BLUE, METEOR and ROUGE when compared to another state-of-art models. The model is also helpful in generating the captions at real time.

Collaborative based Vehicular Ad-hoc Network Intrusion Detection System using Optimized Support Vector Machine

Azath M, Vaishali Singh
Department of Computer Science & Engineering-School of Engineering & Technology,
Maharishi University of Information Technology, Lucknow, Uttar Pradesh 226013, India

***Abstract*—The Vehicular Ad hoc Network (VANET) can be used to provide secured information to the user vehicles. However, these days the immunity of safeguarding the information from vulnerabilities and threats are of great challenge. Therefore, it is necessary to provide a secured solution for the improvement of security with the deployment of advanced technology. In context with this, a blockchain based VANET structure for secured communication incorporated with the enhancement of confidentiality, scalability, and privacy is planned. The k-means clustering model forms cluster formation. The cluster head selection is carried out with Tabu Search-based Particle Swarm Optimization (TS-PSO) algorithm. The proposed approach aims to mitigate the delay with the enhancement of throughput and energy efficiency. Meanwhile, the deployed blockchain will enhance reliability and security. Moreover, the novel War Strategy Optimization (WSO) based Support Vector Machine (SVM) model (Optimized SVM) can be used for the trust-based collaborative intrusion detection in the VANET. Our work targets to detect the intrusion and non-intrusion classes. Meanwhile, our proposed work can be used for the prevention of repetitive detection processes and therein it enhances the security by rewarding the vehicles. An experimental analysis is carried out to ensure its usage in detecting the malicious node from the resource constraint vehicles and also used to achieve better security, energy utilization and end-to-end delay.**

Keywords*—*Vehicular Ad hoc network; intrusion detection; tabu search based particle swarm optimization; war strategy optimization; support vector machine

I. Introduction

The emerging trend of vehicular technology leads to the addition of smart equipment in vehicles and advancement of the intelligent transportation system and self-driving vehicles. The communication among vehicles and the roadside unit (RSU) can be accomplished with the VANET which alerts the drivers about the traffic, emergency alerts, and safety messages [1, 2]. The increase in mobility of vehicles, intricate topology, and diverse communication are the major possibilities of the VANET system to have been attacked by intruders. The main purpose of the intruders is to break the smart communication between the vehicles and RSUs. This might lead to damage in the VANET system and overcoming this intrusion detection system is the best choice [3].

The performance of the IDS relies on its deployed location in the cluster head, vehicles, and RSU and the conventional IDS contains three various architectures including distributed centralized and hybrid IDS [4]. Most probably the detection of various attacks by the traditional approaches is limited and it is necessary to design a precise approach to detect all types of abnormalities in the system. The centralized approach of software-defined networking (SDN) provides better flexibility and security throughout the network; however, a system bottleneck occurs due to failure in the single point. The issues in the SDN such as reliability and scalability are visibly moved by the distributed networks [5, 6]. Moreover, the communication and computation overhead of the SDN controllers are also tackled by the distributed SDN via VANET. It also possesses some demerits and it is necessary to overcome them [7].

The securities of the vehicles are the most challenging ones since most of the vehicles are designed without considering the security system. However, they can perform communication without any delay but still increases the attacks [8]. This can be dealt with the conventional approaches such as encryption and neglecting the irrelevant nodes. Recently the vehicles are linked in the VANET and thus detect the attacks. So to secure the communication between the vehicles and RSUs a Blockchain-based collaborative intrusion detection approach is introduced for the VANETs. Different kinds of swarm-based optimization models such as particle swarm optimization, fish swarm optimization, Cuckoo Search algorithm, Glowworm Swarm Optimization (GSO), Genetic Algorithms (GA) etc. contains more searchability, less cost, less time execution and it is easy to solve the optimization problems. Tabu search creates a metaheuristics search technique that could really evaluate the optimum solution in addition to local optimization problems. The critical feature of Tabu Search is the use of adaptable storage to produce a much more adaptable behavior. PSO is the motion, which is controlled by two factors: information from particle to particle and iteration to iteration. The intrusion detection can be achieved with the SVM-based WSO approach. Prior to this the cluster head and cluster formulation are done with the Tabu Search-based Particle Swarm Optimization (TS-PSO) algorithm. This approach collaboratively trains the samples and achieves better detection.

The major contribution of this study is summarized as follows:

- The cluster formation in VANET is performed via the k-means clustering model.

- The Tabu Search-based Particle Swarm Optimization (TS-PSO) algorithm selects the optimal cluster heads.
- The blockchain-based security performs VANET security. Both intrusion and non-intrusion are detected via the novel War Strategy Optimization (WSO) based Support Vector Machine (SVM) model.

A. Problem Statement

Most vehicles are created without taking into account the security system, it is one of the most difficult areas to secure. They can communicate instantly, which makes attacks more common. Traditional methods, like encryption and ignoring unnecessary nodes, can be used to handle this. Recently, vehicles have been connected to the VANET, allowing them to detect threats.

Therefore, the existing studies created a Blockchain based collaborative intrusion detection approach for the VANETs to secure the connection between the cars and RSUs. The searchability, cost, and execution time of various swarm-based optimization models, such as fish swarm optimization, particle swarm optimization, glowworm swarm optimization, Cuckoo Search algorithm, genetic algorithms, and others, are higher. Tabu search develops a metaheuristics search method that can effectively access both the ideal solution and local optimization issues. The use of adaptable storage to create a significantly more adaptive behavior is a key component of Tabu Search. The SVM-based WSO technique can be used to detect intrusions.

II. Literature Review

A hybrid machine learning model was suggested by Bangui et al. [9] for the detection of intrusion in VANET. The Random Forest (RF) models were used to improve the accuracy of IDS. Compared to other methods, this RF model considerably improves the accuracy of detection based on the CICIDS2017 dataset. The detection accuracy is increased and the computational time is decreased but it failed to describe any security concept.

A hybrid data-driven model was introduced by Bangui et al. [10] for VANET intrusion detection. The explosive development in computing power deals to improve the IDS performance. The possible novel intruders were detected with the help of the post-detection stage. The corsets-based clustering and data classification were combined via a hybrid data-driven model. The computational overhead was less but the execution time was higher and had more complicated process.

In VANET, Zaidi et al. [11] suggested Host-based intrusion detection (H-ID). The statistical and graphical techniques represent the collection of extensive data. The rogue nodes were easily detected with the usage of different traffic conditions. According to the cooperative information, the application layer IDS were observed and evaluated with respect to the state-of-art results. Due to increased vehicular data, the computational complexity was also higher.

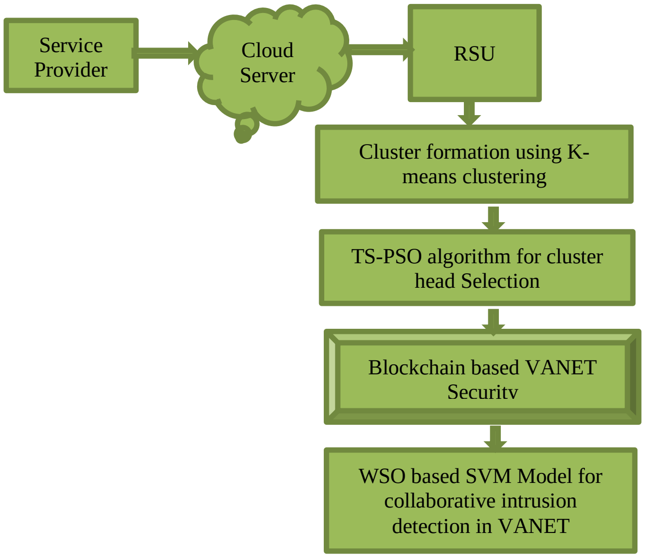
Based on ToN-IoT dataset, the machine learning (ML) techniques were suggested by Gad et al. [12] to detect the VANET intrusion. The ML techniques are the combination of Naive Bayes (NB), Support Vector Machine (SVM), XGBoost, Logistic Regression (LR), and k-Nearest Neighbor (kNN) and Decision Tree (DT). Both multi-class and binary classification issues were easily solved by using this ToN-IoT dataset. The class balancing was performed with the usage of the Synthetic minority oversampling technique. The higher feature dimensionality increases the overall complexity.

The deep learning (DL) model was suggested by Aboelfottoh et al. [13] for intrusion detection in ACVs and VANETs. More accurate and smarter IDS were made via deep learning thereby providing an efficient intrusion detection model but it failed to satisfy the security process. Based on the time series classification approach, the LSTM model was introduced by Yu et al. [14] for the VANETs intrusion detection system. The classification model of LSTM was used to enhance the false emergency message detection accuracy. For both collusion attack and normal scenarios, the time series feature vectors train and the traffic incident classifier were designed to identify traffic parameter patterns with higher computational difficulties.

The context of an intrusion detection system in VANET was designed by Gonçalves et al. [15]. Based on the geographic region, the publicly available VANET datasets were evaluated. The far more popular security policy was used to employ conventional instruments which can aid in the prevention of threats. In vehicular ad hoc networks, Alsarhan et al. [16] suggested an SVM-based intrusion detection system. This model outperformed classification accuracy with a better intrusion detection model and higher execution time than the existing methods such as PSO, ACO and GA. The distributed ensemble learning model was introduced by Ghaleb et al. [17] for misbehavior-aware on-demand collaborative IDS. The remote and locally trained classifiers were encompassed with the weighted random forest-based classifiers. Compared to the previous CIDS model, this distributed ensemble learning approach delineated 97% F1 score performances but the computational cost was higher and it needed more security during intrusion detection.

III. Proposed Methodology

The VANET are critical enablers of eventual collaborative transportation systems. Vehicles on VANETs exchange actual information regarding its location, congestion, and traffic conditions. Nevertheless, VANETs are vulnerable to threats that can result in existing circumstances. IDS depending on automotive collaboration to detect attackers in VANET were the most frequently proposed privacy model. The schematic diagram of the proposed intrusion detection model is shown in Fig. 1. The proposed methodology includes four stages namely cluster formation, cluster head selection, VANET security and Collaborative intrusion detection. Each of these stages is delineated in the following section.



Service Provider
Cloud Server
RSU
Cluster formation using K-means clustering
TS-PSO algorithm for cluster head Selection
Blockchain based VANET Securitv
WSO based SVM Model for collaborative intrusion detection in VANET

Fig. 1. Proposed intrusion detection framework.

A. Cluster Formation

The stable vehicle cluster formations are the major step of this study. In this study, the K-means clustering algorithm was used to perform cluster formation. The edges were represented by using the distances between vehicles and the graph vertex act as each vehicle [18]. Based on roadside units (RSU) transmission region, the cluster formation of each vehicle was calculated. In the d-dimensional real vector, the observation set is $\left(A_1, A_2,.., A_m\right)$ [14]. Within cluster square sum (WCSS) is minimized via the m observation partition into K-sets $(K \le m) s = \left\{s_1, s_2, ..., s_K\right\}$.

$$WCSS = \arg\min_{s} \sum_{j=1}^{K} \sum_{A_i \in s_j} \left\| A_i - \chi_j \right\|^2 \qquad (1)$$

During cluster formation, the points mean S_j in is Xj.

B. Cluster Head Selection

The space solution apart from local optimality was analyzed via Tabu Search (TS) to represent the search process. The component of TS is an adaptive memory, which is more efficient. In a similar period, the respective optima were not attained with multiple objectives. In a rapid manner, the TS had hard combinatorial optimization problems and which led to select the solution design [19]. The particle swarm optimization (PSO) model contains several advantages in case of a direction to initial converging towards local optima, less population diversity, resolving optimization and greater convergence [20]. Tabu Search is a powerful stochastic efficient algorithm that, in theory, might aggregate monotonically to a global optimum, but it required a lot of time to reach the close-to-global minimum. The algorithm can maintain population variety by incorporating TS into PSO as a local development phase, which prevented it from leading to an incorrect local optimal solution.

In this study, Tabu Search based Particle Swarm Optimization (TS-PSO) algorithm was used for the selection of cluster heads in VANET. While compared to the PSO algorithm, the TS takes less computational time with the average energy consumption during CH selection [21]. The tradeoff between both PSO and TS can be neglected by combining the TS-PSO algorithm.

The following steps explain the TS-PSO model for cluster head selection.

- Initialize the base station location and energy nodes.
- The TS-PSO algorithm with a maximum number of iterations is initialized.
- The base station corresponding to the node's distances is calculated via the cluster formation.
- Determine the local best position of the PSO algorithm.
- Tabu memory entries to zero. The initialization of the PSO solution with the Tabu list calculates the global best solution.
- In the Taby memory, create the entry and routes are swapped.
- Evaluate the fitness function of the next position and note the fitness value in the Tabu list.
- The most effective solution from the Tabu list is eliminated.
- Tabu Search based Particle Swarm Optimization (TS-PSO) algorithm is used to optimally select the cluster heads in VANET.

C. VANET Security based on Blockchain Model

The blockchain is made up of a collection of blocks that are linked together. A block is a decentralized network ledger that is connected simultaneously [22]. The actions inside the block are irreversible and unchangeable. Each block inside the blockchain is connected by the subsequent block's hash. Any changes to a single block will have an impact on the rest network. Furthermore, the information loaded into blocks are entirely open. The data transfer from one vehicle to another is the major security issue in VANET. No necessary data is detected by the vehicles before sharing in the VANET task manager. Consequently, there was a probability for updated data to be uploaded into the Vehicular network [23]. This blockchain security model that successfully maintains the security across the system, to overcome these issues. Blockchain is the distributed immutable ledger that can be used to record transactions and asset tracking.

If the vehicle user transfers through one RSU zone to the next, that following RSU requires the vehicle users to be really authorized. This one will substantially add significant cost and reduce the VANET system's performance. The assets might include tangible and intangible. The values in the blockchain can be tracked virtually by the authenticated user thus mitigating the risk and cost. With the distributed data sharing and storage capacity, it can also avoid the hazards of an attack and outage at a single location [24]. Furthermore, the integrity and validity of the initial global strategy can be guaranteed using the open ledger in the blockchain. Based on the reward and punishment system, the cars in the VANET system submit exact information. This stops false information from being uploaded. It is simple to trace the features of each transaction.

D. Intrusion Detection

This section describes the war strategy optimization (WSO) based support vector machine (SVM) for collaborative intrusion detection in VANET.

1) Support Vector Machine (SVM): The machine learning approach SVM [25] was used for intrusion detection in our proposed approach. This proposed approach is based on the WSO-SVM-based collaborative to detect the attacks and normal traffics. The data were represented in n-dimensional space and detection of intrusion was conducted by detecting the hyper-plane first and classifying the malicious node as intrusion and others as normal. The workflow of the proposed SVM is shown in Fig. 2.

To spate, the various points from the input the SVM utilizes the free parameters which rely on the separation margin as depicted in Fig. 3 [26]. However, there occur over fitting issues which can be rectified by the introduction of the WSO algorithm. The main reasons for utilizing the SVM are speed and scalability and also reduced complexity.

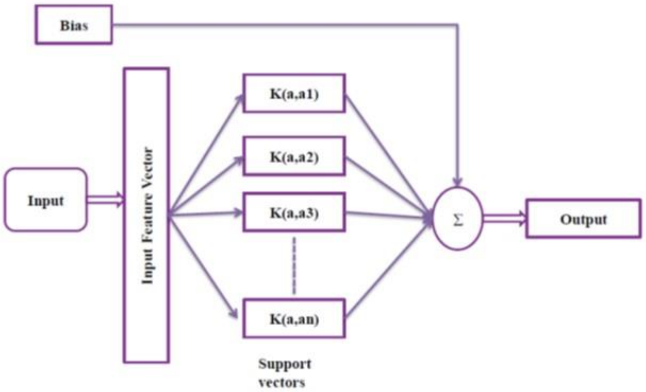


Fig. 2. Flowchart representation of the SVM model.

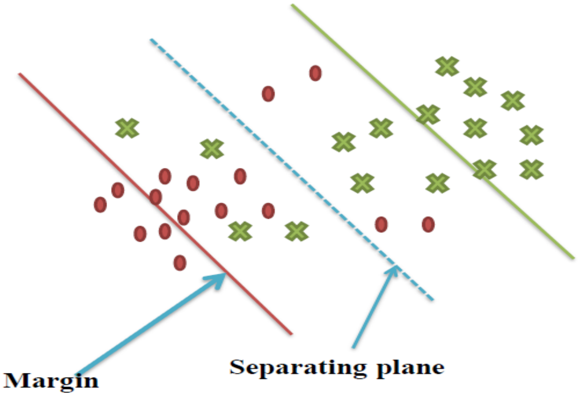

Fig. 3. Separating plane model of SVM.

2) War Strategy Optimization (WSO)

a) This WSO is based on the war strategy followed by the ancient kings based on the mission objectives, struggles, threats, and prospects. War is a continuous process in which the armed soldiers simply get together and fight the enemies.

The numerical expression followed by the strategy that the troops follow the king or commander on the war field. To avert falling prey to local troops the soldiers follow the combined movement tactics along with the king and the commanders.

- Attack Strategy

The war strategies have two models in which the former follows the updated locations of the soldiers with respect to the locations of the king. The soldier with high attack and fitness abilities are considered king. At first, all the soldiers possess the same rank and position and update the ranking location based on the finishing of war strategy. At end of the war the soldier, commander, and king all pretend to be close to each other and can be formulated as,

$$A_i(t+1) = A_i(t) + 2\times\tau\times(D-L) + ran\times(V_i \times L - A_i(t)) \quad (2)$$

The current location of the soldiers is Ai and the updated locations are depicted as A$_i$ (t+1) the location of the commander is D and L is the location of the king with the weight of V*i*.

- Up-gradation of rank and weight

The location of the soldiers can be updated with the location of the attack force. If the new location of the fitness (Fn) is lower than the current location (Fc) then the soldier will remain in the previous location [27].

$$A_i(t+1) = (A_i(t+1))\times(F_n \geq F_c) + (A_i(t))\times(F_n < F_c) \quad (3)$$

Then the rank of the soldier is updated as shown below,

$$S_i = (S_i + 1)\times(F_n \geq F_c) + (S_i)\times(F_n < F_c) \quad (4)$$

The estimation of weights based on the rank can be performed as,

$$V_i = V_i \times \left(1 - \frac{S_i}{Max\_iter}\right)\beta \quad (5)$$

- Defense strategy

The latter strategy was based on the up-gradation of locations of the king, commander, and a random soldier. The ranking and weight-up gradation follow the same strategy.

$$A_i(t+1) = A_i(t) + 2\times\tau\times(L - A_{ran}(t)) + ran\times V_i \times (D - A_i(t)) \quad (6)$$

- Weak Soldiers replacement/relocation

The detection of the worst soldiers is performed for each iteration and replaced with a random soldier as shown below,

$$A_v(t+1) = LC + ran\times(UC - LC) \quad (7)$$

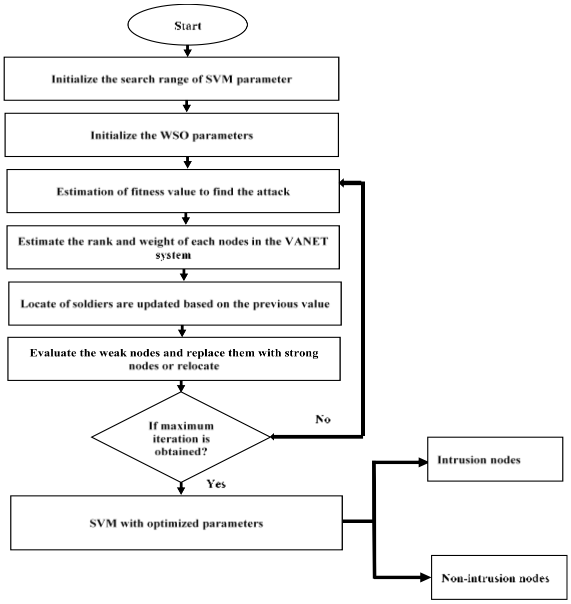
The next approach is to reposition the weak soldier to the median of the whole army as shown below,

$$A_v(t+1) = -(1-rann)\times\left(A_v(t)-median(A)\right)+L \quad (8)$$

3) Enhancement of WSO-based SVM for intrusion detection.

- This proposed approach maintained the balance between exploitation and exploration.
- Each soldier (solution) maintained a unique weight with respect to the rank.
- After finishing the fitness step the weight of the soldiers got updated.
- At the starting stage of iteration the weights changed in large amount and decreases towards the end and this will result in a global optimum value.
- The stated approach simply increases the convergence speed and leads to less computation complexity.

4) Optimized SVM-based collaborative intrusion detection: The machine learning approach SVM provides efficient intrusion detection, and swift implementation, and is simple in nature. However, it possessed some shortcomings like over fitting issues and higher complexities [28]. These were tackled by the WSO algorithm which increased the convergence speed and searchability and increased the detection speed and accuracy. Thus the merging of WSO and SVM is performed in this proposed collaborative intrusion detection approach. The position parameters of SVM are updated by the fitness function of the proposed WSO algorithm. The schematic structure of the proposed WSO-SVM-based collaborative intrusion detection in VANET is illustrated in Fig. 4.



Start
Initialize the search range of SVM parameter
Initialize the WSO parameters
Estimation of fitness value to find the attack
Estimate the rank and weight of each nodes in the VANET system
Locate of soldiers are updated based on the previous value
Evaluate the weak nodes and replace them with strong nodes or relocate
If maximum iteration is obtained?
No
Yes
SVM with optimized parameters
Intrusion nodes
Non-intrusion nodes

Fig. 4. Schematic overflow of proposed optimized SVM-based collaborative intrusion detection approach in VANET.

IV. Result and Discussion

This section discusses the experimental investigation of a proposed framework based on collaborative intrusion detection in VANET. The GTX1050 GPU at 16GB RAM and Intel Core i5-8300H CPU with Tensorflow 1.15 on a GPU-based computer based on NS-2 implement the experimental results [29]. Table I explains the parametric description based on the proposed framework.

In this study, the KDD99 dataset was used for experimental investigation [30]. There were five million records involved in the KDD99 dataset and 41 features described these records.

TABLE I. Parameter Description

Parameters	Ranges
Number of population	50
Maximum number of iteration	100
Number of nodes	50
Simulation range	1.5 kms * 1.5 kms
Kernel function	Gaussian

A. Performance Measures

The performance metrics such as accuracy (A), precision (P) and recall (R) are used to validate the effectiveness of proposed framework [30], [31]. The following equations explain all these performance measures for intrusion detection performance efficiency.

$$A = \frac{T_N + T_P}{F_N + T_N + F_P + T_P} \quad (9)$$

$$P = \frac{T_P}{F_P + T_P} \quad (10)$$

$$R = \frac{T_P}{F_N + T_P} \quad (11)$$

Where, the number of correctly predicted intrusion and the number of correctly predicted non-intrusion classes are true positive (T_P) and true negative (T_N). Moreover, a number of incorrectly predicted intrusion and the number of incorrectly predicted non-intrusion classes are true positive (F_P) and true negative (F_N).

B. Evaluation based on Performance

The analysis of accuracy is plotted in Fig. 5. A different number of nodes such as 10, 20, 30, 40 and 50 are used for the analysis of accuracy. The methods like RF, HDDM, H-ID, and ML are proposed. However, these proposed method offers superior accuracy than previous methods like RF, HDDM, H-ID, and ML in terms of all nodes.

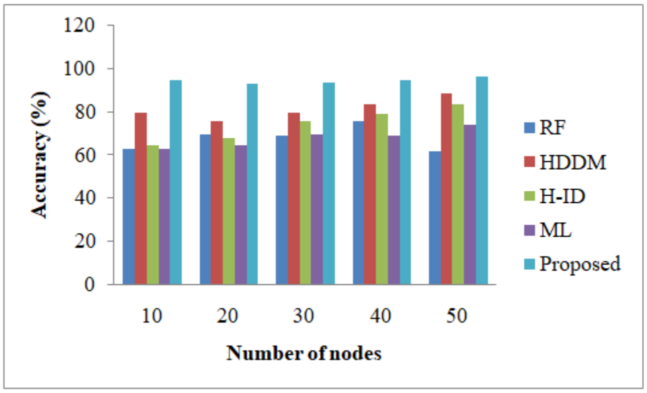

Fig. 5. Graphical representation of accuracy results.

The graphical representation of energy consumption results is plotted in Fig. 6. The methods including RF, HDDM, H-ID, and ML with proposed methods are taken as the state-of-art methods. There are 50 nodes which were taken for this investigation. The proposed method consumed less energy while comparing to the existing methods such as RF, HDDM, H-ID, and ML.

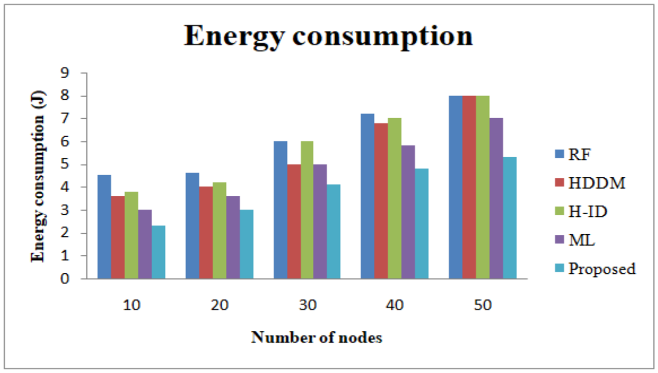

Fig. 6. Graphical representation of energy consumption results.

Fig. 7 represents the graphical representation of end-to-end delay results. The state-of-the-art methodologies include RF, HDDM, H-ID, and ML with proposed methodologies. For this examination, 50 nodes were taken and the delay is represented in time seconds. When compared to existing technologies like RF, HDDM, H-ID, and ML, the proposed method demonstrated minimum delay.

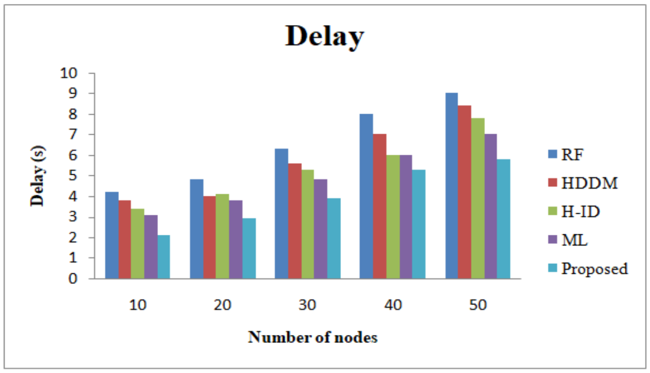

Fig. 7. Graphical representation of end-to-end delay results.

The performance evaluation of this proposed technique based on security was analyzed and compared with state-of-art work such as RF, HDDM, H-ID, and ML and reported in Table II. Since this proposed work utilized a collaborative blockchain-based WSO-SVM technique, it effectively secured the VANET system and avoided the vehicles from attacking. The security of the proposed approach is 95.89% and the other approaches RF, HDDM, H-ID, and ML provide security of 91.9%, 89.06%, 90.56%, and 93.23% respectively.

TABLE II. EVALUATION BASED ON SECURITY

Methods	Security (%)
RF	91.9
HDDM	89.06
H-ID	90.56
ML	93.23
Proposed	95.89

The evaluation based on the performance metrics was estimated and compared with state-of-art works such as RF, HDDM, H-ID, and ML, as stated in Table III. From the table III, it is clear that due to the inclusion of WSO along with the SVM classifier our approach provided better accuracy, precision, and recall of about 96.48%, 95.89%, and 96.56% respectively. Meanwhile, the other existing approaches show lacking strategies for above-stated metrics than this proposed approach.

TABLE III. EVALUATION BASED ON RECALL, PRECISION, AND ACCURACY

Methods	Recall (%)	Precision (%)	Accuracy (%)
RF	87.78	89.37	90.38
HDDM	91.09	90.56	92.77
H-ID	89.09	91.45	89.55
ML	93.45	90.76	93.00
Proposed	96.56	95.89	96.48

V. CONCLUSION

This article introduced a collaborative-based vehicular ad hoc network intrusion detection system using an optimized support vector machine. The cluster formation has been performed via k-means clustering. The Tabu Search-based Particle Swarm Optimization (TS-PSO) algorithm has been used to select the cluster heads for the formulated cluster. The suggested strategy helped to reduce the delay in the transmission of data by improving throughput and energy efficiency. The security of the proposed VANET system has been accomplished with the utilization of blockchain and enhanced its reliability. Additionally, the trust-based collaboration intrusion detection on the VANET can be performed using the optimized SVM model. The KDD99 dataset has been utilized and simulated with NS-2 software to analyze the performance of the proposed work. The proposed method offers minimum energy consumption as well as an end-to-end delay compared to the existing methods such as RF, HDDM, H-ID, and ML with the consideration of 50 nodes. The proposed strategy has a security level of 95.89%, while the other approaches—RF, HDDM, H-ID, and ML—offer security levels of 91.9%, 89.06%, 90.56%, and 93.23% correspondingly.

This study has few challenges in which the efficiency and accuracy of the intrusion detection framework can be enhanced via granularity and in-depth monitoring. The usage of different protocols and data diversity of the modern VANET networks induces a high level of complexity when identifying the intrusions in future.

Abstract—**Recent development of digital photography and the use of social media using smartphones has boosted the demand for image query by its visual semantics. Content-Based Image Retrieval (CBIR) is a well-identified research area in the domain of image and video data analysis. The major challenges of a CBIR system are (a) to derive the visual semantics of the query image and (b) to find all the similar images from the repository. The objective of this paper is to precisely define the visual semantics using hybrid feature vectors. In this paper, a CBIR system using encoded-based feature fusion is proposed. The CNN encoding features of the RGB channel are fused with the encoded texture features of LBP, CSLBP, and LDP separately. The retrieval performance of the different fused features is tested using three public datasets i.e. Corel-lK, Caltech, and 102flower. The result shows the class properties are better retained using the LDP with RGB encoded features, this helps to enhance the classification and retrieval performance for all three datasets. The average precision of Corel-lK is 94.5% and it is 89.7% for Caltech, and 88.7% for the 102flower. The average f1-score is 89.5% for Caltech, and 88.5% for the 102flower. The improvement in the f1-score value implies the proposed fused feature is more stable to deal the class imbalance problem.**

***Keywords*—CBIR; CNN Encoded Feature; LBP; CSLBP; LDP; feature fusion**

I. INTRODUCTION

Content-based image retrieval (CBIR) is the technique to retrieve similar images from a large image database using visual characteristics such as color, shape, structure, Zernike values, and histogram of the images[1, 2]. Nowadays it has an inevitable requirement in various application areas such as video surveillance, medical image retrieval, crime detection, military surveillance, remote sensing applications, the textile industry etc. [3-6]. The efficiency of the CBIR system greatly depends upon the visual feature selection. The high-level semantic features [3,7] of an image are its color, shape, structure, Zernike values, and histogram are used for manual image annotation and are less biased with noise [8,9]. Features represented using the spatial layout of the pixels within an image patch are referred as low-level features or local descriptors [10-12]. Some of the popular low-level image descriptors are Local Binary Patterns (LBP) [13-15], Orthogonal-Combination of Local Binary Patterns (OC-LBP), Center-Symmetric Local Binary Patterns (CS-LBP), Local Ternary Patterns (LTP), Local Directional Patterns (LDP)[15], Scale-Invariant Feature Transform (SIFT) [16] are used for image retrieval. The performance of a unique texture feature varies with different datasets. The major limitation of the texture feature is directly mapping the texture image to its histogram [1, 9, 17-19], which is represented on a scale of 0 to 255, so that all the information learned from the patches of images are not well preserved. With the implementation of Deep learning features a new breakthrough is achieved in the field of computer vision and its applications. It uses the Convolutional neural networks (CNNs) features [14, 20-23] as the image descriptor. The Deep learning technique requires adequate images for its training. The several layers of the CNN encoder represent the image features at different levels [11]. The lower layers contain the detailed image features, whereas the higher layers present the semantic information of the image [10, 11]. The fully connected layer extracts discriminative image features using an order-less quantization approach. Finally, these features are mapped to the class label using the dimension reduction technique and soft-max pooling [10, 24].

An effectual feature extraction technique precisely describes the image contents. It also helps to maintain a distinctive signature for the images of different classes. In recent years image retrieval using feature fusion has been emphasized by many researchers[3, 8] to build a more powerful image descriptor using the feature fusion technique [7,10,23,25-27]. These are more sensitive to noise and image resolution. Moreover mapping the low-level image features to the high-level visual semantics is challenging [7, 8, 28, 29]. Thus, there is a need to design an enhanced CBIR system.

In this work, a deep-learning feature fusion framework is proposed, where the auto-encoding features of the RGB channels are fused with the auto-encoding feature of the texture image. Here two different CNN models are trained independently. The first model usages the RGB channels data, which learns the spatial image information using automatic encoding. The second model usages the texture image data for the training to learn the auto-encoder-based texture features. The spatial and texture features extracted by CNN encoders are fused together to provide more precise feature descriptors for the image. The texture feature of an image i.e. the histogram of the texture image is biased by the background image textures, which impedes the learning ability of the classifier [9, 17]. Textures of similar images are expected to be alike. More effective learning can be possible from the texture image set, as the CNN uses the batch mode for the training. For the extensive analysis of the proposed fusion framework, a CBIR system is developed. Here the encoding features of three different textures such as LBP, CSLBP, and LDP are fused with the RGB channel encoding feature individually. The classification and retrieval performance of the different fused features are presented. These are also compared with encoding features of only RGB channels. The model is tested for three different datasets such as Corel-lK, Caltech, and 102flower. It is observed that the classification result of the LDP_RGB fusion outperforms the results of LBP_RGB, CSLBP_RGB, and RGB. Moreover, the proposed fusion features preserve more class-oriented properties, so that the retrieval rate is enhanced. The performance analysis for the top 80 images retrieval using the proposed auto-encoder-based feature fusion and the auto-encoder-based RGB channel feature are shown in the result section. The retrieval rate using LDP_RGB fusion also surpasses all the other methods discussed.

The major contributions of this work are mentioned below:

- A new enhanced feature fusion technique is used, where the texture image and RGB channel image features are fused.
- The auto-encoding features of the texture and RGB channels are extracted by two different CNN models to save the low variance pixel information of the texture image.
- The CBIR model is tested for three different textures i.e. LBP, CSLBP, and LDP textures with RGB channel encoding feature.
- The model is tested with three different datasets such as Corel-lK, Caltech, and 102flower.
- Improvement in the f1-score implies the proposed feature descriptor handles the class imbalance issue more precisely.
- The retrieval result is enhanced with the fusion of LDP and RGB encoded features.

The rest part of the paper is arranged in the following order: Section II presents a review of feature fusion and CBIR system. Section III shows the proposed feature fusion model, CNN encoding architecture, and performance evaluation metrics. The detailed results are shown in Section IV i.e. the results and discussions. The conclusion of the work is presented in Section V.

II. Related Work

Kayhan, N., et al. [1] build a weighted feature-based CBIR system using modified local binary patterns (MLBP), local neighbourhood differences patterns (LNDP), filtered gray level co-occurrence matrix (GLCM), and the quantization color histogram features. Khan, U. A., et al. [2] used hybrid classification model using three color moments, Haar Wavelet, Daubechies Wavelet and Bi-Orthogonal wavelets features. They have used genetic algorithm (GA) and SVM classification and L2 Norm is used for the similarity measure. Kashif, M., et al. [3] proposed a hybrid image descriptor using local ternary pattern, local phase quantization, and discrete wavelet transform. They used joint mutual information (JMI) based feature selection to derive the optimal feature for effective image retrieval. Carvalho, E. D., et al. [4] proposed a histopathological breast image classification model using phylogenetic diversity indexes. They have also used the phylogenetic diversity indexes to rank the images. Authors claim, it outperforms XGBoost, random forest, and support vector machine. Choe, J., et al. [5] proposed a medical image retrieval model for interstitial lung disease diagnosis using the deep learning features of CT images. Pradhan, J., et al. [7] proposed a regions-of-attention-based feature fusion technique for image retrieval, here authors used multi-directional texture features with spatial correlation-based color features to derive the image semantics. Pathak, D., et al. [9] proposed a retrieval system by concatenating the deep learning GoogleNet features with the hue, saturation, and intensity features of the HIS image, and Histogram of orientated gradient (HOG) feature of the RGB image. Here the authors claim this technique is used to reduce information loss due to image resizing. A. Latif, et al. [10] presented a comprehensive review of the recent development and the state-of-the-art CBIR systems. The study explored the major concepts of CBIR like image representation, image retrieval, low-level feature extraction, and recently used semantic deep-learning approaches, it also includes future research directions in CBIR. M. Sotoodeh, et al. [17] presented a local texture descriptor referred as Color Radial Mean Local Binary Pattern (CRMLBP). The CRMLBP is computed for the sign-difference, magnitude-difference, and central gray value patterns in the RGB color space and their histograms are concatenated. The feature weights are optimized using Particle Swam Optimization (PSO) technique. The performance of this feature vector is tested with various datasets such as Wang, Holidays, Corel data. Sampathila, N., et al. [18] presented an image retrieval method using Grey-level co-occurrence-based Haralik's features and histogram-based cumulative distribution function (CDF) for the brain MRI image retrieval. Here the KNN approach is used to find the distance between the query image and other images. Khan, M. A., et al. [19] proposed an intelligent human action recognition system using Hand-crafted and deep convolutional neural network features fusion. Here the histogram of oriented gradients (HoG) and deep features are fused. A multi-class support vector machine (M-SVM) is used for the classification. Ma, W., et al. [22] suggested a cloud-based privacy-preserving image retrieval service using deep convolutional features with from the encrypted image. For image encryption, a hybrid encryption method is adopted. Wang, S. H., et al. [23] suggested deep feature fusion technique using graph convolutional network and convolutional neural network features for Covid-19 classification. Here they used the CT images to test their model performance. L. T. Alemu, et al. [25] proposed a multi-feature fusion-based CBIR system, where various hand-crafted features with deep NN features and membership score is applied based on their probabilistic distribution. Then an incremental nearest neighbour (NN) selection is used to implement k-NN for dynamic query selection. Wang, W., et al. [26] presented a two-stage CBIR model using the fusion of global and local feature. Authors use a sparse coding for the sparse representation of the local features followed by feature pooling and the Euclidean distance measure is used to find the similarity between the sparse feature vectors. Bella, M. I. T. et al. [28] proposed the image retrieval system using information fusion technique, where the GLCM and HSV color moment features are fused the model is tested with Corel-1K, Corel-5K, and Corel-10K datasets.

Table I presents a survey on the different feature fusion techniques used for image classification and retrieval. However, there is a scope to define a better image descriptor using the strength of the texture feature with the deep CNN feature. In this work, intend to define a more precise feature vector by combining the CNN-encoded texture feature with the encoded RGB channel feature.

III. PROPOSED MODEL

In the case of Deep learning, the image features are fetched automatically using a CNN encoder. The features extracted from the RGB channel carry more information than the Gray-scale image, as it learns from three channels R, G, and B coherently. At the same time, computational complexity increases. Moreover, information stored in all three channels is highly correlated, which impedes the learning rate. In this work, a feature fusion technique is proposed where the CNN-encoded feature of the texture image is fused with the encoded feature of RGB channels. Two different CNN encoders are used to derive the texture and RGB features from an image. The motivation behind two different CNN encoders instead of adding the texture image in the 4th channel in addition to the R, G, and B is that the range of the pixel values of the texture image is comparatively smaller than the pixel values of the R, G, and B channels. So the texture information will not be suppressed during the recursive MAX pooling and ReLU operations.

A. LBP Texture Image

The LBP texture of a 3 x 3 pixel block is achieved by thresholding the pixel values of the neighbours with its center pixel into binary values, where the value is 1 if the value of the neighbour pixels is greater or equal to the value of the center pixel, otherwise 0. The values of all the 8 neighbours are stored in an unsigned-byte form, here the range varies from 0 to 255. Eq. (1) shows the calculation of the LBP texture image, where R is the radius of the circle [14].

$$LBP_{P,R} = \sum_{p=0}^{P-1} S(g_p - g_c)\, 2^P \qquad (1)$$

$$where \;\; S(z) = \begin{cases} 1, & if\ z \geq 0 \\ 0, & otherwise \end{cases}$$

B. CSLBP Texture Image

Center-Symmetric Local Binary Patterns are produced by computing the thresholding difference of pixel values with their symmetrically opposite pixels with respect to the canter of a pixel block. Here the thresholding difference is a smaller integer value T. The CSLBP labels generate shorter histograms, which is a more stable feature for the flat image regions. Eq. (2) represents the calculation of the CSLBP texture image [15].

$$CSLBP_{P,R,T(x,y)} = \sum_{p=0}^{\left(\frac{P}{2}\right)-1} S\left(g_p - g_{p+\left(\frac{P}{2}\right)} - T\right) 2^P \qquad (2)$$

$$where \;\; S(z) = \begin{cases} 1, & if\ z \geq 0 \\ 0, & otherwise \end{cases}$$

C. LDP Texture Image

The LDP pattern illustrates the response values of all eight directional edges of a center pixel. It is calculated using the Kirsch masks in the eight different orientations i.e. (M0 ~ M7) with respect to a 3x3 pixel block, and Eq. (3) and Eq. (4) show the LDP value calculation at a point (x, y).

$$m_i = \sum_{l=-1}^{1} \sum_{k=-1}^{1} I(x+l, y+k) \times M_i(l,k) \qquad (3)$$

$$LDP_{x,y}(m_{0,}\dots, m_7) = \sum_{i=0}^{7} S(m_i - m_k) \times 2^P \qquad (4)$$

Fig. 1 shows the Original images of Corel-lK, Caltech, and 102Flower datasets with their equivalent LBP, CSLBP, and LDP texture images. Here four images are shown from each dataset and the *Image Ref* is a combination of the folder name and the image name.

D. Auto-encoder-based CNN Feature

The deep CNN feature of an image is generated using an automatic encoding technique. The image feature is learned through batch mode training, hence it is expected that the feature preserves the class information. As the layers of CNN architecture are densely connected, the learning becomes faster with automatic weight adjustment for a particular class using supervised learning.

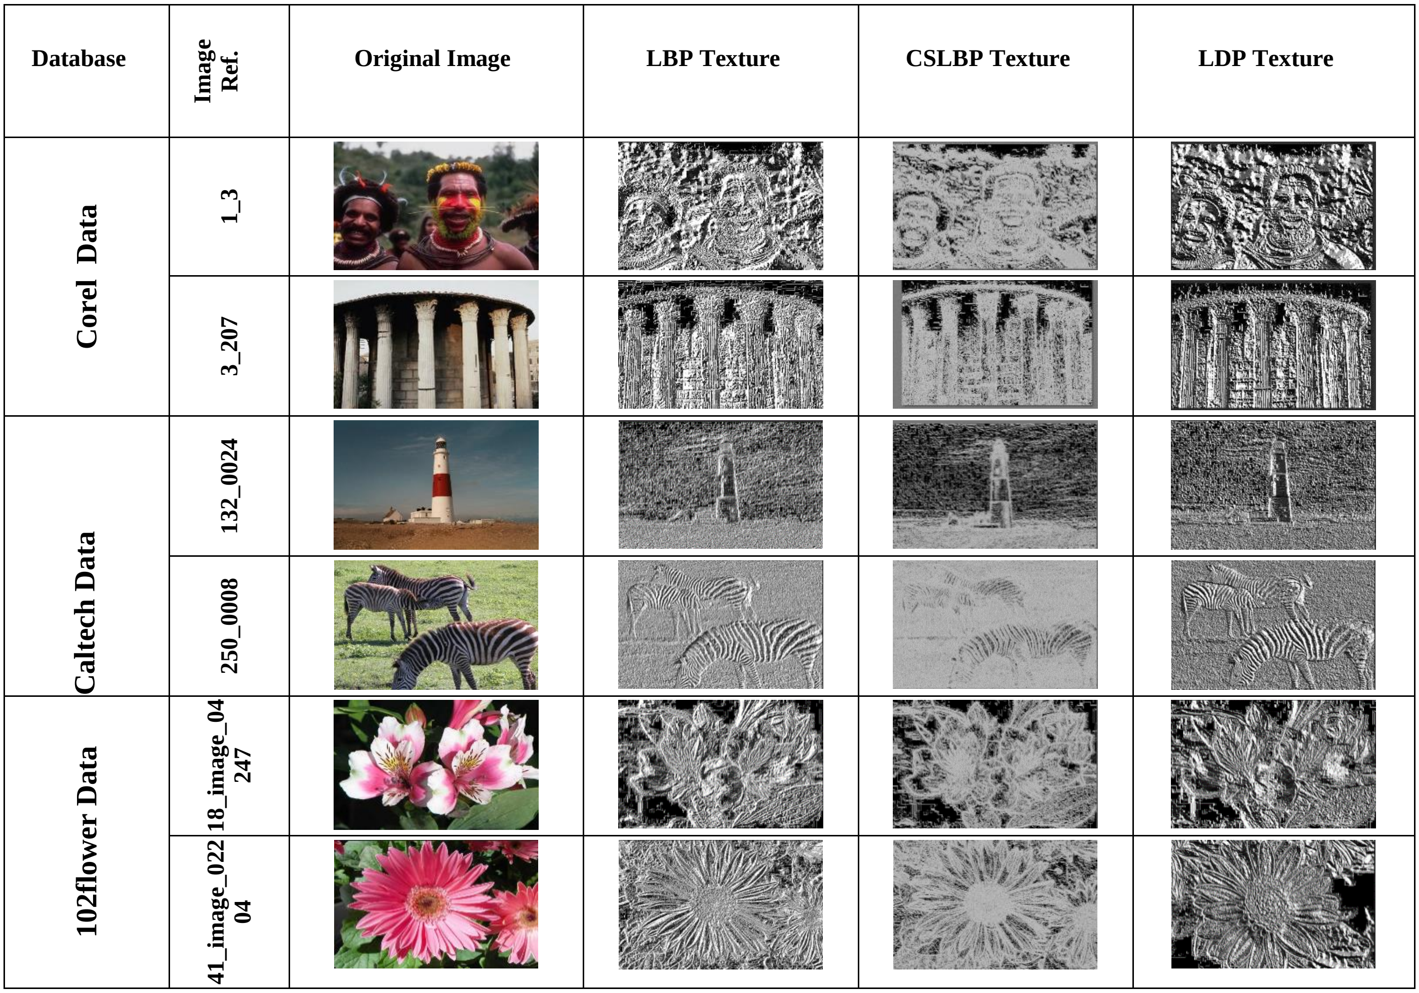

Fig. 1. The Original RGB image with their equivalent LBP, CSLBP and LDP texture image.

E. Feature Fusion Model

Fig. 2 shows the proposed model, here the size of the input image is 512 x 512 for both the CNNs i.e. the RBG and the texture input. The CNN architecture consists of seven layers and each layer contains a convolution operation followed by the ReLU and MAX pooling operations. Non-linearity property is introduced to the convolution output with the ReLU activation function. Whereas the image size reduction is done by the MAX pooling with each convolution operation. The flattened layer is used to reduce the image to a single-dimension feature vector of size 1 x 1024. Further dimension reduction is done with four fully connected layers. The soft-max operation is used to calculate the class label from the feature map using the energy function.

$$(I * f)_{x,y} = \sum_{s=1}^{H} \sum_{t=1}^{W} f_{s,t} . I_{x+s-1,y+t-1} + b \quad (5)$$

$$ReLU(x) = Max(0, x) \quad (6)$$

$$E(w, b) = \frac{1}{n} \sum_{i=1}^{n} L\big(y_i, f(x_i)\big) + \alpha R(w) \quad (7)$$

Where:

L = model loss parameter.

R = regularization factor used to deal with the model complexity.

α = regularization strength control parameter.

The cross-entropy loss is determined as the penalty value in each iteration using that energy function. Eq. (5) represents the convolution operation at point a (x, y) of an image I used the filter f, where the H and W represent the height and width of the image. The ReLU operation is defined using Eq. (6). Eq. (7) represents the regularized training error of an instance. Eq. (8) represents the sigmoid function Si used to map the output value within (0, 1). The cross-entropy loss for each iteration is defined by Eq. (9).

$$S_i(x) = \frac{1}{1 + e^{-x}} \quad (8)$$

$$LogLoss = -\frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{M} y_{ij} log P_{ij} \quad (9)$$

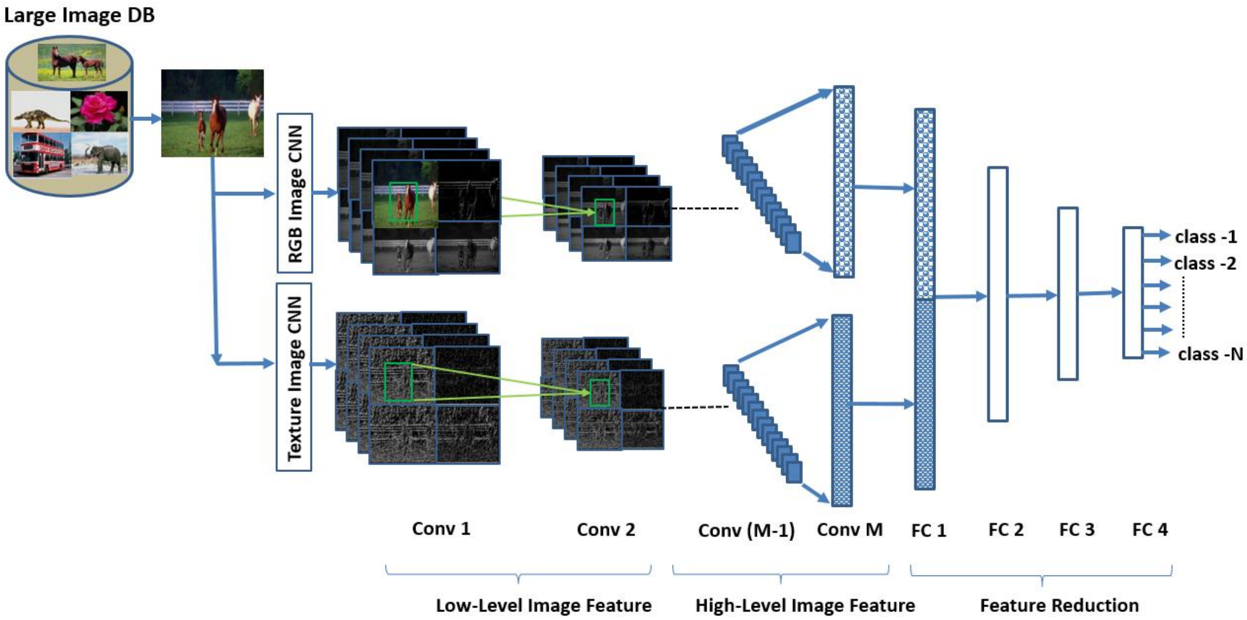

Fig. 2. Block diagram of the proposed CNN encoder-based RGB and texture features fusion.

Where N shows the number of samples and M is the number of labels, the y_{ij} represents if the label j is correctly classified as, for the instance, i. Here P_{ij} is the probability value of the model that assigns label j to the instance i.

The proposed feature fusion model using the CNN feature of the RGB image and the CNN feature of the texture image uses the standard learning rate with an early stop parameter value of 0.99. The model training is done using 80:20 holdout validation. Here a GTX 1650 graphics system with 16 GB RAM is used for the training and testing of the proposed model.

F. Performance Measures

The performance of the proposed feature fusion is evaluated using parametric quantifiers such as precision, recall, and f1-score [13], which are defined below using Eq. (10), Eq. (11), and Eq. (12) respectively.

$$Precision = \frac{True^{+}}{True^{+} + False^{+}} \tag{10}$$

$$Recall = \frac{True^{+}}{True^{+} + False^{-}} \tag{11}$$

$$f1 - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{12}$$

Here the true positive (True+) value shows the number of images correctly identified into their belonging class by the system. The false positive (False+) shows the number of images falsely recognized by the system, and the false negative (False-) shows the number of images falsely rejected by the system. The precision shows the number of images correctly identified into their belonging class with respect to the total number of images identified by the system. Whereas recall represents the number of images correctly identified for a class with respect to all the images belonging to that class. Hence the average recall value is a significant performance measure for a retrieval system. The Caltech and 102flower datasets have a different number of total images in different classes. The harmonic mean of these classes i.e. f1-Score is also presented in addition to the precision [13, 29]. The receiver operating characteristics (ROC) curve, which is plotted using the true-positive rate vs. false-positive rate, illustrates graphically the classifier's performance. The City-block distance measure shown in the Equation (13) is used to measure the similarity between the images.

City-block distance measure:

$$D_{CT} = \sum_{i=0}^{L-1} \left| F_i^q - F_i^t \right| \tag{13}$$

Where:

F_i^q = feature vector of the query image

F_i^t = feature vector of the database image

IV. Results and Discussion

The results of the proposed CBIR model using encoded texture feature fusion are discussed in this section. Here the CNN-based auto-encoding features of the RGB channels are fused with the auto-encoding features of three different texture features i.e. LBP, CSLBP, and LDP. The image retrieval model is tested with three different datasets such as Corel-lK, Caltech, and 102Flower. To avoid the extensive processing time, selective 15 classes of the 102Flower dataset have been considered. The precision, recall, and f1-score of each class are presented for all three datasets. The ROC curve shows the overall classification performance using the CNN encoding features of RGB, RGB_LBP, RGB_CSLBP, and RGB_LDP. The average retrieval performance is shown separately for all three datasets using all the above-discussed four encoding features for top 80 image retrieval. The class-wise retrieval performances are illustrated with the bar graph for all four encoding features. The detailed analysis results of individual classes are discussed in the sub-sections below.

A. Results Analysis of Corel-lK

Table II shows the performance analysis of the Corel-1K dataset maximum average precision value is 94.5% using the LDP_RGB encoder feature. It is 94.2% using LBP with RGB, 94.3% for CSLBP with RGB, and 94.2% using the RGB encoder feature. The classification performance is presented using the ROC curve in Fig. 3(a).

The Recall and f1-score are 94.4%, and 94.5% respectively using the LDP_RGB feature, which is maximum in comparison to the other features. Though there is a small difference in the classification rate, the average retrieval rate is significantly enhanced using the LDP_RGB feature in comparison to the other features for retrieving the top 80 images shown in Fig. 3(b), and the class-wise retrieval analysis is shown in Fig. 4 for the top 10 images. In this dataset, each class consists of 100 images, so there is no major difference in the precision and f1-score values.

(a) ROC Curve

(b) Average Recall Rate of the top 80 Image

Fig. 5. Analysis of the Caltech images using RGB and texture with RGB CNN feature.

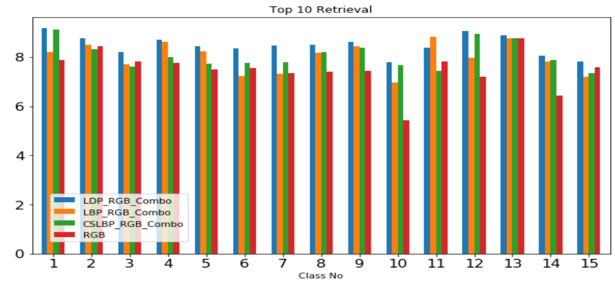

Fig. 6. Class-wise retrieval of the top 10 images Caltech dataset.

B. Results Analysis of Caltech

The result analysis of the Caltech dataset is shown in Table III, in this case, value of maximum average precision is 89.7% using the LDP_RGB encoder feature. Whereas it is 88.9% using LBP with RGB, 88.3% for CSLBP with RGB, and 88.9% using RGB encoder feature. The classification performance is presented using the ROC curve in Fig. 5(a). The Recall and f1-score are 89.6%, and 89.5% respectively with the LDP_RGB feature, which is more in comparison to the other encoding features.

Though there is a visible difference in the classification rate, the average retrieval rate is also enhanced using the LDP_RGB feature in comparison to the other features for retrieving the top 80 images shown in Fig. 5(b), and Fig. 6 show the class-wise retrieval analysis for the top 10 images. As in this dataset, the number of images in the different classes varies the precision, and f1-score values are also different, moreover these values are more stable using the LDP_RGB encoder feature.

C. Results Analysis of 102Flower

The classification performance of the 102Flower dataset is shown in Table IV. Here 15 classes are selected, and the name of the flower and the number of images available for each class is mentioned in the table in the first and last columns respectively. Here the value of maximum average precision is 88.7% using the LDP_RGB encoder feature. Whereas it is 87.9% using the LBP with RGB, 85.6% for CSLBP with RGB, and 84.5% using the RGB encoder feature. The classification performance of the 102Flower dataset is presented using the ROC curve in Fig. 7(a).

There is a significant difference in the classification rate. The result shown in Fig. 7(b) claims that average retrieval rate using LDP_RGB feature is better than other fusion techniques for retrieving the top 80 images. Fig. 8 shows the class-wise retrieval of the top 10 images. The value of the f1-score is also enhanced using the LDP_RGB feature. Table V presents a state-of-art, where the performance of five other works available in the literature, using the same dataset are compared with the proposed feature fusion model. It shows the accuracy of Corel-1k is 94.5% and Caltech256 is 89.7%. A significant improvement is achieved for both datasets using the proposed feature fusion model.

V. CONCLUSION

This paper proposed a CBIR model using the feature fusion technique. Here the CNN-encoded features of the image are fused with the encoded features of the RGB image. As the range of pixel values in the texture image is comparatively smaller than that of the RGB image, two different encoders are employed to extract the CNN features separately. These two features are fused to define a more significant image descriptor.

The proposed model is tested with three public datasets i.e. Corel-lK, Caltech, and 102flower. It is observed that the classification performance is improved by the proposed feature fusion model as compared to the RGB channel encoding feature. The result shows the performance of the LDP with RGB feature fusion is better with respect to the LBP with RGB and CSLBP with RGB features. There is a significant improvement in the retrieval system for the top 10 as well as top 80 image retrieval. Moreover, the enhancement of the f1-score using the proposed feature fusion technique illustrates the class property is better retained using the fused features. The f1-score value improved significantly using the encoder-based LDP with RGB feature fusion for the dataset having class imbalance issues such as Caltech, and 102flower. In future, the model can be tested using the fusion of other textures like LTP, GLCM.

Knowledge Graph based Representation to Extract Value from Open Government Data

An Application to the Public Procurement Domain

Kawtar YOUNSI DAHBI[1], Dalila CHIADMI[2], Hind LAMHARHAR[3]
Mohammed V University of Rabat
Rabat, Morocco[1, 2, 3]

***Abstract*—Open government data refers to data that is made available by government entities to be freely reused by anyone and for any purpose. The potential benefits of open government data are numerous and include increasing transparency and accountability, enhancing citizens' quality of life, and boosting innovation. However, realizing these benefits is not always straightforward, as the usage of this raw data often faces challenges related to its format, structure, and heterogeneity which hinder its processability and integration. In response to these challenges, we propose an approach to maximize the usage of open government data and achieve its potential benefits. This approach leverages knowledge graphs to extract value from open government data and drive the construction of a knowledge graph from structured, semi-structured, and non-structured formats. It involves the extraction, transformation, semantic enrichment, and integration of heterogeneous open government data sources into an integrated and semantically enhanced knowledge graph. Learning mechanisms and ontologies are used to efficiently construct the knowledge graph. We evaluate the effectiveness of the approach using real-world public procurement data and show that it can detect potential fraud such as favoritism**.

Keywords—Knowledge graph; open government data; knowledge graph construction; public procurement; fraud detection

I. Introduction

Open Government Data (OGD) is a concept that continues to prosper and evolve. It includes all data collected or produced by public administrations that are made available for the public to be freely used [1]. The publication of government data has a significant impact that could be identified through multiple aspects: fostering innovation, improving transparency, public accountability, and collaboration, and improving citizens' quality of life [2] [3]. However, despite these efforts, technical barriers limit the effective use of OGD. For example, users may have difficulty finding relevant data due to the large volume of information and the diversity of portals [4][5]. Additionally, the data may be presented in unstructured formats, requiring manual transcription and significant time to process [2], [6], [1]. Furthermore, a single dataset may not be enough to fulfill user requests, so combining data from multiple sources is often necessary. However, syntactic, structural, and semantic heterogeneity can make it challenging to integrate this data effectively [7]. Therefore, using OGD in its raw form requires technical expertise and significant time and effort to discover, process, integrate, and analyze the data. Given the potential benefits of OGD and the technical barriers to its effective exploitation, exploring new approaches and technologies that can facilitate its use is crucial. One promising avenue for such exploration is the use of knowledge graphs, which have already been successfully implemented by tech giants such as Google and widely used in several contexts [8] – [12]. A knowledge graph is a powerful tool for organizing and analyzing complex information, such as that contained in OGD. It is a semantic graph that captures information about entities and their relationships in an easily machine-processable way [12]. The use of semantics in knowledge graphs allows for a more nuanced and contextually rich understanding of the data, leading to more accurate and insightful analyses. Knowledge graphs offer also a centralized solution for integrating different types of data from heterogeneous sources, providing end-users with a single point of access. Furthermore, knowledge graphs support multiple advanced applications, such as Q&A systems, semantic search, reasoning, and knowledge inference, enabling the development of smart services that extract value from OGD[13] [14].

In this paper, we propose a generic approach that explores the potential of knowledge graphs to transform open government data (OGD) into valuable knowledge. The approach involves constructing a knowledge graph from structured, semi-structured, and unstructured OGD data sources, and offers the following contributions:

- Representing OGD in a semantically rich and machine-processable format to enhance their usefulness.
- Integrating heterogeneous data sources into a centralized solution represented by a knowledge graph, which enables users to have a unified and comprehensive view of the data.

By adopting this approach, we aim to address the challenges related to data processability and integration and to provide users with easily usable data that can be effectively and efficiently utilized. The proposed approach offers a powerful solution for maximizing the value of OGD and encapsulates the technical difficulties associated with processing open government data (OGD). The rest of this paper is organized as follows: Section II presents related works, Section III gives an overview of the proposed approach to construct a knowledge graph from OGD, and Section IV presents the use case related to the public procurement domain, which aims to construct a knowledge graph based on public procurement data and performs advanced analysis to detect anomalies such as favoritism and overpricing. The study concludes in Section V.

II. Related Works

In this section, we present related works that propose the construction of a knowledge graph to extract value from Open Government Data (OGD). We give a brief overview of each work and then draw their main limitations.

The authors in [15] propose the construction of a knowledge graph related to the cadaster in the Netherlands. The knowledge graph is exploited to offer improved data browsing, analysis for urban planning, and the development of location-aware chatbots. However, the approach considers only RDF-like datasets.

Authors in [16] propose the construction of a knowledge graph from Zaragoza's open data to provide a single point for the city's knowledge. Semantic enrichment and transformation are supported through the usage of scripts to transform datasets to RDF. However, the approach doesn't propose dataset integration.

In [17], the authors propose to construct a knowledge graph for the description of public services, the objective of the knowledge graph is to provide users with personalized information about different public services based on their profile and circumstances. The implementation of the knowledge graph was achieved by creating the schema defining entities, attributes, and relationships and populating the graph using GRAQL queries.

The TBFY project [18] [19] proposes the construction of a public procurement knowledge graph to support transparency. For semantic enrichment, the approach uses two ontologies. The transformation to RDF is supported by the RML Mapper tool which automates the generation of RDF triples based on the RML mapping. However, it requires the manual definition of the mapping between the data sources and the ontologies.

Authors in [20] propose the construction of a knowledge graph to support the supervision and analysis of fiscal projects funded by the European Union. The proposed approach collects data from the Open Data API provided by the Greek Ministry of Economy and Finance. Semantic enrichment is based on two ontologies. The approach proposes the usage of the ETL unified views for Data transformation to RDF and semantic enrichment and publication of data in an RDF triple store. Data can be retrieved via SPARQL queries. Performance indicators were defined to assess the state of the project and Density-Based Spatial Clustering of Applications with Noise, (DBSCAN) was used to identify Red Flags.

Authors in [21] propose a solution to support budget transparency. The proposed approach is based on the creation of a knowledge graph from data related to the public budget. Data is published by the budget office in the form of an XML file: an annual file for budget distribution and monthly files for monitoring budget execution. The data is semantically enriched with the National Budget ontology and transformed into RDF through the use of an ETL tool. For data exploitation, the approach proposes the publication of data through a SPARQL access point as well as a set of solutions for data visualization.

The related works presented to provide a background for extracting value from open government data (OGD) through their transformation into knowledge graphs. However, they have limitations that we present below. Firstly, most approaches are either domain-specific or related to specific data sources and cannot be adapted to diverse contexts and domains. Secondly, data transformation to RDF is carried out using scripts, ETL, or mapping languages. This process is tedious, time-consuming, and difficult to implement. It requires the intervention of the user to specify the mapping between data sets and semantic models, which requires a good understanding of the dataset content and structure, domain knowledge, and technical expertise. Thirdly, the majority of approaches focus on dataset transformation without proposing solutions for dataset integration, such as entity linking. When it is proposed, it is not generic and is done for specific types of entities based on linking rules specified by the users. Lastly, most approaches consider only structured data sources. This excludes a large proportion of OGD that is published in unstructured formats.

Therefore, in this work, we aim to address these challenges by proposing a generic and domain-independent approach to constructing a knowledge graph. The proposed approach considers structured, non-structured, and unstructured data sources, and provides an efficient solution to semantically transform OGD with a focus on data integration.

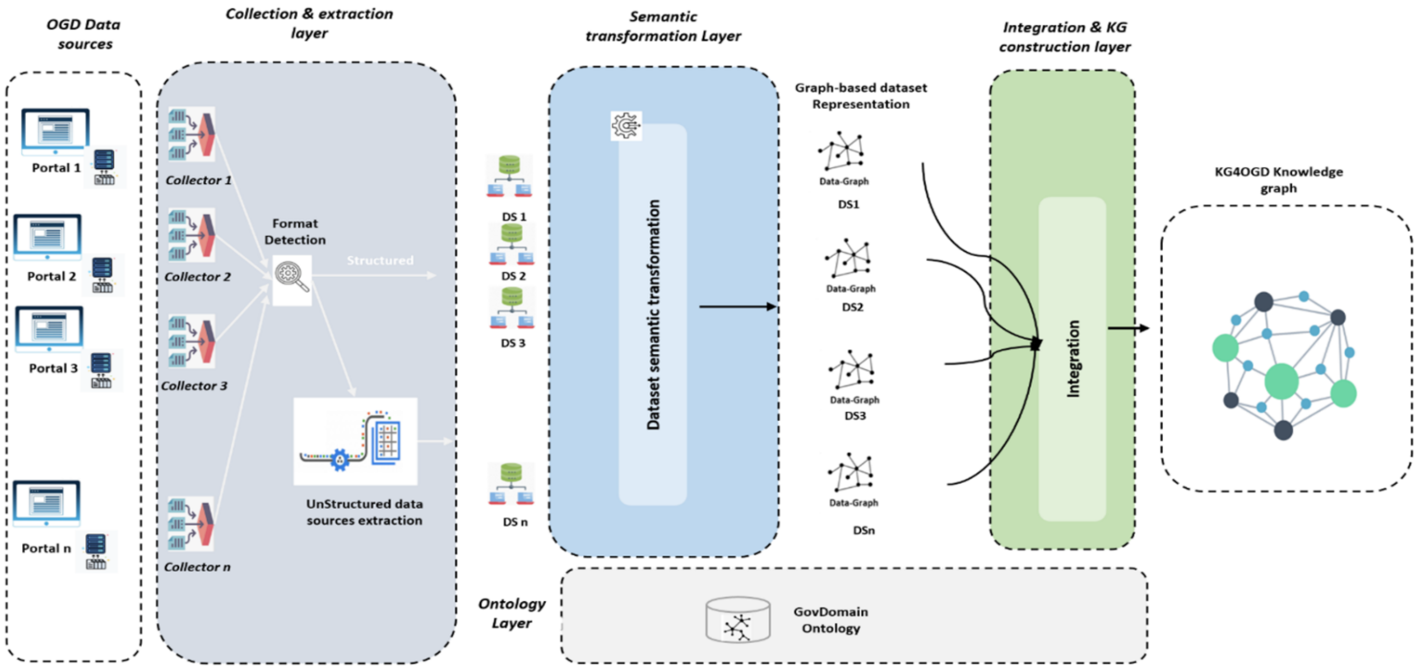

Fig. 1. Overview of the proposed architecture.

III. The Proposed Approach

This section presents a detailed description of the proposed approach for constructing a knowledge graph from Open Government Data sources. The approach is based on a layered architecture that can collect and extract data from structured, semi-structured, and unstructured heterogeneous government data sources. The collected data undergoes semantic enhancement and transformation, after which it is represented as a knowledge graph that offers an interconnected, integrated, and unified representation of data. The constructed knowledge graph can indeed be used through a plethora of applications, such as Q&A, semantic search, knowledge reasoning, and advanced analytics capabilities. These features enable to provide open government data users with useful insights and valuable information.

The proposed architecture depicted in Fig. 1 comprises three main layers: *The Collection and Extraction* layer, the *Semantic Transformation layer*, and the *Integration and Knowledge Graph Construction* layer. These layers are further enhanced by a domain ontology for the representation of domain knowledge. We present below a description of these layers.

A. Collection & Extraction Layer

The Collection and Extraction layer is responsible for discovering and collecting data sources published on various government portals (Pi). Algorithm 1 presents the algorithm that outlines the process performed by this layer.

To discover relevant data sources, the layer employs a set of collectors that use web scraping techniques and can be configured to filter data sources based on keywords, data format, or other specific criteria (CFi) (Line 6 Algorithm 1). This layer is designed to retrieve both structured (datasets) and unstructured data sources, including those published in non-dataset formats such as reports, PDFs, and databases (Line 7 Algorithm 1).

The layer performs format detection (Line 8 Algorithm 1), and structured sources are directly transferred to the Semantic Transformation Layer (Line 10 Algorithm 1).

For unstructured data sources, the layer performs additional processing to extract structured data. For instance, it uses optical character recognition (OCR) and natural language processing (NLP) techniques to identify and extract tables from unstructured data sources, such as PDFs (Line 11 Algorithm 1). Each extracted table is considered a dataset and is transferred to the Semantic Transformation Layer for further processing (Line 14 Algorithm 1).

Algorithm 1: Collect & extract datasets

```
Input: -  $P_i$ government data portal
       -  $CF_i$ Filter criteria
Output: D = {datasets}
S← {}
D← {}
DiscoverDataSource($P_i$ , $CF_i$)
S←RetrieveDataSources()
For each $s_i$ in S
    $fs_i$←DetectFormat($s_i$)
    If $fs_i$ is structured then D.add($fs_i$)
    Else IdentifyTable($s_i$)
        For j← 1 to n
            $t_{ij}$← ExtractTable ($s_i$)
            D.add($t_{ij}$)
        EndFor
    EndIf
EndFor
Return D
```

B. Semantic Transformation Layer

The Semantic Transformation Layer is responsible for adding semantics to the data and transforming it into a machine-processable and understandable format. This layer aims to enhance the usefulness of the collected and extracted datasets by enriching them with semantic information. For this purpose, the layer uses the GovDomain ontology, a domain ontology that formalizes and represents domain knowledge. The Gov domain ontology is intended to model a consensus among governments on the concepts and relationships that exist in published datasets. It is thus an essential tool to solve the problem of semantic heterogeneity.

The semantic transformation layer takes as input the datasets collected and extracted by the Collection & Extraction layer. For each dataset di, it generates an RDF graph-based representation of the dataset GD-di, which is semantically enriched with the GovDomain ontology. The process performed by this layer involves two main steps depicted in Fig. 2: Semantic model construction and RDF graph generation.

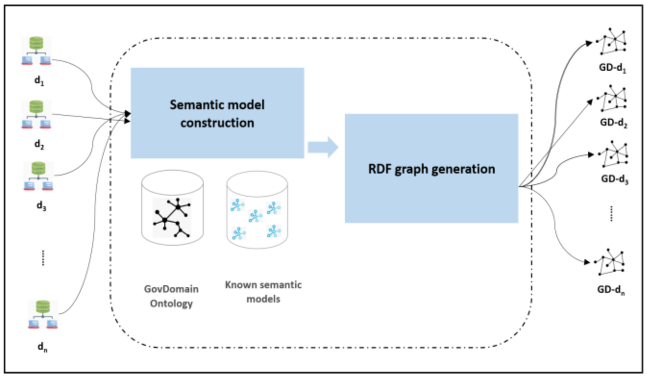

Fig. 2. Semantic transformation process.

The first step consists of constructing a semantic model for the dataset. This model is a requirement for semantic enrichment. It aims to define the structure of the dataset in terms of concepts and relations from the GovDomain ontology. Specifically, it establishes the mapping between the attributes of the dataset and the concepts or properties of the ontology, as well as the relationships between these attributes in terms of ontology relations.

For example, Fig. 3 depicts the semantic model of a public procurement dataset, which includes information on public contracts awarded by public entities, their details (title, reference, description, price, and duration, and the purchasing organization and selected supplier.

Constructing the semantic model for a dataset involves two sub-steps. The first sub-step involves mapping the dataset's attributes to their corresponding semantic types following the domain ontology. A semantic type can be a class URI or a combination of a class and a property from the GovDomain ontology. For instance, in the public procurement dataset, the attributes "Acheteur Public", "Fournisseur "," and "Titre" are mapped to their respective semantic types, which are (PCO: organization, orgName), (PCO: supplier, SupplierName), and (PCO: contract, title)). The second sub-step aims to establish the relations between the attributes in terms of ontology relations. For instance, the relations (PCO: Hasbuyer) and (PCO: HasSupplier) link the class (PCO: Contract) respectively with the classes (PCO: Organization) and (PCO: Supplier).

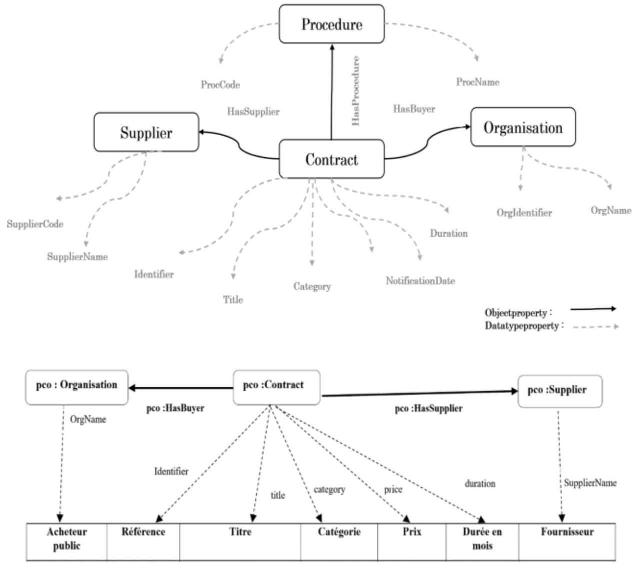

Fig. 3. Example of a semantic model for a dataset related to public procurement.

The manual creation of a semantic model for a dataset is a challenging and time-consuming task, which demands an extensive understanding of the dataset's content and structure, as well as domain-specific knowledge and technical expertise. To address this challenge, we propose an automatic approach to construct the semantic model of a dataset, thereby removing the need for manual intervention in the process. The proposed approach utilizes machine learning to automatically learn the dataset's semantic model by constructing it based on a set of known semantic models that serve as the training data. We employ the algorithm proposed by [22], which offers a method to learn semantic models of structured data sources by mapping them to a domain ontology. The algorithm constructs a weighted graph that represents the space of potential semantic models for a dataset, and provided a ranked list of the top-k best semantic models.

Based on the constructed semantic model the second step (Fig. 3) involves the RDF graph generation. The resulting model is formalized using the RDF Mapping Language (RML). RML [23] allows for the definition and expression of mapping rules between data sources and the RDF model, describing how the existing data can be represented according to the RDF model. The RML mapping document is interpreted by an RML processing engine and used to automatically generate RDF triples from the dataset. The resulting RDF graph provides a graph-based representation of the dataset, thereby enabling machine-readable and machine-understandable access to the dataset's content.

C. Integration and Knowledge Graph Construction Layer

The Integration & Knowledge Graph Construction Layer is responsible for the integration of data into a knowledge graph. This layer takes as input the RDF graphs that result from the semantic transformation of datasets. The integration process involves two steps, which are outlined in Algorithm 2

Algorithm 2: KG construction & integration

```
Input: -GD-$d_1$, GD-$d_2$…. GD-$d_n$: RDF graphs related to datasets { $d_1$, $d_2$…. $d_n$ }
        -C: List of ontology classes described in datasets { $d_1$, $d_2$….$d_n$ }
Output: KG4OGD knowledge graph.
KG4OGD ← ∅
For each GD-$d_i$
    KG4OGD ← KG4OGD.Add(GD-$d_i$)
EndFor
For each cp from C
    Bp ← ConstructBloc(cp)
        For each ($e_i$,$e_j$) ∈ Bp
            If Comp ($v_i$,$v_j$)= true then
            t←ConstructIdentityTriple($e_i$,$e_j$)
            KG4OGD ← KG4OGD.Add(t)
            EndIf
        Endfor
EndFor
Return KG4OGD
```

The first step involves publishing and consolidating all datasets into the knowledge graph (Line 8 Algorithm 2). The second step is crucial for completing data integration and involves entity alignment. Entity alignment refers to the process of identifying and mapping coreferent entities, which are entities that refer to the same real-world entity but with different URIs [24]. This step involves a pairwise comparison of all entities that have been published in the graph. To improve efficiency, we use a blocking technique [25] that reduces the number of comparisons and identifies potential candidates for entity alignment. We apply a class-based partitioning approach to construct blocks, which groups potential co-referenced entities into blocks based on their class (Line 11 Algorithm 2). This method reduces the quadratic complexity of the process by limiting the number of comparisons required. After constructing the blocks, we compare the entities belonging to the same block by examining their discriminative properties, which are unique properties that identify entities of a particular class (Line 13, Algorithm 2). These discriminative properties are described in the domain ontology by adding owl:hasKey axioms. If two entities have equal values for these properties, we consider the entities to be co-referent, and we add identity links between them to the knowledge graph using the owl:sameAs property (Line 14 &15, Algorithm 2).

D. Advantages of the Proposed Approach

The proposed approach makes significant contributions to the field of Open Government Data (OGD). Firstly, it enables the representation of OGD in a structured and semantically rich format that can be easily processed and interpreted by machines. This overcomes the limitations of existing data formats and promotes greater interoperability and reuse of OGD. Secondly, the approach provides an integrated representation of OGD that allows users to view all published data in a unified and complete manner. By utilizing knowledge graphs to integrate data from multiple OGD sources, the proposed approach facilitates data discovery and analysis and enables the identification of previously unseen patterns and relationships across diverse datasets.

When compared to related works, the proposed approach offers significant contributions. Firstly, it addresses the challenge of integrating diverse data sources with structured, semi-structured, or unstructured formats. The approach automates the process of semantically transforming datasets, which can be time-consuming and error-prone when done manually. This is achieved by utilizing learning mechanisms and mapping languages. Furthermore, the proposed approach is domain-independent and presents a generic solution to integrate heterogeneous datasets. It accomplishes this through a schema alignment and entity alignment approach, which is designed to handle all types of entities without the need for human intervention to specify linking rules.

IV. Use Case Study

In this section, we present a use case that implements the proposed architecture and demonstrates its operationalization. The use case focuses on the public procurement domain, which is a critical government sector for ensuring transparency and accountability in government spending.

A. Context

Public procurement is a significant part of government spending, but it is also a domain prone to corruption and fraud [26] [27] [29]. Public Procurement (PP) is a distinct area within Open Government Data (OGD) that plays a critical role in ensuring transparency and accountability in government spending. By releasing public procurement data as open and accessible, governments and civil society organizations can promote fair competition, identify patterns of corruption and fraud, and hold public officials accountable.

The use case aims to implement the proposed architecture in the context of public procurement in France. By integrating public procurement data from several open government data sources into a knowledge graph, we can apply anomaly detection algorithms to identify instances of fraud such as favoritism and overpricing. Favoritism in public procurement [28] refers to the practice of giving preferential treatment to a particular supplier, contractor, or bidder. Overpricing [29], on the other hand, refers to the practice of charging prices that are higher than what would be considered reasonable or fair.

B. Data Sources

In the French context, there exists a multitude of public procurement data sources, but for our specific purposes, we have opted to primarily utilize three sources: the BOAMP, Essential Data on Public Procurement (DECP), and the SIRET database (Cf. Table I).

[1]BOAMP is a French government platform that publishes public procurement notices and announcements, as well as detailed information about awarded contracts. The platform also provides an API that allows users to retrieve data in both JSON and XML formats

[1] https://www.boamp.fr/

Essential Data on Public Procurement (DECP) is a database that features structured and standardized information regarding all public procurement procedures. This expansive dataset includes details such as the contracting authority's name and location, the type and value of the contract, and the selected supplier. These data are consolidated in the French open government data portal[2].

The SIRENE[3] the database is a comprehensive registry of all business entities operating in France, providing information regarding each entity's legal status, activity sector, and location. By leveraging SIRENE data, we can identify the entities involved in public procurement procedures and establish links with other pertinent datasets.

TABLE I. PUBLIC PROCUREMENT DATA SOURCES

Data sources	Publisher	Format	Frequency of update
BOAMP	Direction of Legal and Administrative Information (DILA).	XML,JSON	Daily
Essential Data on Public Procurement (DECP)	The Ministry of the Economy, Finance, and Industrial and Digital Sovereignty	XML , JSON	Monthly
SIRENE Database	French National Institute of Statistics and Economic Studies (INSEE)	CSV	Quartly

By integrating and linking these various data sources in a knowledge graph, we can create a comprehensive and well-organized representation of public procurement data. To achieve this, we need to implement a domain ontology that captures and formalizes knowledge relevant to the field of public procurement

C. Ontology Development

Developing a domain ontology is a requirement for constructing the knowledge graph as it plays a role in the semantic enrichment of government data sources. To this end, we constructed a domain ontology for the public procurement domain by reusing the PCO ontology [30].

The PCO ontology, known as the Public Contracts Ontology, is a domain-specific ontology that models the essential concepts and relationships within the public procurement domain. Its primary objective is to support the integration and analysis of public procurement data from various sources. The ontology encompasses a broad range of concepts and relationships that apply to public procurement, such as procurement notices, contracts, suppliers, products and services, and tendering procedures. Additionally, it includes concepts linked to the legal and regulatory frameworks that oversee public procurement, such as procurement rules and regulations, procurement authorities, and procurement methods.

For the implementation, we have customized the PCO ontology to match the French context. This involved correlating the concepts and relationships in the ontology with the appropriate terms and structures in the French public procurement domain. This adaptation (Fig. 4) ensures that the constructed knowledge graph represents the relevant aspects of the French public procurement domain accurately and is tailored to our use case's particular needs.

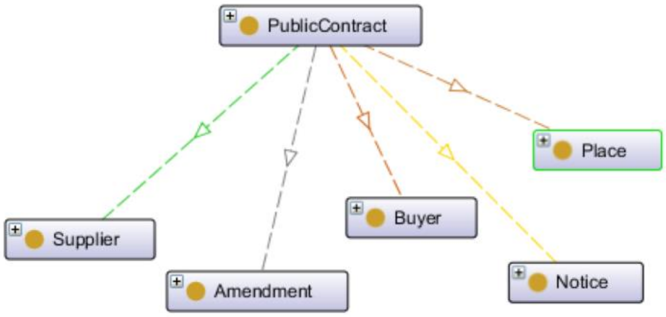

Fig. 4. Public procurement domain ontology implemented in protégé tool

D. Knowledge Graph Construction

The initial step in constructing the knowledge graph involved collecting data from identified data sources. We automated the data collection process by developing data collection scripts using Python and leveraging APIs. We utilized various APIs, such as the BOAMP API, and the API offered by the French government data portal, to collect structured data in different formats, including XML, JSON, and CSV. Fig. 5 shows an example of the collected data.

b-Example of a dataset collected using the French data portal API

Fig. 5. Example of the collected data.

As the collected data was already structured, no further data extraction was required. Our data collection approach allowed us to retrieve data efficiently and accurately while reducing the resources needed for manual data collection. This enabled us to collect a significant amount of data related to public contracts from 2019 to 2022.

After collecting the data, we utilized Karma, an open-source tool, for semantic transformation. Karma[4] is a semi-automatic tool that implements the approach proposed by [22] for dataset transformation, enabling the definition of mappings from datasets to ontologies, building of semantic models, and publishing of data as RDF. With Karma's machine learning capability, it can learn to map datasets to an ontology by using the attribute values of mapped dataset attributes. When users define relationships between classes, Karma learns from them and can suggest properties and classes to model new sources automatically. Karma's validation feature allows users to verify the proposed model's quality, and it also supports the generation of RML mapping, which automates the RDF graph-based representation of the datasets. Incorporating the PCO ontology in the semantic transformation process enriched the RDF graph output for each collected dataset, representing relationships between data elements, entities, and concepts for constructing the knowledge graph. As a first step in the integration process, all datasets were aligned to the same schema, which was the PCO ontology.

The resulting RDF graphs were combined to form the knowledge graph. We further employed entity linking as a means of completing the integration process. We used the OWL: has key and OWL: Sameas axioms to identify unique discriminative properties for entities in the domain ontology and to link co-referent entities, respectively. For example, we used the SIRET identifier to link unique enterprises as suppliers and the SIREN identifier to link public organizations as public buyers.

Through the use of entity linking, we were able to more effectively integrate data from multiple sources into the knowledge graph, providing a unified and integrated view of data.

The data was stored in an RDF triple store using the Apache Jena framework[5] and made available through Apache Jena Fuseki. This allowed users to query the knowledge graph using the SPARQL query language and retrieve relevant information from the integrated datasets. In total, the knowledge graph consolidated data related to 96,845 public contracts.

E. Knowledge Graph Consumption

To demonstrate the value of our approach, we conducted an analysis using the isolation forest algorithm on integrated public procurement data in our knowledge graph. The isolation forest algorithm is a powerful machine learning tool well-suited to detecting anomalies in datasets. It works by creating a random forest of decision trees and isolating data points that are not consistent with the majority of the data. In the case of public procurement data, the isolation forest algorithm can be used to identify anomalies that may indicate corruption or fraud.

In our study, we used a SPARQL query to extract data from the knowledge graph and applied the isolation forest algorithm to our integrated public procurement data. We found a total of 56 anomalies in the dataset, which were categorized as either favoritism or overpricing. The algorithm identified 27 cases of favoritism and 29 cases of overpricing.

We qualitatively assessed the algorithm results and found that the contracts identified as anomalies were consistently awarded to the same suppliers, indicating a potential case of favoritism. Additionally, we observed that the contract prices for these anomalies were significantly higher than the market price or previous prices for similar contracts, indicating a potential case of overpricing.

The results of this case study demonstrate the value of the proposed approach, which proposes to consolidate data from multiple sources into a single knowledge graph and represent it in a format that promotes analysis and processing for value extraction. By utilizing a knowledge graph and the isolation forest algorithm, we were able to identify potential anomalies that may have gone undetected using a traditional approach.

[4] https://usc-isi-i2.github.io/karma/

[5] https://jena.apache.org/

This can help auditors better understand procurement data, detect potential fraud or corruption, and ultimately promote a more transparent and accountable government.

V. CONCLUSION

In this paper, we introduce an approach for extracting value from open government data and transforming it into valuable knowledge. Our approach utilizes a layered architecture to extract and collect structured and unstructured data sources, transform them into a machine-processable, understandable, and semantically rich format, and integrate them into a knowledge graph. The proposed approach offers an efficient and generic way to construct the graph, which can be further utilized for a plethora of applications. The approach was implemented in the context of public procurement and successfully identified anomalies such as overpricing and favoritism. Although the paper is focused on public procurement, the proposed approach applies to other governmental domains. As a future direction, we aim to propose a detailed description of how to exploit the knowledge graph, to further improve the effectiveness of the proposed approach.

***Abstract*—Towards detecting an anomaly in brain images, different approaches are discussed in the literature. Features like white mass values and shape features have identified the presence of brain tumors. Various deep learning models like the neural network has been adapted to the problem tumor detection and suffers to meet maximum accuracy in detecting brain tumor. An Adaptive Feature Centric Distribution Similarity Based Anomaly Detection Model with Convolution Neural Network (AFCD-CNN) is sketched towards disease prediction problem to handle the problem. The model considers black-and-white mass features with the distribution of features. First, the method applies the Multi-Hop Neighbor Analysis (MHNA) algorithm in normalizing the brain image. Further, the process uses the Adaptive Mass Determined Segmentation (AMDS) algorithm, which groups the pixels of MRI according to the white and black mass values. The method extracts the ROI with the segmented image and convolves the features with CNN at the training phase. The CNN is designed to convolve the features into one dimension. The output layer neurons are designed to estimate different Feature Distribution Similarity (FDS) values against various features to compute the Anomaly Class Weight (ACW). According to the ACW value, anomaly detection is performed with higher accuracy up to 97% where the time complexity is reduced up to 32 seconds.**

***Keywords*—Deep learning; brian tumor; disease prediction; anomaly detection; CNN; FDS; ACW**

I. Introduction

The entry of modern diseases challenges human society. There are several diseases identified every year which have a significant impact on human life. Some of the diseases produce temporary illnesses, and some of them introduce permanent damage to the human. More than that, some diseases are claiming the lives of humans. The brain tumor is among them, producing permanent illness and is identified as a more challenging one. Whatever the disease, diagnosing the disease at the earliest would support the person in increasing survival. Analyzing the disease at the earliest would help the medical practitioner effectively treat the person.

Brain tumor analysis has been identified as a complicated task in the medical sector where such a disease would claim a person's life. Various detection models are available, and MRI images become the source of finding the disease, which must be passed through several stages to extract the features. For example, the classification system would use texture, mass values, shape, and binary features in classifying the brain image. Also, several methods include Support Vector Machine (SVM), Decision Tree, Ensemble learning, Genetic algorithms, and Neural networks. The methods differ regarding features being considered and the similar way being used.

Deep learning is the modern development of machine learning models which helps automated decisive support systems in handling huge volume of data towards solid support. Convolution neural network has been identified as more effective than the other deep learning models. The CNN has been designed with layers like the convolution layer, which involves convolving the ROI features into a single dimension. Such dimensionality reduction and feature retention support handling massive volumes of MRI images to support the process of image classification. The brain image classification is done according to the texture features and other features obtained from the ROI. The accuracy can be significantly improved by having a massive volume of samples.

An Adaptive Feature Centric Distribution Similarity Based Anomaly Detection Model is detailed to improve the performance, focusing on including multiple brain image features and their distribution metrics in finding the image class. A Multi-Hop Neighbor Analysis (MHNA) algorithm is discussed to normalize the brain image. Also, Adaptive Mass Determined Segmentation (AMDS) algorithm is adapted toward segmenting the regions of the brain image. Similarly, a convolution neural network with two convolution and pooling layers is designed.

The article is structured to present the introduction of brain tumor detection and anomaly detection in detail with disease prediction at Section I. Section II, discusses the complete related work and methods available in literature in detail. Section III discusses the complete working of the proposed anomaly detection and disease prediction system. Section IV details the experimental results and presents a detailed discussion. Finally, conclusion about the entire work is presented in Section V while future area of research is presented in Section VI.

II. RELATED WORKS

The problem of brain image classification has been discussed in various articles, and a subset of methods is discussed in this section.

A CNN-based model is presented in [1], which preprocess the brain images and extracts the features to train CNN. The method uses a T1 weighted image, enhancing the contrast of MRI images to support the classification. Further, a Deep CNN model is sketched in [2] to predict the status of gliomas. The method generates various mutations of the features and based on that, the classification is performed. A modified version of DCNN is discussed in [3], which focuses on adjusting the feature weights at various layers by removing the fully connected layers. A metastases segmentation model with CNN is presented in [4] to support brain image classification. The model segments the images to obtain the metastases and trains the CNN for efficient classification.

In [5], a transfer learning model named GoogleNet is presented for classifying various classes of tumors. The model extracts the features using a pre-trained CNN model and performs classification using algorithms like SVM, KNN, and softmax. A detailed analysis of various CNN models is sketched in [6], which considers the models like S-CNN (CNN trained from scratch). The method uses two brain image data sets to analyze the performance of various approaches.

An ADAM optimizer model is sketched in [7] for brain image classification, which uses different pre-trained models like Xception, NasNet Large, DenseNet121, and InceptionResNetV2 to extract the features. The features extracted are used to train the CNN model with an ADAM optimizer to perform classification. A cumulative variance-based feature selection approach is presented in [8] to classify various grades of malignant brain tumors. The method extracts the features, selects optimal features using CVM (Cumulative Variance Method), and classifies using KNN, NN, and multiclass SVM.

To support automatic diagnosing and help the medical practitioner, an integrated model is presented in [9], which extracts the features using CNN from MRI images. Extracted features are classified using LSTM (Long Short Term Memory) model. A novel classification model is presented in [10], which uses multi-view DNN to perform segmentation, and segmented features are fused with the dynamic fusion method. Segmented results are used to analyze the performance of segmentation.

A transfer learning-based deep learning model is presented in [11], which classifies the tumor according to the features extracted and compares it with the performance of others. An efficient brain tumor segmentation model is presented in [12], which uses the correlation among the features. The correlation model transformed the features and was used to perform classification. A deep convolution neural network-based model is presented in [12], which fine-tunes the layers to perform classification with higher accuracy. A Gaussian convolution neural network-based model is sketched in [13] for brain image classification. The model is designed to classify pituitary, glioma, and meningioma tumors.

A time-distributed CNN LSTM (TD-CNN-LSTM) scheme is discussed in [14], which extracts the features from time-dependent images using CNN. The classification is performed using LSTM. A DCNN model with Feature SVMnamed ((DCNN-F-SVM) is sketched in [15], which trains features and fuses the network to perform classification with SVM. A dilated 3D CNN model is illustrated in [16], which uses feature maps as the key to classification. A U-Net-based CNN model is discussed in [17], which uses U-Net for segmentation and performs classification with the 3D-CNN model. In [18], the author presents a detailed review and identifies the several challenges in classifying brain images into various classes. A forgery detection model is sketched in [19], which uses a propagation-based scheme in organizing the fingerprint image. A PCA-based classification model is sketched in [20], which classifies the finger quickly. A face recognition model is sketched in [21], which considers contour features in classification.

The methods analyzed in this section are subject to producing poor accuracy in classifying the brain images against different classes considered.

III. ADAPTIVE FEATURE-CENTRIC DISTRIBUTION SIMILARITY-BASED ANOMALY DETECTION WITH CNN MODEL (AFCD-CNN)

The proposed model (see Fig. 1) reads the brain image MRI data set and considers black-and-white mass features with the distribution of elements. The Multi-Hop Neighbor Analysis (MHNA) algorithm is initially applied to normalize the brain image and remove the noise from the image. Further, the method uses Adaptive Mass Determined Segmentation (AMDS) algorithm to group similar pixels of brain images to support feature extraction. Once the segmentation is done, the process extracts the ROI and the features passed through CNN to train the network. The CNN design convolves the elements into one dimension. The output layer neurons are subject to measuring Feature Distribution Similarity (FDS) values against various features to compute the Anomaly Class Weight (ACW). According to the ACW value, the classification is done.

Fig. 1. Architecture of proposed AFCD-CNN anomaly detection model.

The proposed brain tumor detection model reads the brat's image data set and applies MHNA preprocessing and AMDS segmentation to extract the features. Extracted are trained to a convolution neural network with two convolution layers and pooling layers to compute weight measures for anomaly detection.

A. *MHNA Preprocessing*

The brain image considered has been read towards improving the quality of the image. To perform normalization, the method initializes a window size x, which covers K hops for any pixel. The window is further divided into four regions, and the standard deviation value is measured at each region. Second, a region with the least standard deviation of pixels is identified and selected. Selected region pixels are used in estimating the mean standard value (MSV), and based on that, and the method adjusts the pixel value to normalize the pixel. This will be iterated for the k number of iterations, which denotes the hops. Such normalized image has been used to perform segmentation.

TABLE I. SAMPLE WINDOW

112	135	132	124	75
128	148	72	32	87
136	147	**58**	67	77
121	139	42	51	69
119	122	136	145	55

TABLE II. WINDOW WITH ONE NEIGHBOR

148	72	32
147	**58**	67
139	42	51

TABLE III. WINDOW WITH 2 NEIGHBORS

112	135	132	124	75
128	148	72	32	87
136	147	**58**	67	77
121	139	42	51	69
119	122	136	145	55

The example window considered for the problem is given in Table I and a sub section from the Table I with single neighbor is shown in Table II and a window with two neighbors is shown in Table III. According to Table I considered, the proposed MHNA preprocessing algorithm computes the standard deviation value with four different region pixels as follows:

Standard deviation {112,135,132,128,148,72,136,147,58 } among the region one values are computed. Similarly, the same has been measured for other region pixel values according to the center pixel marked. Now according to the standard deviation value, a single region with the least value is selected. For the selected region, the mean standard value is measured, and based on that, the method computes the new value for the concerned pixel.

```
Algorithm:

Given: Brain Image Bmg
Obtain: Normalized Image Nmg.
Start
    Read Bmg.
    Initialize window size w.
    Initialize neighbor k.
    For each pixel
        W= Construct K hop window.
        Crop image feature as Cm = Crop (Bmg,w,k)
        For each region R
            Compute standard deviation Rstd $= \overset{size(Rs)}{\underset{i=1}{}} Std(R)$
        End
        Region R = $\overset{size(Rs)}{\underset{i=1}{Max}}(Rs(i).Rstd)$
        Compute Mean standard Ms = $\frac{\sum_{i=1}^{Size(R)} Dist(p,R(i))}{size(R-1)}$
        Nmg(p) = p+($\frac{3}{8} \times Ms$)
    End
Stop
```

The MHNA preprocessing algorithm computes any pixel's mean standard value according to the selected region. Based on the value measured, the method normalizes the pixels to perform normalization. The normalized image has been used to perform segmentation and classification.

B. Adaptive Mass Determined Segmentation

The brain image obtained from preprocessing has been used for segmentation. The adaptive mass-determined segmentation algorithm uses two different mass values in grouping the tumor's pixels and other brain cells. To perform this, the method traverses through the entire image and finds the set of black mass values and white mass values. The method computes the boundary between the sets using these white and black mass values. Based on the identified boundary, the method groups the pixels under two classes to produce the segmented image.

```
Algorithm:

Given: Brain Image Pimg
Obtained: Segmented Image Simg
Start
    Read Pimg.
    Initialize black mass set Bms, white mass set Wms.
    For each pixel p
        If p.value<100 then
            If p.value ! ∈ $Bms,$ then
                Bms = Bms∪ $p.value$
            End
        Else
            If p.value ! ∈ $wms$ then
                wms = wms∪ $p.value$
            End
        End
    End
    Identify boundary set Bs = $\overset{size(wms)}{\underset{i=(size(Wms)-5)}{Bs \cup}} wms(size(wms)-i)$
    For each pixel p
        If p.value∈ $Bs$ then
            Simg(p) = 256
        Else
            Simg(p) = 0
        End
    End
Stop
```

The segmentation algorithm finds the black-and-white mass values in the image. According to the different sets identified, the method detects the most optimal sets for grouping the pixels under two classes and produces a segmentation image.

C. CNN Training

The method reads the Brats image data set and applies MHNA preprocessing on each of them. The method applies an adaptive mass determination segmentation algorithm with the preprocessed image. The result of segmentation is used to extract the tumor's texture and computes black-and-white mass distribution values. All these features extracted are used to train the neural network. The CNN has been designed with an input layer to take the features and have two different convolution layers where the features are convolved into single-dimensional features. The max pooling layers help to shape the features and pad the features. Finally, the network is designed with a fully connected layer to support classification.

The texture obtained from the image has been split into four regions. According to the areas identified, the method would compute the gray mean value, which produces the following result.

TABLE IV. FEATURE OBTAINED FROM THE TEXTURE

R1	R2	R3	R4
167	185	175	169

Table IV shows the features obtained from the texture extracted from the brain image. Similarly, the method extracts the white and black mass distribution values to form the feature vector as follows:

TABLE V. EXAMPLE FEATURE VECTOR

R1	R2	R3	R4	WMD	BMD
167	185	175	169	76	45

Table V shows the example feature vector produced by the proposed model. The value of WMD is measured as follows:

$$\text{Wmd} = \frac{\sum_{i=1}^{size(T)} T(i)>180}{size(T)}$$

Similarly, the value of BMD is measured as follows:

$$\text{Bmd} = \frac{\sum_{i=1}^{size(T)} T(i)<100}{size(T)}$$

Accordingly, generated feature vector has been used to train the CNN. At the first convolution, the method computes the gray mean values at each region to produce four values, whereas in the second convolution; the method computes the average among the four values to produce a single value, reducing the feature vector size to three. Such feature vector has been used to compute the similarity measure at the test phase.

D. FDS Classification

The proposed model classifies the brain image according to the feature distributional similarity measured against image features. The method applies MHNA preprocessing, eradicating the image noise to perform this. Further, AMDS segmentation is applied to group the pixels of various features. From the segmented image, ROI has been extracted and estimates white and black mass distribution values. Such features extracted are passed through the CNN trained, where the features are convolved in two-stage and apply max pooling. The convolved features are obtained at the output layer, and the method computes the FDS values towards various features like texture, white mass, and black mass values. Using these values, the method computes the similarity value to compute anomaly class weight (ACW). According to the ACW value, the method performs classification.

```
Algorithm:
Given: Brain Image Bmg, CNN Tcn
Obtain: Class C
Start
        Read Bmg, Tcn.
        Pmg = MHNA-Preprocessing (Bmg)
        Smg = AMDS-Segmentation (Pmg)
        Wmd = compute White mass distribution.
        Bmd = Compute Black Mass distribution.
        Texture T = Extract tumor feature.
        Feature vector fv = {T, Wmd, Bmd }.
        Pass through CNN.
        Convolve Fv at stage 1.
        Perform max pooling.
        Perform stage 2 convolution.
        Perform max pooling.
        For each class a

        Compute Texture Distribution similarity TDS.
                $TDS = \frac{\overset{size(C)}{\underset{i=1}{Dist(C(i).T.value,T.value)}}}{size(C)}$
        Compute white mass distribution similarity Wds.
                $WDs = \frac{\overset{size(C)}{\underset{i=1}{Dist(C(i).wmd,T.wmd)}}}{size(C)}$
        Compute black mass distribution similarity Bds.
                $BDs = \frac{\overset{size(C)}{\underset{i=1}{Dist(C(i).bmd,T.bmd)}}}{size(C)}$
                Compute ACW = $\frac{Wds}{Bds} \times Tds$
        End
        Class C = choose the class with maximum ACW.
Stop
```

The proposed approach performs classification by computing ACW value for the sample towards various classes of brain tumors. Finally, a single class is selected according to ACW.

IV. RESULTS AND DISCUSSION

The proposed AFDS-CNN-based anomaly detection on brain images is enforced, and the performance of the model is measured against various classes with different constraints. The results achieved in each test case are discussed in this part. The method uses the Brats data set for performance evaluation.

TABLE VI. EVALUATION DETAILS

Factor	Value
Data Source	Brats 2019
Total Images	3000
No of Image Class	3
Platform	Python

Table VI denotes the constraints used in evaluating the performance of the models where the data set has three tumor classes, and the performance is measured on various factors.

TABLE VII. RESULTS OF CLASSIFICATION

Sl. No	Sample	Binarized Output	Label
1			Malignant
2			Benign
3			Benign
4			Malignant

The classification result produced for different brain images is plotted in Table VII, which has been used in measuring the accuracy of the method toward classification.

TABLE VIII. ANALYSIS OF CLASSIFICATION ACCURACY

Classification Accuracy in % vs. No of Samples			
	1000 samples	2000 samples	3000 samples
ADAM	74	78	82
TD-CNN-LSTM	77	81	86
3D-CNN	80	84	89
AFDS-CNN	85	91	97

The performance of methods in classification accuracy is analyzed in Table VIII, where the AFDS-CNN approach achieved higher classification accuracy in all the test cases.

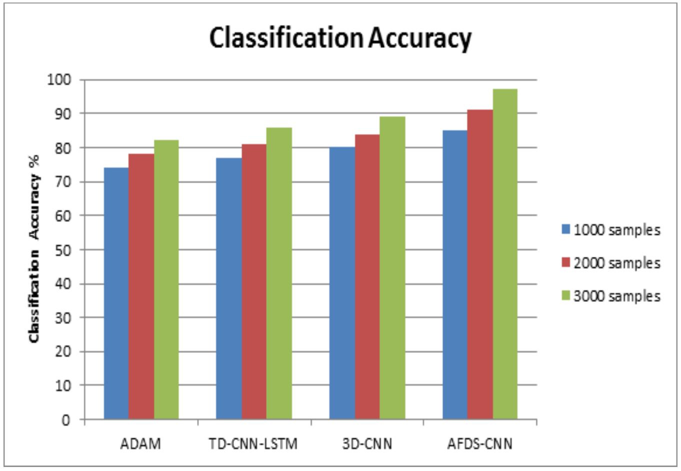

Fig. 2. Performance on classification accuracy.

The classification accuracy produced by different schemes is compared in Fig. 2, where AFDS-CNN achieved higher accuracy in all cases.

TABLE IX. ANALYSIS OF FALSE CLASSIFICATION RATIO

False Ratio in Classification % vs. No of Samples			
	1000 samples	2000 samples	3000 samples
ADAM	26	22	18
TD-CNN-LSTM	23	19	14
3D-CNN	20	16	11
AFDS-CNN	15	9	3

The false ratio introduced in brain image classification is measured and plotted in Table IX. The AFDS-CNN model achieves less false classification ratio compared to others.

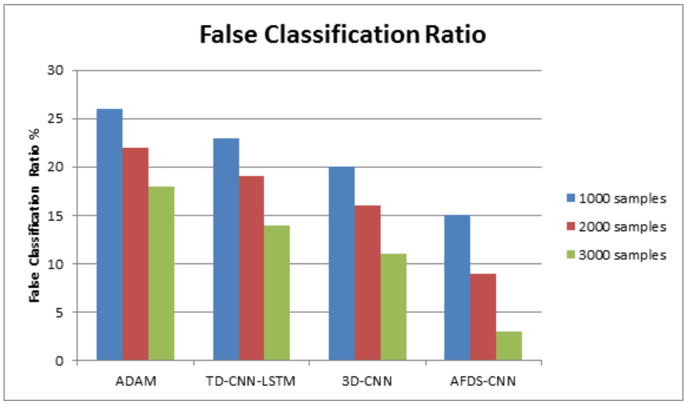

Fig. 3. Performance on false classification ratio.

The ratio of false classification is measured for different approaches according to the number of samples in the data set in Fig. 3. In each class, and the proposed AFDS-CNN has produced less false ratio than others.

TABLE X. ANALYSIS OF TIME COMPLEXITY

Time Complexity in Classification Seconds vs. No of Samples			
	1000	2000	3000
ADAM	54	61	86
TD-CNN-LSTM	43	52	77
3D-CNN	39	46	71
AFDS-CNN	21	27	32

The time complexity in classifying the images is measured and plotted in Table X. The RBP-CNN model produces little time complexity.

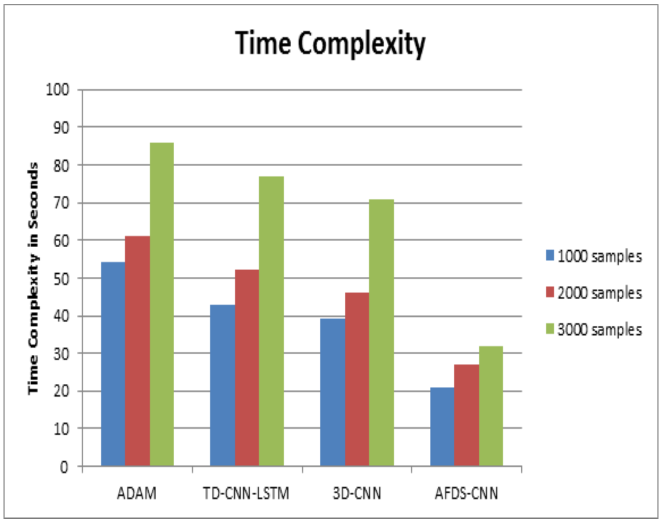

Fig. 4. Time complexity.

The time complexity in classifying the images is measured according to the total time taken for classifying the given image and plotted in Fig. 4. The RBP-CNN model produces negligible time complexity.

V. CONCLUSION

This paper presented a novel adaptive feature distribution similarity-based brain image classification with a convolution neural network (AFDS-CNN). The model applies MHNA preprocessing algorithm to the brain images to normalize the image features. Further, the method applies an adaptive mass discrimination segmentation algorithm to segment the images. With the segmented images, the method extracts texture, white mass distribution, and black mass distribution values. Extracted features are convolved with the CNN designed with different convolution and max pooling layers. At the test phase, the features extracted are used to compute texture distribution similarity (TDS), White mass Distribution Similarity (WDS), and Black mass distribution similarity (BDS) to compute the value of Anomaly class weight (ACW). Based on the value of ACW, the method performs classification and produces an accuracy of up to 98.6% with a reduced complexity of 21 seconds

VI. FUTURE WORK

The problem of brain tumor detection and disease prediction can be further improved by adapting time variant directional and distribution growth of tumor cells in classifying the brain image.

An Algorithm Transform DNA Sequences to Improve Accuracy in Similarity Search

Hoang Do Thanh Tung, Phuong Vuong Quang
Institute of Information Technology, Vietnam Academy of Science and Technology, HaNoi, Viet Nam

***Abstract*—Similarity search of DNA sequences is a fundamental problem in the bioinformatics, serving as the basis for many other problems. In this, the calculation of the similarity value between sequences is the most important, with the Edit distance (ED) commonly used due to its high accuracy, but slow speed. With the advantage of transforming the original DNA sequences into numerical vector form that retaining unique features based on properties. The calculation processing on these transformed data will be much faster, many times faster than a direct comparison on the original sequence. Additionally, from a long DNA sequence, after transformation, it typically has a lower storage capacity, making it have good data compression. The challenge of this job is to develop algorithms based on features that maintain biological significance while ensuring search accuracy, which is also the problem to be solved. Previous methods often used pure mathematical statistics such as frequency statistics and matrix transformations to construct features. In this paper, an improved algorithm is proposed based on both biological significances and mathematical statistics to transforming gene data into numerical vectors for ease of storage and to improve accuracy in similarity search between DNA sequences. Based on the experimental results, the new algorithm improves the accuracy of similarity calculations while maintaining good performance.**

***Keywords*—Similarity search; data transformation; DNA sequence; big data**

I. Introduction

Bioinformatics is an interdisciplinary field that develops software methods and tools for understanding biological data, especially when the data sets are large and complex. It combines technologies of applied mathematics, statistics, computer science, biology, chemistry, physics… and biological mathematics. The term bioinformatics is a part of computational biology, and the combination of these sciences is intertwined and mutual. Thus, the research results in this field not only contribute to biology, but also to other fields. Biological data contains gene sequences (DNA - Deoxyribonucleic Acid) and briefly describes which is made up of four nucleotides: A, C, T and G. DNA is a crucial molecule for all living things, not just humans. The application of DNA in science and daily life is diverse and significant, such as crossbreeding, genetic mutation, comparison of species, prediction of phylogenetics, pedigree, genetic diseases, predict disease risk, etc. The fundamental problem in bioinformatics related to DNA sequence processing is similarity search, which is finding subsequences that are the same or similar to a sequence of interest. This leads to further problems such as calculating the similarity value between sequences to draw a phylogenetic tree and sequence alignment to achieve maximum similarity between sequences. These problems are manageable on small and medium data but become complex with big data.

In similarity search, the commonly used method to calculate similarity value between two sequences is Edit Distance (ED) (also known as Levenshtein). The *ED* similarity value between two sequences is the minimum number of steps required to transform one sequence to other, based on three transformations: adding, editing, and deleting each character in the sequence [1]. For example, similarity value between LOVE and MOVIE is ED(LOVE, MOVIE) = 2 because two steps of LOVE → **M**OVE → MOV**I**E are needed. The advantage of this method is can compare sequences of different lengths, thereby flexibly being applied in many problems. However, its computational complexity is *O(n*m)* where *m*, *n* are the lengths of two sequences being compared. With long data, the results take a long time to obtain, making comparisons in long sequences less efficient. Due to the rapid advancements in technology, biological databases generate vast amounts of information and are continuously growing, resulting in a rapid increase in their size.

The large size of the data leads to a high number of I/O operations, resulting in a high cost of storage space and decreased processing performance. To address this issue, researchers are exploring various methods to index or transform the gene data into numerical form to reduce database access and improve query performance. One of the challenges in this field is to develop algorithms for transforming the sequence in a way that retains the biological significance of the data while reducing its size. Previous methods often utilized simple mathematical statistics, such as frequency statistics or matrix transformations, to build features. In this study, an improved algorithm is proposed that not only takes into account frequency, position appearance, and correlation between position and distance of the characters but also considers the biological significance of the sequence, based on the role and function of amino acids in proteins. This approach helps to retain as many features of the sequence as possible, leading to improved accuracy when searching for similarity between two sequences.

The rest of the paper is organized as follows, Section II will present the related work to the research, Section III presents the proposed improved algorithm, Section IV presents the experimental results of the algorithm proposal, and Section V is the conclusion.

II. Related Work

A lot of research has been carried out to calculate similarity between sequences. Through the survey, a number of published methods were found. Some typical algorithms such as: Smith - Waterman [2] and BLAST [3] are well-known algorithms for performing sequence comparisons through representative sequences. This group of algorithms has high accuracy, but limitation is inefficient when size of database is too large or continuously added. Many other algorithms, improved from the famous BLAST algorithm, also allow performing calculations quickly such as Flash algorithm [4], ProperSearch tool [5], CAFE method [6]. BIS (Bitmap indexing structure) [7], IDC (Incrementally Decreasing Cover) [8], FRESCO (Framework for REferential Sequence Compresion) [9], Modified HuffBit Compress Algorithm [10]. These algorithms perform and compression search by interfering with data structures such as matrix analysis, genomic statistics, frequency changes, etc. In addition, Metric space indexing techniques [4], Williams & Zobel [11] and Ozturk and Ferhatosmanoglu [12] are indexing methods that use special transformations that convert the input DNA sequence into numerical vectors based on features. The objective of these methods is to find the most effective features to generate the vectors, so as to preserve the biological information of the original sequence and perform efficient similarity searches. Studies by Kahveci and Singh [13], Yongkun Li et al [14] have found that using frequency and position-distance characteristics resulted in better performance compared to other features.

The *Hfwd*^{2} method [1] is a technique that partitions a long DNA sequence into smaller subsequences using a window length, and then transforms these windows into numerical vectors that represent the frequency of appearance of the characters (A, C, T, G) as well as their combinations (N-grams). To enhance the features stored in the vector, this method also incorporates the position of each character in the sequence. To address the issue of uneven distribution of characters in the DNA sequence, the authors divide the sequence into two equal parts and generate the vectors based on these two parts to ensure that the comparison is more equal. While this method results in a lower accuracy compared to direct comparison due to the noise introduced during the transformation process, it offers a significant improvement in performance and speed during similarity searches. However, *Hfwd*^{2} has a few limitations, such as the use of a simple positional parameter, and the lack of consideration for the biological significance of the characters in the sequence. Below, we propose an improved algorithm from *Hfwd*^{2}, in which numerical vectors transformation is not only built with features based on frequency, position appearance, correlation between position and distance way of characters, but also interested in the biological significance of sequences based on amino acids, applied on wavelet transform to increase features stored after transformation. Theoretically, it is expected to improve accuracy of calculating similarity value between sequences.

Current methods are still continuing to research solutions to improve accuracy of similarity search with transformation vectors. In this paper, we propose an improved algorithm for transforming gene sequences into numerical vectors. This algorithm considers not only mathematical statistics such as frequency and position appearance, but also the biological significance of amino acids in the sequences. By doing so, we aim to maintain as much information as possible from the original sequence while improving the accuracy of similarity searches.

III. Proposed Method

The transformation of original sequences into numerical vectors has been discussed in the above sections. This approach can optimize storage in databases and increase computational performance. The challenge is to preserve the biological meaning of the sequences in the numerical vectors after transformation, in order to maintain search accuracy. To address this, we propose an improved algorithm compared to *Hfwd*^{2}. This new algorithm considers not just the frequency, position appearance, and correlation between position and distance of characters, but also the biological significance of the sequences based on amino acids. Additionally, the use of wavelet transform increases the amount of information stored in the numerical vectors. Theoretically, it is expected to improve accuracy of calculating similarity value between sequences.

In the pre-processing stage, we also partitioned the DNA sequences into equal length windows and transform each partition into numerical vectors using the feature parameters we have proposed. These vectors are then stored in a centralized database for later retrieval. When a new sequence needs to be compared for similarity, it will undergo the same pre-processing step and then be compared with the vectors in the database. The resulting set of similarities will be outputted. The general process of the method is shown in Fig. 1.

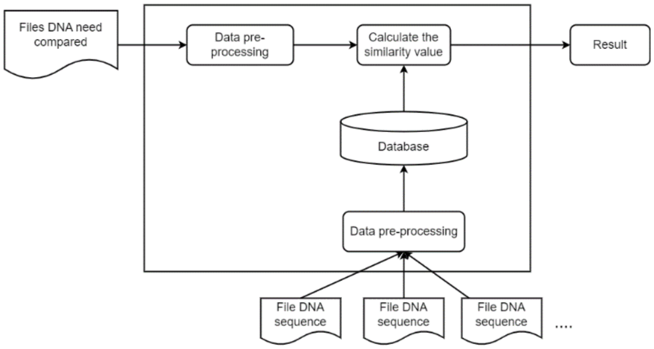

Fig. 1. General process of the method.

Files containing DNA sequences after being collected will be sent to the data pre-processing module. The system will remove any characters that are not A, C, T, G from the sequence, and partitioned the original sequence into equal length windows. The length of these windows can be adjusted to meet the user's needs, and we will explore the optimal range for best results in the experimental section. These operations can be easily performed using support functions from the C# language's String library. Finally, the partitions are subjected to transformation algorithms to generate multidimensional numerical vectors.

These vectors will be indexed so that when making comparisons based on similarity, they will be much faster than the original sequence. The pre-processing model is depicted in Fig. 2.

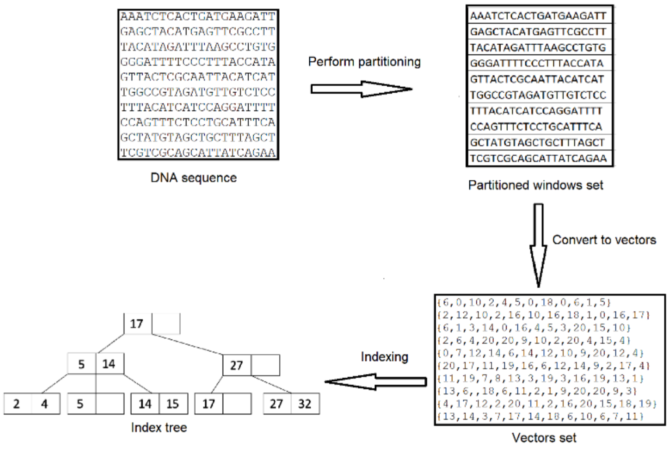

Fig. 2. Data pre-processing and indexing model.

A. Algorithms Feature Extraction for DNA Sequence Transformation

Just like feature extraction in natural language processing, the goal of this step is to show how to transform text data into vectors with numerical values. This is often the most important step that determines whether the final approach is successful for a real problem [15]. Here, we will present a proposal of four features that can be used to generate a numerical vector from the input DNA sequence. These features help to capture important information about the DNA sequence for perform similarity calculation.

Given the sequence S = {s_0, s_1, s_2, ..., s_{l-1}} where *l* is the length of the S, the algorithms to build feature of the sequence S are as follows:

1) Algorithm transform based on combinatoric: Let ω = {a_1, a_2, ..., a_α} where N-grams is the combination of characters built in the sequence S, α is length of the combination of characters. The DNA sequence S will only includes four nucleotides A, C, G, T, so when choosing N=1 we have the combination ω = {A, C, G, T}, when N=2 the combination ω = { AA, AC, AG, AT, TA, TC, TG, TT, GA, GC, GG, GT, TA, TC, TG, TT}, and so on. The larger N gets, the combination grows exponentially. Each element in the ω combination may or may not appear in the original sequence S, and may appear in different positions, which creates unique characteristics for each DNA sequence. This algorithm adds a parameter to calculate the correlation between position and distance compared to Hfwd[2]. The purpose is to store the parameters of frequency, position, and correlation between position and distance of characters that appear in the sequence, and use them as unique features of each sequence to calculate the similarity value later.

a) Frequency appearance

$$\mathrm{W}_{x\alpha} = \begin{cases} 1, x_\alpha = s_i \\ 0, x_\alpha <> s_i \end{cases} \tag{1}$$

Where i = 1,2…, l; $x_\alpha \in$ ω; if character x_α appear in position s_i under consideration, it has 1, otherwise it has 0.

$$a_{x\alpha} = \sum_{i=1}^{l} \mathrm{w}_{x\alpha}(s_i) \tag{2}$$

$a_{x\alpha} \geq 0$ is total appearance of the x_α in the sequence S.

b) Position appearance

$$b_{x\alpha} = \sum_{i=1}^{l} \mathrm{i} * \mathrm{w}_{x\alpha}(s_i) \tag{3}$$

$b_{x\alpha} \geq 0$ is sum of position values of x_α in the sequence S.

c) Correlation between position and distance

$$c_{x\alpha} = \frac{\sum_{i=1}^{l} (\mathrm{i} * \mathrm{w}_{x\alpha}(s_i)) * (\mathrm{i} * \mathrm{w}_{x\alpha}(s_i) - i_{pre} * \mathrm{w}_{x\alpha}(s_{i\_pre}))}{a_{x\alpha}} \tag{4}$$

$c_{\alpha\alpha} \geq 0$ is average of (position * distance), distance calculated as the difference between the current position and the previous position of x_α in the sequence S.

- N-grams selection

With DNA sequences, when N=1 the combination of characters has the value 4^1 = 4, when N=2 the combination has the value 4^2=16, when N=3 the combination has the value 4^3=64, etc. Increasing N can increase the amount of information stored in the vectors, but it also increases the computational cost of generating the vectors and calculating the similarity. According to a suggestion in [1], and based on our own experiments selecting N=1,2,3,4, we has been found that N=2 gives good results for comparisons and is also computationally efficient.

Algorithm 1. CombinatoricTranform(subsequence S)

```
INPUT: subsequence S
OUTPUT: a vector combinatoric 48 dimensions
BEGIN
    Initialize ω = {AA, AC, AG, AT, TA, TC, TG, TT, GA, GC, GG, GT, TA, TC, TG, TT}.
    Initialize vector vCombinatoric 48 dimensions
    FOR (i=0 to 15) {
        vCombinatoric[i] = Count frequency of element in ω (by fomula(2))  }
    FOR (i=16 to 31) {
        vCombinatoric[i] = Calculate sum of localtion of element in ω (by fomula(3))  }
    FOR (i=32 to 47) {
        vCombinatoric[i] = Calculate value of correlation between position and distance of element in ω (by fomula(4))  }
    RETURN vCombinatoric
END
```

The pseudocode for Algorithm 1 outlines the steps to transform an input DNA subsequence into a 48-dimensional numerical vector based on the formulas (1), (2), (3), and (4).

For example, with the sequence S = {AGTAGTGCTA}. We can calculate CombinatoricTranform(S) = {0, 0, 1, 0, 2, 0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 10, 0, 0, 0, 0, 4, 0, 6, 0, 0, 0, 0, 0, 0, 0, 0, 25, 0, 0, 0, 0, 4, 0, 6, 0, 0, 0, 0}.

2) Algorithm transform based on covariance: Covariance is a measure of how much two random variables vary together. It’s similar to variance, but where variance tells you how a single variable varies, covariance tells you how two variables vary together. Theoretically, covariance is used by analysts as a way to look at the overall for one or more related variables. In the context of biological and genetic data, variables are specific positions of nucleotides in the gene. Genetic covariance studies whether two positions of nucleotides on the gene evolve independently or they evolve together [16]. The authors in [17] also presented the idea of using covariance as a feature represented when transform the DNA sequence. This feature could provide additional information about the correlation between nucleotides in the gene, which could be useful in further analysis and comparison with other DNA sequences.

$$cov_{x,y} = \frac{\sum\left(x_i - \bar{x}\right)\left(y_i - \bar{y}\right)}{N-1} \tag{5}$$

Where (x, y) ∈ {(A,T); (A;G); (A,C); (T,G); (T,C); (G,C)}, x_i, y_i is position of x, y on the sequence, $\bar{x}, \bar{y}$ is average position value of x, y in the sequence.

We use the covariance formula to build features through the vector { $cov_{A,C}, cov_{A,G}, cov_{A,T}, cov_{T,C}, cov_{T,G}, cov_{G,C}$ } showing correlation between the positions of the nucleotides together.

The pseudocode for Algorithm 2 explains how to transform an input subsequence into a 6-dimensional vector based on formula (5).

Algorithm 2. CovarianceTranform(subsequence S)

```
INPUT: subsequence S
OUTPUT: a vector covariance 6 dimensions
BEGIN
    Initialize ω = {(A,T); (A;G); (A,C); (T,G); (T,C); (G,C)}.
    Initialize vector vCovariance 6 dimensions
    FOR (i=0 to 15) {
        vCovariance[i] = Calculate value of correlation
        between position and distance of element in ω (by
        fomula(5))
    }
    RETURN vCovariance
END
```

For example, with the given sequence S, we can calculate CovarianceTranform(S) = { -1.33, -2.3, -3, -1.6, -2.8, -1.24}.

3) Algorithm transform based on Haar wavelet: The Discrete Wavelet Transform (DWT) is a widely used method in digital signal processing, data mining, information retrieval, text clustering and classification, digital image processing, etc. due to its simplicity and efficiency. DWT involves dividing a signal into two parts: high frequency and low frequency. The low frequency part is further divided into high and low frequency parts through a process called downsampling. The encoding complexity is linear and allows for multiple resolution levels. The Haar filter, being the simplest possible wavelet, is often used in the analysis of signals with abrupt transitions and is commonly used in analyzing time series or ordinal data. We use Haar filter to divide the original sequence into two parts: approximation (by summing) and detail (by subtracting) in pairs of values in in two vectors.

In the case that a character is unevenly distributed in different regions of the DNA sequence, for example, if character A is abundant in the first half but scarce in the second half, the algorithm for transforming based on these features can have lower efficiency. The goal of applying Haar wavelet is to overcome this limitation, improve the accuracy when calculating and comparing the similarity values of the transformed sequences. The pseudocode for Algorithm 3 presents the process of using Haar wavelet to transform vectors.

Algorithm 3. WaveletHaarTranform(vector u, vector v, integer *l*)

```
INPUT: vector u,v have l dimensions
OUTPUT: a vector l*2 dimensions
BEGIN
    Initialize vector vHigh, vLow l dimensions
    FOR (i=0 to l-1) {
        vHigh[i] = u[i] + v[i]
        vLow[i] = u[i] - v[i]
    }
    Initialize vector vWavelet l*2 dimensions
    FOR (i=0 to l-1) {
        vWavelet[i] = vHigh[i]
    }
    FOR (i=l to l*2 - 1) {
        vWavelet[i] = vLow[i]
    }
    RETURN vWavelet
END
```

4) Algorithm transform based on codon: The human body, along with other organisms, produces proteins through a process called transcription. Genes in biological cells store the information needed to construct proteins in the form of DNA sequences. During transcription, the DNA information is transcribed into messenger RNA (mRNA), which carries the genetic information. This mRNA sequence is then translated into a sequence of amino acids, which make up the proteins. Researchers have discovered that a group of three nucleotides encodes a single amino acid [18]. With four nucleotides, A, C, T, and G, there are 64 possible codons and 20 different amino acids.

	T	C	A	G	
T	TTT Phe	TCT Ser	TAT Tyr	TGT Cys	T
	TTC Phe	TCC Ser	TAC Tyr	TGC Cys	C
	TTA Leu	TCA Ser	TAA stop	TGA stop	A
	TTG Leu	TCG Ser	TAG stop	TGG Trp	G
C	CTT Leu	CCT Pro	CAT His	CGT Arg	T
	CTC Leu	CCC Pro	CAC His	CGC Arg	C
	CTA Leu	CCA Pro	CAA Gln	CGA Arg	A
	CTG Leu	CCG Pro	CAG Gln	CGG Arg	G
A	ATT Ile	ACT Thr	AAT Asn	AGT Ser	T
	ATC Ile	ACC Thr	AAC Asn	AGC Ser	C
	ATA Ile	ACA Thr	AAA Lys	AGA Arg	A
	ATG Met	ACG Thr	AAG Lys	AGG Arg	G
G	GTT Val	GCT Ala	GAT Asp	GGT Gly	T
	GTC Val	GCC Ala	GAC Asp	GGC Gly	C
	GTA Val	GCA Ala	GAA Glu	GGA Gly	A
	GTG Val	GCG Ala	GAG Glu	GGG Gly	G

Fig. 3. Table mapping three nucleotides to codon.

Fig. 3 shows how the various combinations of three bases in the coding strand of DNA are used to code for individual amino acids - shown by their three letter abbreviation. The combination of codons determines the sequence of amino acids in the resulting protein, which ultimately determines its structure and function. In this way, codons are the key to translating genetic information stored in DNA into the functional proteins that carry out vital cellular processes in all living organisms. Almost the same as above, we will use frequency appearance and correlation of position and distance to store the feature. The goal is to capture features related to biological significance and store them in vectors after transforming the input sequences. Thereby improving the efficiency when calculating and comparing the similarity value.

Let β a collection of amino acids, β = {Phe, Leu, Ile, Met, Val, Ser, Pro, Thr, Ala, Tyr, His, Gln, Asn, Lys, Asp, Glu, Cys, Trp, Arg, Gly}.

a) Frequency appearance

$$d_{y\alpha} = \sum_{i=1}^{l} w_{y\alpha}(s_i) \qquad (6)$$

$d_{y\alpha} \geq 0$ is total appearance of the y_α in the sequence S.

b) Correlation between position and distance

$$e_{y\alpha} = \frac{\sum_{i=1}^{l}(i * w_{y\alpha}(s_i)) * (i * w_{y\alpha}(s_i) - i_{pre} * w_{y\alpha}(s_{i\_pre}))}{d_{y\alpha}} \qquad (7)$$

$e_{y\alpha} \geq 0$ is average of (position * distance), distance calculated as the difference between the current position and the previous position of y_α in the sequence S.

The pseudocode of Algorithm 4 explains how to transform an input subsequence into a 40-dimensional vector based on formulas (6) and (7).

Algorithm 4. CodonTranform(subsequence S)

```
INPUT: subsequence S
OUTPUT: a vector codon 6 dimensions
BEGIN
    Initialize β = {Trp, Phe, Tyr, His, Asn, Asp, Cys, Gln, Lys,
    Glu, Ile, Val, Pro, Thr, Ala, Gly, Ser, Leu, Arg }.
    Initialize vector vCodon 40 dimensions
    FOR (i=0 to 19) {
        vCodon [i] = Count frequency of element in β (by
        fomula(6))
    }
    FOR (i=20 to 39) {
        vCodon [i] = Count frequency of element in β (by
        fomula(6))
    }
    RETURN vCodon
END
```

For example, with the given sequence S, will be calculate CodonTranform(S) = {0, 1, 0, 0, 2, 2, 0, 0, 1, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 7, 0, 0, 6.5, 4.5, 0, 0, 6, 0, 0, 0, 0, 0, 0, 0, 5, 0, 0}.

B. The Combine Algorithm Transforms DNA Sequences into Vectors

In Part A, we have presented four algorithms that will be used in vector transformation, this section will present an algorithm that combines the above algorithms to generate the final feature vector. Algorithm to calculate similarity value will be performed on these feature vectors.

Definition 1. Given the sequence S = {s0, s1, s2, ..., sl-1} where l is length of S, we define the vector FCC(S) as follows:

$$FCC(S) = [\text{CombinatoricTranform(S)}, \text{CovarianceTranform(S)}, \text{CodonTranform(S)}] \qquad (8)$$

The final feature vector *FCC(S)* is generated by merging the vectors produced by Algorithms 1, 2, and 4. Example, for sequence S = {AGTAGTGCTA}, we have *FCC(S) = { 0, 0, 1, 0, 2, 0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 10, 0, 0, 0, 0, 4, 0, 6, 0, 0, 0, 0, 0, 0, 0, 0, 25, 0, 0, 0, 0, 4, 0, 6, 0, 0, 0, 0, 0, 1, 0, 0, 2, 2, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 7, 0, 0, 6.5, 4.5, 0, 0, 6, 0, 0, 0, 0, 0, 0, 0, 5, 0, 0, 0, -1.33, -2.33, -3, -1.6, -2.8, -1.24}*

Definition 2. Given the sequence S = {s0, s1, s2, ..., sl-1} where l is length of S, split S into Sa, Sb have equal length, we define the vector FCCW(S) as follows:

$$Va = [FCC(S_a)]$$

$$Vb = [FCC(S_b)]$$

$$FCCW(S) = [V_a + V_b, V_a - V_b] \qquad (9)$$

In case where S has an odd number of characters then length $S_b = S_a+1$, that is the last odd character will be in the subsequence S_b. The vectors V_a, V_b can be calculated from the FCC formula in Definition 1. Applying the Haar wavelet filter according to Algorithm 3, concatenate 2 vectors V_a, V_b to generate an *FCCW* vector containing the features of the original sequence. In this vector, it will contain information about the frequency, the position and the correlation between position and distance of the features mentioned above, through which the vector will be able to store the unique feature of the original sequence. In this way, an original subsequence of any length will be stored under a fixed length vector have 188 dimensions. Pseudocode for Algorithm 5 describes how to transform an input DNA sequence into a list of output final vectors.

Algorithm 5. TranformDNA(sequence S)

```
INPUT: DNA sequence S need tranform, window size W
OUTPUT: feature vectors
BEGIN
        //Calculate the number of windows will be cut from the Input string
        IF (Length(S) % W > 0){wCount = Length(S)/W +1}
        ELSE { wCount = Length(S)/W }
        //Partition sequence S into subsequences with window size
        FOR (i=0 to (wCount – 1))  {
                position = i*W
                listSub += Substring(S, position, W)
        }
        //Transform subsequences to vectors
        FOR (each subsequence in listSub)   {
                Devide a subsequence into two areas Sa, Sb
                Calculation Va = [FCC(Sa)], Vb = [FCC(Sb)] (by fomula(8))
                vectors += WaveletHaarTranform(Va,Vb) (by fomula(9)) }
        RETURN listVectors
END
```

Algorithm 6. *FCCWD*(vector u, vector v)

```
INPUT: vector u, v
OUTPUT: similarity FCCWD between u and v
BEGIN
        posDis = 0; negDis = 0;
        FOR EACH (each vector $u_i$, $v_i$ in u, v){
        IF($u_i > v_i$) {
                posDis += $u_i - v_i$ }
        ELSE {
                negDis += abs($u_i - v_i$) } }
        m = min (posDis, negDis)
        µ = | posDis  - negDis | / 2
        IF(m < µ) {
                RETURN µ/N   }
        ELSE {
                RETURN (µ + (m - µ))/N    }
END
```

The similarity value of two vectors is determined by the distance between the two vectors. To calculate this distance, the algorithm presented in [1] is employed. This algorithm calculates the distance between two vectors by finding the maximum number of operations required to transform from vector *u* to vector *v*. Algorithm 6 will calculate these values for each pair of *(u,v)* and storing the result in the variables posDis and negDis.

- Algorithmic complexity

The generated vectors will only contain numbers, which results in a computational complexity of O(*l*), much improved compared to O(l^2) of the *ED* algorithm.

IV. Experimental Results

In test model, we will take a text input DNA sequence and partition it into smaller subsequences using a selected window length. Next, we will use the *FCCWD* and *Hfwd*^{2} algorithms to transform these subsequences into a set of vectors, which will be stored in a general database. With these vectors, it will be possible to calculate the similarity values between them, and obtain the results. Lastly, we will compare the average results of the improved algorithm with the reference *ED* algorithm to evaluate the efficiency improvement achieved, as illustrated in Fig. 4.

We employed the use of Visual Studio 2019 and the C# programming language, as well as SQL Server 2019 for database management. The tests were conducted on a computer with the following configuration: CPU: Intel Xeon E2224G at 3.5 GHz, RAM: 16 GB, Hard Disk: Intel SSD 250 GB, Operating System: Windows Server 2019.

The test dataset is 171 genes of the family Poxviridae virus (32.9 MB), 172 genes of the family Asfarviridae virus (31.4 MB), 203 genes of the family Herpesviridae virus (32.6 MB), 23 genes of the family Corona virus (0.9 MB) available for download at the website https://www.ncbi.nlm.nih.gov/.

As the scenario has been built, we will compare the results of the similarity value calculation using three methods, with the standard *ED* method being the target to aim for. We will partition the data file into subsequences of different window lengths W = (1000, 2500, 5000, 7500, 10000, 15000, 20000) and evaluate the efficiency based on the average of the calculations. Since the parameters differ, the similarity values may not be on the same frame of reference. To compare the results, we will use the *k* nearest neighbor method on the resulting data. This means, given an input DNA sequence, we will find the cluster of *k* sequences with the closest similarity value for each method. The intersection of the resulting *FCCWD* clusters with *ED* and *Hfwd*^{2} with *ED* will represent the accuracy of the algorithms. As an example, if we search for similarities using the standard *ED* method, the result will be a set A with *k* elements having minimum values. The *FCCWD* method will find a set B also with *k* elements. The intersection of A and B (A ∩ B) will be the elements that *FCCWD* correctly found compared to *ED* as illustrated in Fig. 5.

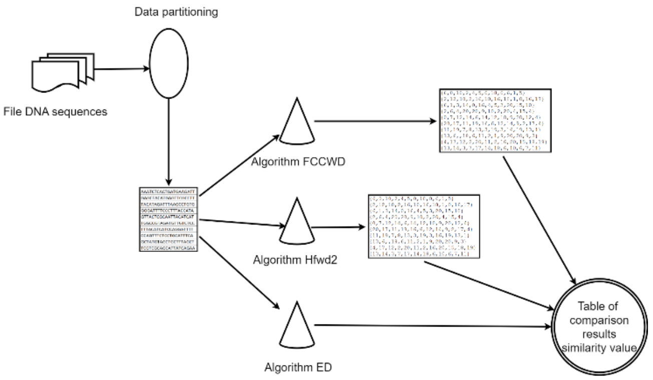

Fig. 4. Model of experiment.

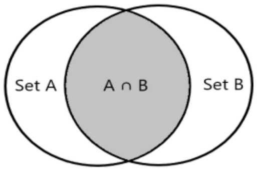

Fig. 5. Example of intersection of 2 result sets.

Fig. 6 and Fig. 7 illustrate the results for scenarios where k equals 5 and 10. The average true positive rate of *FCCWD* is higher than *Hfwd*^{2} under these scenarios. The efficiency of method is highest when the window length is between 5000 and 10000, but noticeably decreases when the window length is smaller than 5000 or larger than 10000.

Fig. 8 and Fig. 9 present the results for scenarios where k is equal to 15 and 20. Although performing worse than *Hfwd*^{2} at W = 1000 with k=20, but the average true positive rate of *FCCWD* still better than *Hfwd*^{2} in the remaining cases. The efficiency of method remains low for window lengths smaller than 5000, but proves to be stable when window lengths are larger than 5000.

The results indicate that when the window length is small, accuracy is lower and gradually improves as the window length increases. With small window lengths, the small number of characters creates high noise levels, leading to larger errors. When the sequence is longer, the accuracy of *FCCWD* is higher because we have added more parameters to store the eigenstate better than the *Hfwd*^{2} method. Therefore, this method is also more efficient when comparing large sequences than *Hfwd*^{2} tested on small windows from 100 to 1000. The best accuracy of the proposed method is the windows length from 5000 to 10000.

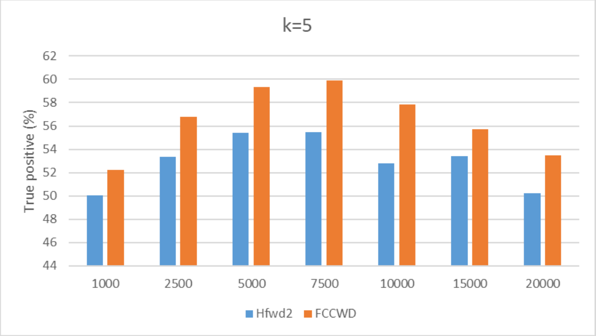

Fig. 6. Compare result with k = 5.

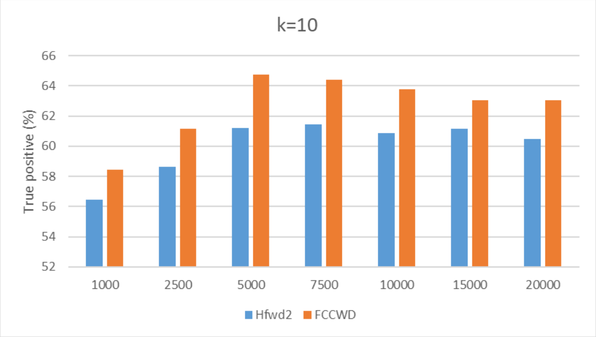

Fig. 7. Compare result with k = 10.

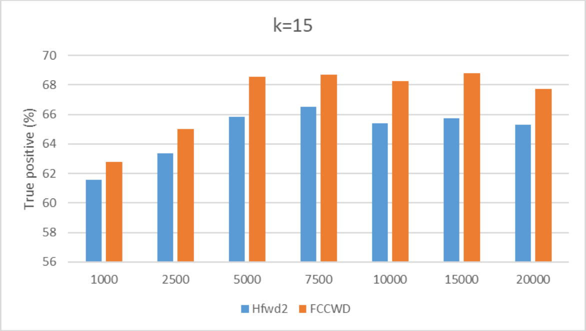

Fig. 8. Compare result with k = 15.

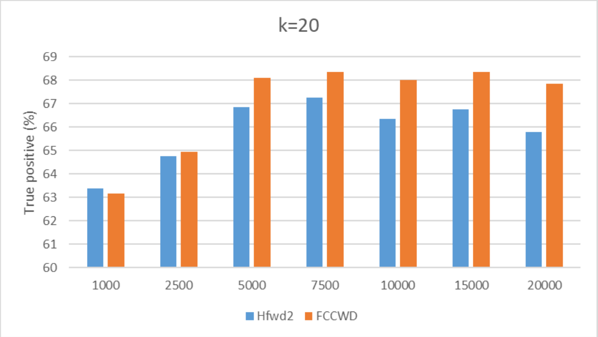

Fig. 9. Compare result with k = 20.

TABLE I. EXECUTION TIME OF METHODS (SECONDS)

W size **Method**	**1000**	**2500**	**5000**	**7500**
ED	25.0029	155.7917	619.9818	1387.816
FCCWD	0.0003	0.0007	0.0014	0.0021
Hfwd^2	0.0003	0.0007	0.0013	0.002
W size **Method**	**10000**	**15000**	**20000**	
ED	2457.2346	5496.9212	9730.9857	
FCCWD	0.0028	0.0042	0.0055	
Hfwd^2	0.0027	0.004	0.0053	

Regarding the computational performance shown in Table I and Fig. 10, the computational performance of both *FCCWD* and *Hfwd*^{2} methods is observed to be highly efficient, with computation times only being a few hundredths of a second. On the other hand, *ED* is significantly slower, ranging from a few tens to tens of thousands of seconds. Although *FCCWD* uses more parameters and has a larger vector dimension, the similarity algorithm has linear complexity, making the increase in cost minimal compared to *Hfwd*^{2}. As the window length of the data increases, the computation time of *FCCWD* increases very little, while *ED* increases very quickly.

The experiment also shows that the data compression ratio is quite good, with the larger window length the more compression, as shown in Fig. 11. Because how large a window is, it will also be transformed into a vector with 188-dimensions. This can help the data after transformation to be easily stored and reused in the next times.

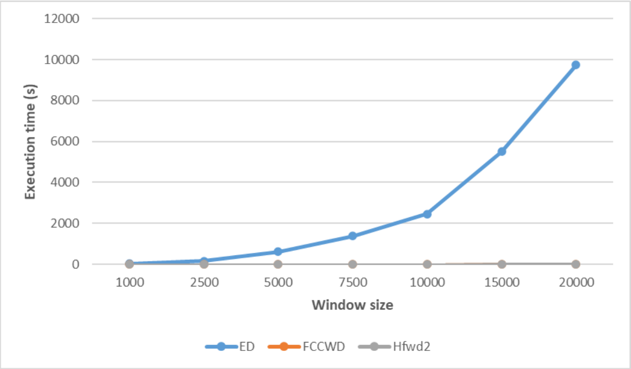

Fig. 10. Time comparison results.

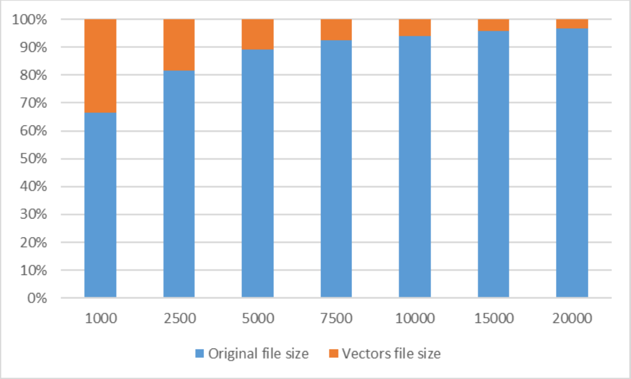

Fig. 11. Compare files size after transformation.

V. Conclusion

With the goal of improving the accuracy of similarity search, this paper propose an improved algorithm that transforms DNA sequences into numerical vectors using multiple feature parameters. These features are a blend of mathematical statistics and biological characteristics of genetic genes, allowing for a better representation of the original sequence information in the transformed vectors. Additionally, the method also enables efficient storage and reuse of the transformed data through reduction of its size. Experimental results demonstrate that the new algorithm improves similarity calculation accuracy while maintaining good performance. Although some cases of high noise still affect accuracy, the algorithm performs better in the case of long window length. In the future, we will continue to look for valuable parameters to further improve accuracy, as well as apply other indexing methods to process large data better.

***Abstract*—Due to the rapid advancement of technology, the volume of online text data from numerous various disciplines is increasing significantly over time. Therefore, more work is needed to create systems that can effectively classify text data in accordance with its content, facilitating processing and the extraction of crucial information. Since these non-automated systems use manual feature extraction and classification, which is error-prone and time-consuming by choosing the best appropriate algorithms for feature extraction and classification, traditional procedures are typically resource intensive (computational, human, etc.), which is not a viable solution. To address the shortcomings of traditional approaches, we offer a unique text categorization strategy based on a well-known DL algorithm called BERT. The proposed framework is trained and tested using cutting-edge text datasets, such as the UCI email dataset, which includes spam and non-spam emails, and the BBC News dataset, which includes multiple categories such as tech, sports, politics, business, and entertainment. The system achieved the highest accuracy of 91.4% and can be used by different organizations to classify text-based data with a high performance. The effectiveness of the proposed framework is evaluated using multiple evaluation metrics such as Accuracy, Precision, and Recall.**

Keywords—Deep learning; text classification; BERT

I. Introduction

Text classification is a common problem in Natural Language Processing (NLP) that aims to classify the text data based on its content. This field has become drastically important due to increase in text based data. The increase in internet usage has resulted in the creation of diversified text data that is made available by numerous social media platforms and websites in different languages. This has resulted in exponential rise in the number of complex documents and texts that demand a deeper understanding of machine learning approaches to effectively identify texts in numerous applications. This field has wide range of applications such as sentiment analysis, email classification, news classification, movie review prediction, etc. [1, 2].

In NLP, numerous ML techniques have been developed over the past few years. A typical text classification system has four stages: preprocessing, feature extraction, feature selection, and classification. These applications must solve a number of issues relating to the nature and organization of the underlying textual information by condensing word variants into short representations while retaining the majority of the linguistic properties. However, there are certain limitations in the traditional methods. Firstly, it is difficult to capture text semantics using these techniques since they solely focus on word frequency attributes and completely ignore the contextual information stored in text. Second, the success of these statistical approaches in machine learning is often dependent on hand-crafted feature extraction and classification, which is time-consuming and error-prone. Moreover, it can be difficult for researchers to develop such pipelines and methods for text classification that can perform better [3, 4].

Hence, due to these problems, recent years have seen a complete shift from these traditional text classification methods towards much stronger state-of-the-art DL based methods. These algorithms do not require a feature extraction phase prior to data classification, as these systems are completely automated because these models are highly capable of extracting robust features from the dataset themselves during the learning phase. Due to which, the deep learning algorithms have achieved state-of-the-art performance in a variety of NLP tasks, hence, the researchers are keen in exploring the applicability of these algorithms in different tasks like question/answering, email classification, news categorization and much more [5, 6].

In this paper, we proposed a fine-tuned Bidirectional Encoder Representations from Transformers (BERT) architecture for text classification. BERT is a brand-new language representation model that Google has introduced in 2018 [6, 7]. The model has succeeded in achieving state-of-the-art performance on text classification problems, hence, has increased the interest of researchers in fine-tuning and deployment of BERT on various text classification problems. In this paper, we fine-tuned BERT architecture on two state-of-the art datasets composed of email and news. The proposed framework is discussed in detail in Section III. The contributions of the proposed study are as follows:

- We developed an automated text classification framework to classify different types of text data.
- The proposed method initially preprocesses data by removing stop-words and extra characters so that classification performance can be improved.
- The preprocessed text is then classified via widely known DL based architecture called BERT by fine-tuning the architecture on our problem.

- The performance of the proposed technique using different evaluation parameters and compare its performance with existing systems.
- In this study, we performed extensive experiments on publically available datasets to show the efficiency and robustness of our algorithm.
- Both of the proposed methods can accurately detect and classify text data effectively and can be deployed by various organizations to classify the text data.

The remaining paper is organized as follows. The literature is critically analyzed in Section II. The proposed methodology is discussed in detail in Section III. Whereas, Section IV evaluates the performance of the proposed technique and compares it with state-of-the-art methods. The study is concluded in Section V.

II. Literature Review

Text classification is a common NLP task that has a wide range of uses, such as sentiment analysis, email classification, detection of offensive language, spam filtering, etc. Now-a-days ML has become a subject of interest for text classification tasks, as these algorithms have shown considerable potential for acquiring linguistic knowledge.

A typical text classification system has four stages: preprocessing, feature extraction, feature selection, and classification. These applications must address a number of issues relating to the nature and structure of the underlying textual information for languages by translating word variants into compact representations while retaining the majority of the linguistic properties. However, these systems have several issues. Firstly, it is difficult to capture text semantics using these techniques since they solely focus on word frequency attributes and completely ignore the contextual structure information in text. Second, the effectiveness of these statistical methods for machine learning frequently depends on challenging technical features and the usage of vast linguistic resources.

The authors in Jang et al. [8] employed MLP to classify textual data. The authors succeeded in achieving 71% accuracy on MLP. However, the performance should be improved. She et al. [3] proposed a hybrid technique that solves CNN's fundamental limitation in expressing long-term contextual information while utilizing CNN's capacity to extract local data. Additionally, the model makes an effort to address LSTM's inherent flaws, which include its tendency to process data sequentially and rank as the poorest feature extractor. When compared to counterpart models, the hybrid model performed better, but its findings lagged below models that make use of an attention mechanism in terms of interest.

Urdu editorials were also classified by Sattar et al. [1] using NB. The authors reduced the dimensionality by eliminating terms with common frequency. With their study, they were able to prove that when Naive Bayes classifier is supplied text with frequent terms it outperforms the model when it isn’t supplied those terms. However, these studies need to be incorporated on multiple Urdu categories rather than only headline classification. The authors in Antoun, et al. [7] used BERT model for Arabic text classification called Arabert which was trained on 24 gigabytes of data. Similarly, in another research, Abdul-Mageed, et al. [4] trained Arabic BERT architecture called MARBERT on 1B tweets. However, the systems mentioned in [4, 7] are computationally expensive.

Koswari et al. [5] proposed an ensemble approach using deep learning algorithms to classify text from news dataset and achieved 87% accuracy. However, the system obtained a low overall performance, hence, its accuracy should be improved. Cai et al. [9] classified news data by employing several deep learning architectures such as RCNN, CNN and RNN. Similarly, the study presented by Lenc et al. [6] proposed the use of CNNs as well as a simple multi-layer perceptron to extract features from Czech newspaper documents before applying multi-label document classification. This technique achieved F1 score of 0.84 using MLP with sigmoid functions. However, these studies only classify news data, hence need to test their architectures on other types of text data before deploying in real-world scenario.

III. Materials and Methods

Due to its vast applicability in businesses and organizations, text classification has become a very significant research area in NLP. The text classification algorithms aim to classify the text data based on its content and meta-data contained in it. This can be achieved by using ML and DL based algorithms to automate the process with an increase in data volumes. In this paper, we propose a novel and robust text classification framework employing a well-known DL based algorithm called BERT. The pipeline of proposed architecture is illustrated in Fig. 1.

Fig. 1. Pipeline of proposed framework.

The proposed architecture is trained and evaluated on two publically available datasets. Initially, we cleaned the datasets by removing stop-words and special characters. Furthermore, we also converted the entire text in small case before actual processing. The cleaned dataset is then supplied to BERT architecture for feature extraction and classification.

A. Data Collection

The proposed framework is trained and evaluated on publically available datasets obtained from different sources. The BBC News dataset consists of a total of 2225 documents that consists of five classes namely business, entertainment, politics, sport, tech that was obtained from 2004-2005 [10]. Fig. 2 shows the dataset distribution showing the class name and number of documents in that class.

The second dataset is gathered from UCI Database [11]. We also performed exploratory data analysis of the second dataset. The database is composed of 5569 emails, of which 745 are spam and others are non-spam. Hence, non-spam emails count for 12% of the dataset and spam emails count for 88% of the whole database. The dataset is highly imbalanced, hence, in these recall and precision as an evaluation metrics are very useful. However, it may be noted that before supplying the database to proposed BERT architecture, we balanced the dataset and randomly chose equal numbers of instances from both classes to avoid the biasness in the classification architecture.

B. Data Preparation

Data cleaning is an essential phase in any NLP task, which aims to modify data in a format that is much easier for the algorithm to analyze or predict. In this phase, we cleaned the dataset by removing special characters and stop words. Special characters and symbols consist of non-alphabet letters such as “([/ (] [| @],]”. Whereas, stop-words are a group of terms that are used frequently in a sentence or used to link sentences, some of these include "a," "the," "is," and "are." These terms need to be eliminated because they provide no information to the model but can be a cause of poor performance of any text classification model. Furthermore, the entire dataset is also converted in small case to help remove any ambiguity during learning process. Fig. 3 shows the preprocessing steps applied to the datasets.

C. Proposed Framework Design

The field of NLP focuses on developing computing methods to automatically interpret and represent human language. For a very long period, the bulk of approaches to examine NLP issues relied on labor-intensive, hand-crafted features and shallow machine learning models. As a result of linguistic information being represented via sparse representations, issues like the curse of dimensionality began to arise due to high-dimensional feature vectors. However, these issues in the traditional methodologies have been solved, thanks to advent of DL based algorithms such as Convolutional Neural Networks, Recurrent Neural Networks, etc. [12]. But, one of the major issues faced in DL architectures is lack of training data. The majority of task-specific datasets only contain some human-labeled training samples because NLP is a diverse area with numerous separate jobs. Modern DL-based NLP models, on the other hand, have improved on larger volumes of data containing millions, or billions, of annotated instances. Over the past decade, researchers have created a number of methods for training general purpose language representation models using the huge volume of content from the web in order to close this data gap. The models trained on massive datasets can now be utilized on smaller problem such as question/answering or sentiment analysis, etc. rather than training models from scratch [2].

BERT, proposed in 2018 by Google AI Language researchers created quite a stir in the ML community as it achieved good results in a wide range of NLP tasks. The framework is intended to assist computers in understanding the meaning of ambiguous words in textual data by establishing context through the use of surrounding material [13, 14]. The architecture of BERT is built using Transformers, where each output element is coupled to each input element and the weights between them are dynamically calculated based on their connection. Earlier language models could only read text input in one of two directions i.e. either left to right or from right to left, but not both simultaneously. However, BERT can read data simultaneously in both directions mainly due to transformers that help its enhanced understanding of linguistic ambiguity and context. Furthermore, earlier approaches like word2vec would map every word to a vector, which only captures a small fraction of its meaning in one dimension which is known as word embedding. But BERT is the first NLP technique that completely relies on self-attention techniques because of the bidirectional Transformers at its core that helps it understand complete meaning as the paragraph develops [15]. This capability of directionality enables the BERT to eliminate the left-to-right momentum due to which the words are usually biased towards a particular meaning as a phrase proceeds, hence reading from both directions, accounts for the impact of all other words on the focus word, and compensates for the augmented meaning [13].

In this paper, a refined BERT base architecture is suggested (shown in Fig. 4) for the text classification problem. BERT-base has 110 parameters and was trained on an English language corpus. BERT-base contains 12 encoders layered on top of each other. BERT-Base features a larger feed forward network with 768 hidden units. In addition, the structure contains 12 attention heads. The system gets computationally expensive as the number of encoders and parameters rises. For these reasons, we chose the BERT-base model because it is lightweight and quick to train.

D. Experimental Configuration and Setup

We trained and evaluated our proposed BERT architecture on publically available datasets i.e. UCI Email dataset composed of Spam and Non-Spam emails. The second dataset consists of BBC News text dataset composed of 5 different classes namely tech, entertainment, sport, politics and business. The model is tested on different hyper-parameters and performed the best on 10 epochs, mini-batch size of 32, a learning rate of 0.001 and a dropout rate of 0.1 (meaning 10% of the random nodes are dropped during training process to lighten up the network). In this study, 75% of the dataset is used for training the model, whereas 25% of the dataset is used for testing purposes. The entire experiment is performed on Python using Anaconda software on a PC with 8GB RAM and Intel Core i5 processor.

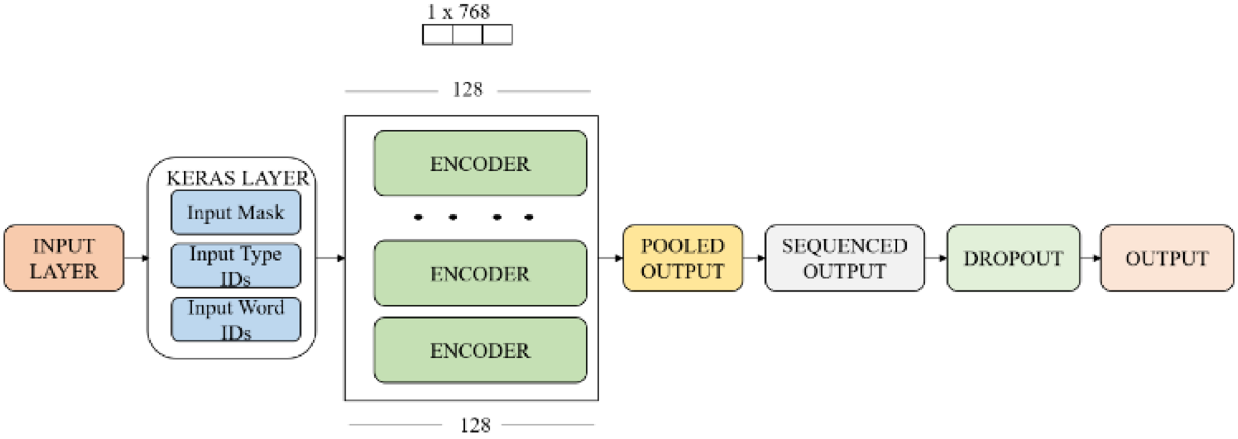

Fig. 4. Proposed framework architecture.

IV. Proposed Method Results

A. Evaluation Parameters

The proposed method is evaluated using different metrics such as precision, recall and accuracy. Confusion matrices help in showing tabular counts of observed and expected values. Different evaluation matrices such as True Positives, True Negatives, False Positives and False Negatives can be calculated using confusion matrices as well. TN depicts the total number of negative cases that were correctly identified. Similar to this, TP denotes the accurately identified positive cases. FP shows the negative cases that were by mistake classified as positive, while FN shows the positive instances wrongly classified as a negative [16, 17]. The value for accuracy, precision and recall can be calculated from the following equations.

$$\text{ACC} = \frac{\text{TN+TP}}{\text{TP+FN+TN+FP}} \quad (1)$$

$$\text{REC} = \frac{\text{TP}}{\text{FN+TP}} \quad (2)$$

$$\text{PRE} = \frac{\text{TP}}{\text{FP+TP}} \quad (3)$$

B. Experiment # 01: Classification of Emails using BERT

In this study, we employed BERT on email dataset containing both spam and non-spam emails. We initially cleaned the dataset before feeding it to BERT architecture. In this study, we employed cased BERT architecture so we changed the text to smaller case and then removed the stop words, keywords, etc.

The proposed method achieved a training accuracy of 92.3% whereas values obtained from precision, recall and f1score are 0.92 and 0.91 respectively as shown in Fig. 5. Whereas, the system achieved testing accuracy, precision and recall of 91.2%, 0.91 and 0.91 respectively as shown in Fig. 6. The confusion matrix of the proposed technique is shown in Fig. 7.

True Class
Predicted Class

	Non-Spam	Spam
Non-Spam	170	17
Spam	16	171

Fig. 7. Confusion matrix obtained from the proposed method.

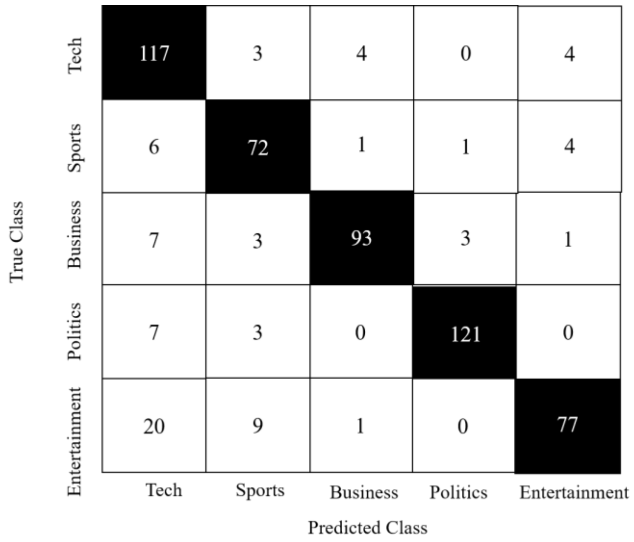
The proposed approach is evaluated on a publicly available dataset comprised of spam and non-spam emails. We trained the BERT architecture by testing out various hyper-parameters and reached the final conclusion on 10 epochs, 32 mini-batch size and Adam optimizer. The different tested hyper-parameters are shown in Table I. The optimal values are also highlighted in the table.

TABLE I. HYPER-PARAMETER OPTIMIZATION ON UCI EMAIL DATASET

Hyper-parameter	**Value/s**
Epochs	4, 8, **10**
Mini-batch	8, 16, **32**
Learning Rate	0.1, 0.01, **0.001**
Optimizer	RMSProp, **Adam**

C. Experiment # 02: Classification of News using BERT

In this section, we discuss the results obtained from the proposed BERT architecture on BBC News dataset. The dataset is composed of five different news categories such as tech, entertainment, sport, politics and business. The proposed method achieved a training accuracy of 89.1% and a testing accuracy of 88.8%. The confusion matrix of the proposed technique is illustrated in Fig. 8. We also evaluated the performance of our proposed framework on precision and recall obtained from the confusion matrix. Training scores of precision and recall are 0.66 and 0.90 respectively as shown in Fig. 9, on the other hand, testing scores for precision and recall are 0.66 and 0.89 respectively as shown in Fig. 10.



True Class
Predicted Class

	Tech	Sports	Business	Politics	Entertainment
Tech	117	3	4	0	4

D. Comparison with Existing Systems

One of the very common problems in NLP is text classification that aims to classify text data according to its contents. With the emergence of ML and DL based approaches, the researchers are keen to explore the results of these algorithms to solve this classification problem. However, most of the systems have certain limitations such as poor accuracy, use of single datasets or no data preparation prior to classification. Hence, there is a need to develop a robust and efficient system that can classify text data based on its content accurately.

Hence, in this thesis, we propose a novel and robust text classification method employing one of the very famous DL architecture known as BERT. The proposed method is trained and evaluated on publically available datasets and achieved the 91% and 89% accuracy on different datasets. Since accuracy as a single metric is not sufficient to assess the performance of a classification system, hence, we also evaluated the performance of our proposed strategy using other evaluation parameters namely precision and recall. The results prove the efficacy and robustness of the proposed technique and our devised framework can be deployed by organizations to classify text data. The comparison of our proposed framework with existing methods is described in Table III.

TABLE III. COMPARISON OF PROPOSED METHOD WITH EXISTING SYSTEMS

Reference	Technique	Result/s
Pappagari et al. [18]	RoBERTa & CNN	ACC= 84.7% & 86%
Briskilal et al. [19]	BERT	ACC= 85%
Jang et al. [8]	MLP	ACC= 71%
Semberecki et al. [20]	LSTM	ACC= 86.2%
Lenc et al. [6]	MLP	F1-Score=0.84
Proposed Method	**BERT**	**ACC=91.4%**

V. CONCLUSION AND FUTURE WORK

With the increase in data volumes, automatic text classification has become a necessity for organizations and businesses. The automated systems help them improve their performances overtime and save a lot of time and resources compared to manual systems. This has resulted in increased interest of researchers in this domain of NLP. In this thesis, we propose a novel and completely automated text classification technique employing DL frameworks. The proposed framework uses a fine-tuned BERT architecture to classify text data based on its content. The architecture proposed in this study is case sensitive, hence, the text is preprocessed by changing it in small case. Moreover, additional keywords and stop words are also removed because they can result in poor overall performance.

The preprocessed text data is then fed to fine-tuned BERT architecture for classification. The proposed technique is trained and evaluated on publically available text datasets i.e. BBC News Dataset and UCI Email dataset. The proposed technique achieved accuracy of 91.4% on UCI Email database and 89.1% on BBC News Dataset. We also compared the proposed system’s performance with existing techniques. The results prove the efficiency and robustness of our method. Hence, it can be deployed in businesses to reduce the workload of manual text classification that will save time and energy required in the manual procedure. In the future, we would like to explore text data in various other languages and also explore other DL architectures.

***Abstract*—This paper aims to highlight the motivations for investigating genetic algorithms (GAs) to solve the DNA Fragment Assembly (DNAFA) problem. DNAFA problem is an optimization problem that attempts to reconstruct an original DNA sequence by finding the shortest DNA sequence from a given set of fragments. This paper is a continuation of our previous research paper in which the existence of a polynomial-time reduction of DNAFA into the Traveling Salesman Problem (TSP) and the Quadratic Assignment Problem (QAP) was discussed. Taking advantage of this reduction, this work conceptually designed a genetic algorithm (GA) platform to solve the DNAFA problem. This platform offers several ingredients enabling us to create several variants of GA solvers for the DNAFA optimization problems. The main contribution of this paper is the designing of an efficient GA variant by carefully integrating different GAs operators of the platform. For that, this work individually studied the effects of different GAs operators on the performance of solving the DNAFA problem. This study has the advantage of benefiting from prior knowledge of the performance of these operators in the contexts of the TSP and QAP problems. The best designed GA variant shows a significant improvement in accuracy (overlap score) reaching more than 172% of what is reported in the literature.**

***Keywords*—Genetic algorithms; traveling salesman problem; quadratic assignment problem; DNA fragments assembly problem**

I. Introduction

The DNA fragment assembly problem is the process of reconstructing an original DNA sequence from a given set of DNA fragments. This is achieved by ordering and aligning these DNA fragments such that the resulting DNA sequence is as short as possible. It is a complex combinatorial optimization problem belonging to the class of NP-hard problems, where there is a need to find the right order of the DNA fragments to assemble them. Several metaheuristic techniques have been developed to solve this problem [1], [2], [3]. This paper exploit the genetic algorithm platform (GAP) developed in the former preliminary paper [4], in which the existence of a polynomial-time reduction of DNAFA into the Traveling Salesman Problem and the Quadratic Assignment Problem was discussed. Then, conceptually designed a GA platform for solving the DNAFA problem, inspired by the existing efficient GAs in the literature for solving the TSP and QAP problems. This platform gathers and offers several GA operators designed to solve hard optimization problems such as TSP, QAP, and DNAFA. The GAP enables the researchers to easily design an adequate variant GA algorithm for hard optimization problems in particular. This work implementing and experimenting on some GA variants judiciously built from the platform (GAP) aims to identify the best variant that efficiently deals with the DNAFA problem. Using this platform, this work is able to individually study the effects of genetic algorithm components on selected metrics, which were presented in terms of time and overlap score. This work focused on examining and discussing the effects of population size, population generation methods, selection types, and crossover types and figure out which component has the most impact on GA performance. Some of these GA components have never been tested in the context of the DNAFA problem, such as SCX crossover, which is worth to be investigated experimentally. Other components have been tested before, but when retest was done on them, a different result was found, such as greedy as a population initialization method. Because of SCX effectiveness in TSP and QAP, we believe the SCX crossover is a smart crossover that will outperform other crossovers. As a result of these comprehensive experiments, this work identifies the best-designed GA variant that outperforms the existing GA algorithms in solving the DNAFA problem. This GA variant features the use of 200 individuals for the population size, along with the greedy method for initializing the population, tournament selection, and SCX crossover. This GA variant showed a significant increase in overlap score compared to what is reported in the literature. The results showed that the SCX crossover was the best crossover among the studied crossovers and gave good results. Furthermore, the results showed that the greedy method is a very powerful method that improved the algorithm's performance by 37%, demonstrating that the population generation method has the greatest impact on improving the results than the other GA components. The experimental results demonstrated the efficiency of the designed approach, as it got a better result for the overlap score ranging from 56.16% to 172.74% than the previous recorded results for most data sets. This work demonstrate experimentally that the best designed GA variant outperforms existing GA algorithms in solving the DNAFA problem for some data sets.

A. The DNAFA Problem

The DNAFA problem is defined as follows: Given a set of fragments, f1, f2,…, fn, drawn from a finite alphabet Σ = $\{A,C,G,T\}$, the goal is to find the shortest superstring that contain all the input fragments $F' =< f'_1, f'_2, \dots, f'_n >$ that maximizes the number of overlaps between every pair of two consecutive fragments and thus minimizes the length of F'.

$$MAX_{<f'_1,f'_2,\dots,f'_n>} \sum overlapping\ (f'_i f'_{i+1}) \qquad (1)$$

$$where\ 1 \leq i \leq n-1.$$

B. Assembly Process

To understand the assembly process, we've defined some key terms.

- Fragment: A short sequence of DNA bases. It is also called read.
- Coverage: The number of fragments at a specific position in the DNA.
- Prefix: A substring from the first characters of a fragment.
- Suffix: A substring from the last characters of a fragment.
- Overlap: Common sequence between the suffix of one fragment and the prefix of another.
- Layout: An arrangement of the collection of fragments based on their overlapping order.
- Contig: Contiguous overlapped fragments without gaps.
- Scaffold: The overlapped contigs, which may contain gaps.
- Consensus: Reconstruction of the complete sequence

In the assembly process, the input for the DNA fragment assembly is a set of fragments. The traditional assembly approach works in the following order: overlap, layout, and consensus [5].

- *Overlap stage:* Finding the overlapping fragments and computing their similarity score (overlap score). This means finding the longest match between the suffix of one fragment and the prefix of another.
- *Layout stage:* Finding the order of fragments based on the computed overlap score.
- *Consensus stage*: Reconstructing the complete sequence from the layout.

This paper is organized as follows: the second section discusses the related works, then the proposed design is discussed in detail in the third section. In the fourth section, the experiments and the method of conducting the investigations are detailed, and then the results are listed in the fifth section. The sixth section discusses these results by comparing them with previous works, and finally, the paper is concluded in the seventh section.

II. Related Works

This section presents the previous related works organized into two subsections: the first subsection summarizes the works solving the DNAFA with GA, and the second subsection introduces the works solving the TSP and QAP with GA.

A. Genetic Algorithm for DNAFA Problem

The basic genetic algorithm schema contains various concepts such as population encoding, population initialization, fitness function, selection, crossover, and mutation. Each concept has its own importance in the algorithm. By studying previous works, it can be noted that each concept can be done in a different way. In more detail, the population can be encoded in different ways in the GA, one such way is through segmented permutation [6], identity permutation [7]. Random generation, as in [8], the greedy approach, and the 2-opt heuristics, as proposed by Minetti et al. [8] and [9], are common strategies for generating the initial populations.

For the fitness function, the most commonly used fitness function is to maximize the overlap score, where the smith-waterman algorithm is used to calculate the overlap between the fragments [7]. The smith water man algorithm takes a lot of time but, even though it is the most precise algorithm for identifying similarity regions between fragments. Overlap score is considered the best measure for measuring the quality of the solution. It was used in most of the previous works [7], [8], and [9].

The crossover operator is the main operator of GA, as it plays a crucial role in efficiently exploring the search space of the optimization problem. The parents' characteristics are mainly inherited by crossover operators. Among the crossovers that were used in solving DNAFA, there was the order-based crossover (OX) as in [5], [10], [6], the edge-recombination (ER) [5], and the partially mapped crossover (PMX) [7], [9]. For the mutation, inversion mutation operators [10], and swap mutation [7], [9]were used for the DNAFA.

GA can be combined with other metaheuristics to achieve good results. For this purpose, Minetti et al. [10] designed a hybrid method named SAX that combined the GA with a simulated annealing metaheuristic. Another work, by Hughes et al. [7] combines different variations of GA in different ways. Also, the authors in [5] applied multiple algorithms, such as simulated annealing and scatter search with the GA. Another recent work is provided by Uzma and Halim [9] they combine GA and Power Aware Local Search (PALS).

The studies of Bucur [6], [11] focus on minimizing the total length of the scaffold (summing the length of the overlapped contigs). Unlike previous works, Bucur used simulated data sets where the fragments were of uniform length, they were able to measure the accuracy since they had the reference genome. However, as they mentioned, the main disadvantage of their method is its increased time complexity.

B. Genetic Algorithm for TSP and QAP

This section reviews GA algorithms designed to solve the TSP and QAP problems. Different types of encoding were used for the optimization problems TSP and QAP. Most works of the wide literatures used the identity permutation such as for TSP in [12], [13] and QAP in [14]. Another advanced types of population encoding were used for TSP such as value encoding [15], and real number encoding [16]. The common strategies of generating the initial populations are the random generation as investigated for TSP in [16] and the greedy method as in [17]. Recently, more advanced strategies have been developed, the author in [13] proposed Multi-Agent Reinforcement Learning (MARL) for solving TSP problems, and [14] implemented the sequential sampling method for solving QAP problems.

For the selection, the roulette wheel is the common selection operator used for optimization problems [15], [13], [18], [16], the tournament selection was implemented for TSP [17], and the stochastic remainder selection was used for QAP [19]. More recently, in [16], a greedy method was designed as a selection operator for TSP.

Several advanced crossover operators have been designed for solving TSP as well as QAP using GA algorithms. The Sequential Constructive Crossover (SCX) is an intelligent crossover designed by Ahmed [12] to solve the TSP. Recently, a modified version of sequential constructive crossover, named greedy SCX (GSCX), was proposed for solving TSP [20]. The reverse greedy sequential constructive crossover (RGSCX) and the comprehensive sequential constructive crossover (CSCX) are two new crossover operators that enhance SCX for solving TSP [21]. Other types of advanced crossover operators were designed in [18] to solve the QAP, relying on the idea of a frequency model. Three crossover operators were introduced for enhancing GA, namely, the Highest Frequency Crossover (HFX), the Greedy HFX (GHFX), and the Highest Frequency Minimum Cost Crossover (HFMCX).

Various types of mutations have been investigated for the TSP and QAP problems, including the exchange mutation [13], [16], [17], and the reciprocal exchange mutation [12]. More advanced mutation operators have been designed for the TSP and QAP problems, such as the interchange mutation in [15], and the inversion mutation in [17]. In [22], the adaptive and combined mutation operators were proposed for solving QAP.

C. *Other Metaheuristics Algorithms for DNA Fragments Assembly*

Particle swarm optimization (PSO) was reported in the literature for the DNA fragment assembly problem. Verma and Kumar [2] used the PSO with the smallest position value (SPV) rule. The PSO can be enhanced when combined with other algorithms, such as in Huang et al. [23], who proposed a hybrid particle swarm optimization algorithm (HPSO). The algorithm was divided into two parts: (1) Tabu search combined with PSO to improve solution quality and (2) simulated annealing combined with variable neighborhood local search (VNS). Additionally, the parallel approach can reduce the computation time, so, Mallén-Fullerton and Fernández-Anaya [2] presented a parallel heuristic based on the PSO and the differential evolution (DE), which is similar to GA, but DE relies on mutation operation, while GA relies on crossover operation to assemble better solutions. Mallén-Fullerton and Fernández-Anaya used a variation of the TSP (the Lin-Kernighan algorithm [24]) with some modifications to be applied for DNA fragment assembly. Another study is that of Huang et al [25], who presented a memetic PSO algorithm with a variable neighborhood search (VNS) approach as well as TS and SA, each of these algorithms is used in different ways and in different combinations. Indumathy and Maheswari [26] used a variant of the standard PSO called the constriction factor PSO (CPSO). Another proposed metaheuristic algorithm for solving the DNA fragment assembly problem is the problem aware local search (PALS) [27]. The main drawback of PALS is its quick convergence to local optima but combining it with other algorithms can overcome this drawback. Minetti et al. [28] used PALS by combining it with SA, this suggested method shows improved performance on the largest data sets when compared with SA and PALS separately. Another algorithm founded for the DNA fragment assembly is the bee colony, Firoz et al. [29] presented the artificial bee colony (ABC) algorithm and the queen bee evolution based on the genetic algorithm (QEGA). Majid al-Rifaie [30] investigated a new algorithm, stochastic diffusion search (SDS), which follows a different strategy for calculating the overlaps, picking a model from given fragments and trying to find the same model in the rest of the fragments. Among the fragments containing the model, the one with the highest similarity is picked, assembled, and then removed from the search space.

The previous paper [4] showed that the DNAFA optimization problem is a special case of two well-known optimization problems: the traveling salesman problem and the quadratic assignment problem. Particularly, that paper theoretically demonstrated that all three optimization problems have a similar topological structure and that they need to explore a search space of solutions with the same complexity to find an optimal solution. For this reason, the GA platform designed to solve the DNAFA problem is inspired by the efficient GA approaches developed for the famous combinatorial optimization problems, TSP and QAP. The GA platform gathers several advanced GA operators and tools that have demonstrated their effectiveness in the context of TSP and QAP.

Table I illustrates the GA parameters' settings from the literature for DNA, TSP, and QAP.

III. The GA Platform

The GA platform consists of the best and most advanced GA tools for the DNAFA problem (shown in Fig. 1.). One could build several variants of the GA to solve it by judiciously integrating the ingredients of this platform in different ways.

A. *The GA Operations of the Designed Platform*

This section describe the different GA operations involved in the platform that suggested earlier [4]. This paper will study all these operations, test them experimentally, and try different versions by combining different tools from the platform to create the best version that will be compared with other algorithms from the literature.

1) Encoding: For the encoding, the work will use the integer encoding, where the fragments encode as numbers, such that fragment one encodes as "1", fragment two encodes as "2" and so on.

TABLE I. GA PARAMETERS SETTING FROM THE LITERATURE FOR DNA, TSP AND QAP

GA Design and Experimental Settings	DNA_FA	TSP	QAP
Individual encoding	Integer numbers (an ordered sequence of integer numbers, each of which represents a fragment number).	Integer numbers (an ordered sequence of integer numbers, each of which represents a city to be visited)	Integer numbers (an ordered sequence of integer numbers, each of which represents an assignment of a task to a resource).
Population initialization	Random, greedy, 2-opt heuristics	Random, greedy, MARL (Multiagent Reinforcement Learning) [13].	Sequential sampling, random
Population size	Varies from 11 to 2500 Individuals.	Varies from 20 to 200 individuals.	Varies from 30 to 200 individuals.
Selection	Tournament.	Roulette wheel, tournament, greedy [31]	Roulette wheel, stochastic reminder selection.
Crossover	OX, ER, PMX, one-point order. CX	SCX, ERX, GNX, PMX, smart multi point crossover, order insert crossover.	SCX, OPX, SPX, HFX, GHFX, HFMCX, MPX.
Mutation	Inversion mutation, swap mutation	Reciprocal mutation, exchange mutation, interchange mutation, inversion mutation	Reciprocal exchange mutation, combined mutation, adaptive mutation, swap mutation [12], [14].
Crossover probability	Varies from (60% to 100%)	Varies from (90% to 100%)	100%
Mutation probability	2%	Varies from (1% to 20%)	Varies from (5% to 15%)
Stopping condition	No improvement for number of iterations.	Optimal rout, number of generations.	Number of generations, CPU time.
Number of runs	From 5 runs to 30 runs	From 10 runs to 30 runs.	20 runs.
Number of generations	Varying from (1000 to 512 K) generations	Varying from (20 to 10,000) generations.	Varying from (5000 to 10k) generations.

Fig. 1. GA platform design for the DNA fragments assembly problem.

2) Initial Population: Initial population includes the population size and the population generation method. For the population size, the work selects two sizes (200 and 500 individuals) and discusses how much time is saved if the population is small and how accurate it is.

For the population generation method, the GA platform design includes the random, greedy, and 2-opt heuristic strategies that have previously yielded good performances as shown in [7], [31], and [9]. Since the primary results showed that the greedy initialization method gave the best solutions, this paper displays its results. However, because the greedy method searches and generates populations intelligently, further experiments will investigate whether the greedy can find the solution from the beginning without relying on the rest of the GA operator.

3) Fitness Functions: As the fitness function is repeatedly applied to each individual of each generation, it should be relatively easy to compute and should also accurately evaluate the quality of each individual [12]. A simple fitness function aims to maximize the overlap score by summing the overlap for each of the adjacent fragment pairs, as expressed by the expression (2) in [9].

$$F = \sum_{i=1}^{n-1} w[i, i+1] \qquad (2)$$

where w $[i,$ i + 1] is the overlap score between fragment i and fragment i + 1. F is simple in complexity since it takes O(n).

To measure the solution quality, the work will use the following formula, which is often used in TSP and QAP problems to measure the solution quality.

Gap = ((ASV-BSV)/BSV) *100

Where ASV refers to the average solution value (average overlap) and BSV refers to the best-known solution value reported in the literature.

4) Selection operators: As roulette wheel selection is widely used and consumes the least amount of time and tournament selection can maintain diversity by giving an equal chance to all the individuals to compete [32], the roulette wheel and the tournament selections are selected to be added to the platform.

5) Crossover operators: Several crossover operators, including SCX, OX, CX, PMX, and ERX, have been chosen for inclusion in the platform. Special attention should be paid to SCX, as it is a smart crossover and was one of the best operators for the TSP and QAP problems and is expected to have the same performance in the DNA_FA context. Moreover, SCX has never been used to solve the DNA assembly problem before; therefore, this paper will present the results related to this crossover.

6) Mutation operator: The swap mutation operator and its variants were widely used for DNA_FA, TSP, and QAP [9] and [17]. Combined and adaptive mutations were designed for the QAP problem [22]. These three mutation types are included in the platform.

7) Stopping condition: The GA platform will stop if the solution is not improved at all during a certain number of iterations or a time limit is reached.

IV. Experiments

This section describes the data sets, the experimental setting, and the variable's values in this study.

A. Data Sets

The GA platform will be assessed on data sets produced by next-generation sequencing, the data sets are obtained from the National Center for Biotechnology Information (NCBI)[1]. These data sets are the same benchmarks used in the previous works mentioned in the related works section. This work used 17 data sets with a varying number of fragments, from 25 fragments to 352 fragments. The mean length of the fragment varies between 286 and 512 pb, the description of these data sets is given in Table II.

B. Experimental Setting

The designed algorithm has been implemented in C++ on a Windows 10 computer with a 2 GHz CPU and 16 GB of RAM. The work maintained the parameter values used in TSP and QAP that led to the best results. Based on Table I, this work chose the values for the GA operators, which are described in detail in Table III. The work applied to each data set 60 experiments using different GA parameters and operators. In detail, it applied two types of population size, three types of initialization, two types of selection, and five types of crossover (2*3*2*5 = 60). Since the GA is a stochastic process, each experiment was run 30 times to ensure the satiability of the given results (30*60=1800 experiments). Since there were 17 datasets, the total number of experiments reached more than 30 thousand (17 * 1800=30,600 experiments)

TABLE II. Benchmarks' Datasets, where Total Data Size is Number of Fragments * Mean Fragment Length

Benchmark	Mean fragment length	Number of fragments	Total data size
x60189 4	395	39	15405
x60189 5	286	48	13728
x60189 6	343	66	22638

The NCBI houses a series of databases relevant to biotechnology and biomedicine and is an important resource for bioinformatics tools and services. Major databases include GenBank for DNA sequences. https://www.ncbi.nlm.nih.gov/guide/

C. *Evaluation Metrics*

The performance of the GA algorithm will be measured in terms of the following:

- Overlapping scores: should be high. The overlap score measured by calculating the length of the overlap between each fragment and all the existing fragments. The overlap scores were computed using the Smith-Waterman algorithm. Two forms of overlap scores were reported in the results: the best overlap scores out of 30 runs, and the average overlap score for 30 runs.
- Computational complexity (time complexity): should be minimized. The time for the complete assembly process was divided into two stages: the time for calculating the overlap score in the preprocessing stage, and the time for the GA to find the best solution. This paper only showed the time of the GA because this work studying the change in the performance of the GA and also because the time for SW is constant for each dataset regardless of which GA variant is studying.

D. *Aspects of Investigations*

This work study the effect of some algorithm components on two metrics: the GA running time and the overlap score. It will discuss the effect of population generation, including the population size and the population generation method, the effect of the crossover types, as well as the effect of the selection types. According to the comprehensive experiments, below are the major interesting investigations aspects.

- Crossover types on overlap score when varying the population generation method.
- Population size on overlap score and GA running time.
- Selection types on overlap score and GA running time when varying the population generation method.

V. Results

This section presents and discusses the results obtained from the experiments conducted in this study. The results in this section are organized in subsections. Each subsection reports the results of a specific investigation, as mentioned earlier. In each subsection, the results will be illustrated with tables or pictures and discussed, in addition to summarizing the findings at the end of each subsection.

A. *The Effect of Crossover Type on Overlap Score when Varying the Population Generation Method*

This section studies the effect of the crossover types on the overlap score when varying the population generation methods while the other GA operators remain constant. For simplicity, the type of selection operation is the tournament, and the population size is 200.

Each of the figures below represents the effect of a specific population generation method on the best overlap score.

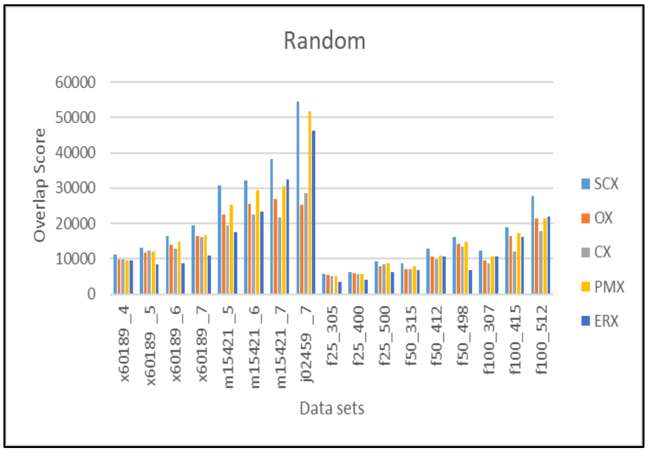

Fig. 2. The effect of crossover types on overlap score when generation population method is random.

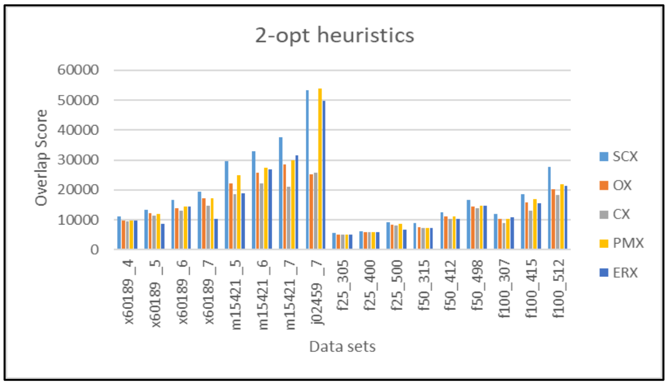

Fig. 3. The effect of crossover types on overlap score when generation population method is 2-opt heuristics.

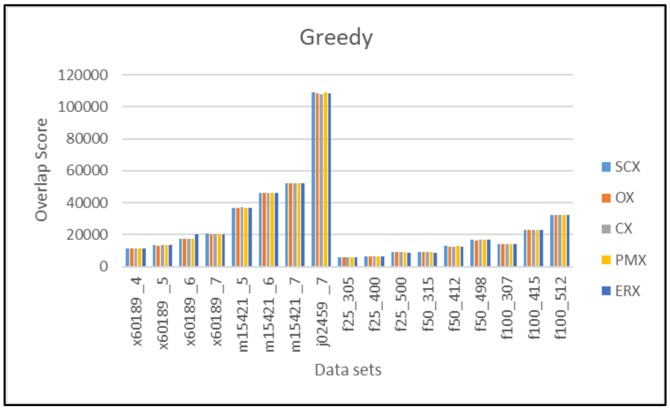

Fig. 4. The effect of crossover types on overlap score when generation population method is greedy.

From Fig. 2, Fig. 3, and Fig. 4, it can be seen that the greedy initialization type is the one that gives the highest overlap score for all the data sets. Moreover, the 2-opt heuristics and random method gave different results but clearly showed that SCX is the best crossover in the majority of cases. Clearly, the SCX has the best accuracy regardless of the population generation methods. SCX is less sensitive to the type of initialization, whatever the type of initialization, it gives good results in every case. Also, the greedy approach improves the performance of all crossover operators. It seems only when population generation method is greedy, it is not clear if SCX is still the best. This reveals the impact of the population generation method and how creating the population in a smart way from the beginning has been a strong factor in improving the results and reducing the differences between the types of crossovers. In more detail, the greedy improved the SCX overlap results by 11.7% compared to random and 2_opt heuristics, also improved the OX and CX results by 25.9% and 31.01%, respectively. And improve the PMX and ERX by 22.01% and 37.7%, respectively. This demonstrates that the SCX was the least sensitive crossover to the population generation method among the crossover types and maintained the highest overlap score. Thus, further investigation is done by checking the time cost for the greedy method using small and large population sizes.

The results of this study are summarized as follows:

- SCX is not sensitive to the type of initialization, whatever the type of initialization, it gives good results in every case.
- OX, CX, PMX, and ERX are sensitive to the type of generating population, as they perform better with the greedy initialization than with the random and the 2-opt heuristics. Because the greedy is good at generating a good initial population.
- The population generation method has a strong impact on improving the results.

B. *The Effect of the Population Size on Overlap Score and GA Running Time*

This subsection investigates the effect of population size on the overlap score, including the best overlap score and average overlap score. In addition, the effect of population size on the GA's running time.

1) The effect of population size on overlap score: Recall that this paper only report for the SCX; Table IV shows the effect when the initialization method is greedy, the crossover type is SCX, and the selection type is tournament. The "gap" column represents the gap on overlap which calculated by the formula in Section III and the "absolute difference" represents the pure difference between 500 and 200 individuals.

In this investigation, when the crossover is SCX, and the generation method is greedy, and the selection type is tournament, the results show that when the initial population is 60% less, the GA still gives high overlap score in all datasets with an average difference of 0.14%. This is important since decreasing the initial population size decreases the computation significantly.

Moreover, for datasets (f*) this work show a significant increase in accuracy compared to what is reported in the literature. The increase reaches 172.57%, with the 200-population size, and 171.9% with the 500-population size. Moreover, when computing the difference between the best overlap score and average overlap score, there was not a significant difference in performance, where the best overlap score is only 0.44% and 0.42% better than the average overlap score on 200 and 500, respectively. Thus, the paper only reports the best overlap score in the rest of the paper. With regard to the gap, the table shows that our results are better in 9 data sets out of 17. When the absolute difference is negative, that means the 200 size is better than the 500. This was clear for eight data sets, and their performance was equal in four data sets, this makes the smaller size more suitable.

The results of this study are summarized as follows:

- Increase the size of the population increase the computational time, however it may give chance to have good results for the big data sets.
- The population sizes of 200 and 500 individuals do not have a noticeable difference in the quality of the solution; therefore, it is preferable to take the smaller size.

TABLE IV. THE EFFECT OF POPULATION SIZE ON OVERLAP SCORE FOR SCX WHEN THE GENERATION METHOD IS GREEDY AND SELECTION TYPE IS TOURNAMENT

Data set	**BSV**	**200 individuals-greedy**			**500 individuals-greedy**			**Gap on the overlap (%)**		**Absolute difference (500, 200)**

2) *The effect of population size on GA running time:* This section studies the effect of population size on the GA running time. The following tables reveal this effect when the type of crossover is SCX, the type of initialization is greedy, and the selection type is tournament. In addition, Table VI compare the use of complex SCX crossover operators with small population size to the use of simple PMX, ERX, OX and CX crossover operators with large population sizes. The 200 and 500 refer to small and large population sizes, respectively.

- The "GA time" column represents the time for the whole GA to find the result,
- The "greedy time" column represents the time for initializing the population with the greedy method.
- The "overlap after greedy" column represents the overlap score after creating the population.
- The "overlap after GA" column represents the overlap score when the algorithm is done.
- The "Increase in overlap "column represents the percentage increase in the overlap score between the overlap score after greedy and the overlap score at the end of the GA.
- The "Absolute difference in time" column shows the difference in time between 500 and 200 individuals for the GA time.

As indicated earlier, the question posed for discussion is whether the greedy might override the algorithm's performance, is the solution comes from the greedy or the GA finds the solution, is the time spent in creating the population or in finding the solution. For this matter, the following table illustrate the overlap score after creating the population with the greedy method, as well as the overlap score when the algorithm is done. In addition to the time taken to create the population and the time taken by the algorithm to find the solution, the least time and the best solution for every data set are marked in bold.

TABLE V. The Effect of Population Size on GA Running Time (in Sec.). For SCX when the Generation Method is Greedy and Selection Type is Tournament

f50_498	**1.5**	0.8	16802	**17051**	1.46%	2.2	1.9	16802	17014	1.25%	0.5
f100_307	**2.6**	2	14100	**14319**	1.53%	5.5	5.3	14103	**14260**	1.10%	2.9
f100_415	**3.6**	1.9	22154	**23008**	3.71%	6.2	4.7	22154	**22993**	3.65%	2.6
f100_512	**4.8**	2.9	31187	**32384**	3.56%	8.6	7.6	31189	32339	3.56%	3.8

The table above shows that a small population size takes less time in the majority of the data sets and gives more opportunity for the algorithm to improve the solution. However, the larger population size takes more time to generate but less time to find the solution. In the case of small data sets, most of the time is taken to create population, while the time taken to find the solution is very small. These results showed that when using a larger population size with the greedy method, the improvement in the solution is small and may be nonexistent in the case of small data sets such as (f25_305, f25_400). Small population sizes are better suited to the greedy method because they allow the algorithm to improve the solution while also taking less time. When the datasets (x60189_4 and f25_500) are excluded, the results in Table V for total time show that there is a 49.21% reduction in time when using a 40% smaller population. Moreover, this table showed us that the greedy method contributed 95% to improving the solution, and the GA improved the solution by 3.51% for the 200-population size and 2.99% for the 500 size. This supports the previous investigation, that SCX with a smaller population size is better.

But it may come to mind that if we choose the larger population size with a simple crossover, could it give an overlap higher than the SCX with the small population size in a reasonable time? So, recalling what previously raised for discussion the following table compare SCX with the smaller population size, with other types of crossovers with a larger population size, for time and overlap score.

The results in Table VI show in 14 out of 17 data sets, using SCX with 40% less population size leads to better results than other crossovers with larger size. In addition to having a 40% smaller population size but comparable accuracy, SCX is also significantly faster than the other crossovers. The results show that SCX is 26.92% faster than PMX in all data sets, except for “x60189 _6” and “f25_500” datasets, and in some datasets, it is 59.46% faster (as in f50_498). Also, SCX is 38.38% faster than ERX in all data sets, except for “x60189 _4” and “f25_500” datasets, and in some datasets, it is 68.75% faster (as in f50_498). Also, SCX is 34.64% faster than OX in all data sets except for x60189_4, and SCX is 32.89% faster than CX in all data sets except for “x60189_4”, “x60189_6”, and “f25_500”. There is a similarity in the performance of all crossovers in the small data sets. But the SCX is still the dominant one. This confirms the results obtained previously that with smallest population size SCX still gives the best solution.

TABLE VI. COMPARING SCX WITH THE SMALLER POPULATION SIZE, WITH OTHER CROSSOVERS WITH A LARGER POPULATION SIZE

f100_512	32384	**4.8**	***32352***	5.1	31823	6.5	32266	6.3	32254	6.3

The results of this study are summarized as follows:

- The greedy method had a clear impact on the GA performance and contributed to improving the solution by 95%.
- Most of the time is spent on creating the population especially with the large population size.
- Smart crossover like SCX with small population size is better than simple crossovers with large population size.

C. The Effect of Selection Types Varying the Population Generation on the Overlap Score

This section studies the effect of the initialization and selection types on the overlap score. The following figures show this effect when the type of crossover is SCX and the population size is 200, since previous investigations show that a small population size is more suitable.

Fig. 5, Fig. 6, and Fig. 7 show the effect of initialization types and selection types on the best overlap score. Clearly, the greedy initialization type gives a better overlap score than the random and 2-opt heuristics in 15 data sets out of 17.

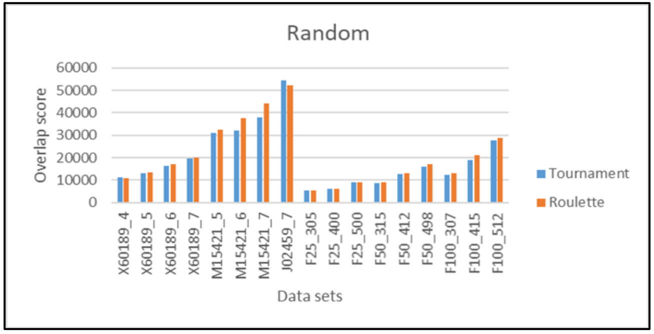

Fig. 5. Effect of selection types with random initialization on best overlap score.

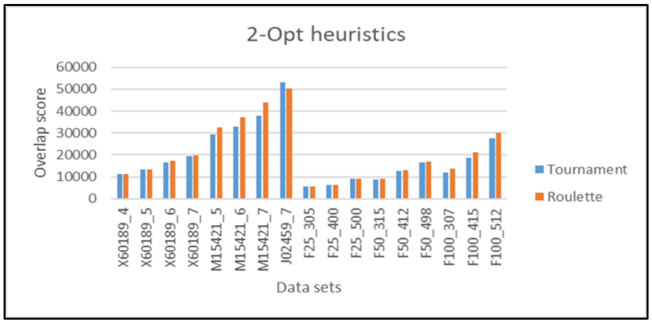

Fig. 6. Effect of selection types with 2-opt heuristics initialization on best overlap score.

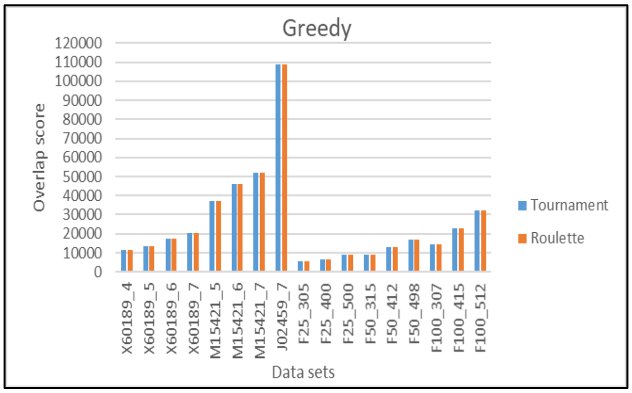

Fig. 7. Effect of selection types with greedy initialization on best overlap score.

Fig. 8, Fig. 9, and Fig. 10 show the effect of initialization and selection types on the average overlap score. The greedy initialization still dominates the random and 2-opt heuristics for the average overlap score as well, giving a higher average in 16 out of 17 data sets. Additionally, the roulette wheel selection is still better than the tournament with the random and 2-opt heuristics. However, with the greedy initialization, the tournament is better.

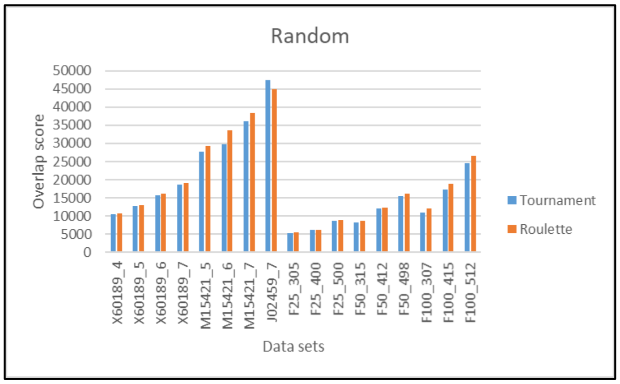

Fig. 8. Effect of selection types with random initialization on average overlap score.

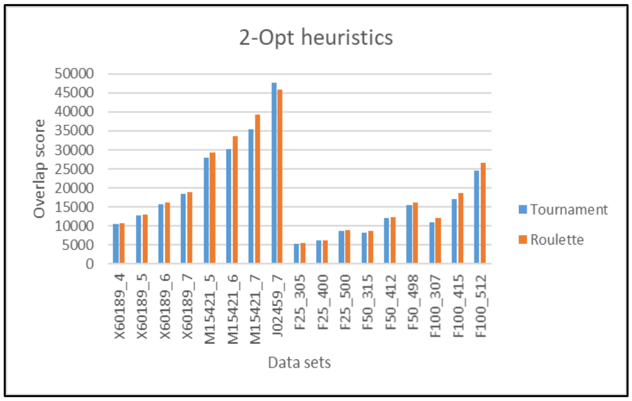

Fig. 9. Effect of selection types with 2-opt heuristics initialization on average overlap score.

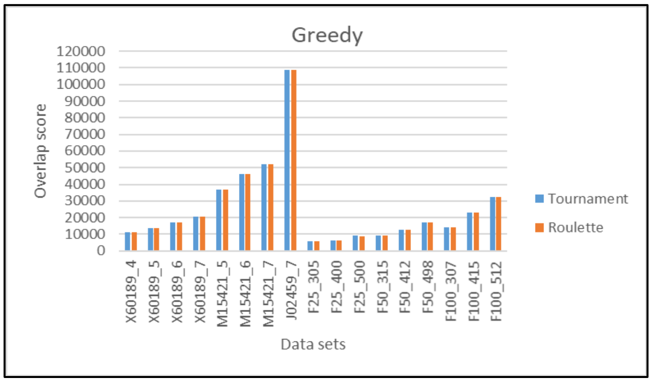

Fig. 10. Effect of selection types with greedy initialization on average overlap score.

The results of this study are summarized as follows:

- The greedy initialization type is the best among the majority of the data sets for the best overlap scores and the best among all the data sets for the average overlap scores.
- The random initialization type is better than the 2-opt for the best overlap score, but their performance is almost similar for the average overlap score.
- The tournament selection type is better than the roulette wheel selection for the best and average overlap scores with the greedy.

D. *The Effect of Selection Types Varying the Population Generation Method on GA Running Time*

Table VII illustrates the results obtained when studying the effect of initialization and selection types on the GA running time. It shows this effect when the type of crossover is SCX, and the population size is 200. The GA time column represents the time it took for the GA to find the result. The least time for every data set is marked in bold green when the selection type is the tournament and marked in bold blue if the selection type is the roulette wheel. The gap column shows the difference in time between the generating methods (i.e., greedy, random, 2-opt heuristic).

Table VII shows that the greedy initialization type is the best from the viewpoint of time complexity. The random and 2-opt heuristics types take more time than the greedy, but the random-type records less time for 12 data sets out of 17, while the 2-opt heuristics record less time for three data sets and equal time for two. As for the selection type, the roulette wheel selection dominates the tournament selection by recording the least time for 14 data sets out of 17. The gap confirms as in the previous section that the greedy generating method is better than the random and 2-opt, and the random is better than 2-opt. In more detail, the results show that the greedy initialization results are fast compared to both random and the 2-opt heuristic in most of the datasets. Except for datasets M15421_7 and J02459_7, the greedy approach is 47.39% and 48.17% faster than random, and 2-opt heuristics when selection type is tournament. Also, greedy approach is 66.90% and 67.19% faster than random, and 2-opt heuristics when selection type is roulette. For the other crossovers OX, CX, PMX, and ERX, the tournament was the best in terms of solution quality, and the roulette was the fastest, because the tournament chose multiple parents every time and compared them to pick the better one.

The results of this study are summarized as follows:

- The greedy initialization type takes less time than the random and the 2-opt heuristics in almost all cases except for the large data set (J02459_7), because the greedy method takes time to create the population, the larger the data, the more comparisons that greedy makes, and therefore it takes longer time.
- The random initialization type is faster than the 2-opt heuristics in 12 data sets out of 17, this is an expected result.
- The roulette wheel selection type is faster than the tournament selection, but the tournament is better for solution quality.

TABLE VII. THE EFFECT OF INITIALIZATION TYPES AND SELECTION TYPES ON THE GA RUNNING TIME (IN SEC.) FOR SCX CROSSOVER ON REAL DATASETS THE BOLD GREEN COLOR REFERS TO THE LEAST TIME FOR THE CORRESPONDING DATA SET WHEN THE SELECTION TYPE IS TOURNAMENT, AND THE BOLD BLUE COLOR REFERS TO THE LEAST TIME WHEN THE SELECTION IS ROULETTE

VI. Discussion

This section discusses the findings that emerged from the results presented in the Results section. And conclude that the small population size (i.e., 200 individuals) is more suitable for most cases. And the greedy type of initialization is the best when look for good overlap score results and time. Furthermore, the results show that the roulette wheel selection type is more suitable than the tournament selection in the context of time, but the tournament is better in the quality of the solution. Also, this work shows that the SCX crossover is the best in the context of best overlap score and average overlap score.

This study has multiple GA versions, but in comparison to the previous works, we selected the best version we got. Moreover, the comparisons are divided as follows:

- Previous works that used the GA, the comparison is presented in Table VIII.
- Previous works that used other metaheuristics algorithms, the comparison is presented in Table IX.

Table VIII compares the designed GA results and the other previous GA work's results in the context of the overlap score. The best results are marked in bold. The "difference in percentage" column shows the difference between our best results and those of the previous works. Clearly, our results for the F-series data sets (from F25_305 to F100_512) dominate all the previous work's results. This work got less than the best results of previous works in eight data sets out of 17, however, our results are still better than [23], [25], and [9] for these data sets.

Moreover, this work obtained better results than the results of all the previous works in nine data sets out of 17.

With regard to the time, the results were given in a reasonable time and there is no significant change or difference in time, because the dominant time is actually not the GA time but the assembly time (i.e., in our case, the Smith-Waterman algorithm.). GA is useful when the data set is large, and this is expected because GA avoids large search space. The results show that the designed GA gives the results in less time for large data sets such as M15421_6, M15421_7, and J02459_7, which have several fragments that vary from 173 to 352 characters.

VII. CONCLUSION

This paper is a continuation of our previous work [4] to solve the DNA fragment assembly problem. As was pointed out in the introduction to this paper, the DNAFA is an optimization problem that attempts to reconstruct an original DNA sequence by finding the shortest DNA sequence from a given set of fragments. We have designed a platform for the genetic algorithm, from which more than one version of the genetic algorithm can be deduced to solve this problem. The design was inspired by the good designs that solved TSP and QAP problems. This study is the first to our knowledge that examines the genetic algorithm for the DNAFA problem from this perspective. In more detail, this study has gone a long way towards investigating the effect of genetic algorithm operators on the quality of the solution to the DNAFA problem. The study focused on investigating the effect of the initial population, size of the population, selection types, and crossover types.

This paper recorded the important results and came out with some findings, the most obvious finding to emerge from this study is that the SCX crossover is a smart crossover and has never been used before with DNA_FA, SCX crossover gave better results compared to the rest of the studied crossover types. Furthermore, the results show that the population generation method has the greatest influence on GA performance in terms of time and solution quality. Also, we configured the best-designed GA variant that outperforms the existing GA algorithms solving the DNAFA problem. This GA variant features the use of 200 individuals for the population size along with the greedy method for initializing the population, tournament selection, and SCX crossover. This study has found that generally, the size of the population does not significantly affect the quality of the solution, especially if the type of initialization is good. The results were good and competitive compared to the results of previous works. Our design showed that the results were better than all previous results from the literature for some data sets.

There is still ample scope to study and solve this problem, an interesting point will be how to find a way to create the population intelligently and without consuming a lot of time, given that the greedy is time consuming. Moreover, further research might explore or investigate the effect of other GA operators (e.g., mutation types and stooping conditions). Also, investigate the effect of combining different types of GA operators (initialization types, crossover operators, and mutation operators) on the results. Another possible area of future research would be to combine the data sets (next generation with the third generation).

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Imam Mohammad Ibn Saud Islamic University for funding and supporting this work through Graduate Students Research Support Program.

Abstract—**The use of digital media, such as social networks, has promoted the spreading of fake news on a large scale. Therefore, several Machine Learning techniques, such as artificial neural networks, have been used for fake news detection and classification. These techniques are widely used due to their learning capabilities. Besides, models based on artificial neural networks can be easily integrated into social media and websites to spot fake news early and avoid their propagation. Nevertheless, most fake news classification models are available only for English news, limiting the possibility of detecting fake news in other languages, such as Spanish. For this reason, this study proposes implementing a web service that integrates a deep learning model for the classification of fake news in Spanish. To determine the best model, the performance of several neural network architectures, including MLP, CNN, and LSTM, was evaluated using the F1 score., and LSTM using the F1 score. The LSTM architecture was the best, with an F1 score of 0.746. Finally, the efficiency of web service was evaluated, applying temporal behavior as a metric, resulting in an average response time of 1.08 seconds.**

Keywords—Fake news; LSTM; classification; web service; machine learning

I. Introduction

In the last few years, the use of technology and digital media has increased. Besides, due to the pandemic, people have chosen to use digital media, such as social networks, to get news [1]. However, a large amount of unverified news could be fake [2]. Fake news has always existed, but there is a greater irruption in open and unrestricted access platforms nowadays. Therefore, the propagation of fake news can cause information theft, scams, collective hysteria, or discredit the honor of a person or an institution [3]. In order to solve the problem of fake news propagation, some techniques based on machine learning, Natural Language Processing, and information retrieval have been proposed to detect this kind of news automatically and make decisions [4]. Machine learning models have been used effectively in text classification to determine whether a text is racist, positive or negative, fake or genuine, and so on.

There are many classification models to determine whether the news is authentic or fake [5]–[10]. In [11], the authors propose a Naïve Bayes model for fake news classification with an accuracy of 84%. On the other hand, in [12], web scrapping and crawler techniques are applied in order to create a dataset with tweets and Facebook web links to train models. Since there are many machine learning models like decision tree, Support Vector Machine (SVM), Naïve Bayes, random forest, and Logistic Regression, some works have compared their performance in the task of news classification as fake or real. On the one hand, in [13], the comparison reveals that Naïve Bayes achieves the best performance on the tested datasets achieving an accuracy of 66%, and, in [14], a Random Forest model allows the classification of news into fake or real with an accuracy of 76.94%. On the other hand, in [15], the authors propose a neural network architecture that outperforms previous approaches with an accuracy of 94.21% on test data. Nonetheless, achieving these high-performance values is challenging for detecting fake news in Spanish due to the limited datasets in this language.

Most of the machines learning models aim to classify news in English. Therefore, this study presents a machine learning based framework to classify news in Spanish into real or fake. The web service with the classifier model was developed following the CRISP-DM and SCRUM methodologies. The main contributions of this study are listed as follows:

- Machine learning model to classify fake news in Spanish. To the best of our knowledge, this model is the first one to classify news in Spanish by using MLP architecture.
- A web site based on web service architecture is built to access the classifier. That is, the machine learning model is integrated to the web service to be available in real-time.

The remainder of this paper is organized as follows. Section II describes previous studies related to fake news classification. Section III then presents the methodology applied in this study. Section IV describes the classification model with the integration into the web service. Section V presents the experimental results and evaluation metrics of the proposed classifier, while Section VI presents the conclusion of this work.

II. Related Work

Since fake news can be harmful to individuals or organizations, effective ways to detect this kind of news have been developed through the years. The problem can be framed as a two-class (real/fake) classification. Therefore, this study reviews approaches for fake news classification based on machine learning classifiers, such as decision trees, support vector machines (SVM), and Naïve Bayes. In [16] , the researchers propose a fake news detection system that uses the decision tree algorithm to classify the news from two sources. Then, they compare the results against the result obtained with the SVM algorithm showing that the results obtained with the decision tree are more accurate than with SVM, with an accuracy of 97.67% and a precision of 94.60% against the SVM results of 91.74% in accuracy and 90.12% in precision.

On the other hand, the work done in [17] compares the SVM with an apriori algorithm performance on a dataset that contains four attributes and 311 instances. In this case, the results show that SVM achieves a better accuracy of 91.87% while the apriori algorithm only gets an accuracy of 31.76%. It means it is better to project data into a hyperplane to look for discriminative features in this projected space rather than look for them directly in the source data space [18]–[20]. In [21], the authors apply a machine learning algorithm and use Natural Language Processing (NLP) to pre-process the data to increase the accuracy of the machine learning algorithms. The researchers pre-process a dataset from the Kaggle website of 20,800 news articles containing 10,387 real news and 10,413 fake news. The pre-processing consists of tokenization, removing stop words, stemming, and vectorizer through term frequency-inverse document frequency (TF-IDF). Then the pre-processed data is used to feed six ML algorithms: logistic regression, Naïve Bayes, K-Nearest Neighbor (KNN), SVM, random forest, and decision tree. They use the K-fold cross-validation, confusion matrix, and classification report (precision, recall, and F1-score) for model evaluation. Thus, after comparing the various models, the accuracy score is used to determine the best one giving the result that random forest and decision tree models achieve the best performance with over 99% accuracy. In comparison, the KNN got the worst accuracy, with ~52% accuracy, and the other models' accuracies were over 96%. The results indicate that NLP contributes to models' training improving their accuracy.

Helmstetter et al. [22] use a dataset collected from Twitter. From the dataset, they use the text features as well as the metadata from Twitter, which corresponds to user-level features (e.g., number of followers) and tweet-level features (e.g., number of retweets). Moreover, they extract additional features, such as the sentiment features using SentiWordNet [23] and the topic features using Latent Dirichlet Allocation (LDA) and Hierarchical Dirichlet Process (HDP) models. Then, the features are scaled and selected in order to feed the learning algorithms that include some ML algorithms; however, the best performance is achieved by the ensemble method XG-Boost which achieves a 0.94 F1-score. Another approach, like the one presented in [24], also proposes a voting ensemble mechanism with three classifiers: Decision Trees, Naïve Bayes, and KNN to achieve a lower error rate than using the models separately. Besides, Wynne et al. [25] proposed a large ensemble model called the two-layer ensemble model, where there is a first layer that contains two sets of voting classifiers with five classifiers each, and the output of these two voting classifiers are used as input for the second layers which contains a third final voting classifier. In this case, the final voting classifier performs best on the LIAR dataset. However, this approach can be time-consuming and needs a good number of resources since one needs to train each of the ten classifiers. Furthermore, Tian et al. [26] use a feature selection method called Genetic and Evolutionary Feature Selection (GEFES) [27] to identify a subset of features by means of a steady-state genetic algorithm. The selected features are used as input for a KNN model to classify news as fake or genuine, improving the model's performance. For experiments, the authors use the dataset BuzzFace which consists of 2282 news from Facebook related to the 2016 US presidential elections. On this dataset, the authors achieved an accuracy of 91.3% for the classification task using the proposed approach.

Some researchers have proposed methods that work with news in other languages different than English. For instance, Billones et al. [28] train ML models with a dataset of news in Filipino and compare the performance of the models with models trained with English news. The results show that the models perform better on the English dataset than on the other language dataset due to the limitation of labeled data amount in other languages. Khalil et al. [29] tackle the problem of few data in other languages creating a large Arabic fake news corpus of 606912 articles. Then they train and test some deep learning algorithms getting the best accuracy of 78.3% with the capsule network [30] that is based on a convolutional neural network. Additionally, many other works use deep learning strategies for English news classification. For instance, Alameri et al. [31] use neural networks and Long Short-Term Memory (LSTM) networks and compare them with classic ML approaches giving as the result that the LSTM outperforms the other models in terms of accuracy, precision, recall, and F1-score. Gupta et al. [32] also use deep learning approaches that include Convolutional Neural Networks (CNN) and LSTM, which are tested individually and, after, are used as an ensemble model to get the probability of truth. In this case, individually, CNN gets better results than LSTM. Mahmud et al. [33] use Graph Neural Networks (GNN) to make predictions based on text and graph data where the text is extracted using text representation learning techniques, and the graph contains the news propagation data. The addition of graph data boosts the performance of the model.

The literature review highlights the importance of deep learning models in the task of news classification and emphasizes the need for datasets in languages other than English, such as Spanish. Therefore, this study proposes conducting a comparative analysis of machine learning models and deep learning models for detecting fake news in Spanish to develop a tool that implements the best method to determine the authenticity of news in real-time.

III. Methodology

This section describes the applied methodologies for creating the fake news classification web service. CRISP-DM was applied to implement the fake news classifier model, while SCRUM was used to develop the web service (see Fig. 1).

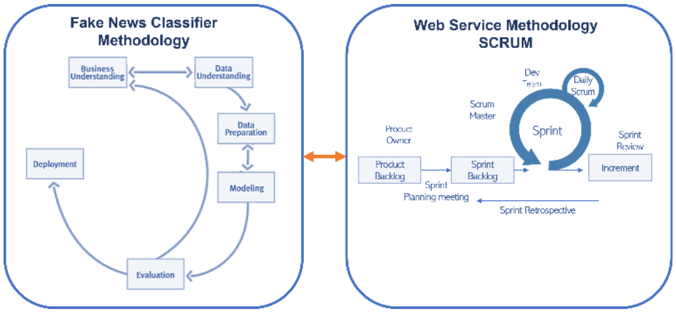

Fig. 1. Methodologies used to implement the proposed classifier.

A. CRISP-DM Methodology

In order to develop the fake news classifier based on deep learning techniques, CRISP-DM Methodology is applied. This methodology consists of six phases: Business Understanding, Data Understanding, Data Preparation, Modeling, Evaluation, and Deployment.

The phases are summarized in the following points:

- Business Understanding: In this phase, the fake news problem is analyzed. To this end, the state-of-the-art frameworks for fake news classification are reviewed, allowing to determine that there are few fake news classifiers in Spanish since most existing approaches focus on English news. Thus, this study aims to develop a fake news classifier for Spanish news.

- Data Understanding: Several datasets were analyzed to create a suitable dataset in Spanish for training the model. The final dataset consists of news extracted from the following sources: Fake-news-in-Spanish[1], Fake and real news[2, 3] and Fake news Corpus Spanish[4]. Besides, news from a website with fake Ecuadorian news was extracted to complement the dataset. The dataset consists of 9294 news and the corresponding labels: 4081 fake news and 5213 real news.

- Data Preparation: In this phase, the data are integrated from multiple sources using Python. Each news is preprocessed by removing stop words; that is, the dataset does not contain words such as “the”, “is”, “are”, etc. Then, stemming is applied to each word to extract the base form of the word. For instance, the stemming of the word “eating” is “eat”. Finally, tokenization is applied for each news.

- Modeling: The review of state-of-the-art approaches for fake news classification (e.g., Naïve Bayes, Logistic Regression, Support Vector Machine, K-nearest neighbor, Decision Trees, and deep-learning-based approaches, to name a few) shows that deep learning models are the most suitable for fake news classification. Therefore, artificial neural network architectures such as MLP (Multilayer Perceptron), CNN (Convolutional Neural Networks), and LSTM (Long Short-Term Memory) were implemented in order to determine the best model for detecting fake news in a Spanish corpus. After the implementation, the models were trained using 80% of news from the dataset. The 20% of data was used for testing.

- Evaluation: The models based on MLP, CNN and LSTM are evaluated by using F1 score. According to the results of this quantitative evaluation, the LTSM model was the model with the best F1 score for classifying Spanish news as fake or real.

- Deployment: In this phase, the classifier was integrated with a web service to be available online.

B. SCRUM

In order to develop a web service that allows the execution of the fake news classifier, SCRUM methodology is followed. This methodology mainly consists of:

- Product Backlog, where is defined all the system requirements.

- Sprint Backlog refers to the requirements to be developed in the spring. They are defined during the spring planning meeting.

- Sprint is the period that the Scrum Team (developers) uses to complete the development of the requirements within the Sprint Backlog. After a Sprint is completed, there are the Sprint Review and the Sprint Retrospective. Each sprint had duration of 50 hours.

The architectural design SOA (Service Oriented Architecture) is defined for the system and a user interface is designed (see Fig. 2). Then, the system that integrates the fake news classifier model was developed using the Flask framework. In addition, HTML, CSS, and JavaScript are used for the front end.

IV. The Proposed Method

This section introduces the fake news classifier integrated into a web service available through the Internet. The overview of the proposed solution is shown in Fig. 3.

[4] https://huggingface.co/datasets/sayalaruano/FakeNewsCorpusSpanish

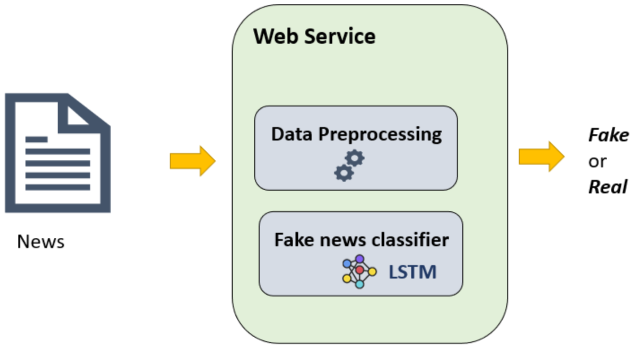

Fig. 3. Overview of the proposed solution.

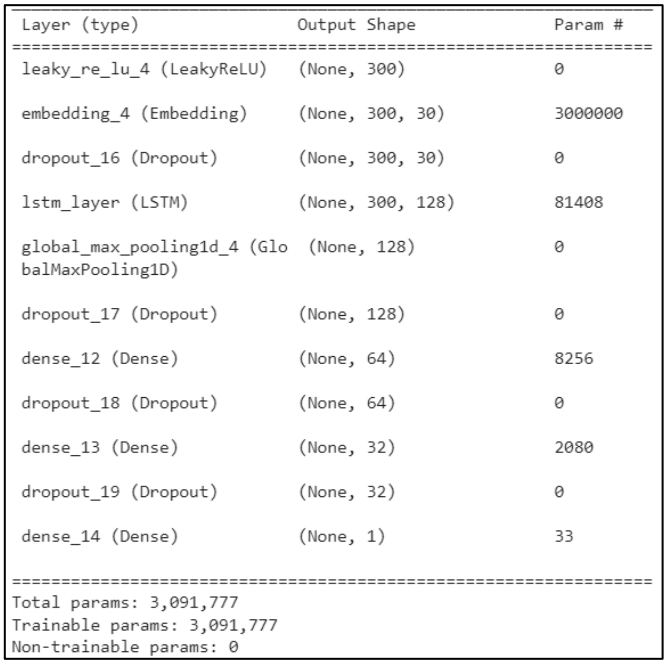
The proposal includes a binary classifier that indicates whether the news is fake or real. The model's input is pre-processed text by removing stopwords, applying stemming, and tokenization. On the other hand, the classifier model is based on an LSTM architecture, and different hyperparameters were evaluated to select the best model configuration. Fig. 4 summarizes the final architecture of the model.

V. Results

This section presents the results of the evaluation of the proposed model. As aforementioned, there was a comparison of several shallow models with deep learning models, specifically with artificial neural networks (ANN). Since ANNs had a better performance, three ANN architectures were evaluated: MLP, CNN, and LSTM to select the best model for the proposed solution.

The evaluation metric used to evaluate the model performance was the F1 score, whose formula is:

$$F1 = 2 * \frac{Precision*recall}{Precision+recall} \quad (1)$$



```

```

Fig. 4. LTMS Architecture.

TABLE I. Evaluation Results

Model Architecture	***F1 Score***
MLP	0.738
CNN	0.678
LSTM	**0.746**

Table I shows the results of the models' evaluation. LSTM achieves the best performance with an F1 score of 0.746, followed by MLP and CNN with an F1 score of 0.738 and 0,678, respectively. Since LSTM is the best model, the developed web service integrates this model.

On one hand, the CNNs performance is poorly against MLP and LSTM since it is more oriented to work with images than with text. On the other hand, LSTM networks perform better than others since these kinds of networks are capable of learning sequences that allow a classification based on the context of the whole text.

During the training stage the values returned by the loss function were decreasing almost constantly all the time, however, the validation loss values just decreased until 100-ish epoch as shown in Fig. 5. It means that after epoch 100 the model starts to overfit then it was trained only until this epoch to avoid overfitting.

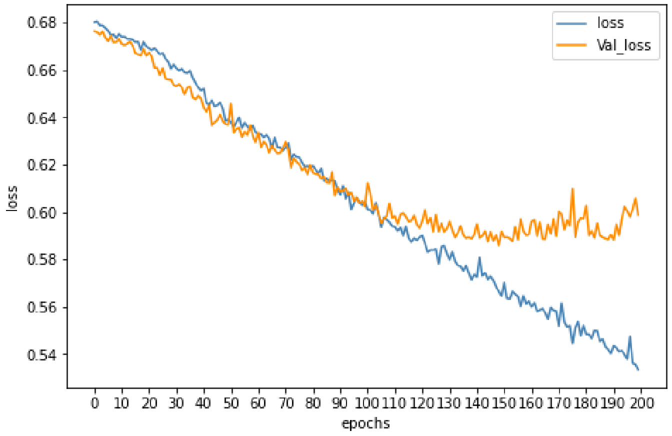

Fig. 5. Loss functions values updates through epochs.

Afterwards, the obtained results are compared with some previous work that have trained machine learning and deep learning models for fake news detection with datasets containing news in Spanish. Table II presents the F1 Scores obtained by six methods on the task of fake news classification in Spanish. The results show that the proposed method achieves the best performance while the random forest approach gets the worst performance. Additionally, it should be noted that there are few works that use a Spanish corpus and in the existing works the used corpus are small containing at most a set of 1500 news against the set of 9294 news that was used in the current research.

Furthermore, the performance of the web service was evaluated to determine the time required for news classification. The web service was deployed on Microsoft Azure, and its time response was considered as a metric, starting from the moment the user sends the request to the web service until it returns a classification response. Moreover, three scenarios were defined based on the length of the news content, which are described in Table III.

TABLE II. F1-SCORE OF DIFFERENT METHODS USED FOR FAKE NEWS CLASSIFICATION

Method	***F1 Score***
Logistic Regression [34]	0.693
Random Forest [35]	0.560
Sentence BERT + Heur[36]	0.701
Ensemble [37]	0.686
XLM-RoBERTa[38]	0.705
LSTM (ours)	**0.746**

TABLE III. SCENARIOS

Scenario	***News length interval (Number of characters)***
Scenario 1 – Small news	1300-2000
Scenario 2 – Medium news	2001-3200
Scenario 3 – Large news	>= 3201

Each scenario consists of 1386 requests to the web service for classifying news. Table IV summarizes the results of time response (seconds) after executing all requests for each scenario with news content of small, medium, and large lengths. The mean response time of the web service is 1.08 seconds, indicating good performance according to [39], as websites with good time behavior must respond within a maximum of 10 seconds before users leave the site.

TABLE IV. RESPONSE TIME

Scenario	***Response Time (seconds)***		
	Minimum	***Mean***	***Maximum***
Scenario 1 – Small news	0.71	1.01	1.43
Scenario 2 – Medium news	0.75	1.05	1.53
Scenario 3 – Large news	0.82	1.17	1.70
Total	0.76	**1.08**	1.55

VI. CONCLUSION

The study proposes a Fake Spanish News Classifier trained in a supervised fashion, utilizing LSTM architecture to determine the authenticity of Spanish news. The selection of LSTM architecture is based on its superior performance compared to MLP and CNN architectures since this architecture allows having a memory state, maintaining a relationship between the sequences of words in the text, which implies better performance when making the classifications. The method was evaluated using both private and public datasets, with experiments showing an F1 score of 0.746 which is good for a dataset with limited news in Spanish. However, this value is lower than the values in other studies that use datasets in English, noticing that the predictions in languages different than English are challenging mainly due to the limitation of data. Besides, a web service integrating the classifier has been implemented to detect fake news in real-time. For future work, the news can be classified into additional labels such as satire or junk science, for a more comprehensive understanding of fake news available on the internet that allows detecting them prior to propagation.

***Abstract*—The Internet of Things (IoT) domain has experienced significant growth in recent times. There has been extensive research conducted in various areas of IoT, including localization. Localization of Long Range (LoRa) nodes in outdoor environments is an important task for various applications, including asset tracking and precision agriculture. In this research article, a localization approach using Support Vector Regression (SVR) has been implemented to predict the location of the end node using LoRaWAN. The experiments are conducted in the outdoor campus environment. The SVR used the Received Signal Strength Indicator (RSSI) fingerprints to locate the end nodes. The results show that the proposed method can locate the end node with a minimum error of 36.26 meters and a mean error of 171.59 meters.**

Keywords—LoRaWAN; localization; RSSI; fingerprinting; support vector regression

I. Introduction

In 2016, everything appeared to spin around the development of the Internet of Things (IoT), where anything from vehicles to washroom scales is connected to the internet to offer additional services to customers [1]. However, it is most likely that the industry applications evolving from machine-to-machine (M2M) technologies are the main driving force for IoT. IoT is the evolution of M2M communications, where a larger number of nodes are connected using ethernet in the backend to reroute the data as needed.

This is a crucial step towards creating smart city applications and the fourth industrial revolution, where experts say that the physical, digital, and biological boundaries will blur in industries [1]. IoT companies are trying to launch their solution for networks because of the increasing demand for Machine-to-Machine communication. While Machine-to-Machine largely depends upon 2G networks for deployment, the IoT emerged with entirely different requirements, such as low costs for the IoT chips and the dense deployment of nodes on a single cell [2][3].

The deployment of IoT has increased the demand for finding the locations of the end devices. It is crucial in the field of IoT to have the localization done with low power and long range [4][5][6][7]. This can be accomplished by implementing low-power wide area networks (LPWAN) technologies. Long-range wide area networks (LoRaWAN), the LPWAN technology, have the significance of providing location-based services with low power and long range.

Localization using LoRaWAN can be performed using multiple techniques or approaches. The simplest of which is the trilateration technique [8][9]. This technique uses at least three gateways to find the location of the end node. It uses the received signal strength indicator (RSSI) to determine the distance between the gateways and the end nodes. It then applies the trilateration algorithm to find the end node's location. The second approach is to find the angle of the received signal on the receiving antenna. Using that angle, the angle of arrival (AoA) technique helps in finding out the location of the end node [10][11][12]. The third approach can be the time-based approach. Time of Arrival (ToA) [13][14][15][16] and Time Difference of Arrival (TDoA) [17] are the two types of time-based techniques. The time-based approaches use the time of the signal to reach the receiver. This time is then converted to the distance, and the localization is performed. The final and most accurate approach is the fingerprinting approach. This approach has two phases, the offline and the online phase. The measurements are taken in the offline phase and uploaded to the database. In the online phase, the location of the end nodes is predicted using machine learning algorithms by learning the data collected in the offline phase. Multiple machine-learning algorithms can be implemented to find the location of the end nodes. Depending upon the application, the classifiers [18][19][20] and the regression-based algorithms [21][22][23] are used. If it is enough to determine the region or an area where the end node is located, then the classification algorithms can be the easy catch. If there is a need to find the exact location of the end node, then the regression-based algorithms can be used to find the ground truth locations of the end nodes.

In this research article, we have implemented the fingerprinting approach to find the location of the end node. Firstly, the measurements are taken in the campus outdoor environment. Using those measurements, the location of the end node is predicted using support vector regression (SVR) to find the overall distance error. The performance of SVR is studied in the areas where the shadowing effect has its maximum presence.

From the technical problem evaluation perspective, the work is subdivided into the following sections. The literature review is discussed in Section II. In Section III, the research methodology is presented. Section IV presents the results. The conclusion is derived in the last section, along with the references.

II. Literature Review

Long Range Wide Area Network (LoRaWAN) technology is the key enabler of IoT technologies. It helped form a large-scale network connected to the internet at a very low cost because the range of LoRaWAN is high, requiring a minimal number of end devices and gateways to cover a large area. The technology has long-range communication with very little power consumption, thereby increasing the battery life of the end devices. Study [24] used LoRaWAN in the real environment in Thailand to present the experimental performance evaluation. The authors have found experimentally that in an outdoor rural environment, the LoRaWAN ranges up to 2 km and ranges 55-100 m in an indoor environment. It was pointed out that the range depends upon the properties of antennas, such as the antenna's height, gain, and directivity. Research [25] used the central business district of Melbourne, a high-density urban area, to present specific measurements to evaluate the performance of LoRaWAN. Their results show that within the radius of 200 m, only the communication is loss-free, while at around 600 m, the communication is a total loss. It isn't easy to have a precise measurement. Author in [26] explained with the results that environmental temperature highly affects communication. The authors showed that perfect communication could be converted to an almost useless one by increasing the environmental temperature. Therefore, it is important to consider the environment and the effect of the environment on LoRa signals to get good localization accuracy. The LoRaWAN technology offers an excellent option for Internet of Things (IoT) uses, such as advanced agriculture irrigation systems and intelligent urban development initiatives, among others. Thousands of end devices can be supported by a single gateway. Localization is significant for these LoRaWAN applications as the LoRaWAN network can have devices within the range of several thousand. Therefore, it is imperative to estimate each end device's location. An example of this can be multiple temperature sensors placed in various urban areas to measure temperature fluctuations. As the number of sensors can be thousands in this application; therefore, it is very tedious to program each of the sensors with their locations.

A natural solution to this problem is to equip GPS with every sensor. While this is a perfect solution, as GPS can have up to 10 m of accuracy, adding a GPS tracker to every sensor or device will increase the overall cost and power consumption [27]. Another problem with GPS is the lack of indoor coverage, as GPS signals can have so much signals losses when penetrating buildings etc. Therefore, it is very much important to find a solution for localization using LoRa. The in-depth studies on LoRaWAN can be found in [28] [29] [30] [31].

The study [32] calculated the positioning errors by constructing RSSI fingerprint data for LoRaWAN and SigFox using k-NN. The accuracy obtained by the authors was 398.4m. Their study used several gateways for measuring LoRa RSSI data.

Research [33] compared the fingerprinting and the range-based approaches. The authors concluded that the fingerprinting approach has less mean localization error than the range-based approach. The mean error using fingerprinting approach was 340 m, and 700 m using the range-based techniques. Similarly, [34] used k-NN, Extra Trees, and neural networks (NN) to find the location of the end node and had the mean error of 394 m, 379 m, and 357 m, respectively. Authors in [35] used the artificial neural network to find the end node's location and got a mean error of 381.8 m.

The study [36] compared linear regression methods, SVR, k-NN, weighted k-NN, and random forest, concluding that the random forest could perform with the minimum localization error of 340 m.

The research [37] used two layers to perform the localization. In the first layer, the authors used k-means clustering; in the second layer, the final position is estimated using the weighted kernel regression model. The authors were able to achieve a mean localization error of 346.03 m.

The literature provides valuable insights into LoRa localization. However, to the best of the author's knowledge, a significant gap still exists in the literature with regard to the performance of SVR, where the shadowing effect has its maximum presence.

III. Methodology

This section describes the hardware setup, the dataset, test point locations, and the methodology used.

A. *LoRaWAN Setup*

Fig. 1 shows the longitudes and the latitudes of the points where the RSSIs are measured. The gateway was placed on the rooftop of a lab with an elevation of 74 m above sea level, and the end node was moved to 14 random locations. The height of the end device was variable as it is challenging to make the elevation of the end device constant with different distances and areas. A total of 14 random locations were selected on the campus to find out the measured RSSI values. All the measurements were taken outdoors. No indoor measurements were taken. The minimum and the maximum distance used between the gateway and the end node are 17 m and 1330 m, respectively, to measure the RSSI. The distances between the End Node and gateways are calculated using Eq. (2).

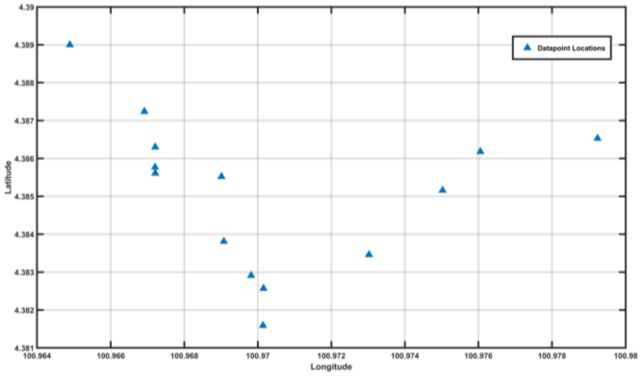

Fig. 1. Longitudes and latitudes of the datapoint location in an outdoor campus environment.

The Dragino LoRa shield served as the endpoint device for the experiments, and the RisingHF (RHF2S008) acted as the gateway. The end node was powered by a portable battery bank, while the gateway was powered through Power over Ethernet (PoE) and included an integrated GPS module, making it convenient for the experiments to determine Differential TDoA. The gateway possessed notable features, which are as under.

- The gateway supported 8 multi spreading factor uplink channels.
- The maximum output power of 27 dBm.
- -141 dBm of Receiver sensitivity.
- It supports ethernet connection, including Wi-Fi, GPRS, 3G, and 4G connections.
- Antenna gain is 3dBi.

The experiments utilized the online public network server called THE THINGS NETWORK as the network server. The LoRa Shield transmits the data to the gateway, which then passes the data, along with metadata such as SNR, RSSI, and timestamps, to THE THINGS NETWORK. The collected data is then uploaded to the computer for the application of Support Vector Regression (SVR) to predict the location of the end node.

B. Support Vector Regression

SVR is the supervised machine learning model that works similar to support vector machine. It finds the best-fit line for the predictions. The Support Vector Regression (SVR) approach differs from other regression models in that it aims to find the best line that falls within a specified range, known as the threshold value, instead of minimizing the difference between the actual and predicted values. This threshold value refers to the space between the hyperplane and the boundary line. However, SVR's computational time for fitting increases rapidly with the number of samples, making it challenging to handle datasets with over 10,000 data points [33].

There are a total of 21 features (RSSIs) for a single ground truth location to predict the location of the end node. We used the standardization in the preprocessing step on our data using z-score and then applied the SVR. The kernel scale used is 1.1. We have used the gaussian as the kernel function. The formula for the gaussian kernel function can be seen in Eq. (1) [38].

$$G(x_j, x_k) = exp(-||x_j - x_k||^2) \qquad (1)$$

Where x_j is the target variable, and x_k is the feature variable.

C. Distance Error

The distance error between the ground truth location and the predicted location is calculated using Eq. (2) by implying the predicted longitudes and the latitudes [39].

$$\boldsymbol{m = 2 * tan^{-1}\left(\frac{\sqrt{sin^2(\frac{l_2-l_1}{2})+cosl_1*cosl_2*sin^2\left(\frac{q_2-q_1}{2}\right)}}{\sqrt{1-\{sin^2(\frac{l_2-l_1}{2})+cosl_1*cosl_2*sin^2\left(\frac{q_2-q_1}{2}\right)\}}}\right)} \qquad (2)$$

Whereas $n=R*m$. The R is the earth's radius, n is the distance between two points on earth, l and q are the latitudes and longitudes, respectively.

IV. Results and Discussions

Fig. 2 shows the RSSI values at different distances. The results were taken by using a single gateway and a single node. There were 14 locations where the RSSIs were measured. Some locations were chosen to make the shadowing effect more significant. At each location, 21 readings were taken.

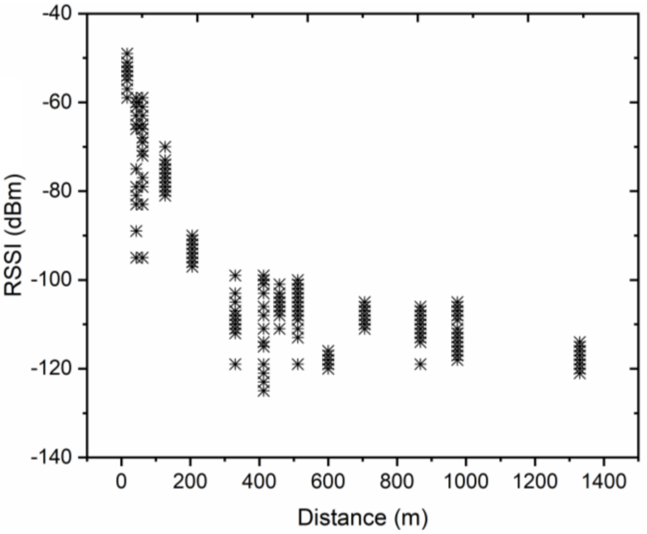

Fig. 2. RSSI values at different distances.

As shown in Fig. 2, the RSSI decreased with the increase in the distance, but there were some exceptions. The exceptions were the locations where the shadowing effect was more significant. This can be seen in Fig. 3 where the average RSSI plot was taken at different locations. As can be seen at the distance of 43m, 330m, 413m and 600m, the average RSSI decreased more because of shadowing, especially at 600m, which we measured behind the building. The RSSI decreased up to -118.4 dBm because of the shadowing effect. It is clear from the graphs that shadowing can be a bottleneck for localization using LoRa, thereby increasing distance error.

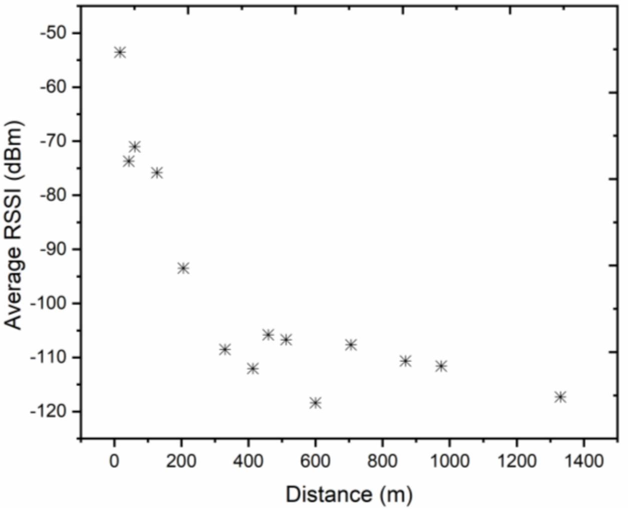

Fig. 3. Average RSSI values at different distances.

Fig. 4 shows the exponential non-linear least squares fitting on the average RSSIs. It is observed that the RSSI decreases with the increase in the distance, but after a certain distance, the decrease in RSSI becomes very minimal.

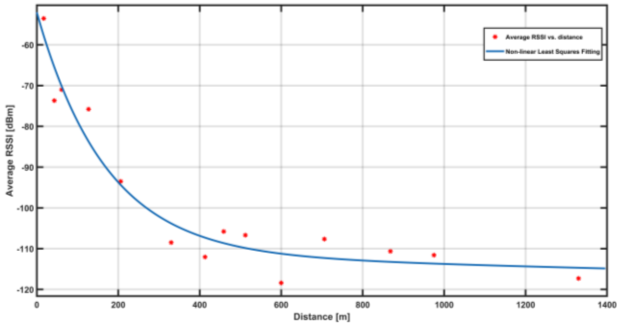

Fig. 4. Exponential non-linear least squares fitting on the average RSSIs.

Fig. 5 shows the SNR values at different distances. It can be observed that there were some locations where the SNR was in negative value because the noise power was more as compared to the signal.

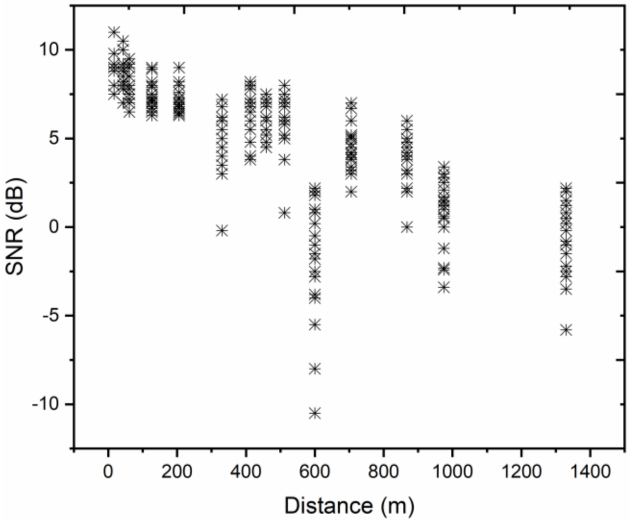

Fig. 5. SNR values at different distances.

Fig. 6 shows the average SNR at every testbed location. It is observed that the SNR measured has a negative value at 600 m (behind the building) and at a distance of 1330 m.

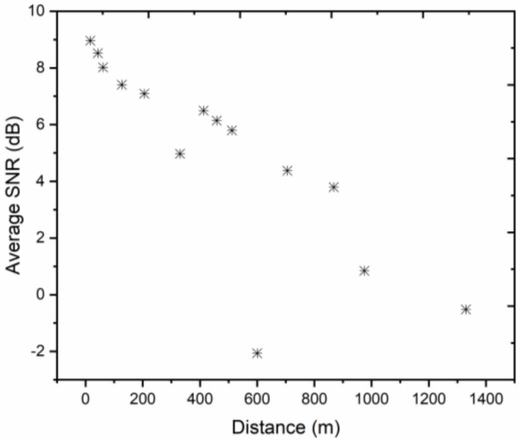

Fig. 6. Average SNR values at different distances.

A combined graph of Average SNR, Average RSSI and distance can be seen in Fig. 7. As can be seen that at a distance of 600 m, the RSSI and SNR are at their lowest value due to the shadowing effect. This is the datapoint directly taken behind the building, which clearly shows that the shadowing directly affects localization accuracy using SVR.

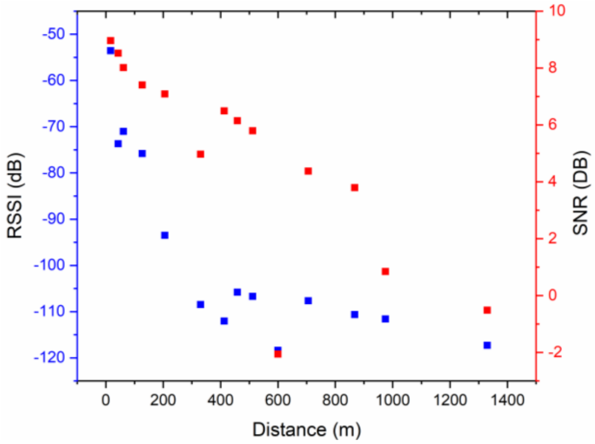

Fig. 7. Distance vs average RSSI and average SNR.

Table I shows the measured average RSSIs, average SNRs, longitude and latitudes of the actual locations, longitude and latitudes of the predicted locations, and the distance errors caused using the SVR. The table shows that the highest distance errors predicted by SVR were the locations where the shadowing effect was most significant. The least distance error predicted by the proposed method is 36.26, the mean error is 171.59 m, and the highest distance error is 755.54 m.

The limitations of the study can be attributed to the environmental factors on the signal strength, which can affect the accuracy of the LoRa localization. Some limitations include signal strength variability due to environmental factors such as obstacles, interference, and atmospheric conditions. The complexity of environmental modeling, such as terrain and buildings, affects the propagation of LoRa signals. Accurately modeling these environmental factors can be complex and require detailed knowledge of the local environment.

One use case scenario where the localization method can still be useful even with a high error is in wildlife tracking. For example, researchers tracking the movement of large animals such as elephants or giraffes in a wildlife reserve can benefit from using localization methods to get a general idea of the animal's location, even with a high error margin. Even if the location error is high, it can still provide valuable information about the animal's general movements, such as where they are likely to feed, rest, or migrate. Additionally, the data collected over time can help researchers identify patterns, make predictions about the animal's behavior, and inform conservation efforts. By tracking the movements of wildlife, researchers can gain insights into their behaviors and habitats and use that knowledge to protect them better.

TABLE I. DISTANCE, AVERAGE RSSI, DISTANCE ERROR AND AVERAGE DISTANCE ERROR IN METERS

Distances between GW and End Nodes (m)	**Average RSSI (dBm)**	**Average SNR (dB)**	**Actual Locations**		**Predicted Locations**		**Distance Error (m)**	**Average Distance Error (m)**
			Longitude	**Latitude**	**Longitude**	**Latitude**		
17	-53.55	8.96	100.96721	4.38630	100.96931	4.38598	236.34	171.59

V. CONCLUSION AND FUTURE WORK

In this research article, the experiments were conducted on a university campus to find the location of the end node. A localization algorithm using Support Vector Regression (SVR) has been implemented on a LoRaWAN architecture. The results show that using the RSSI as features and the SVR as a regression algorithm, the end node can be located with an average distance error of 171.59 meters and a minimum error of 36.26 meters. This shows that the low-powered LoRaWAN can be used for localization in applications where high localization accuracy is not needed. This work can be extended to find the effect on localization accuracy by increasing the number of gateways, the dataset, and the inclusion of other fingerprints like SNR and time fingerprints. Additionally, different environments can be included in the experiments, like indoor areas and finding out the localization distance errors in the combined space of indoors and outdoors.

***Abstract*—Sarcasm is a sophisticated phenomenon used for conveying a meaning that differs from what is being said, and it is usually used to express displeasure or ridicule others. Sentiment analysis is a process of uncovering the subjective information from a text. Detecting figurative language such as irony or sarcasm, is a focused challenging research field of sentiment analysis. Detecting and understanding the use of sarcasm in social networks could provide businesses and politicians with significant insight, since it reflects people's opinions about certain topics, news, and products. This has especially become relevant recently because sarcastic texts have been trending on social networks and are being posted by millions of active users. As a result of this situation, there is now an increasing amount of research on the detection of sarcasm in social network posts. Many works have been published on sarcasm detection, and they include a wide variety of techniques based on rules, lexicons, traditional machine learning, deep learning, and transformers. However, sarcasm detection is a challenging task due to the ambiguity and non-straightforward nature of sarcastic text. In addition, very few reviews have been conducted on the research in this area. Therefore, this systematic review mainly aims at exploring the newly published sarcasm detection articles on social networks in the years between 2019 and 2022. Several databases were extensively searched, and 30 articles that met the criteria were included. The selected articles were reviewed based on their approaches, datasets, and evaluation metrics. The findings emphasized that deep learning is the most commonly used technique for sarcasm detection in recent literature, and Twitter and F-measure are the most used source and performance metric, respectively. Finally, this article presents a brief discussion regarding the challenges in sarcasm detection and future research directions.**

Keywords*—*Sentiment analysis; figurative language; sarcasm detection; irony; machine learning; deep learning; transformer

I. Introduction

Over the last few years, natural language processing (NLP) has been one of the most active areas of artificial intelligence (AI) research. Researchers in this area have made considerable effort to enable machines to mimic the human ability for language, and the results have often been ground-breaking. For example, sentiment analysis, also known as opinion mining, is an NLP task that involves identifying the subjectivity and sentiments present in opinions [1]. Social networks, such as Twitter and Facebook, are gaining increasing popularity and have millions of active users. In particular, Twitter is one of the most popular social networks that attracts millions of users [2]. In addition, text is considered as the most commonly used form of communication, with social network posts varying from short-text data, such as tweets, to long-text posts such as debates.

Sarcasm can be defined as saying or writing the opposite of what is intended. As a result, sarcasm generates ambiguous and non-straightforward data. For instance, "I love to go to the dentist!" is an obvious example of the use of sarcasm for expressing negative feelings. Overall, it is occasionally hard to efficiently recognize sarcasm due to the contradiction between the implicit and explicit meaning [3]. Moreover, textual sarcasm is challenging due to the lack of tone and facial expressions, and this makes it hard for even human beings to detect sarcasm [4]. Therefore, textual sarcasm is a vague task that needs to be studied carefully. A well-designed NLP model for text-based sarcasm detection is, thus, crucial.

Over the past years, a few reviews about sarcasm detection in social networks have been published, but most of them focused mainly on the implementation phase, for example, [5],[6] and [7]. However, some of the previous research did not cover all the approaches used for sarcasm detection. For example, the authors in [5] reviewed and analyzed machine learning-based sarcasm detection studies and found that support vector machine (SVM) is the most frequently utilized classification algorithm for sarcasm detection. However, there are many other techniques in use that need to be studied. The researchers in [7] reviewed the rule-based, statistical-based, and deep learning (DL) approaches for sarcasm detection but did not consider other popular approaches such as transformers, while the researchers in [6] only presented a technical review of sarcasm detection algorithms and reported the mostly frequently used algorithms for sarcasm identification.

Based on the gaps in the literature discussed above, the main aim of this article is to conduct a systematic literature review (SLR) that focuses on identifying and analyzing text-based sarcasm detection articles on social networks based on their development approaches, evaluation metrics, and datasets. Moreover, this article presents an overview of the main sarcasm detection challenges and future possible improvements. To achieve these objectives, the following four research questions will be answered:

- RQ1: What are the main approaches used for the development of automatic sarcasm detection models?

- RQ2: What are the most commonly used metrics to evaluate the performance of sarcasm detection models?
- RQ3: What datasets are most commonly used for detecting sarcasm on social networks?
- RQ4: What are the main challenges in sarcasm detection?

The remainder of this article is organized as follows. Section II provides the problem statement, and Section III describes the methodology used in this SLR. The approaches, metrics, and datasets of the reviewed articles are provided in Sections IV, V, and VI, respectively. Section VII discusses the findings, research problems, and future research directions. Finally, the conclusion is provided in Section VIII.

II. Problem Statement

Over the past decade, the increase in the number of social network users has caused researchers to deeply investigate and analyze data on social networks. Sarcasm detection is one of the most challenging tasks and is a hot topic in the NLP field. Non-straightforward sarcastic data may reflect positive or negative sentiments or both polarities. In fact, it is difficult to detect sarcasm because sarcastic text is often obscure and ambiguous. In other words, there is little agreement on the actual intention behind indirect sarcastic sentences even by humans, and this makes it even harder to accomplish such tasks with AI technology. Most of the text-based sarcasm cannot be interpreted literally since the actual purpose of the sarcastic text might be the opposite of the apparent meaning of the text. Moreover, the lack of body language and voice tone in text-based sarcasm make it difficult to understand sarcasm in text. Another challenge to sarcasm detection is that the context of sarcasm is strongly dependent on cultures, personalities, and languages.

Sarcasm detection is important for tracking people’s opinion and satisfaction in relation to products. Therefore, sarcasm detection is an essential task for decision making by businesses. Social networks, by nature, are rich in sarcastic texts, and this further increases the need for extensive analysis and study. However, applying basic sentiment techniques such as rule-based techniques, with sarcastic text is not sufficient. Therefore, there is a strong need for a well-designed model specifically oriented towards sarcasm detection tasks. The availability of recent review in sarcasm detection field would pave the way for a new novel solution. Therefore, it is crucial to conduct a review that covers the most recent techniques as well as the state-of the art techniques.

Recently, several works have been published on sarcasm detection with machine-learning (ML), DL, and transformer techniques. However, a limited number of the reviews so far have conducted in-depth investigations into sarcasm detection. Therefore, the present SLR comprehensively covers recent articles on text-based sarcasm detection in social networks that were published between 2019 and 2022. In addition, the reviews published so far, that is [8], [9], [10], [11] and [7] have several limitations. For instance, the study in [8] used a different database and selection criteria compared to this study, and the studies in [9] and [10] differ with regard to their research questions. Further, the challenges involved in the development of an effective model for sarcasm detection are not highlighted in [11]. The researchers in [7] did not provide sufficiently detailed characteristics and findings regarding the recent sarcasm datasets and metrics. To sum up, this SLR was conducted with the aim of filling in the highlighted gaps in the previous reviews, as described above. With this survey, our aim is to identify and analyze text-based sarcasm detection articles on social networks based on their development approaches, evaluation metrices, and datasets.

III. Survey Methodology

This SLR uses the Kitchenham guidelines for reviewing articles on sarcasm detection [12]. According to these guidelines, the three stages of a review are planning, conducting, and reporting the review. The following subsections provide the details of these three stages. First, Section A presents the planning stage, including the goals and research questions, database identification and search procedure, and inclusion and exclusion criteria. Second, article selection and quality assessment. Third, from Section IV to Section VI the third stage is reported.

A. Planning

1) Goals and research questions: The primary purpose of this SLR is to identify and analyze articles on the state of the art of sarcasm detection tools based on their development approaches, evaluation metrics, most commonly used datasets, and the major challenges to sarcasm detection identified. To achieve these objectives, the following research questions are investigated:

- RQ1: What are the main approaches used for automatic sarcasm detection models?
- RQ2: What are the commonly used metrics to evaluate the performance of sarcasm detection models?
- RQ3: What datasets are most commonly used for detecting sarcasm on social networks?
- RQ4: What are the main challenges in sarcasm detection?

2) Databases identification and search procedure: Four scientific databases, namely, IEEE, Springer, ScienceDirect, and ACM, were used to search and identify relevant research articles. The search was conducted using nine keywords based on specific selection criteria, which will be described in Section 3. The keywords were selected based on those mentioned in [13],[8] and [9]. Table I presents the number of selected articles based on the keywords and database names.

3) Inclusion and exclusion criteria: The inclusion and exclusion criteria for selecting the most relevant articles were based on the objectives of this SLR. The inclusion criteria were as follows:

a) Articles published in the English language 2. Articles published from 2019 to 2022.

b) Full journal articles.

c) Articles published in the field of computer science.

TABLE I. NUMBER OF SELECTED ARTICLES BASED ON THE KEYWORDS FOR EACH OF THE FOUR DATABASES

Keyword	IEEE	Springer	ScienceDirect	ACM
Sarcasm AND Detection AND Sentiment analysis	11	9	150	83
Sarcasm AND Detection AND Artificial intelligence	12	8	66	48
Sarcasm AND Detection AND machine learning	7	9	155	82
Sarcasm AND Detection AND Deep learning	9	9	139	82
Sarcasm AND Recognition AND Sentiment analysis	2	9	87	83
Sarcasm AND Recognition AND Artificial intelligence	4	8	44	47
Sarcasm AND Recognition AND machine learning	1	9	85	81
Sarcasm AND Recognition AND Deep learning	1	9	84	81
Irony AND Detection AND Sentiment analysis	1	1	92	56
Irony AND Detection AND Artificial intelligence	0	1	47	37
Irony AND Detection AND machine learning	0	1	100	54
Irony AND Detection AND Deep learning	0	1	92	56
Irony AND Recognition AND Sentiment analysis	0	2	62	0
Irony AND Recognition AND Artificial intelligence	2	1	37	41
Irony AND Recognition AND machine learning	2	2	54	0
Irony AND Recognition AND Deep learning	2	0	47	0
Figurative language AND Detection AND Sentiment analysis	4	4	37	12
Figurative language AND Detection AND Artificial intelligence	3	0	16	11
Figurative language AND Detection AND machine learning	1	1	45	12
Figurative language AND Detection AND Deep learning	3	3	44	12
Figurative language AND Recognition AND Sentiment analysis	0	4	17	13
Figurative language AND Recognition AND Artificial intelligence	1	0	14	52
Figurative language AND Recognition AND machine learning	0	2	30	17
Figurative language AND Recognition AND Deep learning	1	3	30	17
Total	67	96	1574	977

A large number of articles met the inclusion criteria, and these were filtered using the following three exclusion criteria.

- Titles and abstracts that were irrelevant to sarcasm detection.
- Duplication.
- Inability of the articles to address the research questions.

As the number of articles retrieved was too large to process manually, it is assumed that the retrieved articles in a database search engine are arranged in accordance with the keywords. According to the first exclusion criterion, articles with titles and abstracts that were not related to sarcasm detection were excluded. Next, duplicate articles that appear in more than one of the databases were excluded. The last criterion relates to whether the articles could address the research questions and involves quality assessment of the candidate articles, as discussed in the following subsection.

4) Article selection: The initial search in the databases returned about 2726 articles. Table I details the number of articles returned for each possible keyword query in all four databases. In general, the maximum number of articles (1574) was retrieved from ScienceDirect database; this is probably due to differences in the content of the databases, interests, and domains. Moreover, the highest number of articles was retrieved with the query “Sarcasm AND Detection AND Machine learning”.

For screening the retrieved articles, the inclusion and exclusion criteria described in the previous subsection are applied. Based on these criteria, 2634 irrelevant articles were excluded, and 92 relevant articles were considered. Following this, 47 duplicated articles were further excluded, and the remaining 45 articles were considered for deeper investigation. Finally, 15 articles that did not address the research questions were excluded, and this left us with 30 articles. Fig. 1 illustrates the article selection process.

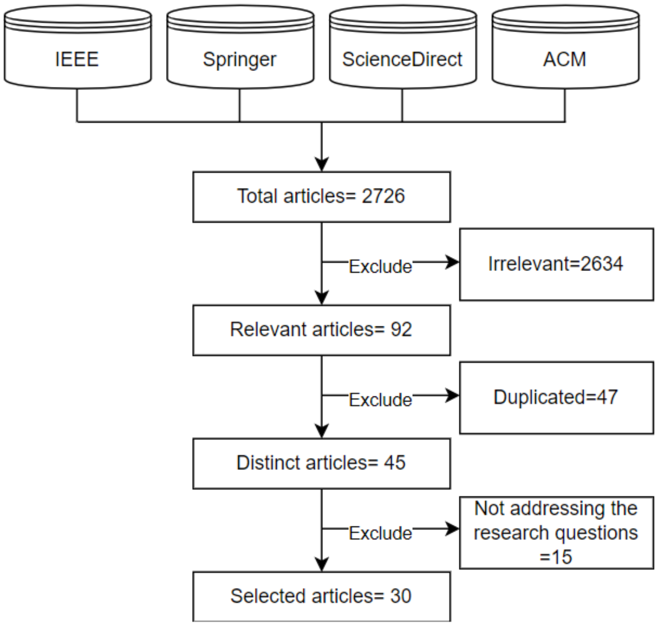

Fig. 1. Flowchart depicting the article selection process.

5) Quality assessment: This section describes quality assessment of the articles based on the method described in [14]. The articles were assessed using the following 10 questions, and articles for which the response was "yes" for at least seven questions were selected.

- Are the article objectives clearly defined?
- Does the article provide a brief description of the previous sarcasm detection approaches?
- Are the evaluation metrices explained clearly?
- Is the article structure designed appropriately?
- Are the data collection processes explained in detail?
- Are the approach, formulation, and analysis described adequately?
- Does the article list the used dataset?
- Is the article understandable and well-written?
- Does the article utilize a well-designed methodology?
- Does the article present and interpret the results clearly?

IV. Sarcasm Detection Approaches and Techniques

There are many studies on NLP methods for sarcasm detection. Recent articles in the field of text-based sarcasm detection on different social networking platforms and online media is surveyed and discussed in this section, but it is not meant to be exhaustive. Sarcasm detection approaches can be categorized based on the classification technique into rule-based, lexicon-based, traditional ML-based, DL-based, and transformer-based approaches. Fig. 2 presents the general structure of sarcasm detection approaches along with their common techniques in the selected articles.

The related works are categorized into five subsections based on the approaches they have explored: Section A focuses on the rule-based approach; Section B, the lexicon-based approach; Section C, traditional ML-based approaches; Section D, DL-based approaches; Section E, the transformer-based approaches. Table II presents a detailed comparison of these works. Overall, traditional ML, DL, and transformer-based approaches are becoming popular in the field of NLP, especially in the area of sarcasm detection. Therefore, in this SLR, studies that focus on these three approaches will be studied in detail.

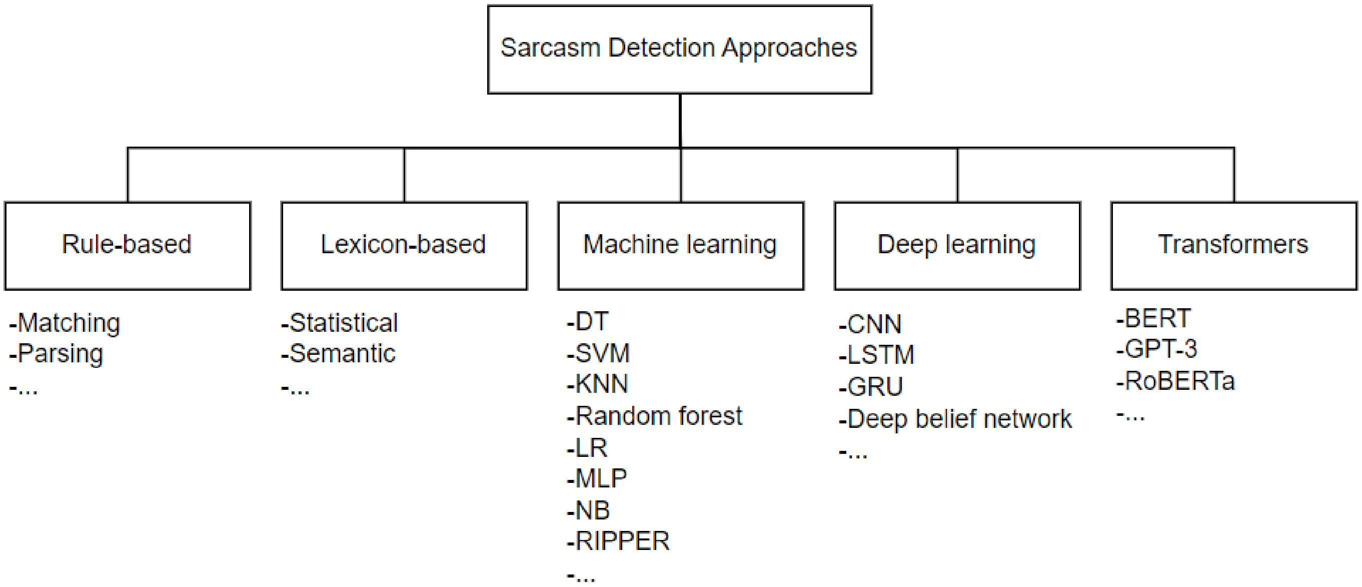

Fig. 2. General structure of sarcasm detection approaches.

TABLE II. SUMMARY OF THE REVIEWED ARTICLES

No.	Article	Model	Year
1	[33]	Combination of a machine learning classifier	2021
2	[31]	Combination of a machine learning classifier	2020
3	[34]	Combination of a machine learning classifier	2021

29	[70]	RCNN-RoBERTa	2019
30	[71]	Encoder model called LMTweets with multiple techniques	2021

A. Rule-based Approach

This approach comprises a set of predefined human-made rules that act as indicators of sarcasm. Different researchers have proposed different approaches for making the rules such as parsing and matching. For example, some authors used hashtags as a key indicator of sarcasm. That is, they assumed that if tweets contain specific hashtags and do not fit in with the rest of the tweets, then that statement is sarcasm [15]. Another author combined two rule-based approaches: the first one is used for developing and recognizing the parse tree, and the other approach captures hyperboles features by using interjection and intensifiers together [16]. A third rule-based approach is “simile,” which involves comparing two things directly. One of the studies that utilized this approach for sarcasm detection was described in [17].

B. Lexicon-based Approach

Lexicon-based approaches rely on a predefined collection of words, referred to as a lexicon, with each of the words assigned to a particular polarity category indicating its nature, namely, positive, natural, negative, which are represented by the numerical values -1, 0, and +1, respectively. The lexicon can be weighted or unweighted, such that the words which induce higher positivity or negativity are given a higher probability [1]. In this sarcasm detection process, a bags-of-lexicon which comprises a positive sentiment, a negative sentiment, a positive context, and a negative context is created. A text is divided into tokens of a single word, and the score of each token is obtained using the lexicon. The overall score of the text is determined by adding the individual scores and calculating the average, which is used to determine the sentiment of the text [18]. Sarcasm is detected when a positive context comprises a negative sentiment or a negative context comprise a positive sentiment [16]. An advantage of the lexicon-based approach is that it is suitable at both the sentence and feature level. Moreover, it can be considered as an unsupervised approach because it does not include a training process. However, a major limitation is that it is domain dependent, as the same word would have different meanings according to its context. For example, the word “small” in the statement “this camera is extremely small” could imply a positive sentiment, whereas the use of “small” in “the TV screen is too small” implies a negative sentiment. This could be overcome by constructing a domain-specific lexicon or adapting the current lexicons [19]. In addition, lexicon-based approaches can be divided into the corpus-based approach and the dictionary-based approach.

1) Corpus-based approaches: The corpus-based approach starts with a pre-defined list of polar words with their orientation; their syntactic and co-occurrence pattern is then investigated to obtain other polar words and their corresponding orientation to obtain a bigger “corpus”. This approach was first proposed in [20]: a list of adjectives (polar words) with their orientation were pre-defined, and new adjectives and orientations were added using linguistic constraints and rules. For example, in the sentence “the question is simple and easy,” there is a connective word “AND” which indicates that both adjectives have the same orientation; in contrast, the connective word “OR” indicates that the adjectives have opposite orientations. This approach is known as “sentiment consistency”.

There are two approaches to determining the orientation of polar words, namely, the statistical approach and the semantic approach [18]. The statistical approach relies on the notion that words with similar orientation are likely to appear together frequently. Hence, the new unknown word can be assigned a certain orientation based on its frequency and co-occurrence with other words for which the orientation is known [21]. Some studies on the statistical approach have been published, such as [22] and [23]. The semantic approach, on the other hand, exploits the sentiment dictionary to discover synonyms and antonyms in order to construct a lexicon that can be used to assign the same orientation to words that are semantically similar [24]. Some studies have utilized the semantic approach to build the lexicon, such as [25] and [26]. In addition, a hybrid method can be used to take advantage of both approaches, as described in the work of Zhang [27].

2) Dictionary-based approaches: The dictionary-based approach is roughly based on the idea that synonymous words have the same orientation, and antonyms have the opposite orientation. Therefore, an initial well-known dictionary, such as Thesauri, is constructed with a pre-defined lists of polar words and their orientation. Then, this dictionary is expanded manually based on synonyms and antonyms of the existing words by adding new words and their orientation iteratively until no more words can be added [28]. Finally, manual evaluation and correction can be performed to ensure the validity of the dictionary. This is known as the bootstrapping technique. A popular recently developed dictionary is SentiWordNet 3.0, which uses the automatic annotation of Synsets of WordNet 3 [29]. In addition, Park and Kim in [30] proposed a rule-based method to label the words in advertisements based on three online dictionaries.

C. Traditional ML-based Approaches

Since the earlier years, many studies on text sarcasm detection utilized supervised ML classifiers. Based on the surveyed studies, SVM is one of the most popular classifiers, as evident in [31], [32] and [33].

In 2020, researchers in [31] proposed a sarcasm type detection approach that utilized the multi-rule based ensemble feature selection model. The main aim of this study was to determine the level of hurt that is expressed in sarcasm. Four classes of sarcasm type were determined, including rude, raging, polite, and deadpan. This study used ensemble learning to identify the optimal feature set among all the features and to classify a tweet as sarcastic or not. Following this, the type of sarcasm was determined by using a rule-based approach. This experiment was conducted by using tweets obtained through the Twitter Application Programming Interface (API) Tweepy and Twython. A study conducted in 2021 [33] developed three kinds of ensemble classification algorithms for detecting sarcasm with the Principal Component Analysis (PCA) algorithm. The ensemble classification algorithm is a combination of SVM, KNN, decision tree, logistic regression, and Multi-layer Perceptron (MLP). The three models were tested on five datasets of different sizes from the Twitter streaming API.

Another related study [34] used different ML techniques, such as SVM and logistic regression, for classification. The main contribution was combining the features extracted from a Convolutional Neural Network (CNN) architecture with contextual handcrafted features to obtain the most optimal features. The experiments were conducted on a Twitter dataset created by the researchers and shared publicly [35]. One of the studies that utilized the supervised ML classifier approach with BERT and GloVe embeddings for sarcasm identification [36] also used a Twitter dataset for evaluation. A related study [32] investigated tweets with a negative mood and hyperboles to detect sarcasm. Several ML algorithms, such as SVM, random forest (RF), and RF with bagging, were utilized to analyze five hyperbole features, namely, interjection, intensifier, capital letter, punctuation mark, and elongated word. This study was conducted on tweets collected using the Twitter streaming API [37].

In 2022, the researchers in [38] proposed an intelligent ML-based sarcasm detection and classification (IMLB-SDC) technique in which an SVM classifier is used for sarcasm identification on social networks. The proposed model consists of different stages, namely, preprocessing, feature engineering, feature selection and classification, and parameter tuning.

D. DL-based Approaches

DL is gaining more attention in the sarcasm detection process, since it can be used to obtain better results from unstructured data. It has the ability to learn from a given text in order to either extract automated features or perform sarcasm classification. Based on our investigations, most sarcasm detection articles combine several DL techniques in a model. The most frequently used DL approaches are CNN, artificial neural network, and long short-term memory (LSTM). These are described below.

CNN is a version of the feed forward neural network with multiple hidden layers. It first emerged in computer vision applications, and since then, it has been widely used recently in NLP applications. The network comprises an input layer, hidden layers that consist of many convolution layers, pooling layers, normalization layers, a fully connected layer, and an output layer. The generic workflow of CNN in sarcasm detection is as follows: The convolution layer extracts the features from the input text (word embedding); the pooling layer reduces the size of the feature by removing the noise and un-needed details; the output of the previous layer is plugged to the normalization layer to normalize the input for the current layer in order to aid convergence; finally, a fully connected network is created and used for classification [18]. However, these steps are not identical for all studies. According to our investigations, most studies combined CNN with other DL algorithms such as recurrent neural network (RNN).

RNN is designed for sequence data and has the ability to remember the needed information. Therefore, it has been widely applied in sentiment analysis and sarcasm detection. The output of such networks depends on all previous computations. In other words, to predict the class of a specific word, the model may use the class of previous words and their relations. However, one of the most serious problems with this technique is gradient vanishing. To tackle this problem, Hochreiter and Schmidhuber [39] introduced LSTM and utilized it for sarcasm classification. Later, a new bidirectional version of LSTM (Bi-LSTM) was introduced. Bi-LSTM has the ability to learn from the relationships between the polar words and classify them without relying on an external lexicon. Such an approach has been found to produce better results in many studies. Another important feature is the attention layer [40], which gives the model the ability to focus on words that contribute more to sarcasm classification.

In [40], the researchers developed an attention-based Bi-LSTM model based on features learned by external pre-defined sentiment lexica, thus eliminating the need for the traditional feature vector and increasing the ability of the model to detect incongruity in sarcastic sentences. The researchers in [41] designed a hybrid system that coupled a soft attention-based Bi-LSTM with a CNN. The attention layer generates a feature vector according to which higher weights are assigned to words that are closely related to the sentence semantics. Consequently, this feature vector with pragmatic features is input in the CNN to generate the final classification. The study aimed to improve the performance in terms of accuracy, recall precision and F-measure. Another study [42] developed an attention-based Bi-LSTM model for sarcasm classification. In this model, the multi-head attention layer consists of five heads. The multiple heads allow the attention layer to move among several disjointed information spaces that reflect different representations. They used SVM for handcrafted feature extraction to be used as input for the proposed model. Another work in [43] utilized an attention-based Bi-LSTM for sarcasm classification. For better word embedding, a question answering network was designed based on five different layers, each of which provides different representations. In [44], an improved attention-based multilevel LSTM model was developed to exploit sentiment semantics in sarcasm detection. The semantic is extracted using the first-level attention-based LSTM network. Then, the sentiment semantic features obtained from the first level are used as the input for the second level. In the second level, the polarity between the sentiment semantic features and all the words in the sentence is captured to detect sarcasm by combining the LSTM and CNN networks. Later, a more complex framework was proposed in [45], in which the researchers proposed a Self-Deprecating Sarcasm (SDS) framework that incorporates GloVe embedding, CNN to extract features, bidirectional gated recurrent unit (BiGRU) to extract context information that would be useful for SDS classification, and two attention layers to assign higher weights to SDS-identified sarcastic words.

Another effective sarcasm identification system was engineered in [46] using the Bi-LSTM framework based on two main phases. In the first phase, weighted word embedding was combined with the trigram model for better word representation. In the second phase, the first phase output was inserted into a Bi-LSTM network. A novel approach was suggested in [47], in which sarcasm detection involved the sentiment of the reply to the sarcasm and the user’s expression habit. In this approach, a dual-channel CNN was utilized for sarcasm detection and sentiment analysis of the reply. Moreover, attention-based LSTM was exploited to identify the user’s expression habit. In a subsequent study [48], the researchers proposed a multi-head self-attention-based GRU model to detect sarcasm while considering automatic, lexical, contextual, and handcrafted features. Feature embedding was performed by a pretrained model and was enhanced using the multi-head self-attention layers to identify keywords that contribute more to classification. In [49], the researchers proposed a novel multi-task system for joint sarcasm and sentiment analysis. The local features are obtained using BiGRU, and the global features are obtained by attention-based CNN. In [50], the researchers proposed a novel feature selection approach with deep belief for detection of cyberbullying on social networks. Additionally, the Salp Swarm Algorithm was exploited to tune the network parameter for better classification accuracy. In a subsequent study [51], an attention-based LSTM sarcasm detection model was proposed to combine both hand-crafted features that are usually extracted from classical ML algorithm, such as verbs, nouns, and adjectives, with automatic features that are extracted by DL approaches. That is, the attention layer is utilized to assign weights to the words according to their level of contribution to sarcasm detection. Moreover, 16 different textual classical features are extracted and combined with the automatic features generated from the attention layer. The main contribution in this study was the proposed feature engineering approach.

To capture the variation in the performance of different classification techniques , the researchers in [52] applied five different ML algorithms, namely, Naïve Bayes, KNN, Repeated Incremental Pruning to Produce Error Reduction (RIPPER), C4.5 Decision Tree, and SVM. Moreover, a CNN network was implemented. Additionally, different pre-processing methods were applied with the classifier to obtain the best results. In fact, a pre-trained model can be used for data preprocessing, as described in the approach in [53]. The BERT model is used for data preprocessing by converting the text into distinct tokens, and the tokens are further processed by four CNN layers. The output of this process is plugged into the LSTM layer for classification. In [10], the researchers proposed a system that combines the classical ML approach to extract different text patterns with sarcasm detection using the LSTM classifier. The basic pre-processing steps are performed on the original text before the classification. Further, in [54], the researchers proposed a new attention-based BiGRU for detecting sarcasm in which hyper parameter tuning is performed using an artificial flora algorithm and embedding is performed by the GloVe model.

Very few works have utilized an ensemble of ML and DL approaches. One such study [55] proposed the use of a DL model in combination with an ML classifier to extract the target of sarcasm from the text. The researchers started by using an ensemble of classifiers consisting of RF, SVM, and logistic regression to classify sarcastic sentences and determine whether they contain a target. On the other hand, an LSTM is used to extract the target using aspect-based sentiment analysis.

E. *Transformer-based Approaches*

The sequence-to-sequence (seq2seq) model is used for many purposes, one of which is language translation, for example, translating Chinese into English [56]. One of the main disadvantages of the Seq2Seq model is that it cannot be applied to long sentences or perform parallelization. The main solution for this limitation was proposed in December 2017 in an article titled “Attention Is All You Need,” which described a model called the “original transformer model” that laid the basis for transformer-based approaches [57]. In the field of NLP, a transformer can be described as a novel architecture that can solve Seq2Seq tasks while handling long-range dependencies. In addition, transformer models are trained on large-scale corpora to learn universal language representations, so the need to train a new model from scratch is eliminated [58].

Most recent studies are based on transformer models that exhibited strong performance in sarcasm detection [59], [60]. These architecture models are frequently based on transformer models such as Bidirectional Encoder Representations from Transformers (BERT) and OpenAI Generative Pre-Training-3 Model (GPT-3) [61], [62]. Recently, many researchers have been focusing on transformer models: for example, in 2021, the authors in [63] developed a context-based feature technique to detect sarcasm based on the DL model, BERT model, and conventional ML model. Two Twitter benchmark datasets, one provided by Riloff and one by Ghosh and Veale, were utilized [64], [65]; in addition, the Internet Argument Corpus (IAC-v2) benchmark was also applied. A related study [60] proposed an enhancement to BERT in order to improve its ability to handle the volume, velocity, and veracity of data.

Similarly, in 2022, the researchers in [66] introduced an enhancement to the BERT model by fine-tuning it to related intermediate tasks before applying it to the target task. The authors in [67] applied the pre-trained COMET model to generate relevant commonsense knowledge. The experiment was conducted on three datasets, including Ghosh and Ptácek from Twitter and SARC-Pol from Reddit [35], [65], and [68]. The researchers in [59] proposed a model called Contextual Response Augmentation (CRA) which uses of BERT, BiLSTM, and NetXtVLAD. The dataset consisted of Twitter and Reddit posts. To evaluate the proposed model, the IAC-V12 and AC-V23 datasets [69] and two datasets collected by Riloff et al. [64] and Ptáček et al. [35] were used. Furthermore, two datasets from Reddit [68] were utilized.

Another study in [70] developed an RCNN-RoBERTa model to tackle figurative language in social networks. This model consists of a pre-trained RoBERTa model combined with a recurrent CNN. The Semantic Evaluation Workshop Task 3 (SemEval-2018) dataset was used to measure the performance of the proposed model. Another researcher [71]proposed an encoder model called LMTweets, which is an ensemble of multiple types of techniques. Five classical classifiers, six DL algorithms, and transformer models were utilized for classification in this model. The experiments were conducted on three datasets, namely, Twitter SemEval-2018-Task, Self-Annotated Reddit Corpus (SARC), and Riloff Sarcastic Dataset [72], [64], [68].

V. Evaluation Metrics

One of the most significant aspects of most articles on models for sarcasm detection is performance evaluation, because the results provide an indication of the significance of a study. In this section, the common evaluation metrics used to assess sarcasm detection in the selected articles will be discussed. Confusion matrix is used for analyzing the performance of a binary-class model by depicting the relationship between the actual class and the predicted class. In this matrix, each row contains information about an actual class, while each column contains information about a predicted class. Accordingly, the confusion matrix aims to analyze how well a classification can recognize instances of different classes. Table III illustrates the confusion matrix [73].

TABLE III. Confusion Matrix

Class	Predicted Positive	Predicted Negative
Positive	TP	FN
Negative	FP	TN

In the sarcasm detection problem, true positives (TPs) are considered as sarcastic tweets that are correctly classified as sarcastic text, and true negatives (TNs) are tweets which are not sarcastic that are correctly classified as not being sarcastic (i.e., these refer to correct decisions, which are represented by the diagonal in the confusion matrix). In contrast, false positives (FPs) are instances which are not sarcastic that are misclassified as sarcastic text, and false negatives (FNs) are sarcastic tweets which are misclassified as text that is not sarcastic. The following subsection describes the most common and significant metrics for evaluation with the confusion matrix.

A. *Accuracy*

Accuracy is a common external measurement that reflects the percentage of the total number of tweets that are correctly classified as sarcastic or not sarcastic. It is calculated using the following equation, in which the denominator represents the total number of sarcastic tweets.

$$\text{Accuracy}=\frac{\text{TP+TN}}{\text{TP+TN+FP+FN}}\times 100 \qquad (1)$$

TABLE IV. SUMMARY OF THE EVALUATION METRICS AND PERFORMANCE OF THE REVIEWED ARTICLES

No.	Articles	Accuracy	F1-Score	Precision	Recall	AUC
1	[33]	99.1	89.0	90.0	89.0	-
2	[31]	92.7	95.5	93.0	98.3	-
3	[34]	94.0	94.0	95.0	94.0	-
4	[36]	-	69.0	-	-	-
5	[32]	77.3	69.0	69.0	69.0	-
6	[38]	-	94.9	94.7	95.2	-
7	[40]	95.3	99.0	-	-	-
8	[41]	97.9	93.5	92.1	96.8	-
9	[42]	-	77.4	72.6	83.0	-
10	[43]	-	70.8	68.9	72.8	-
11	[44]	-	87.1	85.7	89.2	-
12	[45]	93.0	94.0	92.0	98.0	-
13	[46]	95.3	-	-	-	-
14	[47]	73.0	76.0	-	-	-
15	[48]	-	98.7	97.9	99.6	99.6
16	[49]	92.2	-	91.6	92.0	-
17	[50]	99.0	94.0	-	-	-
18	[51]	-	99.0	99.0	99.0	-
19	[52]	-	66.0	-	-	-
20	[53]	99.6	99.5	99.3	99.8	-
21	[10]	-	82.3	89.3	76.4	72.2
22	[54]	96.8	97.0	97.2	97.2	-
23	[55]	21.7	54.9	-	-	-
24	[59]	-	93.1	93.2	93.6	-
25	[60]	70.6	70.5	68.7	72.5	-
26	[63]	99.0	99.0	98.0	99.5	-
27	[66]	-	97.4	-	-	-
28	[67]	-	85.4	85.7	86.1	-
29	[70]	91.0	90.0	90.0	90.0	94.0
30	[71]	75.0	74.0	73.0	85.0	76.0

B. F1-Score

F1-score is a combination of precision and recall measures, which are the most frequently used metrics. Indeed, to calculate F1-score, precision and recall need to be calculated using the equations (2) and (3).

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \times 100 \quad (2)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \times 100 \quad (3)$$

As mentioned before, F1-score is calculated as a harmonic mean of precision and recall, as demonstrated in the equation below.

$$F(i,j) = \frac{(2 \times Precision \times Recall)}{Precision + Recall} \times 100 \quad (4)$$

In general, F1-score values are within the interval [0, 1]; therefore, the higher the F1-score value, the better is the classification. Table IV presents a summary and comparison of the evaluation metrics used in sarcasm detection in the selected articles. The table shows that more than four types of evaluation metrics have been applied to evaluate sarcasm detection. From the table, it can be observed that the most common measures are F1-score, precision, and recall, and they are followed by accuracy. The results in this table are based on the highest results reported by studies that used multiple algorithms or multiple datasets.

VI. DATASET COLLECTION

Dataset collection is a crucial step in the sarcasm classification process that can affect the entire procedure. Building and annotating datasets for sarcasm detection is a challenging task even for human annotators, since the sarcastic text could be implicit, ambiguous, and hard to identify [74], [75]. It is normal for disagreements between annotators regarding the classification of a single text as sarcastic or not, so the task is even harder for an AI program. This section describes the datasets that were used in the reviewed literature. Noticeably, some articles utilized datasets that were used in the reviewed literature. Also, some articles utilized datasets from multiple sources, including social networks, news headlines, sarcastic reviews on online shops, books snippets, and forums, to stress on the generalization of their systems. For instance, the researchers in [55] utilized three different datasets, including book snippets, tweets, and Reddit comments. However, other articles relied on a single source for the dataset, for example, social network posts [52].

Social network posts have limited length; for example, Twitter limits tweets to 280 characters. This makes it simpler to obtain annotated text based on hashtags and API. The monthly number of active users on Twitter is about 330 million, which makes it a rich source of sarcastic tweets [11]. Therefore, most of the reviewed studies rely on Twitter as a source for their datasets, and few articles used datasets from Reddit and other sources. Twitter-based datasets can be built automatically using the Twitter streaming API while searching for a specific hashtag, such as "#Irony" and "#sarcasm" [32]. In this case, the annotation process is guided by the hashtag itself. In addition, it is already accurate to some extent, since the author clearly declares the sarcasm in the tweet. Another process for collecting datasets is manual self-annotation. For instance, in [60], the annotation process was undertaken by three linguistic annotators, each of whom worked on a subset of the dataset, and in [32], four expert annotators participated in the dataset annotation. In [52], the annotation was manually performed by three students. To ensure the reliability of the self-annotation, an evaluation step can be performed later by a third annotator [60].

The number of the collected instances of sarcasm in the considered datasets varied from 1264 to 1055277 [49], [76]. Generally, the higher the number of tweets in the dataset, the higher is the effectiveness of the proposed models. Some studies used a public dataset, such as [44], while other articles collected data on their own, such as [10]. When a public dataset is used for evaluation, it allows for fairer and more meaningful comparison with other works that use the same dataset.

The number of sarcastic and non-sarcastic samples in the dataset obviously affect the performance of the detection model. An imbalanced dataset may skew the performance of the classification model. In general, the models developed using imbalanced datasets are likely to achieve greater accuracy than other models with conflicting F1-score values [77]. For example, the Riloff dataset [64] creates a bias toward non-sarcastic tweets as it consists of 1648 non-sarcastic tweets and 308 sarcastic tweets. A detailed description of the datasets in the reviewed articles is presented in Table V.

TABLE V. DESCRIPTION OF THE DATASETS USED IN THE REVIEWED ARTICLES

No.	Article	Dataset source	Accessibility	#Instances	Annotation	#Sources	Balance
1	[33]	Twitter	Private	NA	Hashtag	Single	NA
2	[31]	Twitter	Private	76,799	Both	Single	NA
3	[34]	Twitter	Public	780,000	Hashtag	Single	No
4	[36]	Twitter	Private	5000	NA	Single	Yes
5	[32]	Twitter	Private	6600	Both	Single	Yes
6	[38]	Others	Public	28501	Self-annotated	Single	Yes
7	[40]	7 datasets from Twitter	Public	12162	Both	Multiple	4 yes, 3 no
8	[41]	Twitter1, Twitter2	Public/Private	55961	Self-annotated	Multiple	Yes, no
9	[42]	Reddit	Public	6534	Self-annotated	Single	Yes
10	[43]	Others	Public	4692	Self-annotated	Single	Yes
11	[44]	Others, others, Twitter	Public	55795	NA	Multiple	NA
12	[45]	7 datasets from Twitter	Public	134407	Both	Multiple	Yes
13	[46]	Twitter, others, others	Public	40000	Self-annotated	Multiple	No, yes
14	[47]	Reddit, Twitter	Public	45301	Both	Multiple	NA
15	[48]	Twitter1, others, Twitter2, Reddit, others	Public	309566	Both	Multiple	4 yes, 1 no
16	[49]	Others, Twitter	Public/Private	1264	Hashtag	Multiple	No, yes
17	[50]	NA	Private	NA	NA	Single	NA
18	[51]	Twitter1, Twitter2, others	Public	83596	Both	Multiple	2 yes, 1 no
19	[52]	Twitter	Public	4618	Self-annotated	Single	Yes
20	[53]	Others, others	Public	55328	Self-annotated	Multiple	Yes
21	[10]	Tweets, Reddit, Others	Private	20000	Self-annotated	Multiple	Yes
22	[54]	Others	Public	28,501	Self-annotated	Single	Yes
23	[55]	Twitter, Reddit, others	Public	1680	Self-annotated	Multiple	NA
24	[59]	Twitter, Reddit	Private	13000	NA	Multiple	NA
25	[60]	Twitter	Public	3000	Self-annotated	Single	NA
26	[63]	Twitter1, Twitter2, others	Public	58436	Hashtag	Multiple	No, yes, yes
27	[66]	Others, Reddit, Twitter	Public	1018291	Self-annotated	Multiple	Yes, yes, no
28	[67]	Twitter1, Twitter2, Reddit	Public	65551	Self-annotated	Multiple	NA
29	[70]	Twitter, Twitter, Reddit, Twitter	Public	NA	NA	Multiple	NA
30	[71]	Twitter, Reddit	Public	47115	Self-annotated	Multiple	No

VII. Discussion

This SLR analyzed 30 articles that were able to address the four research questions. This section discusses the findings of the review, highlights the challenges, and provides future research directions that can help in the development of more accurate and efficient sarcasm detection tools.

A. Findings

In several domains, NLP is an increasingly important topic with regard to AI and its applications. The research community is paying close attention to the sarcasm detection approaches, datasets and metrics. This subsection focuses on several observations from examination of different aspects of sarcasm detection.

1) Approaches: In general, it is impossible to compare the different approaches objectively due to several variations in the dataset sources and task requirements. One of the most interesting findings, as shown in Fig. 3, is that more than half of the reviewed articles used DL as a classification method for sarcasm detection, and there was a noticeable upward trend in the application of DL techniques for solving several NLP problems. In fact, DL has proved its superiority in sentiment analysis, in general, and in sarcasm detection in particular. One possible reason for this is that the automated feature extraction aspect is more effective and gives better insights about the target text than handcrafted features used in other classical sarcasm detection techniques. There are, however, other possible explanations. For instance, with regard to model performance, it is found that the best accuracy for the reviewed articles was obtained with DL models. Moreover, specific DL techniques, such as RNN, are particularly designed for sequence input data, and this fits the requirements of sarcasm detection tasks.

In addition, as depicted in Fig. 3, an interesting observation was that most articles used hybrid approaches in order to exploit the advantages of more than one approaches. The hybrid approach is extremely important in the development of sarcasm detection tools, as demonstrated in several articles in Section IV. Moreover, classical ML algorithms were utilized by 16% of the researchers. In contrast, only a few of the reviewed articles utilized transformer-based approaches. This is probably because transformers are a relatively new invention for application to sarcasm detection models. However, the rapid improvement in computational resources and increase in the available datasets have led to an increase in the application of transformer-based approaches in recent times.

Fig. 4 depicts the frequency at which various sarcasm detection techniques were used in the reviewed articles in this SLR. Among the classical ML approaches, the most commonly used classifier is SVM. Moreover, for DL approaches, the most commonly used technique is Bi-LSTM, and for transformers, the most applied technique is BERT. To sum up, the most frequently utilized sarcasm detection approach is DL. Moreover, the transformer approach appears to be an emerging promising solution with comparative performance to currently popular techniques and it warrants further investigation.

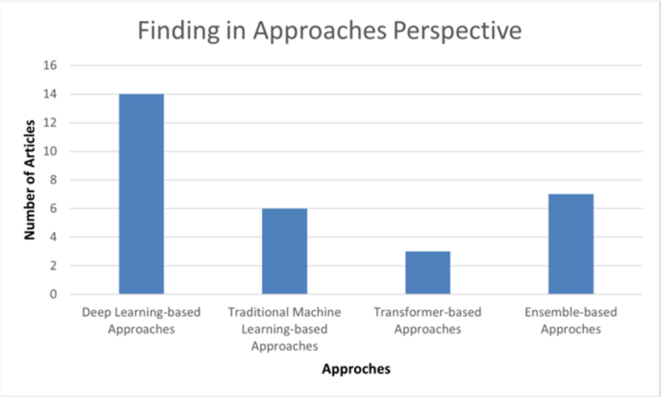

Fig. 3. Trends in the sarcasm detection approaches used by the reviewed articles.

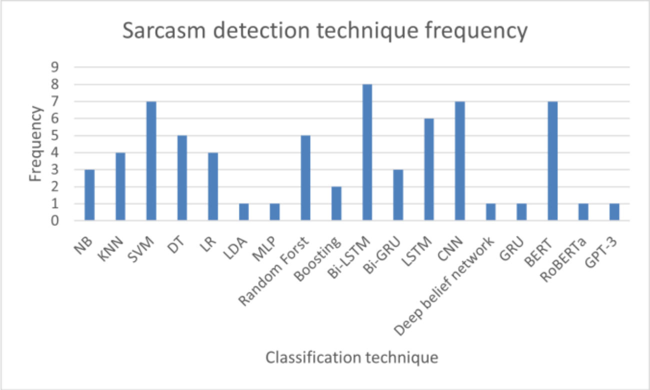

Fig. 4. Classification techniques used for sarcasm detection in the reviewed articles.

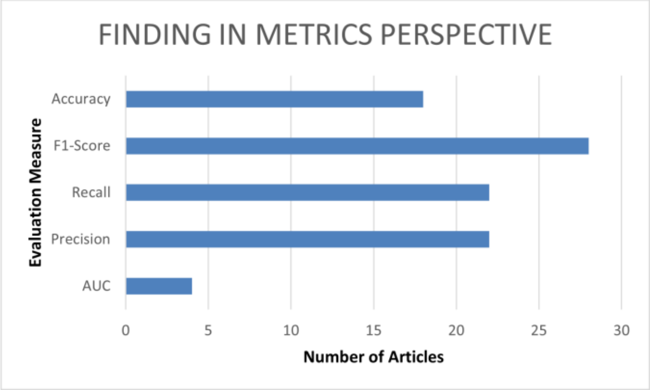

Fig. 5. Frequency of the use of various metrics for evaluation of sarcasm detection models in the included articles.

2) Metrics: As discussed in Section V, researchers used precision, accuracy, recall, F1-score, and AUC as evaluation metrics. As shown in Fig. 5, one of the most significant findings from this SLR is that the majority of researchers utilized F-score, followed by precision and recall. Furthermore, the most obvious finding to emerge from the analysis is that 10% of the reviewed articles used AUC as the evaluation metric. In addition, from the data in Fig. 5, it is apparent that accuracy was used as a metric by 63% of the researchers.

Overall, none of the evaluation metrics fit all sarcasm detection problems due to differences in the characteristics of datasets and approaches used. It is not surprising that F1-score was the most frequently used metric (90% of the researchers used this metric). This is probably because the F-score can balance the precision and recall of the positive class. Moreover, the F1-score could be more suitable than other measures when the target classes are unevenly distributed. Another interesting observation was the correlation between accuracy and dataset balance in the reviewed articles, since the vast majority of datasets were balanced datasets. This may explain why the use of accuracy as an evaluation metric was as high as 63% in the reviewed articles. AUC was the least frequently used metric; this is probably because AUC is based only on the thresholds of the true positive rate and the false positive rate. This is in contrast to the F1-socre, which takes into account the overall recall and precision values. In general, 87% of the observed studies used more than two metrics, and this makes the evaluation framework more robust.

3) Datasets: The dataset sources, number of datasets, dataset accessibility, number of instances, annotation methods, and dataset types of the included articles are discussed here.

An essential factor that affects the sarcasm detection process is the source of the dataset, as shown in Fig. 6. The findings showed that 34% of the analyzed articles used Twitter as a unique source of datasets. One possible reason for this is the huge number of Twitter users, which is 330 million monthly active users [11]. Moreover, Twitter provides concise text that can be automatically annotated by hashtags, and this facilitates dataset building. However, no single public dataset was used across all the reviewed articles.

The most obvious finding to emerge from the analysis is that 50% of the reviewed articles rely on heterogeneous dataset sources. This result may be explained by the different advantages offered by different sources. For instance, Twitter provides short texts while Facebook provides longer texts. Therefore, considering different sources for model building is expected to produce a more comprehensive classification model. Fig. 7 supports this notion, as it shows that 63% of the reviewed studies used multiple datasets rather than a single dataset.

Another important finding that strongly supports the transparency of the evaluation framework is that 71% of the considered articles used public datasets, 23% used private datasets, and 6% used both private and public datasets, see Fig. 8. This enabled the researchers to conduct a fair comparison of the proposed work with others conducted with the same public dataset. Additionally, 73% of the reviewed articles used less than 100,000 instances to build their classification model, while only 17% used more than 100,000 instances, as shown in Fig. 9. A possible explanation for this is that sarcasm detection tasks do not require a huge dataset to differentiate between sarcastic and non-sarcastic text. This is supported by the finding that good performance was observed for most datasets containing less than 100,000 instances. Moreover, the computation overhead is a serious concern when it comes to building a classification model.

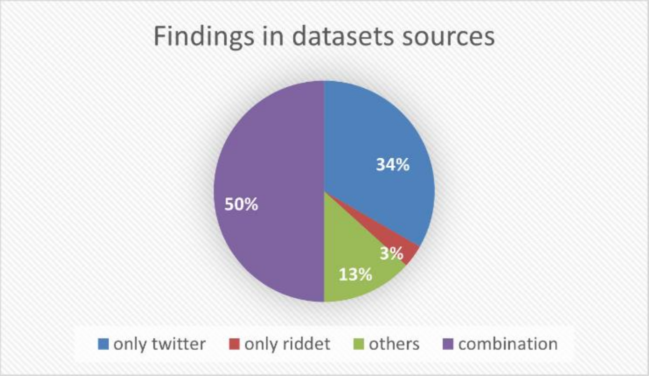

Fig. 6. Dataset sources of the included articles.

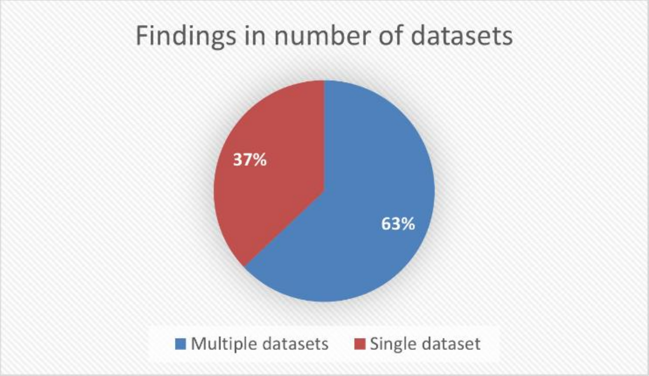

Fig. 7. Use of single or multiple datasets in the reviewed articles.

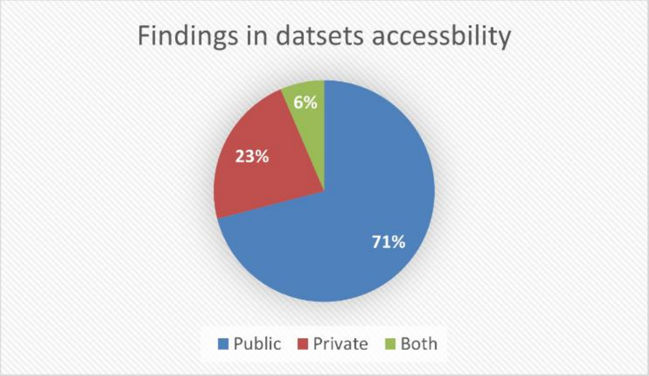

Fig. 8. Accessibility of datasets used in the reviewed articles.

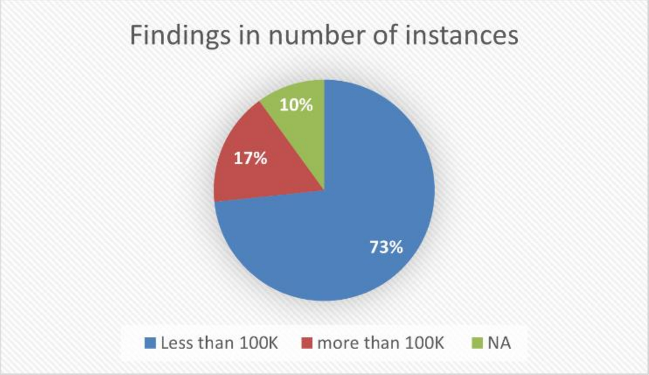

Fig. 9. Number of instances evaluated in the reviewed articles.

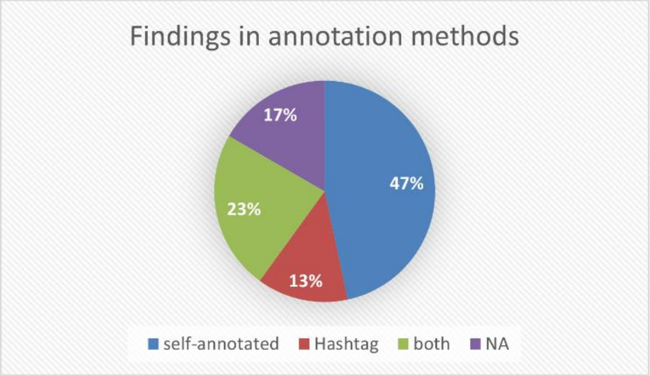

Fig. 10. Annotation methods used in the reviewed articles.

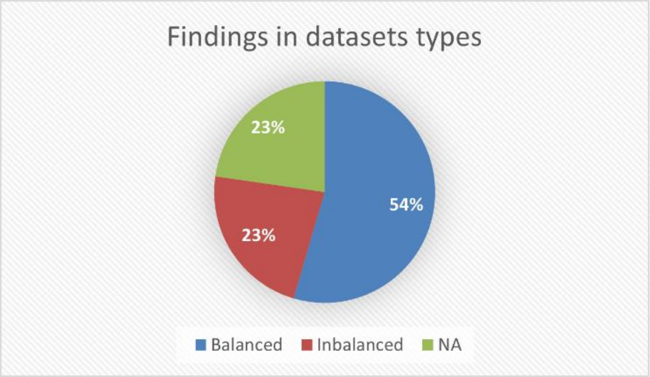

Fig. 11. Distribution of dataset types in the reviewed articles.

Another important issue related to datasets is the annotation method. As expected, 47% of the analyzed articles used self-annotated datasets, illustrated in Fig. 10. Self-annotated datasets are precise because the text is analyzed and annotated by experts and reviewed by another group of experts. However, self-annotation requires a tremendous amount of time [13]. Therefore, tweets could be annotated automatically based on the hashtag included in the tweet; this is a simple and time-conserving approach for annotations that has an acceptable level of correctness. However, only 13% of the considered articles used hashtag-based annotation, and 23% used both the self-annotation and hashtag annotation methods.

Another relevant finding was that 54% of the used datasets were balanced datasets in which the number of sarcastic and non-sarcastic instances was similar, as shown in Fig. 11. This is probably because the nature of the dataset highly influences the model prediction metrics, particularly accuracy and F-measure. These findings reflect those of Eke et al. [13], who also found that an imbalanced dataset can increase the accuracy of the model.

B. *Open Research Questions*

This subsection discusses the common issues and main challenges in the development of sarcasm detection tools for social networks, based on the findings from the reviewed articles.

1) Language used in the social network: The language used in social networks is not only restricted with regard to grammar, but also restricted to words that are not often included in dictionaries. This might pose an additional challenge in the recognition of sarcasm on Twitter and Reddit because of typos, non-vocabulary language, and non-grammatical context. As multilingual text has recently grabbed the attention of researchers, training models in more than one language might be more efficient.

2) Dataset: One of the biggest challenges in training models is the skewness of data. This problem arises when the number of instances in one class, such as sarcastic text, is greater than that in the other class, that is, non-sarcastic text. Furthermore, the quality of the dataset is another challenge. The use of a mixed dataset that uses slang and informal language makes it more difficult to train the classification model, especially if the dataset does not contain hashtags. In such a scenario, creating standard datasets is a solution that may solve the mentioned problems.

3) Text-based sarcasm detection: In speech, sarcasm detection includes features such as eye contact and body language, which help in the recognition of sarcasm. However, text data lack such features. Therefore, it is difficult and takes considerably more effort to identify sarcasm in text.

4) Variable context length: According to the reviewed articles, finding the optimal length of conversational context is a challenge. The Twitter dataset is the most commonly used domain for sarcasm detection, but the short text can be noisy and may not have any relevant features. Therefore, detecting sarcasm from short text is difficult. Overall, the researchers' task is still challenging due to the variability in context length.

5) Emoticons and special characters: In the last decade, the use of emoticons and special characters in social networks has increased. Most people prefer to express their feeling through emojis and emoticons, especially in applications that have restrictions on the number of characters such as Twitter. This increases the likelihood of ambiguity and makes sarcasm detection more difficult. Therefore, researchers should take into account the importance of these features, as they may change the overall sentiment of the sentence.

6) Data annotation: The manual annotation method is a major challenge. The main problem is distinguishing between perceived and intended sarcasm. Most datasets built through manual annotation may, therefore, be limited by differences in the perception of the annotator and the intention of the author of the utterance. As the labeling is based on the perceived sarcasm, this may lead to false positives and false negatives. A solution for this was proposed in [78], according to which the annotator and author of the utterances should be the same individual. Moreover, manual annotation requires a lot of time and the recruitment of domain experts.

7) Lack of real-time sarcasm detection: With the increase in the volume of generated data on social networks, sarcasm detection in real time is a challenging but significant task. Despite this, none of the reviewed articles included real-time data analysis.

Overall, there are still several challenges and open problems in sarcasm detection that need to be worked on. The following subsection provides future research directions.

C. Future Research Directions

This section describes the possible research directions based on our analysis of the 30 articles.

1) Considering more languages: The majority of the recent sarcasm detection works focus on English and ignore other languages. To this end, one possible future direction is to consider multiple language models that have the ability to perform all sarcasm detection sub-tasks for multiple languages.

2) Application of transformers and DL models: While considerably more work will need to be done on transformer-based, DL-based, and hybrid systems, their performance is superior to that of ML and classical NLP techniques. Moreover, the amount of work on transformer-based approaches is still limited, and therefore, there is scope for the development of more transformer-based sarcasm detection models.

3) Tweet correctness techniques: The findings in the datasets indicates that Twitter is the most frequently used source of data for sarcasm detection model evaluation in the reviewed articles. However, tweets are likely to have many typos, which may negatively influence model performance. One possible future direction is to use an automatic technique for typo correction in the early stage of development of sarcasm detection systems.

4) Exploring other social network sources: Twitter and Reddit were the only dataset sources in the reviewed articles. While they are both good sources of data, the addition of more social networks sources would provide a more comprehensive model. Therefore, further work in this domain should focus more on other social networks sources such as Facebook and Instagram.

5) Multi-culture datasets: Sarcasm by its nature differs across cultures. In fact, there could be cultural differences even between people who speak the same language. Therefore, further research could focus on the relationships between culture and sarcasm and the detection of sarcasm in multi-culture datasets.

6) Building multimodal sarcasm detection models: Most of the recent work on sarcasm detection focuses only on text-based datasets. However, considering multimodal models is a good idea for exploring new methods to solve such problems.

7) Use of emojis and emotions: Sarcastic text on social network often contains emojis that are used to express a specific emotion, due to the limitations on the length of posts on some platforms. Therefore, more research is required on new ideas for dealing with data that can improve the performance of such classification models.

VIII. Conclusions

Recently, sarcasm detection, especially in social networks, has grabbed the attention of many researchers. This SLR covers articles on sarcasm detection to answer four research questions. The review of the selected studies provides an analysis of the current approaches, metrics and datasets used to evaluate their models, as well as the challenges facing the development of sarcasm detection applications. In this SLRs, 30 articles published between 2019 and 2022 obtained from four well-known digital databases in Computer Science were analyzed based on their approaches, datasets, and evaluation metrics. Moreover, challenges and open research problems that still prevail in sarcasm detection are discussed. The findings show that the DL approach is most widely utilized, and it is followed by hybrid approaches. Furthermore, Twitter is the most commonly utilized source for datasets, and most researchers used public heterogeneous datasets. With regard to the features of the datasets, most studies used balanced datasets, and there is no consensus among researchers about whether standard, publicly available datasets are suitable for sarcasm detection in social networks. With regard to performance metrics, precision, recall, accuracy, and F1-score were most frequently used in the selected articles, and the majority of the articles used F1-score. Finally, several recommendations, including considering more languages, building multimodal sarcasm detection models and tweet correctness techniques have been suggested to improve the efficiency and performance of sarcasm detection tools.

Current Development, Challenges and Future Trends in Cloud Computing: A Survey

Hazzaa N. Alshareef
College of Computing and Informatics, Saudi Electronic University, Riyadh, Kingdom of Saudi Arabia

***Abstract*—Cloud computing is a new paradigm in information and communication technologies (ICTs) that provides the ability to access shared pools of different computing resources that are related to many cloud users within a pay-per-use or on-demand approach. It has transformed the delivery model of ICT from a product to a service. This provides several different advantages for institutions, companies and users based on savings and reduced capital expenditure through lower operating expenses. This paper provides a comprehensive survey of cloud computing. It first develops an understanding of cloud computing in general and discusses its advantages, current development, challenges and future trends. Subsequently, a detailed discussion on the cloud computing architectures, services models, fault tolerance mechanisms, services selection methods, adoption by industry, and scheduling of cloud-based resources is also presented. Nonetheless, cloud computing has many obstacles which expose it to a number of limitations. Some of these challenges include security of data, fault tolerance, and load balancing. A number of techniques in literature are proposed to cope with these challenges which are discussed and analyzed. Experimental data and usage drift validates the popularity of cloud computing and its adoption in recent years. Future trends in cloud computing support the use of intelligent machine learning (ML) techniques and new technologies to cope with some of the challenges and making cloud computing more efficient, secure and commercially viable to be widely accepted.**

Keywords—Cloud computing; security challenges; machine learning; resource scheduling; information and communication technologies

I. INTRODUCTION

In the present digital age, computer systems and associated applications have become inextricable part of life. Concomitantly, the need for better, cheaper, more efficient and on demand application services and infrastructure is felt like never before. Cloud computing is an approach that provides on-demand access to a shared pool of customizable computing resources (e.g. applications, networks, storage, servers etc.) and services [1]. Service providers can disseminate these resources with only marginal interaction and little management effort. Obtaining dynamic computing resources within the cloud computing paradigm provides the ability to cooperate with and scale up/down the given services, taking the demands of clients into account as well as the cost of the leveraged resources. This effectively contributes to a decrease in the operational cost pertaining to IT services. The scalability of cloud services provides smaller businesses with the ability to take advantage of various state of the art expensive and computing-intensive facilities that were previously affordable by large companies only [2].

Cloud computing enables the provision of information services and network computing resources, such as applications, servers, and storage [3], over the internet without installing them or purchasing them on their own. In 2005, Intel, IBM, and various other enterprises (including universities) within the United States began to operate a cloud computing virtual laboratory enterprise. This type of enterprise began with several experiments at North Carolina State University, situated near the IBM headquarters. In 2007, Google and IBM cooperated to start the processing of a new network computing approach, called cloud computing [4]. The new conversional Intel and Microsoft computing method was tested and thereafter caught the attention of a considerable number of research organizations.

In terms of virtualization, computers, networks, storage, and databases can all be potential cloud computing resources according to certain rules and service agreements. Global giants in the IT industry such as Google, IBM, Amazon, Microsoft, Alibaba etc. are investing in advanced research and innovative ways of utilizing cloud computing most effectively and widely. After launching a cloud computing platform, a significant issue is demonstrating the operative distribution and management pertaining to the virtual sharing of resources based on user demand by improving the effectiveness of the resource usage.

Technology advances and market forces are two related and integrated factors that drive interest in cloud computing. Rapidly improving business cases are producing enhancements in computing infrastructure, which has motivated several enterprise applications and services to consider moving to the cloud. In terms of technology, the existence of lower-cost processors and lower-latency networks, integrated with significant progress in virtualization, has moved computation from local IT platforms to disseminated cloud infrastructures. Evidence shows that, although cloud computing is considered a main business path for the upcoming years, moving to the cloud paradigm is seen to encounter a range of challenges. Some of the prominent ones among these are the issues related to security of the cloud data, scheduling of resources, fault tolerance, load sharing and load balancing. For instance, financial institutions are motivated to shift on cloud computing due to many advantages. Howbeit, the intrinsic security issues and challenges related to resource acquisition for smooth services are still hindering the complete migration. In 2014, more than 50 million users' Dropbox accounts were hacked, which resulted in a wide trust-deficit in the security of cloud computing. When cloud computing is considered a viable alternative, it should offer a similar security level to that of the conventional systems. In order to fulfil this goal, a comprehensive awareness regarding attacks and their countermeasures is required in order to detect malicious activities [5].

In summation, the cloud computing landscape has been considerably improved. Not only have further service offerings and providers packed the space, but improvements have also been made in the infrastructure and services. Cloud computing is considered to form an epitome that provides the ability to access shared pools of different computing resources in a pay-per-use or on-demand manner. With its incorporation into conventional systems, the weaknesses of traditional servers are overwhelmed in terms of efficiency, speed and scalability. It also offers savings in capital expenditure through reduced operating expenses. However, a few obstacles still exist that impose limitations when the technology is used. Lack of security, data consolidation [6], load balancing [7] and fault tolerance [8] represent some of the most important restraints of cloud technology. In addition to these, the adoption and absorption of cloud computing into existing systems, especially in small and medium enterprises (SMEs) [9], poses great challenges in terms of system conversion, change acceptance and embracing a myriad range of accompanying technologies which were previously unavailable. This paper provides a review of the cloud computing paradigm and its main computing and implementation options. It also discusses benefits and challenges of moving to the cloud from users' and companies' perspectives. Many of the aforementioned challenges are discussed in detail and a number of suitable ways are presented, based on literature, to cope up with these challenges. It summarizes the proposed solutions and techniques to deal with cloud computing risks and limitations, and discusses how future technologies, such as artificial intelligence [10], [11] and block chain [12], can embark a new era of prevalence of this technology. Gill et al. [10] has used the concept of "Triumvirate: IoT + AI + Blockchain" to describe the influence and interdependence of AI, IoT and Blockchain technologies that are anticipated to shape the future. They have also highlighted that future companies need to be well informed using Big Data Analytics and Data Science techniques to understand market trends, customer preferences and correlations.

The remainder of the paper is organized as follows: Section II provides a background and overview of cloud computing, including a definition, its structural layers, as well as service and delivery models. Section III then discusses benefits of moving to cloud computing. Challenges pertaining to cloud computing and the ways to cope with them are discussed in Section IV. Section V highlights a number of research trends and directions in cloud computing, whereas Section VI provides a discussion on cloud research trends. Section VII gives a conclusion of this work.

II. Cloud Computing Overview

The term 'cloud', or 'fog' in cloud computing signifies the existence of a remote virtual space. This section presents the definition, architecture, service models, delivery models, and the main characteristics of cloud computing.

A. Definition

There is, as yet, no standard definition of cloud computing. This is due to the dynamic nature of the term and its vast area of application. Nonetheless, industry and academic players are making essential strides towards agreeing on a standard definition ([13], [14], [15], and [16]). For example, as declared by the United States National Institute for Standards and Technology (NIST) [2], "cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" .

Madhavaiah and Bashir [17] analysed a number of definitions from both a business and research perspective and proposed a comprehensive definition: "Cloud computing is an information technology-based business model, provided as a service over the Internet, where both hardware and software computing services are delivered on-demand to customers in a self-service fashion, independent of device and location within high levels of quality, in a dynamically scalable, rapidly provisioned, shared and virtualized way and with minimal service provider interaction". Nonetheless, cloud computing is still an emerging technology with its ability to integrate and be integrated in new and associated technologies, which would significantly impact and form its true definition over a period of time.

B. Structural Layers

Majority of the researchers agree that the structure of cloud computing is based on four layers [1], [13]. The first layer is the Application Layer, which is located at the top of the architecture and is the layer that is the most visible for end-users. It consists of different applications and software packages related to the real cloud. As an example, office tools, storage management applications, email systems, and virus scanning and removal applications. The second layer is the Platform Layer, which provides the programming-level interface in accordance with different application approaches and operating systems (OS). This provision attempts to simplify the deployment of an application in the environment of the cloud. The third layer is the Infrastructure Layer, which is based on dynamically employing virtualization techniques for assigning the storage and computing resources needed. A well-known example of virtualization is VMware. The fourth layer is the Hardware Layer, which creates the data centers that contain various physical components, such as, cooling infrastructure, electrical power components, switches, routers, and servers. Fig. 1 shows a typical cloud computing ecosystem, whereby a number of hardware components and applications make the cloud, and network nodes comprising of different devices are the end users of cloud infrastructure and services.

C. Service Models

Cloud computing architecture represents a service-oriented approach, in which services are provided by every layer through to the top one. Accordingly, the services that are obtained in the cloud computing paradigm are classified based on three different types: the Software as a Service (SaaS) model, the Platform as a Service (PaaS) model, and the Infrastructure as a Service (IaaS) model.

The SaaS model is a cloud computing approach in which various applications remain on the service provider's cloud infrastructure and are provided to many users via web apps and interfaces. The major idea behind SaaS is based on eradicating the practice of applications residing locally on individual users' devices, where the computing power is insufficient to provide high computing performance and effectiveness to users [18]. The genesis of cloud computing can be traced to the SaaS approach [2]. Some examples of SaaS providers are Intercom [19], Trello[20], Hipchat, and Rackspace [21].

The PaaS model is a service approach for providing a platform that creates and operates different applications based on the programming interface that is obtained from and supported by the cloud provider [22]. Consequently, scalability issues, high server rapidity and storage capacities are all addressed under the PaaS approach. Therefore, PaaS users are able to create, operate and deliver their particular applications based on the use of remote IT platforms. Nonetheless, users are unable to monitor core cloud platforms (e.g., storage, OS or servers). An example of a PaaS provider is Microsoft Windows Azure [23].

The IaaS model is an approach whereby virtual infrastructures, such as virtual servers, storage and other fundamental computing resources, are offered by cloud service providers to users in order to enable them to disseminate and operate their particular applications or OS; and to download or upload files or software on the cloud. Using the IaaS approach, users can monitor their software, including applications, which is disseminated throughout the cloud. Nevertheless, such users have a limited ability to monitor the virtual infrastructure that is obtained from the cloud service provider. An example of an IaaS provider is Amazon EC2 [24].

D. *Delivery Models*

Cloud based services are disseminated to users via four main delivery models, based on, (i) the control required, (ii) the number of users, and (iii) privacy and security demands of the users [2], [25], [26]. These delivery models are categorized into: (i) Public cloud, (ii) Private cloud, (iii) Community cloud, and (iv) Hybrid cloud.

The Public cloud consists of a third party that possesses the physical resources in their entirety and delivers different cloud services to users via the Internet. Users who are supported by the cloud provider range from individuals to corporate institutions.

The Private cloud is provided exclusively to a particular institution. This model can assist in monitoring the performance of a system, security guidelines, and data. An institution is also able to disseminate its own particular cloud services, and a third-party institution can handle the model by itself.

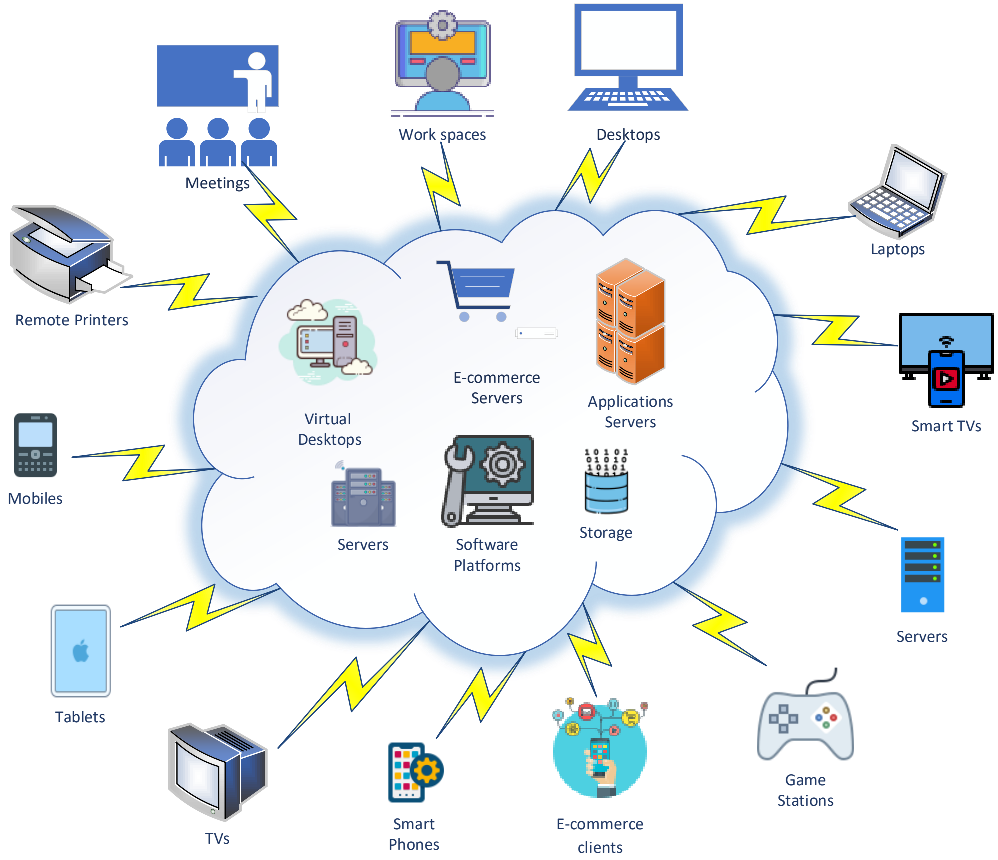

Fig. 1. Cloud computing technology ecosystem.

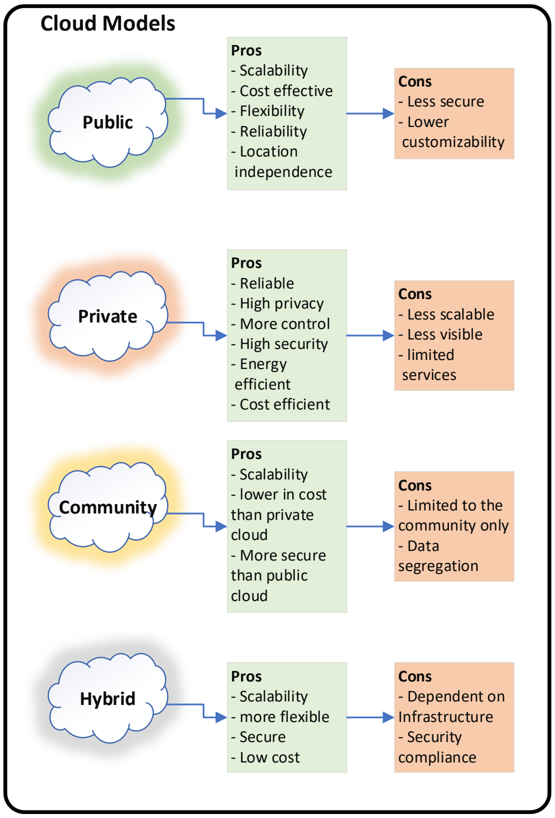

Fig. 2. Cloud delivery models.

The Community cloud represents the provision of different cloud services based on a particular group of institutions with the same mission, compliance conditions, policies, and security demands [22]. A community cloud demonstrates a generalization of the private cloud and, therefore, includes further institutions in each realization.

The merger and combinations of various cloud models (e.g., community, public and private cloud models) represents a hybrid cloud model. They have become very popular in recent years primarily due to popularity and wide usage of cloud services, which now faces complex dynamics of the corporate infrastructures and new business markets. Despite these various models being grouped with each other, they remain distinct and are included in exclusive standards and have distinctive standards and technology with respect to data operability and various applications. The Hybrid cloud inherits the advantages and disadvantages of community, public and private clouds. Consequently, it represents an optimal approach that makes a delicate balance between price and control, which are strong considerations for economic viability as well as user satisfaction with cloud services and applications. Fig. 2 demonstrates the advantages and disadvantages of the cloud delivery models.

E. Cloud Computing Characteristics

Cloud computing is a relatively recent term and the technology has emerged from the usage and trends of computer networks and its associated services and business models. In studies [14], [27]–[29], a number of cloud computing characteristics are discussed. More characteristics may emerge as the technology grows. We present some of the essential characteristics of cloud computing in this section, which define and advocate the core technology and its acceptance specifications.

1) Dynamic (Flexible): cloud resource platforms are dynamically scalable, meaning that, they are able to be enlarged or reduced in size based on user demand, which minimizes the investment risk related to the user and can satisfy the demands of many users. Cloud computing provides users with the sense that infinite computing resources are available to them.

2) Virtualization: cloud computing applications and platforms are created according to resource virtualization concept. Virtualization performs a significant task in developing the effectiveness of resource efficiency and raising the level of service security and reliability.

3) Economies of scale: cloud computing is dominated by large companies, such as IBM, Microsoft, Google, and Amazon, which have the ability to employ large-scale resources that enable them to minimize rental and exploitation costs. As a result, cloud computing companies can recruit as many users as possible. Since there is a large number of potential users involved in any cloud-based service, it becomes financially viable for the service provider to offer the service at a very low cost.

4) On-Demand service: cloud services and platforms are obtained and billed based on users' actual demands. Cloud computing eliminates the risk of a one-time large investment and permits users to acquire only the resources they need. Accordingly, services depend on short-term costs (e.g., on an hourly basis), whereby users release resources once they are no longer required.

5) Dynamic customization: cloud rental resources should be customizable to a considerable extent. For example, in the IaaS delivery model, users are permitted to disseminate virtual and specialized devices. Further services deliver low flexibility and are not applied to general purpose computing. However, it is expected that such services will continue to provide a particular level of customization.

6) High reliability: cloud computing platforms are required to ensure that customer data are secure, so that the application platform is seen to be reliable. In general, platform backups and multiple data are both applied in order to raise platform reliability. Dynamic network management approaches are also applied by cloud computing platforms in order to verify the effectiveness and status of every resource node. The reason for this is that nodes could be dynamically migrated when failure or low effectiveness is encountered. Another reason is to ensure that the performance of the entire system is unaffected in case of a fault.

III. BENEFITS OF MOVING TO THE CLOUD

Owing to the popularity of cloud computing in recent years, the technology incorporates a number of benefits which ascertain the next level of networks and applications sharing, and distribution of services and resources on an economically viable and efficient manner. A number of previous studies [9], [30]–[33] have highlighted some of these advantages. Cloud computing enables on-demand network access and a host of associated applications and infrastructure to a number of customizable computing resources such as servers, software applications, storage spaces, services and other networks. In line with the characteristics identified in the previous section, this section highlights the main benefits and challenges of shifting to the cloud, which mainly include:

A. *Optimum Resource Utilization*

Since most of the cloud computing is based on use-per-pay model, therefore resources are released after every use. This results in the overall utilization of all the computing resources in an efficient and optimized manner, leading to green computing. It is in line with the United Nations' (UN) Sustainable Development Goal (SDG) number 12 [34] that relates to responsible consumption and production of goods and services.

B. *Rent on Demand*

Another major benefit of cloud computing is the availability of all types of computing and infrastructure resources and services for everyone, anywhere, and at any time. Industry 4.0 [35], [36] provides opportunities for growth and sustainability for all kinds of businesses, whether large or small. Future businesses lie in innovation which is the key for success for agile companies of today. Being able to access and utilize state of the art infrastructure and computing resources, as and when needed, startups can easily compete with giants of the industry resulting in better and cheaper products and services for the masses.

C. *Minimized IT Staff*

Moving to cloud computing results in reduction of inhouse IT staff to maintain the existing systems. Some technical staff is, however, still required to work with pre-existing vendors, including specialized vendors, in order to manage particular outsourced applications.

D. *Minimized Infrastructure*

Relocating resources to the cloud, or accessing platform as a service, means that it is possible to maintain a smaller inhouse hardware infrastructure.

E. *Managed Costs*

Since most of the cloud computing service providers gain income on the basis of economies-of-scale, and try their best to cut down the costs, increase the customers and have the latest and updated hardware and software applications. Therefore, prices and licensing can be minimized when adopting cloud computing. The latest costs are based on predetermined services and is derived from the costs model used by the vendor.

F. *Enhanced Vulnerability Control*

Vulnerability control is the ability to track system activities and logs to provide greater control and minimize the risk of attacks by detecting and preventing its occurrence before happening. In the cloud computing ecosystem, the service provider provides services to numerous customers concomitantly and a large revenue is generated as a result. Therefore, the service providers make sure that all the systems are up to date with state-of-the-art technologies in place, and no vulnerabilities or security threats are there.

IV. Cloud Computing Challenges

A number of benefits related to cloud computing are discussed in the previous section. However, it is neither an optimal solution nor risk free, particularly when data is out of users' reach. Other disadvantages of moving to the cloud are reliability issues and system performance, since users are fully dependent on cloud resources. For instance, when accessing the cloud in order to seek a service, the time needed to execute the task (the round-trip time, or RTT) could be an issue for users. This can be exacerbated if the cloud is busy serving other instances or traffic is already congested. Privacy and security are other limitations that are widely known to render cloud computing which is a challenge for users. Some of the major challenges faced by cloud computing are provided as follows:

A. *Reliability*

A cloud computing platform must guarantee the reliability of the application platform and the integrity of customer data. When a large-scale system is experienced, an effective solution is expected in order to receive a high level of reliability. In addition, a dynamic network management system controls the effectiveness and status of the resource nodes, whereby ineffective or failed nodes are dynamically migrated. Consequently, the entire performance of the system is not influenced by these nodes. Ensuring that all systems are working perfectly and reliably poses continuous challenges for the cloud service providers.

B. *Resource Provisioning and Scheduling*

The dynamic deprecation and expansion of resources relies on users' demands, thus presenting new challenges for management systems and cloud platforms. In terms of provisioning of cloud resources, an effective cloud resource provisioning algorithm is highly needed that makes better resource utilization and allocation, reduces response time, and has robustness as well as fault tolerance capabilities. Similarly, scheduling for on-demand resource requirements, or long-term resource reservation is a challenging task, especially when the number of resources and the number of users are extremely large.

C. *Management Issues*

The process of managing a cloud computing platform is extremely complicated. Especially, resource consolidation is one of the key areas of research and have gained substantial attention from the research community in recent years. It involves managing the means of controlling the system's resources effectively, deploying and scheduling different resources in a dynamic manner, and managing clients, their billing systems and service agreements. Nonetheless, applying the approach of having one service provider creates obstacles, such as the following: (i) a lot of much energy is exploited via an enormous data centre in order to have it operational; (ii) centralized cloud data centres are affected by many single point failures; and (iii) data centres are geographically remote from their users, and data need to be moved from their source in order to be processed. This implies that personal or sensitive data generated through the use of different applications are kept in a location other than where they were produced.

D. Fault Tolerance

Fault tolerance refers to the continuity of cloud services even in the existence of any hardware or software malfunction. In case of failure of such components, it is a major challenge to keep all the system running and without performance degradation in presence of a fault.

E. Privacy and Transparency

Privacy and transparency of users' data and cloud services respectively is very crucial in any cloud computing system. In order to gain trust in a cloud-based service, where the users' data and all related credentials are stored in a virtual environment, privacy of data is very crucial. Similarly, transparency of cloud services and virtualization of all systems and infrastructure is of prime importance. Cloud service providers must inform the customers about how their data will be held, stored and transmitted. Things like what security and privacy schemes are deployed, and what internal policies and technologies are in place, are very important from the point of view of a client, especially, when the client is a big organization.

F. Security

Security of cloud computing is far most the biggest challenge in this technology. It deals with all kinds of challenges related to data security, information security, data integrity and confidentiality. Security is one of the main challenges and hurdles when cloud computing implementation and adoption is concerned. Therefore, a detailed discussion on it and the related issues is inevitable for the completeness of this work.

The following section provides a detailed discussion on works related to security challenges, including possible threats, attacks and their countermeasures.

V. Security Challenges and Cloud Computing

One of the potential hindrances in cloud computing adoption is that users are not informed of the physical location of their sensitive data. Since service providers locate cloud data centres in many geographical locations, it leads to a range of security issues and risks. The conventional security approaches, such as intrusion detection systems (IDSs), host-based antivirus software and firewalls, are not able to provide appropriate security through virtualized systems. Fast dissemination of risks derived from the virtualized environments produces different risks [37]. Subramanian and Jeyaraj [37] identify the top 12 threats to the cloud according to the Cloud Security Alliance (CSA), which include compromised credentials and broken authentication, and denial-of-service (DoS) attacks, as presented in Table I. Most of the threats identified are related to data breaching, representing the principal security problem that needs to be addressed.

Kamara and Lauter [38] indicate that many different risks emerge depending on the use of public clouds. Data integrity and confidentiality represent the highest risks and produce different but related issues. The authors propose a crypto-cloud architecture that contains three main features: the cloud storage service provider (CSSP), the consumer of the data, and the data authority (the user that possesses the related data). Encrypted files are uploaded by the data authority and the CSSP permits access to the files. The demanded file is then downloaded and decrypted based on the use of suitable credentials and tokens. This type of architecture faces various security issues at the service-level agreement (SLA), computation and communication levels. For instance, issues occur within the communication level because the same infrastructures and resources are shared through a virtual machine (VM), which increases the possibility of attacks.

TABLE I. Cloud Security Alliance's Top 12 threats

Threat Number	Threat Name
1	Compromised credentials and broken authentication
2	Malicious insiders
3	Denial-of-Service (DoS) attacks
4	Account hijacking
5	Inadequate diligence
6	Permanent data loss
7	The Advanced Persistent Threat (APT) parasite
8	Cloud service abuses
9	Data breaches
10	Exploited system vulnerabilities
11	Hacked interface and App. Program Interfaces
12	Shared technology, shared dangers

Bhadauria and Sanyal [39] categorize these problems into (i) network, (ii) application, and (iii) host levels. Attacks are determined based on the communication levels indicated. The main security risks at the network level are data integrity and confidentiality, where problems related to network security include reused IP addresses, sniffer attacks, Domain Name System (DNS) attacks, and prefix hijacking in the Border Gateway Protocol (BGP). At the application level, security is required in order to prevent attackers gaining control and compromising the application. Problems at this level include hacking, dictionary attacks, hidden field manipulation, CAPTCHA breaking, cookie poisoning and distributed DoS (DDoS) problems. Finally, the main host-level risks are foot printing, Trojan horses, unauthorized access, DoS, password cracking, profiling, worms, and viruses. Applying the aspect of cloud virtualization represents the largest of the computational-level issues.

Data is considered the key source of item related to any crypto-cloud approach. CSA regards a data breach as the highest security risk. Multi-tenancy and maintaining data storage on a remote place (i.e., out of your control) can cause data leakage. Chen and Zhao [40] produced a data life cycle: Generation => Transfer => Use => Share => Storage => Archival => Destruction, which requires protection during all the phases. Data-level security is categorized as data in rest and data in transit. Data in transit does not cause extra security threats in comparison with data in rest, as transmitting data can be performed based on a secured data transfer method. From the hacker's perspective, data in rest poses a high level of attraction.

As regards the cloud services are concerned, these are given by providers to consumers based on appropriate SLAs. Thus, major items related to the crypto cloud include the accountability of ensuring that SLAs are maintained. In practice, there is no exclusive standard for SLAs that are applied for all the requirements of security management. However, a few standards, such as the European Network and Information Security Agency (ENISA) and the European Commission Secure Provisioning of Cloud Services (SPECS), offer security by maintaining SLAs. Applying an SLA assists in obtaining an adequate level of quality of service.

Previous research has indicated that the above issues are encountered via three major attack vectors [5]: the network, the computing hardware, and the hypervisor (the computer software, firmware or hardware that creates and runs VMs). There also exist three kinds of attacker map of the three vectors: the cloud provider, internal users, and the external users. It is also possible for a cloud provider to act as an attacker. Permission and authority is given to employees working on the could, for example, might be exploited in order to steal sensitive user information based on either logical or physical manipulation of the hardware platform. External users can also have an impact on data integrity and confidentiality by interfering with communication channels or through lying dormant within the system in order to attack it later. Internal users, such as the owners of a VM instance, could use the hypervisor to attack other VM instances.

A. Major Cloud Attacks

The following subsection contains a discussion of the different attacks that have been discussed in previous research [41]–[44]. These types of attacks, which can be launched over a cloud infrastructure, are examined and presented along with the countermeasures that can be taken to control them.

1) Network-based attacks: The network represents a major vehicle of attack against applications that are being performed within a cloud platform. The majority of such attacks are closely related to the types of attacks typically recognized in conventional technology, although there are some network-based attacks that specifically relate to cloud computing.

2) Hardware-based attacks: Confidential data is protected from illegal access by being maintained within an encrypted form, interacting through different encrypted channels. However, data has to be decrypted sometimes for performing different computations from time to time. Attackers benefit from a multi-tenant environment in which they can simply access various physical resources (e.g., disk buses, memory buses, and instruction and data caches [L1, L2, L3]). Attackers explore and exploit decrypted data and the secret keys related to different common algorithms (e.g., RSA, DES, and AES) and VM instances.

3) Hypervisor-based attacks: The hypervisor is defined as the software layer which is located between the physical hardware and VMs in order to identify the fundamental architecture. The hypervisor is essential for ensuring the characteristics of cloud multi-tenancy. Moreover, it assigns several physical resources to guest VMs (e.g., peripherals, CPU and main memory). On the security side, hypervisors are the most important layer of protection within the cloud stack, since this is the highest privilege level. If attackers can gain control at the hypervisor level and compromise VM isolation, they can control any resource related to the host system.

B. Countermeasures against Cloud Attacks

Cloud providers apply well-known approaches to protect against network-based attacks (e.g., antivirus gateways, IDSs, and firewalls). Such approaches are currently being extensively disseminated within edge networks in order to protect end systems from various forms of attack and to control and check outgoing and incoming traffic. For hardware-based attacks, newly arising techniques (e.g., Arm TrustZone technology and Intel Software Guard Extensions [SGX]) could prevent side-channel attacks. Another prospect is based on protecting hardware using cryptography. A commonly agreed instruction by cloud providers is the Intel Advanced Encryption Standard New Instructions (AES-NI), which proceeds towards different cache-based software side-channel attacks. In the case of hypervisor-based attacks, several software and hardware isolation mechanisms offer resources secure separation, whereby some hardware mechanisms, such as AES-NI, can have an impact on security within this level and are considered a part of hardware-based hypervisor protection.

Senyo et al. [18] also present a valuable tool for navigation, which could be applied by IT personnel in order to gain further insight into security threats that are based on the use of cloud computing. Personnel can then weigh the advantages and disadvantages of any improved resolutions.

VI. Discussion on Cloud Research Trends and Future Technologies

Cloud computing technology is said to be one of the biggest revenue generators for the software companies in recent years. Fig. 3 shows the spending in public cloud computing IaaS hardware and software worldwide in US billion dollars as depicted by Forbes [45]. It also shows that share of this spending by PaaS and SaaS/ The projected values up to 2026 shows that the spending in this technology will remain on the rise.

One key weakness of cloud technology is indicated by the low level of control over data that is disseminated to the cloud provider. This weakness is a major hazard, causing various problems, such as DoS, malicious insiders, and account or service traffic hijacking, which represents an essential impairment to massive cloud adoption. When users are not able to enter different physical systems, they must rely solely on the infrastructure provider in terms of addressing issues that are incurred with regard to data security. Previously, a capable method was Trusted Computing (TC), by which Trusted Platform Module (TPM) characteristics were applied to offer integrity for the software stack (i.e., the VM layer). The Intel Trusted Execution Technology (TXT) is one example of this method. The Intel SGX also represents a promising technique and is defined as an instruction set architecture (ISA) extension, which provides the ability to execute a number of different instructions within a secure memory location, known as the secure enclave. Accordingly, SGX allows users to apply effective security for their own data and applications without having to trust the cloud operator. A similar characteristic is provided by a further research domain, called homomorphic cryptography [46], which permits different calculations to be performed on encrypted data without acquiring a secret key or any decryption of the data.

Another research trend relies on the use of containers for the purpose of abstracting different applications based on the underlying OS, thus providing the ability for more rapid improvement and simpler deployment. Docker [47] represents a well-known container, whereby spreading the container term depends on the support provided by large providers, such as Amazon, Google, and OpenStack. Containers can also be utilized for improving user application security.

For institutions that require an increased level of data security (e.g., banks, the military, and trading and insurance companies), the requirements with regard to customer information security are very high. Ensuring data security in cloud computing is a common issue of concern for such institutions. Presently, service providers and researchers offer several different resolutions. Within the new application domain, there exist several security concerns that should be resolved. Although a few protection methods have reached a particular level of practical maturity, other related methods remain in their infancy and are inappropriate for dissemination to an operating setup. Several different methods exist for addressing vulnerabilities to data breaches and shared technology risks; however, they require further improvement. It has been seen that solutions to attacks related to the network-level have led to improvements. In contrast, approaches at the application level to addressing DoS risks and account or service traffic hijacking need to be improved, and several researchers are still investing time in these areas. There are also several tasks involving identifying new resolutions that would provide protection against the various hypervisor-based attacks encountered. Furthermore, applications attempt to leverage the infrastructure of the cloud based on utilizing heterogeneous resources derived from several providers.

The broad trend is to aim at using infrastructure from several providers and compared with conventional cloud offerings from single providers, disperse computing apart from resources. Subsequently, new computing approaches that aim at fulfilling market needs are evolving. In practice, many different security problems have been identified in relation to SLAs, computation, and communication. As referred to earlier, there have recently been large and significant security problems, presenting a range of opportunities for hackers to break service cryptosystems. Cloud computing has been demonstrated to be inadequate when it comes to security problems, and cloud service providers need to take into account that security should form an inevitable and important factor, and not be an afterthought.

Recently, a lot of effort is made by the machine learning (ML) community to scale up and enhance the existing data mining and ML algorithms to meet the challenges of handling large amounts of data [48], [49]. The work by Kim et al. [50] demonstrates a network threat detection and classification method based on ML, thus paving a path to the intelligent threat analysis technology. Similarly, the use of artificial intelligence (AI) and ML algorithms for the analysis of cloud services, for security, and for predictive and prescriptive analytics is very promising.

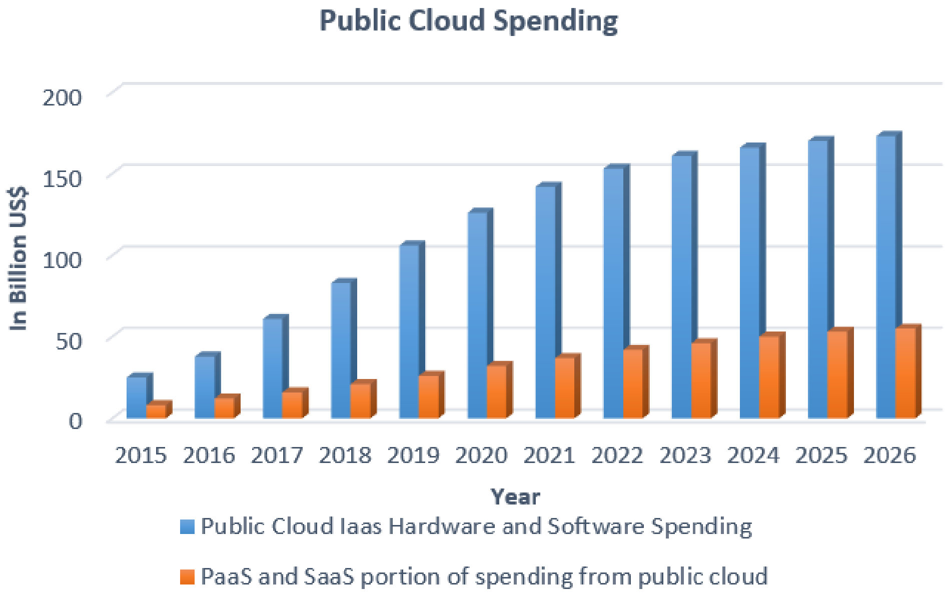

Fig. 3. Public cloud spending. Past, present and future.

VII. Conclusion

Cloud computing is an extremely rapidly developing technology in the domain of computing. There exist several benefits to applying cloud computing, such as anytime-anywhere accessibility, more effective geographical coverage, greater time efficiency, and reduced infrastructure costs. Nonetheless, there are also obstacles to applying cloud computing, such as lack of expertise and resources, cloud services management, privacy, and the need for data security. The majority of the services pertaining to the infrastructure of the hosting cloud, including storage and computing resources, exist in data centres. The hosting of applications in a single provider's cloud is seen to be simple and to offer various benefits. Nonetheless, there are a myriad of associated risks and challenges with cloud computing. Information privacy, security and data integrity are among the top of these. Trends and results from the literature shows that cloud computing is still emerging and new associated technologies are being developed to cope up with the existing challenges. The use of AI in cloud computing can mitigate some of the risks and provide solutions to previously unresolved issues.

A High-performance Approach for Irregular License Plate Recognition in Unconstrained Scenarios

Hoanh Nguyen
Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

***Abstract*—This paper proposes a novel framework for locating and recognizing irregular license plates in real-world complex scene images. In the proposed framework, an efficient deep convolutional neural network (CNN) structure specially designed for keypoint estimation is first employed to predict the corner points of license plates. Then, based on the predicted corner points, perspective transformation is performed to align the detected license plates. Finally, a lightweight deep CNN structure based on the YOLO detector is designed to predict license plate characters. The character recognition network can predict license plate characters without depending on license plate layouts (i.e., license plates of single-line or double-line text). Experiment results on CCPD and AOLP datasets demonstrate that the proposed method obtains better recognition accuracy compared with previous methods. The proposed model also achieves impressive inference speed and can be deployed in real-time applications.**

Keywords—License plate recognition; deep learning; convolutional neural network; keypoint detector; YOLO detector

I. Introduction

Recognizing license plates is a crucial area of research due to its numerous practical applications, including monitoring road traffic, collecting tolls automatically, enforcing traffic laws, and more. A license plate recognition pipeline for recognizing irregular license plates typically includes four stages: license plate detection, perspective correction, segmenting characters and recognizing characters. License plate detection aims to extract license plate regions from input images. The accuracy of the entire system heavily relies on the accuracy of license plate detection, as the extracted regions are utilized in subsequent stages. As real-world images containing license plates are captured under different viewpoints, license plates may have arbitrary direction. As a result, perspective correction is performed to align the detected license plates. For recognizing characters, a segmentation approach is first used to decompose the aligned license plate image containing a sequence of characters into sub-images of individual character. Then, a character recognition approach is employed to classify each character. Classical approaches based on computer vision for license plate recognition [1], [2] primarily focus on extracting features of license plates based on the background color, contours and edges, and use these hand-crafted features for locating license plates and decomposing characters. Recently, numerous CNN-based approaches for license plate recognition have been proposed, leading to significant advancements. These methods first adopt CNN architectures to extract discriminative feature representations from input images. A network is then used to locate the location of license plates. With the detected license plates, a classifier is proposed to search for license plate characters and classify them. Since character segmentation is a challenge problem due to the effect of lighting conditions, shadows, and noise, various approaches [3], [4] have been proposed to directly recognize license plate characters without segmentation. With the success of CNN and text recognition, CNN-based license plate recognition methods have obtained great achievements in both accuracy and efficient. However, previous methods still depend on high-end GPUs or controlled environments such as specific viewing angles or simple backgrounds. Furthermore, with the growing number of license plate designs, license plate recognition systems that concentrate on single-line plates or frontal plate detection and recognition face increasing challenges.

In view of these issues, a novel framework for detecting and recognizing irregular license plates in real-world complex scene images is designed in this paper. The proposed model can locate and recognize various types of license plates with arbitrary shooting angles in difficult conditions. There are three stages in the proposed model: license plate detection, perspective correction, and recognizing characters. For license plate detection, this paper employs a state-of-the-art object detector and extends it for predicting four corner points of license plates, which are then used to rectify distorted license plates. For license plate recognition, this paper designs a segmentation-free model based on a fast and efficient object detection architecture for predicting license plate characters. The results of the experiments conducted on two extensive datasets show that the proposed model boasts both a high recognition accuracy and rapid inference speed.

This paper is structured as follows: Section II presents a literature review of license plate recognition. Section III offers an overview of the proposed approach. The details of the proposed pipeline are described in Section IV. The discussion of experimental results can be found in Section V. Lastly, the conclusion is outlined in Section VI.

II. Literature Review

This section provides a brief literature review on the topic of license plate recognition. This paper focuses on recent methods that are based on deep learning for end-to-end license plate recognition. For studies involving traditional image processing strategies or focused on license plate detection, please refer to [1], [2], [5], [30].

Since license plates usually occupy small portions of input images, various methods proposed to first detect vehicles and then locate license plate regions to improve license plate detection performance. For this purpose, Sergio and Claudio [6] proposed a novel CNN model that includes a YOLO-based network for vehicle detection and license plate detection and an optical character recognition module for character recognition. The model can detect and rectify multiple distorted license plates before feeding the rectified license plates to the optical character recognition module to obtain results. In [7], the authors presented an end-to-end license plate recognition system utilizing the YOLO detector [8], [9]. This approach first locates the vehicles in the input image by a YOLO detector and then detects their respective license plates in the vehicle patches by another YOLO detector. Afterward, the model detects and recognizes all license plate characters simultaneously by forwarding the license plate region into the CR-NET model [10]. The results showed that this approach obtains high accuracy and fast inference speed. However, the model only recognizes single-line license plate taken from a frontal angle.

Due to the effect of environment conditions, character segmentation is a challenge problem. Moreover, any incorrect character location produced by character segmentation will lead to misrecognition of the license plate characters. To solve this problem, various methods proposed to avoid character segmentation. Wang et al. [11] introduced a cascade approach (i.e., VSNet) for irregular license plate recognition. VSNet consists of a license plate detection network that makes predictions using multiple feature levels produced by a fusion network and a license plate recognition network that features an encoding layer for left-to-right feature extraction and a weight-sharing classifier for character recognition. In addition, a vertex-estimation branch is proposed to rectify distorted license plate images. In [12], the authors presented an end-to-end convolutional neural network for license plate recognition that eliminates the need for character segmentation. The network is implemented on FPGA with very fast processing speed. To enhance the accuracy of license plate recognition in unrestricted conditions, Zou et al. [13] proposed a robust license plate recognition framework that uses a combination of Bi-LSTM and contextual position information of license plate characters to locate the characters in the license plate. The authors utilized deep separable convolutions and a spatial attention mechanism for license plate feature extraction to activate the character feature regions and thoroughly extract the features of license plates.

In summary, although the above methods have achieved some significant accomplishments, they have not fully addressed the issue of irregular license plate recognition in unconstrained scenarios. Furthermore, these methods mostly require hardware with high-end GPUs, which is difficult to implement in practical applications.

III. Overview of the Proposed Framework

The proposed method includes three stages as outlined in Fig. 1. Specifically, the proposed method takes images as inputs and sequentially undergoes license plate detection, perspective correction, and character recognition to produce final license plate characters. Both stage 1 and stage 3 are based on simple and efficient deep CNN architectures for fast inference speed. Overview of each stage is described further.

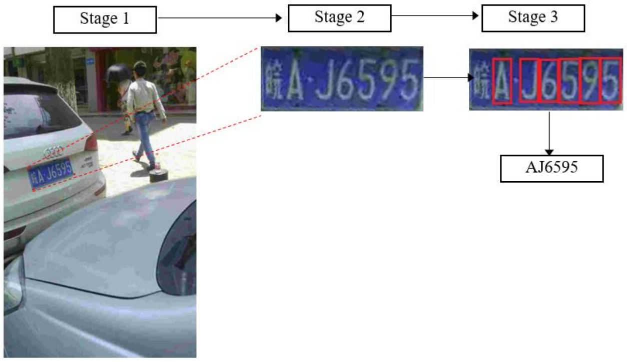

Fig. 1. Overview of the proposed framework.

Stage 1: License plate detection. As shown in Fig. 1, license plate detection aims to locate the four corner points of each license plate. For this purpose, this paper employs a lightweight deep CNN structure used for human pose estimation [14] and modifies it for predicting the four corner points of license plates.

Stage 2: Perspective correction. Perspective deformation images are corrected by applying perspective transformation. First, four corner points are predicted by the license plate detection network. Then, the homography between the camera and the license plate is recovered. Finally, the homography is used to warp the detected license plate into a rectified image as shown in Fig. 1.

Stage 3: Character recognition. For reading license plate characters, this paper considers character recognition as character detection problem and designs a lightweight character detection network that predicts all license plate characters on the detected license plates. The character detection network can predict license plate characters without depending on license plate layouts.

IV. Implementation Details

Fig. 2 illustrates the detailed pipeline of the proposed model. Input images are fed into a fast and efficient license plate detection network for predicting the four corner points of license plate (i.e., top-left, bottom-left, top-right, and bottom-right corners). Based on the detected corner points, perspective transformation is performed to align the detected license plate. Finally, a lightweight deep CNN network is employed to predict license plate characters. The following subsections illustrates the details of each stage.

A. License Plate Detection

This paper uses CenterNet [14] for extracting license plate regions and the corresponding corner points from input images. CenterNet considers the center point of a bounding box as an instance and uses this keypoint to predict the dimensions and offsets of the box. CenterNet strikes a desirable balance between precision and speed and is highly customizable and extensible. It can be easily extended to multiple computer vision tasks including 3D object detection, object tracking, human pose estimation, and many others. In this paper, CenterNet is used to predict the four corner points of license plates (i.e., top-left, bottom-left, top-right and bottom-right corners). Based on the predicted corner points, perspective correction is performed to get rectified license plate images. For this purpose, this paper employs the CenterNet structure used for human pose estimation [14] and modifies it for corner point estimation. The detailed pipeline of the license detection model based on CenterNet is shown in Fig. 3. Consider an input image $I \in \mathbb{R}^{H\times W\times 3}$, where W and H represent the width and height of the input image, respectively, a fully convolutional encoder-decoder architecture is first used to produce feature representations from input images and generate output results. Three heads are produced after one forward pass from the feature extraction network as shown in Fig. 3 (i.e., keypoint heatmap head, corner location head, and corner offset head). All the heads are predicted with the same dimensions (i.e., height and width) $(H/s, W/s)$, where s represents the output stride ($s = 4$ in this paper).

1) Feature extractor. This paper adopts RestNet-50 [15] for feature extraction. ResNet blocks are then augmented with three up-convolutional layers to incorporate higher resolution output feature maps. In addition, a 3×3 deformable convolutional layer is used before each up-sampling layer.

2) Keypoint heatmap head. Keypoint heatmap head is used for predicting the center point of license plates. In this paper, the keypoint heatmap $\hat{K} \in \mathbb{R}^{\frac{H}{S}\times\frac{W}{S}\times 1}$ has one channel since only one class is predicted by the license plate detection network. After one forward pass, a Sigmoid layer is utilized on the keypoint heatmap, and the calculated value at each keypoint is viewed as the certainty score for it being the center of the license plate.

3) Corner locations head. Corner location head predicts the four corner locations of license plate (i.e., top-left, bottom-left, top-right, and bottom-right corners). Each corner is considered as a 2-dimensional property of the center keypoint and parameterized by an offset to the center keypoint. The dimensions of this head are $(\frac{H}{S}\times\frac{W}{S}\times 8)$.

4) Corner offset head. The Corner offset head is employed to rectify the quantization error resulting from the down-sampling of the input. After one forward pass, the coordinates of predicted center keypoints are mapped to a higher resolution input image. This results in a deviation in values because the original image coordinates are whole numbers, whereas the actual center points ought to be decimal numbers. As a result, the local offsets $\hat{O} \in \mathbb{R}^{\frac{H}{S}\times\frac{W}{S}\times 2}$ are predicted for each center point to recover the discretization error.

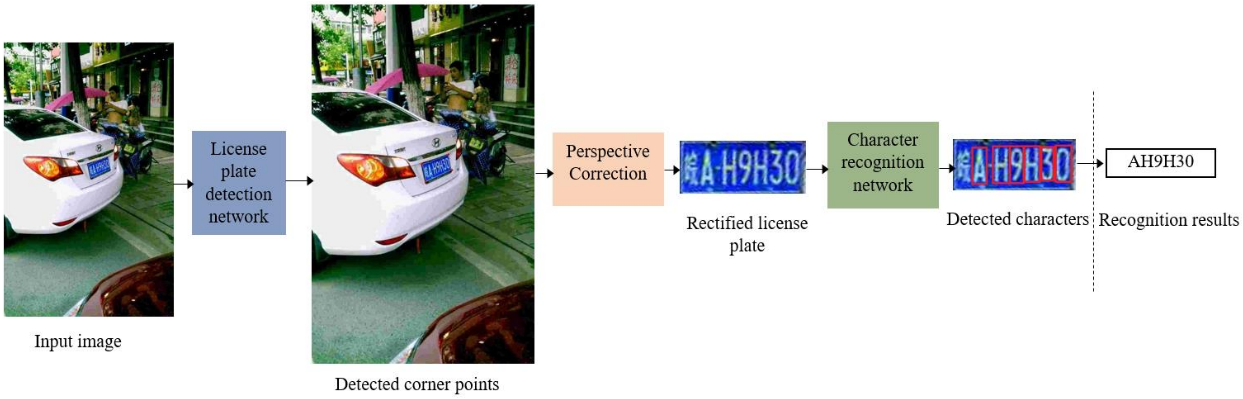

Fig. 2. The detailed structure of the proposed method.

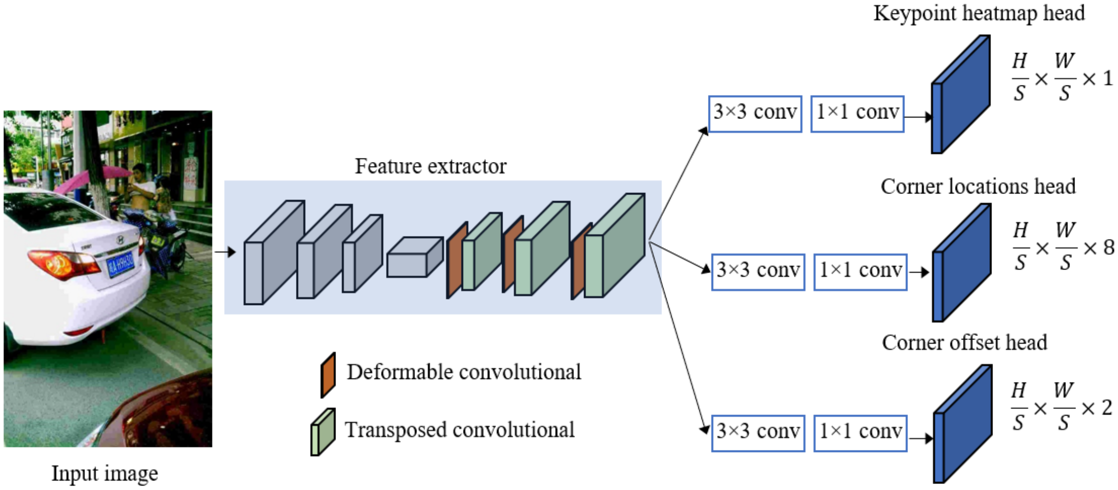

Fig. 3. The architecture of the license plate detection network.

B. Perspective Correction

As license plates can sometimes be difficult to read due to the viewpoint, perspective correction is performed to align the detected license plates. Based on the four corner points generated by the license plate detection network, the homography between the camera and the license plate is first recovered. Then, the homography is used to warp the detected license plate into a rectified image as shown in Fig. 1. To be more specific, based on the detected corner points from input image, this paper first identifies x_{max} and y_{max}, which represent the maximum horizontal and vertical distances between the corner points. Then four corresponding vertices of rectified image are calculated as follow:

$$(tl, tr) = ((0,0), (x_{max} - 1,0)) \quad (1)$$

$$(br, bl) = ((x_{max} - 1, y_{max} - 1), (y_{max} - 1,0)) \quad (2)$$

where tl, tr, br, bl represent the top-left, top-right, bottom-left, and bottom-right corners of the rectified license plate.

Following [16], the perspective transformation matrix H is calculated from the detected corner points and corresponding vertices as follow:

$$\begin{bmatrix} t_i x_i' \\ t_i y_i' \\ t_i \end{bmatrix} = H. \begin{bmatrix} x_i \\ y_i \\ 1 \end{bmatrix} \quad (3)$$

where:

$$dst(i) = (x_i', y_i');\ src(i) = (x_i, y_i), i = 0, 1, 2, 3 \quad (4)$$

and

$$H = \begin{bmatrix} H_{11} & H_{12} & H_{13} \\ H_{21} & H_{22} & H_{23} \\ H_{31} & H_{32} & H_{33} \end{bmatrix} \quad (5)$$

Finally, the rectified license plate region is formed as follow:

$$dst(x, y) = src\left(\frac{H_{11}x + H_{12}y + H_{13}}{H_{31}x + H_{32}y + H_{33}}, \frac{H_{21}x + H_{22}y + H_{23}}{H_{31}x + H_{32}y + H_{33}}\right) \quad (6)$$

C. Character Recognition

Character recognition aims to identify each character on the rectified license plates. For this purpose, this paper considers character recognition as character detection problem and designs a lightweight character detection network that predicts each license plate character without depending on license plate layouts (i.e., license plates of single-line or double-line text). Specifically, the lightweight character detection network is trained to detect 35 classes (i.e., ‘A-Z’, ’0-9’, the digit ‘0’ is recognized jointly with the letter ‘O’) based on the rectified license plates as well as the bounding box and class of each character as inputs. In the case of Chinese license plates, the initial symbol is a Chinese character that signifies the province. As stated in [17] and [7], the character detection network proposed in this work has not been trained to identify Chinese characters because assigning the category to such characters is not a straightforward task.

Table I showcases the design of the suggested lightweight character detection network. The design of the network is influenced by the Fast-YOLOv4 model [18], which is a tiny deep neural architecture that obtains very fast detection speed without sacrificing much accuracy. As shown in Table I, 3×3 convolution layers are used to extract features from previous layers followed by 1×1 convolution layers for reducing the feature channels. In addition, max pooling layers are used to decrease the feature dimensions. The number of channels is multiplied by two following each max pooling layer. Following [9], [19], this paper applies detection head at different scales to predict license plate characters. Specifically, character prediction is performed at layer 13 and layer 20, where the output size is 24×8 and 48×16, respectively. This detection approach is crucial for character recognition because the characters on the license plate may take up either a small or large area of the license plate region, as depicted in Fig. 4. It is worth mentioning that the proposed license plate character recognition system accurately detects and identifies license plates with either single-line or double-line text as it predicts all characters on the rectified license plate.

TABLE I. THE STRUCTURE OF THE PROPOSED LIGHTWEIGHT CHARACTER DETECTION NETWORK

Layer	Type	Filter size, stride	Input size	Output size
0	Conv	3×3×32,1	384×128×3	384×128×32
1	Max-pool	2×2, 2	384×128×32	192×64×32

V. Experimental Results

All experiments were carried out on a computer equipped with an Intel Core i7-10700 CPU, a single NVIDIA GeForce GTX 1080Ti GPU, and 64GB of RAM. All models are designed and evaluated under the framework of PyTorch [20] and mmdetection [21].

A. Dataset and Evaluation Metrics

To assess the proposed method, this paper evaluates experiments on two extensive public datasets: CCPD [22] and AOLP [23].

CCPD [22] consists of 290k images captured under diverse illuminations, environments, and weather conditions. This dataset is more challenge than other datasets for license plate recognition since each image is captured from different positions and angles, which makes license plates have arbitrary direction. The dataset provides sufficient annotations for training the proposed model, including bounding boxes, vertices of each license plate, and license plate characters. Images in the dataset have the resolution of 720 (width) × 1160 (height) × 3 (channels). Following [22], this paper employs 100k images of CCPD-Base subset for training both detection and character recognition network. The remaining 100k images from the CCPD-Base subset and the 80k images from the CCPD-DB, CCPD-FN, CCPD-Rotate, CCPD-Tilt, CCPD-Weather, and CCPD-Challenge subsets are utilized for testing. Additionally, the CCPD dataset also includes the CCPD-Characters subset, consisting of over 1000 individual images for every possible license plate character. This paper utilizes the CCPD-Characters subset for further training the license plate recognition network.

AOLP (Application-Oriented License Plate database) [23] contains 2049 images. The images in this dataset are classified into three categories based on the capturing conditions: access control (AC), traffic law enforcement (LE), and road patrol (RP). The AC subset consists of 681 images of license plates captured in scenarios where vehicles move through a fixed passage at a slower pace or come to a complete stop. The LE subset consists of 757 images of license plates captured by a roadside camera during instances of traffic law violations. The RP subset includes 611 images of license plates captured from vehicles with random viewpoints and distances, making it more challenging for license plate recognition due to the heavily distorted license plates. Since the AOLP dataset only provides annotations for the coordinates of license plate bounding boxes and numbers, this paper manually annotates the four corners of each license plate. In line with [11], this paper trains on the LE and RP subsets and uses the RP subset for testing.

For the evaluation metric, this paper calculates the accuracy of license plate recognition by dividing the number of correctly recognized license plates by the total number of license plates in the test set. A recognition is considered correct only if the IoU_{poly} is greater than 0.5 and all characters have been correctly recognized. Here, IoU_{poly} is calculated as follow:

$$IoU_{poly} = \frac{DP \cap GP}{DP \cup GP} \quad (7)$$

where DP is the detected polygon of license plate and GP is the ground truth polygon of the license plate. DP and GP are calculated based on the detected corner points and ground truth corner points, respectively.

B. Results on CCPD

Table II provides recognition results of the proposed approach and recent approaches on the CCPD dataset. The results demonstrate that the proposed approach obtains the best recognition accuracy on most of the subsets. To be more specific, the proposed model obtains recognition accuracy at 99.7%, 99.2%, 99.1%, 99.6%, and 99.6% on CCPD-Base, CCPD- DB, CCPD- FN, CCPD- Rotate, and CCPD- Tilt, respectively, which outperform all previous methods, including method proposed by Zhang et al. [3]. For CCPD- Challenge subset, method proposed by Zhang et al. [3] obtains the best recognition accuracy. Since CCPD-Challenge subset comprises the most difficult images for the recognition of license plates, the simple and efficient license plate detection network cannot locate some license plates (Fig. 6), which leads to wrong recognition results by the character recognition network. In the future, this paper will investigate more effective fusion strategies to enhance the feature representation of the license plate detection network, which would improve detection results. It is noteworthy that the majority of the comparison methods in Table II determine the recognition results by setting the IoU threshold to 0.6. Additionally, it is observable that the proposed method attains the most significant improvements in the CCPD-Rotate and CCPD-Tilt subsets. Specifically, the proposed network improves recognition accuracy by 3.2% and 2% on CCPD-Rotate and CCPD-Tilt subsets compared with that of model proposed by Zhang et al. [3]. Given that the CCPD-Rotate and CCPD-Tilt subsets contain images with significant perspective distortion, these results show that the proposed model excels at detecting and recognizing license plates that have undergone distortion or rotation. For recognition speed, since the proposed model is designed based on fast and efficient architectures, it obtains the fastest recognition speed among comparing methods. To be more specific, the proposed model needs 8.3ms for processing an image based on single NVIDIA GeForce GTX 1080Ti GPU. The results indicate that the proposed model is efficient and well-suited for real-time applications. As depicted in Fig. 5, this study showcases the recognition results of the proposed approach on the CCPD dataset, including the detection of the four corners of the license plates, the rectified license plates after perspective correction, and the recognition of the characters on the license plates. It is evident that the proposed model performs effectively under various conditions. Fig. 6 shows some failure cases where the proposed model cannot locate license plates in challenging environments or fails to recognize some similar license plate characters.

TABLE II. THE RECOGNITION RESULTS OF THE PROPOSED MODEL AND OTHER MODELS AS EVALUATED ON THE CCPD DATASET

Method	Recognition Accuracy (%)							Inference Time (ms)
	Base	DB	FN	Rotate	Tilt	Weather	Challenge	
SSD [24] + HC [25]	98.3	96.6	95.9	88.4	91.5	87.3	83.8	25.6

TABLE III. COMPARISONS OF RECOGNITION ACCURACY ON THE AOLP DATASET

Method	Recognition Accuracy (%)
Li et al. [29]	88.4
TE2E [17]	83.6
Zhang et al. [3]	91.9
Sergio et al. [6]	98.4
Zou et al. [13]	93.4
Proposed method	**98.8**

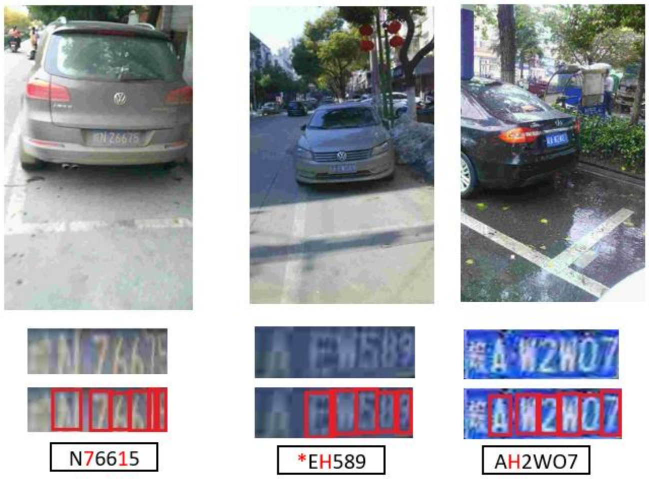

Fig. 6. Some examples of failure cases.

C. Results on AOLP

For the AOLP dataset, AOLP-RP subset is employed to evaluate the proposed model since this subset is more challenging (most of images contain severe perspective deformation license plates). Table III presents the comparison of recognition accuracy on the AOLP dataset. The proposed model emerges as the top performer in terms of recognition accuracy on the AOLP dataset, outperforming other methods. Specifically, the recognition accuracy of the proposed model surpasses that of the method proposed by Sergio et al [6] by 0.4%. This result further strengthens the claim of the proposed model's capability in recognizing license plates that have an irregular shape.

VI. CONCLUSION

This study presents a CNN-based approach for detecting and recognizing license plates with irregular shapes in complex real-world images. The proposed model employs a CenterNet-based CNN structure to predict the four corners of the license plates, followed by perspective correction to align the detected license plates. For character recognition, a YOLO-based segmentation-free model is designed to predict the characters on the license plate. The effectiveness of the proposed method is verified through experiments on the CCPD and AOLP datasets. Specifically, experimental results on two datasets show that the proposed method obtains the best recognition accuracy with the fastest recognition speed. This result demonstrates that the proposed method is highly suitable for intelligent traffic management applications that require real-time processing. In the future, the study intends to investigate additional fusion techniques for extracting more discriminative features from the input images, which can enhance the accuracy of the license plate detection network.

***Abstract*—With the growth of Industrial Internet, various types of data show explosive growth. Data is being moved from the cloud to the edge for computing more frequently and edge computing becomes an important factor affecting the deep application of Industrial Internet platforms. However, the security issue of data transmission sharing is not addressed. Therefore, this paper proposes a security scheme based on timed-release, multi-dimensional virtual permutation, and proxy re-encryption(PRE), to protect the confidentiality of the data during the transmitter; symmetric cryptography is employed to encrypt the transmission data. At the same time, a time server is used, making it impossible for data receivers to get the information about the data before the specified time arrives, it solves the application scenario of data transmission and sharing with timed-release requirements and the efficiency of a large number of data is solved, and the security of data is improved. Finally, the security of the scheme was proved theoretically. Compared to existing PRE schemes, this scheme adds timed-release controlled access, has resistance to ciphertext attacks and end-to-end security features, and uses fewer bilinear pair operations in the algorithm. The performance was tested experimentally and the results show that the scheme improves efficiency while ensuring security and has significant advantages in terms of data security and private data protection.**

Keywords*—*Timed-release; edge-computing; multi-dimensional virtual permutation; proxy re-encryption; symmetric encryption

I. Introduction

Information technologies like big data, cloud computing, and artificial intelligence have developed so quickly in recent years, new ways of manufacturing and structuring are driving the intellectual conversion of the global industrial system [1]. Thus, with the benefits of both the industrial and internet revolutions combined, the industrial internet arose. As a result of big data and artificial intelligence, nowadays, if there is a lack of effective data, massive industrial data will be buried, and the Industrial Internet will lose its value of existence[2], [3]. At the same time, with the accelerating pace of the construction of Industrial Internet platforms, users' demand for security is more urgent. It has gradually evolved from the security of simple industrial equipment use to the security of data stored in the equipment and data transmitted in the network, from tangible security to intangible security[4], [5]. In contrast to the established cloud computing model, edge computing model makes up for the disadvantage of cloud computing away from terminal devices, it is a fundamental technology in the Industrial Internet and helps the Industrial Internet evolve[6]. Edge computing needs to provide the new capabilities of "device openness and data sharing" needed in industrial transformation and upgrading, and reliability-wise, edge computing can satisfy the industrial Internet's development requirements[7], [8]. Data may pass via numerous message-forwarding nodes in the edge computing environment before it reaches the collaborating nodes instead of being delivered directly from one device to another[9]. The data is conveyed by a third party, and if the communicated data is maliciously altered, it will have a significant impact on data security issues. Therefore, in such a scenario, it is crucial to guarantee the security of data transmission between users.

Proxy re-encryption technology is an encryption cryptosystem with ciphertext conversion function, which does not need data decryption in this process, so it can be used to achieve data transmission security[10]. PRE technology ensures the secure access and sharing of data without revealing any relevant information about the plaintext[11], [12]. However, in some application scenarios with timed-release requirements, this technology is not perfect, and the ciphertext generated by PRE needs to have the characteristics of timed-release[13]. Time-dependent encryption includes methods such as timed-release encryption, which can be used in time-sensitive scenarios[14]. Even the selected receiver is unable to decrypt the ciphertext prior to the semi-trusted time server opening the trapdoor linked to the publisher's chosen release time[15], which can be used as a cryptographic primitive to specify the future decryption time, and there are many scenarios in real life where the decryption time needs to be specified in advance[16], [17]. Therefore, PRE technology and timed-release encryption work better together to improve the confidentiality and flexibility of the scheme.

PRE was first proposed by Blace[18], it enables a partially trusted proxy to convert the publisher's ciphertext into the receiver's ciphertext, and increases the flexibility of data sharing. Since it was proposed, numerous PRE techniques have been put forth. Peng et al. [19]presented an identity-based conditional broadcast PRE system that enables users to communicate encrypted data with other users using the fine-grained approach, allows users to generate broadcast ciphertexts for numerous recipients, and share their encrypted data to multiple recipients in batches. Kaitai et al.[20] proposed a conditional proxy broadcast re-encryption method with timed-release, which allows the delegator to delegate the decryption right to multiple delegates in a fine-grained manner without losing security, and the delegator has the ability to schedule the delegation of the decryption right of the broadcast encryption to a certain group of receivers in addition to delegating it. Massive privacy-sensitive data transmitted to edge nodes may attract attacks from network attackers, so data leakage and attacks are a great loss and danger for the Industrial Internet.

To address the aforementioned issues, this work proposes the timed-release based PRE scheme for edge computing. Since the efficiency of public key cryptography is not as high as the symmetric encryption algorithm, it is not suitable for the encryption of large data files. Therefore, a multi-user data-sharing scheme is designed by combining symmetric cryptography, time-release encryption and PRE techniques, and depends on a multi-dimensional virtual substitution mechanism. It effectively protects this publisher's privacy information, prevents malicious tampering and theft, meets the requirements of timeliness and multi-user sharing data, ensures the security of data transmission, reduces the time cost, and improves the operation efficiency.

The rest of the paper is organised as follows. In Section II, we describe the constructed scheme model. In Section III, we describe the design steps of the scheme in detail. In Section IV, we perform security analysis and performance evaluation of the scheme. Section V is discussion. Section VI concludes the paper.

II. Model Design

The traditional PRE scheme uses an asymmetric cryptosystem, which requires a large amount of computation, large consumption and waste of resources for large data files. And in some application scenarios, it is necessary to meet the requirements of time. Thus, a PRE scheme based on timed-release for edge computing is created to ensure the security of data information and address the issue of timeliness. According to the actual application of data information sharing, a multi-user data sharing model is established as shown in Fig. 1.

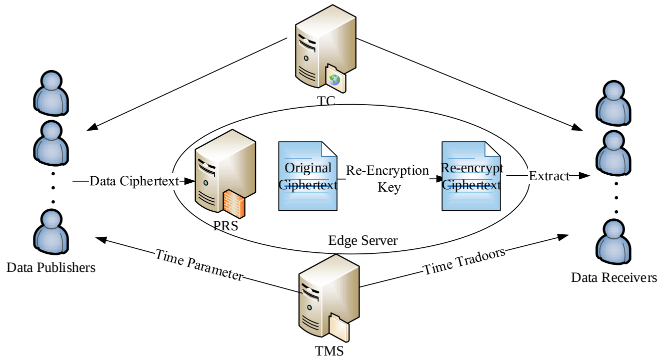

Fig. 1. Multi-user data sharing model.

Both data publishers and data receivers can access data in the network and interact with the proxy re-encryption server (PRS), trusted center (TC) and time server (TS) to create and access data. The third trusted time server generates time parameters according to the requirements, which is used to encrypt the plaintext. The generated time trapdoor algorithm can be used to confirm that the information has not been tampered with. The data publishers upload the data cipher text to the proxy server and then encrypt the original cipher text into the re-encrypted ciphertext by the re-encryption key, from which the data receivers can extract the re-encrypted cipher text without dumping and storing the data that has already been used.

III. Scheme Design

The symbols used in the scheme of this paper and their corresponding meanings are shown in Table I.

TABLE I. Symbols and Meanings in the Text

Symbol	Mention
sk_{ts}/pk_{ts}	Time server's private and public key
sk_i/pk_i	Data publisher $i's$ private/public key
sk_j/pk_j	The private/public key by data receiver j
T_G	Timed-release key
Sk_i'	Initial key array for data publisher i
$Sk_i[n]$	Key control array for data publisher i
$IVF(i)$	Virtual permutation function missing i-th argument
$MVPF$	The complete virtual permutation function
$MITE^{(m)}$	A virtual iteration function that iterates m times
C_T	Original ciphertext
C_S	Session key ciphertext
C_P	Re-encryption of ciphertext
$RK_{i\to j}$	Proxy re-encryption key for users i to j

Multi-user data sharing through timed-release proxy re-encryption algorithm can solve the time limitation problem in data sharing compared to traditional PRE schemes. This topic uses edge server as a tool to realize data sharing, the time server is introduced to create the release time parameters, and the multi-dimensional virtual replacement mechanism is combined in the symmetric key generation stage, which can improve confidentiality and efficiency. According to the multi-user data sharing model, the scheme can be realized as described below.

A. System Initialization

Choose a prime q , a finite cyclic group G and G_T of order q , a bilinear mapping $e: G \times G_T \to G_T$, where g is the generating element of G . Then define the hash functions $H_0: \{0,1\}^* \to G$, $H_1: \{0,1\} \to G$, $H_2: G_T \to \{0,1\}^L$, and randomly select an element γ from Z_q^* as the private key for the time server $sk_{ts} = \gamma$, then the public key for the time server $pk_{ts} = g^{\gamma}$ can be calculated.

B. Key Generation

Randomly select the elements x_i and x_j from Z_q^* as the private keys of data publishing user i and data receiving user j respectively, and make $sk_i = x_i$ and$sk_j = x_j$, then the public keys corresponding to data publishing user and data receiving user are $pk_i = g^{x_i}$ and $pk_j = g^{x_j}$ respectively.

C. Generate Time Trapdoor

Firstly, the time parameter $T \in \{0,1\}^*$ can be generated by the time server to display the publishing time. Then through the calculation of the private key sk_{ts} by the time server and the time parameter T, this time trapdoor can be obtained, corresponding to the timing release key T_G, as shown in the formula.

$$T_G = H_0(T)^{\gamma} \tag{1}$$

D. Session Key Generation

This phase first requires constructing a multi-dimensional key space, then displacing the security subsystem, constructing a multi-dimensional virtual substitution function, and iterating over the security subsystem it displaces in a certain order to finally obtain a session key that conforms to the security rules. This process uses a lightweight cryptographic algorithm based on stream ciphers, and the specific steps are described as shown below.

1) Constructing a multi-dimensional key space: The private key $\mathrm{Sk_i}$ of data publishing user i and its private key array $\mathrm{Sk_i'}$ can be hashed and mapped to generate a key control array $\mathrm{Sk_i[n]}$ by the following formula. Then it is sent to other data publishing users, each data publishing user can get an incomplete virtual iterative function IVF(i) that lacks its own private key, where the user's private key array $\mathrm{Sk_i'} = [\mathrm{k_{i1}}, \mathrm{k_{i2}}, \dots, \mathrm{k_{in}}]$, because it has no actual ability of control function, so it does not pass to other users.

$$Sk_i[n] = \{SK_i \oplus \textstyle\sum_{a=1}^{n} H(Sk_i'[a])\} \tag{2}$$

Data publishing user i substitutes the key control array $Sk_i[n]$ into the incomplete virtual iterative function to obtain a multi-dimensional virtual iterative function $MVPF$ with complete key parameters, mapped into an n-dimensional spatial network with equal probability of security subsystems mapped into the n-dimensional space to establish an n-dimensional key space, where each small space maps a security subsystem as shown in the formula.

$$S = MVPF(Sk_1[n], Sk_2[n], \cdots, Sk_i[n], \cdots, Sk_n[n]) \tag{3}$$

2) Symmetric key generation: If each data publishing user randomly selects m key elements in the key control array, then the m secure subsystems can be noted as $\tau_1, \tau_2, \cdots, \tau_m$, respectively, and a secure symmetric key K can be obtained by iterative operations in a certain order according to the formula.

$$K = \tau_m(MITE^{(m-1)}) \tag{4}$$

E. Transformation Key Generation

The private key sk_i by data publishing user i, the public key pk_j by data receiving user j, through hash mapping, can get RK_1. Then the time server generates the publishing time parameter T and the public key pk_{ts} through the calculation of the following formula, RK_2 can be obtained, and finally the conversion key is obtained by the calculation of the formula, which can also be called this re-encryption key $RK_{i\to j}$, and put online via the proxy server.

$$RK_1 = sk_i \cdot (H_2(g^{\beta}, pk_j)^{\rho})$$

$$RK_2 = \varphi \oplus e(H_0(T), pk_{ts}) \tag{5}$$

$$RK_{i\to j} = (RK_1, RK_2)$$

F. Proxy Re-encryption

1) The original ciphertext generation: The data publishing user has the ability to safely encrypt the data plaintext M using the publicly available symmetric encryption algorithm based on the symmetric key generated in the previous session key phase, which can obtain the desired data ciphertext C_1. Then a random number $\beta \in Z_q^*$ and $\varphi \in G_T$ is chosen and the hash function $H_3: \{0,1\}^* \to Z_q^*$ is defined such that $\rho = H_3(M, \beta)$, and the ciphertext C_2 can be obtained after the calculation by the formula, and the ciphertext C_3 can be obtained through the time server's public key pk_{ts} and the published time parameter T. Finally, these obtained ciphertexts can be calculated by the following formula to get the required original ciphertext C_T and uploaded to the proxy server at the same time.

$$C_1 = SymEnc_K(M)$$

$$C_2 = (M||\beta) \oplus g^{H_2(g^{\beta}, \varphi)}$$

$$C_3 = \varphi \oplus e(H_0(T), pk_{ts})^{\rho} \tag{6}$$

$$C_T = H_1(C_1||C_2||C_3)$$

2) Session key ciphertext: This stage uses the encryption of the session key and then generates the key cipher, which can be used in the subsequent stage of using the proxy server for this PRE algorithm to generate this re-encrypted cipher, where the session key and the public key of the data publishing user are calculated by the following formula to obtain the ciphertext C_S of this session key and upload to the proxy server.

$$C_S = {pk_i}^{\beta} \cdot K \tag{7}$$

3) Data sharing: The PRE ciphertext C_P is obtainable by using that session key ciphertext C_S and the transformation key $RK_{i\to j}$, along with the time server's publication time parameter T. A proxy server that has some level of confidence performs this process, which does not disclose any message about the ciphertext, so the security of this scheme can be guaranteed.

$$C_P = C_S||e(H_1(T), RK_{i\to j})^{\beta} \tag{8}$$

The data recipient can get the plaintext M computing the decryption of that PRE ciphertext. Firstly, the PRE ciphertext C_P and the data receiver's private key sk_j are decrypted to obtain the session key K. Then the original ciphertext C_T is decrypted using the session key K to obtain the plaintext, as shown in the following formula.

$$K = Dec_{sk_j}(C_P)$$

$$M = Dec_K(C_T) \tag{9}$$

IV. Security Analysis and Performance Evaluation

A. Security Analysis

This scheme combines the multi-dimensional virtual permutation mechanism and timed-release encryption and uses the PRE algorithm to implement the transfer of data information, so as to solve the protection of data in the industrial Internet. The common attacks that can be dealt with and the specific analysis are as follows.

1) Confidentiality: In this program, data plaintext is converted into data ciphertext using symmetric encryption algorithm, which is stored in the proxy server, as well as using the public key to encrypt the symmetric key to generate key ciphertext. Because data information and session keys are transmitted in ciphertext throughout the communication process, a network attacker cannot decrypt its data information and restore the ciphertext to plaintext. To decrypt the ciphertext and acquire the plaintext data, only the data publisher and the data receiver are capable. If the proxy server tries to decrypt the data information, then it must get $RK_{i\to j}$ and pk_j, but the proxy server only has pk_j, as a result, it is unable to access information about the original data. This system thus achieves the security of private and sensitive data on the Industrial Internet by guaranteeing the secrecy of the data.

2) Replay attack protection: In this scheme, only within the set time validity period, the user who is receiving the data can get the plaintext data by decrypting the ciphertext that has been re-encrypted. The data-receiving user can get the corresponding reverse key only after getting the ciphertext that was re-encrypted and decrypting it, and because there is a certain time limit for the reverse key at this time, this reverse key can be saved only until this time arrives. However, when a network attacker performs a replay attack, the same reverse key can be obtained by decrypting the data message, but then it discards the message and does not deliver the data, and also cannot obtain the server's authentication, which can be used to ensure that the time trapdoor is always time-limited. Therefore, this scheme can resist the replay attack.

3) End to end: End-to-end security truly entails that the server won't be aware of the communication information shared by cooperating nodes, and the proxy server relies on the edge server, which $RK_{i\to j}$ has decided the conversion rule of decryption, so the server cannot convert the cipher text into other decryption combinations. Secondly, since the data information and session keys are always transmitted in cipher text during the communication, even the proxy server cannot decrypt them and get the data information. By decrypting the ciphertext that has been re-encrypted, only the users who publish data and those who receive it can access the plaintext data, so even if this server is attacked, this data information sent between users will not be disclosed. Therefore, the scheme satisfies end-to-end security.

4) Protection against collusion attack: In this scheme, the private key is secure against collusion attacks. The data receiver and the proxy cannot conspire to gain the private key of the data publisher, assuming that the proxy sends the re-encryption key to the data receiver for malicious collusion. Since $sk_i \cdot (H_2(g^{\beta}, pk_j)^{\rho})$ in β is random. Using the re-encryption key as a base, the data receiver cannot determine the data publisher's private key information. At the same time, the agent cannot conspire with the data publisher to get the recipient's private key, if the publisher of the data and the agent join together, because the re-encryption key $RK_{i\to j} = (RK_1, RK_2)$ does not have any private key information of the data recipient, and cannot get its private key through calculation, so the combination of the two cannot acquire the data receiver's private key. This proves that even if this proxy server and the data receiver or data publisher maliciously collude, they cannot get each other's private keys to decrypt the ciphertext without access rights, so this scheme resists the collusion attack.

5) Select ciphertext security: In arbitrary probabilistic polynomial time, the benefit of addressing the hypothetical issue of DBDH is negligible, so the scheme proposed in this study is to choose ciphertext attack security. Assuming the existence of attacker A and challenger C.

Firstly, A sends queries to C about system initialization, time trapdoor generation, key generation, session key generation, original ciphertext generation, session key ciphertext generation, transformation key generation and proxy re-encryption ciphertext generation, and then C returns the query results to A. C creates the corresponding public and private keys through this system initialization and key generation algorithm, as well as the time server's private key, and performs this re-encryption key algorithm on them to get the re-encryption key, then transmit it to A. A chooses two equal-length plaintexts M_0 and M_1 and sends them to C to challenge it. When A asks C for the original ciphertext generation algorithm, where the session key is kept secret. C randomly picks bits $d \in \{0,1\}$, computes the ciphertext $C^* = Encryption(T_G^*, pk_{ts}^*, K^*, M_d, T^*)$. A then returns a guess $d_1 \in \{0,1\}$ to C. At this point, if $d_1 = d$, the challenge is successful. Assuming that the probability superiority of A overcoming the challenge is ε and $\varepsilon = |\Pr[d_1 = d] - 1/2|$ is negligible. the probability that A guessing correctly in probabilistic polynomial time is negligible, then A fails the challenge, so it can be shown that the scheme of this paper is to choose ciphertext security.

B. Performance Evaluation

The scheme of this paper was analyzed in comparison with some relevant studies in recent years, and the following data were used to compare the time consumption with the literature, as shown in Table II.

Through the existing relevant references, the theoretical computational overheads of the schemes are compared with those of this paper, and the theoretical execution time comparison results of each scheme are shown in Table III. The time required for bilinear is much larger than that of other operations. Because the bilinear pairing used in reference [19] and [20] are more than those used in this scheme, the time used in these two schemes will be more. According to the comparison results of the theoretical time overhead in Table II, we can get that the scheme in this chapter is smaller than reference [19] and [20] in terms of computational overhead, so our proposed scheme has higher efficiency and also higher security, which shows that this scheme has significant advantages in security and efficiency.

TABLE II. THE EXECUTION TIME OF EACH OPERATION

Parameter	Description	Value(ms)
T_p	Bilinear pairing operation time	4.211
T_m	Point multiplication operation time	0.015
T_e	Exponentiation operation time	3.886
T_h	Hash operation time	0.0001
$T_{E/D}$	Symmetric encryption/decryption operation time	0.0046

TABLE III. COMPARISON OF TIME COMPLEXITY OF EACH SCHEME

Reference	Data Processing	Proxy Re-encryption	Sum
Peng [19]	$(n+2)T_e + 2T_p + 5T_m + (n+1)T_h$	$3T_m + 2T_p + 3nT_h + (n+4)T_e$	$(2n+6)T_e + 4T_p + 8T_m + (4n+1)T_h$
Kaitai[20]	$2nT_e + T_p + (2n+5)T_h$	$(n+1)T_e + 8T_p$	$(3n+1)T_e + (2n+5)T_h + 9T_p$
Zheng[21]	$(n+3)T_p + 2nT_e$	$nT_m + nT_p$	$(2n+3)T_p + nT_m + 2nT_e$
Proposed	$(n+2)T_h + T_p$	$nT_e + T_p + 2T_{E/D} + (n+1)T_h$	$2T_{E/D} + 2T_p + nT_e + (2n+3)T_h$

In order to confirm the effectiveness of the plan put forth in this paper, an experimental environment is built for the experimental testing of the algorithm. Experimenting with Charm-Crypto 0.5, PBC 0.5.14 library in Python 3.9 under a Linux system with an Intel(R) Core(TM) i7-10700F CPU @ 2.90GHz and 16GB RAM. Simulation of the time spent comparing the literature with the solution proposed in this paper, and the simulation's outcomes are displayed in Fig. 2. After simulating the time required to implement each scheme. The results of the experiments reveal that the system suggested in this study has a much lower overall computing overhead than the research [19], [20] and [21] schemes.

For study [19], although the dot product operation is added compared to reference [20], it does not have much impact on the time overhead as it is negligible; it also reduces the bilinear pairing operation, which reduces the time overhead and improves the efficiency to some extent.

For study [20], although it uses more hashing operations compared to [21], it does not have as much time overhead as [21] because the execution time of the hashing operation is negligible. However, compared to the scheme in this paper, it still requires more time cost.

For research [21], it uses bilinear pairing operations, which require a lot of time to compute each bilinear pairing, and uses a lot of dot product operations and power operations. Although it uses less time consumption at the beginning, the time overhead increases as the number of users increases. Therefore, the most computationally expensive of these schemes.

Compared with the schemes proposed in the studies [19], [20] and [21], the time consumption of this scheme is the least. Although this paper uses one more symmetric encryption/decryption operation, it does not increase the time overhead because its execution time magnitude is much smaller than the other operations and negligible, and uses a small number of bilinear pairing operations and power operations, in a specific test of execution time overhead the lowest. This scheme uses lightweight operations, which reduces the overall time spent. Because this solution uses fewer bilinear operations, which are precisely the functions with the highest computational overhead, reducing the number of calls to bilinear operations in the algorithm has a clear advantage in terms of efficiency. The lightweight proxy re-encryption algorithm used in this scheme ensures secure data transfer and improves efficiency.

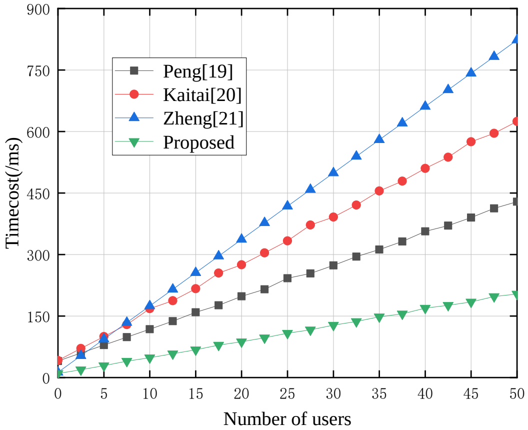

Fig. 2. Comparison of schemes' time cost.

V. DISCUSSION

The scheme in this paper introduces a third-party fully trusted time server to encrypt the plaintext by inserting a time attribute, which can only be decrypted by an authorised recipient within a set timeliness range to obtain the plaintext. Compared to existing PRE schemes, this scheme is more flexible, provides end-to-end data security and reduces the trust requirement for proxies. The security analysis shows that this scheme is resistant to ciphertext attacks and thus has higher security. The computational overhead comparison and simulation experiments show that this scheme can save a lot of transmission time and has better computational overhead performance and is more efficient.

VI. CONCLUSION

This paper analyzes the security needs for data transmission and sharing in an environment using edge computing. For the current PRE study is difficult to meet the efficiency and security for the transmission of many data files, and the requirements of time constraints, this paper proposes a PRE scheme based on timed-release, which offers efficient, flexible and secure data sharing services. The secure sharing of data information is completed by symmetric cryptographic encryption and proxy re-encryption, and time servers are introduced to solve the problem of timeliness and protect privacy and security. On the premise of ensuring data security and confidentiality, reducing time consumption overhead and improving the efficiency of communication, this scheme is appropriate for data sharing from larger files, which can be completed in a short time, and has great advantages and practical value.

***Abstract*—Defects in software are one of the critical problems in software engineering community because they provide inaccurate results and negatively affect the quality and reliability of the software. These defects must be detected in the early stages of software development. Researchers had used Software Defect Detection (SDD) techniques to allow predicting module fault-proneness. By implementing the hyperparameter optimization techniques and exploiting data imbalances in predicting defects, this paper proposes and develops an SDD model with high performance and generalization capability. To classify defects in software modules, machine learning algorithms and ensemble learning techniques are used on the balanced datasets. The balanced datasets are obtained through using a hybrid of synthetic minority oversample (SMOTE) and Support Vector Machine (SVM). To obtain the optimal hyperparameters needed for the used classifiers and for the dataset balanced algorithms, Non-dominated Sorting Genetic Algorithm II (NDSGA-II) is used. To reduce the time and save other used resources, Hyperband technique, which is a multi-fidelity optimization, is used in NDSGA-II. A 10-fold Cross Validation (CV) is applied to overcome the overfitting and underfitting problems. The accuracy, recall, F-measure, and ROC AUC metrics are used to evaluate the SDD model. The results show that the proposed model predicts defects more accurately than the compared studies.**

Keywords—Software defect detection; NDSGA-II; hyperband; imbalance dataset

I. Introduction

One of the critical topics in the software engineering community is the development of high software quality and reliability while making effective use of limited resources. The Software Development Lifecycle (SDLC) is a structured method developed to ensure the production of stable, high-quality software. To ensure a timely and effective software system, it is essential to follow the SDLC's stages, which include requirement collecting, requirement analysis, system design, system development, and maintenance. A software fault may be a human error or a system-related error, failure, or crash. Defects have a significant effect on software quality and even the economics of software. So, fixing defects is an important part of software maintenance, but it also wastes time and resources. Detecting software faults before software deployment is crucial, as the correct detection of faulty software modules or components allows good use of resources and time [1] [2].

"Defect detection technology" is the ability to find bugs in every code change that developers send. SDD used ML approaches to software defect datasets characterized by software metrics (as features) to identify software module or component problems. Researchers had developed and implemented ML approaches for SDD.

One of the most important steps in creating a reliable ML model is tuning the model's hyperparameters. It's important to note that the tuning process differs for categorical, discrete, and continuous hyper-parameters. Manual testing is a common method for altering hyper-parameters, but it requires a comprehensive understanding of ML algorithms and their hyper-parameter settings. Due to the high number of hyper-parameters, the complexity of the models, the length of time required to evaluate the models, and the non-linear interactions between the hyper-parameters, manual tuning is often ineffective [3]. These considerations have motivated more studies in Hyper-parameter Optimization (HPO) approaches especially when working with huge datasets or when using complex ML algorithms with a large number of hyper-parameters. The main goal of HPO is to automate this process to improve the performance of the ML model, find the best ML model for a specific problem, and reduce the amount of human effort needed. To find ideal hyper-parameters, it is critical to use the optimal optimization technique. Because many HPO issues are often non-convex or non-differentiable optimization issues, traditional optimization techniques may be inadequate for them, resulting in a local rather than a global optimum [4]. A Non-Dominated Sorted Genetic Algorithm (NDSGA-II) is used in this paper for hyperparameter search hybrid with hyperband speed configuration.

SDD models were developed using Machine Learning (ML) classifiers. Nevertheless, SDD datasets contain more nondetectable than detectable occurrences; this is known as the "class imbalance problem." In addition, multiple studies on defect detection models revealed that minority classes contain more instances of faults than do majority classes that are defect-free. Hence, applying ML algorithms to such unbalanced data yields biased outcomes for minority-class occurrences. To successfully manage an imbalance in datasets, oversampling techniques are utilized [5].

This paper implements the SMOTE-SVM algorithm to balance the imbalanced data with tuned parameters based on the NDSGA-II hybrid with the Hyperband algorithm. Decision Tree (DT), Random Forest (RF), and ensemble learning with Adaboost (AB) and Bagging (BG) classifiers are the ML classifiers used in this work. The proposed model is evaluated on nine defect detection NASA datasets. This work is structured as follows: The second and third sections provide

"Background" and "literature review," respectively. The methodology and requirements for the experiment are discussed in Section IV. Experiments and their results are presented in Section V. The final section of the paper discusses the conclusion and what comes next.

II. Background

Several facets of SDD are discussed in this section. We describe optimization strategies for hyperparameter tuning and data-imbalance-resolving algorithms.

A. *Class Imbalanced Problem*

Problems with class imbalance arise in datasets where the values for different classes are distributed unevenly. Imagine a dataset in which 95% of the class values are from one class and only 5% are from another; this dataset is unbalanced. Minority classes and values are rarely reported, compared to hundreds, thousands, or even millions of majority examples. When ML classifiers are applied to such datasets, models lose detection capacity and provide off-target results. Biased outcomes are produced when a predictive model is used for classification on an uneven dataset. ML procedures function best with an evenly distributed dataset. In this way, ML models fail to accurately predict class values in unbalanced datasets. For minority class norms, this phenomenon is especially prevalent. Effectively addressing class imbalance issues is critical because minority class values are regarded as more significant than majority class values [6].

By simulating or synthesizing instances from underrepresented groups, defect detection experts have found that sampling strategies can produce more representative datasets. This research reconstructed instances of under-represented groups by using oversampling techniques. As a result, the oversampling techniques significantly improved the ML classifiers' detection performance.

1) SMOTE-SVM: SMOTE is a popular oversampling technique for achieving more equitable class distribution by simulating the emergence of new instances of the minority class along roads connecting existing instances of the minority class to their nearest neighbors. To aid in the establishment of class boundaries, SVM-SMOTE generates new instances of the minority class along boundary lines. The synthetic sampling technique with data generation (Synthetic Minority Oversampling Technique, SMOTE) [7] is one of the efficient special algorithms for re-establishing class parity after oversampling by increasing the number of objects in the minority class. Using k-nearest Neighbor (KNN) approach, SMOTE algorithm generates minority-class synthetic items from similarities in the feature space between existent objects. With this method, we can manufacture an arbitrary number of artificial objects that are "similar" to those in the minority class but are otherwise unique [8].

2) Support Vector Machine (SVM): It is a supervised learning algorithm that works by mapping low-dimensional data points into a high-dimensional feature space to make them linearly separable and then using an optimal separating hyperplane as the classification boundary to partition the data by increasing the difference between the two classes. With the assumption of n data points, SVM's objective function is [4][9][10]:

$$arg\,min_m \left\{\frac{1}{n}\sum_{i=1}^{n} \max\{0,1-\ y_i f(x_i)\} + C\boldsymbol{w}^T\,\boldsymbol{w}\right\} \quad (1)$$

where w is a normalization vector, and C is the penalty parameter of the error term, which is an important hyper-parameter of all SVM models.

Several kernels are available to be used in SVM models to determine the similarity between two data points, x_i and x_j. Hence, the type of kernel would be a crucial hyperparameter to adjust. The most common kernels used in SVM include linear kernels, Radial Basis Function (RBF) kernels, polynomial kernels, and sigmoid kernels. The different kernel functions can be denoted as follows [11]:

- Linear kernel

$$f(x) = \ x_i^T x_j \quad (2)$$

- Polynomial kernel

$$f(x) = \ (\gamma\, x_i^T x_j\ + r)^d \quad (3)$$

- RBF kernel

$$f(x) = \exp\left(-\gamma\, \left||x - x'|\right|^2\right) \quad (4)$$

- Sigmoid kernel:

$$f(x) = \tanh\left(-\gamma\, x_i^T x_j\ + r\right) \quad (5)$$

After deciding on a kernel type, further hyper-parameters must be adjusted, as demonstrated by the corresponding kernel function equations. When the "kernel type" hyper-parameter is set to polynomial, RBF, or sigmoid, the coefficient is the conditional hyper-parameter; r is the conditional hyper-parameter of polynomial and sigmoid kernels. Extra conditioned hyper-parameter, d, defines the "degree" of the polynomial kernel function.

As part of the training process for an SVM classifier, the kernel function type *k* (x_i, x_j) values and the value of the regularization parameter C are calculated so that a trade-off may be made between increasing the distance between classes and reducing the total error [12].

B. *Hyperparameter Optimization (HPO)*

The training of a ML model is subject to number of hyperparameters. These hyperparameters determine the model's strategy for learning a given connection between input and detections. Using hyperparameter optimization (HPO), a model, that has been fine-tuned using the most effective hyperparameters, could be obtained. This model ought to be able to produce minimum-loss solutions. The challenge with optimization problems is that the search space is typically infinite, while the resources available to carry out the search are finite (maximum x amount of time or iterations). Consequently, for an algorithm to search for the global minimum effectively, it must incorporate strategies to make the most of the available funds. HPO's slow execution time is a serious drawback, especially when dealing with a wide variety of hyper-parameter configurations or massive datasets [4].

1) Non-dominated sorting GA-II: As non-dominated sorting is used to generate a preliminary coarse ranking of the population, NSGA-II (Pareto dominance-based) continues to be one of the most well-liked algorithms. The non-dominated solutions can be found using this technique and then moved to the next class before being discarded. The solutions in each obtained class are sorted from best to worst according to the objective's crowding distance, the total of the differences between an individual's left and right neighbors. It's best to have a lot of space between individuals. Non-dominated sorting becomes less discriminative and the left and right neighbors in each goal are generally different solutions when there are more than two objectives, hence this strategy fails for problems with more than two objectives [13].

2) Multi-fidelity optimization technique: In order to work around the problem of having insufficient time or resources, multi-fidelity optimization techniques are frequently used. The original dataset or the features used can be reduced to a subset to save time [14]. Low-fidelity and high-fidelity evaluations are combined in multi-fidelity for use in the real world [15]. Low-fidelity evaluations are those that only test a small fraction of the data and so are very inexpensive, but have poor generalization performance. Better generalization performance is achieved at the expense of increased cost in high-fidelity assessments, where a larger subset is assessed. Poor performing configurations are eliminated from multi-fidelity optimization methods at each iteration of hyper-parameter evaluation on newly generated subsets, leaving only the best performing configurations to be evaluated on the full training set. Bandit-based algorithms are a kind of multi-fidelity optimization algorithms, and they make use of strategies like sequential halving [16] and Hyperband approach [17].

- Successive Halving: By testing each possible combination of hyper-parameters, successive halving can determine which one works best. However, in real-world applications, numerous considerations must be taken into account, such as time and resource constraints. The term "budget" is used to describe these considerations (B). The following is the primary procedure for employing successive halving algorithms for HPO. The first assumption is that there are n sets of hyper-parameter combinations to test and that these sets are tested using equally distributed resources ($b = {}^{B}/_{n}$). Finally, at the end of every cycle, half of the underperforming hyper-parameter configurations are thrown out, while the other half are passed on to the next cycle with double budgets ($b_{i+1} = 2 * b_i$). The preceding steps are continued until the best possible set of hyperparameters is found. The trade-off between the feasible hyper-parameter configurations and available budgets affects the cost-benefit analysis of succeeding halves [18]. With this in mind, the main issue with consecutive halving is deciding how to divide the budget, specifically between testing fewer configurations with a larger budget for each and testing more configurations with a smaller budget for each.

- Hyperband approach [17] is considered a solution to the issue of successive halving methods by dynamically picking an appropriate number of configurations. It seeks to strike a balance between the total budget (B) and the number of hyper-parameter configurations (n) by apportioning a portion of the total budget to each configuration ($b = {}^{B}/_{n}$). Each batch of random configurations is routinely halved in order to get rid of the inefficient hyperparameter setups and boost performance. The total quantity of data points, the minimal number of instances required to train a meaningful model, and the available budgets all contribute to the restrictions b_{min} and b_{max} . After that, we use b_{min} and b_{max} to get the total number of configurations n and the budget size for each (max). Based on n and b, a random sample of configurations is generated and fed into the shown successive halving model. Each iteration of the consecutive halving method takes the top half of the configurations and discards the bottom half, keeping only the best-performing ones. This is done again until the best possible set of hyperparameters is found.

C. Ensemble Learning (EL)

1) Random Forest (RF): RF is a bagging approach that generates many independent, tiny decision trees from the dataset at random. Selecting a small number of attributes at each node in order to find the best branching technique allows for a deeper tree structure. Dataset and feature randomization makes overfitting less likely. In a classification problem, the majority vote is used to determine the final class label [19].

2) Bagging: The goal of "bagging" [20] is to increase the reliability of ML algorithms, especially decision trees. It helps prevent data from being overfit and lowers the model's variance. It takes the original training dataset and randomly selects n subsets of features and data samples, with replacement, to create n new datasets. Parallel models for making detections, using each of the n sub datasets as a single input, are built. The bagging classifier selects as its output the label class predicted by the majority of the base models.

*3) Adaptive Boosting (AdaBoost**):*** It is a technique used to increase the accuracy and performance of numerous weak classifiers by combining them into a single strong classifier. Adaboost's weak classifiers frequently use decision stumps, a variant of the decision tree that consists of a single node (the root) and two branches. Various classes of faulty classifiers are taught. When a less accurate classifier misclassifies a sample, the sample is assigned more weight in the next classifier. Further, the aggregate weight is based on how well each poor-quality classifier performed. Adaboost classifier's ultimate output is just a weighted sum of the results obtained by the individual weak classifiers [21].

D. Classification Algorithm

1) Decision Tree (DT): DT is a predictive modeling algorithm that can partition features in a dataset in multiple ways based on different conditions, resulting in a tree-like structure. The tree is made up of a decision node, which seeks the best feature split, and leaves (termina l nodes), which are used to create a final detection. Different criteria, such as gini and entropy, are used to divide the features. One significant consideration while constructing terminal nodes for the decision tree is deciding when to stop developing trees and when to create more terminal nodes. This can be done using two criteria: maximum tree depth (the number of nodes in the tree after the root node) and minimum node records (the number of training patterns represented by a given node). Once a node is built, the same method can be used on all created data by dividing the dataset into subsets to produce child nodes. The detection process entails selecting the appropriate node in a decision tree and then proceeding to walk down it with the relevant row of data.

III. Literature Review

Several SDD studies had recently been conducted to accurately detect early-stage developmental defects. Researchers had attempted to improve the model’s performance using various methods, algorithms, and measurements. Some of the most current papers relevant to this work are discussed here.

Benala and Tantati [22] examined the effects of five oversampling methods to solve the imbalanced data, including random oversampling, SMOTE, adaptive synthetic sampling (ADASYN), Safe-Level-SMOTE (SL-SMOTE), and SVM-SOMTE, to for SDD using nine imbalanced NASA datasets. They used decision tree (j48-classifier), the RF, Naive Bayes (NB), and EL classifiers. They concluded that SVM-SMOTE is the best oversampling technique due to its ability to produce minority-class instances in a region bordered by support vectors. Kassaymeh et al. [23] suggested a combination of Salp Swarm Algorithm (SSA) and Backpropagation Neural Network (BPNN) to solve the SDD problem. They used BPNN to find the best BPNN parameters. Different performance measures are used to evaluate the results, in which the results of their experiments showed that the combined work is often the best way to solve SDD problems. Goyal [24] proposed a filtering method, called FILTER to accurately predict defects. They used SVM-based classifiers (linear, polynomial, and radial basis functions) and a suggested filtering technique. They declared that their work improves the accuracy, AUC, and F-measure by 16.73%, 16.80%, and 7.65%, respectively, based on five datasets. Azzeh et al. [25] studied the effect and consistency of four kernel functions with feature selection on the performance of SVM for SDD. Four kernel functions, 10 feature subset selection thresholds based on the information gain technique, thirty-eight publicly available datasets, and a single evaluation measure were used in this comprehensive study. Since then, 1520 experiments had been conducted. Since the performance of other kernel functions is constrained, the results showed that SVM with an RBF kernel is the best option for defective datasets. Sharma et al. [26] analyzed the application of the ensemble method of ML technique in the field of SDD. They focused on the global state during the period 2018–2021, which had been examined from a multidimensional perspective, including the selection of a specific ML algorithms, and the research gap that may lead to the future scope of the work that can be accomplished. Ye et al. [27] developed a multi-objective immunity optimization method based on a thorough fitness evaluation mechanism, which allows it to efficiently tackle the used model. Two objectives are optimized: defect detection rate and false alarm rate for defects. Their proposed algorithm is based on comprehensive fitness evaluation, which has a better selection ability to attain the predicted effect of population evolution software and further assists decision makers in selecting a better scheme that meets their needs. In addition, to validate the efficacy of their proposed algorithm, they compared it against eight distinct public data sets, in which the results showed that their suggested work handles the multi-objective undersampling SDD problem more effectively. Shafiq et al. [28] developed an approach for SDD using ML to enhance software quality. They used PC1 data set as input data. Ant Colony Optimization (ACO) is used to determine which characteristics are the most crucial. The chosen characteristics are fed into SVM. The author declared that their results showed that ACO-based SVM performs better than SVM, NB, and KNN classifiers in solving SDD.

IV. Proposed Approach

The proposed approach in this work classifies the defects that exist in the software system and discovers the defect modules during the software development process, so the model that suffers from defects have high priority during quality assurance checks. The framework of the proposed approach in this work is shown in Fig. 1, which is logically divided into the following four phases. The preprocessing, which is Phase I, includes the standardization features and label encoding target features. Phase-II includes oversampling the dataset to balance the class distribution by applying SMOTE-SVM and hyperparameter tuning optimization using NDSGA-II and the Hyperband approach. Phase-III is focusing on training the SDD models using the balanced dataset and making the detections. Phase IV is concerned with evaluating the performance of SDD models and conducting comparative analyses.

This work aims to develop a high-quality approach to detect bugs in the early stages of the software development life cycle, by balancing the modules affected by defects in the dataset using the high-performance balanced algorithm. The SMOTE oversampling approach uses KNN similarity measures between items to generate synthetic instances in the defect class. This leads to the creation of an unknown number of artificial items that are "similar" to those in the current defect class but do not duplicate them. This algorithm has some disadvantages, such as sample overlap, noise interference, and blindness of neighbor selection. To address these problems, SMOTE is hybridized with SVM, so SVM-SMOTE generates new instances of defect classes near borderlines with SVM to help establish boundaries between classes.

However, the behavior of these algorithms is controlled by a set of parameters that remain static during the training process. The quality of the detection can be improved by fine-tuning these parameters to achieve the best possible results. Here, we apply an optimization algorithm called NDSGA-II to search for and fine-tune the hyperparameters of these algorithms and then pick the best possible parameters. Since NDSGA-II is resource-intensive and time-consuming algorithm, it has been integrated with Hyperband approach, to speed up the configuration evaluation by getting rid of ineffective parameters that don't have a global minimum. Testing the model's intermediate scores for a given set of hyperparameters is how it functions. For instance, after a fixed number of rounds, one could examine all the intermediate scores and eliminate the least effective parameters.

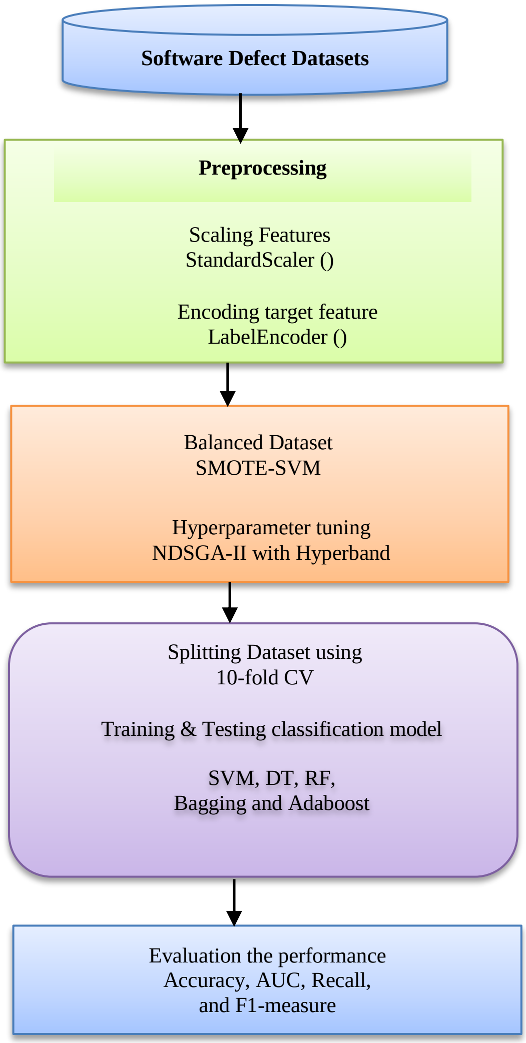

Fig. 1. The proposed approach.

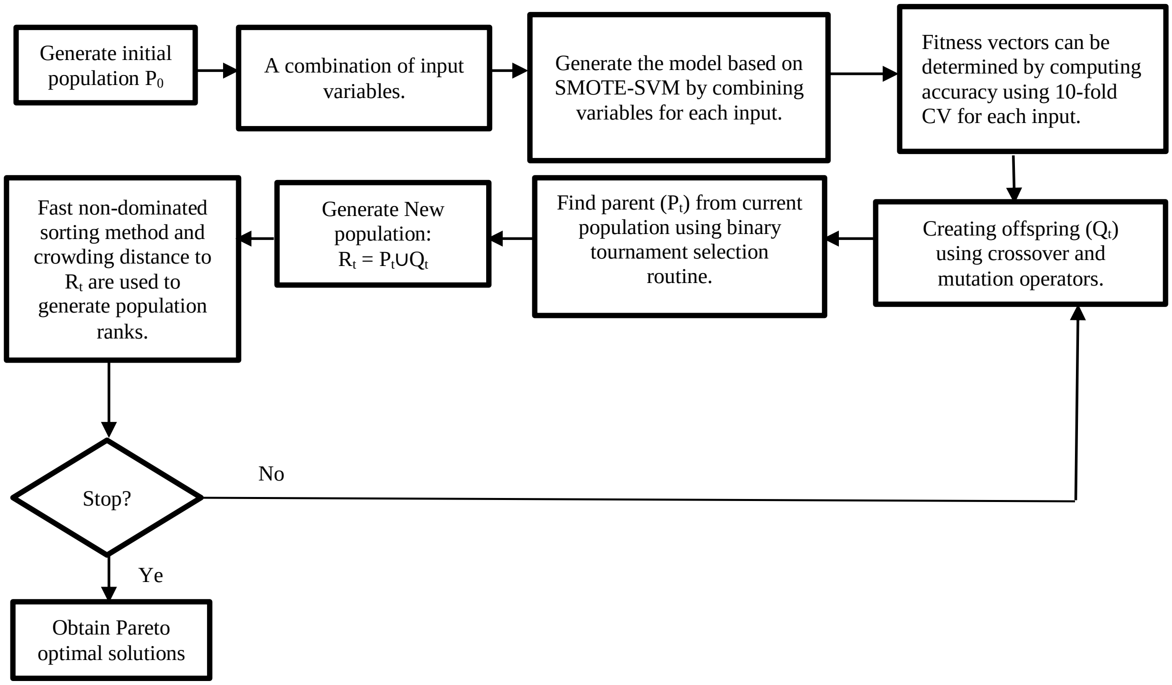
In Fig. 2, the steps of the search optimization technique used to obtain the optimal parameters for the SMOTE-SVM algorithm are illustrated. This process is described in stages as follows:

- Stage 1: Initialize the hyperparameters search space that represents the population (P), which consists of a combination of input variables (V).
- Stage 2: Generate random parent population.
- Stage 3: Apply the SMOTE-SVM-based model described in Algorithm 1 for each variable.
- Stage 4: Each V's accuracy is calculated using 10-fold CV to identify the fitness vectors, and each vector was given a fitness rank proportional to its non-domination frequency.
- Stage 5: Assign ranks to all V in a P by first selecting all of the non-dominated solutions from P and placing them in rank 1, then selecting all of the remaining solutions and placing them in rank 2, and so on.
- Stage 6: Sorts each V according to a dominance rule that said:

A variable ($\ddot{X}$) is said to dominate another variable ($\dot{X}$), if

- ✓ There is no objective of $\ddot{X}$ worse than that objective of $\dot{X}$.
- ✓ There is at least one objective of $\ddot{X}$ better than that objective of $\dot{X}$.

- Stage 7: Offspring resulting from recombination between two unrelated parents enter the progeny P. Throughout the process of mutation, the child's values shift. That process is continued until the P is twice as large as it was at the outset.
- Stage 8: Nondenominational criteria are used to re-classify P. In this way, a new generation will be selected according to established hierarchy.
- Stage 9: In the next iteration, crowding-sort will be used to determine the density of solutions if the partially included case holds. Less dense trials are selected for the next generation until the population count is back to its starting point.
- Stage 10: Iteratively producing and checking poorly configured parameters, then discarding their offspring, is repeated until the maximum number of generations is reached, at which point the optimal hyperparameter is returned.



Generate initial population P_0
A combination of input variables.
Generate the model based on SMOTE-SVM by combining variables for each input.
Fitness vectors can be determined by computing accuracy using 10-fold CV for each input.
Creating offspring (Q_t) using crossover and mutation operators.
Find parent (P_t) from current population using binary tournament selection routine.
Generate New population: $R_t = P_t \cup Q_t$
Fast non-dominated sorting method and crowding distance to R_t are used to generate population ranks.
Stop?
No

Obtain Pareto optimal solutions

Fig. 2. Main steps of obtaining the optimal parameters of SMOTE-SVM algorithm.

```
Algorithm 1: The proposed balancing datasets (SMOTE-SVM-based model)

Input:
    Software defects dataset (Đ):
        where:
            D = Defects ∪ non_defects;
            Defects represents instances in the dataset with defect class
            Non_defects represent instances in the dataset from non_defects class.
Output:  The balanced dataset

for D' ∈ Đ do
begin
    X = instances
    y = target class
    // Encoding target features that contain categorical data
    y_Encode = LabelEncoder (y);
    // Appling standardization technique to be in the same range
    X_Scale = StandardScaler (X);
for each data point <$x_{i,}$ , $y_i$>
begin
    // <xi,, yi>: the defect instances which denotes the minority class in Đ
    Defect support vectors = SVM algorithm (defect subsets, i.e., minority subsets);
    m = kNN (defect support vector);
    If   number of majority neighbors < $\frac{m}{2}$
        $X_{new} = X_i + (\dot{X}i , X_i) * \Re$, where $\Re \in [0,1], Xi \in Smax$,
                        $\dot{X}i \in$ KNN of $X_i$ , and Smax, is a majority instance
    End if
    Else
        $X_{new} = X_i + (\dot{X}i_{-}, X_i) * \Re$, where $\Re \in [0,1], X_i \in S_{min,}$
                        $\dot{X}i \in$ one of KNN of $X_{i,}$ which $S_{min,}$ is minority instance
    $\check{D} = X_{new} \cup Đ$
End for
    return $\check{D}$
End for
```

The following paragraphs discuss the SDD model that is presented in Algorithm 1, where the used defective datasets are imbalanced and the output is the balanced dataset. The necessary preprocessing steps are executed for each dataset. Encoding the categorical data in the chosen dataset is represented by yEncode, and xScale represents the features after standardization. The SVM model is applied in the minority subset, and neighbors of the defect support vector are obtained. If the number of non-defects class neighbors is less than half of the nearest defect support vector, a new object of the majority class is generated; otherwise, the new object will be of the minority class.

V. Experimentations and Results

The methodology behind the experiments is discussed here, as well as the infrastructure used and the datasets that were examined.

A. Environment

The proposed approach was tested on a laptop running Microsoft Windows 10 Pro 64-bit and an Intel(R) Core (TM) i7-8565U Processor at 1.80 GHz (92 MHz). Oversampling methods are taken from the imblearn library, and ML classifiers are imported into Sklearn 1.0.2 using an x64 processor running Jupyter notebook 6.1.4 with Python 3.8.5 and OPTUNA (HPO framework).

B. Description to Dataset and Software Metrics used

This work used nine NASA datasets and was investigated by Shepperd et al. [29]. Halstead metrics, McCabe metrics, size metrics, and other properties are included in these datasets to help establish the quality of a software model. If a dataset has bad class values, it probably is bad. The model is fine if the class value is "0" or "no," but it's broken if it's "1" or "yes." Minority class samples range from being extremely under-represented to being evenly distributed across the datasets. The nine NASA datasets are illustrated in Table I.

TABLE I. NASA DATASET DESCRIPTION

Database	# Of Features	# Of Instances	# Of Defective	# Of Non-Defective	Defective %
KC1	22	1183	314	869	15.45

C. Parameter Setting for SDD Models

Table II details the various classifier parameter settings.

TABLE II. PARAMETER SETTINGS OF THE USED ALGORITHMS

Parameters	Values
NDSGA-II	
iterations	100
Population size	Hyperparameter space
Crossover rate	1
Mutation rate	$\frac{1}{generated\ groups}$
SVM	
Kernel type	Rbf
gamma	0.61719
C	16.1657
degree	1
RandomState	104
KNN	
K	8
m	10
DT, RF	
criterion	entropy

D. Evaluation Criteria

The proposed classifiers' efficacy is measured using standard metrics including the confusion matrix, ROC, AUC, accuracy mean, and F-measure.

- Accuracy: It is a ratio of the number of correct detections to the total number of observations, as illustrated in Eq. (6).

$$Accuracy = \frac{\text{TP+TN}}{\text{TP+FP+TN+FN}} \quad (6)$$

- Precision is the ratio of correct positive detections out of the total number of positive detections as given in Eq. (7)

$$precision = \frac{\text{TP}}{\text{TP+FP}} \quad (7)$$

- Recall is the ratio of correct positive observations to all positive observations made in class, as given in Eq. (8).

$$recall = \frac{\text{TP}}{\text{TP+FN}} \quad (8)$$

- F1 score is a weighted average of precision and recall. F1 is usually preferable to accuracy, particularly if the class distribution is uneven, as calculated from Eq. (9).

$$F1\ score = \frac{2*\text{Recall}*\text{Precision}}{\text{Recall+Precision}} \quad (9)$$

- AUC-ROC It shows TPR versus FPR at different thresholds to differentiate "signal" from "noise." It separates classes and summarizes the ROC curve. High AUC means the model separates positive and negative groups well.

E. Results

1) Results of applying the decision tree algorithm: the results of DT for defect detection using the proposed approach are shown in Table III. The best results obtained on the PC2, MC1, and CM1 datasets, respectively, are as follows: 1) the accuracy achieved 98.18%, 95.59%, and 94.28%. 2) The AUC achieved 9.9798, 0.9546, and 0.9466. 3) F-measure achieved 0.9736, 0.936, and 0.9259.

2) Results of applying the Random Forest algorithm: The results of RF for defect detection using the proposed approach are shown in Table IV. The best results obtained on the KC3, MC1, and PC2 datasets, respectively, are as follows: 1) the accuracy achieved 100 %, 99.66 %, and 99.06 %. 2) AUC achieved 1.0, 0.9974, and 0.9868. 3) F-measure achieved 1.0, 0.9950, and 0.9866.

3) Results of applying the Adaboost algorithm: The results of Adaboost for defect detection using the proposed approach are shown in Table V. The best results obtained on the KC3, PC2, and MC1 datasets, respectively, are as follows: 1) The achieved accuracy is 100%, 99.09%, and 97.28%. 2) The achieved AUC 1.0, 0.9868, and 0.9746. 3) The achieved F-measure achieved 1.0, 0.9866, and 0.9611.

VI. Result Analysis and Discussion

Different experiments were conducted to find out how the oversampling and HPO techniques affected the performance of SDD models. We first investigated how well SDD models with NDSGA-II hybrid using Hyperband approach for HPO and SMOTE-SVM balanced datasets performed. Tables III to VII display the results for various performance measures for the available NASA software defect dataset. Therefore, it can be asserted that we have successfully implemented all the classification algorithms with high performance. From these tables, it is clear that RF is the most accurate method to classify defects, while Adaboost is the least accurate of all evaluation measures. With KC3 dataset, Adaboost and RF classifier were able to achieve 100% accuracy. Table VIII presents the accuracy results of the proposed work with and without parameter tuning on different datasets, to illustrate the influence of tuning these parameters on the model's performance. Also, Fig. 3 and Fig. 4 show the comparison between these methods. These results show that tuning the algorithm's parameters helped make the models more accurate than the other methods which don't tune the parameters.

TABLE VIII. Accuracy Measure for All Classifiers with and without Hyperparameter Tuning

Datasets	Accuracy Without PARAMETER TUNING (%)		Accuracy With PARAMETER TUNING (%)	
KC1	SVM	77.52	SVM	87.92
	DT	85.95	DT	88.20
	RF	91.57	RF	92.415
	Adaboost	80.33	Adaboost	82.022
	Bagging	91.01	Bagging	91.85

	DT	88.88	DT	86.66
	RF	86.66	RF	93.33
	Adaboost	80	Adaboost	88.88
	Bagging	86.66	Bagging	95.555
JM1	SVM	69.23	SVM	82.16
	DT	82.1	DT	83.47
	RF	89.51	RF	89.80
	Adaboost	75.78	Adaboost	75.27
	Bagging	87.92	Bagging	88.54

These results also demonstrated that the proposed method outperformed the method proposed in [22] that also used SMOTE-SVM for balanced defect datasets by an average of 10.59% with DT, 8.0246% with RF, 2.25% with Adaboost, and 14.8276% with bagging. This is due to the ability of the proposed algorithm with using the optimal parameters, shown in Table II, obtained from applying NDSGA-II algorithm. Hyperband approach [17] is used in NDSGA-II to reduce the time and save other used resources.

Table IX compares the method described in this paper to several other methods for detecting software defects.

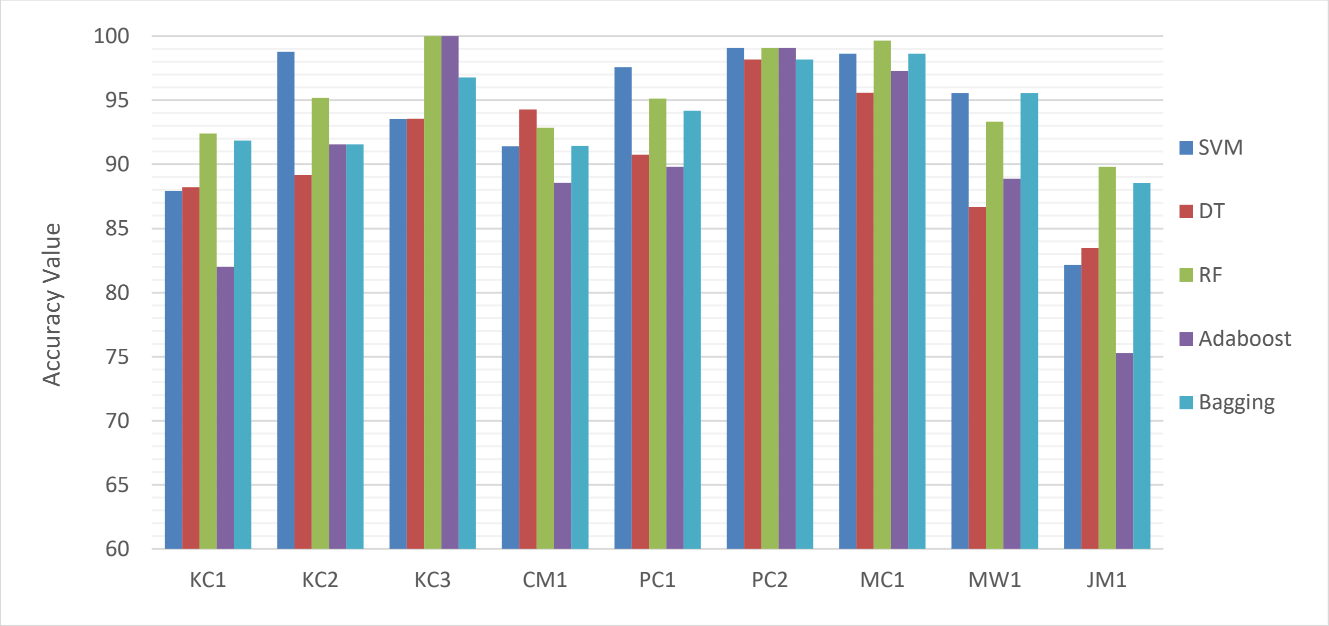

Fig. 3. Comparison accuracy values of five classifiers based on the proposed approach.

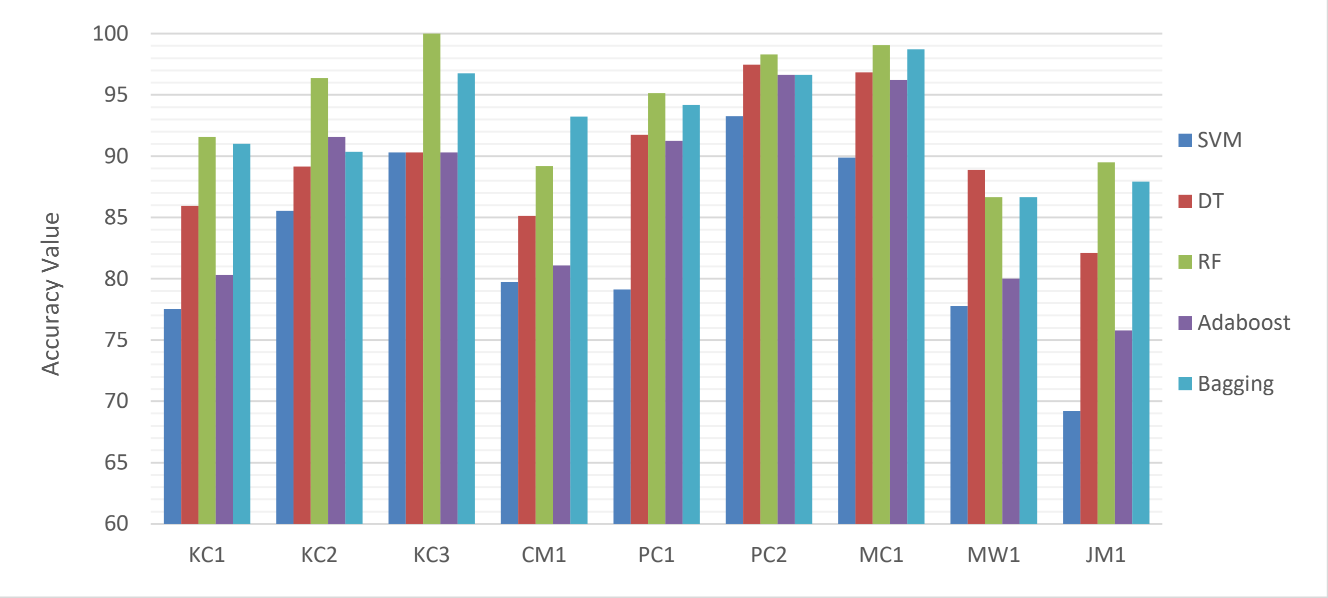

Fig. 4. Comparison accuracy values of five classifiers based on the proposed approach without tuning algorithm parameters.

VII. Conclusion and Future Work

In this work, a new software defect detection (SDD) approach is proposed and developed as an efficient and smart way to find software defects. This approach uses SMOTE-SVM algorithm, to address the issue of imbalanced behavior in NASA datasets. The proposed method used NDSGA-II algorithm with Hyperband approach for hyperparameter optimization of SMOTE-SVM algorithm, followed by using standard ML methods and ensemble techniques for training. The experimental results were assessed using NASA datasets, in which the results showed that our proposed work outperforms the conventional techniques and methods in predicting software faults based on accuracy, AUC, recall, and F-measures. Also, the results showed that RF performed the best with 95.2746% average accuracy, while Adaboost performed the lowest with 90.2754% average accuracy. As future work, we plan to investigate the impact of using deep learning on the improvement of SDD when imbalanced data is used. Also, we plan to use other techniques for HPO, and other assessment measures such as G-measure, balance, and Matthews' Correlation Coefficient (MCC).

***Abstract*—In recent years, the integration of artificial intelligence (AI) technologies has greatly benefited smart city healthcare, meeting the growing demand for affordable, efficient, and real-time healthcare services. Patient monitoring is one area where artificial intelligence has shown great promise. Improved health outcomes have been made possible by the advancement of AI-based monitoring systems, which enable more personalized and continuous patient monitoring. However, to fully maximize the benefits of these systems, a user-centered approach is essential, which prioritizes patients' needs and experiences while ensuring their privacy and autonomy are respected. This study focuses on the application of user-centered design principles in the development and deployment of AI-driven monitoring systems in smart city healthcare. Addressing the challenges and opportunities of AI-driven monitoring systems, the article considers issues such as privacy and security concerns, data accuracy, and user acceptance. Finally, some possible future directions to the challenges are suggested. A user-centered approach to AI monitoring systems is recommended for healthcare providers to enhance patient experience in smart city healthcare.**

Keywords—Smart healthcare; patient monitoring; smart city; artificial intelligence; user-centered

I. Introduction

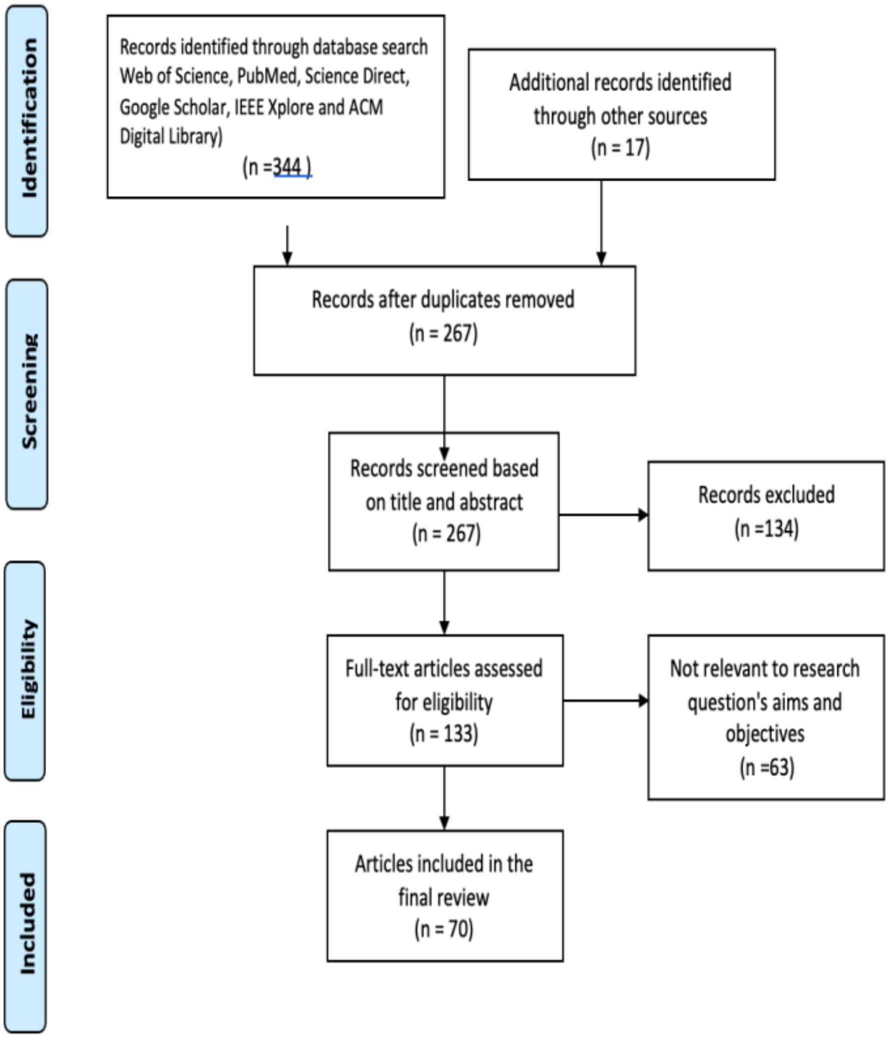
The advancement of technology in the modern era has had a significant impact on the delivery of healthcare services. With the increasing demand for affordable, efficient, and real-time healthcare, smart cities have become a hub for the integration of artificial intelligence (AI) technologies. Smart cities are urban areas that use technology to improve their residents' quality of life. A healthcare system consists of certain groups (such as patients, primary care physicians, pharmacists, and other specialists) and a variety of stages (such as medical issue screening, sickness determination, clinical therapy, and recovery) [1]. Together, all these parties contribute to the implementation of the smart healthcare ecosystem. Global healthcare practices are changing because of a shift in digital technologies. The integration of intelligent technology and healthcare systems enables easy access to healthcare data and connects resources for effective management of unpredictable health care demand [2]. Unlike traditional healthcare, smart healthcare utilizes IoT, 5G wireless technologies, cloud computing, big data and artificial intelligence [3]. These technologies are the most effective communication framework since they allow more accurate collection, recording, and analysis of patient data and direct knowledge sharing between healthcare service providers [4].

Healthcare is an important aspect of smart city development, and the incorporation of AI technologies has the potential to revolutionize healthcare service delivery in these areas. One area where AI has shown significant potential is in patient monitoring. The development of AI-driven healthcare monitoring systems has enabled continuous and personalized patient monitoring, leading to improved health outcomes. Healthcare monitoring is important in maintaining healthcare services for patients such as the elderly or those suffering from chronic diseases. It can reduce the need for medical intervention [5], will rely less on traditional physical health facilities like hospitals and long-term care centers, and will be more individualized as a result. Numerous studies have been conducted on smart healthcare to monitor patient health, for example, Parkinson's disease [6] and mental health [7] and cardiovascular disease [8]. However, to maximize the benefits of AI-driven monitoring systems in smart city healthcare, it is crucial to adopt a user-centered approach. This approach prioritizes patients' needs and experiences while ensuring their data is collected and analyzed in a manner that respects their privacy and autonomy. This is particularly important in smart cities where populations are diverse and have unique healthcare needs. Industry 5.0 and 5G telecommunication technology have made it possible to create low-cost sensing technologies for real-time monitoring and data acquisition [9]. These systems could help increase patient experience and promote health outcomes by emphasizing the needs and experiences of patients.

As the demand for healthcare services in smart cities continues to grow, the integration of user-centered AI monitoring systems has the potential to play a critical role in meeting that demand. By prioritizing the needs and experiences of patients, these systems have the potential to enhance patient experience and improve health outcomes. Therefore, this study aims to investigate the role of user-centered AI monitoring systems in enhancing patient experience in smart city healthcare. The study seeks to understand how we best can overcome the challenges associated with employing AI-driven monitoring systems in smart city healthcare, with a focus on incorporating user-centered principles into the design and implementation of these systems. The remainder of this study is organized as following: Section I summarize the background and motivation for the study. Section II gives a description of the key elements and qualities of a smart city. Section III reviews the adoption of AI in healthcare. Section IV explores AI-driven monitoring system, including remote, mobile and wearable health monitoring systems. Section V shows research studies that have adopted a user-centred approach to develop AI-based monitor systems. In Section VI, the challenges, opportunities, and potential future directions are presented. Finally, Section VII concludes the paper, summarizes the main points and suggests guidelines for areas of future work.

II. Method

This systematic review aims to synthesize the existing literature on the role of user-centered AI monitoring systems in smart city healthcare. The search strategy for this review included electronic databases such as Web of Science, PubMed, Science Direct, Google Scholar, IEEE Xplore and ACM Digital Library as well as manual searches of reference lists of relevant articles. The search terms included “AI-based monitor systems”, “smart city”, “smart health”, “user-centred design in healthcare”, “challenges and opportunities of AI monitor systems”. The inclusion criteria for this review were studies that involved the development of AI-based monitor systems and studies which adopted a user-centred approach to the development of AI monitor systems. Review studies were included to understand the past and current state of the research topic. Exclusion criteria included studies that did not use a AI-based innovations. Two reviewers independently screened titles and abstracts to assess their eligibility, and full text articles were evaluated to be included. A narrative synthesis approach was used to summarize the key findings of the included studies, identifying patterns and themes across studies. The data was analyzed to better understand the challenges, opportunities, and impact of user-centered AI monitoring systems in smart city healthcare. The Prisma model shown in Fig. 1 illustrates the complete process of article search and selection.



Identification
Screening
Eligibility
Included
Records identified through database search Web of Science, PubMed, Science Direct, Google Scholar, IEEE Xplore and ACM Digital Library) (n =344)
Additional records identified through other sources (n = 17)
Records after duplicates removed (n = 267)
Records screened based on title and abstract (n = 267)
Records excluded (n =134)
Full-text articles assessed for eligibility (n = 133)
Not relevant to research question's aims and objectives (n =63)
Articles included in the final review (n = 70)

III. Literature Review

A. *Smart Cities*

Cities consist of various interacting entities, such as citizens, businesses, modes of transportation, communication networks, services, and utilities. The development of cities poses numerous challenges, such as waste management, lack of resources, air pollution, and health concerns [10]. Smart cities are thought to provide opportunities to solve these problems [11]. The main goal of a smart city includes connecting residents, facilitating communication, improving government performance and economic growth, promoting sustainability and improving citizens' quality of life using smart technologies [12], [13].

1) Smart cities infrastructure: A smart city's infrastructure is increasingly dependent on advanced technologies to address population growth-related issues. AI and IoT-enabled devices will improve the quality of life and maximize the efficiency of a wide range of daily services in smart cities, such as smart transport, smart energy, and smart water management [14]. Fig. 2 illustrates the infrastructure of smart cities.

a) Smart healthcare: Smart cities aim to provide smart healthcare solutions. Sensors and smart devices have significantly contributed to the availability of high-quality patient care using smart health technologies.

b) Smart education: In smart education, the focus is on and learner-driven, personalized, and adaptable learning services, interactive, collaborative, and collaboration resources and services. In addition, a smart learning environment facilitates the realization by learners of an effective, efficient, and meaningful learning experience [15].

c) Smart transportation: Smart transportation is a technological advancement in the conventional transportation system that improves public life by delivering optimized services through mobile devices, city-installed devices, or sensors built into cars. These sensors and devices enable easy parking reservations, efficient street lighting, optimal route suggestions, public transit telematics, accident prevention, and autonomous driving [16].

d) Smart buildings: In smart cities, energy efficiency is emphasized, and buildings are designed to function according to individual fulfilment, so that they are more sustainable and energy efficient; for example, the use of smart devices in smart buildings allows many tasks to be handled, including controlling climate, lighting, and many other aspects based on detection of presence [17].

e) Smart energy systems: A smart energy system is built on technological advancements with the goal of decreasing energy consumption and boosting the use of renewable resources. The primary goal of smart energy is to conserve non-renewable resources for use in emergencies [11].

f) Smart manufacturing: Smart RFID tags make it easy to trace a product from the factory to the retailer, greatly reducing time and costs. Smart packaging can also include benefits like brand protection, quality assurance, and customer customization [16].

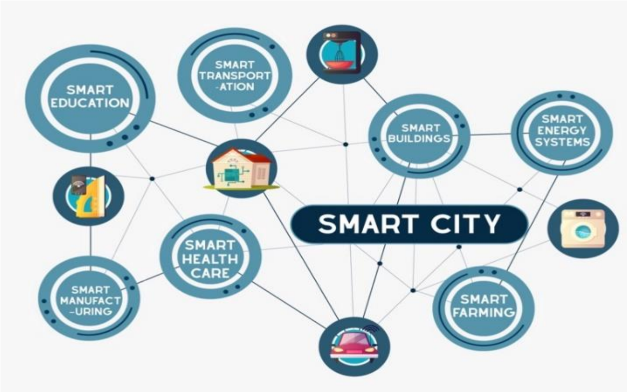

Fig. 2. Components of a smart city.

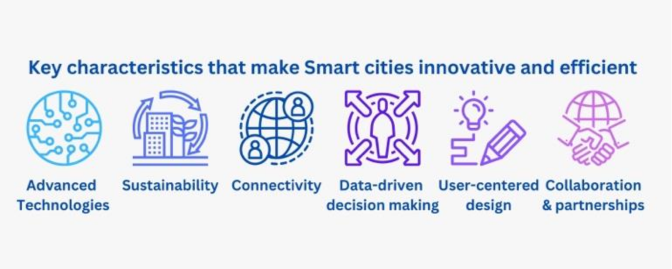
g) Smart farming: Effective agriculture production is crucial for our people to prevent a future potential food crisis. The use of IoT technology in agriculture may undoubtedly contribute to securing enough food demand and improving the overall efficiency of agricultural production processes. Significant crop information could be gathered and used for yield monitoring and the early detection of diseases that could have a major effect on crop yield and quality. Soil and nutrient monitoring would optimize agricultural production methods and result in water savings, which are valuable in some geographic areas [14].

2) Overview of smart cities characteristics: Smart cities can help to enhance city residents' standard of living while also making the city more sustainable and efficient. With the help of technology and data, smart cities can improve city infrastructure and services and solve some of the most pressing problems facing modern cities. Smart cities have several key characteristics that make them innovative and efficient as illustrated in Fig. 3.



Key characteristics that make Smart cities innovative and efficient
Advanced Technologies
Sustainability
Connectivity
Data-driven decision making
User-centered design
Collaboration & partnerships

Fig. 3. Key characteristics that make smart cities innovative and efficient.

a) Advanced technologies: Smart cities infrastructure are based on innovative technologies to combat urban challenges with the help of IoT devices, artificial intelligence (AI), cloud computing, and Big Data analytics, [14], [18], [19].

b) Sustainability: Smart cities are designed to minimize their environmental impact including reducing energy consumption, encouraging the use of green spaces, and improving air and water quality [10], [20].

c) Connectivity: Smart cities are highly interconnected, with advanced communication networks connecting residents, businesses, and government agencies. This enables real-time data exchange and seamless communication [13].

d) Data-driven decision making: In smart cities, data is the driving force behind decisions and services. The data collected through advanced technologies are used to identify trends and improve services to better the quality of live for its residents [21], [22].

e) User-centered design: Smart cities are designed with citizens' needs in mind, with the goal of improving the wellbeing and welfare of their citizens [23]–[25]. Accessible and affordable transportation, green spaces, and sustainable housing are part of this approach.

f) Collaboration and partnerships: For smart cities to succeed, governments, businesses, and residents must collaborate. Collaboration, transparency and sharing of data and resources are essential to solving urban problems and creating a more efficient and sustainable city [20], [25].

Smart cities are the future of urban development, designed to address some of the most pressing issues that cities face. IoT devices, cloud computing, big data and artificial intelligence are examples of advanced technologies that enable real-time data exchange and data-driven decision making. Smart cities are also designed to reduce environmental impact, promote sustainability, improve connectivity, foster collaboration, and focus on the needs of citizens. A user-centered approach will help to ensure that the needs of citizens are considered when designing the city. Collaboration and partnerships are critical to smart city success because governments, businesses, and residents must collaborate to solve urban problems and create a more efficient and sustainable city. Transparency and resource sharing are critical to achieving this goal. By embracing these principles, cities can improve the quality of life for their citizens and ensure a sustainable future for future generations.

3) Smart city for a smart healthcare: Smart cities and smart health are two interrelated concepts that are changing the way we live and manage our health. A smart city is a framework that employ technology and data to handle the issues of waste management, traffic congestion, air pollution and energy use etc. to improve the quality of life for citizens [19], [20]. Smart health, on the other hand, refers to the use of cutting-edge technologies. The Internet of Things (IoT), artificial intelligence (AI), cloud computing, and an array of digital tools has enabled us to improve the way we manage and maintain our health [3], [19]. Combining the benefits of smart cities and smart health can help to create healthier and more sustainable environments for their citizens. Artificial intelligence and machine learning technologies are key tools utilized in smart healthcare, where it can be used to analyze large amounts of data and thus improve diagnostic and treatment precision. It can also be used to predict diseases and disease progression, allowing for earlier intervention and improved patient care [26]. Cloud computing is utilized for numerous disease diagnosis applications, allowing stakeholders to make informed medical decisions [27]. IoT devices can collect and monitor patient data in real time, improving care and reducing the need for in-person hospitalization [28], [29]. These devices can also aid in disease prevention by enabling the user to monitor their own health status, assess their situation, and receive advice and recommendations [3]. Robotic technology can be used to improve surgical precision and reduce the risk of surgical complications [30].

Smart healthcare can provide numerous benefits to both patients and healthcare professionals. Patients will benefit from reduced wait times for doctor's appointments as well as more personalized treatment and care. Furthermore, the technologies can help reduce healthcare costs while improving diagnostic and treatment precision and efficiency [31]. Although smart healthcare has many advantages, there are also challenges to overcome. Such as, privacy and security when using smart healthcare technologies. The collection and sharing of personal health information has the potential to violate privacy and security. As a result, it is critical to have adequate security measures in place to protect patient data [32], [33]. Moreover, Healthcare professionals may also require new training and skills as a result of the technologies, which can be challenging [34], [35]. Smart healthcare is an innovative approach to the healthcare sector in which technology is used to improve patient care and healthcare quality. AI, IoT, and robotics technologies can provide benefit to both patients and healthcare professionals. However, there are obstacles to overcome, such as, training requirements, and concerns about privacy and security. If appropriate safeguards are in place, smart healthcare technologies may continue to have the capability to enhance healthcare services and patient care.

B. Advancements in AI- Driven Healthcare Monitoring Systems

1) Artificial intelligence: Artificial intelligence (AI) is of growing importance as it has the potential to improve healthcare through innovative medical devices and provide more personalized healthcare. The various domains AI plays a role is illustrated in Fig. 4. The application of new mobile devices, the development of smart home technologies, and the growing acceptance of smart health have made it possible for healthcare providers to access various form of medical media, such as X-rays and voice recordings. It is now much easier to obtain and share medical data with other healthcare providers for future care [36]. Smart home technologies have assisted healthcare providers in providing high-quality, low-cost care to patients. Structured and unstructured healthcare data can be processed using artificial intelligence. Machine learning (ML), which includes neural networks, classical support vector and deep learning, are common AI techniques used in the healthcare sector [37].

Research shows that there are various healthcare domains where AI can play a critical role. For example, wearable technologies [38] and [39] allow patients to monitor their health and AI-based clinical decision support systems are continuously used to aid and improve diagnosis [31]. Chatbots have been employed to provide mental health services that could lead to early prevention and support [7]. Surgical robots and mixed reality technology can help perform more precise surgeries [30]. To increase the effectiveness of their operations and patient management, many hospitals are installing artificial intelligence technologies that allow the information to gather from electronic medical records (EMRs) [40]. The drug industry [41], [42] is another area that has benefitted from the application of AI.

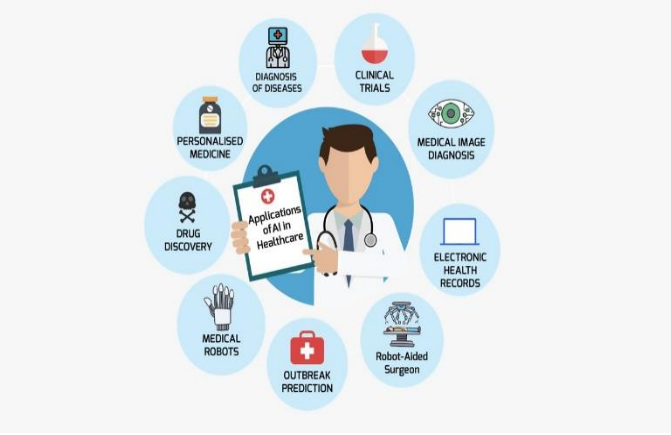


Fig. 4. Application of artificial intelligence in healthcare.

2) AI-driven monitoring system in smart healthcare: AI-driven monitoring systems have attracted researchers' attention due to their significant impact on people's lives. There have been numerous research studies [33], [43], frameworks [44], [45], [46] and services [8], [36] that focus on integrating artificial intelligence for smart healthcare. Table I summarizes the development of health monitoring systems considering the healthcare context, the invention, and AI technology.

- Remote Health Monitoring Systems

Researchers in [8] used IoT and AI to remotely monitor cardiovascular patients using a device that allows for smart monitoring of human vitals such as body temperature, heart rate, oxygen levels. In [36], the authors suggest a smart home healthcare monitoring system where installed sensors and devices can meet the needs of elderly people for continuous care at home. Researchers in [47] offer a system for remote monitoring of chronically ill or older people. The system is designed to automatically identify physiological signals [48] developed a framework for hybrid real-time remote monitoring (HRRM) for chronically ill patients. Researchers in [49] developed a home health monitoring system to track the health conditions of individuals with type 2 diabetes and hypertension. The system would diagnose and monitor patients' blood pressure and diabetes status. Researchers in [50] developed a remote monitoring system for Parkinson's disease patients using a voice signal as input.

- Mobile and Wearable Health Monitoring Systems

Researchers in [44] developed a deep learning-based voice pathology detection system for remote patient monitoring. The mobile application uses parallel CNNs to extract deep-learned features. In [51], the authors suggest a mobile and automatic system to improve patient cardiovascular health management abilities using IoT and AI technologies. A mobile application system is proposed by [45] for obesity management. The application utilizes a genetic algorithm as an AI engine to predict the meals a user will need to consume to meet their calorie, macronutrient, and micronutrient goals. The author in [46] presents a wearable health monitoring device to monitor patients' activities and vitals while they are engaged in activity to support efficient and effective health monitoring. The author in [52] offer a Smart Health Monitoring System framework built using IoT and machine learning to monitor patients affected by coronary artery disease. Research by [53] focuses on developing an AI-based patient monitoring system to observe the vital signs of Covid 19 patients remotely. Another research team in [54] have developed a smart healthcare framework for the detection and monitoring of COVID-19 using smart connectivity sensors and deep learning (DL). The application collects and analyzes patient Chest X-ray images. The system will then predict the patient's status and alert the healthcare professional to take action. In [55], the author offers a smart home healthcare framework for diabetic management using AI technologies. The proposed framework included portable sensors to detect temperature, blood sugar level, and activity of diabetic patients.

Remote diagnosis and treatment are crucial in rural areas and other regions with insufficient qualified medical professionals. Numerous healthcare applications' capacity to gather patient data remotely can help to overcome workforce constraints and process the data automatically for use in patient care as needed [5]. Further, traveling for medical care is not only time- and money-consuming, but it can also be challenging for some people, such as the elderly [56]. Automating smart healthcare monitoring systems limits the risk of human error, which can put both patients and providers at risk [57]. The information obtained is the main difference between face-to-face and remote diagnosis.

AI-based monitoring systems are showing promising results and can help to transform the healthcare industry by providing a more efficient and effective way of monitoring patients' health, reducing the risk of human error, and providing more affordable treatment options. Remote health monitoring systems employ IoT and AI-based technology to remotely monitor cardiovascular, elderly, chronically ill, and Parkinson's disease patients. Mobile and wearable health monitoring systems collect real-time data on patients through use of mobile applications, wearable devices, and IoT technologies. The use of wearable devices and mobile phones has made it easier to collect data for remote diagnosis and treatment. IoT and sensor technology are also used to handle the data collected by these devices. The use of AI in healthcare monitoring has the potential to provide affordable treatment options and improve the overall health of vulnerable citizens. The future of healthcare monitoring is expected to see an increase in the adoption of wearable devices and mobile applications, making the use of AI in healthcare monitoring more prevalent in daily life.

Modern technology, including mobile and wearable devices, has made it easier to find affordable treatment options by collecting real-time data without affecting regular activities. Wearable sensors such as watches, straps and glasses as well as mobile phones are useful methods to collect data [7]. Usually, these devices are linked to a network and establish remote communication with mobile devices. Fig. 5 shows the growing trend of wearable technology and the increasing focus on collecting and analyzing personal health data to improve overall wellness. The use of cloud-based infrastructure and edge computing devices allows for real-time data processing and analysis, which can lead to more accurate and actionable insights. Wearable devices including glasses, watches, and chest straps, can be connected to edge computing devices such as smartphones or middleware servers through Wi-Fi and Bluetooth technology. These devices are used to collect and transmit data related to the wearer's health and fitness, and the data is processed and stored on cloud-based infrastructure for further analysis. Glasses can have a display that can provide the wearer with real-time information such as heart rate and other health metrics. During exercise, the chest strap may monitor the wearer's heart rate and other vital signs, while a watch may track physical activity, calories burned, and sleep patterns. With enough data obtained, it is possible and practical to provide remote diagnosis and remote therapy. IoT and sensor technology are combined to handle the data that has been obtained [56]. The use of wearable devices will grow and become more prevalent in daily life, making them potentially useful to monitor the health of vulnerable citizens [58].

TABLE I. SUMMARY OF HEALTH MONITORING SYSTEMS

Ref.	Healthcare context	Invention	AI technology
[8]	Cardiovascular patients	A device based on IoT and AI that monitor the human vitals, including oxygen levels, heart rate, and body temperature.	K-Nearest Neighbors (KNNs)
[36]	Health conditions of elderly people	A monitoring system that includes video cameras and microphones fitted in the smart home.	Interlaced derivative pattern
[47]	Chronically ill or elderly	A physiological signal monitoring Smart-Monitor system.	Deep Neural Network
[48]	Chronically ill patients	A framework for hybrid real-time remote monitoring (HRRM) for chronically ill patients.	Naïve Bayes, Support vector
[49]	Type 2 diabetes and hypertension	A Smart home health monitoring system that analyzes blood pressure and glucose levels.	Support vector K-NN, Decision tree
[50]	Parkinson's Disease	A healthcare monitoring system for PD patients using voice signal as input	Support vector Gaussian mixture model, Random forest tree
[44]	Voice disorders	A smart mobile healthcare framework that enables voice pathology detection. The system used parallel CNNs to extract deep-learned features.	Parallel convolutional neural network, AlexNet
[51]	Cardiovascular patients.	An AI-enhanced mobile system for cardiovascular health management	Convolutional Neural Network, Recurrent Neural Network
[45]	Management of Obesity	A mobile application for self-management of obesity.	Genetic Algorithm technique
[46]	General health	An IoT and AI-based wearable monitor that tracks the patient's activities and vitals	Neural network
[52]	Coronary disease	A Smart Health Monitoring System. The application includes a pulse sensor that can be placed on a fingertip to monitor early signs of heart disease.	Decision Tree Algorithm and Random, Backwoods Classifier Algorithm, Support vector machine
[53]	Covid 19	AI-Based Patient Monitoring System to observe vital signs of patients. A webpage application is used to communicate between patients and health professionals.	Deep neural network
[54]	Covid 19	A smart healthcare framework for detection and monitoring of COVID-19.	ResNet50, convolutional neural network
[55]	Diabetic patients	A framework for automated monitoring of diabetic patients using sensors and smartphones.	Naïve Bayes, Random Forest, ZeroR, Simple logistic, sequential minimal optimization

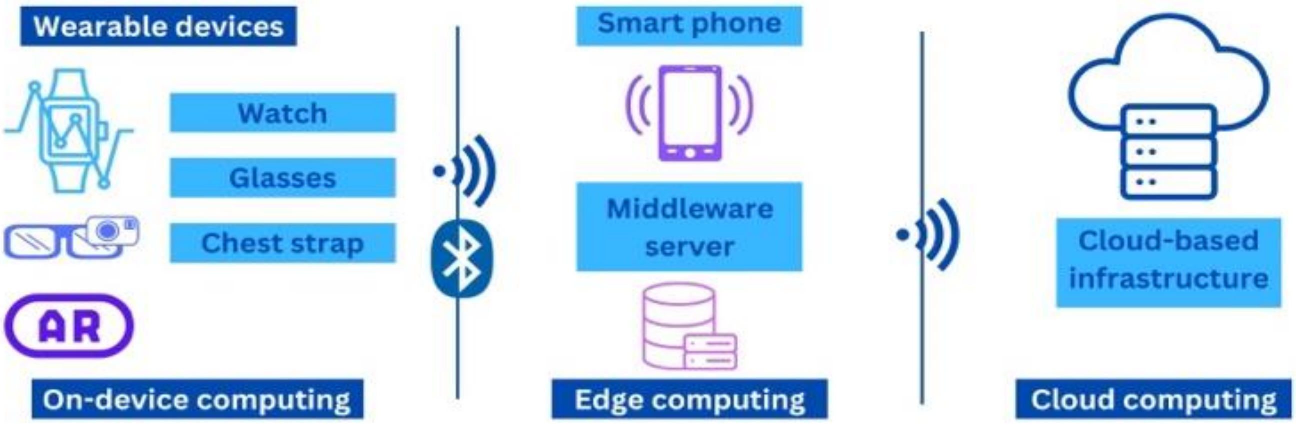

Fig. 5. Wearable device application process.

3) User-Centered Principles in AI-Driven Monitoring Systems: User-centered AI monitoring systems are health monitoring systems that are designed with the end user in mind. These systems employ artificial intelligence (AI) technology to collect, process, and analyze health-related data to improve patients' overall health and well-being. The goal of these systems is to provide personalized health monitoring and support to users without interfering with their privacy [33]. According to research, user-centered AI monitoring systems have the potential to transform the health industry by providing real-time health monitoring and support to patients [26], [59]. Using artificial intelligence technology, health-related data such as vital signs, physical activity levels, and sleep patterns can be automatically collected, analyzed, and used to detect health-related issues [8], [49].

Several studies have highlighted the importance of involving end users in the development of AI monitoring systems. Study [60] presents a comprehensive design methodology for developing mobile health (mHealth) apps for chronic pain management. The methodology focuses on incorporating user-centered design principles to improve the user experience and app adoption. The author discusses the pain management landscape, current challenges with mHealth app development, and highlights the importance of involving end-users in the design process. Also [61] provides a detailed overview of the importance of user-centered design in the development of health apps. The study emphasizes the increasing popularity of health apps and the need for designers and developers to ensure that these apps meet the needs and preferences of users. The authors discuss several key components of a user-centered design approach, such as user research, user feedback, and continuous evaluation, all of which are necessary for ensuring that health apps are effective, usable, and accessible. The authors also offer practical advice for those looking to create user-centered health apps. They emphasize the importance of taking user characteristics like age, gender, culture, and socioeconomic status into account during the design process. The authors emphasize the importance of health apps being accessible and usable for people with disabilities.

A study by [62] developed a voice monitoring system for disorder prevention using a user-centered design approach. The authors present a step-by-step process for developing a voice monitoring system that meets the needs and preferences of users, as well as a thorough overview of the importance of user-centered design in the development of healthcare technologies. The authors suggest a process for user-centered design that includes user research, prototyping, testing, and evaluation. The authors also provide a detailed discussion of the technical challenges involved in developing a voice monitoring system, such as speech recognition and data processing, as well as recommendations for overcoming these obstacles. A study led by [63] investigates dementia patients, their caregivers, and healthcare providers' physical, psychological, and social needs. The study employed a user-centered design method, which included semi structured interviews, workshops, and smart home trials. The findings of this study demonstrate how this methodology can help uncover psychosocial and contextual factors, as well as help to develop more patient-centered interventions. The authors suggest that their findings can be incorporated into clinical practice as well as public health strategy to develop patient-centered interventions. Another study by [32] outlines a user-centered strategy for creating smart home solutions that puts an emphasis on creating home automation systems that meet users' needs and expectations. The authors develop scenarios to better understand user needs and behaviors as well as to point out areas where smart home technology can benefit users in their day-to-day activities. The study found that user-centered design can produce smart home systems that are more efficient and user-friendly, and that it is essential to incorporate user feedback throughout the design process to produce solutions that satisfy their needs.

User-centered AI monitoring systems have the potential to transform the health industry by providing personalized health monitoring and support to patients without interfering with their privacy. Incorporating user-centered design principles in the development of these systems is crucial to ensure that they are effective, usable, and accessible. User-centered design methodologies have been successfully employed in various healthcare technologies, such as mobile health (mHealth) apps for chronic pain management, voice monitoring systems for disorder prevention, and smart home solutions for dementia patients. As shown in Fig. 6 these methodologies involve user research, prototyping, testing, and evaluation, which uncover psychosocial and contextual factors and help to develop more patient-centered interventions. Incorporating user feedback throughout the design process can produce solutions that satisfy user needs and preferences and are more efficient and user-friendly. Understanding the needs, preferences, and behavior of users is critical to the success of these technologies, and incorporating user feedback throughout the design process can produce solutions that satisfy user needs and preferences. As healthcare technologies continue to advance, incorporating user-centered design principles will be essential to develop patient-centered interventions that improve patient outcomes and experiences.

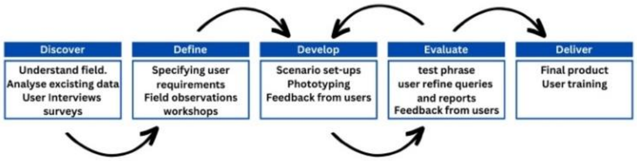

Fig. 6. Collaborative AI system build through a user-centered approach.

IV. Challenges and Opportunities of AI-Driven Monitoring Systems in Smart City Healthcare

A. Challenges

The development and deployment of user-centered AI monitoring systems in smart health is a complex process that is faced with some significant challenges. The main challenges are highlighted here including data privacy and security, data quality and availability, interoperability, clinical validity and user acceptance.

1) Data privacy and security: Health data is highly sensitive and personal information that must be protected.

Ensuring the privacy and security of health data is a major challenge in the development and deployment of user-centered AI monitoring systems [32]. AI systems have a significant and ongoing security challenge due to the complexity of the data and increasing frequency of network attacks. Security faults, for example, an area of concern since medical data, which is gathered by different types of sensors, is subject to errors. These faults can make it challenging to understand or diagnose the patient's condition. Furthermore, real-time monitoring necessitates a fast and dependable network connection, which can be difficult to achieve in rural areas and on low-power systems [33].

2) Data quality and availability: For AI monitoring systems to be effective, they must be trained on high-quality data. Health data consisting of doctors' notes, observations, results of pathology, radiology images, and signals are typically not very extensive and can be challenging to access [64], [65]. A significant challenge is ensuring that the data used to train AI systems is accurate, up-to-date and widely available.

3) Interoperability: AI monitoring systems must be able to integrate with existing health IT systems to be useful [66]. This necessitates that the systems exchange data and communicate with one another in a seamless manner. Ensure that AI monitoring systems are interoperable with existing health IT systems can be difficult, especially in environments where different systems use different data standards.

4) Clinical validity: For AI monitoring systems to be effective in clinical settings, they must be able to provide accurate and reliable information. This necessitates system validation and the accuracy and dependability of the results [64], [67]. It is crucial to ensure AI monitoring systems are clinically valid, especially in the health sector since inaccurate diagnosis and treatment can have severe consequences.

5) User acceptance: AI monitoring systems must be usable and provide transparency to end-users to be effective (Miotto et al., 2017). This includes ensuring that the systems are user-friendly and that users trust the information that they provide [60], [61]. Ensuring that AI monitoring systems are acceptable to end-users can be challenging, particularly in the context of health where users may be concerned about the reliability of the information provided.

6) Trust: The success of user-centered AI monitoring systems in smart health greatly depends on building trust with the users. Users will not accept the results of AI systems if they do not trust the system [68].

Despite of these challenges, the development and deployment of AI-based monitoring systems for smart health remains a significant area of research and development. Identifying and addressing these challenges can help develop user-centered AI monitoring systems in smart health that are effective, usable, and trustworthy, improving patient health.

B. Opportunities

AI-driven monitoring systems have made a substantial impact on people's lives, attracting the interest of researchers. Although there are several challenges in the development and deployment of AI-based monitoring systems there are also numerous advantages, such as personalized Health Monitoring, the delivery of remote diagnosis and treatment, and the collection of real-time data without interfering with regular activities. The opportunities are demonstrated in this section.

1) Personalized health monitoring: These systems use AI technologies to collect, process, and analyze health-related data, allowing for personalized health monitoring and support to the users. The automatic collection of data, such as vital signs, physical activity levels, and sleep patterns, can help detect health-related issues in real-time [8], [49], [61], [69].

2) Real-time feedback: These systems can provide real-time feedback to the user, allowing them to make informed decisions about their health. They can help identify potential health risks and provide personalized health recommendations, such as lifestyle changes or exercise regimens, to help improve overall health [3], [32], [61].

*3) Non-intrusive monitoring***:** User-centered AI monitoring systems in smart health are designed to be non-intrusive, allowing users to monitor their health without interference with their daily activities [33].

4) Improved health outcomes: These systems can help individuals manage their health more effectively and make lifestyle changes to improve overall health outcomes. By providing real-time feedback and personalized health recommendations, these systems can help individuals make informed decisions about their health and well-being [26], [59].

5) Increased access to health services: User-centered AI monitoring systems in smart health can help increase access to health services for individuals in remote or underserved areas. By allowing for remote monitoring and analysis of health-related data, these systems can help bridge the gap in access to health services for these individuals [3], [33].

6) Increased efficiency and reduced costs: The use of AI technologies can help streamline healthcare processes and reduce costs. By automating the collection and analysis of health-related data, these systems can reduce the need for manual data entry and analysis, saving time and resources [3], [26], [70]-[72].

The current research indicates that while user-centered AI monitoring systems hold significant potential for transforming the healthcare industry, there are also certain challenges related to their development and deployment. One of the key challenges is making sure the system is user-friendly and simple to use, as many patients may be intimidated by technology [61]. Furthermore, there are privacy and security concerns associated with the collection and storage of health-related data that must be addressed for these systems to be safe and secure to use [33]. Other concerns include Clinical Validity, Data Quality and Availability and Interoperability of these systems. However, there are some great opportunities in developing and deploying user-centered AI monitoring systems in smart health. One of the main advantages of these systems is their ability to provide users with real-time feedback, allowing them to make informed health decisions [3]. Furthermore, these systems can offer personalized health recommendations, such as lifestyle changes or exercise programs [69] to assist users in improving their overall health.

V. Future Directions for User-centered AI Monitoring in Smart Health

Within this section, potential future directions will be presented regarding the challenges related to developing and implementing user-centered AI monitoring systems in the context of smart health. An overview of the challenges along with the possible future directions is illustrated in Table II.

TABLE II. Overview of Challenges and Possible Future Directions

Challenges	Examples	Potential future directions
Data Privacy and Security	Health data is highly sensitive and must be protected from security faults, such as sensor errors.	Invest in strong security measures, such as encryption, secure communication, and monitoring for breaches and unauthorized access.
Data Quality and Availability	Ensuring that data used to train AI systems is accurate, up-to-date and widely available.	Invest in data infrastructure that makes obtaining, storing, and managing health data easier.
Interoperability	AI monitoring systems must integrate with existing health IT to exchange data and communicate.	Follow common data standards and invest in tools that make integrating AI monitoring systems with existing health IT systems easier.
Clinical Validity	Ensure AI monitoring systems are clinically valid.	Invest in research and validation of AI monitoring systems to ensure they continue to provide valid and trustworthy information.
User Acceptance	AI monitoring systems must be usable and provide transparency.	Involve end-users in AI monitoring systems to ensure usability and trust. Education and training are needed to promote adoption.
Trust	Users must trust the system to accept the results of AI systems.	Develop user-friendly systems that provide accurate and reliable health-related data and are transparent in their operation.

It is critical to implement strong security measures to protect health data to address the challenge of data privacy and security. This can include employing encryption and secure communication protocols, as well as monitoring for breaches and unauthorized access on a regular basis. Furthermore, it is critical to be transparent about the use of health data and to obtain patient consent before using their data for AI training or monitoring. Data Quality and Availability are other critical factors to consider when developing high-quality AI monitoring systems. To tackle these issues, it may be necessary to invest in data infrastructure that makes obtaining, storing, and managing health data easier. Furthermore, health data sharing may be necessary to encourage the development of high-quality monitoring AI systems. As a solution to the interoperability challenge, it may be necessary to adopt common data standards and invest in tools that make integrating AI monitoring systems with existing health IT systems easier. Furthermore, it is critical to foster open communication and information sharing among different organizations to ensure that AI monitoring systems can work seamlessly with existing health IT systems. The challenge of clinical validity can be addressed by investing in the research and validation of AI monitoring systems. Additionally, ongoing monitoring and evaluation of the systems is required to ensure that they continue to provide valid and trustworthy information. User acceptance is an important factor that can determine the success of user-centered AI monitoring systems in smart health. To address this issue, we must ensure that end-users are involved in the design and development of AI monitoring systems. This can include user testing and gathering user feedback to ensure that the systems are usable and that users trust the information provided. Furthermore, education and training may be required to promote widespread adoption of AI monitoring systems. Finally, building trust with the users is a critical factor in the success of user-centered AI monitoring systems in smart health. To build trust, these systems must be user-friendly and easy to use, and provide accurate and reliable health-related data. Additionally, the systems must be transparent in their operation and provide clear explanations for the health recommendations provided to the user.

User-centered AI monitoring systems in smart health hold significant potential for transforming the healthcare industry by providing real-time health monitoring and support to patients. User-centered AI monitoring systems are designed to improve the patient experience in healthcare by using technology to collect and analyze data from patients. These systems use artificial intelligence algorithms to monitor patients and provide real-time information about their health status. However, careful consideration must be given to the design and deployment of these systems to ensure that they are user-friendly, secure, and provide accurate and reliable health-related data. By addressing these challenges, it is possible to develop user-centered AI monitoring systems in smart health that are effective, usable, and trustworthy, thereby improving patient health outcomes.

VI. Discussion and Conclusion

In recent years, smart health technologies have been gaining popularity as a means of providing high-quality patient care, including user-centered AI monitoring services. These systems hold great potential to transform the health industry by providing real-time health monitoring and support to patients. Based on the results of this research paper, there appear to be several key factors that need to be addressed when developing user-centered AI monitoring systems for smart health. These include data protection and security, data quality and availability, interoperability, clinical validity, user acceptance, and building trust among users. This is consistent with the results of previous studies that have emphasized the importance of these factors in designing effective AI healthcare monitoring systems. The current paper differs from previous studies in that it emphasizes the importance of user-centered design and involving end-users in the development process. Although previous studies have also recognized the importance of user-centered design, this paper highlights the need to involve end users in the design and development of these systems. This suggests that there may be a need for greater collaboration between developers and end-users in the development of user-centered AI monitoring systems for smart health. The research also indicates the importance of user research, user feedback, and continuous evaluation in ensuring that these systems are developed in a manner that prioritizes the needs and preferences of users. User-centered design has been shown to produce more efficient and user-friendly health monitoring systems and incorporating user feedback throughout the development process is crucial to producing solutions that meet the needs of patients and caregivers. Overall, the findings suggest that, while user-centered AI monitoring systems have significant potential for transforming healthcare, they must be designed and deployed with care to ensure that they are effective, usable, and trustworthy. By addressing the challenges identified in this study, it may be possible to develop AI monitoring systems that are better able to support patients and improve health outcomes.

Future research in this field should focus on developing and deploying artificial intelligence (AI) technologies that can collect, process, and analyze health-related data in a secure and privacy-sensitive manner. Furthermore, research should be conducted to identify ways to increase trust in these systems, such as developing user-friendly interfaces, providing clear and transparent information about how data is collected and processed, and ensuring that the data used to train these systems is diverse and representative of the population it is intended to serve. In conclusion, how we treat and monitor patients is impacted by the continually shifting number of devices in a smart city. As a result, developing smart devices often results in compatibility and security issues. Artificial intelligence and deep learning approaches can be used to improve the management and coordination of device data and network models to address this challenge and ensure smooth connectivity between smart devices.

***Abstract*—Forest fires are a global environmental problem that can cause significant damage to natural resources and human lives. The increasing frequency and severity of forest fires have resulted in substantial losses of natural resources. To mitigate this, an effective fire detection and monitoring system is crucial. This work aims to explore and review the current advancement in the field of forest fire detection and monitoring using both drones or unmanned aerial vehicles (UAVs), and deep learning techniques. The utilization of drones fully equipped with specific sensors and cameras provides a cost-effective and efficient solution for real-time monitoring and early fire detection. In this paper, we conduct a comprehensive analysis of the latest developments in deep learning object detection, such as YOLO (You Only Look Once), R-CNN (Region-based Convolutional Neural Network), and their variants, with a focus on their potential application in the field of forest fire monitoring. The performed experiments show promising results in multiple metrics, making it a valuable tool for fire detection and monitoring.**

Keywords—Forest fire; deep learning; drones; unmanned aerial vehicles; object detection; YOLO; Faster R-CNN

I. Introduction

Forests are critical for our planet. They regulate our climate, purify our air and water, and are home to countless plants and animals. Sadly, forests around the world are under real threats from climate change, deforestation, and other human activities. One of the most devastating impacts on forests are wildfires. More recently, forest fires have become an annual phenomenon across the world. Statistics show that millions of acres of forests are yearly burnt. This has caused tremendous loss of forest resources, major economic damages to forest organizations, and lives of humans and animals. The rise in wildfires is largely attributed to climate change. Warmer temperatures and drier conditions make it easier for fires to start and spread. When a wildfire starts, it can spread quickly through the entire forest. Wildfires can have a significant impact on the environment and the economy. They can permanently damage forests, which can take years to be restored. In addition, wildfires can result in substantial financial damage as companies and industries relying on forests are compelled to shut down or move [1].

A wide range of techniques are used to detect and monitor forest fires, mainly we retain two main techniques based on sensors and imagery. The first one is based on deployed sensors that can detect environmental measurements such as temperature, humidity, gas levels, etc. These sensors, which may be strategically positioned throughout the forest, will notify authorities if they detect any fire. The second technique is imagery-based; it uses images coming from fixed cameras, satellites, or drones. It provides authorities with a bird-eye view of the fire and its precise location [2, 3].

Recently, with the great advances in deep learning (DL) and its applications, new opportunities are available to the problem-solving of computer vision in the field of forest fires monitoring. We remind that the traditional approach uses only visual analysis of images taken by satellites or aerial cameras. The existing system only detects wildfires within the camera view; it cannot identify the exact location of the fire [4]. This gap led us to propose, in this paper, an automated system that helps identify potential forest fires using object detection algorithms, such as YOLO (You Only Look Once) and R-CNN (Region-based Convolutional Neural Net-work).

The rest of this paper is organized as follows: The Section II presents the background of our research; the Section III gives a detailed overview of related works; the Section IV describes our proposed method; and before concluding this work, the Section V presents the obtained results and the discussion of the efficiency of our proposed system.

II. Background

A. Computer Vision (CV)

The biological vision is an inspiring model for computer vision. The mammalian visual system can decipher a complex scene in an instant, sophisticated enough to distinguish, ripe fruit from a poisonous berry, or fire from the sun. Similarly, computer vision is an emerging field that is rapidly evolving, making significant progress in recent years.

In general, computer vision is concerned with the automatic extraction, analysis, and understanding of information from images. This can be a difficult task, as images are often cluttered and contain complex noises. However, recent advances in ma-chine learning have allowed for significant progress in this area. For example, deep learning (a subset of machine learning) is a powerful technique that has been used to achieve amazing results in computer vision [5].

There are many different applications of computer vision, including object recognition, face detection, and scene understanding [6].

B. Deep Learning (DL)

Deep learning, inspired by the brain, allows a computer to deeply learn from data by creating relevant large neuronal network models [7].

Deep learning is a relatively new field of machine learning, and it is already having a major impact. It is used in a variety of applications, including image recognition, speech recognition, and natural language processing [8].

Deep learning is a powerful tool that can be used to solve many complex problems. However, requires an important processing power and a large amount of data in order to train fast its models and learn effectively [9].

C. Object Detection

Object detection is the task of detecting instances of objects in an image, regardless of their position or orientation. This can be a very difficult task, as there can be a great deal of variation in the appearance of objects. For example, two different people can have very different opinions on what constitutes a "tree". Despite this challenge, object detection is a very important task in many applications, such as security, car self-driving, and robotics. In addition to detecting objects in an image, CV can also be used in following their movement. This is very helpful in keeping track of people or vehicles in a security system, or in avoiding obstacles for autonomous vehicles. There are many different types of techniques for object detection, but one of the most popular ones are those DL-based. DL is able to learn from both unstructured and unlabeled data. This makes it ideal for object detection, as it can learn to identify objects from a variety of different sources [10]. Furthermore, one of the advantages of deep learning for object detection is that it can learn to identify objects that are not easily detectable by humans. For example, deep learning can be used to detect objects in images that are blurry or have low contrast. Additionally, it can be used to detect objects that are occluded or partially hidden. Another advantage of deep learning for object detection is that it can learn to identify objects from a variety of different views. This is helpful because it means that the object detector will be more robust and will be able to identify objects even when they are not perfectly visible.

There are a few different object detection models that are popular among developers and researchers [11], including YOLO, and Faster R-CNN models. Each of these models has its own strengths and weaknesses. Object detection algorithms can be broadly classified into two categories: one-stage and two-stage. One-stage algorithms detect objects in a single step, whereas two-stage algorithms divide the process into two phases. The first phase uses a classifier to determine potential object positions, and the second phase employs a region proposal method to pinpoint the objects' most probable locations, as depicted in Fig. 1. One-stage algorithms are faster but less accurate, while two-stage algorithms are slower, but more accurate. One-stage algorithms are favored in real-time scenarios where processing speed is more prioritized than accuracy, whereas two-stage ones are utilized when accuracy is of utmost importance.

The components of object detection architecture typically comprise five parts: the input, backbone, neck, dense layer, and sparse layer. The input is the image fed into the network, which is usually pre-processed for standardization such as resizing or normalization. The backbone, which is typically a pre-trained convolutional neural network, extract features from the input image. The neck combines the extracted features from the backbone. The dense layer is a fully connected layer that generates the final object detection results using the combined features from the neck. The Sparse layer performs similarly to the dense layer, with one key difference: its connections are sparse, meaning that not every neuron in the current layer is linked to every neuron in the prior layer. This architectural design is often used to optimize neural network performance by reducing the number of parameters and improving computational efficiency. The Sparse layer is commonly employed in feature extraction and object detection tasks, and it also outputs the final object detection results.

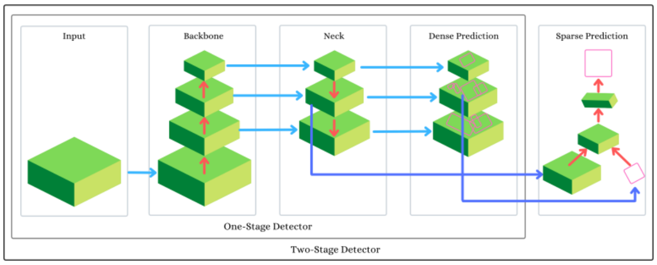

Fig. 1. Object detection architectures: one-stage and two-stage approaches.

1) R-CNN (Region-based CNNs) and its variants: R-CNN (Region-based Convolutional Neural Network) and its variants are a family of deep neural network architectures for image classification and object detection [12, 13]. R-CNN was originally proposed for object detection in natural images. The main idea of R-CNN is to use a CNN to process a region of an image, extract features from it, and then classify it. The R-CNN architecture has been successful in many object detection tasks, including detecting objects in both natural images and video.

Variants of R-CNN include Fast R-CNN [14] and Faster R-CNN [15]. Fast R-CNN is an improvement over R-CNN that uses a Region Proposal Network (RPN) to propose regions, rather than using a sliding window. Faster R-CNN is an even further improvement that shares convolutional layers between the RPN and the classifier, resulting in even faster performance [16].

2) YOLO (You Only Look Once): The YOLO object detection system is a widely used method for detecting objects in images and videos, originally created by Joseph Redmon and Ali Farhadi [17, 18]. YOLO is a real-time object detection system that is fast and accurate. YOLO has been used in a variety of applications and is considered to be the best of object detection systems of the literature.

YOLO is a deep learning model that is able to effectively identify objects in images and video frames. This is done by first partitioning an image into a set of grid cells, and then using a specially designed neural network to predict the bounding box coordinates and class probabilities for each cell.

YOLO is constantly being improved and its new versions are being released. The first version, YOLOv1, was released in 2016. YOLOv2 was released in 2016. YOLOv3 was released in 2018. YOLOv4 was released in 2020. YOLOv5 was released in 2021. And the latest YOLOv6 [19], YOLOv7 [20], and YOLOv8 [21] (v6 and v7 released in 2022, and v8 released in 2023), included further improvements in terms of accuracy, speed, and they introduced a new segmentation pipeline.

III. Related Works

Zheng et al. [22] worked on the classification of dynamic scenes to facilitate the process of detection and tracking of objects and thus improve the performance of visual surveillance. The proposed model, Bi-heterogeneous convolutional neural network (Bi-CNN), extracts spatial and temporal information from the video sequences to categorize them. The model was trained and tested on a dataset composed of drone videos. They achieved a mean accuracy of 93%.

Jiao et al. [23] proposed a model based on YOLOv3 that can be deployed in architecture using UAVs. The developed platform is presented with all the technical choices of the UAV and the analysis station. The DL model is therefore deployed on a ground station. They were able to achieve a speed of photo transmission of 3.2 images per second with a fire recognition rate of 83%. The same authors, in a second work [24], upgraded the equipment used to reach a transmission speed of 30 frames per second and an accuracy of 91%.

Lohit et al. [25] used object detection to solve a post-fire problem related to reforestation. The authors use a drone equipped with a Raspberry Pi board on which deep learning models are deployed. A comparative study is performed between the models DenseNet121, Resnet152, and MobileNetv2. The dataset used is composed of UAV images, UAV Dataset (from Kaggle), and Open-source photos. The best results were obtained when using the model DenseNet121 with an accuracy of 93.1%.

Wang et al [26] initially chose the YOLOv4 object detection architecture as the neural network's backbone. Due to the large number of parameters, heavy computational load, and significant memory requirements, this model is not suitable for implementation on embedded development kits with limited computational power. As a result, they replaced the YOLOv4 model's backbone with a MobileNetV3 model to create an initial lightweight YOLO + MobileNet model and reduce the number of parameters in the model as well as the computational load. The model was then further compressed by removing redundant parts of the proposed network structure. Finally, using knowledge distillation, they improved the detection accuracy of the compressed model and obtained the final model.

Yanık et al. [27] presented a new drone-based architecture for smoke and fire recognition tasks in low-cost forests equipped with image processing and object detection capabilities. To do so, they used a drone equipped with a Raspberry on which a lightweight deep learning model based on MobileNet is deployed. The study focuses on the issue of battery consumption in order to increase the number of flight hours of the UAV. The proposed model "ssdlite mobilenet" is tested on four variants of parameters related to the number of images in the training and testing phases on the COCO dataset.

However, most of the time, object detection systems tend to be inaccurate and inefficient for detecting potential forest fires when image quality is bad or when the fire area is relatively small. As such, an accurate and efficient object detection system is required to detect potential forest fires from images or videos immediately. In this paper, we propose an automated system that uses an object detection technique to detect potential forest fires and quickly alert the appropriate authorities. In this way, they can rapidly respond to such crises and reduce the impact of the fire on forests.

IV. Proposed Method

According to the above research works, computer vision-based methods provide improvements over traditional methods. This is where our research comes in, we propose an automated system to detect fire in forests by using drones. The drone is equipped with a high-resolution camera, which films the area to be inspected for fire hazards. Video from the Drone's camera is transferred to an object detection system. The object detection system uses different techniques to automatically detect potential forest fires from a video. The coordinates of the detected fires are then transferred to the Geographic Information System (GIS). The GIS then creates a map of the detected fires and sends the map to the fire department. The map shows the location of the fire and the drone's current location. The fire department then sends a fire patrol to this location. The drone continues to film the area and continues to send videos to our system. The object detection system keeps following the fire and sending the updated fire location to the GIS. The GIS then updates the map and sends it to the fire department. The Fire patrol is then able to follow the fire and put it out (see Fig. 2).

The methodology proposed consists of five key steps, outlined in Fig. 3.

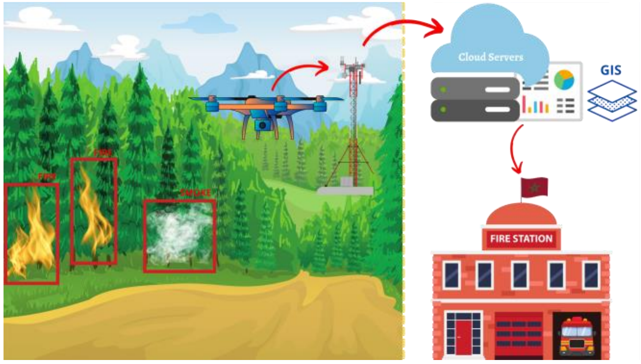

Fig. 2. Proposed architecture.

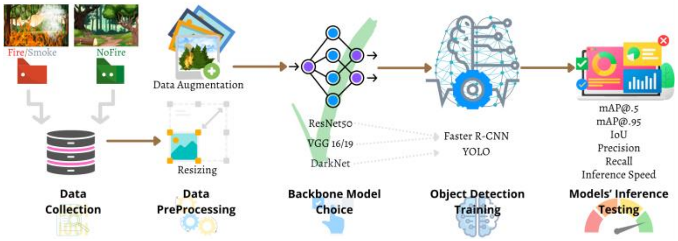

Fig. 3. Proposed method.

A. Dataset Collection

The first step in our proposed method is to collect a dataset of images containing forest fires. Our dataset (after data augmentation) reaches a total of 4236 images with the labels Fire and Smoke. These photos were taken with both ground-level cameras and aerial drones. The ground cameras were used to capture detailed images of forest fires in real-time, providing accurate representations of the fires (some images were shot by us on the campus, see Fig. 4). Aerial drone images, on the other hand, were used to provide a broader perspective by capturing larger areas of an entire forest, allowing us to monitor the extent and size of the fire's affected area. Additionally, photos were gathered from publicly accessible datasets such as online image libraries and websites. These images, which depict real-world scenarios of forest fires, were used to further expand the dataset and provide a more diverse dataset for an effective learning.

To facilitate the labeling process, we leveraged the open-source software Label-Studio, which required significant time and effort from our project team. To streamline the task, we divided the dataset among all members, enabling us to complete the process efficiently.

It is worth noting that we have taken the necessary precautions to ensure that the images are diverse in terms of the various types of fires, fire intensities, and environments in which they occurred. This was done to ensure that the model could detect fires accurately in a variety of conditions, thus improving its performance and generalization ability.

Fig. 4. Images of the man-made supervised fires.

B. Data Preprocessing

The next step in our proposed method is to preprocess and augment the collected dataset. Preprocessing includes cropping and resizing the images to the required size (640x640), as well as converting the images to a standard format such as JPG or PNG (JPG in our case). Data preprocessing plays a crucial role in object detection and can determine the success or failure of an object detection system. By resizing the images to a standard size, we can ensure that all the data is of the same size, making it easier to work with and compare.

Augmentation involves applying various distortions and transformations to the images, such as rotations, horizontal flips, vertical flips, and random crops, to increase the variety of the dataset and make it more robust. Data preprocessing is performed to increase the available training data and improve the ability of the object detection system to recognize objects from various perspectives. Resizing and augmenting the data help to increase the chances of success in object detection.

C. Backbone Model Choice

When selecting a backbone model for object detection, we have several options to consider, including VGG-16, VGG-19, and ResNet50, which have been found to be effective in our previous research [4]. It is important to carefully evaluate the strengths and weaknesses of each model in our object detection system to determine which one performs best on our specific dataset. To do this, we can benchmark each model and compare its performance for the Faster R-CNN model. DarkNet is specifically used as the backbone model for YOLOv6, v7, and v8.

ResNet (Residual Network) is a deep learning model introduced by Microsoft Research in 2015 [28]. It is known for its ability to train very deep neural networks with hundreds or even thousands of layers, using a technique called skip connections or shortcut connections. These connections allow the model to learn residual functions, or the difference between the input and the desired output, rather than trying to learn the entire mapping from scratch. This helps to alleviate the vanishing gradient problem and enables ResNet to achieve very good performance on a variety of tasks. In this work, we will utilize three backbone combinations with the faster R-CNN architecture, including:

- C4 feature extractor: a type of feature extractor used to extract relevant information from the feature maps produced by a convolutional neural network for object detection.
- Feature Pyramid Network (FPN): a type of neural network architecture used for object detection that combines high-resolution and semantically strong features to produce a multi-scale feature representation.
- 5 levels of down-sampling (DC5): a design choice in a feature extractor where the image is down-sampled five times to produce a lower resolution version while preserving important features, making object detection easier and faster to process.

VGG was developed by the Visual Geometry Group at the University of Oxford [29], it is a convolutional neural network architecture known for its simplicity and good performance on image classification tasks. It consists of a series of convolutional and max pooling layers, followed by a few fully-connected layers. VGG-16 and VGG-19 are two variations of the VGG model that differ in the number of layers and the number of parameters.

DarkNet is a neural network framework developed by Joseph Redmon [17]. It is the basis for the YOLO object detection algorithm, which is known for its speed and real-time performance. DarkNet consists of a series of convolutional and max pooling layers, followed by multiple fully-connected layers. It is designed to be simple and easy to extend, making it a popular choice for researchers and practitioners working on object detection and other computer vision tasks [30].

D. Object Detection Training

The fourth step in our proposed method involves fine-tuning and training our object detection models on the preprocessed and augmented dataset. The dataset is split into train (70%), validation (20%), and test (10%) sets. We use a variety of models including YOLOv6, v7, and v8, and faster R-CNN (RS50 and VGG16/19). The backbone model serves as the foundation for our models. We have selected faster R-CNN as it is a more efficient and precise object detection algorithm compared to R-CNN and Fast R-CNN, and it has the capability to process complex images and learn high-level features with fast inference speed [16]. YOLO, particularly its newer versions, is also well-known for its speed and accurate results.

We train our models using labeled data, which typically consists of bounding boxes around objects in the image and information about the class of objects contained within the box. The input data for faster R-CNN is in the form of TensorFlow record (TFRecord) files, while YOLO uses TXT annotations and YAML config files. The goal of this step is to create a highly accurate and reliable model for detecting forest fires.

E. Models Evaluation

Finally, we evaluate the models' performance on the collected dataset by using the test set (10%) to assess the mean average precision and inference speed of each model. The testing phase is crucial as it enables us to measure the models' performance on previously unseen data and helps us to determine the overall efficiency of the models in detecting different types of forest fires.

V. Results and Discussions

In this section, we describe the results and discussion of our proposed method for object detection using a drone-mounted camera. To assess the accuracy of the proposed system, we have evaluated the results of object detection against a dataset of real forest fires. Moreover, the system was tested on fake and real forest fires and smokes to study the robustness of the proposed system.

A. Hardware Characteristics

The experimental setup used in this work consisted of a drone (DJI Mavic Air) equipped with a high-resolution camera, a computer, and the proposed object detection system. To run the proposed object detection model, we used a high-performance computing machine with the following hardware specifications:

- Two Intel Gold 6148 (2.4GHz/20-core) processors.
- Two NVIDIA Tesla V100 graphics cards, each having 32GB of RAM.

B. Evaluation Metrics

There are a variety of different metrics that can be used to evaluate the performance of an object detection algorithm, including:

1) Average Precision (AP): It is a fairly straightforward metric that simply measures the average precision of the detector across all classes. This is a good metric to get a general idea of how well the detector is performing. However, it doesn't give any insight into how well the detector is performing in specific classes. AP is calculated by first computing the precision-recall curve for a given set of detections, then taking the average of the precision values at regularly spaced recall levels. Given a set of detections [31], the formula for average precision (AP) is:

$$AP = \sum_{k=0}^{k=n-1}[Recalls(k) - Recalls(k+1) * Precisions(k)] \quad (1)$$

Where Recalls(n)=0, Precisions(n)=1, and n=Number of thresholds.

2) Mean Average Precision (mAP): It is a more sophisticated metric that takes into account the precision of the detector in each class. This is a good metric to get a more detailed picture of how well the detector is performing. However, it can be more difficult to interpret than AP. The mAP metric is usually reported at several confidence thresholds (e.g., 0.5, 0.95). The formula for mean average precision (mAP) is:

$$mAP = \frac{1}{N}\sum_{i=1}^{N} APi \quad (2)$$

Where APi is the Average Precision of class i and N is the number of classes.

3) Intersection over Union (IoU): It is a metric that measures the amount of overlap between the detected object and the ground truth object. This is a good metric to make sure that the detected object is a good match for the ground truth object. However, it can be more difficult to be interpreted than AP or mAP. Given two rectangles, with coordinates (x1, y1, x2, y2) and (x3, y3, x4, y4), the formula for Intersection over Union (IoU) is:

$$IoU = \frac{(Area\ of\ Intersection)}{(Area\ of\ Union)} \quad (3)$$

$$Area\ of\ Intersection = (min(x2, x4) - max(x1, x3)) * (min(y2, y4) - max(y1, y3)) \quad (4)$$

$$Area\ of\ Union = (x2 - x1) * (y2 - y1) + (x4 - x3) * (y4 - y3) - Area\ of\ Intersection \quad (5)$$

In general, AP is the primary metric used to measure the performance of an object detection model. However, mAP is also commonly used as it provides a more thorough overview of the model's performance. IoU is used as a complementary metric to provide insights into how well the model is doing in terms of localization.

C. Evaluating the Results

In this study, several object detection models were evaluated for their performance in detecting forest fires and smoke. The models included Faster R-CNN (with different backbone networks) and YOLO models (v6, v7, and v8 with different architectures and computational requirements) trained on a dataset of forest fire and smoke images; we trained the Faster RCNN models over 500000 iterations and 1000 epochs for the YOLO models. The models were trained and evaluated using several metrics, including mAP at 0.5 and 0.95 IoU thresholds, recall, and precision. The inference time (s/image) was also measured on two Nvidia Graphics cards V100.

The YOLO models v6, v7 and v8 although they appeared successively in time, they are not necessarily progressively improved versions, and the meaning of (n) is nano, (s) is small, (l) is large model, and (x) is extra-large model (in the case of YOLOv7; this model does not provide a large version). The nano (n), small (s), and large (l) variations of the YOLO models have different numbers of layers and parameters, which can affect their accuracy and inference time.

Table I summarizes the achieved results for the implemented models on the testing set. The Faster R-CNN models with the ResNet-50 (RS50) and Feature Pyramid Network (FPN) backbones showed the best performance, with the Faster R-CNN (RS50) FPN achieving a mAP@0.5 of 90.57% and a mAP@0.95 of 80.34%. This model also had the lowest inference time among the Faster R-CNN models, with an average of 0.0281 seconds per image. On the other hand, the YOLO models showed slightly lower performance compared to the Faster R-CNN models, with YOLOv8n achieving a mAP@0.5 of 89.45% and a mAP@0.95 of 79.28%. However, the YOLO models had a much lower inference time, with YOLOv8n having an average of 0.0011 seconds per image.

Fig. 5 to 10 shows the performance of Faster R-CNN (RS50) FPN and YOLOv8n over iterations on the validation set. These figures show that both models achieved a relatively stable performance over iterations, with Faster R-CNN (RS50) FPN achieving a higher mAP@0.5 and mAP@0.95, and YOLOv8n having a lower loss.

However, the YOLO models performed well in terms of inference time, with YOLOv6n, YOLOv8n, YOLOv8s, and YOLOv8l having an inference time of fewer than 0.0011 seconds per image. This makes YOLO a good choice for real-time applications such as drone data, where fast processing speed is essential. The Fast-RCNN (RS50) C4, Fast-RCNN (RS50) DC5, and Fast-RCNN (VGG19) models also showed good results, however, the processing speed was higher compared to YOLO models.

In sum, the choice between YOLO and Faster RCNN models for the task of forest fire detection would depend on the desired trade-off between accuracy and processing speed. For applications that prioritize high accuracy, the Faster R-CNN models, particularly the Faster R-CNN (RS50) FPN model would be the best choice. On the other hand, for real-time applications that require fast processing speeds, the YOLO models, particularly YOLOv8n, would be the best option (Fig. 11).

In conclusion, the choice between YOLO and Faster RCNN models for the task of forest fire detection would depend on the desired trade-off between accuracy and processing speed. For applications that prioritize high accuracy, the Faster RCNN models, particularly the Faster RCNN (RS50) FPN model, would be the best choice. On the other hand, for real-time applications that require fast processing speeds, the YOLO models, particularly YOLOv8n, would be the best option (Fig. 10).

TABLE I. ACHIEVED RESULTS FOR THE IMPLEMENTED MODELS (ON THE TESTING SET)

Model Name	**mAP@0.5 %**	**mAP@0.95 %**	**IoU %**	**Recall %**	**Precision %**	**Inference time (s/image)**
Faster R-CNN (RS50) C4	89.32	79.12	89.36	90.31	89.17	~0.0553
Faster R-CNN (RS50) DC5	89.16	78.96	88.15	89.74	88.96	~0.1374

VI. Conclusion

Forests are of utmost importance to maintain the balance of the ecosystem and provide various ecological, social and economic benefits. However, the increasing frequency and severity of forest fires pose a significant threat to the sustainability of forests and their functions, making early detection and prompt actions critical for limiting the damages. The use of drones fitted with sensors and cameras presents a cost-effective and efficient solution for detecting fires in real-time. The proposed method consists of four major steps, including video recording, object detection, GIS mapping, and fire department notification, to provide an efficient and cost-effective solution for real-time monitoring and early fire detection. This study conducts an extensive evaluation of the recent advancements in deep learning object detection techniques, including YOLO, Faster R-CNN, and their variants, with a specific emphasis on their suitability for forest fire monitoring. Based on the experimental findings, these techniques exhibit positive outcomes in several metrics, thereby presenting a promising tool for detecting and monitoring fires. To select the appropriate model for detecting forest fires and smoke based on drone images, it is important to find a balance between accuracy and processing speed. For higher accuracy, the Faster RCNN model is recommended, whereas for real-time applications that prioritize speed, the YOLO model, particularly the YOLOv8n version, is the better choice with a mAP@0.5 of 89.45%, a mAP@0.95 of 79.28% and an inference time of almost 0.0011 seconds per image.

As part of our upcoming tasks, we are currently exploring the utilization of thermal images captured by UAVs. Additionally, we are examining the individual contributions of each RGB layer during model training to effectively decrease the overall number of parameters.

ACKNOWLEDGMENT

This work is supported by the Mohammed First University under the PARA1 Program (Low-cost, real-time Forest Fire Detection System based on Wireless Sensor Networks - SDF-RCSF). And the computational resources of HPC-MARWAN are provided by the National Center for Scientific and Technical Research (CNRST), Rabat, Morocco.

Information Science Department, Saga University, Saga City, Japan

Abstract—**Method for frequent high resolution of optical sensor imagery data acquisition from satellite-based SAR (Synthetic Aperture Radar) image for disaster mitigation is proposed. The proposed method is based on Generative Adversarial Network: GAN-based super resolution and conversion method from a SAR imagery data to the corresponding optical sensor imagery data in order to increase observation frequency. Through experiments, it is found that it is possible to convert SAR imagery data to the corresponding optical sensor imagery data and also found that the spatial resolution of SAR imagery data is improved remarkably. Thus, initial stage of disaster (small scale of disaster) can be detected with resolution enhanced optical sensor imagery data derived from the corresponding SAR imagery data which results in prevention of secondary occurrence of relatively large scale of disaster. It is also found that 2.5 m of spatial resolution of optical sensor imagery data can be acquired every 2.5 days in the case that only Sentinel-1/SAR and Sentinel-2/MSI (Multi Spectral Imager) are used, for instance.**

Keywords—Frequent observation; Synthetic Aperture Radar: SAR; super resolution; Generative Adversarial Network: GAN; GAN-based conversion of images

I. Introduction

The purpose of this research is to detect relatively small-scale weather caused disaster (an initial stage of disaster) such as landslide disaster, slope failure, flood, road submergence, sediment disaster, etc. for mitigation of a secondary occurrence of relatively large scale of disaster. For this purpose, observation frequency and spatial resolution are key issues.

In case of weather caused disaster, optical sensor data cannot be acquired due to weather conditions, rainy and cloudy nevertheless it is easy to detect disaster areas in the optical sensor images. On the other hand, SAR imagery data can be acquired in such weather conditions it is not so easy to detect disaster areas in the SAR imagery data though. Also, SAR imagery data can be acquired in nighttime. Therefore, observation frequency of SAR sensors is much higher than that of optical sensors. Furthermore, there are a variety of spatial resolutions of optical and SAR sensor data. High spatial resolution of sensor data is required for an initial stage of the disaster detection.

The method proposed here allows enhancement of the acquired SAR and optical sensor imageries using the well-known GAN[1] [1]-based Single Image Super Resolution: SISR[2] [2] and Very Deep Super Resolution: VDSR[3] [3] as well as improved super resolution [4] and also conversion of a SAR imagery data to the corresponding optical sensor imagery data [5], [6]. By combining between the optical sensor imagery data derived from the SAR imagery data and the actual optical sensor data, observation frequency is increased remarkably. Thus, frequent high resolution of optical sensor imagery data can be obtained from the SAR imagery data. This is a basic idea of the proposed method.

The proposed method is validated with satellite-based SAR and optical sensor imagery data derived from the Sentinel-1/SAR and Sentinel-2/MSI sensors. There is well reported research works on the conversion of Sentinel-1/SAR imagery data to optical sensor of imagery data through learning processes based on GAN with training samples of Sentinel-1/SAR and Sentinel-2/ MSI imagery data [7]. Before the conversion, super resolution is applied to Sentinel-1/SAR and Sentinel-2/MSI imagery data then learning processes of GAN-based conversion of SAR to optical sensor imagery data. Therefore, 10 m of spatial resolutions of Sentinel-1/SAR and Sentinel-2/MSI are improved to 2.5 m of spatial resolution with the spatial resolution enhancing factor of 4.

Meanwhile, SAR imagery data is geometrically affected by the well-known fore shortening, layover, and shadowing. Therefore, some treatments, orthographic transformation and terrain correction are required to avoid such influences. In this paper, effects of these treatments are investigated.

The following section describes the related research works followed by the proposed method. Then, experiments conducted are described followed by conclusion with some discussions.

II. Related Research Works

As for the disaster mitigation from space related previous research works, there are the following published papers,

Visualization of 5D assimilation data for meteorological forecasting and its related disaster mitigation utilizing VIS5D[4]

of software tool is demonstrated for disaster mitigation with remote sensing satellite imagery data [8]. Flooding and oil spill disaster relief using Sentinel of remote sensing satellite data is well reported [9]. Convolutional neural network considering physical processes and its application to disaster detection is proposed and validated with remote sensing satellite imagery data [10].

Present Status for Disaster Observation Systems Working Group is reported for research working group of Japan-US Space Research Cooperation [11]. Four Dimensional GIS and Its Application to Disaster Monitoring with Satellite Remote Sensing Data is proposed [12]. An Expectation to Remote Sensing for Disaster Management is announced for the United Nation and Japan-US Science/Technology and Space Application Program [13].

The Conference on GIS and Application of Remote Sensing to Disaster Management Four Dimensional GIS and Its Application to Disaster Monitoring with Satellite Remote Sensing Data is reported [14] together with the Current Status on Disaster Monitoring with Satellites in Japan [15]. Opening Remarks of Satellite Based Disaster Management is made for the Disaster Management Working Group [16].

Disaster related activities are introduced for Japan US Science and Technology as well as Asian Disaster Reducing Center [17]. Internet GIS and Disaster Information Clearing House is proposed [18]. Opening address of the disaster management symposium, United Nations Center for Regional Development is made [19] together with the Virtual center for disaster management for United Nations Center for Regional Development as well [20].

Joint Research on Disaster Management is also proposed and accepted in the United Nations, Center for Regional Development, UNCRD Headquarter [21]. Visualization of disaster information derived from Earth observation data is investigated [22]. Disaster monitoring with ASTER[5] onboard Terra satellite is proposed and demonstrated its usefulness [23].

ICT technology is for disaster mitigation in particular for Tsunami warning [24]. On the other hand, cellular automata-based approach for prediction of hot mudflow disaster area is investigated [25]. Simulation of hot mudflow disaster with cellular automata and verification with satellite imagery data is conducted [26].

Backup communication routing through Internet Satellite, WINDS[6], for transmission of disaster relief data is attempted [27]. Meanwhile, deceleration in the micro traffic model and its application to simulation for evacuation from disaster area is proposed and validated [28] together with cellular automata approach for disaster propagation prediction and required data system in GIS representations [29].

Cell based GIS as Cellular Automata for disaster spreading prediction and required data systems is proposed [30]. On the other hand, disaster relief with satellite based Synthetic Aperture Radar data is attempted [31]. Sentinel 1A SAR Data Analysis for Disaster Mitigation in Kyushu is well reported and demonstrated its usefulness [32]. Convolutional neural network considering physical processes and its application to disaster detection is proposed and validated [33].

Flood damage area detection method by means of coherency derived from interferometric SAR analysis with Sentinel-1A SAR is proposed [34]. Change detection method with multi-temporal satellite images based on wavelet decomposition and tiling is proposed in particular for disaster mitigations [35]. A comparative study of flooding area detection with SAR images based on thresholding and difference images acquired before and after the flooding is conducted and evaluated its usefulness [36].

III. Proposed Method

The proposed method uses GAN-based super resolution and conversion method from a SAR imagery data to the corresponding optical sensor imagery data in order to increase observation frequency.

The method proposed here allows enhancement of the acquired SAR and optical sensor imageries using the well-known GAN-based SISR and VDSR as well as improved super resolution and also conversion of a SAR imagery data to the corresponding optical sensor imagery data. By combining between the optical sensor imagery data derived from the SAR imagery data and the actual optical sensor data, observation frequency is increased remarkably. Thus, frequent high resolution of optical sensor imagery data can be obtained from the SAR imagery data. This is a basic idea of the proposed method.

On the other hand, VDSR is a convolutional neural network architecture designed for performing single image super-resolution processing. A VDSR network learns the mapping between low-resolution and high-resolution images. This mapping is possible because the low-resolution and high-resolution images have similar image content, differing mainly in fine high-frequency content.

VDSR uses residual learning method. This is what trains the network to estimate the residual image. In the context of super-resolution processing, the residual image is the difference between a high-resolution reference image and a low-resolution image upscaled using bicubic interpolation to match the size of the reference image. A residual image contains information about the detailed high-frequency content of the image.

The VDSR network detects the residual image from the luminance of the color image. The luminance channel Y of an image is the brightness of each pixel as a linear combination of red, green, and blue pixel values. On the other hand, the two chrominance channels Cb and Cr of the image represent chrominance information in different linear combinations of red, green and blue pixel values. VDSR is trained using only the luma channel. This is because human perception is more sensitive to changes in brightness than to changes in color. Train the VDSR network to estimate the residual image. Then you can reconstruct the high-resolution image by adding the estimated residual image to the up-sampled low-resolution image and converting the image back to the RGB color space.

[5] https://asterweb.jpl.nasa.gov/eos.asp

[6]https://ja.wikipedia.org/wiki/%E3%81%8D%E3%81%9A%E3%81%AA_(%E4%BA%BA%E5%B7%A5%E8%A1%9B%E6%98%9F)

Magnification is relative to the size of the low-resolution image of the size of the reference image. Low-resolution images especially lose information about the high-frequency content of the image, so SISR becomes even worse at higher magnifications. VDSR uses a large receptive field to solve this problem. This example trains a VDSR network using expansion by scaling by multiple factors. Augmentation by scaling allows the network to take advantage of the low-magnification image context, which improves results at high magnifications. Furthermore, the VDSR network can be generalized by accepting images with non-integer magnifications.

The proposed method is validated with satellite-based SAR and optical sensor imagery data derived from the Sentinel-1/SAR and Sentinel-2/MSI sensors. There are well reported research works on the conversion of Sentinel-1/SAR imagery data to optical sensor of imagery data through learning processes based on GAN with training samples of Sentinel-1/SAR and Sentinel-2/ MSI imagery data.

In accordance with study [7] (M. Schmitt1, L. H. Hughes1, X. X. Zhu, THE SEN1-2 DATASET FOR DEEP LEARNING IN SAR-OPTICAL DATA FUSION[7], DOI:10.5194/isprs-annals-IV-1-141-2018, License CC BY 4.0, Conference: ISPRS TCI Symposium 2018)[8], the following conversion can be done from Sentinel-1/SAR to Sentinel-2/MSI,

1) Training datasets: SEN1-2 is dataset composed of 282, 384 pairs of corresponding Synthetic Aperture Radar and optical image patches acquired by the Sentinel-1 and Sentinel-2 remote sensing satellites, respectively.

2) Methods of data evaluation: Semi-automatic download and image preparation using Google Earth Engine and MATLAB[9].

3) A dataset [10] containing 282, 384 pairs of images acquired from Sentinel-1 (SAR satellite) and Sentinel-2 (optical satellite) and matched with the surrounding topography using Google Earth Engine and MATLAB.

4) Image generation by “pix2pix”- by extracting 3964 pairs of SAR and optical images from the dataset.

5) SAR image of Sentinel-1 in the dataset is only VV polarization. Then the result of this analysis is conversion from VV polarization SAR image to RGB optical image: Image size is unified to 256 by 256.

6) Dataset Name: SEN1-2.

7) Developed in 2018.

8) Dataset structure: Top level: ROIs1158_spring, ROIs1868_summer, ROIs1970_fall, ROIs2017_winter - folders corresponding to 4 different random ROI distributions and four weather seasons Second level: s1_i, s2_i - Folders corresponding to scenes from which patches were cut. s1 indicates the Sentinel-1 SAR image and s2 indicates the Sentinel-2 optical image.

9) Dataset size: Number of files: 564,768 Storage: 44,742MB.

10) Description: SEN1-2 dataset includes Sentinel-1 and Sentinel-2. It contains 282,384 pairs of corresponding SAR and optical image patches acquired by two satellites respectively. The patches are distributed over the Earth's landmass and span all four weather seasons. This is reflected in the structure of the dataset. The SAR patch is provided with an 8-bit single-channel image representing the sigma note backscatter values in dB scale. The optical patch uses 8-bit color images representing bands 4, 3, and 2.

11) License Terms apply: The CC-BY dataset contains Copernicus data (2017)[11].

12) Data Size: as shown in Fig. 1.

ROI of region of interest and seasons are listed here in Fig. 1. There is huge volume of the satellite imagery data. Fig. 2 shows just 40 image pair of a small portion of SEN1-2 image dataset, Sentinel-1/SAR (greyscale) on the right and the corresponding areas of Sentinel-2/MSI (color) on the left side out of 842 datasets. These images are mostly farm areas, forested areas, rural areas, and the others and are used for training for GAN.

Install the following to use NVIDIA's GPU board in deep learning.

CUDA Toolkit,

Driver software for GPU board,

Libraries such as cuDNN,

Build environment for Anaconda,

Install PyTorch,

Perform processing to convert a grayscale VV polarization SAR image into an RGB optical image. The number of epochs is 100 and the mini-batch size is 128.

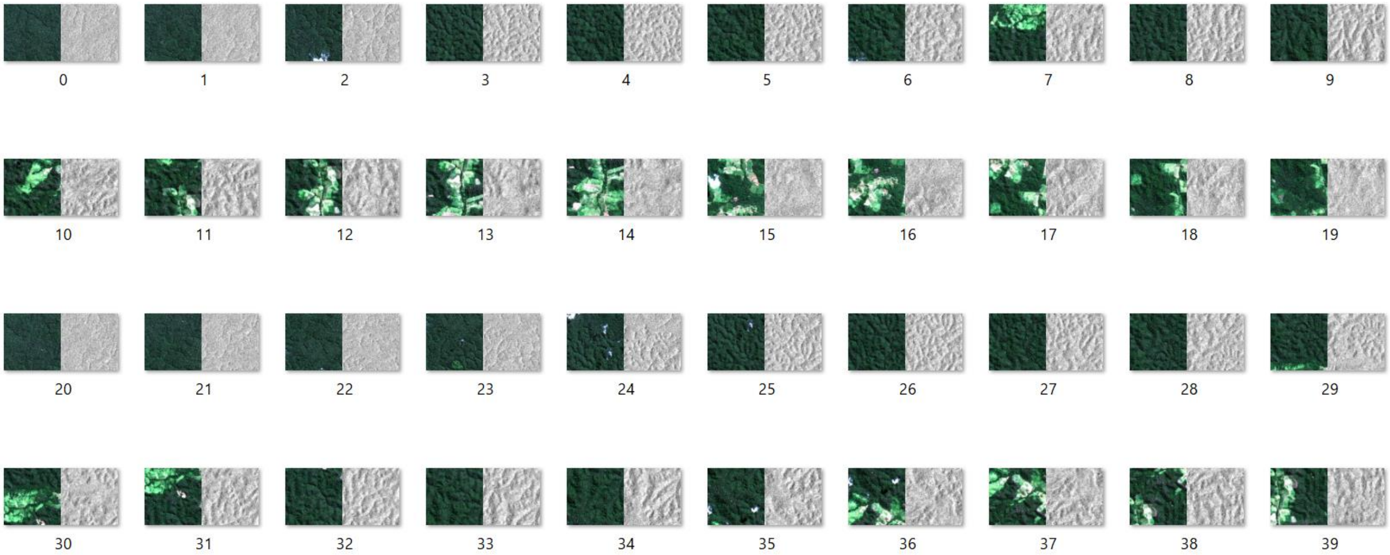

Fig. 2. Small portion of the SEN1-2 image datasets.

After the necessary datasets are read, then create a ConcatDataset class so that both SAR images and optical data can be called during training and learned. Build pix2pix Generator and Discriminator respectively. Train using loaded datasets and constructed generators and classifiers.

Before the conversion, super resolution is applied to Sentinel-1/SAR and Sentinel-2/MSI imagery data then learning processes of GAN-based conversion of SAR to optical sensor imagery data. Therefore, 10 m of spatial resolutions of Sentinel-1/SAR and Sentinel-2/MSI are improved to 2.5 m of spatial resolution with the spatial resolution enhancing factor of 4.

Without high-frequency information, the image quality of high-resolution images is limited. Furthermore, SISR is an ill-posed problem because a single low-resolution image can generate multiple candidate high-resolution images.

The residual image is the difference between the high resolution reference image and the low resolution image upscaled using bicubic interpolation to match the size of the reference image. Then CNN training the residual image is performed.

Software that rewrites only the conversion function of the image conversion software "waifu2x"[12] using Caffe and builds it for Windows using CUDA (or cuDNN) can convert faster than CPU. From the download site[13], it is possible to download the zip file of waifu2x-caffe.zip (650 MB, Source code (zip), Source code (tar.gz)).

The pix2pix is a machine learning model that generates a fake image based on the content of a certain image, whereas ordinary GANs generate fake images from random noise, in other words, image-to-image conversion. It is a model that learns the features. For learning, it is necessary to prepare a pair of an input image and a correct image.

Meanwhile, there is a learning model called pix2pixHD derived from pix2pix that learns image-to-image conversion. The differences between pix2pix and pix2pixHD include improved generators, classifiers, and loss functions. By generating a fake image with a magnification, it becomes easier to capture the local and global features of the image. Also, pix2pix used a loss function called the “L1 loss function” that learns low-frequency components, but by improving it, it became possible to generate high-resolution images.

IV. Experiment

A. Spatial Resolution Enhancement based on Super Resolution

Spatial resolution of Sentinel-1/SAR and Sentinel-2/MSI images in the SEN1-2 image dataset can be enhanced with the super resolution by the enhancing factor of 4. Fig. 3 shows just an example of the enhancement based on waif2x-caffe. Also, Fig. 4 shows the frequency components of the original and the spatial resolution enhanced image. It is obvious that the enhanced image has much high frequency components rather than the original image. Therefore, the spatial resolution of Sentinel-1/SAR and Sentinel-2/MSI can be improved by the factor of 4 which results in 10 m resolution of Sentinel-1 and 2 are to be 2.5 m of spatial resolution.

B. Generation of Optical Sensor of Imagery Data from the Corresponding SAR Imagery Data

Through the learning processes with SEN1-2 of 842 datasets of the Sentinel-1/SAR and Sentinel-2/MSI imagery data, the learning models of pix2pix and pix2pixHD are created. Therefore, optical sensor imagery data is to be created with an unknown SAR image is input. Fig. 5 shows the input SAR image and the created optical sensor images with pix2pix and pix2pixHD. For a reference, original optical sensor image is shown in Fig. 5. In Fig. 5(c), the created optical sensor images by pix2pix and pix2pixHD are shown upper and lower parts, respectively. Also, four cases of image creations are shown in Fig. 5(c) with the different epochs. 670 of training

[12] https://github.com/lltcggie/waifu2x-caffe/releases

(c) Created optical sensor images

Fig. 5. Example of images of the input SAR, actual original and created optical sensor images with pix2pix and pix2pixHD.

For the object is a forest area, there is no big difference from the correct image. In addition, when pix2pix and pix2pixHD are compared, it can be seen that pix2pixHD can obtain high resolution even with a small number of epochs.

C. *Example of Disaster Area Detection with the Trained Models of pix2pix and pix2pixHD*

Sentinel-2/MSI images were generated from Sentinel1/SAR to verify the possibility of detecting a slope failure that occurred in Sakae Village, Nagano Prefecture, using a trained model with pi2pix and pix2pixHD. Information on the slope failure area is shown below. The location is latitude, longitude 36.858234 N, 138.610001E.

Fig. 6 shows a photograph of the slope failure area. In addition, other research papers have confirmed that the slope failure caused a maximum surface displacement of 13 cm from August 2020 to May 2022 in an area of about 400,000 m^2 in the southeastern part of the landslide area.

Fig. 7 shows Google map of the slope and the location of the slope failure area and the elevation of the slope. Also, Fig. 7(c) and Fig. 7(d) show Sentinel-2/MSI and Sentinel-1/SAR images, respectively.

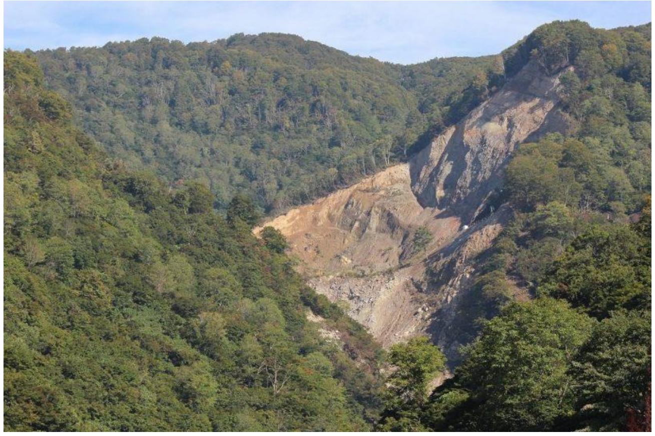

Fig. 6. Photograph of the slope failure area.

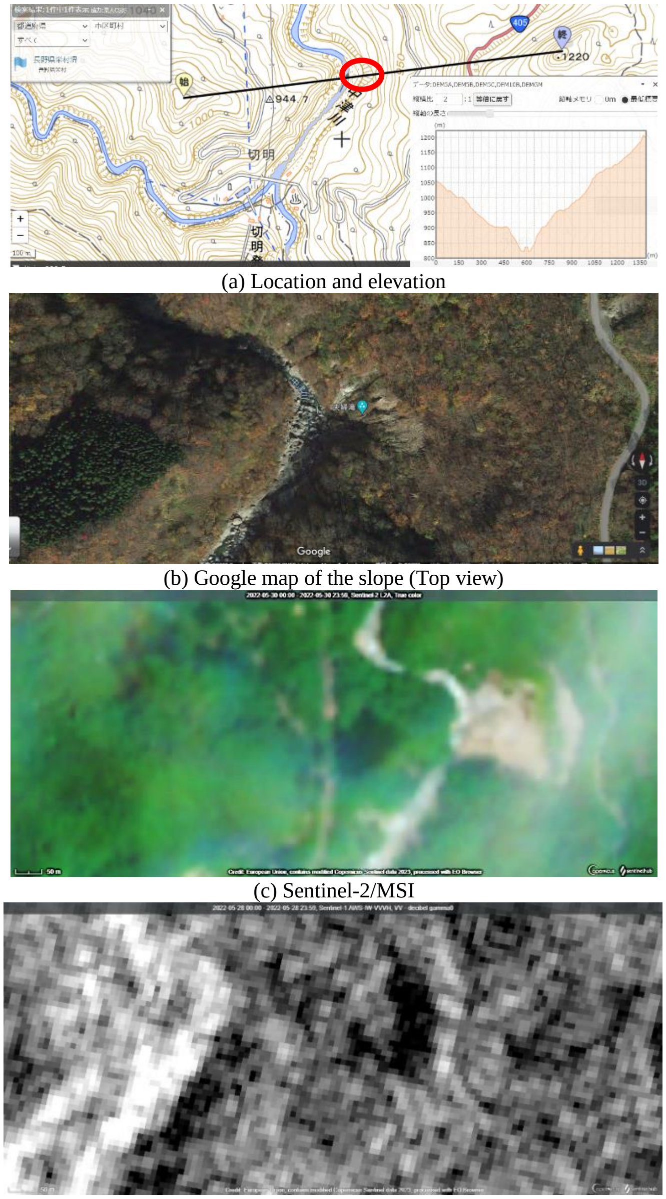

(a) Location and elevation

(b) Google map of the slope (Top view)

(c) Sentinel-2/MSI

(d) Sentinel-1/SAR

Fig. 7. Location of the slope failure area and the elevation of the slope and Sentinel-1/SAR as well as Sentinel-2/MSI images.

It is not so easy to identify the slope failure area using SAR image. Therefore, if the optical sensor image can be created from SAR image, then the slope failure area can be detected easily. The Sentinel-1/SAR of 2022/08/28 was input to the trained model with 842 image data of Sentinel-1/SAR and Sentinel-2/MSI and converted into an optical image (VV polarization) by GAN. Fig. 8 shows Sentinel-1/SAR and the created quasi-Sentinel-2/MSI images (optical sensor image).

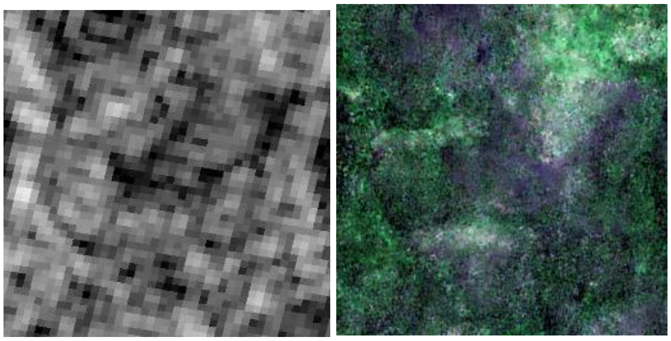

Fig. 8. Sentinel-1/SAR and the created quasi Sentinel-2/MSI images (optical sensor image) of the slope failure area.

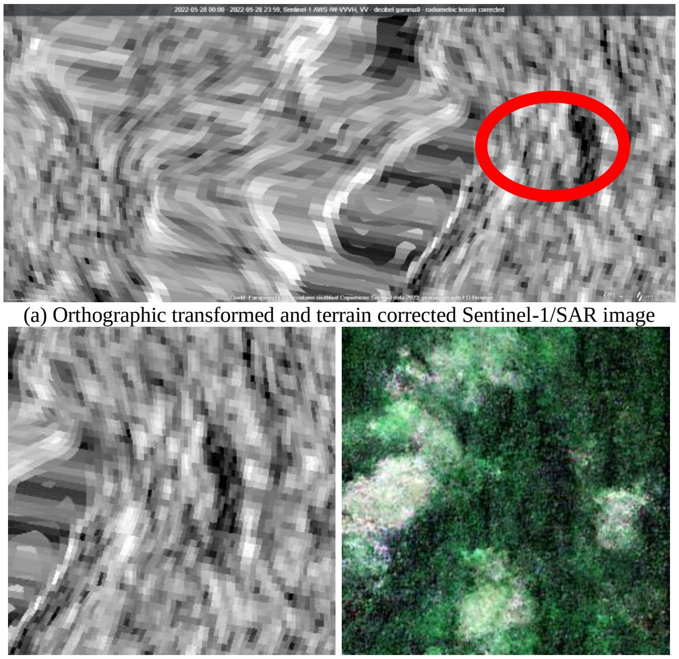
Essentially, SAR image is acquired with oblique view and has geometric distortions due to the fore shortening, layover, and shadowing. Therefore, some treatments are required to eliminate the influences of geometric distortions. That is, orthographic transformation and terrain correction are required for Sentinl-1/SAR image. Fig. 9(a) and Fig. 9(b) show the orthographic transformed and terrain corrected Sentinel-1/SAR image. By using this corrected SAR image, optical sensor image is created. The created image with pix2pixHD is shown in Fig. 9 (c).



(a) Orthographic transformed and terrain corrected Sentinel-1/SAR image

(b) Portion of Sentinel-1/SAR (c) Created optical sensor image

Fig. 9. Orthogonal transformed and terrain corrected Sentinel-1/SAR and the created optical sensor image with pix2pixHD.

From Fig. 9, the location and the area of slope failure is getting much clear in particular, Fig. 9(c) of the created optical sensor image from the SAR image.

Sentinel-1/SAR is C-band SAR and has VH and VV polarization of receiving signal (where VH stands for that transmit with vertical polarization and received with horizontal polarization), the experiments conducted for not only VV but also VH polarizations. From these experiments, the following is concluded.

1) In comparing VV and VH, the VV backscattering intensity of the slope failure part is larger than that of VH.

2) In the comparison of optical images by pix2pixHD, the VV optical image of the slope failure part is more like an optical image than that of VH.

3) Comparing the effects of orthographic transformation and terrain correction, the correction effect of VV backscattering intensity at the slope failure part is larger than that of VH.

Sentinel-1/SAR is C-band SAR and does not have HH polarization, so it cannot be compared with QPS/SAR-2[14] data of HH polarization in X band with 70 cm of spatial resolution, but it can detect slope failure parts to the same extent as VV and the effects of orthographic transformation and terrain correction are considered to be about the same.

V. Conclusion

Method for frequent high resolution of optical sensor image acquisition from satellite-based SAR image for disaster mitigation is proposed. The proposed method uses GAN-based super resolution and conversion method from a SAR imagery data to the corresponding optical sensor imagery data in order for increasing observation frequency.

Through experiments, it is found that it is possible to convert SAR imagery data to the corresponding optical sensor imagery data and also found that the spatial resolution of SAR imagery data is improved remarkably. Thus, initial stage of disaster (small scale of disaster) can be detected with resolution enhanced optical sensor imagery data derived from the corresponding SAR imagery data which results in prevention of secondary occurrence of relatively large scale of disaster.

Furthermore, it is found:

1) In comparing VV and VH, the VV backscattering intensity of the slope failure part is larger than that of VH,

2) In the comparison of optical images by pix2pixHD, the VV optical image of the slope failure part is more like an optical image than that of VH.

3) Comparing the effects of orthographic transformation and terrain correction, the correction effect of VV backscattering intensity at the slope failure part is larger than that of VH.

4) Sentinel-1/SAR is C-band SAR and does not have HH polarization, so it cannot be compared with QPS/SAR-2 data of HH polarization in X band, but it can detect slope failure parts to the same extent as VV and the effects of orthographic transformation and terrain correction are considered to be about the same.

VI. Future Research Works

Further investigation needs to be conducted on the creation of optical sensor image with the different parameters of pix2pixHD with more training datasets of spatial resolution enhanced Sentinel-1/SAR and Sentinal-2/MSI images.

AUTHOR'S PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 670 journal papers as well as 500 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html.

A Comparative Study of Twofish, Blowfish, and Advanced Encryption Standard for Secured Data Transmission

Kwame Assa-Agyei, Funminiyi Olajide
Department of Computer Science, Nottingham Trent University, Nottingham, United Kingdom

***Abstract*—Now-a-days, network security is becoming an increasingly significant and demanding research area of interest. Threats and attacks on information and Internet security are getting increasingly difficult to detect. As a result, encryption has emerged as a solution and now plays a critical role in information security systems. Many techniques are required to safeguard shared data. In this work, the encryption, decryption times, and throughput (speed) of the three most commonly used block cipher algorithms: Twofish, Blowfish, and AES were investigated using different file types. Comparison of symmetric encryption techniques of experiments on these types of algorithms uses a lot of computer resources including CPU time, memory, and battery power. Previous research has yielded diverse results in terms of time complexity, speed, space complexity, power consumption, and security. However, this research evaluated the effectiveness of each algorithm based on the following parameters: process time and speed. An application was developed for data simulation to test different file formats and for the encryption process and speed using Python 3.10.**

Keywords—Cryptography; twofish; blowfish; advanced encryption standard; throughput; data encryption; decryption

I. Introduction

Due to the increasing number of incidents in which personal data between two parties is taken by intruders, it is critical to protect data communicated over the Internet nowadays[1]. People spend so much time connected to a network that network security has become an extremely important part of data communication. These are vulnerable to security attacks such as unauthorized access to a file or alterations to its contents. One of the main reasons invaders succeed is that most of the information obtained from a system is in a form that can be read and comprehended. The solution to this dilemma is to utilize Cryptography. This is the art and science of securing information from unwanted individuals by changing it into an indiscernible form to its attackers while it is stored and transported [2]. There are numerous encryption methods that are widely available and utilized in information security. They are classified as Symmetric (private) or Asymmetric (public) Key Encryption. Only one key is needed to encrypt and decrypt data in symmetric keys encryption or secret key encryption. Asymmetric keys employ two keys: private and public keys. The public key is used to encrypt data, while the private key is used to decrypt it (e.g. RSA and ECC) [3]. A block cipher algorithm is a symmetric key cryptosystem whose security is based on sophisticated non-linear transformations and whose encryption speed is quite fast. As a result, the block cipher algorithm has evolved into a vital encryption technique that is widely utilized in applications such as secure data transfer, storage encryption, digital signing, and entity certification [4]. The primary purpose of the security mechanism is to give message privacy while also ensuring data confidentiality, integrity, and non-repetition. The primary function of network security is to enable efficient data authentication and authorization through the use of cryptographic algorithms [5]. A cryptographic algorithm is typically computationally heavy and thereby, consumes a lot of computing power such as CPU time, memory usage, and power consumption [6].

Previous research has revealed inconsistencies in the efficacy of various encryption methods. The current work analyzed symmetric (AES, Twofish, and Blowfish) cryptographic algorithms using multiple file types such as binary, text, and image files with a unique key bit size of 128. These encryption methods were compared based on three different parameters: encryption time, decryption time, and throughput. The effectiveness of each technique is demonstrated using simulation data. This study addresses the following research questions.

RQ 1: What is the performance difference between the various algorithms using a constant key bit size of 128?

RQ2: Which block cipher technique works better in the context of process time and throughput using different file types? Hence, the current study makes the following key contributions.

1) To perform an extensive evaluation of the encryption, decryption times, and speed using a unique key bit size of 128.

2) To analyze the performance using different file types.

3) To perform an extensive analysis of the performance of selected algorithms, namely: AES (Rijndael), Twofish, and Blowfish

The rest of the paper is organized as follows: Section II presents the related work. The experimental analysis and setup is presented in Section III. Section IV and V present the performance results and discussion of this research. Finally, the conclusion is drawn in Section VI.

II. Related Work

In recent years, several surveys based on various cryptographic techniques, such as the Blowfish, Twofish, and

AES algorithms, have been published. Various researchers discuss network security and cryptography challenges. This research explains and analyses earlier work in the field of data encryption to provide a broader perspective on the performance of the encryption methods.

Nema and Rizvi [7] conducted a critical analysis of various Symmetric Key Cryptographic algorithms. The objective is to identify the strengths and weaknesses of cryptographic algorithms. During the analysis, the research work observed that Blowfish was the best among all in terms of Security, Flexibility, Memory usage, and Encryption performance. Tyagi and Ganpati [8] evaluated the performance of Symmetric Key Encryption Algorithms to have a deeper understanding of the cryptography process and to perform a comparative analysis of symmetric encryption algorithms of cryptography. Blowfish algorithm runs faster than other popular symmetric key encryption algorithms: DES, 3DES, and AES. It also concluded that Blowfish gives better performance than DES, 3DES, and AES in terms of encryption time, decryption time, and throughput. 3DES has the least performance among all mentioned algorithms. The authors in [9] analysed an approach to identifying cryptographic algorithms from the cipher text. The focus of the study is to identify the performance of the cryptographic algorithm on cipher text only. The unique research work concluded that the identification rate can obtain around 90% if keys are the same for training and testing cipher texts. When they use different keys for training and testing cipher texts, it identifies AES from any one of the other four cryptographic algorithms with a high identification rate in one-to-one identification. A study conducted to assess the performance of encryption algorithms based on execution time, memory required for implementation, and throughput across two different operating systems. Based on the simulation results, AES and Salsa20 are preferable to Blowfish for plain text data encryption [6]. Singh et al., [10] presented a fair comparison between the most common four encryption algorithms namely; AES, DES, 3DES, and Blowfish in terms of security and power consumption. The simulation results showed that AES had a better performance than other common algorithms. Singh and Supriya [11] reviewed in-depth the well-known encryption methods such as RSA, DES, 3DES, and AES. They added that a variety of encryption techniques are available and that the advantages and disadvantages of each algorithm will determine which method is optimal for encrypting plain text. Each method is effective for real-time encryption. Each technique is distinctive in its own way, may be appropriate for various purposes, and has advantages and disadvantages of its own. The AES algorithm has been shown to be the most effective in terms of speed, time, throughput, and the avalanche effect, according to studies and a literature review. Ramesh and Suruliandi [12] evaluated the efficacy of some few particular symmetric algorithms in 2013. The experimental findings and input text file size led to the conclusion that the Blowfish method generates higher throughput while requiring less execution time and memory. In comparison to AES and DES, B1owfish performed around four times faster. Comparing Blowfish to AES and DES, memory usage is lower. Since AES required more computing resources than other algorithms, its performance results were subpar. Blowfish is not only the quickest encryption algorithm, but it also offers excellent security because of its large key size, making it suitable for usage in a wide range of applications, including packet encryption, random bit generation, internet-based security, and many more. Gautam et al., [13] conducted an experiment on cryptographic algorithms to analyze their performance and usage. The outcomes of the research on AES and TWOFISH are regarded as the two top candidates for achieving the aims of the study focus. These two outperform the other encryption methods in terms of speed, entropy, and optimal encoding, however, AES still has an advantage over TWOFISH due to its higher efficiency. The authors in [14] evaluated the performance of DES and Blowfish using different memory sizes. Both algorithms have high security to resist differential cryptanalysis and linear cryptanalysis attacks. They evaluated encryption function speed based on different memory sizes. The experimental results showed Blowfish is much faster than DES but as the speed increase for Blowfish, it is slower compared to DES. This was because of the needs to have more memory for sub-key and S boxes initialization. Kuma and Karthikeyan [15] conducted a comparison study on the effectiveness of the Blowfish and Rejindael (AES) algorithms for the chosen cryptographic algorithms in terms of energy consumption, changing data types like text or documents and images, power consumption, changing packet size, and changing key size. The simulation findings revealed that Blowfish surpasses AES in almost all of the test scenarios. The study found that while AES is better for image encryption, blowfish is better for text-based encryption. It is also shown that performance changes when the AES algorithm's key size is altered. Overall, the study found that AES can be used in circumstances needing a high level of security. Blowfish, however, is a performance-wise viable option. Suresh and Neema [16] explored hardware implementation of Blowfish algorithm for the secure data transmission in Internet of Things. It concluded that of all the cryptographic algorithms, the Blowfish algorithm is the best in terms of execution time, memory usage, throughput, power consumption, and security, and thus, well suited for IoT. The authors in [17] analysed the parameters of various cryptographic techniques, including AES and Blowfish, for performance, including encryption speed, CPU usage over time, and battery consumption. The outcomes showed that in terms of processing speed and throughput, the Blowfish approach performed better than the AES algorithm. The algorithm has a higher throughput while running more quickly and with less energy. According to the study, blowfish is the best option. AES, 3DES, Blowfish, and Twofish were the focus of an empirical investigation by Dibas and Sabri. The outcome demonstrated that, in terms of execution time, AES is the most effective encryption and decryption algorithm. In terms of encryption and decryption, Blowfish performed far better than 3DES. The findings obtained by Twofish were the worst. The authors found that, in terms of memory usage for encryption, AES and 3DES used less memory whereas Blowfish and Twofish used more memory and had the largest ciphertext sizes [18]. In 2020, Gosh conducted a side-by-side comparison of the three algorithms AES, Blowfish, and Twofish while taking into account various factors like speed and computation time. Conclusion: In terms of the evaluated evaluation measures, such as encryption time, decryption time, and throughput, Twofish clearly outperformed AES and Blowfish [19]. Raigoza and Jituri [20] evaluated the performance of symmetric encryption algorithms. The aim of this paper is to assess and contrast the performance of the Blowfish algorithm and the widely used Advanced Encryption Standard (AES). The AES algorithm outperformed Blowfish in terms of speed, with a difference of around 200 to 300 milliseconds. And, when the data size was altered, there were minor changes between the methods evaluated, such that the encrypted data for the AES and Blowfish algorithms tended to be roughly the same length. When the authors changed the ASCII value range, both the AES and the Blowfish algorithms increased overall execution time as the ASCII value increased, but the regression line slope for the Blowfish was more than the AES. Given the same rising ASCII values, the encrypted data from the Blowfish algorithm tended to be greater in size than the AES-encrypted data. The authors in [21] conducted an experiment to evaluate the effectiveness of the most widely used symmetric algorithms in terms of Security, Architecture, Limitations, and Efficiency and to draw attention to the shortcomings of various algorithms. AES was discovered to be the best algorithm in terms of security, efficiency, and architecture. The authors in [22] examined AES and Twofish encryption schemes. The simulation's findings were as follows: (1) for text encryption, AES is faster than Twofish, but as RAM is increased, Twofish overtakes AES. (2) AES is faster for image encryption, although Twofish performs equally well with more RAM. (3) Twofish works better for sound encryption, and its speed increases even more with more RAM. The authors in [23] evaluated the various encryption methods for secure data transmission. The study came to the conclusion that Blowfish outperformed AES, DES, and 3DES in terms of encryption and decryption times, power use, memory utilisation, latency, jitter, and security level. The authors in [24] investigated performance of selected security algorithms in cloud computing to evaluate and contrast the effectiveness of AES (Rijndael), Blowfish, and RSA. Result of the simulated outcomes, indicated that Blowfish performed better than the AES and RSA algorithms. According to Yegireddi and Kumar [25] conducted a survey to assess the efficiency of well-known conventional encryption techniques. It concluded that AES and Blowfish are the only algorithms that give speed and security due to their variable key.

III. Experimental Analysis

We have implemented the various symmetric encryptions in Python. Our performance evaluation is based on the implementation of three symmetric algorithms AES, Twofish and blowfish for encryption and decryption, and throughput. The following criteria were used: a) encryption and decryption time; b) throughput; and c) 128 key bit size for AES, Twofish, and Blowfish. To show the outcomes for the conclusion, the values for each criterion were logged and graphically plotted. The simulation was run on a laptop with an Intel® CoreTM i5-10210U CPU running at 2.40 GHz and 16 GB of RAM. Version 21H2 of Windows 11 Pro for Workstations was used. A key size of 128 bits was utilised as the benchmark in this experiment to acquire trustworthy values for evaluating the efficiency of AES, Blowfish, and Twofish cryptographic algorithms. The experiment was run three times and the mean execution time was recorded. The three block-cipher methods—AES, Blowfish, and Twofish—are also listed in Table I as a summary.

TABLE I. Key and Block Size

Factors	AES	Blowfish	Twofish
Key sizes	128	128	128
Block size	128 bits	64 bits	128 bits

IV. Performance Evaluation

A. Process Time (Encryption and Decryption Time)

Tables II to VII show the comparison of results. It is worth noting that AES-128 key bit size has the quickest encryption and decryption time on average.

B. *Throughput*

The throughput of an encryption scheme defines the speed of encryption. The encryption scheme's throughput is calculated by dividing the total plaintext in bytes encrypted by the encryption time [14]. In this experiment, the throughput is derived from calculated as the total plaintext in Kilobytes encrypted/encryption time (KB/sec) divided by their mean time generated. AES has the highest throughput making it the fastest of the three followed by blowfish. The results are shown in Tables VIII to X.

V. DISCUSSION OF RESULTS

Tables I to IX show the encryption time, decryption time, and throughput. Performance analysis varies based on a particular file type, but on average, AES outperforms Blowfish and Twofish in terms of speed and process time. Furthermore, the figures in Fig. 1 and Fig. 2 are based on the average of total encryption/decryption and throughput of AES, Blowfish, and Twofish. An overview of all the comparisons can be summarized into the following Table XI. The summary in Table XI is based on values from Fig. 1 and Fig. 2. AES-128 produced fast encryption, decryption times and speed than Blowfish and Twofish. The results show that Blowfish can match the encryption and decryption speeds of AES.

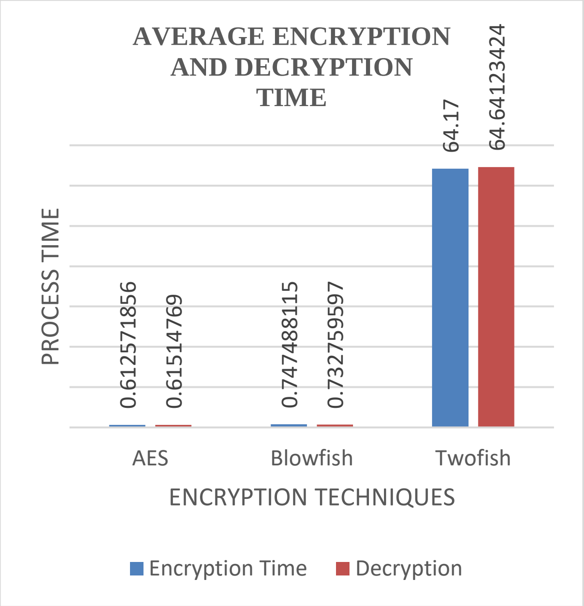

Fig. 1. Average process for AES, blowfish and twofish.

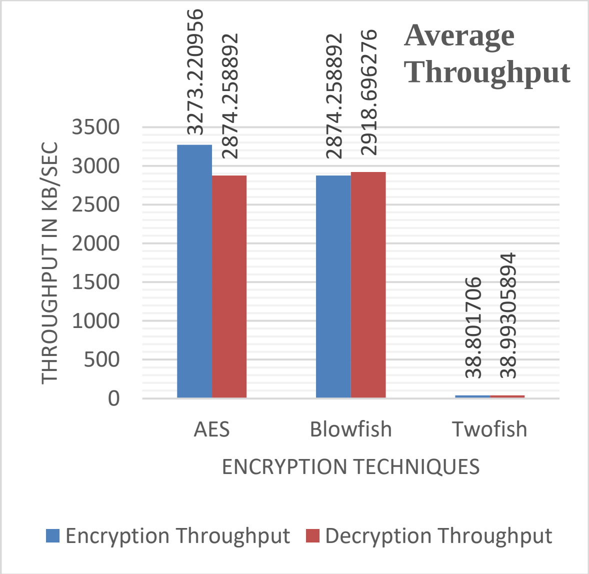

Fig. 2. Average throughput for AES, blowfish, and twofish.

TABLE XI. AES, BLOWFISH, AND TWOFISH AN OVERALL COMPARISON

Parameters	AES	Blowfish	Twofish
Key bit size	128	128	128
Encryption	Very fast	Fast	Too slow
Decryption	Very fast	Fast	Too slow
Throughput (Speed)	Very high	High	Low

VI. CONCLUSION

In today's rapidly expanding Internet and network applications, encryption algorithms play a critical role in ensuring information security. Based on a key bit size of 128 in this study, we evaluated three symmetric key encryption algorithms: AES, Twofish, and Blowfish. Based on the experimental results, the 128 key bit of AES algorithm has the shortest process time and runs quicker than Twofish and Blowfish. Overall results proved that the AES algorithm is more suitable for secure data transfer.

Elitist Animal Migration Optimization for Protein Structure Prediction based on 3D Off-Lattice Model

Ezgi Deniz Ülker
Department of Software Engineering, European University of Lefke, Mersin-10, Turkey

***Abstract*—Predicting the structure of protein has been the center of attraction for the researchers. The aim is to make a reliable prediction of the protein structure by obtaining the minimum energy values among amino acids interactions. According to the generated shape of amino acids, the functionality of the proteins can be determined. However, it is known as one of the most challenging tasks in the field of bioinformatics considering its high computation complexity. Metaheuristic algorithms are mainly preferred by researchers from various fields, since their performances are quite satisfactory in solving such complex problems. Animal Migration Optimization (AMO) algorithm is a metaheuristic approach which mimics the behavior of animals during the migration process. However, in this research to reach a high solution quality, an elitist version of Animal Migration Optimization (ELAMO) algorithm is considered and in particular it is applied to Protein Structure Prediction (PSP) problem. The performance of ELAMO is tested on some well-studied artificial and real protein sequences, and then compared with powerful optimization algorithms which are specially designed for solving PSP problem. The results show that ELAMO is quite capable in solving this problem. Hence, it can be used as an efficient optimizer for solving complex problems that require better solution quality in the field of bioinformatics.**

Keywords*—*Animal migration optimization; bioinformatics; elitism; metaheuristics; protein structure prediction

I. Introduction

In molecular biology, comprehending the structure of a protein sequence reveals the hidden functionalities of the life [1]. When the proteins are folded in different ways, the information necessary for understanding their functionalities will arise. Proteins are formed by the combination of amino acids which are connected by peptide bonds [2]. According to Christen Anfinsen's leading work, proteins can be found in the lowest energy levels which are called Gibbs energy level, when they are in three dimensional states [3]. Protein Structure Prediction (PSP) problem is located on finding this state by seeking the minimum Gibbs energy level. As the amino acid sequence becomes large, predicting the structure of a protein sequence becomes complex.

Researchers developed an approach called 'HP model' for protein folding prediction [4]. In the HP model, a protein description is made up of smaller pieces called monomers and which are either represented on 2D or 3D surface. 'H' and 'P' letters are used to define each of the monomers which are hydrophobic or polar, respectively. It is aimed to find the optimal structure of a given H-P chain that is defined as the maximum number of H-H bondings. Although the HP model is specifically designed for solving protein folding with its simplicity, it does not provide satisfactory solutions for PSP. The problem is proved to be an NP-hard problem due to large number of amino acids sequences and requires quite efficient algorithms to solve them [5–7].

One of the biggest limitations of protein folding is having the multiple local optimum points in the free-energy space and the global optimum is located in between these points which is quite challenging to obtain [8]. In order to design a scheme by avoiding the large computational cost, such models with eliminated properties in protein folding have been preferred [8–10]. An accurate example of these kinds of models is the off-lattice model which is presented by Stilinger et al. [8]. The model is employed to simplify the protein folding.

Animal Migration Algorithm (AMO) is a bioinspired metaheuristic approach proposed by Li et al. [11]. It is founded on an animal's instinct to follow their close neighbors during the migration and has quite validated performances on many optimization problems. Despite of the noticeable properties of AMO, there may be some disadvantages such as low convergence rate by choosing the next possible solutions only among the current animal's neighborhood or having a less chance by finding the global optimum because of following the wrong neighbors. In order to avoid these limitations and make it guarantee that the algorithm converges to the global optimum in less number of iterations, Elitist Animal Migration Optimization (ELAMO) is proposed on the basis of an animal's instinct to follow their leaders, not only their closest neighbors [12]. ELAMO has a validated performance in solving combinatorial NP-hard problem. However, to the best of our knowledge neither AMO nor ELAMO have been proposed for solving bioinformatics problems, particularly, for the PSP problem. In this paper, ELAMO algorithm is adapted to bring another aspect in solving Protein Structure Prediction (PSP) problem by using 3D AB Off-Lattice Model.

The rest of the paper is designed as follows; in Section II, some important studies for solving the PSP over the years have been given. In Section III, three dimensional AB off lattice model and the adaptation of Elitist Migration Algorithm to PSP problem with the model equations are given. In Section IV, ELAMO algorithm's performance is compared on both synthetic and real protein sequences with some powerful optimizers. The obtained results with the visual representations of minimum energy configurations and discussions are given in detail in this section. Lastly, in Section V, the concluding remarks are given.

II. Related Work

It is known that many metaheuristic algorithms are verified to be quite efficient in solving complex and even NP-hard problems. In specific, it is found that Bee colony optimization algorithms and its variants are used to solve PSP problem by Li et al. [13]. Kalegari and Lopes proposed an improved Differential Evolution algorithm for solving PSP using 2D and 3D off-lattice models efficiently [14]. Another Differential Evolution algorithm variant is proposed by Rakhshani et al. for solving complex protein structure prediction problems [15]. Deep learning practices are also tested for the PSP by Senior et al. [16] and achieved promising results. Schauperl and Denny performed an AI based protein structure prediction in drug discovery [17], Chowdhurry et al. [18] solved protein prediction problem using a deep learning model and Weißenow et al. [19] have solved PSP problem using AI model accurately. Multi-meme algorithms are also adapted for solving PSP by Krasnogor et al. [20]. Lin and Zhang introduced a novel-hybrid global optimization method by forming Genetic Algorithm and Particle Swarm Optimization to solve PSP in which aiming to produce lower energy conformation levels [21]. Boiani and Parpinelli proposed a hybrid algorithm called cuHjDE-3D which is formed by self-adaptive Differential Evolution that uses jDE and Hooke-Jeeves Direct Search (HJDS) [22].

The literature review revealed that the standard metaheuristic algorithms have limited performance in solving PSP problem. Before attempting to solve the problem, researchers either modify or hybridize the standard algorithms. By introducing such boosted algorithms, the researchers aimed to use the strengths of the algorithms on PSP problem.

In this study, none of the machine learning methods are implemented. Instead, a modified version of AMO algorithm has been studied to observe how it evaluates the problem by using its parameters. One of the main contributions of this study is to adapt animal migration algorithm by enhancing its diversity using elitist approach for protein sequence prediction problem and achieving satisfactory results.

III. Materials and Methods

A. Three Dimensional AB Off-Lattice Model

The AB off-lattice model is stimulated by HP model and considered as one of the useful models for solving Protein Structure Prediction Problem. When the AB off-lattice model was introduced, it was initially designed for 2-D protein structures. However, then the model was upgraded for solving 3-D models as well [8, 23].

In a protein sequence 20 types of amino acids exist which are categorized in two; hydrophobic and hydrophilic. This is simply performed according to their affinity to water. The amino acids then translated to two specialized monomers ‘A’ and ‘B’. As K-D method proposes I, V, L, P, C, M, A, G are hydrophobic amino acids represented by letter A and D, E, F, H, K, N, Q, R, S, T, W, Y are hydrophilic amino acids represented by letter B [24]. The name AB of AB off-lattice model is because of these specialized monomers A and B.

The amino acids are bonded with each other by chemical bonds and can be placed anywhere in the 3D space. The reason of that is called off-lattice is the positions of the amino acids which are not restricted by a lattice. In the AB off-lattice model, bondings are formed by set of angles; folding (θ) and rotation (ϕ). In a protein sequence which contains n monomers also contains n-2 folding angles and n-3 rotation angles. The optimal structure of AB off-lattice model produces the free energy which gives general information about the physical and chemical concept of protein sequences. Fig. 1 shows the representation of an artificial protein sequence ABAA with folding (θ) and rotation (ϕ) angles where ‘A’ and ‘B’ are hydrophobic and hydrophilic amino acids, respectively. Folding angles [θ1, θ2] and rotation angle [ϕ1] are needed to be optimized for having the minimum free energy level.

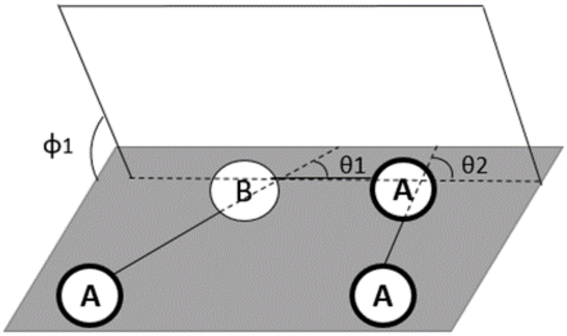

Fig. 1. 3D AB-off lattice model representation for ABAA artificial protein sequence.

Adaptation of protein structure prediction to a numerical optimization problem by 3D AB-off lattice model is done as follows,

$$Energy = \sum_{i=2}^{n-1} \frac{1-\cos\theta_i}{4} + 4\sum_{i=1}^{n-2}\sum_{j=i+2}^{n}\left[r_{ij}^{-12} - C(\varepsilon_i,\varepsilon_j) r_{ij}^{-6}\right] \quad (1)$$

where ε_i is the characteristic of the i^{th} amino acid. If $\varepsilon_i = 1$, then *i* is a hydrophilic amino acid. If $\varepsilon_i = -1$, then *i* is a hydrophobic one. The folding angles (θ) are bounded [-180°, 180°].

To obtain the distance between amino acids *i* and *j*, the following equation is used.

$$r_{ij=}\sqrt{\left[1+\sum_{k=i+1}^{j-1}\cos\left(\sum_{l=i+1}^{k}\theta_l\right)\right]^2 + \left[\sum_{k=i+1}^{j-1}\sin\left(\sum_{l=i+1}^{k}\theta_l\right)\right]} \quad (2)$$

The following equation shows the basic rotations for two amino acids.

$$C(\varepsilon_i,\varepsilon_j) = \frac{1}{8}\left(1+\varepsilon_i+\varepsilon_j+5\varepsilon_i\varepsilon_j\right) \quad (3)$$

In AB-off lattice model, it is assumpted that strong correlations between AA pairs result with the value of $C(\varepsilon_i,\varepsilon_j) = 1,$ relatively weaker correlations between BB pairs result with the value of $C(\varepsilon_i,\varepsilon_j) = 0.5$ and different pairs BA or AB pairs result with the value of $C(\varepsilon_i,\varepsilon_j) = -0.5$. Using the assumptions obtained through AB-off lattice model, the protein structure problem is converted into a numerical optimization problem that can be handled by evolutionary optimization techniques. By having various ordering of distances and rotations, different energy levels of amino acids are obtained and as the algorithm iterates the optimum energy level is obtained.

B. Adaptation of ELAMO to PSP Problem

Animal migration is a common behavior which belongs to animal herds to be used in discovering better places to live and reproduce. Animal Migration Optimization (AMO) algorithm based on this behavior and proved to be a validated optimizer in solving optimization problems [11]. Our approach is simply based on the main steps of AMO by including the elitism behavior in it. In the Elitist Animal Migration approach, the neighborhood structure of the standard AMO is reconstructed. Thus, the animals in the herd follow their leaders not only their close neighbors.

During the migration process, an animal's position depends on its neighbor. In standard AMO, migration is done by following five closest neighbors of each animal. However, in our elitist approach, an animal's instinct to follow the leader of the herd is essential. In a typical animal herd, there are three kinds of animal; Alpha (α), Beta (β) and Omega (ω).

Alpha (α) is responsible from all animals in the herd such as finding the preys or discovering new life areas. If the alpha dies, a new leader is selected among the beta (β) animals who are in charge after the alpha (α). The rest of the animals are considered as omegas (ω) who obey the rules of the herd. In the algorithm ELAMO, only α and β animals are in charge of migration. The number of α is 1 and the number of β is fixed to 4. Thus, all of the animals in the herd move towards to new life areas by following these leaders. As the algorithm iterates, new α and β animals are selected with respect to their positions among the rest of the animals. The following figures; Fig. 2 and Fig. 3 demonstrate the neighborhood structure in AMO and ELAMO, respectively where each animal represented by a circle theoretically.

Elitist animal migration algorithm is built up on two fundamental steps; Animal migration and population updating.

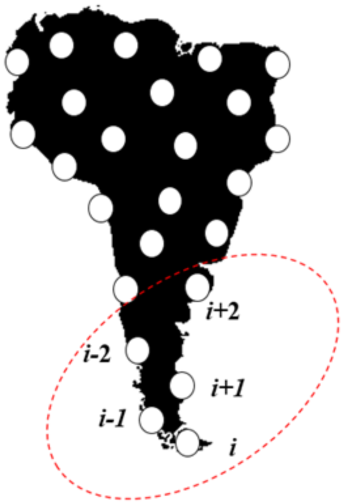

Fig. 2. The neighborhood structure of AMO algorithm where *i* is an animal and *i* ± 1,2 are the closest neighbors.

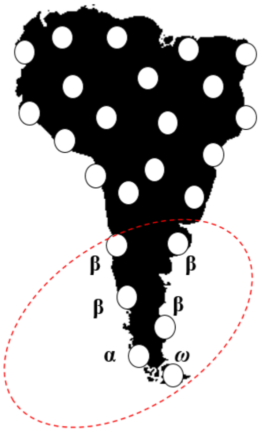

Fig. 3. The neighborhood structure of ELAMO algorithm.

In animal migration step, animals change their positions towards their α and β animals as given in (4). In population updating step, displacement of animals is introduced. Some animals may be eliminated due to death or they may compete for their positions and the losers are discarded from the population. The new positions are updated according to their fitness values as it is shown in (5).

Animal migration step;

$$X_{i,G+1} = X_{i,G} + \delta\left(X_{neighborLeader,G} - X_{i,G}\right) \quad (4)$$

where δ is a random number produced by Gaussian distribution and G is the dimension for each animal ∈ [1... D] and $X_{\mathrm{neighborLeader}}$ is the leader's position randomly selected from the neighborhood structure of an animal X_i.

Population updating step;

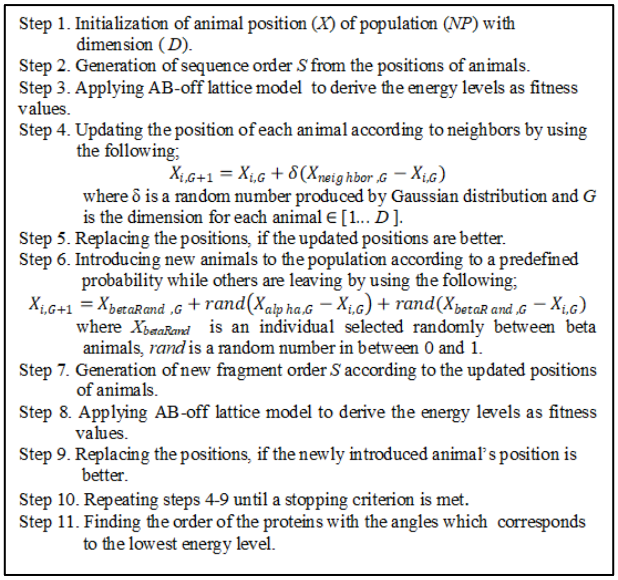
$$X_{i,G+1} = X_{betaRand_a,G} + rand\left(X_{alpha,G} - X_{i,G}\right) + rand\left(X_{betaRand_b,G} - X_{i,G}\right) \quad (5)$$

where X_{betaRand} is an animal selected randomly between beta animals, X_{alpha} is the position of alpha, rand is a random number in between 0, 1 and a ≠ b.

The main control parameters of ELAMO are δ and $rand$ which influence the population by having equilibrium between the diversity; exploring new possible areas in the search space and intensity; focusing the search area around the leaders α and β.

The adaptation of ELAMO to PSP problem is given in the Fig. 4. One of the main motivations is to reach the higher optimization level by changing the neighborhood structure. In standard AMO, the closest neighbor's position might be used just because they are considered as the closest neighbors and even if their positions are relatively worse than the others. However, in ELAMO, the best positions are chosen at each iteration and are followed by all of the animals.

As it is explained clearly in no-free lunch theorem [25], when an algorithm's performance is sufficient in some aspects, the performance may not reach to that level as it is expected for the other aspects. In ELAMO, individuals are discarded from the population as the elitism feature requires even in the beginning of the iterations. Therefore, it may be considered in ELAMO the balance of diversification and intensification may be negatively affected by the loss of individuals in the earlier stages of optimization.



Step 1. Initialization of animal position (X) of population (NP) with dimension (D).
Step 2. Generation of sequence order S from the positions of animals.
Step 3. Applying AB-off lattice model to derive the energy levels as fitness values.
Step 4. Updating the position of each animal according to neighbors by using the following;

$$X_{i,G+1} = X_{i,G} + \delta(X_{neighbor,G} - X_{i,G})$$

where δ is a random number produced by Gaussian distribution and G is the dimension for each animal ∈ [1... D].
Step 5. Replacing the positions, if the updated positions are better.
Step 6. Introducing new animals to the population according to a predefined probability while others are leaving by using the following;

$$X_{i,G+1} = X_{betaRand,G} + rand(X_{alpha,G} - X_{i,G}) + rand(X_{betaRand,G} - X_{i,G})$$

where $X_{betaRand}$ is an individual selected randomly between beta animals, $rand$ is a random number in between 0 and 1.
Step 7. Generation of new fragment order S according to the updated positions of animals.
Step 8. Applying AB-off lattice model to derive the energy levels as fitness values.
Step 9. Replacing the positions, if the newly introduced animal's position is better.
Step 10. Repeating steps 4-9 until a stopping criterion is met.
Step 11. Finding the order of the proteins with the angles which corresponds to the lowest energy level.

Fig. 4. The main steps of ELAMO algorithm for PSP problem.

A herd with α, β and ω animals correspond an AB-off lattice model for a set of sequences. All of the animals in the herd are the potential solutions in solving PSP by corresponding distances, angles and interactions between particles. According to these values, energy levels are derived. In PSP, the objective function is the energy level function and the optimal solution refers to the lowest energy value.

IV. Results and Discussion

In this section, two sets of analyses were used. First, a set of artificial Fibonacci protein sequences which have been used as benchmarks commonly in the literature is studied [8, 26] and then real protein sequences were analyzed. The data sets are experimentally examined structures for testing the efficiency of the methods for PSP problem.

A list of benchmark sequences with the 'A' and 'B' monomers are given in Table I where N is the sum of the monomers. A comparative study is performed in Table II to observe the performance of ELAMO with respect to some powerful optimization algorithms; Improved Particle Swarm Optimization (EPSO) [27], Internal Feedback strategy based on Artificial Bee Colony Algorithm (IF-ABC) [28], Combination of Genetic Algorithm and Particle Swarm Optimization (GAPSO) [21] and standard AMO which ELAMO is originated from. It is also important to note that the results of the compared algorithms included to the comparison table as they appeared in their original studies.

All simulations are implemented on an Intel Core i5 CPU with 4 GB RAM running at 3.10 GHz by C++ language. All benchmark sequences are evaluated for 30 independent runs with random initial points. All protein sequences are optimized by AMO and ELAMO for 50,000 number of iterations.

TABLE I. Details of the Artificial Protein Sequences

Coded Sequence	N
ABBABBABABBAB	13
BABABBABABBABBABABBAB	21
ABBABBABBBABBABABBABABBABBABABBAB	34

Fig. 5 is the representation of the changing lowest free energy values for three artificial protein sequences by the algorithms chosen for comparison. It can be clearly seen from both Table II and Fig. 5 that ELAMO has reached better energy values than the other algorithms for all artificial sequences.

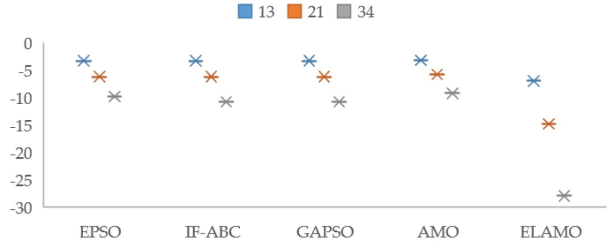


Fig. 5. A comparative free energy values obtained by different algorithms for Fibonacci sequences.

As shown in Fig. 5, almost all of the algorithms converge in similar rate in the first level of iterations; however as the iteration goes on convergence rate of ELAMO stands out for all benchmarks than the others. When the original algorithm AMO compared with the others, it is seen that all of the selected algorithms converge better than AMO.

All of the algorithms selected for comparison are either the hybrid version of one or more algorithms or the improved versions of the originals. AMO algorithm is the only one its performance was not boosted. It might be the main reason of the observation above which is about the lower convergence rate of AMO. On the other hand, this is a good indication that AMO has been improved efficiently to handle such kind of problems with high convergence rates.

In order to observe the effect of the added elitism feature on AMO, a detailed comparison between AMO and ELAMO is studied and shown in the Table III, where *Best* is for the lowest free-energy value obtained after 50,000 number of iterations, *Avg* is the averaged free-energy values of 30 independent runs and *Stdev* is for the standard deviation value.

TABLE II. The Lowest Free-Energy Values of Benchmark Sequences Obtained by the Algorithms

List of sequences	N	EPSO	IF-ABC	GAPSO	AMO	ELAMO
ABBABBABABBAB	13	-3.294	-3.294	-3.294	-3.216	-6.982
BABABBABABBABBABABBAB	21	-6.198	-6.198	-6.210	-5.751	-14.811
ABBABBABBBABBABABBABABBABBABABBAB	34	-9.834	-10.806	-10.789	-9.219	-27.989

The results denote the improved solution quality of ELAMO over AMO as well as robustness. However, for all of the artificial sequences the *Best* and the *Avg* values of ELAMO are superior than the values AMO. However, only for the sequence with the length 34, the *Stdev* value is not satisfactory as it is expected. ELAMO algorithm produces encouraging results for the lowest-free energy values and the average values, but does not achieve the development of standard deviation for this sequence. When the *Stdev* values are compared for the sequence with the length 21, it is seen that AMO is quite close to ELAMO. The reason of this unexpected performance might be because of α and β animals' convergence pace in the search space, while some of the ω animals are still in the optimization process. As the iterations progress, the majority of ω animals find their way towards the optimum.

TABLE III. COMPARATIVE RESULTS BEST, AVERAGE AND STANDARD DEVIATIONS ACHIEVED BY AMO AND ELAMO

	AMO			ELAMO		
N	**Best**	**Avg**	**Stdev**	**Best**	**Avg**	**Stdev**
13	-3.21	-2.44	0.52	-6.98	-6.38	0.39
21	-5.75	-4.71	1.17	-14.81	-14.31	0.99
34	-9.21	-8.02	1.20	-27.98	-26.30	1.83

Researchers dealt with well-preferred real protein benchmark functions for a better analyzing of their algorithms and employed to their works [15, 28–31]. The same protein sequences were used in this study as benchmark functions and rewritten according to the K-D method where I, V, L, P, C, M, A, G are hydrophobic amino acids represented by letter 'A' and D, E, F, H, K, N, Q, R, S, T, W, Y are hydrophilic amino acids represented by letter 'B'. The list of the amino acid sequences were selected from the widely used Protein Data Bank (PDB) database with different lengths to make a more efficient comparison with the other algorithms. The IDs, lenghts and contained amino acids are given in the Table IV.

In the study with real protein sequences, only one standard algorithm chosen for the thorough check. Instead, specially designed hybrid algorithms with significant performances are selected. Table V lists the lowest free energy values obtained by ELAMO as well as other competitive algorithms to make an extensive comparison. Convergence values can be seen even in earlier iterations in the Fig. 6.

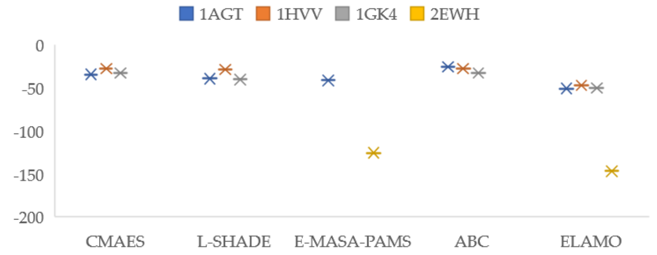

Fig. 6. A free energy values obtained by different algorithms for real protein sequences.

It can be seen from the figure that at the very first level of optimization all of the algorithms' convergence rates are very similar, but in the latter iterations elitism feature begins to appear in ELAMO and this affects the convergence rate in a very desirable way. The test parameters and results of the compared algorithms are accepted as they appear in the references [15, 28–31]. The best results for AMO and ELAMO are obtained over 30 runs. The stopping condition is set 200,000 iterations.

It can be acquired from both Table V and Fig. 6 that the performance of ELAMO can be distinguished from the others by having more precise solutions of the problems. Considering all of the results, it is possible to say that the algorithms' performances are very competitive but in the view of high solution quality, the performance of ELAMO is quite noteworthy.

In the comparison of ELAMO with one of the standard algorithms ABC, it is observable that ELAMO produces better results. For the other competitive algorithms, we can say that CMAES and L-SHADE performances are similar to each other, while E-MASA-PAMS superior than both and produces comparable results with ELAMO. However, in both analysing, we can see that ELAMO always contributes with the lowest free energy values and it can be a distinct evident by applying a set of modifications on the right steps of the AMO algorithm, influence the performance of ELAMO in a quite remarkable way. It is note to point that the compared algorithms can not be further analzyed since there is no *Stdev* or *Avg* reported in the literature.

In the light of findings, the visual representation of the folded protein structures by the best run of ELAMO are shown in the Fig. 7 **(a)** to **(d)**. In the figures, green dots represent the hydrophobic monomer; 'A' and the purple represent the hydrophilic monomer; 'B'. As the figures reveal, the hydrophobic monomers are frequently enclosed by the hydrophilic monomers in the folding structures. This is a natural phenomena for avoiding contact with water molecules and is verified by the following figures as well.

Fig. 7. Visual representations of minimum energy configurations for each protein sequence by ELAMO.

V. Conclusions

In this paper, an Elitist Animal Migration Optimization (ELAMO) is fitted to optimize the structure of protein sequences with 3D AB off-lattice model. According to the reformed structure of ELAMO, rather than following the neighbors, only the group leaders are followed. This movement results with high solution quality and the elimination of animals during the migration process makes the algorithm not to trap in local optimum points. To enable a more accurate comparison, standard AMO and effective algorithms are included in our experiment. Even though ELAMO has not been specially designed for solving PSP problem, its effectiveness in modelling of real protein sequences is successful.

ELAMO eliminates the animals whose positions are not adequate even in the early stages of optimization and the rest of the animals in the herd only can follow their leaders. This elimination brings faster convergence rate without trapping into local optimum points in the process. It is known that the optimization is built on consecutive iterative processes until the termination criterion is obtained. During this process, some individuals may be eliminated due to their undesired characteristics which may be improved in the latter iterations. In ELAMO, the elimination is performed even at the first level of iterations and the desired characteristics are also eliminated. It is important to keep in mind that this may bring low solution quality as the length of the protein sequence increases.

Also, when the problem complexity increases in terms of large number of amino acids, the algorithm's performance may not be as efficient as it is expected. It is because of the lack of proper design for PSP problem. In the future, ELAMO may need to be strengthened by adding some boosting steps to be efficient in solving more complex protein sequences.

***Abstract*—Recently, Deep learning algorithms, particularly Convolutional Neural Networks (CNNs), have been applied extensively for image recognition and classification tasks, with successful results in the field of medicine, such as in medical image analysis. Radiologists have a hard time categorizing this lethal illness since brain tumors include a variety of tumor cells. Lately, methods based on computer-aided diagnostics claimed to employ magnetic resonance imaging to help with the diagnosis of brain cancers (MRI). Convolutional Neural Networks (CNNs) are often used in medical image analysis, including the detection of brain cancers. This effort was motivated by the difficulty that physicians have in appropriately detecting brain tumors, particularly when they are in the early stages of brain bleeding. This proposed model categorized the brain image into four distinct classes: (Normal, Glioma, Meningioma, and Pituitary). The proposed CNN networks reach 95% of recall, 95.44% accuracy and 95.36% of F1-score.**

I. INTRODUCTION

A brain tumor develops as a result of the overproduction and proliferation of cells in the skull. The body's command center, the brain, can be burdened by tumors, which can also be harmful to a person's health [1]. It has been reported in the study that brain tumors account for between 85% and 90% of all major Central Nervous System (CNS) tumors [2]. Radiologists have extensively used the medical imaging technique for tumor detection [3], [4]. Among the current medicalities, MRI is the method of choice for brain tumors because of its astronomical nature. Radiologists routinely manually detect brain cancers. Depending on the radiologist's level of training and experience, the tumor grading process can take a while. The interpretation is expensive and wrong. The associated challenges are attributed to specific traits, such as the substantial variation in form, dimensions, and magnitude for the same tumor type. Additionally, various diseases have similar appearances [5], [6]. A successful Computer Aided Diagnosis (CAD) system requires the development of feature extraction [7]. This is a challenging process that necessitates prior knowledge of the domain problem because the accuracy of the classification depends on the correctly extracted features. Since DL is a subset of machine learning, it does not use any manually created features [8]. In several disciplines, the use of DL and ML for segmentation, detection, prediction, classification and early diagnosis using medical data has been promoted [9]–[25]. ML and DL as fields of Artificial Intelligence (AI) find their applications in many others field such as handwritten recognition and natural language processing [26]–[29].

Deep Learning (DL) is a subfield of Machine Learning (ML) that uses artificial neural networks with multiple layers to model complex patterns and relationships in data [30], [31]. Image classification is a task in computer vision where a model is trained to identify and categorize objects in images [32], [33]. In the context of brain tumors, convolutional neural networks (CNNs) are often used for image classification [34]. A CNN is a type of neural network specifically designed for image processing and analysis. It uses convolutional layers to detect local patterns and features in images, allowing it to learn and classify objects within an image [35]. In the case of brain tumor classification, a CNN is trained on a large dataset of medical images of brains, where each image is labeled as containing a tumor or not. The CNN then uses the features it has learned to classify new, unseen images as containing a tumor or not. This can aid for the early diagnosis and treatment of brain tumors.

CNN was initially utilized in 1980 [36], [37]. In essence, it is a disguised Multilayer Perceptron (MLP) network. CNN's computational capacity is based on a model of the human brain. Humans use an object's visual appearance to detect and identify it. Tens of thousands of photos of the same item are used to educate our kids how to distinguish objects. This aids a youngster in recognizing or foreseeing things that they have never encountered before. Similar in operation, CNN is well recognized for processing images.

In this paper, we proposed CNN-based model for medical image analysis, which is a sophisticated algorithm that utilizes DL techniques to categorize brain images into four distinct classes: Normal, Glioma, Meningioma, and Pituitary. These four classes encompass the most common types of brain tumors and are critical in providing accurate and precise diagnosis and treatment. The model's impressive performance metrics, including a recall rate of 95%, an accuracy of 95.44%, and an F1-score of 95.36%, demonstrate the model's ability to detect brain tumors with high precision and accuracy. The recall rate, which is a measure of the model's ability to correctly identify all positive cases, is at an impressive 95%, indicating that the model has a low false-negative rate. Additionally, the accuracy score, which measures the model's ability to classify the images correctly, is also at a remarkable 95.44%. Finally, the F1-score, which is a combined measure of the model's precision and recall, is at a remarkable 95.36%, indicating the model's overall performance in categorizing brain images. These high-performance metrics are critical in medical image analysis as they help physicians diagnose and treat brain tumors accurately and efficiently. The proposed model is an essential tool for radiologists and physicians, as it reduces the subjectivity involved in manually interpreting medical images and provides a reliable and objective method for diagnosis.

The remainder of this article is structured as follows: Section II explores the related works to the search for brain tumor detection. In Section III, the proposed CNN-based model is presented, including its architecture, training methodology, and evaluation metrics. Section IV provides an overview of the materials and methods utilized in the study. Section V presents the experimental results, and in Section VI, the study's findings and conclusions are discussed.

II. Related Works

DL and AI play a crucial role in MRI image processing through techniques such as segmentation, recognition, and categorization. They are also employed in the classification and detection of brain cancer. Numerous studies have been conducted on the identification and segmentation of brain MRI images. A review of international literature was conducted to assess the use of DL in identifying and categorizing brain tumors.

In [38], the authors used newly designed CapsNets to allow CapsNet to access neighboring tissues while remaining focused on the core target. As a result, a modified CapsNet architecture for brain tumor classification is presented, with coarse tumor boundaries incorporated as extra inputs into its pipeline to increase CapsNet's focus. The proposed method outperforms its competitors significantly.

The authors in [39] used a convolutional neural network to perform multimodal brain tumor categorization for early diagnosis (CNN). With an accuracy of 92.66 %, the CNN model can categorize brain cancers into 5 types (Normal, Glioma, Meningioma, Pituitary, and Metastatic). The grid search optimization approach is used to automatically define critical hyperparameters in CNN models. The suggested CNN model is compared to popular cutting-edge CNN models such as AlexNet, Inceptionv3, ResNet-50, VGG-16, and GoogleNet. Using huge publicly available clinical datasets, satisfactory classification results are produced. This methodology has a number of drawbacks that may be listed as follows, despite the fact that the recommended methods for classifying brain tumors differ. The accuracy provided by current techniques is unsatisfactory due to the significance of MRI classification in the medical field. Some classification algorithms could not be fully automated since they required a human to manually identify tumor locations.

The authors in [40] described a technique for improving classification performance. To put the suggested method to the test on a big dataset, the authors employ three feature extraction methods: intensity histogram, gray level co-occurrence matrix (GLCM), and bag-of-words model (BoW). Using the enlarged tumor region as the ROI enhances the intensity histogram, GLCM, and BoW model accuracies by 82.31% vs. 71.39%, 84.75% vs. 78.18%, and 88.19% vs. 83.54%, respectively. Ring partitioning can improve accuracy by up to 87.54%, 89.72%, and 91.28% in addition to increasing region. These experimental findings demonstrate that the proposed strategy for classifying brain cancers in T1-weighted CE-MRI is both possible and effective.

In [41], the authors suggested a method for classifying brain tumors utilizing a set of deep characteristics and ML classifiers. In the proposed framework, they get deep characteristics by brain magnetic resonance (MR) pictures using the notion of transfer learning and numerous pre-trained deep convolutional neural networks. The top three deep features for multiple ML classifiers are chosen and concatenated into a deep feature set, which is then fed through multiple ML classifiers to predict the final output.

The authors in [42] proposed a method to improve the segmentation of brain tumors in magnetic resonance imaging (MRI) by incorporating an additional classification network. The segmentation is performed using a convolutional neural network (CNN) which is trained on a dataset of MRI images with corresponding tumor masks. The CNN is then combined with a classification network that is trained to distinguish between different types of tumors. The output of the classification network is used to refine the segmentation results by identifying and removing false positives. The authors evaluate their method on two publicly available datasets and compare it to other state-of-the-art methods. They report that their method achieves higher accuracy and Dice similarity coefficient (DSC) scores than the other methods. They also perform ablation studies to analyze the contribution of the classification network and find that it significantly improves the segmentation results.

In [43], the authors provide an overview of the challenges in brain tumor segmentation and discuss how deep learning techniques have been applied to address these challenges. The survey covers various types of deep learning models, including convolutional neural networks (CNNs), recurrent neural networks (RNNs), and generative adversarial networks (GANs). The authors also discuss the advantages and limitations of these methods and provide insights into future directions for research.

III. The Proposed CNN-Based Model

The structure of a CNN-based model can be customized and optimized by selecting specific hyperparameters. These hyperparameters play a crucial role in determining the overall architecture of the model, including the number of convolutional layers, the activation functions used in each layer, and the number of hidden units per layer. The number of convolutional layers determines the depth of the neural network and its ability to extract high-level features from the input image. The more convolutional layers the model has, the more complex and sophisticated features it can extract, leading to better performance. However, adding too many layers can also result in overfitting, where the model becomes too specialized to the training data and performs poorly on new data.

The choice of activation functions also affects the model's ability to extract features accurately. Activation functions introduce non-linearities to the model, allowing it to model complex relationships between the input and output. Common activation functions used in CNNs include ReLU, sigmoid, and tanh, among others. The choice of activation function can significantly impact the model's performance, and selecting the right activation function is critical in optimizing the model's accuracy. After extensive experimentation, we arrived at the optimal selection of hyperparameters for the multi-layered model depicted in Fig. 1. This is chosen in: Five layers of convolution2D that differ in the number of filters, so that it doubles as you go deeper, starting with the first layer, which contains 32 filters, and ending with the last layer, which contains 512 filters, all to extract many features; five layers of max pooling in order to extract important information from the previous convolution2D layer; flattening layer, to render the information in one dimension; then a Dense layer with 128 units; finally, the Dance layer with 4 units, due to the number of final classes was used in which the SoftMax function was used because it is the most used function in multi-class models (in our case 4 classes). In all these layers, the ReLU activation function was used because it is the most advanced compared to the other functions. Fig. 2 displays the layout of our proposed CNN architecture.

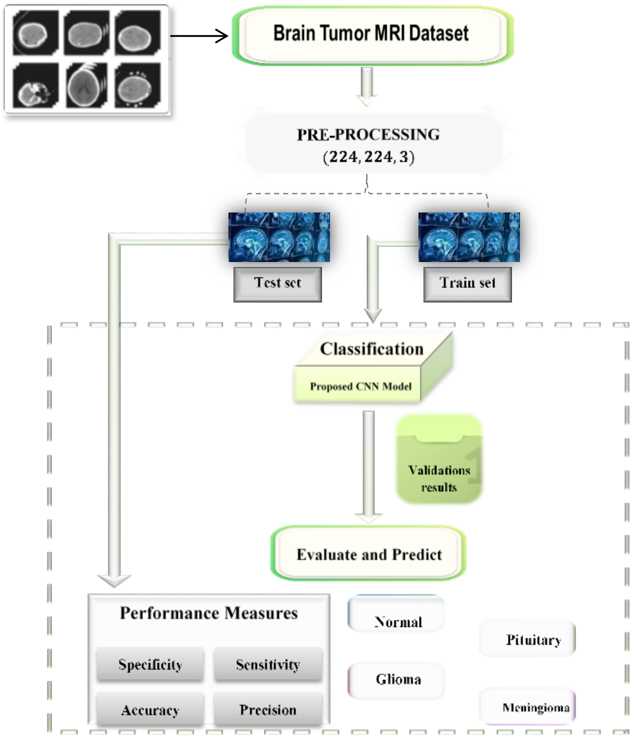

Fig. 1. Flowchart of a System for Detecting Brain Tumors.

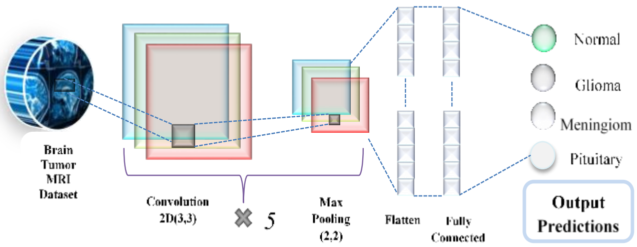

Fig. 2. The proposed CNN model architecture.

Brain tumor detection is a critical problem in medical imaging, and a Convolutional Neural Network (CNN) can be used as a detection system. A CNN is a type of DL algorithm that is designed to analyze image data and can be trained to recognize specific features in the images. In the case of brain tumor detection, a CNN is trained using a large dataset of medical images that includes both normal and abnormal scans. The CNN is then used to identify and locate areas of the brain that may contain a tumor. This is done by processing the images and identifying certain patterns and features that are characteristic of brain tumors. The output of the CNN can be used to assist medical professionals in the diagnosis of brain tumors and to guide further testing and treatment. The use of a CNN as a brain tumor detection system has the potential to improve the accuracy and speed of diagnosis, which can be crucial in treating brain tumors effectively.

IV. Materials and Methods

A. Dataset Collection

The "Brain Tumor MRI Dataset" on Kaggle is a collection of magnetic resonance imaging (MRI) scans of the brain. The dataset includes MRI scans of both healthy individuals and individuals with brain tumors, which have been annotated by medical experts. The annotations indicate the presence, location, and type of brain tumor in the MRI scans. In Figure 3, sample images from the dataset are depicted.

In fact, a publicly available Kaggle database is utilized, as is described in this section, which also provides some information on the database. The following three datasets were combined to generate this one: Figshare1, SARTAJ dataset2, Br35H3.

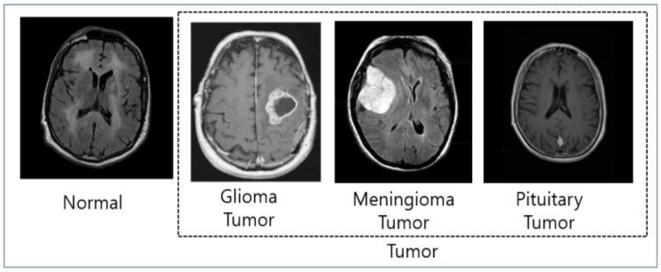

Fig. 3. Some sample images of the dataset.

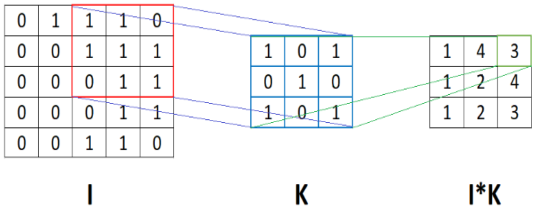
[1] https://figshare.com/articles/dataset/brain_tumor_dataset/1512427
[2] https://www.kaggle.com/datasets/sartajbhuvaji/brain-tumor-classification
[3] https://www.kaggle.com/datasets/ahmedhamada0/brain-tumor-detection

The 7022 MRI scans of the human brain in this dataset are divided into four classes. The dataset can be used for a variety of research purposes, including developing and evaluating computer vision algorithms for brain tumor detection and classification, as well as for training ML models for medical diagnosis and treatment planning. However, it is important to note that the generalizability of the models developed using this dataset should be carefully evaluated, as it is based on a limited sample of MRI scans.

B. Background on CNN

DL models use a hierarchical framework to learn high-level abstractions from input images [44]. Due to the availability of large-scale annotated datasets and the fact that CNN has demonstrated to be the most effective DL method for assessing medical pictures. The well-known CNN models [45] ImageNet, AlexNet, VGG16, GoogLeNet, Inception-V3 and ResNet101 have made significant strides in image recognition. However, the area of medical imaging lacks a comparable annotated dataset. Medical image classification using CNN is frequently done using one of two methods [46]. The first is called "learning from the ground up," while the second is called "Transfer Learning." The network layers that make up the CNN include a convolution layer, an activation layer, a Maxpooling layer, and a classification layer. Each of these levels is explained as follows [47], [48].

1) Convolution layer: The convolutional layer comes first [7]. This layer is in charge of identifying an input word's attributes. This step merely combines the entry neuron by a filter depending on the input and requirement to produce the feature map [49]. A neural activation function is used to introduce nonlinearity. The animal visual cortex served as a model for CNN computing. It decodes visual data and has a fine sensitivity to the input's smallest subregions [50]. The convolutional layer's main elements are its receptive field, stride, dilation, and padding [51]. Fig. 4 displays the application of the convolutional layer.



$$I = \begin{array}{ccccc} 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 \end{array} \qquad K = \begin{array}{ccc} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{array} \qquad I*K = \begin{array}{ccc} 1 & 4 & 3 \\ 1 & 2 & 4 \\ 1 & 2 & 3 \end{array}$$

Fig. 4. Convolution layer application.

2) Activation layer: The activation function is a crucial component of a Convolutional Neural Network (CNN) model as it defines the output of a neuron in response to a given input. The activation function determines the range of values that the neuron can output and allows the model to introduce non-linearity into the decision boundary, making it possible to learn complex relationships between the input and output variables. Common activation functions used in CNNs include the Rectified Linear Unit (ReLU), the Sigmoid function, and the Hyperbolic Tangent (Tanh) function. The choice of activation function depends on the specific problem being solved and can have a significant impact on the performance of the CNN. It's important to carefully choose the activation function in a CNN, as the wrong choice can lead to slow training and convergence, or even prevent the network from learning the desired patterns in the data [5].

3) Pooling layer: It comes after the convolution layer. This layer's task is to shrink the feature map, which implies fewer computations and parameters are required to operate the network. Therefore, it can be claimed that a summary of the features is the output of this layer. There are several techniques to pool data; in this instance, max pooling was utilized. The feature map's most objects that are covered by the filters are selected using max pooling [5].

4) Classification layer: In our CNN architecture, the classification layer comes last. This extensively used classifier which is a fully - connected feed-forward network. The neurons in the layers with complete connections are all connected to the neurons in the layer below. By merging the traits of the preceding layers, this layer recognizes the input image and predicts classes based on it. A total number of output classes is based on the number of classes in the source dataset. In this paper, the classification layer uses the "SoftMax" activation function to classify the features created from the input images in the previous layer into separate groups depending on the training data [5].

C. Confusion Matrix and Evaluation Metrics

A confusion matrix is a table used to evaluate the performance of a classification model by summarizing the predicted and actual class labels of a dataset. It displays the number of true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) for each class. In a binary classification problem, the confusion matrix is a 2x2 table with two rows and two columns representing the actual and predicted classes. The first row represents the actual negative and the second row represents the actual positive. The first column represents the predicted negative and the second column represents the predicted positive. For a multi-class classification problem, the confusion matrix is an n x n table, where n is the number of classes. The rows represent the actual classes and the columns represent the predicted classes. Each cell in the matrix represents the number of instances that belong to a particular actual class and a particular predicted class [52]. Based on the entries in the confusion matrix, several evaluation metrics can be computed to assess the performance of the classifier. Some commonly used evaluation metrics include:

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{1}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{2}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{3}$$

$$\text{F1-score} = 2\times\frac{\text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \tag{4}$$

$$\text{Precision} = \frac{\text{TN}}{\text{TN+FP}} \tag{5}$$

The results of a confusion matrix can be used to calculate various performance metrics, such as accuracy, precision, recall, and F1 score. A high number of true positives and true negatives indicate a high accuracy of the model, while a high number of false positives and false negatives indicate low accuracy. Precision indicates the proportion of positive predictions that are actually correct, while recall indicates the proportion of actual positive instances that were correctly predicted. The F1 score is the harmonic mean of precision and recall, and is a good overall indicator of a model's performance. In summary, a confusion matrix provides detailed information about the performance of a model, while evaluation metrics provide a concise, single value representation of the model's performance [53].

V. Experimental Results

A. Algorithms Best Parameters

The main objective of this project is to build a system capable of classifying medical images and giving correct decisions with a large percentage. All this depends on the quality of the existing data, the convolutional neural network, the number of its layers and coefficients, and the layers used to process the data needed to train the network.

Our study proposed a CNN architecture model; we retrieved the input 224×224 MRI image data with RGB color channels having a batch size of 32 by our CNN model. Initially, we added five convolutional layers; in addition, there are five max-pooling layers, one flattening layer, and activation (ReLU). The model develops the capacity to produce hierarchical qualities automatically by use of a succession of hidden layers. A final class label is determined by using a Softmax function on the outputs of this layer. In this proposed model, we have an output layer that generates a quadridimensional vector representing four different classifications of cerebral tumors. Table I displays the summary of our model CNN proposed architecture.

TABLE I. The Summary of Model Description

Layer (type)	Output (shape)	Parameters
Input layer	(224, 224, 3)	0
Conv2D	(224, 224, 32)	896
MaxPooling2D	(112,112,32)	0
Conv2D	(224,224,32)	18496
MaxPooling2D	(112,112,64)	0
Conv2D	(56,56,128)	73856
MaxPooling2D	(28,28,128)	0
Conv2D	(28,56,256)	295168
MaxPooling2D	(14,14,256)	0
Conv2D	(14,14,512)	1180160
MaxPooling2D	(7,7,512)	0
Flatten	(None, 25088)	0
Dense	(None, 128)	3211392
Dense	(None, 4)	516

This table describes the architecture of a CNN for image classification. The table lists each layer in the network, its type (e.g., Conv2D, MaxPooling2D, Dense, Flatten), the output shape of the layer, and the number of parameters in that layer. The network starts with an input layer that takes in an image of shape (224,224,3), which means the image has a height and width of 224 pixels and 3 color channels (representing RGB values). The next layer is a Conv2D layer with 32 filters, which means it will learn 32 different feature maps from the input image. The MaxPooling2D layer performs down-sampling by taking the maximum value in a region of the feature map and reduces its size. This process is repeated several times with increasing number of filters in the Conv2D layer and reducing the size of the feature map in the MaxPooling2D layer. Finally, the feature maps are flattened into a 1D vector and passed through two dense (fully connected) layers to output the final prediction. The numbers of parameters in each layer, along with the total number of trainable and non-trainable parameters are also listed. The total number of parameters in the network is 7,789,484, and all of them are trainable. To train the model, we need training data and for validation also we need test data. Once we are satisfied with the test result of the model, we can use it to make predictions on new data. In addition, for the properties and parameters of the model starting with the number of epochs =50 (epochs are the number of typical repetitions of the training).

To configure our training model, we need to call the compile method with the loss function we want to use. The type of optimization and the metrics our model should evaluate during training and testing we will use: The Adam optimizer is due to the fact that, as mentioned earlier, it is one of the most widely used optimizers because it is the fastest method and also converges quickly to correct for learning rate latency and high contrast. The categorical cross entropy loss function is used when there are multiple label classes. Metrics is a function used to evaluate the performance of your model.

The best parameters for algorithms in CNNS involve a variety of elements, such as learning size, batch size, optimiser, loss function, activation functions, and epochs. Different parameters have to be tuned based on the network architecture, dataset, and task. Table II presented the best parameters of our proposed model.

TABLE II. The Best Hyper-Parameters used for the TL Models in Training Phase

Network	Learning rate	Batch Size	Optimizer	Loss Function	Epochs
Proposed model	1.00e10-4	32	Adam	Categorical cross entropy	50

B. Training Results

Our experiment was based on a dataset of brain MRI images. We trained a CNN model to detect whether the MRI image contains a tumor (glioma, meningioma and pituitary tumor) or not. Finally, we compared the diagnostic and computational results of our model with the related works. On our training data set, our proposed model has a 95.44% accuracy rate. The graph depicts the accuracy and loss during the construction and validation phases of our proposed CNN model are presented in Fig. 5 and Fig. 6.

The graphs show the performance of the model in terms of accuracy and loss as it is being developed and tested. Accuracy refers to the measure of how well the model is able to correctly predict the outcomes or classes of the input data. It is usually expressed as a percentage, where higher values indicate better performance. Loss, on the other hand, is a measure of how much error there is between the predicted outputs of the model and the actual outputs. Lower values of loss indicate that the model is more accurate in its predictions.

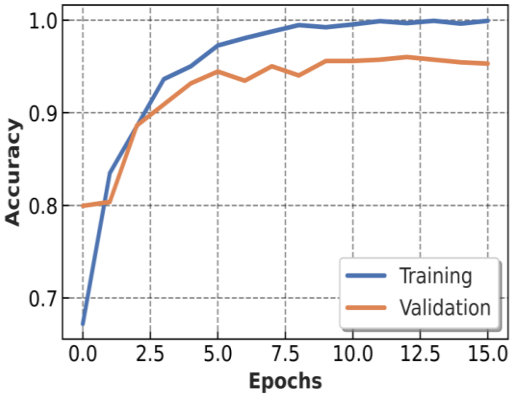


Fig. 5. Accuracy of the proposed model.

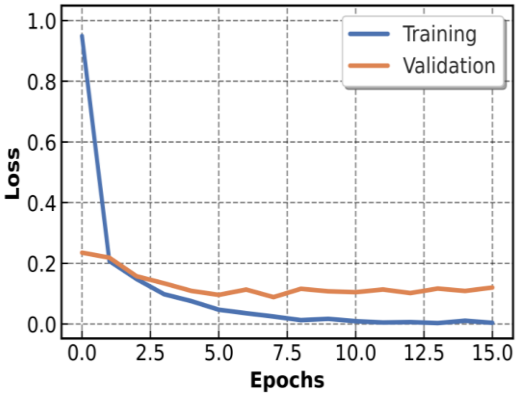

Fig. 6. Loss of the proposed model.

These graphs show the accuracy and loss of the CNN model at different stages of its development. The construction phase likely refers to the phase where the model is being trained on a dataset to learn the patterns and relationships in the data. The validation phase refers to the phase where the model is being tested on a separate set of data to evaluate its performance and generalizability.

C. Testing Results

The proposed model achieved an impressive accuracy of 95.44% in the detection of brain cancers. Table 4 presents the detection performance results of the model with an 80% train and 20% test split, showing the confusion matrix of the classifier model, which displays the number of correctly and incorrectly classified samples in each class. The confusion matrix, depicted in Figure 7, reveals the model's strong performance across all four classes: glioma, meningioma, no tumor, and pituitary. The ROC curve, as shown in Fig. 8, displays the true positive rate, also known as recall, against the false positive rate. The proposed model demonstrated excellent performance on the brain MRI dataset, accurately classifying a high number of samples in each class. For instance, 148 out of 156 samples in the glioma class and 193 out of 195 samples in the no tumor class were correctly classified. Overall, the results demonstrate the model's effectiveness in accurately detecting brain cancers, particularly in the early stages of brain bleeding. However, there are also some misclassified samples, as shown in the entries in the off-diagonal cells of the matrix. For example, five samples from the glioma class were misclassified as meningioma, and 3 samples from the pituitary class were misclassified as no tumor.

Based on this confusion matrix, it is possible to compute various evaluation metrics such as accuracy, precision, recall, and F1-score presented in Table III to quantify the performance of the proposed model. These metrics can provide a more comprehensive understanding of the model's performance and help identify areas for improvement.

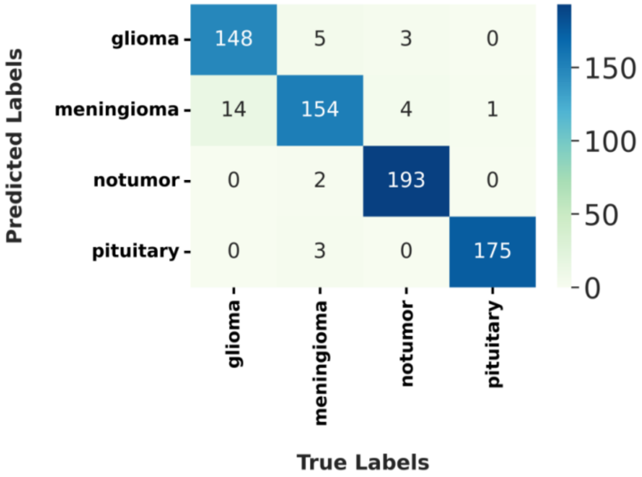

Fig. 7. The confusion matrix of the proposed model.

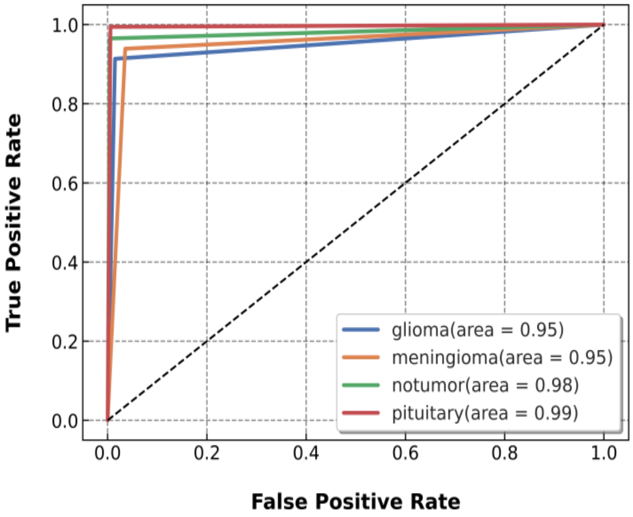

Fig. 8. ROC curves findings for the proposed model.

TABLE IV. CLASSIFICATION REPORT OF THE PROPOSED MODEL

Classes	Precision	Recall	F1-score	Support
Glioma	0.91	0.95	0.93	156
Meningioma	0.94	0.89	0.95	173
Notumor	0.96	0.99	0.98	195
Pituitary	0.99	0.98	0.99	178

This table represents the evaluation metrics of a classifier model that has been trained on a medical imaging dataset with four different classes: Glioma, Meningioma, No tumor, and Pituitary. The metrics shown are precision, recall, F1-score, and support. Precision is the fraction of true positive predictions among all positive predictions, recall is the fraction of true positive predictions among all actual positive cases, F1-score is the harmonic mean of precision and recall, and support is the number of samples in each class. The results show that the model performs well in all classes with F1-scores ranging from 0.93 to 0.99, indicating that the model has good precision and recall values.

D. Discussion

The proposed CNN model achieved the highest accuracy rate among other deep neural models for classifying cerebral tumors into four classes on MRI images. This model has the potential to aid medical professionals in diagnosing brain tumors accurately and efficiently. The architecture of the model is designed for optimal performance on medical image datasets, making it a promising tool in the field of medical image analysis. Comparison with other studies that used various techniques, such as capsule networks, data augmentation and partitioning, and feature sets with ML classifiers, showed that DCNNs are the most effective technique for classifying brain tumors based on MRI scans. The accuracy of the models ranged from 90.89% to 95.44%, indicating the effectiveness of deep learning techniques in this domain. However, it is essential to note that the generalizability of these models to other datasets and clinical scenarios should be evaluated with care. As with any ML model, its effectiveness is dependent on the quality and size of the dataset used to train and validate it. Thus, the performance of the proposed model should be assessed on other datasets, and it should be tested under different clinical scenarios before being deployed in real-world settings. The proposed method is also applicable for different MRI classifications, and it can be combined with transfer learning techniques to achieve more accurate classifications in the future. Transfer learning can help reduce the amount of data needed to train a model, and it can improve the accuracy of the model by leveraging the knowledge learned from other datasets.

While the proposed CNN model for classifying cerebral tumors based on MRI images appears to be highly effective, there are several limitations to consider. First and foremost, the model's accuracy and effectiveness may be limited to the specific dataset used to train and validate it. To ensure its generalizability, it is crucial to evaluate the model on other datasets and clinical scenarios. Another limitation of the proposed model is that it may not be suitable for classifying other types of tumors or medical conditions. It is important to recognize that the model was specifically designed and optimized for classifying cerebral tumors based on MRI images, and it may not be effective in other medical image analysis tasks. Moreover, like any deep learning model, the proposed CNN model requires a significant amount of data to be trained effectively. While the model achieved high accuracy rates on the specific dataset used, it may not perform as well on smaller or lower-quality datasets. Additionally, the model may be computationally expensive, which may limit its practical application in certain settings. Table IV shows the comparison of the proposed model's performance with other methods based on classification precision. Our proposed model achieved the highest accuracy of 95.44% compared to previous work in this field, which shows the superior quality of the model.

TABLE V. COMPARISON WITH PREVIOUS WORK

Authors	Method/ Brain tumor data	Accuracy (%)

This work	**CNN Multi-classifying/MRI images**	**95.44**

VI. CONCLUSIONS AND PERSPECTIVES

To summarise, the proposed CNN model for classifying cerebral tumors based on MRI images is a promising tool for aiding medical professionals in diagnosing brain tumors accurately and efficiently. The high accuracy rate achieved by the proposed model compared to other deep neural models indicates the effectiveness of DCNNs in classifying brain tumors based on MRI scans. The proposed model's architecture is designed for optimal performance on medical image datasets, making it a promising tool in the field of medical image analysis. However, it is essential to recognize the limitations of the proposed model, such as the need to carefully evaluate its generalizability to other datasets and clinical scenarios, as well as the potential computational cost and data requirements. Future research should focus on developing more robust and accurate models by exploring alternative approaches and using larger and more diverse datasets.

Additionally, the proposed model's applicability for different MRI classifications and potential incorporation of other types of medical imaging data, such as CT scans, PET scans, or MRS data, offer exciting possibilities for improving the accuracy and effectiveness of medical image analysis. The development of more sophisticated models and techniques will lead to more accurate and efficient diagnosis and treatment of cerebral tumors, ultimately benefiting patients and medical professionals alike.

Our future research will focus on developing more robust and accurate models by exploring alternative approaches and using larger and more diverse datasets. It may also be worth investigating the potential for incorporating other types of medical imaging data.
