***Abstract*—As technology continues to evolve, humans tend to follow suit, and currently social media has taken place as the defacto method of communication. As it tends to happen with verbal communication, people express their opinions in written form and through an analysis of their words, one can extract what an individual wants from a product, a topic, or an event. By looking at the emotions expressed in such content, governments, businesses, and people can learn a lot that can help them improve their strategies. Therefore, in this study, we will use different algorithms to improve the Moroccan sentiment classification. The first step is to gather and prepare Moroccan Dialectal Arabic Twitter comments. Then, a lot of different combinations of extraction (n-grams) and weighting schemes (BOW/ TF-IDF) and word embedding for feature construction are applied to get the best classification models. We used Naive Bayes, Random Forests, Support Vector Machines, and Logistic regression and LSTM to classify the data we prepared. Our machine learning approach, which incorporates sentiment analysis, was designed to analyze Twitter comments written in Modern Standard Arabic or Moroccan Dialectal Arabic. As a final benchmark of our paper, we were simply a sliver shy away from the 70% mark in our accuracy by relying on the SVM algorithm. Although not a game-changing result, this was enough to encourage us to continue developing our model further.**

Keywords—Sentiment analysis; Arabic Moroccan dialect; tweets; machine learning

I. Introduction

Natural Language Processing (NLP) attempts to make the machine capable of understanding and generating human language, whether it be written or audible [1] NLP is also one of the most important and challenging areas of artificial intelligence. It has many obstacles [2], especially in Arabic, which will be a topic we discuss later in this article. Sentiment Analysis (SA), or opinion mining, is the mathematical study of people's opinions, emotions, sentiments, ratings, and attitudes about products, services, organizations, individuals, issues, events, topics, and attributes [3]. SA has become one of the most prominent applications of NLP.

In recent years, Machine Learning (ML) and Deep Learning (DL) techniques has been widely used in various classification and prediction problems such as handwritten recognition [4]–[7], medical applications [8]–[13], social media analysis [14]–[16], etc. In particular, applying Arabic sentiment analysis makes it possible to extract the public's opinion on one or many topics through tweets. The use of social media has become a major contributing factor in the performance of Arabic SA tools [17]. With the rise of social media platforms such as Twitter, Facebook, and Instagram, individuals can now express their opinions and feelings on various topics in real-time. This provides a rich source of data for researchers and businesses to understand the sentiment of the public.

Many researchers have opted to use different approaches like sentiment analysis and opinion mining to classify people's views and comments, ranging from negative, positive, and neutral perspectives. These techniques involve using Machine Learning (ML) algorithms to analyze large amounts of textual data to identify patterns and classify the sentiment expressed in the text. By using these techniques, researchers can understand the public's opinion on a variety of topics, such as politics, sports, entertainment, and social issues. One of the challenges of performing Arabic sentiment analysis is the complexity of the Arabic language. Arabic is a highly inflected language with many variations in grammar and vocabulary across different regions. This makes it difficult to develop accurate sentiment analysis tools that can accurately classify the sentiment of the text. However, recent advances in natural language processing and machine learning techniques have made it possible to overcome these challenges.

The following research is an attempt to apply sentiment analysis on Moroccan people's tweets in order to extract reactions from them by using local idioms and terms in their native dialect as a basis. With the increasing use of social media platforms such as Twitter in Morocco, it has become an important source of information for individuals, businesses, and governments. Therefore, there is a growing need for sentiment analysis to help these groups understand the opinions and emotions expressed by the public. Our goal is to develop a sentiment analysis (SA) model that can accurately classify Arabic Moroccan dialect tweets as negative, positive, or neutral. To achieve this, we gathered a large dataset of Moroccan Dialect Arabic (MDA) tweets from Twitter. However, collecting this dataset was not a straightforward task. Moroccan Arabic is a complex dialect that varies greatly from region to region, and there is no standard written form of the dialect. Therefore, we had to collect tweets that were written in the dialect and filter them to collect various sorts of terminology to identify MDA efficiently.

To develop our SA model, we employed various techniques such as word recognition, named entity recognition, stop word removal, and stemming to preprocess the collected tweets. We also experimented with different feature extraction techniques such as n-grams and weighting schemes like Bag of Words (BOW) and Term Frequency-Inverse Document Frequency (TF-IDF) to construct effective features for our model. Additionally, we used word embedding to capture the semantic relationships between words and phrases. We employed several machine learning algorithms such as Naive Bayes, Random Forests, Support Vector Machines (SVM), Logistic Regression, and Long Short-Term Memory (LSTM) to classify the tweets based on their sentiment. These algorithms were trained on a portion of the dataset and tested on a separate set of tweets to evaluate their accuracy and effectiveness. Our SA model is unique in that it specifically focuses on Moroccan Dialect Arabic tweets and uses local idioms and terms to improve its accuracy. The results of our experiments are promising, as our model achieved high accuracy in classifying tweets as positive, negative, or neutral.

The structure of this article can be outlined as follows: In Section II, the related work on the topic is discussed to provide context and background for the reader. Section III is dedicated to explaining the methodology used in this research, including the steps taken to collect and prepare the data, the feature selection and extraction techniques used, and the machine learning algorithms applied for classification. The results of the experiment are presented in Section IV, where we discuss the performance of the different models. Finally, in Section V, we conclude the paper by summarizing the findings, discussing their implications, and suggesting directions for future research.

II. Related Works

We have noticed that the majority of the SA's research is focused on English. As a result, many high-quality frameworks and tools for English text are now available. For other languages, such as Arabic, however, research efforts are still needed to propose tools that are more refined. However, in recent years, many research topics continue to improve upon Arabic sentiment analysis and other dialectical Arabic sentiment analysis. Duwairi and Qarqaz build a Sentiment Analysis (SA) model for Arabic comments on social media platforms [18]. They used word bi-grams as features for representing the text in their model. They also evaluated the performance of different classifiers, including Support Vector Machine (SVM), Naive Bayes (NB), and K-Nearest Neighbour (KNN), with the use of term frequency (TF) and term frequency inverse document frequency (TF-IDF) weighting methods. Furthermore, Ayah Soufan [19] used text data from Twitter and GoodReads to conduct sentiment analysis for the Arabic language. He also worked on two different tasks: binary and multi-class categorization. He noted that the outcomes vary depending on the dataset and model employed. Modern Standard Arabic (MSA) and Arabic dialects differ on all "linguistic representation levels such as morphology, lexicon, phonology, syntax, semantics, and pragmatics," which is why the results vary depending on the dataset.

In [20], the authors compare different types of ensemble methods. By simply using individual classifiers, on Arabic sentiment analysis, it became apparent that SVM was the better performer, by a decent margin. However, when compared to the performance of a combination of different classifiers, no individual classifier performed nearly as well.

Another work [21] by using NB classifier, described a method for automatically generating a corpus that can be used to train a multilingual sentiment classifier to classify tweets into positive and negative categories.

In [22], the authors collected and labeled a dataset of 17000 Tunisian dialect comments from Facebook, which they used to build a Tunisian dialect sentiment analysis (SA) system using three classification algorithms: support vector machine (SVM), Naive Bayes (NB), and Multi-Layer Perceptron (MLP). They found that their method outperformed models trained on other dialects or on a MSA) dataset.

In the study [23], the authors proposed a framework that employs a variety of approaches and efficient models for both Arabic text pre-processing and ASA. In the case of ASA, their study revealed that Deep learning (DL) models are more efficient and accurate than ML (SVM, NB, and ME). In all of the following scenarios, DL models outperformed traditional models: when using unigrams, when using stop words, without stop words, when using stemming, a without stemming. This study demonstrated the significant accuracy and performance potential of DL for ASA.

In another work [24], the authors analyze the sentiment of 4625 comments written in MSA and multidialectal Arabic from Yahoo!-Maktoob using support vector machines (SVM) and naive Bayes (NB) classifiers, which are commonly used for sentiment classification. They tested the classifiers using both balanced and imbalanced datasets, but the results were unsatisfying as the highest accuracy achieved was 70%.

III. Materials and Methods

A. Global Overview of the Proposed System

Fig. 1 is a plain summary of the approach we decided to adopt throughout our study.

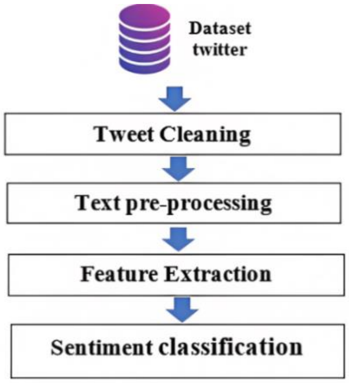

Fig. 1. Simplified Process for SA.

B. Moroccan Dialect Recognition Challenges

Darija is a Moroccan dialect (MD) of Arabic that is widely utilized by Moroccans, brand sites on social media, television programs, and Ads that tend to reach out to the public. It is influenced by various other languages, including Berber, French, Spanish, and Andalusian Arabic, and has its own distinct grammar, vocabulary, and pronunciation, However, Darija maintains its distinctive characteristics in terms of spelling, syntax, vocabulary, and pronunciation [25]. In recent times, the use of written forms of Darija has increased significantly across various platforms. Some difficulties still stand in the face processing Darija, some of which are:

- Domain Dependency [26]: Factors such as culture, context, and basic usage of the language heavily affect performance.
- Code Switching: The French-Spanish colonization of Morocco left a lasting effect on Darija's history, providing her both French and Spanish words/sentences. On top of that, Berber language, which around 40% of Moroccans speak fluently, managed to find a spot in the basic structure of the language. As a result, MSA, Berber, French, Spanish, and English can all be found in Darija writing [27].
- Romanized Arabic: There is no orthographic standard in Darija. It can be written in Arabic [28], Latin, or both (Arabizi). A combination of the two is often used on social media, with numbers being used as substitutes to inexistent letters in the Roman alphabet, such as welcome=Mer7ba = مرحبا, happy= fer7an=سعيد, sleep=n3ass=النوم.

However, the biggest challenge of them all is the limited resources, and the difficulty of extracting datasets.

C. Process of Moroccan Arabic Dialect Tweet for Sentiment Analysis

In this section, we present a Machine Learning (ML) process for SA conducted on twitter comments written in MDA. This process starts by cleaning tweets, pre-processing them and before classification, where we performed a features selection process aiming to reduce the dimensionality and improve the quality of our classification models. Finally, comes the evaluation step where the performance of our model is measured. Fig. 2 describes the proposed ML system of Arabic Tweet for sentiment analysis.

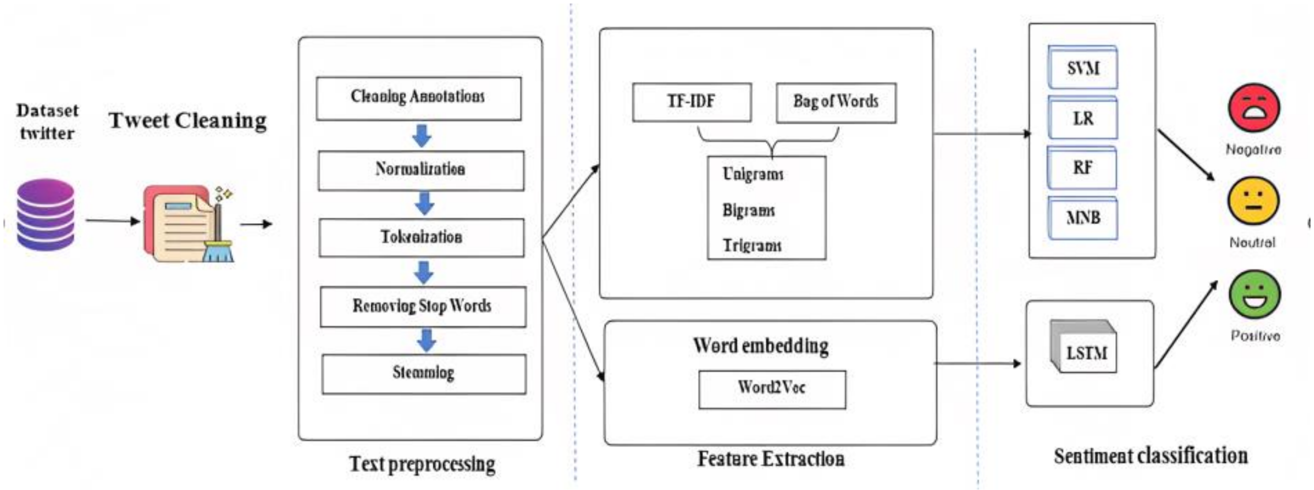

Fig. 2. Sentiment analysis: A ML approach.

D. Dataset Description

In our study, we used a dataset of SA for social media posts in Arabic dialect, publicly available from the Modeling, Simulation and Data Analysis (MSDA)[1]. The data (tweets), scrapped from active users located in a predefined set of Arab countries consisting mainly of Lebanon, Algeria, Egypt, Tunisia and Morocco, got narrowed down to tweets relevant to Morocco only. The selected dataset contains 1605 positive tweet, 1620 negative tweet and 1630 neutral tweet. In Table I, we present some illustrative samples.

The word cloud schemes in Fig. 3, Fig. 4, and Fig. 5 present the density of words in relevance to the class from where it originates.

E. Data Pre-processing Steps

1) Tweet cleaning: In order to clean our dataset, we had to remove the tweets:

- Written in Roman alphabet.
- Those are spam or insults.
- Composed of a single word.

2) Cleaning annotations: In order to rend our tweets more functional, all “http/https“ are removed, as well as special symbols (*, &, $, %,-,_,:,!,><). Whatever we remove, we replace with an empty space. We apply the same for the emoji’s.

TABLE I. ANNOTATED SAMPLE.

Comment	English translation	Sentiment
لن نضيع اوقات اطفالنا بتعليم لهجة ما عندها فايدة و كافي ان كل طفولتهم تروح في التعليم نزيدو لهم لهجة تتعبهم و تمحي هويتهم	We will not waste our children's time by teaching them a dialect that's useless. It's enough that their time is consumed by education, and to top it all we add a dialect that would tire them and erase their identity.	Negative
هاد الولد ممتل المغرب في أكبر مسابقة ديال صناع المحتوى في العالم العربي.. وليوم هو في النهائيات	This boy is the Moroccan representative in the biggest content creation contest in the Arabic world, and today he's a finalist.	Neutral
ترامب عين البروفيسور منصف السلاوي للإشراف على تطوير اللقاح , لمغاربة حصلو له مغربي ولا .فواش نقولو أمريكي ولا بلجيكي	Trump appointed Prof. Monsif Essalaoui as a supervisor for vaccine development. Moroccans didn't know what to call him 'Moroccan', 'American, or 'Belgium'.	Positive

Fig. 3. Positive class word occurrence.

Fig. 4. Negative class word occurrence.

Fig. 5. Neutral class word occurrence.

3) Tweets pre-processing: In order to boost the performance of the SA process, we must perform several pre-processing steps on the collected tweets. These steps are as follows:

- Normalization: Normalization is necessary, as there is no universally accepted rule for the spelling of certain Arabic letters. We perform our normalization by deleting all unnecessary spaces, and then replacing every un-normalized letter with its normalized version. As indicated in Table II, based on the Pyarabic library, normalization is as such:

- Tokenization: as an integral step in SA, reduces typographical variation of words. It is also necessary since it is required to use techniques such as Feature Extraction [29]. As the Arabic language is known to be hard to deal with, a dictionary of features that can transform words into feature vectors, or feature indexes, is a must. This way, the index of the word is linked to its frequency in the complete Dataset.

TABLE II. NORMALIZATION OF SOME ARABIC LETTERS

UnNormalized Arabic Letters	Normalized Letters
ؤ، ىء **Hamza**	ء
أ، ا **Alef**	ا
ال، أل **Lamalef**	ال
ى **Yah**	ى
ة **Hah**	ه
ؤ **Wow_hamzah**	و

- Removing stop words: Not all stop words are actually helpful in understanding the full meaning of the tweet, which is why deleting some of them is an essential step. Deleting words like articles, prepositions, conjunctions, and pronouns that are overused and do not provide any information about the subject of the documents must be carefully done.

- Data Stemming and Lemmatization: Stemming is a process where, by removing prefixes and suffixes, a word is returned to its root form [30] . Similarly, lemmatization finds the basis of the word while taking into consideration its morphological nature; a meaning conserving lemma is then extracted. We opted to use the following stemmers in our study:

- ISRI Stemmer [31] is a stemmer that uses the same sequence as other stemmers to derive the root-base of Arabic words[2]. On the other hand, ISRI does not need to confirm the extracted root with a stored root dictionary, as the other stemmer does, because locating the correct root is not critical. ISRI eliminates two- and three-letter prefixes, normalizes Hamza, and eliminates connector letters such ("ثم ").

- Assem's Arabic Light stemmer is frequently used for a variety of text processing tasks, such as text categorization, information extraction, text summarization, and search engine indexing. It is important for researchers to carefully evaluate and compare different stemmers in order to select the one that is most suitable for their specific needs and context[3]. Table III present examples of executing tasks.

- Tashaphyne is a stemmer tool specifically designed for analyzing the sentiment of Arabic roots [32]. It has been shown to be effective at mapping Arabic words to their basic roots for sentiment analysis tasks, resulting in significant improvements compared to baseline performance [33].

F. Features Extraction

N-gram is a traditional method for identifying formal terms in tweets that takes into account the occurrences of N-words in the tweet. The value of n is used to refer to N-grams of larger sizes [34]. During our research, we used unigrams, bigrams, and trigrams to get the best results. Table IV is the perfect example on the results obtained by applying this method on our tweets.

We employed two alternative feature extraction algorithms: Bag of Words [35] generates a vector that represents the frequency of occurrences of words. The Bow model, frequently used in text processing to classify and recognize documents, is known for simplicity and effectiveness. The TF-IDF was created to address the limitations of the more basic strategy of counting each term's occurrences, in which highly common terms end up with very big values and uncommon words (which are normally a good discriminant between texts) can be buried in the noise. The TF-IDF approach is used to weight terms based on their relevance within the document and corpus [36]. Words with a high TF-IDF score are those that appear frequently in a document but not across the corpus.

TABLE IV. FEATURES EXTRACTION

Task	Result	Simulated English result
Cleaned text	['مستوى','صل','طلب','مغرب', بركة,'إصلاح','ثان','خارج', 'جيل','ذهب']	[‘ disappoint ’,’ current ’,’ level ’,’ Moroccan ’,’ student ’,’ graduat ’,’ high ’,’ school ’,’ juvi ’,’ Salut ’,’ golden ’,’ gener ’]
Uni-gram n=1	['مستوى', 'صل', 'طلب', 'مغرب', 'خارج', 'إصلاح', 'بركة', 'جيل']	[‘ disappoint ’,’ current ’,’ level ’,’ Moroccan ’,’ student ’,’ graduat ’,’ high ’,’ school ’,’ juvi ’,’ Salut ’,’ golden ’,’ gener ’]
Bi-gram n=2	['مستوى صل', 'صل طلب', 'طلب مغرب', 'مغرب خارج', 'خارج إصلاح', 'إصلاح بركة', 'بركة جيل']	['disappoint current', 'current level', 'level moroccan', 'moroccan student', 'student graduat', 'graduat high', 'high school', 'school juvi', 'juvi salut', 'salut golden', 'golden gener']
Tri-gram n=3	['مستوى صل طلب', 'صل طلب مغرب', 'طلب مغرب خارج', 'مغرب خارج إصلاح', 'خارج إصلاح بركة', 'إصلاح بركة جيل']	['disappoint current level', 'current level moroccan', 'level moroccan student', 'moroccan student graduat', 'student graduat high', 'graduat high school', 'high school juvi', 'school juvi salut', 'juvi salut golden', 'salut golden gener']

Term Frequency is calculated by dividing the total number of words in a document by the number of times each term appears in the document.

$$tf_{i,j} = \frac{n_{i,j}}{\sum_k n_{i,j}} \tag{1}$$

Inverse Document Frequency is the log of the number of documents divided by the number of documents that contain the word.

$$w_{i,j} = tf_{i,j} \times \log\left(\frac{N}{df_i}\right) \tag{2}$$

t_{ij} = Occurrences of i in j.

df_i = Documents containing i.

N = Total number of documents.

This increases the weight of rare words across all documents in the corpus. Note that when we compute the TF-IDF for every word in every document of a corpus, it will form a matrix of shape (documents * vocabulary).

Word embedding methods turn words into digital vectors. These vectors include more or less information about the semantics and syntax of the word depending on the model employed and the context in which it was used [37]. There are numerous word embedding strategies available.

Word2vec is a renowned word-embedding model developed at Google in 2013. It incorporates a neural network layer to either predict adjacent words to the target word (context) in the case of the skip gram architecture, or the word from its neighbors in the case of the CBOW (Continuous bag of words). Word2vec's input and output are a one-time encoding of the dataset's vocabulary words. During training, a window moves through the corpus [38], training the neural network to predict surrounding words or a target word for each word by assigning a probability to the words. After training, the network layer is the vector representation of a word. In our case, we implemented a Wikipedia-made word2vec model for Arabic language.

G. *The Used Classifiers*

The data was classified using four supervised machine-learning algorithms: Naive Support Vector Machine classifier (SVM), Multinomial Naive Bayes (MNB), Logistic regression (LR), Random forest (RF), and one DL algorithm: Long Short-Term Memory (LSTM). We aim to answer the following question: Can ensemble learning (combining different classification algorithms) improve Arabic sentiment classification?

In what follows, we explain those algorithms:

1) Support vector machine: Support vector machine is a supervised learning technique commonly used to classify jobs. In a high-dimensional space, it is extremely efficient. It also works well when the number of dimensions is more than the number of data. SVM is a discriminative classifier whose basic principle is to construct decision boundaries that distinguish between a set of objects belonging to various classes [39].

2) Multinomial Naive Bayes (MNB): Multinomial Naive Bayes is a supervised machine-learning algorithm that relies on annotated data for training. It is based on the Bayes theorem and is well suited for high-dimensional input data like text. It is a generative model that relies on conditional probabilities and assumes that the features are conditionally independent [40]. Despite its simplicity, it is a very effective algorithm and can outperform more complex classifiers on short datasets. It is also relatively robust, easy to implement, and fast to run.

3) Logistic regression: The statistical model of logistic regression is used to investigate the associations between a set of qualitative variables X and a qualitative variable Y. A logistic function is used as a link function in the generalized linear model. The optimization of the regression coefficients in a logistic regression model can also be used to forecast whether an event will occur (value of 1) or not (value of 0). This outcome is always between 0 and 1 [41]. The event is more likely to happen if the anticipated value is above a certain threshold, but not if it is below the same threshold. The hypothesis representation of logistic regression defined as follow:

$$h\theta(X) = \frac{1}{1+e^{-(\beta_0+\beta_1 X)}} \qquad (3)$$

The cost function of LR is defined as follow:

$$\mathrm{J}(\theta)=\frac{1}{\mathrm{M}}\sum_{\mathrm{i}=1}^{\mathrm{M}} \mathrm{cost}\left(\mathrm{h}\theta\left(\mathrm{x}^{(\mathrm{i})}\right),\mathrm{y}^{(\mathrm{i})}\right) \qquad (4)$$

With M is the size of training set.

4) Random forest: Random forest is a consensus approach for solving regression and classification problems in supervised machine learning (ML). Each random forest is made up of several decision trees that work together to provide a single prediction [42].

5) Long short-term memory: Long short-term memory (LSTM) networks are a type of recurrent neural networks (RNN) that have a longer memory than traditional RNNs. They are well suited for learning from large, complex data sets that have long delays between important events. LSTM units are used to build the layers of an RNN, which is then called an LSTM network. LSTMs allow RNNs to retain information over a long period of time [43] by using a memory cell that is similar to computer memory, where it can read, write, and delete information as needed. This memory cell is gated, meaning that it decides whether to store or delete information based on its perceived importance, as determined by learned weights. There are three gates in an LSTM: an input gate, a forget gate, and an output gate. Fig. 6 illustrates a LSTM memory cell structure. These gates control whether new input is accepted (input gate), whether information is suppressed because it is not important (forget gate), or whether it is allowed to influence the output at the current time step (output gate) [44]. The importance of each piece of information is determined by the learned weights of the LSTM, which are updated as the algorithm learns over time.

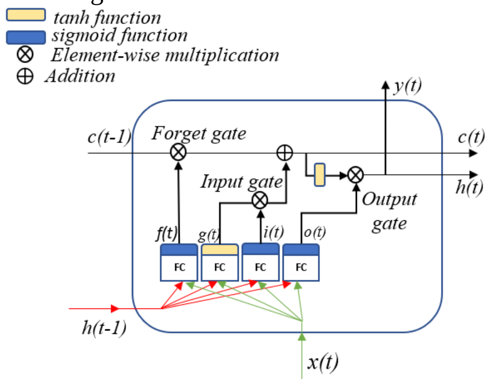

Fig. 6. Single LSTM memory cell.

IV. Results and Discussion

A. *Confusion Matrix and Performance Evaluation Measures*

A confusion matrix, also known as a contingency table, is a tool used to evaluate the accuracy of a machine learning model's predictions in classification problems. It compares the model's predictions to reality and shows how often the predictions are correct. To understand how a confusion matrix works, it is important to familiarize oneself with the four key terms: true positive (TP), true negative (TN), false positive (FP), and false negative (FN). These terms represent the different outcomes of a prediction and are defined as follows:

- TP (True Positives): the cases where the prediction is positive, and where the actual value is actually positive. Example: the doctor tells you that you are pregnant, and you are indeed pregnant.
- TN (True Negatives): the cases where the prediction is negative, and where the actual value is actually

negative. Example: the doctor tells you that you are not pregnant, and you are indeed not pregnant.

- FP (False Positive): Cases where the prediction is positive, but the actual value is negative. Example: the doctor tells you that you are pregnant, but you are not pregnant.
- FN (False Negative): Cases where the prediction is negative, but the actual value is positive. Example: the doctor tells you that you are not pregnant, but you are pregnant. Various measures can be derived from a confusion matrix. In this work, we utilized four scoring performance metrics: accuracy, precision, recall, and F1 score. The following equations provide these metrics:

$$F_1 \text{ score} = \frac{2*(\text{ precision} \times \text{recall})}{\text{precision} + \text{recall}} \quad (5)$$

$$\text{Recall}= \frac{\text{TP}}{\text{FN+TP}} \quad (6)$$

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (7)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (8)$$

B. Training of ML Models Results

Our implementation and training of the model heavily relied on the Scikit-Learn library. Vectorization, pipeline and training were imported from its sub libraries. Similarly, our different scripts (based on SVM, Random Forest, Naïve Bayes, and Logistic regression) were applied and tuned using this library. GridSearchCV adjusted the parameters, and followed up with training and comparison; for LSTM, it was the TenserFlow library. We also used Google Colab platform to train our models.

C. Testing of ML Models Results

From Table V we are able to gauge the average accuracy obtained by using different algorithms on top of two separate vectorization methods (BOW, TF-IDF), which is in and of itself topped off with stemming algorithms, including the ISRI Stemmer, Assem's Arabic Light Stemmer and Tashafyn light Stemmer. Several tests were carried out on the dataset in order to assess the influence of stemming after it had been pre-processed (without undergoing stemming). Based on the outcomes of these tests, we can safely deduce that the SVM algorithm is the highest performer, boasting an accuracy of 0.68. Combining ISRI Stemmer, TF-IDF, Uni-gam + Bi-gam, and the SVM classifier resulted in this accuracy. However, when looking at the Tashafyn light stemmer system, we obtained the highest accuracy after using a mix of Bag of Words, Uni-gam + Bi-gam + Tri-Gam, and the SVM algorithm once again. This accuracy clocked at 0.678. As we compare these results with those obtained when using no Stemming, we notice that stemming proved itself an indispensable method that reliably improves performance and accuracy.

TABLE V. CLASSIFICATION OF EXPERIMENTATION RESULTS

Stemming Mechanism	**Classifier**	**TF-IDF**			**Bag of Words**			**Word Embedding**
		Uni-gram	**1g+2g**	**1g+2g+3g**	**Uni-gram**	**1g+2g**	**1g+2g+3g**	
No-stemming	LR	63.00%	63.00%	65.00%	64.00%	64.00%	65.00%	-

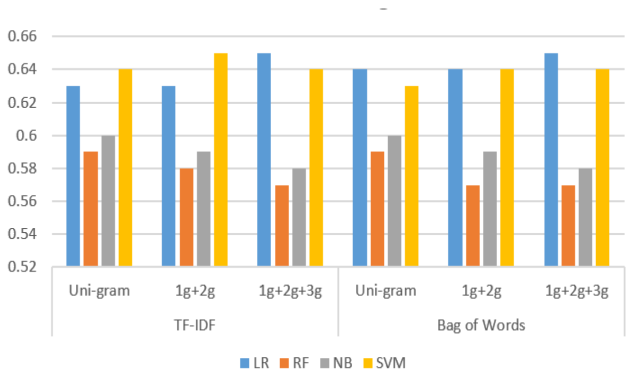

Fig. 7. Classifiers' accuracy with no stemmers.

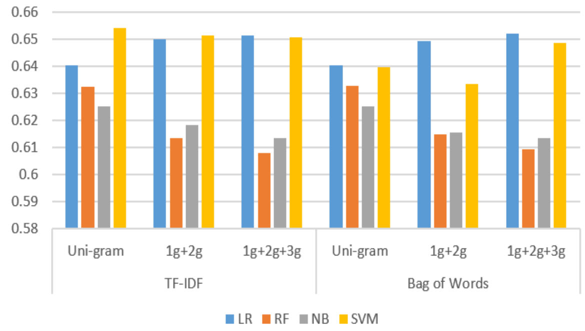

Fig. 8. Classifiers' accuracy with assem's arabic light stemmer.

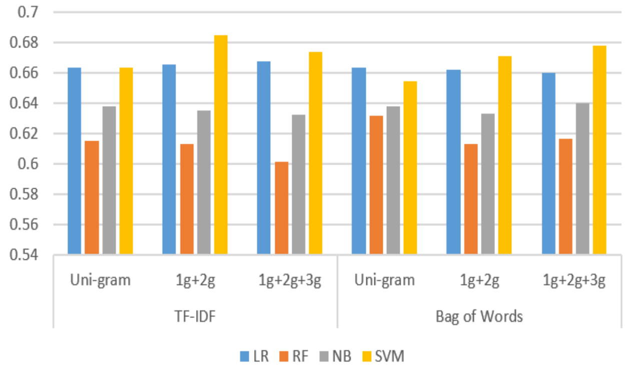

Fig. 9. Classifiers' accuracy with tashafyn light stemmers.

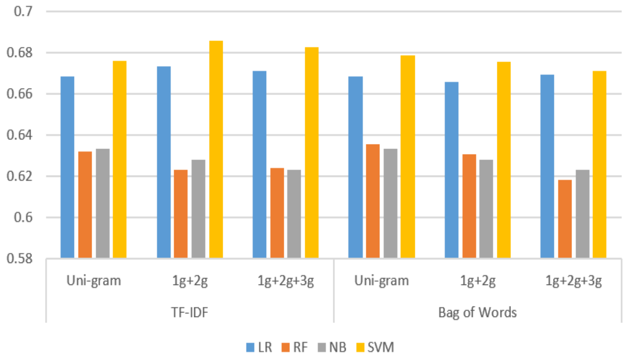

Fig. 10. Classifiers' accuracy with ISRI stemmers.

Fig. 7, Fig. 8, Fig. 9 and Fig. 10, which managed to better visualize the performance spread using the different stemmers, show a clear pattern where SVM and LR are the top performers even when taking into account the different feature extraction methods implemented (TF-IDF and Bag of Words). We managed to push the SVM accuracy all the way to 68.59% using the ISRI Stemmer as well as the combination of TF-IDF and 1g-2g feature extraction methods (these same methods also resulted in the highest value for LR: 67.36%). It should also be noted that despite implementing three different types of stemmers, we do not see very strong variations in the accuracy score across the board. This is largely because these custom-made stemmers for the Arabic language still leave a lot to be desired in terms of efficiency and performance.

Table VI summarizes our top scorer's (ISRI Stemmer+ (Uni-gram+Bigram) + SVM+TD-IDF (feature extraction)) Performance evaluation measures- the Precision, Recall, and F1-score for each one of our selected sentiments (positive, negative, or neutral). We notice that our model is extremely accurate when classifying neutral sentiments, as it has the highest precision score of 0.74.

TABLE VI. PERFORMANCE EVALUATION METRICS

Model		Precision	Recall	F1-score
ISRI Stemmer +(Uni-gram+Bigram)+SVM+TD-IDF (feature extraction)	neg	0.64	0.64	0.64
	neu	0.74	0.74	0.74
	pos	0.66	0.66	0.66

The confusion matrix of the model that had better performance in the detection sentiment analysis is shown in Fig. 11. On the diagonal, we can see 260 neutral sentiments were correctly predicted as neutral, and 198 positive sentiments were also correctly predicted as positive, and the same can be said for the 168 negative sentiment. On the other hand, it is obvious that the outliers of the matrix are heavy on numbers, as the maximum that a model should have wrongly predicted should not exceed 5-10.

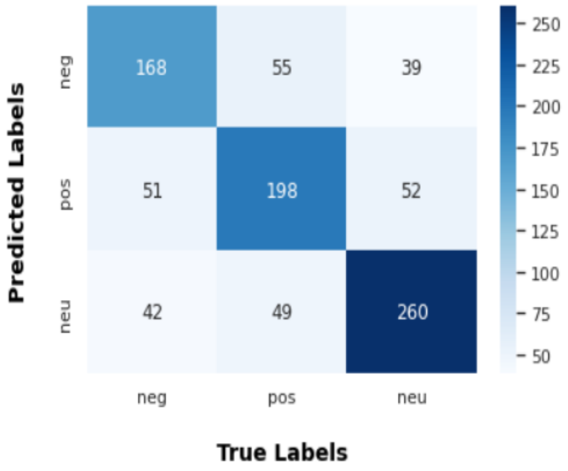

Fig. 11. Confusion matrix of the model (ISRI Stemmer+ (Uni-gram+Bigram) + SVM+TD-IDF (feature extraction).

For LSTM model that we adapted for our research, we managed to achieve the results described in Table VII. We immediately notice that the Accuracy, Recall, and F1-score all receive a slight bump in their values as we apply the different Stemmers. However, for our Precision score, our max value remains the one where no Stemmer is applied.

TABLE VII. LSTM'S MODELS PERFORMANCE

Stemmers	Accuracy	Recall	F1-score	Precision
No-stemming	61.50%	68.57%	67.29%	66.06%
Tashafyn Light Stemmer	63.00%	72.83%	68.97%	65.49%
ISRI Stemmer	63.90%	73.10%	69.25%	65.79%
Assem's Arabic Light Stemmer	62.00%	71.70%	68.30%	65.22%

D. *Discussion*

The ROC curve is an evaluation metric commonly used to plot the True Positive Rate vs. the False Positive Rate. While this metric is mainly used for classification problems that are binary, we managed to push it in order to encompass out multiclass classification problem, all by using the one vs. Rest technique (We calculate the AUC-ROC curve by considering each label independently). In Fig. 12, based on the results from the SVM model, we see how our Neutral label is our best performer, while the Negative and Positive labels are lagging slightly behind. While the Negative and Positive labels intertwine at different thresholds, the Neutral label maintains an advantage throughout. Our results are far from perfect, but they are not disappointing as there is still much to improve upon our study.

The support vector machine (SVM) algorithm outperformed all other classifiers on all datasets, showing a significant difference in performance. SVM is a popular choice for sentiment analysis studies due to its various advantages, such as its ability to handle high-dimensional spaces efficiently and its robustness when working with a sparse set of samples. It also considers all features relevant.

As one can tell from Table VIII, LSTM was nowhere near as powerfully performant as the SVM algorithm. Though Word Embedding is said to be more advanced compared to the bag of words method, in our case where we are processing the Darija Language, it is actually held back by the fact that the Dictionary used in the Word2Vec method is based on the Arabic language and not Darija. This means that when classifying Darija words, many are found to be unclassifiable.

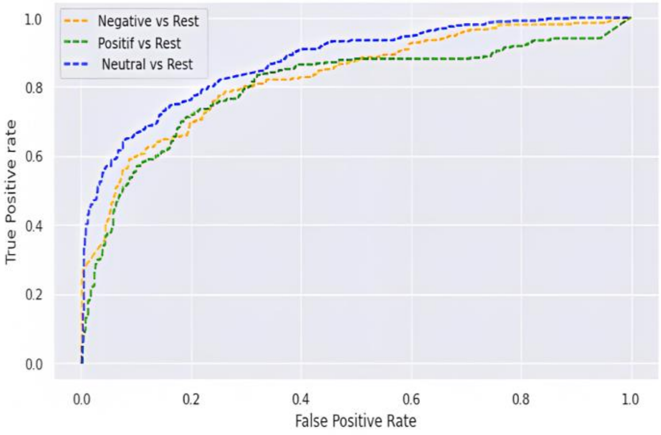

Fig. 12. ROC curves one vs rest.

TABLE VIII. SUMMARY OF ALL THE EXPERIMENTAL FINDINGS PROVIDED IN THIS RESEARCH

Reference	Dataset	Feature Representation	Classification Algorithm	Best Accuracy
[18]	Scrapping dataset	(TF) and term frequency inverse document frequency (TF-IDF)	Supervised Classification(SVM, NB, and K-nearest neighbour (KNN)	67,19%

[22]	TSAC (Tunisian Sentiment Analysis Corpus)	None	(SVM) and Naive Bayes (NB)	76,41%
[24]	Yahoo!-Maktoob	None	SVM, NB	68.2%
This work	**dataset of Sentiment Analysis for social media posts in Arabic dialect from MSDA**	**(TF) and term frequency inverse document frequency (TF-IDF),** **Word embedding** **Bag of words, N-gram**	**LR, RF, MNB, SVM, LSTM**	**68,59%**

V. CONCLUSION AND PERSPECTIVES

In this study, we went through the steps and methods that allowed us to test the different approaches of sentiment analysis' performance and efficiency. Our Dataset, consisting of 4855 tweets/comments split into three balanced groups of negative, positive and neutral sentiments, underwent multiple thorough processes in order to take advantage of it. We began by incorporating a variety of pre-processing techniques (stemming, normalization, tokenization, stop words, etc.) to improve Sentiment Analysis of Moroccan Tweets. Then, in the hopes of drawing out the maximum possible accuracy, five classification algorithms: NB, LR, RF, SVM, and LSTM, were combined as an application of the Ensemble Method. Finally, we delved into a comparison of three types of FE method: BOW, TF-IDF and WE. The results for individual classifiers made it clear that SVM performed on a higher level compared to the other algorithms. There was also a noticeable performance boost when it came to using Stemmers vs. using no stemmers; the only drawback being an increase in the computational time. Our next step is to use other DL models such as BERT

We plan to further improve our SA model by incorporating more advanced deep learning techniques, such as BERT, and exploring other FE methods that may provide better accuracy. We also aim to expand our dataset to include more diverse sources of Moroccan Arabic language and include more topics to enhance the model's performance on a wider range of subjects. Additionally, we plan to extend our research to cover other Arabic dialects to provide more comprehensive sentiment analysis for the Arabic language. Finally, we hope to collaborate with other researchers in the field to develop a standardized evaluation framework for Arabic sentiment analysis to facilitate comparison and benchmarking between different approaches and models.

***Abstract*—According to estimations made by World Health Organization, heart disease is the largest cause of mortality throughout the globe, and it is safe to assume that diagnosing heart diseases in their earliest stages is very essential. Diagnosis of cardiovascular disease may be carried out by detection of interference in cardiac signals, one of which is called phonocardiography, and it can be accomplished in a number of various ways. Using phonocardiogram (PCG) inputs and deep learning, the researchers aim to develop a classification system for different types of heart illness. The slicing and normalization of the signal served as the first step in the study's signal preprocessing, which was subsequently followed by a wavelet based transformation method that employs mother wavelet analytic morlet. The results of the decomposition are first shown with the use of a scalogram, afterwards, they are utilized as input for the deep CNN. In this investigation, the analyzed PCG signals were separated into categories, denoting normal and pathological heart sounds. The entire utilized data was divided into two categories as training and test data as 80% to 20%. The developed model demonstrates the degree of clinical diagnosis, sensitivity, specificity and AUC-ROC value. As a result, it has been determined that the proposed method was superior to the mother wavelet as well as other classifier approaches. Consequently, we were able to acquire an electronic stethoscope that has a diagnostic accuracy of more than 90% when it comes to identifying cardiac problems. To be more specific, the proposed deep CNN model has an accuracy of 93.25% in identifying aberrant heart sounds and 93.50% in identifying regular heartbeats. In addition, given the fact that an examination may be completed in only 15 seconds, speed is the primary advantage offered by the suggested stethoscope.**

***Keywords*—Deep learning; CNN; heart disease; phonocardiogram; classification; detection; PCG**

I. Introduction

It is common knowledge that cardiovascular diseases are now among the most serious and widespread. [1] Disorders of the cardiovascular system are the primary cause of mortality on a global scale [2], thus determining the significance of clinical and scientific substantiation and the importance of ensuring early diagnosis of heart diseases [3]. The ease of implementation, functional value, and dependability of these approaches are the most vital qualities to look for in a solution.

There is a variety of approaches to make a heart disease diagnosis [4]. One of the most employed approaches is electrocardiography (ECG) [5]. On the other hand, the electrocardiogram provides a direct description of the status of the heart at the moment of registration. In certain instances, the electrocardiogram does not accurately represent all of the current problems (such as the existence of cardiac disturbances), which necessitates the fulfillment of additional requirements for registration [6].

Phonocardiography, often known as PCG, is a useful adjunct to electrocardiography since it enables investigation and detection of the existence of abnormalities in the cardiac cycle and its valve system [7]. Heart sound measurement that is produced by the diastolic and systolic phase are known as phonocardiograms. The technique involves capturing and analyzing heart sounds, made at various stages, including during its contraction and relaxation. Moreover, this approach can detect the functional condition of cardiovascular illnesses in a manner that is both reasonably priced and not too complicated. In this case, the phonocardiosignal serves as the diagnostic information source, and phonocardiography is the term for the applied recording technique.

In recent times, the field of cardiology has seen a surge in the number of research projects that make use of data analysis. For the purpose of making an accurate diagnosis, the data obtained from PCG and ECG are examined [8-11]. The auscultation of the heart remains an essential diagnostic tool for determining the well-being of the cardiovascular system [12]. As a result, diagnostic techniques have been developed that reasonably minimize the need for non-invasive detection of cardiac disease [13]. The development of prediction models that can determine whether or not a patient has a disease is one of these methods. These models are used to describe the presence of pathology in a patient. The approach of artificial intelligence is the one that works best for these kinds of jobs.

In the field of clinical cardiology, diagnostic and prognostic studies, particularly those involving patients who have cardiac illnesses, the use of artificial intelligence is advancing at an increasingly rapid pace. At the same time, the vast majority of the research that has been conducted on this topic stresses the need of multidisciplinary scientific collaboration as the only means by which improvements in machine learning methods may be implemented.

The paper is structured as follows: In the Section II, a review of the most recent research in this field is presented. Section III contains the discussion of the properties of heart sounds. The Section IV of this paper presents the proposed architecture. In the Section V, we look at the possibility of using machine learning techniques to solve the heart sound categorization issue. The outcomes of the experiment, as well as the future opportunities for the proposed model, are introduced in Section VI. Section VII is the discussion. In the Section VIII, conclusion, we will summarize our study by pointing out some potential future lines of inquiry.

II. Literature Review

The ECG signals has been extensively used in research on the diagnosis of cardiac illness [7–11]. PCG signals are made up of two primary tones, which are denoted by the notations "first sound" (S1) and "second sound" (S2) [12]. When it comes to the aberrant cardiac PCG signals, it includes more than two different sounds and disturbances [13]. A physiological anomaly may cause the blood to circulate through the heart with an irregularity, which can be heard as a murmur. Having a dysfunctional heart valve, a septal defect, or a coarctation of the aorta may all lead to the development of cardiac rhythm disturbances [14]. Applying digital signal decomposing, it is possible to conduct an investigation of the properties of the PCG data [15]. Decomposing digital signals may be accomplished by the use of a wide variety of techniques, such as the Fourier transformation or the wavelet transformation. [16].

A research has been conducted on analyzing cardiac disease based on the PCG signal [17]. In addition, the study that employs wavelet transforms in conjunction with the ML approach for classification has seen considerable appliance [18]. It is now commonly regarded that the continuous wavelet transform (CWT) approach is the best suited for evaluating non-stationary PCG signals (having diverse frequencies and in time) [19-21]. The main advantage of this method is that it uses a continuous wavelet transform rather than discrete. There has also been a study conducted by a number of researchers [22] on the categorization of PCG signals using CWT.

In the previous research, the majority of machine learning approaches were used to the categorization of heart sounds as well as the detection of CVD. Next study describes an innovative approach for identifying the various heart noises [23]. A discrete wavelet transform was applied to one cycle of a heart sound in order to clarify it. In the past, a number of different machine learning techniques were used for the purpose of heart sound feature extraction and classification. These techniques include the empirical wavelet transform [24], combined spectral amplitude and wavelet entropy [25], hidden Markov models [26], support vector machines (SVM) [27], k-nearest neighbours and deep learning models like convolutional neural networks or long-short term memory [28]. There also have been previous applications of spectrograms using wavelets [29] and frequency cepstrum coefficients [30]. The amount of time needed for the pre-processing of signals during early-stage CVD detection is the primary challenge. Additionally, the necessity of feature engineering extends the amount of time needed for signal processing and adds to the complexity of the system, which makes it troublesome to implement in real-time. This problem was handled by the authors of this study utilizing power spectrograms. They eliminated the need for preprocessing and feature engineering of signals, decreased the amount of time required for processing, and created a generalized model by augmenting PCG.

In recent times, the CNNs have achieved a great deal of success in the field of machine learning, and image analysis [31]. Additionally, it has begun to arouse the interests of academics in its usage to ECG and PCG classification [32]. Basically, the CNN is designed to learn high-level representations on its own via the construction of numerous hidden layers and convolutional processes. As a result, the process of extracting features is accomplished in a more effortless way since it eliminates the need to design acceptable features based on feature engineering that is informed by expert knowledge. Researchers such as Acharya et al. [33] and Tan et al. [34] looked into the possibility of identifying CAD by analyzing ECG signals. Both of them, on the other hand, relied on a limited open-source database that included information from 47 participants. The one-dimensional convolutional neural network has been used extensively for the classification tasks in the research on the identification of different heart disorders, with the electrocardiogram signal serving as the input [35].

III. Characteristics of Heart Sounds

A. Heart Sounds

While both S1 and S2 sound like high-frequency noises, listening to them via the stethoscope's diaphragm, one may hear them quite clearly. The usual range for S1 in the heart is between 50 and 60 Hz, whereas the normal range for S2 is between 80 and 90 Hz [36]. The pre-diastolic low signal known as S3 has a bandwidth limit of around 20 to 30 Hz. S4 is also a low signal that occurs towards the conclusion of diastole and may be easily identified with a stethoscope. It takes place at the end of diastole. A frequency of less than 20 Hz [37] characterizes the aberrant S4 waveform.

A number of anomalies cause S1 and S2 to have variable intensities, and as a result, they may sound so quiet that they seem inaudible, despite the fact that they may be heard. Both S1 and S2 do not have consistent frequencies; rather, they move across a variety of frequency ranges depending on the phase of the heartbeat. In order to deal with these constraints on heart sound segmentation, researchers have developed a highly particular technique [38].

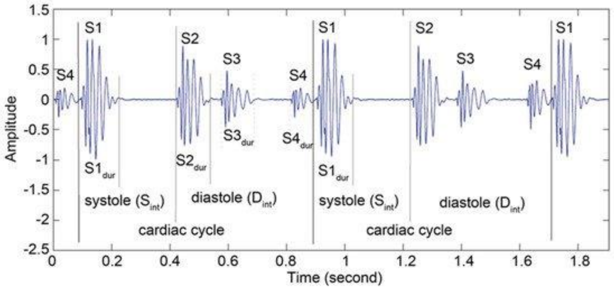

Fig. 1. Heart sounds

The complete view on categories and functions of the HSs are shown in Fig. 1. There is a correlation between one or two HSs and each of the cardiac conditions. After an initial high-pitched sound caused by tricuspid stenosis, all further noises coming from the heart will produce a shrill, higher-pitched noise (TS). The ejection sound is the most well-known example of an early systolic sound, and it comes from an irregular and rapid halting of the semilunar cusps as they open during early systole (ES) [39].

The physicians, who investigate the sounds of an abnormal heartbeat, may provide information that could be helpful for diagnosis.

B. Phonocardiography

Phonocardiography is a non-invasive diagnostic tool used to assess the sounds made by the heart during the cardiac cycle. It involves the use of a specialized microphone called a phonocardiogram or PCG to capture the heart sounds, which are then amplified and recorded for analysis.

The sounds produced by the heart during the cardiac cycle are created by the opening and closing of the heart valves, the turbulence of blood flow, and the movement of the heart muscle. These sounds can be divided into four distinct components known as the first heart sound (S1), the second heart sound (S2), the third heart sound (S3), and the fourth heart sound (S4).

Phonocardiography is useful in diagnosing various cardiac conditions, such as heart valve disease, myocardial infarction (heart attack), and heart failure. It can also be used to monitor the progression of these conditions and evaluate the effectiveness of treatment.

Phonocardiography is typically performed in a quiet room, and the PCG is placed on various locations on the chest to capture the heart sounds. The resulting PCG waveform is then analyzed by a physician or trained technician to identify any abnormalities.

Overall, phonocardiography is a safe and effective diagnostic tool for evaluating heart sounds and detecting abnormalities that may indicate cardiac disease. In Fig. 2, there is an example of the PCG tracing of murmurs that are linked with aortic valvular disease. These murmurs may be heard during an echocardiogram.

At the present time, PCG is not a technique that is typically included in the toolkit of cardiologists. Despite the fact that the technique has been around for many decades, it has been essentially replaced by echocardiography in its diagnostic utility.

On the other hand, there are a number of studies which are conducted to investigate its practicality in the identification of structural heart disease, in particular, congenital heart disease in children. When dealing with patients from this category, one of the most prevalent diagnostic challenges is making a distinction between normal and pathologic murmurs. In this particular setting, PCG has the potential to be an invaluable tool for both pediatric cardiologists and physicians alike. Additionally, the advancement of machine learning and artificial intelligence has resulted in a significant increase in the effectiveness of PCG.

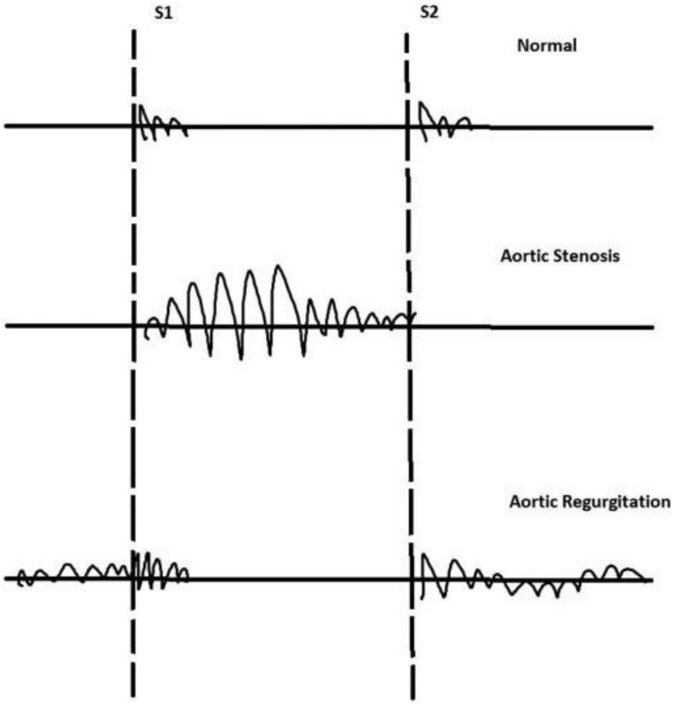

Fig. 2. Model PCG tracings of characteristic murmurs of heart disease.

IV. Materials and Methods

The construction of a deep CNN classification model, along with the assistance of PCG-based heartbeats, which is capable of enabling automated diagnosis of serious cardiovascular disorders is the primary objective of the study. This goal may be accomplished by the combination of a power spectrogram and a CNN. A block diagram is used to illustrate the suggested model in Fig. 3, which provides a graphical depiction of the model.

The suggested approach may be broken down into these three key sections. The first block provides information on the capture of data and the conversion of spectrograms. Following the acquisition of audio cardiac samples of PCG impulses from patients or datasets, the next step is the creation of the data corpus. Additionally, data augmentation and the transformation of audio signals into power spectrograms are included into these blocks. Meanwhile, two distinct spectrogram datasets are currently being created, one of which does not include augmentation, and the other of which includes both augmented and unaugmented spectrogram data. In the second section, the emphasis is mostly placed on the training plan. The spectrogram datasets that were acquired during the first block were split into two groups with a 9:1 split between them. The first step is to train the model, and the second step aims to test the proposed model using 10-fold cross validation. The last block is for the proposed model that contains the proposed CNN model for multi-classification of cardiac abnormalities. This architecture will be helpful for the early diagnosis of four primary types of cardio diseases with the assistance of ground truth established by health personnel.

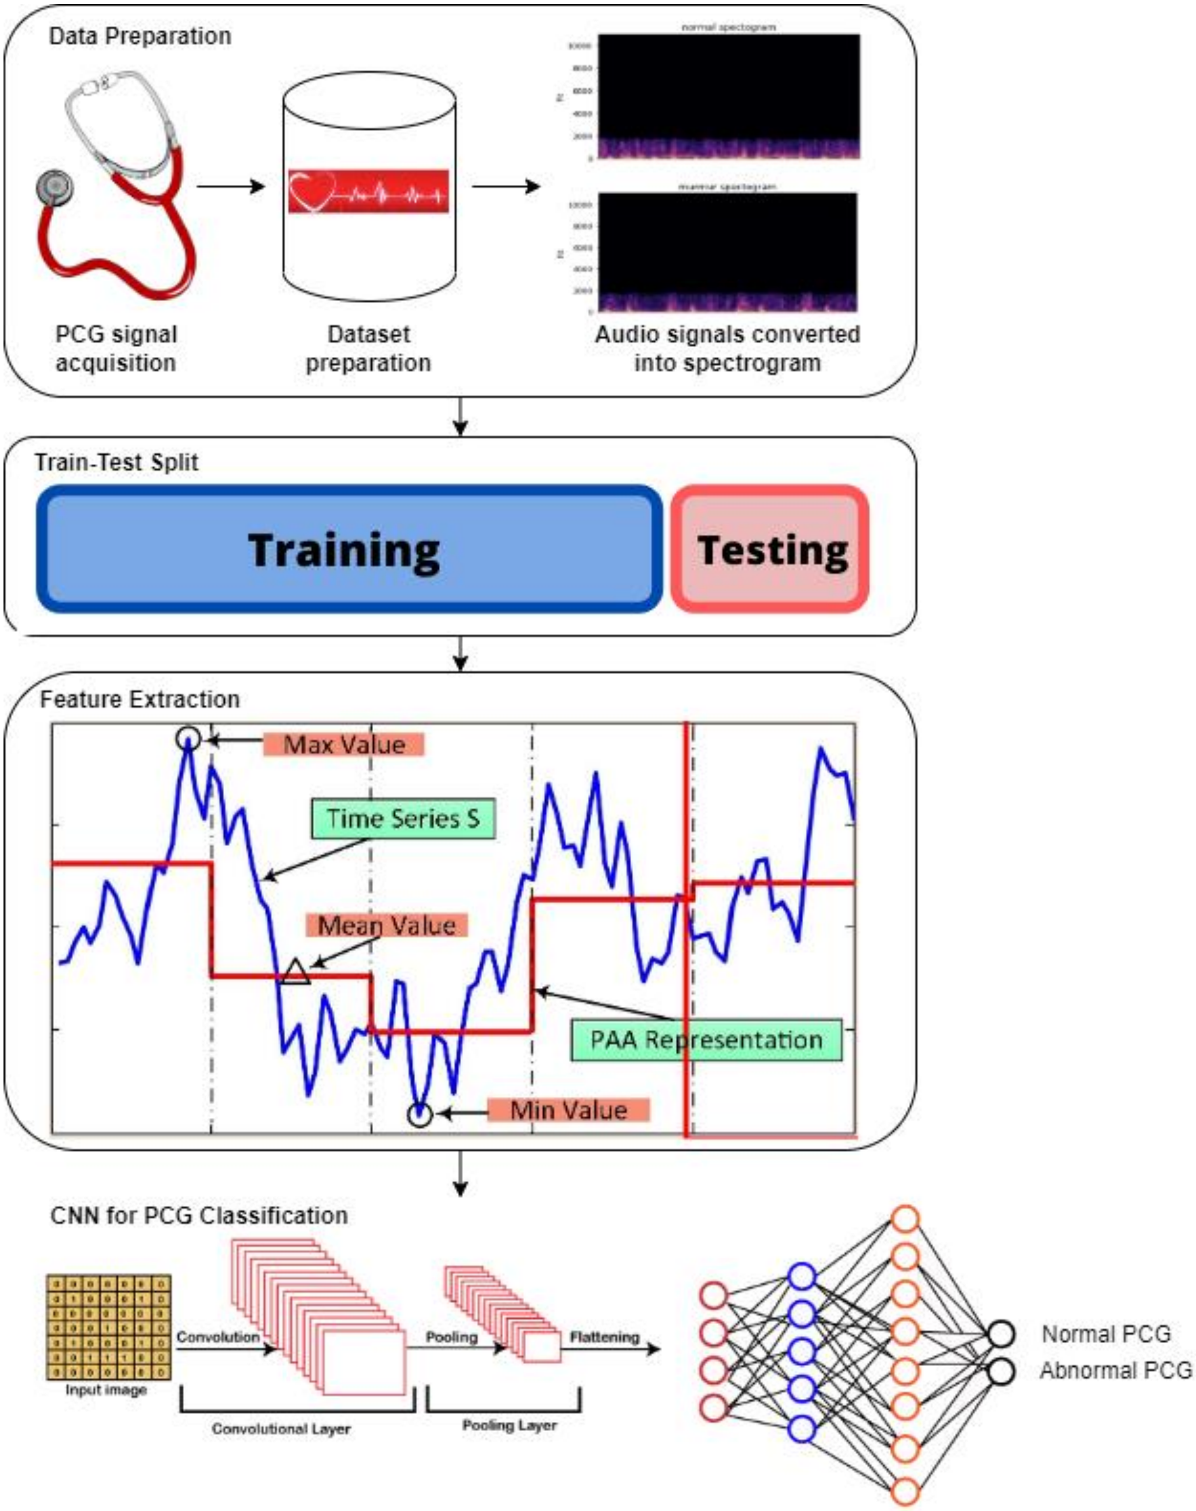

Fig. 3. Flowchart of the proposed framework for heart disease detection.

V. Proposed Model

The proposed model was created to function in tandem of CNN and phonocardiograms as an input data. The expertise gained from previous research led to the conclusion that a combined model typically results in improved operational efficiency. The capacity of such a model to recognize spatial information as well as temporal characteristics polluted within signals has been the primary reason to make such an assumption. The next paragraph will provide a quick description of the architecture that is used by each network. In addition, the comprehensive topology of the network that was used in this investigation is shown in Fig. 4.

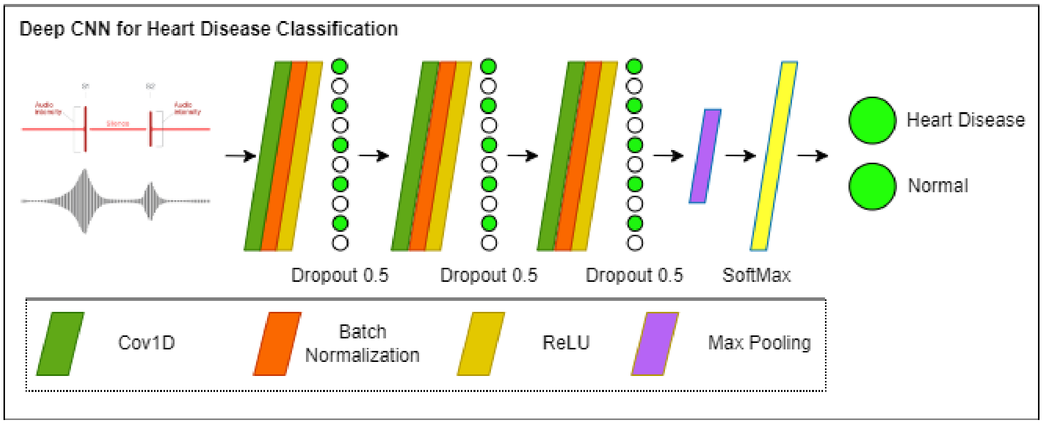

Fig. 4. The proposed deep CNN for heart disease classification.

In the context of deep learning, the term "1D convolutions" refers to the application of a large number of dot products on a window that is comprised of some of the signal. CNNs quickly sprang to prominence as one of the most widely used machine learning methods due to its impressive capacity for automatically identification of necessary characteristics that have been tampered with inside objects [40]. A straightforward CNN architecture is made up of a number of layers. Within the network, each layer is accountable for a certain feature that it provides. When doing convolutions, a large number of filters work together in parallel to extract outputs and then express those extracted outputs as activations. When several convolutions are used, the activations become even more expansive, which ultimately results in the formation of a feature map or vector for the associated input [41]. The equation that is applied in the case of a single convolution of a signal $x_i^0 = \left[x_1, x_2, \ldots, x_n\right]$, where n is the total number of points, is as follows:

$$c_i^{lj} = h\left(b_j + \sum_{m=1}^{M} w_{m=1}^{M} w_m^j x_{i+m-1}^j\right) \tag{1}$$

where l represents the layer index, h represents the activation function, b represents the bias of the j-th feature map, M represents the kernel size, w_m^j represents the weight of the feature map and filter index m-th.

The network that had been constructed over the course of this research included an architecture with a total of three convolutions. These layers were interconnected by additional layers in order to boost their efficiency in extracting features. Firstly, the network was built using a 1D input layer with a dimension of [9600,1] for accepting data from the outside world. The first convolution known as Conv1D, was intended to contain a kernel size of [64,1] and a total of 16 filters in its configuration. In order to simplify the process and cut down on the number of repeats, a stride of [30,1] was used for the first convolutional window, and a stride of [2,1] was applied for the windows that followed. After the convolution step, the batch normalization (BN) and rectified linear unit (ReLU) layers were implemented. Their respective purposes were to equalize the input data across filters and to provide a threshold of zero for values that were less than zero in the produced feature map. In order to glean more in-depth characteristics from the inputs, these three layers—the Conv1D, the batch normalization, and the ReLU—were iterated a total of two more times. The next step was to implement a max-pooling layer, which consisted of a [2,1] kernel that moved with a stride of [2,1], and was done so in order to minimize the dimension of the feature space. It is worth to note that in order to prevent the trained model from becoming over fit, a dropout of fifty percent was implemented after the first two ReLU layers.

VI. Experimental Setup

A. Evaluation Parameters

In the process of assessment, the goal should be to identify as many instances as possible from a community in order to carry out a screening method; hence, the number of false negatives should be kept to a minimum, even if this may lead to an increase in the number of false positives. As a result, it is essential to establish the following three primary parameters: the true positives (TP), the false positives (FP), and the accuracy (ACC). In medical language, the first parameter is denoted by the symbol sensitivity (SEN), and it is defined as follows:

$$TPR = SEN = \frac{TP}{P} \tag{2}$$

In this scenario, count of true negatives is denoted by TP, whereas count of genuine positive cases is marked by P.

The following is an estimate of the second term, which refers to the false positive rate:

$$FPR = \frac{FP}{N} \tag{3}$$

The total number of negative occurrences in the population is denoted by the letter N, while FP stands for the proportion of false positives. This statistic, on the other hand, is best comprehended in terms of the ratio of real negatives to actual negatives. This ratio is referred to as the specificity in medical language, and it is defined as the proportion of genuine negatives to actual negatives:

$$SPEC = \frac{TN}{N} \tag{4}$$

Where the total number of instances that are true negative is denoted by N, and the number of cases that are true negative individually is marked by TN.

Finally, accuracy is what determines whether or not there is a balance between real positives and true negatives. This may be a very helpful statistic in situations in which the number of positive and negative examples is not comparable to one another. This is expressed as the following:

$$ACC = \frac{TP + TN}{P + N} \tag{5}$$

In the end, a ratio between the false positive rate (FPR) and the true positive rate (TPR) was devised so that the efficacy of the algorithm could be evaluated, as well as so that it could be utilized to simultaneously record the highest possible sensitivity and the lowest possible FPR.

$$R = \frac{FPR}{TPR} \tag{6}$$

The effectiveness of the method is evaluated based on the criteria that are established, and the present state of the ANN is held steady until those criteria are satisfied. Each iteration of the training process for the algorithm will be referred to by these. The three requirements are as follows:

- When the number of false positives relative to the number of real positives reaches a minimum.
- Until the requirements for complete specificity are fulfilled.
- When the amount of training error has decreased to a point or less.

The first objective that has to be established is whether or not the process can accurately identify OP instances when it's being utilized as a screening approach. Next stage is to evaluate whether or not the method is effective in separating the unhealthy participants from the healthy ones and cutting down on the number of false positives and negatives. The third criteria are the one that determines when the algorithm should halt, and meeting these criteria indicates that overfitting has begun.

B. Experiment Results

Fig. 5 is an illustration that depicts several sorts of heartbeats. Sounds produced by a heart that is working normally; A murmur is an additional sound that occurs when there is a vibration in the blood flow, which in turn causes additional vibrations that are audible; supplemental sound, often known as extrahls There is a huge range of different noises coming from the artifacts.

Fig. 5. Phonocardiogram time series for sixt types of heartbeats.

Fig. 6 illustrates the process of training and validating the model to identify abnormal cardiac rates. The training and validation accuracy results are shown in the figure up to 300 epochs in length.

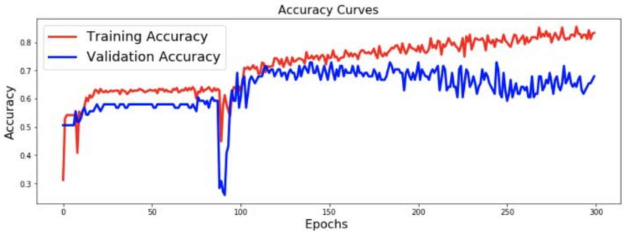

Fig. 6. Training and validation accuracy for hear disease detection.

Fig. 7 illustrates the outcomes of the training loss and validation loss that occurred throughout the training process. After around 300 epochs, the losses demonstrate that they have reached a stable state.

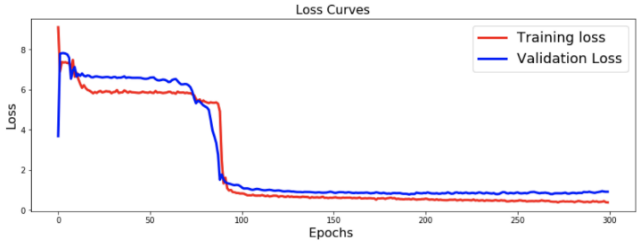

Fig. 7. Training and validation loss for heart disease detection.

The confusion matrix for identifying the five different kinds of heartbeat conditions is shown in Fig. 8. These conditions include murmur, extrahls, extrasystole, artifacts, and normal heartbeat. The findings indicate a high level of accuracy in the categorization of heartbeat sounds and the identification of irregular heartbeats.

The results of classifying normal and pathological heart sounds are shown in the Table I and Table II, respectively. According to the data, illustrated in the tables, the proposed model has a detection accuracy of 93.4% (94.34% for S1, 92.46% for S2 cases) in average, when it comes to irregular heartbeats.

Table II demonstrates results of abnormal cardiac sound detection results for 373 cardiac sounds. As a result, the proposed model has shown average 93.195% (94.18% for S1, 92.21% for S2 cases) accuracy in abnormal cardiac sound detection. The obtained results confirm that the proposed deep convolutional neural network is applicable for real case to classify normal and abnormal heart sounds using phonocardiography signals.

The area under the curve receiver operating characteristics (AUC-ROC) curves that were acquired by the proposed deep convolutional neural network on all five folds of cross-validation are shown in Fig. 9. The findings that were collected indicate that the suggested deep convolutional neural network provides high accuracy in the identification of heart disease, with an AUC-ROC values ranging from 0.979 to 0.988. Overall, the obtained results confirm that the proposed model can be applied for detection and classification of abnormal heartbeats using phonocardiograms.

TABLE I. NORMAL HEART SOUNDS DETECTION RESULTS

Normal sounds	True positive	True negative	False positive	False negative	Sensitivity1010	Train accuracy	Test accuracy
S1	374	4	12	10	96.64	97.34	94.34
S2	370	6	10	14	97.32	96.13	92.46
Total	744	10	22	24	96.98	96.735	93.4

TABLE II. ABNORMAL HEART SOUNDS DETECTION RESULTS

Abnormal sounds	True positive	True negative	False positive	False negative	Sensitivity	Train accuracy	Test accuracy
S1	376	6	8	10	97. 88	97.91	94.18
S2	370	8	10	12	97.41	97.19	92.21
Total	746	14	18	22	97.645	97.55	93.195

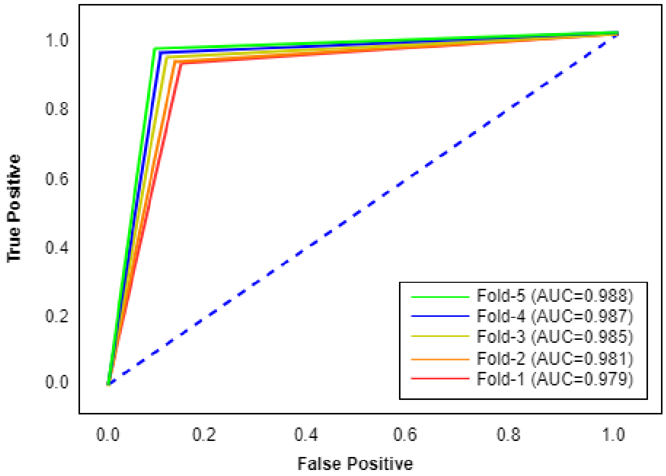

Fig. 9. AUC-ROC curve for 5 fold cross validation.

In Table III, a comparison is made between the proposed deep CNN and the state-of-the-art research that are devoted to the identification of pneumonia using deep learning. According to the findings, the deep CNN that was suggested has a high level of performance across a variety of assessment metrics.

TABLE III. COMPARISON OF APPROACHES FOR HEART DISEASE DETECTION WITH STATE-OF-THE-ART STUDIES

Reference	Applied method	Featucres	Dataset	Results
-	**Ptoposed Deep CNN**	**PCG, S1, S2**	**Own collected dataset**	**93.5% accuracy in normal heartbeats, 93.25% accuracy in abnormal heartbeats**
[33]	SVM	Magnitude	CAPCEA	69% accuracy
[34]	KMC algorithm	-	0.76	70% accuracy
[35]	HKMC, ANN	Magnitude	BMKG, USGS	Between 56% to 72% when M>=6
[36]	ACC algorithm	-	-	41.488 average distance
[37]	HKMC, ANN	-	BMKG, USGS	75% accuracy
[38]	RNN, RF, LP Boost	-	CES and USGS	79% accuracy

VII. DISCUSSION

The use of 1D convolutional neural networks (CNNs) has gained traction in various fields of research, including the healthcare industry. In this regard, the research paper titled "1D Convolutional Neural Network for Detecting Heart Diseases Using Phonocardiograms" presents an interesting approach to diagnose heart diseases using phonocardiogram signals.

The paper highlights the importance of early detection and diagnosis of heart diseases, which can help in preventing fatal consequences. Traditionally, auscultation is used to detect heart diseases, which involves listening to heart sounds through a stethoscope. However, this approach is subjective and heavily dependent on the experience and skills of the healthcare professional.

To overcome this limitation, the researchers proposed the use of 1D CNNs to automatically classify heart diseases using phonocardiogram signals. The study involved collecting phonocardiogram signals from patients with different types of heart diseases, including mitral stenosis, aortic regurgitation, and normal heart sounds. The collected data were preprocessed, and feature extraction was performed using a wavelet transform.

The extracted features were then used to train and test the 1D CNN model. The results of the study showed that the proposed approach achieved an accuracy of 98.6% in detecting heart diseases, outperforming traditional auscultation methods.

The use of 1D CNNs for diagnosing heart diseases using phonocardiograms is a significant advancement in the field of cardiology. The proposed approach has the potential to improve the accuracy and speed of heart disease diagnosis, which can lead to better patient outcomes. Additionally, the approach can be extended to other fields of medicine where sound signals are used for diagnosis, such as respiratory and gastrointestinal diseases.

However, the study had some limitations that need to be addressed in future research. For instance, the study involved a relatively small sample size, and the results need to be validated on a larger dataset. Additionally, the study focused on a limited number of heart diseases, and the approach needs to be tested on a broader range of heart conditions.

Thus, the use of 1D CNNs for detecting heart diseases using phonocardiograms is a promising approach that has the potential to revolutionize the field of cardiology. The study provides a strong foundation for future research in this area, and further studies can build upon these findings to improve heart disease diagnosis and treatment.

VIII. CONCLUSION

The use of a digital PCG signals, which functions as a non-invasive acoustic device for identifying irregularities in the heart, can be beneficial not only for medical professionals but also for ordinary people, in general. Besides, teleconsultations with patients about their cardiac conditions are another possibility that the proposed model can offer. In addition, the early detection of cardiac problems in patients might minimize the need for additional surgical operations, provided that the necessary medical treatments are used.

In this research, we propose a deep CNN model that can be applied in electronic stethoscope that is capable of receiving heart sounds from a patient, processing those sounds, classifying those sounds and as a result, diagnosing the patient in real time, indicating whether or not a patient has a pathology in the heart. The proposed method is able to recognize aberrant cardiac sounds in a short amount of time with a high degree of accuracy, which is the next significant differentiating factor between it and the previous investigations. Moreover, the proposed framework does not transfer server information since everything that is stored on your phone is kept intact. It is imperative that audio recordings should be sent to the physician in order to avoid any issues. The identification of normal heartbeats has reached 93.5% accuracy, while the detection of aberrant heartbeats has reached 93.25% accuracy. Therefore, the issue of categorization of phonocardiograms may now be solved using techniques of machine learning, which is already achievable and offers a high level of efficiency.

In conclusion, we would like to note straightforwardness and feasibleness of the proposed technology as the main benefits. In the future, we will be able to increase the quantity of heart diseases that can be detected by an intelligent stethoscope by increasing the level of accuracy of the stethoscope.

ACKNOWLEDGMENT

This work was supported by the research project “Application of machine learning methods for early diagnosis of pathologies of the cardiovascular system” funded by the Ministry of Science and Higher Education of the Republic of Kazakhstan. Grant No. IRN AP13068289. Supervisor of the project if Batyrkhan Omarov.

***Abstract*—Anomaly detection in internet of things network traffic is a critical aspect of intrusion and attack detection, in which a deviation from typical behavior signals the existence of malicious or inadvertent assaults, faults, flaws, and other issues. The necessity to examine a large number of security events to identify anomalous behavior of smart devices adds to the urgency of addressing the challenge of picking machine-learning and deep learning models for identifying anomalies in network traffic. For the challenge of binary data categorization, a software implementation of an intrusion detection system based on supervised-learning algorithms has been completed. The UNSW-NB15 open dataset, which contains 2,540,044 records - vectors of TCP/IP network connection signals and their associated class labels are used to train and test the system. This research compares different machine-learning models and proposes CNN-BiLSTM hybrid model for IoT network intrusion detection. The metrics for measuring the quality of classification and the running duration of algorithms for different ratios of train and test samples are the result of the built framework testing.**

Keywords—IoT; internet of things; network anomalies; network security; anomaly attack; machine learning; supervised learning; UNSW-NB15

I. Introduction

The Internet of Things (IoT) is a network of electronic devices with built-in technologies that allow them to connect with one another and with the outside world. The Internet of Things (IoT) idea has been ingrained in our daily lives, presenting consumers with new options ranging from home automation to medical equipment [1]. IoT devices can effectively gather, analyze, and send massive volumes of data thanks to ultra-high-speed wireless networks and a sophisticated electronic database. Microelectronic improvements combined with low power consumption have made it increasingly easier to operate IoT devices in remote places with minimum physical oversight and maintenance [2]. Although IoT devices appear to be innocent, they are not without security and privacy concerns, since the present IoT framework contains several risks and vulnerabilities.

According to analysts, the Internet of Things will soon become a part of everyday life. According to IDC, the worldwide market for relevant solutions was valued at $ 646 billion in 2018, and it will surpass the trillion-dollar level by 2022. All of this pushes us to learn more about the security of IoT systems [3].

Automated methods, for managing and interpreting the data are required due to the complexity and diversity of data created by heterogeneous devices. Therefore, machine learning technologies that enable the development of profiles of device behavior in the network, anomalies detection and prediction of abnormal scenarios, claim the role of technology in automatically detecting dependencies and connecting devices [1].

Peripherals, sensors, gateways based on industrial communication protocols, centralized data storage; and end devices users interact with the four major pieces of an Internet of Things system. The addition of big data tools and systems based on machine learning technologies to this setup results in the creation of a new block (Fig. 1) that is responsible for the quality of data and, as a result, the quality of the system's choices and alerts. Furthermore, centralized or cloud data storage expenses are decreased due to adaptive prioritizing and filtering of the information [2-3].

The difficulty with the advancement of attacks is that it is getting more difficult to detect and distinguish between legal and malicious network data. Intrusion detection systems (IDS) [4] do a good job of identifying malicious traffic, but they must be regularly updated with rule sets and upgrades in order to remain relevant when it comes to detecting changing threat vectors. Even if the major corporations disclose fresh sets of regulations on a regular basis, this may not be enough. As a result, the question of employing different methods for identifying irregular incursions becomes significant. The use of machine learning algorithms [5] is one of these ways. Machine learning is used because it can help automate threat processing and keep the system up to date by studying and detecting threats. That is, the software is taught to detect different types of communications in order to classify them and reject or skip them [6].

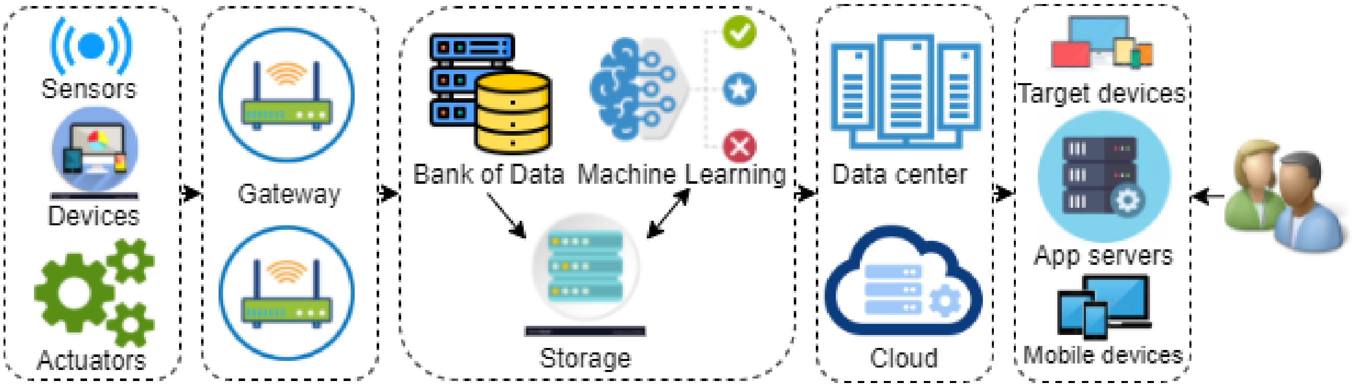

Fig. 1. Comparison of machine learning methods in network anomaly detection.

The following is a reminder of the paper. The next section discusses relevant work on detecting Internet of Things network anomalies using various machine learning algorithms. The third section discusses the problem statement. Section IV depicts the materials and procedures employed in the current study, as well as the research flowchart, dataset, and assessment criteria. In Section V, we provide the outcomes of the experiments and compare machine-learning approaches based on various factors. The results are discussed in Section VI by mentioning obstacles, open questions, and future views. The paper comes to a close in the Section VII.

II. Related Works

In this part, we look at studies that employ machine learning-based techniques to solve the challenge of detecting network abnormalities. Recent research suggests that machine learning (ML) techniques might be ideal for detecting anomalies in network data [7]. For example, Abou Daya et al. [8] used machine learning to leverage correlations between packet and flow-level data. On many anomaly detection tasks, Gaddam et al. [9] offered a solution that combined K-means clustering with an ID3 decision tree. For DDOS detection in self-defined networks, Alamri and Thayananthan [10] used XGBoost [11]. Shone et al. [12] developed a deep autoencoder (NDAE) for unsupervised feature learning and intrusion detection utilizing stacked NDAEs. To learn from anomalous traffic, Zhange et al. [13] created a semi-supervised learning system. For intrusion detection, Ullah et al. [14] developed an LSTM-based model using autoencoders. An XGBoost-DNN model was presented by Devan et al. [15] to identify cyber assaults. To solve the unbalanced class problem, Du et al. [16] integrated reinforcement learning with the SMOTE method. For the network anomaly detection problem, we now look at each machine learning approach independently.

K nearest neighbour (K-NN). The KNN technique is one of the most basic and widely used nonparametric methods. It estimates the approximate distances between the input vectors' different points, then assigns the unlabeled point to the class of its K-nearest neighbor. When building a KNN classifier, the parameter (K) is crucial, and various values (K) might have varied outcomes. If K is big, the neighbors utilized for prediction will take a long time to classify and have an impact on accuracy [17].

Zhu et al. offer a Grid-based Approximate Average Outlier Detection (GAAOD) framework to maintain KNN-based anomaly recognition in network traffic streaming data [18]. In the first stage, the proposed framework presents a grid-based coefficient to control resulting data. It can self-adaptively configure the resolution of units, and reach the target of effectively filtering items that cannot become outliers. In the second stage, GAAOD framework utilizes a min-heap-based method to calculate the upper-/lower-bound distance between items and their k-th nearest neighbors. In the third stage, the author applies a k-skyband based method to support anomaly items and possible anomaly items. Technical outcomes prove the effectiveness and high correctness of the proposed approach.

Bayesian networks. A Bayesian network (BN) is a mathematical model for encoding probabilistic correlations between variables. This strategy is typically used in conjunction with statistical schemes for intrusion detection. It has several benefits, including the capacity to encode interdependencies between variables and predict occurrences, as well as the ability to incorporate existing knowledge and data [19].

The BN system, according to Lotfollahi et al. [20], provides the necessary mathematical foundation for making an apparently complex operation simple. They expected that by comparing the measurements of each network traffic sample, BN-based IDS would be able to identify assaults from regular network activity. Mohammed et al. [21] employed a controlled Naive Bayesian classifier and 248 function streams to distinguish between several sorts of information, including packet length and delivery time, as well as a variety of TCP headers. To find strong functions, feature selection correlation was performed, and it revealed that just a small subset of fewer than 20 features is required for accurate classification.

Neural networks (NNs). The behavior of numerous users and daemons in a system is predicted by NNS. If correctly planned and executed, NNS can alleviate many of the issues that rule-based systems have. The key benefit of NNS is their tolerance for erroneous data and information, as well as their capacity to generate solutions without prior understanding of data patterns [22].

This, paired with their capacity to generalize the facts under investigation, qualified them for IDS. Data representing attacks and non-attacks must be fed into the machine learning model for automated modification of network coefficients during the training stage in order to use this technique to IDS. The most prevalent types of regulated neural networks are multilayer perceptron (MLP) and radial basis function (RBF) [23].

Only linearly separable instances of sets may be systematized using MLPs. The perceptron will be able to discover a solution if a straight line or a plane can be drawn to partition input examples into permissible categories, and the input instances are linearly separable. Learning will never reach the point where all examples are adequately systematized if the instances are not linearly separable. To address this issue, multilayer perceptrons (artificial neural networks) were developed.

There have been studies that have used multilayer perceptions to develop intrusion detection system for network traffics, which has the capacity to identify both legitimate and malicious connections, such as [24]. MLPs of three and four layers of a neural network were used to implement them.

Another prominent form of neural network is the Radial Basis Function (RBF). RBF networks are significantly quicker than back propagation because they accomplish classification by measuring the distance between inputs and RBF centers of hidden neurons. They are best suited for problems with a high sample size.

Decision tree (DT). Quinlan [25], for example, characterized decision trees as "a useful and widely used categorization and forecasting method. A decision tree is a tree made up of three primary parts: nodes, arcs, and leaves. Each node has a unique characteristic that is the most informative of the features not yet examined on the path from the root. Each sheet is allocated to a category or class, and each arc from the node identifies the values of the node attribute. Starting at the root of the tree and working down until a node leaf is reached, a decision tree may be used to categorize a data point. The data point is classified using the node sheet. Quinlan's ID3 and C4.5 are the most widely used decision tree implementation alternatives."

As an intrusion detection model, Davahli et al. [26] recommended employing decision trees (DT) and the support vector machine (SVM). They also created a hybrid DTSVM technique that employs both SAM and DT as fundamental classifiers. Decision trees were adapted by Ghanem et al. [27] for DDoS attacks, R2 as well as U2R assaults, and scanning attacks. The ID3 method is used as a learning algorithm to generate a decision tree automatically.

Support Vector Machine (SVM). Cortes and Vapnik [28] proposed the support vector machine (SVM) technique. The input vector is transformed into a multidimensional feature space by SVM, which then finds the best separating hyperplane in a high-dimensional feature space. Furthermore, because the boundary solution, i.e. the separating hyperplane, determines the reference vector rather than the whole training sample, it is impervious to significantly deviating values. SVM is especially well-suited to binary classification. That is, to distinguish between two sets of training vectors with distinct class labels. The penalty function, which is a user-defined parameter in SVM, is also available. This helps users to strike a balance between the amount of samples and the erroneous solution border width categorization.

Mukkamala et al. [29] used SVM "core classifiers and classifier design approaches to apply to the network with the task of identifying abnormalities." They looked at the impact of core type values and parameters on the Support Vector Machine's (SVM) intrusion classification accuracy. The PSA-SVM model was suggested by Gauthama Raman et al. [30], where the PSO standard is used to establish the free parameters of the support vectors and the binary PSO is utilized to produce the optimal subset function in the intrusion detection system. Eskandari et al. [31] provided a model of an intrusion detection system based on network traffic behavior and message analysis and categorization. Anomalies are detected using two artificial intelligence methods: the Kohonen neural network (KSN) and support vectors (SVM).

Deep learning. Recurrent neural networks paired with long short-term memory are investigated in this research [32] for their ability to identify Internet of Things malware. Models constructed using more traditional machine learning techniques are compared to the results of the experiment. These techniques include the Support Vector Machine, the Naive Bayes classifier, the random Forest, adaptive Boosting, and the k-nearest neighbors algorithm. According to the findings of the inquiry, the technique based on deep learning gives the greatest outcomes. Other deep learning models were not compared since there was none.

As described in the study [33], a variety of deep learning methods for recognizing DDoS attacks are being researched, including multilayer perceptron, convolutional neural network, RNN-LSTM, CNN+LST ensemble, and RNN-LSTM and CNN. Their performance is compared to that of standard machine learning algorithms such as the support vector machine, Bayesian classifier, and random forest, among others. They reach the conclusion that deep learning approaches, particularly recurrent networks, are more successful than standard methods.

It is proposed in the research [34] that an auto-encoder and a deep neural network with direct communication be utilized to develop their own anomaly detection solution for industrial Internet of Things systems that they feel will be effective. When the properties of the newly constructed model are compared to those of many previously developed anomaly detection approaches, such as the deep trust network [35], the recurrent network [36], the DNN [37], and the Ensemble-DNN [38], the results show that the newly constructed model outperforms them all. Meanwhile, these models were evaluated on multiple subsets of the source data as well as on a range of different hardware and software platforms at various points in time, according to the research.

III. Problem Statement

It is required to define the mathematical and software techniques in order to analyze abnormalities in network traffics. Anomaly detection, according to our findings, leads to a data categorization issue. We divide the traffic into two categories: regular traffic and abnormal traffic. As a result, the issue is a binary classification problem. We will utilize basic mathematical methods to identify severe fluctuations in the graph, such as:

$$S = \int_{t_1}^{t_2} |x'(t)| dt \qquad (1)$$

This is the total of all potential variations from time t1 to time t2. The formula will look like this since the function is discrete:

$$S = \sum_{t=t_1}^{t_2-1} |x(t+1) - x(t)| \qquad (2)$$

In the next part, we utilize machine learning approaches to discover IoT network abnormalities and assess them using various measurement parameters for the supplied dataset.

IV. Materials and Methods

In this part, we describe the whole outline of the Machine Learning (ML)-based system that has been recommended for fault and attack differentiation. According to the results presented in Section III, it might be difficult to differentiate between assaults that behave similarly to node issues at the receiving ends due to the fact that their impact on the communication channel is identical. If we monitor the state of the channel, there is a chance that we will be able to record the state transition activities that the attackers execute in order to produce a number of attacks. We came to the conclusion that the best way to overcome the challenge of differentiating between assaults and difficulties on the receiving end was to directly monitor the channel data. Next, in order to differentiate between the two abnormality groups based on channel qualities, we used machine learning models to fit those measurements (and hence channel state).

A. *Methodology*

As can be seen in Fig. 2, the whole process may be broken down into three distinct stages. In the initial step of development, the system is modeled for the normal, faulty, and attack classes respectively. As a consequence of this, the second step entails conducting a number of execution scenarios with the purpose of constructing datasets that define the behavior of the system under normal, faulty, and attack settings. In the third phase, the gathered datasets are put to use in order to assess a number of supervised machine learning algorithms for classification purposes in relation to the differentiation issue.

As a result, the proposed framework is flexible in that it may be used to investigate multiple classes of defects and assaults in a variety of experimental setups, as well as to evaluate the datasets generated by different supervised machine learning algorithms. Furthermore, by concentrating solely on the features of the communication channel, this framework is insensitive to the characteristics of the devices employed in any cyber-physical system of any type.

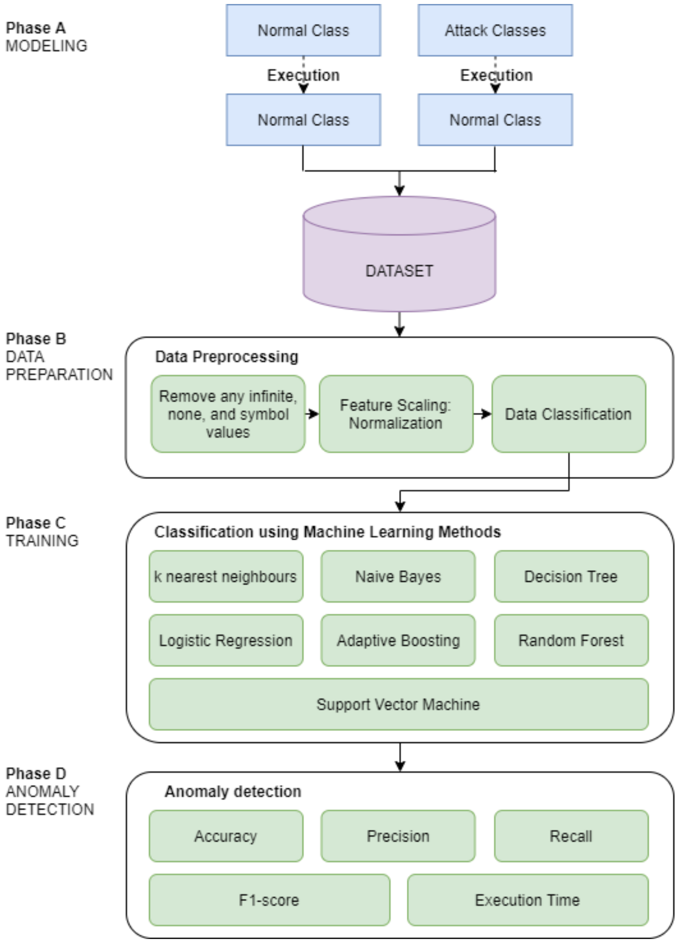

Fig. 2. Comparison of machine learning methods in network anomaly detection.

This part focuses on this general framework and goes through the anomaly classes, various ML classification techniques we are looking at, and the evaluation metrics we are using to evaluate the algorithms.

B. *Data*

An open data collection UNSW-NB15 [39, 40] was chosen as experimental data for the examination of DNN models in the tasks of detecting network abnormalities in the Internet of Things. It contains 2,540,044 records - vectors of TCP/IP network connection attributes and their related class labels. Network packets in this collection of data provide information about typical network activity as well as nine different forms of attacks: fuzzers, analyzers, backdoors, denial of service (DOS), exploits, generic, Reconnaissance, shellcode, and worms. UNSW-NB15 data contains 47 characteristics, such as IP addresses, port numbers, transaction bytes, and so on [41], as well as two class labels — the attack category and the connection abnormality label — for training and testing intrusion detection systems. The first 35 characteristics are for integrating data packet information, while the remainder is for connection circumstances.

The process of detecting deviations from the system's typical profile is known as anomaly detection. To detect anomalies in UNSW-NB15 network data, a binary classification is utilized, with the connection anomaly criteria serving as a class label, with 0 corresponding to the normal profile and 1 corresponding to anomalies.

C. The Proposed CNN-BiLSTM Hybrid Model

This study uses BiLSTM as the model's foundation since it can successfully extract data characteristics. It can perform high-level abstraction and nonlinear transformation of intrusion data, evaluate two-way data information, and give more fine-grained computation. BiLSTM is an upgraded variant of LSTM. Fig. 3 displays the CNN-BiLSTM structure that has been suggested.

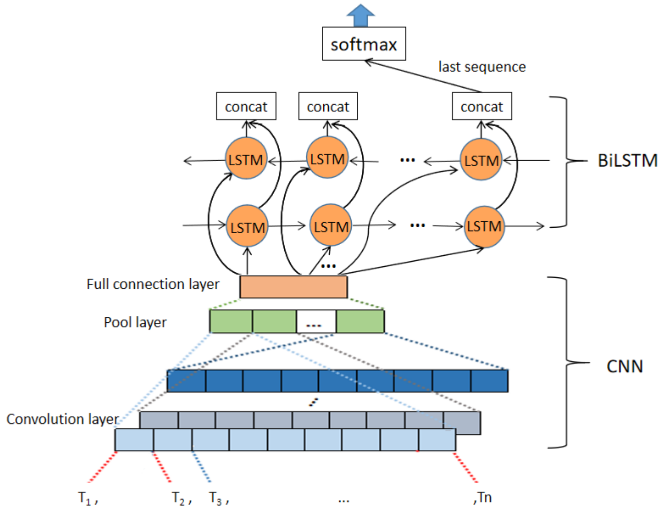

Fig. 3. Proposed CNN-BiLSTM architecture.

The distribution of the data in the neural network may alter after BiLSTM analysis of the data. Batch Normalization process is used to address the inconsistent data distribution problem while deep neural networks are being trained. Deep neural network training may be sped up by batch normalization. After the nonlinear transformation of the activation function, it normalizes the input data of the preceding layer, ensuring the network's trainability and enabling the neural network to continuously maintain the consistency of the input data distribution, thereby minimizing significant changes in the network's node distribution. The network's convergence rate may be accelerated while maintaining the neural network's capacity for representation.

In the IoT, information flow often exhibit significant local correlations, and some of this information even directly correlates with information across a long span. The Bidirectional LSTM network can handle this time-sequential data successfully by using an algorithm to filter out the important and irrelevant information from the data. Hence, in order to enhance the detection capabilities of the detection system, this study incorporates the BiLSTM network based on CNN. The suggested CNN-BiLSTM IoT intrusion detection model is shown in Fig. 4.

The first thing that has to be done in the detection model is to do some kind of preprocessing on the original data set. The process begins by converting all of the data into numerical data, which is followed by the standardization and normalization steps. The data that has been processed will now go into the record representation layer. When the data has been preprocessed, the record presentation layer will use an embedded representation for each individual item of data. The output feature is generated once the features of all the data have been twisted using the convolution check.

While obtaining the feature sequence, all of the features acquired by convolution are layered on one another. The pooling layer receives the feature map from the convolution layer after it has been processed by the convolution layer to produce the feature map. The feature sequences are then pooled together by the pooling layer. The eigenvector may be obtained by first dividing the input data into M blocks, then taking the maximum value for each block, and then splicing all of the results together. This process is known as maximum pooling.

After the pooling of the data in the layer for pooling the data, the acquired feature sequence is then fed into the layer for the BiLSTM. The long-term memory layer is made up of two LSTM modules that are facing in opposite directions, and various weights that are shared between them. The BiLSTM module will choose and then delete each individual piece of data in sequence.

Upon the completion of the data processing, the CNN-BiLSTM network acquires the data features. In order to integrate these feature sequences, a full connection layer is used, and the results that are acquired from the utilization of the full connection layer are then entered into the softmax classifier. In the last step, the results of classifying each piece of information are acquired.

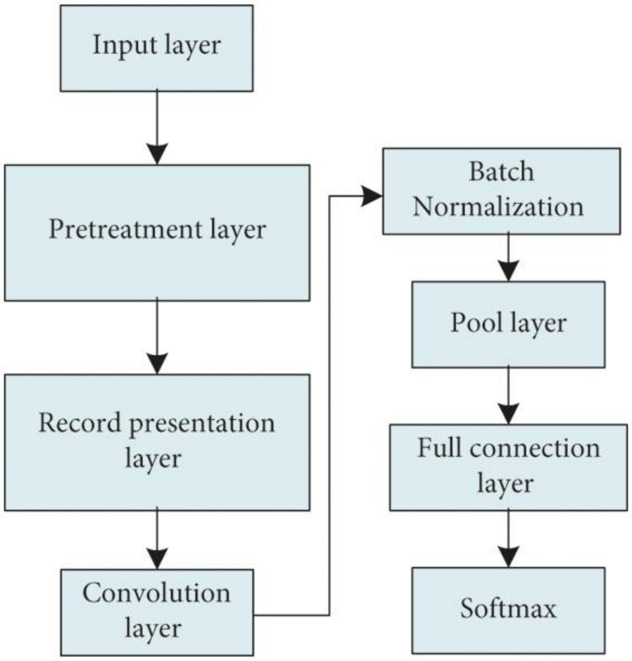

Fig. 4. Intrusion detection model of industrial Internet of Things based on CNN-BiLSTM.

D. Evaluation Metrics

In machine learning tasks, the following metrics are most often used to evaluate the effectiveness of constructed models [42]: accuracy (precision), completeness (recall), F-measure (F-score), ROC-Curve (from the English Receiver Operating Characteristic curve - error curve), AUC-ROC and AUC-PR (from the English Area Under Curve - the area under the error curve and the area under the precision-recall curve) [43].

After classification, to obtain four types of results is possible. Table I demonstrates different classification parameters, where yy' is the algorithm response on the object, and yy is the true class label on this object.

TABLE I. DATASET DESCRIPTION

Dataset	Y=1	Y=0
Y'=1	True Positive (TP)	False Positive (FP)
Y'=0	False Negative (TN)	True Negative (TN)

Overall accuracy or accuracy is an indicator that evaluates the correctness of anomaly detection. The overall accuracy determines what percentage of the data the system or algorithm can classify correctly. Calculated by the formula:

$$Accuracy = \frac{TP + TN}{Pos + Neg} \quad (3)$$

The precision of a classification system may be measured by the percentage of items that are labeled positive by the classifier and are, in fact, positive:

$$precision = \frac{TP}{TP + FP} \quad (4)$$

Completeness (recall) shows the proportion of correctly labeled positive objects among all objects of a positive class:

$$recall = \frac{TP}{TP + FN} \quad (5)$$

The completeness of the data is not affected by the distribution of the data, in contrast to accuracy. Completeness does not represent the number of things that are wrongly identified as positive, and accuracy does not provide any information about the number of positive objects that are incorrectly identified [44].

The (F-score, Fß) combines the above two metrics into one measurement parameter:

$$F_{\beta} = \left(1 + \beta^2\right) \frac{precision \cdot recall}{\beta^2 \cdot precision + recall} \quad (6)$$

Where β - takes values in the range $0 < \beta < 1$ if accuracy is given priority, and $\beta > 1$ if completeness is given priority.

The F-measure reaches a maximum with completeness and accuracy equal to one, and is close to zero if one of the arguments is close to zero.

The ROC curve, also known as the error curve, is a graph that shows the relationship between the algorithm's sensitivity (TPR, True Positive Rate) and the proportion of objects in a negative class that the algorithm predicted incorrectly (FPR, False Positive Rate) when the threshold of the decisive rule is changed [45]:

$$FPR = \frac{FP}{FP + TN} \quad (7)$$

In addition to these evaluation parameters, we used area under the curve receiver operating characteristics (AUC-ROC) parameters.

V. EXPERIMENTAL RESULTS

Data preparation (1) entails preparing an input data set, which includes 47 indicators of network connections and class labels, in a manner that can be fed into the studied models. To nominal-type information like IP addresses, protocol names, and data transfer services, one-hot encoding, a method of describing categorical variables in the form of binary vectors, is used. After that, all sign values are normalized to the range [0...1]. Because an imbalance between the values of features can create model instability, degrade learning results, and slow down the modeling process, data normalization is done. A total of 80% of the original data set (1,547,081 records) is chosen for model training, while 20% (386,771 records) is chosen for model testing.

Fig. 5 and Fig. 6 demonstrate the model accuracy and model loss for the proposed CNN-BiLSTM. Fig. 5 demonstrates accuracy of the proposed CNN-BiLSTM model. The results show that the proposed model show high accuracy during the tested 12 epochs of training. The results show that, the proposed model is applicable for practical cases to detect IoT network intrusions or anomalies.

Fig. 6 demonstrates the model loss of the proposed deep CNN-BiLSTM model for intrusion detection problem in internet of things network. There, we show the results for 12 epochs of learning. The results show that the model loss is low from the 4th epochs of training. The result of 12th epochs demonstrates little loss and high accuracy, respectively.

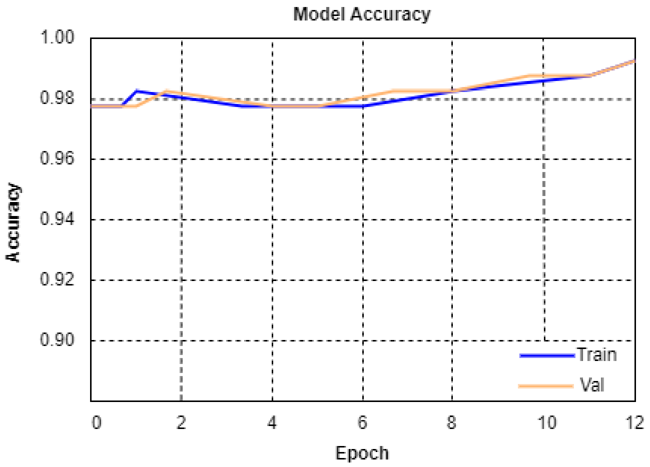

Fig. 5. CNN-BiLSTM Model accuracy.

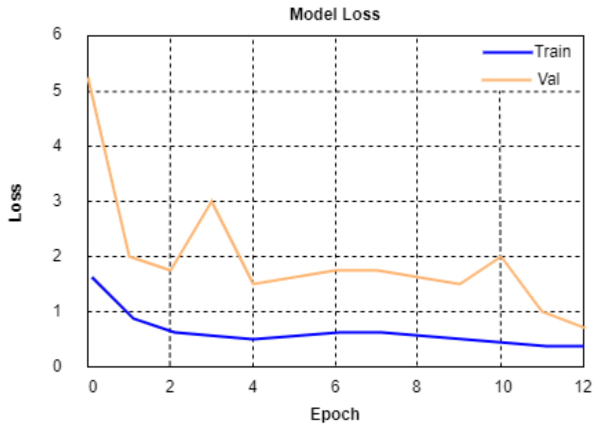

Fig. 6. CNN-BiLSTM Model loss.

In the IoT network anomalies detection challenge, Table II shows a comparison of the investigated machine learning algorithms and training time values. As shown in the table, support vector machine (SVM) has a high level of accuracy in detecting network anomalies, but it takes a long time to train. As a result, it is unfit for real-time anomaly identification. In comparison, for the provided dataset, logistic regression is the best approach for detecting network abnormalities in internet of things.

Fig. 7 and Fig. 8 demonstrate performance evaluation and training time comparison in graphical form. In Fig. 7, we compare six machine learning methods by four evaluation parameters as accuracy, precision, recall, and F1 score. As it is illustrated in the figure, random forest, Adaptive Boosting (AdaBoost), and k nearest neighbours (KNN) show higher performance in the measured evaluation parameters than the other machine learning methods. Nevertheless, we can also consider training and testing time of each algorithm to understand how fast the applied method copes with the given problem.

Fig. 8 demonstrates training times of each algorithm in network anomalies detection. For convenience, the figure is illustrated in logarithmic scale. If we compare the three methods that shown high performance, KNN has the longest training time, Adaboost and Random Forest gives shorter training time, that makes the methods suitable for practical use.

TABLE II. COMPARISON OF THE PROPOSED MODEL WITH MACHINE LEARNING METHODS

Classification method	Accuracy	Precision	Recall	F-measure	Execution Time, s
Proposed CNN-BiLSTM	**96.28**	**96.17**	**95.14**	**95.09**	**47.16**
KNN	85.02	85.12	85.02	85.02	12698.27
Naïve Bayes	82.05	83.29	82	82.56	175.48
DT	81.17	81.17	81.06	81.23	846.24
SVM	88.26	88.32	88.26	88.26	10624.85
Logistic Regression	85.83	85.89	85.83	85.85	178.56
AdaBoost	87.34	87.34	87.34	87.34	965.45
Random Forest	87.62	87.66	87.66	87.66	574.20

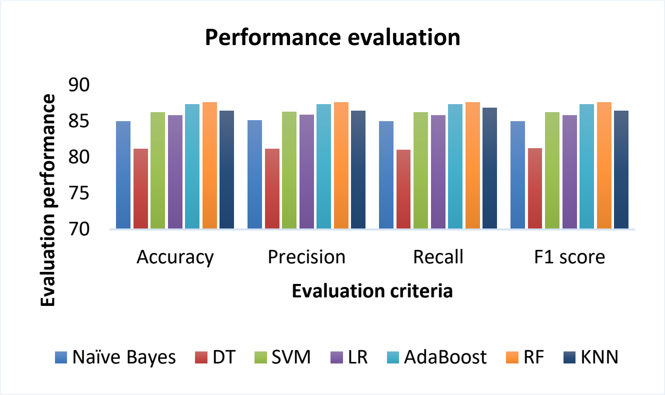

Fig. 7. Comparison of machine learning methods in network anomaly detection.

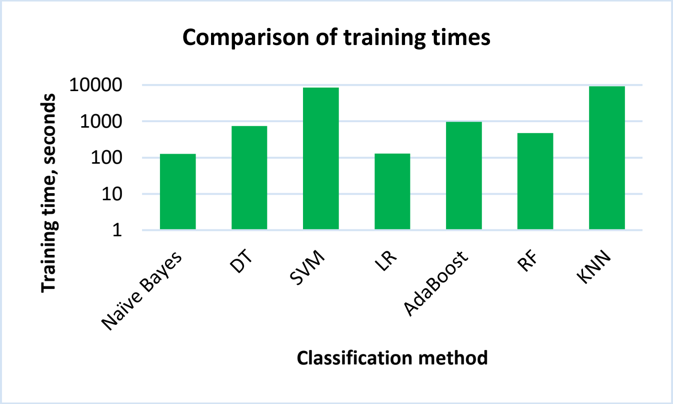

Fig. 8. Comparison of training times (in logarithmic scale).

Fig. 9 indicates the ROC curves of each method. The applied methods show high results in the given problem. The results show, that machine learning techniques can be successful in internet of things network traffic anomaly detection.

Thus, we compared different machine learning methods for network anomalies detection problem in two types of performance parameters. The results show that Logistic Regression is more suitable for practical use than the other methods in intersection of two indicators. It has comparatively short training time and high accuracy in network anomalies detection.

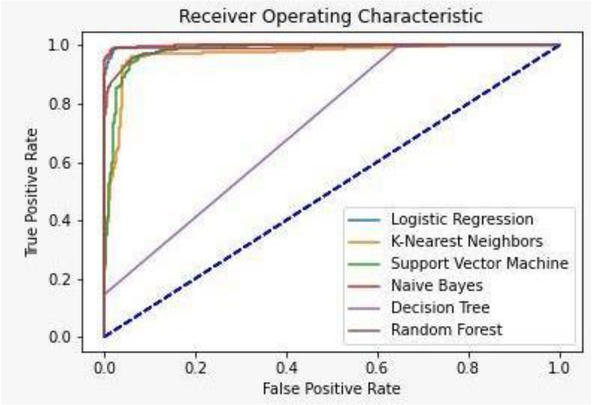

Fig. 9. The ROC curve of the applied methods for IoT anomalies detection.

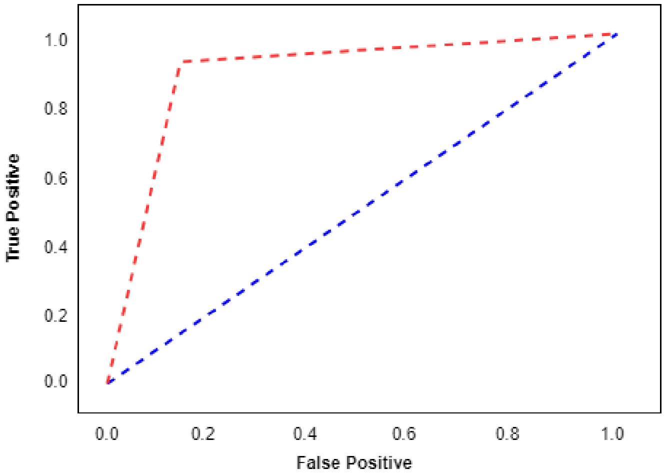

Fig. 10. The ROC curve of the applied method for IoT anomalies detection.

Fig. 10 demonstrates the ROC curve of the proposed CNN-BiLSTM for anomalies detection in internet of things. The obtained results show that, the AUC-ROC curve show high value. The obtained results of all evaluation parameters demonstrate that the proposed CNN-BiLSTM model is applicable for practical cases.

VI. Discussion

The goal of this research is to explore machine learning and deep learning models for identifying abnormalities in Internet of Things network data and develop a new deep learning model for the given problem. Deep learning models were evaluated utilizing a single set of hardware and software, as well as equal sections of the UNSW-NB15 dataset for training and testing. Test models include logistic regression, random forest, KNN, decision tree, Naive Bayes, SVM, and Adaptive Boosting. The built models have high rates of IoT network anomaly detection accuracy, ranging from 80% to 88%. The article proposes CNN-BiLSTM hybrid model for detection of anomalies in internet of things network. The proposed deep model shown about 96% accuracy. In addition, the paper chooses the best machine learning model based on the amount of time it takes to train the model and the importance of identifying abnormalities in internet of things network traffic.

It is intended to continue examining the properties of models employed in cybersecurity jobs in the future. One of the upcoming research objectives is to look at the effect of internet of things network traffic topology on the performance metrics of deep learning models [46]. Based on the findings, a deep CNN-BiLSTM strategy is proposed for recognizing and linking security incidents.

VII. Conclusion

The goal of this research is to look at machine learning models for identifying abnormalities in Internet of Things network data. Deep learning models were evaluated utilizing a single set of hardware and software, as well as equal sections of the UNSW-NB15 dataset for training and testing. Test models include logistic regression, random forest, KNN, decision tree, Naive Bayes, SVM, and Adaptive Boosting. The built models have high rates of network anomaly detection accuracy, ranging from 80% to 88%. The article offers suggestions for selecting the best deep learning model based on the amount of time it takes to train the model and the importance of identifying abnormalities in network traffic.

It is intended to continue examining the properties of models employed in cybersecurity jobs in the future. One of the upcoming research objectives is to look at the effect of network traffic topology on the performance metrics of deep learning models. Based on the findings, it is proposed to build a deep learning-based strategy to recognizing and linking security incidents.

***Abstract*—For effective optimization, metaheuristics should maintain the proper balance between exploration and exploitation. However, the standard firefly algorithm (FA) posted some limitations in its exploration process that can eventually lead to premature convergence, affecting its performance and adding uncertainty to the optimization results. To address these constraints, this study introduces an additional novel search mechanism for the standard FA inspired by the behavior of the scout bee in the artificial bee colony (ABC) algorithm, termed the "Scouting FA". Specifically, fireflies stuck in the local optima will take directed extra random walks to escape toward the region of the optimum solution, thus improving convergence accuracy. Empirical findings on the five standard benchmark functions have validated the effects of this modification and revealed that Scouting FA is superior to its original version.**

***Keywords*—Metaheuristics; firefly algorithm; modified firefly algorithm; global optimization; scout bee; exploitation and exploration**

I. Introduction

The firefly algorithm (FA) is a nature-inspired metaheuristics mimicking how fireflies behave. It was introduced by Yang [1] in 2009 to optimize multimodal problems. Over competing algorithms, FA proved advantageous owing to its simplicity, flexibility, ease of implementation, and few parameters to tune. As a result, FA quickly gains popularity in the scientific community. Furthermore, it has been empirically proven to handle NP-hard problems effectively [2]. Since its inception almost 15 years ago, FA and its modified variants have demonstrated significant success in various fields of application. For example, in multilevel image segmentation [3], as a way to reduce the number of dimensions [4], optimizing convolutional neural networks [5], solving course timetabling problems [6], and dealing with complex engineering tasks [7], [8], among other things. Knowing that FA has a universal application makes it a fascinating subject to pursue. In fact, this metaheuristic approach can be investigated further to provide solutions to real-world problems, such as IoT-based applications [9], time-series forecasting [10], [11], and machine vision-based tasks [12].

Metaheuristic optimization algorithms yielded approximations. Even though it does not guarantee the best solution, it gives the best result possible. The two main concepts of metaheuristics are exploration and exploitation [13]. Exploration searches space globally to locate the region with the optimal solution. On the other hand, exploitation seeks the optimal location of convergence by doing a local search within the area discovered by exploration. Because exploration and exploitation are inherently contrasting processes, it is critical to establish a robust exploration mechanism before starting the exploitation process. Likewise, it is also vital to maintain the proper balance between the two techniques during the search. That is why, if exploration is inefficient, the solution may converge too soon because it will become stuck in suboptimal domains before finding the optimal region [14], [15].

Previous studies reveal that FA is relatively robust at exploitation, although its exploratory ability can be improved [16]. Weaknesses in fireflies' exploration ability can eventually impact their convergence accuracy, adding uncertainty to the optimization results [17], [18]. Consequently, this limitation has narrowed the scope of the FA's applications. A recent approach to counter this drawback applied a damped vibration distribution factor to enhance the attractiveness and randomization formula [2]. Another notable solution utilized a quasi-reflection-based learning approach in the initiation stage of implementation to diversify the FA's population [19]. In addition, [20] enhanced the FA's exploration by adding genetic operators and using a dynamically modified step size. A hybrid method [21] used the group search approach established from the social network search (SNS) algorithm [22]. In [23], a novel method for updating the firefly's new location and the ABC [24] algorithm's scout bee search technique was also introduced to supplement the FA's search operation.

After numerous successful deployments of updated and hybridized FA variants, there are still opportunities for improvement. Initiatives to hybridize metaheuristic algorithms, such as those described in [25]–[27] have emerged. Similarly, the exploration mechanism of the FA can be combined with processes from various metaheuristics. Thus, the strengths of each algorithm could be merged to develop new algorithms that are more robust and accurate.

This work is yet another attempt to improve the FA's exploration process. An additional novel search mechanism inspired by the behavior of the scout bee in the ABC algorithm complements the original implementation. Specifically, fireflies stuck in the local optima will take directed extra random walks to escape toward the region of the optimum solution, thus improving convergence accuracy. This method is known as the scouting firefly algorithm (Scouting FA). This study's most significant contribution is providing a better version of the widely used FA that fixes the established shortcomings of the original version.

The remainder of the paper is organized as follows: Section II highlights the FA and ABC algorithms, and related works. Section III suggests a novel way to improve the FA. Section IV describes the experimental setup. The results and discussions are elucidated in Section V. Section VI gives a summary of the conclusions and future works.

II. Background and Related Works

A. Standard Firefly Algorithm (FA)

The fundamental concept of FA relates to the insects' bioluminescence, which is used to communicate with other fireflies. The following assumptions were made to represent the algorithm mathematically:

1) All fireflies are unisex and attract each other without regard to their sex;

2) Attractiveness is linked to brightness; thus, the firefly with lower intensity will approach the brighter one. Unless there is a brighter firefly, it will move randomly; and

3) The firefly's brightness corresponds to the optimization problem's objective function.

In the FA, convergence accuracy and speed largely depend on two key factors: the variation of light intensity and the formulation of attractiveness [28]. The attractiveness β is relative, depending on how a particular firefly perceives other fireflies. The relativity of β is computed relative to the distance r_{ij} between the firefly i and j. Accordingly, the farther apart the fireflies are, the less light they can see from one another, as governed by the inverse square law. Besides, the fact that light is absorbed by the atmosphere is also a significant factor to consider.

The Cartesian distance r_{ij} between any two fireflies i and j located at x_i and x_j is given by:

$$r_{ij} = \|x_i - x_j\| = \sqrt{\sum_{k=1}^{d}(x_{i,k} - x_{j,k})^2} \quad (1)$$

where d is the dimension of the optimization problem.

Correspondingly, the light intensity $I(r)$ varies with the distance r monotonically and exponentially, as depicted in the formula:

$$I = I_0 e^{-\gamma r} \quad (2)$$

where I_0 is the initial light intensity and γ is the light absorption coefficient that controls the light intensity.

As a firefly's attractiveness is proportional to the light intensity perceived by adjacent fireflies, the attractiveness β of a firefly can be derived by:

$$\beta = \beta_0 e^{-\gamma r^2} \quad (3)$$

where β_0 is the attractiveness at $r = 0$.

The formula to determine the movement of a less-bright firefly i that is attracted to brighter firefly j is given by:

$$x_i = x_i + \beta_0 e^{-\gamma r_{ij}^2}(x_j - x_i) + \alpha\varepsilon \quad (4)$$

where the $\beta_0 e^{-\gamma r_{ij}^2}(x_j - x_i)$ calculates the attraction, while the α is randomization with the vector of random variables ε_I taken from a Gaussian distribution or uniform distribution in range [0, 1].

B. Artificial Bee Colony (ABC) Algorithm

The ABC algorithm is another well-known nature-inspired metaheuristic [24]. It was formally established by Karaboga in 2005 and modeled on how honeybee swarms search for food. Artificial bee colonies are classified as employed, onlookers, and scouts. Employed bees identify food sources within the search space and relay information about the food sources to onlookers via dance moves. The onlookers choose one of the food sources based on its attributes, while the scouts search for new food sources randomly. Initially, all the bees in the colony were scouts.

When the scout finds a new food source using Eq. 5 and starts to consume it, that scout is turned into an employed bee. The abandonment of the food sources will commence once the "limit" given by Eq. (6) is met. Conversely, the employed bee will become a scout once the "trial" exceeds the "limit." The "trial" counter will increase if the scout cannot discover a new food source; otherwise, it will be reset to zero.

$$x_i^j = x_{min}^j + rand(0,1)(x_{max}^j - x_{min}^j) \quad (5)$$

Assume that the abandoned source is x_i and $j \in \{1, 2,...,D\}$, then the scout discovers a new food source to be replaced with x_i.

The limit parameter l is computed using:

$$l = (CS * D)/2 \quad (6)$$

where *CS* is the colony size and *D* is the dimension of the problem.

C. Related Works

According to the no-free-lunch theorem [29], no single approach can solve all optimization problems. Thus, the original implementations of metaheuristics are modified to perform better. Two outstanding FA versions incorporating the ABC algorithm are discussed below.

A hybrid of firefly and multi-strategy ABC for optimizing single-objective problems is presented in [27]. The FA performs the global search, while the novel multi-strategy ABC does the local search. Nevertheless, this approach displayed computational complexity because two independent search techniques coexisted throughout the search process. Furthermore, switching the search from FA to the multi-strategy ABC employs a diversity measure that raises computational costs.

The work of [23] is another impactful study that enhanced the exploration of FA using the scout bee search mechanism of the ABC algorithm. In their approach, non-improving fireflies will be replaced by new fireflies at random locations within the specified lower (lb_j) and upper bounds (ub_j) based on the formula:

$$x_{i,j} = lb_j + rand * (ub_j - lb_j) \tag{7}$$

where $x_{i,j}$ signifies the *i*th firefly and the corresponding *j*th element; and *rand* is a uniform random number.

The above method provides an entirely random position for fireflies that exhibits no improvements above a specific threshold limit. This can cause fireflies already nearing convergence to spread farther away, necessitating additional exploitation and exploration. This implementation method may impact both the convergence accuracy and the convergence rate.

III. Scouting Firefly Algorithm

The Scouting FA aims to improve the standard FA's exploration ability by allowing the fireflies stuck in the local optimum over a specific threshold limit ("limit") to take directed extra random walks to scout unfamiliar regions in the search space further. The formula for "limit" is identical to that stated in Eq. 6. Afterward, a greedy selection will be utilized. If the new solution has a higher fitness value than the previous one, its position will be updated by Eq. 8; otherwise, no movement will occur.

The directed extra random walk formula is defined as:

$$x_{i+1} = x_i + (\alpha_i - 0.5) * (ub - lb) \tag{8}$$

where x_{i+1} refers to the new position of the firefly after taking a random walk, x_i is the current position, α_i denotes a random number drawn from uniform distribution $U(0, 1)$, while *ub* stands for upper bound and *lb* for the lower bound. $(\alpha_i - 0.5)$ will ensure that a directed extra random walk is provided, such that, if the generated α_i is < 0.50, the firefly will move backward, and if it is > 0.50, a forward movement will be made.

The novelty of Scouting FA over [23] is that instead of providing an entirely random position for fireflies that exhibits no improvements, directed extra random walks with greedy selection is applied. This is to avoid spreading away fireflies that were already nearing convergence. Furthermore, unlike [27], as an alternative for having two independent search techniques that coexisted throughout the search process and the required diversity measure for switching between searches, this study complemented the standard FA as the extra random walks will only be executed when it improves the fitness value even further. The pseudo code of the Scouting FA is described in Algorithm 1.

Algorithm 1: Pseudocode of the Scouting Firefly Algorithm

```
Objective function $f(x)$, $x = (x_1, ..., x_d)^T$.
Generate an initial population of $n$ fireflies $x_i$ $(i = 1, 2, ..., n)$.
Light intensity $I_i$ at $x_i$ is determined by $f(x_i)$.
Define FA parameter: $\alpha$, $\beta$, $\gamma$.
Set value for the threshold limit value, limit, using Eq. 6
while ($t$ < maxGeneration),
    for $i$ = 1:$n$ (all $n$ fireflies)
        for $j$ = 1:$n$ (all $n$ fireflies) (inner loop)
            if ($I_i < I_j$)
                Move firefly $i$ towards $j$ using Eq. 4
                Reset $trial_i = 0$
            else // solution has no improvement
                $trial_i$++
            end if
            Vary attractiveness with distance $r$ via exp[$-\gamma r2$].
            Evaluate new solutions and update light intensity.
        end for $j$
    end for $i$
    for $i$ = 1:$n$ (all $n$ fireflies)
        if ($trial_i$ >= limit) // no improvement for limit times
            Scout for a new position, P, via random walk using Eq. 8
            if ($I_P > I_i$) // greedy selection
                Move firefly $i$ to position P
            end if
        end if
    end for
    Rank the fireflies and find the current global best $g*$.
end while
Postprocess results and visualization.
```

IV. Experimental Set-up

Five well-known benchmark functions were used to validate the performance of the Scouting FA compared to the original implementation. Table I lists these functions, their formula, variable limits, and global optimum.

TABLE I. Benchmark Functions Used in the Experiments

Function	Formula	Limits	Optimum
Sphere	$f_1(x) = \sum_{i=1}^{d} x_i^2$	[-5.12, 5.12]	f(x)=0 at x=(0,0)
Booth	$f(x) = (x_1 + 2x_2 - 7)^2 + (2x_1 + x_2 - 5)^2$	[-10, 10]	f(x)=0 at x=(1,3)
Easom	$f_3(x) = -cos(x_i)\ cos(x_i)\ exp(-\ (x_1 - \pi)^2 - (x_2 - \pi)^2)$	[-100, 100]	f(x)=-1 at x=(π,π)
Rosenbrock	$f(x) = \sum_{i=1}^{d-1} [100(x_{i+1} - x_1^2)^2 + (x_i - 1)^2]$	[-5, 10]	f(x)=0 at x=(1,1)
Ackley	$f_2(x) = -20 \exp\left(-b\sqrt{\frac{1}{d}\sum_{i=1}^{d} x_i^2}\right) - \exp\left(\frac{1}{d}\sum_{i=1}^{d} cos(cx_i)\right) + a + \exp(1)$	[-5, 5]	f(x)=0 at x=(0,0)

The control parameter values used in the simulations are given in Table II.

TABLE II. CONTROL PARAMETERS OF STANDARD FA AND SCOUTING FA AS IMPLEMENTED IN THE STUDY

Parameter	Value
Maximum generation (*maxGeneration*)	300
Population size (*n*)	30
Randomization parameter (α)	1.0
Attractiveness (β) at *r = 0*	1.0
Light absorption coefficient (γ)	0.97

All experiments were carried out in Python 3.10.5 on an Intel(R) Core (TM) i7-11370H processor running at 3.30 GHz and with 40 GB of random-access memory.

V. RESULTS AND DISCUSSION

Due to the stochastic nature of the metaheuristic algorithms, each iteration is seeded with a random number to ensure that each solution is unique. Experimental results are shown in Table III. The best, worst, and mean optimal fitness value were noted and compared. The results of the mean optimal fitness value were generated in 100 independent runs to eliminate the effect of the stochastic simulation discrepancy [28]. If an algorithm gets the best results for the performance metric, the results are shown in bold and in a slightly bigger font size.

TABLE III. COMPARATIVE ANALYSIS WITH STANDARD FA AND SCOUTING FA IMPLEMENTATIONS FOR THE FIVE BENCHMARKS

Functions	Optimization Method	Best	Worst	Mean Optimal Fitness Value
Sphere	Standard FA	1.84E-05	1.83E+00	6.44E-02
	Scouting FA	**2.27E-06**	**1.25E-02**	**1.96E-03**
Booth	Standard FA	2.65E-04	4.80E+00	4.79E-01
	Scouting FA	**1.65E-06**	**1.58E-01**	**6.23E-03**
Easom	Standard FA	-1.00E+00	-8.02E-05	-7.11E-01
	Scouting FA	**-1.00E+00**	**-9.70E-01**	**-9.98E-01**
Rosenbrock	Standard FA	8.66E-03	5.30E+01	2.48E+00
	Scouting FA	**4.51E-04**	**1.12E+00**	**2.63E-01**
Ackley	Standard FA	1.18E-02	4.42E+00	2.11E+00
	Scouting FA	**2.67E-03**	**4.04E-01**	**2.63E-01**

As shown, the Scouting FA outperformed the standard FA in all test functions. Even if the worst values are considered, the Scouting FA is closer to the global optimum than the standard FA.

Fig. 1 to 5 compare convergence plots in the five benchmark functions between the standard FA and the Scouting FA.

Fig. 1 demonstrates that when optimizing the Sphere function, the solution in the standard FA is trapped in the local optimum close to 0.20 of the fitness value in the early iterations. On the other hand, the Scouting FA performs better because it avoided premature convergence and gradually moved closer to the global optimum, *f(x)=0 at x=(0,0)*, in just more than 50 iterations.

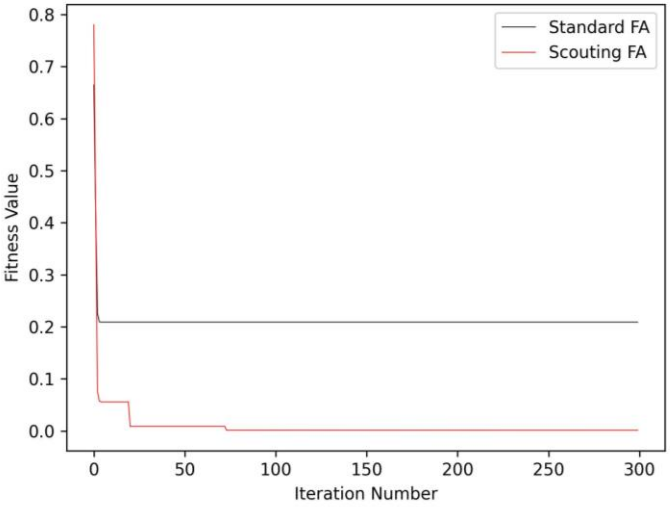

Fig. 1. Convergence plot for the Sphere function.

As shown in Fig. 2, early runs of the standard FA reveal an early convergence nearing 0.20 of the fitness value. When tested using the Booth function, the application of the Scouting FA is more effective. The graph demonstrates the solution progresses towards convergence at the global optimum, *f(x)=0 at x=(1,3)*, in more than 150 iterations.

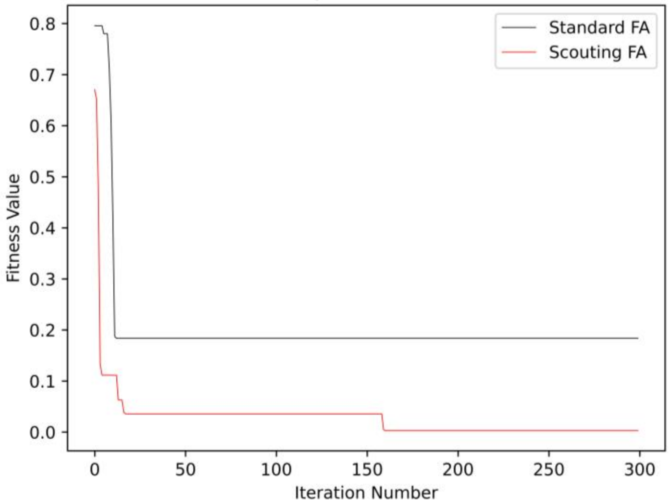

Fig. 2. Convergence plot for the booth function.

As depicted in Fig. 3, in terms of the Easom function, the premature convergence occurs very quickly at nearly -0.80 in the standard FA. Contrary to that, Scouting FA yielded a better result, as escaping from the local optimum is evident. In this problem, the global minimum, *f(x)*=-1 at *x*=(π,π), is nearly achieved at below 50 iterations.

When the Scouting FA optimized the difficult Rosenbrock function, as shown in Fig. 4, there was a significant improvement in achieving a near-optimal result. As illustrated, the Scouting FA's extra random walks slowly improve the solution until it converges close to the global optimum at *f(x)=0 at x=(1,1)* after the 200th iteration.

For a complex optimization problem like the Ackley function, the graph depicted in Fig. 5 revealed that the Scouting FA is considerably better than its original implementation. While standard FA prematurely converges above the 1.5 fitness value, the extra random walks the Scouting FA provides have progressively improved the fitness value until it achieves close to *f(x)=0 at x=(0,0)* before it reaches the 300th iteration.

Fig. 6 shows how 30 fireflies in the five test functions converged after 300 iterations when the standard FA was used. In Fig. 7, the Scouting FA was utilized. As depicted, indeed, with Scouting FA, fireflies can escape being trapped in the sub-optimal solution by taking directed extra random walks.

VI. Conclusions and Future Works

This study improved the exploration of the standard FA by adding the behavior of the scout bee from the ABC algorithm. When the novel search method was used to solve global optimization problems, it made the search more precise, significantly improving convergence accuracy. This result implies that the Scouting FA is more powerful than its original implementation.

In the future, researchers will investigate how well the Scouting FA works when used to tune the hyperparameters of machine learning-based methods for solving real-world optimization problems.

A Robust Steganographic Algorithm based on Linear Fractional Transformation and Chaotic Maps

Steganographic Algorithm based on S-Boxes

Muhammad Ramzan[1], Muhammad Fahad Khan[2]
Department of Computer Science-College of Computing and Informatics,
Saudi Electronic University, Riyadh 11673, Saudi Arabia[1]

***Abstract*—The fundamental objectives of a steganographic technique are to achieve both robustness and high-capacity for the hidden information. This paper proposes a steganographic algorithm that satisfies both of these objectives, based on enhanced chaotic maps. The algorithm consists of two phases. In the first phase, a cryptographic substitution box is constructed using a novel fusion technique based on logistic and sine maps. This technique overcomes existing vulnerabilities of chaotic maps, such as frail chaos, finite precision effects, dynamical degradation, and limited control parameters. In the second phase, a frequency-domain-based embedding scheme is used to transform the secret information into ciphertext by employing the substitution boxes. The statistical strength of the algorithm is assessed through several tests, including measures of homogeneity, correlation, mean squared error, information entropy, contrast, peak signal-to-noise ratio, energy, as well as evaluations of the algorithm's performance under JPEG compression and image degradation. The results of these tests demonstrate the algorithm's robustness against various attacks and provide evidence of its high-capacity for securely embedding secret information with good visual quality.**

Keywords—Steganography; information security; chaotic map vulnerabilities; enhanced chaotic maps; S-box Design

I. INTRODUCTION

History has demonstrated that secret communication has always been an essential requirement in human society. As time progressed, more advanced techniques have been introduced. In the last two decades, the rapid development of digital communication systems has significantly increased the demand for secure data exchange through digital multimedia. Innovative strategies to protect confidential information from intruders have become the focus of recent research. In this regard, modern techniques of cryptography, watermarking, and steganography have gained unusual importance in the last few years [1-5]. Cryptography involves converting useful information into dummy data to protect it from unintended recipients, while watermarking is associated with protecting the data's copyright. Steganography, on the other hand, conceals confidential information into other information [6-8]. With the advent of modern computer technology, remarkable skills for surreptitious communication have been developed. Steganography involves embedding secret information in either the spatial or transform (frequency) domain. In spatial domain embedding, the LSB-substitution technique is most commonly used. However, in the transform domain, invertible transforms such as (DCT) and (DWT) are typically applied to transform the image into its frequency representation [9-11]. While both domains have advantages and disadvantages, frequency domain embedding is robust, while spatial domain offers increased capacity for hiding data. This motivates researchers to deploy a combination of both domains. The transforms DCT and DWT are frequently used in image compression applications due to their favorable features. DCT is the most widely used, requiring fewer computational resources; however, DWT is considered more efficient in quality. Many multimedia applications and algorithms in recent literature are based on the joint applications of DCT and DWT [12-15]. In our proposed method, we apply a hybrid of these transforms for improved and robust outcomes.

In the last decade, chaos has been widely used to enhance the security level of confidential communication. Chaotic systems possess prime features such as irregularity, butterfly effect and unpredictability which making them well-suited for multimedia security applications. Consequently, the study and analysis of chaos-based steganographic techniques have gained popularity in recent years. However, it has been observed that some chaos-based methods are vulnerable to statistical analysis because of the limited chaotic range of the used maps [16-20]. To overcome this issue, authors of [19] proposed a nonlinear combination of one-dimensional chaotic maps that enhances the chaotic range of the resulting system. Such systems are applied in image encryption applications, but to the best of our knowledge, they have not been applied in steganographic methods yet.

The fundamental objectives of a steganographic technique are to achieve both robustness and high-capacity for the hidden information. This paper proposes a steganographic algorithm that satisfies both of these objectives, based on enhanced chaotic maps. The algorithm consists of two phases. In the first phase, a cryptographic substitution box is constructed using a novel fusion technique based on logistic and sine maps. This technique overcomes existing vulnerabilities of chaotic maps, such as frail chaos, finite precision effects, dynamical degradation, and limited control parameters. In the second phase, a frequency-domain-based embedding scheme is used to transform the secret information into ciphertext by employing the substitution boxes. In addition, we exploit the combination of the spatial and transform domains to achieve a significantly high capacity level for embedding secret data. Our technique uses a hybrid of DCT and DWT, and we observe that the combined effect of DCT and DWT increases robustness against several image processing attacks. The strength of the proposed method is evaluated through the most frequently used analysis techniques, and we prove that our technique produces coherent results. The use of enhanced chaotic systems in steganography has been demonstrated to be effective in various studies, highlighting the potential for further development in this field. The structure of the paper is organized as follows: Section II presents the chaotic map fusion technique. Section III describes the design of the S-box. Section IV presents a novel steganographic technique and Section V provides the security analysis and simulation results. Finally, Section VI presents the conclusions.

II. Fusion of 1-Dimension Chaotic Maps

The study of security protocols has demonstrated the extensive applications of one-dimensional chaotic maps due to their simple structure and computational convenience. In our research, we use the logistic map and the sine map to develop a stronger chaotic system for our problem. In the upcoming sections, we explored the essential features of these maps and their implementation in our research.

A. The Logistic Map

It is a mathematical function that has been used in various applications in information security due to its ability to generate chaotic and pseudorandom sequences. The logistic map is defined by a quadratic recurrence, which can be written as:

$$\mathcal{C}_{\mathcal{L}}(\vartheta_{\mathcal{L}}, x_i\ ) = \vartheta_{\mathcal{L}} x_i(-x_i); \qquad (1)$$

Where $\vartheta_{\mathcal{L}} \in (0, 4]$ is called the control parameter. It is also known *as a catalyst* for chaos as the behavior of the map varies when the value of parameter $\vartheta_{\mathcal{L}}$ changes. It is clear from the bifurcation diagram (as shown in Fig. 1(a)) that $\mathcal{C}_{\mathcal{L}}$ produces the chaotic effect only when $\vartheta_{\mathcal{L}} \in [3.57, 4]$. Although the Logistic map is widely used, it has been noted that its chaotic range is limited, which can be a drawback in some applications.

Another important characteristic of a dynamical system is Lyapunov Exponent, which is a quantitative measure of chaos. A system is chaotic if the value of the Lyapunov exponent is strictly positive, as then a minor disturbance in the initial conditions may cause exponential divergence. The larger the Lyapunov exponent, the better is chaotic performance. Fig. 2(a) shows the variations of the Lyapunov exponent of the logistic map.

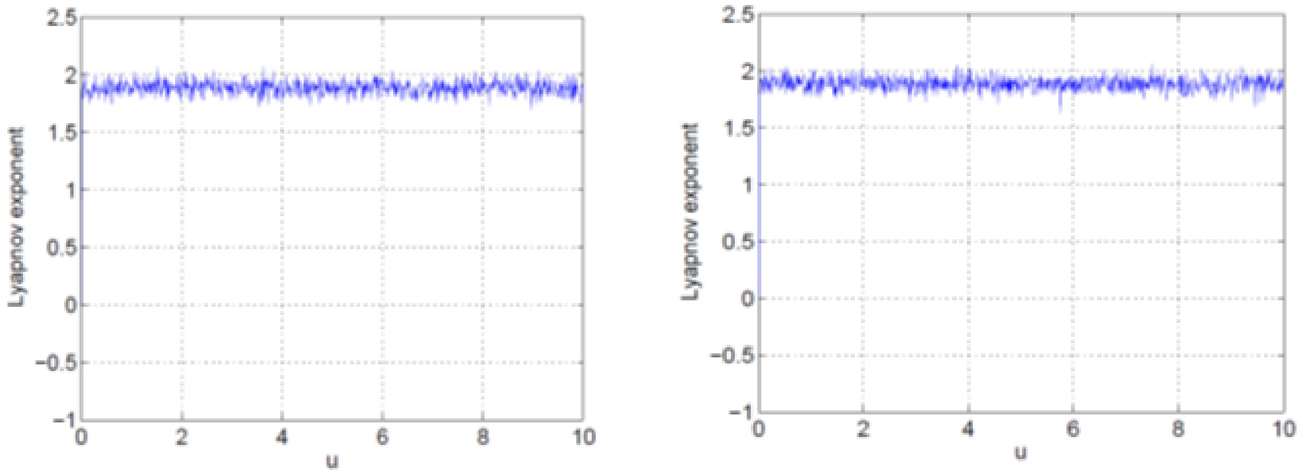
(a) LLS

(b) SSS

Fig. 3. Bifurcation diagrams of LLS and SSS.



(a) LLS

(b) SSS

Fig. 4. The Lyapunov exponent of LLS and SSS.

B. The Sine Map

It is a type of chaotic system that has received considerable attention in the area of nonlinear dynamics. It is a straightforward mathematical model that is capable of displaying intricate and unpredictable patterns. Sine map equation is represented as:

$$\mathcal{C}_{\mathcal{S}}(\vartheta_{\mathcal{S}}, x_i) = \frac{\vartheta_{\mathcal{S}} Sin(\pi x_i)}{4}; \qquad (2)$$

Where $\vartheta_{\mathcal{S}} \in (0,4)$. Like the logistic map, the sine map also exhibits chaotic behavior. However, it has been observed that the chaotic range of the sine map is also limited, as shown in the bifurcation diagram presented in Fig. 1(b). The variations of the Lyapunov exponent of the sine map are shown in Fig. 2(b) Study regarding the combinations of one-dimensional chaotic maps shows that by introducing suitable combinations of such maps, the chaotic range can be enhanced [19]. In the next section, we discuss such combinations in detail.

C. Combinations of Chaotic Maps

Our approach involves creating new chaotic systems that have chaotic properties across their entire domain. We accomplish this by constructing nonlinear combinations of the underlying seed maps, which includes the LLS and SSS. The mathematical expression used for the nonlinear combination LLS is given below:

$$x_{i+1} = \mathcal{C}_{\mathcal{L}}(\vartheta_{\mathcal{L}}, x_i) \times \psi(n) - \mathcal{C}_{\mathcal{L}}(\vartheta_{\mathcal{L}}, x_i) \times \psi(n) - \lfloor \mathcal{C}_{\mathcal{L}}(\vartheta_{\mathcal{L}}, x_i) \times \psi(n) \rfloor; \qquad (3)$$

Where $\psi(n) = 2^n$; $8 \le n \le 14$, is called an adjustment function. The larger the value of n, the better is the chaotic performance. For both LLS and SSS we choose n = 14. Eq. (3) can be rewritten as:

$$x_{i+1} = \vartheta_{\mathcal{L}} x_i(1 - x_i) \times 2^{14} - \lfloor \vartheta_{\mathcal{L}} x_i(1 - x_i) \times 2^{14} \rfloor \quad (4)$$

The figures depicting the bifurcation diagram and the Lyapunov exponent of the LLS chaotic system can be observed in Fig. 3(a) and Fig. 4(a), respectively. A comparison of the bifurcation diagram of LLS with that of the logistic map in Fig. 2(a) reveals that the former exhibits a significantly wider chaotic range than the latter. Additionally, the improved uniform distribution of the density function in LLS compared to its seed maps ensures better chaotic behavior of the newly generated system and its efficient application in information security. The other two chaotic systems discussed in the following subsections exhibit similar properties. The expression for the Sine-Sine system can be obtained by using Eq. (1).

$$\mathcal{C}_{\mathcal{S}}(\vartheta_{\mathcal{S}}, x_i) == \frac{\vartheta_{\mathcal{S}} Sin(\pi x_i)}{4} \times 2^{14} - \left\lfloor \frac{\vartheta_{\mathcal{S}} Sin(\pi x_i)}{4} \times 2^{14} \right\rfloor \quad (5)$$

The bifurcation diagram and the variations of Lyapunov exponent are exhibited in Fig. 3(b) and Fig. 4(b). Just like the previous case, one may observe the improved performance of the new chaotic system.

III. Construction of Cryptographic S-Box

Block ciphers are cryptographic algorithms that convert plaintext into ciphertext by breaking it up into fixed-length blocks and applying a series of substitution and permutation operations. They are widely used to secure data in various applications, such as electronic payments, online transactions, and communication systems. S-boxes, or substitution boxes, are a key component of block ciphers, as they determine the nonlinear substitution of input bits with output bits in the encryption process. The quality of the S-box plays a vital role in the overall security of the cryptosystem, as any weakness or vulnerability in the S-box can be exploited by attackers to break the encryption. To achieve resistance against differential and linear cryptanalysis in an encryption scheme, the selection of a suitable S-box is crucial. Differential and linear cryptanalysis are two common techniques used by attackers to break ciphers, and a well-designed S-box can help to mitigate these attacks and provide stronger security. To ensure the highest level of security, cryptographers must carefully design and test S-boxes to ensure they are resistant to attacks and produce high-quality encryption output. The selection and design of S-boxes is a complex and ongoing research area, as the security requirements and threats to cryptosystems are constantly evolving. Despite the challenges, the use of strong and secure S-boxes is crucial for the development of robust and reliable cryptosystems.

Where $GL(n;\ \mathbb{F})$ are a group of invertible matrices and PGL of degree n over a field $\mathbb{F}$ is as $GL(n;\ \mathbb{F})$ by its center. We also form the 8×8 S-box through $GF(2^8)$ on $PGL\big(2, GF(2^8)\big)$:

$$f\ :\ PGL\big(2, GF(2^8)\big) \times GF(2^8) \rightarrow\ GF(2^8)$$

Defined as:

$$\tau(z)\ = \frac{\alpha z + \beta}{\gamma z + \delta} \quad (6)$$

Here τ is LFT of $\in GF(2^8)$, which satisfying the non-degeneracy condition $\alpha\delta - \beta\gamma \neq 0$. Where $\alpha = 21$, $\beta = 8$ and $\gamma = 3$ and $\delta = 17$.

IV. Steganographic Scheme

The proposed scheme highlights some most essential steps for information embedding process. First, substituting the information through a highly nonlinear S-box. Secondly, instead of depending on either spatial or transform domain only, it employs a combination of both the domains to reach the acceptable level of embedding capacity as well as robustness. Thirdly, the scheme is based on stronger chaotic combinations which depict extraordinary features when compared with the individual seed maps. Lastly, it involves both DCT and DWT. The combined effect of both these transforms contributes to the robustness of the proposed method.

1) The detailed steganographic strategy is explained through the flowchart (Fig. 5). We explain the whole process in the following steps.

2) Take the host image (sized 512×512) in the spatial domain and shape it into a vector of length m.

3) Take the secret image $\mathcal{I}$ (to be embedded), that is $1/5$ of the host image size and substitute it using the S-box shown in table 1.

4) Break the substituted image into two parts $\mathcal{I}_{\infty}$ and $\mathcal{I}_{\in}$ in the ratio 70% and 30% respectively.

5) First, $\mathcal{I}_{\infty}$ is embedded at random positions of the host image, using the chaotic system *LLS*. This gives the partial stego image in the spatial domain.

6) Reshape this partial stego image into a matrix form and convert into the frequency domain by applying the combination of DWT and DCT.

7) Revamp the obtained image into a vector of length *m* and pick the largest frequency components (30% of the whole).

8) Use the chaotic system *SSS* to embed $\mathcal{I}_{\in}$ at the random positions of the selected largest values. This produces the frequency domain version of the stego image.

9) At this stage, apply the inverse of *DCT* and *DWT* to reach the final version of the stego image.

*10)*The original embedded image can be extracted from the stego image by applying the reverse of the above-explained method.

The simulation results are expressed in Fig. 6, Fig. 7. We apply the steganographic algorithm on two 512×512 images of baboon and Lena.

V. Statistical Security Analysis

In this section, we measure the cryptographic strength of the proposed scheme with the help of some useful analysis such as entropy, contrast, correlation, homogeneity, peak signal to noise ratio (PSNR) and mean squared error (MSE). We analyzed two benchmark images, baboon and Lena, using the proposed scheme. Notably, the scheme exhibits a remarkable feature of producing steganographic images that have high resemblance to their original counterparts. Moving on, let's discuss these security parameters one by one.

A. *Contrast*

The analysis of contrast is a method employed to evaluate the degree of sensitivity of image textures to variations in intensity. In simpler terms, it measures how much the texture of the image changes when the intensity of the image is changed. The contrast of an image is directly related to the texture of the image, and is an important factor in determining the quality of an image. Images with high contrast are usually considered to be of higher quality, since they have a greater range of intensity and a more distinct texture. The mathematical expression for the contrast is given as:

$$\text{Contrast} = \sum_i \sum_j | -j|^2 p(i,j), \qquad (7)$$

Where Table II and III present the values of contrast for each image, which are computed from the (i,j) th-element of GLCM represented by P(i,j).

B. *Information Entropy*

Entropy analysis is used to measure the randomness or the degree of disorder of a system. Entropy is a critical security parameter used to evaluate the strength of a cryptographic scheme. It is a measure of randomness or uncertainty in the data, indicating the degree of unpredictability in the scheme. In the context of steganography, entropy measures the level of randomness in the distribution of pixels in the steganographic image. A higher entropy value implies that the distribution of pixel values in the steganographic image is more random and unpredictable, making it harder for an attacker to identify the hidden data. In general, higher entropy values are desirable as they indicate a higher level of security. A scheme with a low entropy value is more predictable, and hence less secure, as it makes it easier for an attacker to detect the presence of hidden data. Therefore, a higher entropy value indicates a higher degree of randomness in the scheme and, consequently, a more secure scheme. However, achieving a high entropy value may not always be practical, as it can negatively impact the quality of the steganographic image. A scheme that produces high entropy values but produces a visually distinguishable steganographic image may not be useful in practice. Thus, a balance between high entropy values and image quality needs to be struck to ensure that the scheme is both secure and practical. The mathematical formula for information entropy is given by:

$$\text{Entropy} = -\sum_i \sum_j p(i,j) \log P(i,j), \qquad (8)$$

Tables II and III present the numerical outcomes for both the original and steganographic images. The algorithm we employed demonstrated favorable outcomes for entropy.

TABLE II. Original Image: Results of Majority Logic Criterion

Images	Entropy	Contrast	Correl.	Homog.
Baboon	5.4598	0.3389	0.9689	0.8753
Lena	5.3721	0.1342	0.9752	0.8654

TABLE III. STEGO IMAGE: RESULTS OF MAJORITY LOGIC CRITERION

Images	Entropy	Contrast	Correl.	Homog.
Baboon	5.6790	0.3409	0.9573	0.8845
Lena	4.9612	0.1217	0.9703	0.9603

C. Correlation

Correlation is another important security parameter used to evaluate the strength of a steganographic scheme. It measures the relationship between adjacent pixels in an image, indicating how much the pixel values are dependent on one another. A high correlation value implies that the adjacent pixel values are similar, and hence predictable, whereas a low correlation value indicates that adjacent pixels are less dependent on one another and more unpredictable. In steganography, a lower correlation value is desirable as it indicates a less predictable steganographic image, making it harder for an attacker to detect the hidden data. This is because the insertion of hidden data modifies the pixel values, disrupting the natural correlation between adjacent pixels. Therefore, a low correlation value indicates that the scheme is successful in hiding the data in the image, and thus more secure. However, it is important to note that achieving a low correlation value may not always be feasible, as it may come at the cost of image quality. If the scheme introduces too much noise or distortion into the image to reduce the correlation value, the resulting steganographic image may be of poor quality, making it distinguishable from the original image. Hence, a trade-off between low correlation and image quality needs to be achieved to ensure that the scheme is both secure and practical. Mathematical expression for correlation is given by:

$$Correlation = \sum_i \sum_j \frac{(i-E_X)(j-E_Y)}{D_X D_Y} p(i,j), \quad (9)$$

Where E_X, E_Y, D_X, D_Y represent the expected values and standard deviations of X and Y.

D. Homogeneity

Homogeneity is another security parameter that measures the uniformity of the intensity distribution in an image. It is a measure of the smoothness of the image, indicating how closely the pixel values are clustered around the average value. A higher homogeneity value indicates a more uniform distribution of pixel intensities in the steganographic image, making it more difficult for an attacker to detect the presence of hidden data. In the context of steganography, a high homogeneity value implies that the steganographic image closely resembles the original image, with minimal variation in pixel intensities. This is desirable as it indicates that the hidden data has been successfully embedded into the image without significantly altering its appearance. Thus, a high homogeneity value suggests a more secure scheme. However, as with other security parameters, achieving high homogeneity values while maintaining acceptable image quality can be challenging. A scheme that produces high homogeneity values but results in poor quality steganographic images may not be practical. Hence, a balance between high homogeneity and image quality needs to be achieved to ensure that the scheme is both secure and practical. The numerical results of the homogeneity analysis of the steganographic images are presented in Table II, providing a quantitative measure of the scheme's homogeneity. Its mathematical formula is:

$$Homogeneity = \sum_i \sum_j \frac{P(i,j)}{1+|i-j|} \quad (10)$$

E. Mean Squared Error

It is a security parameter used to evaluate the quality of a steganographic image. It measures the average squared difference between the pixel values of the original and steganographic images. A lower MSE value indicates a smaller difference between the original and steganographic images, and hence a higher quality steganographic image. In the context of steganography, a lower MSE value implies that the scheme has successfully embedded the hidden data into the image without significantly altering its appearance. This is because the scheme has introduced minimal distortion or noise into the image, resulting in a steganographic image that is visually similar to the original image. Thus, a low MSE value suggests a more secure scheme. However, achieving a low MSE value while maintaining high security can be challenging. A scheme that produces low MSE values but results in a visually distinguishable steganographic image may not be practical. Hence, a balance between low MSE values and image quality needs to be achieved to ensure that the scheme is both secure and practical. The numerical results of the MSE analysis of the steganographic images are presented in Table IV, providing a quantitative measure of the scheme's quality.

$$MSE = \frac{1}{MN} \sum_{i=1}^{M} \sum_{j=1}^{N} X(i,j) - Y(i,j))^2, \quad (11)$$

Where $X(i,j)$ and $Y\,(i,j)$ represent the reference image and the steganographic image and i,j represents the pixel's position in an $M \times N$ image.

TABLE IV. MSE AND PSNR

Image	MSE	PSNR
Baboon	0.0024	58.2405
Lena	0.0017	57.6436

F. Peak Signal to Noise Ratio

It is a security parameter that measures the quality of a steganographic image by comparing the maximum possible signal value with the level of noise or distortion introduced by the embedding of hidden data. A higher PSNR value indicates a higher quality steganographic image with less noise or distortion. In steganography, a higher PSNR value indicates that the scheme has successfully hidden the data in the image without significantly degrading its quality. This is because a high PSNR value implies that the steganographic image is visually similar to the original image, with minimal distortion or noise. Thus, a high PSNR value suggests a more secure scheme. However, achieving high PSNR values while maintaining acceptable security can be challenging. A scheme that produces high PSNR values but results in a visually distinguishable steganographic image may not be practical. Hence, a balance between high PSNR values and security needs to be achieved to ensure that the scheme is both secure and practical. The numerical results of the PSNR analysis of the steganographic images are presented in Table II, providing a quantitative measure of the scheme's quality. Where, a maximum pixel value in the image is given by MAX_I . PSNR is defined by:

$$\mathrm{PSNR} = 20\log_{10}\frac{\mathrm{MAX_I}}{\sqrt{\mathrm{MSE}}} \tag{12}$$

G. Robustness Analysis

To assess the resilience of the suggested steganographic technique, we perform several tests such as applying JPEG compression, adding noise, and cropping effect on the steganographic images. We determine the resemblance between the extracted steganographic image and the original one. Our algorithm's robustness is demonstrated by the high correlation between these two images. Mathematically, the estimation of similarity can be expressed as:

$$\text{Similarity measure} = \frac{\sum \mathrm{r_i s_i}}{\sqrt{\mathrm{r_i}^2 \mathrm{s_i}^2}} \tag{13}$$

Where r_i and s_i represent the corresponding elements. In the subsequent subsections, we will examine the impact of individual image processing operations one by one.

TABLE V. SIMILARITY UNDER VARIOUS ATTACKS

Attacks	Baboon	Lena
Compression	1.1124×10^{-4}	1.1125×10^{-4}
Noise	1.0906×10^{-4}	1.0957×10^{-4}
Cropping	1.1087×10^{-4}	1.1087×10^{-4}

H. JPEG Compression

In steganography, it is important to evaluate the robustness of the proposed scheme under different scenarios, including image compression. JPEG compression is a widely used lossy compression algorithm that can introduce significant distortion in the image, which may result in loss of hidden data. Therefore, it is crucial to test the proposed scheme's robustness under JPEG compression.

To evaluate the effect of JPEG compression on the steganographic images, we subjected the steganographic images of baboon and Lena to JPEG compression and studied the resultant images. The results of the study are presented in Fig. 8(a) and Fig. 9(a), which show the steganographic images before and after JPEG compression. Additionally, Table V presents the numerical results of the study, which prove the robustness of our proposed scheme. The results of the study demonstrate that the proposed scheme is robust to JPEG compression, as the hidden data remains intact even after compression. This is evidenced by the high values of security parameters such as entropy, correlation, homogeneity, PSNR, and low values of MSE for the compressed steganographic images. Thus, the proposed scheme is suitable for secure data transmission over channels that may introduce compression, such as the internet, where image compression is commonly used to reduce transmission time and bandwidth requirements.

I. Noise Addition

In addition to evaluating the robustness of the proposed scheme under JPEG compression, it is important to assess its performance under other forms of image degradation, such as noise. Salt and pepper noise is a common form of noise that can affect the steganographic images during transmission, and it is important to ensure that the proposed scheme is robust against such attacks.

To evaluate the effect of salt and pepper noise on the steganographic images, we subjected the steganographic images of baboon and Lena to varying levels of noise and studied the resultant images. The results of the study are presented in Fig. 8(b) and Fig. 9(b), which show the steganographic images before and after applying salt and pepper noise. Additionally, Table V presents the numerical results of the study, which demonstrate the proposed scheme's robustness against noise attacks. The results of the study indicate that the proposed scheme is quite robust against salt and pepper noise attacks, as the hidden data remains intact even after the introduction of noise. The high values of security parameters such as entropy, correlation, homogeneity, and PSNR, and the low values of MSE for the steganographic images with noise, suggest that the scheme can effectively protect the hidden data from being compromised.

J. Cropping Effect

The cropping effect is an important consideration in evaluating the effectiveness of a steganographic scheme. The cropping of an image refers to the removal of a portion of the image, which can be used to hide the secret data. Therefore, it is essential to assess the robustness of the steganographic scheme against cropping attacks. To evaluate the cropping effect on the proposed scheme, we cropped the steganographic images of baboon and Lena left side. Cropped image is shown in Fig. 8(c) and Fig. 9(c) respectively. Table V presents the numerical results of the study, which demonstrate the robustness of the proposed scheme against cropping attacks. The results of the study indicate that the proposed scheme is quite robust against cropping attacks, as the hidden data remains intact even after the removal of a significant portion of the image. The high values of security parameters such as entropy, correlation, homogeneity, and PSNR, and the low values of MSE for the steganographic images with different cropping percentages, suggest that the scheme can effectively protect the hidden data from being compromised.

VI. Conclusion

Based on the proposed steganographic algorithm using enhanced chaotic maps, the results of the statistical security analysis demonstrate its robustness and high capacity for securely embedding secret information with good visual quality. The use of a novel fusion technique based on logistic and sine maps in constructing the cryptographic substitution box overcomes existing vulnerabilities of chaotic maps such as frail chaos, finite precision effects, dynamical degradation, and limited control parameters. The algorithm's statistical strength was assessed through several tests, including measures of information entropy, correlation, contrast, energy, homogeneity, peak signal-to-noise ratio, mean squared error, as well as evaluations of the algorithm's performance under JPEG compression and image degradation. These tests demonstrate the algorithm's ability to resist various attacks while maintaining good visual quality. In summary, the proposed steganographic algorithm satisfies the fundamental objectives of achieving both robustness and high-capacity for hidden information, and it offers a secure and effective means of embedding secret information in digital images. The algorithm's strengths in terms of security and visual quality make it a promising tool for applications where the protection of sensitive information is critical.

Informatics Department, State University of Malang, Malang, Indonesia[4]

***Abstract*—Many people are trading in the forex market during the COVID-19 pandemic with the hope of earning money, but they are experiencing shortages due to the lack of information and technology-based tools for existing daily data. Sometimes traders only use moving averages in trading data, even though this information needs to be processed again to get the right inflection point. The objective of this research is to find inflection points based on Forex trading database. Another algorithm can also be used to determine the inflection point between two points on a moving average. This can be supported by the Bisection method used because it can guarantee that convergence will occur. The results show that the points resulting from the bisection calculation on the moving average provide a fairly accurate decision support for the location where the inflection point is located. From 10,000 data there is a standard deviation of 0.71 points which is very small compared to an average of 20 pips (points used as the difference in price values in forex). The use of the bisection method provides an accuracy of the results in seeing the inflection point of 87%.**

Keywords—Bisection method; moving average; inflection point; forex trading; decision support

I. Introduction

Since the COVID-19 pandemic, the value of trade transactions has decreased, this is due to unstable economic conditions and tends to decline and so many speculators do wait and see [1–4]. Based on these problems, this research is focused on finding a solution by processing a database containing transaction data and forex value movements obtained from the meta trader application connected to the broker server [5–7]. From this problem arises the question, how to know the inflection point on a curve that can be seen by the user in real time [8].

Many researchers use the moving average method to assist in making buy or sell decisions based on a certain time frame, but often moving averages are less accurate because errors often occur, especially when there is a change in trend. For this reason, an additional method is needed that can overcome the problems that occur in moving averages, especially in determining inflection points.

The bisection method is a way to determine the value of a curve by dividing the interval in half; this method is used to find the equation of a straight line [9–11]. Because the downward movement of the curve tends to be linear, the researcher uses this method to determine the inflection point [12-13]. The bisection method could help estimate the value of past data so that the results are expected to determine the inflection point properly.

In this research, it will be proved that by looking for inflection points, it can speed up the decision-making process accurately, because the method to be used in this study uses the Bisection Method, which can speed up the search for the midpoint of a line. So, it is expected that between these inflection points an up or down curve can be found which has an important role in decision making.

II. Literature Review

A. Forex Database

To be able to observe price movements in forex trading, a connection is needed to the account of one of the brokers that serves forex trading. To be able to get a database related to forex prices, you can choose a currency pair such as USD and JPY. After selecting a currency pair, price movements can be observed directly depending on the desired timeline. Starting from every 1 minute, 15 minutes, 30 minutes, 1 hour, 4 hours, daily, weekly, and even monthly [14].

To be able to accurately perform formula calculations accurately, of course you cannot use all time frames. For this reason, this study uses a 1-hour and 4-hour and daily time frame to check currency price movements [15-16].

The data obtained from previous researchers is the dataset that will be used in this study. The dataset is not directly used in research but it is necessary to clean the data using SPSS to find out that the data is free from outliers. SPSS helps find statistics from a data set, i.e., statistics that include median, mean, mode, variance, and standard deviation.

The resulting statistical data will be processed by Python to remove invalid data, usually invalid data due to redundancy, political factors that affect foreign exchange rates, certain major factors such as explosions, wars, and others. Many researchers do data cleaning with various parameters that are felt to interfere with research, but with a statistical approach it is expected that the dataset will be of better quality.

Data on currency price movements can be downloaded using the .csv format [17-19] so that later it can be used for further calculation processes. Forex price movement data in the form of candlesticks can be seen in Fig. 1.

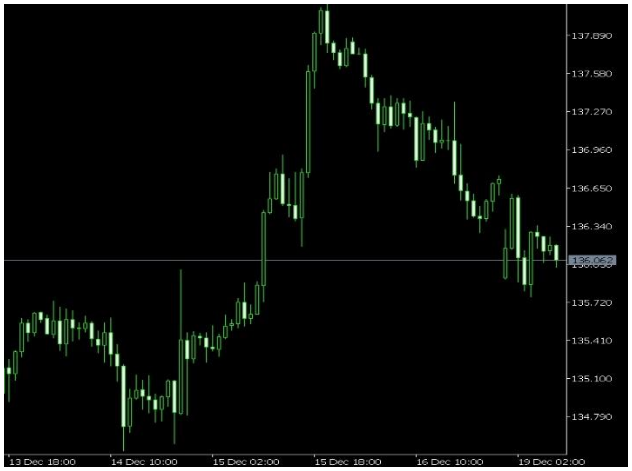

Fig. 1. Candlestick chart for an hourly chart.

To get hourly price data both the price at open, close, high and low can be seen in detail in Fig. 2.

Fig. 2. Forex price data per 1 hour in .CSV form.

Open price data indicates the price at the beginning of the new time frame. High data indicates the highest value the price reached during that time frame. Low data indicates the lowest value the price reached during that time frame. Close data indicates the price at the end of the time frame [20-21].

B. *Inflection Point*

The inflection point is the point where a curve will change sign, for example from a curve that tends to decrease in value to change with a value that tends to increase [20]. This change is usually marked with an acceleration that is zero. The acceleration itself is obtained from the second derivative of a function equation; in this study the function is the movement of exchange rate data over time.

In this study, the inflection points where *f''(x)=0* has a relationship with the bisection method because both will stop at a point with a zero value, zero for the acceleration at the inflection point and for the middle value of the Bolzano method [22-23]. The value of *f(x)* in this study is the lowest or highest value of the exchange rate as shown in Fig. 3.

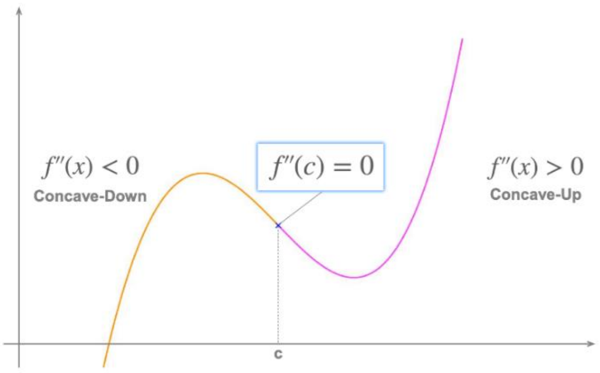

Fig. 3. Example of an inflection point.

C. *Bisection Method*

The Bisection method is a root search algorithm at an interval [24-26]. The interval divides into two parts, then chooses from these two parts which part contains roots and which part does not contain roots is discarded. This is done repeatedly until the roots of the equation are obtained or close to the roots of the equation [27] This method is applicable when you want to solve the equation *f(x)=0* where *f(x)* is a continuous function. Bisection Method can be seen in Fig. 4.

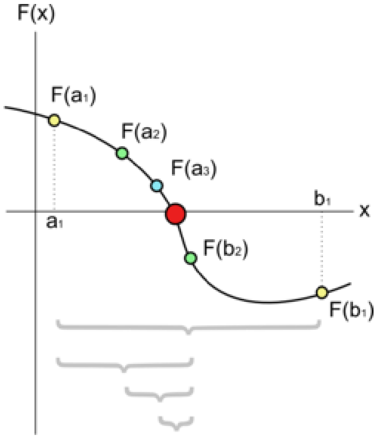

Fig. 4. Bisection method.

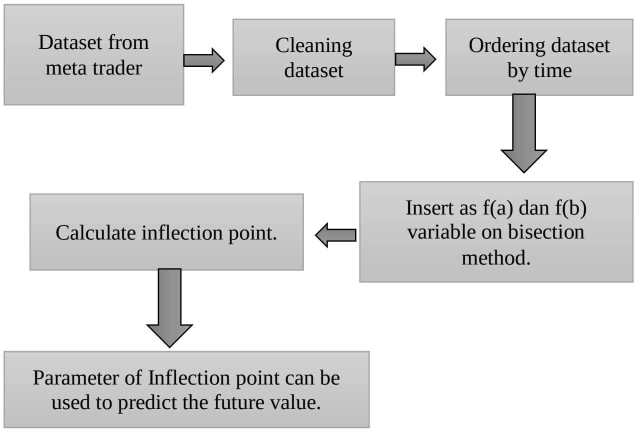
Suppose it is guaranteed that f(x) is a continuous function on the interval [a, b] and *f(a)f(b)* < 0. This means that f(x) must at least have roots on the interval [a, b]. Then define the midpoint of the interval [a, b] namely c = (a+b)/2. From this we obtain two subintervals namely [a, c] and [c, b]. After that, check whether *f(a)f(c)* < 0 or *f(b)f(c)* < 0. If *f(a)f(c)* < 0 then b = c (meaning point b is replaced by point c which serves as point b in the next iteration), otherwise a = c. From the first iteration we obtain a new interval [a, b] and a new midpoint c. Then check again as before until you get a small enough error.

III. Methodology

This research uses a simple research method that can be seen in the picture. Before the research was carried out, the researcher collected datasets obtained from meta traders. This dataset is then processed using python to look for data patterns, outliers and dataset variances that are beyond reasonable limits.



Dataset from meta trader
Cleaning dataset
Ordering dataset by time
Insert as f(a) dan f(b) variable on bisection method.
Calculate inflection point.
Parameter of Inflection point can be used to predict the future value.

Fig. 5. Flowchart of research stages.

After the dataset has been successfully cleaned, the dataset is sorted by time, this aims to make it easier to take points that will be used as points f(a) and f(b). This point is then entered into the bisection formula by determining the new point c=(a+b) / 2, where point c is the midpoint or inflection point. Of course, there are many midpoints, so it is necessary to look for several possibilities from several existing datasets. From this point, it can be predicted that the forex price will go up or down so that better decisions can be made. The flowchart of the various stages as explained can be seen in Fig. 5.

To calculate this inflection point, researchers use the Python programming language which makes it easy to calculate quickly. This algorithm is validated by experts in mathematics and when the validation is appropriate then it is tested on a server, the researcher uses a 10-core server with 16GB RAM. The data entered in the algorithm consists of a one-month timeframe.

TABLE I. VALIDATOR QUESTIONNAIRE

Question Number	Question
1	Is the bisection formula made in accordance with the journal?
2	is the transformation of the formula to the python program appropriate?
3	Have the computational results been compared with the original formula?
4	Are the results of the estimated value in accordance with statistical calculations?

In Table I, the validator fills in the maximum value or approves it for the next stage.

IV. RESULT AND DISCUSSION

The dataset in this study was taken from secondary data on export results in the form of .csv from the Metatrader software. This dataset consists of four data types, namely: High, Low, Open, Close. The next process is to clean the data by not entering datasets that exceed the upper and lower limits based on statistical analysis which includes median, mean, standard deviation and variance.

After the dataset is already cleaned, the next step is to run the dataset in an application made using Python. Python program code can be seen in Algorithm 1.

Algorithm 1:

```
def bisection (f, a, b, tol=1e-6, max_iter=100):
   if f(a) * f(b) >= 0:
     raise ValueError("Interval is not valid: f(a) and f(b) has similar sign.")
  c = (a + b) / 2
  iter_count = 0
  while abs(f(c)) > tol and iter_count < max_iter:
    if f(a) * f(c) < 0:
      b = c
    else:
      a = c
    c = (a + b) / 2
    iter_count += 1

  if iter_count == max_iter:
    print("Outbound Maximum Values")
  return c
```

From the dataset point entered in the program code, it will produce a curve as displayed in Fig. 6.

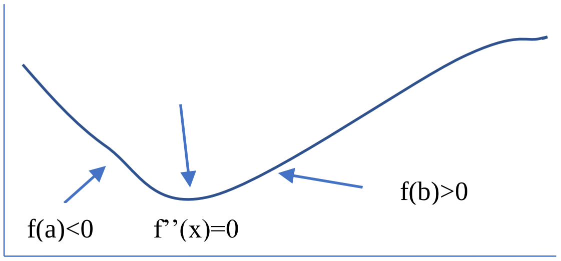


Fig. 6. Graph showing how the bisection program code work in python.

After the application is run, the results will look like in Table II.

TABLE II. RESULTS OF RUNNING MULTIPLE DATASETS

f(a)	f(b)	c (Previous Research)	Predicted (Current Research)
1914.760	1905.340	1910.050	1912.900
1913.450	1909.780	1911.615	1912.250
1918.530	1912.060	1915.295	1916.490
1921.720	1915.360	1918.540	1919.550
1925.080	1920.590	1922.835	1921.090
1923.610	1920.090	1921.850	1922.480
1922.870	1918.920	1920.895	1921.590
1925.440	1921.410	1923.425	1922.870
1925.400	1922.300	1923.850	1924.700
1934.970	1924.520	1929.745	1930.030
1933.780	1930.490	1932.135	1932.080
1934.430	1927.820	1931.125	1931.440
1936.400	1932.260	1934.330	1933.390
1934.760	1929.960	1932.360	1931.830
1941.920	1929.700	1935.810	1935.740

From the table it appears that the predicted value using bisection has a small error range when compared between the 'c' column and the 'predicted' column. With accuracy of an inflection point is 87% by SPSS and standard deviation about 0.71 and 20 pips moving. This will help users when they get information that after inflection there has been an increase in forex prices.

V. Conclusion

The research resulted in several conclusions, namely: a combination of bisection formulas on moving averages that work well. This is because both have the same scalar properties. In addition, the error rate of both algorithms is less than 3%. Furthermore, including optimization in determining future prediction values has been carried out by the bisection method even though it still has an error, but the error is still below 5%; this gives a sense of optimism for users to make decisions on buying or selling forex trading. This study was conducted in several experiments and ran well in the Python language environment with the objective achieved.

***Abstract*—Log data from computers used for network forensic analysis is ineffective at identifying specific security threats. Log data limitations include the difficulty in reconstructing communication patterns between nodes and the inability to identify more advanced security threats. By combining traditional log data analysis methods with a more effective combination of approaches, a more comprehensive view of communication patterns can be achieved. This combined approach can then help identify potential security threats more effectively. It's difficult to determine the specific benefits of combining Packet Capture (PCAP) and Social Network Analysis (SNA) when performing forensics. This article proposes a new approach to forensic analysis that combines PCAP and social network analysis to overcome some of the limitations of traditional methods. The purpose of this discovery is to improve the accuracy of network forensic analysis by combining PCAP and social network analysis to provide a more comprehensive view of network communication patterns. Network forensics, which combines pcap analysis and social network analysis, provides more comprehensive results. PCAP analysis is used to analyze network traffic, conversation statistics, protocol distribution, packet content and round-trip times. Social network analysis maps communication patterns between nodes and identifies the most influential key players within the network. PCAP analysis efficiently captures and analyzes network packets, and SNA provides insight into relationships and communication patterns between devices on the network.**

Keywords—PCAP analysis; social network analysis; network forensic; network communication pattern

I. Introduction

Network forensic analysis is an important tool for identifying and tracking malicious activities on the network [1][2]. Traditional methods of network forensic analysis using log data are not effective in identifying specific security threats [3]. The fundamental causes of these issues are the log data's limits in recreating communication patterns between nodes and its inability to recognize more sophisticated threats. [4]. In recent years, there has been increasing focus on combining packet capture analysis and social network analysis in network forensic analysis to improve the accuracy and completeness of the analysis. PCAP analysis involves capturing and analyzing data packets transmitted over a network, while social network analysis involves visualizing and analyzing the relationships and communication patterns between devices on the network [1][5][6][7]. The research question is how social network analysis can be used in network forensics to identify potential suspects and their relationships within a network.

The combination of these two approaches has the potential to provide a more comprehensive view of network communication patterns and more effectively identify potential security threats. However, little is known about the specific benefits of combining PCAP and social network analysis in network forensic analysis. In this paper, the main contribution is to propose a new approach to network forensic analysis combining PCAP and social network analysis to address the challenges and limitations of traditional approaches.

The goal of this discovery is to combine PCAP and social network analysis to improve the accuracy of network forensic analysis by providing a more comprehensive view of network communication patterns. By combining social network analysis and PCAP analysis, it is possible to gain a deeper knowledge of network activity and communication patterns. Investigators can use this to find unusual or suspect activities on the network, such as secret or encrypted communication.

II. Related Work

A. Research Related to Packet Capture (PCAP) Analysis

Sikos [1] made a comprehensive comparison of Carnivore, Snort, Windump, Wireshark, dsniff, tcpdump, Omnipeek, Solarwind and other packet analysis tools when analyzing PCAP data. The method used is AI-based deep learning inspection combined with semi-supervised machine learning. The research aims to compare the ability to recognize patterns in different packet analyzer applications in order to find the most suitable tool for network forensic analysis activities. The results of DPI (Deep Packet Inspection), a packet analysis tool with machine learning capabilities are valid [8][9][10].

Cappers et al. [5] focused on data reduction and visualization techniques using the EventPad tool. The purpose of this study was to conduct a safety analysis in a behavioral pattern study using PCAP data. This study presents a case study of the EventPad visual analysis tool to obtain attack profiles and traffic analysis using rules and aggregations. The study did not describe any communication patterns at the application level.

Shrivastava et al. [11] focused on capturing attacks on IoT devices using Cowrie honeypots and using machine learning to classify attack types. They apply various machine learning algorithms namely Naive Bayes, J48 Decision Trees, Random Forest, and Support Vector Machines (SVM) to classify attacks such as malicious payloads, SSH attacks, XOR DDoS, espionage, suspicious and clean attacks. Perform feature selection using subset evaluation and best-first search. The training results achieved an accuracy rate ranging from 67.7% to 97.39%.

B. Network Analysis Research using Social Network Analysis (SNA)

Chakraborty et al. [12] conducted a study that advances the understanding of 5G-COVID-19 conspiracy theories. This paper conducts a social network analysis to analyze the content of Twitter data over a seven-day period (the #5GCoronavirus hashtag became trending on Twitter in the UK. The content analysis revealed that 34.8% (n=81) of a sample of 233 tweets contained references to 5G and COVID-19-related opinions, 32.2% (n=75) were critical of conspiracy theories, 33.0% (n=77) were general tweets, not disclosing views or personal opinions) tweets were from non-conspiracy theory supporters, indicating that despite interest in the topic is high, but only a small percentage of users actually believe in the conspiracy theory. Liu et al. [13] provided a large-scale group decision-making model based on the process of propagating beliefs; the process of conflict detection and resolution; and the process of selection using social network analysis methods. In the first procedure, we propose a relation strength-based belief propagation operator, which allows building a complete social network while considering the effect of relation strength on propagation efficiency. In the second procedure, we define the notion of degree of conflict and measure the degree of collective conflict in conjunction with assessments of information and belief relationships among large groups of decision makers. SNA is a modeling of users represented by nodes and interactions between users are represented by lines (edges). This analysis is needed because it brings new opportunities to understand individuals or communities regarding their social interaction patterns [20] [21]. SNA can be used to study network patterns of organizations, ideas, and people who are connected in various ways in an environment [22] [23]. Degree centrality counts the number of connections or interactions a node has. To calculate the value of centrality degree (CD), we use Eq. (1) [24].

$$CD(i) = \sum_{\substack{j=1 \\ i\neq j}}^{N} Xij \tag{1}$$

Closeness centrality (CC) calculates the average distance between a node and all other nodes on the network. This measure describes the proximity of this node to other nodes [24] as in Eq. (2).

$$cc(i) = \frac{N-1}{\sum_{J=1}^{N} dij} \tag{2}$$

Betweenness centrality (BC) calculates how often a node is passed by another node to go to a certain node in the network. This value serves to determine the role of the actor who is the bridge that connects the interaction in the network. To calculate the value of degree centrality we use Eq. (3) [24].

$$Cb(i) = \sum_{J=1}^{N} \sum_{k=1}^{j-1} \frac{gjk(i)}{gjk} \tag{3}$$

One of the most important processes at the digital forensic stage is data integrity in the preservation section. Message-digest algorithms MD5 and SHA-1 as one-way cryptographic hash functions are used in integrity validation [23] [24]. Four non-linear functions in 512bit blocks in the MD5 Algorithm as Eq. (4).

$$F(B,C,D) = (B \wedge C) \vee (\neg B \wedge D)$$

$$G(B,C,D) = (B \wedge D) \vee (C \wedge \neg D)$$

$$H(B,C,D) = B \oplus C \oplus D$$

$$I(B,C,D) = C \oplus (B \vee \neg D) \tag{4}$$

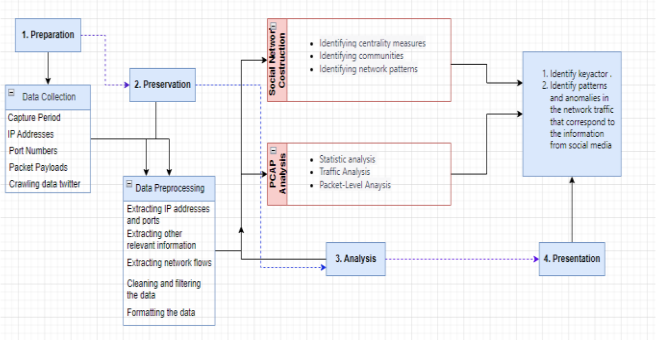
C. PCAP Data and Network Forensics Analysis

PCAP analysis in cyber forensics can be performed using a variety of methods including using software, PCAP software analysis. The software can be used to view and analyze packet content, including headers and payloads, and look for signs of malicious activity [14]. The next approach is statistical analysis, which extracts statistics from PCAP, such as packet count, network traffic and protocol statistics [15]. A rather important approach is packet and payload analysis to extract information from packet headers such as: B. Source and destination IP addresses, protocol and port used, and payload from the packet [10][11] [17][18]. Other findings indicate that computer network traffic results provide a variety of valuable information in graphical form to help identify routine banking transactions (pooled accounts, straw men, smurfing) used to hide movement of prohibited resources or obfuscation, thereby enhancing the visualization of financial analysis aspect. Packet analysis of internet network traffic is an important backtracking technique in network forensics, if the captured packet details are detailed enough, it can even show all network traffic at a specific point in time. This can be used to detect traces of malicious online behavior, data breaches, unauthorized website access, malware infections, and infiltration attempts, and to reconstruct image files, documents, email attachments, and other content sent over the network [1][15] [16][19].

We recommend combining PCAP analysis and social network analysis. This combination will demonstrate advanced network forensic analysis by revealing communication patterns between specific nodes in social media interactions. Combining PCAP and SNA to analyze network forensic activity can be a powerful method for identifying and analyzing malicious activity on the network. The integration of these two technologies can take advantage of the detailed information provided by PCAP data and the broader network-level view provided by SNA. An example of how this combination could be used is to use PCAP data to identify specific patterns or anomalies in network traffic that are consistent with known malicious activity, such as: B. Botnet command and control traffic or data exfiltration. Once these patterns are identified, SNA can be used to identify nodes and edges in the network that match these patterns, which helps identify the source and destination of malicious activity and the relationships between these entities.

III. Combining PCAP Data and Social Network Analysis for Network Forensic Activity

This research uses an experimental method in a laboratory where the independent variable is the number of nodes in social media capturing, and the dependent variable is the result of network forensic analysis, shown in Fig. 1.



1. Preparation
2. Preservation
Data Collection
Capture Period
IP Addresses
Port Numbers

2. Identify patterns and anomalies in the network traffic that correspond to the information from social media
3. Analysis
4. Presentation

Fig. 1. Combining PCAP data and Social Network Analysis (SNA) for network forensic methodology.

A. Data Collection

The first step is to collect PCAP data from the network using an application such as Wireshark or tcpdump. This data includes information about network traffic that occurred during the collection period, including details such as source and destination IP addresses, port numbers, and packet payloads. During the collection process, the keyword "Manchester United" was used to crawl data from Twitter, and 1000 nodes were obtained. Twitter scraping was performed on January 4, 2023 using the netlytic application.

B. Data Preprocessing

This step is performed to filter out packets that are not relevant to the current investigation. For example, only save packets from suspicious IP addresses or use protocols considered important. Parsing, this step is performed to extract relevant information from the PCAP packet. Information that can be extracted includes source and destination IP addresses, protocols used, timestamps, and payload data. Anonymization, this step is performed to remove information that could be used to identify individuals participating in the communication. Information that can be removed includes IP addresses, MAC addresses, and personal information contained in payload data. Normalization, this step is performed to convert the data extracted from the PCAP packets into a format that is easier to use for analysis. For example, converting timestamps to a more readable format or converting used logs to a simpler format. Aggregation, this step is performed to combine data from multiple PCAP packets into a larger unit. For example, combining multiple packets from the same IP address into a larger unit. Enrichment, this step is performed to add additional information to the data extracted from PCAP packets. Additional information can be in the form of IP geolocation information, WHOIS information, or IP reputation information.

C. PCAP Analysis

Traffic Analysis, this step involves analyzing data to identify patterns and anomalies in network traffic. This may include identifying unusual traffic destinations, unusual traffic patterns, or specific protocols used. Packet level analysis, this step involves examining individual packets in the PCAP data such as: B. Source and destination IP addresses, source and destination ports, and packet payload. This can be used to identify specific keywords, extract files, or extract other information from the payload. Statistical Analysis, this is the process of analyzing and interpreting the data contained in a PCAP file using statistical methods. This can include identifying patterns, trends, and anomalies in network traffic, as well as estimating various metrics such as traffic volume, packet size, and packet arrival time.

D. Social Network Construction

Social network construction creates representations of relationships between individuals or entities in a social network. This may involve identifying relationships between individuals, such as B. friendships, family ties, or professional relationships, and the strength of these relationships, such as B. frequency of personal interaction or communication. These centrality measures can be applied to social networks created from PCAP data and help identify key IP addresses or ports that may be important for understanding communication patterns and how information or malware spreads in the network. Degree centrality, this measure is based on the number of edges (connections) a node has. Nodes with high centrality are those that have many connections in the network. Betweenness centrality, this measure is based on the number of shortest paths through a node. Nodes with high betweenness centrality are those located on many shortest paths, considered as bridges or gatekeepers between different communities. Closeness centrality this measure is based on the average distance of a node from all other nodes in the network. Nodes with high proximity centrality are those that are close to many other nodes in the network. Community discovery is an important task in social network analysis that aims to identify groups of nodes (communities) that are more connected to each other than to the rest of the network. There are various methods for discovering communities on the web. Network pattern recognition is the process of identifying structural patterns in a network, which can provide insight into network organization and function. There are several methods for identifying patterns in networks; some of the most popular are subgraph counts and clustering coefficients.

IV. Experiment

Conversation statistics IP source 192.168.1.14 to 104.211.42.0 show the wireshark session statistics to see which devices are communicating with each other. This data also counts the traffic exchanged between these devices. It helps to understand the communication patterns in the network. Protocol Distribution Use Wireshark Hierarchical Protocol Statistics to see which protocols are used on the network and how much traffic they generate. It shows the distribution of logs and the number of packages present. Fig. 2 shows the number of packets, namely 5840, distributed among the different protocols and conversation statistics.

A. Authors and Affiliations

Fig. 3 shows the distribution of content packets in Wireshark's packet details panel to examine the contents of individual packets and see their structure. It can help understand the data exchanged in the network and identify potential problems. Fig. 4 shows that round trip time (RTT) is a measure of how long it takes to send a packet of data from one device to another and receive a response. RTT can use this value to measure network latency and identify potential delays. = 55 milliseconds.

Fig. 5. The results of data acquisition and PCAP file integrity check.

Fig. 5 shows data collection verification and file integrity verification in network forensics refers to the process of collecting and verifying the authenticity and integrity of digital evidence from the network. This process is critical to ensuring that evidence collected is accurate and available for investigation or trial. Data collection involves capturing and copying data from the network, while file integrity checking involves checking hashes or digital signatures of captured data to ensure it has not been tampered with. These steps are important to maintain the chain of custody and maintain the authenticity of the evidence. Digital forensic analysis using SNA includes identifying primary and secondary actors. This assessment makes the investigative process more focused on specific actors.

Fig. 6. Degree, closeness and betweeness Centrality.

Fig. 6 generates degree centrality as the number of connections or edges a node has to other nodes in the network. Nodes with high centrality have many connections to other nodes. In this study, 10,000 nodes were obtained using the manchester united keyword. The main actor has 951 degrees on the node labeled: utdfaithfuls. Perform key player identification to determine the degree of influence a participant has in the network. It is important to identify who are the actors who play the most important role in the communication model. This betweenness centrality takes into account the number of shortest paths between other nodes passing through a given node. High centrality nodes are "bridges" between other nodes in the network. The degree, proximity, and betweenness centrality metrics tables will show the following information for each node (or vertex) in the network Degree centrality, this is a measure of how many direct connections a node has to other nodes in the network. This is usually expressed as the number of edges intersecting the node. Closeness centrality, this is a measure of how close a node is to all other nodes in the network. This is usually expressed as the sum of the shortest distances between a node and all other nodes in the network. Betweenness centrality, this is a measure of how often a node acts as a bridge between other nodes in the network. This is usually expressed as the number of shortest paths between pairs of nodes passing through a given node.

For this experiment, the tag **utdfaithfuls** Beetweenness centrality: 1718 nodes with utdplug. Graphical visualization of the top three communication modes at the highest level is shown in Fig. 7. Graph visualization is a commonly used technique in social network analysis to show the relationships between individuals or entities in the network. It visualizes the network as a graph or graph, with nodes representing individuals or entities and edges representing the relationships between them. The size and color of nodes and the thickness and direction of edges can be used to represent attributes or measures, such as relationship strength or centrality measures. This helps visualize patterns, relationships, and communities in the network and makes it easier to understand the network structure and its properties.

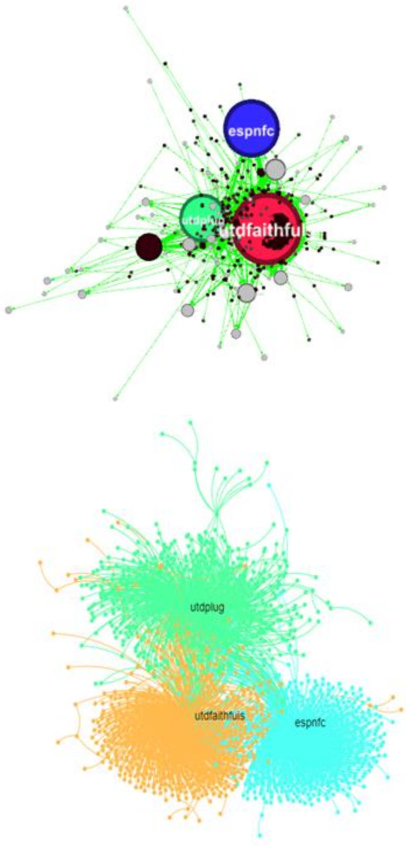

Fig. 7. Graph visualization of the top 3 pad communication patterns with the highest degree.

	3	Clustering coefficient	0.005
	4	Density	0.001
	5	Network Diameter	71
	6	Cluster	3

As Table I (A), (B) in network forensics, combining PCAP analysis with social network analysis can have a big impact on research in a number of ways:

1) Better suspect identification. Based on their connections to and interactions with other network members, prospective suspects in a network can be found via social network analysis. This can give a more complete picture of the network and increase the precision with which suspects are identified.

2) An improved comprehension of network behavior can be obtained by combining social network analysis and PCAP analysis, which can give a more in-depth understanding of communication patterns and network behavior. Investigators can use this to spot unusual or suspect activities on the network, such as secret or encrypted communication.

3) Enhanced incident response. By integrating PCAP analysis with social network analysis, detectives can more precisely pinpoint the origin and consequences of a crime.

The outcomes of benchmarking the integration of PCAP analysis with social network analysis in network forensics can give important insights into the most efficient ways to carry out investigations, uncover potential security concerns, and improve network security generally.

V. Conclusion

Network forensics using PCAP analysis combined with social network analysis shows more comprehensive results. PCAP analysis is used to analyze network traffic, conversation statistics, protocol distribution, packet content and round-trip time. Social network analysis maps communication patterns between nodes and identifies the most influential key players in the network. PCAP analysis efficiently captures and analyzes network packets, while SNA provides insight into the relationships and communication patterns between devices on the network. The availability of data sources is also a factor to consider when deciding to combine PCAP and SNA. The combination of PCAP and SNA can provide a more complete view of the network when limited log data is available. When the nature of the threat includes both technical and social aspects, a combination of these two approaches may be required. PCAP and SNA can provide a more comprehensive view of the network and improve the accuracy of forensic analysis. This is because SNA can provide context about captured packets and help identify relationships and patterns that might not be apparent from packet analysis alone. Potential future suggestions for improving forensic cyber analysis include artificial intelligence and machine learning, which includes AI and machine learning algorithms that can help automate the data analysis process, making it more efficient and accurate.

Faculty of Business and Communication, Universiti Malaysia Perlis, Perlis, Malaysia[5]

***Abstract*—Usability is an important element that enables the identification of the efficiency for application or product. However, many applications have been developed for general users' needs and are unable to provide adequate applications usage for disabled people. This study focuses on the development of usability evaluation model and the validation process on the proposed model through experts. The developed model later evaluated by group of experts through focus group method. Focus group method enables to identify the 13 variables derived to develop the model are appropriately placed and useful in the evaluation process. The results shows that the selected variables are appropriate to identify usability of mobile application for the hearing impairment through three variables tested namely, gain satisfaction with the model, satisfaction with the model presentation, and support for tasks. Conclusively, the developed model can identify usability of mobile applications for hearing impairment and enable in identifying useful criteria to be included during application development process in real life process. As future study, the model can be tested among the hearing impairment people and practitioner to establish the results obtained which contributes to usability practitioners and application developers for the disabled.**

***Keywords*—Usability; hearing impaired; validation; evaluation; MAEHI**

I. Introduction

Usability is an important element in any system or application to analyse any incurring usability issues. Usability commonly referred as a guideline for measuring usability of the system using models. These models provide insight into measurements to be used for usability analysis data collection [1]. Models such as International Standard Organization (ISO) 9241-11 [2] and Nielsen's (2005) [3] model are among the common usability evaluation models that will be used in user evaluation to identify the issues [1]. However, when a specific targeted user application is developed, the user's requirement must be incorporated into the application. If the requirement is missing, the application will fail to satisfy the user and becomes difficult to use.

Different disabilities having different levels of cognitive and mental strength [4][5][6]. Thus, applications developed for these people should consider these issues to ensure the usefulness of such application. Mobile devices are proliferating at an incredible rate. Statista (2022) [7] releases that currently, smartphone users have increased up to seven billion worldwide whereas almost 80% of the population in the world is owning a smartphone. These rates are extraordinary, given to relative introduction of many applications in mobile that eases people's daily life.

As such, this mobile application industry is growing remarkably, and the penetration of mobile apps can be seen growing in foreseeable future. Mobile phones once have only been used for answering calls now have grown up for muti use among the users. Many have gained benefits from various use of the mobile phone [1]. As this is the case, mobile phone does not bound only for the normal people but benefits the disabled people around the world as well. The compatibility of these mobile phones and its applications are being studied continuously as an objective to enhance the usability of all type of people as said in [1] to be more useable.

Usability has been a pivotal part of the discussion in many domains [8][9]. Usability evaluation is being conducted to measure an application satisfaction achieved by the users and commonly measured subjectively which is a collection of satisfaction rating of application among users [10]. However, this method is less defined [10]. Few renowned usability models are used as references to measure the applications such as ISO 9241-11 (1998) and Nielsen's (2005) [3] model although many other usability models have been constantly studied thereafter.

The focused issue is about the application developed for special people which is rather challenging compare with applications for normal people. Measurements used for general purpose application are unable to measure important features of the needs of these disabled users [1][11].

According to a survey conducted in the United States, the number of hearing-impaired users using smartphone applications is in the second highest percentage (i.e. 31%) after physically disabled people [12]. This shows that the hearing-impaired are one of the major disabled users of the smartphone and its applications. The hearing-impaired are those whose hearing is impaired to some degree at the time of birth [13]. These people are unable to produce coherent speech due to the lack of auditory input and thus the inability to monitor their voices [1] [14]. They rely on sign languages or any methods with gestures for communication purposes [15] [1].

As such, a study was conducted and a usability assessment model for the hearing - impaired, called Model for Mobile

Application Evaluation for Hearing Impaired (MAEHI), has been proposed to overcome these deficiencies [1]. This model proposed consists of six dimensions, 15 criteria and 47 metrics. This study will conduct the expert review methods for the developed MAEHI model for verification process to ensure the reliability of the proposed MAEHI model that has been developed.

The verification of the model performed through the method of expert review. The expert review was conducted to verify the proposed MAEHI for usability assessment of mobile applications with hearing impairment. One of the important ways to detect and remove defects is by expert review [16]. This study therefore adopted this technique to verify the proposed MAEHI. All the components developed, and the appropriate organization and presentation can be confirmed by verification [17].

This paper consists of the verification process of the model that was conducted to ensure that the model needs to be met for the deaf user. As such, the next section consists of discussing the focus group method for the assessment of the model followed by section three discussing the results of the focus group and section four discussing the conclusion.

II. Methods

The main aspect to be verified in the proposed MAEHI is the use of the appropriate dimension, criteria and metrics and the overall applicability, originality, and comprehensibility of the proposed dimension in MAEHI model [1] as shown in the Fig. 1, which is categorized into five components: consistency, ease of use, comprehensible, verifiable, and overall impression.

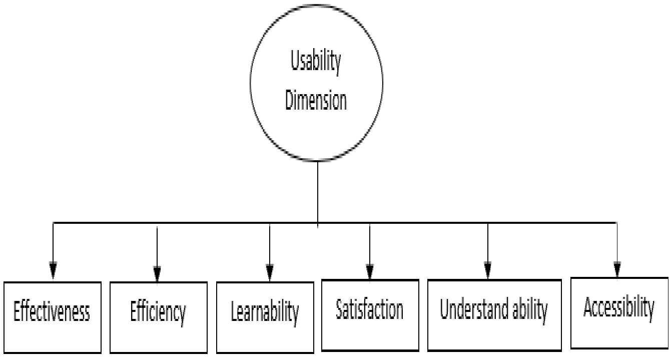

Fig. 1. MAEHI model dimension [1].

Among the 15 dimensions that were shortlisted, only six were chosen for final model development of MAEHI [1]. These criteria with the dimensions are designed in the model form as full model version and presented in [1].

Potential usability experts were therefore identified for the validation process of the model in Fig. 1, particularly researchers, academics, application developers or practitioners, as well as disability experts, particularly on the hearing impaired. As suggested by Hallowell, and John Gambatese (2009) [18] and Rogers, Margaret, and Emilia Lopez (2002) [19], the expert was selected. Once the model was verified, the validation was carried out to ensure that the model developed can provide adequate results in evaluating the deaf application's usability.

Domain users and experts from Malaysia National Research and Development, User Experience Lab, Malaysian Institute of Microelectronic Systems (MIMOS) participated in the MAEHI evaluation. This is a well-known software development organisation with numerous technology-focused areas and the only usability laboratory certified in Malaysia with MS ISO / IEC17025:2005 [20]. As part of this study, the model evaluation with experts and usability testing was conducted in cooperation with MIMOS. Experts validated the MAEHI in terms of its ability to be used in real testing environment through the focus group discussion.

The next section is implementing the focus group activity which includes planning, conducting, and analysing the outcome [21][22]. The objective of the focus group is to evaluate and validate the MAEHI in terms of its ability in producing reliable results to be implemented in real-world environments. As such, conduct planning is made up of a few steps as it is important to ensure that the focus group is properly conducted.

Planning was carried out thoroughly to ensure a good implementation of the focus group. There are four activities for the focus group implementation, adapted from Mazza, Riccardo, and Berre [23] to define focus group objectives, identify participants, prepare materials, and schedule meetings. Each activity is further explained in the section below.

A. *Defining Objective of Focus Group*

In particular, the focus group's objective is to evaluate and validate the MAEHI in terms of its ability in producing reliable results to be implemented in real-world environments.

B. *Identification of Participants Defining Objective of Focus Group*

At the MIMOS National Research and Development Center, Kuala Lumpur, participants for the focus group were selected from a group of application developers and usability practitioners. This study, however, only considers practitioners with more than three years of experience in this field [24]. Through emails and phone calls, 11 software developers and usability practitioners were approached. However, only seven were willing to participate as the others were involved in the organization's projects. The seven participants are within the recommended range for a focus group [25] (i.e., between six to ten members). The focus group was organised for the convenience of the expert group at MIMOS User Experience Lab in Kuala Lumpur.

C. *Meeting Scheduling for Focus Group*

The meeting of the focus group was scheduled at the Kuala Lumpur MIMOS User Experience Lab. The meeting place was chosen within the organization itself to accommodate its busy schedule with organizational projects. Since the venue was within the organization itself, it is convenient for the participants [26].

D. Material Preparation for Focus Group

Based on the activity to be carried out, the material used for the focus group was prepared. Materials such as participant documentation for evaluation have been prepared earlier to ease the focus group process.

The focus group was conducted with the developer's group and usability practitioners as scheduled. Upon arrival, all the participants were warmly and informally welcomed, as some arrived earlier than the scheduled time. This creates a space for knowing much better about the field in which they work and makes them feel relaxed before the formal discussion begins. Next, the materials needed for the session of the expert focus group were given. A brief introduction to the focus group objective was mentioned and the focus group purpose was reminded to experts. They were briefed on the model for validation purposes to be evaluated. The explanation given was quite easy for them as they were from the usability domain. It took nearly two hours to discuss the entire model assessment process, which is a common and acceptable duration [23][24].

All participants tested the developed MAEHI in the mobile application they downloaded from the app store on their smartphones during the evaluation process. Experts filled out the evaluation form to indicate their satisfaction with the ability of the developed model to be implemented in usability measurements in the real-world environment.

E. Instrument Development

The experts validated the developed model through an evaluation with predefined criteria adapted from past studies [27]. These criteria include gain satisfaction with the model, satisfaction with the Model presentation, and support for tasks. In the first criterion that is gain satisfaction with the model variables were 'Relevance for the intended application,' 'Perceived usefulness,' and 'Clarity'. This criterion is to reveal a model or framework's accuracy. The second criterion that is satisfaction with the Model presentation is represented by two variables that are "Ease of Use" and "Organization". This allows the experts to determine whether the model developed is practical and easy to evaluate and well organized for usability [28].

In the third criterion, four variables are used to measure task support satisfaction, where they were tested on "Practicality," "Completeness," "Incomprehensibility" and "Ability to produce expected results." These variables allow the model's understandable relevance to imply an evaluation and completeness of the application [29]. Each criterion will be assessed based on its own variables with two scales in, "Agree" and "Disagree."

F. Data Analysis

Once the evaluation is completed by the experts, the forms are collected, and its data is analysed by obtaining the ratio value for each item and an overall proportion of the measures to identify the experts' level of agreement on the model. The model evaluation findings will be further discussed in the next section.

III. Results and Discussion

After testing the developed model and discussing its ability to be used in the real-world environment, The results of these measures were the endorsement in the real-world environment of the validity of the proposed model. Consequently, each criterion and the results will be discussed as below.

Through this, the model has been validated by the experts in executing for usability assessment use on its relevance. Table I shows the experts' feedback.

TABLE I. Expert Agreement on Gain Satisfaction with the Model

Variables	%	Results
Relevancy to the intended application	86%	Experts agreed that the model developed is relevant since it focuses on targeted users for accessibility. They also found that the developed model appropriately highlighted accessibility.
Perceived usefulness	86%	Experts agreed that the usability model developed is suitable for the evaluation of hearing-impaired mobile apps. Furthermore, all experts agreed that this usability assessment made it possible to identify problems for hearing impaired users as the existing usability models are not able to meet their needs.
Clarity	100%	All the experts agreed unanimously that the phases provided for the developed model were clear in all the evaluations and tasks. The method provided for both data calculation and collection were agreed for use as clear.

The results of the expert evaluation validation were shown in Table I for their satisfaction gain with the model. Based on the experts' view, the developed model is identified as being useful for evaluating the usability of the mobile application with hearing impairment [30]. In addition, expert feedback also revealed that the model developed is clear for use with real users and can identify usability - related issues especially for hearing impaired users.

The expert feedback based on the, Satisfaction with the Model presentation is outlined in Table II.

TABLE II. Expert Agreement on Satisfaction with the Model

Variables	%	Results
Perceived Ease of use	86%	Experts agreed on the model's ease of use for the intended application. However, one expert was not convinced that this evaluation could be carried out on the hearing impaired as they would face communication problems during testing as they would need a translator if they communicated with normal hearing people.
Organization	86%	Experts agreed that the model developed was well organized and satisfied with the way all the procedures to be evaluated were organized in terms of their structure sequence and understandability arrangement.

According to Table II, recorded by the experts' feedback, they found that the usability model was easy to implement in the real environment, apart from well-organized measurements. The experts were pleased to find the model suitable for the evaluation of hearing-impaired mobile apps. There was, however, a slight reluctance to collect data with the hearing impaired as communication barrier is an important issue for usability practitioners to understand [31].

Table III shows that the model is practical for the hearing-impaired usability assessment to be conducted. The model is also comprehensive and easy to understand and implement. In addition, the results show agreeable views that the model developed can produce adequate results.

TABLE III. EXPERT AGREEMENT ON TASK SUPPORT SATISFACTION OF THE MODEL

Variables	%	Results
Practicality	100%	Experts showed some reluctance to practice with disabled people on the real environment. They agreed, however, if the evaluation was carried out using a controlled method, in which it would be possible. The other experts mentioned that the metrics and criteria were suitable and that expected results were easy to obtain.
Completeness	86%	Experts found the model to be appropriate in the use of usability assessment for hearing impaired mobile applications.
Understandability	100%	The proposed model was viewed in an understandable way as all the experts agreed that it was a well - organized evaluation and that it was easy to understand, especially for those with usability experience.
		All the experts agreed on the proposed model that it could produce expected results. They expressed satisfaction with the conduct of the evaluation and the dimensions covering the requirements of users with hearing impairment. In addition, experts also agreed that the model could produce expected results and identified usability issues in the evaluation of the application.

A summary of all the percentages obtained and calculated on average identifies the overall score for each criterion. For all variables, the overall percentage of agreement for each criterion is above 86%, indicating a high percentage of agreement on the model and acceptance of the model's applicability in the real-world environment. Thus, these results show that the proposed model is practical for the usability assessment of hearing-impaired mobile applications to be implemented in the real-world environment.

IV. CONCLUSION

Experts delightfully wanted to participate with the actual hearing-impaired users in the usability test to further evaluate the model. This also demonstrates the experts' eagerness to directly test the model developed in the real environment. They also shared the intention to collaborate with the hearing-impaired with this developed model in future testing and usability evaluation as they found that the model is particularly useful when the user is disabled. Emphasis has been given to the fact that usability assessment model is less important for disabled user applications, which many developers tend to ignore. The developed model will be used for usability testing for future study to demonstrate the practicality of use in the real environment and to identify the model's ability to collect useful analytical data.

Online Signature Verification for Forgery Detection

Muhammad Rizwan[1], Farhan Aadil[2], Mehr Yahya Durrani[3], Rajermani Thinakaran[4]
Department of Computer Science, COMSATS University Islamabad, Attock Campus, Punjab, Pakistan[1, 2, 3]
Faculty of Data Science and Information Technology, INTI International University, Negeri Sembilan, Malaysia[4]

***Abstract*—The increasing trend of using e-versions of document transmission and storage requires the electronic verification of sender/author. This research presents an efficient and robust online handwritten signature verification system targeting verification rates better than the available state-of-the-art systems in the presence of skilled forgeries. Fourier analysis is employed on the signatures to represent feature vectors in higher dimensional space followed by Local Fisher Discriminant Analysis to obtain compress representation while enhancing inter-class scatter between signature patterns. Signature modeling is performed using m-mediod-based modeling approach where m-mediods are put on to represent data distribution in each class. Connected component labeling is applied to binarized images of Urdu text to extract ligatures which are separated into primary ligatures and diacritics. Fast Euclidean Distance is used as dis(similarity). A total of 2414 signature samples including skilled forgeries are considered in our study. The evaluation of the proposed system on Japanese signature dataset provided by SigWiComp2013 realized promising results than the competitors.**

Keywords*—Fast Euclidean distance; m-mediod; local fisher discriminant analysis

I. Introduction

A person’s authentication is much more demanding in the current era and requires more secure methods to serve the purpose. From the last few decades, there has been an increase in research interest aiming at the development of robust online handwritten signature verification systems. Biometrics can be defined as a process to identify an individual through some characteristics unique to him. Literature categorizes biometric traits into physiological traits and behavioral traits. Physiological methods include facial patterns, fingerprints, iris, hand geometry and retina. While behavioral verification employs traits like handwritten samples (signature, handwriting etc.) and the voice of a person.

Normally, the process of signing is unique to every individual. Two persons with the same name may present different signatures and signing process (inter-personal variation). On the other hand, depending upon the environment or conditions (physical health, fatigue, signing instrument/surface) during the signing process, the same individual’s sign may differ in some aspects (intra-personal variations).

Two approaches are widely researched in literature, which are offline/static signature verification systems and online/dynamic signature verification systems [1]. Offline verification systems [2] bank upon extracting features such as size, shape, signing time and rotation angle etc. from scanned signatures. The actual signing process is performed at paper using a pen and then transformed into digital form by scanning it into computer. Online handwritten signature verification (OHSV) systems [3], on the other hand, record dynamic signature properties such as pen pressure, angle, pen up/down time etc. along the entire signature length.

Online Signature Verification [4, 5] catches the attention of researchers from the past few decades and still is an enduring research area. An online signature is made up of a series of sample points. The features of an online signature can be represented as time series data. Time series is a series of values which are measured as a function of time [6]. Researchers have researched and proposed a variety of procedures and methodologies for the evolution of highly robust online signature verification systems to date including Template Matching Approaches, Structural Approaches and Statistical Approaches. Time series of two signatures compared with Euclidean Distance (ED) -based dynamic time warping (DTW) is shown in Fig. 1. Usually, time series data exhibits higher dimensionality which is sometime difficult to incorporate in its original form. There exists in variety of approaches that transform higher dimensional data to lower dimension and speed up the upcoming processes. These include Fourier Transform [7, 8], Discrete Wavelet Transform (DWT) [9, 10, 11], and Discrete Cosine Transform (DCT) [12, 13]. Using DWT in feature extraction from handwritten digital signatures yielding superior verification rate in comparison to time domain verification system is found in [14].

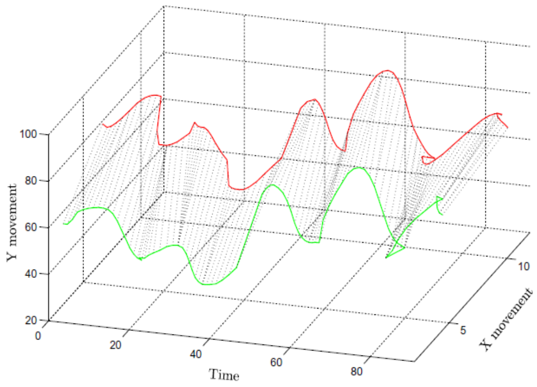

Fig. 1. Two signatures compared with ED-based DTW (Image Source: [15]).

Manjunatha et al. in [9] proposed a three step method (signal modeling, feature extraction and feature matching) for verifying the signature uses both genuine and forged signatures. The *x* position and the *y* position of all the signature points are extracted and represented, for each point, as one dimensional (1D) time domain signal along with pen moving angles as a third time domain signal. Due to length variability of these time domain signals, DWT is employed to reduce the dimensionality and extract features from these signals in a compact representation. However, system performance can further be improved by exploiting a different transformation. In [10], DWT is used to enhance the feature vectors in order to maximally separate genuine and forged signatures. More recently, Cpalka et al. in [13] used the combination of DWT and DCT for signatures' local information extraction. Wavelet packet with a fixed number of features and coefficients is employed to get better results than wavelet transform in [11].

Diaz et al. in [12] presented DCT based online signature verification approach in which a feature vector is created by applying DCT on 44 signatures features and extract the DCT coefficients to represent the feature vector in the reduced feature space. In [13], Cpalka et al. applied DCT on the coefficient vectors obtained from wavelet transform for dimensionality reduction.

Fourier Transform can also be seen as a promising approach for dimensionality reduction. As a proper transform can become an efficient tool for analyzing dynamic characteristics in time series patterns, Fast Fourier Transform also revealed many useful characteristics, in terms of signal frequency which was not the case in the actual signal [8].

II. Proposed Online Signature Verification Methodology

Our study is aimed at developing an OHSV system. Firstly, our emphasis was on selecting a suitable feature vector representation method for dimensionality reduction. Next, a feasible distance-oriented approach among the available state-of-the-art approaches for similarity measurement is identified for modeling and classification of signatures. The main contribution of our research work is the introduction of a new feature vector representation scheme to get more desirable results than the current results witnessed in different signature competitions held worldwide as well as handling forgeries at various levels.

A. *System Overview*

Mostly every static/dynamic signature verification system is trained by enrolling samples (reference signatures) which are then preprocessed. From the preprocessed signature samples, features are extracted which are useful in distinguishing these samples at the classification stage. Signature Modeling is then carried out for the registered individual’s signature samples and a threshold is computed. Classification phase requires a query signature (test signature) of user claiming to be a particular individual which is preprocessed, and same features are extracted as done in the training phase. If the user is already enrolled in the system, then the query signature is compared against the learnt model and accepted or rejected based on the threshold value [16]. For a new user, first its model of normality is learned from the provided set of reference signatures and a confidence or threshold value is computed and then compared with the corresponding model of normality to verify an individual. Dissimilarity score crossing a certain threshold rejects that user, otherwise authenticates him.

The process of OHSV can be sub-categorized into following steps namely data acquisition, preprocessing, feature extraction, and classification (training and verification) [17].

B. *Data Acquisition*

An OHSV system starts with some input to the system. For an OHSV system, input is captured at runtime (i.e., dynamic) which is usually taken by means of a digital tablet or alike devices. This captured information is then processed after digitization. In general, performance assessment of OHSV systems or algorithms is reported by the authors by exploiting their self-established databases, which are not accessible to other researchers. On the other hand, a variety of standard signature databases established by different institutes and research groups have been witnessed in prior research work in the domain of OHSV. In our research work, input comes from Japanese Online dataset taken from SigWiComp2013[17].

C. *Preprocessing*

Both the training and testing sets of signatures are inherent to noise and may also vary in length which makes preprocessing an important step. The degree of signature's preprocessing should be carefully done [10], [18]. Preprocessing should be performed with the objective to minimize loss to the signature temporal information, endpoints of strokes and points where the signature trajectory changes [19]. The most important function of preprocessing is to remove noise and additional jerks in the signatures [3], [20], [21]. We haven’t applied any preprocessing on the signature samples in our research work.

D. *Feature Extraction and Enhancement*

Feature extraction is the most pivotal step of verification process as the accuracy of system is highly relied upon over features used. Feature is any unique property or attribute that can be measured to represent signature effectively. Features for an online signature verification system are termed as (i) global features, which represent the whole signature; (ii) local features, which are extracted for each recorded point of signature sample; (iii) and segmental features, where features are extracted for each segment of signature sample unlike local or global features [22, 23]. A variety of features have been proposed and used in that falls within one of the stated categories. Total writing time, number of pen ups/downs and the number of strokes etc., are the examples of global features [18], [21], [24]. Some of the local features are speed, local curvature, pressure, tangential and centripetal acceleration [18], [21], [23]. Areas of high/low pen's pressure and high/low speed are the two common segmental features [3], [9], [25], [26].

E. *Dynamic Feature Vector*

The dynamic feature set refers to how the signature is signed than how it appears/looks. Signature dynamics are challenging for imposters to imitate (paper citation) because these not only captures the information of the signature’s overall shape, but also information of the individual sampling points (signature strokes) and other dynamics (speed) of the various signature strokes. Features are extracted from each point in OHSV as OHSV data requires to be represented in sequence of points. Dynamic features such as speed *Spi* and mean distance *MDi* for each sample *i*, are identified to have good discriminative potential. Selection of features plays an important role in the later processing and classification.

For this system, the dynamic information (raw data vector) obtained from the dataset comprises the following three-dimensional (3D) time-series data represented as in (1). Where *xts* and *yts* show position information of the signature and pts comprises pen down/up information at each sampling point at time *ts*. In this research, we are using pen down/up, speed and mean distance as our feature vector.

$$\mathrm{T(S)} = \{(\mathrm{xts}, \mathrm{yts}, \mathrm{pts})\} \quad (ts = 0{,}1{,}2, \dots, \mathrm{n}) \quad (1)$$

Firstly, we compute the derivatives of the original *x* and *y* signature time series. We exploit these derivatives to computed speed *sp* for each signature sample *i* as given in (2).

$$\mathrm{Sp}_i = \sum_{s=1,t=1}^{n} \sqrt{\left(\mathrm{xs} + 1 - \mathrm{xs}\right)2 + \left(\mathrm{yt} + 1 - \mathrm{yt}\right)2}\ (i = 1{,}2, \dots, \mathrm{n}) \quad (2)$$

Next, we have extracted the mean distance feature (*MDf*) by averaging the two dimensional (2D) raw data feature vector *V(S)* as represented in (3).

$$\mathrm{V(S)} = \{(\mathrm{xts}, \mathrm{yts})\} \quad (ts = 0{,}1{,}2, \dots, \mathrm{n}) \quad (3)$$

Now our feature vector for signature sample *S* takes the form given in (4).

$$\mathrm{T(S)} = \{(\mathrm{MDf}, \mathrm{Spf}, \mathrm{Pf})\} \quad (S = 1{,}2, \dots, \mathrm{n}) \quad (4)$$

After performing these basic operations on the acquired features, dimensionality of the signature samples is taken into account prior to signature model learning and classification.

F. *Dimensionality Reduction for Feature Vector Representation*

Dimensionality reduction is an important technique at this stage to deal with higher dimensionality problems in time series data. The goal of dimensionality reduction technique is to reduce the dimension of the samples while preserving most intrinsic and essential information even if multimodal scenarios exist within a dataset class.

It is possible to work in the raw point original coordinate space where signature sampling points are comparatively shorter. Conversely, direct manipulation of sampling point sequences for instance, greater than thousand or even more, seems to be impractical and unfeasible for feature extraction. The intention of applying dimensionality reduction is to come out with a feature extraction function *F* that decreases data dimensionality from *y* to *x* with *x* ≪ *y*. Similarity signature modeling and classification is then carried out in the reduced output feature space.

Time series data modeling and representation has also been carried out in prior research using a renowned transformation namely Discrete Fourier Transform. Time series is modeled compactly using a fixed number of coefficients [8], which results in quick signature modeling and classification. For each normalized signature, Fourier descriptors are computed and the selection of descriptors exhibiting highest magnitudes is made. Fisher discriminant analysis (FDA) is then employed with the imaginary as well as real part of the harmonics selected using empirical evaluation to identify the most suitable and appropriate features along with their associated weights. Traditionally, FDA [4] has been employed to serve the purpose but FDA fails to handle multimodality problem within classes. To cope with the multimodality issue, locality preserving projection is proposed [27] but it fails to handle labeled data due to its unsupervised nature. Local fisher discriminant analysis (LFDA) [28] is proposed and widely used to deal multimodality in time series data at localized level by taking into account the local structures of data.

In this research work, we employed Discrete Fourier Transform (DFT) to represent the data distribution in the higher dimensional space data given in (5) followed by LFDA to obtain reduced and compressed representation. The n-point fourier transform of $\{MD_i\}$, stated as a series $\{\overline{MD_f}\}$ of n complex numbers $f = 1, \dots.., n$ at discrete points. Where j is the imaginary unit $j = \sqrt{-1}$ and MD_f are complex numbers with the exception of CD_0 which is real. As the centroid distance-based time series is z-normalized, CD_0 which represents the mean of time series will always have a value of 0 and is ignored. Normally, DFT sequences are truncated after n terms. In our case, the feature vector is made up of $2(n-1)$ entries (from real and imaginary parts). More formally, let $x_i$and $\widehat{x_i}$be the real and imaginary part of $\overline{MD}$.

$$\overline{MD_f} = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} MD_i \exp\left(-\frac{j2\pi f i}{n}\right) \quad f = 1, 2, \dots\dots, n \quad (5)$$

Signatures can be denoted in the reduced coefficient feature space by a $2(n-1)$ dimensional vector of DFT coefficients $F_{\boldsymbol{DFT}}$ as shown in (6). The given $\mathrm{F_{DFT}}$ can be efficiently employed for feature vector representation of signature samples.

$$F_{DFT} = [x_1, \widehat{x_1}, \dots\dots x_{n-1}, \widehat{a_{n-1}}] \quad (6)$$

Parodi et al. [29] proposed a template protection scheme which needs a fixed-length and compact feature vector representation of the signature time series. Liu et al. [8] exploited Fourier analysis to have fixed-length compact feature vector representation for their proposed individuality model for OHSV. Lagendijk et al. [30] acquired a fixed-length representation of fingerprint minutiae by exploiting fourier transform. Discrete cosine transformation has been used by Rashidi et al. [31] to get reduced feature vector representation.

G. *Signature Modeling*

It has been seen in the work of Liu et al. [8], and Lagendijk et al. [30] that DFT based dimensionality reduction is a suitable selection for compressed representation of signature time series data in the reduced space with data samples exhibiting length variation. DFT gives a uniform and unwavering features space representation of signature samples to cope with the issue of varying lengths in signature datasets. We bring DFT based coefficient feature space representation into play to accomplish the learning of signature patterns in online signature datasets. The resulting learnt output patterns from the learning process can then lead to the correct identification of a previously unseen signature pattern and assigning it to the class it belongs to. It needs much skill to realize a learning system to serve the purpose. The complexity of the realization of a learning system is directly dependent on the number of different signature patterns (inter-class and intra-class variability) exhibited by the enrolled users. In this study, signature modeling doesn't take larger dataset for training session. The learning process is capable of proficiently learning signature patterns in the presence of small training set where the membership count for previously unseen pattern is sufficient for not considering it as an abnormal pattern.

Multimodal m-mediods based modeling and classification approach [32] best suit the sample's estimated multi-modal distribution contained by a given signature pattern. Our model learning method works with coefficient feature space representation of training data (data) yielded from DFT as an input. Labeled information (labels) is also taken by the system as an input. The number of outputs mediods to be perceived (#output) along with the maximum iterations in training (train_iter) as the input parameters are taken by the system. The outcome of this method is the number of outputs mediods (#output) along with their associated weights. Given training samples *TS(i)* having enhanced and improved feature vector representation of signature samples be associated with signature class *i*, its normality model is generated as:

1) Initialize the Learning Vector Quantization (LVQ) network with the number of outputs mediods. LVQ is initialized with the number of outputs mediods (Moutput) empirically and taking the number of samples presented in a class as upper limit yield in (7). WhereꚌ is the number of samples in a given class and *m* is used to denote the number of values randomly thrown to get the desired number of outputs mediods in the dataset.

$$\text{Moutput} = \begin{cases} \text{Ꚍ}\ if\ \text{Ꚍ} < 3*m \\ 3*m\ if\ \text{Ꚍ} > 3*m \end{cases} \tag{7}$$

2) Initialize the weights *Wc* as per output mediod. A variety of methods exist for weights initialization. A very general and common approach is to assign random weight values, but it may slow down the training process of LVQ. Also, it may output some of the clusters with no representation associated with it. To cope with this problem, we approximate a multivariate Gaussian distribution function (PDF) by exploiting the training data. This PDF approximation generates samples in greater number maximizing the possibility of closeness of at least one sample from the generated samples with groups concealed in the training dataset. The weight vectors in our approach are estimated from the training data using a single multivariate Gaussian probability distribution function PDF $N(\mathrm{\mu},\sum)$ in (8). Where $M \in TS(\mathrm{i})$, μ and $\sum$ are the mean and covariance estimations to $TS(i)$. $PDF\ N(\mathrm{\mu},\sum)$ is then employed to get the number of outputs mediods Moutput along with the initialization of corresponding weights *Wi* with $1 \le i \le$ *Moutput*.

$$\text{PDF N}(\mathrm{\mu},\textstyle\sum) = \frac{1}{\sqrt{2\pi\sum}} exp\left[-\frac{(M-\mu)^2}{2\sum}\right] \tag{8}$$

3) Pass the feature vector (input) from $TS(i)$in succession and selection of the output mediod that is the nearest representative of provided input data during network training. That nearest output mediod is termed as the winning output mediod. Suppose DFT be the input feature vector and *Wc* denotes the associated weight of output mediod *i*, selection of the winning output mediod *i* is made in a way that the distance (Euclidean) between DFT and *Wc* is the smallest among all the output mediods, specified in (9) where *k* is the index of output mediod *i*.

$$\mathrm{k} = \mathrm{argmin}_i \|\mathrm{Wc}, \mathrm{F_{DFT}}\| \forall\, i \tag{9}$$

4) Adjust *Wc* to train LVQ so that it starts revealing the trend of the $TS(\mathrm{i})$. In this process, the neighboring mediods are also important. *Wc* of *i* and its neighboring mediods are adjusted to reveal topology preserving estimation of $TS(i)$. As a result, we have output mediods exhibiting similar trend which are very nearer in the LVQ network structural space. A subgroup of the weights comprising the wining neuron *i* with the center surrounded by its neighborhood is updated in (10) where $\alpha(t)$ is the learning rate of LVQ.

$$\mathrm{W_k(t+1)} = \mathrm{W_k(t)} + \mathrm{\alpha(t)}\|\mathrm{Wc}, \mathrm{F_{DFT}}\| \tag{10}$$

5) Converge the network training gradually from rough to refining of *Wc* by dropping down the learning rate. At the start, higher values are taken in the learning process to accomplish representation of input space by a quick adjustment of *Wc*. Convergence slows down after successive iterations resulting in lesser effect of new arriving data on LVQ. The LVQ network continues to learn and adjust itself to correctly describe the trends in signature data. Exponential decrease in $\alpha(t)$ over time *t* is given as in (11) where $train_{iter}$ are the maximum training iterations.

$$\mathrm{\alpha(t)} = 1 - e^{\frac{2(t-train_{iter})}{train_{iter}}} \tag{11}$$

6) Iterate through step 3-5 for all the training iterations and discard the output mediods holding no sample.

7) Determine the index *(x, y)* of the closest pair of *Wc* as in (12). Where Wi and *Wj* denotes the weight vector representations for output mediods *i* and *j* respectively.

$$(x,y) = \mathrm{argmin_{(i,j)}}\|\mathrm{Wi,Wj}\| \times \sqrt{|\mathrm{Wi}| + |\mathrm{Wj}}| \forall\, i,j \wedge i \neq\ j \tag{12}$$

8) Pairs which are closet are merged by using the weighted average. For instance, *Wx* and Wy are the weight vectors linked with output mediods indicating the most similar groups and *x* and *y* are the # of sample signatures mapped to these mediods respectively. *Wxy* (new weight vector) for the resultant merged group can be computed using (13).

$$\mathrm{W}_{xy} = \frac{|\mathrm{Wx}\ |\times\mathrm{Wx} + |\mathrm{Wy}\ |\times\mathrm{Wy}}{|\mathrm{Wx}\ | + |\mathrm{Wy}|} \tag{13}$$

9) Repeat Step 6-8 as late as weight vector *Wc* count add up to *m* and adjoin *W* to *M(i)* demonstrating the sample *i*.

Once we have done with mediods identification *M(k)*, the next step is to figure out set of normality ranges (NR) for each class. Normality ranges are identified to keep a set of samples to be a part of class that falls within the defined ranges and to maximally distinguish between normal and abnormal samples in the best possible way. However, defining an NR doesn't seem so simple as the work normality suggests because these ranges are defined in generalizations in terms of common patterns a signer exhibits. Since, a given class k may encompass different normality ranges *NR(k)* and each mediods within that class may comprises different *NR(k)*; a set of *NR(k)* for each class is identified after finding out the mediods as follows:

1) Start with NR(k) = {}.

2) From the list of identified mediods M(k), determine the index of the closest pair *(i, j)* at index *(x, y)* and update *NR(k)*. Suppose *Mi* and *Mj* are the two mediods indexed at *(x, y)*, closeness of mediod pair *(i, j)* is determined in a way that the Euclidean distance between *Mi* and *Mj* is the smallest among all the other identified mediods exist in the list, specified by (14) and (15).

$$(x, y) = \text{argmin}_{(\text{i,j})} \|\text{Mi}, \text{Mj}\|\big|\forall\, i, j \wedge i \neq\ j \qquad (14)$$

$$NR^{(k)} = NR^{(k)} \cup \left[\left|M_x, M_y\right|\right] \qquad (15)$$

3) Mediod Pairs which exhibit closeness are merged by using the weighted average. For instance, x and y are the weights linked with mediods *Mx* and *My* indicating the most similar pair. *Mx* and *My* are merged together to get a new vector *Mxy* which is computed using (16).

$$\text{M}_{xy} = \frac{|\text{Mx}\ |\times\text{Mx} + |\text{My}\ |\times\text{My}}{|\text{Mx}\ | + |\text{My}|} \qquad (16)$$

4) Repeat step 2 & 3 until M(k) converges to 1.

From the normality ranges *NR(k)* of a given class, normality ranges for each mediods *NR(m)* are identified. For each signature sample, traverse each class we have in the *TS(i)* in a continuous fashion and find out the closest match of mediods with that sample. We use *NR(k)* (attainable normality ranges) to get *NR(m)*. Given the *NR(m)* is the closest mediod for a given class; it results in the utmost samples of a given class to be kept in the NR of that mediod whereas allowing least possible samples from other classes to be contained within *NR(m)*. This process results in minimizing the false acceptance and false rejection of signature samples.

H. Signature Classification

After the identification of mediods *M(k)* and their equivalent normality ranges *NR(k)*, classification of signature samples *TS(i)* in a multimodal fashion is carried out. Classification involves grouping objects exhibiting similar behavior in their corresponding classes. The classification process for new signatures samples is carried out based on closeness of that previously seen/unseen sample to the learnt models of the available identified classes in the dataset. DFT based representation of feature vector for an unseen sample is computed and passed to the list of identified mediods of the entire set of dataset classes to serve the purpose as follows:

1) Calculate the query sample distance *QS(i)* with all the *M(k)* of different classes and ascending sort the outcomes.

2) Initialize index i of the mediod nearest to *QS(i)* to 1.

3) Label the i^{th} nearest mediod index with *Mi* and the equivalent class index to *Mc*. If the query sample *QS(i)* falls within the NR of i^{th} mediod, classify it in the equivalent class and finish the classification phase.

4) Increment the index from *i* to *i+1*.

5) Repeat step 3 and 4 until the value of index *i* exceeds the normality range of that mediod.

III. Experimental Studies of Proposed OHSV System

In this section, we present the experimental evaluation results to prove the effectiveness of our proposed methodology. Starting with an introduction about the dataset used in our experimental evaluations, we present the verification rates reported by the system at different levels of forgeries followed by comparisons with the competitors at hand.

A. Experimental Dataset

Japanese signature data collection is carried out using HP Elite Book 2730p tablet PC and a Microsoft INK SDK based developed data collection software with a sampling and resolution rate of 200Hz and 50 pixels/cm respectively. The online Japanese dataset contains ASCII files with the representation as: X, Y, and Z where X and Y denote position information and Z represent pen position information (Pen up (0), Pen down (100)). In the overall dataset collection process, 30 signers took part after a practice session to get acquainted with the signature capturing device. Forgers are allowed to see the genuine signatures of the authors whereas the original authors (signers) signed their signatures without having access to their previous signatures. The division of dataset into training and testing phases is as follows:

1) Training set: A total of 462 signatures (genuine) from 11 signers with 42 samples of each author and a total of 396 forgeries (skilled) with 36 samples per author are provided for the training session.

2) Testing set: The testing set contains 20 authors with 42 genuine signatures per author along with 36 forgeries each for both tasks. A detailed description is given in Table I.

The dataset reported is used in ICDAR2013[17] Competitions on Signature Verification and Writer Identification for Online and Offline Skilled Forgeries. Systems submitted by the online signature verification community that revealed best results under their experimental conditions are shown in Table I.

TABLE I. Results for Japanese Online Signature Verification (Source: [17])

Mode	Detection Accuracy	FAR	FRR
Online	70.55	30.22	29.56
Online	**72.55**	**27.36**	**27.56**
Online	72.47	27.50	27.56

B. Evaluation Criteria

Evaluation of Signature verification systems is based upon the error rate they yield. The lower the error rate, the higher the performance of the system. There might be two types of errors. When a system accepts the signature exhibited by a forger, it is termed as False Acceptance Rate (FAR). Conversely, if the system rejects the signature exhibited by a genuine signer, it is referred to as False Rejection Rate (FRR). Most authors report the performance in terms of FAR and FRR. FAR and FRR are inversely proportional which means that if we try to keep FAR down, FRR goes up and vice versa. Some authors have used the term Equal Error Rate (EER) which is the point at which both FAR and FRR are equal. Lower EER means higher accuracy. When it comes to comparison of the different biometric verification systems, EER is a widely used metric.

C. Experiment: Evaluation of Proposed OHSV System

The objective of training is 1) to detect the genuine signature class from the available n reference signatures; 2) to detect the forged signature imitated by some other author for each class.

D. Training

In the training phase, we have sub-divided the training set into training and cross-validation for model learning and parameter tuning. In the first step, we identify the system parameter and then perform model learning based on those parameters. Model learning and verification is performed by exploiting858 reference signatures including genuine signatures and skilled forgeries. By varying the parameters i.e., threshold, # of mediods, # of iterations etc. An ideal value of threshold (i.e., 1.055) is identified. The detailed methodology is discussed in section 3.6. After threshold identification for each class, cross-validation involves the tuning of parameters i.e., threshold and normality ranges with the intention of minimizing false positive and false negative by exploiting the model and labeled information.

E. Evaluation

This phase sub-divides the evaluation set into training set and test set. From the training set, model is learnt, which in conjunction with the tuned parameters from the first phase is used to classify the test signatures into genuine and forged ones. Model learning and verification is performed by exploiting 1560 test signatures including genuine signatures and skilled forgeries. The detection and the forgery accuracy obtained in the training and the evaluation along with the competitor results are given in Table II and III respectively.

TABLE II. DETECTION & FORGERY ACCURACY IN TRAINING

Mode	# of authors	# of signatures (Total)	Detection Accuracy %	FAR %	FRR %
ICDAR2013	11	858	72.55	27.36	27.56
Our proposed approach	11	858	84.23	15.77	17.54

TABLE III. DETECTION & FORGERY ACCURACY (EVALUATION)

Mode	# of authors	# of signatures (Total)	Detection Accuracy %	FAR %	FRR %
ICDAR2013	20	1560	72.55	27.36	27.56
Our proposed approach	20	1560	82.84	17.16	19.46

IV. CONCLUSION AND FUTURE PERSPECTIVES

A. Conclusion

In handwritten signatures, there is a great interest toward the development of effective and robust signature methods for online signatures. The last few decades have witnessed extensive research in the development of OHSV systems and a wide range of verification techniques and framework proposed with promising results. However, there exist a number of challenges which make OHSV a hot research area. Due to the inter-class and intra-class variability, detection of signatures with respect to their corresponding classes with maximum precision is still a challenging task. Similarly, the robustness of the verification system against the imposter's imitation of generating the genuine signature patterns by minimizing false positive and false negative ratio is another challenge at hand.

To meet the challenges of OHSV systems, this research work is aimed at developing an OHSV system for the identification of signatures and the detection of skilled forgeries with accuracy greater than the available state-of-the-art approaches. To cope with the challenges of OHSV systems, we have presented a compact feature vector representation by incorporating speed, pen positions and mean distance as features for our system as given in Section III. From this compact representation, we have learnt the signature model and classify the signatures according to the identified system parameters. During the training phase, we have obtained 84.23% detection accuracy with 15.77% false acceptance rate and 17.54% false rejection rate. In the evaluation phase, we obtained 82.84% detection accuracy with 17.16% false acceptance rate and 19.46% false rejection rate.

B. Future Perspectives

Development of an OHSV system for targeting skilled forgeries is a very challenging task. We have attempted to address some of these issues with our proposed OHSV approach. The proposed system realizes very promising signature verification rates. However, the verification rates are slightly lower as the size of dataset in the evaluation phase increases. The most obvious extension of the proposed system is to speed up the processing by varying features as well as exploiting some other feature vector representation technique to achieve more compact and compressed representation. Another possible extension is to integrate our proposed approach with offline signature verification and then evaluate system performance in the hybrid environment in the near future.

***Abstract*—Removing as much noise as possible in an image while preserving its fine details is a complex and challenging task. We propose a wavelet-based and non-local means (NLM) denoising method to overcome the problem. Two well-known wavelets: dual-tree complex wavelet transform (DT-CWT) and discrete wavelet transform (DWT), have been used to change the noise image into several wavelet coefficients sequentially. NLM filtering and universal hard thresholding with cycle spinning have been used for thresholding on its approximation and detail coefficients, respectively. The inverse two-dimensional DWT was applied to the modified wavelet coefficients to obtain the denoised image. We conducted experiments with twelve test images on the set12 data set, adding the additive Gaussian white noise with variances of 10 to 90 in increments of 10. Three evaluation metrics, such as peak signal noise to rate (PSNR), structural similarity index metric (SSIM), and mean square error (MSE), have been used to evaluate the effectiveness of the proposed denoising method. From these measurement results, the proposed denoising method outperforms DT-CWT, DWT, and NLM almost in all noise levels except for the noise level of 10. At that noise level, the proposed denoising method is lower than NLM but better than DT-CWT and DWT.**

Keywords—Image denoising; discrete wavelet transform (DWT); dual-tree complex wavelet transform (DT-CWT); non-local means (NLM); cycle spinning

I. Introduction

The emergence of noise in digital images is possible during image acquisition, transmission, and processing steps [1]. The additive Gaussian noise is the type of noise most often found [2]. Hence, suppressing this noise type from digital images is necessary before further processing like texture analysis, feature extraction, and segmentation [3]. Maintaining the essential features of the images, such as edges and textures, is one of the main issues faced during the denoising process [4]. However, since noise, texture, and edge are high-frequency components, it is arduous to distinguish them in the denoising process, and the denoised images could ineluctably lose some details [5].

Numerous denoising methods have been developed in the literature. Among such methods, wavelet transforms and non-local means (NLM) filters are one of the suggested denoising methods [6]. In the wavelet transforms method, the noisy image is decomposed into the low- and high-frequency sub-bands, followed by wavelet thresholding on these frequency sub-bands. The wavelet thresholding is quite effective applied to the high-frequency sub-bands but fails when applied to the low-frequency sub-band [7]. In most of them, discrete wavelet transform (DWT) was widely used, but it has three other main issues. These issues are lack of poor directionality, shift-invariant, and aliasing [8]. Conversely, the non-local means filter is highly effective in retaining the proper morphology of the signal at low-frequency. At the same time, the NLM filter fails to properly denoise the high-frequency [7]. Another drawback is a very time-consuming process.

The ill effects of noise can be reduced by addressing the shortcomings of both above-denoising methods. Motivated by this, a denoising method is proposed by utilizing the efficacy of both wavelet- and NLM-based methods. The NLM is more efficient in denoising the low-frequency content, and applying it in the wavelet domain can significantly decrease the processing time [9]. On the other hand, although DWT offers the advantages of smoothness and adaptation, as Coifman and Donoho [10] suggest, DWT exhibits visual artefacts known as Gibbs phenomena in the vicinity of discontinuities. To address this issue, the translation-invariant denoising method called cycle spinning is applied to remove such artefacts. Meanwhile, DT-CWT is a well-known method introduced to solve the main issues of DWT. Its implementation is to be combined with NLM can be found in [11] [12] [13]. Two well-known wavelets, i.e., DT-CWT and DWT with one-level decomposition, are applied sequentially. Only the low-frequency sub-band is denoised utilizing the NLM filtering. Since the high-frequency sub-bands contain noises, those are denoised using hard thresholding with cycle spinning-based. The inverse DWT on the modified sub-bands are used to reconstruct the image.

The main contributions of the proposed denoising method are summarized below:

1) The proposed denoising method utilizes the advantages of the wavelet- and NLM-based methods for eliminating high-frequency and low-frequency noises present in the noisy image, respectively.

2) The main disadvantage of DWT, i.e., it does not effectively eliminate the low-frequency noise, lack of poor directionality, shift-invariant, and aliasing, is mainly resolved by NLM, cycle spinning, and DT-CWT.

The fundamentals of the DWT, DT-CWT, wavelet thresholding, cycle spinning, and non-local means filter are summarized in the Section ‘‘Theoretical Background’’, and the proposed denoising algorithm to suppress noise is explained in the Section ‘‘The Proposed Method’’. In the Section ‘‘Experimental Results’’, the performance of the proposed denoising method is evaluated using test images simulated with additive white Gaussian noise. Section ‘‘Conclusion’’ describes our conclusions.

II. Theoretical Background

Discrete Wavelet Transform

In general, the discrete wavelet transform (DWT) is an image decomposition at the sub-band frequency of the image. The wavelet transforms sub-band component is generated by decreasing the decomposition level. DWT implementation can be done by passing the signal through a low and high pass filter. Filterization itself is a function used in signal processing [9]. The decomposition of averages and differences plays a vital role in understanding the wavelet transform. Averaging is done by calculating the average value of 2 pairs of data using Eq. (1).

$$p = \frac{x+y}{2} \tag{1}$$

where, p is pixel in the digital image, x is the first number in decimal is obtained, and y is the second number in decimal is obtained.

While the reduction is carried out with the following Eq. (2).

$$p = \frac{x-y}{2} \tag{2}$$

The decomposition process is carried out on the results of the flattening process. The result of the decomposition process is a combination of the flattening process results with all the image pixel reduction processes. The decomposition process is carried out in two stages. The first stage is performed on all rows, and then is carried out in the column direction on the resulting image of the first stage.

The signal is passed through a high-pass filter and a low-pass filter, and then half of each output is taken as a sample through a down-sampling operation or referred to as a one-level decomposition process. The output of the low-pass filter is used as input for the next level of the decomposition process. This process is repeated until the desired level of the decomposition process. The decomposition process produces the wavelet coefficient, a combination of the output of the last high-pass and low-pass filters. The wavelet coefficient contains compressed transformed signal information.

The one-level decomposition is written using the mathematical expressions in Eq. (3) and (4):

$$y_{high}[k] = \sum_n x[n]h[2k= n] \tag{3}$$

$$y_{low}[k] = \sum_n x[n]k[2k= n] \tag{4}$$

where $y_{high}[k]$ is the result of high pass filter (which is a detail of signal information), $y_{low}[k]$ is the result of low pass filter (which is a rough approximation of the scaling function), $x[n]$ is source signal, $h[n]$ is high pass filter, and $g[n]$ is low pass filter.

Using this DWT coefficient, the Inverse Discrete Wavelet Transform (IDWT) process can be carried out to reconstruct it into the original signal, as shown in Eq. (5).

$$y_{high}[k] = \sum_n x[n]h[2k= n] \tag{5}$$

In the discrete wavelet transform, an image is decomposed into sub-images (sub-bands) at different frequencies and orientations, namely low-low (LL), low-high (LH), high-low (HL), and high-high (HH). An illustration of the discrete wavelet transform is shown in Fig. 1.

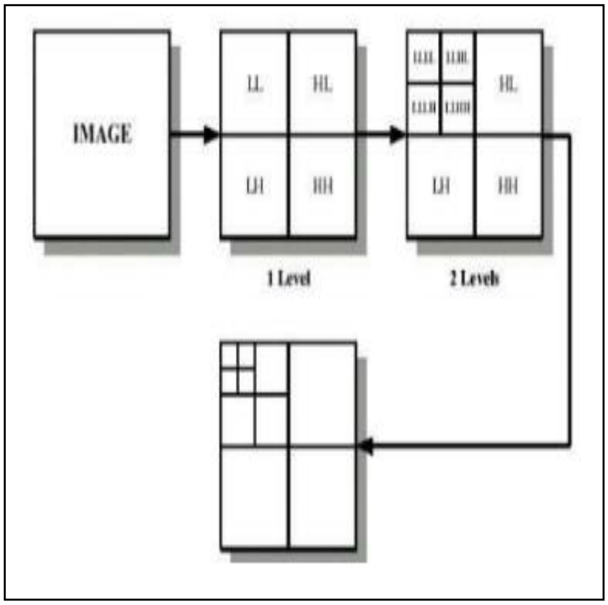

Fig. 1. Two dimensional discrete wavelet transform.

Several parameters, such as the selected mother wavelet function and decomposition level, should be chosen carefully when DWT-based processing methods are used [14]. Due to improper selection of the mother wavelet function and the number of decomposition levels may cause distortion or under denoising of the signal [15]. To ensure an effective denoising procedure of the image denoising, we selected the mother wavelet families of Coiflets with the order of 4 (Coif4) and one-level decomposition.

Dual-Tree Complex Wavelet Transform

Dual-Tree Complex Wavelet Transform (DT-CWT) was the combination of the advantages of DWT and CWT (complex wavelet transform). It is shift invariance, perfect reconstruction, either in directional selectivity, has a little redundancy, and the minimalist computation algorithm. DT-CWT transformation was a variation of DWT implementation, but the main difference is DT-CWT uses two tree filters, as shown in Fig. 2.

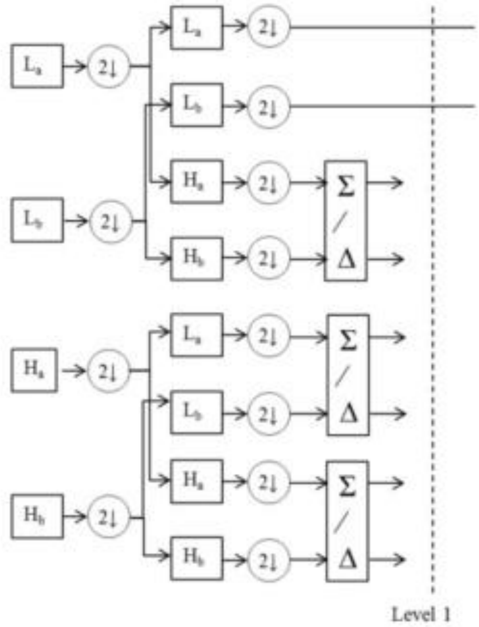

Fig. 2. Two dimensional dual-tree complex wavelet transform.

Unlike the DWT, the DT-CWT is built through a complex-valued wavelet function $\varphi_c = (t)$ and a complex-valued scaling function. The complex-valued wavelet function is built as follows: The complex-valued scaling function is expressed similarly [16].

$$\varphi_c(t) = \varphi_r(t) + j\varphi_i(t) \tag{6}$$

where $\varphi_r(t)$ is even and real, $j\varphi_i(t)$ is odd and imaginary, but $\varphi_i(t)$ is real. In addition, $\varphi_r(t)$ and $\varphi_i(t)$ form a Hilbert transform pair.

Consider 2D DT-CWT associated with the row-column implementation of the 1D DT-CWT.

$$\varphi(x, y) = \varphi(x)\varphi(y) \tag{7}$$

where $\varphi(x)$ and $\varphi(y)$ are given by formula (6). To represent an integrated real 2D signal completely, the row or column of the complex conjugate filter is required. Three sub-bands are produced in both the first and second quadrants, corresponding to six directions in space: $\pm 15^0$, $\pm 45^0$, and $\pm 75^0$.

We used one-level decomposition when applying DT-CWT in this study.

Wavelet Thresholding

Wavelet thresholding is a method that maintains wavelet coefficients whose value is greater than a particular threshold value and ignores small wavelet coefficients. This value is called the threshold value, and the estimator can be written as:

$$\hat{\mathbf{f}}_\lambda(\mathbf{u}) = \sum_{j=0}^{j-1} \sum_{k=0}^{2^{J-1}} \mathrm{I}\left\{\left|W_{(j,k)}^{(n)}\right| > \lambda\right\}^{W_{(j,k)}^{(n)}\psi_{j,k}(u),} \tag{8}$$

where λ is threshold value, I_A represents the indicator function of set A. The estimator in Equation (8) can be considered a non-linear operator in the coefficient vector, which produces vector $\hat{\theta}$ of coefficient estimation. The thresholding estimator is defined as.

$$\hat{\theta}_{j,k} = \frac{\sigma}{\sqrt{n}} \delta\lambda \left(\frac{\sqrt{n w_{j,k}^{(n)}}}{\sigma} \right) \tag{9}$$

with $\delta\lambda$ is thresholding function and λ is threshold parameter.

The thresholding steps can be sequenced as follows: select thresholding function, value estimation σ, and selection of threshold parameter.

1) Thresholding function: According to Coifman and Donoho [10], there are two thresholding functions: hard and soft thresholding. Both can be written with their respective equations as follows:

$$\delta_\lambda^H(t) = \begin{cases} t, & \text{if} |t| > \lambda \\ 0, & \text{other} \end{cases} \quad \text{for hard thresholding} \tag{10}$$

$$\delta_\lambda^S(t) = \begin{cases} t - \lambda, & \textbf{if } \mathbf{t} > \lambda \\ 0, & \text{if } |t| \leq \lambda \\ t + \lambda, & \textbf{if } \mathbf{t} < -\lambda \end{cases} \text{, for soft thresholding function} \tag{11}$$

The hard thresholding function is better known because there is a discontinuity in the function, so the t values above the threshold λ are not touched. On the other hand, the soft thresholding function is continuous since the t value is above the threshold λ. In this study, we used hard thresholding rules.

2) Value estimation σ: Wavelet thresholding is enforced rules where at least to estimate the value σ because its value is usually unknown. The value σ is deviation standard value from the observation $T_1, T_2, T_3, \ldots, U_n$. The authors in [14] proposed an estimation σ is based on empirical wavelet coefficient at the high level resolution. This consideration is because, at the highest coefficient level, there is usually a lot of noise. Given in [17], the Median of Absolute Deviation (MAD) estimation to estimate value is expressed as

$$\hat{\sigma} = \frac{median(|W_{J-1,k}^{(n)} - median\,(W_{J-1,k}^{(n)})|)}{0\ 6745} \tag{12}$$

with $\mathbf{J = \log_2(n)}$. Because coefficient $W_{J-1,k}$, $\mathbf{k = 0}$, $\mathbf{2^{J-1} - 1}$ close to zero, then it can be replaced median value ($W_{J-1,k}^{(n)}$) above with zero.

3) Selection of threshold parameter: There are two selection categories to select the optimal threshold value: selecting one threshold value for all resolution levels (global selection) and selecting a threshold that depends on the resolution level (level-dependent thresholding). Ogden [17] provides two threshold choices for global threshold selection that only depend on the number of n observation data. Both are tabulated by Donoho and Johnstone [17], known as the universal threshold $(\lambda_j = \sqrt{2 \log n})$ and the minimax threshold. Minimax threshold values are always smaller than universal threshold values for the same sample size. Choosing a threshold that depends on the level of resolution means choosing λ_j depending on the resolution j. Thus there is a possibility of differences in the threshold value λ_j selected from for each level of wavelet j. This study used the universal threshold, which applied to the detail coefficients.

Cycle Spinning

References [14] introduced a translation-invariant denoising method called cycle spinning. This method calculates different estimates of noisy image by shifting images to different phases and then linearly averaging these estimates. The cycle spinning will result in different estimates of the original image with statistically other noises reduced by the averaging.

If we show the two-dimensional circular shift by S_{ij}, the denoising operator by T, and the thresholding operator by η, then cycle spinning can be expressed as:

$$\hat{C} = \frac{1}{k_1 k_2} \sum_{i=1,j=1}^{k_1 k_2} C_{-1-j} \left(T^{-1}\left(\eta\left(T\left(C_{ij}(x)\right)\right)\right)\right), \tag{13}$$

where k_1 and k_2 are the maximum number of shifts. In this study, we used two shifts.

Non-local Means

The non-local means (NLM) was proposed by Buades et al. [17]. Given the 2D noise image $v = \{v(k) | k \in K\}$, where k is the pixel index and K is the number of pixels, then the NLM is calculated as a weight average of all the pixels in an image,

$$\text{NLM}[v](k) = \sum_{j \in v_i} w(a,b)\, v(j) \tag{14}$$

where v_i is a square neighborhood of the pixel k referred to as the search window, $w(a,b)$ is the weight depend on the similarity between the pixels a and b, and satisfying the conditions $0 \leq w(a,b) \leq 1$ and $\sum_j w(a,b) = 1$. The weight is built as follows.

$$w(a,b) = \frac{1}{Z(a)} \exp\left(-\frac{\|x(\eta_a) - x(\eta_b)\|_2^2}{h^2}\right) \tag{15}$$

where η_a is a square neighborhood of fixed size and centered at a pixel a referred to as the similarity window, $x(\eta_a)$ denotes the vector of pixel values within the similarity windows, and $Z(a)$ is the normalizing factor,

$$Z(b) = \sum_b \exp\left(-\frac{\|x(\eta_b) - x(\eta_b)\|_2^2}{h^2}\right) \tag{16}$$

where the parameter filter h controls the degree of filtering. We set the parameter of NLM as follows: the patch size is 7x7 pixels, the search window is 5x5 pixels, and the filtering parameter h is obtained from the deviation standard value.

III. Proposed Method

The wavelet-based and NLM denoising techniques are efficient and have complementary benefits and drawbacks. Therefore, combining both can produce a powerful denoising method. However, the direct cascading of these methods will result in a denoising system that is ineffective and costly in computation. Henceforth, this study combines wavelet-based and NLM techniques to get the desired results.

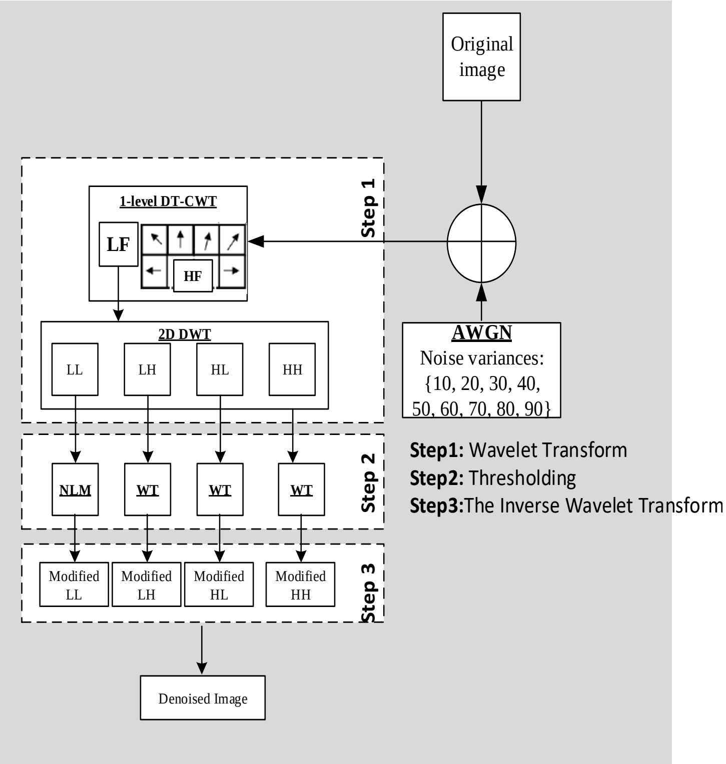

Fig. 3. Block diagram of the proposed denoising method.

The block diagram of the proposed denoising method is shown in Fig. 3. It consists of three steps: decomposition of the noisy image using DT-CWT and DWT, denoising of the low- and high-frequency sub-bands, and reconstruction. A detailed description of the proposed denoising method and its advantages over DWT, DT-CWT, and NLM is discussed in the following.

Step 1: Decomposition: Decompose the noise image into one real and imaginary approximation coefficient and the six real and imaginary detail coefficients using 2D DT-CWT with one-level decomposition. Process the real approximation coefficient through DWT to obtain the high- and low-frequency sub-bands. The decomposition process, including the selection of the decomposition level and the mother wavelet function, has already been briefed in Section II.

Step 2: Denoising of the low- and high-frequency sub-bands: Denoise the low-frequency sub-band obtained in one level of decomposition using the non-local means filter. Next, carry out the hard-thresholding-based cycle spinning to the high-frequency sub-bands. The selection of NLM parameters and wavelet threshold has already been briefed in Section II.

Step 3: Reconstruction: Reconstruct the denoised image by inverse 2D-DWT using denoised low-frequency and high-frequency sub-bands. The reconstruction process has already been briefed in Section II.

In the proposed denoising method, the thresholding of high-frequency sub-bands will effectively eliminate the high-frequency noise components present in the noisy image. Besides, the NLM filter will denoise the low-frequency sub-band and retain the morphological structure of the image. The proposed denoising process consists of only one-level DWT decomposition in contrast to the earlier DWT method requiring more significant decomposition levels to effectively denoise the low-frequency components. In addition, hard thresholding-based cycle spinning of the high-frequency and NLM filter of the low-frequency sub-band can be performed simultaneously. As a result, the overall computing cost of the process is significantly decreased.

IV. Experimental Results

As was the case with the experiment carried out by Balasubramanian et al. [8], the effectiveness of the proposed denoising method is evaluated on four standard test images: Lena, the boat, the house, and the cameraman corrupted by AWGN with zero mean and standard deviation σ=10 to 90 with increment 10. The proposed denoising method has been implemented by writing Python code. Python function random is used to add additive white Gaussian noise to the test images.

During experiments, to evaluate the effectiveness of the denoising performance, apart from the peak signal-to-noise ratio (PSNR) and mean square error (MSE), which is the general measure of denoising performance, we also measure the structural similarity index (SSIM).

As we stated earlier, our proposed denoising method is compared with the conventional DT-CWT, DWT, and NLM using PSNR, MSE, and SSIM. The parameters of each method have been set according to our experiment to have uniformity in comparison. The denoising experiment has been performed, and the results of PSNR, MSE, and SSIM are tabulated in Table I.

A detailed examination of the tabulated results led to the following findings:

- Cameraman image: The proposed denoising method outperforms DT-CWT, DWT, and NLM when the noise level of 40 and above for all measurement results. In contrast, the obtained PSNR and MSE are lower than NLM when the noise level of 30 and below. However, still better than DT-CWT. Lower than DWT when the noise level is 10 when measured using PSNR. Including a noise level of 20 when measured using MSE. For the SSIM result, the proposed denoising method outperforms all except the noise level of 10. At that noise level, NLM is better than the proposed denoising method.

- House and Boat images: When observing both images using PSNR, MSE, and SSIM results, the proposed denoising method is superior to DT-CWT, DWT, and NLM in almost all the noise levels except for 10. At that noise level, NLM is better than the proposed denoising method. However, the proposed denoising method is still better than DT-CWT and DWT.

- Lena image: Out of these three other test images; Lena's image is the only best gain of our proposed denoising method because it the superior to all techniques used for comparison in all noise levels with different measurement techniques results.

To compare the visual quality of the denoising methods, the free noise, noisy, and denoised images when AWGN added with variances of 70 are shown in Fig. 4.

- Cameraman image: Based on denoising results on this image show the proposed denoising method has better appearance of the denoising result. The noise in the texture of clothes and background can be effectively removed, including the noise present at edges.

- House image: The proposed denoising method results on house image can be seen in Fig. 4. It can be seen that the proposed denoising method is better in removing amount noise on the texture of house wall and sky as background. Comparatively, noise present in the edges also can be removed very well.

- Lena image: Like the cameraman and house images, the result of the proposed method in removing the noise in the hat, skin, mirror, hair, and wall is better than other denoising method.

- Boat image: Visually, the proposed method result is more effective in suppressing the noise in the boat image.

From the analysis above, it can be stressed that the suggested work effectively addresses the individual limitations of NLM and DWT approaches.

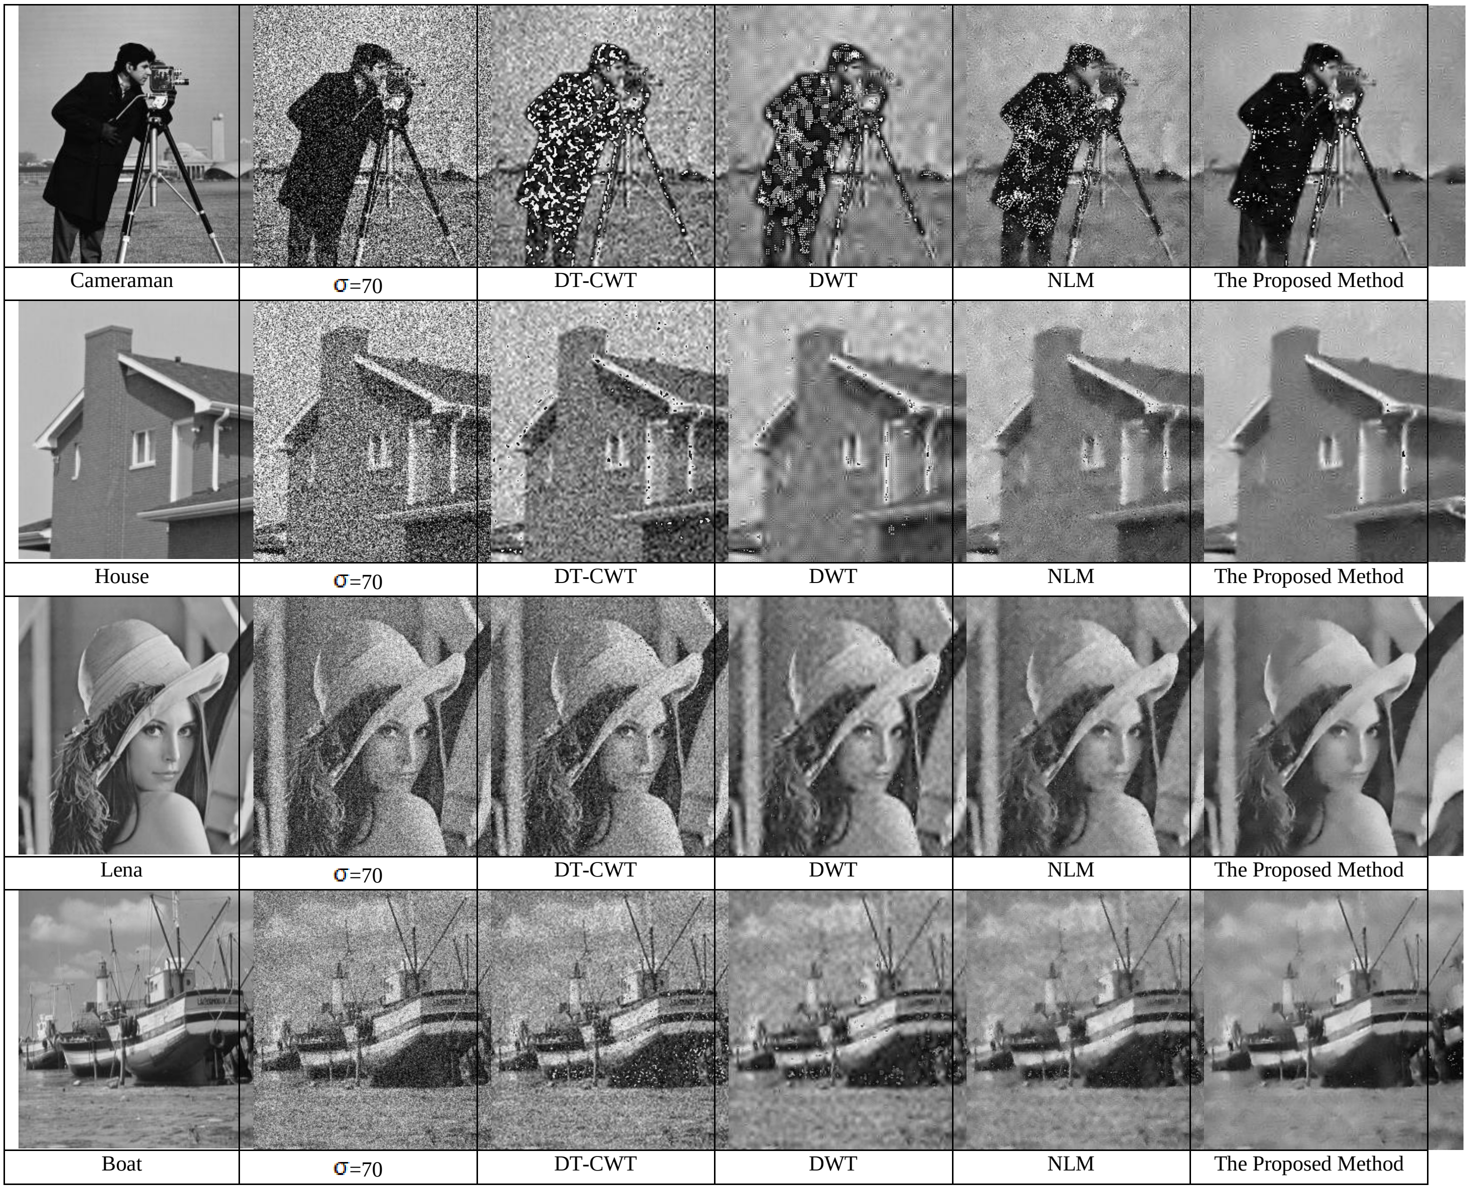

Fig. 4. The comparison denoising results.

V. Conclusion

Noise shows the image quality that has begun to lose detail, where large numbers of dots will appear in the image. Noise appearance dramatically affects an image's sharpness, clarity, and quality. Therefore, noise within an image must be appropriately addressed to minimize noise while maintaining fine image details, such as edges and textures. This paper presents the denoising method to handle such issues. The proposed denoising method utilizes the efficacy of wavelet- and NLM-based denoising. In the proposed denoising method, the noisy image is first decomposed using the DT-CWT, followed by DWT, to obtain the low- and high-frequency sub-bands. The high-frequency sub-bands are then threshold in the output of DWT to eliminate high-frequency noise using hard thresholding with cycle spinning. Meanwhile, the NLM removes the low-frequency noise. When the proposed method is applied to Lena, the boat, the house, and the cameraman images with AWGN variance noise of 10 to 90 in increment 10, the effectiveness outperforms the conventional DT-CWT, discrete wavelet transforms, and NLM. This superiority is numerically analyzed using three evaluation metrics: SSIM, PSNR, and MSE, also including when analyzed based on its visual quality results.

Future improvement is needed to increase the capability of the proposed denoising method, such as by selecting the mother wavelet and decomposition level, NLM parameter setting, and experimenting with another image to know the capability of the proposed denoising method in a different case.

Advanced Detections of Norway Lobster (Nephrops Norvegicus) Burrows using Deep Learning Techniques

Atif Naseer
Science and Technology Unit, Umm al Qura University, Makkah, Saudi Arabia
ETSI Telecomunicación, Universidad de Málaga, Málaga, 29071, Spain

***Abstract*—Marine experts are facing lot of challenges in habitat monitoring of marine species. One of the biggest challenges is the underwater environment and species movement. The other challenge is the data collection of marine species. People used the camera sensors and satellite data in the past for data collection but in this era the scientists are using underwater Autonomous Underwater Vehicles (AUVs), the Remotely Operated Vehicles (ROVs), and certain sledges with high-definition still and video cameras to record the underwater footages. The ocean is composed of thousands of species which make the environment more challenging to monitor any specific specie. This work will focus on specie named Norway lobster (*Nephrops* norvegicus). The *Nephrops* norvegicus is one of the commercial specie in the Europe and generates millions of dollars yearly. This specie lives under the seabed and leaves behind the burrow structure on the sea ground. The *Nephrops* spend most of their time under the seabed. The scientists are currently monitoring the habitat of *Nephrops* norvegicus by underwater television (UWTV) surveys that is collected yearly on many European grounds. The collected data is reviewed manually by the experts who count the burrows on the sheet. This work focuses on the automatic detection of *Nephrops* burrows from underwater videos using the deep learning techniques. This work trained the Faster R-CNN models Inceptionv2, MobileNetv2, ResNet50, and ResNet101. Instead of training the models from scratch we used the transfer learning technique to fine tune these networks. The data is obtained from the Gulf of Cadiz (FU30) station. Twenty-eight different set of experiments are performed. The models are evaluated quantitatively using the mean Average Precision (mAP), precision and recall curves. Also, the models are qualitatively analyzed by visually presenting the output. The results prove that deep learning techniques are very helpful for marine scientists to assess the *Nephrops* norvegicus abundance.**

***Keywords*—Nephrops norvegicus; deep learning; stock assessment; faster RCNN**

I. Introduction

Marine ecosystems include the open, deep oceans and marine species. The environment has high level of dissolved salts. Marine ecosystem is one of the main sources of our daily food. The marine species have different physical and biological characteristics. Coral reef is a good example of marine ecosystem that is associated with other marine life like fishes and turtles. The oceans cover 70% of our planet, so the marine ecosystem covers most of our earth. As compared to the terrestrial ecosystem, the marine ecosystem is very challenging to study. Most of the challenges come due to the complex medium of sea. The environment of marine ecosystem has certain challenges like color variations, species movement, and turbidity [1]. Marine scientists are monitoring the environment from decades by collecting underwater species images using satellite, shipborne and camera. With the advancement of technologies, several new techniques like ROVs and AUVs are used by the scientists to record the images and videos of marine ecosystem. The scientists are still facing many challenges in the sea due to the illumination, views, variation in the lighting conditions and free natural environment [2].

Marine ecosystems have thousands of underwater species. Out of these species one of the important specie in Europe is Nephrops norvegicus (a Norway Lobster). This specie is considered as a commercial specie in Europe. This specie supports Europe with almost 60,000 t [3] and an income of 300 million € per year approximately [4].

The International Council for the Exploration of the Sea (ICES) is a marine science organization that leads the scientific forums on all domains of marine sciences. Their major goal is to advance the marine ecosystem. They provide state-of-the-art goals and facilities that help the scientists to do research in the marine eco system. There are many working groups under the umbrella of ICES that are conducting annual survey and monitoring the habitat of marine species. One of the major groups for Nephrops habitat monitoring is Working Group on Nephrops Surveys (WGNEPS), formerly known as the Study Group on Nephrops Surveys (SGNEPS). The aim of this group is to provide international coordination for Nephrops UWTV and trawl surveys in the North Atlantic. Each year the WGNEPS conducted a UWTV and trawl survey to assess the population of Nephrops. Nephrops populations are assessed and managed by Functional Units (FU) where there is a specific survey for each FU. Fig. 1 shows an individual Nephrops. Nephrops norvegicus lives in the sandy-muddy sediments and create burrows in the seabed [5]. An individual Nephrops specimen ranges in length of 2 – 5.5 cm with a maximum length of 24.0 cm. The most common length is about 19.0 cm [6].

A special equipment is used in the survey for data collection. Every year the UnderWater TeleVision (UWTV) and Trawl surveys are conducted all over the Europe by WGNEPS to estimate the abundance of Nephrops norvegicus specie. The surveys are used to provide population estimates for Nephrops based on Functional Units (FU). The survey data is stored in disks in the form of high-definition images and videos. The data is analyzed manually using the TV survey to classify and count the Nephrops burrows. Currently, the Nephrops data are collected through the yearly UWTV surveys and are reviewed by the marine experts manually. This manual process is very time consuming and leads to many errors due to environmental complexity and data variation. In this work, we are using the data obtained from the Gulf of Cadiz (FU30) station.

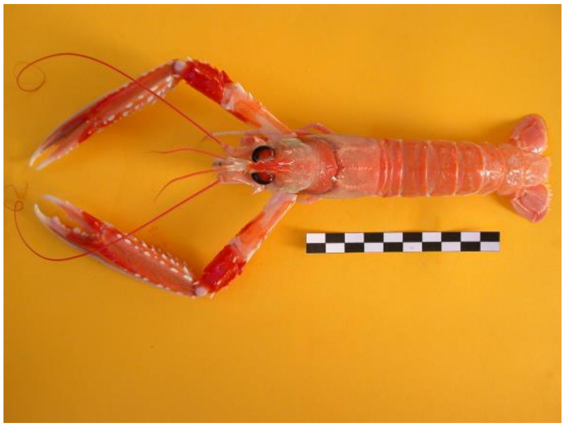

Fig. 1. Nephrops norvegicus.

Artificial Intelligence (AI) is an emerging field that solves many object detection problems including underwater species classification and detections. However, to detect and classify the Nephrops burrows for habitat monitoring, literature is unable to provide many solutions. One of the main reasons is the unavailability of Nephrops survey data. The complexity of data is also one of the reasons. This thesis is an effort to automate the existing method of Nephrops counting.

In our previous work [7] we trained and tested the MobileNet and Inception model and compare their results. In this work, we used denser Faster R-CNN models for training. We used the transfer learning technique and fine tune the MobileNetv2, Inceptionv2, ResNet50 and ResNet101 with FU30 dataset. The results obtained the good level of accuracy. ResNet101 obtained the highest level of accuracy among the other models.

The rest of the paper is organized as follows. Problem statement and definition is defined in Section II, the methodology is presented in Section III followed by the experiments and results in Section IV. The paper is concluded in Section V.

II. Problem Statement and Definition

We describe the problem of detections of Nephrops burrows in videos as currently the burrows are counting manually using the TV surveys. In this work, we demonstrate that the deep learning techniques will help to automatically detect and count the Nephrops burrows. Before going into the details, it is important to define the Nephrops burrows and their pattern.

Definition: A Nephrops burrow is an opening with following signature features: The burrow opening is like a half-moon shaped. The opening has proof of expelled sediments that creates scratches and tracks on the burrow opening. The pattern of burrows makes them unique as compared to other species burrows.

III. Proposed Methodology

This section discusses the approach for automatically identifying the Nephrops burrows from the video sequences using the deep learning techniques. The proposed methodology is illustrated in Fig. 2. The first part of the work is to collect the data from different stations of UWTV survey. In this study we are using the data collected from the Gulf of Cadiz (FU30) station. Specialized equipment is used for data collection at FU30. The second part of the methodology is the preprocessing of data that includes data cleaning, image annotations and data preparation. The third part is the detection of Nephrops burrows by applying the deep learning techniques. The deep learning models are trained and tested on the different datasets. We used transfer learning and fine tune the Faster R-CNN algorithms for model training.

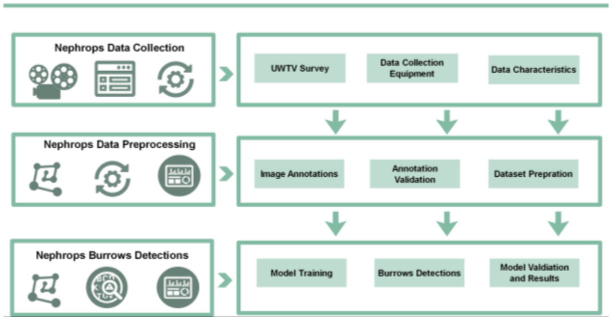

Fig. 2. Proposed methodology for Nephrops burrows detections.

A. *Data Collection*

In this research we used the data from the Gulf of Cadiz (FU30) station. To observe the habitat of *Nephrops* at FU30 station, a survey is designed yearly to collect the data. The survey used specially designed equipment for data collection.

1) Data collection equipment: A special sledge is designed in the survey of FU30 station. The sledge is equipped with Sony FDRAX33 camera that is used to capture the videos in high quality. The camera is mounted at an angle of 45 degree. Two laser lights are used in the sledge that define the field of view. The field of view is set to 75 cm. Fig. 3. shows the inner view of the sledge used in FU30 station survey.

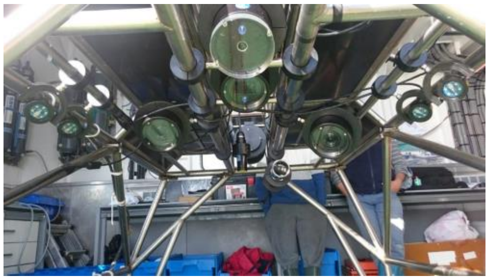

Fig. 3. Sledge inner view used in FU30 survey.

2) Data collection procedure: In 2018, the survey at FU30 is conducted at 70 different stations. The station is defined as a geostatistical location in the sea where the *Nephrops* density is assumed to be present and estimated in the past. The sledges are placed on a big ship and at each station it is dropped down in the sea and deployed to the sea ground. To maintain a constant speed of sledge, it is towed between 0.6–0.7 knots. This condition of sledges is the best possible condition for *Nephrops* burrows counting. The sledge is mounted with high-definition video camera that records the video footage of 10–12 min at 25 frames per seconds. The area covered by the sledge during this video footage is around 200m approximately. The sledge position is recorded after every 1 to 2 seconds for calibration. Two laser lights are placed that confirmed the field of view of the video footage. The field of view is set to be 75cm and the sledge distance over ground (DOG) is estimated from the position of the sledge. Fig. 4. shows the sample image collected during the survey.

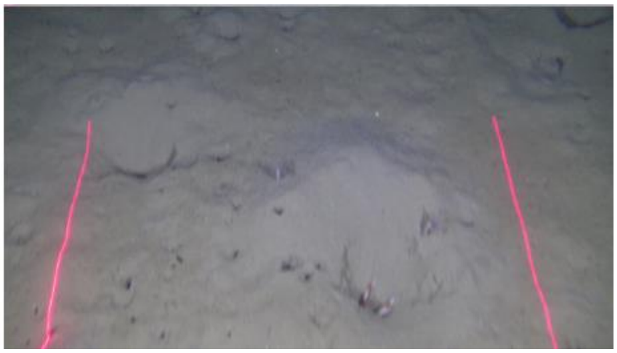

Fig. 4. FU30 Sample image.

3) Data characteristics: At FU 30, Video footages of 10-12 minutes has been recorded at 25 frames per second in good lighting condition. The video is recorded with a resolution of 3840 x 2160. We got the data of FU30 from the UWTV survey of 2018. A total of 70 stations are surveyed. After evaluating all the stations carefully, we only choose seven stations for annotations. The stations are selected based on their higher contrast, good video quality, lightning conditions, and high burrows density rates. The recorded videos are saved to the disks for manual *Nephrops* counting.

B. Data Preprocessing

The data preprocessing is one of the important phases of our methodology. Without performing the preprocessing step, the data comes with lot of noise and error that can affect the accuracy of the model training. The preprocessing is defined as cleaning of data, annotating the images and validation and preparation of dataset.

1) Data cleaning: The collected data is converted into frames and each frame is observed carefully. The frames with poor lighting and visibility are discarded initially. Also, the frames with zero burrows density are discarded before the annotations.

2) Image annotations: Image annotation is the most critical part of this study. Before the annotation, a comprehensive training is required to understand the burrow's characteristics. Certain protocol is followed in manual counting that should be observed during the manual image annotations. For image annotation, we used the Microsoft VoTT [8] tool. The *Nephrops* burrow is annotated by drawing the bounding box around it. The annotations are saved in the Pascal VOC format.

3) Annotation validations: Each annotation is validated by the Marine experts from the Gulf of Cadiz. The final annotations for model training are obtained after several iterations of validations. The validated annotations are saved in the XML format.

4) Dataset preparation: The annotated image dataset is divided into training and testing data separately. Each station consists of around 15,000 - 18,000 frames. From 2018 survey, almost 105,000 frames were recorded from seven different stations. The training and testing dataset is divided to 80-20 ratio respectively. Table I shows the training and testing dataset distribution used in this study.

C. Nephrops Burrows Detection

AI plays an important role nowadays in automating the analysis. In marine sciences many scientists apply AI techniques to monitor the habitats of marine species. Computer Vision and Deep learning shows a significant improvement in the object detection [9,10], classification [11,12], and segmentation [13].

1) Model training: To train the models, the transfer learning [14] technique is utilized to fine-tune the Faster R-CNN Inceptionv2 [15], MobileNetv2 [16], ResNet50[17], and ResNet101[18] models in TensorFlow [19].

Inception networks are considered as one of the big milestones in CNN. For computational complexity, the Inception v2 network used smart factorization method with 5x5 convolution and two 3x3 convolution. We fine tune the network parameters with a learning rate of 0.01 and a batch size of 1. The value of Maxpool stride and Maxpool kernel size are set to 2. The gradient clipping [20] value if set too low or too high will result in the model instability so we set its threshold value to 2.0. For activation function we used the Softmax and Mask RCNN is used as a box predictor.

MobileNetv2 architecture is used with the relatively small dataset. MobileNetv2 architecture used a depth-wise separable convolution instead of conventional convolution. The architecture of this network is composed of 32 convolutional layers and 17 residual bottleneck layers. We fine tune the certain parameters of the network to get the optimize results. The learning rate is set to 0.01. The batch size is set to 24 with truncated normal initializer. For activation function we used Rectified Linear Unit (ReLU) and Convolutional box predictor is used as a box predictor.

ResNet50 [17] is a variant of the ResNet model. The ResNet50 is 50-layers deep convolutional network. Out of these 50 layers, 48 are convolutional layers, one max pool, and one average pool layer. In the first convolution only one layer is used with a kernel size of 7 × 7,64 kernels with stride 2 and a max pool of size 3 × 3. In the second convolution, nine layers are used with a kernel size of 1 × 1,64; 3 × 3,128. In the third convolution, 12 more layers are used with 1 × 1,128; 3 × 3,128, and 1 × 1,512 kernel. The fourth convolution uses 18 more layers with kernel sizes of 1 × 1,256 ;3 × 3,256 and 1 × 1,1024. Nine layers are used in the fifth convolution with kernel sizes of 1 × 1,512; 3 × 3,512 and 1 × 1,2048. Finally, the last convolution layer is used for avg pool and a Softmax function. We set the learning rate of 0.003 with batch size 1 and L2 regularization. The Softmax is used as an activation function and Mask RCNN is used as a box predictor.

The ResNet101 [18] is a considered to be 101 layers dense convolutional neural network. The first convolution layer has a kernel size of 7 × 7,64 with stride 2 and a max pool of size 3 × 3. The second convolutional layer used nine layers with kernel sizes of 1 × 1,64 and 3 × 3,28. The third convolutional layer used 1 × 1,128; 3 × 3,128, 1 × 1,512 kernels. Sixty-nine layers are used in the fourth convolutional layer with following kernels 1 × 1,256; 3 × 3,256 and 1 × 1,1024. The fifth convolution uses 9 layers with 1 × 1,512; 3 × 3,512 and 1 × 1,2048. Finally, the last convolutional layer is used for avg pool and a Softmax function. The learning rate is set to 0.0003 with 24 batch size and L2 regularization. The Maxpool kernel size and Maxpool stride is set to 2 and Mask RCNN is used as a box predictor.

Table II shows the parameter list and their values used in the Inceptionv2, MobileNetv2, ResNet50 and ResNet101 model.

2) Model validation: The models used in this study for training used approximately 80% of the annotated dataset. The remaining 20% is used for the testing. All the models are trained over 70k iterations and the turning checkpoints during the training is recorded after every 10k iterations. For validation of models the models are evaluated using mAP, precision and recall curve and through visual inspection of the output images with detections.

IV. EXPERIMENTS AND RESULTS

1) Experiments: In this section we will summarizes all the experiments and results performed to automatically detect the *Nephrops* burrows. The models are trained and tested with FU30 dataset. Four different combinations of set of experiments are performed with the current dataset. Each set of experiment is iterated 7 times hence a total of 28 experiments are performed.

2) Results

a) Quantitative analysis: The mAP of all the models trained and tested by FU 30 stations are calculated during the quantitative analysis. In this study we trained the models with 70k iterations. The model performance is recorded in terms of precision and recall values after every 10k iterations. The precision is the prediction accuracy measurement and recall are the measurement of positive predictions. The mAP is calculated for each model which is a very common metric to evaluate the performance of object detection algorithms. The mAP is defined in the in Eq. (1).

$$mAP = \int_0^1 P(R)dR \qquad (1)$$

Precision can be seen as how robustly the model identifies *Nephrops* burrows' presence, and Recall is the rate of True Positive (TP) over the total number positives detected by the model [21]. The precision and recall curves are used to measure the model behavior.

In our study, the ground truth annotations and model predictions are rectangular boxes that usually don't fit perfectly. In this paper, the detections are considered as TP if the detection and ground truth overlap more than 50%. This is calculated by the Jaccard index J, as defined in Eq. (2).

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|}, \qquad (2)$$

Here, A and B are the set of pixels in the ground truth annotation and model predictions respectively, and | . | means the number of pixels in the set. If J ≥ 0.5, a TP is detected, but if J < 0.5, detection fails with a False Negative (FN). This methodology is used to calculate the precision and recall values.

Table III shows the maximum mAP obtained by MobileNetv2, Inceptionv2, ResNet50, and ResNet101 models, respectively. The maximum mAP obtained using the MobileNet model is 65.69. The maximum mAP obtained by the Inception model is 77.18. The ResNet50 and ResNet101 models achieve better precision values as compared to MobileNet and Inception. The maximum mAP in ResNet50 is 80.16 while in ResNet101 it is 81.59.

The results are also presented in the form of precision and recall curves. Fig. 5 shows the results obtained with the models trained and tested by FU 30 dataset. The best mAP is 81.59 with ResNet101 model.

b) Qualitative analysis: In this section, the performance of different models on the dataset is analyzed qualitatively. The visualization results are from the MobileNetv2, Inceptionv2, ResNet50, and ResNet101 models that are trained and tested by the FU30 dataset.

Fig. 6 shows the Nephrops burrows detections visually using the MobileNetv2, Inceptionv2. ResNet50, and ResNet101 models with FU 30 dataset. The green rectangular boxes on the images shown are the TP detections by the model. The blue bounding boxes are the actual ground truth annotations while, the red bounding boxes are the False Positive (FP) detections that are detected by the trained models. In this example, MobileNetv2 model detects one TP burrow while the inception and all other models correctly detects the two TP Nephrops burrows.

The overall study shows that the ResNet101 model performs better in terms of mAP and provides an accuracy of more than 80%.

V. Conclusion and Future Work

The aim of this study is to automatically detect and classify the Nephrops norvegicus burrows from underwater videos. We used the dataset from the Gulf of Cadiz (FU30) survey in 2018. We trained four different Faster R-CNN models to study the detection of Nephrops burrows using deep learning. The results show that the deep learning algorithms are very effective in detecting the burrows automatically. The ResNet101 model performs better and achieves the mAP of 81.59. This practice helps the marine scientists to correctly estimate the abundance of Nephrops from the underwater videos. The automatic detection algorithms could replace the manual counting process of marine experts and provide an accurate count in very less time.

In future work, we will plan to use a bigger curated dataset from different stations working under the ICES. The more data will improve the performance of accuracy of the deep learning models. Also, the newer model based on YOLO architecture will be trained in the future work. Finally, we will plan to integrate the spatial and temporal information of the Nephrops burrows to estimate the burrow sizes and their complexes.

Acknowledgment

We thank the Spanish Oceanographic Institute, Cádiz, Spain for providing the dataset for research.

College of Information Technology and Computer Science, University of the Cordilleras, Baguio City, Philippines[2]

***Abstract*—Medicinal plants are a practical and cost-effective alternative for treating common ailments, especially in areas with limited access to public healthcare systems. This paper introduces a prototype of an intelligent interactive system that merges chatbot technology with artificial intelligence (AI) to address inquiries related to treatment alternatives and the application of different medicinal plants for prevalent health conditions which promote and advance alternative healing practices in the locality. The platform is a hybrid online chat service that prioritizes consumer health and encourages the responsible use of medicinal plants. This study used a survey questionnaire to gather information from traditional healers and users and concerned government agencies about how well the system prototype performed. The system's performance was assessed in terms of effectiveness, efficiency, and customer satisfaction, with respondents providing an aggregate rating of "Strongly Agree". Significantly, this study lays the groundwork for education on the use of local medicinal plants to cure illnesses and highlights the importance of providing users with accurate and reliable information on the safe use of medicinal plants. This approach empowers users to make informed decisions about the plants they use, reducing the likelihood of harmful effects and optimizing the potential benefits of medicinal plants. By supporting this effort, this study contributes to the achievement of the third Sustainable Development Goal of the UN, which aims to promote health and well-being by offering the local populace a low-cost option as a first line of defense for improving their health and wellness.**

Keywords—Chatbot; artificial intelligence; intelligent interactive system; applied computing; consumer health; medicinal plants; traditional medicine

I. INTRODUCTION

Individuals who have limited access to the nation’s healthcare system frequently rely on herbal cures and medicines that treat a wide variety of illnesses and diseases. The World Health Organization (WHO) estimates that 21,000 pharmacological flowering plants have medicinal potential, which represents more than 30% of all plant species [1].

The Philippine TAMA Law of 1997 or the Traditional and Alternative Medicine Act represents a legitimate justification for highlighting the significance of traditional and complementary medicine for people's insurance. It was established to enhance the quality and health care services provided to the Filipino populace. The Philippine Institute of Traditional and Health Care (PITAHC) has been tasked with implementing the law whose primary purpose is to promote alternative and traditional medical items, methods, and techniques that are effective, safe, efficient, and readily available [2].

The Traditional Knowledge Digital Library (TKDL) website in the Philippines was created to ease the execution of the law. The use of traditional medicine in customs and activities associated with healing can be researched and examined by readers. The TKDL website lists 864 medicinal plants with 3,737 different medical uses [3]. Moreover, a group of researchers in the province of Catanduanes made available recorded data on specific plant species that are effective for treating a wide range of common ailments; the procedures used by healing practices while employing medicinal plants; and how the indigenous people's wisdom and experience shaped the plant medicines’ formulation and its usage, and how they observed their effects on their patients [4][5]. Whilst there is significance in using herbal treatments in medicine, there isn't a publicly available internet database that might give plant medicinal information in the form of a virtual conversation, making it challenging to spread and advance such information. Residents of Catanduanes' distant areas, who depend mostly on in-demand herbal medications from clinics, may have problems because of the absence of such a repository. Utilizing information and communications technology (ICT) may facilitate quick and accurate data analysis, effective decision-making, and an improved understanding of the requirements [6]. Knowing that folks prefer to communicate online, specifically on social media platforms like Facebook, developing an application addressing this issue would allow people in rural locations to be educated on plant healing techniques from the comfort of their own homes. ICT facilitates quick and easy access to knowledge, concepts, and experiences from numerous cultures, civilizations, and beliefs [7].

The use of Chatbot technology combined with AI can provide real-time access to information. Developing a chatbot with integrated AI can help provide humans with decision-making capabilities and web application experiences [8]. Using machine learning and natural language processing (NLP), chatbots facilitate human-to-human communication. In a range of fields, including medicine, agriculture, education, business, and e-commerce, NLP-based chatbots analyze and interpret real human language. Intelligent agents are capable of a variety of tasks, from straightforward physical work to intricate operations. One of the simplest and most popular types of intelligent human-computer interaction is a chatbot which is a basic illustration of an AI system. The use of chatbots in a diversity of businesses has been extensively researched in the past, but research on medicinal plants has not yet been conducted.

The aim of the present study is to bridge the gap and offer design considerations for developing a prototype system that can retrieve up-to-date information on medicinal plants and their applications, which can then be disseminated to people in underserved areas or in places without access to proper medical care.

This paper presents the development of MedPlantBot, a prototype system that integrates chatbot technology with AI. Its purpose is to provide a comprehensive database of various medicinal plants, including taxonomic classification, medicinal benefits, and categorization. The MedPlantBot framework model was carefully designed and built on established chatbot design techniques and AI frameworks, leveraging Google's Dialogflow to provide users with insightful guidance on appropriate medicinal plants for their specific health concerns. This user-friendly system is available round-the-clock and can be accessed from anywhere with internet connectivity, making it a convenient source of prompt and accurate information for both simple and complex queries. The evaluation of the Chatbot system prototype in this study utilized the Chatbot Usability Questionnaire (CUQ), a survey instrument that measured the chatbot’s performance. MedPlantBot has the potential to assist individuals in making informed decisions regarding their health and well-being.

This study aimed to develop an AI Chatbot model that could recommend medicinal plants for treating various ailments, illnesses, and diseases. The study involved identifying plant species with medicinal properties, analyzing the design techniques of existing Chatbots and AI Chatbot frameworks, and developing a framework model for the MedPlantBot Chatbot system. Additionally, the study evaluated the performance of the framework's prototype in terms of efficiency, effectiveness, and satisfaction. The development of MedPlantBot which shares information about using medicinal plants to treat illnesses is a game-changer in healthcare computing. This innovative technique harnesses the power of AI and NLP to offer users customized treatment programs that integrate traditional knowledge of medicinal plants. By merging the use of medicinal plants with modern healthcare practices, this chatbot presents an exciting opportunity to enhance healthcare outcomes and encourage a more comprehensive and sustainable approach to medicine. In essence, this study has the potential to provide residents with a cost-effective alternative to their initial healing practice, hence fostering better health and wellness. This coincides with the United Nations' third Sustainable Development Goal, which is Good Health and Well-Being.

The subsequent sections are organized as follows: Section II examines related works. Section III details the methodology employed by our proposed prototype system. Section IV contains the results and discussion. Section V summarizes our research findings while Section VI discusses the study’s ramifications and future undertakings.

II. Related Works

This section presents the analysis of the design methodologies of existing chatbots. This study discovered that creating a chatbot requires a range of strategies and approaches.

A. Chatbot Design Process

Building a chatbot begins with determining the scope and needs [9]. It emphasizes that two strategies such as conversation flow and knowledge modeling are important considerations while creating the chatbot. An adequate definition of the questions and answers must come first. The design of the chatbot, which is built using a decision tree algorithm that creates branches based on user input intents, is noteworthy. It simplifies the search procedure. Also, [10] constructed the MedBot using random forest, an ML decision tree algorithm, to make decisions. Significantly, this highly accurate approach minimizes uneven data.

Fig. 1 shows the general design of a chatbot system [11]. It is recommended to build a chatbot utilizing the aforesaid design, which comprises natural language and the user interface. backend, answer generation, natural language understanding (NLU), and dialogue management [12][10]. Ahmad et al. describes how a chatbot system works [13]. The user submits text using the chatbot's graphical interface. The text is then divided to find terms that may be used as patterns in pattern recognition. Finally, the system produces dynamic replies that are sent to the user. Many chatbots use the term "pattern matching" method that uses pattern recognition. Matching patterns are used to deliver valid replies to user inquiries founded on matching groups, such as plain statements, natural language, and semantic analysis and interpretation of the queries.

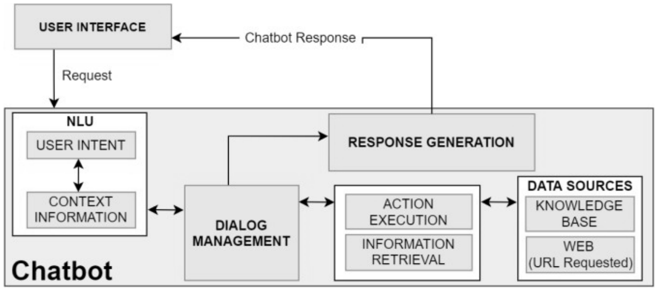

Fig. 1. Chatbot architecture.

Based on the Google Dialogflow (GDF) architecture and NLP, [12] created an AI Chatbot application that gives users access to information on COVID-19. The Chatbot agent combined a rule-based and a learning-based algorithm using the GDF framework design architecture to create a hybrid agent. The user interfaces for end users, natural language comprehension, and natural language creation make up its three (3) components. Similar work was done by Ranavare et al. who used GDF to create an NLP-based chatbot system. The purpose of the lesson was to inform the students about placement activities [14]. Furthermore, Muhammad et al. provides a thorough explanation for creating AI-enabled and speech-recognition chatbots that are utilized for English discussions where GDF acts as the AI’s engine [15]. Software developers leverage NLP-based GDF in constructing conversational user interfaces. GDF's APIs permit the incorporation of cognitive and AI services from other cloud providers. Facebook Messenger and other related services are already incorporated. Chatbots for popular messaging applications may be easily made by developers. Considerations for the design of intentions, entities, questions, and solutions must all be incorporated into a GDF-based intelligent chatbot. GDF provides knowledge base applications and sentiment classification [16]. According to the high-level design of Dialogflow, any channel technique that GDF provides can be used to connect a user to the platform. This platform converts real English into data that computers can comprehend by utilizing comparable sentences to build a machine-learning model. The GDF backend interacts with other APIs, databases, or services to complete the user's query [17]. The client interacts with the input device as shown in Fig. 2. The GDF engine accepts the query of the user. GDF then tries to determine the user's intent. Based on the intent, the fulfillment is conducted, and the data is sent from its source. The response is then processed into data that is usable. Eventually, the output device provided the user with the necessary information. The essential components of a chatbot are intents. To parse user data, intents' logic and elements are employed. This synchronizes the user's inputs with the result. In addition to contexts, Dialogflow supports entities, utterances, actions, training texts, and responses [9][18][19][15]. The intent describes each intended Chatbot action and the possible queries that could be used to complete the task. User requests are expressions or utterances that must be matched to the intent's questions. Entities are used to detect and extract meaningful information from natural language feeds. The inclusion of annotations to training words enables GDF to recognize generated data. Annotated group of words permits the specification of which variables to match and against which entities to match them. Once established in actions and parameters, tagged parameters are automatically applied.

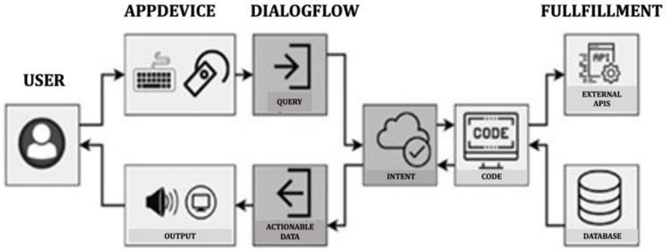

Fig. 2. Google dialog flow architecture.

B. *Evaluating AI Chatbot System Performance*

The system prototype is evaluated to determine whether it achieved the goal for which it was built. Furthermore, it enables design iteration before takeoff, which aids in the delivery of a successful and efficient product.

The AI Chatbot System's performance is evaluated based on three (3) metrics, namely, effectiveness, efficiency, and satisfaction [20]. Table I lists the quality characteristics arranged in accordance with ISO25000 based on an analysis of the evaluation instrument used in the existing chatbot system.

TABLE I. LIST OF QUALITY CHARACTERISTICS ARRANGED IN ACCORDANCE WITH ISO25000

Criteria	***Category***	***Quality Attribute***	***References***
Efficiency	Performance	• Degradation with grace • Adaptability to manipulation	• Adamopoulou & Moussiades, (2020) • Ahmad et al. (2018)
Effectiveness	Functionality	• Computers may interpret and modify natural expressions • Effective speec synthesis • Correctly translate instructions	• Adamopoulou & Moussiades, (2020) • Ahmad et al. (2018) • Daniel et al. (2021)
	Humanity	• Succeeds on the Turing test • Natural, convincing, and fulfilling interaction.	• Huang et al. (2021) • Karanja (2018)
Satisfaction	Affect	• Salutations and personality expression • Recognize the participant's mood and act accordingly • Make things mor enjoyable an captivating.	• Muhammad et al. (2020) • Neapolitan et al. (2018) • Ranavare et al. (2020)
	Ethics & Behavior	• The morals of users and their cultural awareness • Respect and safeguard privacy. • Nondeception	• Huang et al. (2021) • Sabharwal & Agrawal (2020) • Sánchez-Díaz et al. (2018)
	Accessibility	• Reacts to socia signals or lac thereof • Able to discer purpose c meaning	• Talan et al. (2022) • Vergadia (2022)

III. METHODOLOGY

This study established a process for building the system prototype from data gathering and collection of medicinal plants that exist in Catanduanes to identifying the technology and designing the system's framework as the basis for the development of the AI-based chatbot system grounded on the mixed-approaches strategy combining documentary analysis with qualitative and quantitative research methods. The methodology used in this study to construct the Chatbot framework was based on a review of [21], as shown in Fig. 3.

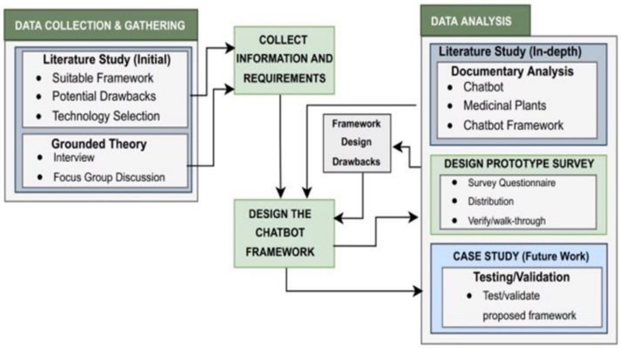

Fig. 3. Research methods for the development of the MedPlantBot Chatbot.

A. Data Collection and Gathering

An initial review of the existing literature, in-depth interviews, and focus group discussions was conducted to identify the needs and select the appropriate technology and framework design for the study. Participants of the study were chosen voluntarily, and it was ensured that they had research experience and a deep understanding of the subject under investigation. Consequently, between January 2022 and March 2022, participants were interviewed in the province of Catanduanes, including domain experts, users, and practitioners of medical plants, as well as representatives from relevant government agencies and researchers who studied medicinal plants.

B. Data Analysis

A comprehensive literature analysis was conducted to organize and assess the documentary evidence of different discoveries from studies on frameworks, chatbots, and herbal medicines. The researcher looked up and analyzed previous research on chatbots in several internet databases.

1) Medicinal plants data: Focus groups, interviews, and documentary analyses and assessments of past studies on the Catanduanes' medicinal plant study were undertaken by the researcher. There were 56 medicinal plants that have been identified [4]. The same study was carried out by [22]. The author provided a list of 115 medicinal plants utilized by Catanduanes' indigenous healers. From the list, ten (10) medicinal plants, such as Acapulco, Ampalaya, Bawang, Bayabas, Niyug-niyogan, Sambong, Tsaang-gubat, Ulasimang bato (pansit-pansitan) and Yerba Buena have been approved for usage by the Philippine Department of Health (DOH) and PITAHC [23]. Based on the information gathered, Catanduanes is home to all the medicinal plants endorsed by DOH and PITAHC.

Twenty-six (26) medicinal plants in Catanduanes were identified by the researchers. Limited research undertaken between 1998 and 2014 yielded the data, which included information on taxonomic classification, symptoms or diseases healed, and the preparation and application of the plants. Fig. 4 depicts the names of these plants: Ageratum Conyzoides, Areca Catechu, Capsicum Frustescens, Centella Asiatica, Cordia Dichotoma, Crinum Latifolium, Cyprus Halpan, Dicranopteris Linearis, Diplazium Esculentum, Drynaria Quercifolia, Duknay, Elephantopus Scaber, Emilia Sonchifolia, Euphorbia Hirta, Gliricidia Sepium, Hyptis Capitata, Imperata Cylindreica, Kolowratia Elegans, Ludwigia Micrantha, Lygodium Circinnatum, Lygodium Flexuosum, Musa Paradisiaca, Myristica Simiarum, Pariya, Solanum Torvum, and Stachytarpheta Jamaicensis.

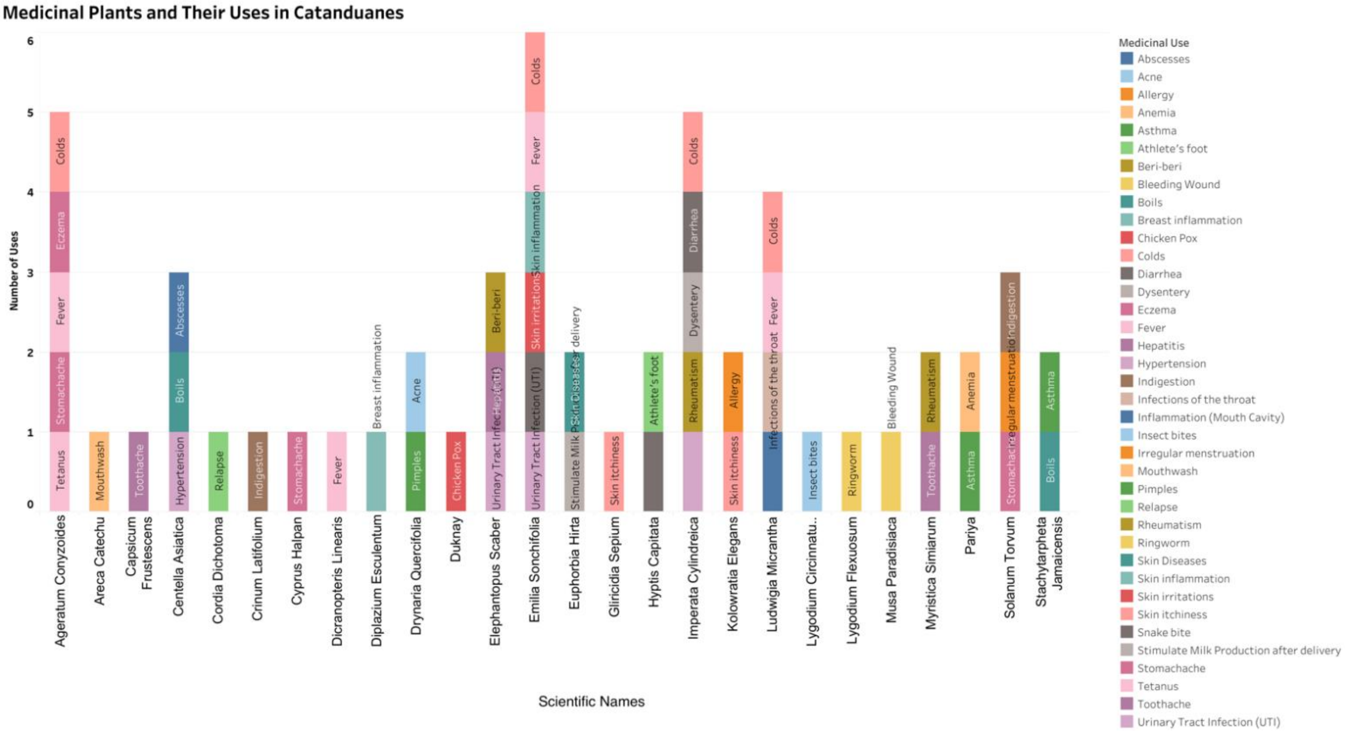

Fig. 4. Catanduanes medicinal plants and their application.

2) Proposed medplantbot system design architectural framework: After collecting the foundational data on medicinal plants, this study created training datasets, a knowledge base, and a conversational flow that revolves around the subjects and elements of a Chatbot based on the medicinal plant data from Catanduanes. The knowledge base offers a list of keywords, synonyms, and other phrases when conducting a keyword search. A group of knowledge bases consisting of MedPlantBot's frequently asked questions about medicinal plants is shown in Fig. 5. Each knowledge base contains medicinal plants profile, including their description, taxonomic classification, therapeutic uses, ailments cured, method of preparation, and application. The conversation flow for learning about medicinal plants from the MedPlantBot FAQ and knowledge base is shown in Fig. 6. It explains how to advance through the various tiers of the dialogue. The orange and green boxes reflect the user's input and MedPlantBot response, respectively. The flow of conversation directs communication while creating a chatbot. The connection between chatbots and humans remains flexible and personalized.

As indicated in Fig. 7, the overall serverless system design architecture for the MedPlanBot prototype system was then established. The framework comprises the system's architecture, which is designed on a serverless infrastructure for scalability and cost-effectiveness. The system employs multiple services, including Django, GDF, and Google Cloud Functions, to deliver a seamless and effective user experience. The design also includes natural NLP and machine learning (ML) algorithms to improve the chatbot's capacity to effectively comprehend and react to user queries. The created framework seeks to provide a user-friendly and reliable platform for accessing information about medicinal plants in Catanduanes. The MedPlantBot framework consists of multiple components that aim to offer a user experience that is smooth and efficient. These include (a) User Interface (UI). The UI is built using Django, a high-level python web application framework that enables the quick creation of websites. Users interact with the chatbot via text or voice through the UI; (b) GDF. The GDF serves as the main natural language understanding (NLU) and conversation engine. It receives user queries, identifies their intent, and retrieves relevant data from the data source. The response is processed and made usable before being sent to the output device to provide the user with the appropriate response. (c) Google Cloud Functions (GCF) is a serverless cloud-based core fulfillment solution that does not require server administration, operating system updates, or software configuration [24]. Its fully customizable chat widget provides consumers with live chat support. To connect a GDF-generated MedPlantBot to a website, obtain the account key from the GDF portal and then browse to the bot integration part of the chatbot platform, where the application id is provided.

The MedPlantBot framework employs NLU, AI, and serverless architecture to provide a customized chatbot experience. The seamless integration of these technologies facilitates user access to medicinal plant information. The framework strives to improve the user experience and give users a dependable and accurate platform.

Fig. 6. The conversational flow of the MedPlantBot system.

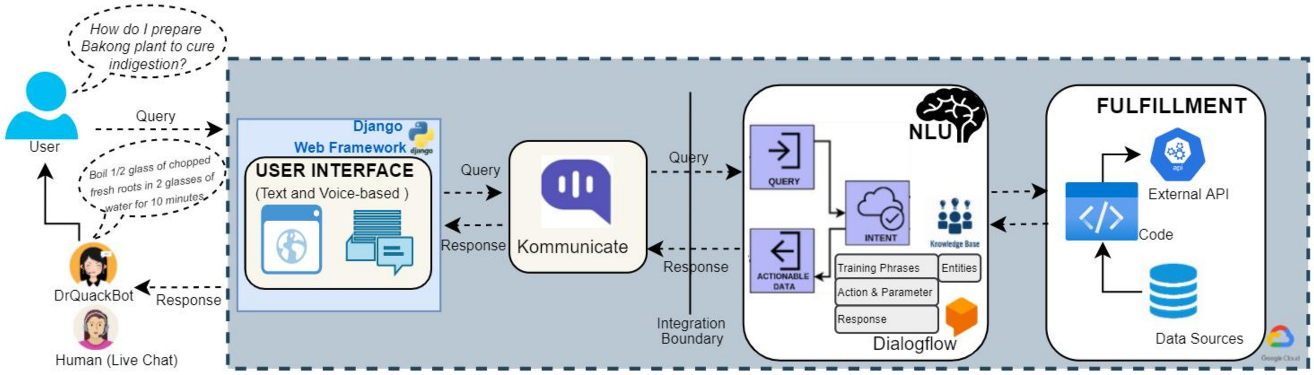

Fig. 7. MedPlantBot system design architecture.

3) Design prototype survey: The objective of this study is to develop a prototype system providing customers with accurate and useful information about medicinal plants. To evaluate its effectiveness, the researchers used a survey questionnaire that included three metrics: effectiveness, efficiency, and customer satisfaction [20]. The effectiveness metric measures how well the chatbot can provide accurate and relevant information. The efficiency metric measures how quickly the chatbot can respond to customer queries and provide solutions. The customer satisfaction metric measures how satisfied customers are with the overall performance of the chatbot.

The questionnaire was distributed to a selected group of one hundred fifty (150) participants, comprising traditional healers and herb users from Catanduanes with a keen interest in the use of medicinal plants for health and wellness, and IT professionals with expertise in chatbot technology and system design. The participants were chosen using the chain-referral and snowball methodology. During the survey, participants were required to engage in an online chat with MedPlantBot using any device such as a laptop, desktop computer, tablet, or smartphone. The survey questionnaire consisted of a series of questions that measured the participants' agreement with the chatbot's performance using a 5-point Likert scale. The scale included the following responses: Strongly Agree (SA), Agree (A), Neutral (N), Disagree (D), and Strongly Disagree (SD). Weighted mean statistics and frequency counts were used to evaluate the responses and determine the chatbot's overall performance. Along with the survey questionnaire, a non-disclosure agreement was provided to safeguard the participants' responses. The participants voluntarily participated in this study, and they had the right to quit at any time for any reason.

4) Designed framework's drawback: The survey results revealed that respondents advocated for the inclusion of more comprehensive explanations of medicinal plant data, such as videos, images, and web pages. This suggestion was considered and incorporated into the knowledge bases of the proposed framework. Yet, the survey results demonstrated that only a small proportion of respondents could predict the user experience. Thus, future studies will require a larger data set covering all medicinal plants information found in the province of Catanduanes and a bigger sample size to obtain more precise and reliable results.

5) Case Study (Future Work): Prior to the future use of the recommended platform, the system must be thoroughly tested to ensure that it meets the needs and expectations of the clients and that it functions properly. User acceptability testing, system testing, integration testing, and unit testing are a few instances of validation activities.

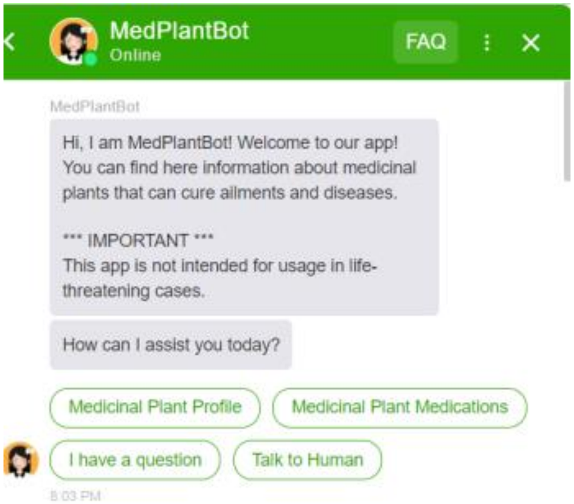
IV. RESULTS AND DISCUSSION

The focus of this research is to create, develop, and evaluate the effectiveness of an AI-based chatbot system that recommends beneficial plants and explains how to utilize them to treat diseases and illnesses. This section presents the developed MedPlantBot system prototype and its evaluation result.

A. The Developed MedPlantBot System Prototype

The MedPlantBot system prototype was developed using the dynamic approach when retrieving data. The prototype's system has functional and non-functional requirements. The functional requirements for the MedPlantBot are as follows: both regular users and admins must be given access to the system, and admins must be given the ability to administer inquiries, answers, and knowledge bases; the chatbot must be able to interact with users via text and speech, require the user to supply their name and email address before starting a conversation, answer user questions instantly, and be simple to integrate with well-known platforms like Messaging Apps, Google Assistant, Facebook pages, Skype, Telegram, and others; and the system shall permit real-time human interaction to answer questions that cannot be answered by the chatbot, and b) Non-Functional Requirements include, the system employs concise, clear, and easy-to-understand language; it shall maintain the knowledge bases and FAQs that are required for retrieval up to date, and it shall have an interactive and user-friendly interface. In less than three seconds, the system must immediately assign a live chat representative, react to inquiries in no more than three seconds, maintain discussion transcripts, be changeable and flexible, and must ensure the availability and accessibility of the system from any location; be able to seamlessly integrate with external APIs, and not need more than 24-hour maintenance outage per day.

Fig. 8 to 12 demonstrate the dialogue between the user and MedPlantBot. The first window that displays after login into the system is depicted in Fig. 8. The bot explained the application's objective. The user can choose from a menu of topics such as medicinal plant profile and medicinal plant drugs, enter the desired question, or talk with the available human agent to address their concerns.



Hi, I am MedPlantBot! Welcome to our app! You can find here information about medicinal plants that can cure ailments and diseases.

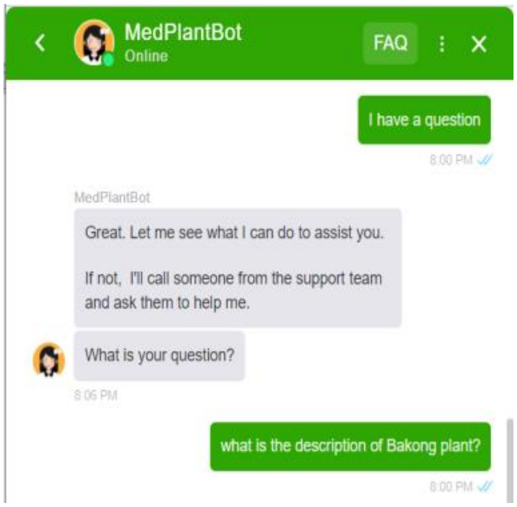
*** IMPORTANT ***
This app is not intended for usage in life-threatening cases.

How can I assist you today?

Fig. 8. MedPlantBot's welcome screen.

Fig. 9 shows an example of a user selecting "I have a question" from the menu. "What is the description of the Bakong plant?" asks the user. The customer is looking for information on Bakong, a medicinal plant. Fig. 10 depicts

MedPlantBot's response to the query. To help the user become more familiar with the Bakong plant, the bot supplied both a description and an image of the plant. The description and the image are presented where it was retrieved from the MedPlantBot system's knowledge base.



I have a question

8:00 PM

MedPlantBot

Great. Let me see what I can do to assist you.

If not, I'll call someone from the support team and ask them to help me.

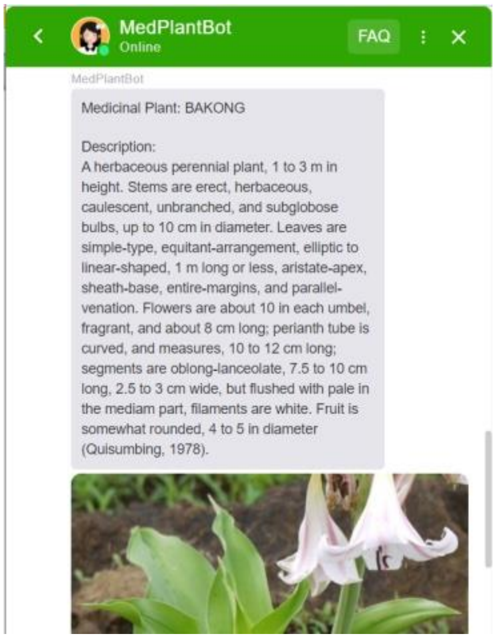
What is your question?

8:06 PM

what is the description of Bakong plant?

8:00 PM

Fig. 9. An inquiry about a certain medicinal plant.



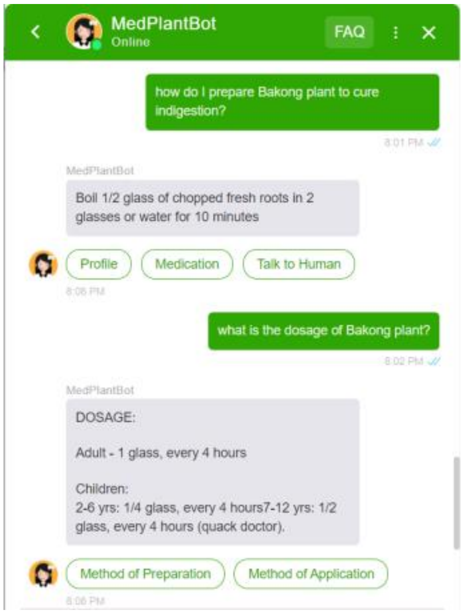
MedPlantBot

Medicinal Plant: BAKONG

Description:
A herbaceous perennial plant, 1 to 3 m in height. Stems are erect, herbaceous, caulescent, unbranched, and subglobose bulbs, up to 10 cm in diameter. Leaves are simple-type, equitant-arrangement, elliptic to linear-shaped, 1 m long or less, aristate-apex, sheath-base, entire-margins, and parallel-venation. Flowers are about 10 in each umbel, fragrant, and about 8 cm long; perianth tube is curved, and measures, 10 to 12 cm long; segments are oblong-lanceolate, 7.5 to 10 cm long, 2.5 to 3 cm wide, but flushed with pale in the mediam part, filaments are white. Fruit is somewhat rounded, 4 to 5 in diameter (Quisumbing, 1978).

Fig. 10. The response to the query of what a Bakong medicinal plant is.

Fig. 11 shows the user's request for instructions on how to prepare Bakong plant to treat indigestion. A response to the query is provided once it is found on MedPlantBot's knowledge base. As reflected, the MedPlantBot gave the customer the instruction: "Boil ½ glass of chopped fresh roots in 2 glasses of water for 10 minutes." And if additional questions arise, the user can choose an option from a menu such as a plant profile, medication, or even talking with the available human agent. The user can just put the desired question in the box if he prefers not to choose from the available alternatives.



how do I prepare Bakong plant to cure indigestion?

8:01 PM

MedPlantBot

Boil 1/2 glass of chopped fresh roots in 2 glasses or water for 10 minutes

8:06 PM

B. *MedPlantBot's Performance Evaluation Result*

The proposed MedPlantBot prototype design framework underwent evaluation using a CUQ instrument, which assessed its effectiveness, efficiency, and satisfaction. A total of 150 people were contacted to provide comments and suggestions for improving the application's design. As shown in Fig. 13, the MedPlantBot system received a high-performance rating of

4.76 out of 5, indicating a strong level of agreement among users. This positive response is attributed to the user-friendly approach and architecture of the system.

While the feedback was generally positive, some respondents did provide improvement suggestions. Specifically, users requested clearer notifications that the application should not be used for life-threatening situations, as well as more detailed explanations of medicinal plant information, such as videos, images, and web pages, and they even suggested that the system should cover all medicinal plants with therapeutic properties found in Catanduanes These suggestions could further improve the user experience and usability of the MedPlantBot system if implemented.

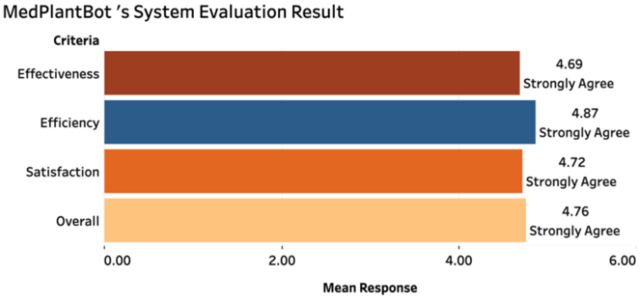

Fig. 13. MedPlantBot's system evaluation result.

V. Conclusion

This paper has introduced a new design paradigm for MedPlantBot, an AI chatbot that leverages medicinal plants to provide natural remedies for a variety of ailments. The study has identified local medicinal plant species and provided detailed descriptions of their taxonomy, applications, and uses. The development of chatbots requires a combination of various strategies and approaches, as demonstrated by several studies.

The findings of this study indicate that chatbots are extremely user-friendly and can provide appropriate responses and treatment recommendations for a wide variety of ailments, making them readily available to anyone seeking natural remedies. Using a survey questionnaire, the effectiveness of the MedPlantBot framework in delivering herbal medication was evaluated. Respondents strongly agreed that the chatbot provides an intuitive interface that is highly efficient, effective, and satisfying. Users lauded the chatbot's ability to prescribe relevant herbal treatments and provide customized treatment plans. The MedPlantBot system prototype has the potential to contribute significantly to the healthcare industry, while simultaneously encouraging sustainability and ethical practices. This discovery could serve as a springboard for the development of comparable technologies that can aid in the responsible use of natural resources.

VI. Implications and Future Work

The MedPlantBot technology has the potential to revolutionize healthcare through natural therapies. Its encouragement of medicinal plant use increases awareness of the importance of natural resources and contributes to the protection of biodiversity. In addition, the MedPlantBot serves as an educational tool for the community to learn more about the therapeutic usage of local medicinal plant resources. This framework offers a low-cost method for enhancing public health and welfare, aiding policymakers, and healthcare professionals in the development of herbal medication recommendations and regulations. Likewise, this research helps to the creation of a more sustainable and ethical approach to the use of medicinal plants, leveraging technology to ensure environmentally responsible resource management.

Future research can be carried out to enhance the chatbot's performance and broaden its capabilities, which can ultimately benefit more individuals in search of natural therapies. The MedPlantBot can be assessed and analyzed in terms of chatbot design characteristics based on ChatbotTest [18] such as a) *Personality*. The onboarding process is crucial for chatbots. Onboarding is uncommon, however. We observed that many users see Pedagogical Conversational Tutor (PET) more like a search engine than a conversational partner and that this perception is shared by many users: b) *Onboarding*. The Microsoft Azure Bot Framework-based personality-adaptive chatbot prototype is constructed on the web and can be inserted into a variety of channels since it is browser-based. For the task of employment suggestion, which is separated into two sub-dialogs, the appropriate discussion tree is triggered depending on the input personality: c) *Understanding*. The adoption of a chatbot for tourist planning in a unique way. By understanding the adoption variables, tourism businesses may use chatbot technology to improve the customer experience and increase consumer engagement; d) *Answering*. It must have access to an external body of wisdom and knowledge (for example, through data corpora) to perform the role of competence and respond to user inquiries, should keep data unique to the situation: e) *Navigation*. Information that links customers with programs services – which may contain a contact record's regular features as well as a textual description of the resource; f) *Error management*. The handling of errors in iHelper must be improved right away since typos are not caught. Using spell-checking APIs might help with this; and g) Intelligence. The conversation flow of intelligence chatbots may be tailored to clients and their use cases. The design component of chatbot software is essential. Furthermore, exploring the possibility of integrating a geographic information system (GIS) to map and expand the dataset of medicinal plants may be a promising avenue for future endeavors.

Suppressing Chest Radiograph Ribs for Improving Lung Nodule Visibility by using Circular Window Adaptive Median Outlier (CWAMO)

Dnyaneshwar Kanade[1], Jagdish Helonde[2]
Research Scholar, School of Engineering and Technology, Sandip University[1]
Professor, School of Engineering and Technology, Sandip University[2]

***Abstract*—Chest radiograph ribs obstruct lung nodules. To see the nodule under the chest radiograph ribs, remove or suppress them. The paper describes a circular median filter approach for finding outliers in chest radiographs. The method uses 147 Japanese Society of Radiological Technology x-ray pictures (JSRT). Pixels with intensities two standard deviations above the median are median outliers. Contrast-Limited Adaptive Histogram Equalization enhances nodule visibility (CLAHE). The method is tested on modest chest radiographs and compared to the Budapest University Bone Shadow Eliminated X-Ray Dataset methodology. The initial test uses 50 modest chest radiographs (Test 1). The proposed approach is applied after active shape modelling (ASM) lung segmentation. True positive nodules are seen on 89% of chest radiographs of various subtleties. Test-2 and Test-3 used 20 subtlety-level photos. In Test-2, the peak signal-to-noise ratio (PSNR), mean-to-standard deviation ratio (MSR), and universal image quality index (IQI) are evaluated for the full image and compared to the existing algorithm. For all three parameters, the suggested technique outperforms the algorithm. Test-3 computes nodule MSR and compares it to Budapest University's Bone Shadow Eliminated Dataset and original chest radiographs. The new algorithm improved nodule area contrast by 3.83% and 23.94% compared to the original chest radiograph. This approach improves chest radiograph nodule visualization.**

***Keywords*—Lung cancer; chest radiograph; contrast limited adaptive histogram equalization; median outlier**

I. Introduction

Imaging techniques such as radiography, magnetic resonance imaging (MRI), and computed tomography (CT) are all regularly utilized in the field of medical diagnosis for the purpose of locating lung cancer. Despite the fact that MRI and CT are more sensitive and accurate techniques, chest radiography is still the most recommended type of process for the initial diagnosis and detection of lung cancer due to the fact that it is a noninvasive form of operation, has a low radiation dosage, and is affordable. It is necessary to eliminate the shadow of the chest ribs from the chest radiograph before beginning the process of identifying candidate nodules from the chest radiograph. The chest rib shadows have been removed from the chest radiograph using a variety of methods that have been proposed in a number of studies. These methods also detect lung nodule-like components in the chest radiograph. This article discusses the elimination of chest rib shadows from chest radiographs using the median outlier technique and the detection of nodule-like parts using the thresholding technique. Both of these techniques are discussed in detail in Section III. Before the nodule was found, the images were improved using a technique called CLAHE. This allowed for a clearer view of the area. The lungs are segmented with ASM [1], [2], [3], [4]. The image database maintained by the JSRT [5] is utilized by the proposed approach (CWAMO). The proposed method is unsupervised and does not require either large dataset or training of it. The adaptive nature of the median outlier filter archives consistent results for differently illuminated chest radiographs. The proposed method is evaluated for its usefulness by calculating different measure such as PSNR, universal IQI and MSR for the entire image and nodule area and then compared them with the existing algorithm.

The paper can be structured in the following manner: In the Second II, several similar efforts on the removal of bone shadows from chest x-ray pictures are discussed. In the Section III of this research project, both the problem statement and the technique are discussed. Experimentation is performed in Section IV. Section V presents a comprehensive study of the currently used method as well as the proposed improvements, and Section VI brings the entire research to a close.

II. Related Work

The current state of the art incorporates a number of techniques for the suppression of ribs and the segmentation of lung nodules, all of which are based on standard chest radiography practices. The outcomes of the offered strategy are evaluated in light of the dataset called the "Bone Shadow Eliminated Image Dataset” [6] developed by Budapest University (BSE-BU). By appointing a slope to every point in the image, a one-of-a-kind process creates a model that ignores the information about its positioning. These slopes can be graphed using a slope field and are represented by a function that requires two inputs to operate. Three characteristics are sufficient to identify the ribcage, as indicated by research that was carried out on a range of tasks. The function was analyzed through the use of principal component analysis, which resulted in the generation of the function's final iteration, which was a two-variable, third-order rational function. Due to the fact that it spans chest bones, the nodule is difficult to identify with conventional chest radiography. Independent Component Analysis [7] is used in the process, which suppresses the rear ribs and clavicles (ICA). By utilizing this method, the visibility of the nodule will be improved, and the strain on the automatic nodule recognition module will be decreased. Active appearance models and active shape models are integrated with a k-nearest neighbor classifier and a filter bank composed of different scales of Gaussian derivatives for the purpose of evaluating and contrasting various supervised segmentation algorithms. The techniques were tested using a database that was available to the general public and had 247 chest radiographs. In this database, all of the elements had been manually segmented by two human observers. The process of segmenting the clavicle is challenging regardless of the approach used [8]; dynamic shape models produce the greatest results, but the performance of humans is noticeably superior. Iterated contextual pixel classification (ICPC) [9] is an iterative, pixel-based, supervised, statistical classification procedure. The initial segmentation of the ribs acquired by pixel classification is updated by the ICPC, which does so by reclassifying each pixel by making use of both its original attributes and the knowledge regarding the class labels of neighboring pixels. The methodology is analyzed by using thirty radiographs taken from a database maintained by the JSRT. ICPC achieves a classification accuracy of 0.86 spl plus mn or 0.06 in an experiment using sixfold cross-validation, whereas the second human observer achieves an accuracy of 0.94 spl plus mn or 0.02 in the same experiment. In [10], x-rays is described. This system combines three different methods of doing so. The interior, border, and head of the clavicle are each classed in a separate category and divided into two stages, respectively. This is the data that is sent into the active shape model so that it can be segmented. In order to arrive at the desired end result, information regarding the shape obtained from the active shape model is combined with appearance data obtained from the inside of the clavicle, the border, the head, and dynamic programming. The method is evaluated against a wide variety of techniques that have been published in the past as well as against impartial human observers using a huge database. The approach that is advised produces a mean contour distance of 1.1 millimeters and an intersection over union distance of 0.86 millimeters when applied to 249 test photographs. a one-of-a-kind method that segments x-rays through the use of a dynamic programming strategy, so releasing them from the shadows that are cast by the rib cage and the clavicle [11]. When moving to a new place, the separated shadows will no longer be present. After being cleaned, the images are put through a hybrid lesion detector that uses data on gradient convergence, contrast, and intensity. The use of a support vector machine helps get rid of inaccurate findings. The method can eliminate 80% of bone shadows and 84% of them in the posterior region, despite having an average segmentation error of 1 millimeter. The frequency of false positives was reduced from 2,94 to 1 thanks to shadow reduction, which achieved a sensitivity of 63% for malignant tumors. The following is a rundown of the five primary stages involved in the suggested methods: After the lung has been segmented, the clavicle and ribs are located, their edges are determined, their profiles are computed, and suppression is carried out by making use of the projected profiles. The clavicle and the rib components are hidden from view in the image provided by the bone-suppression algorithm [12]. On a total of 491 photographs, the effectiveness of rib suppression was analyzed. It was found that 83.06% (or 6.59%) of the rib structures on a typical chest image were suppressed, which is approximately comparable to an average of one visible rib on a rib-suppressed image. This was discovered through the use of image analysis software. This conclusion was reached after comparing the rib areas recognized by the computer with the rib areas sketched by hand. Data mining and image processing are used to create a system for automatic rib recognition [13]. To begin, a number of template matching techniques and approaches based on graphs are employed to determine the position of the rib center line. After that, a support vector machine is utilized in order to model the way in which the ribs are positioned with respect to one another as well as to locate mistakes. In conclusion, decision trees are utilized in order to enhance the result of center line recognition. The JSRT dataset is used to conduct an analysis of the approach. The findings of rib recognition are greater than ninety-two percent for sensitivity and ninety-eight percent for specificity. A novel method expresses [14] that there is a different method for dividing up the ribs in chest radiography. Several applications of the Gaussian filter were required in order to get rid of the dataset's chaotic background. Detail images could be generated using the multi-scale wavelet decomposition, and then features extracted from the detail images using the Gaussian derivative. In order to properly categorize ribs, the support vector machine (SVM) rib model was developed. The convolutional neural filter (CNF) [15] for bone suppression is based on a convolutional neural network, which possesses excellent image processing capabilities and is frequently used in the field of medicine. [CNF] stands for "convolutional neural filter." The system that utilized CNF and consisted of six convolutional layers was successful in suppressing 89.2 percent of the bone. An intensive multitasking U-Net is offered as a solution to the problem of segmenting bones from a chest radiograph [16]. This solution is based on a sufficient dataset. A four-fold cross-validation is used to assess the performance of the proposed network on 88 chest radiograph pictures. The suggested technique for segmenting all bones results in average DSC values of 88.38%. These values are listed from highest to lowest. The proposed research produced lung digital x-rays, bone digital x-rays, and bone-free digital x-rays from 59 high-resolution CT images of the lung [17]. These DRs were utilized for the purpose of the suggested cascade convolutional neural network's internal evaluation as well as its training (CCNN). The authors propose an improved lung-simulated DR with varied bone intensity weightings by utilizing a 3-step image processing architecture. In addition to DR modeling and feature expansion, CT segmentation was also performed. Networks for bone identification and suppression are available through the CCNN. During the process of external validation, the trained CCNN was examined on a total of 30 chest radiographs. The clavicles and ribs have the ability to disguise even relatively minor abnormalities, which can lead to incorrect diagnoses. To reduce the number of radiological interpretation errors, particularly DL processes that are associated with tuberculosis identification, the purpose of this study [18] is to develop a deep learning-based bone suppression model. This model will identify and remove these obstructing bony structures from the frontal CXRs (TB). Multiple bone suppression models, each with their own unique deep architectures, are trained, optimized, and finally evaluated at a number of different institutions using the combined loss function that was mentioned before. The theory was put to the test with the help of DeBoNet, which is a collection of models for convolutional neural networks [19] that inhibit frontal CXR bones. A specific collection of computed tomography images and their bone-suppressed analogues were used in the training and evaluation of U-Nets, Feature Pyramid Networks, and several other custom models. In terms of PSNR (36.797771.6210), MS-SSIM (0.98480.00), and other measures, DeBoNet surpassed the top three models that were used in its development. A novel approach generated a virtual dual energy (VDE) image with MTANN that suppressed ribs and clavicles to expose hidden nodules [20]. On chest radiographs, the ability of radiologists to detect pulmonary nodules was compared to the performance of bone suppression imaging using deep learning and bone subtraction imaging using a dual energy technique (CXRs) [21]. A completely automated system performs an analysis of digital posteroanterior (PA) chest radiographs [22]. This analysis begins with the segmentation of the lung field. Even the lungs that are normally neglected in conventional approaches are included in the segmented lung region because it includes the lungs that are concealed behind the heart, spine, and diaphragm. A projected nodule selection strategy is put into action once the partitioned region has been processed using a straightforward multiscale method in an effort to enhance the visibility of the nodules. To remove false positives, cost-sensitive support vector machines (SVMs) detect actual nodules. On two different feature-selected data sets, a number of Gaussian and polynomial SVM learning tests with variable parameter settings were carried out. The best SVM models have a false-positive rate of 1.5 per image when the sensitivity is set at 0.71. When the sensitivity is increased to 0.78 and 0.85, the rate increases to 2.5 and 4, respectively. The suggested approach generates seven or eight frames per second while maintaining the highest possible sensitivity (0.92–1.0). Using a Laplacian of Gaussian (LoG) filter as the basis for an approach to chest X-ray dot-like augmentation is discussed [23]. The directional texturing of lung nodules is improved when the X and Y axes are given the ability to have varied scale values. Image capture, image pre-processing, candidate nodule recognition, and feature extraction are the individual components that make up a computerized technique for recognizing nodules on chest radiographs [24]. The program is responsible for processing both SCLC and NSCLC pictures. In order to analyze the geometrical and textural properties of fifty photographs, twenty-five from each category were selected. Textural features were determined using GLCMs. Experiments involving the selection of image features provided novel results [25]. In order to get the best combination of traits, 210 different features were evaluated. Employing a procedure known as "forward stepwise selection," For each feature set, the area under the ROC curve served as the criterion for evaluation. It is suggested in [26] that images be pre-processed using a median filter. The thresholding method developed by Otsu is utilized in the segmentation process. The GLCM algorithm and various measurements of the physical dimensions are utilized throughout the process of feature extraction. ANNs are used to categorize the phases of disease. In this study, twenty-three wavelets from four different wavelet families—Daubechies, Haar, Biorthogonal, and Reverse Biorthogonal Spline—are compared in order to determine if lung nodules are benign or malignant [27]. In order for researchers to differentiate very small items from the background, they use three different sizes of regions of interest. For testing the suggested system, actual database pictures accompanied by tags are employed. Detecting lung nodules in chest radiographs is made possible by a computer system that uses multi-scale image processing [28]. This strategy accounts for the wide range of sizes that lung nodules can take, such as Active Shape Model lung field segmentation; quadratic classification with Lindeberg's multi-scale blob detector for nodule candidate detection; multi-scale edge focusing for blob segmentation; k-nearest neighbor classification; k-nearest neighbor classification. When looking at the comprehensive JSRT database, we find that allowing two false positives per image results in the detection of 50.6% of nodules. The percentage rises to 69.5% after the addition of 10 false positives. The classification of image thresholding techniques, the standardization of their formulas, and the comparison of their performances are all carried out [29]. The shape of the histogram, the grouping of the measurement space, the entropy of the data, the qualities of the objects, the spatial correlation, and the local gray-level surface data are all factors that differentiate the thresholding procedures. A comparison of forty different thresholding methods for nondestructive testing and document photos is shown here. Considering integrated performance indicators side by side We have developed thresholding methods that are more effective than nondestructive testing and document photography. Background may be removed with the help of the local mean and standard deviation, thanks to an innovative locally adaptive thresholding technique [30]. Integral sum image preparation calculates the local mean. A variance-based threshold selection criterion is developed by projecting the two-dimensional histograms of the original image and the local average image onto a one-dimensional space [31]. This results in the establishment of a variance-based threshold selection criterion. The suggested image thresholding strategy outperforms the Otsu, two-dimensional Otsu, and least class variance thresholding techniques, according to results obtained on bi-level and multi-level thresholding for artificial and real-world images. These results indicate that the proposed strategy is superior. The detailed study that provides a description of the finding of lung tumors on a chest graph [32] is presented. The approaches of watershed segmentation, thresholding, active contour, and differential operator, as well as expanding region [33], are compared. Two radiologists [34] used a retrospective investigation of a total of 100 patients, of whom 50% had lung nodules and the remaining 50% had no nodules, to confirm the chest CT findings. Using a computer-aided design (CAD) program, researchers compared four different methods for diagnosing lung nodules and masses. One hundred incidents were investigated in total. The mass algorithm outperformed the other three. A new hybrid deep learning framework (CNN) was created by combining convolutional neural networks, visual geometry group-based neural networks (VGG), data augmentation, and spatial transformer networks (STN) [35]. The validation accuracy for the suggested technique is 73%, whereas the accuracy ratings for vanilla gray, vanilla RGB, hybrid CNN and VGG, and modified capsule networks are 67.8%, 69%, and 63.3%, respectively, for the complete dataset. An improved region growth (IRG) algorithm was used to segment the lung tumor in a way that was both more accurate and quicker than the traditional methods [36]. When applied to CT scans of four different patients, the overall strategy resulted in a 98% increase in segmentation accuracy when compared to the straightforward approach. The tumor was successfully contained by the multipoint growth-start combination. The technique improved tumor identification by a margin of less than 13% while also increasing compliance accuracy to an adequate level. A novel computer vision technology called understandable decision trees is used to predict the aggressiveness of lung cancer by employing decision trees [37]. This technique combines decision trees and deep learning. The deep learning component of this strategy was created with the use of a large set of pathological markers that are readily available to the public and are related to lung cancer. These techniques estimate chest X-ray biomarker scores utilizing two data sets tagged with malignancy. We found that fitting shallow decision trees to datasets that had been stratified based on the chance of cancer produced the best results. The most effective decision tree model has a specificity of 80%, a sensitivity of 86.7%, and a positive predictive value of 92.9%. Most of the proposed techniques are supervised in nature and need large dataset. These techniques also require training the model which takes lot of time. On the other hand, the non-supervised techniques proposed by other researchers assume equal illumination of all the images which is not the case in reality.

III. Proposed Method

A. Assumptions

Prior to using the proposed method for suppressing the chest radiograph ribs for improving nodule visibility and detecting nodule-like areas, the following assumptions are made:

1) The JSRT digital x-ray images [6] with bone shadow are the ones that were used for the dataset for the suggested approach. The dataset is made up of 154 traditional chest radiographs that show a lung nodule and 93 radiographs that do not show a lung lesion.

2) In the JSRT dataset, each chest radiograph with a lung nodule has only one nodule.

3) The study makes use of images ranging from a subtlety level of 5 (the nodule is extremely evident) to a subtlety level of 2 (the nodule is very subtle). The proposed method doesn't use images with a subtlety level of 1, which is sometimes called "very subtle," because it's very hard to pull nodules out of those images because they have low contrast, are small, or overlap with normal structure.

4) The circular median filter used has a radius of 50 pixels, and the threshold used is two standard deviations.

5) The block size of CLAHE [1] is 127, and the number of histogram bins is 256.

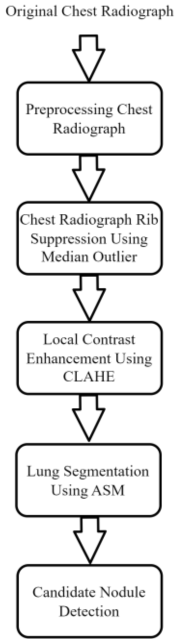
6) The maximum slop of CLAHE is 10.

7) For comparing the proposed method results, the JSRT bone shadow-eliminated images dataset by Budapest University (BSE-BU) [7] is used.

B. Algorithm

The proposed method is divided into five steps, namely: (1) Preprocessing of the image (2) Chest radiograph suppression (3) Contrast enhancement using CLAHE (4) Lung segmentation using ASM (5) Candidate nodule detection using Bernsen local contrast thresholding with a circular window (CWLCT) (Fig. 1).

1) Preprocessing of chest radiograph: In the preprocessing phase, the original chest radiograph pictures are boosted for contrast and then down sampled to a resolution of 1024 by 1024 pixels, which is a reduction from their original size of 2048 by 2048 pixels, before being used to suppress rib shades.



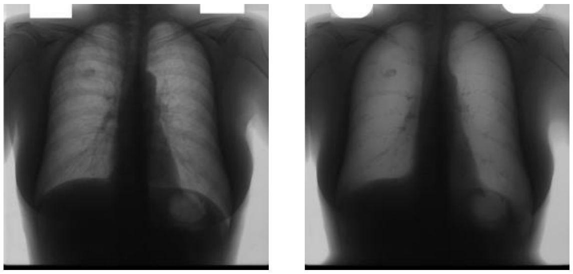
Original Chest Radiograph
Preprocessing Chest Radiograph
Chest Radiograph Rib Suppression Using Median Outlier
Local Contrast Enhancement Using CLAHE
Lung Segmentation Using ASM
Candidate Nodule Detection

Fig. 1. System flow chart.

2) Chest radiograph rib suppression using median outlier: A circular median filter is applied to the chest radiograph in order to reduce the visibility of the ribs' shadows. The size of the image and the maximum height of a rib on the chest radiograph are used to establish the value for the radius of the circular median filter. The circular window was centered at the pixel *f(x,y)* to calculate the median of the pixel intensities of the image region under the circular window. By using the standard deviation as the threshold value, the pixel intensity at *f(x,y)* will be replaced with the median value ***m*** if it is brighter than the median by the threshold value t; otherwise, it will be kept at its original value.

$$I_1(x,y) = \begin{cases} m \; if \; I(x,y) > m+t \\ I(x,y) \; otherwise \end{cases} \quad (1)$$

Where *I(x,y)* is the original gray level intensity at pixel *f(x,y)* and *I_1(x,y)* is modified gray level intensity at pixel *f(x,y).*



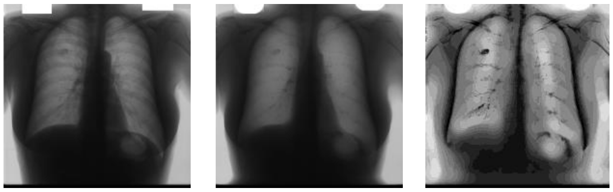
(a) (b)

Fig. 2. Rib suppression. (a) Original chest radiograph. (b) Rib suppressed chest radiograph.

Fig. 2(a) shows original chest radiograph while Fig. 2(b) shows ribs suppressed image using proposed AMO method.

3) Local contrast enhancement by CLAHE: Due to the concentration of the histogram in regions with nearly constant contrast, standard AHE has a tendency to overamplify the contrast in these areas. AHE may thus lead to noise amplification in regions with near-constant noise. In order to lessen the issue of noise amplification, contrast amplification is restricted in adaptive histogram equalization (CLAHE).

The magnitude of the contrast amplification in CLAHE close to a particular pixel value is determined by the slope of the transformation function. This is proportional to the value of the histogram at that pixel value as well as the slope of the cumulative distribution function (CDF) for the surrounding area. Before computing the CDF, CLAHE performs a clipping operation on the histogram at a value that has been previously determined in order to reduce amplification. Because of this, the slope of the transformation function is restricted due to the constraints placed on it. The so-called clip limit, also known as the value at which the histogram is clipped, is established based on the normalization of the histogram and, as a direct consequence of this, the size of the neighborhood region. Fig. 3(c) shows an enhanced image using CLAHE.



(a) (b) (c)

Fig. 3. Contrast enhancement using CLAHE (a) Original chest radiograph. (b) Rib suppressed chest radiograph (c) Contrast enhanced image.

4) Lung segmentation: An active shape model is used for extracting lung areas from the chest radiograph. One of the most reliable methods for picture segmentation is ASM. The active shape model is a parameterized contour model. The parameters are obtained using principal component analysis (PCA) and the statistics of numerous sets of points collected from various contours of comparable images. In ASM, the object's boundary is established by n points. These points produce the descriptor vector, which is generated as

$$x = (x_1, y_1, x_2, y_2, \ldots\ldots.. x_n, y_n)^T \quad (2)$$

where x_i and y_i are the i-th point on the contour's x and y coordinates respectively. The principal component analysis-calculated s training vectors have a mean shape of

$$\bar{x} = \frac{1}{s}\sum_{i=1}^{s} x_i \quad (3)$$

There will be a covariance matrix, defined as

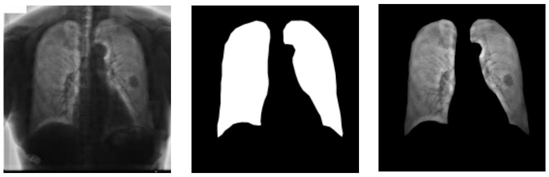
$$S = \frac{1}{1-s}\sum_{i=1}^{s}(x_i - \bar{x})(x_i - \bar{x})^T \quad (4)$$

The covariance matrix's first t biggest Eigen values are picked. Due to the fact that only the eigenvalues with the greatest significance are taken into account, the number of parameters is drastically reduced and ultimately falls below n. The appropriate eigenvectors are all present in the matrix. The model's inputs are calculated as follows:

$$b = \Phi(x - \bar{x}) \quad (5)$$

From this, the approximate form is determined as follows.

$$x \approx \bar{x} + \Phi b) \quad (6)$$



(a) (b) (c)

Fig. 4. Lung segmentation. (a) Original chest radiograph. (b) ASM lung mask. (c) Lungs part of chest radiograph.

The appropriate b vector is found for a given contour when all of its components fall inside the range ±m√λi, with the right constant m. Starting with the mean shape, the parametric description of an object's contour is looked up. Until convergence or a preset number of iterations are reached, two alternate steps are used. Each contour point perpendicular to the contour is moved in the first step of the procedure. After numerous iterations of position testing on both sides of the contour, the ideal position is identified. Picture resolution is used in the training model to determine where an intensity gradient profile should be placed at each contour node. Finally, the ideal replacement location for the contour point is determined using the Mahalanobis distance. Then, all of the contour points are modified in order to fit a model to the new point set. The ideal b parameter is searched using (6). As the image's spatial resolution increases, the entire procedure is repeated numerous times. The proposed method used 100 chest radiographs from the JSRT dataset to train the model. The original chest radiograph is shown in Fig. 4(a). Fig. 4(b) displays the segmented lung mask that was produced using ASM. By using this mask on the original X-ray image, as seen in Fig. 4(c), the lungs are segmented.

5) Candidate nodule detection: The proposed method uses Bernsen local contrast thresholding [38] with a circular window with diameter w for image binarization instead of a square window while calculating local contrast, as shown in Fig. 5. For pixel P centered at i and j, a square window of size w x w takes 22% more neighboring pixels into account than the circular window having diameter w. The circular window used in the proposed method for image binarization plays an important role while calculating the local contrast for the boundary pixels of the true positive nodule. In the post-processing stage, morphological operations are used to remove unwanted regions. A significant reduction in false positive nodules is obtained by using prior knowledge of the true positive nodule. Based on the circularity index of the candidate nodules final candidate nodule segmented image is obtained as shown in Fig. 6(b) the white nodule is true positive while gray is false positive.

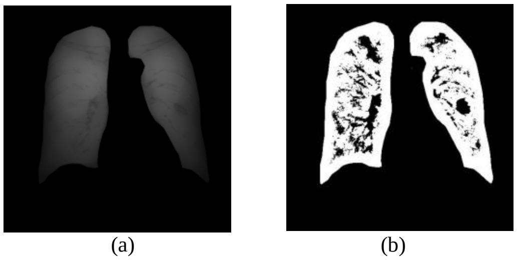


Fig. 5. Local contrast thresholding. (a) Rib suppressed chest radiograph. (b) Binarization using local contrast thresholding.

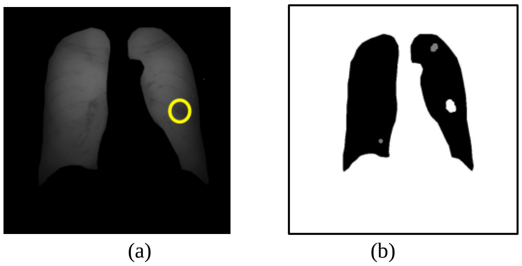

Fig. 6. Post processing. (a) Original chest radiograph with annotation. (b) Candidate nodules (White is True Positive).

IV. Experimentation and Results

1) Test-1: 50 images with subtlety level 5 to 2 are used for experimentation. After preprocessing and lung segmentation using ASM, circular window local contrast thresholding technique applied for binarization. It is observed that the 90 % of the true positive nodules extracted are part of candidate nodules. The average rate of false positive nodules per image is 3.5 fp/image. Fig. 7 shows the results of candidate nodules extraction using local contrast thresholding with circular window for the images with subtlety level 5 to 2.

2) Test-2: Test-2 deals with the image quality measures of the proposed rib suppression algorithm by comparing it's results with the (Budapest University Bone Eliminated JSRT dataset) existing algorithm [7]. The second test, known as Test-2, evaluates entire image quality. In Test-2, we make use of the sample original images; images from the Budapest University Bone Eliminated JSRT dataset, as well as images obtained utilizing the proposed approaches. The quality of the images was evaluated in this study with the use of a number of different criteria. The criteria that will be used for the evaluation are 1) Peak Signal to Noise Ratio (PSNR), 2) Mean to Standard Deviation Ratio (MSR), and 3) Universal Quality Index (IQI).

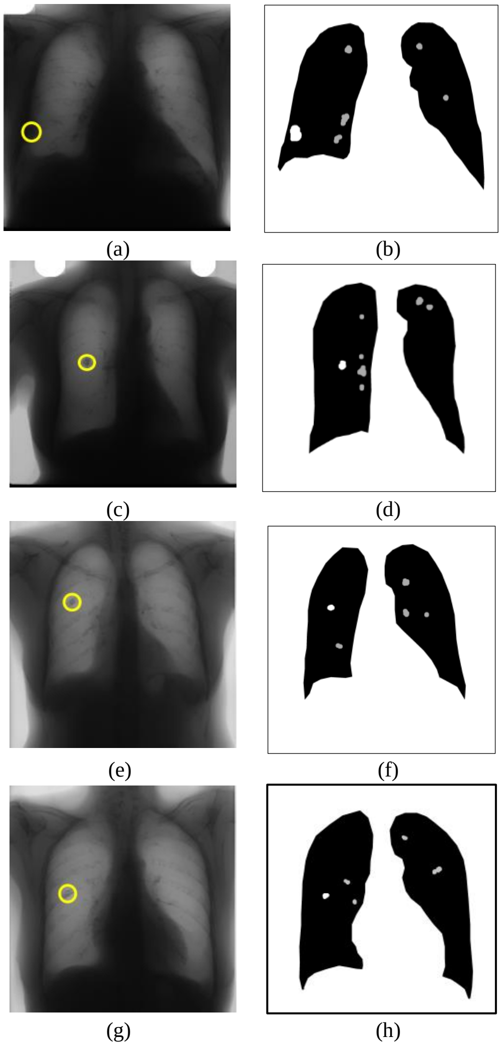

Fig. 7. Some of the results obtained -Rib suppressed using proposed method Images with subtlety levels 5,4,3 & 2 sequentially (Left Column-(a), (c), (e), (g)), results of candidate nodule segmentation (White-True positive nodules) using local contrast thresholding and circular window (Right column-(b), (d), (f), (h)).

For image level analysis all above three measures are used while for nodule area analysis only MSR is used.

a) Test 2.1 Peak signal-to-noise ratio: Peak signal-to-noise ratio (PSNR) is expressed in decibels (dB) (decibels). PSNR is defined as

$$PSNR = 20log_{10}\left(\frac{MAX_I}{\sqrt{MSE}}\right) \qquad (7)$$

where MAX_I is the highest value a pixel can have within an image, and MSE is determined by:

$$MSE = \frac{1}{ij}\sum_{m=0}^{i-1}\sum_{n=0}^{j-1} \parallel I(m,n) - K(m,n) \parallel^2 \quad (8)$$

Where I is original JSRT database image and K is either Budapest Bone Shadow Eliminated Image or Rib suppressed image using proposed method. Table I shows comparison of PSNR of Budapest University Images and result Images of the proposed method while Fig. 8 shows it graphically.

b) Test 2.2 Mean to standard deviation ratio of Image: After calculating the mean and standard deviation of the entire image, it is simple to calculate the mean-to-standard deviation ratio (MSR). MSR stands for mean to standard deviation ratio. It would be better if MSR increased. Table II shows comparison of MSR of JSRT original images, Budapest University Images and result Images of the proposed method while Fig. 9 shows it graphically.

c) Test 2.3 Universal image quality index: The image similarity across Rib suppression using existing algorithm and proposed method can be measured.

Let $I = \{i_n \mid n = 1, 2, ..., N\}$ and $J = \{j_n \mid n = 1, 2, ..., N\}$ be the original and Rib suppressed image signals, respectively. Universal image quality index (UQI) [39] is defined as

$$Q = \frac{4\sigma_{ij}\bar{\imath}\,\bar{\jmath}}{\left(\sigma_i^2+\sigma_j^2\right)[(\bar{\imath})^2+(\bar{\jmath})^2]} \qquad (9)$$

The average pixel intensity of the original image is denoted by $\bar{\imath}$ and $\bar{\jmath}$ indicates average pixel intensities of the Rib suppressed images. The minimum value of Q is 0 and maximum value of Q is 1, where the value 1 is considered to be the best value. It is only possible if and only if $i_n = j_n$ for all $n = 1, 2, ..., N$.

Table III shows comparison of MSR of JSRT original images, Budapest University Images and result Images of the proposed method while Fig. 10 shows it graphically.

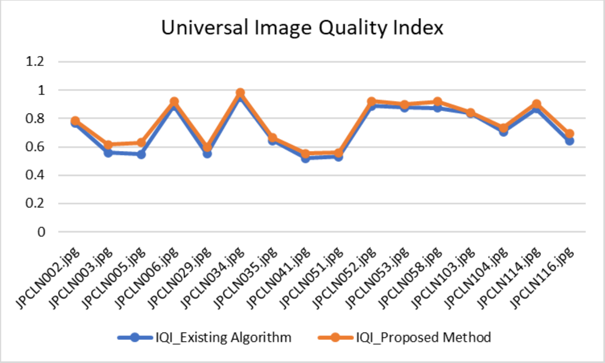

Fig. 10. Universal image quality using budapest bone shadow eliminated images dataset and proposed method.

3) *Test-3*

a) *Test 3.1 Mean to standard deviation ratio of nodule area:* In Test-3, the MSR is calculated for the nodule region, which takes into account its surroundings as well. The MSR of the nodule area calculated using the suggested method is compared to the MSR of the nodule area calculated using JSRT's original dataset and Budapest University's Bone Shadow Eliminated Image dataset. The Fig. 11(c) shows the sample result of the nodule area after suppressing ribs shadow from the chest radiograph using proposed method.

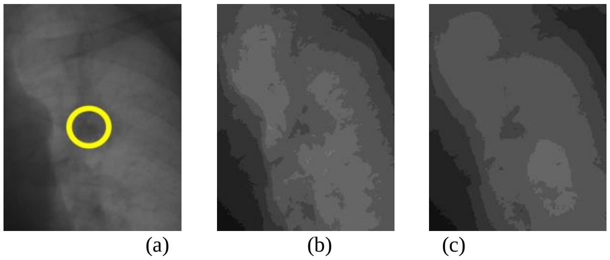

Fig. 11. Cropped nodule area (a) Nodule area in the original chest radiograph, (b) Nodule area in budapest bone shadow eliminated images dataset (c) Nodule area in the proposed method.

V. RESULT ANALYSIS

To evaluate the performance of the proposed method, a total of three tests are conducted. In Test-1, fifty images from the JSRT dataset with subtlety levels ranging from 5 to 2 are utilized. After preprocessing, the lungs are segmented using ASM. The ribs are removed using the proposed method (CWAMO), and finally, candidate nodules are extracted using circular window-based local contrast thresholding (CWLCT). From the results, it is observed that in 89% of the chest radiographs, true positive nodules are detected accurately. Test-2 was conducted to evaluate the performance of the proposed method at the image level. In this test, three measures were used for evaluation, namely PSNR, MSR, and IQI. Table I and Table III show the PSNR and IQI comparison between the existing algorithm and the proposed method. Fig. 8 and 10 depict it graphically. Table II shows the MSR comparison between the original image (with rib shadows), the bone shadow-eliminated image by Budapest University, and the proposed method (CWAMO). Fig. 9 shows the above comparison graphically. Four sample images ranging in subtlety from 5 to 2 were used for each of the measures.

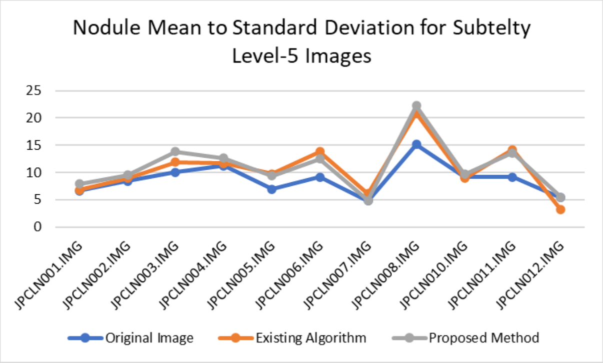

Fig. 12. Comparison between nodule MSR of original image, MSR of budapest bone shadow eliminated images dataset and MSR of proposed method for subtlety level-5.

As shown in Fig. 12, 13, 14, and 15, Test-3 employs ten sample images from each subtlety level (Level 5 to Level 2). It is observed that for all the above subtlety-level images, the proposed method performs equally with the existing algorithm.

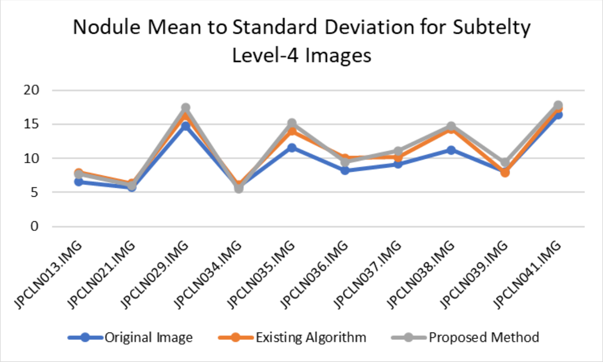

Fig. 13. Comparison between nodule MSR of original image, MSR of budapest bone shadow eliminated images dataset and MSR of proposed method for subtlety level-4.

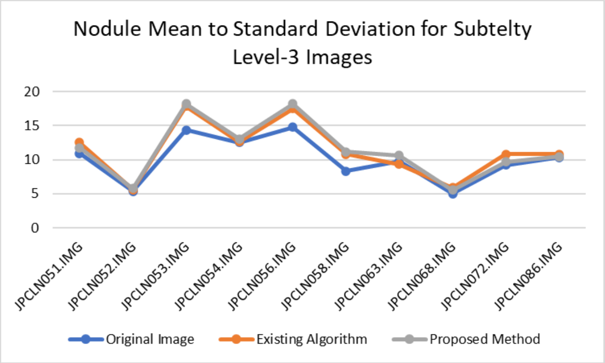

Fig. 14. Comparison between nodule MSR of original image, MSR of budapest bone shadow eliminated images dataset and MSR of proposed method for subtlety level-3.

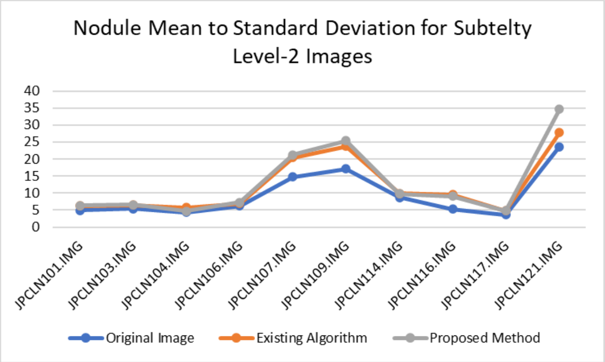

Fig. 15. Comparison between nodule MSR of original image, MSR of budapest bone shadow eliminated images dataset and MSR of proposed method for subtlety level-2.

For all three image quality measures, the proposed method performs over and above the existing algorithm. The ROI for evaluation in Test-3 was the nodule area, including its surroundings.

VI. Conclusion

The proposed work of bone suppression on chest radiographs using proposed method (CWAMO) achieves the goal of enhancing the accuracy of nodule detection in the chest radiographs. The first experimental setting, known as Test-1, uses chest radiograph images with modest levels 5 to 2 to detect actual positive nodules with an accuracy of 89%. This results in a significant reduction in the number of false positive nodules found in each image. During Test-2, the peak signal-to-noise ratio (PSNR), the mean-to-standard deviation ratio (MSR), and the universal image quality index (IQI) are analyzed for the entire image and compared with existing algorithm. The suggested technique performs better than the existing algorithm across all three parameters. Test-3 calculates the nodule MSR and then compares it to the Bone Shadow Eliminated Dataset created by Budapest University as well as the original chest radiographs. When compared to the existing bone shadow eliminated dataset, the new algorithm achieved an improvement in nodule area contrast of 3.83% and 23.94% shadow. This strategy results in an improvement in the visibility of nodules on chest radiographs. In conclusion, the utilization of CWAMO not only eliminates the shadow that is cast by the ribs on the chest radiograph, but it also assists in the localization of the nodules that are obscured by the shadows cast by the bones on the chest radiograph.

AUTHORS' PROFILE

Dnyaneshwar Kanade Research Scholar, School of Engineering and Technology, Sandip University, Nasik, India. He received the B.E. degree in Electronics Engineering from the Savitribai Phule Pune University (Formerly University of Pune), in 1996 and the M.E degree from Babasaheb Ambedkar Marathwada University, Aurangabad, in 2007. He has 3 Granted Patents on his name. He has published many papers in national and international journals. His research interest includes biomedical signal and image processing, Embedded System Design and IOT. He is a Lifetime member of Indian Society for Technical Education (ISTE).

Dr. Jagdish Helonde Professor, Department of Electrical & Electronics Engineering, School of Engineering and Technology, Sandip University, Nasik, India. He received the B.E. degree in Electrical Engineering from the Govt. College of Engineering, in 1981 and the M.Tech degree from VNIT Nagpur in 1983. He obtained Ph.D. degree in Electrical Engineering from RTM Nagpur University, Nagpur, India in 2002. He has a teaching experience of 40 years. He has guided more than 10 Ph.D scholars. He has published three patents. He has presented 14 papers in National Conferences and 34 in International Conferences. He has published 52 papers in international journals. His research interest includes biomedical signal and image processing, energy management, statistical signal processing, non-conventional energy sources etc. He is a Lifetime member of Institution of Engineers (India) and Indian Society for Technical Education (ISTE).

Disease Identification in Crop Plants based on Convolutional Neural Networks

***Abstract*—The identification, classification and treatment of crop plant diseases are essential for agricultural production. Some of the most common diseases include root rot, powdery mildew, mosaic, leaf spot and fruit rot. Machine learning (ML) technology and convolutional neural networks (CNN) have proven to be very useful in this field. This work aims to identify and classify diseases in crop plants, from the data set obtained from Plant Village, with images of diseased plant leaves and their corresponding Tags, using CNN with transfer learning. For processing, the dataset composing of more than 87 thousand images, divided into 38 classes and 26 disease types, was used. Three CNN models (DenseNet-201, ResNet-50 and Inception-v3) were used to identify and classify the images. The results showed that the DenseNet-201 and Inception-v3 models achieved an accuracy of 98% in plant disease identification and classification, slightly higher than the ResNet-50 model, which achieved an accuracy of 97%, thus demonstrating an effective and promising approach, being able to learn relevant features from the images and classify them accurately. Overall, ML in conjunction with CNNs proved to be an effective tool for identifying and classifying diseases in crop plants. The CNN models used in this work are a very good choice for this type of tasks, since they proved to have a very high performance in classification tasks. In terms of accuracy, all three models are very accurate in image classification, with an accuracy of over 96% with large data sets.**

***Keywords*—CNN; identification; models; pathogen; plant; classification; machine learning**

I. Introduction

The identification and classification of plant diseases is essential for agriculture, as the presence of pathogens can cause significant damage and reduce production [1]. Some of the most common diseases include: root rot, which is caused by fungi that attack the roots of the plant; powdery mildew, which is caused by fungi that affect the leaves and flowers of the plant; mosaic, which is caused by viruses that affect the growth and appearance of the leaves of the plant; leaf spot, which is caused by bacteria that affect the leaves of the plant; and fruit rot, which is caused by fungi or bacteria that affect the fruit of the plant [2], [3]. It is important to identify the disease as early as possible to take measures to combat it, either by fungicide treatments or traditional measures that help prevent the spread of the disease. Since ancient times, agriculture has been an important source of food [4], hence the importance of identifying diseases and being able to treat them, since diseases are the cause of a great loss of crop production, since about 36% of crops are lost because of not identifying diseases at early stages [5]. Early-stage identification of plant diseases can greatly reduce their considerable impact. This involves the use of computer technology in agriculture to help identify these diseases [6]. ML technology has proven to be useful in plant disease identification. One specific technique that has proven to be effective is transfer learning (TL) supported by CNN [7]. The idea behind TL allows models to leverage what they have previously learned to improve their performance on new tasks [8]. CNNs can be used to identify plant diseases by analyzing plant images. The CNN is trained on a labeled image dataset, where labels correspond to different types of diseases [3], [9]. During the training process, the CNN learns to recognize patterns in the images that are indicative of a particular disease. Once trained, the CNN can be used to classify new plant images as carrying or not carrying a particular disease [10]. This approach can be very effective in identifying plant diseases, as it allows the use of visual information, which can be very useful in identifying certain types of diseases that may not be evident from other types of data [11]. In this work we use the transfer learning models: DenseNet-201, ResNet-50 and Inception-v3. DenseNet-201 is a CNN with 201 layers deep. ResNet-50 is a CNN with 50 layers deep; Inception-v3 is a CNN with 48 layers deep. The models work with their own training architecture; therefore, they deliver different results. The models have been trained with Google's ImageNet dataset. Both models are characterized by training with large volumes of images and achieving a high level of accuracy [12]. This is due to their ability to learn specific image features through convolution and pooling layers [13], [14]. However, the specific performance of a model depends on several factors, such as the quality and quantity of training data, model architecture, and parameter optimization. This work aims to identify and classify crop plant diseases from PlantVillage dataset, diseased plant leaf images and their corresponding labels, using CNN with Transfer Learning.

II. Related Work

Lately, researchers and scientists related to the agricultural industry and computer science have conducted different studies related to plant diseases using ML techniques, specifically with CNN. For example, in [15] they developed a model to detect, quantify the severity and classify plant images in different species. To illustrate this, in [16] they developed a hybrid application with web technology and CNN models to detect plant diseases in real time. The model used in the web application achieved an accuracy performance rate of 0.9935 for which they used 9914 training arguments. Also, in [17], [18] implemented a CNN for automatic identification and classification of weeds using a mixed crop land, this model was trained in five different epochs; 10k, 20k, 100k, 200k and 242k images, with the purpose of automatic identification and classification of diseases. The results achieved for each epoch: in 10k the weed accuracy reached 0.67; in 20k the weed accuracy reached 0.962; in 100k the accuracy reached 0.983; in 200k the accuracy reached 0.95 and in 242k the accuracy improved significantly. Similarly, the authors in [18], [19] proposed a model for classifying disease affected leaves, for which they used images and obtained directly from cotton crop fields. They used the CNN DarkNet-19, which obtained a performance rate in accuracy of 0.91. Plant diseases directly affect food security, thus decreasing production. The identification of these diseases is the first important step for their treatment. That is why, in [20] they developed a mobile application with CNN to diagnose in real time 26 diseases of 14 crop species. It was validated and tested with 87k images, divided into 38 classes. The model achieved a classification accuracy of 0. 957. Similarly, in [21] they proposed a CNN with EfficientNet model to identify and classify images with diseases into categories. The model obtained an optimal performance rate of 0.9972 accuracy. Also, in [22] through the ResNet-50 model they classified diseases, applying CNN techniques for image prediction. In the same line, [23] used computer vision and ML technology to detect diseases in field crops. The proposed model achieved an accuracy of 0.978 in detecting four crop plant diseases. CNNs have contributed significantly to the detection of plant pathogens. As such, in [24] performed a work with CNNs using different optimization algorithms for detection. They used 5571 manually collected images, the model achieved an accuracy performance of 0.9259. Image recognition through ML is an active area by scientists and researchers. For example, in [25] they proposed a semi-automatic algorithm to detect diseases in crop plants, making use of CNNs. They used the KijaniNet model, who achieved an accuracy performance of 0.8448 and 0.6257.

III. Methodology

This section presents the theoretical basis of the DenseNet-201, ResNet-50 and Inception-v3 models and the development process to identify and classify crop plant diseases. For this purpose, initially the image dataset of infected and healthy plants, collected from PlantVillage, is loaded. This is followed by data cleaning, exploratory analysis and then training and validation of the model using the CNN architecture, which is particularly well suited for image recognition tasks.

A. CNN Architecture

The architecture of a CNN consists of several layers, including input layers, convolution layers, pooling layers, fully connected layers, and an output layer. For this case, the input layer is where the input image is provided to the CNN. Convolution layers perform filtering operations on the input data, using filters that are slid over the image to detect specific patterns. Pooling layers reduce the dimensionality of the data by grouping values from a subregion of the image and replacing them with a single value, such as the maximum or average value. The fully connected layers are used to classify the patterns detected in the previous layers. The output layer provides the final predictions of the CNN, as shown in Fig. 1. In general, CNNs are used for computer vision tasks.

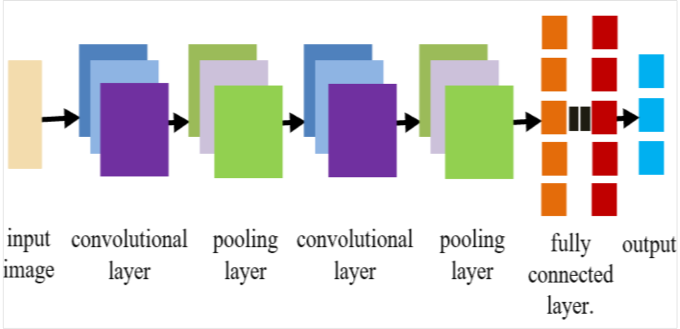

Fig. 1. CNN architecture.

B. Convolutional Layer

A convolution layer is a layer in a CNN that performs filtering operations on the input images. The layer is composed of a set of filters, each of which is slid over the input image and applied to a subregion of the input image [26]. Each filter looks for specific patterns in the image, such as edges or textures [27]. A filter is a small matrix of numbers that is multiplied with the image pixels in a specific window, and the products are summed. In general, convolution layers are used to detect patterns in the input data and to extract relevant features from these data.

C. Activation Functions

In CNNs, the activation function is a mathematical equation that is defined at the output layers of a neuron before being sent to the next layers of the network. The activation function aims to regulate the output of a neuron, allowing the network to learn more complex patterns [28] [29]. Some commonly used activation functions are: Sigmoid, ReLU, tanh and Softmax. Each activation function has its own characteristics and advantages, and the choice of the appropriate activation function depends on the specific problem and data set.

D. Pooling Layer

A network layer in a CNN architecture that is used to group a set of inputs into similar groups. This is achieved through the use of clustering algorithms. Pooling layer is commonly used in unsupervised learning tasks [30], such as image segmentation.

E. Fully Connected Layer

It is known as the densely connected layer. In this layer, all neurons are connected to all neurons in the previous layer, and this layer is part of a neural network layer [31]. In other words, each neuron in a fully connected layer receives an input from each neuron in the previous layer and produces an output that is passed to each neuron in the next layer. Fully connected layers are commonly used in neural networks for tasks such as image classification and natural language processing.

F. Reducing Overfitting

The overfitting technique was applied to reduce the complexity of the model and to regulate and thus prevent the model weights from becoming too large. For this case dropout was used in the neural network layers [32]. This is for the purpose of optimizing performance since overfitting is a common problem in ML in which a model is overfitted to the training data and, as a result, may exhibit performance deficiency.

G. Transfer Learning

TL is a process in which knowledge acquired in one task is used to improve performance in a different task. It is a form of ML in which the model reuses what it has learned to improve its performance rate on another task [33]. TL is especially useful in ML as it allows models to leverage what they have previously learned to improve their performance on new tasks; the process of TL is seen in Fig. 2.

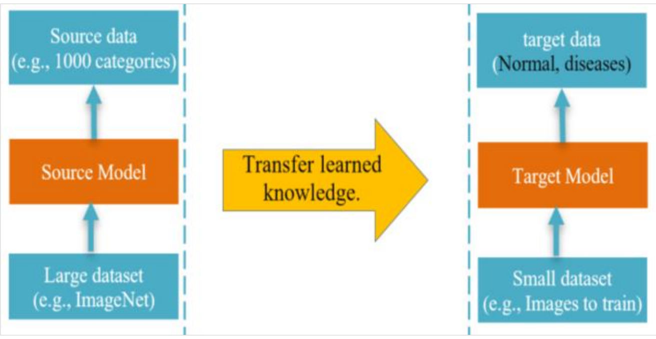

Fig. 2. Transfer learning process.

H. Model architecture

Three models were trained with images with and without disease. Each of the models used in this work is described below.

I. DenseNet-201

DenseNet-201 is characterized by the use of dense blocks, which are layered blocks in which each layer is connected to all other layers in the block [27]. This allows feature reuse and helps mitigate the problem of leakage gradients that can occur in deep neural networks. The number "201" refers to the number of convolutional layers in the network. The model architecture is shown in Fig. 3.

J. ResNet-50

ResNet-50 is a variant of the CNN ResNet. The key innovation of the ResNet-50 is the use of residual connections, which allow the network to create new residual functions for input to the layers, rather than attempting to learn the original unreferenced functions [34], this helps mitigate the problem of gradient loss that can occur in deep neural networks [30] [35]. The main use of this network is in image classification. The number "50" refers to the number of layers as presented in Fig. 4.

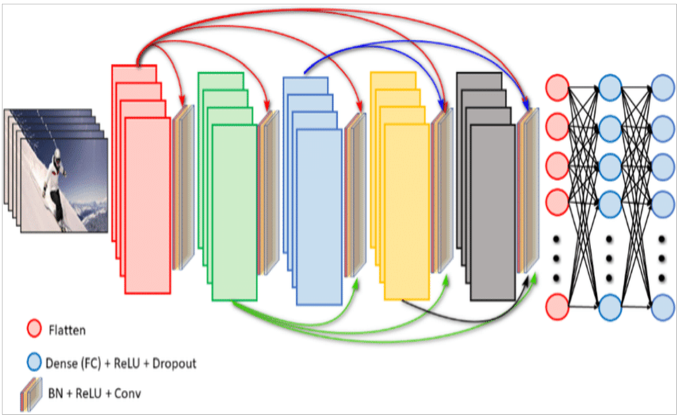

Fig. 3. Architecture of the DenseNet-2021 model.

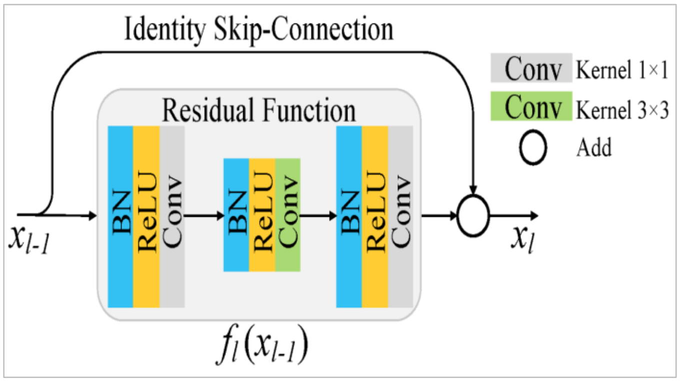

Fig. 4. ResNet-50 architecture.

K. Inception-v3

Inception-v3 is a CNN designed for object recognition in images. It uses a combination of filter layers of different sizes and depths to capture features at different scales and levels of abstraction in the input images [36] [37]. The architecture, as depicted in Fig. 5, includes an "Inception" mechanism that combines multiple filtering operations in a single layer to reduce the number of attributes and improve computational efficiency. Inception-v3 has been trained on a large set of images (ImageNet) and has been widely used in different cases of image classification and identification, object recognition, object detection, etc.

L. Understanding Data

There are a variety of diseases that affect plants, among the most common are: Mildew: caused by fungi that appear as white spots on the leaves; powdery mildew: caused by fungi that appear as a kind of powder on the leaves; Rust and Mosaic: are two diseases that are caused by fungi or insects that cause spots and deformations on the leaves, as shown in Fig. 6. These diseases can be treated with fungicides and pesticides. Also, it is important to take preventive measures such as good ventilation or good soil drainage. In this work we used an original dataset, obtained from the PlantVillage repository, and this is composed of approximately 87 thousand images of healthy and diseased crop leaves that are organized in 38 different categories. For training and validation the dataset is divided in a proportion of 80% for training and 20% for validation, and then a directory with 33 test images is created for prediction purposes.

The image set is composed of 38 disease types. Each of the diseases associated with the plant types is described below: [Tomato with blight, healthy tomato, healthy grape, orange with virus, healthy soybean, healthy peach, pumpkin with downy mildew, healthy potato, corn with blight leaf, young tomato with blight, tomato with leaf spot, strawberry with frost, apple with scab, tomato with yellow leaf, healthy cherry, healthy blueberry, healthy corn, tomato with bacterial spot, rotting apple, cherry with downy mildew, healthy apple, peach with bacterial spot, royal apple, tomato with objective spot, healthy bell pepper, grape with blight, tomato with mosaic virus, potato with blight, healthy strawberry, black rotten grape, early potato with blight, common corn, beetle grape, healthy raspberry, tomato with mildew, tomato with spider mites, bell pepper with bacterial spot].

From the types of diseases described above, the name of 14 plants is obtained, excluding healthy leaves: [corn with gray leaf spot, corn with rust, corn with fever, healthy potato, rice with leaf spot, potato with fever, healthy corn, potato, healthy rice, healthy rice, rice with hispa, rice with leaf blast, healthy wheat, young potato, red brown wheat and red yellow wheat] and 26 types of images with disease. With this, we proceed to import the dataset; then we process and perform an exploratory analysis, train the DenseNet-201, ResNet-50 and Inception-v3 models and then apply the optimizers.

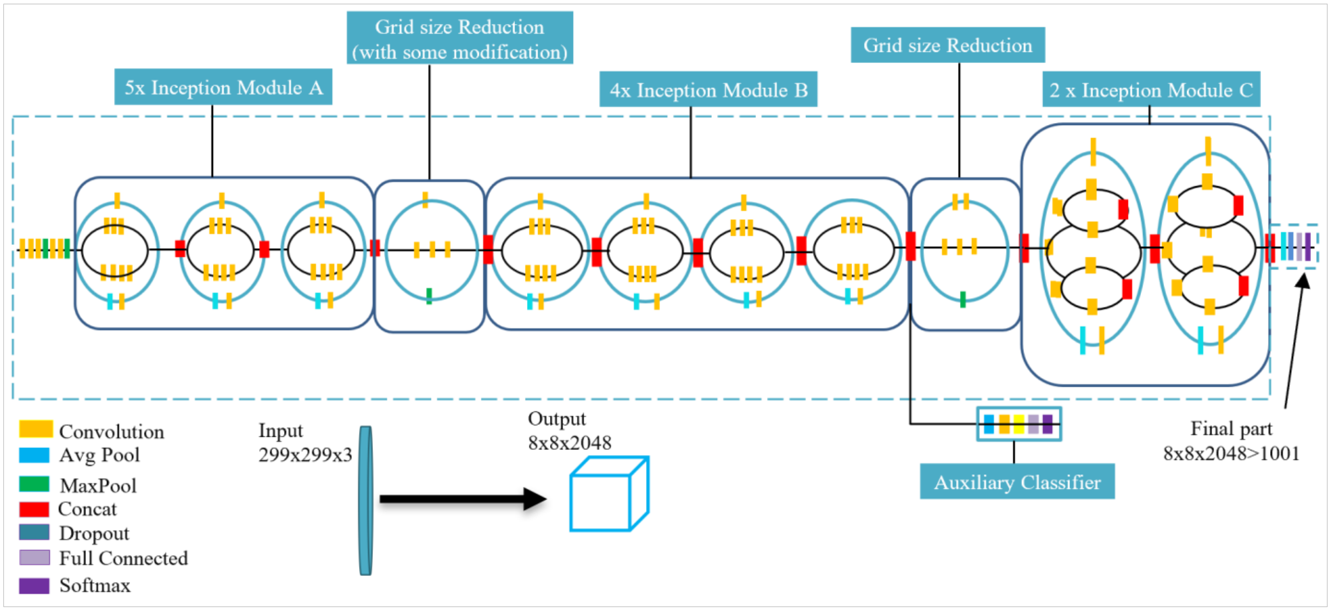

Fig. 5. Architecture of Inception-v3.

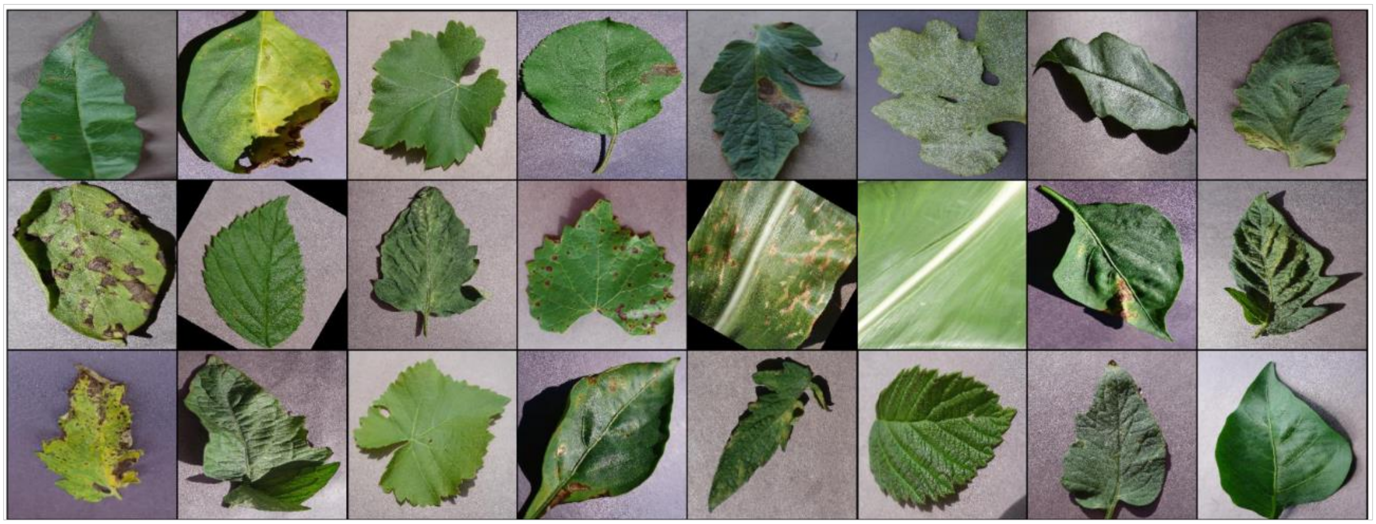

Fig. 6. Images for training.

M. Data Cleaning and Processing

The cleaning and processing process are important tasks in data analysis. Cleaning involves reviewing the data to detect and correct errors, duplicates, and missing values. Data processing involves transforming the data into a more suitable format for analysis, such as grouping, combining, or creating new variables. These tasks are essential to ensure that the results of the analysis are accurate and reliable. For the development of this work we used tools and libraries such as: the Python programming language, libraries such as numpy: for numerical calculations; pandas: to work with data frames; the pytorch module; matplotlib: to process information in graphs and images using tensors; torch.nn: to create neural networks; torch. utils.data: to load data; PIL: to load images; torch.nn.functional: function to calculate loss; torchvision.transforms: to transform images into tensors; torchvision.utils: for data verification; torchvision.datasets: to work with classes and images and torchsummary: to get the model summary.

N. Exploratory Data Analysis

Exploratory data analysis (EDA) is a process of investigating data using statistical tools and visualizations. The main objective of EDA is to understand the structure and distribution of the data, as well as to detect patterns and trends. EDA is an essential step in the data analysis process, as it provides a better understanding of the data before applying statistical and ML techniques. It can include techniques such as histograms, boxplots, scatterplots, among others, to visualize the data and detect patterns and trends. In addition, EDA can also help identify problems in the data, such as outliers or missing values, and make decisions on how to clean and process them before continuing with the analysis. Table I and Fig. 7 show the number of images for each disease.

The next step is to prepare the data for model training, this step is critical to ensure that the model performs optimally. This may include tasks such as normalization, scaling, transformation, and splitting into training and test sets. It is also very important to ensure that the data is in the correct format and is representative of the production data to avoid problems such as overfitting. It is at this stage that libraries become relevant, for example, torchvision.datasets(), is used to load the image dataset. After loading the data, the pixel values of each image (0-255) are transformed to 0 - 1, since CNNs understand much better when the data is normalized. The pixel matrix is converted to a torchTensor and then divided by 255. For example, the image can have the following form (3,256,256), where 3 is the number of channels (RGB) and 256x256 is the width and height of the image. Also, we have the batch_size library (), it allows to count the total number of images given in the CNN input. For example, if we have 1500 image samples for training and we need to set up a batch size of 150 samples from the training dataset, then what the network does is to randomly take the 150 samples and retrains the network, this process continues until all the samples in the network are propagated. Similarly, dataLoader (), the Liberian dataLoader that comes with PyTorch load data in parallel from the dataset. It also provides a convenient way to iterate over the dataset, in small batches, with the ability to shuffle the data before each epoch with the option to use multiple threads for data loading. This library is also accompanied by the num_workers function, which allows to calculate the number of processes that generate batches in parallel. Another very important point is in the configuration, the variable 'shuffle=true', this is very important so that the batches between epochs do not resemble each other.

TABLE I. NUMBER OF IMAGES PER DISEASE

Disease	No. of images
tomato blight	1851
healthy tomato	1926
healthy grapes	1692
orange greening	2010
terveellistä soijaa	2022
Squash mildew	1736
Potato healthy	1824
Northern Corn	1908
Tomato early	1920
Tomato with spots	1745
corn with leaf spot on leaves	1642
strawberry leaf with virus	1774
Peach healthy	1728
apple with scab on leaves	2016
Tomato with yellow leaves due to virus	1961
tomato with bacterial spot	1702
black apple	1987
Blueberry healthy	1816
Moldy cherry	1683
Peach with bacteria	1838
Apple Cedar	1760
tomato target point	1827
Healthy peppers	1988
grapes with leaf spot	1722
potato with Tizon	1939
tomato with virus	1790
Healthy strawberry	1824
Apple healthy	2008
rotten grapes	1888
young pope	1939
Cherry healthy	1826
Corn Common	1907
Grape black	1920
Healthy raspberry	1781
Tomato with mushroom	1882
Tomato with mites	1741
Bell pepper with bacterial spots	1913
Young corn	1859

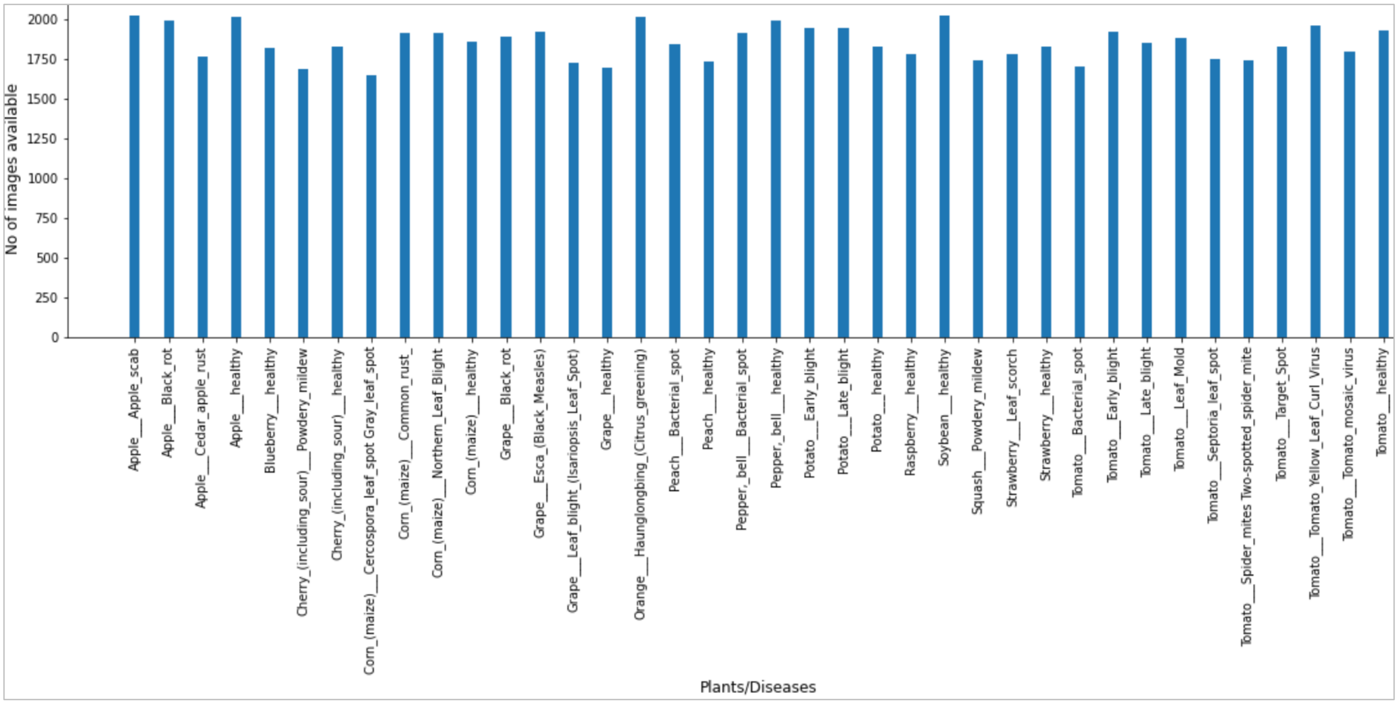

Fig. 7. Images for each type of plant disease.

O. Training and Testing of the Model

For the model training process, we worked with the training data set, in this case 80% of the images in the data set. During model training, the internal parameters were adjusted to minimize the loss function between model predictions. The training ends when it reaches a certain level of accuracy or when it reaches the maximum number of iterations. Meanwhile, to test the models, we worked with the difference of the training data set (20%). This stage is very important, since the aim is to evaluate the model's capability and to measure its accuracy. For which the following metrics were used, such as accuracy, recall Score-F1 and the performance curve (ROC). It is important to point out that both the training and testing processes are performed on different datasets, and another dataset was also used for validation. For training we chose to use GPUs instead of CPUs, considering that the volume of data is large, and a CPU is not able to respond to the demands, and GPUs are optimized to perform such tasks, as they can process multiple calculations simultaneously. In addition, they have a large number of cores to perform calculations and handle large amounts of data, which makes the memory bandwidth of a GPU the most suitable. Also, functions that help with the training are used, such as: Training_step(): this was used to find out how erroneous the model turned out to be after training. This function is not only an accuracy metric, but is necessary for the model to improve during training; Validation-setp(): this function is used to measure the accuracy across the threshold and is counted if the difference between the model prediction and the actual label is less than the threshold; Validation_epoch_end(): is used to track losses in validation accuracies and training losses after each epoch. However, it must be ensured not to be tracking the gradient; Epoch_end(): Used to print the validation accuracy losses and training losses and the learning rate after each epoch. We also use the accuracy function to calculate the overall accuracy of the models in the batch of the results. For example, in Fig. 8, we can see the training summary of the ResNet-50 model using Keras.

Fig. 8. ResNet-50 model training summary.

In the training process, some functions that are very useful should be taken into account, such as evaluate (), a function used for the validation process, and the function fit_one_cycle(), a function that performs the entire training process. Some techniques were also used such as: 1) Learning Rate Scheduling: allows using a learning rate after each training, instead of using a fixed rate; 2) Weight decay: regulation technique that prevents the weights from becoming too large to add a term to the loss function; 3) Gradient Clipping: this technique allows limiting the values of the decays to a small range to avoid undesired changes in the parameters due to large decay values, it is a simple but very effective technique. After training the models, the confusion matrix of each model is constructed, as in the case of the ResNet-50 model shown in Fig. 9. The confusion matrix is very important, since it helps to understand and compare the predicted data with the real data; however, for a better understanding, four basic concepts must be known: true and false positives and true and false negatives. That is, true positives and true negatives are simply the hits, while false positives and false negatives are the misses. This tool is important since it allows visualizing the performance of each of the models. Each column represents the number of predictions of each class, while the rows represent the actual values. Finally, the hits and misses are placed in each of the cells, Fig. 10, we can see a confusion matrix of 15 x 15, because we have 15 classes of plants. In the main diagonal we have the hits (true positives and true negatives) and in the remaining cells the number of misses (false positives and false negatives). Now, with the confusion matrix constructed, the performance of each model can be seen in detail, such is the case of the resNet-50 model in Fig. 9. This process is repeated for the other models (DenseNet-201 and Inception-v3).

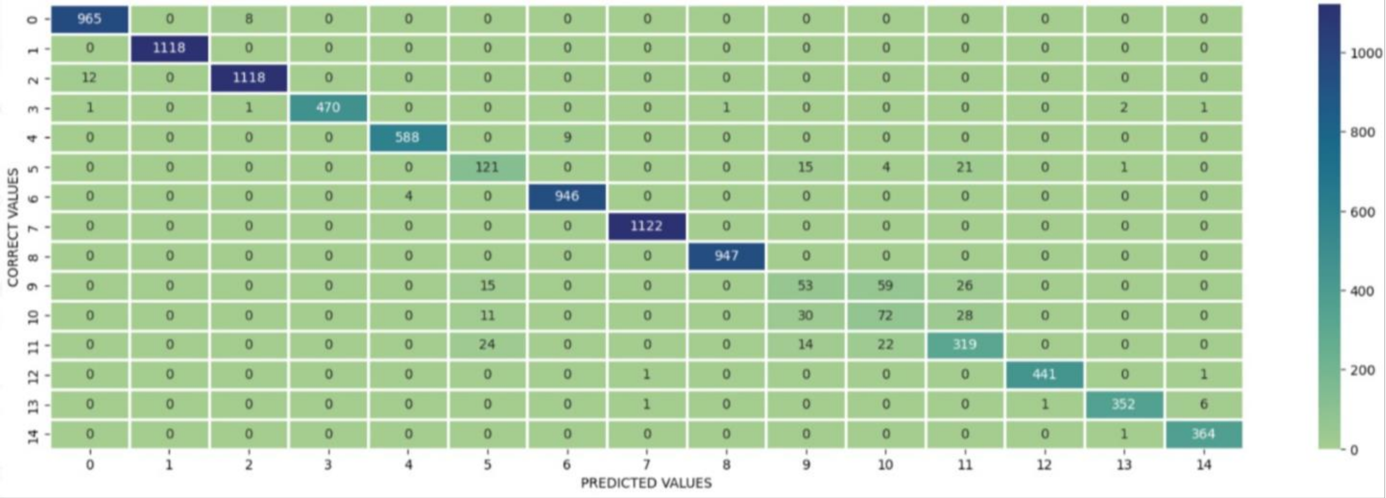

Fig. 9. Confusion matrix of the ResNet-50 model.

IV. Results and Discussion

This section presents the training results of the DenseNet-201, Inception-v3 and ResNet-50 models. For which an original dataset, obtained from the PlantVillage repository, was used, and is composed of approximately 87 thousand images of healthy and diseased crop leaves. The performance of each of the models is subject to the following metrics such as accuracy, precision, recall, F1 score and ROC curve as presented in Table II. The results of the DenseNet-201, Inception-v3 and ResNet-50 models vary depending on the dataset and the specific tasks they perform, as shown in Table II.

Table II shows that the DenseNet-201 and Inception-v3 models achieved better performance in image classification, showing slightly better accuracy than ResNet-50. In terms of accuracy, DenseNet-201, has been characterized as one of the best models for image classification, and it is thanks to its density block design that allows greater propagation of information between layers and better feature extraction. However, the DenseNeet-201 model is usually slower due to its larger number of parameters. On the contrary, the ResNte-50 and Inception-v3 models are faster due to their efficient design. A very important point to take into account is the available computational power and memory limitations. Fig. 10, Fig. 11 and Fig. 12 show the performance of the models. For example, in Fig. 10, graph (Results Loss), shows the performance of the loss and accuracy of the DenseNet-201 model, the blue line represents the training data and the red line the test, as can be seen in the first two epochs the error decreases very significantly, then the error decreases as it goes through the epochs or iterations, and in turn makes the comparison with the test data, however, as it progresses the two lines are separated, this means that it is entering an over fit, ideally the two lines should be joined. With respect to the graph (Results Accuracy) in Fig. 10, which is the result of the Accuracy, it is also evident that from the second epoch there is a very significant increase of hits, and from the third epoch onwards it has been improving its accuracy, however, the red line as the epochs progress is separating from the blue line, which is what should not happen, because it means that the test data are separated from the training. Similarly, it can be seen in Fig. 11, graph (Results Loss), shows the loss and accuracy performance of the ResNet-50 model, the blue line represents the training data and the red line the test, as can be seen in the first two epochs the error decreases very significantly, and progressively decreases the error as it advances the iterations in the epochs, and in turn makes the comparison with the test data, however, as it advances the iterations the two lines are separated, this means that it is entering in an over adjustment, the ideal is that the two lines are joined. With respect to the graph (Results Accuracy) of Fig. 11, it is the result of the Accuracy, it is also evident that from the first epoch there is a very significant increase of hits, and from the second epoch it has been improving its accuracy, however, the red line as it advances the iterations of the epochs is separating from the blue line, it is what should not happen, because it means that the test data is separated from the training. Similarly in Fig. 12, graph (Results Loss), the performance of the loss and accuracy of the Inception-v3 model is presented, where the results are very similar to the Densenet-201 and ResNet-50 models. And with respect to the graph (Results Accuracy) of Fig. 12, is the result of the Accuracy, its performance of this model is very similar to the Densenet-201 and ResNet-50 models, these similarities are seen in Fig.12 graph (Results Accuracy).

TABLE II. MODEL EVALUATION RESULTS

DenseNet-201				
	accuracy [%]	recall [%]	f1-score [%]	support
accuracy			0.98	9316
macro avg	0.93	0.93	0.93	9316
weighted avg	0.98	0.98	0.98	9316

ResNet-50				
	accuracy [%]	recall [%]	f1-score [%]	support
accuracy			0.97	9316
macro avg	0.89	0.89	0.89	9316
weighted avg	0.96	0.97	0.97	9316

Inception-v3				
	accuracy [%]	recall [%]	f1-score [%]	support
accuracy			0.98	9316
macro avg	0.93	0.93	0.93	9316
weighted avg	0.98	0.98	0.98	9316

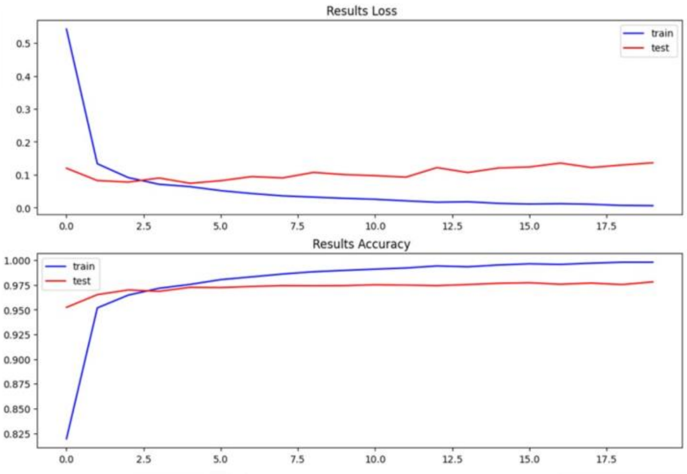

Fig. 11. Comparison of results of the ResNet-50 model between loss and accuracy.

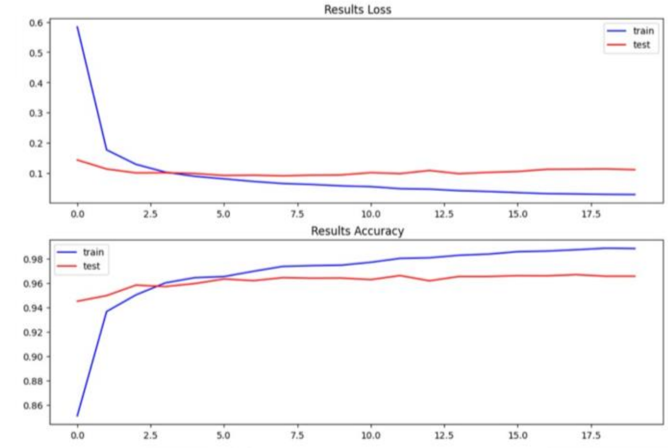

Fig. 12. Comparison of results of the Inception-3 model between loss and accuracy.

The results presented in Table II, Fig. 10, Fig. 11 and Fig. 12, allow an analysis of the performance of each of the trained models (DenseNet-201, ResNet-50 and Inception-v3). In general terms, the performance of the three models has been successful in the identification and classification of diseases in crop plants. For example, the DenseNet-201 model achieved an accuracy of 98%, slightly higher than the performance of the ResNet-50 model. This result is superior to that obtained in [20] where they used this model to classify images, it is important to specify that the accuracy rate will depend on different factors, such as the volume of data with which it was processed, as in [18] where this model achieved an accuracy of 99%, higher than the result obtained in this work. The ResNet-50 model achieved an accuracy level of 97%, slightly lower than the performance of the DenseNet-201 and Inception-v3 models. However, the level obtained does not mean that the model has weaknesses in identifying and classifying images; on the contrary, 97% accuracy is significantly very good. Considering that, for example in [24] this model obtained an accuracy of 92%, it is also considered an optimal rate for its level of accuracy, in [22], [23] used this model for image prediction where it reached an accuracy level of 97.8%, slightly higher than that obtained in this work. This indicates that the performance of the model varies depending on the volume of the data set and the quality of images, among other factors. With respect to the Inception-v3 model, in this work it reached an accuracy level of 98% as shown in Table II, slightly higher than the ResNet-50 model, the Inception-v3 model is characterized by having multiple filters and kernel sizes in each layer, it is a lighter model than DenseNet-201 and ResNet-50, it has fewer parameters, which makes it ideal for identifying and classifying diseases in planes through artificial vision. The level of accuracy obtained is considered optimal, considering that it is close to 100%, this model also obtained a good performance in [16], where it reached an accuracy of 99% in the classification of images of different species, slightly higher than that obtained in this work. Similarly, in [17] they used this model to identify and classify weeds using mixed cropland, where it reached an accuracy level of 92%, a figure much lower than that obtained in this work. However, this does not mean that the model does not perform well in these tasks; on the contrary, the accuracy will depend on the volume of data and the quality of images with which it is processed. Finally, the three models used in this work have achieved optimal performance and accuracy in the process of identification and classification of diseases in crop plants. It is important to point out that the DenseNet-201 and Inception-v3 models obtained the best results in accuracy with 98%, so they would be a viable alternative in technological terms for the identification of diseases in crop plants.

V. Conclusion

The three CNN models (DenseNet-201, ResNet-50 and Inception-v3) used in this work have demonstrated an effective and promising approach, being able to learn relevant features from the images and classify them accurately. A dataset consisting of more than 87 thousand images of healthy and diseased crop leaves, categorized into 38 different categories, was used. For the purpose of identifying and classifying crop plant diseases, using CNN with Transfer Learning. The performance of each of the models was analyzed, as shown in Table II, Fig. 10, Fig. 11 and Fig. 12. The models used are characterized by excellent performance in image identification and classification. For example. The DenseNet-201 and Inception-v3 models achieved an accuracy of 98% in the identification and classification of plant diseases, slightly higher than the ResNet-50 model, but this does not mean that the ResNet-50 model does not have an optimal performance, on the contrary, it achieved 97% accuracy. Likewise, Fig. 11 (Results Loss) shows the training results of the DenseNet-50 model, where it is evident that the blue line from the second iteration drastically reduces the error and progressively decreases as the iterations advance in the epochs. However, at the end it separates from the red line, this is not good for the prediction, because it is an indication of an over adjustment to a greater number of iterations. In the case of Results Accuracy, it is also evident that from the second epoch onwards there is a very significant increase in accuracy, and from the third epoch onwards its accuracy has been improving. The ResNet-50 model in Fig. 12 and the Inception-v3 model in Fig. 12 have a very similar behavior to the DenseNet-201 model.

Finally, the DenseNet-201 and Inception-v3 models achieved the best results in the identification and classification of diseases in crop plants; therefore, they are the two models that are recommended for implementation for this type of task. In the future, a possible complement to this work would include the development of a mobile application so that the implemented model can be consumed.

Automatic Detection of Oil Palm Growth Rate Status with YOLOv5

Desta Sandya Prasvita, Dina Chahyati, Aniati Murni Arymurthy
Faculty of Computer Science, University of Indonesia, Depok, Indonesia

***Abstract*—Oil palm plantations are essential for Indonesia as a source of foreign exchange and a provider of employment opportunities. However, large-scale land clearing is considered a cause of deforestation, which harms the environment and society. So, it is necessary to manage plantations that are sustainable and still maintain the preservation of forests and biodiversity. One solution is to apply remote sensing technology. The research was conducted to develop a multi-class detection method for the growth rate of oil palm trees, with five categories: healthy palm, dead palm, yellowish palm, mismanaged palm, and smallish palm. The deep learning-based object detection method, YOLO Version 5 (YOLOv5), is used. This study compares the YOLOv5 network models, namely YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. Parameter setting is also carried out in the BCE (Binary Cross Entropy) with Logits Loss Function to handle the problem of unbalanced data distribution in each class. The YOLOv5 model with the highest mAP value is the YOLOv5l and YOLOv5x, the YOLOv5x requires longer training time. In this study, hyperparameter optimization was also carried out using hyperparameter evolution techniques. However, it has yet to provide increased results because the experiments conducted in this study are still limited.**

Keywords*—*Automatic detection; deep learning; oil palm; YOLOv5

I. INTRODUCTION

Palm oil consumption has witnessed a growth of approximately 9% annually in the last decade, and it is anticipated to rise further. This optimistic outlook for the palm oil industry is attributable to its increasing demand in domestic and global markets. Since 2004, the use of palm oil has occupied the highest position, with an average growth of 8% per year. In Indonesia, oil palm serves as a plantation commodity that has an important role in the economy as a source of foreign exchange and a provider of employment. Indonesia is also the world's largest palm oil producer [1]. Oil palm plantations, despite their positive impact on the economy, are often associated with negative impacts that can harm society, such as environmental degradation and conflicts with local communities. [2]. Oil palm plantations are considered a cause of deforestation that can damage biodiversity, with 2% of Indonesia's forests being turned into plantation areas [3]. Based on the background and problems related to oil palm plantations, especially in Indonesia, it is necessary to manage oil palm plantations sustainably so as not to harm the community. That is with an agricultural system oriented towards economic, social, and ecological balance. With proper agricultural practice and technology, it is believed that oil palm plantations will continue growing, with environmental sustainability maintained. Precision agriculture aims to optimize the use of resources to achieve the best results while protecting the environment with land management systems [4].

Remote sensing technology has been widely used in mining, agriculture, and plantations. This technology can be used for remote monitoring of plantation areas. Monitoring plantations manually by human labor is difficult, especially in oil palm plantations in Indonesia characterized by large plantation areas and difficult access. Methods for obtaining optimal results for detecting individual trees have also been developed. Based on previous research, three groups of approaches are used for tree detection. The three methods are classical digital image processing [5] [6] [7] [8], classical machine learning [9] [10], and deep learning. The tree-detection-based deep learning approach is divided into an approach based on CNN classification [11] [12] [13] [14] [15] [16] and another approach based on object detection [17] [18] [19] [20]. The first approach is based on classical digital image processing. There are four main stages to a classical digital image processing-based approach: image pre-processing, treetop detection, tree crown delineation, and post-processing. In the classical machine learning-based tree detection approach, feature extraction is required, which is then trained to build a classification model. The classification model is used to detect trees in images using the sliding window technique. The third approach is based on deep learning for tree detection. Deep learning methods are currently popular for object detection because of their object detection accuracy.

There are advantages and disadvantages to each technique for oil palm tree detection. The classical digital image processing approach has the advantage that it does not require a training process for the construction of classification or detection models that require high and expensive computational costs. Another advantage is the time it takes to detect quickly. However, this classic digital image processing approach has a weakness. It is not easy to use to detect, especially in the case of overlapping trees. On the other hand, the classic machine learning approach has the advantage of seeing overlapping trees. However, accuracy depends on the feature extraction used. Another weakness is that, while the detection process generally uses a sliding window technique, it takes a long time to detect trees. In addition, the sample size of the training image must have been determined when constructing the classification model. In contrast, the objects we detected were of various sizes both the classical machine learning approach and the deep learning approach using the CNN classification-based method share similar advantages and disadvantages. However, the CNN classification-based method does not necessitate feature extraction and has demonstrated superior performance. In contrast, the deep learning method based on object detection can detect objects that overlap with different trees or objects of various sizes and has a much faster detection process. This approach only requires a training process, which is costly and expensive in the computation, especially in cases with many classes.

From the background of the problem, multi-class detection with a deep learning method based on object detection in oil palm trees is state-of-the-art and still has exciting challenges. Zheng et al. [19], in their research, carried out multi-class detection of the growth rate of oil palm trees, with five categories: healthy palm, dead palm, yellowish palm, mismanaged palm, and smallish palm. However, it still has sub-optimal performance and needs improvement. One is the still low F1-score for the dead palm and mismanaged palm classes, namely 43.24% and 44.59%, respectively. The reason for this is that the class contains a relatively small sample of data compared to the quantity of data available in other categories. This study developed a research method based on the work of Zheng et al. to improve the detection results on the growth status of oil palm trees. Zheng et al. have published training datasets, which were used and compared in this research. This research has developed a model that utilizes YOLOv5 for detecting the growth status of oil palm trees, a technique that has already demonstrated success in detecting date palms [17] and tree damage [20]. This study has made several notable contributions, including: 1) utilizing the YOLOv5 method to detect tree growth status, 2) addressing the issue of unbalanced class distribution by adjusting the parameter of BCE with Logits Loss, and 3) conducting hyperparameter optimization experiments for YOLOv5.

II. Literature Review

In the development of deep learning methods based on object detection, such as R-CNN [21], R-CNN [22], faster R-CNN [23], and YOLO [24], the detection process increases in terms of both speed and accuracy. Therefore, an object detection-based deep learning approach is the state-of-the-art approach of this research. There were three primary references used in this study. The first was a research study conducted by Zheng et al. In this research, we developed a model to detect the growth rate of oil palm trees, categorizing them into healthy palms, mismanaged palms, smallish palms, yellowish palms, and dead palms. The data used was derived from unmanned aerial vehicle (UAV) images of oil palm plantation areas in South Kalimantan and Papua, Indonesia. The features in the UAV image data were red, green, and blue (RGB) features. There were five classes: dead palms, healthy palms, mismanaged palms, smallish palms, and yellowish palms. The method for detecting oil palm trees is called Multi-Class Oil Palm Detection (MOPAD). There are three main modules in MOPAD. The first module is the Refined Pyramid Feature (RPF) Module for feature extraction, including four steps: rescaling, integration, refinement, and disintegration. The second is the Multi-Level Region Proposal Network (RPN) with faster R-CNN to generate oil palm candidates. The third is the Hybrid Class-Balanced Loss Module to improve the detection of multi-class palm oil using Class-Balanced Cross-Entropy Loss (CBCEL) and Class-Balanced Smooth L1 Loss (CBSLL). An evaluation was carried out using the evaluation metrics recall, precision, and F1-score. Regarding the achieved performance, this study has produced in detecting oil palm trees at two sites, with F1-scores of 87.91% and 99.04%, precision values of 92.42% and 98.90%, and recall values of 83.82% and 99.19% [19]. However, the detection of multi-class oil palm trees was still low, with an average F1-score of 72.83% and with the most frequently detected classes being dead palms and mismanaged palms. A few challenges persisted in this study, one of which was the low F1-scores in detecting the growth of oil palm trees.

The latest object detection method widely used is YOLO. This method outperforms faster R-CNN in terms of detection speed. YOLOv5 was successfully implemented to detect tree damage due to snowfall automatically. The study utilized image data captured using drone technology from southeastern Norway, featuring RGB channels. The built model was then validated using precision (P), recall (R), $mAP@0.5$, and $mAP@[0.5,0.95]$ accuracy metrics. The validation results for P, R, $mAP@0.5$, and $mAP@[0.5,0.95]$ for all classes were 0.62, 0.61, 0.65, and 0.37. In this research, we employed the YOLOv5 method to detect tree damages caused by snow, which has not been attempted in previous studies. Furthermore, our findings demonstrate that YOLOv5 is capable of addressing the challenge of class imbalance, particularly when the percentage of damaged and dead trees is considerably lower than that of healthy trees. [20].

The YOLOv5 method was also applied to automatically detect date palms using drone imagery [17]. The data for the study were obtained using drones on agricultural land in the United Arab Emirates. The research experiment was carried out by comparing several versions of the YOLOv5 network, including YOLOv5s (small), YOLOv5m (medium), YOLOv5l (large), and YOLOv5x (extra-large). The initial model weights were the pre-training weights from training on the COCO dataset to recognize 80 classes, which were then adjusted for hyperparameters to obtain optimal parameters. The hyperparameter tuning method used was to use a genetic learning algorithm. The test results showed that YOLOv5 had a higher mAP value than SSD300, YOLOv3, and YOLOv4. The detection speeds of YOLOv5s, YOLOv5m, and YOLOv5l were also higher than those of SSD300, YOLOv3, and YOLOv4, but YOLOv5x had the longest average detection time. The YOLOv5 method, recognized for its speed, is an efficient object detection approach that surpasses other CNN-based methods such as R-CNN, fast R-CNN, and faster R-CNN in terms of speed.

This study developed a research method based on the work of Zheng et al. to improve the detection results on the growth status of oil palm trees. Zheng et al. have published training datasets, which were used and compared in this research. This research built a model for detecting the growth status of oil palm trees using YOLOv5, which has been successfully applied in detecting date palms and tree damage.

III. Method

This research went through three main stages: 1) data preparation, 2) development of the YOLOv5 model, and 3) model testing. The data used were the image data provided in a study by Zheng et al. During the data preparation stage, we regenerated the data and separated it into three parts: training data, validation data, and testing data. In the training phase, we concurrently utilized the training and validation data. We employed the training data to construct the model, while the validation data was used to test the model at each iteration and determine the best possible model. In the testing phase, we tested the model created during the training stage using the testing data and performed an evaluation. Fig. 1 illustrates the stages of the research methods.

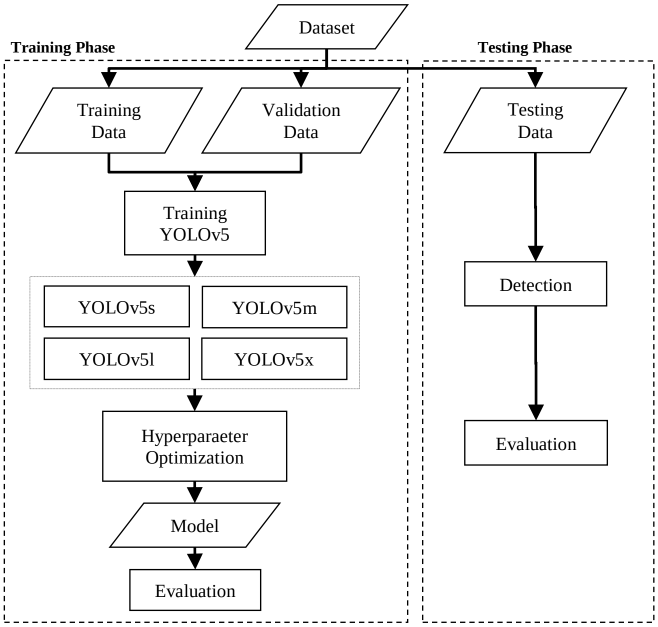

Fig. 1. Research method.

A. Data and Preparation

The dataset used in this study was composed of data from previous studies [19], available at https://github.com/rs-dl/MOPAD. The data acquisition location was Papua, Indonesia (140◦29′ 17′′E, 6◦57′ 42′′S), and the data acquisition was executed using a Skywalker X8 air bridge and a Sony a6000 camera. A spatial resolution of 8 cm with three RGB bands was used. This area had various types of land cover, such as oil palm plantations, rivers, buildings, other vegetation, etc.

For further processing for the development of the YOLOv5 model, the data obtained is carried out at the data preparation stage, namely data regeneration and reformatting. There were 2,303 image data, each measuring 1,024 x 1,024 pixels. Data regeneration was performed using the roboflow online tool. There were three stages in data regeneration: train/split test, pre-processing the data by scaling, and generating YOLOv5 format compliant data. In the train/test split process, the data were divided into training, validation, and testing data, each totaling 1,600 data, 135 data, and 136 data (70%, 15%, and 15%). The rescaling process resized the data from 1,024 x 1,024 pixels to 416 x 416 pixels. Next, necessary formatting adjustments were made to YOLOv5.

TABLE I. THE NUMBER OF IMAGES FOR TRAINING, VALIDATION, AND TESTING DATA

Type	Training Data	Validation Data	Testing Data	Total
Healthy palm	79,988	17,453	17,401	114,842
Dead palm	193	45	57	295
Mismanaged palm	407	68	51	526
Smallish palm	24,486	4,832	4,721	34,039
Yellowish palm	1,339	270	275	1,884
Total	106,413	22,668	22,505	151,586

The dataset included annotations of oil palm trees classified into five labels based on their growth rate. Specifically, the study detected five growth stages of oil palm trees, including dead palms, healthy palms, mismanaged palms, smallish palms, and yellowish palms. Overall, the dataset contained 151,586 oil palm tree annotations for all classes. Table I shows the number of annotations for each category and training, validation, and testing data.

B. The YOLOv5 Network Architecture

The object detection neural network architecture consists of three main components: the backbone extracts image features, the neck incorporates the features extracted from the previous layers, and the head predicts object classes and bounding boxes. The YOLOv5 architecture can be seen in Fig. 2.

YOLOv5 has many key components in each part of its networks, such as focus, Conv (convolution), C3, and Spatial Pyramid Pooling (SPP). The focus module divides the input image into four parallel slices (S) to create a feature map using the convolution module. The convolution module is a basic module that uses convolution operations combined with batch normalization and a leaky-ReLU activation function for feature extraction. The C3 module is designed based on a Cross-Stage Partial (CSP) connection network that is used to improve model learning capabilities. The backbone model uses the SPP module for mixing and unifying spatial features. It down-samples the input features through three parallel max pooling layers and then aggregates them to the featured initial.

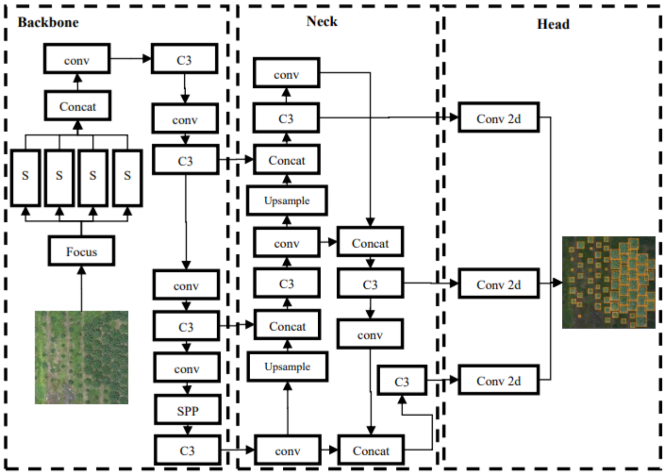

Fig. 2. The network architecture of YOLOv5.

C. Dealing with Imbalanced Data

An imbalance in class distribution can lead to the model better at predicting classes with more data and worse at predicting classes with fewer data. The dataset used in this study has a highly unbalanced distribution. Fig. 3 shows that the healthy oil palm class had a wide data distribution, as marked with a yellow bar. However, there was very little data on yellowish, mismanaged, and dead palm classes depicted in red bars.

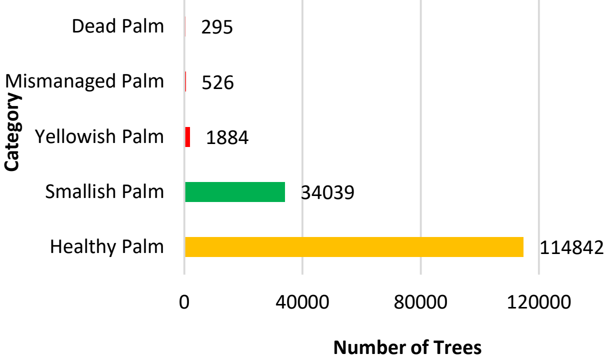

Fig. 3. Data distribution for each class.

The loss function for objectivity in YOLOv5, class probability, was calculated using BCE with Logits Loss Function. The parameters in BCE with Logits Loss were adjusted to overcome the problem of the unbalanced proportion of data in the class. Setting BCE with the Logits Loss parameter made trading of recall and precision possible by adding weight to positive examples. In the case of multi-label classification, the loss ($l_c(x,y)$) can be explained in equation (1).

$$l_c(x,y) = l_c = \{l_{1,c}, \dots, l_{N,c}\}^T,$$
$$l_{n,c} = -w_{n,c} p_c y_{n,c} . log\sigma(x_{n,c}) + (1 - y_{n,c}) . \log 1 - \sigma xn, c \quad (1)$$

Where c is the class number, n is the sample size in the batch, and p_c is the weight of the positive for class c. For example, if the data set contains 5 positive and 200 negative examples of a class, then the pos_weight for that class must equal $\frac{200}{5} = 40$. The loss will act as if the data set contains 40×5=200 positive examples [25].

D. Training the Network

Model training was performed utilizing transfer learning from pre-trained weights of 100 epochs trained on the large Common Objects in Context (COCO) dataset. The pre-trained model was trained to recognize 80 types of objects. The training was carried out for 300 epochs to train the model to recognize objects corresponding to the dataset's five oil palm growth status categories. At each epoch, validation data were executed using the $mAP@[0.5,0.95]$ evaluation metric value. The best model was chosen with the highest $mAP@[0.5,0.95]$ value. The training image data input size was 416 x 416 pixels, with a batch size of 32.

This research built training models for four different versions of YOLOv5, namely, YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. The difference between the four YOLOv5 versions lies in the number of feature extraction modules in the convolution layer. YOLOv5s has the least feature extraction modules and kernels, and YOLOv5x has the highest feature extraction and kernels. The bigger the model, the better the result, but it has more parameters, requires more CUDA memory, and takes longer to train.

YOLOv5 has around 30 hyperparameters which are used for various training settings. In addition to using hyperparameters in the pre-trained model COCO dataset, this research also optimized the hyperparameters. A hyperparameter tuning process was carried out using hyperparameter evolution [26]. Hyperparameter evolution is a powerful optimization method that uses a genetic algorithm (GA) to optimize hyperparameters in various stages. The first stage is hyperparameter initialization, which utilizes the default parameters of YOLOv5 COCO. The second stage is defining fitness, where the objective function is set to measure how well the model performs. The third stage is evolution, where the GA is utilized to find the optimal set of hyperparameters. Finally, the visualization stage provides a graphical representation of the optimization process. The metric evaluation value of $mAP@[0.5,0.95]$ determines the fitness value. The number of evolutions performed is 300, with each epoch being 10. Visualizations are performed to evaluate the evolution results. Considering the cost of the YOLO training process, the model used for hyperparameter evolution in this study was YOLOv5s only.

E. Evaluation

The model was tested using both validation and testing data. Validation data was used during each epoch of the training process to test the model, while testing data was used to evaluate the final YOLOv5 model. Testing of the object detection model was carried out using the mean average precision (mAP) evaluation metric. The mAP is the average precision (AP) in all detected classes. The AP value is only for each category. The average of 11 interpolation points on the precision-recall curve was calculated to obtain the AP value. According to the 2017 COCO challenge evaluation guidelines, mAP was calculated by the average AP over 80 object classes and all 10 IoU thresholds from 0.5 to 0.95 with a step size of 0.05, i.e., $mAP@[0.5,0.95]$. The calculation of the mAP value can be seen in equations (2) and (3).

$$mAP = \frac{1}{n}\sum_{k=1}^{n} AP_k\,,\ where\ \ n = the\ number\ of\ classes \quad (2)$$

$$AP_k = the\ AP\ of\ class\ k \quad (3)$$

To obtain the AP value, precision and recall values were needed to build a precision-recall curve. Precision is the ratio of the correct prediction for positive data compared to the overall positive predicted result. The precision value can be calculated using the following equation, TP (true positive) is the positive data correctly predicted to the positive class, and FP (false positive) is predicted as an object but false. The precision value can be obtained by using equation (4).

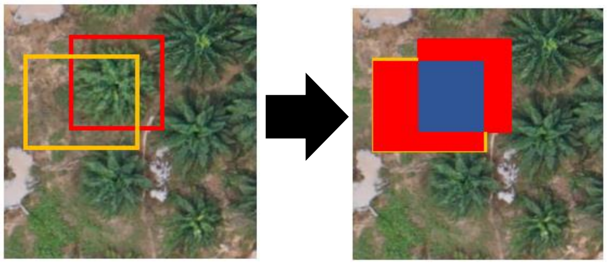
$$Precision = \frac{TP}{TP+FP} \quad (4)$$

A recall is the ratio of true positive predictions to the total number of correct positive data. The recall value can be calculated using the following equation, TP (true positive) is the positive data correctly predicted to the positive class, and FN (false negative) incorrectly predicts the object there. The recall value can be obtained using equation (5).

$$Recall = \frac{TP}{TP+FN} \tag{5}$$

In object detection, TP and FP values are determined using the IoU value. The IoU value is used as the threshold. If the IoU threshold value is 0.5, and the IoU value for a prediction is 0.7, then the prediction result is expressed as TP. Meanwhile, if the IoU threshold is 0.3, it is expressed as FP. Equation (6) is used to calculate the IoU value. An illustration of the calculation of the IoU value can be seen in Fig. 4.

$$IoU = \frac{Area\ of\ Overlap}{Area\ of\ Union} \tag{6}$$



(a) (b)

Fig. 4. Illustration of calculation of IoU value; (a) The ground truth; (b) The red color is the area of overlap, and the blue area is the area of union.

The expected model is a model with high precision and recall values. Therefore, the ideal to measure the model is F1-Score. Mathematically it can be expressed in equation (7).

$$F_1 = 2 * \frac{Precision*Recall}{Precision+Recall} \tag{7}$$

IV. Results and Discussion

A. BCE with Logits Loss Setting Parameters

One positive class weight vector was chosen as the parameter to manage imbalanced classes in the BCE with Logits Loss function. Positive classes were the class categories in the dataset that you want to detect, namely, the healthy, smallish, yellowish, mismanaged, and dead palm classes. The formula for determining class weight vectors can be seen in equation (8), where c is the detected object category. The number of positive classes is the amount of data in class c, and the number of negative classes is the amount of data in classes other than class c.

$$pos\_weight[c] = \frac{number\ of\ negative\ classes}{number\ of\ positive\ classes} \tag{8}$$

Table II provides the result of setting the BCE with Logits Loss parameter and its calculations.

TABLE II. BCE with Logits Loss Parameter Setting

Class	Count	BCEWithLogitsLoss Setting
Healthy Palm	114842	$\frac{34039+1884+526+295}{114842} = 0.32$
Smallish Palm	34039	$\frac{114842+1884+526+295}{34039} = 3.45$
Yellowish Palm	1884	$\frac{114842+34039+526+295}{1884} = 79.46$
Mismanaged Palm	526	$\frac{114842+34039+1884+295}{526} = 287.19$
Dead Palm	295	$\frac{114842+34039+1884+526}{295} = 512.85$

To set the BCE with the Logits Loss parameter in YOLOv5, it can be found in the file yolov5/utils/loss.py. There were two variables, namely BCEcls, and BCEobj. BCEobj was for objects or backgrounds, and BCEcls was for object classes. The parameter was defined in h['cls_pw'] by changing the value of the vector.

```
# Define criteria
BCEcls = nn.BCEWithLogitsLoss(pos_weight=torch.tensor([h['cls_pw']],
device=device))
BCEobj = nn.BCEWithLogitsLoss(pos_weight=torch.tensor([h['obj_pw']],
device=device))
```

The parameter was defined in h['cls_pw'] by changing the value of the vector as follows.

```
# Define criteria
BCEcls =
nn.BCEWithLogitsLoss(pos_weight=torch.tensor(torch.tensor([[512.,
287., 0.3, 3.5, 79]]), device=device))
BCEobj = nn.BCEWithLogitsLoss(pos_weight=torch.tensor([h['obj_pw']],
device=device))
```

B. Results of the Training Process

The training was conducted with two experiments to obtain the optimal model for detecting oil palm trees. The initial experiment employed a pre-trained model, whereas the subsequent one involved leveraging the evolution method to optimize hyperparameters. Notably, the training procedure was executed utilizing Google Colab Pro+.

- Training with Pre-Trained Default Models

The experiment in the training process was to compare all YOLOv5 networks, including YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. The training used 300 epochs with a batch size of 16. Table III compares evaluation metrics and training time for all YOLOv5 models.

YOLOv5l produced the highest mAP value among all YOLOv5 models, with $mAP@[0.5{,}0.95]$ of 0.90. Although the YOLOv5x model had a deeper network, it did not improve the results and even had the lowest average F1-score of 0.95. YOLOv5s, YOLOv5m, and YOLOv5l had a training time of 3 hours, and YOLOv5x had a training time of five hours with 300 epochs.

TABLE III. COMPARISON OF EVALUATION METRICS AND TRAINING TIME OF THE YOLOV5 MODEL

Model YOLOv5	P	R	mAP @$[0.5, 0.95]$	Average F1-score	Time
YOLOv5s	0.95	0.96	0.86	0.96	3.005 hours
YOLOv5m	0.95	0.97	0.89	0.96	3.185 hours
YOLOv5l	0.96	0.98	0.90	0.97	3.652 hours
YOLOv5x	0.95	0.95	0.90	0.95	5.550 hours

- Training with the Model by Tuning the Hyperparameter Evolution

Hyperparameter optimization experiments were carried out using the YOLOv5 model with the smallest network, namely, YOLOv5s. The number of evolutions used was 300, each using ten epochs. Fig. 5 is a visualization of the hyperparameter tuning process evolve. The yellow color indicates higher concentrations. The vertical distribution suggests that the parameter had been deactivated and not mutated.

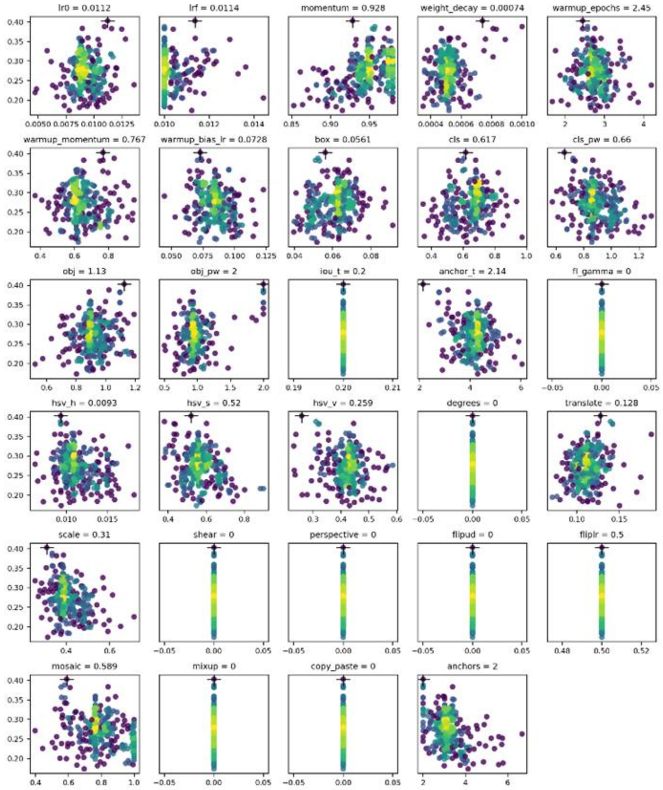


Fig. 5. Visualization of hyperparameter optimization results.

The evolved model did not improve yields compared to the default models. Fig. 6 compares the $mAP@[0.5,0.95]$ and F1-scores for detecting oil palm trees. The process of hyperparameters optimization with evolution required high costs, and evolutions required GPU processing that took days. In other words, some experimental limitations still existed at this stage, with a limited number of evolutions, namely, 300, and 10 epochs for each evolution.

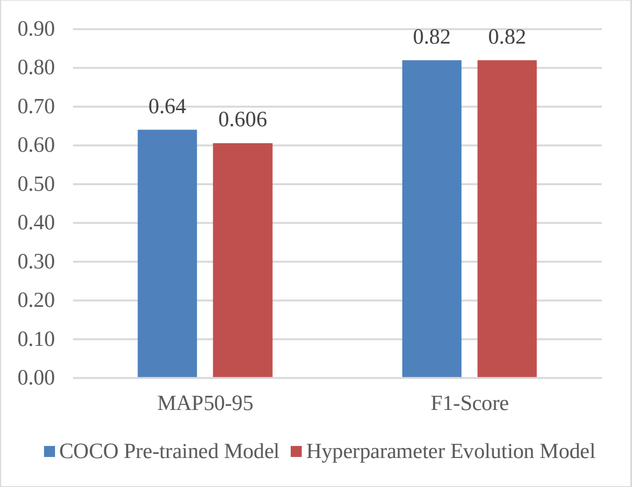

Fig. 6. Model comparison with hyperparameter evolution model and pre-trained models.

C. Model Testing Process

We compared the performance of YOLOv5 on small, medium, large, and extra-large networks using testing data. To evaluate the results, we used the F1-score and $mAP@[0.5,0.95]$ metrics on the testing data. The difference in F1 score, precisely in the mismanaged palm class, was quite far, with the lowest F1-score obtained using YOLOv5s. The F1-score for the mismanaged palm class increased significantly using YOLOv5l, in which case the increase amounted to 11.3%. Results showed that the detection of the mismanaged oil palm class had the lowest F1-score. The highest F1-score was found in the dead palm class using YOLOv5l. The F1-score comparison for each YOLO-v5 model can be seen in Fig. 7.

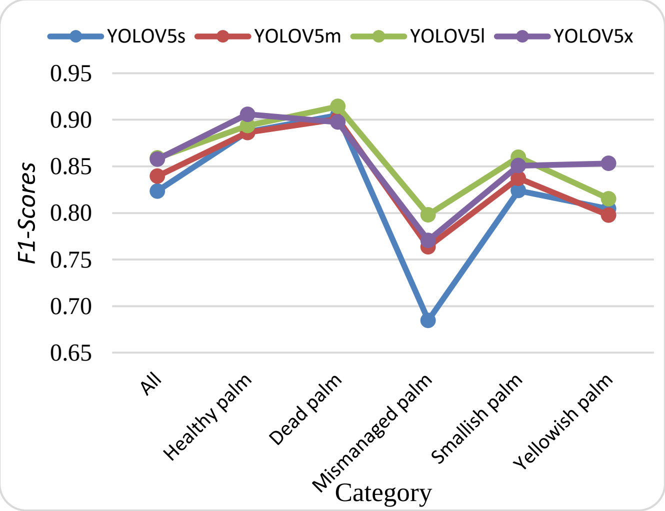

Fig. 7. Comparison of F1-Scores across YOLOv5 models.

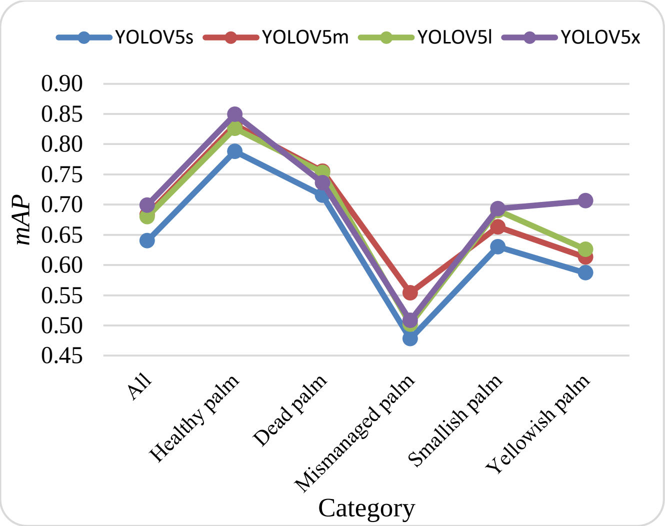

Fig. 8. Comparison of $mAP@[0.5,0.95]$ values across YOLOv5 models.

The comparison of $mAP@[0.5,0.95]$ for each YOLOv5 model can be seen in Fig. 8. The evaluation of the detection of oil palm growth rate showed that the model is suitable for detecting healthy oil palm trees. The highest $mAP@[0.5,0.95]$ value for the healthy palm oil class was 0.849, in which YOLOv5x was used. The class that was difficult to detect using YOLOv5 was the mismanaged oil palm tree class. The lowest $mAP@[0.5,0.95]$ value was 0.478, obtained with YOLOv5s, and the highest was 0.554, obtained with YOLOv5m. Detection of smallish and yellowish palms using YOLOv5 models was still difficult, but the $mAP@[0.5,0.95]$ values for these classes were better than that of the mismanaged class. For the dead palm class, the $mAP@[0.5,0.95]$ value was also quite good, which was above 0.7.

Based on the evaluation of $mAP@[0.5,0.95]$, the YOLOv5s model had the lowest scores for all classes. YOLOv5m, YOLOv5l, and YOLOv5x were in the range of $mAP@[0.5,0.95]$ evaluation values, which were not much different. YOLOv5x was sufficient to increase the value of $mAP@[0.5,0.95]$ by 0.04 compared to other YOLOv5 models. If we look at the results of the $mAP@[0.5,0.95]$ evaluation, using the YOLOv5 model with medium and large networks generated good detection results. Using the YOLOv5 extra-large network, there was not much increase in the detection results. Only the yellowish palm class saw a significant increase in the $mAP@[0.5,0.95]$ value by around 0.4.

D. Evaluation of Detection Results

The $mAP@[0.5,0.95]$ evaluation metric shows that the model was very good at detecting healthy palms and quite good at detecting dead palms. It can be seen in Fig. 9, an example of a randomly selected detected image. The detection results circled in red in Fig. 9(b), 9(c), and 9(d) are the results of mismanaged class errors (FP for mismanaged classes). The objects should have been detected as healthy oil palm trees but came out as ambiguous detection results. For instance, the objects were detected more than twice as mismanaged and healthy palms. The detection results for the mismanaged class also showed ambiguity in that one object was detected more than once, as shown in Fig. 9(a). A tree of the mismanaged palm class was detected more than once. As seen in the image with a yellow circle, the oil palm tree objects overlapped. False positive (FP) detection errors in the yellowish palm class can also be seen in Fig. 9. The yellowish class detection results are marked with a green box and a blue circle. Some objects should have been detected as members of the healthy palm class, but they were detected as part of the yellowish palm class instead. From the analysis of detection results, it was acknowledged that the model still had FP errors in detecting mismanaged and yellowish palms. From the characteristics of the image, it can be analyzed that FP errors in both the mismanaged and yellowish palm classes occurred in tree objects that overlapped each other.

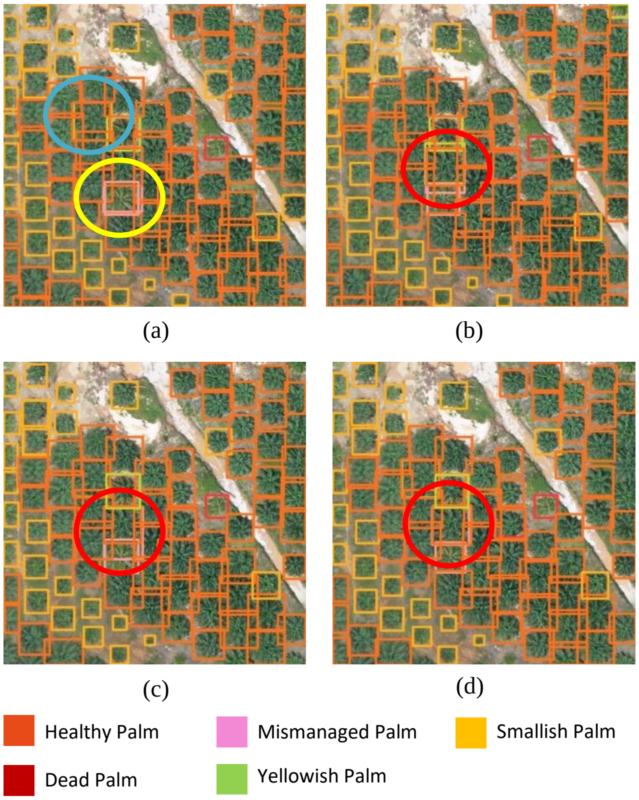

Fig. 9. Detection results for the first image sample: (a) YOLOv5s Model; (b) YOLOv5m Model; (c) YOLOv5l Model; (d) YOLOv5x Model.

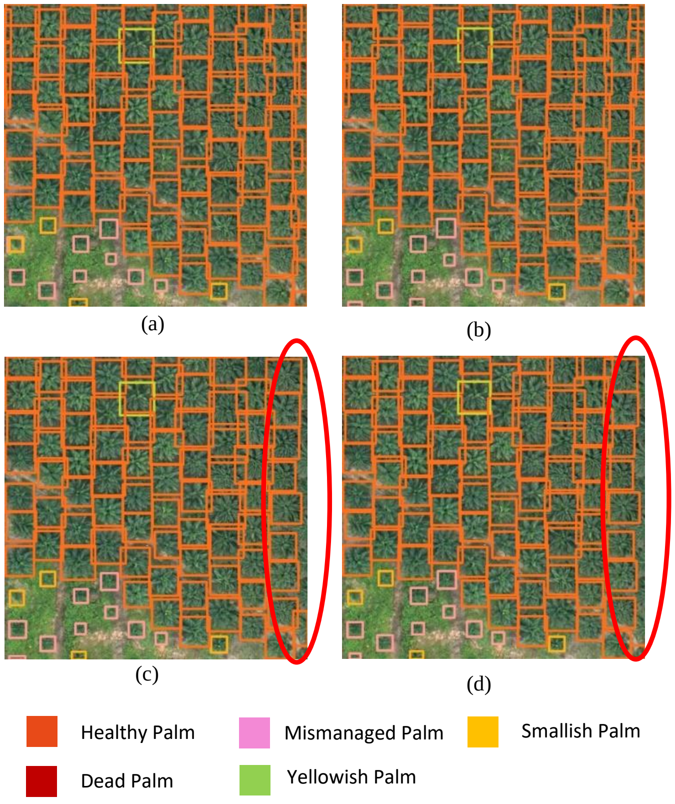
Fig. 10 is an example of another detection result; there were trees in the mismanaged palm category that did not overlap, which are marked with purple bounding boxes. In contrast to the previous image, this image provides precise detection results, where oil palm trees of the mismanaged palm class were successfully detected without any false positive (FP) detection. Fig. 10 also compares YOLOv5 in each network (small, medium, large, and extra-large). In the area marked with blue circles, YOLOv5s, and YOLOv5m showed FP in the healthy palm class, where the background was detected as healthy palms. The YOLOv5l and YOLOv5x models could improve the detection results, as the red circles show.



(a) (b) (c) (d)

Fig. 10. Detection results for the second image sample: (a) YOLOv5s model; (b) YOLOv5m model; (c) YOLOv5l model; (d) YOLOv5x model.

E. Comparison of the Proposed Method with Previous Research

A comparison between the method proposed in previous studies and YOLOv5 was made. In the research conducted previously by [19], the evaluation of detection results was carried out using the F1-score. Zheng et al. named the detection method MOPAD, with an average F1-score of 72%. In addition, they also conducted experiments with other methods, such as CNN and Faster R-CNN, with an average of 28% and 56% for the two methods. As seen in Table IV, this study has improved F1-score results even with the YOLOv5s network, with an average F1-score of 72%. The highest F1-score was obtained using YOLOv5x, with an average F1-score of 86%.

The highest average F1-Score is the YOLOv5x model, but the difference in the average F1-Score is only 1% compared to the YOLOv5l. The training time for the YOLOv5x model is longer than the YOLOv5l, with a difference in training time of about two hours. It can be seen in Table IV. The analysis results show that the best oil palm growth rate detection model is YOLOv5l. Besides having a faster training time, YOLOv5l outperforms its competitors in detecting five different classes related to the growth rate of oil palm trees. Specifically, three categories - dead palm, mismanaged palm, and smallish palm - achieve the highest F1-score with YOLOv5l. The evaluation of each class was as follows: healthy palms on YOLOv5x, dead palms on YOLOv5l, mismanaged palms on YOLOv5l, smallish palms on YOLOv5l, and yellowish palms on MOPAD.

TABLE IV. COMPARISON OF THE PROPOSED METHOD WITH PREVIOUS RESEARCH

Method	Healthy	Dead	Mis-managed	Smallish	Yellowish	Average F1-score
CNN (ResNet-101) [19]	0.75	0.07	0.03	0.36	0.19	0.28
Faster R-CNN [19]	0.90	0.06	0.42	0.66	0.74	0.56
MOPAD [19]	**0.91**	0.55	0.51	0.77	**0.88**	0.72
YOLOv5s	0.89	0.90	0.68	0.82	0.80	0.82
YOLOv5m	0.89	0.90	0.76	0.84	0.79	0.84
YOLOv5l	0.89	**0.91**	**0.80**	**0.86**	0.81	0.85
YOLOv5x	**0.91**	0.90	0.77	0.85	0.85	**0.86**

V. CONCLUSION

This study found several contributions, including: 1) The application of the YOLOv5 method for detecting the growth level of oil palm trees. 2) A comparison of the YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x models. 3) Handling unbalanced class distributions by setting positive class vector parameters in the BCE with the Logits Loss function. 4) Conducting experiments to optimize hyperparameters with evolutions.

Based on the experiments conducted in this study, the YOLOv5 model improved the results of detecting the growth level of oil palm trees. The highest F1-score was obtained with the YOLOv5x model, but it took the longest learning time. The YOLOv5l model is the best because the training time is shorter, and the difference in F1 scores is slightly smaller than the YOLOv5x model by 1%. In addition to outperforming other YOLOv5 models' F1-score, the evaluation results for each class show YOLOv5l achieved the highest F1-score for 3 out of 5 classes. The detection results showed that the model still had errors in predicting trees of the mismanaged and yellowish palm classes, and the FP value for overlapping trees was still relatively high.

Setting positive class vector parameters in the BCE with the Logits Loss function could solve the unbalanced class distribution problem; where there was an imbalance in the class distribution, there the imbalance was extreme. Still, adjusting BCE with Logits Loss function parameters could produce an evaluation value for each class that was still quite good. Hyperparameter optimization by evolutions required high costs, where the training process could take days to complete. This study was limited to hyperparameter optimization experiments on the YOLOv5s model with 300 evolutions and ten epochs for each evolution. The hyperparameter optimization with evolutions results did not show a significant increase in the model.

This study applied a deep learning method based on object detection, a state-of-the-art method in oil palm tree detection research. This research still faced challenges, especially in detecting multi-class oil palm trees. It is insufficient to only feature RGB images for detecting tree growth and health level, providing only color and texture information. To better detect the growth level of oil palm trees, it is advisable to add remote sensing sensors.

ACKNOWLEDGMENT

This research is partially supported by an internal publication grant from the Faculty of Computer Science, University of Indonesia.

***Abstract*—Sentiment analysis is an important part of natural language processing (NLP). This study evaluated the sentiment of Romanized Sindhi Text (RST) using a hybrid approach and ground truth values. The methodology of sentiment analysis involves three major steps: input data, process on tool, analysis of data and evaluation of results. One hundred RST sentences were used in this study's sentiment analysis, which can be positive, neutral, or negative. The statements in the corpus of this study are simple to understand and are used in everyday life. This research used an online Python tool to process a text and get results in the form of outcomes. The results showed that 86% of the sentences have neutral sentiments, 9% of the total results of sentiment analysis have negative sentiments, and only 5% of sentences of Romanized Sindhi Text have positive sentiments. The accuracy of the RST was measured on an online calculator and the value was 87.02% on the basis of ground truth values. An error ratio of 12.98% was calculated on the basis accuracy found on the online calculator of confusion matrix.**

***Keywords*—Sentiment analysis; natural language processing; hybrid approach; python tool; Romanized Sindhi**

I. INTRODUCTION

Sentiment analysis is the most important task of NLP, in which it analyses the community's opinions about social actions such as social media apps, academic activities, and technology [1, 2]. Sentiment analysis is the analysis of opinions about users [3, 4]. The principle part of artificial intelligence (AI) and man-made brainpower in NLP is to measure the content and investigate the importance of the content [5]. The information or text utilized for the Natural Language Processing looks like unstructured and organized information or text [6]. Text investigation is the cycle of changing unstructured content information over to organized content information as significant. Text examination utilized apparatuses for a few contents and measured factual information by utilizing artificial intelligence calculations [7]. Text investigation is additionally used to assess the client's assessment, and item audits with criticism are used to give a better reaction to future assignments. Text is utilized to recognize examples, and the fundamental thought of the examination comes from various wellsprings of data. Sentiment analysis is mostly used for the analysis of comments about any product or any other social activity [8, 9].

This research focused on the Romanization of Sindhi language by using hybrid model for the evaluation/analysis of sentiments. After the analysis of results on tool, author evaluates the results on the basis of ground truth / reality basis. The significance of this research study is to evaluate the results of tool and actual aim of the sentence in selected language.

Sentiment Analysis applied in this study project on 100 sentences of RST. Sentiment Analysis is done on the online Python tool and it may the result in Positive, Neutral and Negative Sentiments. After the task performed on tool, all sentiments were compared on ground truth values and accuracy was measured as 87.02%.

II. STRUCTURE OF ROMANIZED SINDHI TEXT

Structure of sentiment analysis of RST is same as English language [10]. The structure of Romanized Sindhi Text depend upon the three main attribute of grammar as like: subject à Verb à Object, same as like an English sentence [11]. The structure of Romanized Sindhi Text is easy to understand by the tool and it recognized the sentence by using above three attributes and it may give better output [12].

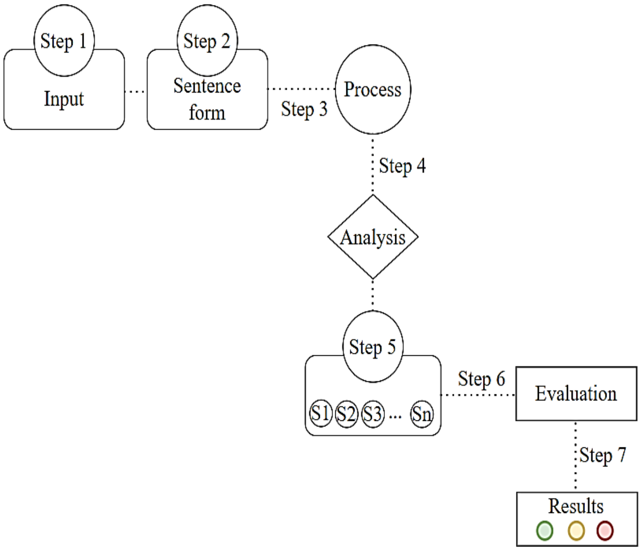

Fig. 1. Research methodology of sentiment analysis.

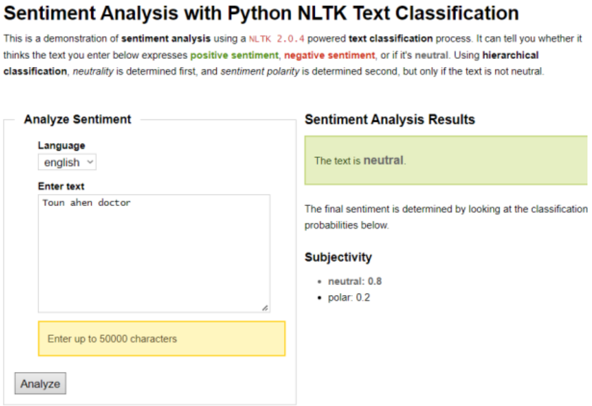
Fig. 1 show the methodology of sentiment analysis of RST depends on three major steps such as: Input data, Process on tool, analysis of data and evaluation of results. According to the first step of the methodology, input data is collected. The data in the RST is the input data in the form of sentences. After this step, the data is processed on a tool in the shape of sentences, but the sentences may be single or multiple. After the second step of processing, tool is to analyze the data and it may the output results in the shape of sentiments. These sentiments are positive, neutral and negative.

III. Analysis of Romanized Sindhi Text Analysis

One Hundred RST sentences were used in this study's sentiment analysis. A text's sentiment can be positive, neutral, or negative [13-15]. The statements in the corpus of this study are simple to understand. These sentences are used in everyday life. A data set is a fundamental element of research and is used as input towards the online Python tool (as shown in Fig. 2), which then processes a text and gets results in the form of outcomes. Sentiment analysis results, on the basis of ground truth value Data set of this research, is shown in below Table I.



Sentiment Analysis with Python NLTK Text Classification

This is a demonstration of **sentiment analysis** using a NLTK 2.0.4 powered **text classification** process. It can tell you whether it thinks the text you enter below expresses **positive sentiment**, **negative sentiment**, or if it's neutral. Using **hierarchical classification**, *neutrality* is determined first, and *sentiment polarity* is determined second, but only if the text is not neutral.

Analyze Sentiment

Language: english

Enter text:

```
Toun ahen doctor
```

Enter up to 50000 characters

Analyze

Sentiment Analysis Results

The text is **neutral**.

The final sentiment is determined by looking at the classification probabilities below.

Subjectivity

- neutral: 0.8
- polar: 0.2

Fig. 2. Input/output view of online Python tool.

TABLE I. Sentiment Analysis of Romanized Sindhi Sentence

#	Sindhi Sentence	Romanized Sindhi Sentence	Sentiment Analysis	Ground through value
1	تون آهين ڊاڪٽر	Toun ahen doctor	The text is neutral.	Neutral
2	مان آهيان شاگرد	Maa'n ahiyan shagrid	The text is neutral.	Neutral
3	مان کيڏان راند	Maa'n khedan rand	The text is neutral.	Neutral
4	مان پيان پاڻي	Maa'n piyan pani	The text is neutral.	Neutral
5	علي ماريو نانگ	Ali maryo nang	The text is neutral.	Neutral
6	ڊاڪٽر سڏيو مريض کي	Doctor sadiyo mariz khe	The text is neutral.	Neutral
7	هي آهي بدصورت	He ahy bad surat	The text is neg.	Negative
8	مان لکيو خط	Maa'n likhyo khat	The text is neutral.	Neutral
9	مان پڙهيو ڪتاب	Maa'n parhyo kitab	The text is neutral.	Neutral
10	تو ساڙيو گهر	Toun sadyo ghar	The text is neutral.	Negative
11	مان ڪيو ڪم	Maa'n kayo kam	The text is neutral.	Neutral
12	تو ٻڌو گانو	Toun budho gano	The text is neutral.	Neutral
13	حنا ٿوڙيو ڪلاس	Hina tourdyo glass	The text is neutral.	Negative
14	مان کوليو دروازو	Maa'n kholiyo darwazo	The text is neutral.	Neutral
15	مان سکي انگلش	Maa'n sikhi English	The text is neutral.	Neutral
16	تو ٿاهي چانهن	Toun thai chanhe	The text is neutral.	Neutral
17	تون آهين خوبصورت	Toun ahen khoubsorat	The text is neutral.	Neutral
18	تون آهين ڪنو	Toun ahen kino	The text is neutral.	Negative
19	آهين تون ٺيڪ	Ahen toun thek	The text is neutral.	Neutral
20	ڪتو ڀونڪي ٿو	Kuto bhonke tho	The text is neutral.	Neutral
21	مان لکيو آرٽيڪل	Maa'n likhyo article	The text is neutral.	Neutral
22	هتي ارام ويهه	Irum waihu hite	The text is neutral.	Neutral
23	مون کي آهي ڏک	Moun khe ahe dukh	The text is neutral.	Neutral
24	مان آهيان خوش	Maa'n ahiyan khush	The text is neutral.	Neutral
25	هتي سارا اُٺي بيهه	Sara uthee beehu hite	The text is neutral.	Neutral
26	تون آهين استاد	Toun ahen ustad	The text is neutral.	Neutral
27	مان سکان ٿي سنڌي	Maa'n sikhan thi Sindhi	The text is neutral.	Neutral
28	مان سکان ٿي ميٿ	Maa'n sikhan thi math	The text is neutral.	Neutral
29	علي ماريو واڳون	Ali maryo wagoon	The text is neutral.	Negative
30	ڪرسي علي ويهه تي	Ali waihu kursi te	The text is neutral.	Neutral
31	انعم اچ	Anam achu	The text is neutral.	Neutral
32	ڏاڍو خراب آهي بيڊ	Dadho kharab ahy bad	The text is neg.	Negative
33	گندگي آهي بيڊ تي	Gandagi ahy bad te	The text is neg.	Negative
34	مان آهيان استاد	Maa'n ahiyan ustad	The text is neutral.	Neutral
35	چا آهين تون ڊاڪٽر	Cha ahin toun doctor	The text is neutral.	Neutral
36	مان هلائي مشين	Maa'n halai machine	The text is neutral.	Neutral
37	انعم اچ ويهه هتي	Anam ach hite waihu	The text is neutral.	Neutral

#	Sindhi Sentence	Romanized Sindhi Sentence	Sentiment Analysis	Ground through value
38	مان وڃان ٿو اسڪول	Maa'n wanjan tho school	The text is neutral.	Neutral
39	آهين تونشاگرد	Ahin toun shagrid	The text is neutral.	Neutral
40	آهيان مان ڊاڪٽر	Ahyan Maa'n doctor	The text is neutral.	Neutral
41	هوءَ آهي استاد	Huoaa ahe ustad	The text is neutral.	Neutral
42	مون کي آهي ڪم لنڊن ۾	Moun khe ahe kam London maen	The text is neutral.	Neutral
43	تون رهين ٿو نواب شاهه ۾	Toun rahen tho Nawabshah maen	The text is neutral.	Neutral
44	تو کاڌو انب	Toun khado amb	The text is neutral.	Neutral
45	هوءَ ڊوڙي ٿي روڊ تي	Huoa dore thi road te	The text is neutral.	Neutral
46	مان ڪيان ٿي پسند پيزا	Maa'n kayan thi pasand pizza	The text is neutral.	Neutral
47	هي ڪري ٿو نظر انداز مون کي	He kre tho nazarandaz moun khe	The text is neutral.	Negative
48	هي آهي هوشيار	He ahy hushiyar	The text is neutral.	Positive
49	مان ڪيان ٿي پسند ڪيلا	Maa'n kayan thi pasand kela	The text is neutral.	Neutral
50	ڪيان ٿي مان پسند ڪيلا	Kayan thi Maa'n pasand kela	The text is neutral.	Neutral
51	مان کيڏان ٿي فٽ بال	Maa'n khedan thi football	The text is neutral.	Neutral
52	مان کيڏان ٿي ڪرڪيٽ	Maa'n khedan thi circket	The text is neutral.	Neutral
53	مان پڙهان ٿو ڪتاب	Maa'n parhan tho kitab	The text is neutral.	Neutral
54	تون مدد ڪندي منهنجي	Toun madad kande mounhje	The text is neutral.	Positive
55	تون هليو وڃ هاڻي	Toun halyo wanj hanne	The text is neutral.	Neutral
56	ۂ گهر ۾ بيڊ تي ڪچرو آهي	Kichro ahy bad te aen ghar mean	The text is neg.	Negative
57	بيڊ کي ٿوڙين ٿو	Torin tho bad khe	The text is neg.	Negative
58	تون پهنجي گهر وارن جي لاء پازيٽو سوچيندو آهين	Toun pahinje ghar waran je parhae je lae Positive sochindo ahin	The text is pos.	Positive
59	علم حاصل ڪرڻ هڪ پازيٽو رستو آهي	Ilim hasil karan hik Positive rasto ahy zindagi guzarin jow	The text is pos.	Positive
60	علم سکي ڪري بين کي سيکارڻ پازيٽو ڳاله آهي	Ilim sikhi kry biyan khe saikharinn Positive galh ahy	The text is pos.	Positive
61	توهان جو بيڊ ء ڪرسي ڀڳل آهي	Tawha jow ahy bhaghal bad aen kursi	The text is neg.	Negative
62	تون هليو وڃ هاڻي مهرباني ڪري	Toun halyo wanj hanne maherbani kre	The text is neutral.	Neutral
63	علي سمهي ٿو	Ali sumhe tho	The text is neutral.	Neutral

#	Sindhi Sentence	Romanized Sindhi Sentence	Sentiment Analysis	Ground through value
64	سارا کائي ٿي انب	Sara khae thi amb	The text is neutral.	Neutral
65	ڪير آهين تون	Kair ahen Toun	The text is neutral.	Neutral
66	پيءُ جو نالو	Peeu joww nalo	The text is neutral.	Neutral
67	ماءُ جو نالو	Maau joww nalo	The text is neutral.	Neutral
68	ڀاءُ جو نالو	Bhau joww nalo	The text is neutral.	Neutral
69	ڀيڻ جو نالو	Bheen joww nalo	The text is neutral.	Neutral
70	مان ڪيان ٿي پسند چانور	Mai kayan thi pasand chanwar	The text is neutral.	Neutral
71	صنم آهي هتي	Sanam ahe hete	The text is neutral.	Neutral
72	هي آهي منهنجي ماءُ	He ahy mounhje maau	The text is neutral.	Neutral
73	هي آهي منهنجو پيءُ	He ahy mounjoww peeu	The text is neutral.	Neutral
74	علي آهي هتي	Ali ahe hete	The text is neutral.	Neutral
75	سارا آهي استاد	Sara ahe ustad	The text is neutral.	Neutral
76	اقرا آهي ڊاڪٽر	Iqra ahy doctor	The text is neutral.	Neutral
77	ماڻهو پسندڪن ٿاچانور	Mannho pasand Kan tha chanwar	The text is neutral.	Neutral
78	ماڻهو پسند ڪن ٿا اڀاريل چانور	Mannho pasand kan tha umarial chanwar	The text is neutral.	Neutral
79	ماڻهو پسند ڪن ٿا چانهن	Mannho pasand kan tha chanhe	The text is neutral.	Neutral
80	توهان ڀڳل بيڊ تي ويٺا آهيو	Tawha waitha ahiyo bhaghal bad te	The text is neg.	Negative
81	توهان بدسورت آهيو	Tawha bad sourat aahiyo	The text is neg.	Negative
82	اسان سڀني کي هڪ ٻئي جي لاء پازيٽو سوچ رکڻ گهرجي	Asan sabhni khy hik biay je lae Positive soach rakhan ghurjy	The text is pos.	Positive
83	توهان جو ننڍو ڀاء ڏاڍو بدڪردار آهي	Tawha jow nandho bhau dadho bad kirdar ahy	The text is neg.	Negative
84	مسجد ۂ گهر کي ساف رکڻ پازيٽو ڳاله آهي	Masjid aen ghar khy saff rakhan Positive soach ahy	The text is pos.	Positive
85	تون کيڏين ٿي مون سان	Toun kheden thi moun san	The text is neutral.	Neutral
86	ڊبو آهي ڳاڙهو	Dabho ahy gahro	The text is neutral.	Neutral
87	مان ڏيني ٻلي	Maa'n detho bhli khe	The text is neutral.	Neutral
88	ڪتو آهي هتي	Kuto ahe hete	The text is neutral.	Neutral
89	تون ڳالهين ٿو انگلش	Toun galhaeen tho English	The text is neutral.	Neutral
90	اسان کي نه وساريو	Naa wesaryo asann khe	The text is neutral.	Neutral

#	Sindhi Sentence	Romanized Sindhi Sentence	Sentiment Analysis	Ground through value
91	نه ڊرڇو	Naa drejow	The text is neutral.	Neutral
92	تون ڳالهايو ڪوڙ	Toun galhayo koor	The text is neutral.	Negative
93	کٽو چانهن	Khanno chahen	The text is neutral.	Neutral
94	نه اچو هتي	Naa acho hete	The text is neutral.	Negative
95	ٻلي ڊورڙي ٿي	Bilii dorhe thi	The text is neutral.	Neutral
96	هي آهي ٿوم	He ahy tom	The text is neutral.	Neutral
97	وڻ آهي وڏو	Wanu ahe wadho	The text is neutral.	Neutral
98	سج آهي گرم	Sijh ahy garam	The text is neutral.	Neutral
99	مان کاڌو ڪيڪ	Maa'n khado cake	The text is neutral.	Neutral
100	مان استاد کان نه ٿو ڊرجان	Maa'n Naa tho drjan tho ustad khan	The text is neutral.	Negative

Table I shows the data set of the research, which depends on one hundred sentences of RST. The data was obtained from the RST, which was obtained from different sources. Sentiment Analysis RST was done on the online Python tool. The obtained results of sentiment analysis are in the form of positive text, neutral text, and negative text. From the output results of the Python tool, 573 sentences have neutral sentiments, 8 sentences have positive sentiments, and 12 sentences have negative sentiments. After the task was performed on the tool, all sentiments were compared based on ground truth values.

IV. Algorithm for the Sentiment Analysis of Romanized Text (Sindhi)

```
Start
Take input: In sentence form of RST
Apply: apply one by one sentence till 100 sentences.
Analysis on tool: Analysis on the tool results (Neu, Neg and Positive) based on input sentence.
Evaluation: based on the ground truth values.
Process: Sentence run on tool Repeat steps 2 to 6 when get appropriate
End
```

V. Evaluation of Romanized Sindhi Text

Results are evaluated based on RST's sentiment analysis, which is carried out using a web-based Python tool and ground truth values. The one hundred sentences in the RST are subjected to a sentiment analysis examination. The evaluation of RST is based on two key elements of the research, the first being the ground truth values and the second being the online Python tool. The results came from tool are in three categories of the sentiments positive, neutral and negative as shown in Table II and Fig. 3. According to the results of the Python tool, 573 sentences had neutral, 12 sentences had negative, and 8 sentences had positive sentiments on the sentences of RST. According to the results of ground truth values 323 sentences had neutral meaning, 64 sentences had negative meaning, and 208 sentences had positive meaning in the RST.

TABLE II. SENTIMENTS ANALYSIS OF RST PYTHON VS GROUND TRUTH VALUES.

S. No.	Sentiment	Analysis By Python	Ground Truth Values
1	Neutral	86	76
2	Negative	9	17
3	Positive	5	7
Total		100	100

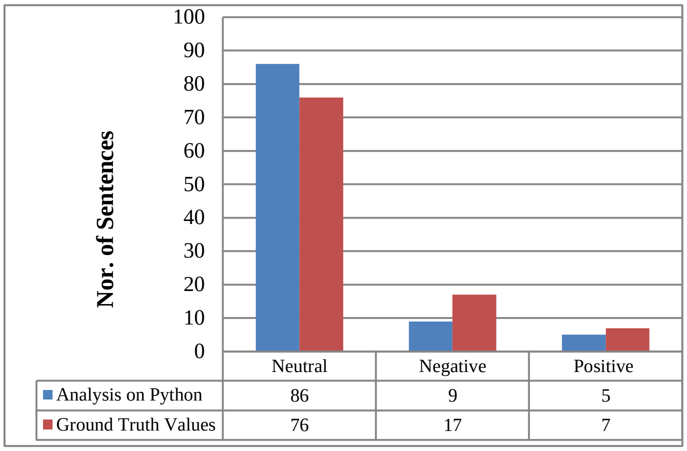


Fig. 3. Comparison of sentiment analysis (python tool and ground truth values).

According to the results of RST on Python, 86% of the sentences have neutral sentiments, 9% of the total results of sentiment analysis have negative sentiments, and only 5% of the total sentences of Romanized Sindhi Text have positive sentiments, as shown in Fig. 4.

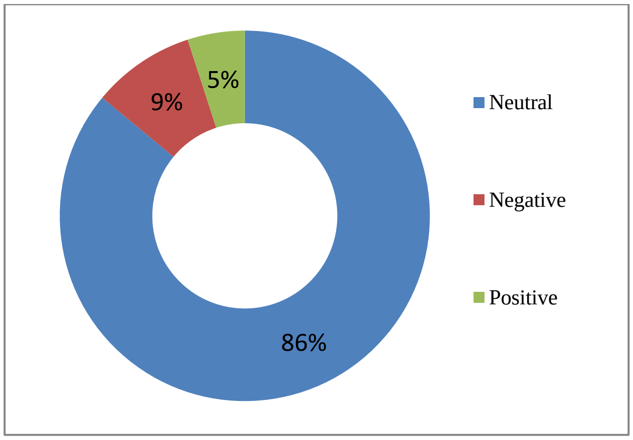

Fig. 4. Analysis of sentiments on online python tool.

As the results of RST on Ground Truth Values of sentiment analysis show, 76% of the sentences have neutral sentiments, 17% of the total results of sentiment analysis have negative sentiments, and only 7% of the total sentences of RST have positive sentiments. Analysis of sentiments for RST on Python Tool is shown in Fig. 5.

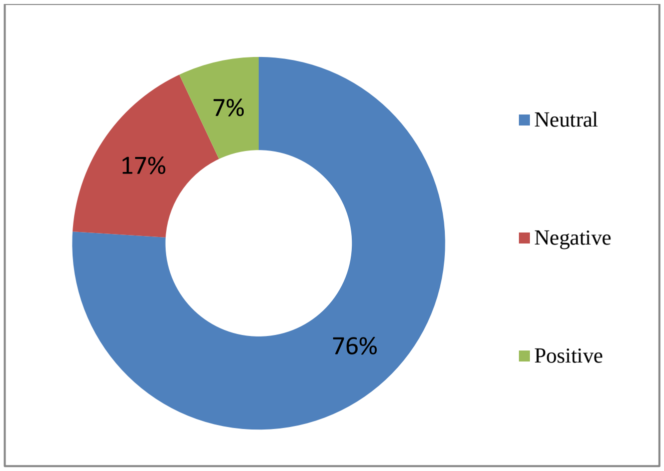

Fig. 5. Analysis of sentiments on ground truth values.

VI. Accuracy of Sentiment Analysis of Romanized Sindhi Text

Sentiment analysis of RST has been done using the online Python tool for 100 sentences. In sentiment analysis, positive, negative, and neutral sentiments were measured. Output results of the sentiment from tool were compared with the Ground Truth Value of the sentences. After performing the task of sentiment analysis, the accuracy of the output results from the tool was measured on the basis of the ground truth values of the sentences [16, 17].

For the accuracy evaluation, a confusion matrix has been created on the basis of ground truth values, as shown in Table III, True Negative (TNeg), True Positive (TP), True Neutral (TNeu), False Neutral (FNeu), False Positive (FP), and False Negative (FNeg) [16]. After calculating the values of the parameters from the confusion matrix, the accuracy of the RST was measured on an online calculator, and the value is 87.02% on the basis of ground truth values as shown in Fig. 6. Also, error ratio of 12.98% was calculated on the basis of accuracy found on online calculator of confusion matrix.

TNeg = Both values (Ground truth value and tool (Python) are negative.

TP = Both values (Ground truth value and tool (Python) are positive.

FP = Ground truth values are negative or neutral and values from tool (Python) are positive.

FNeg = Ground truth values are positive or neutral and values from tool (Python) are negative.

TABLE III. Confusion Matrix on the Basis of Ground Truth Values

S. No.	FNeg	FP	TP	TNeg
1	0	0	1	0
2	0	0	1	0
3	0	0	1	0
4	0	0	1	0
5	0	0	1	0
6	0	0	1	0

VII. Issues of Sentiment Analysis of Romanized Sindhi Text

Sentiment analysis of RST has been done on the online Python tool for 100 sentences. But during, before, and after performing the task of sentiment analysis on RST, faced issues with the completion of this task [18, 19]. While performing the task of sentiment analysis on RST, positive sentences were not identified by the tool (Python), but after the characters of the Romanized text were changed, and then the results came. Other issues are discussed below:

1) Even when a single word (positive or negative) is used for sentiment analysis on tool, output result was a neutral sentiment.

2) Input sentences were interrogative used for sentiment analysis, but the results were neutral sentiment.

3) When Punctuation was used as input in sentences, the results were mostly neutral sentiment.

4) Input sentences were used as Negative, but the results were neutral sentiments. But for the negative sentences of English word, bad is used in Romanized Sindhi sentences, the result was negative.

5) Input sentences were used as Positive, but the results were neutral sentiments. But for the positive sentences of English word, positive were used in Romanized Sindhi sentences, the result was positive.

6) When country name comes in any sentences output comes as neutral.

7) When (ignore) word of English comes in sentences with subject+verb+Object of Romanized Sindhi text used on tool and the result came neutral.

8) Neutral output comes when sentences without subject are used on tool.

VIII. Conclusion

In this research, sentiment analysis has been done on Romanized Sindhi text using a machine learning tool (a hybrid approach) and ground truth values. The machine learning tool is a Python online tool that is freely available to perform different tasks of NLP by using input text. In this task, we used a data set of RST. Sentiment Analysis of RST has been done on 593 sentences, and the sentiments of the sentences are positive, negative, and neural. According to the results for the sentences of RST on the Python tool of sentiment analysis, 86% of the total sentences have neutral sentiments and as per Ground Truth Values of Sentiment Analysis 76% of the sentences have neutral sentiments. The overall accuracy of the sentiment analysis was measured from the confusion matrix, and the accuracy is 87.02%. Sentiment analysis of RST has been done using the online Python tool for the one hundred sentences. In sentiment analysis, positive, negative, and neutral sentiments were measured. Output results of the sentiment from tool were compared with the Ground Truth Value of the sentences. After performing the task of sentiment analysis, the accuracy of the output results from the tool was measured on the basis of the ground truth values of the sentences [16, 17].

Acknowledgments

Consolidated Definition of Digital Transformation by using Text Mining

Mohammed Hitham M.H[1], Hatem Elkadi[2], Neamat El Tazi[3]
PhD Student[1] , Associate Professor[2, 3]
Faculty of Computers & Artificial Intelligence, Cairo University, Cairo, Egypt[1, 2, 3]

***Abstract*—Digital transformation has become essential for the majority of organizations, in both public and private sectors. The term "digital transformation" has been used (and misused), so frequently that it is now somewhat ambiguous. It has become imperative to give it some conceptual rigor. The objective of this study is to identify the major elements of digital transformation as well as develop a proper definition for DT in the public and private sectors. For this purpose, 56 different definitions of DT collected from the available literature were analyzed, and we found that they extracted elements from definition of DT manually. So, text mining (TF-IDF and Fp-tree) techniques are used to identify the major constituents and finally consolidate in generic DT definitions. The approach consists of five phases: 1) collecting and classifying DT definitions; 2) detecting synonyms; 3) extracting major elements (terms); 4) discussing and comparing DT elements; 5) formulating DT definitions for different business categories. An evaluation tool was also developed to assess the level of DT elements coverage in various definitions found in the literature, and, as a validation, it was applied to the formulated definitions.**

Keywords—Digital transformation; text mining; association rules; FP tree

I. Introduction

In a world of emerging and continuous change, digital transformation (DT) has become a necessity for most organizations, both in the private and public sectors. The word "digital transformation" has been used in a broad sense to include many ideas that lead to widely divergent viewpoints. Few attempts have been made to define DT. Based on a review of 56 definitions, we could identify two fundamental approaches to defining DT: One is based on the scope of the study [1-37], [39-42] and the other is based on the perspective of expert(s) interview as [38] in the private sector or in [43] for the public sector. According to [1], the phrase "digital transformation" does not have a generally accepted definition. Without properly defining the DT, proper assessment and proposition of DT solutions (Framework, Model, or Architecture) are not possible. In a recent study [1], an effort was made to define digital transformation, but, this study had two limitations: a) it did not classify the prior definitions and b) it extracted the manually DT elements (based on their frequency). To the best of our knowledge, no study has so far defined DT elements using text mining techniques. To go beyond these limitations, we propose a comprehensive approach, using text mining algorithms to objectively extract the DT elements. We categorize the prior DT definitions into two groups: in the public sector and in the private sector. In this study, text mining is used to answer the research question: What are the key elements of the DT definitions in the public and private sectors as well as in general (all definitions)? The rest of this paper is organized as follows: In Section II, the proposed an approach is described. In Section III, results of text mining techniques are presented. In Section IV; results of digital transformation elements are discussed. In Section V, definitions of DT are proposed. In Section VI, we present a tool to asses various DT definitions. Finally, the conclusion, limitations and future work are presented.

II. Proposed Approach for Defining DT Elements

Our general approach for defining major elements in digital transformation definitions is outlined in Fig. 1. We will give a brief description of each phase as follows:

A. Phase One: Collecting and Classifying DT Definitions

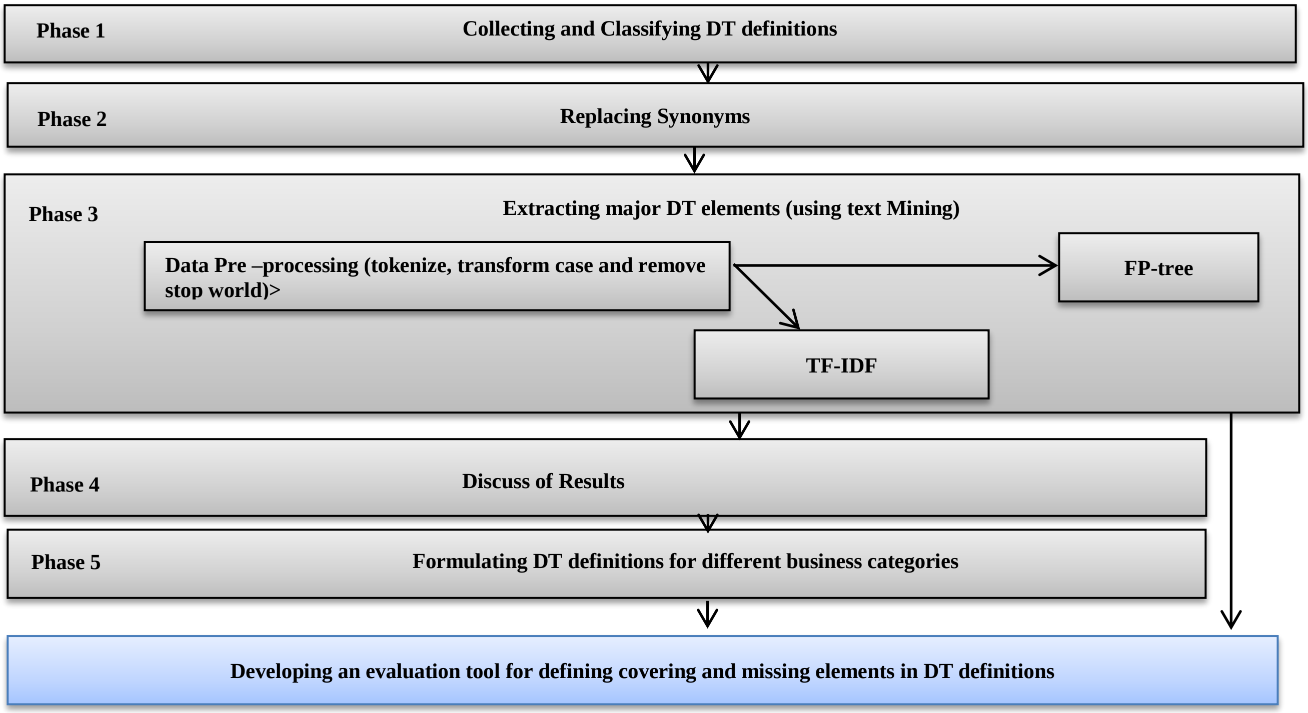
The first phase is responsible for gathering existing definitions from recent literature specialized academic literature as well as from the websites of specialized private companies such as IBM, Google, and Oracle... (Our data set included 56 definitions).

After reviewing them, it has been found:

- Several publications [1-20] in the literature do not specify to which type their definitions applied. We will try to define the appropriate type for them later.
- 21 Private sector definitions from the companies' perspectives (14 definitions) ([21] [23-31] [37] [39-41], and from researchers' perspectives (7 definitions) [22], [32-36] [38].
- 15 Public sector definitions from researchers' perspectives (15 definitions) [42-56].

B. Phase Two: Replacing Synonyms

Analysis of the acquired dataset revealed the existence of specific bigrams and n-grams (e.g. big data, business process, business model, etc) that must appear as block. Thus, the synonym identification phase was proposed, where these n-grams are ligated and replaced in the dataset, for example big data replace with (Bigdata). We also replace some words like "artificial intelligence" and "internet of things" with their shorthand (AI, IOT).



Phase 1
Collecting and Classifying DT definitions
Phase 2
Replacing Synonyms
Phase 3
Extracting major DT elements (using text Mining)
Data Pre –processing (tokenize, transform case and remove stop world)>
FP-tree
TF-IDF
Phase 4
Discuss of Results
Phase 5
Formulating DT definitions for different business categories
Developing an evaluation tool for defining covering and missing elements in DT definitions

Fig. 1. Proposed approach for defining DT elements in DT definitions.

C. *Phase Three: Extracting Major DT Elements (Using Text Mining)*

The main elements (terms) of the definitions of digital transformation are extracted from the 56 collected definitions using traditional text mining techniques. This requires proper preprocessing of the acquired text (tokenizing, removal of stop words, stemming, and case transformation). The TF-IDF method, being the most widely used method [60] in the literature, was used to identify the most frequently used terms and according to [61], Fp-tree algorithm offered good results for extracting association rules from text. Therefore, in this work we used the TF-IDF method (one gram) to extract frequently occurring terms from DT definitions and used Fp trees to extract association DT elements.

III. Results of Text Mining Techniques (Results of Phase Three)

Following results are obtained on laptop running Dell-core i7, Windows 10. The approach was implemented using Python 3.7.4 and RapidMiner Studio-9.10.1. Table I, shows the experimental parameters for text mining algorithms. The confidence in the Fp-tree in all DT categories is 1.

We will discuss the results of applying the TF-IDF and FP tree algorithms to DT definitions elements as follows:

TABLE I. Parameters Settings of Text Mining Algorithms

Category of definitions	Frequency in Fp-tree	Min acceptable weight in TF-IDF
Public	3	0.14
Private	3	0.14
General (All definitions)	4	0.14

A. *Method 1: Applying TF-IDF*

Firstly, we use TF-IDF to define the most frequently used words.

- The main elements in the public definitions.

Table II shows the results when applying TF-IDF on DT definitions in public definitions.

TABLE II. TF-IDF for DT Definitions in Public

Words	Weight
businessprocess	1
government	0.78
service	0.67
digitaltechnology	0.50
digital	0.39
citizen	0.33
digitaltransformation	0.28
bigdata	0.22
businessmodel	0.22
egovernment	0.22
Public sector	0.22
leverage	0.22
datamining	0.17
change	0.17

- The main elements in the private definitions

Table III shows the results when applying TF-IDF on DT definitions in private definitions.

- The main elements in the all definitions (general).

Table IV shows the results when applying TF-IDF on DT definitions in all definitions.

TABLE III. TF-IDF FOR DT DEFINITIONS IN PRIVATE

Words	Weight
digitaltechnology	0.52
business	0.48
businessprocess	0.43
digital	0.38
businessmodel	0.33
change	0.33
customer	0.24
operation	0.24
cloudcomputing	0.19
customerexperience	0.19
iot	0.19
innovation	0.14
transformation	0.14
organization	0.14

TABLE IV. TF-IDF FOR DT DEFINITIONS IN ALL

Words	Weight
businessprocess	0.60
digitaltechnology	0.42
change	0.36
business	0.36
digital	0.34
businessmodel	0.32
organization	0.30
government	0.25
service	0.21
customer	0.16
process	0.14
value	0.14
digitaltransformation	0.14

B. *Method 2: Applying Association Rules*

In this sub-section, we will apply association rules (Fp-tree) to each category of DT definitions as follows:

- The main elements in the public definitions.

The results of running the Fp-growth algorithm are shown in Table V. It can be seen that the final set contains three words that appear to be associated with one another: businessmodel, businessprocess and digitaltechnology.

TABLE V. ASSOCIATION RULES IN PUBLIC DEFINITIONS

Premises	Conclusion	Support	Confidence
businessmodel	businessprocess	0.22	1
Citizen	businessprocess	0.22	1
bigdata	digitaltechnology	0.22	1
service, citizen	businessprocess	0.167	1
leverage	businessprocess	0.167	1
government, citizen	businessprocess	0.167	1
leverage	businessmodel	0.167	1

- The main elements in the private definitions.

The results of running the Fp-growth algorithm are shown in Table VI. We would be able to see that the final set contains three words that appear to be associated with one another: customerexperience, businessmodel and businessprocesses.

- The main elements in general DT definitions (all definitions).

The results of running the Fp-growth algorithm are shown in Table VII. We would be able to see that the final set contains four words that appear to be associated with one another: business-model, businessprocess, DigitalTechnology, and digital.

TABLE VI. ASSOCIATION RULES IN PRIVATE DEFINITIONS

Premises	Conclusion	Support	Confidence
BusinessProcess	DigitalTechnology	0.25	1
Improve	BusinessModel	0.15	1
Operation ,Customerexperience	BusinessModel	0.143	1
businessmodel, operation	customerexperience	0.143	1
Change, Organization	BusinessProcess	0.143	1
Digital, Customer	BusinessProcess	0.143	1

TABLE VII. ASSOCIATION RULES IN GENERAL DEFINITIONS

Premises	Conclusion	Support	Confidence
Createvalue	BusinessModel	0.073	1
createvalue	Leverage	0.073	1
businessmodel, createvalue	Leverage	0.073	1
BusinessProcess	BusinessModel	0.073	1
Createvalue	BusinessModel,BusinessProces	0.073	1
BusinessProcess, customerexperiences	BusinessModel	0.073	1
BusinessProcess, createvalue	BusinessModel	0.073	1
People	DigitalTechnology	0.073	1
BusinessModel, DigitalTechnology	Digital	0.073	1
BusinessModel, customerexperiences	BusinessProcess	0.073	1
BusinessModel, Leverage	BusinessProcess	0.073	1
BusinessModel, createvalue	BusinessProcess	0.073	1
Createvalue, Leverage	BusinessModel, BusinessProcess	0.073	1

IV. PHASE FOUR: DISCUSSION OF RESULTS

Based on the results of applying the TF-IDF and Fp-tree to DT definitions, we can note that in the private definitions, the most important technologies are IoT and cloud computing, compared to data mining and big data in the public definitions. We also found that definitions in the private sector focus on business, the customer, and innovation, while in the public sector they focus on services, government and citizens. We can define intersecting elements between DT definition categories as shown in Fig. 2. In general digitaltechnology, digital, businessmodel, and businessprocess are intersecting elements across all DT definition categories. This suggests these are minimum elements to define DT. It can be noted that all intersection elements originated from method one (TF-IDF), except (BusinessProcess->BusinessModel) l which identified from method two (Fp-tree) in the intersection between public and general definitions. So we didn't draw a Venn diagram in FP-tree.

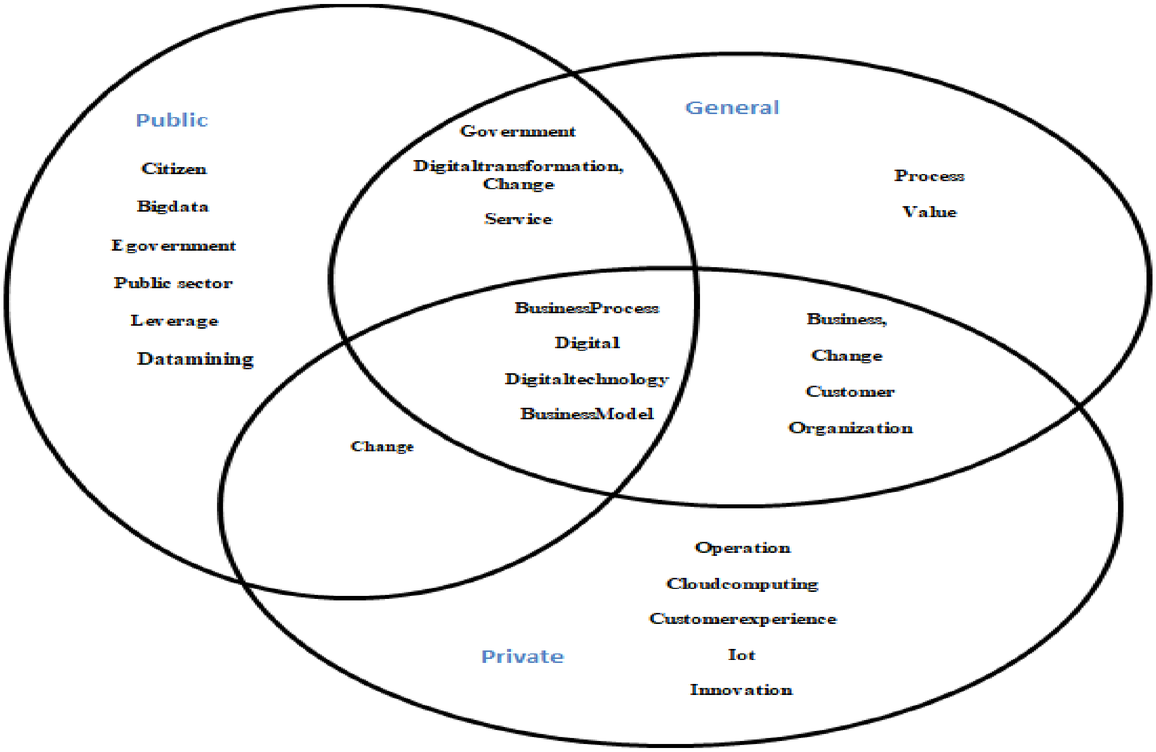


Fig. 2. Intersection between DT Elements in DT Definitions (TF-IDF).

V. Phase Five: Proposing DT Definitions

Based on the DT elements that have been defined before, we can define DT in three categories as follows:

- DT Definition in General.

DT is a process that leverages digital technologies to change an organization of government or business, business model and business processes, to create value for consumer (customers or citizens).

- DT Definition in Public.

DT is a process that leverages digital technologies (bigdata, data mining), to change government, business process, business model, services and citizens.

- DT Definition in Private.

DT is a process that leverages digital technologies (big data, cloud computing and IOT) to change an organization, business model, business processes, to create value for customer.

VI. Proposing a Tool to Asses Various DT Definitions

As mentioned before, we have two main categories of DT definitions (public, private) and combined between them to create a new category called "general". Each category contains a set of elements, as discussed above. In the following, we will try to find the percentage of covered elements by each definition in each category, as well as identify the percentage of missing elements for each definition. For this purpose, we developed algorithm 1. There are two inputs to this algorithm. The first input contains dataset that includes reference numbers and definitions (text). The second input contains a dictionary (data) where key is category: (Public, Private, and General) and value is DT elements for each category that contains two lists: List 0 contains words that appear in definitions in sequence as a block (come from the TF-IDF); whereas List 1 contains words that appear in definitions in sequence but not as a block (come from the Fp-tree algorithm).We follow several steps to calculate the percentage of covering and missing DT elements, which are:

A. For Each Algorithm, the Percentage of Words Covered is Calculated in Each Definition as Follows

- TF-IDF

$$CTF_{IC} = \frac{NW_{IC}}{TW_c} \qquad (1)$$

Where CTF is the percentage of words covered in definitions I (1 ...59) in term frequency, c is category (c set of index: private, public, general), NW is Number of words covered by each definition I in each category c, and TW is total number of words in each category according to TF- IDF.

- FP-tree

$$CTF_{IC} = \frac{NW_{IC}}{WT_c} \quad (2)$$

Where CFP is the percentage of words covered in definition I in Fp-tree, c is category (c set of index: private, public, general), NW is Number of words covered by each definition I in each category c and TW is total number of words in each category according to FP algorithm.

B. The Total Percentage of Words Covered is Calculated in Each Definition as Follows

$$TC_{IC} = \frac{CTF_{IC}+CFP_{IC}}{2} \quad (3)$$

Where TC is total covered words in each definition I, in-TF and Fp-tree.

C. The Percentage of Words Missing in Each Definition is Calculated as Follows

$$MP_{IC} - 1 - TC_{IC} \quad (4)$$

Where MP is missing percentage in each defilation I in each category c.

VII. Discussion of Results (Applying Our Tool)

Table VIII shows an example of results of applying algorithm 1 to 56 definitions from the literature and our proposed definitions (3); see the link in the appendix for the complete results.

A. When Applying our Algorithm to Define Category of First 20 Definitions (from 1 to 20),

- It has been found that 80% of definitions are classified as private definitions.
- It has been found that 15% of definitions are classified as public definitions.
- It has been found that 5% of definitions are classified as general definitions.
- The definition that covered the most elements is [8] in general with (35.1%), in public with (23.85%) and in private with (29.65%).
- The definition that covered the lowest elements in public is [15] with (3.35%) and [4] in private with (7.9%) and in general with (6.5%).

B. When Applying our Algorithm to the Private Category (21 Definitions), it has been found that

- Proposed algorithms agree with (66.66%) in the classification of private sector definitions and differ (28.95%) as they were classified as definitions in the public sector and (4.76%) as a general category.
- The definition that covered the most elements is [34] with (28.95%).
- The definitions that covered the lowest elements are [24] and [30] with (7.9%).
- It has been found only three definitions covering elements in Fp-tree which are [23], [26], and [36] as shown in Table VIII.

C. When Applying our Algorithm to the Public Category (15 Definations), it has been found that

- Proposed algorithm agrees with (86.66%) in the classification of the public definitions and disagree (13.33%) as they were classified as private definitions.
- The definition that covered the lowest elements is [42] with (6.5%).
- The definition that covered the most elements is [47] with (26.5%).
- The definitions that covered most elements in TF are [47] with (53.3%) compared to [53] in Fp-tree with (7.7).

D. When Applying our Algorithm to All Definitions it has been found that

- Proposed algorithm agreed with 75% of the previous studies' classification of DT definitions private (21) and public (15) while disagreeing with 25%.

E. When Applying our Algorithm to our Definitions it has been found that

It can be seen that our definitions cover the largest percentage of the DT elements in general (all definitions) [57] with (42.5%), in the public definitions [58] with (38.5%), and in the private definitions [59] with (38.7%). Overall, our definitions have achieved the highest percentages in (TF-IDF, Fp), which gives us an indication that our definitions are more comprehensive.

VIII. CONCLUSION

Although digital transformation is a hot topic right now, there is no generally accepted definition, which has implications for both researchers and practitioners. Consequently, the goal of this study was to learn more about the concept of digital transformation. According to the analysis of previous definitions of digital transformation, we can divide them into two groups: in the private sector, in the public sector and create a new group called in general. We propose a comprehensive approach to defining major elements in DT definitions in each category as well as in general (all definitions). This approach consists of five phases. The first phase is used for collecting and classifying DT definitions. The second phase is responsible for synonyms and defining the words that must appear together. The third phase is responsible for extracting major DT elements in each category using text mining methods (Fp trees, TF-IDF). The fourth phase is used to discuss and compare DT elements. The fifth phase is used to propose new definitions of DT in the private, public, and general. In the end, we propose an assessment tool (algorithm) to identify the percentage of covered elements for each definition in each category and define the percentage of missing. The results of applying TF-IDF in general showed that: digitaltechnology, digital, businessmodel, businessprocess and change are common elements across all DT definition categories. This suggests these minimum elements to define either in private or in public. In the private category, our algorithm classified 66.66% of them as private, compared to 28.95% classified as public and 4.76% classified as general. While there are 86.66% of people who classify DT definitions in the public domain, and our algorithm puts them in that category compared to 13.13% in the private domain. The assessment tool agreed 75% with the previous classification of definitions and did not agree with 25% of them.

We also use the assessment tool to identify categories of definitions [1–20] that were not previously classified. The assessment tool classified 80% of them as private definitions, while classifying 15% as public definitions and 5% as general. Overall, when using our assessment tool to define category to all defilations (56), it has been found that the most definitions classified as private with 57.14% followed by public category with 39.28% and general 3.57%. This indicates that most definitions of digital transformation focus more on the private sector than others. It can also be noted that our proposed DT definitions covered the largest percentage of the DT elements in general (all definitions) with 42.15%, in private with 38. 7%, and in public with 38.35%. This shows that our suggested definitions are more thorough. This study was limited by the small number of definitions that were examined (56), and this shortcoming will be overcome in future study. We are looking forward to doing a lot of experiments using other text mining algorithms as well as trying to apply our approach to other domains.

Abstract—**In the last three years, the coronavirus (COVID-19) pandemic put healthcare systems worldwide under tremendous pressure. Imaging techniques, such as Chest X-Ray (CXR) images, play an essential role in diagnosing many diseases (for example, COVID-19). Recently, intelligent systems (Machine Learning (ML) and Deep Learning (DL)) have been widely utilized to identify COVID-19 from other upper respiratory diseases (such as viral pneumonia and lung opacity). Nevertheless, identifying COVID-19 from the CXR images is challenging due to similar symptoms. To improve the diagnosis of COVID-19 using CXR images, this article proposes a new deep neural network model called Fast Hybrid Deep Neural Network (FHDNN). FHDNN consists of various convolutional layers and various dense layers. In the beginning, we preprocessed the dataset, extracted the best features, and expanded it. Then, we converted it from two dimensions to one dimension to reduce training speed and hardware requirements. The experimental results demonstrate that preprocessing and feature expansion before applying FHDNN lead to better detection accuracy and reduced speedy execution. Furthermore, the model FHDNN outperformed the counterparts by achieving an accuracy of 99.9%, recall of 99.9%, F1-Score has 99.9%, and precision of 99.9% for the detection and classification of COVID-19. Accordingly, FHDNN is more reliable and can be considered a robust and faster model in COVID-19 detection.**

Keywords—COVID-19; Chest X-ray (CXR); Deep Learning (DL); Convolutional Neural Network (CNN)

I. Introduction

The novel coronavirus disease (COVID-19) is a current pandemic that has sparked widespread concern worldwide. This virus causes severe respiratory illness [1]. Currently, COVID-19 is recognized as the worst disease on the earth. Usually, chest X-ray (CXR) imaging is used for radiographic examination of the suspected cases. In severely impacted or limited resource locations, CXR imaging is favored because of its accessibility, cheap cost, and speedy findings. Via Lenard and Crookes tubes, the first X-ray was coined by Wilhelm Conrad in 1895. The rapid development of the x-ray system and its low cost made it available in most clinical testing [2]. Patients can quickly get CXR images in their homes or quarantine facilities since CXR facilities are available even in the most distant locales. Recently, CXR images based on Artificial Intelligence (AI) have been utilized widely to detect COVID-19 instances [3, 4]. Given the fast spread of COVID-19, however, such testing might reduce the effectiveness of pandemic prevention and control. Therefore, AI techniques, such as Deep Learning (DL), are viable solutions for autonomous diagnosis due to their promising processing of visual data and a vast array of medical images [4].

This section investigates supreme papers that utilized Convolutional Neural Networks (CNN) and other DL architectures to diagnose COVID-19 via CXR images. The CXR image testing factor is determined by (DL) plans and consists mostly of measurements such as COVID-19 segmentation, data correction, and model training [5]. Manually, radiologists often perform COVID-19 classification. However, it is time-consuming, error-prone, and exhaustive since radiologists are expected to diagnose many COVID-19 patients. Furthermore, despite the dramatic increase in COVID-19 patients, the lack of qualified radiologists to make reliable diagnosis continues to be a major problem [6].

On the other hand, healthcare professionals take a sample from the nose to find whether it is a COVID-19 case. Nevertheless, the manual outcome of the test could be a false negative depending on the timing and quality of the test sample. The maximum accuracy, of this testing method, for COVID-19 infections, is 71% [6].

CXR is an alternate important diagnostic method for COVID-19 detection. However, if the CXR images require clarification, COVID-19 is sometimes diagnosed as another disorder. Due to faulty diagnoses, patients frequently receive incorrect medicines, complicating their health. This critical health issue to diagnose COVID-19 has inspired researchers to create more precise and automated CXR-based diagnostic approaches.

Machine learning (ML) methods and the most intense learning have been considered more accurate in identifying COVID-19 [7, 8]. The authors in [9] used DL methods-based CXR images to diagnose COVID-19. Although the presented models in the literature were validated with several CXR images, particularly the positive case images of COVID-19 cases, there was a class imbalance issue in previous studies. Additionally, the authors utilized the transfer learning approach in their model. The scholars applied dataset preprocessing to convert it into a gray level. Next, change the image intensity, resize and extract the best features, and use the transfer learning approach. The authors in [9] focused on getting high COVID-19 classification accuracy. This means applying the same preprocessing on CXR images developing them and then designing a new model in DL for COVID-19 diseases. Several authors (such as in [4, 10]) utilized only CNN to classify COVID-19 patients and didn’t achieve more accurate accuracy.

However, CNN alone is insufficient for reliable COVID-19 detection [6, 11]. Therefore, researchers explored the limitations of the existing models to propose crucial solutions that can increase detection accuracy.

Since the outbreak of COVID-19, the majority of state-of-the-art methods have primarily focused on using transfer learning techniques to implement their systems as shown in the recent survey published in [3]. One of the main challenges in using transfer learning techniques for detecting COVID-19 is the amount of time it takes to apply these methods to large datasets, especially when dealing with CXR images. This is because the model needs to be fine-tuned by retraining it on the new data, which can be time-consuming even with powerful computing resources. To address this issue, a study proposed using several image preprocessing techniques before inserting deep CNN. These techniques involve converting the images to grayscale, adjusting the image intensity, resizing and extracting the best features, and expanding features. This preprocessing transforms the data from two dimensions to one dimension, which can speed up implementation. Additionally, a unique fast deep learning proposal design was introduced to improve COVID-19 classification accuracy while reducing execution time and storage requirements.

Going forward, this article is organized as follows. Section II reviews some of the important proposed models in COVID-19 identification. Section III presents our proposed methodology. Section IV describes the utilized dataset. Section V explains the conducted preprocessing operations. Section VI introduces Linear Discriminant Analysis (LDA) that we use to extract CXR features. Section VII describes feature expansion as a last preprocessing for applying the deep proposal CNN. Section VIII presents the Fast Hybrid Deep Neural Network (FHDNN) and its summary layers. Section IX evaluates the proposal's performance and compares it with related counterparts. Finally, Section X concludes the paper and identifies some future directions.

II. Related Works

Recently, the DL technique has been adopted for analyzing medical images because of its reliable outcomes [12]. Due to no constraint on the dataset employed, DL is suitable for making predictions based on training data and information. [13]. Currently, the existing methods suffer from some crucial issues, such as being time-consuming and expensive. Therefore, developing DL technology to detect COVID-19 faster and more accurately has become necessary. CXRs and CT scans can help achieve this. However, CXRs are less expensive than CT scans, thus, they are preferable.

To classify COVID-19 cases, Aslan, M. F. et al. [14] suggested a DenseNet-SVM structure and utilized binary classification techniques. While the model achieved an accuracy of 96.29%, the author also used eight models of SVM-based CNN and an average accuracy of 95.21%. Alaska, T. B. et al. [15] utilized the LSTM model and validated their work using a 10-fold cross-validation strategy. The results of the models showed excellent classification performance and achieved an accuracy greater than 84%. Additionally, the recall and AUC scores reached 99.43% and 0.625, respectively. Furthermore, using Holdout validation, the CNN-LSTM achieved better performance, where the accuracy, recall, and AUCs cores went 92.3%, 93.68%, and 0.90 respectively. For detecting and diagnosing human lung disorders, four models were proposed by Ibrahim et al. [16]. The models have been used to classify three cases: COVID-19, lung cancer, and Pneumonia. CNN-VGG19 (GRU with ResNet152V2) achieved an accuracy of 98.05% (96.09%). The VGG-inspired model identified the COVID-19 patients successfully from other cases (regular and pneumonia). For multi-class and binary classification, evaluation metrics accuracy, F1-score, recall, precision, and AUC were 97%, 0.95, 95%, 95% and 0.95, and 98%, 0.97, 97%, 97%, and 0.97, respectively [16].

As mentioned earlier, CXR is one of the essential methods to diagnose pneumonia worldwide [17] since it is a fast, cheap [18], and standard clinical method [19-21]. In [22-24], scholars suggested a DL method-based dataset of CXR images. The authors utilized domain DL within environment-deep CNN. The author proposed that the technique was developed specifically for identifying COVID-19 patients from CXR data. For three classes, an overall accuracy of 96.48% was obtained. However, for four class classifications, the COVDC-Net method achieved accuracy reached 90.22%. The authors used 3,884 (1,414) images for three (four) classes. Using image analysis, early detection of the COVID-19 system was proposed in [25]. Using DL method-based CXR image; the authors calculated the impacts of COVID-19 on people. They utilized five pre-trained CNN-based models: ResNet152, ResNet101, ResNet50, Inception-ResNetV2, and InceptionV3. The highest classification accuracy was determined by ResNet50, reaching 96.1% for the dataset (comprised of two classes).

Similarly, the authors in [26] used transfer learning methods: VGGNet-19, VGG16, VGG19 LeNet-5, MobileNetV2, and the Fusion model. The researchers collected CXR images from various sources (from different classes of chests humans) to detect COVID-19 disease. On the other hand, the study [27] used a pre-trained approach called VGG16-CNN to detect COVID-19 cases using CXR images. While the study achieved an accuracy of 97.50% for multiple classifications, the authors tested the models and found varying proportions, such as an F1-score rate, precision rate, recall rate, and overall accuracy. The authors utilized CNN and pre-trained models for feature extraction and achieved several classification accuracies. Accordingly, the alone use of CNN is insufficient for better identifying COVID-19 cases. Fewer images and no preprocessing steps are the causes of poor performance. One of the major difficulties in employing transfer learning approaches to detect COVID-19 is the time required to apply these techniques to big datasets. Due to the model's need for fine-tuning to alter its parameters, this process takes a long time when dealing with big amounts of CXR picture data. This requires retraining the model on the new data, which can take a significant amount of time, even with powerful computing resources. As shown in the survey [4], many methods served to evaluate pre-trained deep CNN models including AlexNet, VGG-16, GoogleNet, MobileNet-V2, SqueezeNet, ResNet-34, ResNet-50, and Inception-V3 to distinguish COVID-19 from normal cases. Many hyperparameters tuning have been applied to find the best batch size, learning rate, optimizer, and a number of epochs. The obtained results were less than our fast HFDNN with high time consumption. Finally, the highest classification accuracy of recent papers reached 99%, obtained using the InstaCovNet-19 DL method [28]. Based on the studies mentioned above, they suffer from some significant limitations:

- Imbalance classes in the utilized datasets.
- Applied classification images using DL without image preprocessing techniques (such as Linear Discriminant Analysis (LDA)). For example, equalization of the intensity (use Histogram Equalization (HE)), removing noise from the images, resizing it, extracting the best features, then feature expansion.
- The evaluation metrics (i.e., accuracy, precision, recall, and F1-score) must improve.
- DL models typically need a lot of training time.
- More hardware is required for DL model execution.

Therefore, before inserting deep CNN, we applied several image preprocessing techniques to tackle the above drawbacks in this study. In the first step of dataset preprocessing, we convert the images into the gray level. Next, the image intensity is adjusted, and the best features are resized and extracted. Lastly, perform features expansion. This processing may ensure that the data is transformed from two dimensions to one dimension, which will speed up implementation. Furthermore, a unique fast deep learning proposal design can improve COVID-19 classification accuracy in less execution time and storage.

III. Methodology

The COVID-19 outbreak has necessitated rapid action against a massive threat to humans. To diagnose COVID-19, understanding and classifying CXR images are crucial. Deep CNN technologies, which aid radiologists, improve the effectiveness of imaging tools. Our goal in this research is to design a novel CNN model capable of achieving an almost perfect classification accuracy with fast execution time and low storage use. Here, we describe the architecture of our proposed method, namely FHDNN as illustrated in Fig. 1.

The proposed CNN model was built and trained on the COVID-19 four class dataset using the Python programming language and the Keras library. The work was developed using an I7- 4710H Intel processor, 2.50 GHz CPU, 8.0 GB RAM, and an NVIDIA Quadro K2100M graphic card.

After extracting features using LDA and feature expansion, the proposed FHDNN is designed to work with eighteen one-dimensional features. It takes a package of input features, processes them, and classifies them into specific categories. The FHDNN consists of multiple layers that are interlinked and arranged in a way that enhances its performance. When processing each input data set, the eighteen features pass through a series of convolution layers, pooling layers, and fully connected layers (FC) to classify objects with probabilistic values between zero and one.

Proposed Fast Hybrid Deep Neural Network
Model
Prediction

Fig. 1. The flowchart of the proposed system for COVID-19 diagnosis.

To conduct the training process, we divided the dataset into two groups: 70% for training and 30% for testing. Next, we applied the training to adjust the model's parameters and prevent overfitting. This ensures that the model has a high generalization power to accurately classify unseen images during testing.

On the other hand, the images used in our experiments were obtained from publicly available datasets on Kaggle called COVID-19 Radiography Database. The dataset used in our study is already labeled into four classes: COVID, normal, lung-opacity, and pneumonia. This large dataset is designed to assist researchers in evaluating their proposed methods in terms of accuracy and time consumption. A detailed description of this dataset, including the number of samples in each class, is presented in Section IV (Dataset). Accordingly, to solve this problem we are designing FHDNN to predict COVID-19 diagnosis. Before using the model, the dataset passes some steps to reduce storage size, increase implementation speed, and improve classification accuracy:

- Converting the dataset into the gray level and ensuring all images are converted from three channels to 1 channel.
- Adjust image intensity using the HE method.
- Resizing all dataset images for speed execution. The operation extracts the best features using LDA for the best classification.
- Performing feature expansion after preprocessing from CXR images is crucial in improving the accuracy of the algorithms. The expanded features' approaches are Average, Maximum, Minimum, Mode, Standard deviation, and Variance ratio.

Lastly, we implement FHDNN to provide fast and highly accurate diagnostics for COVID-19 diseases from CXR images. In the, following sections, we will detail the different parts of the developed methodology.

IV. Dataset

Although there are numerous COVID-19 infections across the world, a large number of CXR images are freely accessible online. Many authors published a Kaggle database [24] to make the database open in front of researchers worldwide. Usually, the CXR images of COVID-19, viral pneumonia, and lung opacity are available in the database. Here, we have four classes of images in the dataset as follows:

- Class 0: 3616 confirmed COVID-19 cases.
- Class 1: 10,192 normal cases.
- Class 2: 6,012 lung- Opacity cases.
- Class 3: 1345 pneumonia disease cases.

Lastly, Fig. 2 shows the viral pneumonia chest CXR. Across the dataset, the seam size (299*299) images are consistent.

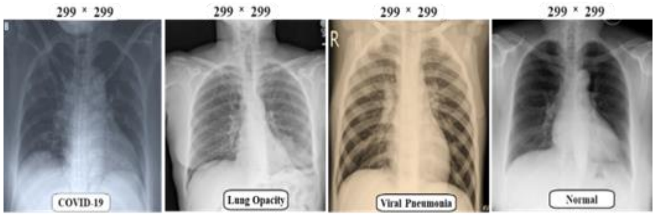

Fig. 2. Sample of CXR images for each class.

V. Dataset Preprocessing

Dealing with enormous amounts of data necessitates the use of the most efficient features for minimizing hardware requirements, such as memory and processing CPU. As mentioned earlier, the experiments' dataset of (21,165) images is classified into four classes. In the beginning, convert the images to one gray level (i.e., one color level). Grayscale is a monochromatic (gray) shade ranging from pure white on the lightest end to pure black on the darkest end. Less information must be provided for each pixel is the reason for differentiating images from any other color ones. Typically, the grayscale intensity is kept as an 8-bit integer, allowing 256 shades of gray ranging from black to white. The soothing impact on the eyes increases the gift of the green color, reduces the contribution of red color, and puts blue between these two [29] (formulated as follows):

$$\text{Grayscale} = \big((0.3 * Red) + (0.59 * Green) + (0.11 * Blue)\big) \quad (1)$$

During this stage, no image of RGB on the dataset has been identified, and the same color levels will all images have. Next, the second stage eliminates noise. CXR images appeared to have a gray level. However, there is an overlap in the image to ensure that it is converted to one group. Fig. 3 shows sample CXR images converted from multi-colors to grayscale.

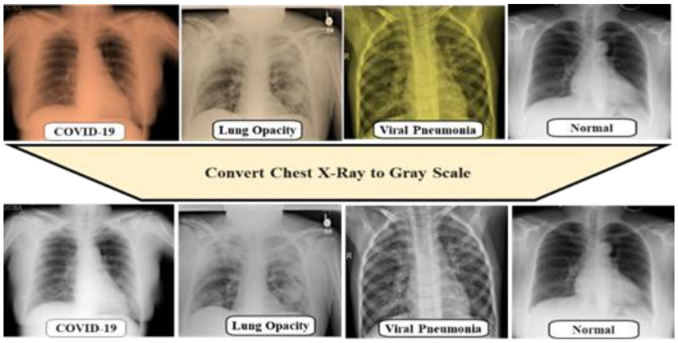

Fig. 3. CXR image samples from different datasets converted to gray level.

CXR images need to distribute lighting over the image by HE adequately. HE is a crucial topic in digital image processing used for contrast adjustment via an image's histogram (i.e., HE is used to enhance contrast). Furthermore, it modifies the image strength to increase opposition [30]. Image improvement aims to improve its quality, highlight desired elements, and make it less intrusive. In an image's histogram, the gray level values are plotted versus the number of pixels at that value. Mathematically, equilibrium can be formulated as follows.

$$\boldsymbol{G(x) = \left(\left(\frac{T(x)}{n}\right) * L\right) - 1} \qquad (2)$$

Where the new image after equalization is denoted as G(x), L is the number of gray levels, n is the number of pixels, and T(x) refers to the cumulative sum of each gray level. Fig. 4 shows an application of HE on CXR images.

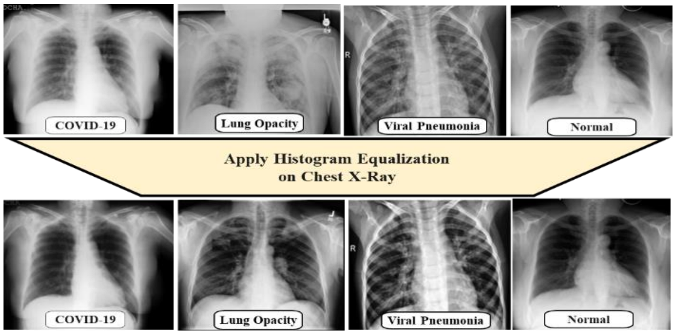

Fig. 4. Applying a Histogram of a CXR image before and after equalization (images are from different datasets).

Image speed and storage size are crucial in image processing, where the image plays an influential role in processing the data in terms of speed. Therefore, we reduced the number of images (of each dataset) to increase processing speed with low storage capacity. At this point, image size must be reduced for faster implementation and less storage space. For giving different resolutions and aspect ratios, resizing images have appeared in many applications. We resized the images from (299 x 299) to (50 x 50). Fig. 5 shows four samples resized from the original 299 x 299 to size 50 x 50. The required formula for resizing is written as follows [31]:

$$\boldsymbol{Ratio = W \,/\, H} \qquad (3)$$

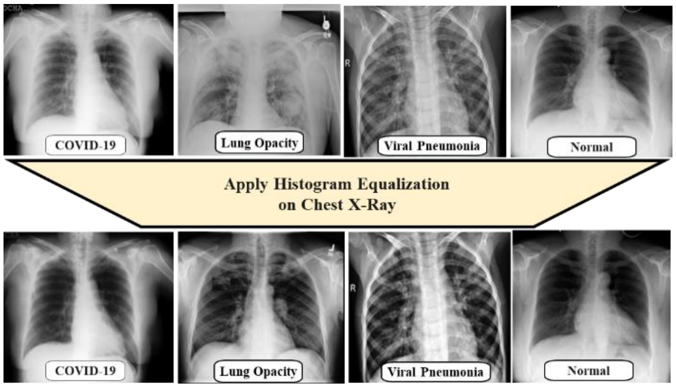

Fig. 5. Sample of resizing four images of the adopted classes.

VI. Features Extraction

The accuracy of the utilized algorithms (ML or DL) can be increased by extracting features (from CXR images) because of an increase in the infection probability. In the literature, since it obtains the best features of image characteristics [32], LDA is the most favored method for extracting discriminative feature pattern classification [33]. LDA starts after completing the earlier stages of image processing. However, when dealing with high-dimensional and small sample-size data, classical LDA suffers from the singularity problem. Under supervision, the LDA reduces dimensionality inside a single classification and separates the classifications so we can select the best image type [34]. The main pros of LDA are that it separates two or more classes and models the group differences in groups by projecting the spaces in a higher dimension into space with a lower extent. Both features create a new axis that minimizes the variance and maximizes the two variables' class distance. Calculate each class's average from the CXR image within the dataset by LDA Algorithm. The mathematical equations used in LDA are similar in action are identical in action [33]. Image preprocessing techniques are applied before model training to achieve better detection accuracy and reduce training duration. Specifically, preprocessing will ensure that the image is transformed from two dimensions to one dimension, consequently speeding up the implementation. Additionally, a propionate fast deep learning proposal design must be utilized for further detection accuracy and higher speed. After implementing LDA, the stages are gray level, histogram equalization, stages are resized, and the best features are extracted.

The development of DL algorithms products is a significant contribution to dataset reprocessing. In the beginning, the images are converted to a single channel with suitable resizing and highlighting desired elements extracting the features. Next, we perform classification between classes and reduce dimensionality within a single category. Accordingly, database preprocessing is essential for enhancing data quality to speed up deep learning with optimal performance.

VII. Feature Expansion

This section explains a feature expansion approach for the one-dimension. As mentioned earlier, LDA is implemented after completing preprocessing on a dataset of CXR images. The output of the LDA got three components from CXR images [35].

The proposed feature expansion is capable of increasing the number of features from three to eighteen. This procedure applies a window that slides through the pattern to expand the high and low elements. The window is a (one × ten) shaped matrix and will be transformed with the input pattern matrix. For data classification, feature expansion can improve classification accuracy by enabling deep CNN application on any dataset from CXR images. Furthermore, feature expansion is helpful if there is a variance in the CXR or a change in the x-ray equipment, such as reducing noise in an image. According to the literature, experiment results demonstrated that the feature expansion method improves the classification performance of CNN algorithms for detecting COVID-19. Finally, the expanded features' approaches (as explained below) are average, maximum, minimum, mode, standard deviation, and variance ratio.

A. Average

The average (or mean) of a set of numbers is calculated by dividing their summations by how many they are. Mathematically, the mean format $\bar{x}$ of a data set is the sum of all data values divided by the count or size n. The following equation can be used to determine the average or mean of a window within the dataset [35].

$$mean = x^{-} = \frac{\sum_{i=1}^{n} x^{i}}{n} \qquad (4)$$

B. Maximum

Finding the maximum value within a window and checking with all data is important. A real-valued function f defined on a domain (X) has a global (or absolute) maximum point at

$$x_i.if\ f(x_i) \geq f(X) for\ all\ x\ in\ X \qquad (5)$$

The value of the function at the top ended the total weight of the process [36].

C. Minimum

The minimum value of a function is determined by finding the lowest value within a window. The value of the process at a minimum point is called the minimum value of the position [36]. Symbolically, this can be written as follows:-

$$x_i.if\ f(x_i) \leq f(X) for\ all\ x\ in\ X \qquad (6)$$

D. Mode

Mode is the number (or value) that appears most frequently in a data set. For data without any repeating values, there is no mode at all. Furthermore, the mode value depends on the given dataset. It is formulated as follows [37].

$$Mode = L + h\ \frac{(\boldsymbol{f_m - f_1})}{(\boldsymbol{f_m - f_1}) + (\boldsymbol{f_m - f_2})} \qquad (7)$$

Where L the lower limit of the modal class is, h is the size of the class interval, and f_m denotes the frequency of the modal class. f_1 (f_2) .This is the frequency of the class preceding (succeeding) the modal classes.

E. Standard Deviation

Standard deviation is a formula used to determine the values of scattered data. It is the deviation of the values or data from an average to a mean. A smaller (larger) standard deviation indicates that the results are nearer to (far from) their average. It is important to mention that no negative value can standard deviation be. It is formulated as follows [38].

$$the\ Standard\ deviation = \sqrt{\frac{\sum(\boldsymbol{X}-\boldsymbol{\mathcal{X}}^{-})^2}{\boldsymbol{n}-\boldsymbol{1}}} \quad (8)$$

Where X is each value in the sample t, $\mathcal{X}^{-}$ refers to sample means, and n is the number of values in the sample.

F. Variance Ratio

Statistically, variance (symbolized by σ^2) refers to the spread between numbers in a data set. In other words, variance calculates how far every number is from the average (i.e., from other numbers in the group). Both traders and analysts use it to find volatility through the dataset. Variance is calculated as follows [39]:

$$\boldsymbol{\sigma^2} = \frac{\sum_{i=1}^{n}(\,x_i - x^{-}\,)^2}{N} \quad (9)$$

Where $\mathcal{X}^{-}$ refers to the mean of all values in the dataset, $\boldsymbol{x_i}$ is each value in the dataset, and $\boldsymbol{n}$ is the number of values in the dataset.

VIII. Fast Hybrid Deep Neural Network

A. Preliminaries

In the state-of-the-art, researchers and authors who use transfer learning for COVID-19 detection need to consider the trade-offs between accuracy and computational resources, as well as the time required to fine-tune the model on large datasets. It is important to carefully balance these factors to ensure that transfer learning can be applied effectively in the state of the art for COVID-19 detection. These trade-offs are not easy to ensure. Although the ensemble model can enhance the efficiency of each model separately, its implementation requires fine-tuning the aforementioned deep models which is a very challenging task since it requires powerful machines.

Alternative methods have been proposed to extract deep features and feed them into an SVM classifier without utilizing transfer learning, as demonstrated in [40]. However, this approach is less time-consuming, but it lacks a high generalization power because the extracted features are tailored to the ImageNet dataset initially used to train the model. Consequently, the SVM classifier may not achieve a very high accuracy level.

To solve this problem, the proposed HFDNN aims to extract features using LDA and apply some feature engineering to feed a DNN for detection. This strategy will avoid fine-tuning existing models to large datasets, and considerably speed up the training process. Before the dataset was enlarged, it underwent preprocessing, and the best features were extracted using LDA. Next, we altered it from two dimensions to one dimension to shorten training time and hardware needs. By using this method, existing models won't need to be adjusted for large datasets, and the training process will be greatly accelerated. In this section, we explain our proposal, the fast hybrid deep Convolutional Neural Network model to detect COVID-19 from CXR images.

B. Modeling

A rapid diagnosis of COVID-19 is necessary to treat and control the disease. CXR is an essential tool that can be used to find COVID-19. Therefore, this study aims to improve classification accuracy and reduce training time and hardware requirements. Furthermore, it should accurately identify COVID-19 cases so doctors can treat patients appropriately. Therefore, we proposed to utilize a novel deep-learning method to predict COVID-19 using CXR images based on deep CNN. The proposed model implements the preprocessing on the dataset from CXR images in some steps before applying the proposed deep CNN for the COVID-19 classification. As explained later, our model's (FHDNN) objectives are the automatic identification of four classes: 1) normal, 2) lung opacity, 3) viral pneumonia, and 4) COVID-19. As it is named, FHDNN is a quick deep CNN used to classify CXR images for detected COVID-19. The proposed FHDNN deals with features (eighteen features) that must be one-dimensional. FHDNN takes an input package of features, processes it, and classifies it under specific categories. It consists of several layers intertwined with each other and arranged in a way that makes it more highly. For each input data set, eighteen features pass through a series of convolution layers with filters, Pooling, and Fully Connected layers (FC) to classify objects with probabilistic values between (zero and one). The architecture of FHDNN for COVID-19 detection is depicted in Fig. 6. FHDNN comprises twenty-seven layers categorized as follows:

- Eight Conv1D layers: Eight convolutional layers are used for feature extraction of type 1D.
- Seven MaxPooling 1D layers.
- Three Dense layers: They are divided into 1) One layer representing a fully connected layer in a convolutional neural network; and 2) two dense layers are placed before the Flatten to obtain robust features closer to them.
- Eight LeakyReLU layers: The Activation function is LeakyReLU.
- One Flatten layer: The full connection step in CNNs.

C. Layers of FHDNN

As mentioned earlier, the FHDNN is expected to achieve accurate classification results due to dealing with one-dimension CXR images (after preprocessing datasets). Table I lists and explains the FHDNN layers in terms of Filters, Strides, and Padding. We listed detailed explanations and clarification of each layer with the activation and setting of all parameters in each layer. The difference is the structure of the input data and how the filter (also called a feature detector or a convolution kernel) moves across the data. It is worth mentioning that the attained FHDNN model layers and their parameters in this network are one-dimensional (will be explained and shown according to the order of layers).

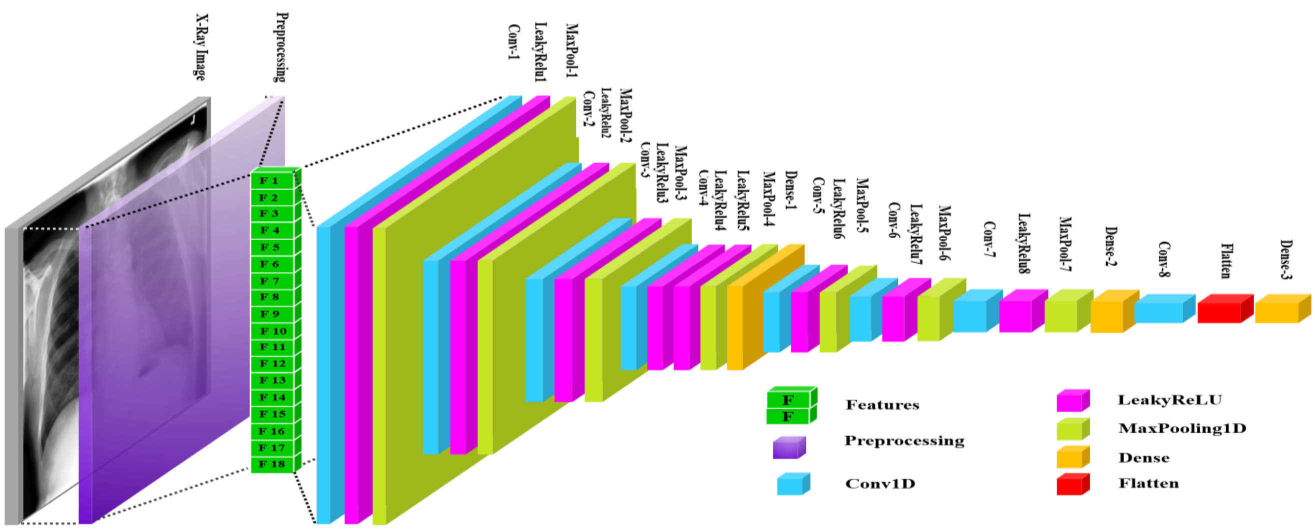

Fig. 6. FHDNN architecture.

TABLE I. INFORMATION OF FHDNN LAYERS

No	Layer	Filter	Strides	Padding
1.	Max pooling 1D-1	16	1	-
2.	LeakyReLU-1	-	-	-
3.	Convolution 1D -1	16	1	Valid
4.	Max pooling 1D-2	32	1	-
5.	LeakyReLU-2	-	-	-
6.	Convolution 1D-2	32	1	Valid
7.	Max pooling 1D-3	32	1	-
8.	LeakyReLU-3	-	-	-
9.	Convolution 1D-3	32	1	Valid
10.	Max pooling 1D-4	128	1	
11.	LeakyReLU-4	-	-	-
12.	Convolution 1D-4	128	1	Valid
13.	Dense 1D-1	128	-	-
14.	Max pooling 1D-5	256	1	-
15.	LeakyReLU-5	-	-	-
16.	Convolution 1D-5	256	1	Valid
17.	Max pooling 1D-6	512	1	-
18.	LeakyReLU-6	-	-	-
19.	Convolution 1D-6	512	1	Valid
20.	Dense 1D-2	1024	-	-
21.	Max pooling 1D-7	1024	1	-
22.	LeakyReLU-7	-	-	-
23.	Convolution 1D-7	1024	1	Valid
24.	LeakyReLU-8	-	-	-
25.	Convolution 1D-8	50	1	-
26.	Dense 1D-3	4	-	-
27.	Flatten 1D-1	50	-	-

The utilized layers are arranged as follows:

- Eight convolutional layers in the proposed lightweight CNN model have sequential filters (16, 32, 32, 128, 256, 512, 1024, and 50). This layer applies kernels that slide through the pattern to extract low- and high-level features [41]. The kernel is a (one × three) shaped matrix to be transformed with the input pattern matrix. The stride is (one × one) that parameter is the number of steps tuned for shifting over the input matrix. During the design process, the padding was omitted from the border elements. The padding is designated as 'VALID' in the remaining convolutional layers and does not consider the boundary components.
- Eight LeakyReLU layers are set to (alpha=0.3). The activation function LeakyReLU is used as an activation function after every convolutional layer. The LeakyReLU layers were used twice after the convolutional layer with filter size 128. Next, the third layer after the LeakyReLU layer is the pooling layer.
- The pooling layer is usually applied to the created feature maps. It aims to reduce the number of feature maps and network parameters by applying corresponding mathematical computation. A (one × one) max pool is used seven times after each convolutional block.
- As we propose a lightweight FHDNN model, three dense layers have been used. The dense layer performs a matrix-vector multiplication, and the values used in the matrix are parameters that can be trained and updated with the help of backpropagation. The output generated by the dense layer is an 'n-dimensional vector. The activation function (linear) uses the two dense layers by setting the vector sequential as follows (128, 1024). The activation function (softmax, 4) is the last dense layer to classify four classes.

- Lastly, to flatten the matrix into a vector, a flattening layer was used once. Additionally, the most and last crucial layer of FHDNN is fully connected. This layer functions like a multilayer perceptron. Rectified linear unit (LeakyReLU) activation function is commonly used on a fully connected layer. In contrast, the softmax activation function is used to predict output images in the last layer of a fully connected layer. This step will look at the softmax regression used for multi-class classification problems.

Now, we can explain the experimental parameters obtained from each layer at the proposed system procedures implementation on the CXR Images for diagnosis of COVID-19. As listed in Table II, the FHDNN model includes a mix of convolution neural network layers. Afterward, the parameters of every layer in the FHDNN are presented to show the success of the submitted diagnosis of COVID-19 by using CXR images. The total number of parameters is 3,303,494, and the batch size equals 64. Finally, Table II also summarizes the proper trainable parameters for each layer of the FHDNN model.

TABLE II. SUMMARY OF THE FHDNN MODEL

Layer (type)	Output Shape	Number of parameters
Conv1d (Conv1D)	(None, 16, 16)	64
Leaky_re_lu (LeakyReLU)	(None, 16, 16)	0

Flatten (Flatten)	(None, 100)	0
Dense_2 (Dense)	(None, 4)	404

IX. PERFORMANCE EVALUATION

A. Evaluation Metrics

After the model is trained, we evaluate its performance using the images of the testing dataset. In this work, we adopted the following evaluation matrices: Accuracy, Precision, Recall, and F1-Score. Before delving into the results, we need to explain these metrics. After the model's movement, the FHDNN's performance on the testing dataset was evaluated. It is important to mention that this study did not use cross-validation. Therefore, the holdout validation technique has been used instead because the dataset has enough samples for testing and training.

A confusion matrix table is usually used to explain the classifier's performance (i.e., model classification) on a data set in which its actual cases are known. The confusion matrix comprises four parameters (TP, FP, TN, and FN). While TP and TN refer to the patient being classified correctly, FP and FN mean it misdiagnosed the case (i.e., classified incorrectly). This section briefly defines the evaluation metrics in AD classification. Following, we explain the evaluation metrics.

1) Accuracy: It is widely used to measure the model's accuracy validation (training) or classification. As mentioned above, via a confusion matrix, the number of TP, TN, FP, and FN are calculated, which further helps check the proposed model's efficacy. Accordingly, as formulated in Eq. (1), the accuracy is the number of correct classifications (i.e., TP and TN) divided by the total number of classifications.

$$\boldsymbol{Accuracy} \;= \frac{\boldsymbol{TP+TN}}{\boldsymbol{TP+TN+FP+FN}} \tag{10}$$

2) Precision: It calculates how many cases classified as positive (infection) by the model was supposed to be indicated as positive. It is defined as the ratio of classified TPs to the total number of classified positives (correctly (TP) and incorrectly (FP). Thus, it is formulated as follows.

$$\boldsymbol{Precision} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FP}} \tag{11}$$

3) Recall: The third measure of the confusion matrix is Recall (or sensitivity). The recall is the number of positive cases foretold adequately by the model is estimated by the recall, sensitivity, or "actual positive rate. Recall calculates how well the model has classified the positive examples. It is defined as the ratio of classified TPs to the real positives and is written as follows.

$$\boldsymbol{Recall} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FN}} \tag{12}$$

4) F1-score: It is the harmonic mean of precision and recall. Perfect precision and Recall can achieve the highest F-score (i.e., close to 1).

$$\boldsymbol{F1-score} \;= \boldsymbol{2} * \frac{(\boldsymbol{Recall} * \boldsymbol{Precision})}{\boldsymbol{Recall} + \boldsymbol{Precision}} \tag{13}$$

Preparing the dataset preprocessing is one of the prime aspects of training and testing deep learning for the desired results. The CXR images have passed through multi-steps in preprocessing before entering the FHDNN layers, providing an accurate effect in the classification procedure.

B. Model Performance

The training time required to train the FHDNN algorithm is important to look at the accuracy obtained from the classification algorithm. For instance, 100 epochs are recommended in FHDNN training. When using FHDNN, the training time is 14 sec, which differs from the attained feature extraction algorithms. The obtained error rate (α) from training the classifier is 0.0001. Table III lists the results of applying FHDNN with the four classes (COVID-19 class, normal, lung-opacity, and viral Pneumonia, based on the performance confusion matrix. As listed in Table III, the performance metrics of the proposed modes achieved the following results. Firstly, the accuracy of the model reached 99.9%. Secondly, the model's foretelling of positive samples is assessed by precision. Meanwhile, the models' level of precision showed that FHDNN has the most fantastic weighted average value of 99.9% for the four classes. Thirdly, the actual positive rate (sensitivity) measures the number of positive cases correctly foretold by the model. The Sensitivity of the model reached 99.9%. Lastly, the F1-score achieved an almost perfect value, 99.9%.

TABLE III. PERFORMANCE OF THE PROPOSED MODEL

Type	Accuracy	Precision	Recall	F-score
COVID-19	99.9%	99.9%	99.9%	99.9%
Normal	99.9%	99.9%	99.9%	99.9%
Lung- Opacity	99.9%	99.9%	99.9%	99.9%
Viral Pneumonia	99.9%	99.9%	99.9%	99.9%

C. FHDNN vs. Counterparts

Using CXR images, many DL models-based COVID-19 classification systems have been utilized widely. For example, AlexNet, ResNet, VGG16, VGG19, and GoogleNet. To demonstrate the superiority of our work, we compare it with the achievements of some CNN-based models in the literature. The comparisons are based on: classification classes, accuracy, precision, recall, F-score, and training time. Additionally, we compared our proposal with 12 studies that utilized CNN models.

Before comparing the models with ours, it is important to mention that the convolutional layers for MobileNetV2, DenseNet-121, ResNet50, VGG19, and ChestX-Ra6 are 53, 121, 50, 16, and 6, respectively. Their training times are 6457.20, 7571.84, 7018.10, 8215.94, and 6150.62 sec, respectively (see Fig. 7). It is important to mention that different computer configurations could provide different results. Although some studies calculated the training time, they consumed a very long training time. Specifically, the models completed the training in thousands of seconds (i.e., hours). On the other hand, our model needed only 13 sec. Some examples can be found in references [27] [42-52]. Except for the study [50], most models performed on 3 and 2-class classifications. However, our model is better than [50] in all evaluation metrics (accuracy, precision, recall, and F-score). Furthermore, our training time is significantly less than it. Similar to our work, the models [42] classified four classes; however, our model outperformed in performance evaluation metrics and training time. Accordingly, our model outperformed the counterparts.

When it comes to detecting COVID-19 using transfer learning techniques, one of the significant challenges is the amount of time it takes to apply these methods to large datasets. This process is particularly time-consuming when dealing with large amounts of data of CXR images, as the model needs to be fine-tuned to adjust its parameters. This requires retraining the model on the new data, which can take a significant amount of time, even with powerful computing resources. As a result, researchers and practitioners who use transfer learning for COVID-19 detection need to consider the trade-offs between accuracy and computational resources, as well as the time required to fine-tune the model on large datasets. It is important to carefully balance these factors to ensure that transfer learning can be applied effectively in the state of the art for COVID-19 detection. These trade-offs are not easy to ensure. To solve this problem, the proposed HFDNN aims to automate COVID-19 disease classification to maintain high accuracy and reduce execution time. The dataset was first preprocessed before being extended and the best features were retrieved using LDA. Next, in order to decrease training time and hardware requirements, we changed it from two dimensions to one dimension. This strategy will avoid fine-tuning existing models to large datasets, and considerably speed up the training process as shown in Fig. 7.

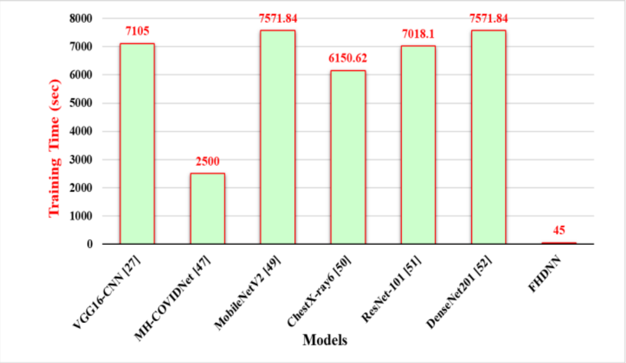

Fig. 7. Training time of each model (sec).

D. Performance matrix and comparison with related works

In this subsection, we explain the performance matrix and comparison with related works. Though the model is complex in architecture, it has twenty-seven convolutional layers. Still, the model classification performance is better than the other models. One of the main concerns of this study is designing a model that provides higher classification accuracy and reduces the training time with the lowest requirement hardware for large or small amounts of data. For that reason, a lightweight FHDNN model has been designed to measure whether it performed well for these criteria in the case of a multiclass environment.

1) Accuracy: Fig. 8 shows the tested obtained accuracy using some of the models of DL and our work. It is clear from the figure that our model achieved the highest classification accuracy, which has an accuracy of 99.9%.

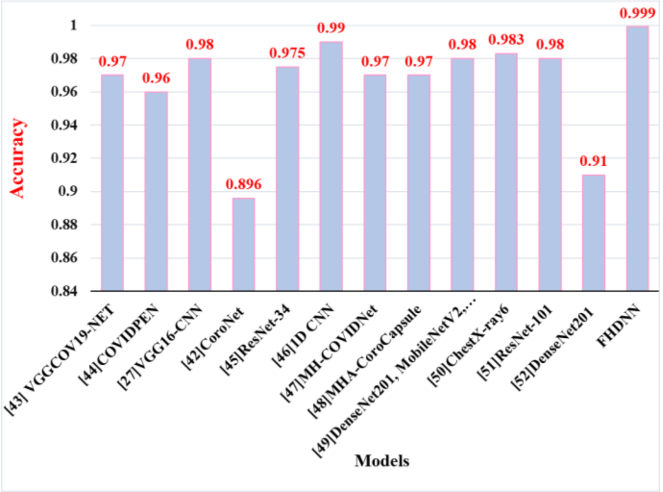

Fig. 8. The accuracy of the models.

2) *Precision:* The second is the precision that assesses the model precision in foretelling positive samples. Meanwhile, the six models' level of precision showed that FHDNN has the most excellent weighted average value (99.9%) for four classes than other models. Fig. 9 shows that the precision of FHDNN has the most excellent weighted average value (0.999) for four classes than other models of CNN.

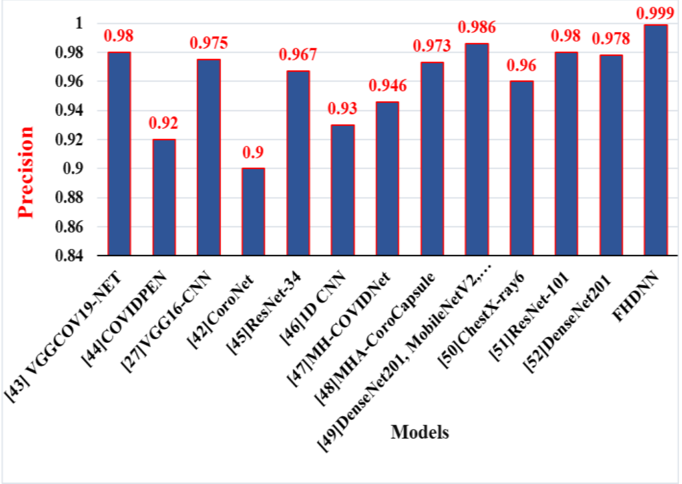

Fig. 9. The precision of the models.

3) *Recall:* As shown in Fig. 10, the results show FHDNN method outperforms the close models of CNN in a variety of weighted average sensitivities. The FHDNN determined weighted average has (0.999) of sensitivity, but the VGG19 has (0, 98), GoogleNet has (0, 92), DenseNet201 has (0.92), etc.

4) *F1-score:* As mentioned earlier, the F1-score is the harmonic mean of precision and recall. As shown in Fig. 11, the F1- score value of the different models also shows that the FHDNN has a value (of 99.9%), the highest compared to the related work comparison models. The results state that DL methods outperform the comparative models in classification F1-score (percentage).

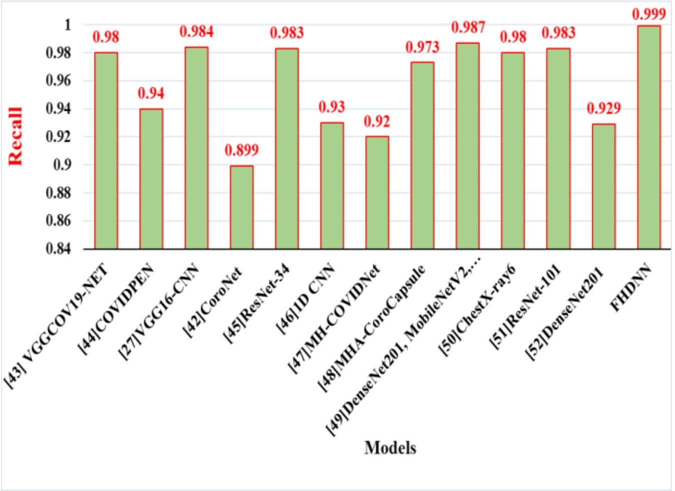

Fig. 10. Recall (sensitivity) of the models.

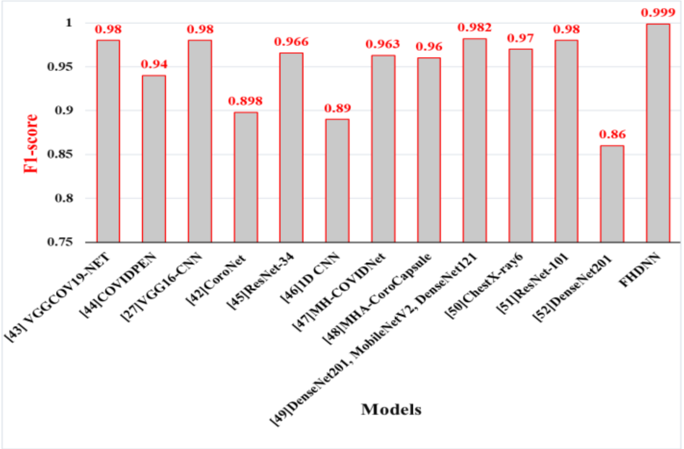

Fig. 11. F1-score of the models.

This article presented a DL method for fast detection and classification of COVID-19 disease. The preprocessing stage has been performed on the dataset to achieve better speed and accuracy. The comparison demonstrated that we achieved better results than some relevant previous works, knowing that it dealt with an extensive and unbalanced database. Furthermore, different DL models were applied to the same dataset for comparison, but they got lower results in all measures than in our proposal, FHDNN. The result states that FHDNN possesses the highest important parameters that measure each model's performance compared with other CNN models. Meanwhile, our model's accuracy, precision, and sensitivity show that FHDNN has 99.9% of the most outstanding value. The F1-score value of the DL models also states that the FHDNN has 99.9% and stays the most excellent weighted average compared to the CNN comparison models with less than FHDNN a value.

X. Conclusion

COVID-19 is one of the cases in which doctors and medical physicians face difficulties in correctly identifying these diseases. CXR imaging has several advantages over other imaging and detection techniques. If trained correctly, a machine can classify CXR images more accurately than a human. Numerous results have reported COVID-19 detection from a smaller or large set of CXR images. However, the literature did not say the effect of image enhancement and lung x-ray preprocessing of a large or small dataset of CXR images.

Therefore, this article proposed a novel lightweight new deep CNN (FHDNN) model to detect COVID-19 diseases using CXR images. To calculate our model's performance for detecting COVID-19 diseases, we trained our model using 21,165 CXR images after completing all preprocessing stages. These are classes unbalanced using various preprocessing techniques such as gray image level, resizing, and then enhancement by histogram equalization. Furthermore, we proposed extracting the best features by LDA, then the feature expansion approach and converting from two-Dimension to one-Dimension reduce time training. The proposed FHDNN model for multiple classifications (normal, pneumonia, lung-opacity, and COVID-19) achieved 99.9% in all performance metrics (accuracy, precision, recall, and F1-score). These results demonstrated the superiority of our model over the proposed CNN models (previous works). Our FHDNN model has achieved excellent performance in diagnosing COVID-19 by using CXR Images, which can help medical physicians diagnose these diseases correctly. In the future, we intend to apply the model and improve it for diagnosing other diseases by CXR images.

Department of Computer Science, Universitas Gunadarma, Depok, Indonesia[1, 3]
Department of Information Technology, Universitas Gunadarma, Depok, Indonesia[2, 4]

***Abstract*—Digital communication of multimedia data (text, signal/audio, image, and video) through the internet network has an important role in the era of industrial revolution 4.0 and society 5.0. However, the easiness of exchanging personal and confidential digital information/data has a high risk of being hijacked by irresponsible people. The development of reliable and robust data encryption methods is a solution to this risk. This paper suggests combining modified Henon Map transposition encryption and Logistic Map keystream substitution encryption to create a novel data encryption method (called RaMSH-1). The proposed algorithm simultaneously transposes data positions and substitute data values randomly, as well as having encryption key combination or key space of 1.05 × 10^{670}. A few images with various sizes and variations of color features, object shapes, and textures have been tested. Based on the results of the analysis of randomness, key sensitivity, and visual, it is evident that the proposed encryption algorithm is resistant to differential attack, entropy attack and brute force attack.**

Keywords—Encryption; Decryption; Digital Image; RaMSH-1 Map Transposition; Logistic Map Substitution

I. Introduction

Data security is an important issue in technological advances. Private data requires data security to protect the data from hacker or cracker [1]. Cryptography is a science related to data security. Cryptography is used to transform plaintext into ciphertext to make the meaning of message difficult to read [2]. Data can be in the form of digital images that can have many meanings. Data security methods such as encryption can be implemented on digital image data.

Transposition and substitution methods are techniques of data encryption. The transposition method in data security is used to randomize data by permuting the position of data sequence from the original data [3]. In the digital image encryption, this method is used to randomize the pixel position coordinate. The new pixel position coordinate is an encrypted image. The substitution methods are used to replace original data with other data [4][5]. This method is used to replace the pixel color intensity value to a different value [6]. The new pixel color intensity value is an encrypted image. These two methods can be combined to strengthen the security of encrypted image.

Transposition and substitution techniques have been used in numerous studies on digital image security. Ping's research suggests applying Henon Map keystream substitution and transposition for encryption. Henon Map comes in two models which are transposition and generating keystream. Henon Map transposition encryption and decryption functions can only be used for square-size-image N×N (width = height) [7].

Research by Lone proposes encryption using Random Matrix Affine Cipher (RMAC) transposition, Henon Map transposition, Logistic Map keystream substitution. The encryption process is carried out sequentially, so it takes longer time in encryption process. Research by Lone has limitation which is that the encryption process cannot be implemented on images with size of M≠N (width ≠ height) [8].

Research by Ratna proposes encryption using Cat Map transposition and Henon Map keystream substitution. The encryption process on image with size M≠N is carried out by adding dummy pixels, so the image size is larger than the original size. The limitation in Ratna's research is that the Cat Map transposition function can only carried out in the image with size N×N [9].

The Henon Map and Cat Map transposition functions have the advantage of being able to randomize the position of pixel coordinates based on the value of key variable, but these functions have limitations which can only be implemented on image with size N×N. Padding the image with size M ≠ N (width ≠ height) into N×N (width = height) can be done but it will enlarge the size of original image, so the encryption process times takes longer.

The Logistic Map functions has the advantage of being able to generate a keystream using two sensitive key variable which can be used to substitute pixel color intensity values, but to strengthen the security of encryption method, the substitution technique can be combined with transposition technique.

This paper proposes a combination of transposition and substitution encryption method called RaMSH-1 (Rama, Madenda, Suhatril, Harmanto). In the transposition encryption section, a modified Henon Map function is proposed, so that it can be applied to all image sizes without padding. Furthermore, the combination of the proposed transposition encryption function with the Logistic Map keystream substitution function aims to increase the encryption key combination so that the probability of finding the key will be smaller.

II. Methods

This research proposes the RaMSH-1 Map transposition and Logistic Map keystream substitutions functions for encryption and decryption methods. The development of proposed method aims to encrypt and decrypt digital image with all size of image and has a high level of security. This study is focused on 8-bit RGB images.

The RaMSH-1 Map transposition is used to randomize the pixel position coordinates and the Logistic Map is used to generate a keystream that is used to replace the pixel color intensity values. The encrypted image is represented by new pixel position coordinates and color intensity values. To convert the encrypted image back to the original image, the pixel position coordinates, and color intensity values must be restored. The proposed methods for encryption and decryption are shown in Fig. 1.

A. RaMSH-1 Map

RaMSH-1 Map is modification of the Henon Map transposition function. Henon Map function has limitation which can only perform encryption and decryption on image with size N×N (width = height) because there are a crossing transposition in coordinates x́ ← y and ý ← x, so some pixels in the original image with different coordinates (x,y) are transposed to the same coordinate (x́, ý) [10]. This cause- the pixels cannot return to the original coordinates when decryption process is carried out. Eq. (1) and (2) are the encryption and decryption functions of Henon Map Transposition.

$$I(\acute{x},\acute{y}) \leftarrow I(x,y)\ where \begin{cases} \acute{x} = 1 - cx^2 + y \bmod (N) \\ \acute{y} = (x+d) \bmod (N) \end{cases} \qquad (1)$$

$$I(x,y) \leftarrow I(\acute{x},\acute{y})\ where \begin{cases} \acute{x} = 1 - cx^2 + y \bmod (N) \\ \acute{y} = (x+d) \bmod (N) \end{cases} \qquad (2)$$

Modification of the Henon Map to RaMSH-1 Map is carried out by transposing x́ ← x and ý ← y. The modulo process is also carried out according to the size of image at these coordinates. Eq. (3) and (4) are the encryption and decryption function of the RaMSH-1 Map transposition.

$$I(\acute{x},\acute{y}) \leftarrow I(x,y)\ where \begin{cases} \acute{x} = 1 - cy^2 + x \bmod (M) \\ \acute{y} = (y+d) \bmod (N) \end{cases} \qquad (3)$$

$$I(x,y) \leftarrow I(\acute{x},\acute{y})\ where \begin{cases} \acute{x} = 1 - cy^2 + x \bmod (M) \\ \acute{y} = (y+d) \bmod (N) \end{cases} \qquad (4)$$

The variable keys of RaMSH-1 Map function are c and d with positive integer values. The width of the image is represented by M. The height of the image is represented by N [11]. The pixel coordinates are represented by (x, y). I(x,y) represents the original image as its value. The value of I(x́,ý) represents an encrypted image whose pixel position coordinates have been randomly generated. RaMSH-1 Map function can be applied in all image size.

B. Logistic Map

The chaotic function known as the logistic map is highly sensitive to the generation of keystream [12]. The original image's pixel color intensity values are substituted with the keystream value, changing the color intensity value. The Logistic Map function to generate keystream is defined in Eq. (5).

$$g_{n+1} = z \times g_n \times (1 - g_n) \qquad (5)$$

The Logistic Map function has two key variables g_0 and z which are real number with range of value $0 < g_0 < 1$ and $3.5 < z \leq 4$. The keystream is calculated by Eq. (6). The keystream is represented as e_n with value from 0 to 255. The value of n is the numbers of pixels in the image where n = (0, 1, …., T-1), T = M×N. Keystream substitution is carried out by XOR process in Eq. (7).

$$e_n = round(|g_n \times 10000|) \bmod 256 \qquad (6)$$

$$\acute{I}(\acute{x},\acute{y}) = e_n \oplus I(\acute{x},\acute{y})_n \qquad (7)$$

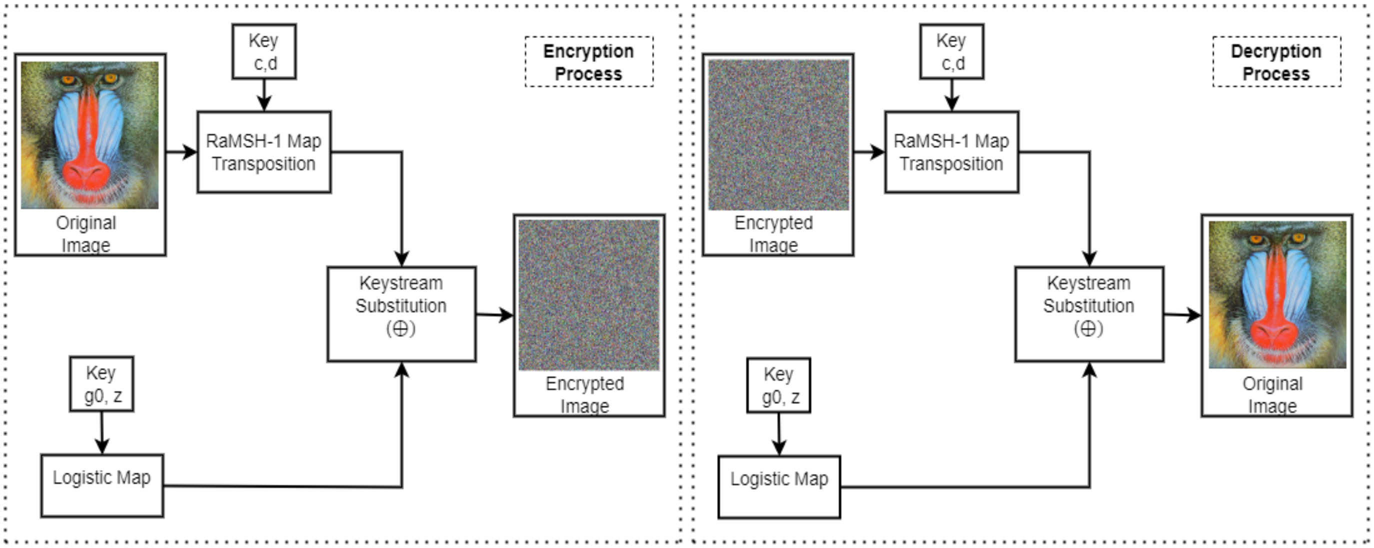

Fig. 1. Proposed methods for encryption and decryption.

C. Proposed Encryption Algorithm

RaMSH-1 Map transposition is used in Eq. (3) to randomize the pixel position coordinates during the encryption process. The encryption algorithm that is proposed is Algorithm 1. Algorithm 2 is used to modify the pixel color intensity values by keystream substitution.

Algorithm 1: Process for Proposed Encryption

```
Input: Variable c, d, g_0, z, Original Image $I(x,y)$
Output: Cipher Image $I'(x',y')$
$M \leftarrow width\ of\ image$
$N \leftarrow height\ of\ image$
$e_n \leftarrow Logistic\,(N, g_0, z)$
$n \leftarrow 0$
    for $x \leftarrow 0$ to $M-1$ do
        for $y \leftarrow 0$ to $N-1$ do
            $x' \leftarrow (1 - cy^2 + x)\ \mathrm{mod}(M)$
            $y' \leftarrow (y + d)\ \mathrm{mod}(N)$
            $I'(x',y') \leftarrow e_n \oplus I(x,y)$
            $n \leftarrow n+1$
        end for
    end for
```

Algorithm 1 step $e_n \leftarrow Logistic\,(N, g_0, z)$ is to call the Logistic Map function for generating keystream. Steps $x' \leftarrow (1 - cy^2 + x)\ \mathrm{mod}(M)$ and $y' \leftarrow (y + d)\ \mathrm{mod}(N)$ are randomization of pixel position coordinates by RaMSH-1 Map transposition. Step $I'(x',y') \leftarrow e_n \oplus I(x,y)$ is generating encrypted image using a keystream replacement to change the value of the pixel's color intensity. The encryption technique uses a single loop to carry out the transposition and substitution operations.

D. Logistic Map Keystream Algorithm

The Logistic Map function in Eq. (5) and (6) are applied in the keystream generation process. The Logistic Map keystream algorithm is used in Algorithm 2.

Algorithm 2: Keystream Generation of Logistic Map

```
    function $Logistic(M, N, g_0, z)$
    $T \leftarrow M \times N$
        for $n \leftarrow 0$ to $T-1$ do
            $g_{n+1} \leftarrow z \times g_n \times (1 - g_n)$
            $e_n \leftarrow round\left(\left|g_{n+1} \times 10000\right|\right)\mathrm{mod}(256)$
        end for
    end function
```

Algorithm 2 step $T \leftarrow M \times N$ is a calculation of pixels number in the image. Step g_{n+1} is the Logistic Map function. Step e_n is a function to generate keystreams Logistic Map. Keystreams were generated in an amount equal to the number of pixels in the image.

E. Proposed Decryption Algorithm

The decryption method uses the same procedure as the encryption process, but instead returns values for pixel position coordinates and color intensity. The proposed decryption algorithm is Algorithm 3.

Algorithm 3: Process for Proposed Decryption

```
Input: Variable c, d, g_0, z, Cipher Image $I'(x',y')$
Output: Original Image $I(x,y)$
$M \leftarrow width\ of\ image$
$N \leftarrow height\ of\ image$
$e_n \leftarrow Logistic\,(N, g_0, z)$
$n \leftarrow 0$
    for $x \leftarrow 0$ to $M-1$ do
        for $y \leftarrow 0$ to $N-1$ do
            $x' \leftarrow (1 - cy^2 + x)\ \mathrm{mod}(M)$
            $y' \leftarrow (y + d)\ \mathrm{mod}(N)$
            $I(x,y) \leftarrow e_n \oplus I'(x',y')$
            $n \leftarrow n+1$
        end for
    end for
```

The variable key used in the encryption and decryption processes is same. The distinction between the encryption and decryption processes is that the decryption process uses encrypted images as input, whereas step $I(x,y) \leftarrow e_n \oplus I'(x',y')$ of algorithm 3 restores encrypted images to their original forms.

III. Result and Discussion

The research experiment of proposed algorithm used image data with variety of colors, shape, and texture. The size of image is M = N: 512×512 pixel, M > N: 1500×1000 pixel, and M < N: 2850×3200 pixel. Matlab R2020a, which runs on a computer system with an Intel (R) Core (TM) i7-4790 CPU, a processor clocked at 3.60 GHz, 16 GB of RAM, and the Microsoft Windows 10 operating system, is the software utilized in this study. The analyses used in the experimental are histogram, correlation, NPCR, UACI, decrypted image quality, key sensitivity, and key space.

A. Histogram Analysis

The distribution of pixel color intensity in an image is displayed using a histogram [13][14]. In this study, the pixel color intensity distribution was represented by a histogram, which can demonstrate the effectiveness of pixel randomization in the encrypted image produced by the proposed technique. If the histogram displays a particular pattern, the information in the image can be interpreted easily [15]. In column 3 of Table I, are encrypted images that visually differ from the original image. Columns 4 and 5 show how the histogram of every original image follows a certain pattern, while the histogram of every encrypted image follows a uniform pattern. This shows how the proposed algorithm can change the color intensity value and randomize all pixel coordinates within the encrypted image. It becomes challenging to interpret the information in an encrypted image [16].

B. Correlation Analysis

The correlation parameter is used to determine how similar two neighboring pixels are to one another in an image's horizontal (I(x,y) and I(x+1,y)), vertical (I(x,y) and I(x,y+1)), and diagonal directions (I(x,y) and I(x+1,y+1)). When the correlation value is near to 1 or -1, two neighboring pixels are either closely associated or have comparable colors [17]. In contrast, if the correlation value is close to 0, either both adjacent pixels have a high degree of randomness or there is low color correlation between them [18]. Eq. (8) functions as the correlation formula, where A and B are similar images that represent two nearby pixels on all three directions. The average value of all the pixels in images A and B is represented by variables $\bar{A}$ and $\bar{B}$, respectively.

$$r = \frac{\sum_x^M \sum_y^N (A_{xy}-\bar{A})(B_{xy}-\bar{B})}{\sqrt{(\sum_x^M \sum_y^N (A_{xy}-\bar{A})^2)(\sum_x^M \sum_y^N (B_{xy}-\bar{B})^2)}} \qquad (8)$$

Columns 5, 6, and 7 of Table II display that the correlation absolute value of the encrypted image ranges from 0.00024 to 0.10269. In columns 2, 3, and 4, the encrypted image has a lower correlation value than the original image. This shows that the proposed algorithm can randomize each bit of information in the encrypted image, making it impossible to crack the data. The level of randomization in pixel color intensities is displayed in Table II. The curve lines of the original images can be seen moving diagonally in columns 2, 3, and 4, which indicates that the two neighboring pixels in the original image have a strong correlation. However, columns 5, 6, and 7 display the random movement of the curve lines of the encrypted image, indicating that the color correlation between two neighboring pixels in the encrypted image is low. The proposed image encryption algorithm can randomize the position and color intensity of every pixel so that the messages contained in the encrypted image are difficult to read, according to the correlation value and correlation curve in Table II.

C. Decrypted Image Quality Analysis

Peak Signal to Noise Ratio (PSNR) and MSE (Mean Square Error) are used to evaluate the quality of encrypted images. Eq. (9) functions as the PSNR formula, and Eq. (10) is used to calculate the MSE value between the original image and the decrypted image [9]. The quality of the decrypted images is evaluated using an RGB image with a resolution of 2850×3200 pixels.

$$PSNR = 20\ Log_{10} \frac{255}{MSE} \qquad (9)$$

$$MSE = \frac{1}{M \times N} \sum_x^M \sum_y^N (I(x,y) - \acute{I}(x,y)^2) \qquad (10)$$

The encryption algorithm used by the previous researcher is listed in Table III column 1. Visually, the original image, the encrypted image, and the decrypted image are shown in columns 2, 3, and 4. MSE value and PSNR value are displayed in columns 5 and 6, respectively. There are numerous encrypted image pixels that differ from the original image in rows 2 and 3. It implies that the Henon Map and Cat Map transposition cannot perform the encryption and decryption on an image with a size of M ≠ N (width ≠ height), resulting in noise in the decrypted image, as seen by values of PNSR ≠ ∞ and MSE ≠ 0. The decrypted image in row 4 is identical to the original image with values of MSE = 0 and PSNR = ∞ [19]. It means that the proposed algorithm can be used to process images of all image size.

TABLE I. ORIGINAL AND ENCRYPTED IMAGE HISTOGRAM

Name	Image		Histogram	
	Original	***Encrypted***	***Original***	***Encrypted***
Baboon (512×512)				Cat (1500×100)				Lung (2850×3200)				
TABLE II. ORIGINAL AND ENCRYPTED IMAGE CORRELATION

Name	Correlation of Original Image			Correlation of Encrypted Image		
	Horizontal	*Vertical*	*Diagonal*	*Horizontal*	*Vertical*	*Diagonal*
Baboon (512×512)	 0.86657	 0.75875	 0.72620	 -0.07237	 -0.00229	 -0.00100
Cat (1500×100)	 0.98543	 0.98256	 0.97936	 -0.09986	 -0.00142	 0.00187
Lung (2850×3200)	 0.99897	 0.99959	 0.99871	 -0.10269	 -0.00024	 -0.00090

TABLE III. DECRYPTED IMAGE ANALYSIS

Encryption Algorithm	Original Image	Encrypted Image	Decrypted Image	MSE	PSNR
Henon Map Transposition & Henon Map Keystream Substitution (Ping, 2018 [7])				1079.84	17.80 dB
Cat Map Transposition & Henon Map Keystream Substitution (Ratna, 2021 [9])				1322.47	16.92 dB
RaMSH-1 Map Transposition & Logistic Map Keystream Substitution (Proposed Algorithm)				0	∞

D. NPCR and UACI Analysis

The NPCR (Number of Pixel Change Rate) parameter measures how differently colored pixels in the original image affect the outcomes of the encrypted image [20][21]. The UACI parameter assesses the average pixel change percentage in the encrypted image. The security level of an algorithm's resistance to differential attack is shown by the NPCR and UACI value [7][22].

Eq. (11) and (12) are the formulas of NPCR and UACI where C1 and C2 are two encrypted images. The D_{xy} coefficient is the similarity value of pixel in same coordinate of both C1 and C2 images. The $C1_{xy}$ and $C2_{xy}$ are color intensity values of the C1 and C2 at the (x,y) position.

$$NPCR = \frac{1}{M\times N}\sum_{x}^{M}\sum_{y}^{N} D_{xy} \times 100\% \quad (11)$$

$$UACI = \frac{1}{M\times N}\sum_{x}^{M}\sum_{y}^{N}\frac{|C1_{xy}-C2_{xy}|}{255}\times 100\% \quad (12)$$

The largest UACI value is 33.37521%, while the largest NPCR value is 99.61014%, according to Table IV. The proposed algorithm is resistant to differential attack [8] and has sensitivity of pixel changes in original image effects to encrypted image results since both values are above the standard 99.6% of NPCR value and 33.3% of UACI value.

E. Entropy Analysis

The entropy parameter calculates the minimal average number of bits required to decode a symbol from a sequence of bits. The entropy value displays the effectiveness of the algorithm's security level and the degree of unpredictability in the encrypted image [23]. Entropy is calculated using Eq. (13), where Pi is the chance that a pixel with the value of i will appear. Entropy can have a maximum value of 8 [8][24].

$$H = \sum_{i=0}^{i=255} P_i Log_2\left(\frac{1}{P_i}\right) \qquad (13)$$

The highest entropy value, according to Table IV, is 7.99980. It shows that the proposed algorithm can randomize the pixel coordinates and change the pixel color intensity value in the encrypted image and is resistant to entropy attacks [14].

TABLE IV. NPCR, UACI, ENTROPY OF ENCRYPTED IMAGE

Name	NPCR (%)	UACI (%)	Entropy
Baboon	99.61014	33.02773	7.99822
Cat	99.60851	33.29189	7.99964
Lung	99.60999	33.37521	7.99980

F. Key space Analysis

The proposed algorithm is composition of Logistic Map substitution and RaMSH-1 Map transposition. The key variables are c, d, g_0, and z. The range of values c, d ∈ $\mathbb{Z}^+$. The range of values for z and g_0 are $3.5699 < r \leq 4$ and $0 < g_0 < 1$, respectively, where g_0, r ∈ $\mathbb{R}^+$ [8]. In Matlab, the largest integer number value is $2^{64} \approx 1.8 \times 10^{19}$ and the largest real number value is 1.8×10^{308}. The default mantissa value in floating-point is 10^{15} [23]. Table V shows the proposed algorithm's key space.

TABLE V. KEY SPACE

Function	Variable Key	Key Space
RaMSH-1 Map	c, d ∈ $\mathbb{Z}^+$	3.24×10^{38}
Logistic Map	g0 ∈ [0, 1]; z ∈ [3.5699, 4]	3.24×10^{631}
Proposed Algorithm	c, d ∈ $\mathbb{Z}^+$ g0 ∈ [0, 1]; z ∈ [3.5699, 4]	1.05×10^{670}

The proposed algorithm's key space is $(1.8 \times 10^{19}) \times (1.8 \times 10^{19}) \times (1.8 \times 10^{308}) \times (1.8 \times 10^{308}) \times (10^{15}) \approx 1.05 \times 10^{670}$. A computer that can perform 10^{24} computations in a second is used to simulate testing every key combination [22]. It would take 3.33×10^{639} years to complete the vast array of computations through the computer in a single year $(1.05 \times 10^{670}) \div (10^{24}) \times 365$ (days) × 24 (hour) × 60 (min) × 60(s) = 3.33×10^{639}. This amount of time for attempting every combination is sufficient to fend off a brute force attack [23][25].

G. Key Sensitivity Analysis

The proposed algorithm using four variable keys. Key of c and d are positive integer numbers. Key of g_0 and z are positive real numbers. The decrypted key value with small changes on decrypted process will affect the decrypted image. The key sensitivity can be seen in Table VI.

Table VI row 2 shows the decrypted keys for decryption process are c = 20, d = 30, g_0 = 0.1, and z = 3.6. Each key is changed with a very small value change in key values. Rows 3, 4, 5, and 6 show the decrypted image still unreadable. In row 5 shows the key sensitivity of g_0 reached 10^{-16} which indicate the proposed algorithm is robust against brute force attack.

TABLE VI. KEY SENSITIVITY ANALYSIS

Key Sensitivity	Key Value	Decrypted Image
Decryption Key	c = 20; d = 30 g_0 = 0.1; z = 3.6	Sensitivity of Decryption Key c	c = 21; d = 30 g_0 = 0.1; z = 3.6	
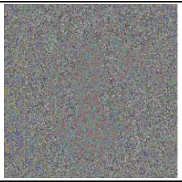
Sensitivity of Decryption Key d	c = 20; d = 31 g_0 = 0.1; z = 3.6	
Sensitivity of Decryption Key g_0	c = 20; d = 30
	$g_0 = 0.1 + 10^{-16}$;
	z = 3.6
		


Sensitivity of Decryption Key z	c = 20; d = 30 $z = 3.6 + 10^{-15}$; g_0 = 0.1	
IV. CONCLUSIONS

The Henon Map transposition function is modified in the RaMSH-1 Map transposition. The proposed algorithm can be applied for all image size without padding. The key variable of proposed algorithm generated a key space of 1.05×10^{670}. The entropy values reached 7.99980 out of 8 as perfect entropy value. The correlation value for all encrypted images is very close to 0, indicating that there is no correlation between the color intensity of neighboring pixels. Entropy and correlation analyses show that the encrypted image's information is all scrambled, which makes it hard to decipher. The results of the key sensitivity reached 10^{-16} which indicate the proposed algorithm is very sensitive. The UACI value of 33.37521 and the NPCR value of 99.61014 respectively show that the proposed algorithm is resistant to differential attack.

V. FUTURE WORK

The proposed algorithm's weakness is that it only uses four variable keys. The algorithm's key space can be expanded. The data security can be improved by combining RaMSH-1 Map transposition, Logistic Map substitution, and Cat Map transposition.

***Abstract*—The swarm intelligence has become an interesting topic for employing of multi-agent robotics with specific purpose. The capability of multi-coordination, scalability and goals-oriented control in spatial and temporal environment are already concerned and proven for several applications such as in military patrol, and drones leader-follower coordination. In marine-based environment, swarm intelligence adopted by ASV or ROV has been used for water quality and environment monitoring with sufficient optimized results making it convenient for rapid assessments. In this paper, the arrangement for building a trusted cyber-physical systems for algal bloom rapid assessment using swarm ship technology were explained in state-of-the-art perspectives. The minimum requirements for sensing, vehicle controlling, and communication of this system with others were explored as well as algorithm chosen for the best known configuration to monitor algal bloom events before spreading so fast to larger area. Some models were explained to show the robustness of autonomous unmanned ship control. From this point of view, we concluded that swarm ship technology has become an important potential implementation for near real time in situ monitoring compared to other decision making method such as laboratory examination or remote sensing-based results. The results of this review open the opportunity to realization of swarm ship technology in cyber physical system for monitoring algal bloom in specific area near real time efficiently.**

***Keywords*—Swarm ship; algal bloom; cyber physical system; rapid monitoring**

I. Introduction

Dissolved oxygen in the water is produced through the process of photosynthesis by phytoplankton. However, the degree of respiration will be greater than photosynthesis when there is no sunlight. This doesn't just happen at night. In the surface layer, the oxygen level will be higher, due to the diffusion process between water and free air and the process of photosynthesis. With increasing depth there will be a decrease in the level of dissolved oxygen, since the process of photosynthesis is decreasing and the existing oxygen levels are widely used for breathing and oxidation of organic and inorganic materials. Dissolved oxygen concentration is an important parameter in determining the quality of waters. Oxygen concentration is influenced by the balance between oxygen production and consumption in the ecosystem. Oxygen is produced by the autotrophic community through the process of photosynthesis and consumed by all organisms through breathing. The solubility of oxygen in the waters is affected by temperature and salinity. The higher the temperature and salinity of the waters, the smaller is the solubility of oxygen. When phytoplankton bloom, the sunlight is blocked from entering the water column. So that dissolved oxygen is decreasing [1]. Phytoplankton is a major component of the food chain and the main production of the marine environment. However, a high abundance of phytoplankton can have a harmful effect on aquatic ecosystems. In addition, they can produce toxic substances that will accumulate in their consumers. This accumulation can be dangerous for humans or animals [2].

The phenomenon of algal bloom occurs quite often in several waters in Indonesia and the world. Research conducted by [3] in Jakarta Bay mentioned the occurrence of eutrophication since 1986 which caused the death of several types of fish and other organisms due to several types of phytoplankton such as Skeletonema which reached 534 x 106 cells / m3 in September 1984 and in April 1985 reached 2,316 x 106 cells / m3. Chaetoceros reached 5.6 x 106 cells/m3 in April 1985. Noctiluca reached 0.4 x 106 cells/m3 in September 1984. Prorocentrum was found to be very dominant in June 1988. The phenomenon of algal bloom on Ringgung beach, Lampung Bay, also resulted in the death of fish farmed in the Floating Net Cage [1]. Other events are also triggered by several types of algae such as Cyanobacteria, Dinoflagellates, Cyanobacteria, and Diatoms in the Ambon Bay and Jakarta Bay areas [4]. Research on the analysis of phytoplankton abundance causing HAB (Harmful Algal Bloom) in Lampung Bay Waters in the western season and eastern season was also carried out to identify algae that have the potential to cause HAB in Lampung Bay and see patterns of phytoplankton abundance relationships that have the potential to cause HAB with nutrients contained in the waters of Lampung Bay, Pesawaran Regency, Lampung Province. In the eastern season, the abundance of phytoplankton that causes HAB in the waters of Lampung Bay is dominated by the species Ceratium sp. with an average of 1,802 ind/L while in the western season the abundance of phytoplankton in Lampung Bay is dominated by Nitczchia sp., with an average abundance of 161,207 ind/L [5]. The incident that occurred in the Thousand Islands, Jakarta Bay on October 15, 2020 was caused by the phytoplankton type Trichodesmium. Real time sampling of phytoplankton that undergoes blooming has been carried out and the parameters analyzed are the composition of phytoplankton types and water quality. This is closely related to seasonal changes and an increase in nutrient content in waters, especially nitrates and orthophosphates, which support the rapid growth of phytoplankton [6].

Factors causing algae abundance carried out in tropical lakes, Telaga Menjer Wonosobo Indonesia mentioned that observations and sampling carried out three times with an interval of one month at seven locations in the photic zone resulted in concentrations of macronutrients and micronutrients in Telaga Menjer spatially even in all locations and temporal concentrations increased slightly the same during the measurement period. The macronutrients Cu, NO_2, Si, and Na are the determining factors for algae bloom in Lake Menjer Wonosobo. The effect of Cu, NO_2 and Si concentrations is inversely proportional to the abundance of algae, while the concentrations of Ca, Na and Mo are proportional to the abundance of algae [7]. Meanwhile [8] links the causes of algal bloom events with climate change in the process of assessing and mitigating risks in mariculture and marine fisheries.

II. Problem Statement

In monitoring the condition of the aquatic environment, some important parameters that need to be considered are the concentration of dissolved oxygen, turbidity conditions (turbidity), water temperature, chlorophyll-a concentration and the type of algae that develops. By using the necessary sensors, and installed directly in a fixed or moving condition, monitoring can be carried out in real-time or periodically.

The use of water vehicles that can move simultaneously opens up the potential for the application of swarming methods, which are inspired by swarming intelligence in animals or mammals in nature. A group robotics system is the application of a multi-agent system that has intelligence when in groups such as multi-robots that apply ant colony optimization algorithms [9]. This system was introduced by [10]. The application of other Swarm Robotic systems can be found in studies conducted by [11] [12] [13] and [14].

To provide some proof-of-concept to this swarmship technology, we need to build several surface vessel integrated with sensors, control and communication system and make some performance measurements.

III. Research Framework

In this study, an algal bloom monitoring system used several autonomous vessels that could directly sense environmental conditions and water quality. At the initial stage the autonomous ship is designed starting from its mechanical part, then equipped with a propulsion system, a control system, These ships will communicate with each other at a certain distance in order to exchange information related to the parameters of acidity, dissolved oxygen, algae concentration and weather in a certain water area. If in the region it is informed of an anomaly related to the parameters measured by one or several ships simultaneously, decision-making for monitoring together will be carried out and the handling is quickly carried out both automatically and by humans. The system to be designed and implemented is 3 – 5 autonomous vessels that have group intelligence in ensuring water conditions related to potentially harmful algae concentrations. Once it is confirmed that the anomalies in the parameters of the waters being monitored have the potential to produce algae abundance, then the next treatment will be carried out automatically or handed over to humans as decision makers. The real-time data retrieved will also be disseminated through the selected communication network so that it can be used for other purposes.

After reviewing several libraries related to Harmful Algal Bloom (HAB) and its monitoring methods, one of the in-situ measurement methods using several autonomous ships that can coordinate with each other using wireless communication by running an intelligent swarm-based optimization algorithm was chosen. In its application, these ships will send spatial and temporal data from the aquatic environment and be monitored through physical cyber systems located on land so that human in-the loop system can be made.

At this time several preliminary studies have been carried out related to the construction of prototypes of Automatic Surface Vehicle (ASV) ships that have sensors, control systems, navigation and standard communications. In the year of this research, several additional ASV ships will be built and developed as a physical cyber system that can communicate with each other in exchange for sensor information and their respective positions. In this section, an intelligent computing model is also developed by ships in order to be able to analyze water quality containing potential toxic algae, exchange of information with other vessels, actions that need to be carried out automatically and feedback systems for these information. Next, by testing several intelligence algorithms that have been analyzed and simulated before, the joint decision making interpreted by the navigation system and the movement of these autonomous ships can be optimized. It is hoped that from the results of some of these trials, several characteristics can be mapped in determining the most effective time in monitoring algal bloom in certain waters. This research also opens up opportunities for further research in terms of mitigating algal bloom conditions quickly and precisely.

IV. Literature Review

Early detection of Algal Bloom is an important topic to do, so that earlier and more accurate treatment can be carried out before it spreads more widely to the surrounding waters. Various direct (in-situ) studies in identifying algae that cause it or indirectly in the laboratory have also been carried out by several researchers in the field of environmental ecology. Several technologies have also been used, such as placing special buoys that are used to monitor their abundance, as well as the factors that cause them. But until now, this incident has not been well predicted.

In monitoring, detecting and handling the abundance of harmful algae (Harmful Algal Bloom), several studies have been carried out in several ways. Generally, the method used is to take samples directly in the water environment to be observed, and then the characteristics will be determined in the laboratory. Sampling is carried out several times in several places during a certain time and season. The sample is then examined by cyst extraction, sediment culture experiments, cyst culture experiments, DNA extraction and molecular identification. The parameters measured in general are water quality, oxygen concentration, macronutrients and micronutrients such as nitrates and orthophosphates along with concentrations [15] of phytoplankton and or chlorophyll-A in the sampling area. Another approach taken is to extract information from imagery captured by remote sensing satellites. Research conducted on the [16] [17] algal bloom phenomenon that occurred in the waters of Lampung Bay verified SPOT 4 satellite images using the Red Tide algorithm quantitatively and qualitatively. This remote sensing approach is sharpened by the use of several machine learning algorithms based on CNN with spatial and temporal analysis methods, LSTM alongside random forests, and SVM classification methods as performed by the HABNet application architecture. The results showed that their method could detect the incidence of algal bloom with a maximum accuracy of 91% and a Kappa coefficient of 0.81 for Karenia brevis (K. brevis) type algae on the Florida coast (as many as 2850 events from 2003 to 2018 [18]. The use of biosensors to monitor the incidence of algal bloom is also an opportunity to accelerate the handling of these events such as several studies reviewed where the biosensor has the potential to be installed far enough but can provide measurement information quickly and continuously on algae measurements and biotoxin levels as needed and at a low cost using [19] an environment sample processor (ESP) that can analyze DNA quickly and continuously in-situ.

During the years when research began to consider mobile robotics, the behavior of animal groups appeared in several key observations. The V formation arises from the basic local behavior of each bird. A proposed behavior-based formation control for multi-robotic teams also began as related research such as the coordination of groups of mobile robots using the rules of the nearest neighbors. Another articles focus on algorithms and theories regarding its flocking multi-agent dynamic systems. Some of the reasons to consider are instability and dynamic systems as its problems with oscillations. The chain of formation requires fine tuning of local control. Control engineers should consider 3D scenarios when dealing with a group of AUVs or UUVs [20].

Swarm intelligence is a decentralized collective behavior, a self-organized system (natural or artificial) that can maneuver quickly in a coordinated manner. In nature, this closed loop, that is, collaborative behavior is unique in each species. Nature has proven that when individual beings collaboratively work and think together as a unified system towards a common goal, they are more likely to achieve that goal faster and more accurately than if they tried it individually. In other words, they are smarter together than themselves. Ants lay pheromones that direct each other to the resource, the bees use vibrations, the fish feel vibrations in the water and the birds detect movements that spread through the swarm.

Swarm intelligence in the robotics domain has a wide range of applications and benefits. The main benefits of herd intelligence include:

1) Flexibility: The swarm system responds to internal disturbances and external challenges.

2) Resiliency: The task completes regardless of whether some agents fail.

3) Self-organization: Roles are undefined - they arise.

4) Adaptation: The herd can adapt to predetermined and new stimuli.

5) Decentralization: There is no central control, allowing for fast local collaboration.

The most suitable applications for robot swarms require smaller fleets of robots to perform tasks, such as mapping and foraging in places that are difficult for humans to reach. For example, swarms of search and rescue robots of various sizes can be sent to places that rescue workers cannot safely reach. In general, swarms of robots can be utilized for tasks as mentioned in Fig. 1 [21] [22].

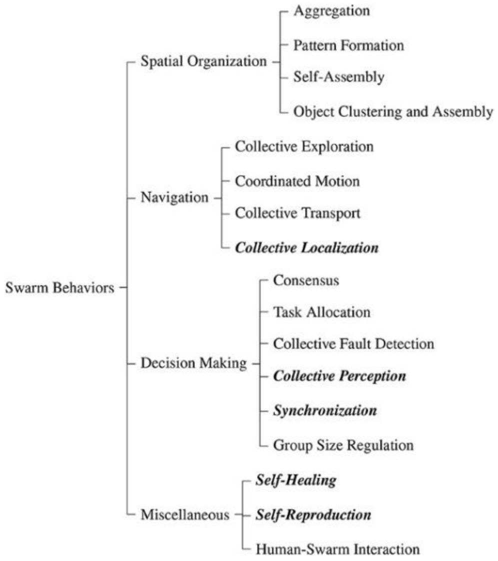

Fig. 1. Taxonomy of the application of swarm behavior to robotics.

V. Challenge and Discussion

Swarmship techology is proposed as a novel solution to the global threat posed by harmful algal blooms. This work is being done in parallel with the development of physical USVs that can strain and skim algae from the water [23]. The rate of algae collection need to be studied relative to: the diffusion of the algae in the water (due to turbulence), the composition of the swarm as either few large USVs or many small USVs, and the quantity of constant-size USV collected by the swarm formation. The results should be shown as plots of uncollected biomass vs. time, and as maps of the algae distribution after the swarmship have begun collection. Both a partitioning and non-partitioning controls approach are taken, which impose different hardware and communication requirements on the swarmship.

Meanwhile we developed several ships which has water quality monitoring device as shown on Fig. 2.

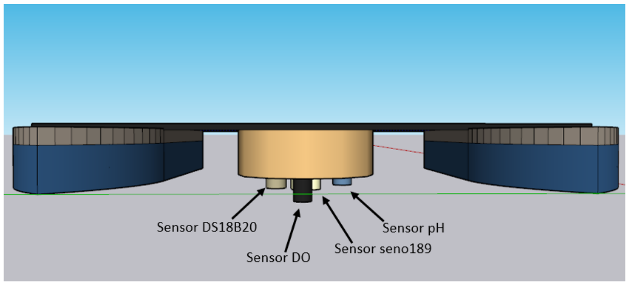

Fig. 2. Ships model for algal monitoring.

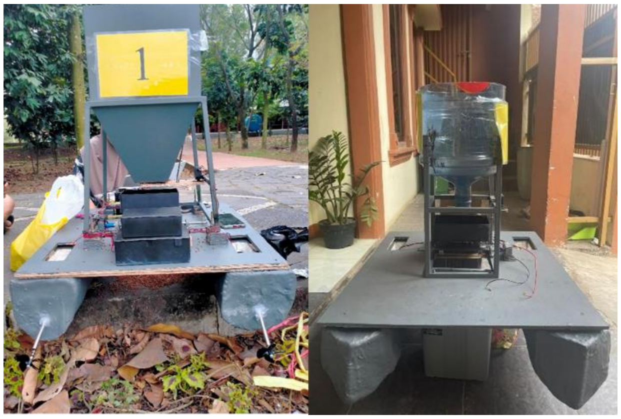

Fig. 3. Two models of swarmship implemented.

To aid in the development of this swarmship, several sets of scenarios are needed to inform the swarm designer about (i) the ability of the swarmship to collect a diffusive substance, i.e. the algae, (ii) whether how many USVs should be used, and (iii) what scaling effects are present as more and more USVs are need to be added to the swarm formation. Collecting a diffusive substance is an interesting problem, although somewhat specific to this application, but the second and third points are generally applicable to any swarm technology. Fig. 3 shows two kind of USVs used.

Several sets of simulations were needed to be performed, with a list of the most important parameters. These simulations address and are referred to as: Diffusive Collection, USV Size vs. Quantity, and USV Density. As its scenarios, swarmships move through water at a speed of one unit per second and collect 90% of the algae that they pass over.

As previously mentioned, this simulation environment is a very complex system. These simulations only included the effect of algae diffusion, due to turbulence in the water. This work also started with a homogeneous algae distribution. In reality, algae is sometimes distributed homogeneously The inclusion of collision tracking, algae advection, and the possibility of a heterogeneous initial algae distribution are three areas targeted for the swarmships system for future work as shown on Fig. 4.

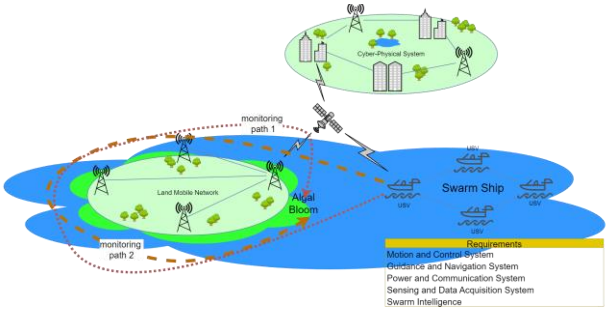

Fig. 4. Illustration of swarmship technology for harmful algae monitoring.

VI. Conclusion

From this point of view, we concluded that swarm ship technology has become an important potential implementation for near real time in situ monitoring compared to other decision making method such as laboratory examination or remote sensing-based results. The results of this review open the opportunity to realization of swarm ship technology in cyber physical system for monitoring algal bloom in specific area near real time efficiently.

***Abstract*—The existence of organic waste must be utilized by the community so that it does not only end up in landfills but can also be processed into something constructive so that it is useful and has high economic value. Organic waste can be converted into raw materials to manufacture of biomass briquettes. Machine learning techniques were developed for technological applications, object detection, and categorization. Methods with artificial reasoning networks that use a number of algorithms, such as the Naive Bayes Classifier, will work together in determining and identifying certain characteristics in a digital data set. The manufacturing method goes through several processes with a waste classification model as a source of learning data. The image data is based on five types: coconut shells, sawdust, corn cobs, rice husks, and plant leaves. The research aims to identify and classify types of waste both organically and non-organically so that it will make it easier to sort waste. The results of testing the organic waste application from digital images have an accuracy rate of 97%. The model design carried out in training data is useful for producing a data model.**

Keywords—Classification; organic waste; raw material; machine learning

I. Introduction

Waste that has not been treated optimally can damage the environment and make the water not clear, thus disrupting life and health around human habitation [1]. Household waste has dominated in generating waste in the city of Makassar, with an average of 900 tonnes per day sent to the Antang Final Disposal Site [2]. The Head of the Makassar City Environment Service said that high public consumption during the COVID-19 period, both before and during the implementation of the Large Scale Social Restrictions (LSSR) to Enforcement of Restrictions on Community Activities (ERCA), did not significantly decrease in the presence of waste ranging from 850-950 tons. The community must make use of the organic waste that already exists so that it doesn't just wind up in landfills but is also transformed into something productive with significant economic value [3].

Utilizing waste produced by the community and businesses, urban development aims to create urban areas with greater productivity, capacity, efficiency, creativity, competitiveness, innovation, and use of information technology [4]. The application of technology, object detection, and classification was developed using machine learning methods. Methods with artificial reasoning networks that use a number of algorithms will work together in determining and identifying certain characteristics in a digital data set [5]. Machine and deep learning are programmed with capabilities to learn, digest, and classify data [6] and have good skills in computer vision by classifying objects in digital images [7][8].

A method with a specialized approach that uses particular electronic systems or devices to detect an object is needed because a concentration of waste in one location makes it difficult to understand the potential for new renewable energy in detail [9]. The increase in population, ways of consumption, and lifestyle of urban residents increase waste production and problems in big cities. Problems identified include the amount of waste generation, types of waste, and various waste characteristics [10]. To make waste classification easier, the research intends to detect and categorize different waste types, both organic and non-organic.

II. Related Work

One source of energy that could be produced is organic waste, which the government needs to handle properly [11] [12]. On the other hand, the demand for energy from communities and development organizations is rising [13], particularly for new and renewable sources of energy, which are becoming more and more limited in Indonesia [14]. With information on the different types of waste, landfill locations, transportation routes, and cleaning personnel, the geographic information system has been able to offer waste management services in every sub-district of the city of Makassar [15].

Governments and communities face a problem because they have not fairly and effectively utilised the potential of organic waste, especially in Makassar, Indonesia. To meet the energy needs of residents in a city or region, it can be converted into raw materials for briquettes [16][17]. This project's objective is to establish a prediction system data model for converting organic waste into a fuel that meets societal and industrial goals. An important scientific contribution is the use of detection methods on organic waste objects. Fourteen districts: Ujung Pandang, Bontoala, Makassar, Tamalanrea, Panakukkang, Wajo, Tallo, Mamajang, Manggala, Mariso, Rappocini, Biringkanaya, Ujung Tanah, and Tamalate, already exist inside the city of Makassar. This

*Corresponding Author.

case study is used to develop a system model based on the city's geographic characteristics [18].

III. Material and Method

A. Approach and Type of Research

The research approach uses quantitative methods. This type of research is based on experimental studies (results of literature studies), interviews, and direct observations of city environmental service officers, city government, and communities in the city of Makassar, South Sulawesi province, Indonesia [19].

Object detection is carried out on various sources of organic waste. After obtaining information about the source of the waste, it is then analyzed through digital image detection to determine the classification of the type of waste [20]. Classification is useful for determining raw materials in sorting and grouping for the purposes of effectively and efficiently making biomass briquettes [21][22].

B. Data Sources and Data Collection Techniques

To meet energy needs, it is essential to design a system that can provide data on the market and fuel availability. The amount of energy potential found in organic waste source materials is the anticipated piece of information. The design information in Fig. 1 provides an overview of the anticipated procedures for obtaining data on population numbers and needs [18][19].

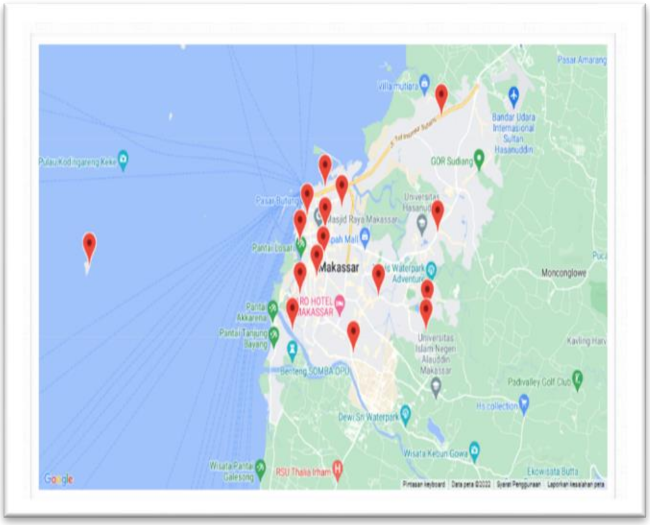

Fig. 1. Model for a waste location mapping system.

Organic waste is used to determine primary data. The Makassar City Environmental Service provided information on the need for secondary data by observing and speaking with staff members and locals on the origin of the organic waste collected.

The primary study data are the raw materials and specifications of organic waste utilized to make biomass briquettes, as compared to 5 (five) different types of organic waste sources. Organic waste can consist of coconut shells [23], sawdust [24], corncob [25], rice husks [26], and plant leaves [27]. The collected garbage data is made from a collection of digital image data in Table I. The predetermined image parameters are color, size (average), texture shape, reference mass, and manual mass (in the photo).

TABLE I. Dataset Organic Waste

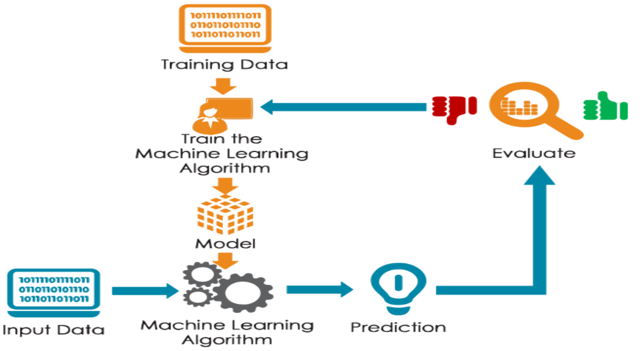
No	Type	Image	Color	Size (average)	Shape and Texture	Mass Reference (Average)	Manual Mass (100%)
1	coconut shells		chocolate green	width: 3mm diameter: 95mm	circle variation	140g /unit	75g / half
2	sawdust		white yellow chocolate	/variation	/variation	/variation	40gr (8 oz)
3	corncob		yellow chocolate white gray	width: 21cm diameter: 47mm	tube beam	260g/unit (with corn)	260g/unit (with corn)
4	rice husks		yellow chocolate black	long: 9mm diameter 2.4mm	oval	/variation	50gr (8 oz)
5	plant leaves		green yellow chocolate	/ variation	leaf	/variation	40gr (16 oz) (vegetable leaves)

C. Research Mechanism

The object and model detection mechanism is based on the Machine Learning method approach by conducting a classification consisting of fully connected output with a Convolutional Neural Network (CNN) architecture [28][29].

D. Naive Bayes Classifier

One of the supervised learning algorithms in Fig. 2 that is used in machine learning for binary and multiclass classification processes is the Naive Bayes Classifier Algorithm in Fig. 3 [30][31].



Training Data
Train the Machine Learning Algorithm

Model
Input Data
Machine Learning Algorithm
Prediction

Fig. 2. How machine learning works.

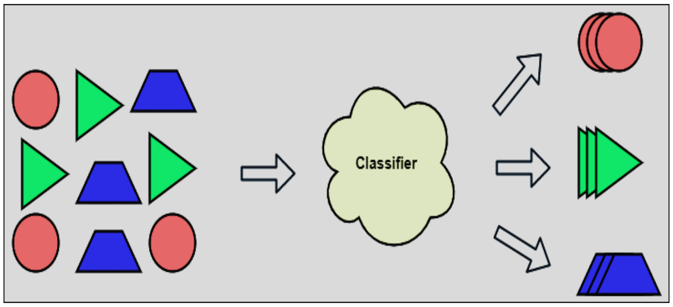

Fig. 3. Naive Bayes classifier method.

E. Formulation

Based on the Bayes principle, the Naive Bayes Classifier is a classification technique as shown in Fig. 4. It is generally agreed that the Naive Bayes Classifier outperforms a variety of other classification techniques. First, a very strong (naive) assumption of independence from each condition or event is the key feature of Naive Bayes. Second, it provides a straightforward, straightforward paradigm. Finally, large data sets can be used with the model [31].

$$P_{ro}(C_l|X_a) = \frac{P_{ro}(C_l)P_{ro}(X_a|C_l)}{P_{ro}(X_a)} \qquad (1)$$

Where:

X_a : attributes

C_s : class

$P_{ro}(C_s|X_a)$: probability of even C_s given X_a has occurred

$P_{ro}(X_a|C_s)$: probability of even X_a given C_s has occurred

$P_{ro}(C_s)$: probability of event C_s

$P_{ro}(X_a)$: probability of event X_a

X_a can be written as follow:

$$X_a = X_1, X_2, X_3, \dots, X_n \qquad (2)$$

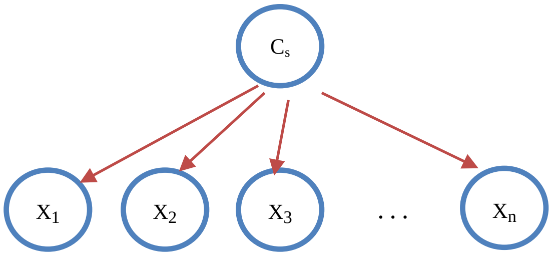

Fig. 4. Naïve Bayes.

F. Data Collection Techniques

The five types of organic waste were taken on a bright and plain background so that the various waste objects could still be seen [32]. Image data creation is carried out in detail by taking pictures of each type of waste [33]. Taking pictures of several combinations of one object with another object [34]. Images are photographed manually using smartphones and digital cameras specifically to get the best image and resolution.

G. Hardware Requirement

Specifications for some of the equipment used in the study include laptop Intel® CoreTM i5-5200U CPU @ 2.20GHz, Windows 10, Memory 8 GB, and AMD RadeonTM Graphics R5 M330. With the OPPO A5S smartphone, which features dual cameras with a configuration of 13 MP (wide), f/2.2, and 2 MP (depth), as well as an AF feature, LED flash, panoramic, HDR, and video 1080p@30fps, you may take images of five different forms of organic waste [35][36].

H. Preprocessing Data

Preprocessing data is a step that includes data collecting, data labeling, and data augmentation operations.

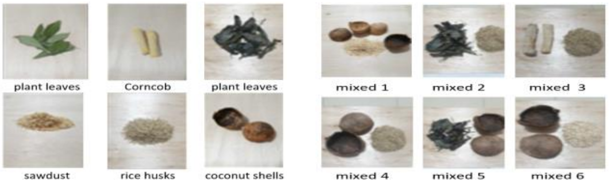
1) Data collection: Three thousand seventy-four photos totaled the information that was gathered and created. Organic waste can consist of coconut shells (cs) [23], sawdust (sd) [24], corncob (cc) [25], rice husk (rh) [26] and plant leaves (pl) [15]. The amount of information contained on the types of organic waste is shown in Table II.

TABLE II. DATASET ORGANIC WASTE

No	Waste Type	Digital Image
1	Coconut shells	686
2	Sawdust	717
3	Corncob	449
4	Rice husk	513
5	Plant leaves	709
Total		3.074

After data collection then proceed with the data preprocessing process. This process is carried out by dividing the pixel image into sizes with low, medium, and high criteria. Digital images will be used as training data to make them more effective in identifying types of organic waste [37].

Images of the five types of organic waste were taken against a bright and plain background to ensure these various types of waste objects could still be seen. Image data is collected by taking pictures of each kind of waste with a certain combination model as shown in Fig. 5 [38].



(a) (b)

Fig. 5. Preprocessing data and type of waste (a) One type of waste (b) More than one type of waste.

2) Labeling: The data labeling process aims in Fig. 6 to give the discarded image data that was taken a name or label so that it can be quickly identified. A train folder and a test folder are the components of creating a folder. At the same time, the test folder is used for running tests and validating data in the training process, and the train folder stores data that is processed throughout the learning process. It is separated into five different categories of organic waste for data labeling.

3) Augmented data: The technical stage in data augmentation is useful for augmenting existing training data using the TensorFlow library. This process is carried out by naming the image data taken to be neat, structured, and orderly.

The data augmentation process seeks to modify image data using the Adobe Photoshop application. Modifications are made based on the type of organic waste by combining many image data into one image data. Efforts were made by combining ten organic waste image data into one digital image data. For optimization purposes, resize the organic waste image data from the original size of 5184 x 3456 pixels to 224 x 224 pixels.

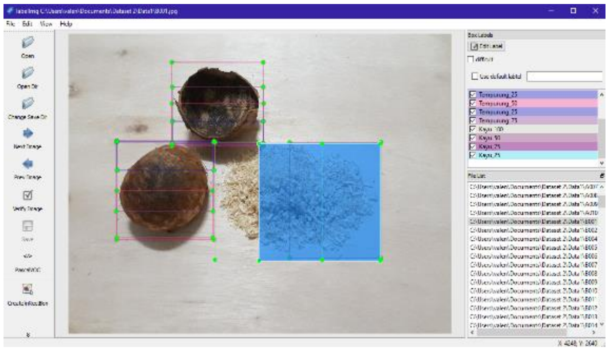


Fig. 6. Object size and mass predictive labeling.

I. Data Classification

There are 2473 training data and 293 digital photo test data as shown in Table III for five types of organic waste.

The combination of waste images in Table IV collected in combination A for five types in one image, combination B for three types in one image, and combination C for two types of waste are all in a folder. The other folders provide classification information for each of the five different forms of waste. The categorization that follows is based on the folder that was made.

TABLE III. ORGANIC WASTE

No	Waste Type	Train	Test
1	coconut shells (cs)	548	76
2	sawdust (sd)	589	55
3	corncob (cc)	364	45
4	rice husk (rh)	414	47
5	plant leaves (pl)	558	70
Total		2.473	293

TABLE IV. DATA COMBINATION

No	Combination of Organic Waste	Number of Combinations
1	cs, sd, cc, rh, pl (A)	5 pcs
2	cs, sd, rh (B)	3 pcs
3	cs, sd (C)	2 pcs
4	cs, rh (C)	2 pcs
5	cs, pl (C)	2 pcs
6	sd, pl (C)	2 pcs
7	rh, pl (C)	2 pcs
8	rh, cc (C)	2 pcs
9	rh, sd (C)	2 pcs
10	cs (D)	1 pcs
11	sd (D)	1 pcs
12	cc (D)	1 pcs
13	rh (D)	1 pcs
14	pl (D)	1 pcs
Total		23 pcs

Undoubtedly, a wide range of related factors will affect where and how organic waste is obtained. Table V lists the influential elements that must be calculated and considered.

TABLE V. INFLUENCE FACTORS

No	Factors	Influence
1	Photo Capture Distance	size
2	Object Location (x, y on photo)	accuracy
3	Weather/Temperature	texture
4	Lighting	coloring
5	Place/Environment	area/background

J. Data Modeling

The model is created using a number of procedures with the waste type classification model serving as a source of learning data. Five categories are utilized to organize the image data. A data model can be created by doing model design using training data. An illustration of the proposed data modeling flowchart is shown in Fig. 7.

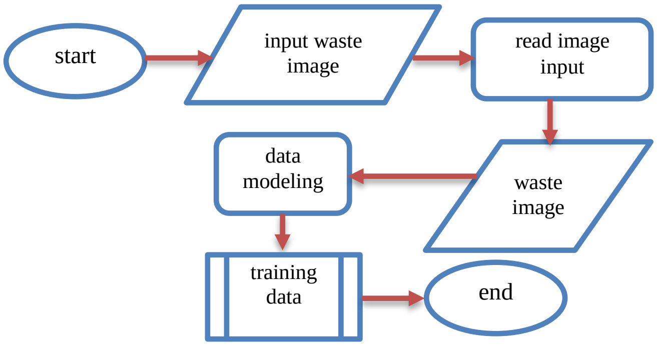

Fig. 7. Modeling flowchart.

K. Evaluation Method

A confusion Matrix is an evaluation method that can be used to calculate the classification process's performance or level of correctness. Create a table containing four unique combinations of the expected and actual values. In the Confusion Matrix, the classification process outcomes are denoted by four terms: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). The equation that follows is created.

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + FP + TN} \times 100\% \quad (3)$$

$$\text{Precision} = \frac{TP}{TP + FP} \quad (4)$$

$$\text{Recall} = \frac{TP}{TP + FN} \quad (5)$$

$$\text{F1} = \frac{2\times Recall \times Precision}{Recall + Precision} \quad (6)$$

IV. RESULTS AND DISCUSSION

To produce a good model requires the support of methods, algorithms and organic waste datasets that are relevant and sufficient in number.

A. Modeling CNN

They use two CNN models from scratch and CNN with ResNet transfer learning. The design of the CNN model is carried out with training to produce a model (classifier rules) that classifies waste sources as raw materials for making biomass briquettes. The proposed CNN model is in the form of parameters connected to a vector (flatten) to enter the fully connected layer. After that, enter the dense layer, which reduces the size to 1024 outputs and then reduces them to 256 outputs.

The subsequent stage moves into the last layer of classification, which employs the softmax function to generate the number of classes corresponding to the category in the data. It then moves on to the stage of the image prediction process. The waste detection procedure is as follows.

```
data = np.ndarray(shape=1, 224, 224, 3), dtype=np.float32)
def entry(input_name_img, input_id):
image = Image.open(r"c:\potential\image/"+input_name_img)
size = (224, 224)
…
labels = ['coconut shell', 'sawdust', 'corn cobs', 'rice husk', 'plant leaves']
prediction = model.predict(data)
# print prediction
detection = str(labels[np.argmax(prediction)])
sql = "UPDATE image SET desc = %s WHERE id_image = %s"
val = (detektion, input_id)
cursor.execute(sql, val)
conn.commit()
input_nama_img = str(query_dict['img'])[2:-2]
input_id = str(query_dict['id_c'])[2:-2]
print(content-type: text/html\n\n")
entry(input name img, input id)
```

B. UML Interface Design

There are use cases that are useful for knowing the activity of the relationship between the user and the system in Fig. 8.

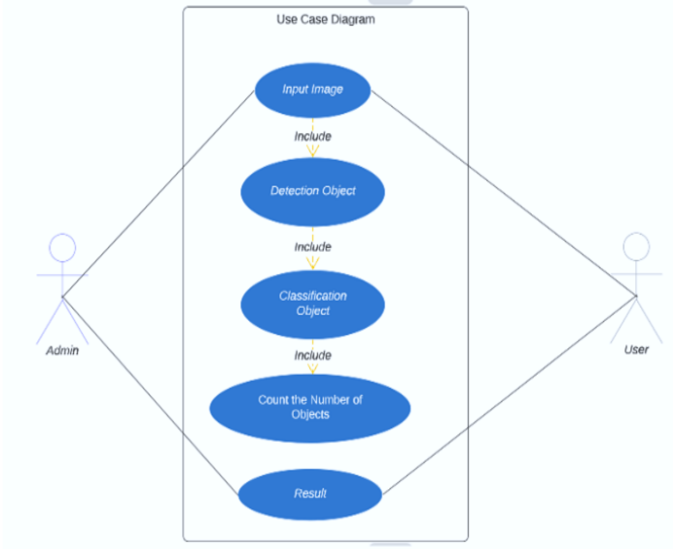

Fig. 8. Use case diagram.

Class diagram Fig. 9 illustrates the structure of class formation in the design of organic waste detection applications.

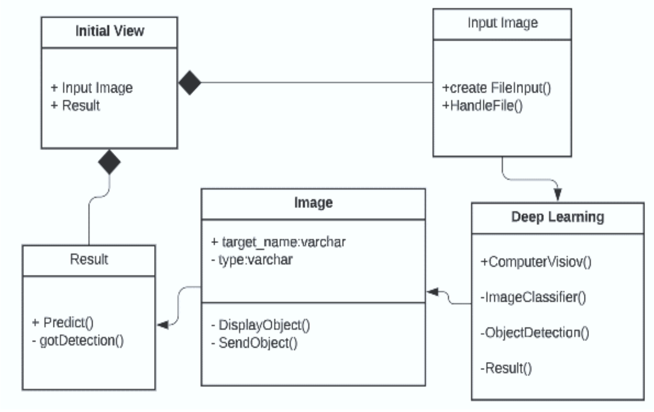

Fig. 9. Data training class diagrams.

Fig. 10 training data according to predefined batch values for all trained data. The results of the weight values are in the form of a JSON file that is used to help classify organic waste.

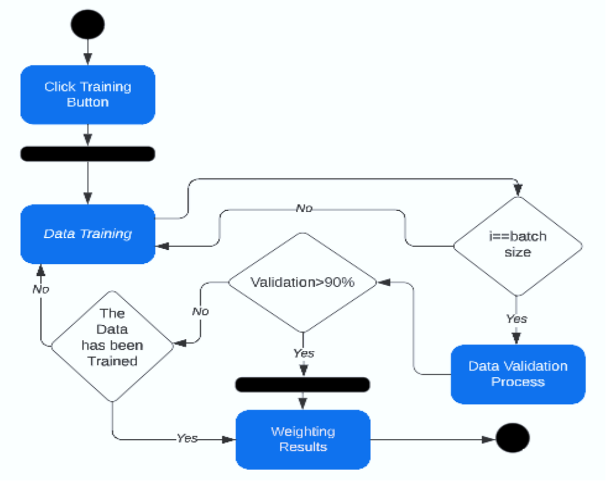

Fig. 10. Data training activity diagrams.

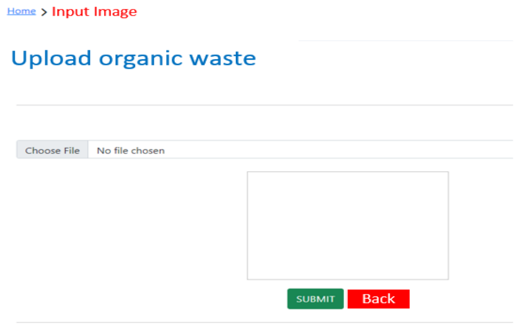
C. Application Interface Design

Input objects are needed by taking pictures in the system to carry out the process of predicting waste images. The data will be executed according to the program that can be detected. Fig. 11 displays the image that will be displayed after pressing the submit button in Fig. 12.



Home > Input Image

Upload organic waste

Fig. 11. Image input display on the application.

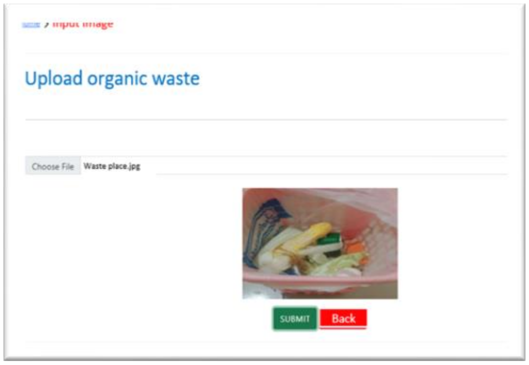


Fig. 12. Image upload view.

D. Training

The stage begins with collecting data used as training data. The image dataset for training purposes consists of 800 coconut shell waste, 750 sawdust, 750 corn cobs, 700 rice husks, and 700 plant leaves. The modeling phase divides the initial dataset into training and test data. The following are the stages of data modeling carried out in the study.

Modeling Script 1: Test data and validation make up each of the two sections of the test data with

```
test_size=0.20, random_state=300)
test_size=0.5, random_state=100)
```

Modeling Script 2: Merging data into each data frame.

```
train size 3359
val size 420
test size 420
```

Modeling Script 3: Organizing test, train, and validation data using the shut-in module.

```
datasource_path = “waste/”
dataset_path = “dataset2/”
```

Modeling Script 4: The process determines how many epochs to use.

```
#Define Input Parameters
Dim = (224, 224)
# dim = (456, 456)
```

Modeling Script 5: The data transformation process used in the image is transformed into image augmentation.

```
rescale=1. / 255, shear_range=0,2, zoom_range=0,2, horizontal_flip=True)
val_datagen
test_datagen
```

Modeling Script 6: Defines the origin directory by source files for the training phase.

```
train_generator = from_directory(‘dataset1/train/’ …,)
val_generator = from_directory(‘dataset1/validation/’ …,)
test_generator = test_datagen.flow_from_directory(‘dataset1/test/’,
num_class = tes_generator.num_classes
labels = train_generator.class_indices.key()
```

Modeling Script 7: Create tf.data to provide high compatibility for TensorFlow.

```
train_data = tf_data_generator(train_generator, input_shape)
test_data = tf_data_generator(test_generator, input_shape)
val_data = tf_data_generator(val_generator, input_shape)
```

Model Script 8: Sequential process for activation.

```
model_Sequential()
model.add(Conv2D(128, (3, 3), padding=’same;, input_shape=input_shape))
model.add(Activation(‘relu’))
model.add(conv2D(32, (3, 3)))
model.add(Activation(‘relu’))
model.add(MaxPooling2D(pool_size=(2, 2)))
model.add(Dropout(0.25))
…
model.add(Flatten())
model.add(Dense(512))
model.add(Activation(‘relu’))
model.add(Dropout(0.5))
model.add(Dense(num_class))
model.add(Activation(‘softmax’))
# Compile the model
print(‘Compiling Model…….’)
model.compile(Optimizer=’adam’, loss=’categorical_crossentropy’,
metrics=[‘accuracy’])
```

Modeling Script 9: Adding a top layer defined set false to the base model.

```
predictions = layer.Dense(num_class, activation=”softmax”)(x)
model = Model(inputs=base_model.input, outputs=predictions)
```

Modeling Script 10. Preparing the model to be ready for the training process.

```
# Compile the model
…
metrics=[‘Accuracy’])
from efficientnet.tfkeras import EfficientNetB1
# get base models
…
```

Modeling Script 11. Creating a machine learning process model in considering class patterns.

```
EPOCH = 2
…
Epoch 1/2
210/210 [=======] – 528s 2s/step – loss: 0.2357 – accuracy: 0,9357 –
val_loss: 0.0439 – val_accuracy: 0.9929
Epoch 2/2
210/210 [=======] – 466s 2s/step – loss: 0.1083 – accuracy: 0,9687 –
val_loss: 0.0244 – val_accuracy: 0.9952
```

Modeling Script 12. The training results get a loss of 0.2 and 0.1 and an accuracy of 0.9.

```
history.history[‘loss’]
[0.2356509417295456, 0,10834924131631851]
history.history[‘accuracy’]
[0.9356759786605835, 0,96873140335508301]
```

model.save (save_model_path, include_optimizer=False) is useful so that TensorFlow does not save the state of the optimizer at the last time it was saved but to save storage media and simplify the deployment process in Fig. 13.

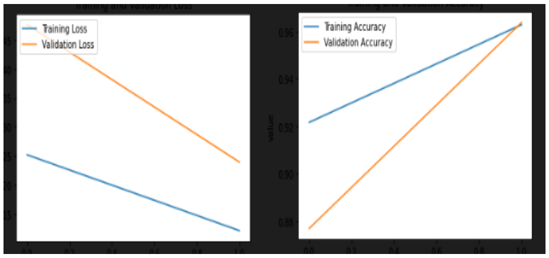

Fig. 13. Training data.

After training is done, then be plotted with extra training. Then the model results will be obtained, which can be saved to detect objects.

```
MODEL_BASE_PATH = “image_model”
PROJECT_NAME = “waste organic”
SAVE_MODEL_NAME = “image_model.h5”
```

E. Testing

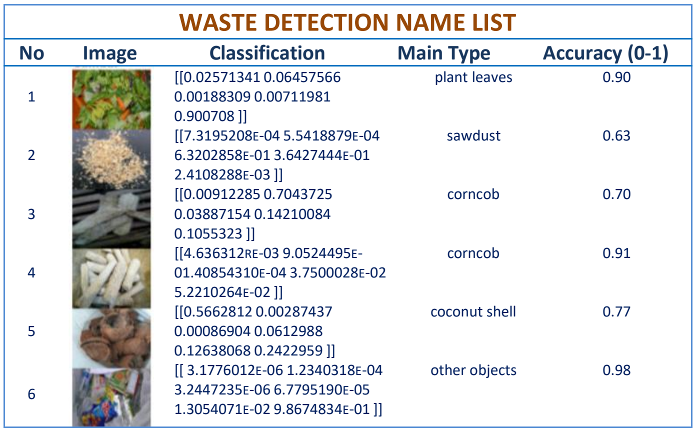
After determining the training data, test data is needed which consists of 120 coconut shells, 113 sawdust, 113 corncobs, 105 rice husks, and 105 plant leaves. Before loading the model, it is necessary to define parameters and label the five types of waste. After that, a function is created for pre-processing.

```
model = load_model(‘\medium_project/keras_model.h5’)
data = np.ndarray(shape=1, 224, 224, 3), dtype=np.float32)
…
prediction = model.predict(data)
print(prediction)
```

The script is an image prediction process. Prediction results are displayed in an array based on index 0,1,2,3,4,5. The process of detecting according to five characteristics of waste such as coconut shell, sawdust, corncobs, rice husks, and plant leaves.

```
1/1 [========================] – 0s 415ms/step
[[1.7525636e-02  3.1258736e-03  4.1368250e-03  5.6559354e-04  9.7464603e-01]]
```

Based on the picture in the script for detecting organic waste, which is the result of waste detection, the results of the prediction of waste produce a value of 9.7 or 97% accuracy in detecting the type of waste. Fig. 14 below is the result of testing the image input on object detection.



WASTE DETECTION NAME LIST

No	Image	Classification	Main Type	Accuracy (0-1)
1		[[0.02571341 0.06457566 0.00188309 0.00711981 0.900708]]	plant leaves	0.90
2		[[7.3195208E-04 5.5418879E-04 6.3202858E-01 3.6427444E-01 2.4108288E-03]]	sawdust	0.63
3		[[0.00912285 0.7043725 0.03887154 0.14210084 0.1055323]]	corncob	0.70
4		[[4.636312RE-03 9.0524495E-01.40854310E-04 3.7500028E-02 5.2210264E-02]]	corncob	0.91
5		[[0.5662812 0.00287437 0.00086904 0.0612988 0.12638068 0.2422959]]	coconut shell	0.77
6		[[3.1776012E-06 1.2340318E-04 3.2447235E-06 6.7795190E-05 1.3054071E-02 9.8674834E-01]]	other objects	0.98

Fig. 14. Waste detection name list.

F. Evaluation

Class 1 coconut shell, Class 2 sawdust, Class 3 corncobs, Class 4 rice husks, and Class 5 plant leaves are among the 735 picture data used for each class. The column shows the actual type class, and the row shows the type being tested. The first column of the first row displays the results that are in Class 1 coconut shell. The coconut shell image tested reads as TP (True Positive) of 661, so the number of images is read exactly according to the type of organic waste class.Likewise for other classes as shown in Fig. 15.

	Class 1	Class 2	Class 3	Class 4	Class 5	Classification overall
Class 1	661	26	18	14	16	735
Class 2	26	661	18	14	16	735
Class 3	18	20	657	22	18	735
Class 4	18	24	25	658	10	735
Class 5	14	16	20	24	661	735

Fig. 15. Confusion matrix.

Testing accuracy, precision, and recall by the confusion matrix using test data that is not sourced from datasets show an accuracy value of up to 73%. This research has produced an application that is able to detect objects properly. Through object detection, it will be known that the image is a potential organic waste which is a raw material for processing biomass briquettes. Even though the results in detecting objects still have a value with a percentage that has not reached a value of 70%, this is a relatively good approach to be used as an alternative model in selecting objects that will be the raw material for making briquettes.

Detection of objects in the form of powder is still relatively difficult to distinguish from similar objects considering that objects consist of small and separate parts. Comparison with large and unified objects will certainly produce a better accuracy value. To overcome this, further research is needed on object detection with the segmentation method.

V. Conclusion

Research on organic waste has produced object detection, namely: the results of identifying the type of organic waste by detecting digital image objects can predict the type of waste contained in the inserted image. The results of testing the organic waste application from digital images have an accuracy rate of 97%.

Acknowledgment

We would want to express our gratitude to the Makassar City Environmental Department as well as to the general public and business owners.

AUTHORS' PROFILE

Norbertus Tri Suswanto Saptadi was born on June 07 1975 in Cirebon, West Java, Indonesia. He is currently a doctoral student in Electrical Engineering (Informatics), Hasanuddin University, Indonesia. He accomplished Bachelor Degree of Informatics, University of Digital Technology Indonesia in 1998. Master of Management, Hasanuddin University in 2004. Master of Information Technology, Gadjah Mada University in 2007. Engineer Professional Education, Hasanuddin University in 2020. His research interests include artificial intelligence, data science, software engineering, and IT governance. He is member of the Indonesian National Resilience Institute (Lemhannas RI).

Ansar Suyuti was born on December 31 1967 in Sidrap, South Sulawesi, Indonesia. He received a bachelor's degree in 1991, a master's degree in 2002, and a doctorate in 2013 from Universitas Hasanuddin in Makassar, Indonesia. His primary topic of study is Electrical Power Engineering. He is a professor at Universitas Hasanuddin's Department of Electrical Engineering. He is the current head of the Power System Distribution Laboratory. His research interests include distributed generation planning, sensor networks, and environmental engineering, and he has produced numerous articles in electrical power engineering. Prof. Ir. Ansar Suyuti is a member of the Technical Committee for IPU.ASEAN. Eng is also a member of the Association of Electrical Power Engineering Experts and is an assessor for the National Accreditation Bureau for Higher Education. He is the Rector of Institut Teknologi BJ Habibie, Indonesia.

Amil Ahmad Ilham was born on October 10 1973 in Bulu, South Sulawesi, Indonesia. He accomplished his Bachelor Degree of Electrical Engineering, Hasanuddin University, Indonesia in 1997, Master of Information Technology, The University of Newcastle, Australia in 2003 and Doctor of Informatics from Kyushu University in 2011. He is currently a lecturer at Hasanuddin University, Department of Informatics, since 1998. His research interests are Information Systems and Data Analytics. He is the Vice Dean for Academic and Student Affairs of Faculty of Engineering, Hasanuddin University, Indonesia.

Ingrid Nurtanio was born on August 13 1961 in Makassar, South Sulawesi, Indonesia. Her accomplished Bachelor Degree of Electrical Engineering, Hasanuddin University in 1986, Master of Electrical Engineering, Hasanuddin University in 2002, Doctor from Institut Teknologi Sepuluh Nopember in 2013. Her is currently a lecturer at the Hasanuddin University of Informatics, Indonesia since 1988. Her research interests are Artificial Intelligence.

Predicting Hypertension using Machine Learning: A Case Study at Petra University

Yasmin Sakka[1], Dina Qarashai[2], Ahmad Altarawneh[3]
Faculty of Administrative and Financial Sciences-Management Information Systems Department,
University of Petra, Amman, Jordan[1, 3]
Healthcare Center, University of Petra, Amman, Jordan[2]

***Abstract*—Hypertension is a key cardiovascular disease risk factor (CVD). Identifying these high-risk individuals is crucial since it would save time and money before using any sophisticated, invasive, or costly diagnostic technique. This endeavour may be accomplished in part with the use of modern machine learning techniques. Specifically, a prediction model may be created based on several easily-obtained, non-invasive, and inexpensive indicator characteristics of high-risk individuals. This research is an effort to forecast hypertension risks based on Petra University's population. This case study was done between 2019 and 2020 at Petra University. Using hospital-visited patients' medical records, the gathered data was used to develop a model. The research comprised a comprehensive dataset of 31500 patients, comprising 12658 hypertension cases and 18842 non-hypertensive cases. SMOTE was used as a dataset for the categorization of hypertension. The SMOTE-k-nearest neighbour prediction model performs exceptionally well, as evidenced by its excellent performance (83.9% classification accuracy, 85.1% specificity, 83.3% sensitivity, and 89.6% AUC) when compared to other classifiers using 10-fold cross-validation with full features and no oversampling on the hypertension dataset. The data extracted from Petra University Health Center is considered to be very helpful for ML and is availed to produce a decision tree to identify the data related to hypertension.**

Keywords—Hypertension; machine learning; medical records; sensitivity; specificity

I. Introduction

There are 8.5 million fatalities worldwide attributed to hypertension, making it the leading cause of cardiovascular disease. Among these, 88% occur in low- and middle-income nations [1]. Access to unhealthy foods, sedentary lifestyles, and rural-urban migration are major contributors to the rising rate of hypertension in South Asia [2, 3]. The identification, treatment, and management of hypertension are similarly lowest in South Asia, and there has been little progress in these areas over the previous three decades [1]. Due to low levels of screening awareness, many cases of hypertension in South Asia go unreported [4]. Heart disease, stroke, renal failure, and premature death may all result from hypertension, although they are often avoidable with early diagnosis and treatment.

Physical inactivity, low levels of knowledge, smoking, an unhealthy diet, a lack of access to healthcare, and the high cost of drugs all play roles in explaining why hypertension is more common in South Asia [4-6]. However, most of the studies utilized unreliable methods to assess risk, had insufficient sample sizes and failed to adequately reflect the general population. The Framingham Risk Score for predicting coronary heart disease [7] and the American College of Cardiology/American Heart Association (ACC/AHA) Pooled Cohort Equations Risk Calculator are just two examples of risk prediction models that have been successfully used to identify and stratify patients according to risk factors and initiate preventative therapies [8].

When it comes to the creation of risk stratification tools for the diagnosis of cardiovascular illnesses, machine learning (ML) methods have recently been demonstrated to outperform classic statistical approaches [9,10,11]. The field of computer science known as "machine learning" allows computers to "learn" independently of explicit programming and handle massive datasets with complicated relationships. In contrast to more conventional statistical approaches, ML algorithms are not dependent on causal inference; nonetheless, this does not make them any less important for assessing causal effects in observational research. When compared to more conventional statistical methods, ML eliminates bias, the automated handling of missing variables with little changes to the original data, the mitigation of confounding factors, and the balancing of data [10]. More importantly, traditional statistical methods often fail when used in "big data" situations, whereas ML techniques succeed. Therefore, machine learning techniques may be used to create automated systems for illness prediction, decision support, and estimating hypertension prevalence in a community [10].

A dearth of research integrating socio-demographic and clinical data with signal processing, which might improve model performance, was observed in a recent review of ML approaches in hypertension identification [12]. ML algorithms were employed in prior work to automatically classify individuals with hypertension based on their unique phenotypes, but this analysis lacked socio-demographic information [13]. In a separate study, researchers in India used information gathered by community health workers from 2,278 individuals to create ML risk classification algorithms for diabetes and hypertension [14]. ML was employed in two different studies in China to analyze EHRs for signs of hypertension [15].

In the previous studies related to the machine learning models, the success lies in the complex pattern which can predict the data which is not observed in any other model. The concept of machine learning develops the power of interpretability by introducing the strategies of the description, predictive relevant outcome and the predictive description of relevant data. These are all presented in the form framework providing an interpretation of the discussion. The data obtained by machine learning provide the accuracy and the relevancy of the demand of human audience [16]. The study proposed by Alaa et al. [17] stated that people who are at a higher risk of cardiovascular attack need more preventative measures for the protection of their hearts. The clinical guideline has presented the model for risk prediction to identify the optimal performance of the patient groups. The data is collected from the machining process to improve the complex learning outcome and the complex interactions. Automatic machine learning (Autoprogress) is one of the techniques used to improve the traditional approaches and the risk prediction of CVD. This increases the accuracy of the data which is obtained from the large population.

However, no research has yet employed ML models to predict hypertension at the population level and verified the models using big datasets in South Asian nations, despite the progress in ML models for individual risk prediction for various illnesses. The present study aimed to determine the model's predictive abilities for hypertension and sought to employ ML techniques to discover characteristics related to hypertension diagnosis.

Therefore the remaining paper is based on an academic article structure which is as follows: in the first part, all the studies and models related to the study have been outlined. Then in methodology, the SMOTE model theory with its implication has been described; how the study has been processed. All the findings and the parameters have been mentioned in detail. Finally, for future research, the direction has been provided with the study limitation, conclusion and proposed ideas based on the study findings.

II. Related Work

Artificial intelligence has a great impact on the field of medicine, diagnosis of the disease or the treatment of diseases. Scientific development has introduced several strategies with the help of advancements in medical technologies and the proposed models. In this study, the use of machine learning and its algorithms with the induced models have displayed the data of the study. This method of study has embedded its pipelines in the data mining procedure. The rules of decision-making and the learning pattern of the algorithms can extract the data. The study uses the predictive models of the SMOTE model comprising of logistic regression, K-nearest neighbour, Naïve Bayes method, REP tree, Random forest, Artificial neural network, and Repeated incremental pruning to produce error reduction (RIPPER). Previous studies have been used to state the classical strategies of statistics. In the study of Dagliti et al. [2018]. The predictive constructive model which has been used is the model validation and the predictive model construction. The missing data have been handled by the Random Forest (RF) to correct the imbalances in the logistic regression for suitable strategies. In this study, the parameters of the feature selection of retinopathy, neuropathy, and neuropathy in different scenarios have been identified in diabetic hospitals. The considered variables are hypertension and hemoglobin, gender, age, and smoking habit. The compilation of this analysis has led to different models to translate easy clinical practices [18]. The major risk of cardiovascular disease is hypertension. The classification of hypertension in traditional Chinese medicine has too much effective methodology according to the syndromes of the patients. The data mining has the multi-learning model of labelling like BrSmote SVM which was developed to deal with the diagnosis and the class unbalancing of the data set. The experiment represents that it has diversified the evaluation of the average precision, one error, and the coverage with the loss ranking [19].

The classification of the multi-labelling is one of the problem classifications which is used for the data mining of the patient and the learning of the strategies of machine learning. This practice has developed the fast accumulation of clinic data [20]. The technique motivated the task of the medical diagnosis and the text categorization. These are divided into two main categories which are the transformation of the problem method and the second is the adaptation of the algorithm method. The problem transformation has more than one regression and hence they depended on the learning algorithm's methods where the algorithm method learning depends directly on the research data for the evaluation [21].

III. Material and Methods

A. Study Design

This case study was done at Petra University from 2019 to 2020. Using medical records of people who went to the hospital, the data was collected to build a model. The study began after the ethics committee gave its approval, and it was done according to the rules of the Declaration of Helsinki. There were a total of 31500 complete cases in the study. Of these, 12658 had high blood pressure and 18842 did not. All of the people who signed up gave their medical record number and baseline and anthropometric information. During the study, patient information was kept secret at all times. The ML-based model which has been used is the SMOTE model consisting algorithmic method which is used to assemble all the predictive models by machine learning pipelines. These consist of feature processing, comprising data imputation, calibration and the classification of the algorithmic predictive models [17].

The basic and familiar risk factors are their age (in years), gender, blood pressure (in mmHg), blood glucose (in mmol/lit), urea (in mmol/lit), and creatinine (in umol/l) which were all used as parameters. We removed data where 30% of the values were missing. After the initial data screening, all of the records went through the labelling process so that the dataset could be cleaned up. This gave us the labelled standard records. This will be used to build a machine-learning model that will use the patient's blood biochemical tests to diagnose hypertension. The model's features are chosen based on how easy they are to use, to collect data, and they must be statistically significant for univariate logistic regression ($p < 0.05$). All the predictive parameters were assessed by using the area under the receiver operating curve of characteristic (AUC-ROC). The overall SMOTE model improved all the risk predictions by 10-fold cross-validation classification performance evaluation of different classifiers on the hypertension dataset on full features without oversampling and 10-fold cross-validation classification performance evaluation using ten classifiers on the hypertension dataset on full features using oversampling. In this experiment, the dataset was run on ten machine learning classifiers using 10-fold cross-validation. 90% of the data was utilized to train the classifiers in the 10-fold cross-validation, whereas only 10% was used to test them.

B. *Synthetic Minority Oversampling Approach (SMOTE)*

The proposed disease prediction model, which was called the "Synthetic Minority Oversampling Approach (SMOTE)," was used to classify hypertension by applying it to a dataset. This technique is the most specific and powerful method used for sampling which follows the algorithm technique to calculate the distance of the space features in minority examples. This helps to develop the synthetic data within the premises of the minority example and required help from the neighbouring data. This technique is also known as borderline SMOTE [22]. The idea is generated from this method to produce the synthetic sample from near boundaries. These algorithms are more effective towards the binary classes having more than two features. This method is predicted by the over-sampling method produced by Chawla et al. [23]. This method has been used to increase the number of the sampling by interpolating the clustered samples which are in minority. The selection of accurate parameters has been mentioned to function correctly for the interpretation of the SMOTE algorithms. This model has three parameters which are: (k) for the neighbour which is very close, (perc. over) used to determine the extra cases of the minority classes, and accurate selection of the parameters. In this model, the method of optimization is one of the best findings for solving the evolutionary biological process [24]. The flow diagram of the over-sampling method (Fig. 1) and the improved hybrid model (Fig. 2) is presented.

Fig. 2. Improved SMOTE model. [24].

The model's features are chosen based on how easy they are to use to collect data, and they must be statistically significant for univariate logistic regression (p <0.05). The inputs were the number of nearest neighbours, the number of SMOTEs, and the number of minority class samples (MCS). The outputs were synthetic MCS to solve the problem of imbalance in classification [26].

IV. RESULTS

The suggested model uses the Synthetic Minority Oversampling Approach (SMOTE), which is based on the oversampling technique and generates synthetic samples for the minority class. This method assists in addressing the overfitting problem brought on by random oversampling. By overlaying several good examples, it focuses on the dataset to generate new cases [27, 28]. As a result, while evaluating the suggested model, the AUC value is taken into account. Table I displays the recommendations for evaluating any classifier using AUC [29].

In this experiment, the dataset was run on ten machine learning classifiers using 10-fold cross-validation. 90% of the data was utilized to train the classifiers in the 10-fold cross-validation, whereas only 10% was used to test them. The results of ten classifiers' 10-fold cross-validation are shown in Tables II and III.

TABLE I. AUC VALUES DESCRIPTION [3]

AUC Range	Description
AUC = 0.50	Bad classification (no discrimination)
0.50 < AUC < 0.70	Poor classification (poor discrimination)
0.70 ≤ AUC < 0.80	Acceptable classification (acceptable discrimination)
0.80 ≤ AUC < 0.90	Excellent classification (excellent discrimination)
AUC ≥ 0.90	Outstanding classification (outstanding discrimination)

TABLE II. 10-FOLD CROSS-VALIDATION CLASSIFICATION PERFORMANCE EVALUATION OF DIFFERENT CLASSIFIERS ON THE HYPERTENSION DATASET ON FULL FEATURES WITHOUT OVERSAMPLING

Predictive model	**Classifiers' performance evaluation metrics**			
	Accuracy (%)	***Precision (%)***	***Recall (%)***	***AUC (%)***
Logistic regression	76.5	74.4	76.5	79
K-nearest neighbour k=3	78	76.7	78	81.5
PART (rule-induction algorithms)	77.5	78	77.5	71.2
Repeated Incremental Pruning to Produce Error Reduction (RIPPER)	77.5	77.3	77.5	65
NaiveBayes	79	77.8	79	81.7
Decision Tree (J48)	75.5	74.1	75.5	74
REPtree	76	75.1	76	72.2
Support Vector Machine (SVM)	76.5	74.1	76.5	62.4
Random forest	73	70.8	73	79
Artificial Neural Networks (ANN)	74	74.4	74	75.1

Therefore, Table II presents ten classifiers for the hypertension dataset with complete features and no oversampling. Accuracy, precision, recall, and AUC were some of the assessment performance metrics utilized to rate the suggested hypertension prediction model. It became clear that most classifiers can discover trustworthy results using these metrics. The greatest AUC value, equivalent to 81.7, was obtained experimentally for hypertension prediction (high blood pressure detection) using the Naïve Bayes classifier without oversampling.

The minority class of the family history of high blood pressure dataset is oversampled using the SMOTE method. Investigated is the class imbalance caused by the oversampling of the family history of high blood pressure dataset.

The hypertension dataset's entire characteristics were used in the tests, which made use of all classifiers, as shown in Table III. The findings show that all classifiers that used accuracy, precision, recall, and AUC values generated positive outcomes. Based on oversampling AUC values of 89.6 for the k-nearest neighbor, outstanding results were obtained. So, without oversampling, the suggested SMOTE-k-nearest neighbor prediction model outperformed the classifiers. As a result, the SMOTE-k-nearest neighbor prediction model performs exceptionally well, as evidenced by its excellent performance in Table III (83.9% classification accuracy, 85.1% specificity, 83.9% sensitivity, and 89.6% AUC) when compared to other classifiers using 10-fold cross-validation on the hypertension dataset with full features and no oversampling.

The AUC curve, which is a visual depiction of a classification model's true-positive and false-positive rates, is shown in Fig. 3. AUC around one indicates a superior classification with a good class separability metric. AUC which is around 0 indicates a poor model with no distinguishing class. AUC of 0.5 means that the model is unable to distinguish between classes. As shown in Table III, the majority of classifiers provided good classifications, with the k-nearest neighbor getting the greatest AUC rate, which is equivalent to 89.6 and denoting excellent classification, as shown.

TABLE III. 10-FOLD CROSS-VALIDATION CLASSIFICATION PERFORMANCE EVALUATION USING TEN CLASSIFIERS ON HYPERTENSION DATASET ON FULL FEATURES USING OVERSAMPLING

Predictive model	**Classifiers' performance evaluation metrics**

V. DISCUSSION AND CONCLUSION

The data which has been extracted from Petra University Health Center is considered to be very helpful for ML. It has been availed to produce a decision tree to identify the data related to hypertension. There are many implications to modifying the solutions which can perform preventive measures. These solutions have been identified by using projecting models. According to the previous studies the SMOTE model is proven to be a successful model with the combination of others like BrSmote model for the analysis of the classification of the accuracy into five multi-label classifiers and the ten multi-label classifiers. The average and loss ranking is more sensitive and accurate in SMOTE model as compared to BrSmote model. The diseases like hypertension and other syndromes can be classified to improve the diagnosis of the patients [19]. These models can be very predictive for those people who can develop hypertension at very high risk. [16]These predictive models provide better risk communication. They can guide people who are concerned about their health decision and diagnosis of disease. This awareness in the community develops positive impact.[25] Furthermore, the lowest classification of the number is based on the class interest and the parameter which are required for the diagnosis. In the real world, the classification varies with the nature of the risk management, detection of fraud and the diagnosis of the disease in the medical history [30]. This positive mediation helps to decide the significant level of understanding. In the future, this research can improve the reliability of the predictive models. It can minimize the count of unhealthy effects on a large population by using accurate algorithms. There are many assessing tools for predicting different algorithms. These predictors are boosting gradient machines, supporting vector machines, classifiers of naive Bayes, and neural artificial networks.

Medical Name Entity Recognition Based on Lexical Enhancement and Global Pointer

Pu Zhang, Wentao Liang
School of Computer Science and Technology, Chongqing University of Posts and Telecommunications,
Chongqing, P. R. China

***Abstract*—Named entity recognition (NER) in biological sources, also called medical named entity recognition (MNER), attempts to identify and categorize medical terminology in electronic records. Deep neural networks have recently demonstrated substantial effectiveness in MNER. However, Chinese MNER has issues that cannot use lexical information and involve nested entities. To address these problems, we propose a model which can handle both nested and non-nested entities. The model uses a simple lexical enhancement method for merging lexical information into each character's vector representation, and then uses the Global Pointer approach for entity recognition. Furthermore, we retrain a pre-trained model with a Chinese medical corpus to incorporate medical knowledge, resulting in F1 score of 68.13% on the nested dataset CMeEE, 95.56% on the non-nested dataset CCKS2017, 85.89% on CCKS2019, and 92.08% on CCKS2020. These data demonstrate the efficacy of our proposed model.**

Keywords—MNER; nested NER; Global Pointer; lexical enhancement

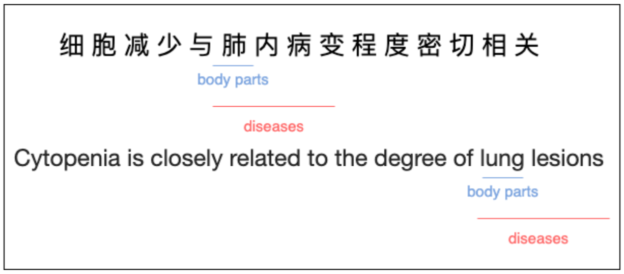
I. Introduction

Electronic medical records are a digital repository of a patient's comprehensive medical and health information that can be used for medical and healthcare services. These are vital repositories of medical knowledge and therapeutic experience, containing detailed content about patients' diagnoses and treatment histories. These enable deeper analysis to extract and consolidate valuable medical knowledge, transform implicit knowledge into explicit knowledge, and build a medical knowledge system with a clear hierarchy, well-defined concepts, rich connotations, and significant practical implications. However, due to the high percentage of unstructured data in electronic medical records, direct exploitation is difficult. MNER is a vital step in the extraction of medical information and is essential for biomedical text mining.

MNER has received a lot of attention in recent years, which has resulted in a lot of assessment contests. The China Conference on Knowledge Graph and Semantic Computing (CCKS) held NER evaluation challenges for medical texts from 2017 to 2021. Meanwhile, AliCloud and the Chinese Information Processing Society of China (CIPSC) have released the Chinese Medical Information Extraction (CMeIE) subtask of the Chinese Biomedical Language Understanding Evaluation (CBLUE).

The previous studies in Chinese MNER have mainly used methods based on English MNER to improve the model performance [1]. Although these methods produce good results, they rely on word-level annotation models. However, unlike English, Chinese is not naturally tokenized and does not segment words by spaces in sentences, leading to additional ambiguities when using word segmentation as an additional step in Chinese MNER, which could result in inaccurate entity boundary detection and class prediction due to improper word segmentation errors [2]. As a solution to this problem, character-based Chinese MNER techniques that are better at avoiding segmentation errors have been proposed. Considering that character-based approaches cannot fully exploit lexical information, Zhang et al. [3] introduced the Lattice-LSTM model, which combines lexical information into a character-based recognition model. However, the complex structure of Lattice-LSTM made it difficult to combine with other models.

On the other hand, in the Chinese MNER, the challenge of identifying nested entities has remained unsolved. Several earlier models are based on sequence models, however not all entities in electronic medical records are self-contained, and there may be nested structures between them. As shown in Fig. 1, in the sentence, where the entity "肺 (lung)" is nested within the other entity "肺内病变 (lung lesions)". Because of the complexity of the nested entity structure and the irregularity in its granularity and number of nested levels, it is difficult to rapidly and accurately gather nested entity information for semantic comprehension, a critical component of improving Chinese MNER.



细胞减少与肺内病变程度密切相关
body parts
diseases
Cytopenia is closely related to the degree of lung lesions

diseases

Fig. 1. Example of nested entities.

To address the aforementioned challenges, our research provides a Chinese MNER model based on lexical enhancement and Global Pointer. The model first adds lexical information to each character in the electronic medical record by using the lexical enhancement method, and then uses the Global Pointer method to score the beginning and end of each character to identify the medical entity. The following are the primary contributions of our work:

1) We incorporate the word lexicons into the character representations by introducing a lexical enhancement approach. The approach matches each character with a dictionary built from a corpus to get word sets. Then the word set is compressed and combined with character representation. The experimental results demonstrate that the model with lexical enhancement can improve performance.

2) The Global Pointer is used as the entity recognition module. Extensive experiments are carried out on the nested dataset CMeEE and the non-nested datasets including CCKS2017, CCKS2018, and CCKS2020. The experimental results show that the Global Pointer model can use a unified method to deal with both nested and non-nested entity recognition problems and has better performance than some recent models.

3) The pre-trained model is retrained with Chinese medical corpus for experimentation. It has better results than the basic pre-trained model.

The final experimental results show that the proposed model can be universally applied to nested and non-nested Chinese MNER tasks, and both yield the best results on the four datasets.

The remaining sections are organized as follows: Section II presents the related work on MNER. Section III introduces our proposed model. Section IV presents experiments and results analysis on our model. Section V concludes this paper.

II. Related Work

The purpose of NER is to discover entities in a text and classify them into specified categories such as person, organization, place, and so on. NER is a critical component of information extraction that allows structured information to be extracted from unstructured text input. Effective NER models are required for a variety of downstream tasks, including entity linking, relation extraction, and event extraction. MNER focuses on recognizing and categorizing clinical terminologies such as symptoms, medicines, and therapies in medical data. The MNER task is often treated as a sequential labelling issue, with the objective of assigning a category to each word or character in the text.

The neural network models are now the recommended strategy for English NER. The Bi-LSTM-CRF [4] model is the most typical, incorporating Bi-directional Long Short-Term Memory (Bi-LSTM) for feature extraction and Conditional Random Fields (CRF) for decoding. Unlike English text, Chinese text does not possess clear boundary information. Hence, Chinese NER methods can be broadly categorized into two groups: word-based methods and character-based methods. In the word-based method, word segmentation is performed first, followed by entity recognition [5]. However, this approach may result in the propagation of errors from inaccurate word segmentation, thus leading to incorrect NER. The character-based method, on the other hand, operates on each word individually and does not have the issue of error propagation, but cannot utilize lexical information. Consequently, researchers in word-based models are striving to improve the use of word information [6]. The majority of current studies demonstrate that character-based methods often surpass word-based methods in Chinese NER, due to the issue of error propagation in word segmentation. So, we build a character-based model for Chinese MNER that incorporates lexical information to address the limitations of traditional character-based methods.

MNER in the Chinese language is primarily researched using deep learning-based approaches. Bi-LSTM-CRF model has been proposed for predicting the sequence labels in a posterior conditional random field. Gridach et al. [7] were the pioneers in using a Bi-LSTM-CRF model for NER in the biomedical domain. Dang et al. [8] fine-tuned the word vectors using linguistic information based on the Bi-LSTM-CRF model. Liu et al. [9] combined a multi-channel convolutional neural network with the Bi-LSTM-CRF model and used lexical and morphological features of words as information for entity recognition.

In addition to the Bi-LSTM-CRF model, there have been several studies that apply other deep learning models to the medical field for MNER. For instance, Qiu et al. [10] utilized a residual dilated convolution model for efficient and quick NER in the medical field. Zhang et al. [11] proposed a hybrid model of Dilated Convolutional Neural Network (DCNN) and Bi-LSTM for hierarchical encoding, taking advantage of DCNN to gain global information with fast computational speed. Du et al. [12] proposed a multi-task learning approach with multi-strategies based on MRC. NER in the medical field can be approached as a sequence labeling task or a span boundary detection task.

However, the methods mentioned above are based on sequence labeling and cannot be directly used to solve the identification problem of nested named entities, because the same lexical entry in a nested named entity may have two or more different labels at the same time.

Solving the identification problem of nested entities will also improve the accuracy of the model in extracting entities. Previously, a combination of rule-based and machine-learning-based approaches was often used to deal with nested named entities. First, the inner non-nested named entities are identified using the Hidden Markov Model (HMM). Then, the other named entities are identified using rule-based post-processing. Alex et al. [13] proposed several CRF-based models for nested named NER on the GENIA dataset. These methods apply CRFs to entity types in a specific order, so that each CRF can use the output of the previous CRFs. This cascading approach can achieve the best results for nested named NER. In 2009, Finkel and Manning [14] implemented the task of nested NER from a parsing perspective. They constructed a selection tree to map all named entities to a node in the tree. Rule based and machine learning based methods have high accuracy and can make rules according to a specific domain to extract nested named entities. However, there are some problems such as difficulty in recognizing the same type of nested named entities, high time complexity, and difficulty in scaling to large datasets with long sentences.

Recently, the research of nested NER has become a hot topic in the field of information extraction. Span-based methods have become increasingly popular due to their high performance. For example, Xu et al. [15] used a local detection approach, where each possible entity span is classified independently. Sohrab and Miwa [16] introduced a simple deep neural model that enumerates all possible spans and classifies them using LSTM. Wang et al. [17] proposed a transition-based method that builds nested entities incrementally by performing a series of actions designed for this purpose. Tan et al. [18] extended the span-based approach by including a boundary detection task that predicts entity boundaries in addition to classifying spans. Quoc et al. [19] proposed a two-stage entity recognition method to address the limitations of span-based models. Our method is also a span-based approach, but unlike previous studies, our model predicts each character as the beginning or end of each span without enumerating each span. As a result, it is highly efficient.

III. Proposed Model

To address the problem that traditional lexical enhancement methods are complicated and cannot be easily transferred to different deep learning neural network architectures, a simpler approach is used to quickly merge lexical information into each character's vector representation. Meanwhile, the entity recognition module uses a span-based entity recognition approach as the entity recognition module. The Fig. 2 depicts the model's general architecture:

A. *Lexical Enhancement*

The input sentence $s = \{c_1, c_2, \cdots, c_n\} \in V_c$ is processed as a sequence of characters by the Chinese character-based NER model, where $\mathcal{V}_c$ denotes the character vocabulary. Each character c_i is represented by a word vector:

$$x_i^c = e^c(c_i) \tag{1}$$

where e^c denotes the character embedding lookup table.

Character-based NER techniques have the disadvantage of not fully utilizing the information contained in words. To address this, we use SoftLexicon, a lightweight dictionary matching approach for entity recognition in Chinese electronic medical records. SoftLexicon incorporates lexical information into character representations, addressing the issue of character-based NER models' inability to use word information while simplifying the lexical enhancement process [20]. The lexical enhancement features are constructed in three steps:

First, in order to preserve the lexical information of characters, all matching words for each character C_i are divided into four sets of "BMES," which are constructed as follows:

$$\begin{aligned}
&\mathrm{B(c_i)} = \{\mathrm{w_{i,k}}, \forall \mathrm{w_{i,k}} \in \mathrm{L}, \mathrm{i} < \mathrm{k} \leq \mathrm{n}\} \\
&\mathrm{M(c_i)} = \{\mathrm{w_{j,k}}, \forall \mathrm{w_{j,k}} \in \mathrm{L}, 1 \leq \mathrm{j} < \mathrm{i} < \mathrm{k} \leq \mathrm{n}\} \\
&\mathrm{E(c_i)} = \{\mathrm{w_{j,i}}, \forall \mathrm{w_{j,i}} \in \mathrm{L}, 1 \leq \mathrm{j} < \mathrm{i}\} \\
&\mathrm{S(c_i)} = \{\mathrm{c_i}, \exists \mathrm{c_i} \in \mathrm{L}\}
\end{aligned} \tag{2}$$

Where $\boldsymbol{w}_{i,j}$ denotes the subsequence $\{c_i, c_{i+1}, \cdots, c_j\}$ and L is the lexicon we built. We constructed it from the already labelled texts of the train and dev sets and counted the number of their occurrences for the second step. The set $\mathrm{B(c_i)}$ represents the word set with the character $\mathrm{c_i}$ at the beginning and the length is greater than 1, the set $\mathrm{M(c_i)}$ represents the word set with the character $\mathrm{c_i}$ in the middle and the length is greater than 1, and the set $\mathrm{E(c_i)}$ represents the character $\mathrm{c_i}$ at the end and the length is greater than 1, the set $\mathrm{S(c_i)}$ represents a single character $\mathrm{c_i}$. If the word set corresponding to the current character is empty, it is set to the special word "NONE". Fig. 3 is an example of the SoftLexicon vocabulary extension. In this way, word embedding can be introduced and there is no loss of information because the tag matching result can be accurately restored by the four word sets.

Fig. 3. SoftLexicon method.

In the second step, transform each word in the word set using a pre-trained word vector; then perform weight normalization on all words in the four word sets, using a static weighting method based on statistics, that is, the frequency of each word in the static data. This frequency can reflect the importance of the word to a certain extent, and the frequency is obtained statistically when building a dictionary. The weighted method is as follows:

$$\boldsymbol{v}^s(S) = \frac{4}{Z}\sum_{w \in S} z(w)\boldsymbol{e}^w(w) \tag{3}$$

where S is the "BMES" word sets, $z(w)$ is the frequency of word w in the dictionary in the static statistics, Z is the sum of all words in the word set, and e^w is the lexical embedding lookup table.

Finally, the representations of the four word sets are combined into a one-dimensional feature, which is then stitched onto the representation of that character vector to obtain the final input vector.

$$\boldsymbol{e}^s(\mathrm{B,M,E,S}) = [\boldsymbol{v}^s(\mathrm{B}); \boldsymbol{v}^s(\mathrm{M}); \boldsymbol{v}^s(\mathrm{E}); \boldsymbol{v}^s(\mathrm{S})] \tag{4}$$

$$x^c \leftarrow [x^c; \boldsymbol{e}^s(\mathrm{B,M,E,S})] \tag{5}$$

where v^s is the result of the calculation in the previous step.

B. Global Pointer

In our work, we use the Global Pointer [21] as an entity recognition module, which is a span-based entity recognition method. Span-based methods identify named entities by classifying sub-sequences of sentences. This method outperforms sequence annotation-based methods in preventing error propagation and is able to easily detect nested named entities as they belong to different sub-sequences.

The Global Pointer concept is similar to a simplified multi-head attention mechanism, with as many heads as there are entities. For a sequence of length n, NER is performed by the αth category. The sequence has a total of $\frac{n(n+1)}{2}$ candidate entities, containing all possible entities. The entity recognition task is to select the actual entity from these $\frac{n(n+1)}{2}$ candidate entities. The Global Pointer scores each character to determine whether it is the beginning or the end of an entity. Based on this idea, the lexically enhanced vector token x^{ci} can be transformed into $\boldsymbol{q}_{i,\alpha}$ and $\boldsymbol{k}_{i,\alpha}$:

$$\boldsymbol{q}_{i,\alpha} = \boldsymbol{W}_{q,\alpha}\boldsymbol{x}^{ci} + \boldsymbol{b}_{q,\alpha} \tag{6}$$

$$\boldsymbol{k}_{i,\alpha} = \boldsymbol{W}_{k,\alpha}\boldsymbol{x}^{ci} + \boldsymbol{b}_{k,\alpha} \tag{7}$$

where $\boldsymbol{W}$ is the weight matrix and $\boldsymbol{b}$ is the bias. The $\boldsymbol{q}_{i,\alpha}$ and $\boldsymbol{k}_{i,\alpha}$ are the vector representations of the token which used to identify the entity of type α. Specifically, for span s $[i{:}j]$ of type α, the start and end positions are represented by $\boldsymbol{q}_{i,\alpha}$ and $\boldsymbol{k}_{i,\alpha}$. The score of an entity of type α can then be calculated as follows:

$$s_\alpha(i,j) = \boldsymbol{q}_{i,\alpha}^{\top}\boldsymbol{k}_{j,\alpha} \tag{8}$$

In the inference step, the segments for which the condition $s_\alpha(i,j) > 0$ is satisfied are considered the output entities of type α.

The use of Global Pointers alone is insufficient to accurately identify different types of entities as it does not take into account the length and span of the entities. For example, in the sentence "细胞减少与肺内病变程度密切相关 (cytopenia is closely related to the degree of lung lesions)", "细胞减少与肺 (cytopenia and lung)"may be mistaken as a single entity, as "细(fine)" is the start of the entity "细胞减少 (cytopenia)" while "肺(lung)" is the end of the entity "肺 (lung)". The model treats this combination of start and end positions as one entity. To overcome this issue, it is critical to incorporate relative position information into the Global Pointer method, which is more sensitive to the length and span of entities. Global Pointer uses rotational position encoding to encode relative position information. This encoding is based on a transformation matrix $\boldsymbol{R}_i$ with the property $R_i^{\top}R_j = R_{j-i}$, which can be applied to q and k respectively. The dot product between q and k is then transformed by the relative position information, resulting in a more accurate representation of the entity.

$$\begin{aligned} s_\alpha(i,j) &= \left(R_i\boldsymbol{q}_{i,\alpha}\right)^{\top}\left(R_j\boldsymbol{k}_{j,\alpha}\right) \\ &= \boldsymbol{q}_{i,\alpha}^{\top}R_i^{\top}R_j\boldsymbol{k}_{j,\alpha} \\ &= \boldsymbol{q}_{i,\alpha}^{\top}R_{j-i}\boldsymbol{k}_{j,\alpha} \end{aligned} \tag{9}$$

C. Loss Function

Entity recognition is a multi-label classification problem, so we use a multi-label classification loss function for category imbalance to perform multi-label classification for each label category in the $\frac{n(n+1)}{2}$category after obtaining scores for all segments of each label category. Because the number of entities present in each input text phrase is frequently fewer than $\frac{n(n+1)}{2}$, direct bi-classification causes serious category imbalance problems. Therefore, the method treats the problem as a two-by-two comparison of target and non-target category scores and uses cross-entropy to compute self-balancing weights to avoid the label category imbalance problem, which can be formulated as follows:

$$\mathcal{L} = \log\left(1 + \sum_{(i,j)\in P_\alpha} e^{-s_\alpha(i,j)}\right) + \log\left(1 + \sum_{(i,j)\in Q_\alpha} e^{s_\alpha(i,j)}\right) \tag{10}$$

where i, j represent the start and end indexes of a span, P_α refers to a set of spans that have entity type α, while Q_α refers to a set of spans that either do not have an entity type or have a different entity type from α. The function $s_\alpha(i,j)$ calculates the score for a span $s[i:j]$ to be an entity of type α.

IV. Experiments

A. Experimental Settings and Evaluation Metrics

The PyTorch deep learning framework is used to create the experimental model. For our experiments, we used pre-trained models including BERT-Base-Chinese [22] and RoBERTa-large [23]. To incorporate more medical information, we also used Bertcner [24], which was retrained on a medical corpus based on BERT-Base-Chinese.

Table I lists the hyper-parameter settings used in the model:

TABLE I. The Hyper-Parameter Settings

Parameters	**Value**
learning rate	2e-5
batch size	16
epochs	10
max sequence length	256
hidden size	768

We calculate the classification metrics including True Positive (TP), False Positive (FP), and False Negative (FN), and evaluate the performance of the model using the metrics of precision (P), recall (R) and Micro-F1($F1$):

$$\Pi\rho\varepsilon\chi\iota\sigma\iota o\nu = \frac{\sum_{i=1}^{n} \mathrm{TP}_i}{\sum_{i=1}^{n} \mathrm{TP}_i + \sum_{i=1}^{n} \mathrm{FP}_i} \tag{11}$$

$$\mathrm{Recall} = \frac{\sum_{i=1}^{n} TP_i}{\sum_{i=1}^{n} TP_i + \sum_{i=1}^{n} FN_i} \tag{12}$$

$$\mathrm{F1} = 2 \cdot \frac{Precision \ \cdot \ Recall}{Precision + \ Recall} \tag{13}$$

B. Introduction of Nested Dataset

The Tianchi Chinese Biomedical Language Understanding Evaluation Benchmark, jointly provided by Peking University, Zhengzhou University, Pengcheng Laboratory, and Harbin Institute of Technology (Shenzhen), published the CMeEE dataset, with a total of 938 files annotated with 47,194 sentences divided into nine major medical entity categories: diseases (dis), clinical (sym), and so on. We conducted experiments and analyzed them on this dataset to validate the effectiveness of our model. The data sources of the dataset include clinical trials, electronic medical records, medical books and search logs from real-world search engines. As biomedical data may contain privacy information such as patients' names, ages and genders, all collected data are anonymous and reviewed by ethics committees to protect privacy.

The CMeEE dataset differs from traditional NER in that there is a nested relationship between entities, which is a common phenomenon in medical texts and makes the model processing more complex. The nested entity instances accounted for about 11% of the training set. The dataset contains 15,000 sentences in the training set, 5,000 sentences in the validation set, and 3,000 sentences in the test set. To protect privacy, all data were anonymized and reviewed by an ethics committee.

C. Baselines of Nested Dataset

The comparison models used are the benchmark models officially released by CBLUE, and these methods are implemented based on the pre-trained model, including:

1) BERT-Base-Chinese: The basic model used had 12 layers, 768 hidden layers, 12 headers, and 110 million parameters.

2) RoBERTa-large: RoBERTa removed the next sentence prediction target and dynamically changed the masking pattern applied to the training data.

3) Bertcner: A medical pre-training model was obtained by crawling a 1.05G clinical text consisting of different medical domain corpora obtained on the web to train the BERT model again.

4) ZEN [25]: A BERT-based Chinese text encoder was enhanced by n-gram representation, considering different character combinations in training.

5) Mac-BERT-Base/large [26]: The Mac-BERT was an upgraded BERT that included a new Masked Language Model (MLM) as a correction pre-training assignment, which reduced the differences between pre-training and fine-tuning.

6) PCL-MedBERT: A pre-trained medical language model was proposed by the Intelligent Medicine Research Group in the PengCheng Lab, which excelled in medical question matching and NER.

In addition to the officially provided baselines, the following experiments are used for comparison:

7) TPLinker: Wang et al. [27] developed a single-stage joint extraction approach for addressing entity relationship extraction designs that could find overlapping relationships between one or two entities while being unaffected by exposure bias. The approach utilized to identify entity pieces was chosen as a comparison method in this paper.

8) Muti-head: Li et al. [28] developed a training strategy based on fragment annotation to solve the lack of entity data annotation. The essential idea was to employ negative sampling, which prevented NER models from being trained on unlabeled items.

9) Biaffine: Yu et al. [29] introduced a new NER approach that treats NER as a problem of dependent syntactic analysis, using graph neural networks to model the global information of the input sequence.

D. Results and Analysis of Nested Dataset

As shown in Table II, the F1 scores for entity recognition using only pre-trained models including BERT-Base-Chinese, RoBERTa-large, Bertcner, ZEN, Mac-BERT-Base/large, and PCL-MedBERT range from 60.7% to 62.8%. Compared to the human score of 67%, there is a gap of at least 4.2%. One important reason for this gap is the presence of many nested entities in this dataset, which cannot be recognized by these basic models based on sequence modeling. Therefore, our model uses a span-based model called Global Pointer as the entity recognition module. This model can calculate whether each character in the input text can be the beginning or end of an entity. It can recognize small entities nested within larger ones without a limit on the nesting level. We conducted three sets of experiments to validate this approach. Specifically, GP+BERT-Base-Chinese improved performance by 4.66% as compared to utilizing only BERT-Base-Chinese. When compared to the model utilizing only Bertcner, using GP+Bertcner improved the score by 4.58%, while using Global Pointer with RoBERTa-large, the GP+RoBERTa-large model improved the score by 5.99%. Additionally, our model GP+ BERT-Base-Chinese outperformed two other span-based models, Muti-head and Biaffine, by 1.93% and 3.91%, respectively. The above results demonstrate the effectiveness of Global Pointer. This also demonstrates that if nested entities can be recognized, it can significantly improve the performance of model and make it more suitable for MNER.

TABLE II. RESULTS OF CMEEE DATASET

Methods	F1(%)
BERT-Base-Chinese	62.1
RoBERTa-large	62.1
Bertcner	62.8
ZEN	61.0
Mac-BERT-base	60.7
Mac-BERT-large	62.4
PCL-MedBERT	60.6
TPLinker	64.32
Muti-head	64.83
Biaffine	62.85
GP[a]+ BERT-Base-Chinese	66.76
GP[a]+BERT-Base-Chinese+ SoftLexicon	67.43
GP[a]+Bertcner	67.38
GP[a]+Bertcner+SoftLexicon	67.71
GP[a]+RoBERTa-large	68.09
GP[a]+RoBERTa-large+SoftLexicon	**68.13**
Human	67.0

[a] "GP" means Global Pointer

To verify that a character-based model with added lexical information would perform better, we conducted experiments using SoftLexicon as a vocabulary enhancement method. Compared to experiments using only Global Pointer, we found a generally improved performance, with an increase of approximately 0.1% to 0.67%. This demonstrates that, under the same experimental conditions, adding lexical information into word embeddings has a certain gain effect on entity recognition.

We also conducted comparative experiments using Bertcner, which was trained on medical corpora based on the BERT-base model. When using pre-trained models directly for experiments, Bertcner outperformed BERT-Base-Chinese by 0.7%. With the addition of Global Pointer, GP+Bertcner outperformed GP+BERT-Base-Chinese by 0.62%. When SoftLexicon was added, GP+Bertcner+SoftLexicon still resulted in a 0.28% improvement over GP+BERT-Base-Chinese+ SoftLexicon. These results demonstrate that using BERT models trained on medical corpora can further improve the recognition of medical entities.

E. Introduction of Non-nested Datasets

Three non-nested datasets provided by the CCKS competition were used in the experiments. the CCKS-2017 dataset has 300 electronic clinical records and 29,866 labeled entities, categorized into five entity types: treatments, signs and symptoms, diseases and diagnoses, examinations and tests, and body parts. the CCKS-2019 dataset has 23,401 labeled entities, annotated into six entity types: diseases and diagnoses, examinations, tests, procedures, medications, and anatomical sites. The CCKS-2020 dataset has 32,120 labeled entities, with the same entity type classification as CCKS2019.

F. Baselines of Non-nested Datasets

The comparative models are presented below:

1) RoBERTa-Bi-LSTM-CRF[30]: The model contains three layers, a character embedding layer, a Bi-LSTM layer, and a CRF layer, relying on character-based word representations learned from a supervised corpus. The Bi-LSTM-CRF model can improve medical named entity recognition by capturing contextual information using bi-directional LSTM, and by modeling dependencies between tags using CRF.

2) RoBERTa-Bi-GRU-CRF[31]: The neural network model integrated Bi-GRU and CRF for sequence labeling tasks. Bi-GRU is a gated recurrent unit, an improved RNN that can solve the gradient vanishing and long-term dependency problems. By feeding the Bi-GRU output into CRF, the Bi-GRU-CRF network may use both bi-directional context information and label constraints for sequence tagging at the same time.

3) Bertcner[24]: A medical pre-training model was obtained by crawling a 1.05G clinical text consisting of different medical domain corpora obtained on the web to train the BERT model again.

4) Ra-RC [32]: The model used RoBERTa as an encoder to capture contextual information and adds part-level features on top of it to enhance the understanding of Chinese language.

5) AR-CCNER [33]: The model used part-level characteristics to augment character semantic information and a self-attention technique to record character interdependence.

6) ACNN [34]: This method effectively learned global context information using an attention mechanism and multi-layer CNNs and captured both short-term and long-term contextual information.

7) BE-Bi-CRF-JN [35]: This method combined the original text in NER tasks with its medical encyclopedia knowledge by establishing connections and interactions to enhance the ability of entity recognition.

8) RGT-CRF [36]: This model used two sets of features, word-based and word-based features, to make full use of the characteristics of Chinese language. The model also used a rule generator to automatically construct rules to improve the generalization ability of the model.

G. Results and Analysis of Non-Nested Datasets

As shown in Tables III, IV and V, we conduct experiments on the CCKS2017, CCKS2019, and CCKS2020 datasets to evaluate our model's performance on non-nested datasets. The experimental results indicate that using Global Pointer as the entity recognition module has a significant improvement compared to using only pre-trained models. Compared with BERT-Base-Chinese, RoBERTa-large, and Bertcner, using the Global Pointer method shows an improvement of 2.37% to 5.35% on the three datasets.

[d] “GP” means Global Pointer

Compared with the mainstream model using BiLSTM-CRF, our GP+RoBERTa-large model has gained 1.61%, 4.93%, and 3.74% F1 performance improvement over RoBerta-Bi-LSTM-CRF on the CCKS2017, CCKS2019, and CCKS2020 datasets.

In addition, we have compared our model with some other methods, such as the Ra-RC model that uses bi-directional long short-term memory networks to learn radical features of Chinese characters, the AR-CCNER model that uses convolutional neural networks to extract aggressive features while using self-attention mechanism to capture dependencies between characters, and the ACNN model that uses a multi-layer CNN structure to capture short-term and long-term contextual relationships for experiments, our model still outperformed these models in terms of F1 performance.

To verify the effect after adding vocabulary information, SoftLexicon was added separately to introduce vocabulary information for experimentation. Compared with the GP model without using vocabulary information, there is an improvement of about 1%. We also compared our model with other models combining lattice method with Chinese character information such as RGT-CRF. The performance is comparable on CCKS2017 dataset and improved by 0.72% on CCKS2019 and by 0.88% on CCKS2020 in terms of F1.

Finally, we experimented incorporating medical information into MNER model by using Bertcner trained on medical corpus data to obtain semantic features. Compared with basic pre-training model, GP+Bertcner+SoftLexicon has an improvement of 0.1%-0.5% improvement on the F1 over GP+BERT-Base-Chinese+SoftLexicon. When comparing it with BE-Bi-CRF-JN, there are improvements of about 1% and 8% on CCKS2018 and CCKS2020 datasets respectively.

H. Limitation Analysis

Compared with other methods, our model achieved the best results. However, there are still many entities that have not been recognized. In order to promote future work on MNER, this section analyzes the reasons for identification errors. The causes of errors are broadly classified into the following two cases:

1) Ambiguity: Some entities may have different meanings or belong to different categories in different contexts, resulting in difficulties and inaccuracies in entity recognition. To solve this problem, contextual information should be used to determine the true meaning or category of the entity.

2) Inadequate medical knowledge: Because the medical field contains a large number of terms and complex concepts, identifying and classifying these entities can be difficult for non-professionals. For example, in order to correctly classify entities such as diseases, drugs, symptoms, and treatment plans, it is necessary to have a thorough understanding of these concepts. Furthermore, medical knowledge evolves quickly, with new research findings and treatment methods constantly emerging. In this case, relying solely on pre-trained models may not meet real-time demands; collaboration with domain experts can ensure timely model updates, allowing for the resolution of new challenges.

V. Conclusion

In this paper, we propose a model which uses the Global Pointer with a lexical enhancement method and demonstrate its effectiveness for Chinese MNER on nested and non-nested datasets. By using lexical enhancement to incorporate word lexicons into the character representations, our model can perform Chinese NER at the character level and avoid the word segmentation errors. By using Global Pointer, our model can recognize both nested and non-nested entities by enabling a global view that takes the beginning and end locations into account. Experiment results, conducted on the CMeEE, CCKS2017, CCKS2019, and CCKS2020 datasets, show that the proposed model has excellent performance on these four data sets. Our results establish a new benchmark for Chinese MNER and open avenues for further research and exploration. In future work, we will investigate the way to leverage unlabeled data and extend our work to more datasets.

Research Scholar[1], Associate Professor[2]
School of Computer Science and Engineering, Vellore Institute of Technology,
Chennai Campus, Chennai, India[1, 2]

***Abstract*—In today's world, Recommender System (RS) is the most effective means used to manage the huge amount of multimedia content available on the internet. RS learns the user preferences and relationships among the users and items. It helps the users to discover new interesting items and make use of different media types such as text, audio, video and images. RS can act as an information filtering model which can overcome the issues related to over-fitting and excess information. In this work, a new distributed framework named DAE-SR (Deep AutoEncoder based Softmax Regression) is introduced for context-aware recommender systems which focus on user-item based interaction and offers personalized recommendations. The proposed model is implemented in PYTHON platform. The dataset used for experimentation is Foursquare dataset. The performance of the proposed context-aware RS is beneficial to both the users and service providers. Its helps in decision making process and can offer relevant recommendations to users. The performance is evaluated in terms of various metrics such as accuracy, recall, precision and so on. From the implementation outcomes, the proposed strategy achieved good accuracy (98.33%), precision (98%), run time (1.43 ms) and recall (98.1%). Thus, it is proved that the proposed DAE-SR classifier performs better compared to other models and offer dependable and relevant recommendations to users.**

Keywords*—Recommender Systems (RSs); context-aware; softmax regression; deep autoencoder; multimedia information

I. Introduction

With the exponential development of products and services over the internet, individuals face issues related to data deluge as each individual have to make choices in a reasonable manner to save their valuable sources such as money and time [1-3]. Individuals possess admirable communication skills for expressing the ideas among each other in a proper form. The use of contextual information made the designers to increase the abundance of communication between human and computer interaction which enables the growth of intellectual applications. Now, RSs can be useful in various modern applications which expose the user towards a massive collection of items. These structures usually offer a list of recommended items to the user in which each individual can predict or prefer an item [4-5]. These procedures are helpful to the users to choose the most suitable items and may ease the process of finding the desired items in the recommendation list.

The web crawler has turned out to be one of the key innovations for clients to naturally get data from assigned locales. The customary web crawler innovation has uncovered a few issues, for example, low material exactness because of basic sifting conditions regarding crawling themes, low productivity because of substance duplication and long website page refresh time [6-7]. Web crawler innovation is acquainted as a method to productively obtain and process data, and it includes different research territories, for example, distributed computing, data recovery, machine learning and web application [8-9]. Web crawlers are for the most part used to make a duplicate of all the visited pages for last handling. Additionally, crawlers can be utilized to assemble particular sorts of data from website pages, for example, gathering email addresses [10-11]. Quick fetching of relevant pages for the given topic with very less searches is possible with focussed crawler.

RS aims to seek the satisfaction of the individual/user via personalization and chooses the most appropriate services, items and provides it to the users considering the details such as user profile, opinions, preferences, purchase history, relationships with clients and interactions with services and products offered. The dual main entities of the RSs are the users, items which learn to create predictions by learning the parameters which minimize the loss among the actual and predicted preferences. Moreover, the RSs can be classified into 3 types such as CF (Collaborative Filtering), CB (Content-based) and HR (Hybrid Recommendation). Among these three categories, CB model gain advantages over the traditional RS system by exploiting the features of context-information as user activity, time, and location.

The integration of RS with context information influences the value of these models by enhancing the possible relevant recommendations in accordance to the varying user requirements. The CEP (Complex Event Processing) is integrated with RSs to provide personalized recommendations and allows the business users to put on event-driven rules for controlling and filtering the input parameters of recommendation engines [12-14]. The concept of context-based RSs minimizes the gap among the information models and users, therefore these information models can actively realize the user's context and offer better experience to users [15-16]. Recommender systems (RSs) are a subclass of data filtering frameworks that look to anticipate the rating that a client would provide for an item.

Recommender frameworks have been connected to variety of uses, e.g., films, music, news, books, look into articles, seek inquiries, social labels, and money related administrations. As a rule there are three different ways to plan recommender frameworks, i.e., cooperative separating, content-based filtering [17], and the hybrid filtering [18]. Recommender models have attracted consideration in both industry and academia. Such frameworks help to oversee data over-burden via assembling the data self-sufficiently and fitting it to singular interests [19]. A recommender framework would have the capacity to catch the clients' preferences. Social Recommender Systems (SRSs) or Recommenders for the Social Web demonstrate the client's preferences by utilizing the data he or she and their companions have distributed in online informal communities [20-21].

A. *Motivation*

Recommender Systems gained benefits by solving the problem of handling abundant data in the internet. Individuals plan to make effective and smart decisions on the huge number of available choices in various fields such as: a place the person wishes to visit, a movie the person likes to watch, a book he/she wants to read etc. The main motive behind this generation of recommender system is to offer the intelligence that benefits both the consumers and organizations. However, there is an emerging trend of using contextual information to afford meaningful personalized recommendations. The context enhances the basic interaction of user-item to realize recommendations of higher quality. Moreover, recommendation using content-based framework effectively use the information content describing the item or user such as item description or user profile to execute accurate recommendations. Also, content-based (CB) recommenders are more suitable with sparse datasets and may not suffer from the cold-start issue. As the textual data is used to represent the item description and user profile, this content based context-aware model make use of the common evaluation metrics to measure the similarity between the contents. The recommendations based on contextual information emphasize that the choice made by individuals is liable on certain context, rather than being invariant of it. Sometimes, the same users might select diverse services/products under a dissimilar context. Hence, this condition motivated the authors to develop a precise prediction of preferences by consumer depending on the appropriate contextual data which is being combined with the recommendation method.

B. *Contributions*

In this work, context-aware approach is developed by utilizing the contextual user information, in order to produce more accurate recommendation according to user’s preferences. This recommendation model makes use of the information from the dataset in order to create user recommendations on basis of given number of choices. The main novelty of the proposed DAE-SR recommendation model is to develop a context-aware/content-based RS that estimates the characteristics of restaurant and relevant context factors against the user preference model to create top recommendations for restaurant names based on the similarity score calculated. These scores can be used later to sort out the top restaurants for each user according to their expectation. Our proposed (DAE-SR) RS adopts a user preference model by using features of liked/visited restaurants by the user and takes relevant context factors, e.g., restaurant ratings, location, current weather, and time of the day. Most of the existing research works use CF based recommendation because of its higher performance accuracy. Since, CF approach is more effective and reliable one of the major drawbacks reported was the higher scalability. Hence, a new recommendation framework is presented in this work based on context-aware which improves the quality of recommendations. The major contributions of this paper are summarized as follows:

- To introduce a distributed framework for context-aware RS based on text mining and machine learning algorithms in order to afford quick and correct suggestions to user on good restaurants name.
- To present the content-based context-aware RS to create an item list that reveals the user’s preference and minimizes the error in the classification process.
- To develop a hybrid DAE-SR based recommendation on restaurant names which is trained with the meta-heuristic algorithm called JO (Jaya Optimization) algorithm which has good ability of exploration and exploitation.
- The three similarity measures such as Dice’s, Jaccard and Cosine similarity coefficients are used to compute the similarity of the content and to obtain high accuracy in receiving top recommendations.

C. *Organization*

The paper is organized as follows. In Section I, a brief introduction about the topic is given. Section II gives the works related to our proposed algorithm and Section III gives the proposed methodology. The result of the proposed algorithm is provided in Section IV and the entire work is concluded in Section V with future suggestion and references.

II. Related Works

The main motivation of related works section is to explain about the importance behind each research. In this this section, the discussion about the features of existing approaches, its applications, limitations, metrics and datasets used is clearly described in Table form.

Afolabi *et al.* [22] have presented a semantic web content mining scheme for RS in shopping by online. Through a web crawler, the web textual dataset was gathered built in Java. The combination of an existing ontology and a developed ontology was utilized for the textual data's semantic preprocessing. Next, the recommendation was created by the Naïve Bayes algorithm. The large dimensions of attributes were handled by the annotations to ensure the preprocessing models optimized semantic understanding.

Amato *et al*. [23] presented a technique SOS: A multimedia RS for Online Social systems. In this viewpoint, the RS was introduced for supporting the browsing of information accumulations and helping users to discover what they truly required. A new RS for big data applications was introduced in this research, which was able to deliver recommendations based on the interactions between users.

A hybrid learning based recommender framework was proposed by Tarus *et al.* [24]. In this paper, hybrid information based RS was introduced on the basis of sequential pattern mining (SPM) and ontology. The domain knowledge about the learning and learner resources was represented and modelled by the ontology, although the SPM algorithm determines the learners' sequential learning patterns.

RS with Linked Open Data (RS-LOD) and matrix factorization process (MF-LOD) was proposed by Natarajan *et al.* [25] for reducing the problems of cold- start and sparsity. The cold start issue was solved by the RS-LOD approach, and the data sparsity problem was eliminated by the MF-LOD approach. The hidden feedback data was elongated the user vector, and the similar semantic items were elongated each item. The collaborative filtering RS's precision was enhanced by the Semantic features from LOD.

Iqbal *et al.* [26] proposed a context-aware kernel-based recommendation scheme that creates the design over the user-item matrix of context rating. The importance of contextual information was considered for this recommendation. The KCR (Kernel Context Recommendation) algorithm was accurate, flexible and scalable enough to include the various contexts and was utilized for creating the practical recommendations.

A Preference Relation based PMF framework for RSs was proposed by Pujahari and Sisodia [27]. User's PR was taken as input, and the recommendation was also generated. The user's and item's neighborhood data were integrated into the design. The users' preferences towards items were obtained by the Probabilistic Matrix Factorization (PMF) system. This approach was introduced for Collaborative Filtering (CF) in RS. Aghdam [28] proposed a hierarchical HMM (hidden Markov model) in which the changes were identified in the preferences of user on time through modelling the user's latent context. The user as a hidden Markov process was modelled by the user-selected items.

Sangaiah, A.K *et al.* [30] developed a new technique with the help of ML (Machine Learning) methods to conserve the confidentiality of PBSs (Position Based Services) roaming users. The emergence of the three-phase procedure was used for the identification of PBS user position by means of combining k-NN (k-Nearest Neighbours) and DT (Decision Trees). The destination of the user was estimated by means of the HMM (Hidden Markov Models) and the position track sequence. The service policy followed was the mobile edge computing which was useful for ensuring the PBS timely delivery.

Sangaiah, A.K *et al.* [31] presented an energy-aware model (EAM) named green adversary for the application of smart industrial environment. The proposed model conserves the information and position confidentiality whereas the existing models make use of the cyber-physical systems by mutually using the software and hardware parts in which the energy consumption was minimized. However, this limitation was tested on the recommended approach related to the CPS (Cyber Physical Security) smart industrial applications and has removed the severe effects and also tested on CPS real-world applications.

Sangaiah, A.K *et al.* [32] presented whale optimization algorithm (WOA) to obtain optimal solution for network issues. WOA was powerful heuristic algorithms that boosted the exploration process and prevented bottleneck. However, the main drawback of this algorithm was a low convergence rate. Likewise, Bat algorithm (BA) was a novel meta-heuristic algorithm presented by Sangaiah, A.K *et al.* [33] to achieve optimal solutions in terms of sustainability and quality. It has the ability to monitor and control the network activities. Though, the performance of BA for huge data was not efficient. It was considered as a major disadvantage in BA.

Gupta Garima and Rahul Katarya [36] presented an Ensemble Particle Swarm Optimization (EnPSO) approach which was considered as an AutoML (AutomatedML) to minimize the model selection complexity. The presented EnPSO optimizes the recommendations intelligently using the identification of best ensemble model. The dataset used for testing was MovieLens in which the recommendations were improved with the AutoML system. The accuracy of the model was verified with the RMSE metric with lower error as 0.918 compared to the baseline IBCF (Item-Based Collaborative Filtering) with Singular Value Decomposition (SVD) having 0.961 higher errors. The main challenge was to find an effective way to reach the performing scheme with the vast search space. The limitation of the suggested approach was that EnPSO cannot provide effective performance gains within the constrained time for some cases.

Katarya Rahul, and Yamini Arora [37] developed a novel scheme called CapsMF (Capsule Networks Matrix Factorization) for product RS. The DNN (Deep Neural Network) text analysis architecture was enhanced with the Bi-RNN (Bi-directional Recurrent Neural Network) for the representation of text descriptions in robust form. The integration of Probabilistic MF with the DNN has the ability to generate recommendations in improved manner. The accuracy of the system was analysed with MAE (0.8878) and RMSE (1.157) shows improved outcomes. The major limitation observed was the training time was quite higher with the Caps Network during the experimentation process.

Katarya Rahul [38] presented a reliable RS model using the improved CF technique. A new self-devised method named P-distance algorithm was used to predict the ratings and acts as a dual-level filtering procedure to identify the nearest neighbours. The experiments were tested on 3 datasets such as Douban, Movielens and Jester. The performance was evaluated with MAE and RMSE metrics to show the effectiveness of the proposed algorithm. Sparsity was the major problem identified with this reliable RS.

Katarya Rahul [39] developed a hybrid RS utilizing KMC (K-means clustering) with ABC (Artificial Bee Colony) optimization procedure. The hybrid KM-ABC approach offers accurate movie predictions by considering the user ratings.

Various metrics such as accuracy, recall, precision, MAE were evaluated for verifying the system performance on the Movielens dataset. The experimental results on the dataset indicate that the proposed KM-ABC based recommender system has gained improved performance regarding reliability, accuracy, and personalization for the recommendation of movies. The drawback associated with this system was that only user ratings were considered and the other user characteristics were not considered.

Yadav *et al.* [40] presented a review on RS using FL (fuzzy logic). With the combination, with fuzzy logic three categories were reviewed such as content-based, memory-based and model-based systems. FL was utilized to assign the fuzzy values to the user items and represents the preference of user in robust form. The Fuzzy recommender was used to compute similarity using the fuzzy values rather than the user-based crisp data. This review offers significant knowledge about the various fuzzy based RS models. The fuzzy logic imitates the decision making process of humans which cover all the intermediate values.

Katarya Rahul [41] developed an improved RS utilizing dual-level MF (matrix factorization). This improved framework incorporates product ontologies for learning the items recommendations. The proposed matrix – factorization based RS initiates each item by generating similarity measures with each other. The similarity was created with the help of genres and a matrix was created using the given user ratings, so that the user gets his corresponding recommendation. Sparsity was the major problem identified with this reliable RS. The dataset used for experimentation was MovieLens dataset and the metrics used for evaluation were MAE and RMSE.

Katarya Rahul and Om Prakash Verma [42] introduced a web-based RS which was mainly based on successive information of user's navigation on web pages. FCM (Fuzzy C Means) approach was integrated to receive top-N clusters. Weights were calculated for each of the page category and the top page recommendations were predicted for the targeted user. The experimentation was performed on the real-world MSNBC dataset. Compared to other clustering approaches the proposed FCM model has gained 33%accuracy. The proposed RS required lower computation speed of 402 seconds whereas the other methods show similar as well as enhanced outcomes.

Katarya Rahul and Om Prakash Verma [43] presented a hybrid model for music recommendations. The proposed HMRS (Hybrid Music RS) represents the combination of both collaborative-content features. The algorithms such as BF (Bellman-Ford) and DFS (Depth First Search) were utilized with the multi-layered context graph. Here the similarity score was computed using PC (Pearson Correlation) coefficient. The overall results were optimized with the PSO algorithmic procedure. The music dataset used was Last.fm and the accuracy of the system was evaluated with recall metric on Top-N recommendations.

Katarya Rahul *et al.* [44] developed a location-based RS framework with the help of improved RW (Random Walk) model. Both the structural as well the attribute properties were utilized to recommend the location in SNs (Social Networks). The computations of accurate recommendations on locations were done with the improved RW model. The experimentation was conducted with three real-world datasets such as Gowalla, Brightkite and Foursquare. The accurateness of the system was evaluated with precision, F1 score and recall metrics.

Katarya Rahul *et al.* [45] presented a HF (Hybrid Filtering) approach in analysing the user behaviour in content-aware RS. The dual filtering strategies used are the pre-filtering and post-filtering models. The HF model eliminates the recommended items which has the lesser chance of relevance. Based on the significance of the contextual attribute both the filters were combined which forms a hybrid model. This HF approach minimizes the sparsity problem also it was quicker than the post-filtering method. The experimentation was performed on 50 movies that were selected equally from Movielens dataset and the precision calculation determines the accurateness of the system. Sanchez et al. [46] presented a RS for food delivery on the basis of number of orders. Nearest-neighbour (NN) algorithm was used for the evaluation of users preferred restaurants and buying patterns. Teixeira et al. [47] introduced a diabetic friendly restaurant recommendation using MAS (Multi-Agent System) for multi-criteria decision making. The users with diabetic illness can be benefitted and can find out suitable nearby restaurants. Table I represents the review on various recommendation systems.

A. *Research Gaps*

Most of the works developed in the context aware recommender system concentrates only on improving the accuracy of recommendation. But, the major purpose is to improve the recommendation accuracy when considering the design objectives such as a user's item's context. Moreover, the main challenge of a RS is to generate a significant recommendations using context based rating of user and item information. Hence, the recommender system should be accurate, flexible and that should predict the contexts accurately. Moreover, some of the recommender systems are providing the improved accuracy but not providing the rating of contexts. Some of the recommendation systems shows decreased computational complexity but fails in the accurate prediction and also results in the difficulty of generating recommendations.

The running time of the previous RS is noted to be higher while providing the recommendations which depend on the previous preferences of users. The preference may sometimes change based on time because of the mood change of users otherwise the change of contexts. Numerous earliest techniques are presented based on the statement of every user having the static pattern. But without these changes, the recommendation does not equal the user's choices. The context aware dependent recommendation systems are dealing with this problem through the contextual data. The contextual data usage is difficult because of attaining all contextual data for processing. Moreover, the different types of contexts used in the RS extend its dimensionality. Hence, to overcome all these issues, the authors of this work presented a Distributed Focused Web crawling with Machine Learning and Text Mining algorithms for the effective context aware recommendation system.

TABLE I. REVIEW ON VARIOUS RECOMMENDATION SYSTEMS

Author and Reference	Technique Used	Dataset Used	Applications	Metrics	Limitation
Afolabi *et al.* [22]	Semantic Web Mining + NB classifier	Wed textual data collected using Web crawler	Product Recommendation	Precision, Recall, F-score	Results are not optimal.
Amato *et al*. [23]	SOS	YFCC100M	RS for big data applications	MAE, RMSE	Information overload
Tarus *et al.* [24]	Hybrid recommendation framework	Real world dataset	e-learning	MAE, Precision, Recall	Machine learning techniques are not used.

B. Research Questions

The recommended system aims to execute certain tasks in assisting smart recommendations on restaurants. In this work, context aware-RS have played a most significant role in generating recommendations. Thus, some of the following research questions presented are:

- How are the contexts collected?
- Which contexts are used in smart learning?
- What data mining and recommendation techniques used to processes the contexts?
- What are the recommended activities?

The existing approaches utilized for the recommendation system was discussed in Section II with its research gaps. To avoid the issues presented in the existing RS, a new approach is proposed and the research questions are framed which is solved in this presented work (Section III).

III. Proposed Methodology

The recommendation system uses one of the exceptional pieces of the researches, which can be used to offer better solution for challenges also it uses supplementary refined machine learning algorithms for example, ANN. To analyse the performance of the Context-aware recommendation systems a combination of different approaches is used. The initial attempt is to model the criteria rating, approximately powerful machine learning approaches are used for this process. In order to enhance the prediction accuracy the deep learning model is used in this work. This paper make use of deep auto encoder and Softmax regression trained (DAE-SR) with a Jaya optimization (JO) algorithm for providing effective recommendations. We selected the Jaya optimization algorithm, since it has a high tendency to high convergence rates, low training time, and escape local minima compared to other optimization algorithms.

Fig. 1 shows the overall workflow diagram for the proposed strategy. For the web data acquisition, crawler is a significant tool. However the frequent updates of the data sources, distribution channels and web data structures are resulted in high costs of crawler program maintenance and development. From the raw web data the textual information's keywords are extracted by means of measuring keyword comprehensive weights via informative features. Textual information's keywords reflects the ideal way for data mining also establishes the knowledge representation model, after that constructs the index library. At last, for the deep machine learning strategies build a prediction model to obtain relevant recommendations. The prediction is performed based on the strategy named as DAE-SR to obtain effective results. The textual information pre-processing consists of following phases. They are:

- Information Collection and Processing.
- Pre-processing.
- Similarity Calculation.
- Recommendation Prediction.

A. *Information Collection and Processing*

For collecting the news the web crawler provide important theoretical support. Web crawler is a central part of search engines. The use of web crawler is not difficult when getting the news from the internet. Implementing a new crawler and not extending the existing crawler module by the user is the major problem with crawler. It is used to rescue the web pages also attach them into the local source. In a centralized location, collecting and processing the entire contents of web is the general-purpose of web crawlers. Every day a huge volume of web pages are frequently added and data is persistently changing due to the rapid emergence of internet. On the basis of event pattern or event procedure rule, the CEP is said to be a real-time data processing methodology. It is used to retrieve the high level knowledge from the large extent of data. It can also be utilized to analyze the trends, track the data from multiple sources, and patterns. The events that happened in past, are used in any order which can be allowed by CEP.

B. *Textual Information Pre-processing*

Pre-processing strategies named as stop words removal, word extraction, stemming and also term frequency–inverse document frequency (TF/IDF) are the important approaches in textual information pre-processing. Based on the words existing in the user opinion feedback reviews, the words are tokenized, count of frequency of word and stem are done by using the pre-processing strategies. Fig. 2 shows the process of pre-processing.

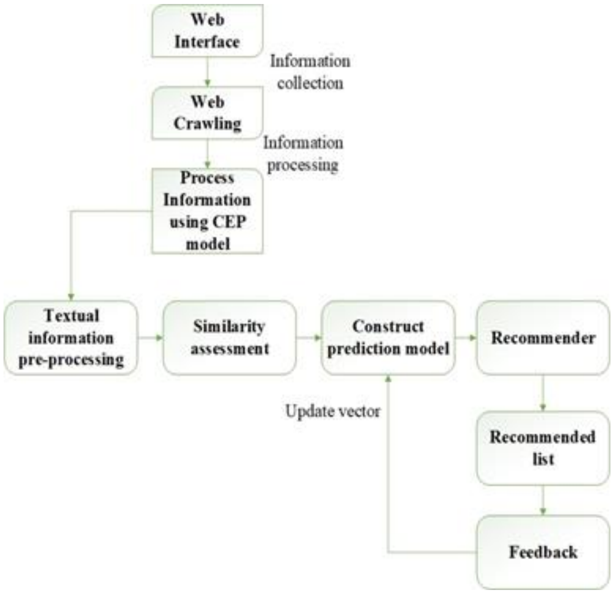

Fig. 1. Workflow diagram for proposed methodology.

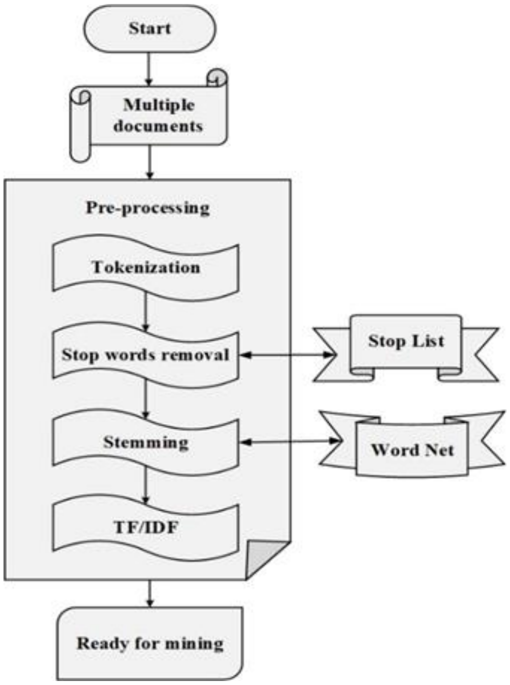

Fig. 2. Model of text-mining pre-processing.

Pre-processing plays a vital role in text mining (TM) applications. Pre-processing is the first step, which involves the combination of other steps such as token extraction, stemming, removal of stop words, and TF/IDF tasks.

1) Word (tokenization) extraction: The procedure of converting the sensitive data into tokens is called as tokenization. Here the significant amount of text structure is reduced to a word, phrase, or symbol. Using NLP (Natural Language Processing), the word in the document set *D* is tokenized.

2) Stop words: Pronouns, prepositions and articles are generally present in documents. These words may not add much meaning and considered as useless. Some of the stop words used are ‘with, an, is, the, has, in, be and, at’ etc. In text mining applications stop words are not considered as keyword, so it is eliminated from the document.

3) Stemming: The process of extracting the base form of words by eliminating the affixes and stem the root of a word into the original word is termed as stemming, example; programs, programming, programmed → ‘program’ etc.

4) Term frequency–inverse document frequency computation (TF-IDF): For text mining, TF-IDF is commonly applied as a weighting factor. A word how important to a document is given in this method; it is also known as numerical statistics.

a) Term weighting systems: Term weights schemes i.e. Document Frequency (DF), Term Frequency (TF) and Inverse Document Frequency (IDF) are frequently used. For the arithmetic representation of collection of web pages, the VSM (Vector Space Model) is the best widely held and proficient approach. Each web page is deliberated as a vector of terms in VSM model such that $d=(t_1,t_2,......,t_n)$, and an equivalent weights vector $w=(w_1,w_2,......,w_n)$, where $w_{1,}w_2,.......w_n$ the weights of $t_1,t_2,......,t_n$ are correspondingly, based on the used term weighting system. Table II gives the example of two dimensional based VSM model.

b) Term frequency (TF): In the web page, TF is related through the weight of a definite term. Normalized TF is measured in this paper. By finding the amount of raw frequency of the term t in web page w is calculate weight of term t is displayed in Eq. (2). The square root of the addition of the square of frequencies of all terms in the web page is known as Euclidean norm.

$$TF_{t,w} = \frac{fr_{t,w}}{\sqrt{\sum_{t=1}^{n} fr_{t,w}^{\;2}}} \tag{1}$$

Table III shows the example of collection of web pages, in this highest TF value is mentioned as bold and underlined cells is the second highest value in the matrix. As shown in Table III, on page 3 the term ‘payment’ has the highest *TF* value (0.7071). The term ‘payment’ is placed two times in page 3 and 4. The TF value is normalized to webpage’s Euclidean norm.

TABLE II. TWO DIMENSIONAL MATRIX BASED VSM MODEL

Web Page \Term	**account**	**service**	**banking**	**payment**	**cheque**	**insurance**	Page Length*
Page 1		1		1		1	3
Page 2	1		1		1	1	4
Page 3	1	1		2	1	1	6
Page 4	1		1	2	2	1	7

Term Frequency **	3	2	2	5	4	4
Page Frequency ***	3	2	2	3	3	4

* The number of distinctive terms in the web page
** Summation of term occurrences in entire web pages.
*** The number of web pages in which the term appears.

TABLE III. COLLECTION OF WEB PAGE AND HIGHEST TF VALUE

Web Page \Term	**account**	**service**	**banking**	**payment**	**cheque**	**insurance**
Page 1		0.5773		0.5773		0.5773
Page 2	0.5000		0.5000		0.5000	0.5000
Page 3	0.3535	0.3535		0.7071	0.3535	0.3535
Page 4	0.3015		0.3015	0.6030	0.6030	0.3015

c) Document frequency: The number of web pages within the collection is represented as DF (weight of term *t*), here the term *t* is found. It is a global weighting term.

$$DF_t = \sum_{p=1}^{N} \begin{cases} 1 & t \in p \\ 0 & t \notin p \end{cases} \qquad (2)$$

TF–IDF: The terms within the collection of web pages are denoted by TF-IDF, which is an effective ranking measure. It also reproduces the statement that less frequent word in the collection is more significant word in web page and viz. The dot product of TF and IDF of a term is denoted as TF-IDF. Table IV gives the example on the basis of TF–IDF weight scheme.

$$TF - IDF_{t,w} = TF_{t,w} \times IDF_t \qquad (3)$$

Where

$$IDF_t = \log\left(N \middle/ DF_t \right) + 1$$

The term ‘payment’ appears three times in the document, so it has highest TF-IDF value shown in Table IV. Also, the term ‘banking’ and ‘service’ appears twice in the collection.

C. Similarity Calculation

After the text pre-processing the opinions are grouped together according to their similarities, while the huge number of reviews are received. Similarity measurement is necessary in text mining approaches. Similarities among the string are calculated by similarity measures. Dice’s coefficient, Jaccard similarity coefficient and cosine similarity are defined below:

1) Dice’s coefficient: This metric is utilized to measure the documents similarity, and the inventive formula is given in Eq. (4).

$$SQ = \frac{2|B \cap C|}{|B| + |C|} \qquad (4)$$

Where, $|B|$ *and* $|C|$ signifies the number of terms present in documents. *SQ* represents the similarity quotient.

2) Cosine Similarity (CS): Two vectors of an inner product space similarity are calculated by this method, cosine of the angle is measured. Cosine of 0° value is 1, for some other angle it is <1. Mostly, in positive space cosine similarity is used, its results efficiently limited in (0, 1). Cosine Similarity [CS or *cos(θ)*] can be computed using the following eqn. 5 & 6,

$$CS = cos\,\theta = \left\{ \frac{Dot\ product(V,M)}{\|V\| * \|M\|} \right. \qquad (5)$$

$$cos\,\theta = \frac{\sum_{i=1}^{n} V_i M_i}{\sqrt{\sum_{i=1}^{n} V_i^2}\sqrt{\sum_{i=1}^{n} M_i^2}} \qquad (6)$$

Where, V_i and M_i signifies the components of vector V and M.

3) Jaccard Similarity (JS) Coefficient: JS is utilized to match the diversity and similarity of model sets. The other names are Jaccard coefficient/ index. The size of intersection divided by the size of union of the sample sets is known as Jaccard coefficient and computes the similarity among finite set of samples as shown in Eq. (7),

$$JS(B,C) = \frac{|B \cap C|}{|B \cup C|} \qquad (7)$$

Where, B and C represent the dual sets.

D. Recommendation Prediction: Hybrid DAE-SR Model

The performance of proposed recommendation model is investigated via neural systems to analyse the textual item content. In this paper, we proposed Softmax regression-based deep auto encoder network (DAE-SR) model trained with Jaya Optimization (JO) algorithm. Compared to the existing models activated in RS, in which the DAE provides better outcomes because of its high capability to reconstruct the inputs. Meanwhile, the softmax regression is utilized for classifying the ratings. We picked the JO algorithm since it has a high propensity to escape nearby minima, low preparing occasions, high assembly rates contrasted with other enhancement calculations, which is utilized to produce improved recommendation prediction.

TABLE IV. EXAMPLE ON THE BASIS OF TF–IDF WEIGHT SCHEME

Web Page \ Term	account	service	banking	payment	cheque	insurance
Page 1		0.7510		0.6494		0.5773
Page 2	0.5624		0.6505		0.5624	0.5000
Page 3	0.3976	0.4599		**0.7954**	0.3682	0.3535
Page 4	0.3391		0.3922	0.6783	0.6783	0.3015

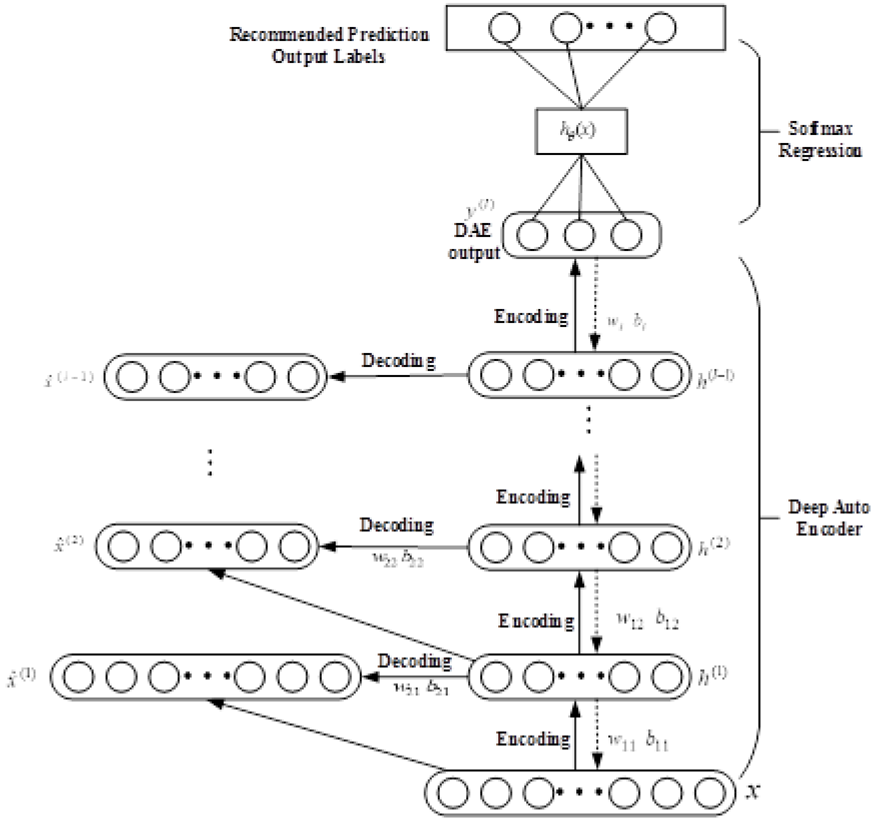

Fig. 3. Architecture of DAE-SR model.

Fig. 3 represents the architecture of DAE-SR model. It can be seen that DAE and softmax regression can be perfectly linked as a soft-hybrid model, which can make full use of labelled instances and achieve supreme accuracy with Jaya optimization algorithm. Here, we mainly explain the hybrid model of DAE-SR for recommended prediction. The deep auto encoder which is the popular deep learning model can learn discriminative features to produce autonomous distributed depictions of contents of items and users. Table V signifies the details of hyperparameters.

TABLE V. HYPERPARAMETER DETAILS

Hyperparameter	Value
No. of hidden layers	3
Batch size	16
Number of epochs	50
Activation	softmax
Learning rate	0.001
Optimizer	Jaya Optimization (JO)
Epoch	100

A DAE is said to be a deep neural network, which is fabricated via stacked Auto encoders. Pre-training that stacked AE from the bottom to top is a major phase of training a DAE. The result features of the hidden layer designated as input of the top-layer of the DAE, when the constraints of bottom layer of the DAE are decided. Through the Jaya optimization algorithm the procedure of the error back propagation is originated to fine-tune the constraints of the complete network. The number of layer fix as l also the function of objective can be displayed as in Eq. (8):

$$s\left(w_l, w_{i,k}\,|_{k=1}^{l-1}, b_{i,k}\,|_{k=1}^{l-1}\right) = \underset{w_l, w_{i,k}, b_{i,k}}{\arg\min} \frac{1}{2N}\sum_{i=1}^{N}|y_i - g_l(f_l(h_i^{l-1}))|^2 \tag{8}$$

Where, activation esteem of $(l-1)^{th}$ hidden layer indicated by $h_i^{l-1} = f_{l-1}(f_{l-2}(\cdots f_1(x_i)))$, and y_i signifies the label of x_i. w_l is the final layer weight, $w_{i,k}$ and $b_{i,k}$ represent the weight and bias of k^{th} layer, correspondingly. Moreover, the constraints of DAE are restructured as:

$$w_l := w_l + \Delta w_l = w_l - \mu d^l h^{l-1} \tag{9}$$

$$w_{1,k} := w_{1,k} + \Delta w_{1,k} = w_{1,k} - \mu d^k h^{k-1} \tag{10}$$

$$b_{1,k} := b_{1,k} + \Delta b_{1,k} = b_{1,k} - \mu \sum_{j=1}^{R} d^k \tag{11}$$

Where, the value $d^l = (h^l - Y)h^l(1-h), d^k = w^t_{k1} d^{k+1}(1-h^k)(when\, k < l)$, learning rate is represented as μ and size of input features denoted as R. The repetitions of $w_{1,k}$ and $b_{1,k}$ are performed till the function of objective reaches the max-epoch/iteration. Hence, the output of DAE is given to the SR model for further processing. Softmax Regression (SR) is a single-layer neural network used to evaluate the conditional probabilities linked with all the possible number of classes. A logistic regression display is the most straight forward type of a neural system. It comprises of an info layer with numerous traits and a bias unit, and just a single yield layer, or class. It is basically a double classifier. The Softmax Regression calculation applies binary strategic regression to different classes without a moment's delay. Let $D = \{(z^{(1)}, y^{(1)}, ..., (z^{(n)}, y^{(n)})\}$ be the training set, $z^{(i)}(i \in \{1,2,....,n)\}$ signifies the training data, $y^{(j)}(j \in \{1,2,.....,n\})$ signifies the label of training data. Given a test instance z, to evaluate the posterior probability $p(y = k \mid z)$. Softmax regression consists of input, classifier and output. A Softmax function is defined as the following Eq. (12):

$$P\left(y = \frac{j}{z^{(i)}}\right) = \phi_{soft\max}\left(z^{(i)}\right) = \frac{e^{z^{(i)}}}{\sum_{j=0}^{k} e^{z_k^{(i)}}} \quad (12)$$

Where,

$$z^{(i)} = w_0x_0 + w_1x_1 + ... + w_mx_m = \sum_{l=0}^{m} w_l x_l = w^T x \quad (13)$$

The Softmax function computes the probability that the training sample x_i belongs to class j given the weight and net input z_i. The process of finding the optimal weight parameters is the need for training DAE which minimize the objective function, where the models are trained by JO algorithm [29]. Compared to other optimization algorithms, this JO algorithm is said to be a powerful global optimization approach which can be used to solve the constraint as well as unconstrained problems using the benchmark function. Some of the advantages of JO algorithm are: It does not have any specific algorithm parameters to conduct the real computational experiments and has better algorithm convergence. The supreme reason to choose JO is the victorious nature of this algorithm which makes it more powerful than other evolutionary and swarm intelligence algorithms. The main objective of JO algorithm is, for a particular problem if the solution is once achieved the optimal result is reached simultaneously thereby avoiding the worst result. JO algorithm is most pretentious in application viewpoint and endeavours extraordinary accomplishments to discover the genuine solution successfully. Compared to other optimization procedures this JO algorithm utilizes only dual parameters such as number of iterations and size of population. An imperative benefit of using this algorithm is that it minimizes the time required for the optimization process and ignores the endeavour of varying constraints. Table VI specifies the pseudocode of Jaya Optimization.

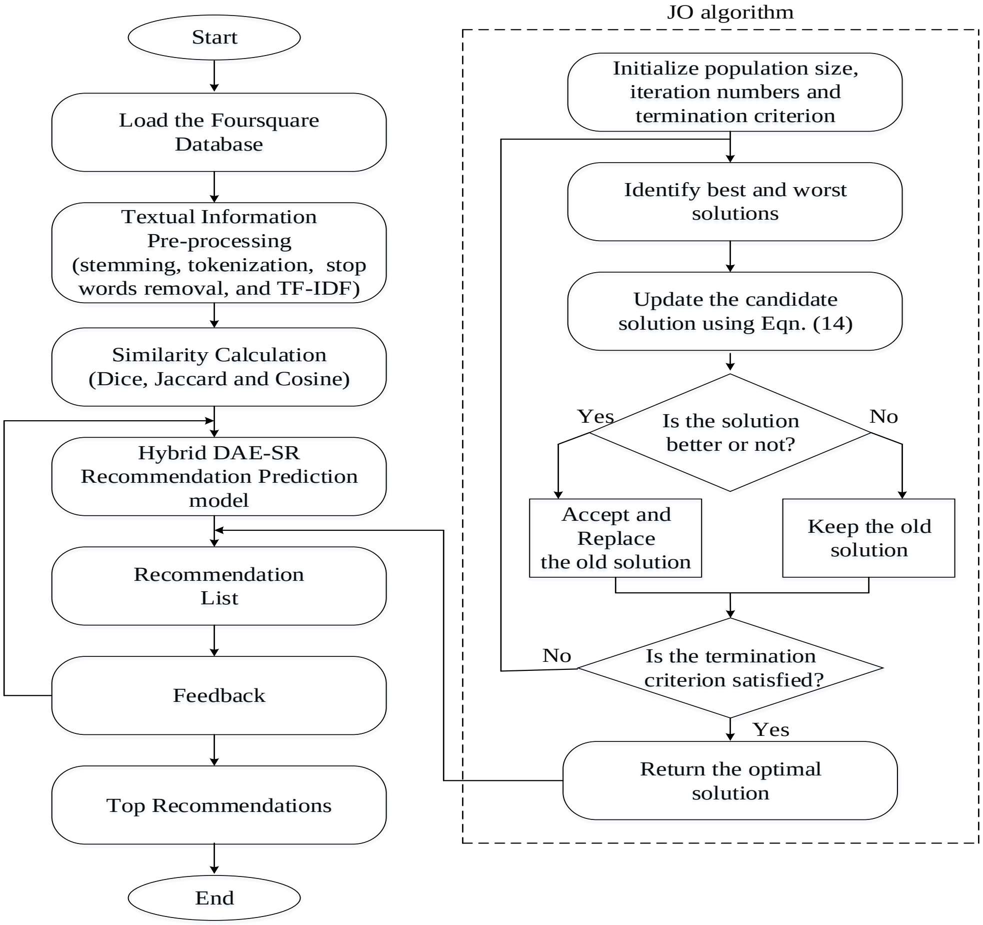
TABLE VI. PSEUDOCODE OF JAYA OPTIMIZATION

```
Jaya optimization algorithm procedure
Initialize: population size P, number of iterations I
Initialize P solutions randomly
Find $f(z_i)\ \forall i = 1,2,...,P$
Sort the population as $z_1$ -best solutions, $z_P$ -worst solutions
t=1
while $(t \le I)$ do
    for $i = 1,...,P$ do
        for $j = 1,...,D$ do
            Set $rn_1 \in [0,1]$
            Set $rn_2 \in [0,1]$
            $z'_{i,j} = z_{i,j} + rn_1 \cdot (z_{best,j} - |z_{i,j}| - rn_2 \cdot (z_{worst,j} - |z_{i,j}|))$
        end for
        if $f(z'_i) \le f(z_i)$ then
            $z_i = z'_i$ (Update)
        end if
    end for
    $t = t + 1$
end while
```

Suppose if the objective function is $f(z)$ with dimensional D factors represented as $(j = 1,2,..,D)$and the estimation value is $z_{i,j}$ for j^{th} variable of i^{th} competitor solution. The position of i^{th} solution candidate is $z_i = (z_{i,1}, z_{i,2}, ..., z_{i,D})$. The solution of best competitor can be expressed as $z_{best} = (z_{best,1}, z_{best,2}, ..., z_{best,D})$ has the finest estimation of $f(z)$in the present population whereas the solution of worst competitor in the present population is $z_{worst} = (z_{worst,1}, z_{worst,2}, ..., z_{worst,D})$. The solution of $z_{i,j}$ is simplified using the expression,

$$z'_{i,j} = z_{i,j} + rn_1 \cdot (z_{best,j} - |z_{i,j}| - rn_2 \cdot (z_{worst,j} - |z_{i,j}|)) \quad (14)$$

Where, the values of best and worst solutions of the j^{th} variable can be represented as $z_{best,j}$ and $z_{worst,j}$. The dual random numbers are rn_1 and rn_2 within the range [0,1], the updated solution is $z'_{i,j}$ and the absolute value of $z_{i,j}$ is signified as $|z_{i,j}|$. In each iteration, the attraction towards the best solution is denoted as$(z_{best,j} - |z_{i,j}|)$. Once the finest solution is achieved via the JO algorithm, it moves towards the finest outcome neglecting the worst solution. Thus, the proposed DAE-SR model obtains top recommendations on the restaurant names by considering the user reviews. Here, DAE-SR is trained on a data. This network gains knowledge from this data, which is compiled as "weights" of the network. These weights optimized with the JO algorithm have improved the performance of DAE-SR network in recommendation system. This optimization has good exploration and exploitation ability and hence avoid local optima problem with good convergence rate. The method presented in this paper gives a new way of improving the accuracy of the system.



Start
Load the Foursquare Database

Keep the old solution
Is the termination criterion satisfied?
No
Yes
Return the optimal solution

Fig. 4. Flowchart of proposed model.

Fig. 4 displays the flowchart of proposed model. The process starts by collecting the data from the Foursquare dataset. Next step is pre-processing of textual information with the stemming, tokenization, stop words removal and TF-IDF approaches. Three different similarity measures such as dice, Jaccard and cosine metrics are used to evaluate the similarity among the features. Among the three measures, cosine similarity has gained improved performance which can be used for further processing. Finally, the recommendation prediction is performed with the DAE-SR machine learning model. Here, the proposed DAE-SR model is optimized using JO algorithm that generates optimal best solutions with the feedback model and the Top recommendation on restaurant names is displayed. Some of the advantages of the proposed work are:

- Savings in cost and processing time.
- No cold-start issue and work well with sparse datasets.
- Quicker than traditional recommendation systems.
- Effective decision making and.
- Useful for people who visits new places.

E. *Answers to the Research Questions*

The presented context-aware recommendation model extracts valuable information from learner contexts and also leads to obtain better recommendations. In this wok, the contexts were collected using Search engine (Foursquare dataset). Next, the proposed RS named (DAE-SR) adopts a user preference model by using features, e.g., restaurant ratings, location, current weather, and time of the day. The recommendation technique used to process the context is DAE-SR with JO algorithm. The main recommended activity of the proposed model is to generate relevant and personalized recommendation about restaurants.

F. *Application of the Proposed Work*

Restaurant Recommendation is very useful to users because users can get information easily about different restaurants worldwide. These recommendations offer information's like popular restaurant names, menus, location, phone numbers and directions at a glance via the user's smartphone. Nowadays, there are number of social networking sites in which users post reviews about restaurants and rate businesses. However, before the creation of these online sites people went to restaurants occasionally visiting an interesting place or hearing reviews from neighbours, friends etc. With the technological advancements, there are number of online websites in which the people can check the details about the restaurant before visiting it directly. The information can be available in the form of ratings, price ranges, reviews, and hours of operation. After analysing all these factors, users can make valuable decisions. Checking the information via these online sites seem to be a time consuming task since users have to visit number of pages about different recommendations in order to find the right restaurant of their choice. Above all, when people visit a new place, travel or move to new place users prefer the same search procedure again. Therefore, the proposed DAE-SR model offers an effective recommendation system for the selection of restaurants. Using this we can build a customized real-time restaurant recommendation system. With this proposed system, we can provide recommendation for restaurants that will suit people's preference. For example, consider a newcomer who has just visited Chennai. He wants to have *'pricey but good selection of beer snobs'*. He is unsure about the good restaurants around his location. By inputting, this search query into our proposed model, he can get the top restaurants nearer to his location that are highly rated and get him interested in using our recommendation system as a user. Fig. 11 shows the best example as the application of the work in real world. Experimental results have shown that the proposed DAE-SR model achieved better performance than the existing recommendation procedures.

IV. Experimental Results

The recommender system helps the users in an effective manner to obtain useful and personalized information, in order to make comprehensive decisions in the day to day life of consumers. In experimental analysis, enactment of proposed DAE-SR is associated with the existing classifiers for example, K-Nearest Neighbour (KNN), Deep Neural Network (DNN) and Artificial Neural Network (ANN). For evaluating the proposed approach, the data is being collected from the public source and the dataset is named as Foursquare dataset. The restaurant reviews are discussed in this dataset. It contains restaurant name, location, day and time and the reviews. In terms of accuracy, precision and recall the proposed strategy is estimated. The implementation tool used in this work is PYTHON. The performance is compared based on the similarity. Dice's coefficient, Cosine similarity and Jaccard Similarity Coefficient are the tree similarity methods, which are used in the proposed strategy. Cosine similarity accuracy is better than the other similarity.

A. Description about Dataset

The dataset used for the implementation process is the Foursquare dataset. This is a publicly available data source being collected from https://www.kaggle.com/danofer/foursquare-nyc-rest?select=readme.txt. However, this dataset covers the details of check-in, tag and tip data of the restaurant locations in NYC gathered from October 24, 2011 to February 20, 2012. The foursquare dataset comprises of 3,112 users, 3,298 venues (locations) with 27,149 check-ins and 10,377 tips. Customer satisfaction can be analysed based on the reviews of reviewers acquired by the restaurants. Hence, the successful growth of restaurants is mainly based on the reviewer's reviews. It contains the details such as restaurant name, location, day and time and the reviews. Here, 70% of data is used for training and remaining 30% of data is used for testing purpose.

B. Evaluation Metrics

The procedure of analysing, collecting and reporting the data regarding the system performance is termed as performance evaluation. The performance of machine learning models is measured by means of the suitable evaluation metrics such as accuracy, recall and precision.

1) Precision value: It is the ratio of total number of recommendations that are relevant among the number of total recommendations provided.

$$Pr ecision = \frac{TP}{TP + FP} \tag{15}$$

2) Recall value: It is the ratio of number of recommendations provided among the total relevant recommendations.

$$Re call = \frac{TP}{TP + FN} \tag{16}$$

3) Accuracy value: This metric gives the required related documents from the total documents. The accuracy metric tries to evaluate the effective decision making of recommendation algorithms. It can be used to estimate the amount of correct as well as incorrect classifications as relevant or irrelevant items which can be predicted by the recommender system and hence useful for user tasks such as finding good items.

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \tag{17}$$

(TP- True positive, TN- True Negative, FP- False Positive, FN- False Negative).

C. Performance Analysis

The analysis of proposed DAE-SR is shown and compared with DNN, ANN, KNN for Dice's Coefficient, Jaccard similarity and cosine similarity are explained in this section.

Table VII gives the performance value of DNN, ANN, KNN and proposed DAE-SR for Dice's Coefficient. Fig. 5 displays the comparison analysis of dice similarity coefficient. For DNN, ANN, KNN and proposed DAE-SR classifier the precision values obtained are 85.4, 88.5, 91 and 95.16%, followed by recall value 80.2, 84.9, 87.9 and 94.22% respectively. The accuracy values for DNN, ANN, KNN and proposed DAE-SR classifier are 85.3, 90, 90.4, and 94.66%. Compared with the existing techniques our proposed approach gained better performance.

TABLE VII. DICE'S COEFFICIENT BASED PERFORMANCE

Performance Metrics	KNN (%)	ANN (%)	DNN (%)	DAE-SR (Proposed) (%)
Precision	85.4	88.5	91	95.16
Recall	80.2	84.9	87.9	94.22
Accuracy	85.3	90	90.4	94.66

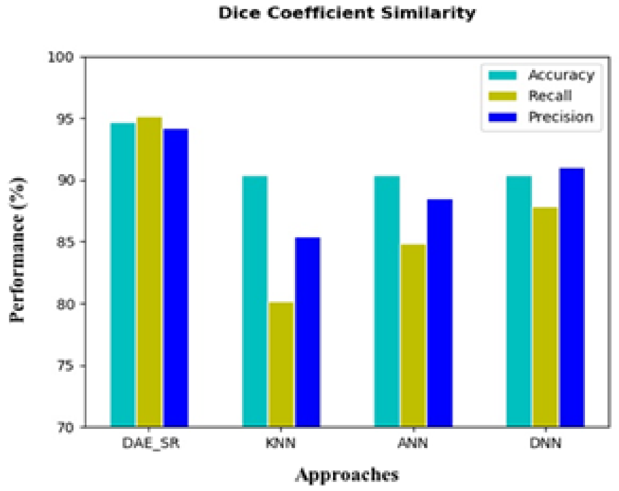

Fig. 5. Performance analysis of DNN, ANN, KNN and proposed DAE-SR for dice's coefficient.

TABLE VIII. PERFORMANCE ANALYSIS VALUE OF JACCARD SIMILARITY

Performance Parameter	KNN	ANN	DNN	DAE-SR (Proposed)
Precision	87.9	90	92.3	97
Recall	83.4	86.2	89	96.7
Accuracy	86.7	91.5	93	97.25

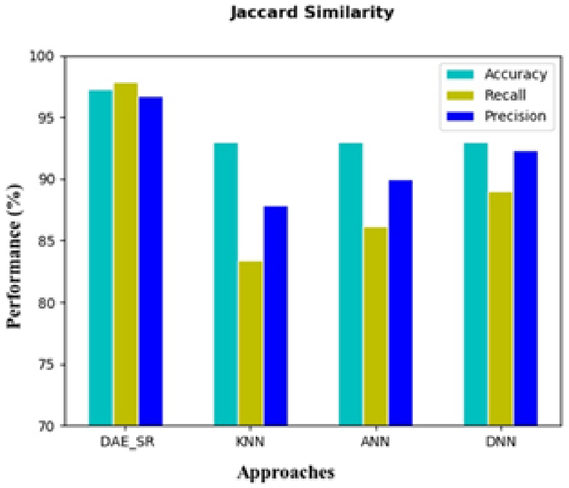

Fig. 6. Graphical representation of jaccard similarity performance.

Table VIII represents the Jaccard Similarity performance value comparison of different classifiers with proposed classifier. Fig. 6 shows the analysis of DNN, KNN, ANN and proposed DAE-SR for Jaccard similarity. For DNN, ANN, KNN and proposed DAE-SR classifier precision value are 87.9, 90, 92.3 and 97%, recall value are 83.4, 86.2, 89 and 96.7% also accuracy value are 86.7, 91.5, 93 and 97.25%. It is obviously agreed, compared with other classifier the proposed approach has better performance.

TABLE IX. PERFORMANCE OF COSINE SIMILARITY

Performance Metrics	KNN	ANN	DNN	DAE-SR (Proposed)
Precision	90	92	94	98
Recall	85	88	92	98.1
Accuracy	89	93	96	98.33

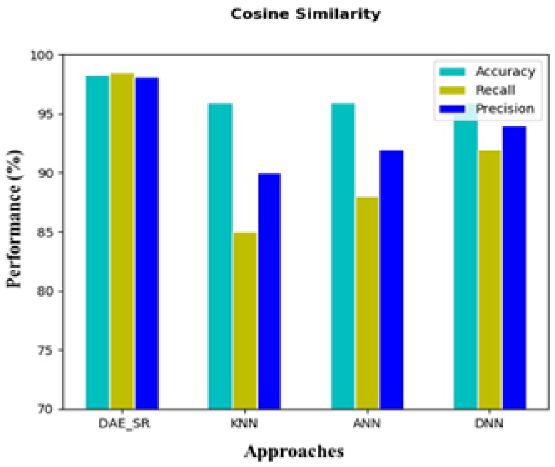

Fig. 7. Graphical representation of DNN, ANN, KNN and proposed DAE-SR for cosine similarity performance.

Table IX signifies the performance of Cosine similarity. Fig. 7 displays the analysis of DNN, ANN, KNN and proposed DAE-SR classifier on cosine similarity. The accuracy acquired with DNN, ANN, KNN and DAE-SR is 89, 93, 96 and 98.33% respectively. From the above results, it is finely known compared with other classifier the proposed DAE-SR approach achieved better performance. Also, cosine similarity based performance is high when compared to the other similarity. As in our proposed method, the generating value accuracy is better in Cosine similarity. Table X represents the comparative results of RMSE and MAE. The proposed DAE-SR model shows lower error values which clearly signify the accurateness of the system compared to the existing methods.

Fig. 8 displays the comparison outcomes of RMSE and MAE of the proposed approach with existing approaches. Minimum or decreased in RMSE and MAE is considered as better outcome. Error minimizing gives better accuracy for the proposed scheme compared to other approaches. In figure 8, compared to two existing approaches, the proposed strategy produced minimum error outcomes.

TABLE X. COMPARATIVE RESULTS OF RMSE AND MAE

Approaches	RMSE	MAE
DAE-SR (Proposed)	0.15	0.02
Natarajan *et al.* (2020) [25]	0.9	0.8
Iqbal *et al.* (2019) [26]	0.8832	1.092

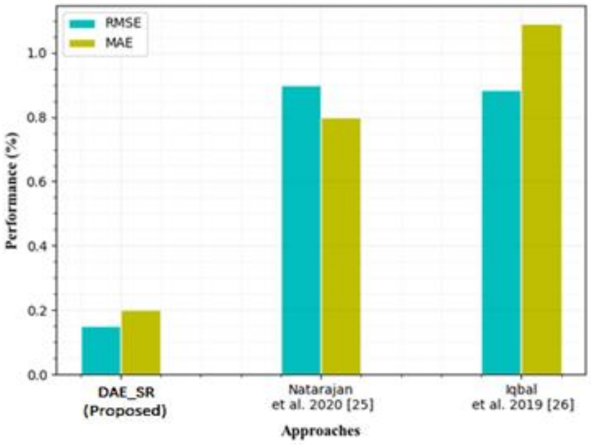

Fig. 8. Comparison of different performance measures.

TABLE XI. COMPARISON OF PERFORMANCE OUTCOMES OVER DIFFERENT EXISTING WORKS

Method/Metric	Precision	Recall	Accuracy
DAE-SR (proposed)	98%	98.1%	98.33%
Natarajan *et al.* (2020) [25]	56.4%	56%	84.1%
Afolabi *et. al.* (2019) [22]	46.9%	42.2%	-

Table XI gives the various performance outcomes comparison regarding different existing works. Fig. 9 shows the precision, recall, and accuracy comparison of DAR-SR with different existing works. In this research, we have used DAE-SR for the effective recommended system. The proposed approach produced better outcomes than the other two previous works. Our proposed model achieves maximum 98% precision, 98.1% recall and 98.33% accuracy values. The proposed scheme achieves above 98% performances because of the best classification approach DAE-SR with JO.

TABLE XII. ACCURACY COMPARISON WITH EXISTING METHODS

Authors	Techniques	Accuracy (%)
Venugopal and Sandhya	**DAE-SR (proposed)**	98.33%
Natarajan *et al.*[25]	RS-LOD	84.1%
Ray *et al.*[34]	Ensemble	92.36%
	RNN	86.00%
	GRU	90.00%
	LSTM	89.00%
	Bi-LSTM	89.00%

Table XII signifies the accuracy comparison with existing methods. The accuracy of the proposed DAE-SR model is compared with various state-of-the-art models to evaluate the performance of the proposed recommendation procedure. The existing models on recommendation system gained lower classification accuracy with RS-LOD, RNN, Ensemble, LSTM, GRU and Bi-LSTM as 84.1%, 86.00%, 92.36%, 89.00%, 90.00% and 89.00% respectively. The proposed model achieved supreme accuracy of (98.33%) because the context-aware RS based on text mining and machine learning algorithms afford quick and correct suggestions to user on good restaurants name. Table XIII specifies the run time comparison with existing methods. From the table it is observed that the proposed DAE-SR recommendation model requires less run time 1.43 milliseconds for computation whereas the other models specify higher computational time which reduces the system efficacy.

TABLE XIII. RUN TIME COMPARISON WITH EXISTING METHODS

Techniques	Run Time
DAE-SR (proposed)	1.43 ms
IDA-CF [35]	2.6 ms
CF [35]	12 sec
NRA [35]	27 sec
FRS [35]	28 sec

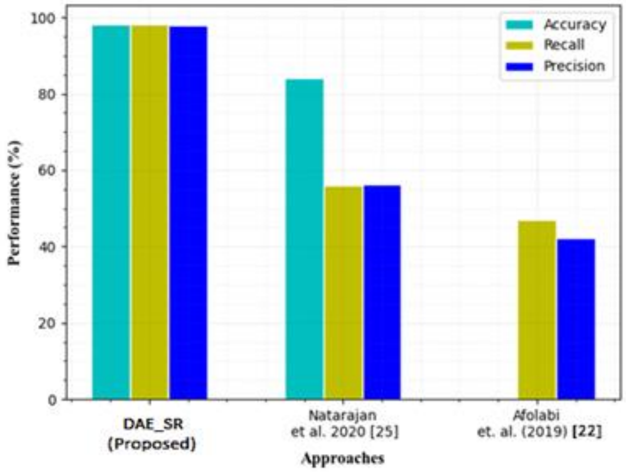

Fig. 9. Performance comparison of DAE-SR.

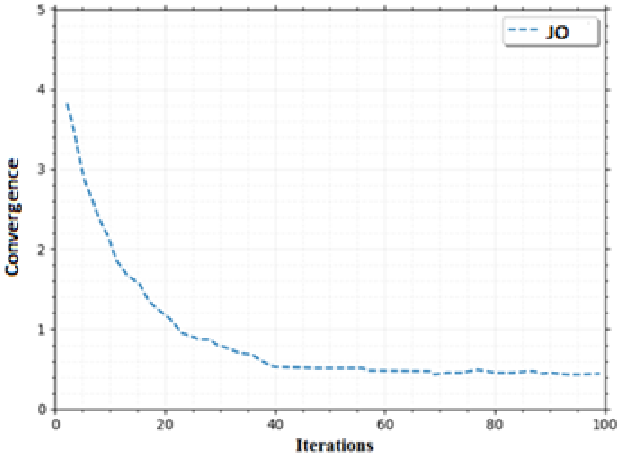

Fig. 10. Convergence graph for JO.

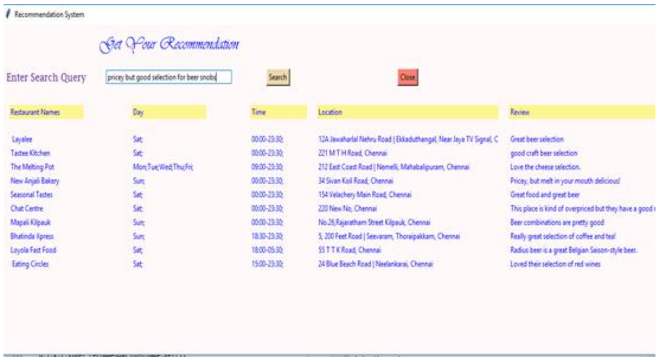
Fig. 10 demonstrated the convergence graph for the JO algorithm. It illustrated that, the proposed JO algorithm achieved the optimum convergence after the 40 iterations, because the JO is a potential optimizer for an engineering issues. Compared to other algorithms, the exploration and exploitation ability of JO algorithm is very impressive and superior. And it has a very good balance among exploitation and exploration.

D. Recommendation Analysis

The following section gives the recommendation analysis in terms of a graphical user interface (GUI). Similarity-based outcomes are taken here for the statistical measures and compared with the existing classifiers. The proposed model DAE-SR achieved better performance, and it produced accurate recommendation outcomes.



Enter Search Query: pricey but good selection for beer snobs

Restaurant Names	Day	Time	Location	Review
Layalee	Sat;	00:00-23:30;	12A Jawaharlal Nehru Road | Ekkaduthangal, Near Jaya TV Signal, C	Great beer selection
Tastee Kitchen	Sat;	00:00-23:30;	221 M T H Road, Chennai	good craft beer selection
The Melting Pot	Mon;Tue;Wed;Thu;Fri;	09:00-23:30;	212 East Coast Road | Nemelli, Mahabalipuram, Chennai	Love the cheese selection.
New Anjali Bakery	Sun;	00:00-23:30;	34 Sivan Koil Road, Chennai	Pricey, but melt in your mouth delicious!
Seasonal Tastes	Sat;	00:00-23:30;	154 Velachery Main Road, Chennai	Great food and great beer
Chat Centre	Sat;	00:00-23:30;	220 New No, Chennai	This place is kind of overpriced but they have a good
Mapali Kilpauk	Sun;	00:00-23:30;	No.26,Rajaratham Street Kilpauk, Chennai	Beer combinations are pretty good
Bhatinda Xpress	Sun;	18:30-23:30;	5, 200 Feet Road | Seevaram, Thoraipakkam, Chennai	Really great selection of coffee and tea!
Loyola Fast Food	Sat;	18:00-05:30;	55 T T K Road, Chennai	Radius beer is a great Belgian Saison-style beer.
Eating Circles	Sat;	15:00-23:30;	24 Blue Beach Road | Neelankarai, Chennai	Loved their selection of red wines

Fig. 11. Content based restaurant recommendation.

Recommendation of the good restaurants name, location and the reviews of the recommender is displayed in this analysis. Fig. 11 shows the content based restaurant recommendation. The recommendation text box shows the restaurant name, location, day and time also the customer reviews. There are large amount of data is there. The user's information that is related to the restaurant is shown by GUI.

E. Discussion

The proposed study introduces a DL based restaurant recommendation system named DAE-SR which extracts user preferences from online comments and recommends top restaurants to the users. With the technological advances and changes in human lifestyle makes the selection of appropriate restaurants as very difficult due to the wide range of ethnicities, ingredients, culinary styles, personal tastes and cultures. The proposed DAE-SAR based recommendation systems offers valuable decisions to users on where to eat. The proposed DAE-SR model attained an increased accuracy of 98.33% whereas the existing models RNN, LSTM, Ensemble, GRU, BiLSTM and RS-LOD gained lower results such as 86%, 89%, 92.36%, 90%, 89% and 84.1% respectively. Thus, the presented model obtained improved accuracy due to better convergence, low run-time and GUI modelling.

V. Conclusion

Recommender system provides precise online recommendations to the web users, it can also be known as knowledge management and information distribution tool. In this paper, a novel distributed framework for context aware recommender system is proposed based on text mining and machine learning algorithms. Based on the user opinion feedback reviews from the social networking services the top restaurants are recommended to the customers. The existing works on recommendation system proved that the use of individual CF based recommendation provide recommendations only via ratings/user interests and items. In this work, a new RS model is presented which proved that the contextual information is more relevant in the generation of recommendations under diverse conditions such as ubiquity and mobility. The proposed DAE-SR classifier offers suitable suggestions to users on the restaurant recommendations compared to the existing DNN, KNN and ANN methods. Experimental outcomes reveal that the proposed DAE-SR based recommendation system outperforms the other classifiers in terms of accuracy, precision, and recall values based on the similarity measures. The accuracy (98.33%) of proposed strategy DAE-SR outperforms the other strategies with cosine similarity. The main advantage of DAE-SR is, it may not suffer from cold-start issue and work well with sparse datasets. The limitation of this study is that only one dataset is used for analysis. Moreover, it is limited by the total amount of available content for providing meaningful recommendation. In future work, we can evaluate our proposed method with different datasets for different applications.

***Abstract*—The COVID-19 pandemic has significantly changed learning processes. Learning, which had generally been carried out face-to-face, has now turned online. This learning strategy has both advantages and challenges. On the bright side, online learning is unbound by space and time, allowing it to take place anywhere and anytime. On the other side, it faces a common challenge in the lack of direct interaction between educators and students, making it difficult to assess students’ engagement during an online learning process. Therefore, it is necessary to conduct research with the aim of automatically detecting students’ engagement during online learning. The data used in this research were derived from the DAiSEE dataset (Dataset for Affective States in E-Environments), which comprises ten-second video recordings of students. This dataset classifies engagement levels into four categories: low, very low, high, and very high. However, the issue of imbalanced data found in the DAiSEE dataset has yet to be addressed in previous research. This data imbalance can cause errors in the classification model, resulting in overfitting and underfitting of the model. In this study, Convolutional Neural Network, a deep learning model, was utilized for feature extraction on the DAiSEE dataset. The OpenFace library was used to perform facial landmark detection, head pose estimation, facial expression unit recognition, and eye gaze estimation. The pre-processing stages included data selection, dimensional reduction, and normalization. The PCA and SVD techniques were used for dimensional reduction. The data were later oversampled using the SMOTE algorithm. The training and testing data were distributed at an 80:20 ratio. The results obtained from this experiment exceeded the benchmark evaluation values on the DAiSEE dataset, achieving the best accuracy of 77.97% using the SVD dimensional reduction technique.**

Keywords*—*Convolutional neural networks; imbalanced data; deep learning; PCA; COVID-19; online learning; students’ engagement; SVD; SMOTE

I. Introduction

During the COVID-19 pandemic, the education sector has been compelled to adopt online learning. The conventional classroom learning has transformed into online learning or "school from home." E-learning has become a standard solution for learning, and virtual conference technologies, such as Zoom, Google Meet, and others, have given online learning flexibility and accessibility from anywhere and at any time, suitable with the current digital era. However, despite the numerous advantages of online learning, one significant obstacle that needs to be addressed is the lack of direct interaction between teachers and students. During virtual conferences, some students may not turn on their cameras, making it challenging to determine their presence and participation in the online class. Consequently, it becomes difficult for teachers to observe the level of student engagement during online learning, especially during screen sharing to explain teaching materials. This situation presents a common obstacle in online learning. To address this obstacle, it is necessary to conduct research to develop methods of automatic students’ engagement detection during the online learning process.

Students’ engagement detection is an essential factor in improving the learning process. It is a qualitative indicator in the learning process [1]. It entails three structured learning dimensions: behavioral engagement, emotional engagement, and cognitive engagement [2]. While all the three dimensions of engagement are crucial for measuring students' level of involvement in the learning process, emotional engagement is the most widely studied. Detecting students' emotional engagement is particularly important in education because it has a significant impact on their learning rate and overall academic performance. Whitehill et al. [3] showed that both human and automatic engagement judgments are correlated with task performance. The study found that post-test student performance could be predicted based on engagement labels with similar accuracy to pre-test results.

The problem of automatically detecting students’ engagement in online learning based on video data can be solved using a machine learning approach. Zang et al. [3] investigated engagement detection in online learning through a data-driven approach based on facial expressions and mouse usage behavior. Their study demonstrated that utilizing multiple features for detection could significantly improve the accuracy of engagement detection. In contrast to previous studies that solely relied on students’ facial expressions, they also took into account students' mouse usage behavior in their approach. Bhardwaj et al. [4] proposed a deep learning model named Convolutional Neural Network (CNN) for students’ engagement detection, while Selim, et al. [5] conducted students’ engagement detection in online learning using Hybrid EfficientNetB7 together with TCN, LSTM, and Bi-LSTM. Khenkar et al. [6] also proposed an engagement detection method based on micro-body gestures using 3D Convolutional Neural Network (CNN).

Ashwin et al. [7] also conducted engagement detection using CCTV video recordings in a computer laboratory, in which case CCTV video recordings were successfully used to analyze students' engagement. Convolutional Neural Networks (CNN) were successfully implemented with a good level of accuracy in identifying students' engagement levels. This study's results revealed a positive correlation between students' scores (student learning) and students' predicted engagement levels. Meanwhile, Sharma et al. [8] detected students' engagement using video recordings of students' learning through emotional analysis and tracking of eye gaze and head movements based on two machine learning algorithms, namely the Haar Cascade algorithm (for face and eye detection) and the Convolutional Neural Network algorithm (CNN) (for emotion classification). Based on these studies, CNN is a powerful deep learning model that has been successfully used in various studies to detect students' engagement levels in online learning. By analyzing emotional features, tracking eye gaze directions, and estimating head movements, CNN could predict students' engagement levels, which is essential for improving the effectiveness of online learning.

One of the widely used datasets for video-based students' engagement detection is the DAiSEE dataset (Dataset for Affective States in E-Environments). The DAiSEE dataset was first introduced in the study of Gupta et al. in 2016 [9]. The benchmark accuracy value of the DAiSEE dataset for the affective level of engagement was 51.07%. Based on the benchmark evaluation result, there are still many opportunities for improving the classification performance of the DAiSEE dataset. The data distribution for each label of the affective level of engagement is unequal, with 1% for very low engagement, 5% for low engagement, 50% for high engagement, and 45% for very high engagement. This data imbalance can result in errors in the classification model, leading to overfitting or underfitting. One solution to address this issue is to balance the data using undersampling or oversampling techniques [10], [11]. Ali et al. [12] presented a data-level approach and an algorithm-level approach for handling class imbalance problems. Bach et al. [13] examined some undersampling and oversampling methods for highly imbalanced data. The conclusion of their research was that the Synthetic Minority Oversampling Technique (SMOTE) boosted by the Edited Nearest Neighbours (ENN) method allowed for an improvement in classification precision. Fernandez et al. [14] also revealed through their research that the SMOTE algorithm improved performance in supervised learning problems.

Therefore, imbalances in the DAiSEE dataset must be addressed. The current research's objective was to perform data balancing and feature selection to improve the benchmarking performance of the video-based students' engagement detection model on the DAiSEE dataset.

This article is organized as follows. Section II explains related works from previous studies. Section III describes the proposed model and methodology for students' engagement detection. Section IV presents the results of the methodology implementation. Section V provides a discussion of the results, and Section VI presents the conclusions of this study.

II. Related Works

Many studies related to the detection of students' engagement have been carried out. Bhardwaj et al. [4] used two datasets. The first one is the FER-2013 dataset, which is an image dataset used to train the CNN model, and the second one is the MES dataset, which is a tabular dataset used to do weight and subsequent calculations of the MES (Mean Engagement Score). The engagement level of students is classified into two classes: "engaged" and "not engaged." The proposed model achieved an accuracy level of 93.6%, a precision level of 98.48%, and a recall level of 87%. The proposed automated approach will certainly help educational institutions achieve an improved and innovative online learning method.

Selim et al. [5] also used the DAiSEE dataset to detect students' engagement and compared the performance of the proposed method with the VRESEE dataset. They proposed a Hybrid EfficientNetB7 model combined with TCN, LSTM, and Bi-LSTM. EfficientNet was pre-trained on the ImageNet dataset, which includes eight models ranging from EfficientNet B0 to EfficientNetB7. The study also compared the proposed and previous models on the DAiSEE dataset. The results of the three proposed models were as follows: EfficientNetB7+TCN, EfficientNetB7+Bi_LSTM, and EfficientNetB7+LSTM were at the levels of 64.67%, 67.39%, and 67.48%, respectively, outperforming the state-of-the-art ResNet+TCN model that was at 63.59%. When evaluating the proposed models on the VRESEE dataset, the highest accuracy achieved was 94.47% (from the use of EfficientNetB7+Bi_LSTM).

Paidja et al. [15] used the DAiSEE dataset for engagement emotion classification. They proposed a Convolutional Neural Network (CNN) model and performed feature extraction using five facial landmarks and the Euclidean distance between points and center points from the facial image. They also compared CNN with other machine learning algorithms, such as Support Vector Machine (SVM) and Deep Neural Network (DNN). The accuracy results obtained indicated that CNN successfully recognized engagement emotions better than the other methods. However, the limitation of their research was that it did not use the entire DAiSEE dataset as only 77 out of 9068 videos were used.

Abedi et al. [16] described the improvement of the state-of-the-art technology for detecting students' engagement using a ResNet and TCN Hybrid Network. This research also used the DAiSEE dataset and evaluated the performance of the ResNet+TCN method, comparing it to several previous studies on the DAiSEE dataset. The experimental results showed that the proposed ResNet+TCN model could improve the classification accuracy performance by 63.9%. It is very challenging to detect the minority engagement level with a very small sample in a supervised classification problem.

Zhang et al. [17] proposed an Inflated 3D Convolutional Network (I3D) for automatic students' engagement. The research also used the DAiSEE dataset for students' engagement detection, coupled with the use of OpenFace and AlphaPose for feature extraction. The proposed method achieved an accuracy of 52.35%.

Bajaj [18] et al. proposed SOTA hybrid ResNet+TCN for the detection of students’ affective states. They also used the DAiSEE dataset with ResNet for feature extraction and TCN (Temporal Convolutional Network) for classification. The accuracy level reached by the study was 53.6%. The biggest challenge posed by this dataset is high class data imbalance.

Liao et al. [19] used the DAiSEE dataset and presented the Deep Facial Spatiotemporal Network (DFSTN) model for engagement prediction. To extract facial spatial features, they utilized pre-trained SE-ResNet-50 (SENet). The experiment obtained an accuracy of 58.84%.

Hasnine et al. [20] examined the extraction and visualization of students' emotions for engagement detection in online learning. The proposed model for emotion extraction and engagement detection consists of several steps. First, the OpenCV Face Recognition is implemented to detect emotions and eyes. This step results in emotion weight and eye gaze weight. These weights are used to calculate the Concentration Index (CI), which is then used to determine a student's engagement level based on specific rules. If the CI is greater than 65%, the student is detected to be highly engaged. If the CI is between 25% and 65%, the student is considered to be engaged. Otherwise, if the CI is less than 25%, the student is detected to be disengaged.

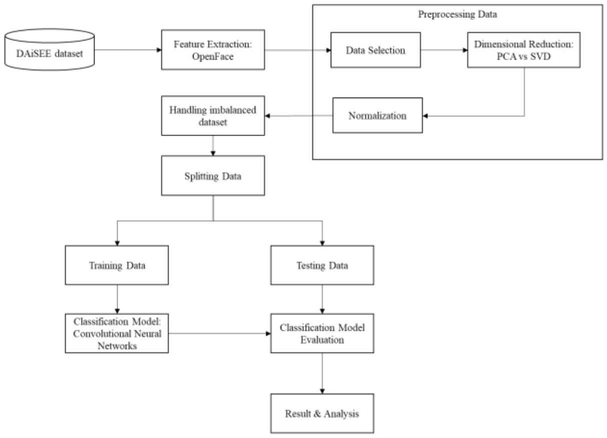
Brenner et al. [21] presented a social robot system that could detect a person's engagement by utilizing proxemics, body posture, and attention features. The proposed model achieved precision, recall, and F1 score results of 0.81, 0.82, and 0.81, respectively. The intended use of the proposed system is to design robots whose behaviors indicate awareness of a person's engagement.

Previous research commonly used video recording data to detect students' engagement. The DAiSEE dataset is one of the most popular datasets used in previous studies [5], [9], [15]–[19], [22]. Other datasets that have been used for this purpose include the EmotiW 2018 dataset [23], the EmotiW 2020 dataset [24], the Engagement Recognition (ER) database [25], the UPNA head pose dataset [26], and other video recordings [3], [7], [8], [20], [27].

The limitations of previously discussed DAiSEE dataset studies are related to model performance. The performance of detection models such as one with the DAiSEE dataset improved in accuracy from an average benchmark accuracy of 57.9% in 2016 [9] for baseline benchmarking, to 63.9% in 2020 [26], to 67.48% in 2022 [5]. The levels of accuracy are still relatively low, however, so there remain many challenges to overcoming this problem. In addition, the selection of the features to be extracted to increase the model accuracy still needs improvement.

III. Methodology

The research methodology used is illustrated in Fig. 1. It is important to note that the facial images appearing in this discussion were taken from the DAiSEE open dataset developed by [9].



Preprocessing Data
DAiSEE dataset
Feature Extraction: OpenFace
Data Selection
Dimensional Reduction: PCA vs SVD
Handling imbalanced dataset
Normalization
Splitting Data
Training Data
Testing Data
Classification Model: Convolutional Neural Networks
Classification Model Evaluation
Result & Analysis

Fig. 1. Research methodology.

The explanation for each stage in the research methodology is as follows:

A. Dataset

The dataset used in this study was composed of secondary data from an open dataset called DAiSEE (Dataset for Affective States in E-Environments). The dataset was downloaded from https://people.iith.ac.in/vineethnb/resources/daisee/index.html. DAiSEE is a multi-label video classification dataset comprising 9,068 recorded video clips from 112 students, aimed at identifying students' affective states, including boredom, confusion, engagement, and frustration. Each affective state is labeled into four levels: very low, low, high, and very high. The videos were annotated by psychology experts and a crowd. This study focused solely on engagement levels, which were denoted by numbers: 0 for very low, 1 for low, 2 for high, and 3 for very high.

B. Feature Extraction

The subsequent step, feature extraction, was carried out using the OpenFace library. This open-source library is widely used for face recognition purposes, with the capabilities of facial landmark detection, head pose estimation, facial expressions (facial action units) recognition, and eye gaze estimation.

C. Data Pre-Processing

The next stage, data pre-processing, aimed to prepare data for the modeling stage. This stage involved three steps: data selection, feature dimensional reduction, and data normalization. The outcomes of this stage were feature matrices that could be utilized in the subsequent stage.

D. Imbalanced Dataset Handling

The oversampling or undersampling techniques could be employed to address data imbalances, which could lead to prediction errors in the model. Undersampling aimed to balance the data by reducing the number of instances in the majority class to match the number in the minority class. On the other hand, oversampling balanced the data by increasing the instances in the minority class to match those in the majority class.

E. Data Splitting

The feature matrix with balanced data was used in the training and testing processes of the classification model. The training data were used to form the classification model, while the testing data were used to evaluate the performance of the model formulated.

F. Classification Model

Fig. 2 is an illustration of the classification model formulation process. The video recording data collected with feature extraction were used as input data in the CNN classification model. The output of the CNN classification model was the prediction class or engagement level of the input video data.

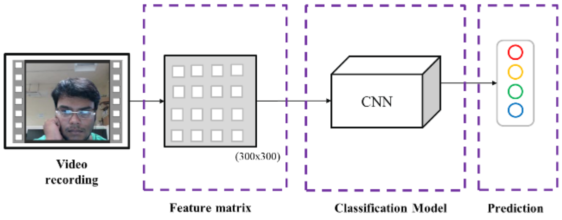


Fig. 2. The classification model formulation process.

G. Classification Model Evaluation

After obtaining the classification model through the training process, the model was tested using the testing data. The test results were then evaluated using metrics such as accuracy, precision, recall, and F1-score. These values were used to determine the performance of the proposed method. To further evaluate the classification model, the confusion matrix was referred to.

The confusion matrix in Fig. 3 is a matrix visualization of the prediction number and the actual data number on the classification model used. True positive (TP) is the number of correctly predicted data in the positive class. False positive (FP) is the number of incorrectly predicted data in the positive class. True negative (TN) is the number of correctly predicted data in the negative class. False negative (FN) is the number of incorrectly predicted data in the negative class [28].

		Prediction	
	Class	Positive	Negative
Actual	Positive	TP	FN
	Negative	FP	TN

Fig. 3. Confusion matrix in binary classes.

The accuracy evaluation value compares the number of correctly predicted data with the entire data being tested. It can be calculated using Equation 1 based on the confusion matrix in Fig. 3.

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (1)$$

The precision evaluation value compares the number of correctly predicted data in the positive class with the overall positive predicted results. It can be calculated using Equation 2.

$$Precision\ (Pc) = (TP) / (TP + FP) \quad \square re$$

The recall or sensitivity evaluation value compares the number of correctly predicted data in the positive class with all the actual data in the positive class. It can be calculated using Equation 3.

$$Recall\ (Rc) = (TP) / (TP + FN) \quad (3)$$

Meanwhile, the F1-score evaluation value compares the average weighted precision and recall. It is better in measuring a classification model's performance than the precision or recall value. It can be calculated using Equation 4.

$$F1\text{-}Score = 2 * [(Pc * Rc) / (Pc + Rc)] \quad (4)$$

IV. Results

A. Dataset

The current study used an open dataset named DAiSEE, which is a video dataset that recognizes students' affective levels, including engagement. Each video has a clip ID and engagement level label: very low, low, high, or very high. Fig. 4 shows some examples of the downloaded DAiSEE dataset.

Fig. 4. Some examples of the downloaded DAiSEE dataset.

The data distribution for each engagement level can be seen in Table I. According to the table, the data for each level of engagement were highly imbalanced. Low and very low engagement levels were minority classes with data presentation of 0.7% and 5.1% of the total available data, respectively. If data of this sort are processed, it will cause errors in the classification model due to overfitting. This can be addressed by balancing the data with undersampling or oversampling techniques.

TABLE I. DISTRIBUTION OF DATA ON THE DAISEE DATASET FOR EACH LEVEL OF ENGAGEMENT

Engagement Level	Number of Videos	Percentages
0 (very low)	61	0.7%
1 (low)	455	5.1%
2 (high)	4422	49.5%
3 (very high)	3987	44.7%
Total	8925	100%

B. Feature Extraction

The OpenFace library extracted facial features from each video frame. It can be downloaded on the following GitHub page: https://github.com/TadasBaltrusaitis/OpenFace. Fig. 5 is an example of video output generated from the OpenFace library.

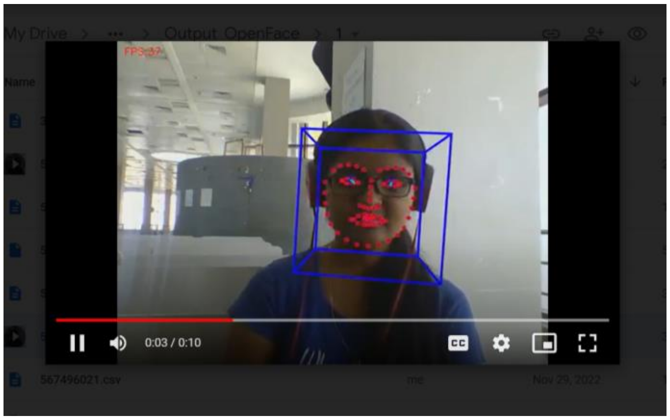

Fig. 5. An example of video output generated from the openface library.

In addition to the video output above, each video generated a CSV file. The file would display the columns frame, face ID, timestamp, confidence, success, and 709 facial feature values covering facial landmark detection, head pose estimation, eye gaze estimation, and estimation of facial expressions in the forms of facial action unit (AUs) features. The CSV file was also modified to store data of file name and the level of engagement for each frame. The DAiSEE dataset comprises 10-second videos with a frame rate of 30 fps, producing 300 frames for each video.

C. Data Pre-Processing

As shown in Fig. 1, there were three pre-processing stages: data selection, dimensional reduction, and data normalization.

1) Data selection: The first data selection stage involved selection of videos to facilitate the computational process. The video selection process was carried out in the following sub-stages:

- Find id_people from the video name (taken from the first five digits)
- Search for unique id_people
- Count and sort in the ascending the number of videos for each unique id_people
- Add up the cumulative value to the threshold = 61 (the total value of the minority class)
- Choose a video name based on the selected unique id_people

The results of feature extraction using the OpenFace library had a confidence column. This column refers to the confidence level of the model as to whether the detected face_id was a face or not. The confidence value ranged from 0 to 1. The closer it was to 1, the more confident the model was that the detected object was a face. On the other hand, the closer it was to 0, the less confident the model was that the detected object was a face.

	A	B	C	D	
1	frame	face_id	timestamp	confidence	su
344	65	0	2.133	0.03	
345	65	1	2.133	0.98	
346	66	0	2.167	0.03	
347	66	1	2.167	0.98	

Fig. 6. An example of a frame that detected two face objects.

As shown in Fig. 6, in frame 65, two objects, face_id 0 and face_id 1, were detected at the timestamp of 2.133 seconds. face_id 0 was detected at a confidence level of 0.03, and face_id 1 was at 0.98. If more than one object was found in a frame, data selection would be performed, where the object with the highest confidence value was to be selected. The data distribution for each engagement level before and after data selection in stages 1 and 2 can be seen in Table II.

TABLE II. DATA DISTRIBUTION BEFORE AND AFTER THE DATA SELECTION PROCESS

Engagement Level	**Imbalanced Data**		**Stage 1 Data Selection**		**Stage 2 Data Selection**	
	A	***B***	***A***	***B***	***A***	***B***
0 (very low)	61	0.7%	61	22.6%	59	23.4%
1 (low)	455	5.1%	63	23.3%	56	22.2%
2 (high)	4422	49.5%	70	25.9%	64	25.4%
3 (very high)	3987	44.7%	76	28.1%	73	29.0%
Total	8925	100%	270	100%	252	100%

A = Number of Videos, B = Percentages

2) Dimensional reduction: The length of the feature vector generated for each frame was very large, i.e., 1x709. Therefore, it became necessary to reduce the dimensions of the features to obtain unique features that could be used as differentiators for each level of engagement. The algorithms used at this stage were PCA (Principal Component Analysis) and SVD (Singular Value Decomposition). The explained variance value refers to the percentage value of the variance from the initial data. The number of components extracted covered a minimum of 80% of the explained variance in the data. In other words, at least 80% of the variance of the data was successfully captured. The greater the value of the explained variance, the better the original data were represented. Based on Table III, component = 300 was chosen because it had the highest explained variance value for both PCA and SVD. In addition, it was chosen so that each video produced would form a feature matrix with a square size of 300 x 300. Thus, using PCA and SVD, the number of features was reduced from 709 to 300.

TABLE III. THE EXPLAINED VALUES OF PCA AND SVD

Number of Components	PCA	SVD
2	81.91727	72.52122
3	96.99637	90.64553
10	99.80054	99.77922
50	99.99682	99.99676
100	99.99963	99.99962
200	99.99996	99.99996
300	99.99998	99.99998

3) Normalization: The feature matrices produced in the dimensional reduction stage had different ranges of values. It became necessary to normalize the data to prevent them from turning into noise in the model training process. The data normalization method used in this independent study was the min-max normalization method. This normalization method produced new feature values that had the same range from 0 to 1.

D. Imbalanced Dataset Handling

Based on Table II, the data for each level of engagement needed to be more balanced. It was necessary to balance the data to avoid overfitting prediction results. SMOTE (Synthetic Minority Over-sampling Technique), which synthesizes new data by re-sampling the minority class data to balance the data to the majority class, was used as an oversampling technique. A comparison was made between the number of data before and after applying SMOTE (see in Table IV).

TABLE IV. THE NUMBER OF DATA BEFORE AND AFTER SMOTE APPLICATION

Engagement Level	Before SMOTE	After SMOTE
0 (very low)	59	73
1 (low)	56	73
2 (high)	64	73
3 (very high)	73	73
Total	252	292

E. Data Splitting

Before entering the training stage of the classification model, the pre-processed data were divided into training and testing datasets, with 80% of the data being used for training and the remaining 20% for testing. The training data were used to form a supervised learning classification model, while the testing data were used to evaluate the classification model. The distribution of training and testing data for each engagement level can be found in Table V.

TABLE V. THE NUMBER OF TRAINING AND TESTING DATA

Engagement Level	Training Data	Testing Data	Total
0 (very low)	58	15	73
1 (low)	59	14	73
2 (high)	58	15	73
3 (very high)	58	15	73
Total Videos	233	59	292

F. Classification Model

The CNN classification model consisted of two stages, namely feature extraction and classification. The former consisted of four convolutional and pooling layer combinations as can be seen in Fig. 7. The feature maps on convolutional layer 1, layer 2, layer 3, and layer 4 were 32, 64, 128, and 256, respectively. The kernel size was 5 with the activation function using "ReLU". The latter used max-pooling with a pooling size of 2 x 2.

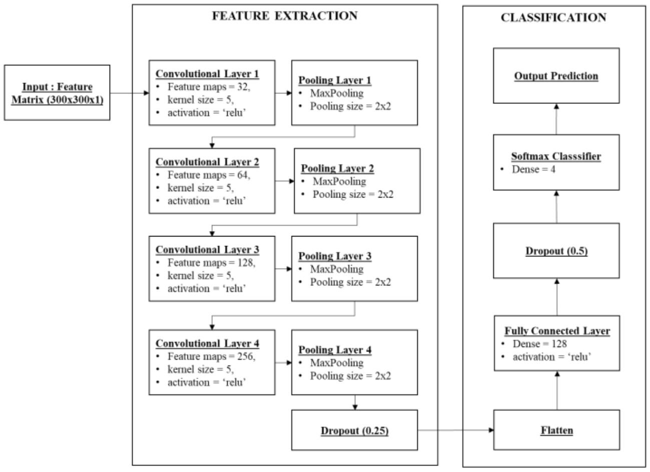

Fig. 7. Classification model of CNN.

The learning parameters used during the model-building process were batch size, epoch, learning rate, and optimizer. The trial-error approach was used to make the parameter selection. Table VI details the parameters of the CNN model used.

TABLE VI. THE AMOUNT OF TRAINING AND TESTING DATA

Parameter	Parameter Values
Number of epochs	800, 1600
Optimizer	Adam
Batch size	32, 16, 8, 4, 2
Learning rate	10^{-5}, 10^{-4}

In learning with artificial neural networks, the best model is often not found in the most recent epoch. Therefore, checkpoints and early stopping are used in the training process. A checkpoint is a CNN model that records each time the loss value decreases by a specified difference. In this way, if the loss value tends to increase or stagnate, the CNN model that manages to achieve the lowest loss value will be stored. Early stopping is a technique to stop the CNN learning process when the loss value has not shown a significant decrease in the number of certain epochs or when the model is said to have converged. This method is used because it can optimize the maximum number of epochs but saves more training time by stopping CNN training when it shows no improvement in learning. In early stopping, there is the patience parameter (p), which is used to determine the conditions for stopping training when it is found that the number of epochs remains the same as there is no decrease in the loss value. The patience value used in this independent study was half the number of epochs.

V. Discussion

Based on the previous discussion, dimensional reduction was carried out with two approaches: PCA and SVD. Therefore, in evaluating this classification model, a comparison was made between the classification models from PCA-reduced data and SVD-reduced data.

Table VII shows the best evaluation value for each experiment. It can be seen that PCA-CNN had the highest accuracy of 72.88% in model 19, with an average accuracy value of 69.66% and parameter values as follows: optimizer = Adam, epoch = 1600, learning rate = 10-4, and batch size = 4. In comparison, model 8 had a higher maximum accuracy of 74.58% but with a standard deviation value greater than that of model 19 (3.54 > 3.34). The smaller standard deviation value was chosen because it means that the accuracy value in the experiment was closer to the average value.

TABLE VII. The Best Evaluation Value for Each Experiment

Parameter/Evaluation	**PCA**				**SVD**			
Model	**2**	**8**	**14**	**19**	**25**	**28**	**35**	**38**
optimizer	Adam	Adam	Adam	Adam	Adam	Adam	Adam	Adam
Epoch	800	800	1600	1600	800	800	1600	1600
Learning rate	10-5	10-4	10-5	10-4	10-5	10-4	10-5	10-4
Batch Size	16	4	4	4	2	8	2	8
Average Accuracy	60.64	68.14	60.51	69.66	61.02	70.34	64.41	71.02
Standard Deviation	2.76	3.54	4.01	3.34	6.61	3.58	7.19	3.17
Minimum Accuracy	55.93	59.32	55.93	69.66	52.54	64.41	55.93	67.8
Maximum Accuracy	64.41	74.58	67.8	72.88	74.58	76.27	77.97	77.97

For experiments using SVD-CNN, the highest accuracy value was found in model 38, with a maximum accuracy value of 77.97% and an average accuracy value of 71.02%. The best parameter values obtained in this model were as follows: optimizer = Adam, epoch = 1600, learning rate = 10-4, and batch size = 8. Model 38 was found to have the smallest standard deviation value. This model was quite stable in providing accuracy evaluation values from the ten iterations performed for each model.

Regarding the learning rate parameter, the SVD-CNN and PCA-CNN experiments both had a learning rate of 10-4, producing the best accuracy model. Compared to the learning rate of 10-5, the learning rate of 10-4 provided faster computation time because the lower the learning rate, the higher the accuracy of the network, which means that the training process takes longer. For epoch size, the SVD-CNN and PCA-CNN experiments had the same number of epochs, 1600, which produced the best accuracy model. As can be seen in Table VII, when the epoch number of 800 was applied, the optimal accuracy value had yet to be reached. However, in terms of computational time, the larger the epoch number, the greater the time required. If we look at the batch size parameter, the SVD-CNN and PCA-CNN experiments had different parameter values generated by their best models. SVD-CNN had the best batch size of 8, while PCA-CNN had the best batch size of 4. The smaller the batch size, the more batches will be generated, requiring greater computation time. Table VII shows that SVD-CNN was better than PCA-CNN in terms of accuracy, batch size, number of epochs, and learning rate and required shorter computation time.

TABLE VIII. COMPARISON OF PRECISION, RECALL, AND F1-SCORE FOR EACH EXPERIMENT

			Engagement Level				
Experiment	*Model*	*Evaluation*	*0 (very low)*	*1 (low)*	*2 (high)*	*3 (very high)*	*Average*
PCA-CNN	Model 19	Precision	0.62	0.73	0.92	0.73	0.75
		Recall	0.87	0.57	0.73	0.73	0.73
		F1-Score	0.72	0.64	0.81	0.73	0.73
SVD-CNN	Model 38	Precision	0.85	0.83	0.81	0.67	0.79
		Recall	0.73	0.71	0.87	0.80	0.78
		F1-Score	0.79	0.77	0.84	0.73	0.78

Table VIII presents the comparison of precision, recall, and F1-score between PCA-CNN and SVD-CNN experiments. The two best models, models 19 and 38, had precision values higher than the recall values. This indicates false negatives or prediction errors in the actual engagement level data. Meanwhile, the F1-score indicates the average comparison value of weighted precision and recall. In model 19, engagement level 2 (high engagement) had the highest F1-score, i.e., 0.81. This high F1-score indicates that the classification model had fairly good precision and recall values.

Based on the accuracy, precision, recall, and average F1-score values, SVD-CNN performed better than PCA-CNN. Not only were they used for dimensional reduction, SVD and CNN were also used to select important features from the overall features. If analyzed from the variance value generated at the data pre-processing stage, PCA-CNN and SVD-CNN had the same variance value at component value = 300. The higher the variance value, the better the data representation to obtain unique information from the data. Meanwhile, if analyzed from the correlation value between features and engagement level, SVD-CNN had a higher correlation value than PCA-CNN. The features obtained from the SVD results had the best correlation value with the engagement level data. Therefore, in this study, SVD-CNN was superior to PCA-CNN.

The comparison of the values achieved by previous models and those by the model proposed in the DAiSEE dataset can be seen in Table IX. The PCA-CNN and SVD-CNN models with data balancing produced the highest accuracy performance at 72.88 and 77.97, respectively, with fewer features than the previous models.

TABLE IX. COMPARISON OF THE ACCURACY VALUES OF PREVIOUS MODELS WITH THE PROPOSED MODELS IN THE DAISEE DATASET

Model	**Feature (per frame)**	**Feature Dimensions**	**Accuracy**
I3D (Inflated 3D Convolutional Network) [17]	OpenFace (1x600) and AlphaPose (1x36) with feature selection	Not mention	52.35%
SOTA hybrid ResNet+TCN [16]	ResNet	1x512	53.6%
LRCN (Long-term Recurrent Convolutional Networks) [9] – **baseline benchmarking on DAiSEE**	**Not mention**	**Not mention**	**57.9%**
DFSTN (Deep Facial Spatiotemporal Network) [19]	SE-ResNet-50 (SENet)	1x2048	58.84%
ResNet + TCN [16]	ResNet	1x512	63.90%
3D DenseAttNet (DenseNet self-attention neural network) [22]	DenseAttNet	224x224x3	63.59%
EfficientNet B7 + LSTM [5]	EfficientNet B7	1x2560	67.48%
PCA-CNN with balanced data (proposed model)	OpenFace (1x709) with dimensional reduction PCA	1x300	72.88%
SVD-CNN with balanced data (proposed model)	OpenFace (1x709) with dimensional reduction SVD	1x300	77.97%

VI. CONCLUSION

In this study, we have successfully improved the benchmark performance of the DAiSEE dataset. The DAiSEE dataset experienced improvements from an average benchmark accuracy of 57.9% in 2016 [9] for baseline benchmarking, to 63.9% in 2020 [26], to 67.48% in 2022 [5]. We applied data balancing using oversampling and undersampling in the Convolutional Neural Network (CNN) classification model. The DAiSEE dataset also went through the pre-processing stages of data selection, dimensional reduction, and normalization. The features used in this study were taken from the OpenFace library, including 709 facial feature values from facial landmark detection, head pose estimation, eye gaze estimation, and facial expressions (facial action units (AUs)) estimations. Dimensional reduction was performed on the OpenFace features obtained using PCA and SVD techniques. A component number of 300 was applied in the PCA and SVD dimensional reduction, which means that the number of unique features was reduced from 709 to 300.

The PCA-CNN model had the highest accuracy rate of 72.88%, and the SVD-CNN model did 77.97%. The best CNN model parameter values were as follows: learning rate = 10-4, optimizer = Adam, epoch = 1600, and batch size = 4 (PCA-CNN) and 8 (SVD-CNN). The two PCA-CNN and SVD-CNN best models had precision values higher than the recall values (0.75 > 0.73 for PCA-CNN and 0.79 > 0.78 for SVD-CNN). This indicates that there were false negative events such as prediction errors in the actual engagement level data. Meanwhile, the highest F1-score values were 0.73 (PCA-CNN) and 0.78 (SVD-CNN), which shows that the classification models had fairly good precision and recall values.

From all the experiments that have been carried out, it can be concluded that SVD-CNN had better performance than PCA-CNN in evaluating average, maximum, precision, recall, and F1-score values accuracy. If analyzed from the variance value generated at the data pre-processing stage, PCA-CNN and SVD-CNN had the same variance value at component value = 300. The higher the variance value, the better the data representation to obtain unique information from the data. Meanwhile, if analyzed from the correlation value between features and engagement level, SVD-CNN had a higher correlation value than PCA-CNN. Moreover, it can also be interpreted that the features obtained from the SVD results had the best correlation value with the level of engagement contained in the data. Therefore, in the current study, SVD-CNN was superior to PCA-CNN.

Although this study has provided better evaluation results than previous studies on the DAiSEE dataset, there remains a room for improvement for further research. It is necessary to explore alternative approaches to determining the optimal component values to produce features that have a more significant impact on the classification model. Additionally, conducting a more in-depth analysis of features beyond facial expressions can increase the accuracy of students' engagement detection.

Department of Information System-Faculty of Computers and Artificial Intelligence, Beni-Suef University, Egypt[2]

***Abstract*—Although some believe it has been wiped out, the coronavirus is striking again. Controlling this epidemic necessitates early detection of coronavirus disease. Computed tomography (CT) scan images allow fast and accurate screening for COVID-19. This study seeks to develop the most precise model for identifying and classifying COVID-19 by developing an automated approach using transfer-learning CNN models as a base. Transfer learning models like VGG16, Resnet50, and Xception are employed in this study. The VGG16 has a 98.39% accuracy, the Resnet50 has a 97.27% accuracy, and the Xception has a 96.6% accuracy; after that, a hybrid model made using the stacking ensemble method has an accuracy of 98.71%. According to the findings, hybrid architecture offers greater accuracy than a single architecture.**

Keywords—Covid-19; coronavirus; transfer-learning; CT-scan and ensemble method

I. Introduction

COVID-19 is caused by the virus SARS-CoV-2. Lung infections can cause anything from a simple cold to potentially fatal illnesses. Symptoms of the respiratory system are usually seen with coronavirus infections. In addition, people can occasionally get minor, self-limiting ailments like the flu that have detrimental effects. Fever, a cough, and trouble breathing might be caused by respiratory issues, exhaustion, and a sore throat [1]-[3].

Huge losses have been caused by the global spread of the COVID-19 pandemic. The urgent issue that health care and medical organizations are addressing is the quick detection of COVID-19 [1]. COVID-19 presents a serious threat to public health and the country's social and economic life because of the quick rise in the number of newly verified and reported cases.

An automated system that can measure the patient's infected zone and assess the progress of infected people by CT scan image analysis and clinical diagnosis is required. Even for skilled medical professionals, diagnosing COVID-19 is challenging [4], [5].

The two most common methods for diagnosing COVID-19 are computed tomography and X-rays. Medical health guidelines advocate chest imaging as a quick and efficient treatment, and it has been acknowledged as the first instrument in viral screening in a series of papers. Chest X-rays and CT scans have promising results despite frequently being examined by qualified radiologists. Computer-aided diagnosis (CAD) is required to reduce error rates while saving time and money [6] since radiologists see many patients daily and the diagnostic procedure takes a long time.

CT scans provide a series of slices of a specific location without including the numerous physiological features, in contrast to traditional X-rays. Compared to traditional X-rays, CT scans offer a considerably more thorough picture of the diagnosis [7].

Deep learning has been used in several studies to analyze radiological images. They were created to address the drawbacks of COVID-19 medical procedures that depend on radiological imaging. CNN is the method that is most effective for identifying the most significant deep learning algorithms. Consequently, the data processing field has shown a lot of interest in deep learning algorithms, especially at CNN [8].

This paper proposes a highly accurate automated computer-aided diagnostic approach for COVID-19 classification. In order to create a hybrid model using stacking ensemble with improved performance on the SARS-COV-2 dataset, a study was done to examine the implementation of three pre-trained convolutional neural network (CNN) models based on transfer learning. This work's main novelty and contributions are as follows:

- Reducing the number of false negative and positive values in the modelling process.
- The base and hybrid models were trained for 100 epochs.
- Comparing the recommended model to that of current DL frameworks in order to determine its effectiveness.
- Comparing the hybrid model's performance to the base-line models.
- Applying the stacking ensemble method in a new way instead of the familiar ways of stacking, which saves more time.

The following parts are organized as follows: The state-of-the-art studies are summarized in Section II, and resources and methods are covered in Section III. Results and analysis are presented in Section IV. The summary and recommendations for future work are presented in Section V.

II. Related Work

Many studies were conducted to diagnose COVID-19 either using CT scan images or using x-rays. This section summarizes the most recent studies, focusing on CT scan images.

Kogilavani, S. V., et al. [8] proposed using many CNN architectures, such as MobileNet, DeseNet121, VGG16, NASNet, Xception, and EfficientNet. The accuracy rates were 96.38%, 97.53%, 97.68%, 89.51%, 92.47%, and 80.19%, respectively.

Ebenezer Jangam et al. [9] developed a stacked ensemble method using VGG-19, ResNet-101, DenseNet-169, and WideResNet-50-2 as four pre-trained computer vision models. With the help of three separate chest CT scans, the suggested model was trained and assessed. The suggested technique has an accuracy of 0.8473, 0.99, and 0.935 on these datasets.

Rohit Kundu et al. [10] presented a bagging ensemble method of three transfer learning models, including Inception v3, ResNet 34, and DenseNet 201, which has been utilized to improve the performance of the individual models. The proposed model had a 97.81% accuracy rate.

A deep learning model, called truncated VGG16, was created by Mukul Singh et al. [11] to screen COVID-19 CT scans. For feature extraction from CT scan pictures, the VGG16 architecture has been fine-tuned; principal component analysis (PCA) is also used to choose features. For the final classification, four distinct classifiers are compared. On 208 tested images, the best classifier was a bagging ensemble with SVM, which obtained an F1 score of 95.3%, an accuracy of 95.7%, a precision of 95.8%, and an area under the curve (AUC) of 0.958.

For the diagnosis of COVID-19 from CT scans, Bejoy Abraham et al. [12] suggested using the kernel support vector machine with features extracted from five distinct CNNs (MobilenetV2, Darknet53, Shufflenet, Xception, and EfficientnetB0). The technique achieved 0.916 accuracy, a 0.91 F-score, and 0.917 sensitivity.

Nirmala Devi Kathamuthu, et al. [13] suggested applying a variety of foundation models, including VGG16, VGG19, Inception V3, Densenet 121, Xception, and Resnet50; the best model of these models attained an accuracy of 98% using ct-scan images. The difference between this model and ours is the data augmentation technique used, the training parameters, and the fact that we finally built a hybrid model using the stacking ensemble method.

Gifani et al. [14] employed fifteen pre-trained convolutional neural networks (CNNs) architectures: EfficientNets (B0-B5), NasNetLarge, NasNetMobile, ResNet-50, SeResnet 50, Xception, DenseNet121, ResNext50, and Inception ResNet v2. Thus, to further improve recognition performance, they created an ensemble approach based on majority voting on the ideal concoction of deep transfer learning outputs. The experimental results show that the majority voting of five deep transfer learning models with EfficientNetB0, EfficientNetB3, EfficientNet5, Inception ResNet v2, and Xception outperform individual transfer learning structures in terms of precision (0.857), recall (0.854), and accuracy (0.85) metrics for diagnosing COVID-19 from CT scans.

Horry, Michael J., et al. [15] developed a conceptual transfer learning framework to support COVID-19 detection with image categorization utilising deep learning models for X-ray, ultrasound, and CT scans, including Resnet50, Inception V3, Xception, VGG16/VGG19, InceptionResNet, DenseNet, and NASNetLarge. They settled on the VGG19 model, which was then adjusted with the proper parameters to reach extremely high levels of COVID-19 detection versus pneumonia and normal in all three types of lung images, with a precision of up to 86% for X-rays, 100% for ultrasounds, and 84% for CT scans.

The authors of [16] propose an augmented CNN to identify COVID-19 on CT scan and X-ray chest images and to differentiate COVID-19 patients from non-COVID-19 cases. While using these augmented images to train CNN, a classification accuracy of 98.97 percent for X-ray images and 95.38 percent for CT scan images was achieved.

Tanvir Mahmud et al. [17] presented the hybrid neural network CovTANet for the early prediction and diagnosis of COVID-19 using CT scans. A segmentation network was used to predict the lesions with a 95.8% accuracy rate.

A transfer learning strategy was employed by Chun Li et al. [18] to propose a way of training the model using a few CT images. The evaluation accuracy of this method was 87.6% for COVID-19 severity using pre-trained ChexNet.

In order to detect COVID-19 from a CT scan, Varan Singh Rohila et al. [19] offer a DCNN model known as ReCOV-101 that makes use of ResNet-101 as its basis. To increase the dataset, data augmentation, transfer learning, and the 94.9 percent accurate "skip connection" method are employed. From the previous review, further work needs to be done to increase the reliability and accuracy of COVID-19 detection using CT scan images.

Limitations of the previous studies include:

- The difficulty of sharing medical data is data privacy.
- The datasets that are currently accessible are incorrect, unclear, noisy, and incomplete.
- Most studies in the literature are conducted using datasets from different internet sources.

III. Method

The method used to achieve the objectives of the study is briefly described in this section. The diagram of the suggested method is shown in Fig. 1. Each model was trained individually on the training set; after that, the models were concatenated using stacking ensemble learning and fine-tuned using the training set. Fig. 3 and Fig. 4, which are subfigures of Fig. 1, explain the proposed model in more detail.

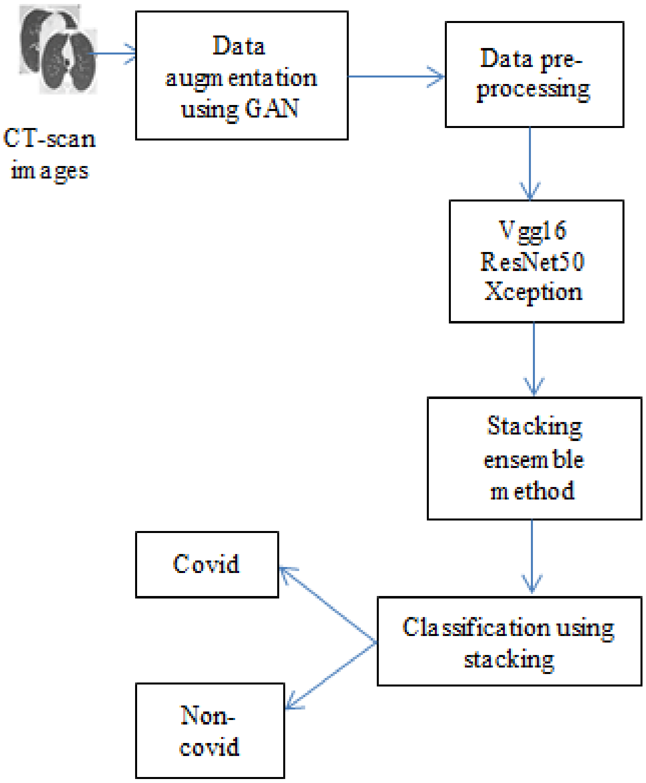

Fig. 1. Proposed model architecture.

A. Dataset

The SARS-CoV-2 CT scan dataset [20] was used in the proposed work to identify COVID-19 cases. This dataset is the most global because it contains more CT scan images that are clear and free of noise, and it is also used in more studies. The dataset consists of 2482 CT scan images, 1252 positive for COVID-19 (+ve) and 1230 negative for COVID-19 (-ve). These data were compiled from information provided by actual patients who went to hospitals in Sao Paulo, Brazil. This dataset aims to advance research and develop artificial intelligence (AI) tools that can detect SARS-CoV-2 or COVID-19 infection by looking at CT images.

B. Data Augmentation

A form of neural network design called a generative adversarial network (GAN) has much potential for artificial intelligence. The min-max two-player zero-sum game is an important factor in GAN. In this game one player profited by the same amount from the other's loss. The actors in this scenario are two separate GAN networks known as the discriminator and generator.

The primary goal of the discriminator, indicated as D, is to determine whether a sample is real or fake[21]. A fake sample of an image is produced by the generator, known as G, in contrast, in order to deceive the discriminator.

The discriminator determines the probability that a particular sample is real. The probability value will probably be greater for a real sample. A probability value that is very close to 0 indicates fake samples. When the discriminator is no longer able to distinguish between a real and fake sample and the probability value is close to 0.5, the generator can have an ideal answer [21]**.** Fig. 2 shows a sample of COVID and non-COVID images generated by GAN.

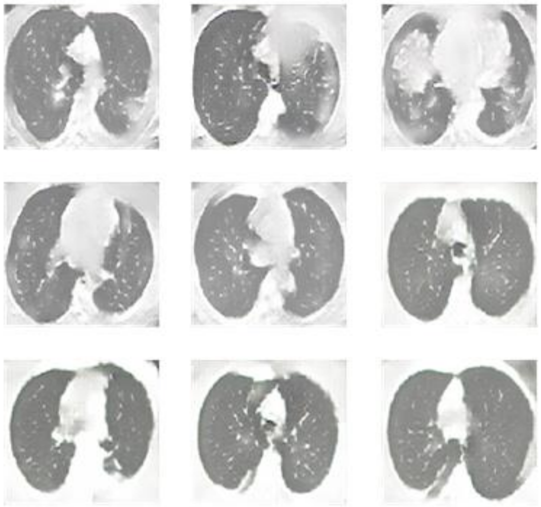

Fig. 2. Sample of COVID and non-COVID images after augmentation.

C. Data Pre-processing

Pre-processing has been done on the CT scan images. The image must fit the input size required to train the deep learning algorithm and make predictions using the data. To test the input size of the network, the data is rescaled. The image size in the proposed system has a dimension of 224 x 224. The data is consequently rescaled to match the supplied dimensions. These images were divided into two groups with an 80/20 split: a training set and a testing set. Table I shows the dataset after augmentation and preprocessing.

TABLE I. SARS COV-2 DATASET AFTER PREPROCESSING

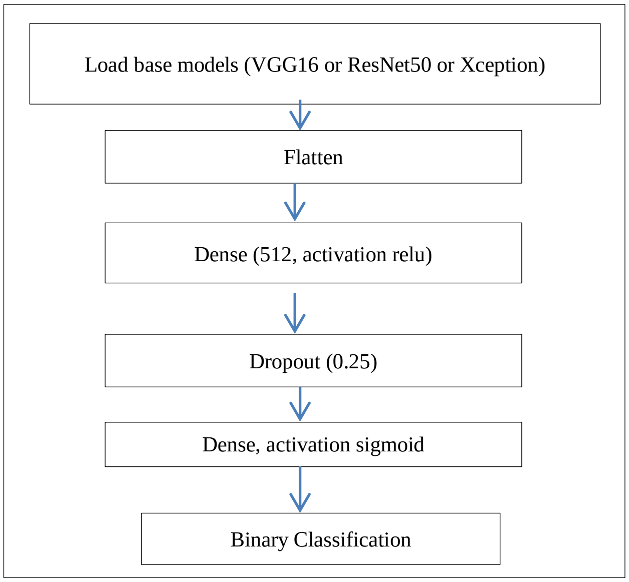
Dataset	Covid	Non-Covid	Total
Training	1239	1239	2478
Testing	311	310	621
Total	1550	1549	3099

D. Classification Phase with Different Deep Learning Models

In order to classify the CT scan images, Xception[22], Resnet 50[23] ,and VGG 16 [22] are used as examples of deep learning architectures. These models are trained through transfer learning. The stacked model is then used to integrate the earlier models, which were each trained for 100 epochs, into one. Complete details are provided below.

E. Transfer Learning

Transfer learning using ImageNet was used to solve the problem of insufficient data. For each model, the weights from the ImageNet training were downloaded. The applied layer training procedure used the feature maps as input. To prevent losing any data during subsequent training rounds, freeze the layers of the model that have already been trained. A fully connected deep neural network was fed with the most recent feature map, which was flattened. The other layers were trained to extract more data from the later convolution layers because they were closer to the output features. As illustrated in Fig. 3, we added three additional layers to the top of each model: namely, dense with an output of 512, a dropout layer, and another dense layer with a sigmoid classifier. For each of the neural networks used in this study, a dropout layer of 0.25 was added to avoid overlapping [24]. The network was trained with a sigmoid classifier using an Adam optimizer for 100 iterations, with a batch size of 32 and a learning rate of 0.00001.



Load base models (VGG16 or ResNet50 or Xception)
Flatten
Dense (512, activation relu)
Dropout (0.25)
Dense, activation sigmoid
Binary Classification

Fig. 3. Proposed transfer learning base models.

F. Stacking Ensemble Method

Ensemble approaches come in a variety of forms, including average, weighted average, boosting, bagging, and stacking. In this paper, stacked generalization is used, which is an ensemble technique that learns how to integrate the predictions from various existing models in the most effective way [25].

This study employs a neural network as a meta-learner when neural networks are used as sub-models. In more detail, the sub-networks can be incorporated into a more extensive multi-headed neural network, which will then figure out how to integrate the predictions from each input sub-model most effectively. It makes it possible to think of the stacking ensemble as a single, enormous model.

All of the loaded models are utilized as a distinct input to the bigger stacking ensemble model, which can be defined just after models are loaded as a list. To prevent the weights from being modified while the new, larger model is being trained, each of the loaded models must have all of its layers marked as not trainable.

This method has the advantage of immediately giving the meta-learner the outputs of the sub-models. This new model will employ a different input head for each input layer from each sub-model. This indicates that any input data must be delivered to the model in multiples of k, where k is the total number of input models, which in this case are 3.

The results from all the models can then be combined. Here, a straightforward concatenation merge was employed. Then, a hidden layer is built to interpret this "input" for the meta-learner, and an output layer is defined to produce its own probabilistic prediction. The base model's training parameters were used to train the stack model as well. Fig. 4 shows the architecture of the stacked generalization.

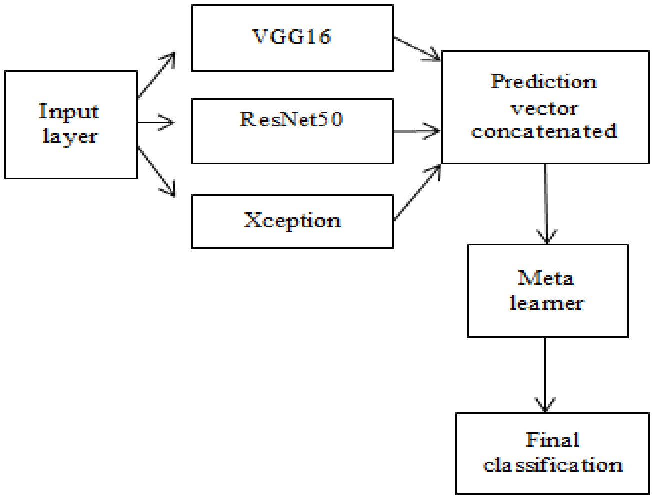


Fig. 4. Stacked generalization architecture.

IV. Results

This section discusses the results of both base and hybrid models using different evaluation measures.

A. Performance Evaluation Measures

A number of metrics, such as accuracy, precision, recall, and F1-score, can be used to evaluate the model's performance.

Accuracy: The ratio of correctly anticipated observations to all observations is the easiest and most obvious performance statistic. Given in the equation below:

$$\text{Accuracy} = TP+TN/TP+FP+FN+TN \tag{1}$$

where

- True positives (TP) are instances in which we made a prediction that someone had the disease and they actually did.
- True Negatives (TN): As expected, they are free of the illness.
- False positives (FP): Although we expected them to have the illness, they don't.
- False negatives (FN): Despite our prediction, they are infected.

The ratio of correctly predicted positive observations to all positively expected observations is known as precision. Given in the equation below:

$$\text{Precision} = TP/TP+FP \tag{2}$$

Recall is the percentage of accurately predicted positive observations among all observations in the current class. This is known as sensitivity. Given in the equation below:

$$\text{Recall} = TP/TP+FN \quad (3)$$

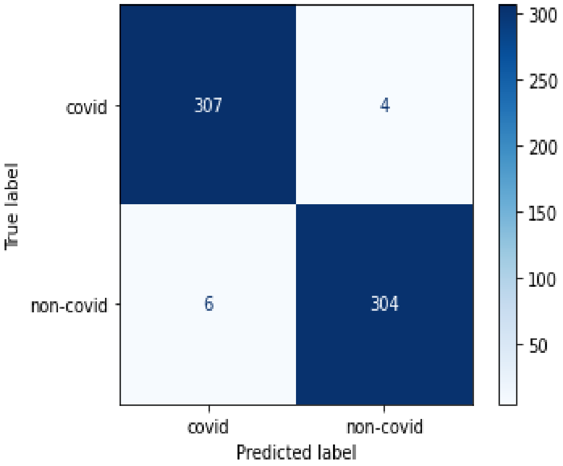
The mean of recall and precision is known as the F1 score. It is provided in the equation below:

$$\text{F1Score}=2*(\text{Recall}*\text{Precision})/(\text{Recall}+\text{Precision}) \quad (4)$$

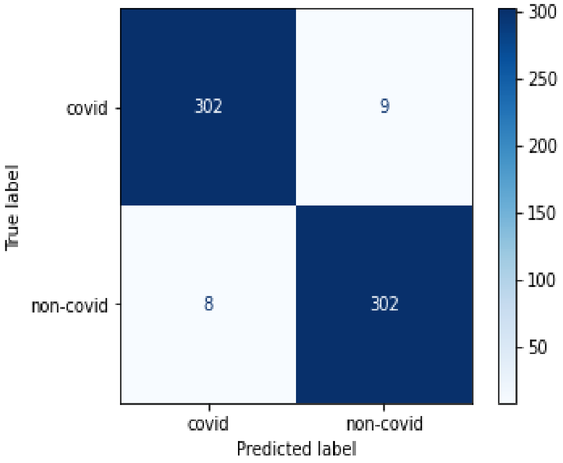
Table II displays the three used models and the hybrid model evaluation measure, while Fig. 5 displays the confusion matrix of the base and hybrid models.

TABLE II. EVALUATION MEASURES OF THE MODELS

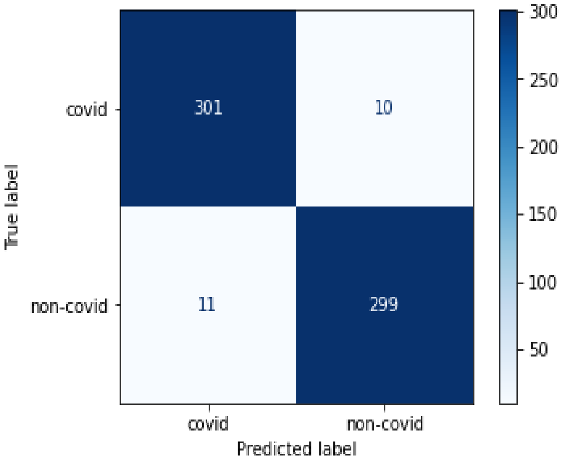
Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
VGG16	98.39	98.7	98.06	98.39
Resnet50	97.26	97.1	97.4	97.26
Xception	96.62	96.76	96.45	96.6
Hybrid	98.71	98.39	99.0	98.7



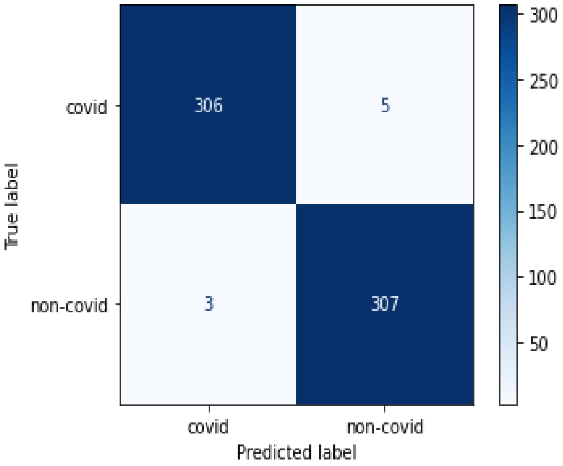
(a) VGG16 predicted 307 as COVID and 304 as non-COVID out of 621 images.



(b) Resnet50 predicted 302 as COVID and 302 as non-COVID out of 621 images.



(c) Xception predicted 301 as COVID and 299 as non-COVID out of 621 images.



(d) The stacked method predicted 306 as COVID and 307 as non-COVID out of 621 images.

Fig. 5. Base and hybrid model confusion matrix.

As shown in Table II and Fig. 5, the hybrid model achieved better results than the single model in terms of accuracy, recall, and f1-score.

V. DISCUSSION

Generally, the outcome is based on testing data, which is comprised of 20% of the entire images from the sars-cov2 dataset. Using the Keras library, the deep model employed in this study was developed. Keras is compatible with deep learning libraries such as TensorFlow and Theano. The model was developed using Google Colab, which enables you to create and run Python code in your browser and offers free access to the GPU.

A. Comparison

The suggested model is compared with other research done using the same dataset (Table III). This comparison shows that although many studies in the literature have combined more deep learning models, these studies are weak compared to ours. The best advantage of our proposed model is that we used GAN as an augmentation technique rather than traditional methods for increasing the number of images used to train the models, trained the model for 100 epochs with the suggested training parameters discussed in Fig. 3, and eliminated overfitting by applying the stacking ensemble method.

TABLE III. COMPARISON

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
VGG16 [8]	97.68	_____	______	____
VGG19+DenseNet169+ResNet101[9]	94	90	98	94
Inceptionv3+Resnet34+DesNet201[10]	97.81	97.77	97.81	97.77
Five pre-trained CNN models +KSVM[21]	91.6	____	91.7	91
VGG16[22]	98	97.99	97.99	97.90
Proposed model	98.71	98.39	99.0	98.7

VI. CONCLUSION AND FUTURE WORK

In this proposed work, greater transfer learning models such as VGG16, Resnet50, and Xception are trained individually on the training data before being combined to enhance the model's performance and prevent over fitting. Kaggle's collection of CT scan images contains fewer images than necessary, so data augmentation using GAN is used to obtain more images. Performance metrics, including precision, F1-score, and recall, are used to assess the model's performance. The stacked model outperforms the single model in terms of accuracy, coming in at 98.71. By comparing the proposed method with other studies applied to the same dataset, it is obvious that the proposed method gives high recall, accuracy, precision, and the f1-score.

The future work of this study will train the suggested model for more epochs using different preprocessing techniques, apply the suggested model to another dataset, and attempt to use a different optimizer.

A New Big Data Architecture for Analysis: The Challenges on Social Media

Abdessamad Essaidi, Mostafa Bellafkih
RAISS Laboratory-Department of Mathematics and Computer Science,
National Institute of Posts and Telecommunications (INPT), Rabat, Morocco

***Abstract*—The streams of social media big data are now becoming an important issue. But the analytics method and tools for this data may not be able to find the useful information from this massive amount of data. The question then becomes: how do we create a high-performance platform and a method to efficiently analyse social networks' big data; how to develop a suitable mining algorithm for finding useful information from social media big data. In this work, we propose a new hierarchical big data analysis for understanding human interaction, and we present a new method to measure the useful tweets of Twitter users based on the three factors of tweet texts. Finally, we use this test implementation score, in order to detect useful and classification tweets by interested degree.**

Keywords—Social media; useful information; big data analysis; stream processing; classification tweets

I. Introduction

Big data on social networks and the progress of tools for calculating and analyzing these data have occupied the first place of investment in the last few years [1]. As a result, much of the literature devoted to Big Data in social media oscillates between two approaches. That is why, in recent years, there is so much interest in public debate on social media [2]. For this, an analysis of the information induced by the use of this type of data was strongly linked by social data. Also, and above all, the appearance of a new form of society "led by the analysis of Big Data." Following this proliferation of information on social media, it seemed useful to us to propose a new analysis method based on big data to draw up an initial assessment of the effects of big data on its practices [3], its objects and its results.

To this end, we analyzed the social network community around two main questions that we felt should not be separated: how does Big Data transform society? [4], How does this data affect personnes practice (Covid-19 use case)?, This double approach – which we wanted to keep in the preparation of this article – shows the fact that the proliferation of information in social networks is today confronted with a real change in the processes of transformation of societies which affects it so directly.

The main objective of this article is how big data in social networks affect the practice of society based on the new architecture of Big Data. The development and analysis of this massive data would thus provide those who use it with new knowledge. This new knowledge will affect the behavior of individuals, their interactions, their uses. We also provide a detailed comparison of the various tools and architectures used to process data stream [5]. Lastly, we offer our own architecture based on comparisons made. So how does big data in social media affect society practice?

To talk about this issue in depth, this paper starts with a review of previous social media research on human interaction data and social big data stream processing architectures on social media platforms, followed by the discussions of our proposed big data analysis architecture, and we suggest a new method with new measuring process based on important aspects, such as number of likes, comments and retweets on the Twitter platform that can be used to calculate the LCR score for tweet text. Finally, we use our data mining algorithm to predict the tweet texts (useful or not), and as the key to crucial insights on human behavior.

II. Research Background

A. *Existing Systems*

Most works focus on how big data affect the practice of society focused on the concept of analyzing content and patterns of interaction in social networks.

Felt [6], this qualitative research is a study on the analysis of social media data in addition to traditional, qualitative methods to analysis of big data.

Ghani et al. [7] based their study on an overview of recent works and provided a general perspective on the subject of social media big data analytics research. This study also provides a comparison of possible big data analysis techniques and their quality attributes.

Bello-Orgaz et al. [8] have worked this study on the revising new methodologies designed to enable efficient data mining and merging information from social media and new apps and frameworks that are now emerging under the social media "umbrella", social media as well as big data paradigms.

Immonen et al. [9] based their work on the introducing a new framework to assessment and manage quality of social networks data at each treatment phase of the Big Data. The proposed solution delivers real-time validated data to social network users, which results in better decision-making. This data is extracted from social media and used to determine customer satisfaction with the quality of a product.

B. *Social Media*

The social media platform has become the primary contact with our family, friends and colleagues. People share all the information in a lot of different forms, like messages, video as well as audio on the social networks to shares their feeling distinguished or bad. The world average for Internet users is 2.5 hours a day on platforms social media. Social networking platform users produce a significant amount of information and data that cannot be processed through traditional data analytics. Therefore, social networking platforms are making substantial investments in this information and big data because it provides insights into the analysis of media, which shapes public opinion, etc. [10].

Social media messages are rich with possibilities for data mining and analysis. This shift on social media provides new challenges for researchers interested in analyzing public publications and messages of social networking user platforms to better understand human interaction and improve the human condition [6].

Social media platforms like Twitter were viewed as a critical source of useful information.

During Covid-19, people post updates regarding their statuses on social media platforms like Twitter, request assistance and other relevant information, report damage to infrastructure, injured people, etc.

Information posted on social media during crises, their worth varies considerably. Most publications do not contain any useful information nor are they useful for disaster response. Most of the posted messages contain a deluge of noise that is of a personal nature, do not contain any useful information, or are irrelevant [11].

The proposed model for obtaining information on social media, which is shown in Fig. 1, aims to collect clean data consisting of posts containing potentially useful information. This information can be used for various purposes, such as helping injured people affected by Covid-19.

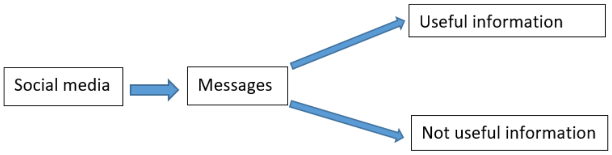

Fig. 1. Information on social media.

C. Big Data

Big data is a term that aims to describe massive volumes of data and offer an alternative to conventional solutions of analyse databases in order to make sense of it and make the most of it.

The Data mining on social media and efficient utilisation of this Big data became a significant issue for numerous research fields such as massive data processing, big data analytics techniques, machine learning, semantics of the data, information fusion, computational intelligence, and social networks.

The big data concept has been specified by the three essential dimensions 3V: volume, variety, and velocity that were set out in 2001 by Laney [12] as: “high-volume, high-variety and high-velocity information, new approaches to information processing and use this information for various purposes such decision making”.

This set of Big Data 3V models, which is shown in Fig. 2, provides a direct and broad definition related to what constitutes a big data-based problem, software, application, or framework, as well as what does not. In this context, it may be described in brief as follows:

- Volume: Designates big amounts of different data and from various sources, including mobile digital data development devices as well as digital devices. The benefit of collecting, processing and analyzing these large quantities of data creates a number of difficulties in obtaining for knowledge human interaction and enterprises [8-13].
- Variety: The variety of data refers to different types of structural heterogeneities within a dataset. These various types of information collected via social networks, smartphones or sensors, such as text, data logs, pictures, videos, audio, and the like. Additionally, these data is structured (such as relational databases data), semi-structured, or of an unstructured form [8-14].
- Velocity: Refers to the rate at which are generated and speed of data transfers. Proliferation rapid and growth of digital devices technologies as smartphones and sensors have resulted in record levels of data creation, and the various forms of streamed data from variety sources. As a result, velocity of big data proliferation at the time of the development process should be taken into consideration [14, 15].

Big Data represents the central set of technologies and parts for processing user-generated data used on social media platforms. Without regard on the type of data (structured, informal or semi-structured), they can be containing useful information.

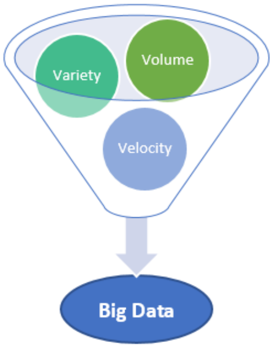

Fig. 2. The 3V model of big data.

III. Social Big Data Stream Processing Architectures

In this section, we provide a brief summary of Big Data characteristics generated by social media platforms, and we will look at the two major flow processing architectures, Kappa and Lambda—that are adopted for executing analytics.

When looking at popular online social media containing stacks of big data, makes the underlying processing of this data becomes challenging, and requires the implementation of an application-specific.

Big data technology influences current data management, and makes comparative analysis of these data essential to academic and industry communities.

Given the huge interest in social media platforms big data by universities, industry, a variety of solutions and techniques have been published over the past few years. With their progressive maturity, there is an increasing need to evaluate and compare such solutions. As a result, the science community was particularly interested in big data techniques. In fact, comparative analysis greatly facilitates the comparison of performances and provides useful information [16].

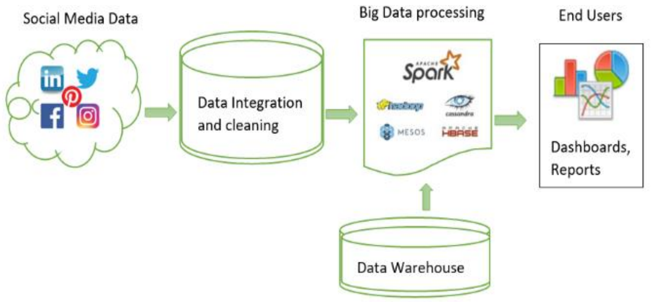

Fig. 3. Social media big data processing.

The social media businesses want to adapt real-time advertising placement algorithms analytics for insight generation, and Fig. 3 is shown the model of Social Media Big Data processing.

The analyzing big data continuously in real time is not an easy task.

There are many architectural propositions for analyzing big data in real-time streaming, but the most interesting one is Lambda and Kappa architecture.

A. Lambda Architecture

Lambda Architecture, suggested in 2011 by Marz and his team [17], offer the option to calculate arbitrary functions on an arbitrary dataset in real time by breaking down the problem into three layers (batch layer, speed layer and serving layer) [18], and provides a series of architectural principles that can be integrated and treatment of flow and batch data, in a low latency and a single Big Data architecture.

The Lambda Architecture consists of three main layers that interact with incoming data: the batch layer, serving layer, and speed layer. Fig. 4 illustrates the core technologies, components, processes, and responsibilities that constitute each layer of the Lambda Architecture.

The batch layer contains ever-increasing master dataset stored and pre-computes batch views on a distributed filesystem (such as HDFS) and produce batch views. MapReduce is used for processing the batch data, which is the Hadoop programming model. The serving layer indexes the batch views and does not require random writes, but must random reads. To implement the serving layer, usually technologies such as HBase, Storm and Cassandra are used. The last layer is the speed layer which only handles new data and uses an incremental model whereby the real-time views are incremented. At this layer stream processing system is generally based on Strom technology.

B. Kappa Architecture

The Kappa architecture, which was first described by Kreps, is perfectly suitable for processing data flows [19]. In this architecture, the key thought is to use one simple layer in real time for processing data flow and batch processing [16].

In the kappa architecture, everything is a stream [20], and you need is a stream processing engine data. So, what we would traditionally call batch processing of data is simply streaming through bounded datasets. However, Kappa is only focused and offers the option of creating a streaming and data batch treatment system based on the same technology. Similarly, queries search for a single location of the Kappa architecture instead of two of the Lambda architecture.

As shown in Fig. 5, the Kappa architecture is composed of the streaming layer module, responsible for orderly data events and one Serving layer, manages query results.

Summarizing, the kappa architecture focuses on the processing of data streams more than storage and this architecture is better adapted for cases where there is no need to permanently store the data.

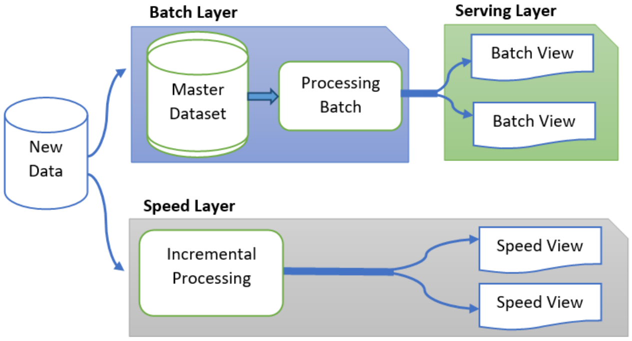

Fig. 4. Lambda architecture.

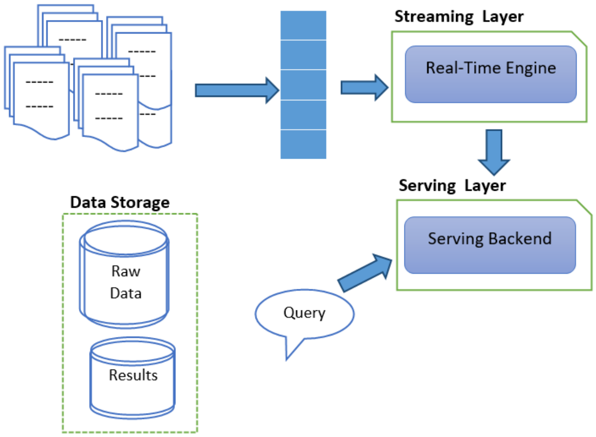

Fig. 5. Kappa architecture.

In the present paper, we have reviewed studies on the processing of big data mining on social media and focused on the concept of analyzing, we present our analysis processing, and we suggest a new method with new measuring process based on important aspects, such as number of likes, comments and retweets on the Twitter platform that can be used to predict the tweet texts (useful or not). Finally, we use our data mining algorithm of the tweet texts is used to calculate the LCR score for tweet text.

IV. Our Proposed Big Data Analysis Architecture for Understanding Human Interaction

Definition of the environment in which Big Data is processed continuously in real time, regardless of the type of data is no easy feat. There are much architectural proposals for real-time big data analysis, but the most interesting thing about our problem is developing architecture for extracting high-quality information about relevant messages [21]. In this section, we are presenting motivation to offer the architecture that best suits our use case and how it works.

The wide-spread popularity of social media has grown considerably the ratio of various streamed data, no matter what type of information or data (structured, semi-structured or non-structured). This information comes from regular people and this data may be in any of the next two statuses: data Useful (in motion) and not Useful (at rest) [22]. Therefore, various data quality distributions of generated by people using social networks are naturally fuzzy and non-structured [23], range from high-grade to low-grade. All this information can include the personal opinion of social media users [24], behaviors and thoughts, which makes it more and more important to extract useful information. Due to the availability of user-generated content can encapsulate helpful and high quality. Such increased in data generation has brought attention to the needs of analyzing big data in real time [25].

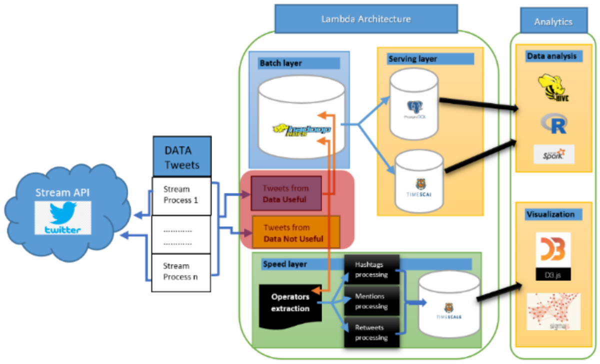

Fig. 6. Stream analytics system architecture for analyzing twitter text data.

As shown in Fig. 6, the practice example demonstrates the analysis process in Hadoop for analysis Twitter text data.

A researcher can retrieve data stored on Twitter through the public API provided by the social networking service Twitter to process specific information. However, in many cases, they do not provide data required by researchers. For example, may be needed for some additional data or perform cleaning and filtering operations to obtain useful data, such as the number of Retweets of user content or their popularity or reputation. Therefore, collecting useful data is a set of skills and methods and discipline of users in order to capture all the big data without any restrictions.

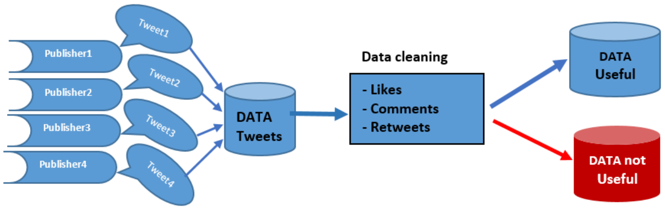

Fig. 7. Our proposed analysis procedures model.

As shown in Fig. 7, the Our Proposed Analysis Procedures to select the most relevant and interesting Tweets by cleaning and filtering using factors based on overall number of likes, overall number of comments and overall number of tweets. However, we need a more advanced method that can detect useful tweets.

LCR score, which is shown in equation (1), is our method used to measure the performance of the model.

$$f(L,C,R) = C1 \times Likes\_count + C2 * Comments\_count + C3 * Retweets\_\text{count} \quad (1)$$

Where f(L, C, R) is LCR score, C1, C2 and C3 is coefficients parameters and Likes_count, Comments_count and Retweets_count is the number of (Likes, Comments, Retweets).

The measuring process is shown in equation (1) that combines likes, comments, and retweets (LCR Score) for a tweet. And we rank those tweets based on the LCR score for each one. It should be noted that news tweets and it contains important information generally have a high number of retweets and that this type of score will be useful for our analysis of the information. We therefore assigned a high C3 coefficient for retweets to this type of content and a relatively low C2 coefficient for comments and a very low C1 coefficient for likes when calculating the LCR score.

In Table I, the three factors of tweet texts are shown, and we note that the Tweet texts not Useful and is not taken into account since the LCR Score is equal to zero.

TABLE I. Three Factors of Tweet Texts

Retweets_count	Comment_count	Likes_count	LCR Score	Tweet texts
R > 0	C >= 0	L >=0	LCR> 0	Useful tweet
R= 0	C= 0	L= 0	LCR= 0	Not Useful tweet

Data mining of the tweet texts algorithm is used to calculate the LCR score for tweet text, based on the overall number of likes L, the overall number of comments C and the overall number retweets R for a tweet texts in D (D represents the raw data). The algorithm LCR begins with an initial score equal to zero. Thus, that the Tweet text Not Useful and is not taken into account. then, the LCR score is computed step by step for a tweet text, and sequential patterns that combines likes count, comments count, and retweets count— is going to use these operators to find the raw data tweet useful.

Algorithm 1: Data mining of the tweet texts

```
Input:
D (The raw of dataset)
L (The likes count)
C (The comments count)
R (The retweets count)
LCR (Score of tweet text)
Output:
LCR (Score of tweet text)
Initialize Tweet_text = Scan(D)
    If Tweet_text contains content
      L= Likes_count
      C = Comments_count
      R = Retweets_count
      LCR = Score(L,C,R)
    End
```

V. Results and Discussion

Big data in social networks occupy a big place in our lives, and during the COVID-19 pandemic, social media have become essential to be in contact with our loved ones.

The tweets data analyzed in Table II are pre-defined data (not in real-time). We use this tweets text to test implementation of the LCR score, in order to detect useful and to classification tweets by interested degree.

TABLE II. Results Values Calculated by LCR Score For Pre-stored Tweets Texts

Tweet text	Retweets count	Comments count	Likes count	LCR Score
The EU says it may have a digital identity portfolio by 24, regardless of the challenges	106	11	89	429
WHO: COVID-19 - we all need to remain vigilant.	142	333	270	1362
Swedish company DSruptive Subdermal that specializes in microchip implants has created a way to store COVID-19 passport data. Here’s how it works.	340	70	265	1425
Andrew Tate nails the covid narrative in 90 Seconds!	1013	53	2292	5437
UNICEF vaccine ad	1245	547	1345	6174

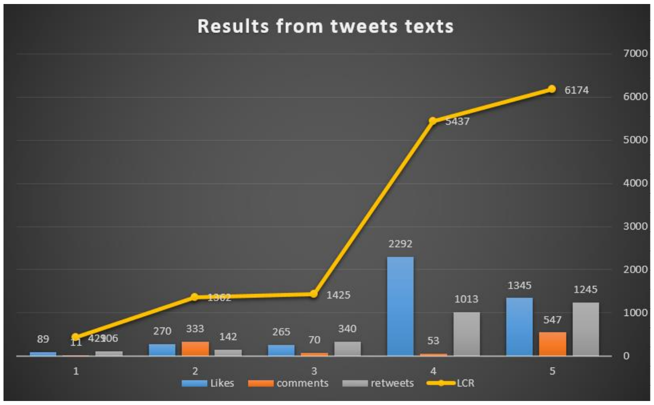

Fig. 8. Procedures a part of result from tweets texts.

The results in Fig. 8 show that an important Tweets stimulate the users to retweet, where the important information generally have a high number of retweets. The high precision of the LCR Score manifests in the form of a large number of retweets, which brings useful information. Furthermore, the results indicate that the number of likes and the user's ability to comment on the tweet are relatively low factors in detecting useful tweets. The experiments carried out allow us to know the most useful tweet from which the important information is disseminated and retweeted in a major time. To conclude, the more Retweets we have, the stronger to detect useful tweets are and the more significant the calculated LCR score is.

The work presented in this document represents our efforts towards creating a truly representative and comprehensive Big Data benchmark suite, using a high volume of data collected on Twitter by viral tweets related to COVID-19. We suggest a new approach with new measures that can be used for prediction the tweet texts (useful or not), then we make several interesting observations throughout diffusion graph and an analysis in detail using factors based on number of likes, number of comments and number of tweets on the Twitter platform.

We have compared of the two most known architectures for analyzing streamed big data in Section III. We're talking about the criteria here of choice of our architecture for analyzing Twitter text data and how well it meets our problem's requirements. The proposes of this work is about building a new Big Data architecture and advanced method capable to analysis the tweets texts and detecting useful tweets. By two solutions main challenges for analysis of social media data. First, how to detect not useful and irrelevant messages from big data analysis and second, categorization of this informative tweet into different degree of interest. By utilizing data from past detectoing, we show the performance of LCR score algorithm for multi-class classification factors. We observe the tweet texts to contains useful information always help improve the classification accuracy.

To evaluate the performance, the proposed method and obtained results show that the method achieves good results to detect useful and to classification tweets by interested degree.

VI. Conclusion

In this article, we reviewed studies on the procesures of big data mining on social media and focused on the concept of analysing. By the main stream processing and our proposed big data analytics architecture for understanding human interaction, the LCR measuring process method provides a framework for such research and is summarized in three sections: tweet texts input, tweet texts analysis (LCR score), and tweet output (tweet containing useful information or not useful). From a big data analytical framework perspective and our method, the discussions are focused on the analysis-oriented, and results-oriented of tweet texts information. It has to do with the perspective of data mining, this document gives a technologies of data mining algorithm of the tweet texts information and classification.

In the future phase of research, we're going to be implementing additional elements of our Architecture for analyzing Twitter texts data in order to analyze the batch data and real-time data. We shall test the speed layer with social networking platforms, by combining technologies such as Hadoop, Storm and Kafka.

***Abstract*—In December 2019, the COVID-19 epidemic was found in Wuhan, China, and soon hundreds of millions were infected. Therefore, several efforts were made to identify commercially available drugs to repurpose them against COVID-19. Inferring potential drug indications through computational drug repositioning is an efficient method. The drug repositioning problem is a top-K recommendation function that presents the most likely drugs for specific diseases based on drug and disease-related data. The accurate prediction of drug-target interactions (DTI) is very important for drug repositioning. Deep learning (DL) models were recently exploited for promising DTI prediction performance. To build deep learning models for DTI prediction, encoder-decoder architectures can be utilized. In this paper, a deep learning-based drug repositioning approach is proposed, which is composed of two experimental phases. Firstly, training and evaluating different deep learning encoder-decoder architecture models using the benchmark DAVIS Dataset. The trained deep learning models have been evaluated using two evaluation metrics; mean square error and the concordance index. Secondly, predicting antiviral drugs for Covid-19 using the trained deep learning models created during the first phase. In this phase, these models have been experimented to predict different antiviral drug lists, which then have been compared with a recently published antiviral drug list for Covid-19 using the concordance index metric. The overall experimental results of both phases showed that the most accurate three deep learning compound-encoder/protein-encoder architectures are Morgan/AAC, CNN/AAC, and CNN/CNN with best values for the mean square error, the first phase concordance index, and the second phase concordance index.**

Keywords—Antiviral drugs; computational drug repositioning; coronavirus; deep learning; drug-target interactions

I. Introduction

Since December 2019, Coronavirus disease (COVID-19) has become a crucial public issue across the world. There is a real need to develop antiviral drugs for COVID-19 to stop viral infections. Recent efforts have been carried out to design novel inhibitors or utilize a drug repurposing strategy to determine anti-COVID-19 drugs that can serve as promising inhibitors versus coronavirus protease [1, 2].

Drug discovery and development is a time-consuming, complicated and costly task, including the identification of candidates, synthesis, characterization, screening, assays for therapeutic efficacy, and clinical trials [3, 4, 5]. However, drug development success rates are extremely low. In clinical phrases, numerous investigational drugs have failed due to insufficient achievement, safety concerns, or commercial purposes [6]. Alternative drug development strategy drug repositioning seeks to identify novel uses for present drugs and can decrease the risk and costs associated with the development of new drugs [7, 8]. Inferring potential drug indications via computational drug repositioning is an efficient method. The drug repositioning problem is a top-K recommendation function that presents the most probable drugs for certain diseases based on drug and disease-related data. For drug repositioning, it is crucial to accurately predict drug-target interactions (DTI), which define the binding of substances to protein targets [9]. The precise identification of molecular drug targets is essential for drug discovery and development [10, 11] and is particularly important for discovering effective and safe treatments for new pathogens, such as SARS-CoV-2 [12].

Diverse issues in bioinformatics and cheminformatics applications [13], and more specifically, drug development and discovery [14], have been successfully solved using deep learning (DL) techniques [15, 16]. By comparing DL techniques to traditional machine learning (ML) algorithms, DL algorithms designed to predict drug-target binding affinities (DTBA) occasionally do better [17]. These DL-based DTBA prediction algorithms differ in two key aspects. The representation of the input data is the first aspect. The input drug features can include, for instance, extended connectivity fingerprint (ECFP), ligand maximum common substructure (LMCS), simplified molecular input line entry system (SMILES), or a combination of these features. The second aspect relates to the DL system design created using various neural network (NN) types [18]. The construction of the many NN types varies and may include a number of layers, hidden units, filter sizes, or an integrated activation function. Each variety of NN has particular advantages that make them better suited for particular applications. These variant types of NN are Feedforward Neural Networks; FNN, Radial Basis Function Neural Networks; RBNN, Multilayer Perceptron; MLP, Recurrent Neural Networks; RNN, Convolutional Neural Networks; CNN, and Modular Neural Networks; MNN, etc. [19].

Deep learning (DL) models for predicting drug-target interactions (DTI) often use encoder-decoder architectures [20]. The encoder converts ligand or protein representations into numerical vectors for training or evaluating the DL model. There are many different encoder-decoder architectures available for DTI prediction, but only a few have been explored in previous research. In this study, we propose a DL-based method for drug repositioning, which involves two experimental phases. Firstly, training and evaluating different deep network architectures of compound encoders (Morgan, CNN, CNN_RNN, MPNN, Transformer) and protein encoders (Transformer, AAC, CNN, CNN_RNN, Conjoint_triad) using the benchmark DAVIS Dataset [21]. The trained models have been evaluated using the mean square error and the concordance index metrics. Based on the experimental evaluation of this phase, the most superior five DL compound-encoder/protein-encoder architectures are Morgan/Transformer, Morgan/AAC, CNN/AAC, Morgan/CNN, and CNN/CNN. Secondly, predicting antiviral drugs for Covid-19 using the trained models. In this phase, the trained models created in the first phase have been experimented with to predict different antiviral drug lists for Covid-19. These lists have been evaluated by comparing them to a recently published antiviral drug list for Covid-19 [22] using the concordance index metric. The experimental evaluation of this phase showed that the most superior five DL compound-encoder/protein-encoder architectures are Morgan/Conjoint_triad, Morgan/AAC, CNN/AAC, CNN/CNN, and CNN/CNN_RNN. The overall experimental evaluation of both phases showed that the most accurate three DL compound-encoder/protein-encoder architectures are Morgan/AAC, CNN/AAC, and CNN/CNN with best values for the mean square error, the first phase concordance index, and the second phase concordance index. To summarize, there are two main contributions to this paper:

- Training and evaluating different twenty-one deep network architectures of compound encoders and protein encoders for drug repositioning using the benchmark DAVIS Dataset.
- Predicting antiviral drug lists for Covid-19 using the trained twenty-one models, and then comparing them to a recently published antiviral drug list for Covid-19.

The rest of this paper is organized in the following manner. While Section II provides an overview of the key scientific concepts, Section III reviews the related work. The conceptual model, system architecture, used benchmark DAVIS dataset, and reference Coronavirus antiviral medicine list are all described in Section IV along with the suggested technique. Section V describes the tools and libraries exploited in implementation and then presents the experimental evaluation using two main experiments: Evaluating the trained models using the DAVIS dataset and predicting antiviral drugs for Covid-19 using the trained models. Finally, the paper is concluded in Section VI.

II. Background

DTIs have a very important function in the drug discovery procedure. DTIs recognize the interaction sites between protein targets and drug compounds and describe the attributes of the interactions sites. DTI aims in recognizing new ligands versus specified protein targets. A large number of researches have gotten advantages from recognizing DTIs containing drug repositioning [23, 24]. Costly and time-consuming laboratory tests are required to determine the affinity value for a sizable number of drug-target combinations. Therefore, computational approaches have gotten more attention in the recent years [25].

A crucial step in predicting drug-target interactions DTI is feature extraction (also called feature encoding) from the input data. Feature extraction obtains useful, discriminating, and non-trivial information from input data to facilitate subsequent learning phases. Fig. 1 illustrates the two types of feature encoding techniques: data-driven and non-data-driven. The main distinction between these two groupings is that data-driven approaches develop characteristics for each input automatically. In strategies that are not data-driven, features are calculated in a fixed way for each input. The data-driven approaches are mainly based on deep learning methods, which is a set of machine learning algorithms that uses a model of the human visual system to create new hierarchical feature representations [26].

Fig. 1. Feature encoding methods [26].

A neural network with two or more hidden layers is deemed a deep learning. The input layer receives the input features directly, while the output layer generates predictions through a series of non-linear transformations utilizing hidden layers. Each output node corresponds to a class-based prediction task. If there is only one node in the output layer, then the network is considered a single-task deep learning. Otherwise, it is known as a multi-task deep learning [27].

A basic sequence, a derived atomic fingerprint, or a mixture of both can constitute the input feature space for a deep network. Numerous studies have used a network's input to be a raw molecular sequence. Other works convert a raw sequence to a more appropriate form, such as one-hot coding, to feed it to deep networks like CNN. In one-hot coding, each character in the sequence is represented by a binary vector with its matching bit set to one and the other bits set to zero.

There are many feature encoding architectures in DTI prediction such as Convolutional Neural Network CNN and Message-Passing Neural Network MPNN. For example, the Transformer encoders [28] are multi-layered bidirectional Transformer encoders following the initial Transformer model. The Transformer encoder is capable of modelling a sequence without the aid of a CNN or RNN. Transformer, in contrast to these earlier sequence processing layers, can efficiently encode the relationship between far-flung tokens (atoms) in a sequence. Various Transformer-based NLP models surpass earlier techniques in many benchmarks due to this effective context modelling.

Molecular descriptors must be created from symbolic representations of molecules, such as the SMILES (Simplified Molecular Input Line Entry System) format, in order to do deep learning. “Morgan Fingerprints,” a vector representation of molecular attributes, is a commonly adopted way to describe a molecule. Morgan fingerprint, also known as extended-connectivity fingerprint (ECFP) [29], is often used algorithm, or encoder specification. ECFPs are innovative category of topological fingerprints for molecular characterization. For the purpose of modelling structure-activity, ECFPs were created. ECFPs are circular fingerprints with a variety of useful properties: their ability to be calculated quickly; they are not predefined and can represent an essentially infinite number of different molecular features; and their features indicate the presence of specific substructures, which makes it simpler to interpret analysis results.

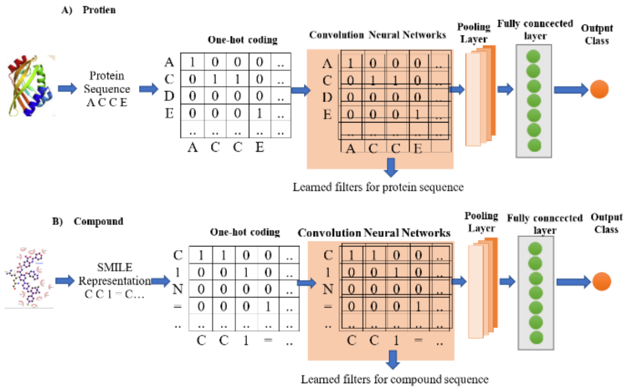

Fig. 2. One-dimension convolutional layer operation on a protein sequence and a molecule sequence [26].

The most popular deep neural network encoder is CNN, which operates on a grid data structure like digital images. As depicted in Fig. 2 [26], CNN consists of multiple convolutional and pooling layers arranged in an arbitrary order. Convolutional layers discover a series of filters that derive a group of local patterns from a specific receptive field of the layer input. In subsequent convolutional layers, the receptive field also expands. By down-sampling the layer's input, the pooling layer expands the receptive field. Moreover, the pooling layer does not define any additional parameters. The CNN input might consist of one-dimensional or two-dimensional matrices that are scanned along the sequence in only one or two directions, respectively. Until now, 1D CNNs have been used for DNA sequences for categorization, DNA-protein binding, and motif extraction, among other tasks [30, 31, 32].

In CNN, Fig. 2 depicts how to apply the one-dimension convolutional layer on a small molecule sequence or a protein sequence. In Fig. 2A, a protein sequence is depicted as an amino acids' sequence contained in a matrix where every amino acid is encoded by a single-hot code (all bits are zeros except the corresponding bit of the symbol is one). As seen, by reducing the loss function on both positive and negative task samples, the filter is moved along the sequence. Fig. 2B depicts the SMILE sequence as a string of characters. Every character represents an atom or molecule structural indicator. Every character is then encoded with a one-hot code and inserted in each matrix column. In both instances, the learned filter is displayed.

III. Related Work

Deep learning methods are now widely used in many research fields like; speech recognition [33, 34, 35] and image processing [36, 37, 38], involving bioinformatics such as genomics works [39,40] and quantitative-structure activity relationship (QSAR) researches in drug discovery [41]. The primary benefit of deep learning architectures aims to offer improved raw data representations through non-linear modifications in every layer [42]; hence facilitates the learning of the data's hidden patterns.

Several studies utilizing Deep Neural Networks (DNN) for the prediction of DTI binary class with various input models for drugs and proteins have been conducted previously [43,44,45], as well as a few studies utilizing stacked auto-encoders [46] and deep belief networks [47]. Likewise, stacked auto-encoder-based models using Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) were used to describe genomic and chemical structures as real-valued vectors [48, 49]. The protein-ligand interaction scoring is performed by using deep learning methods. The protein-ligand interaction scoring commonly utilizes CNNs, which learn from the three-dimensional compositions of the protein-ligand complexes [50, 51, 52, 53].

Pahikkala et al. [54] used a method called KronRLS (Kronecker Regularized Least Squares), which only requires two dimension-based chemical similarity-based representations of the medications and the Smith-Waterman similarity representation of the targets. Latterly, the SimBoost approach was suggested to forecast the scores of binding affinity with a gradient boosting machine by utilizing feature engineering to provide DTI [55]. They exploited similarity-based information of DT pairings and attributes acquired from the pairs' network-based interactions. Both kinds of research obtained similarity-based information using 2D representations of the substances and typical machine learning algorithms.

The ensemble of deep learning models (EnsembleDLM) for DTI prediction was presented [56]. EnsembleDLM utilizes a set of chemical compounds and proteins and assembles the predictions from numerous deep neural networks. It provides good achievements in cross-domain applications spanning various bio-activity types and protein classes. By using transfer learning, the EnsembleDLM obtained a good performance (Pearson correlation coefficient and concordance index).

To construct negative DTIs, a new similarity-based strategy was presented [57]. Multiple least absolute shrinkage and selection operator (LASSO) models were presented to incorporate various collections of feature sets in order to investigate the strength of prediction and forecast DTIs. In addition, LASSO Deep Neural Network (LASSO-DNN) model was developed to predict DTIs based on the features retrieved from the LASSO models with the highest achievement. LASSO-DNN was compared to LASSO, standard logistic (SLG) regression, support vector machine (SVM), and conventional DNN models. The LASSO-DNN outperformed the SLG, LASSO, SVM, and regular DNN models, as demonstrated by the results of the experiments.

Wang et al. [58] provided the three-step strategy for identifying obscure DTIs using deep learning. The first step is an illustration of drug-target pairings, where the drug compounds are encoded as fingerprint characteristics. In contrast, the protein sequence features are produced by applying Legendre Moments (LM) to a position-specific scoring matrix (PSSM), including evolutionary protein information. The second step involves compression and fusion of features. The sparse principal component analysis (SPCA) was utilized to reduce the dimension and redundancy of the features.

Eventually, the prediction task that used the deep long short-term memory (DeepLSTM) model was exploited. The experimental results proved that the suggested technique outperforms other DTI prediction methods.

DTI prediction model with 2D paired distance maps of proteins and molecular graphs as inputs for targets and medicines was presented [59]. To retrieve the interactive effects of targets and drugs, the mutual interaction neural network (MINN) by integrating two interacting transformers (Interformer, for short) with an enhanced communicative message passing neural network (CMPNN) (titled Inter-CMPNN) was proposed.

In conclusion, the majority of computational algorithms suggested forecasting DT interactions concentrated on binary classification, wheresoever the primary objective is to assess whether or not a drug-target pair interacts. Yet, the interactions of protein-ligand suppose a continuum of binding affinity values, often known as binding strength. Increased availability of affinity information in drug-target KBs (knowledge bases) enables the application of sophisticated learning approaches like deep learning architectures to predict binding affinities. The main contribution of this research is to train and evaluate twenty-one different deep network architectures of compound encoders and protein encoders for drug repositioning.

IV. Research Methodology

A. Proposed Approach

Fig. 3 shows the proposed approach conceptual model, which exploits a benchmark dataset called DAVIS [21] and a reference Coronavirus antiviral drug list [22], and then outputs a ranked list of candidate drugs for Coronavirus for each trained deep learning model. According to various compound-decoders/protein-decoders, twenty-one DL models have been trained.

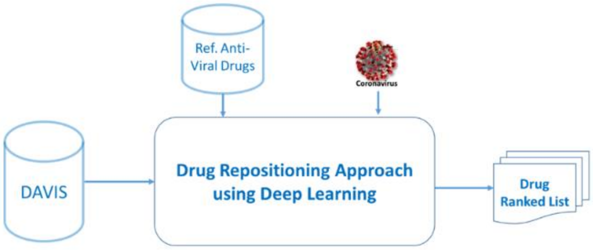

Fig. 3. The proposed approach conceptual model.

This research work has two main objectives. Firstly, training and evaluating models of different deep learning compound-encoders and protein-encoders using the benchmark DAVIS Dataset. Secondly, predicting antiviral drugs for Covid-19 using the trained models. To achieve these objectives, Fig. 4 shows the system architecture, which includes two phases: the training phase and the prediction phase. In the training phase, both drug compounds and disease target proteins of the DAVIS dataset are encoded using different neural network architectures and then their embeddings are decoded to generate the trained model. For example, as shown in Fig. 4, the drug compound is encoded using the Transformer architecture, and the disease target protein is encoded using the CNN architecture. The procedure of converting ligand or protein representations into numerical vectors utilized to train or assess a model of machine learning is known as encoding. Table I and Table II show the compound-encoders and protein-encoders exploited in this research, respectively. The cross-validation technique was applied on all DAVIS dataset instances.

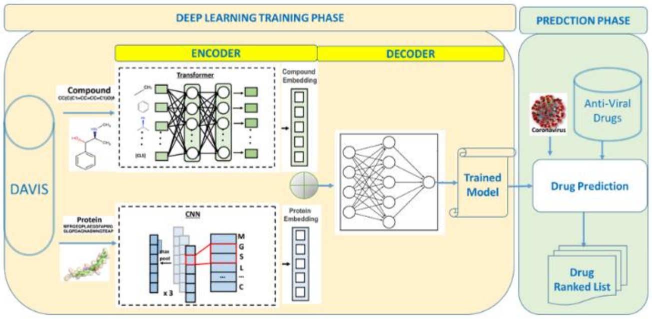

Fig. 4. The system architecture.

TABLE I. The Compound-Encoders and their Descriptions

Compound Encoder	Description
Morgan	Extended-Connectivity Fingerprints
CNN	Convolutional Neural Network on SMILES
CNN_RNN	A GRU/LSTM on top of a CNN on SMILES
MPNN	Message-passing neural network
Transformer	Transformer Encoder on ESPF

TABLE II. The Protein-Encoders and their Descriptions

Protein Encoder	Description
Morgan	Transformer Encoder on ESPF
CNN	Amino acid composition up to 3-mers
CNN_RNN	Convolutional Neural Network on target seq
MPNN	A GRU/LSTM on top of a CNN on target seq
Transformer	Conjoint triad features

In the prediction phase, the proposed solution exploits the trained model to predict a ranked list of drugs candidate for Coronavirus. The predicted ranked list of drugs is evaluated versus a reference list of antiviral drugs published recently for

Coronavirus. Fig. 5 shows how different trained models are generated and how different deep learning architectures are exploited. For example, the trained model 1 was generated by encoding drug compounds and disease target proteins using DNN and CNN, respectively. In the same way, the trained model 2 was generated by encoding drug compounds and disease target proteins using DNN and Transformer, respectively. In this research, twenty-one combinations of neural network architectures were experimented.

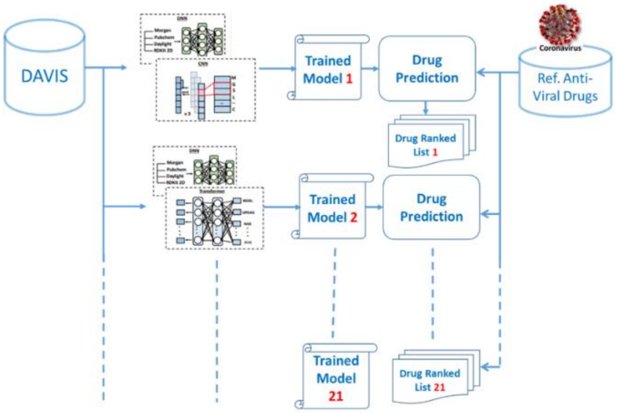

Fig. 5. Predicting twenty-one different drug-ranked lists for coronavirus.

B. The Benchmark Dataset

The selectivity assays of the set of kinase proteins and the pertinent inhibitors with their definite dissociation constant (Kd) values are included in the DAVIS dataset [21]. The DAVIS dataset compound SMILES strings were retrieved from the Pubchem compound database using their Pubchem CIDs [60]. The DAVIS dataset's protein sequences were retrieved from the UniProt protein repository using gene names and RefSeq accession codes [61]. Table III shows the number of Drug-Target Interaction Instances.

TABLE III. DAVIS DATASET SUMMARY

Proteins	Compounds	Interactions
424	68	30056

C. The Reference Coronavirus Antiviral Drug List

Recently, [22] used virtual screening and molecular docking methods to locate prospective inhibitors from existing drugs that can respond to COVID-19. Based on their binding energy (kcal/mol), the authors ranked 121 drugs as potent drugs against SARS-CoV-2 since they tightly bind to their main protease. Table IV presents a list of ranked Drugs based on their docking scores Binding energy (BE).

V. RESULTS AND DISCUSSION

A. Implementation Setup

In this research, the DeepPurpose DTI prediction tool was exploited. This tool provides a set of eight ligand encoders that can be combined with other protein representations and architectures to generate new models [62]. The DeepPurpose tool contains seven distinct protein encoders, which can be divided into two distinct categories: expert-designed algorithms and text-processing based on neural networks. Among algorithmic encoders, the ACC encoder produces a vector of 8420 elements describing the frequency of all amino acid k-mers for k values up to three [63]. In contrast, the conjoint triad encoder offers a 3-mer frequency count utilizing a restricted amino acid alphabet [64]. Neural network encoders, in contrast, apply directly on the sequence.

TABLE IV. A LIST OF RANKED DRUGS BASED ON THEIR DOCKING SCORES BINDING ENERGY (BE) [22]

Drug	BE	Drug	BE
Beclabuvir	-10.4	Pibrentasvir	-6.9
Nilotinib	-9.9	Valaciclovir	-6.9
Tirilazad	-9.6	Valganciclovir	-6.9
Paritaprevir	-9.2	Pirodavir	-6.8
Raltegravir	-9.1	Vidarabine	-6.8
Venetoclax	-9	Zanamivir	-6.8
Bictegravir	-8.9	Daclatasvir	-6.7
Danoprevir	-8.9	Alovudine	-6.6
Pimodivir	-8.8	Entecavir	-6.6
Voxilaprevir	-8.7	Famciclovir	-6.6
Faldaprevir	-8.6	Idoxuridine	-6.6
Setrobuvir	-8.6	Laninamivir	-6.6
Letermovir	-8.5	Tenofovir	-6.6
Bisantrene	-8.4	Cidofovir	-6.5
Rilpivirine	-8.4	Dasabuvir	-6.5
Indinavir	-8.2	Didanosine	-6.5
Ombitasvir	-8.2	Efavirenz	-6.5
Saquinavir	-8.2	Fiacitabine	-6.5
Simeprevir	-8.2	Lobucavir	-6.5
Digitoxin	-8.1	Penciclovir	-6.5
Dolutegravir	-8.1	Telbivudine	-6.5
Remdesivir	-8.1	Tenofovir disoproxil	-6.5
Lopinavir	-8	Umifenovir	-6.5
Maraviroc	-8	Capravirine	-6.4
Calanolide A	-7.9	Grazoprevir	-6.4
Darunavir	-7.9	Interferon alfa-2b	-6.4
Elbasvir	-7.9	Peramivir	-6.4
Etravirine	-7.9	Sorivudine	-6.4
Velpatasvir	-7.9	Zidovudine	-6.4
Vesatolimod	-7.9	Boceprevir	-6.3
Digoxin	-7.8	Emivirine	-6.3
Tipranavir	-7.8	Gancicolovir	-6.3
Amprenavir	-7.7	Ribavirin	-6.3
Maribavir	-7.7	Stavudine	-6.3

Nelfinavir	-7.7	Cenicriviroc	-6.2
Ruzasvir	-7.7	Dexelvucitabine	-6.2
Sofosbuvir	-7.7	MK-0608	-6.2
Doravirine	-7.6	Oseltamivir	-6.2
Mericitabine	-7.6	R1479	-6.2
Ritonavir	-7.6	Taribavirin	-6.1
Atazanavir	-7.5	Chloroquine	-6
Dapivirine	-7.5	Hydroxychloroquine	-6
Delavirdine	-7.5	Ledipasvir	-6
Fosamprenavir	-7.5	Elvucitabine	-5.9
Asunaprevir	-7.4	Emtricitabine	-5.9
Baloxavir marboxil	-7.4	Tromantadine	-5.9
Elvitegravir	-7.3	Acyclovir	-5.8
Sovaldi	-7.3	PSI-6130	-5.8
Tenofovir alafenamide	-7.3	Triazavirin	-5.8
Vedroprevir	-7.3	Aciclovir	-5.7
Galidesivir	-7.2	Fingolimod	-5.7
Methylprednisolone	-7.2	Lamivudine	-5.7
Clevudine	-7.1	Zalcitabine	-5.7
Telaprevir	-7.1	Ingavirin	-5.6
Thalidomide	-7.1	Rimantadine	-4.6
Abacavir	-7	Favipiravir	-4.4
Adefovir dipivoxil	-7	Amantadine	-4.3
Cobicistat	-7	Docosanol	-4.3
Nevirapine	-7	Foscarnet	-4.3
Tenofovie alafenamide	-7		

Every amino acid is transformed into a numerical value as a fixed-length one-dimension array using the DeepPurpose CNN encoder. Subsequently, it employs a convolutional neural network [65] to learn spatial information from the sequence (local amino acid neighborhoods) that may be pertinent to the DTI binding model.

Fig. 6 shows different compound-encoders and different protein-encoders developed by the DeepPurpose DTI prediction tool [60].

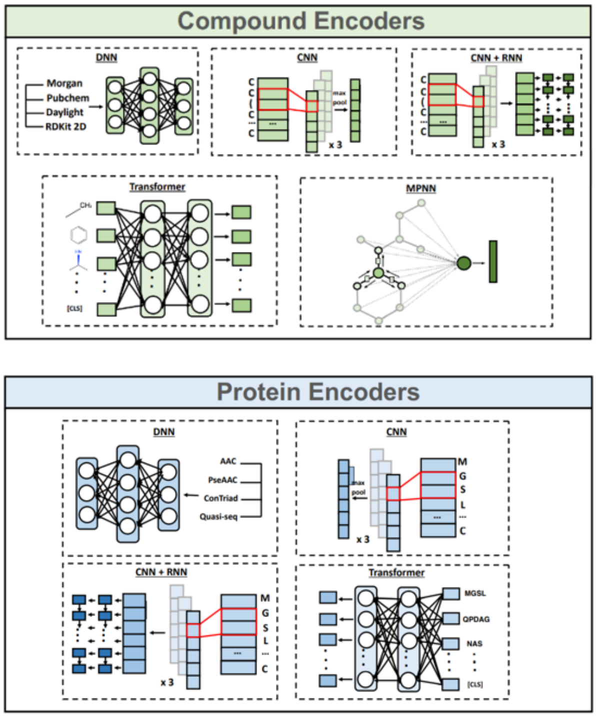

Fig. 6. Compound-encoders and protein-encoders developed by the DeepPurpose tool [62].

The DeepPurpose DTI prediction tool enables developers to set some pamperers for the model training phase. Table V shows some parameter settings for NN architectures, which had been used during the model training phase.

TABLE V. PARAMETER SETTINGS FOR NN-BASED TRAINED MODEL

Parameter	Range
Filter length (compounds)	[32,64,96]
Filter length (proteins)	[32,64,96]
Hidden neurons	1024; 1024; 512
Batch size	256
Epoch	100
Learning rate	0.001
CNN Drug Kernels	[4,8,12]
CNN Target Kernels	[4,8,12]

B. Evaluation Metrics

1) Mean squared error (MSE): During training, a learning model attempts to reduce the gap between the actual (real) value and the prediction. The mean squared error (MSE) is picked as the loss function because a regression problem is used. Equation 1 shows how the MSE is calculated.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(P_i - Y_i)^2 \quad (1)$$

Where P is the vector of predictions, Y is the vector of actual outputs, and n represents the total number of samples.

2) Concordance index (CI): The Concordance Index (CI) was used to evaluate the effectiveness of a model that outputs continuous values [17]. CI determines whether the anticipated binding affinity values of two random drug–target pairs were predicted in the same sequence as their true values were. Equation 2 shows how the CI is calculated.

$$CI = \frac{1}{Z}\sum_{\delta_i > \delta_j} h(b_i - b_j)$$

$$h(x) = \begin{cases} 1, & if\ x > 0 \\ 0.5, & if\ x = 0 \\ 0, & if\ x < 0 \end{cases} \quad (2)$$

Where b_i represents the prediction value for the greater affinity δ_i, b_j represents the prediction value for the lesser affinity δ_j, Z is a normalization constant, and h(x) is the step function.

C. Phase 1: Evaluating the Trained Models using the Davis Dataset

Based on exploiting different deep learning compound-encoders/protein-encoders, twenty-one trained models were evaluated using the benchmark DAVIS Dataset. The cross-validation technique was applied. Both Fig. 7 and Fig. 8 show the evaluation results for the different twenty-one trained models in terms of MSE (Mean Square Error) and CI (Concordance Index) evaluation metrics. It is noted that the most superior five DL compound-encoder/protein-encoder architectures are Morgan/Transformer, Morgan/AAC, CNN/AAC, Morgan/CNN, and CNN/CNN.

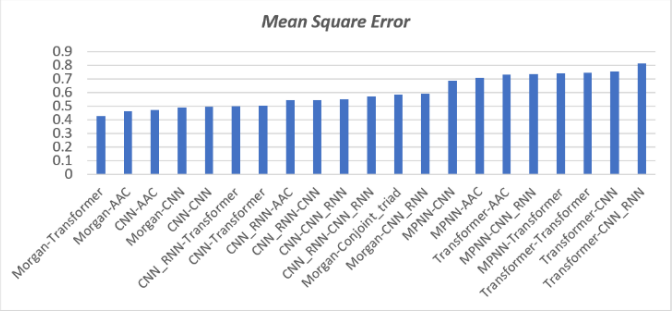

Fig. 7. The MSE evaluation results for the different twenty-one trained models.

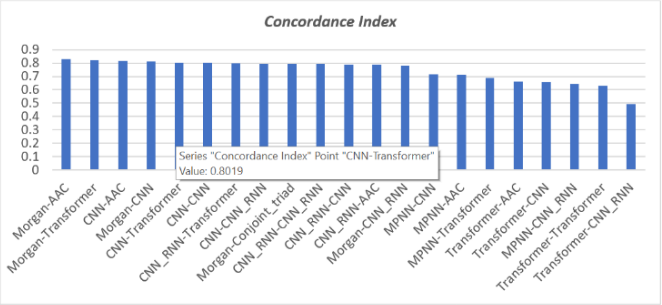

Fig. 8. The CI evaluation results for the different 21 trained models.

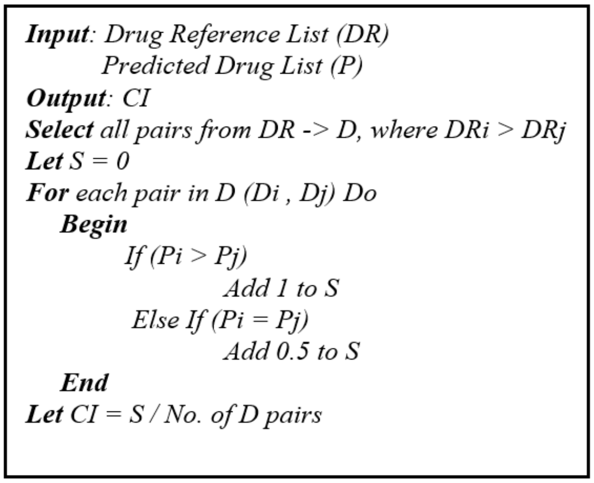
D. Phase 2: Predicting Antiviral Drugs for Covid-19 using the Trained Models

To evaluate the predicting accuracy for the trained models versus the 121-reference antiviral ranked drugs, the Concordance Index was used to compare each predicted ranked list versus the reference antiviral ranked drugs. Fig. 9 shows the Concordance Index calculating algorithm for a Predicted Drug List versus the Covid-19 Drug Reference List. Fig. 10 shows the Concordance Index for the twenty-one Predicted Drug Lists versus the Covid-19 Drug Reference List. As shown in Fig. 10, the most superior five DL compound-encoder/protein-encoder architectures are Morgan/Conjoint_triad, Morgan/AAC, CNN/AAC, CNN/CNN, and CNN/CNN_RNN.

The overall experimental evaluation for the two experimental phases can be summarized in Fig. 11, which shows the evaluation results using the CI metric for the different twenty-one trained models in the model testing phase using the DAVIS dataset and in the predicting phase versus the coronavirus drug reference list. As shown in Fig. 12, it is worth noting that the most accurate three deep learning compound-encoder/protein-encoder architectures are Morgan/AAC, CNN/AAC, and CNN/CNN with best values for the mean square error, the first phase concordance index, and the second phase concordance index.



```
Input: Drug Reference List (DR)
       Predicted Drug List (P)
Output: CI
Select all pairs from DR -> D, where DRi > DRj
Let S = 0
For each pair in D (Di , Dj) Do
   Begin
         If (Pi > Pj)
                   Add 1 to S
          Else If (Pi = Pj)
                   Add 0.5 to S
   End
Let CI = S / No. of D pairs
```

VI. Conclusion

This research proposed a deep learning-based drug repositioning method to train and evaluate twenty-one models based on deep learning compound-encoders and protein-encoders. The trained models have been evaluated using two experiments. Firstly, testing the trained models by applying the cross-validation technique on the benchmark DAVIS Dataset. Secondly, comparing the predicted antiviral drug lists by the trained models to a recently published antiviral drug list for Covid-19. The experimental evaluation showed the most accurate three deep learning compound-encoder/protein-encoder architectures are Morgan/AAC, CNN/AAC, and CNN/CNN with best values for the mean square error, the first phase concordance index, and the second phase concordance index. As a future work, the same 21 different deep network architectures of protein and compound encoders are suggested to be trained and to be evaluated using other datasets and other viral diseases.

Development of a Smart Sensor Array for Adulteration Detection in Black Pepper Seeds using Machine Learning

Sowmya Natarajan[1], Vijayakumar Ponnusamy[2]
Department of ECE, SRMIST, Chennai, India[1, 2]

Abstract—**Black pepper is an expensive commodity with a high risk of adulteration. Ground papaya seed is the main adulterant in pepper because it cannot be discriminated visually. There are few destructive methods. Since pepper is costlier, non-destructive method of adulteration is must but it is challenging one. The existing non-destructive method uses costlier equipment, bulky, involve laboratory-based testing, time consuming in the process. To overcome the above issues, this article presents the development of Non-destructive E- nose gas sensor for pepper adulteration detection. This system determines the VOC in a controlled environment. The proposed system utilizes MQ2 and MQ3 gas sensor arrays to identify Volatile Organic Compounds present in pepper seeds to discriminate adulterant and non-adulterant sample. The sensor data are utilized to perform the qualitative analysis to determine the adulteration using a support vector machine learning algorithm. The proposed sensor system with Support Vector Machine learning algorithm outperforms in comparison with existing methods with 100% classification accuracy. Conclusion: The developed gas sensor system is connected to the internet via the IoT application model to show results on the web pages and enables access by the authenticated user from anywhere. Client server model with MQTT protocol is used for developing IoT application.**

Keywords—Gas sensor system; volatile organic compounds; pepper seeds; papaya seeds; machine learning

I. Introduction

In India, adulteration in food products is highly uncontrollable, mainly the products sold in semi–urban, urban slum areas and rural areas. Due to these substandard or poor-quality products, consumers are cheated by paying more prices [1]. Among the whole spice items, pepper is a significant herb utilized for seasoning food. It is known to be the "King of Spice." Black pepper is called piper nigrum. It consists of chemical, and nutritional components, namely vitamins (K, A and C), protein, starch, polyphenols, piperine, and essential oils. Traditionally, techniques like sensory, analytical evaluation, iodide test and microscopic determination were deployed for adulteration identification in food products.

Real-time controlling, low cost, high sensitivity, and simple operated electronic nose were employed to determine the freshness of packed food items. The model [2] proposes the determination of Total Volatile Organic Compounds (TVOCs) from packed foods to find their freshness. A sensor mote comprised of low-power metal oxide gas sensors and humidity sensors are employed for this purpose, which is self-powered from the far-field Radio Frequency Energy Harvesting (RFEH). Packed fish and pork samples are utilized for examining the TVOC, which are kept in the refrigerator at ambient temperature for eight days. The acquired sensor data are trained with the 1D Convolutional Neural Network (CNN), Multilayer perceptron, and Support Vector Machine (SVM). The Multilayer perceptron model achieves a maximum of 99% classification accuracy for packed pork and 93.3% of classification accuracy for packed fish.

Spice powders are commonly adulterated by wheat, corn and rice flour. The study [3] presents a DNA barcoding methodology for identifying adulteration in spice powder. This study employs 91 commercial spice varieties brought from retail shops to detect adulteration using DNA sequences (ITS2 and psbA- trnh- Gen bank accession number). Concluded that with the help of 78- ITS2 and 77- psbA- trnh DNA sequences(barcodes), it is possible to identify that out of 91 varieties, 39 samples are pure,43 samples adulterated, 4 were uncertain and five samples were undetected.

The following literature work discusses the determination of adulteration determination through spectral information and VOCs.

A. Related Work

The appearance of papaya seeds is similar to the black pepper seeds, so adulteration is made easier, but the determination of papaya seeds becomes tedious through normal visualization. The significant flavor in black pepper is a terpene which is a VOC. Significant key odorants of black pepper are β - pinene, α –pinene, myrcene, α – phellandrene, limonene, methyl propanal, 2, 3 methyl butanol, butyric acid etc. The work [4] develops Molecular Imprinted Polymer (MIP) coated gold Nano Particle (Au NP) sensor for the determination of α-pinene VOCs in black pepper. The molar ratio of α- pinene template to monomer is investigated on the MIP film adsorption characteristics. The molar ratio of the alpha-pinene template to monomer was achieved as 1:4 on MIP absorption characteristics.

Total flavonoids, phenol, and piperine are the bioactive compounds present in the pericarp of pepper berries. Pericarp determines the color intensity and texture of the pepper. The study [5] various methods to determine the chemical components in the pericarp of pepper berries. A colorimetric assay was deployed for the identification of total flavonoids and total phenols. It is identified that the total phenol content is

1421.95± 22.35mg/100 gram, and the total flavonoid is 983.82 ± 8.19mg/100g. High-Performance Liquid Chromatography (HPLC) was utilized for piperine compound identification and found as 2352.19 ± 68.88mg/100g. Gas chromatography/Mass spectroscopy (GC/MS) identifies the characteristic peak areas of VOCs at 510nm wavelength -total flavonoids and 750nm wavelength -total phenols.

To determine the presence of adulteration in the paprika powder, the work [6] proposed a portable NIR spectrometer. The paprika powder samples are adulterated with acacia gum, potato starch, and annatto powder samples at various concentrations ranging from 0-36%. The acquired spectral data are validated through Partial Least Squares- Discriminant Analysis (PLS-DA) and Partial Least Square Regression (PLSR) algorithms. PLS-DA outperforms better classification to differentiate the adulterated samples at an accuracy of 90%. This model can predict the adulteration of annatto powder with Root Mean Square Error Prediction (RMSEP) at the rate of 1.74 and R2P of 0.87.

Research work [7] discusses the detection of papaya powder in black pepper powder by utilizing Thin Layer Chromatography (TLC) and GC/MS technique. Experimentation made for 20g of addition of papaya seeds powder in 1000g of pepper powder. It includes the analysis of Column chromatography through Gas Chromatography/Mass Spectrometry (GC/MS), which indicates the "366nm wavelength" fluorescent spot marker at Rf = 0.943. The "366nm wavelength" also detects the mixture of 2- decenal, n-nonanal and trans 2 – undecenal aldehydes present in the papaya seeds.

Terpene gas detecting sensor array is developed to determine the concentration of terpene gas in pepper sample [8,9]. Molecular Imprinted Polymer (MIP) and combination of MIP and Conductive Polymer (MMC) sensors is developed and compared the sensitivity in detecting the Terpene, limonene, and α-terpene. Among the two sensors MOC outperforms with higher sensitivity. 500ppm terpene concentration is detected using MOC sensor at the rate of 6.5 and 100 times more sensitivity for limonene and α-pinene.

This research work developed Molecular Imprinted Polymer (MIP) coated with gold nano particle (AuNP) excited Localized Surface Plasma Resonance (LSPR) [10] for the detection of α- pinene vapor. MIP powder and coating film adsorption characteristics are found by using gas chromatography and mass spectrometry. Molar ratio of α-pinene to monomer is investigated on the MIP film adsorption characteristics. Molar ratio of alpha- pinene template to monomer achieved as 1:4. less than 3 sec of time is required to determine 90% of terpene vapour transmittance. Good selectivity and sensitivity of this developed MIP coated AuNP sensor is realized at 1400 r/ min at the rate of spin coating. On field responses also recorded for limonene, α- pinene, γ-terpene and also verified to be reversible, rapid and selective.

Sichuan pepper plays a significant role as a flavoring agent due to its unique aroma and taste. Another work [11] focused on determining adulterants in the Sichuan pepper by utilizing NIR spectroscopy. Wheat bran, rosin powder, rice bran, and corn flour mixtures are added to Sichuan pepper intentionally to gain extra profit in the market. The acquired NIR spectral samples are validated through Partial Least Squares (PLS) analysis. It predicts the adulteration level in Sichuan pepper with the coefficient of prediction of 0.994 rosin powder mixture, 0.967 corn flour mixture, 0.948 rice bran mixture, and 0.969 wheat bran mixture, respectively.

Near-infrared and Fourier Transform - Infrared spectroscopy (NIR & FT-IR) [12] were used to determine adulteration in black pepper. NIR-FTIR spectroscopic data are processed with chemometric analysis to detect adulterants in black pepper. The adulterants are defatted spent black pepper, chili, papaya seeds, black pepper husk, and pinheads. The NIR& FT-IR spectral data are combined and applied to the binary classifier using Orthogonal Projections to Latent Structures Discriminant Analysis (OPLS-DA) model, which achieves 98% classification accuracy for adulterant.

NIR-Hyper Spectral Imaging (HSI) was employed to identify papaya seeds and their powder adulteration in black pepper, berries, and powder [13]. Adulterations of papaya seeds are made at different levels of concentrations with black pepper. Hyperspectral images are obtained and classified through Soft Independent Modelling Class Analogy (SIMCA) and Partial Least Squares (PLS) analysis. SIMCA model achieves better classification accuracy of 90% with less than 8% of error rate for adulteration determination in black pepper, berries, and its powder. PLS achieves a better prediction capability of $R^2P>0.8$, and the ratio of prediction deviation is higher than 2.5.

Among all the country's pepper production, Sarawak state in Malaysia produces a superior quality of pepper. It deserves a large price in the global market due to its better quality. Sarawak pepper samples are compared with the Indian ground black pepper sample for species adulteration determination. Different VOCs in the black pepper was determined by utilizing the geo–tracing module built with Metal-oxide Semiconductor (MOS) gas sensor array [14]. Totally 200 counts of black pepper samples are obtained from India and Malaysia. The sensor data are processed and analyzed with Principle Component Analysis (PCA). The PCA result produces an overall classification accuracy of 92.5% for discriminating the India and Malaysia pepper samples.

Identification of Volatile Organic Compounds (VOCs) is carried out with the E- nose model [15]. Gas chromatography Mass Spectrometry methods also carried out for the aphid attacks in the tomato plants also without infestation. Principle Component Analysis (PCA) delivers better results for the infected and healthy plants at an accuracy of 86.7%.

Table I gives a brief discussion of the methodologies employed for pepper VOCs/adulterant detection. MIP-coated sensor motes, E-nose sensor system and spectroscopic methods are discussed for the adulteration determination in the whole pepper seeds and its powder sample. Among all the methods, the NIR-FTIR model achieves a maximum of 98% classification accuracy in discriminating the adulterants in the black pepper seeds.

TABLE I. METHODOLOGIES FOR PEPPER VOLATILE ORGANIC COMPOUNDS (VOCS) AND ADULTERANT DETERMINATION

Literature work employed	Techniques& Methodology employed	VOCs/Adulterant components detected in pepper samples	Accuracy achieved
Wilde, A.S., (2019) [12]	NIR-FTIR&OLS-DA	Defatted spent, husk and pinheads	98%
Lee, H.E., (2020) [14]	Geo–tracing with Metal-oxide Semiconductor (MOS) gas sensor array&PCA	Sarawak pepper	92.5%
Iqbal, N., (2010) [9]	E-nose sensor system& pattern analysis	Terpenes (VOCs)	<20%
Paradkar, M.M (2014) [7]	Gas Chromatography/ Mass spectrometry& Pattern recognition	Papaya powder	94.3%

Spectroscopic, E-nose sensor array system, MIP coated sensor mote and geo-tracing techniques were employed to determine the adulteration in pepper samples. Literature works focus on determining the Volatile Organic Compounds of pepper samples and the presence of other adulterants in pepper seeds. Moreover, these experimental methods are carried out in a lab environment; samples are analyzed in whole and powdered form, and it takes time delay to produce the results. Real-time data analysis enables the system to be more effective and predict the results on the field spot. To overcome these drawbacks, this research work contributed as follows:

- Design a low-cost, portable gas sensor array system for rapid data collection in the field.
- Machine Learning algorithm-based adulteration detection mechanism is developed to handle the variation factor such as placing the sensor inside a measurement chamber, aged pepper sample, sensor placement during data collection and able to achieve an accuracy of 100% adulteration determination.
- The designed sensor system is IoT enabled to visualize and update the results on the webpage, which can be accessed by an authenticated end user anywhere.

The article is organized as follows: Section II describes the materials and methods employed for adulteration determination. Cost comparison analysis. Section III discusses the results of SVM algorithm for classification of adulteration. Section IV conclude the research work.

II. MATERIALS AND METHODS

This section discusses the working principle of the designed systems. The Artificial Intelligence (AI) enabled sensor system design, sample preparation, data collection, and processing of them using machine learning algorithms were discussed.

A. *Design of Gas Sensor Array System for Pepper Adulteration Detection*

The designed sensor array with an Artificial Intelligence-enabled system is shown in Fig. 1 which composes of MQ series MQ2 and MQ3 gas sensors for volatile organic compounds, gas detection from pepper samples, Arduino – UNO board, Raspberry – pi module is used for data acquisition processing and classification of gas sensor data.

Finally, the output of the test results of the adulterant detected is communicated to the web server and can be accessed by the authenticated users through the Graphical User Interface (GUI) of the web page.

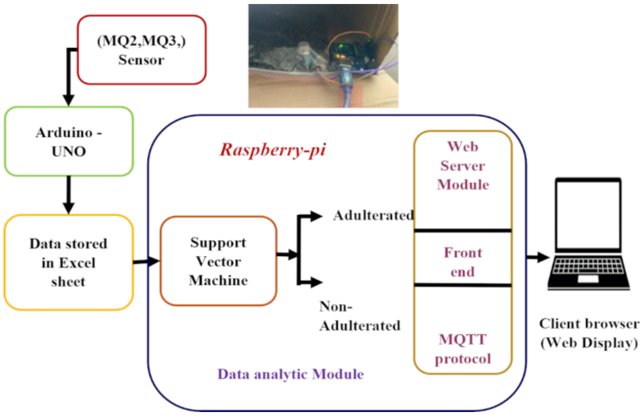

Fig. 1. System model of artificial intelligence (AI) enabled pepper adulteration determination.

Fig. 1 shows the general block diagram for the pepper adulteration detection system. The samples and sensors are kept inside the zip lock bag. Arduino UNO acquires the gas sensor data and stores it in an excel sheet. The stored information is transferred to the Raspberry Pi module through a serial port for data processing. The machine learning algorithm of the Support vector machine is utilized to classify the adulterated and unadulterated black pepper samples. Message Queuing Telemetry Transport (MQTT) protocol is utilized for communicating the result of classifiers to the webpage running in the web server module. Graphical User Interface designed to display the acquired sensor data results on the web page.

The following section explains the individual blocks of the sensor system array.

1) MQ2 sensor: MQ2 sensor module detects gas compounds such as Propane, hydrogen, Liquefied Petroleum Gas (LPG), propane, methane, smoke, carbon monoxide, and alcohol. The resistance of the sensor is directly proportional to the concentration of the volatile organic compound. The resistance measurement of the sensor detects the presence of the piperine compound. The concentration of piperine in the black pepper sample is about 2,531-8,073mg/100g. Resistance of the MQ2 sensor produces effective gas detection at approximately 200-1000 Parts Per Million (ppm) (i.e., 200mg/L-10,000mg/L) in the gas.

2) MQ3 sensor: MQ3 detects an alcohol, terpene, methane, hexane, LPG, carbon monoxide, and benzene detector. Resistance of the sensor varies according to the changes of volatile organic compounds in the measuring environment. This sensor works well for detecting gas components from 0.05-10ppm (i.e., 0.05mg/L-10mg/L). The terpene compound volatile concentration in black pepper determined ranges from 5.1%-28.7% per 100 grams.

3) Arduino Uno: Arduino UNO acquires the analog signal from the sensor system and converts it into digital values through the analog-to-digital converter. Raspberry Pi processes the received data from the Arduino UNO board through the serial port.

4) Raspberry-pi (data analytic module): Raspberry-pi receives the Arduino data and analyses the data for classification of adulteration. The sensor data are pre-processed to remove the outlier data. Using the machine learning algorithm of the SVM model, the data are classified as adulterant or non-adulterant. The results are communicated to the web display through the MQTT protocol.

5) Web display: The web page is designed to display the results of the detected adulterants with password authentication in the client browser. The user has to provide the login credentials to view the results of the tested samples. Only authenticated users can access the results of the tested samples. MQTT protocols transmit/receive the information between the web server module and raspberry-pi.

B. Sample Preparation and Data Collection

The pepper and papaya seed samples are brought from the local market and fruit shops for testing. The papaya and pepper samples are mixed at different proportions to make adulterated samples.

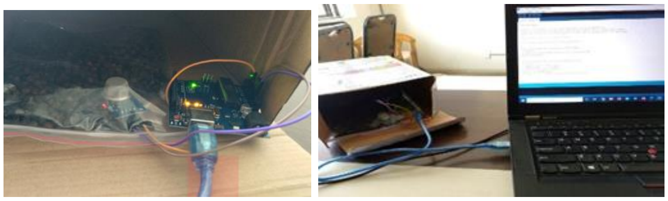

Fig. 2. Experimental setup for data acquisition.

Sample preparation steps are discussed and listed in Table II. The first set of experiments was carried out for 50 grams of pepper adulterated with 5 grams of papaya seeds (10%). Likewise, the adulterated samples are prepared at various concentrations in the ratio of 5:50, 10:50, 15:50 and 20:50, which means that 5 grams of papaya in 50 grams of pepper on top of it 5 grams of papaya in 50 grams of pepper. Similarly, the procedure was repeated for other concentration levels of pepper adulteration mixture.

TABLE II. SAMPLE PREPARATION

S.No	Pepper sample (in grams)	Papaya seeds (in grams)	% of the concentration of adulterant (papaya mixture in pepper sample)
1.	50 grams	5gms	10%
		10gms	20%
		15gms	30%
		20gms	40%
2.	100 grams	10gms	10%
		20gms	20%
		35gms	35%
3.	150 grams	15 gms	10%
		30gms	20%
		45gms	30%
4.	400grams	40gms	10%
		80gms	20%
		120gms	30%
		160gms	40%
5.	500 grams	100 gms	20%
		150gms	30%
		200gms	40%
		250gms	50%
6.	600grams	60 gms	10%
		120gms	20%

*gms- grams

Fig. 2 shows the placement of sensors on the sample inside a zip lock air-tight bag and the sensor data acquisition using the data streamer of an excel sheet through Arduino Uno. The number of sensor data acquired from the pure pepper and papaya seeds adulterated samples at various concentrations of the mixture is illustrated in Table III.

TABLE III. DATA ACQUIRED FOR VARIOUS LEVELS OF ADULTERATION

S. no	Pure and adulterant Cases	Total no of samples acquired
1.	50(Pure)+[5+5+5+5] grams	1500
2.	100(Pure)+[10+10+15] grams	1300
3.	150 (Pure)+ [15+15+15] grams	1200
4.	400(Pure)+[40+40+40+40]grams	1500
5.	500(Pure)+[100+50+50+50] grams	1400
6.	600(Pure)+[60+60]	900
Total no of samples		7800

Table III shows the number of sensor data obtained for each case of adulteration. Total number of 7800 spectral sensor communicated through MQTT protocol to Raspberry Pi for machine learning algorithm classification.

In Table III, “50 Pure+ [5+5+5+5]" describes that in 50 grams of pure pepper, 10% addition of adulterant (i.e., 5 grams of papaya seeds). Followed by adding 5 grams of papaya seeds three times and sensor data acquired for each adulteration addition. Likewise, the papaya seeds are added at various concentration levels in 100 grams, 150 grams, 400 grams, 500 grams and 600 grams of pure pepper samples.

C. *Cost Analysis*

This section compares the cost of the proposed sensor system design with the existing sensor module for pepper adulteration determination and is presented in Table IV. Our proposed work mainly focuses on designing low-cost, portable, rapid adulteration detection.

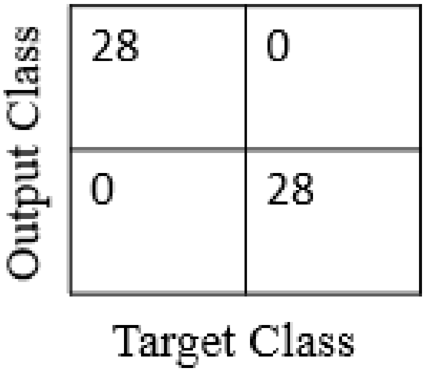
Table IV list the equipment utilized for pepper adulteration detection with its cost details. The proposed gas sensor system consists of a Raspberry –pi module of ₹ 4900/-, Gas sensors (MQ2, MQ3) cost around ₹ 500/- and Arduino UNO of ₹ 1850/-. The further jumper cable and USB cable are utilized. The designed sensor system cost is near to ₹ 7500/-.

TABLE IV. COST DETAILS

Equipment name	Adulterant determination	Cost
NIR-FTIR [wilde.A.S., 2019] [12]	defatted spent, husk and pinheads	₹ 5,86,528/-
GC-MS[Paradkar, M.M (2014)] [7]	Papaya powder	₹10,00,000/-
MOS- gas sensor array Lee, H.E,. (2020) [14]	Species/country origin variation (pepper)	₹15,000/-
Proposed gas sensor system	Papaya seeds	₹ 7500/-

III. RESULT AND DISCUSSION

This section delineates pepper adulteration identification using a support vector machine algorithm. The acquired gas sensor samples are collected and arranged so that 15% of the whole data set is assigned for the validation set, 70% is applied for the training set, and the remaining 15% is allotted for the testing phase.



Output Class \ Target Class		
	28	0
	0	28

Fig. 3. Confusion matrix binary Classifier.

SVM-based binary classification model could classify whether an adulterant is present or not. The support vector machine algorithm is trained using various level adulterant mixed data as in Table III.

Fig. 3 shows the confusion matrix for the binary class classification model. An accuracy of 100% is achieved for adulterant discrimination.

Fig. 4 shows the scatter plot MQ2 and MQ3 sensor data between pure pepper and adulterated samples. The response was recorded for the MQ2 and MQ3 sensor datasets. In the scatter plot, data lies on the diagonal lines with a different cluster that comes with points of 130(green points) of MQ2& 465 (green points) of MQ3. From the scatter plot, the adulterant's presence can be classified successfully.

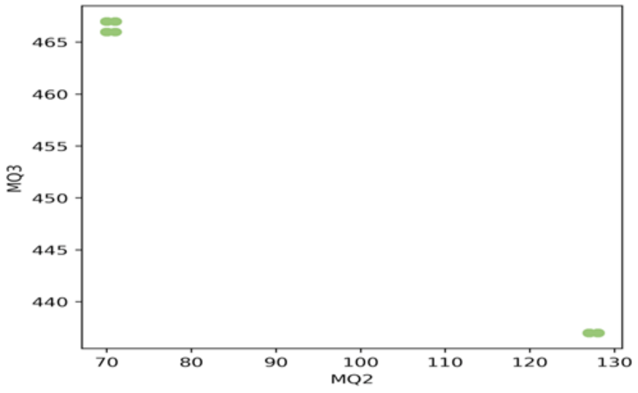


Fig. 4. Scatter plot of MQ2 and MQ3 sensor.

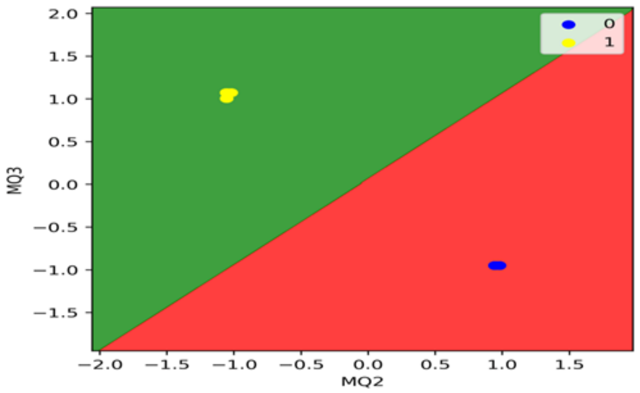

Fig. 5. Cluster plot of MQ2 and MQ3 sensors

In Fig. 5, the SVM algorithm shows that the data are fitted correctly according to their respective classes. The classification accuracy of the SVM model achieves 100%. The diagonal line indicated the separation of data and mapped in two regions (-1, 1) and (1,-1) successfully. It infers that the data are classified into their respective classes.

A. *Web Interface*

Our gas sensor model is designed with an application to give a real-time web interface for visualization of the detected adulterants. This web interface enables users to access the adulterant result anytime from anywhere.

TABLE V. COMPARISON CHART

Literature work employed	Techniques & data analysis methods	Compounds identified in the black pepper/powder sample	Accuracy achieved
Wilde, A.S., (2019) [12]	NIR-FTIR&OPLS-DA	defatted spent black pepper, black pepper husk and pinheads	98%
Lee, H.E., (2020)[14]	Geo–tracking with Metal-oxide Semiconductor (MOS) gas sensor array&PCA	50 various Sarawak pepper	92.5%
Paradkar, M.M (2001) [7]	Gas Chromatography/Mass Spectrometry& TLC pattern	Papaya powder	94.3%
Proposed method	Gas Sensor system& Binary SVM classifier	Papaya seeds	100%

Table V provides some of the existing works employed for pepper adulteration identification using different methodologies and achieves maximum classification accuracy of 98%. In Table V. the research work discussed deploying laboratory evaluation methods, which are expensive, consume time for determination, and are not portable. Our proposed system is rapid, portable, and low-cost for the determination of papaya adulteration in black pepper and achieves 100% of accuracy.

IV. CONCLUSION

Nowadays, adulteration in food is one of the serious problems faced by consumers. New creative, rapid, non-destructive, portable techniques need to develop for adulteration detection. Many electronic nose sensor systems can be able to detect adulteration in pepper, but those techniques would consume time to deliver the results with moderate accuracy. A low-cost gas sensor array system was developed to detect adulterants rapidly. The proposed system detects adulterants in pepper with gas sensors of MQ2 and MQ3. The sensor readings are processed with a support vector machine algorithm for adulterant classification, which achieves 100% accuracy of detection. The proposed gas sensor array module output performance can be viewed and accessed by the authenticated user through the GUI of the web interface from anywhere. In the near future, work can be taken forward to determine the various concentration levels of adulterants mixed in pepper seed samples by utilizing other gas sensor modules.

ACKNOWLEDGMENT

Sowmya Natarajan involves in collecting the pepper and papaya samples and acquired the gas sensor data by testing the samples with various levels of adulterated and unadulterated samples. The data processing and classification and the research direction contributed by Vijayakumar Ponnusamy.

***Abstract*—Security is one of the most important issues in layout of a Digital System. Communication these days is digital. Consequently, utmost care must be taken to secure the information. This paper specializes in techniques used to defend the facts from thefts and hacks the use of quit-to-cease encryption and decryption. Cryptography is the important thing technique related to Encrypting and Decrypting messages. We use Digital Signature preferred (DSS) and the Digital Signature Algorithm (DSA). The code for this algorithm is written in MATLAB. The DSA Algorithm is commonly used in cryptographic applications to provide services such as entity authentication, key transit, and key agreement in an authenticated environment. This structure is related with steady Hash Function and cryptographic set of rules the government groups in USA as it is taken into consideration to be one of the safest approaches of protection system. This fashion- able could have a top notch effect on all of the Government Agencies and Banks for protective the facts.**

Keywords*—*DSA; digital signature algorithm; hash function; public key; private key; RSA

I. Introduction

Cryptography is the system of conversion among undeniable text to cipher textual content and to straightforward text. Fig. 1 shows how Cryptographic manner is achieved:

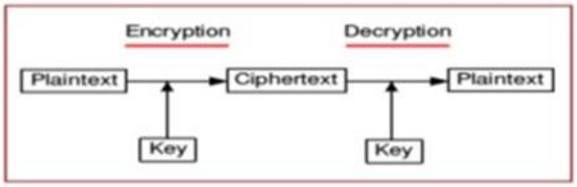

Fig. 1. Cryptographic operations.

- The sender converts the obvious textual content to its cipher shape with a key. This manner is called as Encryption.
- The cipher textual content is received through the receiver.
- The Received cipher text is transformed to a readable shape with a key. This technique is referred to as Decryption.

A. *Types of Cryptography*

As shown in the Fig. 2, the entirety of the cryptographic algorithms can be classified in to three main categories

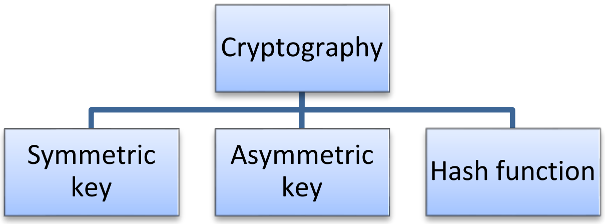

Fig. 2. Types of cryptography.

1) Private key cryptography: Private Key cryptography, also known as symmetric key cryptography, employs the same key for both message sign encryption and decryption. Symmetric key cryptography is tremendously effective since there may be no time put off for Encryption and Decryption of messages [1].

2) Asymmetric key: Asymmetric keys are the foundation of Public Key Infrastructure (PKI), a cryptographic scheme that requires two different keys, one to lock or encrypt the plaintext and one to unlock or decrypt the cipher text. It uses public key for Encrypting messages and Private key for the Decryption of messages. Public key can be shared to everybody but private key's kept secret [2].

3) Hash function: A hash function is a mathematical algorithm that takes an input, or message, and produces a fixed-size output, also known as a hash or digest. The output is deterministic, meaning that the same input always results in the same output, making it challenging to find two inputs that produce the same hash. This property makes hash functions useful in various applications, including data integrity verification and digital signature generation. Examples of widely-used hash functions include SHA-256, SHA-3, and MD5.The following picture illustrated hash function.

II. Related Work

Cryptography is a branch of cryptology that deals with designing algorithms for encryption and decryption to ensure the confidentiality and/or authenticity of messages. In 1991, the DSA was proposed by the U.S. [3]. The growing use of services like e-commerce and open network communications has highlighted the crucial role of public key cryptosystems as security solutions [4]. In public key cryptographic system, Digital Signature provides vital sort of authentication [2]. A digital signature generated as a checksum by making use of the text/data to which it will be later appended to and will look like a whole text [4]. Since the generation of this digital signature is dependent on the transmitted message along with the secrete key, one cannot easily understand the transmitted data or can reproduce the signature nor can they be able to tamper the transmitted data without getting noticed by the transmitter/receiver. A virtual signature is computed using a set of regulations and a fixed of parameters so as to conceal the identity of the original signatory and also to prove the integrity of the records [4].

Digital signatures have been in use since the early days of digital data transmission, due to the discovery of one-way functions. Many digital signature schemes have been shown to be secure under certain theoretical assumptions. A recent advancement has been the development of an offline signature verification system based on a displacement extraction technique, where a questionable signature is compared to a valid one. The proposed digital signature uses a set of rules and generates dynamic values through a new hash feature.

A signature scheme is a technique for signing an electronic communication that has been saved. A signed communication can therefore be sent across a computer network. Prior to studying various signature methods in this section, let's first talk about some key distinctions between traditional and digital signatures. The first concern is file signing. A traditional signature is one where the document being signed really contains the signer's signature. However, a virtual signature is now not connected bodily to the message this is signed, so the set of rules this is used need to by some means bind the signature to the message. A virtual signature, however, is no longer physically attached to the message it is signed, therefore the set of rules that are utilized must somehow link the signature to the message. The verification issue comes next. By comparing it to other real signatures, a conventional signature is made legitimate.

For instance, when a customer conducts a credit card purchase, the salesperson is required to check the signature on the income slip against the signature on the bottom back of the credit card to confirm it. Of direction, this approach isn't always reliable because it's quite easy to fake another person's signature. In contrast, a publicly acknowledged set of verification procedures may be used to produce digital signatures. Thus, all and sundry can affirm a virtual signature [5].

Chaum is credited with originating the idea of blind signatures [9]. This technology enables a user to have a message signed by another user without divulging any details about the message. Blind signatures have a wide range of practical uses, including electronic cash, untraceable electronic mail, electronic voting systems, time-stamping and anonymous access control.

To overcome several security issues identified in RSA algorithm [1], Gupta et al. suggested an hybrid approach for encryption and decryption algorithms by making use of RSA and Diffie-Hellman algorithm[DH], Named after the founder by Whitfield Diffie and Martin Hellman. A DH algorithm is an extensive algorithm which is majorly used in several internet connectivity protocols. Several example protocols like SSL, IPsec, SSH [1,9,11]. The DH is based on two key principles, a public and a private key. The transmitter and the receiver exchange the secret value among them by making use of these available key values [10]. In the proposed algorithm [1], the authors have combined both algorithm to get a secure and efficient cryptographic environment by exploiting the benefit of security from public key system and the reduction of computing time from secret key system.

The primary goal of Gupta et.al, proposal's combination of these two algorithms is to create a better and more secure cryptosystem by using the speed and security of the secret key system and the public key system, respectively. Users often find it simple to interact securely across open networks using this hybrid technique, especially when sending confidential messages or information. For improved algorithm functioning, efficiency can be altered in terms of time complexity. Additionally, the size of the keys used for encryption and decryption can be further decreased [12].

In contrast to the original RSA technique, which relies on 1024-bit prime numbers, the Iswari et al approach uses 256-bit prime numbers to reduce the computing time needed for key creation. Due to problems with factorization and discrete logarithm calculations, RSA and ElGamal are combined to retain security factors and complexities even when little bit prime numbers are utilised [13].

Patidar and Bhartiya introduced an innovative concept to enhance the conventional RSA method during information transmission between two parties through a network. They utilized a third prime number to form a modulus n that is harder to decipher by outsiders. This improvement combines a refined version of RSA with a unique design approach. Although the technique speeds up communication encryption and decryption, maintaining secure key storage remains crucial as it safeguards against potential attacks [14].

Shikha et al. presents a modified approach to the traditional RSA algorithm that enhances its security by incorporating exponential powers, multiple public keys, and K-NN algorithm. The modified approach also provides verification at both sender and receiver sides, which ensures authenticity of a message. This approach reduces encryption and decryption time for encrypting and decrypting input messages while making it difficult for intruders to hack the information being transmitted [15].

Jaju et al. proposed an updated version of the RSA technique that utilizes three irreducible numbers instead of two prime random numbers for calculating the common modulus, and passing the value of X in both the public and private keys instead of n. This modification is believed to enhance security and improve speed compared to the original RSA technique. The three prime integers, p, q, and r, must be factored to determine the common modulus n, which is a computationally intensive task, making the system more secure. In case of a factorization attack, it becomes difficult to uncover the value of n as X is included in the public key, rather than n. While the new method offers improved security and faster key generation, the encryption and decryption processes take longer than in the original RSA approach [16].

By removing the distribution of n, a big number whose factor, if uncovered, weakens the RSA method, Minni et al. presented a different safe technique. The updated algorithm's slower key generation time as compared to the RSA technique is one of its drawbacks [17].

Thangavel and colleagues proposed a modified version of the RSA public-key cryptography system, utilizing four prime numbers. The four primes are used to calculate the value of N and determine the values of E and D. The computation of E is more complex as it requires finding the values of e1 and e2 before calculating E1. This added step makes the system more secure and longer to attack. The only value made public is n, so an attacker with knowledge of n cannot determine the other primes and uncover the values of N and D. The system's complexity is further increased by the addition of the E1 parameter. The authors demonstrated the superior security of this approach, making it a safer alternative to the conventional RSA. [18].

Islam et al. proposed a modified RSA (MRSA) scheme to address some weaknesses in RSA algorithm computation. The MRSA approach uses 'n' unique prime numbers for key creation, with three components in both the private and public key. The component N is the product of four large prime integers (w, x, y, and z) selected randomly. The public key consists of three elements, e, f, and N, where e and f are selected randomly from a group of three. In their implementation, the authors noted that the MRSA has different crucial parameters that impact the security and speed of the algorithm. [19].

III. Proposed Algorithm

A. RSA Algorithm

RSA is named behalf of its inventors [6]. RSA is an era for Encryption and Decryption of messages. RSA is primarily based on Asymmetric Key Cryptography which means that it makes use of two keys, one for Encryption and Other for Decryption. One key is kept Secret and the other is kept Public [7]. The methods of cryptography may be demonstrated as steady until it's cracked. Since RSA uses very massive numbers it is difficult to think out which is the variety taken. For Example, if one hundred digit numbers are taken for p, q. The end result 'n' can be around 200-digit quantity. The recognized Factoring Algorithm will take a piece time for an attacker to crack the records. Any Cryptographic technique which cannot be cracked without difficulty are referred to as steady, as of now RSA algorithm is secured.

In the Standard RSA algorithm, two additional prime numbers are used in the Enhanced RSA (ERSA) [10] algorithm. This concept was inspired by the High Speed and Security RSA algorithm [11], which used two random numbers for key generation.

B. DSA Algorithm

Digital signature widespread (DSS) is used to verify the originality of the Digital Messages or the documents dispatched [8]. Digital signature is a cryptographic cost, which is observed the usage of most effective from the message signals and the private key owned via the non-public key holder. By virtual signature we can offer security for privacy, Authentication, Integrity, and Non-repudiation. There are three main virtual signature techniques below Digital Signature Standard. They are the DSA Algorithm, the RSA Algorithm.

DSA algorithm works on the premise of public key cryptography [4].DSA set of rules is used by the receiver of a message to verify whether the message is changed or is it in its unique form. DSA uses Public key to verify the sender's message, but verifying is complicated compared to RSA.DSA set of rules works on three steps like,

- Key generation
- Signing
- Verification

Fig. 3 shows how the Encryption of message sign is executed; the message sign is sent through Hash characteristic to generate a hash code [3].

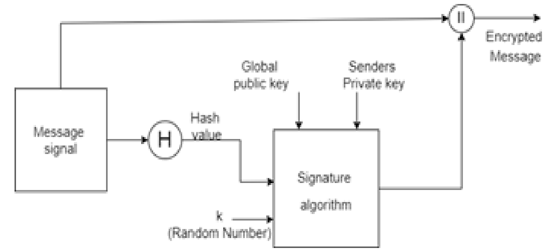

Fig. 3. DSA encryption process.

Then the hash code and random variety 'okay' is given as an input for signature algorithm in conjunction with worldwide public key and sender's private key. Then the message signal and signature could be appended to get an encrypted message.

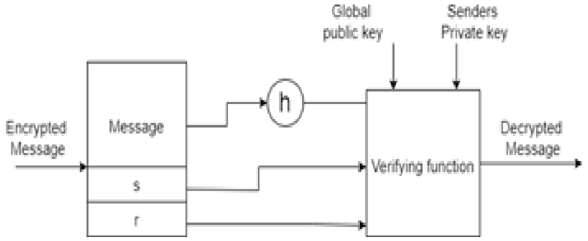

Fig. 4. DSA decryption process.

Fig. 4 shows how the Decryption of message sign is finished, once the Encrypted message is obtained with the resource of the receiver, he desires to decrypt the message to get decrease returned the unique message signal [4]. The Encrypted message signal will encompass the proper message sign, signature parameters like s and r. The message signal is given to the verifying characteristic, at the side of it global public key and sender's personal secret is given to it. And we get the decrypted fee that is not anything however the parameter "v".

C. Hash Functions

It is essentially meaningful for Hash features to compress data such that the output is comparatively shorter than the input, and possess the traits of a great hash function. There are three most important characteristics:

- The information that is being hashed needs to be fully determined via the hash fee.
- The hash characteristic makes use of all the enter records. The complete input statistics must be used by the hash characteristic.
- The hash function uniformly distributes the information across the entire set of possible hash values.

A Hash characteristic is a mathematical feature that converts an input fee into a compressed numerical value – a hash or hash fee. The period of the output always relies upon on the hashing set of rules. The maximum popular hashing algorithms may have a hash period ranging from 160 to 512.

IV. Result and Discussion

The following section discuss about the performance evaluation of proposed algorithm in comparison with standard RSA algorithm.

A. Execution Time Analysis

Table I depicts the overall time taken for the process of encryption and decryption using various algorithms. In the proposed algorithm the Block cipher symmetric algorithm is used for key selecting technique. It can be observed that even though Enhanced RSA has less computation time. In spite of using the block cipher approach for encryption and decryption the proposed algorithm still gives a better time results when compared to either the RSA algorithm or DSA algorithm alone.

TABLE I. Key Selection Procedure and Execution Timing

Algorithm	Key Selection Procedure	Execution Timing
RSA	Any two significant primes	5.9 Seconds
Enhanced RSA	Any two significant primes	2.9 Seconds
DSA	Using Block cipher symmetric algorithm	5.9 Seconds
Proposed DSS with E-RSA	Using Block cipher symmetric algorithm	3.9 Seconds

B. Visual Analysis of Digital Signature

The proposed approach of Digital Signature Scheme based totally on the linear block cipher RSA basically symmetric key set of rules. However, in this case, we employed an asymmetric key set of rules to create the symmetric key technique and applied it in a digital signature scheme. In addition to acknowledging informed agreement and acceptance by a signatory, digital signatures can offer added guarantees of the proof of provenance, identity, and standing of a digital document. The suggested digital signature scheme's actual structure is shown in Fig. 5 to Fig. 9 depicts the assessment performance of recent Digital Signature Scheme. Algorithms are simulated using MATLAB Tool.

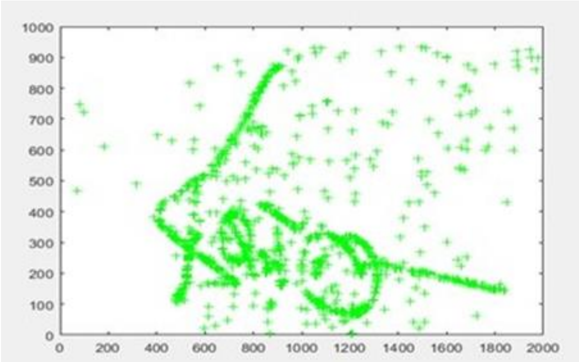

Fig. 5. Signing of sample signature.

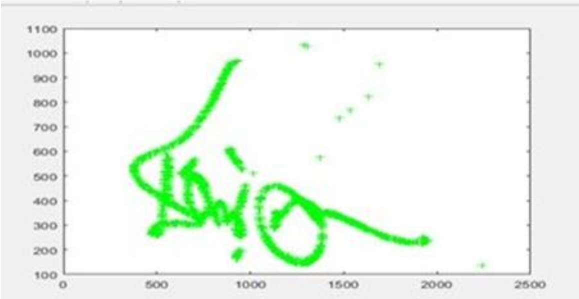

Fig. 6. Identification process of sample signature.

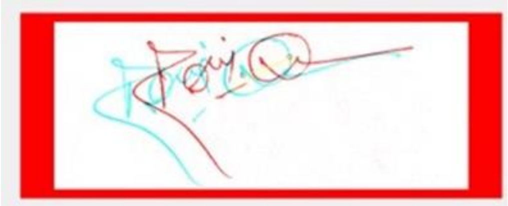

Fig. 7. Signature verification 1.

Fig. 8. Signature verification 2.

Fig. 9. Verified signature.

V. Conclusion and Future Scope

In this research article a technique has been implemented to evaluate the performance of DSA with RSA. In order to further improve the efficiency in terms of execution time, we have modified the existing signature scheme by incorporating Lightweight hash function. The proposed technique is validated by performing the comparative investigations with other existing techniques. The outcomes achieved validated that we have achieved the better performance than other techniques. Even though the research work accomplishes the primary objective of attaining the improved time efficiency, there is a scope of improvement in transaction of data integrity. Hence in future the proposed system can be extended to focus on the integrity of data by improving the Hash function that is suitable for the Digital signature scheme.

Department of Computer Science and Engineering, Panimalar Engineering College, Chennai, India[1, 2, 4]
Department of Computer Science and Engineering, Panimalar Institute of Technology, Chennai, India[3]

Abstract—**In recent days, the demand for dealing large set of distributed data obsoletes the relational database and its structured query language (SQL) solutions in practice and paves the way for novel solutions in the name of non-relational database as not-only SQL (NoSQL). The NoSQL offers dynamic, flexible, scalable, highly available, greater performance and near real-time access to the distributed nature of voluminous data used for current industrial applications. Apart from these giant features of NoSQL, the SQL is still found to be in operation because of its popularity and standard. This paper projected an algorithm to convert the relational documents of MySQL into any document oriented NoSQL databases automatically without destructing the existing relational database setup and installing the NoSQL from scratch in the core machines. Java Script Object Notation (JSON) is a human readable data interchange format, being used in web development. The characteristics of JSON widened its use cases from web development to database storage. The Mongo DB, one of the most popular document oriented NoSQL adapts JSON format for its storage. The proposed algorithm is built based on its schema definition and the performance is captured through evaluating it against a sample database from hospital management system. The findings are discussed with great interest of addressing the challenges and revealing the scope for improvement.**

Keywords—Distributed data; document oriented NOSQL; hospital management system; Mongo DB; my SQL

I. Introduction

Databases Management System was created as a result of an increase in demand from industries for preserving their customer, stock, and account-related data and the process of obtaining relevant information from the data (DBMS). Systematic maintenance, as well as the effective storage and retrieval of data, are made possible by DBMS. Data are initially maintained using file systems, which store information directly in files without any connection to one another. Several models were presented as a result of the constraints in data access patterns that were found. International Business Machines (IBM) created a hierarchical model in 1960 that enables data organization in a tree structure by altering the parent-child relationship.

The network model, put forth by Charles Bachman in 1969, allows for the arrangement of data in a graph-like structure, with nodes serving as records and arcs as the connections between them. E. F. Codd created the relational model in 1970, which organizes data as tables and is currently regarded as a special model employed in important industries due of its features [1].

When dealing with situations in the real world, the data is contained in a single container referred to as an object. This begins the object-oriented database that has been in use since 1985 [2]. In order to create a new database known as an object relational database, the capabilities of relational databases and object-oriented databases were combined. By adding more dimensions to the data by displaying it as a cube, online analytical processing capability (OLAP) is offered in place of transaction processing.

Big data has replaced the traditional data that used to occur over a longer period of time in sectors that deal with data created every day. Even today's data volume is measured in petabytes or zettabytes, and 50% of the data are unstructured. The performance of the relational database, which exclusively processes structured data, is good for reasonable workloads but degrades as it is scaled up. Big data and analytical processing have made Relational Database Management Systems (RDBMS), which use Structured Query Language (SQL) to operate, ineffective [3]. Carlo Strozzi was the first to suggest Not Just SQL (NoSQL). This RDBMS was file-based and lacked a SQL interface. NoSQL, often known as non-relational databases, was first introduced in 2009 by Eric Evans [4, 5]. It is recognized as a promising database to handle massive data.

NoSQL is an alternative to RDBMS, facilitate mechanisms to store and retrieve enormous data in a distributed platform. The features on NoSQL over RDBMS are listed below.

- Horizontal Scalability – new nodes can be added to dynamic accommodate the storage requirements / requests
- Sharding – balances the workload distribution over the clusters in the distributed environment
- High Availability – due to its distributed nature, there is no single point of failure. Replication promises the high availability
- Better Throughput – offer better throughput to even high volume data than RDBMS
- Faster Performance – facilitate faster performance for big data than RDBMS

NoSQL is a popular language due to its enormous storage capacity as well as the following characteristics that set it apart from SQL.

- ACID Free: The acronym ACID stands for atomicity, consistency, isolation, and durability and supports the SQL transaction notion [6, 7]. NoSQL, a distributed database, provides improved data storage by relying on consistency but does not guarantee ACID properties.
- BASE: BASE stands for fundamentally available, soft state (data may vary over time), and finally consistency. It assures a high degree of availability through replication (no requirement to have identical copies in all nodes for all the time). In order to prioritize availability above consistency, eBay proposed this database design behavior, and NoSQL adopts it [6-9].
- CAP: Eric Brewer proposed the CAP theorem at a symposium on the fundamentals of distributed computing in 2000. It states that in network shared data systems, there is a trade-off between consistency, availability, and partition tolerance. BASE, which is a reverse notion of ACID and it is derived from the CAP theorem, is not feasible to hold up in distributed database, any two only achievable at time [6, 8] and depicted in Fig. 1.

Fig. 1. Visual representation of CAP theorem.

The rest of the paper is organized as follows: In Section II the significant past efforts made are analyzed and the basic detail about migration is discussed. The Section III discusses the migration algorithm in high interest. Section IV discloses the results obtained out of the device and Section V is intended to conclude the work.

II. Literature Review

A. Motivations for Migration Model

The latest and well-known initiatives to convert relational databases to NoSQL databases in order to address the emerging demand of modern applications have been thoroughly examined and are given in this section.

For the effective conversion of relational data into non-relational ones, the researchers offered a variety of methodologies, including data model-based, cloud-based, layer-based, web-based, and cross query engine based ones [10]. According to a research article by Liana Stanescu et al. [11], a base algorithmic view, the necessity of converting MySQL, a relational database, to a NoSQL database, nurturing the features of Mongo DB through addressing the fundamental principles to be followed in the transformation process, was elaborately captured.

Also, a framework was created using the NET platform, and an algorithm was created. The effectiveness of the algorithm was assessed based on the execution time of Create, Read, Update, and Delete (CRUD) operations over the databases provided with different workloads [12, 13]. The tuples are projected as documents, the columns are shown as fields in Mongo DB, and each MySQL database is represented as a collection. Using either embedding or referencing techniques, the key relationships in MySQL should be translated into Mongo DB.

Mahamood [14] described a method and created an interface using VB. Net that automatically converts Microsoft SQL Server tables to Mongo DB collections, in a manner comparable to the work mentioned with Liana Stanescu et al. [13].

Researchers Gyorodi, Kumar, Krishnan and Nair also conducted performance evaluations of MySQL and Mongo DB [15-18]. The results of the experiment demonstrated Mongo DB's superior efficiency. Additionally, the effectiveness is confirmed using the Yahoo Cloud Server Benchmarking (YCSB) tool by Kumar and Chakraborttii [19-20]. Saber et al. [21] discussed the efficiency of Mongo DB for handling Internet of Things (IoT) data in comparison to relational databases.

Singh [22] created a data conversion method that converts relational databases into Mongo DB collections and was discovered to be a successful pattern for cloud storage. In addition to the data transformation paradigm, Bajwa et al. [23] suggested data cleaning methods. A query-based transformation module to move from relational to non-relational data was developed by Al-Mahruqi et al. [24] and is designed to be used with apps.

B. Elemental Facts on Migration Model

The tables in MySQL databases are transformed into a collection of documents like in Mongo DB throughout the migration process, which is illustrated in Fig. 2 as a general process flow.

The mentioned transformation by Liana Stanestcu et al. [11-13] uses the metadata information of relational data bases and influences the Entity Relationship (ER) model, maps the key relations (1:1, 1: N, and M: N) found in RDBMS that are framed using primary and foreign keys against the relationship models in Mongo DB as embedding and referenced or linking.

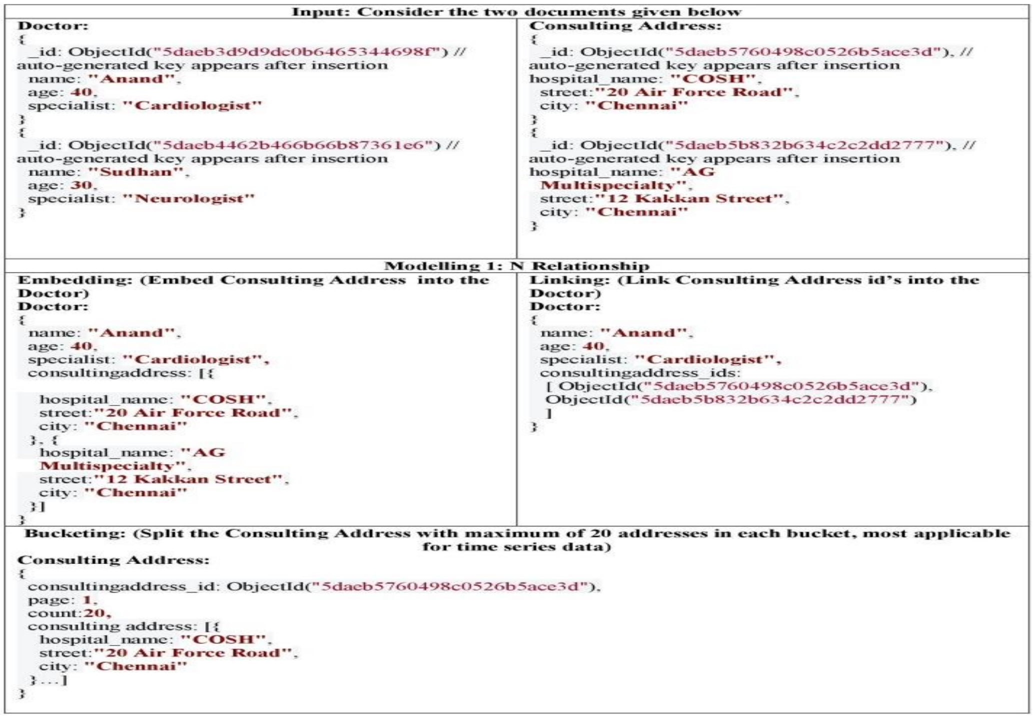
Fig. 2. The generic flow of migration process.

The following discusses in depth the various Mongo DB schema designs that might be used to reproduce the established RDBMS relationships and their recommended method of implementation [25, 26] by Gopinath et al. 2017, Yassine & Awad 2018.

In Mongo DB, there are only two modeling options for one-to-one (1:1) relationships: embedding or linking. When a document is embedded using arrays inside another document, all associated documents are shown as a single document. The embedding strategy increases data size, affects write performance, but makes retrieval simpler because it is combined with a single read. Although though documents are maintained separately, linking involves referencing one document's id through a field in another document using an automatically created key since relational databases store the data using foreign keys. In contrast to embedding, it shrinks the data yet affects read performance. Embedding is the best option because it offers effective retrieval.

There are three different techniques to model the one-to-many (1: N) relationship: embedding, linking, and bucketing. The first two still function. While bucketing is a third strategy that conforms to efficient retrieval while combining the advantages of embedding and connecting through slicing data into buckets with set data limits. Time series data applications benefit from bucketing. The methods for modeling the 1: N connection that was covered is depicted as a code snippet in Fig. 3.



Input: Consider the two documents given below

Doctor:
```
{
 _id: ObjectId("5daeb3d9d9dc0b6465344698f") //
auto-generated key appears after insertion
 name: "Anand",
 age: 40,
 specialist: "Cardiologist"
}
{
 _id: ObjectId("5daeb4462b466b66b87361e6") //
auto-generated key appears after insertion
 name: "Sudhan",
 age: 30,
 specialist: "Neurologist"
}
```

Consulting Address:
```
{
 _id: ObjectId("5daeb5760498c0526b5ace3d"), //
auto-generated key appears after insertion
hospital_name: "COSH",
 street:"20 Air Force Road",
 city: "Chennai"
}
{
 _id: ObjectId("5daeb5b832b634c2c2dd2777"), //
auto-generated key appears after insertion
hospital_name: "AG
 Multispecialty",
 street:"12 Kakkan Street",
 city: "Chennai"
}
```

Modelling 1: N Relationship

Embedding: (Embed Consulting Address into the Doctor)
Doctor:
```
{
 name: "Anand",
 age: 40,
 specialist: "Cardiologist",
 consultingaddress: [{

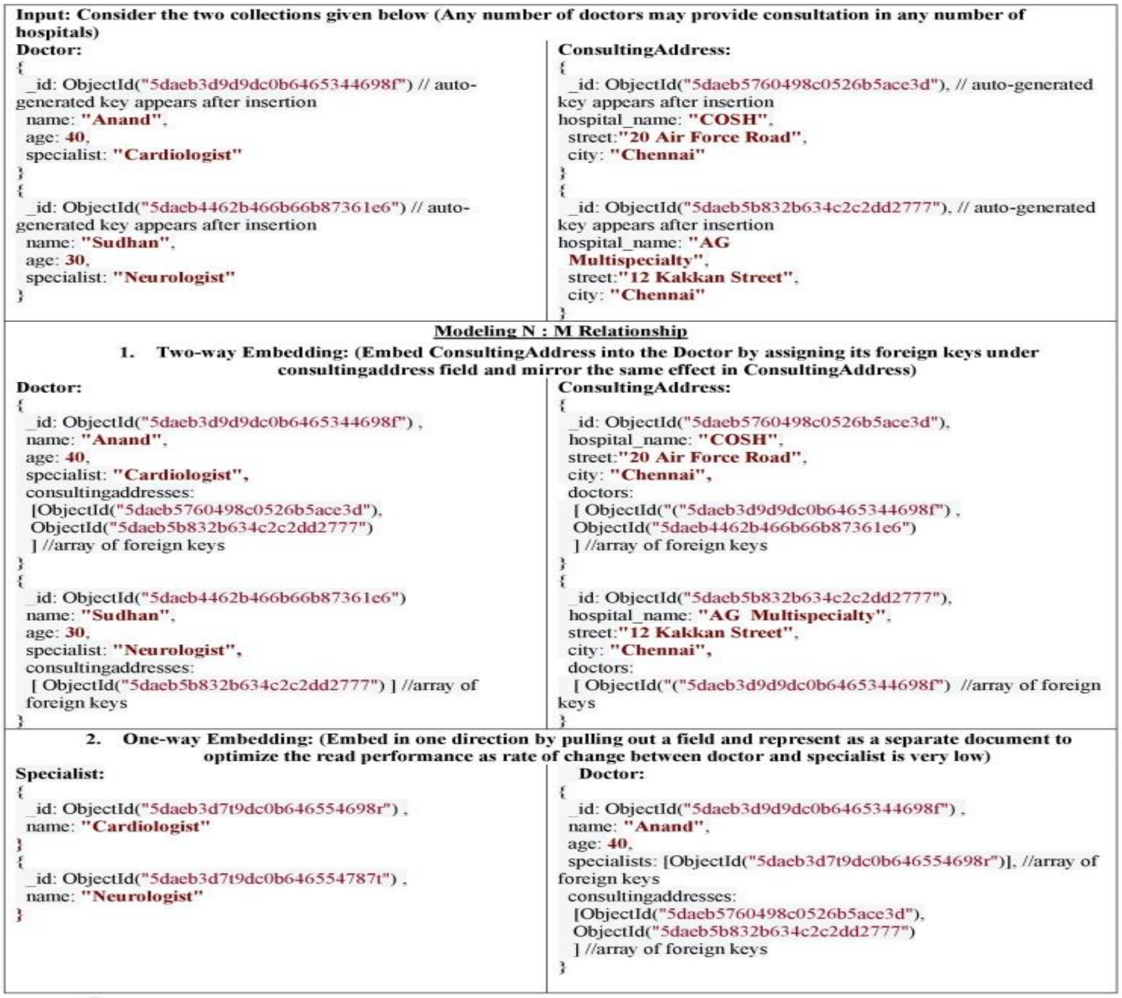
   hospital_name: "COSH",
   street:"20 Air Force Road",
   city: "Chennai"
  }, {
   hospital_name: "AG
   Multispecialty",
   street:"12 Kakkan Street",
   city: "Chennai"
  }]
}
```

Linking: (Link Consulting Address id's into the Doctor)
Doctor:
```
{
 name: "Anand",
 age: 40,
 specialist: "Cardiologist",
 consultingaddress_ids:
  [ ObjectId("5daeb5760498c0526b5ace3d"),
  ObjectId("5daeb5b832b634c2c2dd2777")
   ]
}
```

Bucketing: (Split the Consulting Address with maximum of 20 addresses in each bucket, most applicable for time series data)
Consulting Address:
```
{
 consultingaddress_id: ObjectId("5daeb5760498c0526b5ace3d"),
 page: 1,
 count:20,
 consulting address: [{
   hospital_name: "COSH",
   street:"20 Air Force Road",
   city: "Chennai"
  }...]
}
```

Fig. 3. Strategies to map 1: N relationship in Mongo DB.

The Fig. 4 illustrates two modeling approaches that are commonly used to represent many-to-many (M: N) relationships: two-way embedding and one-way embedding. In two-way embedding, one can insert one document into another by mirroring the foreign keys of the two documents in each field. When the size of the one-way embedding is extremely imbalanced, it is found to be useful as an optimal solution because it only enables embedding in one direction.



Input: Consider the two collections given below (Any number of doctors may provide consultation in any number of hospitals)

Doctor:

```
{
 _id: ObjectId("5daeb3d9d9dc0b6465344698f") // auto-
generated key appears after insertion
 name: "Anand",
 age: 40,
 specialist: "Cardiologist"
}
{
 _id: ObjectId("5daeb4462b466b66b87361e6") // auto-
generated key appears after insertion
 name: "Sudhan",
 age: 30,
 specialist: "Neurologist"
}
```

ConsultingAddress:

```
{
 _id: ObjectId("5daeb5760498c0526b5ace3d"), // auto-generated
key appears after insertion
hospital_name: "COSH",
 street:"20 Air Force Road",
 city: "Chennai"
}
{
 _id: ObjectId("5daeb5b832b634c2c2dd2777"), // auto-generated
key appears after insertion
hospital_name: "AG
 Multispecialty",
 street:"12 Kakkan Street",
 city: "Chennai"
}
```

Modeling N : M Relationship

1. Two-way Embedding: (Embed ConsultingAddress into the Doctor by assigning its foreign keys under consultingaddress field and mirror the same effect in ConsultingAddress)

Doctor:

```
{
 _id: ObjectId("5daeb3d9d9dc0b6465344698f") ,
 name: "Anand",
 age: 40,
 specialist: "Cardiologist",
 consultingaddresses:
  [ObjectId("5daeb5760498c0526b5ace3d"),
  ObjectId("5daeb5b832b634c2c2dd2777")
  ] //array of foreign keys
}
{
 _id: ObjectId("5daeb4462b466b66b87361e6")
 name: "Sudhan",
 age: 30,
 specialist: "Neurologist",
 consultingaddresses:
  [ ObjectId("5daeb5b832b634c2c2dd2777") ] //array of
 foreign keys
}
```

ConsultingAddress:

```
{
 _id: ObjectId("5daeb5760498c0526b5ace3d"),
 hospital_name: "COSH",
 street:"20 Air Force Road",
 city: "Chennai",
 doctors:
  [ ObjectId("("5daeb3d9d9dc0b6465344698f") ,
  ObjectId("5daeb4462b466b66b87361e6")
  ] //array of foreign keys
}
{
 _id: ObjectId("5daeb5b832b634c2c2dd2777"),
 hospital_name: "AG  Multispecialty",
 street:"12 Kakkan Street",
 city: "Chennai",
 doctors:
  [ ObjectId("("5daeb3d9d9dc0b6465344698f")  //array of foreign
keys
}
```

2. One-way Embedding: (Embed in one direction by pulling out a field and represent as a separate document to optimize the read performance as rate of change between doctor and specialist is very low)

Specialist:

```
{
 _id: ObjectId("5daeb3d7t9dc0b646554698r") ,
 name: "Cardiologist"
}
{
 _id: ObjectId("5daeb3d7t9dc0b646554787t") ,
 name: "Neurologist"
}
```

Doctor:

```
{
 _id: ObjectId("5daeb3d9d9dc0b6465344698f") ,
 name: "Anand",
 age: 40,
 specialists: [ObjectId("5daeb3d7t9dc0b646554698r")], //array of
foreign keys
 consultingaddresses:
  [ObjectId("5daeb5760498c0526b5ace3d"),
  ObjectId("5daeb5b832b634c2c2dd2777")
  ] //array of foreign keys
}
```

Fig. 4. Methodologies to map M: N relationship in Mongo DB.

C. Identified Research Gaps

The major efforts are for converting MySQL to Mongo DB was realized in [10-14, 22-26]. In most of the attempts, transformation mechanism was rooted from its schema design. The data type and key relationship exists between the tables plays an significant role in deciding the transformation strategy. Moreover the conversion is automated through an interface developed. In addition to key-relationship, table volume can be utilized in order to take precise decision about opting for embedding or linking. No existing work focused on time series data. By accounting current data type utilized in modern applications, the proposed work provided an automated database conversion solution for time series data.

III. AUTO JSON: A MIGRATION MODEL

The proposed work employs MySQL as a source database and selects Mongo DB as the destination NOSQL database based on inspiration drawn from related contributions listed in the preceding section. The proposed algorithm that automates the transformation of tables in source to collections in desired database is discussed in this section elaborating the data with the execution environment used for it.

A. Hospital Management System: A Source Database

A software program known as a hospital management system controls medical setup operations without the need of paper. The HMS incorporates all pertinent data, including those on doctors, patients, and related services. A hypothetical hospital administration scenario is used as the input database, and Fig. 5 depicts the appropriate relationships between the tables in the database.

Five tables make up the database, and connectors are used to create the relationship between the tables. Each class's primary key attribute is represented by the first entry in that class. It is beyond of scope to go into depth about class functions.

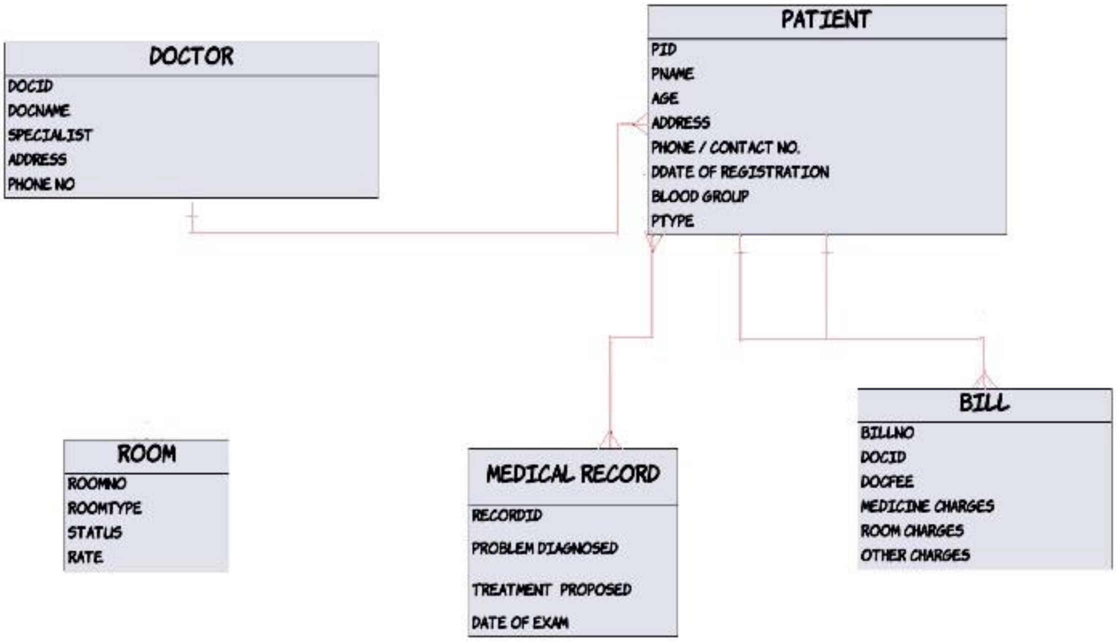


Fig. 5. A class diagram of typical HMS.

B. Migration Algorithm

Tables can be converted into collections using the suggested method's options for bucketing, embedding, linking, one-way embedding, and two-way embedding.

TABLE I. ALGORITHMIC STEPS FOR AUTO MIGRATION ALGORITHM

```
Algorithm 1: Auto JSON (SQL DB, Relationship _Mode,
Table_Volume, Data _Type)
Input: Relational Table (MySQL)
Output: JSON Documents (Mongo DB)
Extract meta data of  SQL DB
Observe the data pattern and relationship exists among the tables
  | if(Relationship_Mode == 1:1 && Table_Volume==High) then
  |     Perform Linking
  | else if (Relationship_Mode == 1: N && Data_type==
  |          Time_series) then
  |     Perform Bucketing
  | else if (Relationship_Mode == 1: N && Data_type!=
  |          Time_series) then
  |     Perform Linking
  | else if (Relationship_Mode == M: N  &&
  |          Table_Volume==High) then
  |     Perform Two Way Embedding
  | else if (Relationship_Mode == M: N  &&
  |          Table_Volume==Low) then
  |     Perform One Way Embedding
  | else
  |     Perform Embedding
Return the Collections in Mongo DB
```

The decision is significantly impacted by a number of factors, including table size, data type, and relationship method. These parameters are referenced about using meta-data that is given in the source database's information schema. Previous attempts focused on the sort of relation that already existed with keys between tables and left out any consideration for the data's nature or table volume. The proposed research optimizes the selection of transformation by taking these aspects into account, as shown in Table I.

The Extract, Transform, and Load (ETL) principle underlies the migration algorithm's operation. In order to convert tables into JSON collections, the meta-data of the table schema must first be extracted. Careful consideration of the schema information, such as field type, table volume, and relationship type, enables selection of options like linking, embedding, bucketing, and one-way or two-way embedding. Lastly, the collections are uploaded to a cloud storage system for further data analytics. Without installing the underlying database packages, the migration method automates the conversion of relational model tables to collections of non-relational model tables.

IV. RESULTS AND DISCUSSIONS

This section provides the details on the experimentation environment, evaluation methodologies and metrics to demonstrate the performance of the proposed migration strategy.

A. Experimetation Setup

The Auto JSON algorithm is coded as python program and executed on the Mongo DB ATLAS platform. Mongo DB ATLAS is a cloud database as a service (DBaaS) contributed by the Mongo DB. It has various provisions listed as follows.

- Provides all the features of Mongo DB
- Simplifies the automation process without overlooking the infrastructure, configuration of database, backups and so on.

- Ensures security and privacy.
- Facilitates choice of deploying the generated database in one of the platforms like Amazon Web Services (AWS), Google Cloud Platform (GCP) or Microsoft Azure.

B. Dataset and Queries for Evaluation

Evaluation is done using data that is in line with the hospital management system described in the preceding section. Compared to creation and read/retrieve, the scope for updating and deleting a record is minimal. The common users are restricted with the read-only and other security privileges. Hence, the following fundamental actions were picked to demonstrate the efficacy of the migration model that converts SQLDB to Mongo DB:

- Create with Insert
- Select

Among various DB functions, create function only allocates the space for data whereas the insertion command only populates the data into the space preserved by create. The delete command removes the entry from the space. Likewise the update command attempts to accommodate few changes on the data. The transformation task has its major focus on creating and presenting the same as JSON collections of Mongo DB. Here create function means a allocating a space provided with the data by means of insertion. Thus the comparative analysis of migration algorithm from MySQL and Mongo DB is captured by means of projecting the efficiency with respect to the basic operations named Create and Select.

The steps taken to record the performance of the suggested migration model is listed as follows:

- Register for a Mongo DB ATLAS user account.
- Put in the required libraries to assist migration.
  - pip install jsonmerge
  - pip install pymongo
  - pip install sqlalchemy
- Use Python to create the SQLDB code .
- Transform to Mongo DB Collection by running the migration algorithm in python as illustrated in Fig. 6.

C. Performance Evaluation

The primary objective of the proposed work is to improve the efficiency in terms of execution time and memory utilization. In general execution or response time with respect to the database operations is calculated by accounting the time of observing the result set from the query initiation time. As aligned with this, the formula to evaluate response time is given in Eq. (1).

$$R_T = Q_C - Q_I \quad (1)$$

Where R_T is the response time, Q_C is for query completion time and Q_I is known as query initiation time. In this case, the query is simply initiated by selecting a transformation operation, and it is completed by collecting the appropriate result set as collections. Since the source database contains non-time series data, bucketing is no longer within the purview of this project. The Fig. 7 displays the execution time plot of transformation operations.

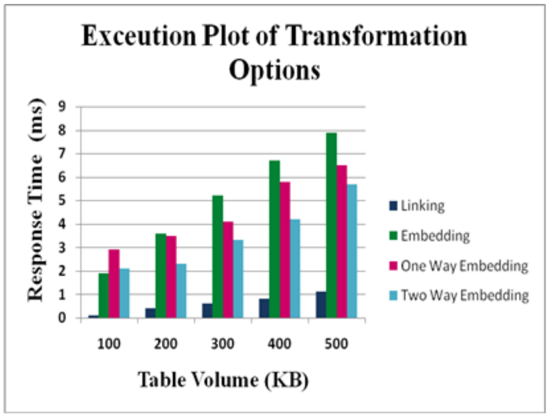

Fig. 7. Execution plot of transformation operations.

The next important metrics is demonstrating the effective memory utilization of the proposed algorithm. This is derived by invoking a comparison over consumption of memory against source and destination database. The effective memory utilization of proposed algorithm is formulated in Eq. (2) and pictorial representation is illustrated in Fig. 8.

$$MEU = (MC / MR) * 100 \quad (2)$$

Where M_{EU} stands for effective memory utilization, M_C denotes memory consumptions observed in Mongo DB collections and M_R gives memory consumptions observed in MySQL relations.

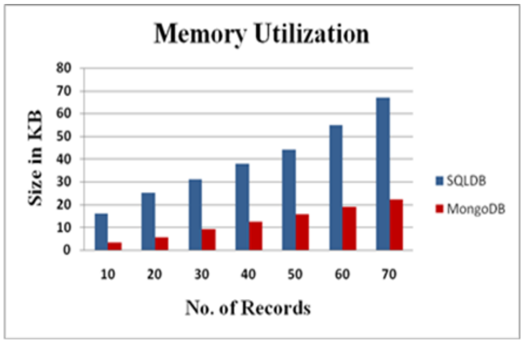

Fig. 8. Comparative analysis of memory usage.

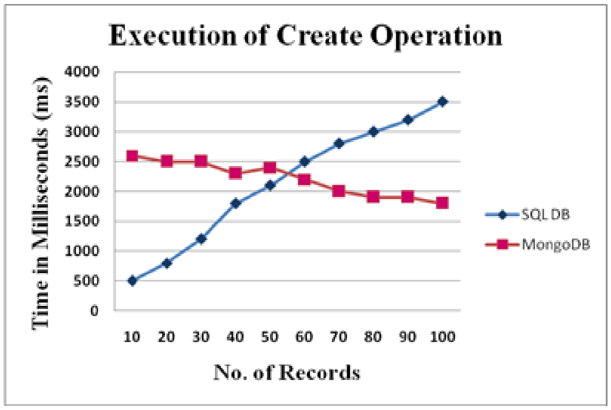

Fig. 9. Evaluated result of create operation.

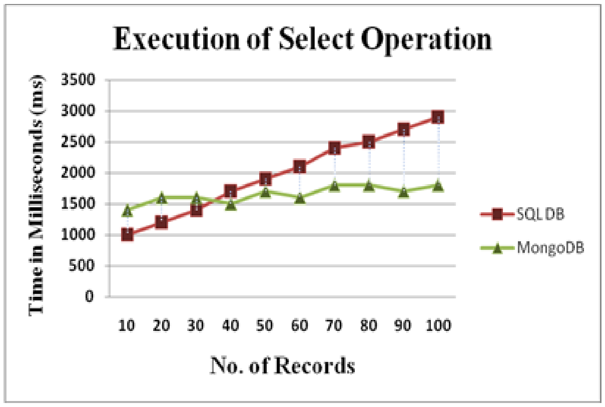

Fig. 10. Assessment map of select operation.

With respect to memory usage, Mongo DB preserves approximately 30% of memory as average when compared to MySQL. The efficiency mappings in association with basic queries into consideration are portrayed as Fig. 9 and 10, respectively.

V. Conclusion

It comes as no surprise that cloud and data storage provides enormous data storage that is compatible with ZB as well as mobile phones that provide storage in addition to 256 gigabytes (GB). A reliable, available, intact, quick, and secure database is necessary to extract intelligent information from this vast amount of data. The ideal substitute for handling massive data in multiple phases, such as transmission, storage, and analysis, is Mongo DB. Based on its schema information, an effort is performed here to convert the columnar SQL data to Mongo DB collections. The earlier methods mainly focused on relationship mode obtained by key and ignored the data volume and nature. Table type and size play important roles in selecting an appropriate transformation choice in this method.

The developed migration mechanism is tested using Python programming in the Mongo DB ATLAS environment. It captures the responsiveness in terms of transformation and query execution efficiency. A faster reaction is made possible by linking, which is 5.9% faster than two-way embedding, 7.6% faster than one-way embedding, and 8.4% faster than embedding. As comparison to the average relational table, the create operation performs 10% faster, and the select operation executes 13% faster. With relational databases taken into account, the memory utilization ratio of the migration procedure is estimated to be 30% on average.

In future the effectiveness of proposed migration model can be evaluated with complex queries including Update and Delete involving time-series data.

Authors' Contribution

Author 1 implemented the concept and drafted the article with assistance of authors 3 and 4, respectively. The author 2 reviewed the article.

Conflict of Interest

***Abstract*—The Internet of Things (IoT) is an innovative technology that connects the digital and physical worlds as well as allows physical devices capable of different capacities to share resources to accomplish tasks. Most IoT objects have limited battery life and are heterogeneous. Assignment of these objects is, therefore, extremely challenging. Energy consumption and reliability are the primary objectives of task allocation algorithms. We present an optimization solution to the IoT task allocation problem based on the krill herd algorithm. The algorithm increases the energy efficiency and stability of the network while providing a reliable task allocation solution. An extensive test of the proposed algorithm has been conducted using the MATLAB simulator. Compared to the most relevant method in the literature, our algorithm provides a higher level of energy efficiency.**

Keywords—Internet of things; resource allocation; task scheduling; energy efficiency

I. INTRODUCTION

In recent years, the rapid development of wireless and emerging technologies, particularly the Internet of Things (IoT), Blockchain [1], 5G connectivity [2], cloud computing, smart grids [3], optical networks [4, 5], machine learning [6], and artificial intelligence [7, 8] has provided many advantages. The IoT has recently been praised as a major technological advancement. As the name implies, it is a system specifically designed to connect computers, electronic and mechanical devices, and items equipped with unique identifiers capable of transmitting data over computer-to-human or human-to-human relationships [9]. Its primary goal is to mobilize network components for active cooperation and to make their resources available for certain applications. Developing the IoT sample requires the coordination and execution of smart items and the ability to interoperate significantly [10]. The concept of interoperability describes how nodes collaborate in a collaborative application using resources, including storage, processing, electrical energy, and object potential, to accomplish a task [11]. A crucial issue in IoT is task allocation, in which tasks can be executed within certain boundaries [12]. The task assignment aims to increase network performance [13]. IoT presents many challenges due to its heterogeneity, scale, properties, continuous processing, and shared sense [14]. The task allocation process cannot be completed in a centralized manner, with frequent scenarios being adjusted [15]. The IoT consists of ubiquitous networking involving many nodes spread across a wide area [16]. The quick changes in the network make it impossible for nodes to determine network topology. Therefore, integrating nodes and reconfiguring them are challenging. IoT task allocation is a common NP-hard problem. Solving this problem requires a meta-heuristic algorithm [17].

Customer service quality is adversely affected by IoT task allocation. Performance and quality of responses will be greatly impacted by how these tasks are performed, or in other words, how resources are allocated to requests. Based on evolutionary algorithms, various methods for allocating tasks in the IoT exist. Among the best ways to improve IoT device performance is to implement better resource allocation algorithms, which would decrease operational costs and reduce communication delays. According to [18], a better task allocation solution can lead to IoT devices providing users or information systems with enhanced services. Finding a final solution to an NP-hard problem takes substantial computation time. By employing an intelligent guessing strategy, meta-heuristic algorithms can quickly find optimal solutions to task allocation. Meta-heuristic algorithms are much faster than algorithms that evaluate all possible solutions sequentially. Meta-heuristic algorithms usually produce better results than greedy algorithms.

IoT paradigm realization requires the development of cooperative intelligent objects with key interoperability capabilities. Among these interoperability characteristics is the coordination among nodes in order to develop and deploy applications collaboratively, taking into account the limited resources available for a given task, such as electrical energy, memory, processing, and object capability [19]. IoT task allocation is crucial in finding a perfect match between scheduled tasks of an application and Edge-based devices to ensure instant response and efficient utilization of resources. In order to avoid problems concerning energy consumption and response time, we need a protocol for optimizing the process of allocating processing devices to tasks. This problem is considered an NP-hard problem.

In recent years, some studies have solved the task allocation problem using different meta-heuristic algorithms [20, 21]. Although meta-heuristic algorithms usually produce superior results than conventional methods, many areas remain to be improved. Our primary objective is to propose an improved meta-heuristic algorithm for solving the IoT task allocation issue. Our contributions include the following:

- When searching for the best nodes to execute tasks, two criteria are considered: the optimal path length (the number of hops between the first and last node of a task execution) and the capabilities of nodes correspond or near to the task capabilities.

- The krill herd algorithm is used to verify both parameters and determine the best path nodes.
- Assign task allocation capabilities to the nodes on the best path.

The remaining sections of the paper are organized in the following manner. The Section II outlines IoT challenges and reviews previous IoT task allocation methods. A detailed description of the proposed method appears in Section III. The results of the experiments are presented in Section IV. The paper is concluded in Section V.

II. Background

A. IoT Challenges

IoT presents many technical and management challenges, despite its ability to create a billion-device network. Most of these challenges can be summed up as follows.

- Security and privacy: As the IoT evolves new security and privacy challenges arise due to applications implemented and objects communicating over lossy networks. Due to IoT devices' limited power and processing capacity, it is not easy to apply encryption algorithms [22].
- Management: In IoT, devices must be deployed, provisioned, configured, controlled, monitored, diagnosed, updated, and regularly maintained [23].
- Availability: As new devices, services, and connected things emerge, accessing the desired node presents a challenge [24].
- Scalability: The architecture of an IoT network can change at any time as new nodes are added. The scalability of nodes needs to be verified by forming a global architecture. The solution should address different aspects of the problem [25].
- Mobility: Device mobility in IoT brings challenges, and IoT must ensure continuous global connectivity without disrupting communications [26].
- Reliability: IoT platforms, applications, and systems must be fully operational, aggregate data from multiple sources, and rely on reliable communication protocols. Constraint nodes should be able to respond quickly to an emergency at any time [27].
- Interoperability: As IoT devices have a wide range of platforms, protocols, and systems, the challenge is interoperating these heterogeneous platforms, protocols, and systems. Interoperability refers to the ability of nodes to exchange information [28].
- Low power energy communication: In IoT devices, low power consumption leads to long life cycles, low leakage currents, low charge-discharge rates, and quick startup times. Utilizing other energy resources or using lightweight algorithms can reduce overall power consumption [29].

B. IoT Task Allocation

Colistra, Pilloni [30] discussed the resource allocation issue for distributed IoT applications and middleware architectures that could provide solutions. Additionally, a consensus protocol was proposed for distributing the execution load among network objects to allocate resources efficiently. A homogeneous allocation of resources among nodes is demonstrated using the proposed protocol. Compared to the optimal allocation obtained with a centralized method, the algorithm converges with about a 6% error based on simulations and real-world experiments.

Khalil, Ozdemir [31] formulated the task allocation problem as an optimization problem with a single objective of reducing energy consumption. They proposed two approaches based on different objectives. These protocols are then injected with heterogeneity-aware heuristics that account for the different energy levels of network entities. To maximize the stability periods, they developed two more protocols, which reduce the interval before each virtual object dies. Different measurements and benchmarking parameters are used to evaluate the proposed protocols, and they are compared with the most relevant algorithms available. Regarding stability and energy consumption, the proposed protocols outperform existing work in the literature.

Low-latency IoT services are provided by fog-aided IoT networks, which offload computationally intensive, time-sensitive tasks to fog nodes located in the local area. IoT networks feature enhanced flexibility thanks to battery-limited mobile IoT devices. The QoS of mobile IoT may be degraded due to varying wireless channel conditions. A task allocation algorithm analyzed by Yao and Ansari [32] reduces average task completion latency by distributing tasks to different fog nodes and adapting to different mobile environments constrained by QoS requirements and the power of mobile IoT devices. Integer linear programming is then used to formulate the problem. Collecting mobility patterns and information from the user takes much work. A task allocation algorithm based on online learning was proposed and demonstrated through extensive simulations.

Sensitive delays, efficient resource allocation, and reliable transactions challenge IoT. To address these issues, Xiao, Gao [33] Introduced a blockchain-based IoT architecture that ensures the integrity of resource transactions and service providers' profits. In addition, they proposed the Task Offloading and Resource Allocation (TO-RA) algorithm, which is implemented as smart contracts on the blockchain. Based on blockchain's advantages, the proposed architecture optimizes resource allocation in IoT. To complete task offloading, they proposed a subtask-virtual machine mapping strategy. Then, based on the task offloading strategy, stack cache supplementation was proposed to complete resource allocation and address possible load imbalances in the system. The TO-RA algorithm outperforms conventional approaches regarding efficiency, reliability, and consistency.

The computational model developed by Mebrek and Yassine [34] considers energy consumption and transmission latency when offloading tasks in IoT applications. The competition was modeled as a game in which IoT devices decide how to distribute their tasks based on energy consumption and latency. The authors propose a decentralized task distribution algorithm in which players update their strategies based on the actions of other players. Nash equilibrium is proven to be achieved by the proposed algorithm. The computational model is then evaluated extensively and compared with existing studies.

Najafizadeh, Salajegheh [35] proposed a multi-objective simulated annealing algorithm to secure task allocation on cloud and fog nodes. A goal-programming approach is applied in order to discover a compromise solution. Additionally, a new goal referred to as "client-driven access level and schedule" is created regarding the distribution of tasks between fog and cloud nodes. Compared to moth-flame optimization, tabu search, and PSO algorithms, the proposed algorithm showed improved efficiency regarding deadlines by 50%, accuracy by 88%, and service delivery by 10%.

Hussain and Begh [36] implemented Hybrid Flamingo Search with a Genetic Algorithm (HFSGA) to optimize task scheduling for cost minimization. On seven essential benchmark optimization functions, HFSGA is compared with other well-known optimization algorithms. Furthermore, Friedman Rank Tests are conducted to ascertain the results' significance. It produces better results in terms of task completion percentages, makespan, and costs when implemented. As compared to existing algorithms such as round-robin, genetic, PSO, and ACO, this work shows better results.

Weikert, Steup [37] proposed a multi-objective task assignment method in dynamic IoT networks prone to mobility and failure issues. They combined and improved upon task allocation optimization algorithms for error-prone and mobile networks by predicting future node positions and archiving data to enhance diversity. An elitism mechanism preserves satisfactory outcomes. Consequently, this algorithm allocates IoT tasks despite node failures and considers future node positions simultaneously. Various error rates and mobile node counts are used in the evaluation. The investigation revealed enhanced network lifetime, latency, and availability metrics.

III. Proposed Method

This section proposes an algorithm for solving the problem of task allocation. Two parameters determine the assignment of tasks: the ability to execute subtasks by a given node and the path distance required to execute those subtasks. The issue declaration is defined in the first subsection, and the proposed method is described in detail in the second subsection.

A. Problem Statement

G = (V, E) represents task allocation as a graph, where nodes denote tasks, while edges indicate routes between tasks. A user's applications are divided into numerous tasks with sequential maintenance connections, and tasks are attached using a directed acyclic graph (DAG). The edges are all of the same form (i→j) and i, j∈N. Nodes represent tasks, and edges represent communications between them. *J* cannot be executed until the implementation of i is finished, and once all of its parents are complete, j becomes ready. In an edge from i to j, i is the parent node of j, and j is its child. Each DAG node has a weight corresponding to its computation cost, and each edge has a weight corresponding to its connection cost. An example of a DAG is shown in Fig. 1.

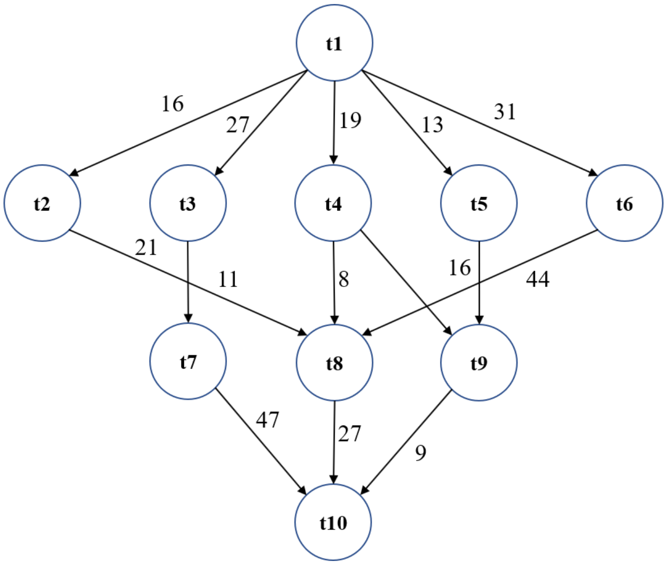

Fig. 1. A simplified DAG for IoT task allocation.

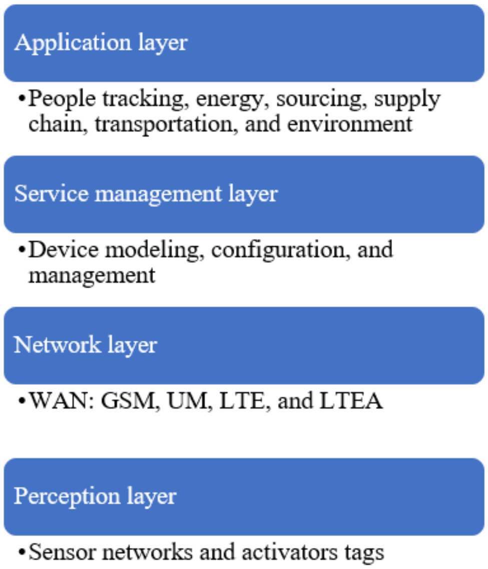

Application layer
•People tracking, energy, sourcing, supply chain, transportation, and environment
Service management layer
•Device modeling, configuration, and management
Network layer
•WAN: GSM, UM, LTE, and LTEA
Perception layer
•Sensor networks and activators tags

Fig. 2. The global IoT architecture.

B. Network Model

As shown in Fig. 2, the adopted IoT architecture for this study includes four layers: perception, network, service management, and application. Low-level tags, such as RFID and bar codes, make up the perception layer. In this layer, sensors and smart devices collect and process information in real time. In the network layer, several technologies are used to provide the necessary networking features. Sensors and smart devices create a high volume of Internet data objects that the embedded features in this layer should support. In the service management layer, information is analyzed, security is controlled, processes are modeled, and devices are managed. Sensor data can be alternated or non-intermittently sent. Task allocation is also part of its responsibilities. The application layer classifies programs based on real-time requirements, business models, convergence, and network type.

C. Krill Herd Algorithm for IoT Task Allocation

The krill herd algorithm solves continuous optimization problems using swarm intelligence. According to some studies, it is more efficient than some existing algorithmic approaches. It is simple to implement, robust, and only requires one control parameter (time interval) compared to other swarm-intelligence methods. The krill herd algorithm searches for food by traversing a multidimensional search space, where krills traverse various variables to make decisions. The distance between rich food and krills corresponds to the cost function. Three operational processes determine the location of a krill individual over time, including motion-induced processes, foraging movements, and random physical diffusion. Krill movements are visualized based on two distance measurements: the minimum distance between a krill and food sources and the least distance between each krill and the biggest herd. An n-dimensional decision space can be expressed in Eq. (1), in which *i*=1 to *nk* represents the number of krills, *Di* represents indiscriminate diffusion, *Fi* represents foraging activity, and *Ni* represents movement caused by other krill individuals. Krill movement can be expressed as Eq. (2). The variables in Eq. (2) are defined in Table I.

$$\frac{dX_i}{dt} = N_i + F_i + D_i \tag{1}$$

$$N_i^{new} = \begin{bmatrix} N^{max}\left\{\sum_{j=1}^{NN}\left[\frac{K_i - K_j}{K_{worst} - K_{best}}\right]\left[\frac{X_j - X_i}{X_j - X_i + \varepsilon}\right]\right\} \\ \left\{2\left(rand + \frac{I}{I_{max}}\right)\overline{K_1, bestX_1, best}\right\} \end{bmatrix} \tag{2}$$

The forager's enjoyment of the food area determines the foraging movement using Eq. (3). Also, Eq. (4) is used to calculate the equation for sensing distances. In these equations, F_i^{old} refers to the last foraging motion, ω_f is inertia weight ranging between 0 and 1, V_f is foraging speed, and N is movement induced by every krill. Krill physical diffusion can be calculated by Eq. (5) as a random process, in which δ is a random directional vector [−1 &1], and D^{max} is the maximum diffusion speed.

$$F_i = V_f\left\{2\left(1 - \frac{I}{I_{max}}\right)\overline{K_1, foodX_1, food} + \overline{K_1, bestX_1, best}\right\} + \omega f F_i^{old} \tag{3}$$

$$d_{s,i} = \frac{1}{5N}\sum_{j=1}^{N}\left\|X_i - X_j\right\| \tag{4}$$

$$D_i = D^{max}\left(1 - \frac{I}{I_{max}}\right)\delta \tag{5}$$

Eq. (6) calculates the position vector, where *UB* and *LB* are upper and lower bounds, C_t is constant between 0 and 2, and *NV* is the variable amount.

$$X_i(t + \Delta t) = X_i(t) + \Delta t\frac{dx_i}{dt} \tag{6}$$

Good results will be obtained when the estimation vector values appear to be optimal. Eq. (7) and (8) provide genetic and mutation operators.

$$X_{i,m} = \begin{cases} X_{r,m} & rand_{i,m} < C_r \\ X_{i,m} & else \end{cases} \tag{7}$$

$$C_r = 0.2\overline{K_{1,best}} \quad r \in \{1,2,\dots,i-1,i+1,\dots,N\}$$

$$X_{i,m}\begin{cases} X_{gbest,m} + \mu\left(X_{p,m} - X_{q,m}\right) & rand_{i,m} < Mu \\ X_{i,m} & else \quad Mu = 0.05/\overline{K_{1,best}} \end{cases} \tag{8}$$

$$p, q \in \{1,2,\dots,i-1,i+1,\dots,K\}\ and\ \mu\ is\ between\ 0\ and\ 1$$

The krill herd algorithm solves the IoT task allocation problem by mapping the solution to the location of the krill group. Assuming T = (T_1, T_2, ..., T_m) and R = (R_1, R_2, ..., R_n), allocation results can be described by matrix x = [x_{ij}], i, j = (1, 2, ..., n), when T_i is allocated on R_j, xij = 1. Alternatively, if the x_{ij} value is 0, they can be used to determine a krill group's position. It simulates induced movement and feeding to determine the optimal location of krill groups so that IoT tasks can be allocated optimally. IoT task allocation using the krill herd algorithm involves the following steps:

- Set parameters for krill herd, such as the maximum number of iterations and the number of krill groups.
- The initial krill group position is generated based on the location of IoT resources. Each position of the krill corresponds to a scheme for allocating IoT resources.
- Obtaining the fitness function for each krill and evaluating the merits and demerits of each krill.
- The speed and position of krills are updated randomly to generate a new population of krills.
- If the termination condition of the algorithm is not satisfied, then proceed to step (4).
- The optimal allocation of IoT tasks is determined by the optimal location of the krill population.

IV. Experimental Results

In this section, a comparative analysis of the suggested task allocation method is presented based on the application DAG as well as connection costs (Fig. 1). The use of MATLAB is attributed to its ability to calculate matrix and calculation functions, perform practical functions, and exchange data with different programming languages. It focuses on computational methods and provides high-level programming capabilities. Mathematical issues in joint academic mathematics are presented in MATLAB. Therefore, MATLAB R2012a is used to simulate the proposed method.

We used the dataset from [38] as a basis for this study. A task allocation policy in the IoT directly impacts application performance and the best use of resources. Identifying the optimal way to assign tasks in the IoT is a significant challenge. The procedure for assigning tasks in the IoT environment is as follows. At first, tasks and resources are mapped based on this task and resource data. Consequently, by mapping resources among tasks, applicators can ensure task yield and QoS. In the end, the submitting user receives an overview of the consequences.

The convergence diagram for the method is shown in Fig. 3. Results show that about 180 generations of the proposed algorithm led to the correct answer. To prove that the proposed algorithm meets the repeatability criteria, it was repeated 20 times, 40 times, 60 times, 80 times, and 100 times. The stability diagram of the proposed algorithm is shown in Fig. 4. It is clear that successive iterations do not produce significantly different results. Consequently, the proposed algorithm is repeatable and robust.

Energy consumption is directly affected by IoT task allocation. Data centers in IoT structures can reduce their energy consumption by moving low- or idle-load servers to other servers, shutting them down, and shifting idle workloads to other servers. Fig. 5 shows the energy consumption of different algorithms for different task counts. According to the results, the suggested algorithm offers greater energy efficiency than others by increasing the number of tasks.

TABLE I. VARIABLES IN EQ. (2)

Variable	Definition
rand	A random number from 0 to 1
N_i^{old}	Final inertial weight
ω_n	Inertial weight in the range of (0,1)
$x_{1,best}$	The corresponding position of $x_{1,best}$ of i^{th} krill
$K_{1,best}$	Finest fitness rate of i^{th} krill
I_{max}	Maximum iteration
N_{max}	Large induced speed in ms^{-1}
ε	Minimum positive number
X	Exact location
K_{best}, K_{worst}	Best case and the worst case of an individual krill
K_j	Value of fitness of the acquaintance (j=1 to NN)

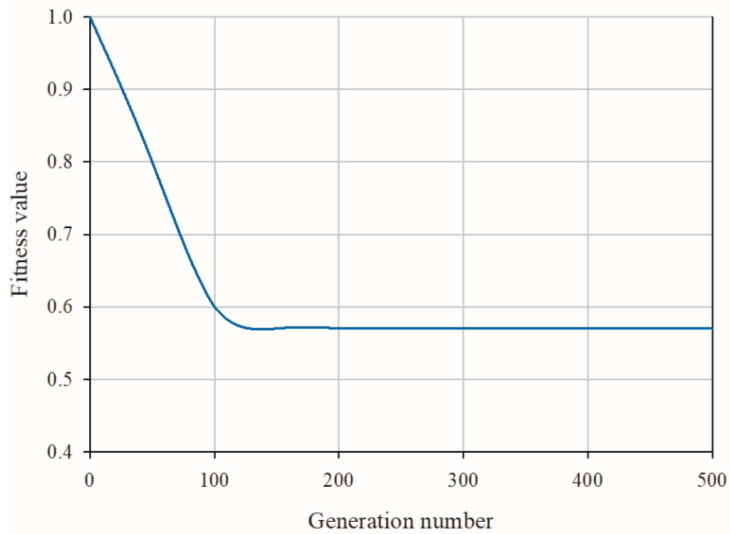

Fig. 3. Convergence diagram of the proposed method.

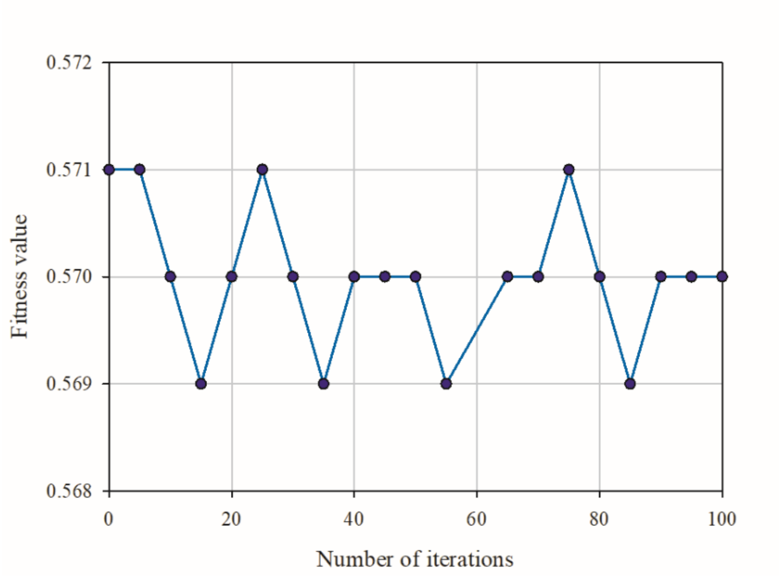

Fig. 4. Stability diagram of the proposed method.

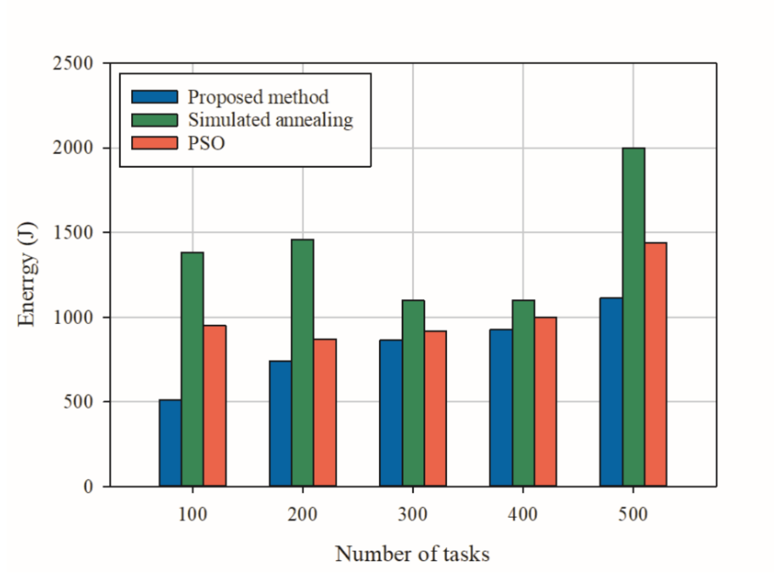

Fig. 5. Energy consumption comparison.

V. Conclusion

The primary objective of most IoT networks is to enable devices with varying capabilities to share their resources and cooperate in order to accomplish a desired function. The majority of IoT objects are heterogeneous in nature and have limited computational and energy capabilities. Consequently, assigning tasks to these objects presents a significant challenge. Most of the existing works in the literature use heuristic optimization techniques to address different aspects of the task allocation problem without taking into account the heterogeneity of the objects or the limits of their resources. This paper aimed to demonstrate the feasibility of developing meta-heuristic algorithms to assign and schedule IoT tasks. Based on the krill herd algorithm, a new method is proposed for scheduling tasks that minimize network latency and ensure energy efficiency. Our solution outperformed other algorithms, such as PSO and simulated annealing, when choosing optimal assignment decision policies for task assignments and scheduling. Further, our approach ensured low-latency communication and energy efficiency by optimizing both local and global processes. We intend to examine the similarity between the task capabilities in future work in order to predict the execution path of the tasks. To achieve even better results, we plan to explore how the task capabilities can be better coordinated by comparing them against one another.

***Abstract*—In recent years, flower growing has developed into a lucrative agricultural sector that provides employment and business opportunities for small and marginal growers in both urban and rural locations in India. One of the most often cultivated flowers for landscaping design is the Marigold flower. It is also widely used to create garlands for ceremonial and social occasions using loose flowers. Understanding the appropriate stage of harvesting for each plant species is essential to ensuring the quality of the flowers after they have been picked. It has been demonstrated that human assessors consistently used a category scoring system to evaluate various flowering stages. Deep learning and convolutional neural networks have the potential to revolutionize agriculture by enabling efficient analysis of large-scale data. In order to address the problem of Marigold flower stages detection and classification in complex real-time field scenarios, this study proposes a fine-tuned Faster RCNN with ResNet50 network coupled with data augmentation. Faster RCNN is a popular deep learning framework for object detection that uses a region proposal network to efficiently identify object locations and features in an image. The Marigold flower dataset was collected from three different Marigold fields in the Anand District of Gujarat State, India. The collection includes of photos that were taken outdoors in natural light at various heights, angles, and distances. We have developed and fine-tuned a Faster RCNN detection and classification model to be particularly sensitive to Marigold flowers, and we have compared the generated method's performance to that of other cutting-edge models to determine its accuracy and effectiveness.**

Keywords—Deep learning; convolutional neural networks; object detection; marigold flower blooming stage detection

I. Introduction

One of the main economic pillars in India is agriculture. For roughly 58% of Indians, agriculture is their main source of income. The field of horticulture known as "flower farming," also referred to as "floriculture," deals with the study of cultivating and selling flowers and foliage plants. It primarily focuses on growing ornamental plants, cultivated greens, potted flowering plants, tubers, rooted cuttings, cut flowers, and other floriculture products. In recent years, flower farming has become a successful agriculture industry that offers employment and entrepreneurship prospects in both urban and rural areas, as well as for small and marginal farmers [1]. One of the most often cultivated flowers for garden ornamentation is the Marigold, which is also widely used as loose flowers to create garlands for ceremonial and social occasions. The Marigold is one of the most popularly grown flowers for landscape decoration. It is also frequently used as loose flowers to make garlands for ceremonial and social occasions. Marigold is mostly used to treat various skin disorders, such as varicose veins, contusions, and bruises. Additionally, inflammation and minor skin wounds can be successfully addressed. Marigold cream aids in the healing of sunburns and eczema wounds. Marigold farming is a profitable activity that requires little maintenance and effort. Marigold cultivation is a profitable activity as it requires less investment and gives better harvest with a high profit [2].

To guarantee the quality of the flowers after harvest, it is crucial to understand the ideal stage of harvesting for each plant type. The flower's life is considerably decreased when it is harvested too early or too late. A flower normally becomes larger as it progresses from bud to bloom. A flower like a daisy, Marigolds can only be picked when completely opened [3].

Identifying the plant flowering status have traditionally needed human evaluators to manually inspect flower fields and report flowering status. It has been shown that human assessors regularly assessed different flowering stages using a category scoring system. For instance, you could want to know when 30% of the flowering plants in a field have blooms that are fully open. This made it possible for researchers to compute the time between various blooming phases [4]. Deep learning advancements and innovations make it possible to quickly characterize the flowering patterns of field-grown plants. It is frequently necessary to regularly spot and count newly opening blooms on plants when cultivating flowers like Marigold.

Marigold farming is a profitable activity as it requires less investment and gives better harvest with a high profit. To guarantee the quality of the flowers after harvest, it is important to understand the ideal stage of harvesting for each plant type. Deep learning advancements and innovations make it possible to quickly characterize the flowering patterns of field-grown plants. Using a cutting-edge object detector called Faster Region-based Convolutional Neural Network, we propose an efficient method to detect and classify Marigold flowers of various stages in diverse field conditions. The proposed method is inspired by successful studies using deep

Convolutional Neural Networks (CNNs) in difficult computer vision and object detection tasks.

This study suggests a Faster RCNN network coupled with image augmentation to address the challenge of Marigold flower stages identification and classification in complicated real-time field situations. In order to detect and classify emerging blooms of Marigold flower plants, the objectives of the study are: (1) To acquire and pre-process images of Marigold flowers in challenging real-time environments; (2) To develop and tune a Faster RCNN detection and classification model to become particularly sensitive to Marigold flowers; and (3) To assess the accuracy and efficacy of the developed approach by comparing its performance to that of other cutting-edge models.

II. Related Work

D. Thi Phuong Chung and D. Van Tai [5] represent a deep learning based technique for fruit detection. They have e EfficientNet architecture that recognized fruit objects from the Fruit 360 dataset and achieved 95% accuracy. A. Rocha et al. [6] introduced a novel method for classification of fruit and vegetables from images. A multi-class fruit-and-vegetable categorization task in a semi-controlled setting, like a distribution centre or the supermarket checkout line, is used to validate the newly presented fusion approach. According to the findings, the solution can lower the classification error by up to 15% compared to the baseline. I. Sa et al. [7] present a novel approach to fruit detection using deep convolutional neural networks. The goal is to develop a fruit detection system as it is a critical component of an autonomous agricultural robotic platform and is essential for estimating fruit production and automating harvesting. They have proposed a multi-modal Faster RCNN model that, when compared to earlier work, delivers state-of-the-art results, with F1 score performance for the detection of sweet pepper increasing from 0.807 to 0.838.

Moreover, T. Abbas et al. [8] mentioned different smartphone applications like LeafSnap [9], and Pl@ntNet [10], that can be used to identify flowers rapidly. I. Patel and S. Patel [11] proposed an optimized deep learning model that detects the flower species. For that, they have integrated Faster RCNN with Neural Network Search and Feature Pyramid. The mAP score obtained on the standard Oxford flower species dataset is 87.6%. D. Wu et al. [12] proposed a methodology for detecting Camellia oleifera Fruit using YOLOv7 object detection model. For the research, they have collected the dataset from the complex scene and applied different evaluation metrics. The values derived for mAP is 96.03%, Precision is 94.76%, Recall is 95.54%, and F1 score is 95.15%. S. Nuanmeesri et al. [13] proposed a novel method that predicts disease from Marigold flower images. The outcome demonstrated that the model created using the watershed dataset is the most effective. The model's validation accuracy was 88.03%, validation loss was 4.21%, and model testing accuracy was 91.67%.

From the literature survey, we have found that deep learning algorithms and models can be applied for detecting objects from real-time environment and it has a great significance and theoretical value. Moreover, there is a need for an automated model that provides improved accuracy and generalization across different growing conditions and environmental factors. There are challenges existed in developing models that can handle the variability in marigold flower appearance across different growing conditions, such as varying lighting, background, or growth stages. This research aimed to develop and propose a more sophisticated model that can handle these challenges and improve the accuracy and generalization of marigold flower blooming stage identification and classification.

III. Materials and Methods

A. Acquisition and Pre-Processing of Marigold Flower Images in Complex Scene Environment

One Canon DSLR Dual Lens Camera and two smartphones were used to capture images of Marigold flowers in the Marigold cultivation agricultural fields under natural daylight illumination. Three distinct agricultural Marigold fields in the Anand District of Gujarat, India, were chosen for the study. Three regular harvesting times in the winter November and December months have chosen for the capturing of images. The collection consists of 550 photos in total, each with a resolution of 4000 by 2250 pixels and taken at various heights, angles, and random distances in natural light conditions. The dataset was captured in two stages. The acquired images are having different conditions like top angled, side angled, heavily occluded, lightly occluded, overlapped, etc. are represented in the Fig. 1.

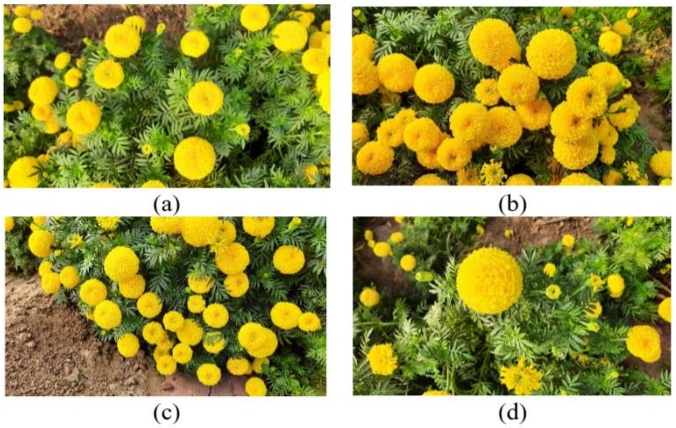

Fig. 1. Examples of Marigold images taken in various settings (a) Occlusion in image, (b) Overlapped marigold flowers and buds, (c) Image captured from side angle (d) Image captured from top angle.

Because they provide the supervised learning algorithm with the training data, image annotations play a key role in computer vision algorithms. Using the graphical image annotation tool namely, LabelImg [14], which is built on Python, the complete dataset was annotated and saved in XML documents. The images are annotated in two classes; bud and flower which are represents and differentiates their growing stages.

B. Data Augmentation

Data augmentation refers to the process of artificially expanding the size of a training dataset by creating modified versions of images in the dataset [15]. This can be useful in object detection, especially for Faster RCNN, as it helps prevent overfitting and can improve the model's ability to generalize to new, unseen data. The most popular technique of fundamental augmentation is geometric transformation [16]. The transformation's parameters may be preset or chosen at random. In this research, the common techniques for data augmentation used are flipping, scaling and rotating. Flipping is the process used to rotate an image either along its vertical axis or along its horizontal axis. In contrast to vertical flipping, which flips the image on the vertical axis, horizontal flipping flips the image on the horizontal axis [17]. An image can be rotated by adding a rotational angle. The image is rotated in a random direction to produce enhanced images. Here, the left and right axes of rotation are chosen at random. The dataset includes an image that can be zoomed in or out. One of the most popular data augmentation techniques is zooming. It is possible to conduct a zoom between 0.5% and 1.0%.

After the data augmentation applied, the final augmented training set consists of 1583 images that help to improve the generalization ability of the detection model and avoid the overfitting of the detection model.

IV. Proposed Model for Marigold Flower Blooming Stage Detection in Complex Scene Environment using Faster RCNN with Data Augmentation

The Fig. 2 represents the stepwise architecture of the proposed model for Marigold flower stages identification and classification.

There are two main types of object detection models: one-stage models and two-stage models. One-stage object detection models, also known as single-shot detectors, are designed to detect objects in a single pass over an input image [18]. These models use a single neural network to simultaneously predict object locations and class labels. Two-stage object detection models, on the other hand, are designed to detect objects in a two-step process. The first step involves generating a set of potential object locations, known as region proposals, using a separate network called a region proposal network (RPN). The second step involves classifying the region proposals and refining their locations using another network. Two-stage models typically achieve higher accuracy than one-stage models, but at the cost of slower inference speed. One-stage models, on the other hand, are faster but can be less accurate, especially for small objects or objects with high aspect ratios [19] [20]. This research is mainly focuses on identifying two stages of Marigold flower growth; fully grown flower and a bud. Bud is a small flower object that is to be detected by the proposed model. Therefore, in this research we have proposed a two-stage object detection model i.e. Faster RCNN.

We are primarily interested in object detection in our study because it is the first step in determining whether a flower is a bud or a fully blown blossom. So, using Faster RCNN, we simulate a particular generic detector. In order to create an effective technique for looking for instances of flowers and buds in a flower image, we make use of the object suggestions trained by an RPN and their associated features derived from a ResNet50 CNN architecture. By combining the convolutional strengths of RPN and Fast RCNN utilising the present neural network formulation, we further combine RPN and Fast RCNN into a coherent model. The feature network, RPN, and detection network are the three deep networks that make up the suggested methodology. A boxing approach used by faster RCNN enables the operator to specify the potential regions that will be introduced into the RPN. With the suggested approach, we begin by performing a CNN model using our dataset of Marigold flowers. After examining the input image, a selective search procedure is then used to extract a region of interest (RoI). The candidates between the closest raster frames are then refined using the prepared deep model to classify the extracted ROIs into candidates.

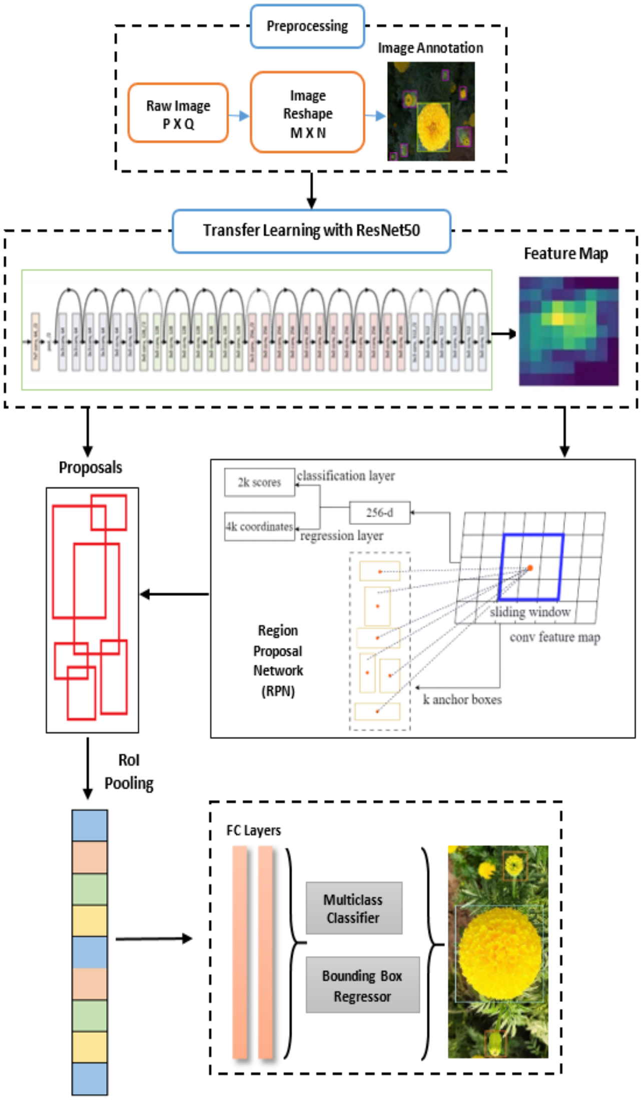

Fig. 2. A proposed two-stage object detection model for marigold flower blooming stage detection in complex scene environment using faster RCNN with data augmentation.

A. Image Pre-Processing and Annotation

In object detection, pre-processing refers to the steps taken to prepare the input data for the object detection model. This may include tasks such as resizing the image, normalizing pixel values, converting the image to grayscale, etc. [21]. In this research, image is reshaped and annotated with two labels i.e. flower and bud. The dataset is splitted into training and validation sets by having a ratio of 90:10. No repeated images among the training, validation and test sets were ensured to prevent overfitting of the model [22] [23].

Image annotation in object detection refers to the process of labeling objects within an image to train a machine learning model for object detection. The annotated data is used to train the model to detect and classify objects within new, unseen images [24]. Image annotation involves drawing bounding boxes around objects of interest and assigning a label to each bounding box. The goal of image annotation is to provide the model with enough data to learn the features and characteristics of different objects, so it can accurately detect them in new images [25]. LabelImg is a graphical image annotation tool that is used to label images for object detection in machine learning. The tool provides an interface for drawing bounding boxes around objects in an image and assigning class labels to the objects. The resulting annotations are saved in an XML file that can be used as input for training machine learning models. The Fig. 1 illustrates the image annotation performed using LabelImg tool. As mentioned earlier, the images are annotated in two classes; bud and flower which are represents and differentiates their growing stages.

Here, a 2D bounding boxes annotation for flower species detection is applied, as illustrated in Fig. 3. The 2D bounding boxes are applied by drawing rectangles or cuboids around flower objects in an image, and then, labels of respective flower classes are applied to them.

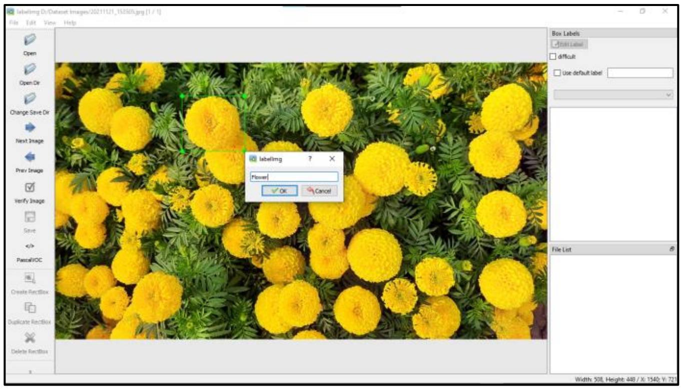

Fig. 3. Image annotation using lableImg.

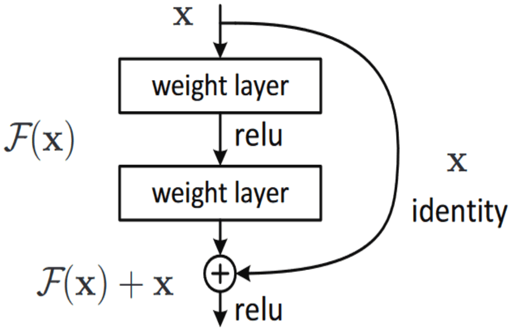
B. Faster RCNN with ResNet50

Faster RCNN is a popular object detection architecture that is used for Marigold flower stages detection. Faster RCNN is a state-of-the-art object detection algorithm that combines the two-stage object detection framework with deep convolutional neural networks [26]. The first stage is a region proposal network (RPN) that generates a set of candidate object regions. These regions are then fed into the second stage, which is a Fast RCNN network that classifies the regions and refines the bounding box locations. The two stages work together to efficiently detect objects in an image by first proposing a large number of potential regions and then using the Fast RCNN network to accurately classify and locate the objects. The key advantage of Faster RCNN is its end-to-end training, which enables it to learn to detect objects directly from image data without relying on heuristics or manually-designed features [27].

The proposed Faster RCNN model with ResNet50 for flower object detection can be divided into the following modules:

1) ResNet50 backbone: This module consists of the pre-trained ResNet50 network that serves as the feature extractor. It takes an image as input and outputs a feature map [28]. In Faster RCNN, the ResNet-50 backbone is used as the feature extractor network to produce a compact feature representation of the input image [29]; the input image being fed into the backbone convolutional neural network. For that, the input image is first resized by considering the shortest px with the longer side not exceeding 1000px. The output of the backbone network is a feature map. These feature maps are then fed into the Fast RCNN network for classification and bounding box regression. The use of a pre-trained ResNet50 network as the feature extractor allows Faster RCNN to leverage the information learned from the large-scale image classification task, improving its object detection performance. Additionally, the use of ResNet50 as a backbone allows for transfer learning, where the feature extractor can be fine-tuned for the specific object detection task using a smaller dataset [30].

With the primary goal of resolving the vanishing/exploding gradient issue, ResNet architecture established the Residual Network concept. The network employs a method known as "skip connection" for that. The ResNet architecture is known for its use of "skip connections" or "shortcut connections" [31]. These skip connections help alleviate the problem of vanishing gradients in very deep neural networks. Skip connections in ResNet work by allowing the network to bypass one or more layers, effectively allowing the gradients to be backpropagated directly to earlier layers as illustrated in Fig. 4. This helps to preserve the information from the original input, making it easier for the network to learn and improve.



x
weight layer
$\mathcal{F}(\mathbf{x})$
relu
weight layer
x
identity
$\mathcal{F}(\mathbf{x}) + \mathbf{x}$
relu

Fig. 4. An illustration of skip connection [32].

Without using skip connection, input 'x', multiplied by the layer's weights, followed by adding a bias term:

$$H(x) = f(wx + b) \tag{1}$$

or

$$H(x) = f(x) \tag{2}$$

With the introduction of skip connection, the output of the layer changes to

$$H(x) = f(x) + x \tag{3}$$

The loss function used in ResNet50, like most of deep learning models, is typically a categorical cross-entropy loss. This loss measures the dissimilarity between the predicted class probabilities and the true class label, and is commonly used for multi-class classification problems. The following is an equation to calculate the categorical cross-entropy [33].

$$Cross - entropy = -\frac{1}{N}\sum_{i=1}^{N} logP_{model}\left[y_i \in C_{y_i}\right] \quad (4)$$

2) Region Proposal Network (RPN): The Region Proposal Network (RPN) is a crucial component of the Faster RCNN object detection framework. Its primary responsibility is to generate a set of candidate object regions in the input image, called region proposals. A region proposal network generates several regional proposals [34]. These proposals submit to the identification network's detection. The three components of RPN are the anchor window, loss function, and set of region proposals [35]. RPN adopts the sliding window methodology because a small sub-network is evaluated on a dense 3x3 sliding window in the RPN design. The IoU ratios and the ground-truth bounding boxes can thus be used by the RPN to produce numerous anchors [36].

The RPN uses anchor boxes, which are predefined bounding box shapes, to guide the generation of the region proposals. The network outputs are then combined with the anchor boxes to produce the final set of region proposals. The step-wise process is described as follows [37]: (i) RPN utilize a sliding window for each region over the feature map. (ii) To generate region proposals, k (k=9) anchor boxes are employed for each site, with 3 scales of 128, 256, and 512 and 3 aspect ratios of 1:1, 1:2, and 2:1. (iii) Whether an object is present or not, a CLS layer produces 2k scores for k boxes. (iv) For the box centre coordinates, width, and height of k boxes, a reg layer outputs 4k. (v) There are WHk anchors overall with a WH feature map size.

The total loss of the RPN is calculated by the multitask loss function. The calculation formula is [38].

$$L(\{p_i\},\{t_i\}) = \frac{1}{N_{cls}}\sum_i L_{cls}\,(p_i,p_i^*) + \lambda\frac{1}{N_{reg}}\sum_i p_i^* L_{reg}\,(t_i,t_i^*) \quad (5)$$

Where N_{cls} represents the number of batch training data, N_{reg} represents the number of anchors, λ represents the balance weight.

$L_{cls}\,(p_i,p_i^*)$ is the logarithmic loss function defined as;

$$L_{cls}\,(p_i,p_i^*) = -\log[\,p_i^* p_i + (1 - p_i^*)(1 - p_i)\,] \quad (6)$$

$p_i^* L_{reg}\,(t_i,t_i^*)$ is the regression loss calculated by the following Smooth L1 function:

$$L_{reg}\,(t_i,t_i^*) = \begin{cases} 0.5\,(t_i - t_i^*)^{\,2}\,, & |\,\mathrm{x}\,| < 1 \\ |t_i - t_i^*| - 0.5, & otherwise \end{cases} \quad (7)$$

Where p_i is the probability of the anchor being predicted as the target, and p_i^* is the truth value of the prediction result: if the anchor is predicted as a positive sample, the value of tag p_i^* is 1; otherwise, the value is 0; $t_i = \{t_x,\ t_y, t_w, t_h\}$ is the location of the predicted detection box; and t_i^* is the ground truth coordinate.

RPN network must therefore check in advance which location contains the object. The detection network will then receive the relevant locations and bounding boxes and use them to identify the object class and deliver the object's bounding box.

3) RoI pooling layer: RoI (Region of Interest) pooling is a technique used in Faster RCNN for processing the region proposals generated by the RPN [39]. RoI pooling is a layer in the Fast RCNN network that takes as input the feature map produced by the ResNet-50 backbone and a set of region proposals. The RoI pooling layer resizes each region proposal to a fixed size, regardless of its original size or aspect ratio, and aggregates the features within each region into a compact feature representation [40]. This enables the Fast RCNN network to perform classification and regression on the objects in the image, regardless of their size and aspect ratio. RoI pooling is critical for Faster RCNN's ability to accurately detect and classify objects of different sizes and aspect ratios in an image. The RoI pooling layer allows the Fast RCNN network to have a fixed input size, making it easier to train and optimize, while still allowing it to handle objects of varying sizes in the image.

4) Fast RCNN classifier and bounding box regressor: In Faster RCNN, after the RoI pooling layer, the features of the region proposals are fed into the classifier and bounding box regressor [41]. The classifier is a fully connected layer that performs object classification by predicting the probability of each region proposal belonging to each of the predefined object classes. The classifier outputs a score for each region proposal and class, indicating the likelihood of the presence of an object of that class in the region. The bounding box regressor is another fully connected layer that performs bounding box regression [42]. It takes as input the feature representation of the region proposals and outputs the adjustments to the locations of the region proposals, refining their locations to better fit the objects in the image.

Together, the classifier and bounding box regressor form the Fast RCNN network, which accurately detects and classifies objects in the image by combining the information from the region proposals, the classifier scores, and the refined bounding box locations.

V. Network Training Platform and Parameter Settings

The experiment is carried out using a machine having NVIDIA Tesla V100 32GB PCIe based GPU card equipped with 64GB RAM and Intel Xeon 6226R processor. It has 4 units of 6TB SATA 7200 RPM 3.5" HDD and it is running with Ubuntu 21.04 operating system. We have used TensorFlow 2 Object Detection API with CUDA 11.2, CuDNN 8.1.0 and Python 3.8 virtual environment.

An illustration of a training pipeline developed for experiment with numerous separate activities is shown in Fig. 5. The image annotation tool is used to build the labelled flower datasets (i.e. LabelImg). All of the datasets for tagged flowers are saved as .csv files, which are then transformed into .record files and used as inputs by the networks to forecast bounding boxes and confidences for objects. TensorFlow's object identification model needs a Label Map that converts each of the applied labels into an integer value. Both the training and evaluation processes use this Label Map. Files with the ending ".pbtxt" are label map files. We have used ResNet50 as a pre-trained CNN and modified the Faster RCNN detection model that is trained using COCO 2017 dataset and made available by Tensorflow Object Detection API - Model Zoo [43]. Finally, loss functions are used to measure the accuracy of the training process and an inference graph are generated at the end of the training pipeline.

Fig. 5. A training pipeline for experiment.

A. Hyperparameters

The model parameter values that a learning algorithm ultimately learns are defined by hyperparameters, which are variables whose values have an impact on the learning process. The selection of hyperparameters that aid in an object identification model's optimum accuracy has an impact on the model's accuracy as well. Therefore, figuring out the best values for these factors is a challenging task [44]. Hyperparameter tuning, often known as optimization, is the process of selecting the best set of parameters for a model's learning procedure [45]. In this research, we have setup multiple hyperparameters such as learning rate, batch size, number of steps, activation function and dropout rate. The learning rate for the proposed model sets to 0.002, the batch size chose was 16. The input size was set to 640 × 640. The training Epoch was set to 1000. During the training process, Tensorboard visualization tool was used to record data and observe loss, and save the model weight of every epoch.

B. Evaluation Indicators of Model

In this study, the model's performance was accurately and impartially assessed using Precision, Recall, Mean Average Precision (mAP), and F1 score. The number of correct targets divided by the total number of targets is known as the precision evaluation index [46]. The detection impact will generally be better the higher the Precision. Precision is a highly logical evaluation metric, however occasionally a high Precision score does not mean everything. Thus, mAP, Recall, and F1 score were developed for thorough examination.

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \; X\ 100 \qquad (8)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \; X\ 100\% \quad (9)$$

$$\text{Average Precision (AP)} = \int_1^0 P(r)\, dr \quad (10)$$

$$\text{Mean Average Precision (mAP)} = \frac{1}{n}\sum_{i=1}^{n} AP_I \qquad (11)$$

Other than above evaluation indicators, IoU is also used. The amount of overlap between the predicted and ground truth bounding boxes is indicated by the IoU value, which ranges from 0 to 1 as described in Fig. 6 [47].

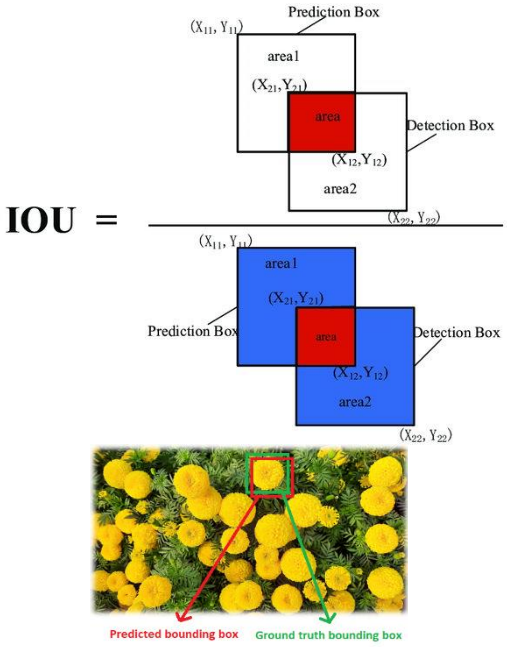

Fig. 6. A description of Intersection-over-Union (IoU)

There is no overlap between the boxes if the IoU is 0. When the union of the boxes equals their overlap and the IoU = 1, this signifies that the boxes are entirely overlapping. The equation for the same is illustrated as Eq. (3).

$$\text{Intersection over Union (IoU)} = \frac{\text{Area of Intersection}}{\text{Area of Union}} \quad (12)$$

VI. Results and Discussion

To experiment, we have used TensorFlow Object Detection API. It is an open-source framework which is built on top of the TensorFlow library, offers a variety of pre-trained object detection models as well as tools for creating and training unique object detection models. The pre-trained models, also known as the Model Zoo, feature various models that are pre-trained on the COCO dataset, which is a large-scale object detection, segmentation, and captioning dataset. We have used the learned weights from these pre-trained model and fine-tuning these pre-trained models on our own Marigold datasets.

The proposed Faster RCNN with ResNet50 model is compared with one-stage object detection model that is SSD (Single Shot Detector). By examining the Faster RCNN of various networks, the training model and the subsequent classification results of mean average precision are obtained and presented in Table I and Table II. We have experimented both of the object detection model with the original dataset and augmented dataset. On the original Marigold dataset, the proposed Faster RCNN with ResNet50 model provides 88.71% mAP score with 4.312 average detection speed per second. SSD MobileNet model obtained 74.30% mAP score which is lower as compare to the proposed Faster RCNN with ResNet50 model.

We have synthetically increases the size of the dataset and experimented both of the model. This time, the proposed Faster RCNN with ResNet50 model provides 89.47% mAP score and SSD MobileNet model obtaines 78.12% mAP score. Although, it is observed that the average detection speed of SSD MobileNet is quite high as compare to the Faster RCNN with ResNet50.

TABLE I. RESULTS AND PERFORMANCE COMPARISON AMONG DIFFERENT DETECTION MODELS

Data Augmentation	Target Detection Networks	mAP (%)
Without Data Augmentation	Proposed Faster RCNN ResNet50 V1 640X640	88.71
	SSD MobileNet V1 FPN 640X640	74.30
With Data Augmentation	Proposed Faster RCNN ResNet50 V1 640X640	89.47
	SSD MobileNet V1 FPN 640X640	78.12

TABLE II. COMPARISON OF AVERAGE DETECTION SPEED AMONG DIFFERENT DETECTION MODELS

Target Detection Networks	Average Detection Speed (s/Image)
Proposed Faster RCNN ResNet50 V1 640X640	4.312
SSD MobileNet V1 FPN 640X640	0.64

Fig. 7 contains the examples of Intersection over Union (IoU) detection results of the proposed object detection on real-time Marigold Dataset captured in complex scene environment. The figure (a) and (b) are the images with detection results. It shows the detection of two classes; flower and bud. These two classes represent the flower growing stages that can be helpful to decide the harvesting time.

In conclusion, several studies have been conducted in the past to address the issue of marigold flower object identification and classification. Marigold flower blooming stage identification and classification using deep learning techniques such as Faster RCNN, YOLO, and SSD has gained significant attention in recent years. These techniques offer faster and more accurate detection and classification of marigold flower blooming stages. YOLO and SSD are faster, they are also less accurate than the two-stage models, particularly on small objects [48]. Several researchers proposed variety of methods for classification using the machine learning and deep learning algorithms that achieved good performance. However, they have considered image classification based on discrete features of flower image [49][50][51][52]. In this research, we have proposed a method based on two-stage object detection. The proposed method allows for more precise localization and classification of objects and can be used to quickly and accurately identify the blooming stage of marigold flowers. Moreover, two-stage object detectors are more robust to variations in lighting conditions, background clutter, and occlusions compared to single-stage detectors. This makes them ideal for identifying marigold flowers blooming stages, which can be affected by different lighting conditions and may have complex backgrounds.

VII. CONCLUSION

In order to detect Marigold flower stages in intricate agricultural field settings, a real-time and accurate identification strategy based on a two-stage Faster RCNN object detection network with data augmentation was presented in this study. We have gathered and analysed data on Marigold flowers in a variety of field settings as part of our research. All of the dataset's images were divided into two classes: bud and flower. The flower growth stage is represented by these two classes. Geometric data augmentation techniques were also used to improve the dataset. Then, utilising the ResNet50 backbone network, we fine-tune the two-stage object detector, namely Faster RCNN. We conducted an experiment and compared the outcomes with SSD MobileNet, a single-stage object identification model. The findings suggest that data augmentation can significantly enhance the proposed model's capacity for detection. The Faster RCNN with ResNet50 model has been proposed an 89.47 mAP score and a 4.312 average detection speed per second. The detection of two classes; flower and bud represent the flower growing stages that can be helpful to decide the harvesting time for the Marigold flowers. This research provides a pathway for the researchers who are working for the automatic detection and harvesting of flowers other than the Marigold.

***Abstract*—This Mangrove forests in the United Arab Emirates (UAE) provide valuable ecosystem services such as coastal erosion protection, water purification and refuge for a wide variety of plants and animals. Therefore, the first step toward understanding the mangrove forests is the monitoring of this important ecological system. This paper proposes an original study to characterize the mangrove forest environment in the UAE by using polarimetric synthetic aperture radar (PolSAR) remote sensing. Free access C-band dual- PolSAR Sentinel 1 data have been exploited. The elements as of the covariance matrix as well as the entropy/alpha decomposition parameters have been studied. Results show that the VH intensity, the coherence between VV and VH polarimetric channels, the entropy and alpha angle provide the most pronounced signatures that discern mangrove forests. Thus, these parameters could be exploited to improve the accuracy of the remote sensing monitoring and mapping techniques of mangrove forests in the UAE.**

Keywords—Mangrove forests; dual-PolSAR; sentinel 1; United Arab Emirates; entropy/alpha decomposition

I. INTRODUCTION

Mangrove forests, which appear in the transitional zones between land and sea in most tropical and subtropical coastlines, play a major role in the coastal ecosystem. In the UAE, mangrove forests are mainly located in tidal lagoons with a total extent estimated to be 38km^2 [2]. They are dominated by gray mangroves (i. e. Avicennia Marina) which tolerate water with high salinity and dry weather conditions (see Fig. 1(c) and Fig. 1(d)). To preserve this important ecosystem, a number of approaches have been proposed to monitor and analyze mangrove forests. Studying mangroves using field methods is time consuming, expensive and difficult because of the harsh environment in mangrove ecosystems. Hence, remote sensing has served as a sustainable tool in studies of mangrove forests. A number of methods have been proposed to monitor and analyze mangrove forests using remote sensing data [17], [10], [11]. Regarding the remote sensing data sources, most previous studies can be grouped into two main groups, those employing optical data and those using Synthetic Aperture Radar (SAR) data.

Optical remote sensing data have been widely used for mangrove monitoring due to the availability of very high temporal and spatial resolution imagery [17], [10], [11]. Nevertheless, such systems are limited in utility by the cloud at mangrove sites and by narrow spatial coverage. Few studies have been conducted to map the mangrove forests in the UAE using optical remote sensing data [6], [7], [8].

Synthetic aperture radar (SAR) data have been explored for mangrove forest mapping. SAR offers benefits that include no sensitivity to cloud or precipitation, wide spatial coverage and sensitivity to the geometrical structure of forests (Zhang et al., 2018). In the literature, several studies have been proposed to study the mangrove forests including bio-mass estimation [16], mapping [5], discrimination of species [15], etc. However, there is no study exploiting SAR data in UAE mangrove forest monitoring. The objective of this paper is to fill this gap.

Full polarimetric SAR (PolSAR) data provide much more backscattering information of mangrove forests than single polarization data [9]. Nevertheless, the majority of currently-available SAR data, such as the free-access Sentinel-1 (VV and VH polarizations) and ALOS (HH and HV polarizations) data, are dual (not full) PolSAR. In comparison to full-pol, dual-pol mode is widely used in the radar remote sensing applications due to its high spatio-temporal coverage.

However, little attention has been given in the literature to entropy-alpha-anisotropy polarimetric target decomposition for mangrove forest analyses despite its wide application for the analysis of vegetation polarimetric responses [3]Using L-band ALOS PALSAR full-pol data, it has been demonstrated that Entropy-alpha-anisotropy target decomposition provided valuable measures of scattering mechanisms of the mangrove forest structure [3]. It has been demonstrated that ALOS PALSAR dual-pol entropy-alpha-anisotropy parameters improved the classification accuracies of mangrove species [20].

In this paper, an extended analysis of the dual-pol response of mangrove forest in the UAE is proposed. The dual-pol parameters including the elements of the covariance matrix as well as the entropy/alpha decomposition parameters are studied to derive strong signatures of the mangrove forests. Single look complex VV and VH Sentinel 1 dual-pol data are tested in this study.

This paper is organized as follows: Section II introduces the study area and the experimental data. Section III introduces dual SAR polarimetry. In Section IV, the polarimetric response of mangrove forests is studied. Finally, Section V gives the conclusions of this paper.

II. Study Area and Data

The study area (see Fig. 1(a) and Fig. 1(b)) is located in Ras Al-Khaimah (RAK) in the eastern coastal areas of the United Arab Emirates facing the Arabian Gulf (see zone A Fig. 1(d)). It consists of a coastal forest of Avicennia Marina mangrove trees with high density (zone B Fig. 1(b)) and low density (zone C Fig. 1(b)) with height ranges from a few centimeters to 3–8 m [1], [14] traversed by inundated (zone D Fig. 1(b) and non inundated (zone E Fig. 1(b)) flat saline loamy clay bare surfaces and surrounded by Ras Al-Khaimah city (zone F Fig. 1(b)). This ecosystem is common in mangrove forest sites of the UAE. Hence, the objective of this paper is to characterize the mangrove forests using the studied dual-pol data and to derive the most significant polarimetric descriptors that emphasize the zones B and C (i. e. mangrove forest) from zones A, D, E and F.

For the experimental data, C-band Sentinel-1 images in the interferometric wide Swath (IW) mode have been employed. The data were acquired on 07 October 2021. The VV and VH single look complex (SLC) products with a spatial resolution of approximately 3×20 m (range×azimut) have been considered in order to characterize the mangrove signatures. The data have preprocessed according to [13]. For better speckle filtering while preserving the polarimetric information, the speckle filtering has been performed using the iterative minimum square error (IMMSE) filter [18]with the input parameters (Initial filter: 11×11 Lee sigma filter [12], number of iterations: 7).

III. Dual Polarimetric SAR Descriptors

In dual polarization SAR, one polarization H (horizontal) or V (vertical) is transmitted. Both polarization H and V are received simultaneously. Hence, the number of parameters is lower compared to fully polarimetric data (i.e. transmitting and receiving both H and V polarization simultaneously). The dual-pol data can be represented by 2×2 covariance matrix:

$$C_2 = \begin{bmatrix} \left\langle \left| S_{VV} \right|^2 \right\rangle & \left\langle S_{VV} S_{VH}^* \right\rangle \\ \left\langle S_{VH} S_{VV}^* \right\rangle & \left\langle \left| S_{VH} \right|^2 \right\rangle \end{bmatrix} \tag{1}$$

Where $\langle \; \rangle$ is the averaging operator and * is the complex conjugate. S_{VV} and S_{VH} are the dual polarization complex SAR parameters.

The dual-pol descriptors can be obtained directly from the covariance matrix or derived by applying a decomposition. The most important dual-pol descriptors are the intensity channels which are the diagonal elements of the covariance matrix i.e. $\left\langle \left| S_{VV} \right|^2 \right\rangle$ and $\left\langle \left| S_{VH} \right|^2 \right\rangle$. From the off-diagonal element, the complex coherence between the VV and VH polarimetric channels can be estimated

$$\rho = \frac{\left\langle S_{VH} S_{VV}^* \right\rangle}{\sqrt{\left\langle \left| S_{VV} \right|^2 \right\rangle \left\langle \left| S_{VH} \right|^2 \right\rangle}} = |\rho| e^{j\varphi} \tag{2}$$

Hence two additional dual-pol descriptors which are the coherence $|\rho|$ and the phase difference φ between VV and VH polarimetric channels respectively are considered in this study. The eigen-decomposition of C_2 gives [4]

$$\mathbf{C}_2 = [\mathbf{U}_2] \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix} [\mathbf{U}_2]^{*\mathbf{T}} \tag{3}$$

Where λ_1 and λ_2 are the eigen-values, U_2 contains the eigenvectors and ^{T} denotes the transpose operator.

The Cloude-Pottier parameters: entropy H and the mean α angle dual-pol descriptors are [4]:

$$H = -\sum_{i=1}^{2} p_i log_2(p_i) \tag{4}$$

$$p_i = \frac{\lambda_i}{\lambda_1 + \lambda_2} \tag{5}$$

Where

$$\alpha = \sum_{i=1}^{2} p_i \alpha_i \tag{6}$$

The mean amplitude of the mechanism is:

$$\lambda = \sum_{i=1}^{2} p_i \lambda_i \tag{7}$$

Fig. 2 to 5 gave the parameters of the studied zone.

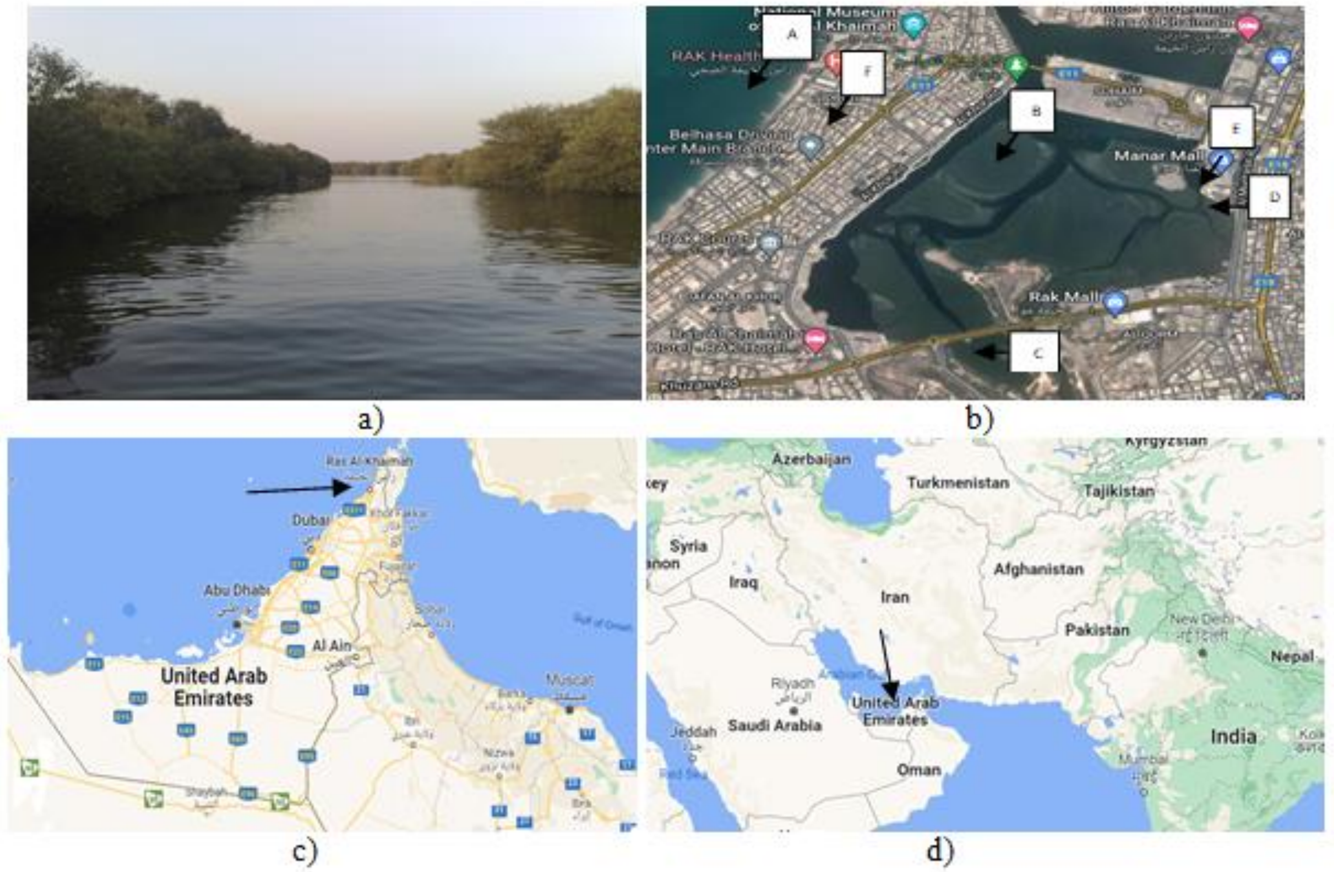

Fig. 1. (a) and (b) Spatial distribution and environment mangrove forests in Ras Al-Khaimah mangrove Greek in the UAE, (c) and (d) The study area (see arrows).

A. VV and VH Intensities

The mangrove forests grow between sea and land areas. They are characterized by a homogeneous crown shape, medium leaf size and arched aerial roots (see Fig. 1(c)). These factors define the roughness, topography, texture, and dielectric constant on which the backscatter, is highly sensitive. Mangrove forests generally are characterized by a volume scattering mechanism (i. e. multiple scattering). Hence, they are highly depolarizing targets. As a result, the VV and VH image exhibit high backscattering intensities (see Fig. 2 zone B). However, in double bounce scattering, one channel does not display high backscattering intensities depending on the orientation of the target. For example for dihedral oriented 45° and dihedral oriented 0°, the VV and VH channels does not exhibit strong backscattering intensity, respectively. These scattering mechanisms occur generally in man-made target such as buildings (see Fig. 2 zone F). Hence, very strong VV and HV intensities (i.e. specular backscattering) are observed in the city zone (see Fig. 2 zone F). In L-band data such those collected from ALOS PALSAR system, high backscattering signal observed in flooded forests originates from double bounce returns between the water surface and forest components can occur [9]. However, in actual C-band Sentinel 1 data, this phenomenon is not pronounced as for L-band since the wave have not the same ability to penetrate inside the mangrove canopy. Hence, this phenomenon is not emphasized as in the city zone where the double bounce is specular. However, double bounce can be noticeable in mangrove trees with low density (see Fig. 2 zone C) and in the boundaries between mangrove forests and flat surfaces (see arrows in Fig. 2).

The surface scattering mechanism does not depolarize the incident wave. The sea and the inundated zone constitute perfect surface reflections. Hence, they show weak backscattering intensities in HH and HV polarizations. The non inundated surface (zone E) is a rough and non-depolarizing target. Thus, it displays strong backscattering intensity in HH polarization only

B. Coherence

The coherence |ρ| measures the degree of linear dependency of VV and VH polarimetric channels. It ranges from 0 to 1. If VV and VH signals are linearly related then |ρ|=1. Fig. 3(a) displays the coherence image of the test site. The mangrove forests are characterized by random scattering mechanisms since they are depolarizing targets. As a result, it can be observed that the zone B (i.e. mangrove forest) displays low coherence values. On the other hand, the A, C, D and E and F zones provide more deterministic scattering (i.e. surface scattering for A, D and E zones and double bounce scattering for C and F zones). As a result, the coherence parameter display high values.

C. Phase Difference

Fig. 4 (a) displays the phase difference image between VV and VH polarimetric channels. It can be observed that this descriptor does not display any particular signature. In fact, this parameter appears noisy and not able to discern the studied zones.

D. H/α

The entropy H is used to characterize the heterogeneity of the media scattering. For deterministic scattering H=0 (e. g. dihedral (i.e. double bounce scattering see Fig. 6) and surface scattering (i.e. simple reflection see Fig. 6) while for random scattering H=1 (e. g. volume scattering see Fig. 6). α angle is an indicator of the type of the scattering mechanism. For surface scattering, α =0°, α =90°for double bounce scattering and α≈50°in dual-pol case (i. e. dihedral scattering such in man-made structures see Fig. 6) for volume scattering such in forests (see Fig. 6).

The sea area, the inundated zone and the non inundated zones represent surface scattering. Hence the entropy and alpha angle display relatively low values. The city zone is characterized by double bounce scattering (man-made structures) hence H= 0 and α =90°. Fig. 5 demonstrate that the majority of mangroves zones are characterized by volume scattering (i. e. H=1 and α≈50°). Some isolated points in the mangrove forests are characterized by a double bounce scattering (i. e. H=0 and α=90°) due to the double reflection ground-trunk.

In mangrove forests with low density (Fig. 5 zone C) and the borders between the mangrove forests and the flat surfaces (Fig. 5 arrows), double bounce scattering is also pronounced.

E. Mean of Eigenvalues λ

The mean of eigen-values λ is an intensity parameter as VV and VH intensities. Fig. 7 displays the λ image. It can be observed that zone A and D zones display low values. The city zone d display very high values. B zone and D zone show high λ values.

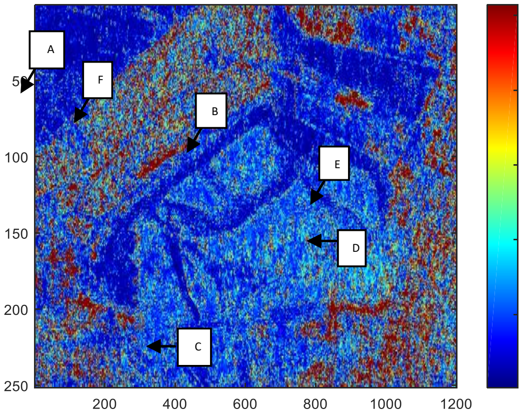

Fig. 7. λ image.

IV. Discussion

The polarimetric characterization of the mangrove forest environment of the UAE shows that the HV intensity image is more able to discern the mangrove forest than the VV intensity image. Since the mangrove forests are highly depolarizing targets, the VH image better discern their extent. Hence, since the inundated zones between the mangrove regions are no-polarizing zones, they are better described. The open area (E) is also a non-polarizing target. Hence, it is better emphasized from the mangrove trees. The coherence image emphasizes also the mangrove forest zones since all the behavior displayed low coherence values except the mangrove zones which are characterized by random scattering. The environment of the mangrove forest is non-depolarizing (H=0) whereas dense mangrove trees are highly depolarizing. Hence, the entropy parameter is a powerful indicator to discern dense mangrove trees. However, the entropy parameter cannot emphasize double bounce generated by ground-trunk scattering and surface scattering generated by the inundated and non inundated zones since H=0. It is interesting to observe that the entropy H and the coherence |ρ| are highly correlated since 1-|ρ| image provided practically the same information as H image (see Fig. 3). Hence, only the entropy can be kept to characterize the mangrove forest environment.

In the environment of mangrove forests in the UAE, only dense mangrove zones are characterized by a volume scattering. Hence, alpha angle is able to emphasize this area. However, in high entropy zones, the alpha angle cannot provide additional information. Alpha angle is generally significant in medium and low entropy values. In fact, contrary to the entropy parameter, alpha angle is able to discern double reflection from simple reflection (i. e. H=0 for both reflections whereas alpha =0 for simple reflection and alpha =90° for double reflection see Fig. 6). This phenomenon is observable mainly at the borders between mangroves and flat surfaces which present double bounce reflections (see arrows in Fig. 5 (b)). It is also interesting to observe that in low density mangrove forests double bounce reflection is dominant (see zone C in Fig. 5(b)). Concerning λ image, it can be observed that this descriptor does not introduce additional information to VV and VH intensity image.

In conclusion, the combination of polarimetric descriptors HV intensity, entropy (or coherence) and alpha angle is able to emphasize the mangrove forests of the UAE (with high and low density) from their environment. It is important to notice that the choice of the polarimetric filter it crucial. In fact, Fig. 4 (b) displays the entropy image of the test site after applying the 7×7 Lee sigma filter (using PolSAR-pro software). It can be observed that the filter is not able to preserve the polarimetric information in the city zone which displays high entropy. This phenomenon is due mixing of different scattering media [19]. As a future research direction, we propose to use the entropy and alpha angle parameters in segmentation and classification algorithms of mangrove forests in UAE. We could also use other types of decomposition for the characterization of polarimetric images in the mangrove forest environment in the UAE.

V. Conclusion

In this paper, the environment of mangrove forests in the UAE has been studied using free access C-band dual- PolSAR Sentinel 1 data. Among the studied polarimetric descriptors, results show that the VH intensity, the coherence between VV and VH polarimetric channels, the entropy and alpha angle provide the most pronounced signatures that discern mangrove forests. Thus, these parameters could be exploited for further applications related to mangrove forests in the UAE.

An In-depth Analysis of Uneven Clustering Techniques in Wireless Sensor Networks

Hai-yu Zhang
School of Finance and Economics, Taiyuan University of Technology, Taiyuan 030024, China

***Abstract*—The low-cost and convenient feature of Wireless Sensor Networks (WSNs) has made them popular in many sectors over the last decade. The WSNs are now widely used as a result of recent advancements in low-power communication and being energy-efficient. The WSNs typically use batteries to power sensor nodes. The finite stored energy in batteries and the hassle of battery replacement have led to a critical focus on energy efficiency for WSNs. Clustering and data aggregation are the most efficient methods to address the energy concerns of WSNs. This paper comprehensively reviews several uneven clustering methods and compares the various uneven clustering algorithms. The methods are described in terms of their goals, attributes, categories, advantages and disadvantages. Probabilistic clustering is used when there is a need of simplicity and speed. As a result, this study compared all these types of protocols based on their clustering properties, CHs properties, and on the type of clustering process; and current research gap effective techniques are also addressed.**

Keywords—Wireless sensor networks; data aggregation; uneven clustering; energy-efficient; review

I. Introduction

Wireless Sensor Networks (WSNs) can be distinguished from other wireless ad-hoc networks by their unique characteristics. WSN nodes are less powerful devices that have less memory and processing power [1, 2]. Recent advances in CMOS and nanotechnology have made sensor nodes smaller, cheaper, and more efficient computationally [3]. Sensor nodes are clustered together with microprocessors, batteries, transceivers, and sensors. Numerous sensor nodes can be connected in a network without requiring any predefined infrastructure, and the sensor nodes can configure themselves [4]. Sensor nodes in the WSN detect physical variables such as humidity, temperature, and pressure in the air. Furthermore, it can detect acoustic signals, infrared, and vehicle movements [5]. The micro-sized processing unit processes the value sensed by these sensors and forwards it to the base station with the help of a communication unit through one-hop or multi-hop transmission [6].

Many applications use WSNs to monitor and track, including surveillance in the military, healthcare, industrial automation, agriculture, inventory control, disaster management, etc. WSNs provide connectivity for remote regions, such as deserts, forests, deep seas, battlefields, and complex industrial and research facilities [7]. Sensor nodes are deployed in remote provinces with limited electricity for charging and other replacement options. The initial phase of transmitting data from the source nodes to the base station is more costly than sensing data in WSNs [8]. Therefore, an energy-efficient communication strategy is crucial in transmitting data from the sensor nodes to the base station, which will prolong the lifetime of the WSN. These problems can be resolved with the help of a well-known method called clustering [9].

Using the clustering strategy, different nodes are grouped into heterogeneous and homogeneous clusters. In general, clustering involves designating a single node as the CH and segmenting a given area into discrete sectors. In order to create an energy-efficient WSN model, CH is essential. To enhance network performance, the CH may be altered in practice during some iterations [62]. Furthermore, unique specialized nodes, such as CHs, make all significant choices on behalf of SNs with the aid of clusters. Clustering can be categorized as either single-hop or multi-hop. There are many drawbacks and benefits to single-to-multi hop communications, such as the energy losses associated with single-hop transmission due to greater range. In the meantime, the multi-hop technique can boost energy consumption to solve the wireless sensor network's scalability issue, thereby boosting both energy consumption and scalability [61, 63]. There are two types of sensors in these clusters: normal nodes and Cluster Head (CH) nodes [10]. Fig. 1 depicts the clustering architecture of WSNs. Communication in WSNs is divided into two types: intra-cluster and inter-cluster. Intra-cluster communication occurs between cluster members, whereas inter-cluster communication occurs between clusters. The cluster member nodes sense real-world parameters, and the measured values are transmitted to the CH. The CHs combine the values received to eliminate redundant information present due to the same values sensed by some nodes. The final data is transmitted directly to the base station through intermediary CHs [11]. Cluster members can send data to CHs only, and CHs can send data to the base station, eliminating the need to transmit redundant data. Clustered WSNs have many advantages over conventional WSNs, including better utilization of bandwidth, less overhead, enhanced link connectivity, efficient topology balancing, stability in network topology, and reduced routing table size [12].

In the last few decades, a variety of even and uneven clustering methods have been presented for enhancing energy efficiency in WSNs. The motivation behind this work is the lack of a thorough review of clustering protocols. The main contribution of this study is to do critical analysis and review outcomes of uneven clustering and provide a detailed analysis of each method. Furthermore, this study compares clusters based on a variety of cluster properties, including cluster properties and clustering processes. This paper is organized as follows. Section II discusses the characteristics and objectives of uneven clustering. The classification and explanation of clustering algorithms are presented in Section III. Section IV categorizes and tabulates algorithms. The paper concludes in Section V.

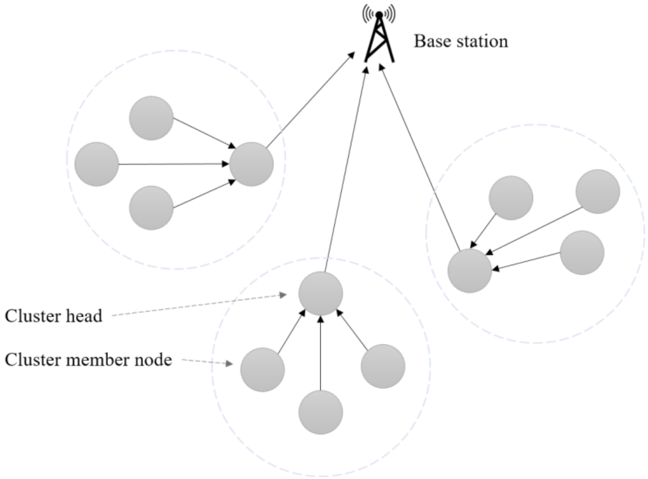

Fig. 1. Clustering architecture of WSN.

II. Background

In this section, an overview of uneven clustering is presented, as well as a detailed discussion of its objective and characteristics.

A. WSN Applications

The use of WSNs is expanding rapidly in various applications or is still in its infancy. There are four general categories of WSN applications according to their use, including; urban, industrial, environmental, and health. There are various subgroups within each category. Each category and subcategory in this section is described in more detail. Examples of their characteristics are discussed, highlighting their advantages and disadvantages.

- Urban applications: WSNs offer a wide range of sensing capabilities, allowing them to gather extensive information about any target area, indoors, outdoors, or even inside buildings. In an urban environment, WSNs can measure any phenomenon's spatial and temporal characteristics. Monitoring various parameters is crucial for ensuring citizens' optimal well-being in large cities [13]. WSNs provide authorities with real-time data needed for optimal city operation. Specifically, increasing the number of vehicles heading toward common destinations creates problems and time waste. WSNs can track traffic to reduce congestion, indicate parking spots, etc. Various systems can improve human lives in the era of informatics. WSNs also apply to indoor environments, like smart homes, which involve machine-to-machine connections. Indoor air quality monitoring and localization of motion are two examples [14]. Keeping public roads safe and functional depends on efficient vehicular transportation. In the transportation domain, various WSN-based systems have been proposed by researchers. Drivers can receive information from these systems during their use of roads, which can improve their safety on the road. Increasing demands for safety and security in cities are driving the use of WSNs in structural health monitoring. Thanks to the rapid advancement of wireless technologies, structural monitoring systems have been significantly improved by combining WSN technology. WSN-based structural health monitoring systems offer compelling advantages over traditional wired systems, including reduced installation and maintenance costs [15].

- Industrial applications: WSNs have been used in a variety of applications in industrial settings in recent years. In critical infrastructure, they are incorporated into supervisory control and data acquisition systems. In conjunction with IoT applications, these systems enable smart monitoring and control. Using WSNs in industrial automation systems also includes controlling and monitoring industrial equipment. WSN requirements for industrial wireless systems differ from general WSNs [16]. Incorporating sensors into designs, floor plans, manufacturing equipment, and other critical areas benefits industries greatly. Industrial application of WSNs reduces failure rate and enhances the effectiveness and efficiency of factory operations. Integration of wireless technology in the industrial sector requires security and reliability. Insecure routing protocols, hostile deployment locations, and open architecture render industrial WSNs subject to varied attacks. The limited processing, memory, range of communication, and energy of WSNs makes them easy targets for adversaries. Providing secure and reliable services, WSNs are a reliable and suitable technology for factories and industries [17].

- Environmental applications: WSNs provide environmental information to decision-makers. Environmental monitoring encompasses both natural and man-made environments, indoors and outdoors. There are various methods of monitoring, such as sensor-based monitoring on the ground, field sampling analysis in laboratories, and aerial and satellite remote sensing [18]. Diverse challenges remain for environmental monitoring nodes. Environment-specific WSNs are typically located in remote areas disconnected from the power grid. The primary challenge lies in selecting proper topologies and operating strategies aiming to ensure the nodes are as energy efficient as possible [19].

- Health applications: Having many advantages, like short delay, superior performance, economical cost, etc., WSNs are widely used in the healthcare sector. The healthcare WSN involves the real-time transmission of patient health information through the Internet to health professionals, so patient confidentiality and integrity are crucial. Physiological parameters are detected by placing sensor nodes on patients. This allows the monitoring center to track the patient's vital signs in real-time remotely [20]. The monitoring center receives the information and processes it on time. WSNs allow the collection of human health data, which is helpful when researching human diseases and conditions. A wide range of applications of WSN can also be found in drug management and drug development, blood management, etc. Future telemedicine monitoring systems can take advantage of WSNs more conveniently and cost-effectively [21].

B. Uneven Clustering

Clustering can be even or uneven. Compared to uneven clusters, even clusters have equal sizes. Network partitioning occurs when CHs near the base station die before they mature. The problem is commonly known as the energy hot-spot issue [22]. A disparity in power consumption results in hot spots in WSNs, decreasing the network's life expectancy [23]. As a solution to hot-spot unevenness, clustering techniques are used for load balancing among the CHs. In uneven clustering, cluster sizes near the base station are smaller than those far from it. This way, uneven clustering solves the load balancing or hot-spot problem in clustering [24]. Fig. 2 illustrates how clusters of uneven type are formed based on competition radius calculations. Eq. (1) gives the formula to calculate the competition radius of nodes that are homogeneous in type and size, where *c* is the weighted factor ranges between 0 and 1, R_0^c refers to the highest competition radius value, d(s_i, Ds) denotes the distance between the node s_i and base station, and d_{min} stands for minimum distance between the node and base station.

$$R_c = \left[1 - c\,\frac{d_{max} - d(s_{1,DS)}}{d_{max} - d_{min}}\right] R_c^0 \qquad (1)$$

In a network with nodes whose energy levels differ, i.e., heterogeneous type nodes, the formula for competition radius is given below. In Eq. (2), α and β are weighted factors having a value between 0 and 1, E_{max} refers to the maximum value of residual energy, R_{max} refers to the maximum competition radius value, and E_r signifies the remaining energy of node s_i.

$$R_{c=}\left[1 - \alpha\,\frac{d_{max} - d(s_{i,}DS)}{d_{max} - d_{min}}\,\beta\left(1 - \frac{E_r}{E_{max}}\right)\right] R_{max} \quad (2)$$

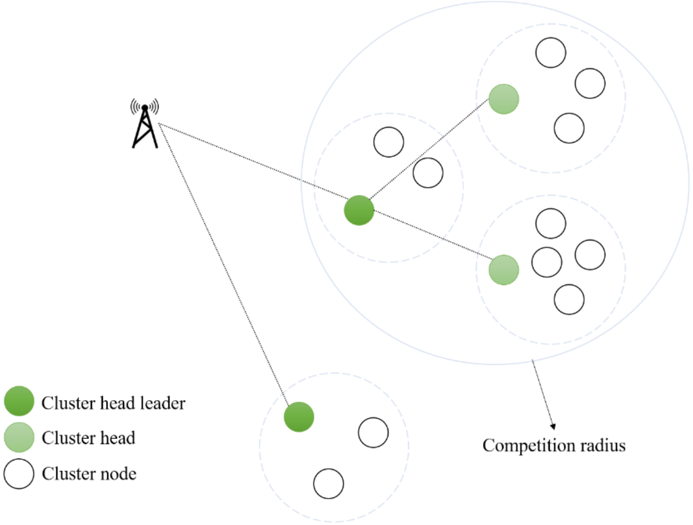

Fig. 2. Competition radius.

The intra-cluster communication does not require any aggregation of data, but the inter-cluster communication requires aggregation of data by the CHs before transmitting to the next node or directly to the base station. The parameter Erelay represents the energy consumed in the data transfer from node s_i to node s_j, and its calculation is given in Eq. (3).

$$Erelay = d^2(S_i + S_j) + d^2(S_i, DS) \qquad (3)$$

This requires that the node S_i have to select the next node S_j who have the highest remaining energy and minimum E_{relay} in the route candidate node set.

C. Objective

In uneven clustering, the main objective is to avoid hotspots, which arise from unequal energy consumption by the nodes of WSNs, thereby reducing their lifespan. The remaining objectives of uneven clustering are the same as those of even clustering. Additionally, uneven clustering aims to achieve the following.

- Load balancing: Uneven clustering provides load balancing by dividing networks into clusters of variable sizes, with smaller clusters closer to the base station and larger clusters located farther from the base station. Energy can be saved in inter-cluster data transmission, extending the network life [25, 26].

- Network lifetime: Uneven clustering has the primary purpose of enhancing the network's lifetime, which is essential for all the real-time applications that require energy conservation among the nodes of the WSNs due to the limited amount of energy available. A good routing algorithm and rotating CPUs can be used to conserve energy with uneven clustering [27, 28].

- Data aggregation: To reduce the redundancy caused by the same value sensed by several node members, CHs aggregate the received values. The final data is sent to the base station directly or indirectly through midway CHs, which minimizes the number of messages sent and minimizes the load on the network as a whole. Data fusion or data aggregation refers to a process combining all incoming packets. Data fusion enhances data and reduces unnecessary noise [29].

- Fault-tolerant: Sensor nodes are positioned in remote regions, such as deserts, forests, deep sea, battlegrounds, and complex industrial and research setups, where there may be the possibility of them being damaged or malfunctioning. The applications that may suffer causalities from data loss require fault-tolerant nodes. The self-organized WSNs solve this problem by re-clustering, but re-clustering not only interrupts the current process but also increases overhead [24, 30].

- Scalability: Sensor nodes ranging from hundreds to thousands are positioned in real-time according to application requirements. The routing method should be designed to handle these vast numbers of sensor nodes. The transmitting node should know the receiving CH when cluster data is exchanged using cluster heads. Hierarchical clustering allows networks to be subpartitioned into layers, and each layer can be subpartitioned into clusters that facilitate scalability and minimize routing table size [31].

- Stable network topology: In any type of clustering, sensor nodes are elected as CHs, and CHs are subject to changes in topology at the cluster level. CHs are equipped with all the information about their members' nodes, including their location, energy level, and ID. Hierarchical clustering is effective at the level of managing the topology of the networks. Changes in cluster membership should be reported to the base station, as re-clustering is required to maintain the effectiveness of the topology [32].

D. Uneven Clustering Characteristics

1) Clusters properties: Cluster properties include cluster size, cluster count, and types of communication within and between clusters.

- Size: Clustering can be even or uneven. The even clustering results in the same size of clusters. However, in uneven clustering, the clusters surrounding the base station are smaller, and the others are larger to balance the load. Hence, energy can be conserved in the inter-cluster data transfer, thereby extending network life [33].

- Count: Depending on the application, clusters may be fixed or variable in size. In some applications, the total number of CHs is 5%, while in others, CHs are selected by random elections [34].

- Inter and intra-cluster communication: Within WSNs, there are two types of communication: inter and intra-cluster. Within a cluster, intra-cluster communication occurs between members and CHs. Inter-cluster communication takes place between CHs [35].

2) Cluster heads properties: By single or multi-hop communication, CHs collect data from members, aggregate the collected data, and send the aggregated data to the base station.

3) Method of clustering properties: The clustering method has four basic characteristics, which are as follows:

- Objective: Clustering serves several objectives, such as energy conservation, fault tolerance, load balancing, and enhancing the lifespan of WSNs [36].

- Methods: Clustering or grouping of nodes can be centralized or distributed. A centralized approach controls cluster formation, selection of CHs, etc., whereas a distributed approach does not have central control [37].

- Nature: Clustering can take a reactive, proactive, or hybrid approach. Continuous transmission of data indicates that nature is proactive. In reactive nature, data is dispatched when sensed data has reached a predefined threshold. The term hybrid refers to the combination of proactive and reactive nature according to the requirements of specific applications [38].

- The base of selecting CH: CHs are selected according to three criteria: attribute-based strategies, probabilistic strategies, and preset. Probabilistic strategies are those in which CHs are chosen randomly without predetermined protocols. Attribute-based strategies determine CHs depending on various indicators such as remaining energy, distance from base stations, the density of nodes, etc. In the present method, the CHs are elected before the nodes or clusters are deployed [39].

III. Review of Uneven Clustering Algorithms

Uneven clustering is intended to prevent the hot-spot problem arising from the unequal distribution of energy consumption by the nodes of WSNs, reducing the network's life span. Uneven clustering accomplishes the same objectives as even clustering. Uneven clustering algorithms are categorized into three categories: probabilistic, deterministic, and preset. Additionally, "static, dynamic, and hybrid" classes are used to categorize the clustering protocols. Clusters in static clustering, once formed, remain the same for the duration of the network. The benefit of this approach is a decrease in clustering overhead. However, the static method might not work properly since some nodes might run out of energy and shut down before other nodes do. Dynamic clustering, in contrast, differs from the static technique in that it will carry out fresh clustering at each instance. Even so, it has a drawback of expensive overhead and won't generate much traffic to put strain on the nodes. The last benefit of hybrid clustering is that it decreases communication overhead while increasing energy efficiency and network longevity [64]. Following sections review the existing uneven clustering methods.

A. Preset Uneven Clustering Approaches

Preset clustering algorithms are used to design WSNs in which the locations of CHs are known in advance. Although WSN topologies change due to node or link failures, preset clustering algorithms ignore these conditions. Therefore, real-time applications cannot be implemented with these algorithms. The proposed approach by Soro and Heinzelman [40] organizes the network hierarchically with Unequal Clustering Sizes (UCS), distributing the energy uniformly among the CHs and extending the lifespan of the network. The positions of each CH are determined in advance and are arranged in a circle around the base station. Each cluster consisted of sensor nodes arranged in a Voronoi pattern around a CH, forming layers around the CH with a particular number of clusters. The Voronoi regions are pie-shaped areas. First layer clusters are equal in size, forming a symmetrical circular association. However, the clusters in the second layer differ in shape and size from the first layer. In every layer, the radius can be adjusted to vary the region that clusters cover, thereby changing the number of nodes within each cluster. According to experimental results, UCS is approximately 10%-30% more efficient than the even-sized cluster scheme that depends on the effectiveness of CH aggregation. UCS can work better for networks that collect a lot of data. This UCS has a long lifespan for heterogeneous and homogeneous networks with a static cluster. The UCS also achieved more even dissipation in uniform-type networks. A comparison of preset-type uneven clustering methods is provided in Table I.

B. Deterministic Uneven Clustering Approaches

Deterministic clustering algorithms control clusters and select CHs efficiently. In these algorithms, the CHs are selected by considering several factors, including available energy, the proximity of the base station, the density of nodes, etc. These criteria change as neighboring nodes exchange messages. Deterministic clustering algorithms can further be divided into three groups, compound-based, heuristic-based, and fuzzy-based.

1) Compound-based approaches: In unequal clustering, various metrics, such as linked graphs, the Sierpinski triangle, etc., are used to make the clusters compound-based. Numerous deterministic compound-based approaches have been suggested to minimize the energy consumption of clustering. As a solution to the hot-spot issue in WSNs, Guiloufi, and Nasri [41] proposed Energy Degree Distance Unequal Clustering Algorithm (EDDUCA). The CHs in EDDUCA are chosen based on reserved energy, node density, and distance between nodes and cluster centers. In addition, the size of clusters made by EDDUCA is the same regardless of their distance from each other and the base station. EDDUCA applies the Sierpinski triangle procedure to separate networks into uneven clusters based on their size. In the Sierpinski triangle procedure, n nodes are homogeneously distributed in the square shape zone. Two diagonal lines are drawn in the rectangle-type zone, and four triangles are drawn. Small triangles are then formed by linking the midpoints of the sides of each triangle. The results of the experiments showed that EDDUCA significantly reduced the consumed energy, balanced the consumed energy among clusters, and balanced the consumed energy among sensor nodes, thereby extending the longevity of wireless sensor networks.

Xia, and Zhang [42] have developed the Unequal Clustering Connected Graph Routing Algorithm (UCCGRA) to load balance between CHs of clusters and diminish the energy consumed in inter-cluster communication. Uneven clustering and connected graph theories are the basis of UCCGRA. Firstly, CHs are chosen by a vote to balance energy consumption. Because they are smaller and have more load than CHs, located far from the base station, CHs near the base station can maintain some power for inter-cluster communication. A multi-hop inter-cluster routing scheme is introduced based on the connected graph of CHs and base stations that allow multiple ways to reach the base station from CHs. Results prove that UCCGRA enhances the reliability and flexibility of data communication. It also prolongs the lifespan of a network by evenly distributing the CHs, balancing the scale, reducing energy consumption among CHs, and optimizing energy consumption among CHs.

Guo, Zhang [43] have proposed PEG-ant based on the PEGASIS protocol and used the improved ACO method instead of greedy algorithms. Each neighbor of the current node is considered a candidate, and residual energy, energy consumed, and pheromone quantity are considered factors while selecting the next node. In comparison to the original PEGASIS, PEG-ant achieved global optimization. Through the chain made by the PEG-ant, the path is more evenly distributed, and the total communication distance is also reduced. The chain nodes are balanced based on residual energy. Compared to existing protocols, PEG-ant significantly prolonged the lifespan of WSNs and effectively managed energy consumption.

2) Heuristic-based approaches: The uneven heuristics clustering in WSNs uses optimization algorithms to provide the optimal solution. To achieve the most optimal performance or solution, each algorithm uses a different fitness function. These methods are generally centralized but may be distributed in exceptional cases. There are various Deterministic heuristic-based clustering methods proposed to make this process energy-efficient.

Data aggregation and clustering based on tree structures can grant WSNs a longer lifespan. Kaur and Mahajan [44] offerd a hybrid approach based on Ant Colony Optimization (ACO) and Particle Swarm Optimization (PSO) algorithms called ACOPSO. The first step is identifying CHs, followed by the shortest distance communication process to gather sensed information from CHs. CHs are connected to sinks by the shortest path calculated by ACOPSO. ACOPSO used comprehensive sensing to reduce the packet size in WSNs. The simulation results demonstrate that the proposed protocol prolongs the network life span compared to GSTEB based on stability measurements. In this system, all nodes are arbitrarily distributed in an area of 100 by 100 square meters, with the base station located 50 meters apart.

Sabor, and Abo-Zahhad [45] developed the Unequal Multi-hop Balanced Immune Clustering (UMBIC) approach to enhance the lifespan of heterogeneous/homogeneous WSNs with unequal densities at small and large scales. To manage both inter- and intra-cluster energy consumption, UMBIC uses Uneven Clustering Methods (UCM) and a Multi-objective Immune Algorithm (MOIA). In UMBIC, the UCM divides the network into clusters of different sizes based on the distance to the base station and remaining energy. With MOIA, the most advantageous clusters are identified, and a routing tree is created between them, ensuring connectivity between nodes and reducing communication costs. The UMBIC protocol enhances the lifespan of the networks, eliminates hotspots, and optimizes energy consumption. Additionally, UMBIC reduces overhead and simplifies computation since the base station gathers information only once.

A novel chemical reaction optimization (nCRO) paradigm is used by Srinivasa Rao and Banka [46] to propose unequal clustering and routing algorithms. The nCRO-UCRA method was developed to resolve the hot-spot problem using the nCRO method, which is a novel chemical reaction optimization. To accomplish this, nCRO-UCRA formulates linear programming for two main issues: multi-hop routing and the choice of CHs. The network is divided into uneven-type clusters. CHs are selected on the basis of a derived cost function. Finally, nCRO-based routing is applied to select a next-hop CH based on the degree of each node and distance. The encoding of molecular configurations and the potential energy function of novel types are used to implement these methods. Experiments have demonstrated that the nCRO-UCRA outperforms existing technologies such as EPUC, PSO, EAUCF, and EBUC regarding remaining energy, the number of alive nodes, network lifespan, and the average packet delivery ratio.

Fuzzy and Ant Colony Optimization Based Combined MAC, Routing, and Unequal Clustering Cross-Layer protocol developed by Gajjar, Sarkar [47], named FAMACROW, combined hierarchical energy-efficient clustering with media access to reduce energy consumption and prolong network life. In the fuzzy logic system, three factors are used to determine CHs: remaining energy, node density, and communication link quality. As a solution to the hot-spot issue, FAMACROW employs an uneven clustering method. In the inter-cluster routing protocol, the relay node is chosen based on the distance between the CH and the base station, the remaining energy, congestion control length, and delivery probability. Compared to the IFUC, FAMACROW provided a 75%-88% increased network lifespan, 82% extra packets, and 41% improved energy efficiency.

Xunli and Feiefi [48] proposed Sink Mobility based Energy Balancing Unequal Clustering (SMEBUC). In energy-restricted WSNs, coverage and connectivity are two main QoS factors that affect the efficiency of WSNs by decreasing the energy consumed by nodes and extending the coverage lifetime. The distribution of nodes in cluster-based WSNs leads to increased energy inequality. SMEBUC solves these problems by selecting the CHs based on the energy and by making the clusters unequal in size using the improved Shuffled Frog Leaping Algorithm (SFLA). The CHs are used constantly to identify node weights and CH replacement times. The objective is to determine which relay node between CH and the base station would be most appropriate. Additionally, SMEBUC employs the sink location mobile algorithm to prevent the appearance of hot-spot problems. The results of the experiments indicate that SMEBUC outperforms LEACH and EBUCP, achieves more energy efficiency, and provides a solution to the hot-spot problem in a multi-hop routing protocol by replacing CHs after a period of time.

The compact Bat Algorithm (cBA) was used by Nguyen, Pan [49] to present a novel optimization algorithm for the uneven clustering problem in WSNs. The cBA generated new candidate solutions for space search based on a probabilistic model, which has proven to be promising so far. An explicit probabilistic model was built, and samples were taken from the built models to find the candidate solution. In order to construct the operations of selecting and optimizing behaviors, cumulative distribution and probability density functions are used extensively. Probabilistic modeling is a valid alternative optimization strategy for devices with restricted hardware capabilities. The presented algorithm achieves the efficient use of limited memory devices and provides competitive results.

Zhu and Wang [50] propose an energy-balanced unequal clustering routing protocol based on the improved sine cosine algorithm (DUCISCA). As a first step, DUCISCA uses a time-based algorithm for cluster head competitions. The number of neighbors, the residual energy of the candidate CHs, and the distance to the base station determine the broadcast time in this algorithm. Secondly, a competition radius based on node distance and residual energy is proposed. Energy consumption can be balanced between nodes at different locations to prevent hot spots. It also implements a time-based broadcast mechanism. Finally, the improved sine-cosine algorithm (ISCA) based on Latin hypercube sampling and adaptive mutation is introduced to improve convergence and jump out of the local optimum. The experiment results indicate that DUCISCA balances energy consumption across the entire network and extends the lifetime of the network more effectively than previous approaches.

3) Fuzzy-based approaches: The presence of uncertainties in WSNs requires the use of the fuzzy logic system to make effective and efficient decisions. Various clustering algorithms use fuzzy logic to make effective decisions about clustering. Over classical approaches, fuzzy logic offers lower execution complexity, development costs, less memory, greater flexibility, and auto fault tolerance. Fuzzy inputs for selecting the cluster heads are remaining energy, the density of nodes, distance to the base station, and distance among the neighbor nodes. Fuzzy outputs offer the option to select the CH and the size of the cluster. Several deterministic fuzzy-based clustering strategies have been proposed to minimize clustering energy consumption.

Baranidharan and Santhi [51] offered Distributed load balancing Unequal Clustering (DUCF). Fuzzy logic is used to select the CHs. DUCF arranges clusters of unequal sizes in order to keep energy usage balanced among them. The CHs are chosen using a fuzzy inference procedure incorporating residual energy, degree, and distance between the base station and the nodes. DUCF limits cluster sizes based on fuzzy input parameters. DUCF balances the load between clusters by varying cluster sizes. Multi-hop data transmission by DUCF conserves energy by balancing energy consumption among nodes and reducing energy usage in CHs. DUCF produced better results in various network scenarios than LEACH, CHEF, and EAUCF.

Multi-objective fuzzy clustering algorithm (MOFCA) is offered by Sert, and Bagci [52]. Hot spots can currently be solved by developing unequal-sized clustering methods, which generate smaller clusters to reduce the intra-cluster relays when reaching the base station. Changing the location of deployed nodes may also introduce the energy-hole problem. Prior studies have not considered both problems (Hot-Spot and Energy-Hole) jointly in uniformed or non-uniform distributions. Thus, MOFCA was a solution to static and dynamic network problems. MOFCA uses the remaining energy, the distance to the base station, and the density of nodes as input variables for the fuzzy inference system to overcome the uncertainty in WSNs in nature. Results show that MOFCA is a more energy-efficient protocol in terms of FND, HND, and total residual energy. MOFCA considers both dynamic and static nodes, and mobility is implemented by changing the location of nodes without consuming any energy.

The Secure Unequal Clustering Protocol with Intrusion Detection (SUCID) proposed by Maheswari and Karthika [53] achieved QOS variables such as security, lifespan, and power. It contains several different procedures, including initialization of the nodes, election of the TCH, the election of the FCH, cluster maintenance, and identification of intruders. Using the neuro-fuzzy grouping method, the tentative CHs (TCHs) were initially selected based on the three input variables, distance to the base station, residual energy, and distance between the nodes in close proximity. Using "DHO: Deer hunting optimization" based on TCH, final CHs and optimal cluster heads were selected based on the fitness derived from five variables, including distance to the base station, remaining energy, degree of nodes, the centrality of nodes, and link quality. Cluster maintenance was used to balance the load, and a deep belief network was used on the cluster heads to detect intruders in the WSN. Results from experiments showed that SUCID maximized energy efficiency, network lifespan, delayed average, and intruder detection rate by combining DBN and IDS.

Siqing, Yang [33] introduced Fuzzy Logic for Multi-hop Networks (FLCMN), which partitions the time into rounds with equal intervals. Each round comprises two stages: clustering and data transmission. The FLCMN algorithm uses fuzzy logic inference to determine the CH. There are three input parameters for fuzzy logic inference systems: density of nodes, residual energy of neighbors, and the average remaining energy of neighbors. Cluster Head Formation is the subsequent phase, where nodes broadcast a message, and after comparing the degree, a node is selected as the CH. Once CH has sent a message to join, nodes select their nearest CH. FLCMN supports multi-hop data transmission. Hot-spot problems can be prevented by FLCMN, as well as the distribution of nodes within clusters can be regulated. As part of FLCMN, clusters are also connected in a multi-hop manner in a Fibonacci series sequence, which prevents unnecessary data transmissions by the CHs, thereby extending the life of WSNs. The FLCMN algorithm performs better regarding network lifetime and energy consumption than existing DFLC, LEACH, and EAMMH algorithms when comparing network lifetime and energy consumption between nodes.

C. Probabilistic Uneven Clustering Approaches

CHs are selected at random without regard to predetermined protocols in probabilistic clustering algorithms. These types of algorithms are simple, energy-efficient, and optimized. Probabilistic clustering is primarily used to extend the life of WSNs. Energy-efficient clustering requires a low message and time complexity. Algorithms for probability clustering comprise two types: random and hybrid algorithms.

1) Random probabilistic algorithms: In random probabilistic algorithms, CHs are randomly chosen, simple in nature, and have the lowest overhead. Lee, and Choe [54] presented a mathematical framework and developed a clustering algorithm called the Location-based Unequal Clustering Algorithm (LUCA). Cluster sizes are determined by their distance from the CH. The cluster size of LUCA clusters increases as the distance from the base station increases to diminish the energy consumption of the whole network. According to simulation results, LUCA outperforms the conventional equal clustering algorithm in terms of energy efficiency.

Kim and Hussain [55] suggest a randomized and distributed clustering algorithm, PRODUCE, that includes clusters of unequal size. CHs located near the base station may concentrate on inter-cluster communication, whereas CHs farther away may focus on intra-cluster communication. This prevents excessively long-distance communications in the network from negatively affecting signal strength. Simulation results demonstrate that the proposed algorithm considerably boosts coverage time and network lifetime at high node densities, especially when coverage time and network lifetime are important factors.

Huang and Hong [56] present an energy-efficient multi-hop routing algorithm based on grid clustering, called EEMRP. Several parameters, including network area levels, the position of nodes, and the energy of nodes, are considered by the algorithm to minimize energy consumption. Cluster heads are relieved of the burden of transferring data among clusters via multi-hop routing by introducing communication nodes. EEMRP extends the lifetime of the network by 17.5–25.2% compared to other algorithms, according to simulation results.

Handy, Haase [57] modified the LEACH protocol and extended its stochastic CH selection algorithm by a deterministic component. The network lifetime is increased by about 30%, depending on the configuration. Further, they developed a three-factor metric to define the lifespan of microsensor networks, the last node dies, half of nodes alive, and the first the node dies.

2) Hybrid probabilistic algorithms: In hybrid probabilistic algorithms, CHs are selected using a hybrid method, which involves randomness and parameters like distance from the base station, residual energy, node density, etc., which balance the clusters. Due to the iterative and competition-based nature of hybrid probabilistic algorithms, these algorithms have a higher message and time complexity.

Li, and Liu [58] examine unequal clustering in a uniform distribution of WSNs from a theoretical point of view. They then develop an efficient clustering scheme to minimize energy consumption. Additionally, lightweight and optimal protocols are designed for the routing and rotation of cluster heads to ensure even power consumption. Simulation results indicate that the proposed approach extends network lifetimes over the best-so-far unequal clustering-based routing approach.

Bozorgi and Bidgoli [59] propose improving the energy efficiency of previous clustering methods and extending the lifetime of the network with a hybrid unequal clustering method. A novel clustering strategy is used in the proposed protocol. Nodes in a network use their neighbors' information based on the arrangement of nodes. By using this strategy, overhead can be reduced significantly. Clustering results in nodes nearer to the base station receiving and relaying data with more energy than nodes farther away. As a hybrid static-dynamic clustering scheme, no control message must be transmitted at each round to reduce overhead. There are two new routing techniques proposed. Member nodes support CHs with sufficient energy and distance to share the cluster's load with cluster heads. Discretion licensing is another new technique that prevents incomplete packets from being sent in real-time. According to simulation results, the proposed method reduces network overhead, improves network stability, balances energy, and extends the lifetime of networks.

Priyadarshi, Singh [60] propose a novel Hybrid Energy Efficient Distributed (HEED) algorithm for networks with non-uniformly distributed nodes. A novel HEED protocol has been developed for extending the lifetime of clustered non-uniform sensor networks. HEED and its variants are compared based on the amount of energy dissipated and the number of live nodes. The planned HEED protocol has a longer lifespan and is more energy efficient than the existing HEED protocol.

TABLE I. COMPARISON OF PRESET UNEVEN CLUSTERING APPROACHES

Protocol	**Nodes type**	**Nature**	**Location-aware**	**Objective**	**Node or relay aggregation**	**Mobility-aware**	**Cluster count**	**Inter-cluster communication type**	**Intra-cluster communication type**
UCS	Heterogeneous and Homogeneous	Proactive	Yes	Network lifetime and load balancing	Yes	No	Variable	Multi-hop	Single-hop

As comparison tables show, CHs are chosen using a hybrid probabilistic method that takes into account randomness and a variety of factors, including residual energy, distance from the base station, node density, etc. Higher message and time complexity result from hybrid probabilistic algorithms' iterative and competition-based nature. Deterministic clustering algorithms manage clusters and choose cluster leaders wisely. Based on factors including remaining energy, node density, and distance from the base station, deterministic clustering algorithms choose cluster heads.

IV. DISCUSSION AND RESULTS

Tabular comparisons of uneven clustering are presented in Tables I, II, and III. As a starting point, clustering algorithms are evaluated according to the following characteristics: size (even or uneven), cluster count (static or dynamic), and type of communication (multi-hop or single-hop). In the next step, we compared several clustering algorithms based on the characteristics of cluster heads. For example, mobility can be fixed or mobile, nodes can be heterogeneous or homogeneous, roles can be aggregated or relayed, methods like probabilistic, deterministic, and preset, and objectives for each algorithm. In addition, we examined several clustering algorithms based on selecting cluster heads, the nature of the cluster, and its location awareness.

In uneven clustering, three protocols are distinguished: preset, probabilistic, and deterministic. There are two types of probabilistic clustering: random clustering and hybrid clustering. Although random-type clustering fails to conserve energy, it is simple and achieves very low overhead. A hybrid probabilistic algorithm selects CHs based on randomness and parameters such as residual energy, distance from the base station, node density, etc. Hybrid probabilistic algorithms' iterative and competition-based nature leads to higher message and time complexities. Clustering algorithms based on deterministic principles control clusters and elect cluster heads optimally. Deterministic clustering algorithms select cluster heads based on parameters such as remaining energy, node density, distance from the base station, etc. These parameters can be obtained locally, and the neighbor nodes exchange messages to update them. There are three deterministic clustering algorithms: fuzzy-based, compound-based, and heuristic-based.

Clustering algorithms based on fuzzy logic consume more power during algorithm execution and message exchange. It is impractical for various applications to use heuristic-based clustering algorithms due to the need for global information and the fact that the base station fully manages the algorithms. Depending on the application, this is the most appropriate choice. Clustering algorithms based on weights are iterative, which adds complexity to messages. In compound-based unequal clustering, different metrics are used, such as Sierpinski triangles and linked graphs. Deterministic compound-based methods are proposed to make clustering more energy-efficient.

Most clustering methods are static at the moment, and they cannot adapt to network changes. Therefore, dynamic processes of clustering may prove more effective in the future. The mobility of networks is not intended in this case. For clustered WSNs, we have three components: members of clusters, cluster heads, and finally, the base station. WSNs with mobility require frequent configuration changes, increasing overhead. The WSN is typically data-centric and requires data-centric methods, as discussed earlier. Most algorithms focus on proactive networks, but very few are reactive. Clustering methods may become more reactive in the future.

V. CONCLUSION

The purpose of WSNs is to provide valuable information over long periods with the least amount of energy consumption, exhibiting optimal performance with reduced delays. The low capacity of the battery may, however, pose a serious problem regarding energy consumption. Clustering is found to be an effective technique in power management in WSNs. However, clustering is susceptible to hot-spot problems. Using uneven-type clustering, the load is distributed equally, the hot-spot problem is resolved, and the WSN's lifetime is enhanced. We classified the various uneven clustering algorithms into three broad groups: preset, deterministic, and probabilistic clustering algorithms. The methods are described in terms of their goals, attributes, categories, advantages, and disadvantages. Probabilistic clustering is used when we need simplicity and speed. We employ this type of clustering when we need WSN surveillance on a large scale. To implement more robust and reliable applications, we need deterministic clustering. The heuristic type clustering can be used when we need an optimized solution for an application-specific situation. In this paper, we also compared all these types of protocols based on their clustering properties, CHs properties, and also on the type of clustering process.

Univariate and Multivariate Gaussian Models for Anomaly Detection in Multi Tenant Distributed Systems

Prof. Pravin Ramdas Patil[1], Dr. Geetanjali Kale[2]
Assistant Professor[1]
Head of Department and Associate Professor[2]
Department of Computer Engineering, SCTR’s Pune Institute of Computer Technology,
Pune, Maharashtra, India[1, 2]

***Abstract*—Due to the flaws in shared memory, settings, and network access, distributed systems on a network always have been susceptible to cyber intrusions. Co-users on the same server give attackers the chance to monitor the activity of many other users and launch an attack when those users' security is at risk. Building completely secure network topologies immune from risks and assaults has traditionally been the goal. It is also hard to create an architecture that is 100 percent safe due to its open-ended nature. The precise parameters and infrastructure design whereby the strike is instantiated are a constant which can always be detected regardless of the sort of attack. This work now have the chance to simulate any abnormality and subsequent attack possibilities using network parameter values thanks to the increased usage of algorithms for machine learning and data-gathering tools. This work proposes a Gaussian model to forecast the likelihood of an attack occurring depending on certain system parameters. This work model a univariate and a multivariate Gaussian model on the training dataset. This work makes use of various threshold values to predict whether the data point is an inlier or an outlier. This research examines accuracies for various threshold values. An important challenge in an anomaly detection situation is class imbalance. As long as this work just utilizes training data, a class imbalance is not a problem. Our data-driven results show that combining machine learning with Gaussian-based models might be a useful tool for analyzing network intrusions. Although more steps are being made to boost digital space security, machine learning algorithms may be utilized to examine any abnormal behavior that is left uncontrolled.**

Keywords—Multi-tenant distributed system; anomaly detection; outlier detection; machine learning; Gaussian model

I. Introduction

One of today's most demanding technologies is cloud computing. Cloud computing offers an infinite quantity of IT facilities to deliver amazing computing speed, but on the flip side, it has serious security problems with public clouds for multitenant cloud environments. Most government and commercial companies are compromising with the limited IT resources and performance from existing resources since they are not migrating their sensitive and private data over the public cloud due to security concerns. The aforementioned problems will be solved by finding a way to protect private space over public clouds.

Multiple clients can use the services provided by multi-tenant distributed systems. As a result, each client has access to the activity of the others. By being one of the clients of such a system and taking advantage of such surveillance, attackers can launch assaults against one or more other tenants of the system [1]. To stop any entity in the system from suffering damage, such an attack must be promptly detected [2]. The scourge of attacks in such distributed systems has been a hot topic among researchers despite improvements in cyber security measures. Although cyber security protections have improved, experts continue to focus on the problem of intrusions in such distributed multi-tenant systems. Multiple tenants can cohabit on the same network thanks to multi-tenant distributed systems (MTDS). The MTDS service provider does not inquire about the tenant's motivations when they request co-allocation. This situation presents a chance for renters with bad intentions to observe and collect confidential information about the target occupants. [4] Because the attacker tenant has access to sensitive information, the tenant may prepare an attack that has a greater likelihood of success. [3]

There have already been several attempts to use a variety of techniques to identify the existence of intrusions in distributed applications. [5], [6] Earlier, the emphasis was on applying statistical techniques to compute specific function values, but more recently, cutting-edge approaches including deep learning have been applied. In this regard, artificial neural networks have been investigated.

Although rule-based engines were used to identify assaults, they frequently fall short of spotting any newly discovered threats. Transfer learning may be helpful in this situation, but there is no guarantee that the variables of the source work and the destination job are identical, which has been a significant obstacle to its application. [7]

This work suggests a Gaussian-based classifier strategy in this research for identifying the potential for intrusions in a multi-tenant distributed system to identify inliers and outliers. This work defines a threshold value. This work also looks at the accuracy of different threshold values. Authors are thankful to Patil and Ingale [8] for providing us with the dataset.

Section II of paper includes literature survey of research work done in the area of network attack detection. It explores

Machine learning algorithms used to detect network attacks and to improve cyber security. Section III describes experimentation performed to create and collect dataset. As network attack is not a continuously or regularly occurring event hence lesser number of attacks are performed to create dataset. This dataset includes majority non attack instances and very few attack instances. This section includes statistical and graphical representation of collected dataset. Section IV explains creation of univariate and multivariate Gaussian models for anomaly detection and respective models performance analysis. Section V contains conclusion of research work done.

II. Related Work

Network attack detection has historically made heavy use of signature-based detection. This approach uses an analysis of an attack's "signature," or distinctive qualities, to foretell potential hazards in the future [9]. Methods to discover the best attack signatures were suggested by Hilker et al. [10]. Han et al. [11] advocated crafting network traffic using several attributes. The system cannot identify any new attacks that were previously undiscovered owing to a lack of knowledge about them, which is a significant problem with this technique. Additionally, each new effort to locate signatures requires human labor in addition to time.

Additionally, there have been initiatives to employ machine learning algorithms in this field. Algorithms based on supervised learning have traditionally been used to identify network attacks. [12] For assault detection, Zseby et al. favoured the use of selecting features and subsequent mapping [13]. Evolutionary algorithms were used by Rafique et al. [14] to evaluate the effectiveness of classifying malware. The chance of assault is extremely low, it should be highlighted, therefore a model may get away with forecasting all data as non-negative and yet show good accuracy, making the entire process exceedingly costly.

Prior strategies likewise emphasized the application of boosting techniques and feature reduction in transfer learning. TrAdaBoost was introduced by Dai et al. [15] and reweights the data from the positive and negative classes to give the uncommon examples that indicate attacks more weight in the outcome. TCA-transfer component analysis was used by Pan et al. to feature project the domains closer to one another in the common space [16]. HeMap is a technique created by Shi et al. [17] that projects features using linear transformations. Patil and Ingale [8] tackled the class imbalance problem and used an ensemble based meta classifier to detect anomaly.

The detection of assaults has also been done using model-based methods. This strategy falls under the category of transfer learning and makes the crucial assumption that the source task and the target task share at least some parameters or model priors. Bekerman demonstrated how transfer learning may help increase the resilience of malware detection in uncharted situations. [17].

A noteworthy finding in all of these prior methods was that the stark class disparity seen in network assaults was hardly discussed. Additionally, due to this imbalance, effectiveness of other measures should also be discussed in order to shed light on the results that were produced. We model a Gaussian model on the training dataset. The advantage of this method is that class imbalance does not cause any hindrance.

Research community is contributing towards improving cyber security and security of multi-tenant distributed systems. Despite being all these efforts, attackers are successfully able to place compromised or virtual machine having anomaly to reside with target virtual machine. This leads to increase in the probability of having successful attack on a target virtual machine. Detection of new types of attack possible because of co-residence, co-location and co-tenant of attacker virtual machine with a target virtual machine is still remains a challenge to researchers. Univariate and Multivariate Gaussian models are created to detect network attacks. Performance analysis of individual models created is performed.

III. Dataset Preparation

A. Dataset Collection

Dataset has been collected by Patil and Ingale [8] by using Netdata, a programme for real-time performance monitoring that creates system logs. The logs have been collected across 28 files. This work combines all the files into a single dataset for easy handling. The dataset consists of 4986 inliers instances and 60 outlier instances with 63 columns. All the columns names are noted in Table I.

B. Dataset Preparation

Contributors dropped the column ‘anomaly score’ as it is generated by the software. Authors also separate ‘label’ from the remaining dataset. Authors also drop the columns whose standard deviation is less than 0.3 but also store the original dataset. Contributors are left with 36 columns in the remaining dataset. This work plot some of the important columns as a categorical plot except anomaly score from Fig. 1 to 12. Authors don’t have to worry about class imbalance because model on the training dataset while training is done.

Authors then standardize the dataset as there is need to perform PCA on it. PCA is applied by a keeping 98% variance. After applying PCA, Dataset have 38 columns in the original dataset and 18 columns in the dataset on which columns were removed having standard deviation less than 0.3. This work plots the first two components of the new dataset on a 2D axis as shown in Fig. 13. Authors also perform PCA on the original dataset.

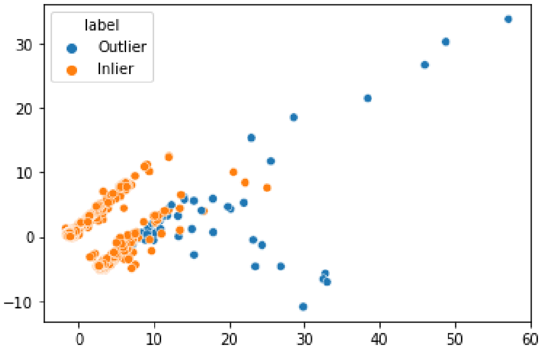

Fig. 13. First two components of the dataset after PCA.

This work, as shown in Fig. 14, plots the first three components of the new dataset on 3D axes. Here authors can clearly see a separation between inliers and outliers.

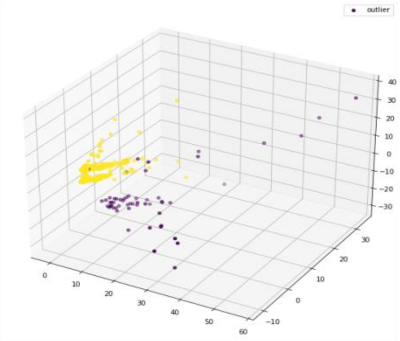

Fig. 14. First three components of the dataset after PCA.

Now authors have two datasets, one with all columns and another with columns left after removing columns with a standard deviation less than 0.3. Authors apply PCA to both datasets. This work split both datasets into three sets, train, test, and cross-validation set. The training set consists of 4000 inliers. The testing set consists of 586 inliers and 30 outliers. The cross-validation set consists of 400 inliers and 30 outliers.

IV. Gaussian Model for Anomaly Detection

A. Univariate Gaussian Model

Gaussian distribution is a continuous probability density function for a real-valued random variable in statistics. It is given by Eq. (1).

$$f(x; \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2} \quad (1)$$

Where f(x) is the probability density function, μ is the mean and σ is the standard deviation.

This work calculates the mean and standard deviation of each column of both datasets and model a Gaussian distribution on all columns. The final probability is calculated by taking the product of the probabilities of all columns. Negative logarithms of probabilities are plotted as histograms as shown in Fig. 15 to 19. Fig. 15 shows probabilities of train inliers. Fig. 16 shows probabilities of test set. Fig. 17 shows probabilities of test set with columns having standard deviation less than 0.3 removed. Fig. 18 shows probabilities of cross validation set. Fig. 19 shows probabilities of cross validation set with columns having standard deviation less than 0.3 removed.

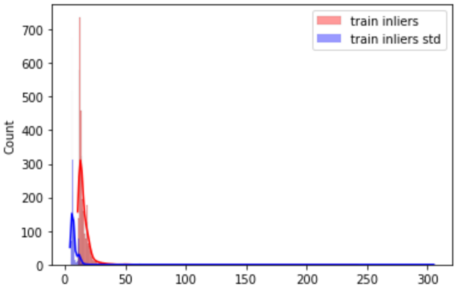

Fig. 15. Probabilities of train inliers.

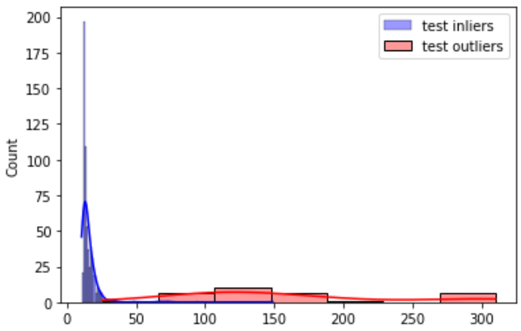

Fig. 16. Probabilities of test set.

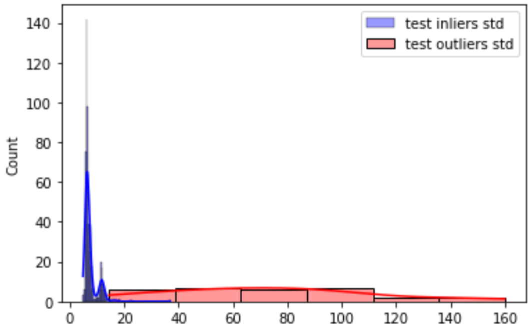

Fig. 17. Probabilities of test set with columns having standard deviation less than 0.3 removed.

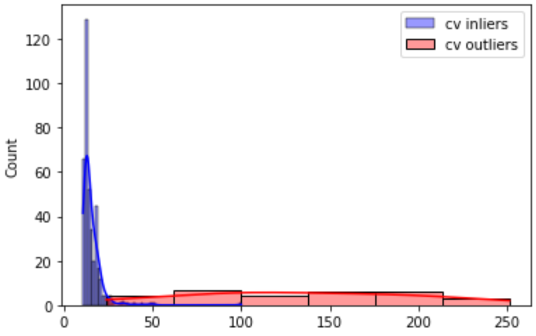

Fig. 18. Probabilities of cross validation set.

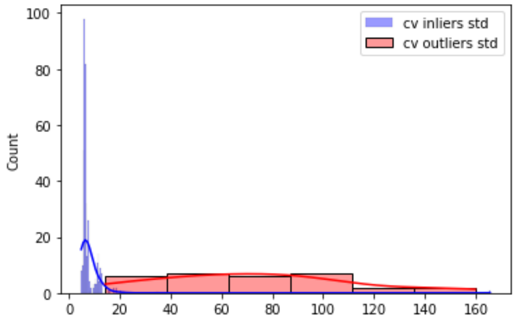

Fig. 19. Probabilities of cross validation set with columns having standard deviation less than 0.3 removed.

Authors set a threshold probability value to classify the test and cross-validation set. Different thresholds are set and accuracy is observed. Table II and III show accuracies for the original dataset.

TABLE II. VARIATION OF ACCURACY WITH DIFFERENT THRESHOLD VALUES FOR TRAIN AND TEST INLIER SET

Threshold	Train accuracy	Test inlier accuracy
1e-10	0	0
1e-15	63.625	64.16
1e-20	89.725	89.078

1e-40	100.0	80.0
1e-45	100.0	76.66

B. *Multivariate Gaussian Model*

The multivariate normal distribution, multivariate Gaussian distribution, or joint normal distribution are expansions of the one-dimensional normal distribution to higher dimensions in probability theory and statistics. It models the probability in one shot instead of calculating individual probabilities and multiplying them. Multivariate Gaussian distribution is given by the Eq. (2).

$$\mathcal{N}(x;\mu,\Sigma) = \frac{1}{(2\pi)^{\frac{d}{2}}}|\Sigma|^{-\frac{1}{2}}\exp\left\{-\frac{1}{2}(x-\mu)\Sigma^{-1}(x-\mu)^{T}\right\}(2)$$

Where μ is the length-d row vector of means of all columns, ∑ is the covariance matrix of shape d x d. d is the number of features.

Authors calculate the mean and covariance matrices of both datasets to model a multivariate Gaussian distribution. Authors set a threshold value and classify the dataset between inlier and outlier and calculate accuracies for various threshold values. Negative logarithms of probabilities are plotted as a histogram as shown in Fig. 20 to 24. Fig. 20 shows probabilities of train inliers. Fig. 21 shows probabilities of test inliers and test outliers. Fig. 22 shows probabilities of test inliers and test outliers with columns having standard deviation less than 0.3 removed. Fig. 23 shows probabilities of cross-val inliers and cross-val outliers. Fig. 24 shows probabilities of cross-val inliers and cross-val outliers with columns having standard deviation less than 0.3 removed.

V. CONCLUSION

This work states that univariate and multivariate Gaussian models for anomaly detection are successfully created. Data imbalance is not an issue here because these models fit on the train set and this work uses a threshold to predict inliers and outliers. This work examines the trend between various threshold values and accuracies. The proposed method, a Gaussian model to forecast the likelihood of an attack occurring based on certain system parameters uses a univariate and a multivariate Gaussian model on the training dataset and examines accuracies for various threshold values. It also addresses the challenge of class imbalance in anomaly detection situations. This method presents the successful creation of univariate and multivariate Gaussian models for anomaly detection. The data imbalance is not an issue in these models because they fit on the train set and use a threshold to predict inliers and outliers. The study also examines the relationship between various threshold values and accuracies. For univariate Gaussian model variation of accuracy with different threshold values ranges up to 99.175 percent and for train accuracy up to 98.6 percent for test inlier accuracy and up to 100 percent for test outlier accuracy. For multivariate Gaussian model variation of accuracy with different threshold values ranges up to 99.45 for train accuracy, up to 100 for test inlier accuracy and up to 100 for test outlier accuracy with validation.

Future work is about using deep learning techniques such as auto encoders. Machine learning is revealing a plethora of potential for cybersecurity aficionados to explore as more and more data is gathered, specifically with the data that they already own. When this work talks about escalating warfare in the internet age, timely automated identification of any threats or suspicious conduct can avoid a number of mistakes from occurring.

Cloud Service Composition using Firefly Optimization Algorithm and Fuzzy Logic

Wenzhi Wang, Zhanqiao Liu
School of Distance Education, Jiaozuo University, Jiaozuo, 454000, China

***Abstract*—Cloud computing involves the dynamic provision of virtualized and scalable resources over the Internet as services. Different types of services with the same functionality but different non-functionality features may be delivered in a cloud environment in response to customer requests, which may need to be combined to satisfy the customer's complex requirements. Recent research has focused on combining unique and loosely-coupled services into a preferred system. An optimized composite service consists of formerly existing single and simple services combined to provide an optimal composite service, thereby improving the quality of service (QoS). In recent years, cloud computing has driven the rapid proliferation of multi-provision cloud service compositions, in which cloud service providers can provide multiple services simultaneously. Service composition fulfils a variety of user needs in a variety of scenarios. The composite request (service request) in a multi-cloud environment requires atomic services (service candidates) located in multiple clouds. Service composition combines atomic services from multiple clouds into a single service. Since cloud services are rapidly growing and their Quality of Service (QoS) is widely varying, finding the necessary services and composing them with quality assurances is an increasingly challenging technical task. This paper presents a method that uses the firefly optimization algorithm (FOA) and fuzzy logic to balance multiple QoS factors and satisfy service composition constraints. Experimental results prove that the proposed method outperforms previous ones in terms of response time, availability, and energy consumption.**

Keywords*—Cloud computing; service composition; QoS; firefly algorithm; fuzzy logic

I. Introduction

Recent rapid growth in artificial intelligence [1, 2], machine learning [3], optical networks [4, 5], smart grids [6], cloud computing [7], 5G connectivity [8], Blockchain [9, 10], and Internet of Things (IoT) [11, 12] have resulted in an explosion of data in almost all fields of engineering and commerce. With cloud computing, large-scale applications can be deployed quickly and efficiently, affordably on a per-use basis [13]. Cloud computing relies on virtualization to share resources among customers [14]. Virtualization technology enables cloud data centres to dynamically share physical resources, allowing multiple applications to run on different platforms known as Virtual Machines (VMs) [15]. As a result of virtualization, cloud service providers can ensure the quality of service (QoS) distributed among different users while achieving maximum resource utilization and minimal power consumption [16]. Cloud environments deliver services tailored to users' requirements. Existing services are combined into composite services to provide users with value-added services. As cloud computing has proliferated, more providers are providing similar functional cloud services but with diverse nonfunctional characteristics [17]. Consequently, cloud service composition must consider QoS awareness in choosing appropriate services and combining them to meet users' expectations, known as QoS-aware cloud service composition [18]. Cloud services can potentially encapsulate many resources as new technologies develop, and combinatorial optimization problems can be transformed into QoS-aware cloud service composition problems [19].

Cloud services currently available to consumers offer similar functionality at varying QoS levels. Cloud services offer different levels of QoS for a given task, so ranking these services based on QoS makes it easier for users to choose cloud services [20]. There might be a service rated best under one QoS parameter yet rated worst under another. Various QoS parameters can be used to rank the performance of a service. Cloud service composition contexts prioritize QoS parameters differently [21]. In choosing a cloud service, all QoS parameters must be taken into account without overlooking the influence of a primary QoS factor. QoS-aware cloud service composition generally considers only one or two QoS factors and ignores balancing QoS parameters or satisfying connectivity constraints [22]. In this paper, we present a novel method based on firefly optimization (FOA) and fuzzy logic to balance multiple QoS parameters and satisfy the connectivity constraints of service composition. The rest of the paper appears as follows. The next section summarizes related works. The proposed strategy is discussed in detail in Section III. Section IV reports the simulation results. Section V concludes the paper with a discussion of future directions. Generally, this work contributes to:

- A model maturity metric is introduced in this paper in order to provide a comprehensive evaluation of the simulation model lifecycle in cloud environments.
- Based on the cooperation relationship between model services, this paper dynamically calculates the maturity score of the combined model.
- A new algorithm based on FOA and fuzzy logic is proposed in this paper for the composition and optimization of cloud model services.

II. Related Work

Kritikos and Plexousakis [23] presented an approach for composing cloud services that optimally satisfy various user requirements while simultaneously composing different cloud services. Cloud application design tools do not simultaneously support quality, deployment, security, placement, or cost requirements. In addition, the proposed approach considers a type of design choice currently not considered in the literature. Huo, Zhuang [24] propose a novel technique for cloud service composition that formalizes service composition as a nonlinear integer programming problem by incorporating a time attenuation function. Additionally, the discrete gbest-guided artificial bee colony algorithm is presented, representing the exploration of bee hives for food in search of the optimal service composition strategy. Based on experiments, it appears that the time attenuation function can improve the quality of services by making them more consistent with their characteristics at present. In comparison with other algorithms, especially for large-scale data, this algorithm provides the best possible solution in a short amount of time.

Liu, Chu [25] use social learning optimization algorithm (SLOA) to resolve the QoS-aware cloud service composition problem. Improvements to differential evolutionary algorithms and SLOA are incorporated into micro-space and learning spaces. Performance comparison and experimental results demonstrate the efficacy of the SLOA. This work will improve search capabilities and convergence rates by extending the theory of the swarm intelligence optimization algorithm and exploring a novel swarm intelligence optimization model. The challenge of correlation-aware QoS in networks and cloud services is addressed by Huang, Li [26]. This problem is formulated as a multi-constraint optimal path problem, and a novel approach is proposed for solving it. The proposed algorithm is evaluated using extensive simulation. The proposed algorithm yields superior service composition solutions with improved QoS guarantees by taking into account the QoS correlations between the different service types.

Karimi, Isazadeh [27] employed the genetic algorithm to optimize service level agreements globally. Service clustering was applied to reduce the search space, and association rules were applied to a composite service based on their histories to improve service composition efficiency. As compared with similar related works, the proposed method demonstrated higher efficiency. Low-cost access to a simplified, centralized platform or resource is provided by cloud computing. This type of computing allocates resources based on individual needs. However, resources need to be allocated efficiently to meet the expanding needs of cloud users. Service providers are responsible for distributing and sharing resources effectively, preventing resource waste. Furthermore, the user receives the appropriate service based on their request, with the cost of the resource being optimized. Singh, Juneja [28] present an algorithm for automated service composition based on agents, which addresses both service requests and automatic service composition. The algorithm searches for the best services and reduces the cost of on-demand virtual machines.

Wang, Zhou [29] analyzed the relationship between energy consumption, network resource consumption, and QoS performance in a service composition process. An approach to green service composition is then presented. The system prioritizes composite services that run on the same physical server, virtual machine, or edge switch. Green service composition optimization minimizes energy and network resource consumption on physical servers and switches in cloud data centers. Based on experiments, the proposed approach reduces energy consumption by 20-50 percent and network resource consumption by 10-50 percent compared to other approaches. Jian, Li [30] presents an algorithm incorporating the two-order oscillating equation and the historical positions of birds. It enhances bird diversity, strengthens global search algorithms, and improves bird feeding and migration dynamics. Based on simulation results with and without local QoS restrictions, the algorithm minimizes overall QoS restriction execution times. The new eagle search procedure was developed by Jin, Lv [31] by integrating regular mutations with an improved whale optimization algorithm. In order to verify the performance of the new approach, a variety of benchmark functions and problems of cloud service composition are used. The proposed method outperforms the other methods, according to experiments.

Studies presented above suggest a variety of solutions to the problem of service composition. The majority of researchers, however, use a simple additive weighting proposal in order to combine multiple aspects of QoS into a single-objective function. Service composition is primarily a multi-objective problem, in which multiple, often conflicting attributes of QoS must be optimized simultaneously. A number of proposals have been considered to address the problem of service composition from a multi-objective perspective, including a tri-objective service composition [32], a bi-objective service composition [33], and a bi-objective service composition from an energy and global quality of service utility's perspective [14]. However, these studies only identify up to three representative objectives by assigning priorities to QoS factors or reducing a large proportion of QoS factors within two or three objectives. The literature rarely examines service composition scenarios with four or more objectives. The QoS criteria for many applications have expanded to include security, maintainability, reputation, energy consumption, carbon emissions, and ecological impact. With a range of trade-off options available, the decision-making process becomes more flexible. Service composition is strictly a multi-objective optimization problem if we treat all QoS attributes equally.

III. Proposed Method

This section will provide a new IoT-enabled cloud service composition method based on FOA and fuzzy logic systems. We aim to improve the QoS parameters, reduce energy consumption, extend the network's life, improve packet delivery rates, and decrease delays. Due to two advantages of automatic segmentation of the network and diversity in solutions, the FOA can perform better than other algorithms in finding the optimal solution to optimization problems. In the following, we have discussed the network model and problem assumptions, optimization models, objective function, and finally, the proposed method.

A. The Problem Expression and Formulation

Under one set of QoS parameters, a cloud service may be rated as the best, whereas under another set of QoS parameters, it may be rated as the worst. Various QoS parameters can be used to rank cloud service performance. Cloud services that rank highest under one QoS parameter, such as reliability, may rank lowest under another QoS parameter, such as response time. Therefore, QoS parameters are prioritized differently depending on the composition context. A cloud service that is optimal under one QoS parameter may fail if that cloud service is not optimal under another QoS parameter. Therefore, including any of these cloud services as candidate services in the composition will have an impact on the overall performance, since these cloud services perform poorly under parameters other than the primary QoS parameter.

QoS-aware services composition problem is finding a set of candidate services with different functional features that comply with the determined limitations by the user and optimize an objective function. This problem is explained in this section.

- A service composition request as a workflow that is modeled using a Directed Acyclic Graph (DAG), G=(V, E).
- $V = \{T_1.T_2.T_3.\dots.T_n\}$ That n is the number of tasks in the workflow.
- E is the set of edges showing the priority of executing the works.
- Each T_i for $0 \le i \le n$ is a set of candidate services in the workflow.
- $CS_i = \{CS_i^1.CS_i^2 \dots.CS_i^m\}$: That CS_i^J for $1 \le j \le m$ is a candidate service.
- M_i is the number of existing candidate services for T_i.
- Each candidate service CS_i^J has a set of different QoS information.
- $QOS = \{Q_1.Q_2.Q_3.\dots.Q_n\}$ That Q_i for $1 \le i \le k$ shows a QoS feature of cloud services.

Considering the above cases, the goal of the QoS-aware service composition problem is near optimal so that:

$$\forall j = 1 \dots k \begin{cases} \sum_{i=0}^{n} S_i.Q_i < C_j & if\ Q_j\ is\ additive \\ \prod_{i=1}^{n} S_i.Q_i > C_j & if\ \ Q_j\ is\ multiplicative \end{cases} \tag{1}$$

Composition and service selection problem in all computational platforms like cloud environment and IoT is appropriate to meet a user or system requirements that should provide QoS requirements in addition to the user's needs. A fitting function in a service composition problem, like any optimization problem, is used to determine whether the selected service is valuable. This function's output determines the efficiency of the selected services for composition.

Generally, the most important factor for the development and scalability of IoT is considering energy consumption limitations. Hence, energy saving is one of the important challenges in these networks because energy sources in IoT nodes are limited, and changing the energy sources of the nodes on large scales is practically impossible. Based on the mentioned notes, energy consumption is critical for the candidate services' host nodes. Thus, each candidate service must propose its required energy to the service provider module to select one of the most energy-efficient nodes for service composition. Two variables are used in the proposed energy model for the model definition. The first one is the amount of remaining energy and the second one is the amount of consumed energy of the node, which is the amount of consumed energy when executing the user's request. Based on the model, $RE(cs_{ij})$ is the remaining energy of the candidate service host (cs_{ij}), and $CE(cs_{ij})$ is the consumed energy when running the candidate's request (cs_{ij}). Hence, the amount of remaining energy of the host is calculated using 3:

$$RE(cs_{ij}) = CDE(cs_{ij}) - E_{th}(cs_{ij}) \tag{2}$$

where $CDE(cs_{ij})$ is the level of energy in the IoT node equipped with the battery, which is the host of cs_{ij} service, and $E_{th}(cs_{ij})$ is the minimum threshold energy of IoT so that if a node's energy is less than the threshold, the node cannot work in the network and dies.

Since the energy model in this thesis is based on service-oriented calculations, the consumed energy by the service candidate when running cs_{ij} is estimated using equation (3). We assume that the energy consumption of the candidate service cs_{ij} is constant because the services are run on the same IoT platform and use the same resources to answer the service. Moreover, they consume the same amount of energy when data transmission and reception.

$$CE(cs_{ij}) = ECR(cs_{ij}) \times T(cs_{ij}) \tag{3}$$

where $CE(cs_{ij})$ is the consumed energy, and $T(cs_{ij})$ is the run time of the candidate service (cs_{ij}). Finally, the consumed energy of the cs_{ij} candidate service is defined as an EP and calculated by Eq. (4). The profile is estimated based on the ratio of the cs_{ij} candidate service consumed energy to its remaining energy.

$$EP(cs_{ij}) = \frac{CE(cs_{ij})}{RE(cs_{ij})} \tag{4}$$

Based on Eq. (3) to (4), the lower amount of $EP(cs_{ij})$ in a node means that the node is optimal for cs_{ij} service at time T_i. Finally, the EP of service composition is computed using Eq. (5). Hence, the consumed energy of the service composition path x^i is as follows:

$$EP(x) = \sum_{i=1}^{n} EP(x^i | x^i \in s^h) \tag{5}$$

where $s^h$is the set of IoT nodes with a battery. The nodes with lower energy than the threshold energy is removed from the set.

- Response Time: the required time duration for a request transmission and its response reception.

- Availability: the number of successful calls to the total number of calls ratio.
- Successability: the number of responses to the number of request messages ratio.
- Reliability: the number of faulty messages to the total number of messages ratio.
- Latency: the duration of a request process by a server.

In the selection and composition of IoT services, the composing services can be composed and meet the users' needs. Hence, calculating the composed QoS features summation is important, and each serial, parallel, switch, and loop pattern uses its formulas. The requested works and the proposed services are considered a graph for service composition. Thus, the following equations are used for the QoS parameter values calculation in the composing services. Eq. (6) calculated the response time parameter, and Eq. (7) to (11) are used to calculate delay, energy, reliability, availability, and successability parameters in the composing services, respectively.

$$Q_{Responce\ Time}(s) = \sum_{i=1}^{n} Q_{RT}\ (s) \tag{6}$$

$$Q_{Latency}(s) = \sum_{i=1}^{n} Q_{L}\ (s) \tag{7}$$

$$Q_{Energy\ Consumption}(s) = \sum_{i=1}^{n} Q_{EC}\ (s) \tag{8}$$

$$Q_{Reliability}(s) = \prod_{i=1}^{n} Q_{R}(s) \tag{9}$$

$$Q_{Accessability}(s) = \prod_{i=1}^{n} Q_{A}(s) \tag{10}$$

$$Q_{Successability}(s) = \prod_{i=1}^{n} Q_{S}(s) \tag{11}$$

Generally, the fitting function (objective function) is used to determine the value of each solution generated by the optimization problems. This function output determines how much a solution can be useful for meeting the user's or the system's requirements. The fitting function is defined by Eq. (12).

$$Fitness(Sol) = W_1 * Resp + W_2 * Late + W_3 * \frac{1}{Avail} + W_4 * \frac{1}{Succ} + W_5 * \frac{1}{Reli} + W_6 * Energy \tag{12}$$

where W_1, W_2, W_3, W_4, W_5, and W_6 are the positive weights showing the importance of each QoS parameter determined by the user. Eq. (13) and (14) are used for normalizing the parameters' output in the objective function. Eq. (13) is for the minimizer parameters, and (14) is for the maximizer parameters.

$$N_{CS.Q^i} \begin{cases} \frac{Q^i_{max} - CS.Q^i}{Q^i_{max} - Q^i_{min}} & Q^i_{max} \neq Q^i_{min} \\ 1 & Q^i_{max} = Q^i_{min} \end{cases} \tag{13}$$

$$N_{CS.Q^i} \begin{cases} \frac{CS.Q^i - Q^i_{min}}{Q^i_{max} - Q^i_{min}} & Q^i_{max} \neq Q^i_{min} \\ 1 & Q^i_{max} = Q^i_{min} \end{cases} \tag{14}$$

where $CS \cdot Q^i$ is the ith parameter value of QoS related to the CS selected service, $Ncs \cdot Q^i$ is the normalized value, and Q^i_{max} and Q^i_{min} are the maximum and minimum of the ith parameter among all the services.

B. The Proposed Method's Steps

This section has two subsections. The first subsection includes general information about the firefly algorithm and Fuzzy logic, and the proposed method steps are explained in the second subsection. The FOA algorithm was inspired by how fireflies attract mates by producing flashlights. The FOA uses three idealized features of the firefly's flashing light to produce an optimal solution. Fireflies are unisex and attract other fireflies irrespective of their gender.

Further, when two fireflies are distant from each other, their attractiveness decreases, which is directly proportional to their brightness. Finally, the firefly flashing light is incorporated into the optimization process as an objective function [34, 35]. Fuzzy logic is an approach to variable processing that allows multiple possible truth values to be processed through the same variable. Fuzzy logic attempts to solve problems with an open, imprecise spectrum of data and heuristics that makes it possible to obtain an array of accurate conclusions. The fuzzy logic architecture consists of the following components:

- **Rule base:** This contains the rules and membership functions that regulate or control decision-making in the fuzzy logic system. It also contains the IF-THEN conditions for conditional programming and controlling the system.
- **Fuzzifier:** This component transforms raw inputs into fuzzy sets. The fuzzy sets proceed to the control system, where they undergo further processing.
- **Inference engine:** This tool establishes the ideal rules for a specific input. It then applies these rules to the input data to generate a fuzzy output.
- **Defuzzifier:** This component transforms the fuzzy sets into an explicit output (in the form of crisp inputs). Defuzzification is the final stage of a fuzzy logic system.

The proposed method uses the fuzzy logic system and firefly optimization algorithm for optimal service composition. Since the firefly algorithm has a low speed for local search, Fuzzy logic is used to ease finding the optimal composition in terms of the problem objectives. The firefly algorithm can find and compose more optimal services in less time by applying fuzzy values for each QoS parameter. The basis of the work is as follows: first, a firefly is assigned to each service. Then the fireflies create paths based on their movement pattern and

Luciferin value to find the optimal service composition. Finally, the best services are used for composition by evaluating the route found by the fireflies. The Fuzzy values for each service in the Luciferin function are saved for each firefly. The fireflies find the best composition by applying the Fuzzy values with the neighbour nodes' Luciferin.

1) First step: generating primary population: The primary population is generated in this step using random distribution. The IoT nodes generated based on the geographical positions are distributed in the objective area. After the distribution of nodes, the parameters' initial values, like energy, Luciferin value, and the nodes transmission's radius, are assigned to the parameters. Moreover, data related to each QoS parameter are read from the dataset and put in the parameters.

2) Second step: QoS parameters fuzzification: The proposed method's first step includes fuzzifying each IoT service QoS information. This information includes response time, availability, successability, reliability, energy, and delay. These values are the Fuzzy system inputs in this step, in which a Fuzzy value is generated based on the Fuzzy rules for all inputs to evaluate and select the services based on the value. This Fuzzy value is defined as Low, High, Medium, Very Low, and Very High. Then the system analyzes the information based on the inputs and the written rules in the knowledge base of the fuzzy system and generates the final value after defuzzification. These values then transfer to the firefly algorithm as inputs.

The fuzzy rules are written considering different states of the input parameters and finally are saved in the database. Then using a Fuzzy Inference System (FIS), an output value is generated based on different input states. The Fuzzy rules are written using nested If-Then. The proposed Fuzzy system used 25 rules shown in Table I. Fig. 1 to 5 illustrate the membership functions of the FIS input and output parameters. In the Fuzzy rules table, RT is the response time, D is the delay, En is energy, Av is availability, and Fitness is the output parameter.

After generating different fuzzy values based on the fuzzy rules and input parameters, defuzzification is performed on each fuzzy value. Membership functions of the fuzzy system output variables are presented in Fig. 3 to 11.

3) Third step: using the firefly algorithm to select the best services for the composition: Each firefly in this algorithm is an answer to the problem. All answers have fitting values calculated by the fuzzy system that should be optimized. The first step is creating a list of the proposed services to do the existing tasks in the workflow. Each workflow proposed by the user has n tasks. There is a determined number of services to perform each task, and m is the maximum number of the proposed selected services for each task. At first, an n*1 array of random numbers with size m are generated to initialize the algorithm. The array shows the number of existing services in the accumulator that can perform the workflow tasks. In the next step, the matrix is generated to save the list of the services that can perform the tasks in the workflow. The number of proposed services listed to do the workflow's tasks is generated in the next step. Each presented workflow by the user has m tasks, and there is a determined number of services to do each of the services. The optimization process started with some random solutions. The primary solution is selected among the proposed services for each task. In the firefly algorithm, the primary solution is a service composition, an n*1 array with n tasks in the workflow. The stored number in index i of the array shows the ID of the candidate service that executes the Ti task. The following steps are performed to select and compose the most proper services based on the firefly algorithm steps:

- In the first step, some primary population is generated and distributed randomly. Initialization of Luciferin is applied to each firefly, and the primary solutions are generated. These solutions are valued based on the fitting function value.
- In the second step, the considered proposed QoS parameters as inputs of the problem are fuzzified based on the proposed Fuzzy system. Their values in each round of the algorithm are inserted and updated in the Luciferin matrix as the next step fitting value (the neighbour nodes). Since the parameter values change in each round of the algorithm, the proposed fuzzy system is executed based on the Fuzzy rules in each round, and new values are generated.
- In the third step, the firefly algorithm generates new solutions based on the movement steps. A population of fireflies creates new solutions in the proposed algorithm. The generated solutions of each iteration go to the next iteration for more optimal solutions. A firefly position shows a solution for the composing service problem that the primary position of the fireflies is random. Each firefly generated new solutions in each algorithm iteration based on the fitting value using Eq. (15). The solutions are updated based on their quality. If the new solutions are better than the existing ones, they are replaced.

$$x_{\mathrm{j}}=x_{\mathrm{i}}+\beta_0 . e^{-\gamma r i j^2} \quad (15)$$

After that, all fireflies generate their solutions. A probability is used for selecting the most appropriate solution for each firefly, given by Eq. (16). After calculating the selection probability of each node as the next step, one of the nodes is selected randomly.

$$p_{ij}(\mathrm{t})=\frac{L_j(t)-L_i(t)}{\sum_{k\epsilon N_i(t)} L_k(t)-L_i(t)} \quad (16)$$

In the above equation, $L_i(t)$ is the amount of luciferin of each firefly that is calculated using Eq. (17).

$$L_i(t)=(1-\rho)L_i(t-1)+\gamma J(x_i(t)) \quad (17)$$

In the Eq. (17), $L_i(t)$, $L_i(t-1)$ and $x_i(t)$ are respectively the new value of luciferin, the previous value of luciferin, and the fitness of the location of worm i in iteration t of the algorithm, respectively, and ρ and γ are fixed numbers for modeling Gradual decline and fitness effect on luciferin.

The step-by-step movement of the fireflies continues until selecting the most suitable service for composition. After selection, the generated solution evaluation is performed so that the average distance of the selected solution is calculated rather than other solutions. Then the fitting function value is computed for new solutions. If the new solution is better than the existing solution in the memory, the firefly memory is updated using the new solution. Then the parameters are updated. The proposed method flowchart is illustrated in Fig. 6.

TABLE I. PROPOSED FUZZY RULES

The fuzzy rules
If (RT is VL) and (D is VL) and (En is VL) and (Av is VH) then (Fitness is VH)
If (RT is VL) and (D is VL) and (En is L) and (Av is VH) then (Fitness is H)
If (RT is VL) and (D is VL) and (En is L) and (Av is H) then (Fitness is H)

IV. EVALUATION AND SIMULATION

Matlab is used for the simulation of the proposed method. All these experiments are performed on an HP computer with a Core i5 2.0 GHz CPU and 4 GB main memory. The utilized dataset in the proposed method is a dataset provided by Al-Masri et al., called Quality of Web Service (QWS), and provides a base for the services researchers. The QWS dataset includes a set of 2507 web services and measures their QoS. These data are presented in Table II. The parameters are considered objective parameters. Firefly algorithm parameters also are presented in Table III.

A. The Simulation Results' Study

The proposed method's results are compared with [36], [37], and [38] in this section and presented in different tables and figures. Moreover, two experiments are explained in the following to study the proposed method's convergence to optimal solutions and stability test.

In the first experiment, the resulting data of [36] are used to evaluate the proposed method in this thesis. The proposed method in [36] is based on a multi-objective genetic algorithm to investigate the service composition of IoT that is evaluated with the different number of tasks and candidate services for the tasks. Hence, our proposed method is evaluated in this experiment with ten tasks and 10, 30, and 50 candidate services. Fig. 7 shows the proposed method's execution time and comparison with the multi-objective genetic algorithm [36]. Based on the results, the proposed method's execution time is less than the genetic algorithm to find appropriate services for composition. Because the proposed method can find the most suitable network node for the services selection and composition that provides QoS requirements by tracing the most optimal IoT nodes. The routing method and selecting the most suitable resource (IoT node) with proper services for the user's requests will be explained in detail with mathematical equations in the third chapter.

In the second experiment, the resulting data of [37] are used to evaluate the proposed method in this thesis. The proposed method in [37] is based on the Markov chain and ant colony optimization algorithm for IoT services composition. The authors of [37] evaluate their method with the different number of requests. Hence, our proposed method (firefly-fuzzy logic) is simulated and evaluated with the different number of requests in this experiment.

Fig. 8 to 11 show the availability rate, response time, reliability rate, and consumed energy of the proposed method, respectively, which are compared with the method in [37]. Based on the results in Fig. 8, the proposed method (firefly-fuzzy logic) has a higher accessibility rate than the Markov-ant colony because of tracing the network nodes based on energy and distance. Moreover, selecting the most suitable route between the network's nodes (network's resources) is based on the movement pattern of the fuzzy firefly. According to Fig. 9, the response time of the proposed method is less than the method in [37]. Fig. 10 to 11 also show better performance of the proposed method than the method in [37] in terms of reliability.

In the third experiment, the resulting data of [39] are used to evaluate the proposed method in this thesis. The proposed method in [39] is based on the Concurrent Requests Integration Optimization (CRIO) mechanism and Gray Wolf (GWO) for IoT services composition. Fig. 12 shows the consumed energy by the proposed method. The results in Fig. 12 show that the proposed method has a lower energy consumption than the CRIO-GWO.

TABLE II. QWS PARAMETERS DEFINITION

Parameters	Definition
Response Time	The required time duration for a request transmission and its response reception.
Availability	The number of successful calls to the total number of calls ratio.
Energy	The amount of the consumed energy of the host nodes of the candidate services.
Successability	The number of responses to the number of request messages ratio.
Reliability	The number of faulty messages to the total number of messages ratio.
Latency	The duration of a request process by a server

TABLE III. SIMULATION VARIABLES

Parameters	Definition	Value	measurement Unit
N	Number of nodes	100-600	-
MaxIT	Maximum algorithm iteration	100-1000	-
L	Data packet length	1024	bit
$\boldsymbol{E_{initial}}$	Initial energy	0.5 – 10	joule
$\boldsymbol{\alpha_0}$	Firefly algorithm constant	[0 – 1]	-
$\boldsymbol{\beta_0}$	Firefly algorithm constant	1	-
γ	Firefly algorithm constant	0.1 – 10	-

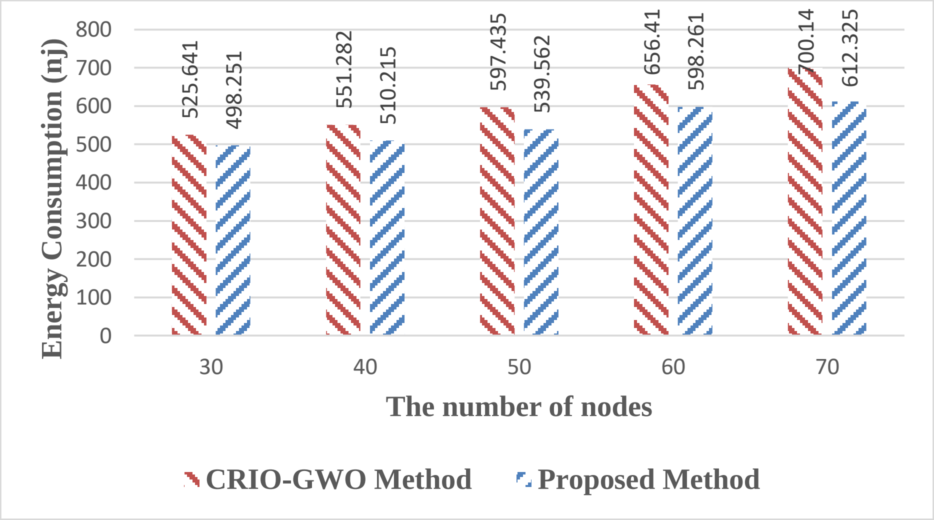

Fig. 12. Energy consumption vs. the number of nodes.

V. Conclusion

In general, cloud computing refers to the provision of dynamically scalable and virtualized resources over the Internet as services. Depending on the user's needs, a variety of cloud-based services may be delivered, which are often composited to meet those requirements. To combine and consolidate cloud services, service composition is emerging as a universal technology. By combining previously existing services, this idea aims to reduce costs and improve efficiency through a new cloud service. An IoT-enabled cloud service composition method using the fuzzy logic system and FOA is proposed in this paper. Energy, reliability, delay, and availability are the objective parameters in the proposed method. There are three main steps involved in this method in order to provide the proper nodes for the composition of cloud services. First, the requirements to start the algorithm are provided, like initialization of parameters and the dataset values normalization. Second, fuzzyification is performed on the parameters after determining the input parameters. Third, the firefly algorithm selects the most suitable nodes (resources) for service composition. Finally, in the fourth section of this paper, the proposed method is simulated using Matlab. A comparison of the proposed method with previous ones showed that the proposed method performed better in terms of response time, availability, and energy consumption. The dynamic nature of the cloud may be considered in our future work. A cloud's processing capabilities are limited, and the number of atomic services may change over time. Future research should focus on how to compose atomic services. In addition to addressing the energy consumption issue, we hope to maintain other metrics in the scheduling, including reliability, stability, trust degree, etc.

Systematic Review of Deep Learning Techniques for Lung Cancer Detection

Mattakoyya Aharonu[1], R Lokesh Kumar[2]*
School of Computer Science and Engineering, Vellore Institute of Technology, Vellore, India

***Abstract*—Cancer is the leading cause of deaths across the globe and 10 million people died of cancer and particularly 2.21 million new cases registered besides 1.80 million deaths, according to WHO, in 2020. Malignant cancer is caused by multiplication and growth of lung cells. In this context, exploiting technological innovations for automatic detection of lung cancer early is to be given paramount importance. Towards this end significant progress has been made and deep learning model such as Convolutional Neural Network (CNN) is found superior in processing lung CT or MRI images for disease diagnosis. Lung cancer detection in the early stages of the disease helps in better treatment and cure of the disease. In this paper, we made a systematic review of deep learning methods for detection of lung cancer. It reviews peer reviewed journal papers and conferences from 2012 to 2021. Literature review throws light on synthesis of different existing methods covering machine learning (ML), deep learning and artificial intelligence (AI). It provides insights of different deep learning methods in terms of their pros and cons and arrives at possible research gaps. This paper gives knowledge to the reader on different aspects of lung cancer detection which can trigger further research possibilities to realize models that can be used in Clinical Decision Support Systems (CDSSs) required by healthcare units.**

Keywords*—Artificial intelligence; deep learning; lung cancer; lung cancer detection; machine learning

I. Introduction

Cancer is an abnormal growth of cells in human body. Lung cancer is leading cause of deaths across the world and there are different kinds of cancers according to WHO. They include breast cancer, lung cancer, colon and rectum cancer, skin cancer, prostate cancer, and stomach cancer. Cancer incidence in 2020 is high with 2.26 billion breast cancer cases, 2.21 million lung cancer cases, 1.93 million colon and rectum cancer, 1.41 million prostate cancer cases, 1.20 million skin cancer cases and 1.09 million stomach cancer cases. These statistics show the alarming nature of the disease across the globe. There are many risk factors for cancers. They include tobacco, alcohol, unhealthy diet, air pollution and physical activity. Some chronic diseases also play their role in causing cancer. The major challenge is to detect the lung cancer at early stage and increase the survival rate of lung cancer patients. In this context, technological innovations need to be understood towards cancer diagnosis automatically. With advancements in artificial intelligence (AI) based approaches such as machine learning and deep learning, it is important to consider them for automatic diagnosis of lung cancer. Since there are number of training samples available and they grow in future, supervised learning is found suitable for automatic lung cancer detection.

Different methods came into existence based on image processing, machine learning, deep learning, and artificial intelligence (AI). The existing methods are investigated in this paper through systematic review. Several ML based approaches such as [2], [3], [4], [5] and [9], to mention few, are some of the representative approaches where supervised learning is used for lung cancer detection. There are plenty of deep learning methods explored in [6], [7], [8], [10], [11] to mention few, that have different advanced learning models with optimizations for improving prediction performance. Our contributions in this paper are as follows. We have made systematic review of methods used for lung cancer detection. It is backed by a methodology and results of research questions. It throws light on various insights besides giving research gaps. The remainder of the paper is structured as follows. Section II reviews literature on existing lung cancer prediction methods. Section III presents research methodology used for systematic review. Section IV provides the results for different research questions. Section V concludes the paper and gives directions for future scope of the research.

II. Literature Review

This section reviews literature on deep learning methods used for lung cancer detection. It also covers machine learning methods, imaging techniques and performance metrics besides important research gaps.

A. Machine Learning Methods

Machine learning techniques with supervised learning are used for lung cancer detection. Bhatia et al. [2] proposed a methodology to diagnose lung cancer using CT images. Their methodology includes Random Forest (RF) and XGBoost methods along with ensemble learning approach. Radhika and Nair [4] explored different ML models such as Logistic Regression (LR), Decision Tree (DT), Support Vector Machine (SVM) and Naïve Bayes. Pradhan and Chawla [5] used ML models along with a novel architecture for realizing Medical Internet of Things (MIoT). Rehman et al. [9] used ML models like SVM and ANN to detect the disease from lung CT scans. Jenipher and Radhika [14] explored in feature extraction and selection with ML models for early prediction of lung cancer Banerjee et al. [16] studied Classification models like SVM, RF for prediction of early-stage lung cancer. Joshua et al. [17] investigated on different ML techniques suitable for image processing leading to lung cancer prognosis. Chaturvedi et al. [19] studied ML models for detection and classification of lung cancer using MRI, X-Ray, and CT-scan imagery. Raoof et al. [26] proposed ML based framework made up of SVM, ANN and so on for lung cancer research. Shanthi and Rajkumar [27]

*Corresponding Author

proposed a feature selection method based on Stochastic Diffusion Search (SDS) to improve ML performance in lung cancer classification.

Singh and Gupta [31] used X-Ray, CT and MRI imagery for lung cancer detection with the help of ML models. DICOM CT images are used by Dev et al. [34] with ML models to detect lung cancer. Saba [38] investigated on recent advancements on ML models for lung cancer research. They used different imaging techniques for proof of the concept. Thallam et al. [40] explored ML models like ANN, KNN, RF and SVM for early prediction of lung cancer. Both ML and IsomiR Expression methods are combined by Liao et al. [46] for cancer diagnosis. Pawar et al. [49] used ML models and image processing techniques to detect lung cancer. Chabon et al. [50] investigated on genomic features for early lung cancer detection in a non-invasive approach. Selvathi and AarthyPoornila [55] studied different ML models such as SVM and KNN for cancer research. Lalitha [60] used ML models for automatic detection of lung cancer. Gupta et al. [62] investigated on supervised ML techniques to detect cancers. Kumar and Rao [63] made research like that of [62].

Katiyar and Singh [66] compared ML models and their efficiency in cancer detection process. Wang et al. [67] focused on pathology analysis using lung cancer images using AI approaches. Houby [68] discussed about disease management techniques associated with ML. Gang et al. [69] proposed dimensionality reduction method along with deep learning to analyses chest X-Ray for detection of lung cancer. Mukherjee and Bohra [70] used ML approaches for disease prediction. Hussain et al. [71] presented different feature extraction methods to improve prediction capability of ML models in disease prediction. Bankar et al. [76] made symptom analysis with data-driven approach using ML techniques for early detection of lung cancer.

B. Deep Learning Methods

Deep learning methods are based on neural networks. They are used widely for processing images such as lung CT and MRI. Tekade and Rajeswari [6] used deep learning models such as VGG and U-net architecture for lung cancer classification. Shakeel et al. [7] proposed "Improved Profuse Clustering Technique (IPCT)" using CT images for lung cancer detection. Shakeel et al. [8] used improved deep neural network and ensemble learning for automatic detection of the disease. Das and Majumder [10] explored different methods linked to deep learning practices for lung cancer detection. Kalaivani et al. [12] used a CNN based model known as DenseNet with CT imagery for disease diagnosis. Shin et al. [13] used deep learning approach for Spectroscopic analysis towards lung cancer diagnosis. Ibrahim et al. [18] used CT scan images investigating on chest diseases such as Covid-19, lung cancer and pneumonia. Their methodology is based on CNN based pre-trained deep learning models such as ResNet152V2 and VGG 19. Cherukuri et al.,[21] the study looks upon clinical tomography exercises. Lakshmana Prabu et al. [22] proposed a deep learning-based approach based on techniques known as "Optimal Deep Neural Network (ODNN) and Linear Discriminate Analysis (LDA)." Selvathi and Poornima [23] proposed deep learning methods for medical data analysis using CT and MRI imagery with the notion of Region of Interest (ROI).

Elnakib and Amer [24] proposed a deep learning method based on VGG16 and AlexNet along with an optimization technique based on Genetic Algorithm (GA) to classify lung nodules from CT images. Wang et al. [25] presented a weakly supervised learning approach with deep learning for classifying lung images. They exploited Fully Convolutional Network (FCN) to realize an automated detection system. Liu et al. [28] explored deep reinforcement learning approaches towards lung cancer detection in presence of Medical IoT. Sajja et al. [29] investigated on deep transfer learning using CT images for diagnosis of lung cancer. Schwyzer et al. [30] used deep neural networks with CT images for lung cancer detection automatically. Ardila et al. [32] used 3D deep learning phenomena with end-to-end screening of CT images for lung cancer prognosis. Avanzo et al. [33] focused on combining deep learning with radiomics for efficient detection of lung cancer. Hashemzadeh et al. [35] investigated on automatic cancer screening applications using deep learning models. Kancherla and Mukkamala [36] proposed a novel methodology for lung cancer diagnosis. This methodology exploits features associated with nucleus segmentation. Xu et al. [37] explored serial medical imaging with deep learning for prediction of lung cancer.

Doppalapudi et al. [39] used deep learning approaches to predict period of lung cancer survival. Coudray et al. [41] proposed deep learning-based approach for classification and mutation prediction linked to lung cancer. Munir et al. [43] explored various methods in ML and deep learning for prognosis of different kinds of cancers. Nasrullah et al. [44] used deep learning techniques along with multiple strategies to detect lung nodules and classify them. Mhaske et al. [45] proposed a deep learning algorithm to analyse lung CT image to find the presence of cancer. Hua et al. [47] focused on lung nodule classification using deep learning approaches. Subramanian et al. [48] proposed a deep learning framework using CNN based methods such as AlexNet, LeNet and VGG16. Kumar and Bakariya [51] used deep learning methods to find the presence of malignant cancers in CT images. Kriegsmann et al. [52] used deep learning models to classify and differentiate non-small cell lung cancer from small cell lung cancer. Yang et al. [53] made a retrospective study of whole slide images with deep learning for multi-class classification of lung cancer. Similarly, Hosny et al. [54] made a cohort radiomics study with deep learning methods for lung cancer prognosis.

Jena et al. [56] proposed a hybrid model based on deep learning, named DGMM-RBCNN, for detection and classification of lung cancer. Pham et al. [57] proposed a two-step deep learning approach for lung cancer detection from histopathological images. Gordienko et al. [58] used chest X-Ray images along with deep learning for lung segmentation to diagnose lung cancer. Sun et al. [59] exploited ROI based approaches and automatic feature selection using deep learning for lung cancer diagnosis. Fang [61] made a hybrid approach using deep learning, transfer learning, GoogLeNet and the features linked to median intensity projections.

Ponnada and Srinivasu [64] proposed efficient CNN model based on deep learning for lung cancer prognosis. Cha et al. [65] used deep learning and chest radiographs to detect lung cancer. Hatuwal and Thapa [72] used Histopathological imagery with deep learning such as CNN for lung cancer prediction. Sungheetha et al. [73] made a comparative study of deep learning models while lung CT image segmentation is explored by Brahim et al. [74]. Salaken et al. [75] proposed a methodology to study low population dataset to extract features using deep learning for lung cancer diagnosis. Lustberg et al. [77] proposed automatic contouring technique with deep learning across the globe for clinical evaluation. Lung abnormality detection method is proposed in [78] for automatic lung cancer detection based on deep learning. Masood et al. [79] proposed a methodology for Pulmonary cancer detection with CT imagery. Bharati et al. [80] used X-Ray images to evaluate their hybrid deep learning method that combines VGG, CNN and data augmentation.

C. *Imaging Techniques*

Lung MRI and CT scan imagery are widely used for lung cancer diagnosis. Rehman et al. [9] used ML models like SVM and ANN to detect the disease from lung CT scans. Shakeel et al. [7] proposed “Improved Profuse Clustering Technique (IPCT)” using CT images for lung cancer detection. Kalaivani et al. [12] used a CNN based model known as DenseNet with CT imagery for disease diagnosis. CT imagery is used by Rahane et al. [15]. Joshua et al. [17] used both MRI and CT scan imagery in their research. Ibrahim et al. [18] used CT scan images investigating on chest diseases such as Covid-19, lung cancer and pneumonia. Chaturvedi et al. [19] studied ML models for detection and classification of lung cancer using MRI, X-Ray and CT-scan imagery. Riquelme et al. [20] used CT scans for lung cancer nodules classification. Lakshmana Prabu et al. [22] used lung CT images for detection of cancer. In [31] X-Ray, CT and MRI imagery are used for lung cancer detection. In [32] CT images and in [34] DICOM CT imagers are used in lung cancer research. Kadir and Gleeson [42] used advanced imaging techniques for lung cancer diagnosis.

D. *Performance Metrics*

Widely used performance metrics in the ML and deep learning-based approaches for lung cancer detection are summarized in the Table I.

TABLE I. WIDELY USED METRICS IN ML AND DEEP LEARNING RESEARCH LINKED TO LUNG CANCER DIAGNOSIS

Metric	Formula	Value range	Best Value
Accuracy	$\frac{TP+TN}{TP+TN+FP+FN}$	[0; 1]	1
Precision (p)	$\frac{TP}{TP+FP}$	[0; 1]	1
Recall (r)	$\frac{TP}{TP+FN}$	[0; 1]	1
F1-Score	$2*\frac{(p*r)}{(p+r)}$	[0; 1]	1

Precision refers to positive predictive value while the recall refers to true positive rate. F1-score is the harmonic mean of both precision and recall which is used to have a measure without showing imbalance while accuracy measure may show imbalance. These metrics are derived from confusion matrix shown in Fig. 1.

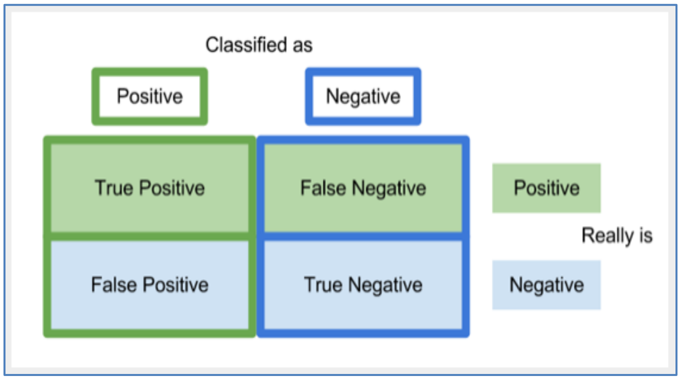

Fig. 1. Confusion matrix.

Based on the confusion matrix, the confusion matrix shows the measures like true positive (TP), false positive (FP), false negative (FN) and true negative (TN). These are determined by comparing result of ML algorithm when compared with the ground truth.

E. *Research Gaps*

With recent advances in deep learning, research has made a significant leap to help identify, classify, and quantify patterns in medical images. Particularly, improvements in computer vision inspired its use in medical image analysis such as image segmentation, image registration, image fusion, image annotation, computer-aided diagnosis and prognosis, lesion/landmark detection, and microscopic imaging analysis, to name a few. Particularly lung cancer is one of the problems that has attracted significant research. Many deep learning-based solutions came into existence. However, there is lot to do to have more accurate detection of lung cancer early. For instance, the research carried out in [22] has significant limitations. First, it has issues in detection of lung cancer early. Second, there is need for improving CNN architectures and cascade them besides making a pipeline with patient-level descriptive statistics for better prediction. Third, ensemble of classifiers could lead to further improvement in prediction of lung cancer.

III. RESEARCH METHODOLOGY

This section presents the research methodology for making systematic review of literature on deep learning techniques for lung cancer detection. It throws light on many aspects of the review process with details on preferred databases for articles, the process of research or conceptual framework, criteria for including or excluding research articles and distribution of articles used in the research.

A. Research Questions

This systematic review has synthesis of literature from 2012 to 2021 on deep learning methods used for lung cancer detection. It has potential to answer the following research questions.

Research Question 1: What are different deep learning methods used from 2012 to 2021 to diagnose lung cancer?

Research Question 2: What are different datasets used from 2012 to 2021 for the research of lung cancer detection?

Research Question 3: What are the different development platforms used for lung cancer detection from 2012 to 2021?

Research Question 4: What are the different performance metrics used for evaluation of lung cancer detection methods?

Research Question 5: What are the imaging techniques used for lung cancer detection from 2012 to 2021?

Research Question 6: What are the results obtained for lung cancer detection from 2012 to 2021?

These research questions help to ascertain answers to various questions in terms of deep learning methods, datasets used for the research, development platforms used for building models, performance metrics widely used, imaging techniques and results.

B. Data Sources

Research articles used in this paper are collected from different sources. Article selection process includes criteria for inclusion and exclusion of articles. The databases or digital libraries from which articles are taken are as follows.

- Wiley (https://onlinelibrary.wiley.com/)
- Google Scholar (https://scholar.google.com)
- Springer (https://www.springer.com/in)
- Elsevier (https://www.elsevier.com/en-in)
- IEEEXplore (https://ieeexplore.ieee.org/Xplore/home.jsp)

C. Search Process

Search for articles is carried out with different search phrases. The search applications associated with digital libraries are used to fine relevant peer-reviewed articles that satisfy inclusion and exclusion criteria. The collected articles include articles and conferences.

Table II shows search process in terms of different phrases used for finding suitable articles on lung cancer detection. It has provision to collect articles from different sources based on the search phrases provided. After collecting research articles, different criteria on inclusion and exclusion are used to filter out the articles further.

TABLE II. SEARCH PHRASES USED IN THE SEARCH PROCESS

Sr. No.	Search Phrase	Description
1	Machine learning techniques for lung cancer detection	This is used for finding lung cancer research based on machine learning approaches.
2	Deep learning techniques for lung cancer detection	This is used for finding lung cancer research based on deep learning approaches.
3	Artificial intelligence techniques for lung cancer detection	This is used for finding lung cancer research based on Artificial intelligence approaches.
4	Lung cancer detection techniques	It is used to find any methods used for lung cancer detection

D. Criteria for Article Selection Process

Inclusion and exclusion criteria for this research are defined as presented in Table III. The criteria are meant for leveraging quality of the articles used for the systematic review. Articles in English language that have been published between 2017 and 2021 are used for systematic review.

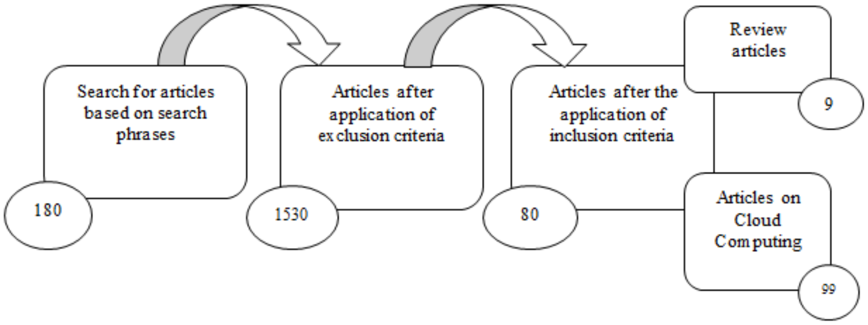
Table III shows the criteria used to select quality articles used in the systematic review. It reflects the state-of-the-art methods used for lung cancer detection.

TABLE III. CRITERIA USED FOR ARTICLE SELECTION PROCESS

SL. NO.	Inclusion Criteria	Exclusion Criteria	Justification
1	Article in English language	Articles other than English	English articles are preferred as there is neither time for translation nor availability of required tools for translation.
2	Lung cancer with either CT or MRI imaging	Datasets other than CT and MRI	Lung cancer detection with these imaging techniques is reliable.
3	Peer-reviewed	Non-peer reviewed	Quality of articles that are peer-reviewed is considered to be high.
4	Machine learning and deep learning	Non machine learning and non-deep learning methods	The machine learning and deep learning techniques are preferred due to their utility.

E. Research Process

We followed a specific research process of search, exclusion, and inclusion criteria of articles that is illustrated in Fig. 2. As many as 180 articles are collected using the search phrases.



Search for articles based on search phrases
180
Articles after application of exclusion criteria
1530
Articles after the application of inclusion criteria
80
Review articles
9
Articles on Cloud Computing
99

Fig. 2. Methodology for article selection process.

Afterwards, the articles are subjected to exclusion criteria which have resulted in filtering of the articles to 153. Then the selection process continued with the inclusion criteria on the 153 articles. This process has eliminated 73 articles from the list and finally we got 80 articles for the systematic literature.

This article selection process has led to the removal of irrelevant articles that do not meet the selection criteria.

As presented in Fig. 3, the articles that satisfied inclusion and exclusion criteria are subjected to data analysis process. It is found that most of the articles belong to 2017 to 2021 publication years. From 2012 to 2016 only five articles are found to satisfy the selection quality process.

As presented in Fig. 4, the article distribution is provided in terms of percentage for each year. The highest number of articles belong to 2019 and 2020 years with 26% while 25% of articles are selected from 2018.

As presented in Fig. 5, IEEE is the publisher from which 11 journal papers and 14 conference papers are selected. From Elsevier publications 12 articles are selected while from Springer publications 10 articles are selected. The articles taken from Google Scholar are 21 while 5 are from MDPI.

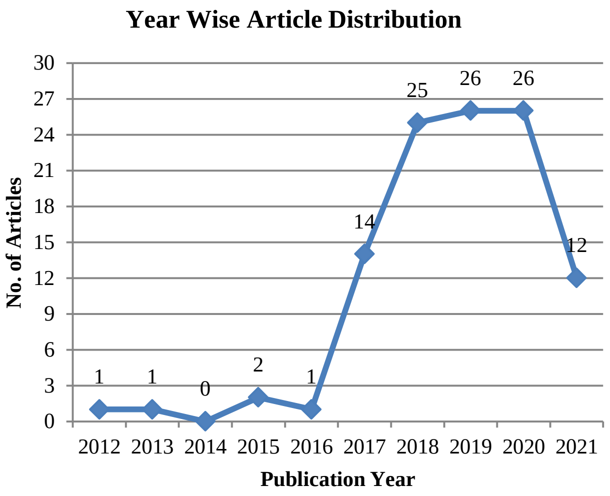


Fig. 3. Shows year wise distribution of published articles used for the review.

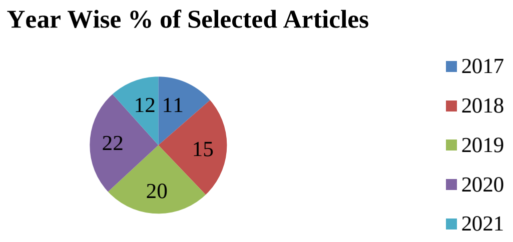

Fig. 4. Year wise % of selected articles.

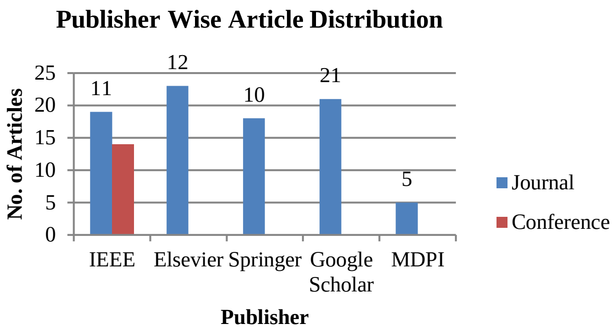

Fig. 5. Shows publisher wise selected article distribution.

As presented in Table IV, the articles used for the survey in this paper are provided and they belong to different journals and conferences from diversified and reputed publishers.

IV. RESULTS OF THE RESEARCH

This section provides results containing answers for many research questions provided in Section III A.

A. Results of Research Question 1

Research Question 1: What are different deep learning methods used from 2012 to 2021 to diagnose lung cancer?

Most authors used Convolution Neural Network to detect the lung cancer from 2012 to 2021.

As presented in Table V, different deep learning methods used from 2012 to 2021 to diagnose lung cancer are provided.

TABLE V. RESULTS OF RESEARCH QUESTION 1

B. Results of Research Question 2

Research Question 2: What are different datasets used from 2012 to 2021 for the research of lung cancer detection?

As presented in Table VI, different datasets used from 2012 to 2021 for the research of lung cancer detection are provided. The data sets from (Lung Image Database Consortium) LIDC, LUNA dataset real time data, and Cancer Image Archive (CIA) etc. all the authors downloaded and used the datasets for their proposed different deep learning algorithms to analysis, classify and predict the lung cancer disease.

C. Results of Research Question 3

Research Question 3: What are the different development platforms used for lung cancer detection from 2012 to 2021. Most of the authors used Python and MATLAB for detect lung cancer.

As presented in Table VII, different development platforms used for lung cancer detection from 2012 to 2021 are provided. The authors used different computer programming languages and tools like Python, Java and MAT Lab for implementing their work.

TABLE VI. RESULTS OF RESEARCH QUESTION 2

Reference	Authors	Publisher	Year	Dataset Used

D. Results of Research Question 4

Research Question 4: What are different performance metrics used for evaluation of lung cancer detection method?

As presented in Table VIII, different performance metrics used for evaluation of lung cancer detection methods are provided. Performance metrics like Accuracy, sensitivity, specificity, f measure and ROC curves using the following metrics, the authors evaluate their developed models.

E. Results of Research Question 5

Research Question 5: What are the imaging techniques used for lung cancer detection from 2012 to 2021?

As presented in Table IX, different imaging techniques used for lung cancer detection from 2012 to 2021 are provided. The imaging techniques like Computer Tomography, X-Ray, and magnetic resonance imaging (MRI) provide different images related to Lung cancer and non-cancer images. The authors used those images as datasets for deep learning models.

F. Results of Research Question 6

Research Question 6: What are the results obtained for lung cancer detection from 2012 to 2021?

As presented in Table X, different performance metric like Accuracy, Specificity, F1 Score and area under the curve (AUC) values obtained by author's for lung cancer detection from 2012 to 2021 are provided.

TABLE VIII. RESULTS OF RESEARCH QUESTION 4

[60]	Lalitha. S	Springer	2021	Accuracy -98.7%

V. CONCLUSION AND FUTURE WORK

In this paper, we made a systematic review of deep learning methods for detection of lung cancer. It reviews peer reviewed journal papers and conferences from 2012 to 2021. Literature review throws light on synthesis of different existing methods covering machine learning (ML), deep learning and artificial intelligence (AI). It provides insights of different deep learning methods in terms of their pros and cons and arrives at possible research gaps. This paper gives knowledge to the reader on different aspects of lung cancer detection which can trigger further research possibilities to realize models that can be used in Clinical Decision Support Systems (CDSSs) required by healthcare units. Besides, this systematic review could answer different research questions that may be of help to other researchers and readers. In future, we will work on filling certain research gaps identified in this paper.

Question Classification in Albanian Through Deep Learning Approaches

Evis Trandafili, Nelda Kote, Gjergj Plepi
Faculty of Information Technology
Polytechnic University of Tirana
Tirana, Albania

***Abstract*—In recent years, there is growing interest in intelligent conversation systems. In this context, Question Classification is an essential subtask in Question Answering systems that determines the question type, therefore, also the type of the answer. However, while there is abundant research for English, little research work has been carried out for other languages. In this paper we deal with classification of questions in the Albanian language which is considered a complex Indo-European language. We employ both machine learning and deep learning approaches on a large corpus in Albanian based on the six-class TREC dataset with approximately 5000 questions. Experiments with and without stop-words show that the impact of stop-words is significant in the accuracy of the classifier. Extensive comparison of algorithms for the task of question classification in Albanian show that deep learning algorithms outperform conventional machine learning approaches. To the best of our knowledge this is the first approach in literature for classifying questions in Albanian and the results are highly comparable to English.**

Keywords—Question classification; deep learning; BiLSTM; transformer; RoBERTa; Albanian corpus; natural language processing

I. Introduction

Large amounts of unstructured text data are generated every day resulting in a continuously increasing demand for information retrieval. Intelligent conversational agents that use Artificial Intelligence (AI) algorithms can facilitate user interaction with computer systems, conduct a conversation and answer natural language questions. In this context, Natural Language Processing (NLP), as a branch of AI, deals with automatic comprehension, interpretation and manipulation of natural language. However, natural language is complex and implies many different forms of communication facets leading to the need to interpret not only narrative or confirmative phrases but also questioning ones. Therefore, question answering systems go beyond the simple retrieval of relevant documents and aim at generating answers in natural language [1], [2].

Question Classification (QC) is the core component of a QA system that directly affects the retrieved or generated answer. QC deals with the assignment of question labels based on the corresponding answer type [3], [4]. This process is usually modelled as a text classification problem employing Machine Learning and Deep learning approaches. A lot of research works has been done to develop intelligent systems for QC in different languages and the recent performance of state of the art QA systems is impressive. However, QA systems lack in performance on low resource languages and create linguistic barriers that hinder the free flow of knowledge, business and communication.

In this paper we deal with question classification for a low resource language like Albanian through modelling this task as a classification problem. An Albanian corpus composed of approximately 5000 questions based on Text REtrieval Conference (TREC) Question Classification dataset with 6 classes of questions has been created. This corpus has been used with three traditional machine learning algorithms Support Vector Machines, Random Forest and Logistic Regression. For each classification algorithm we have explored the use of different approaches to extract information from raw text data, the classical approach tf-idf, FastText embeddings and the RoBERTa pre-trained language model. In addition, the corpus has been used in other experiments that employe three deep learning models, BiLSTM with and without attention, Transformer and RoBERTa. The overall evaluation of the models has been assessed using accuracy, precision, recall and F-score.

The experimental results show that stop-words have a high impact on the classification accuracy. Experimental comparison of different models shows that deep learning algorithms outperform the traditional machine learning approaches. Finally, although a first attempt for Albanian, our approach is comparable with the same approaches for English, leading to promising results for building question answering systems in Albanian and similar low resource languages.

The content of the paper is organized as follows: In Section II we cover Question Classification background and related works. In Section III we present the technologies and software libraries that we used in our experimental environment. In Section IV the Albanian dataset is introduced and its structure is explained in detail. Moreover, in Sections V and VI we introduce learning models, experimental design and analyze the results. Finally, we conclude with Section VII.

II. Related Work

There has been relatively little research done in the field of question classification tasks in the Albanian language. The first paper in this field treated this task as a traditional classification problem. The Albanian question corpus was used to evaluate the performance of three question classification models, which utilized the Support Vector Machine (SVM), Logic Regression

(LR) and Random Forest (RF) algorithms. The SVM model achieved the highest accuracy of 75.7% using FastText, while the use of RoBERTa resulted in a slightly lower accuracy of 0.6% [5]. The question-answering system proposed for the Albanian language in [6] does not implement the question classification component. The system has three modules: the first module preprocesses and indexes the documents, the second module analyzes the question, and the third module retrieves passages and extracts answers.

The current state of the question classification task in the Albanian language is still in its early stages, and further research and development are needed to enhance the performance of classification models. Nonetheless, the available approaches show promising results. Therefore, we will focus on existing studies related to languages other than Albanian.

The three components of question answering systems are question analysis, information retrieval, and answer analysis. The initial step of the question analysis component is question classification, which aims to determine the type of question and, consequently, the type of answer required. The question analysis component and its question classification step play an important role in the question answering systems as it can identify the correct class of a question and as a result restrict the possible answers [3, 4].

In question answering systems, the question type is a key factor that determines which type of questions a system can answer. These systems can be factoid, which answer questions related to facts, or non-factoid, which answer questions like mathematical calculations [7].

Previous work on the question classification problem can be analyzed from different aspects, such as the question classification categories, classification methods and algorithms, features, and so on. The answer to a question depends on the type of question, and questions can be classified into a category based on their common linguistic properties. Furthermore, their answers can also share common linguistic properties [8].

Numerous research studies have focused on developing artificial intelligence systems for question classification in various languages, including English [9], German [10], Italian [11], French [12], Spanish [13], and others.

The TREC [14] dataset, a popular resource for question classification tasks, is widely used in English and has also been translated into various other languages. This dataset contains a large collection of labeled questions and has been instrumental in the development and evaluation of many questions classification models. It is a dataset of 6,000 English questions, categorized into a main classification schema with six labels (human, description, abbreviation, entity, location, and numeric value,) and a fine-grained schema for each of the main categories. In [15], two classes (yes-no-explain and list) were added to the main taxonomy to improve question classification accuracy. The "yes-no-explain" class is used for questions that require a yes or no answer with an accompanying explanation. On the other hand, the "list" class is used for questions that have answers from a predefined list. An additional 250 questions were also added to the dataset. In [16], a Portuguese version of the TREC corpus was proposed.

The DISEQuA Corpus [17], a multilingual question answering corpus that uses a 7-class label classification schema (location, date, object, measure, person, organization, and other) is another widely used corpus. Additionally, paper [18] proposes a much larger taxonomy of 180 classes, making it one of the biggest taxonomies used in QA systems for question classification.

The SVM algorithm is frequently utilized in question classification tasks. In [19], an Arabic version of the TREC dataset is introduced and employed to train a two-stage classification model. The model involves using either the SVM, RF, or ME algorithm, followed by a CNN neural network. The machine learning algorithm is utilized to predict the primary class of the question in the first phase, and then the CNN is used in the second phase to predict the subclass. The SVM algorithm with CNN achieved the best performance, with an accuracy of 89%.

The use of top-words and dependency relations as features with the SVM algorithm in paper [20] resulted in an accuracy of 93.4% in the question classification task using the TREC dataset. Furthermore, the proposed solution in [21] to use syntactic and semantic analysis with SVM algorithms improves the performance of the model compared to the state-of-the-art models. The proposed hybrid method in [22] using the SVM algorithms with semantic and lexical feature extraction results in an accuracy of 96% on the TREC dataset.

The grammatical-based framework proposed in [23] performs better when using the J48 algorithm than SVM in factoid question classification approach, achieving an accuracy of 95.8%. The three main features of this approach are grammatical features, domain-specific features, and patterns.

In [24], the author proposed a Question Classification approach for Italian based on word embedding with sub-word information and Convolutional Neural Networks. The proposed approach is tested on the TREC dataset of questions in English and the Italian translated version, by using advanced vectors learned in an unsupervised manner using the skipgram model and character-based information to initialize the word embeddings. The Italian model achieved an accuracy of 80.42% using FastText, which is comparable to the English model accuracy of 80.16%.

In [25], the author proposed two models based on LSTM networks for question classification. These models were trained and evaluated on the heterogenous TREC and USC dataset, which features a two-level hierarchy annotation schema. The first model was used solely for predicting the main class of the question, while the second model added sub-class prediction to the question classification. The models achieved high accuracy values of 91.20% for the main class and 82.20% for the sub-class using 1000 h dimensions. The authors concluded that these types of networks are highly effective in the question classification task.

In [26], the author proposed the use of a BERT-based model for pregnancy question classification. Two attention mechanisms were evaluated: an additional layer on top of

BERT and the built-in self-attention mechanism of BERT, which resulted in better classification accuracy than the traditional models. The model that used an additional layer on top of BERT achieved the highest accuracy of 88%.

The new approach, which leverages data augmentation to create extra training instances, is presented in [27]. The effectiveness of this approach is evaluated on the TREC question classification datasets using pre-trained models such as BERT, RoBERTa, and DeBERTa. The results indicate that the need for labeled instances is reduced by up to 81.7%, achieving a new state-of-the-art classification accuracy of 98.11% on the TREC dataset.

III. Technologies and Software Libraries

Learning models used in this paper are trained and tested using Python programming language. Python is the most preferred language for computer scientists and researchers working in the field of NLP because of the versatility to use API-s and libraries that enhance performance growth [28].

As a programming environment we used the Jupyter Notebook. It is a free, open source, web based computational notebook that supports over 100 programming languages even if its name is a reference of three core programming languages, Julia, Python and R. Python is the most popular programing language with Jupyter notebook [29]. The notebook has two main components: The first component consists of front-end cells that hold text or code and are executed independently. This is very important for time consuming operations like dataset manipulations. The second component is the back-end kernel that executes the code inside the cells. Kernels can also be run on remote servers.

For our experimental environment, we installed Visual Studio IDE which fully supports work in Jupyter Notebook and Python. In the subsections below we present libraries and modules imported in Jupyter Notebook.

A. Pandas

Pandas is a mature Python library with a stable API used for data analysis [30]. Pandas library is used to deal with the .csv files where the dataset with questions is kept. Pandas offers build in functions that facilitate text manipulation. We used DataFrame, a two-dimensional data structure, to create the .csv file that contains both, questions in English, their equivalent in Albanian and the respective question tag.

B. Scikit-learn (Sklearn)

Ease of use and its computational efficiency make Scikit-learn (Sklearn) the most used Python library for supervised and unsupervised Machine Learning algorithms. It’s task-oriented interface enables easy comparisons of different machine learning algorithms for a given dataset [31].

In our Question Classification task, we used the implementation of Support Vector Machine (SVM), Random Forest and Logistic Regression from Scikit-learn to build Question Classification models [5]. The main object in our supervised learning is the Scikit-learn estimator that implements a *fit* method with two arguments: an array with data and an array with labels. After calculating model learned parameters in *fit* method, we use the *predict* method with a single question input to predict/classify the question. By using the *score* method of the estimator, we compute the accuracy by default.

C. PyTorch

PyTorch is a Python framework which is very popular in deep learning research community. It assembles usability together with performance. PyTorch has proved its overall speed on several common benchmarks. It supports code as a model, offers an easy debugging, is efficient with other libraries and supports hardware accelerators [32]. PyTorch provides an array-based programming model accelerated by GPUs. NLP applications are successfully used with PyTorch because of the tensors which allow the use of GPUs to perform complex computational calculations with significantly improved performance.

D. Hugging-Face

Hugging Face Transformer is a neural network architecture by Google Brain based on attention mechanisms to draw global dependencies between input and output. It outperformed traditional encoder-decoder architectures in translation tasks [33]. Hugging Face is a great source of pre-trained machine learning models based on several transformer architectures like BERT [34], RoBERTa [35], BART [36], etc.

IV. Dataset Preparation

The Albanian questions dataset used in this paper is built by translating into Albanian the six-class fact-based questions dataset from Text REtrieval Conference (TREC) [14], originally with 5452 training examples and 500 test examples. The six-class tags used to identify the type of answer are shown in the Table I below.

TABLE I. Six-Class Tags in Questions Dataset

Question tag	Abbreviation	Description
0	DESC	Description and abstract concepts
1	ENTY	Entities
2	ABBR	Abbreviation
3	HUM	Human beings
4	NUM	Numeric values
5	LOC	Locations

Raw translation from Albanian language was achieved using the library translate-api in python. Google Translate is the most used online translation service, therefore we used its interface for translating the dataset from English to Albanian. However, taking in consideration that Albanian language has a limited translation support, after the automatic translation we checked the dataset manually. Two main issues were noticed:

- The translation was not very accurate.
- Some questions lost their relations with the respective tags.

Therefore, we revised the dataset manually by correcting translations and by removing questions considered not appropriate for use in the dataset. As a result, the final dataset is composed of 4694 questions in Albanian. In Table II we show several examples of questions translated from English using the automatic translation.

The numbers of questions in each of the six classes in questions' dataset is shown in Fig. 1. We can easily observe that the class ABBR is highly unbalanced as the number of questions classified as abbreviations is merely 8% of the number of questions in other classes.

The problem of class imbalance is very popular in real world classification datasets. Questions asking for explanation of abbreviations are infrequent in our everyday life, as a result they are rarely found in written texts compared to other types of questions. This is clearly reflected even in questions' dataset. In this situation the classification risks to ignore the ABBR class.

The solution that we used to learn from the unbalanced questions dataset is the data augmentation technique. We manually increased the number of sentences in the ABBR class by creating new sentences through exchanging some words of the question with their synonyms.

TABLE II. EXAMPLES OF TRANSLATED QUESTIONS

Question tag	English Question	Albanian Question
DESC	How do you match a name to a social security number?	Si shoqërohet një emër me një numër të sigurimeve shoqërore?
ENTY	What's the only work by Michelangelo that bears his signature?	Cila është e vetmja vepër nga Michelangelo që mban firmën e tij?
ABBR	What is the abbreviation of the company name "General Motors"?	Cili është shkurtimi i emrit të kompanisë "General Motors"?
HUM	Who killed Gandhi ?	Kush e vrau Gandin?
NUM	How long does it take for your blood to make one complete trip through the body?	Sa kohë duhet për gjakun tuaj të bëjë një udhëtim të plotë përmes trupit?
LOC	What country is the world 's largest importer of cognac?	Cili vend është importuesi më i madh në botë i konjakut?

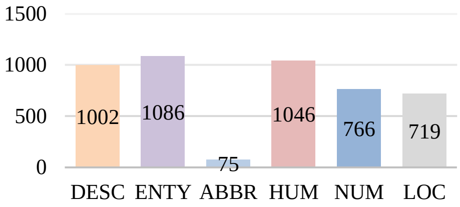

Fig. 1. Class distribution of questions.

Moreover, the most recommended pre-processing method that showed improvement in text classification tasks is stop-word removal. Stop-words are a set of commonly used words in a natural language that hold unimportant information in NLP applications. Their removal allows the model to learn from the most important words. However, the authors in [37] showed that stop-word removal does not always improve accuracy. Text Classification performance should always be fine-tuned by performing evaluations and determining the best combinations of pre-processing methods. As a pre-processing step, we used stop-word removal. We utilized the Spark-NLP [38] python library, which supports stop-word removal for Albanian language. A total of 223 frequently used words with low level information in Albanian language are removed from the dataset. Some examples of stop-words in Albanian are: "*ai*", "*ajo*", "*çfarë*", "*cili*", "*dhe*", "*unë*", etc. To test if stop-word removal is beneficial in terms of accuracy for our question classification model, we preserve a copy of the dataset, prior to stop word removal. The latter is also used for training the model and its accuracy is compared with the accuracy from models trained with the pre-processed dataset. We explore the effects of pre-processing with stop-words in Experiment 2 in Section VI.

In conventional Machine Learning algorithms, the words in the dataset are represented as numeric vectors or word embeddings in order for them to be fed as input to the models. In this paper we applied FastText [39], a popular neural network model used to generate word embeddings by splitting the word in n-grams. Due to its generalization capabilities and the ability to compute word embeddings for out-of-vocabulary words, FastText has shown good accuracy for small datasets and for low resource languages. In [5] we used tf-idf, FastText and RoBERTa to represent word embedding fed to Machine Learning models and the results showed that FastText outperformed in terms of accuracy.

V. LEARNING MODELS AND EXPERIMENTAL SETUP

We model the question classification task as a classification problem. If we are given a question u composed by a sequence of words $x = \{x_1, \cdots, x_n\}$, the classification model should predict the label y, by computing the probability $p\ (y \mid x)$. To effectively deal with this problem, we compared the accuracy of several classification algorithms divided in two main categories:

a) Classical machine learning algorithms: Support Vector Machines, Random Forest and Logistic Regression with tf-idf, FastText and RoBERTa as vector representations. We used the results obtained in [5].

b) Deep learning algorithms: *BiLSTM* [40] is a bidirectional LSTM which takes as input a sequence of vector representations for each word in the question/sentence and outputs the class/label of the question.

Transformer [33] is a new and powerful neural networks architecture developed by Google. In the classification context, it utilizes a similar approach with BiLSTM but using a different and more powerful architecture.

RoBERTa [35] is a transformer model pre-trained on large volumes of raw text data. For the Albanian language it is pre-trained using Wikipedia corpus. In our work, we used the RoBERTa pretrained Albanian tokenizer. RoBERTa transformer model takes as input a sequence of indexes from sentence words acquired from the tokenizer and outputs an array of base size 768 for each part of the sequence. The arrays are then unified, and the average value is calculated and fed to a feed-forward network with two layers and an activation function, in our case RELU.

Moreover, the deep learning models that we used for training have different numbers of learnable parameters, frequently used to measure the classification performance. In Table III, we show the number of parameters in each model.

TABLE III. NUMBER OF PARAMETERS FOR EACH MODEL

Model	No of Parameters
BiLSTM	3.8 M
BiLSTM with attention	4.8 M
Transformer	4 M
RoBERTa	83.7 M

RoBERTa is the model with the highest number of parameters, 83.7M, while BiLSTM is the model with the least number of parameters. If we assess sequence-to-sequence models, BiLSTM with attention has the highest number of parameters while Transformer and BiLSTM have comparable number of parameters.

Classical Machine Learning and Deep Learning models are trained on a computer with a 16 cores CPU and a high-performing graphics processing unit, GPU NVIDIA A100-PCIE 40GB.

The classical Machine Learning algorithms were evaluated using 5-fold cross validation. Each model spent approximately 1-2 minutes to build.

On the other hand, to build deep learning models we performed the 70/10/20 train/validation/test splitting technique. In Table IV the distribution of classes during the split is shown.

TABLE IV. OVERVIEW OF TRAIN/VALIDATION/TEST

Split	Total	DESC	ENTY	ABBR	HUM	NUM	LOC
Train	3191	691	739	51	706	540	464
Validation	564	116	131	6	133	85	93
Test	939	195	216	18	207	141	162

To avoid overfitting, an early stopping method is implemented in the validation set. The models were fine-tuned for 100 epochs and a batch size of 64. Furthermore, we applied the Adam optimizer [41] as the most recommended optimizer in reducing loss and improving accuracy. When training BiLSTM, BiLSTM with attention and Transformer models, we applied $1e-3$ learning rate. Whereas, for RoBERTa model we used $1e-4$ learning rate [35]. Each of deep learning models spent 15-20 minutes when trained in the beforementioned computer hardware. Deep learning models require powerful processing units in order to ensure efficiency and reduce time consumption.

VI. EXPERIMENTAL EVALUATION

In this section we present experimental design and evaluation of Albanian question classification models. We describe the objectives and outcomes of each experiment and highlight performance variations between classical machine learning algorithms, with deep learning models. Classification performance is evaluated using the common metrics of accuracy, precision, recall and F-score.

Experiment 1: Question Classification using the classical machine learning algorithms.

The implementation of FastText for vector representation is shown to increase the classification performance in all the classical machine learning models used for classification [5]. In Table V we show the performance of Support Vector Machine, Random Forest, and Logistic Regression where FastText is used to generate word embeddings. Support Vector Machine proves to be the best performing algorithm among Random Forest and Logistic Regression, with scoring 75.7% for accuracy and 80.0% for F1-score which is not satisfactory if we compare it with state-of-the-art Question Classification models for languages other than Albanian. However, classical Machine Learning algorithms are not time-consuming and require less powerful processing units.

TABLE V. CLASSIFICATION PERFORMANCE IN THE PRE-PROCESSED ALBANIAN DATASET

Models (Albanian)	Accuracy	F1-score macro	Precision	Recall
Support Vector Machine (SVM)	**75.7%**	**80.0%**	**71.6%**	**73.9%**
Logistic Regression (LogReg)	74.0%	79.6%	64.9%	66.1%
Random Forest (RnFor)	70.8%	78.6%	62.5%	64.9%

Experiment 2: Deep learning classification models using the preprocessed Albanian dataset.

The main goal of this experiment is to show the effects of preprocessing on question classification task in Albanian. As discussed in Section IV, as a preprocessing step we chose the stop-word removal. The most frequent Albanian words were removed from the questions dataset. The same Deep Learning models were trained using the preprocessed Albanian dataset. The results are shown in Table VI. RoBERTa proves to be the best performing model compared to BiLSTM, BiLSTM with attention and Transformer.

TABLE VI. DL CLASSIFICATION PERFORMANCE IN THE PRE-PROCESSED ALBANIAN DATASET

Models (Albanian)	Accuracy	F1-score macro	Precision	Recall
BiLSTM	80.8%	78.5%	81.7%	76.6%
BiLSTM + Attention	81.5%	81.0%	86.2%	78.2%
Transformers	85.3%	84.0%	85.1%	83.0%
RoBERTa	**87.6%**	**86.5%**	**85.5%**	**88.2%**

Experiment 3: Deep learning classification models using the Albanian dataset without prior preprocessing.

Questions are sentences with a specific structure that contains a question word which is classified a stop-word. The motivation behind this experiment is to measure the effect of stop-words in question classification in Albanian. The same models as in Experiment 2 were trained and tested on the Albanian questions dataset without removing stop-words from the dataset. The evaluation metrics of the models are shown in Table VII. RoBERTa outperforms the classification performance of other Deep Learning architectures.

In Fig. 2 we analyze the results of Experiment 2 and Experiment 3. Except from the Transformer, that is not significantly affected by stop-word removal, the other models show meaningful performance improvement when the stop-words are preserved in the dataset. When the stop-words were not removed, the accuracy of RoBERTa increased by 3.5%.

TABLE VII. CLASSIFICATION PERFORMANCE WITHOUT PRE-PROCESSING ALBANIAN DATASET

Models (English)	Accuracy	F1-score macro	Precision	Recall
BiLSTM	82.5%	81.3%	85.2%	79.2%
BiLSTM + Attention	83.2%	82.1%	83.0%	81.4%
Transformers	84.4%	82.3%	81.3%	83.4%
RoBERTa	**91.1%**	**90.0%**	**90.0%**	**90.2%**

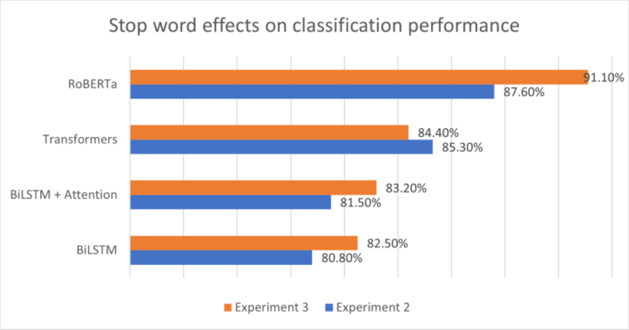

Fig. 2. Accuracy of DL models in experiments 2 and 3.

Experiment 4: Question Classification of deep learning models using the original TREC-6 dataset in English.

The main objective of this experiment is to determine a benchmark for the question classification performance. Albanian is an understudied language and the pretrained models are based on raw data. Furthermore, the automatic translation used to create the Albanian dataset, may negatively affect the performance of our model. English is a computationally rich and very well studied language. In order to assess if we have a decrease in performance due to low resources in Albanian language, we will define the state-of-the-art performance by training the models with the TREC dataset in English.

In Table VIII, we show the evaluation metrics calculated on our Deep Learning models trained with the original TREC-6 dataset. We show an increase in performance by adding attention to BiLSTM model. Furthermore, we confirm the superiority of Transformer in comparison to BiLSTM. The best performing classification is achieved using the RoBERTa pre-trained model with a benchmark from F-measure scoring 95.1%.

TABLE VIII. DL MODELS TRAINED WITH TREC-6 DATASET

Models (English)	Accuracy	F1-score macro	Precision	Recall
BiLSTM	81.8%	81.7%	80.9%	82.8%
BiLSTM + Attention	83.2%	83.2%	86.2%	81.3%
Transformers	86.0%	86.4%	88.1%	85.2%
RoBERTa	**94.0%**	**95.1%**	**95.0%**	**95.3%**

Experiment results show that Support Vector Machines model performs better compared to Random Forest and Logistic Regression, but its classification performance is still poor, with F1-score of 80%.

Among the deep learning models tested with the Albanian corpus dataset, RoBERTa performs better compared to BiLSTM and Transformer with an accuracy of 87.6%. We must state that all deep learning models performed better than SVM, Random Forest and Logistic Regression.

Stop word removal pre-processing task, applied on the Albanian questions dataset, shows a decrease in performance of the all the deep learning classifiers. Question classification with RoBERTa has an accuracy of 87.7% when trained with the dataset where the stop-words were previously removed, and the accuracy improved to 91.1% when trained with the dataset where the stop-words were not removed. We conclude that stop-words should not be removed from Albanian corpus prior to question classification.

The benchmark of 95.1% for the accuracy obtained by RoBERTa using the original TREC dataset in English shows that the performance of the question classification system in Albanian can be improved by working with the Albanian language from a computational linguistic perspective.

VII. CONCLUSION AND FUTURE WORK

Question Classification is a fundamental part of a Question Answering system. In this paper we have modeled the Question Classification problem in an Albanian language corpus using the state-of-the-art Deep Learning models and architectures. To the best our knowledge there is no previous research work addressing the problem of question classification in Albanian language using recent deep learning approaches. We have employed an Albanian questions dataset to train classification models based on classical machine learning algorithms and more recent deep learning approaches. The experiments, both with and without stop-words, demonstrate that the presence of stop-words significantly affects the accuracy of the classifier. Moreover, the comparison between algorithms indicates that deep learning algorithms outperform conventional machine learning approaches.

As future work, we intend to expand the size of the dataset and also increase its overall quality by adding linguistic expertise. In addition, we plan to analyze the impact of the length of the questions on the classifier performance. Finally, it would be interesting to investigate language alignment approaches in order to exploit well-established machine translation algorithms in the process of classification.

An Efficient Source Printer Identification Model using Convolution Neural Network (SPI-CNN)

Naglaa F. El Abady[1], Hala H. Zayed[2], Mohamed Taha[3]
Computer Science Department, Faculty of Computers and Artificial Intelligence, Benha, Egypt[1, 2, 3]
School of Information Technology and Computer Science (ITCS), Nile University, Egypt[2]

Abstract*—Document forgery detection is becoming increasingly important in the current era, as forgery techniques are available to even inexperienced users. Source printer identification is a method for identifying the source printer and classifying the questioned document into one of the printer classes. According to what we know, most earlier studies segmented documents into characters, words, and patches or cropped them to obtain large datasets. In contrast, in this paper, we worked with the document as a whole and a small dataset. This paper uses three techniques dependent on CNN to find the document source printer without segmenting the document into characters, words, or patches and with small datasets. Three separate datasets of 1185, 1200, and 2385 documents are used to estimate the performance of the suggested techniques. In the first technique, 13 pre-trained CNN were tested, and they were only used for feature extraction, while SVM was used for classification. In the second technique, a pre-trained neural network is retrained using transfer learning for feature extraction and classification. In the third technique, CNN is trained from scratch and then used for feature extraction and SVM for classification. Many experiments are done in the three techniques, showing that the third technique gives the best result. This technique achieved 99.16%, 99.58%, and 98.3% accuracy for datasets 1, 2, and 3. The three techniques are compared with some previously published papers, and found that the third technique gives better results.

I. Introduction

Investigating and analyzing digital evidence to identify the details of a crime is known as digital forensics. To find, gather, and examine digital evidence, digital forensics uses a set of specialized tools and methods [1]. In the last ten years, the use of digital documents has exploded. These digital papers may include images of official contracts, bills, checks, and other documents. Maintaining a digital document to a paper copy is easier, cheaper, and more effective, but security is a challenge.

Printed documents as disputed or questioned evidence are fairly common in forensic investigations. Due to the rise in these situations and the greater usage of printers in document creation than handwritten documents, printer inspection has become a crucial requirement in questioned document analysis in recent years. Additionally, numerous printers have been involved in the widespread forgery of printed papers during the past 20 years. In these situations, it is crucial for the investigators to decide the type of printer used and to create a connection between the disputed document and the stated printer.

Personal computers, scanners, and printers can produce forged documents such as certificates, agreements, identity cards, lottery tickets, etc. Modern printers have such high resolution that it is difficult for normal persons to differentiate forged documents from real ones. Traditional approaches use chemical techniques to detect forgeries in printed documents [2],[3]. These procedures need laboratory tools and a specialist to evaluate the samples. Additionally, these methods take a long time and risk damaging the printed paper. Digital techniques, in contrast, use a reference scanner to turn printed papers into their digital equivalent. Using digital approaches for source printer identification makes distinguishing between documents printed on various printers possible. Since all the analysis is done digitally, it is quicker and more automatic.

The two basic digital techniques for detecting source printers are extrinsic (active) and intrinsic (passive). Finding extrinsic signatures, such as watermarks, digital signatures, printer serial numbers, and printing dates, is known as active research. It's so time-consuming and expensive that using it is practically impossible. On the other side, passive characterizes the printer by identifying intrinsic features. Prior research typically used the following techniques to extract statistical features from printed documents: Feature extraction techniques include the Discrete Wavelet Transform (DWT), Local Binary Pattern (LBP), Key Printer Noise Features (KPNF), Gray-Level Co-Occurrence Matrix (GLCM), Speeded Up Robust Features (SURF), Oriented FAST Rotated and BRIEF (ORB), Histogram of gradient (HOG), spatial filters, and others[4], [5], [14]–[16], [6]–[13]. The forensic classification systems adopt support vector machine (SVM), Random Forest (RF), and ensemble techniques. However, feature extraction, feature selection, and classification operations in the abovementioned approaches require much professional human participation.

Additionally, to obtain results that may be generalized, the entire procedure must be repeated multiple times using a random selection of training and testing samples. A branch of artificial intelligence is machine learning (AI) [7]. In general, machine learning attempts to recognize the structure of data and fit that data into models that are helpful and clear. Convolution Neural Network (CNN) is an artificial neural network suggested [17]. Its network structure for shared weights is comparable to simulations of genuine biological brain networks. This feature has the potential to simplify and decrease the number of parameters in the network model. Instead of using the complicated feature extraction and data reconstruction steps used in the conventional identification approach, CNN can use the image directly as the input. Convolutional, activation, pooling, and fully connected layers make up most of a typical CNN. Activation layers are used to enable nonlinear mapping, which enhances feature maps' capacity for expression. Fully connected layers are employed as the classifier and final output layers for classification tasks [18].

Deep learning's success is strongly connected to large amounts of data. A lack of training data can seriously affect the performance of deep learning models. Transfer learning was introduced to resolve this problem. It has many advantages, including reducing training time and improving neural network performance [19]. There are two approaches to implement transfer learning: feature extraction and fine-tuning. The pre-trained network is used as any other feature extractor when extracting features. In contrast to feature extraction, a new, fully connected head is built and layered over the base architecture when fine-tuning.

Deep learning needs a large number of datasets to give more accuracy. In this research, the problem of the large dataset is solved by using transfer learning. The transfer learning CNN was used to save time in creating a model from scratch, training, and small datasets. Transfer learning CNN is divided into two types: the first used a pre-trained model such as (AlexNet [20], VGGNet-16 [21], VGGNet-19, GoogleNet [22], ResNet-18[23], ResNet-50, ResNet-101, Inceptionv3 (24], SqueezeNet[25], XceptionNet [26], DarkNet-19[27], DarkNet-53, ShuffleNet [28]) for feature extraction, and the result was classified using other machine learning classification techniques. The second used a pre-trained model but changed the last layers. An SPI-CNN technique is developed to extract deep features that are fitted into an SVM for classification to get higher performance than with an SPI-CNN model alone. Three different data sets—the first with 10 printers and 1185 documents, the second with 20 printers and 1200 documents, and the third with 30 printers and 2385 documents—were used to test all of the earlier models. The following are some of the contributions of this work:

- The techniques are tested on 30 printers, whereas all previous studies only used a maximum of 20 printers.
- Training new CNN (SPI-CNN) from scratch adapted to this application. Despite their simplicity, neural networks have proven to be extremely successful in producing good results across all datasets.
- The proposed techniques work on a whole document without segmenting it into characters, words, or patches, which speeds up processing.
- An efficient pre-processing stage that combines histogram equalization and gamma correction is implemented, significantly improving the model's performance and increasing accuracy.

The following sections make up the entire paper. Section II briefly describes the related work for classifying the source printer of a printed text document. Section III contains a description of the specifics of our proposed approach. The efficiency of the proposed approach is investigated using detailed experiments. The proposed approach's description and outcomes have been explored in Section IV. Lastly, conclusions from this effort are presented in Section V.

II. Related Work

There are several procedures for detecting document manipulation. Most of these procedures detect the source of the printer to determine the types of printers used in the printing process [16]. The problem of source printer classification has received plenty of attention in the earlier decade [29]. This section will review the most common methods for authenticating a document and confirming that a legal printer printed it.

Mikkilineni et al. [4] introduced a printer identification process that uses an SVM classifier. They studied the impact of font size, font type, paper type, and printer age. Their printer identification technique works for various font sizes, paper types, and printer ages when those variables are constant. A novel color laser printer forensic algorithm is presented by [5]. It is based on an SVM classifier and noisy texture analysis. To estimate invisible noises, two filters are used: the Wiener filter and the 2D DWT filter. The noise texture is then analyzed using the GLCM. The machine classifier is trained and tested using 384 statistical features collected from the data. The proposed method achieves 99.3%, 97.4%, and 88.7% accuracy for brand, toner, and model recognition. In [6], the authors presented a method for detecting document forgeries based on Distortion Mutation of Geometric Parameters (DMGP) with translation and rotation distortion parameters. Both Chinese and English documents can be examined using this method. It can investigate documents based on separate characters. It is strong to JPEG compression and works well with documents of low resolution. The GLCM and DWT were utilized for texture feature extraction to examine the Chinese printed source to determine the impact of different output devices [7]. The feature selection techniques are used to choose the best feature subset, and an SVM is used to determine the source model of the documents. The average experimental results achieve a 98.64% identification rate, which is 1.27% higher than the previously known approach of GLCM. Many important statistical features, such as the Spatial filters, LBP, the Wiener filter, GLCM, the Gabor filter, DWT, Haralick, and SFTA features, are calculated using image processing techniques and data exploration techniques [8]. The highest rate of identification is achieved by the LBP method. It is considered superior to other methods in its various characteristics. In [9], presented a technique for analyzing the relationship between digital printers and printed Chinese characters. An SVM-based classification and feature selection decision fusion are used. The most significant features are methodically selected from GLCM, DWT, spatial, Wiener, and Gabor filters. The identification accuracy rate of the GLCM method gets the maximum rate compared with other approaches. In [10] presents a set of characteristics for describing geometric distortions at the text-line level. Experiments on 14 printers showed that the suggested system outperforms the current state-of-the-art method based on geometric distortion. It provides substantially higher accuracy when working with a limited training size constraint. A classifier trained using one page, one printer, one font, three different fonts, and 14 printers had an average classification accuracy of 98.85%. In [11], a proposed system utilized all printed letters simultaneously to identify the source printer from scanned images of printed documents. All printed letters, as well as local texture pattern-based features, are classified by a single classifier. The method was tested on a public dataset of 10 printers, and a new dataset of 18 printers scanned at 600 and 300 dpi resolution and produced in four different fonts. The authors of [12] identified the document source printer using a passive technique. Some feature extraction approaches have been deployed, such as Key Printer Noise Features (KPNF), Speeded Up Robust Features (SURF), Orientated FAST rotated, and BRIEF. Three classification procedures are considered for the classification job: k-NN, Random Forest, and Decision Tree. The majority vote was for these three classification techniques. Combining ORB, KPNF, and SURF with an RF classifier and adaptive boosting approach yielded the best accuracy of 95.1%. Printer identification using GLCM is presented in [13]. A feature vector is created by extracting a set of features from each character for each letter "e" in the document. Each feature vector is then classified using a 5-Nearest-Neighbor (5-NN) classifier. With training, this approach is unaffected by font type or size, although cross-font and cross-size testing yielded mixed results. A separate 5-NN classifier block for each character would be required to classify a document using all its characters, not only "e"s. The classifier becomes more complex as a result. Techniques for color and picture documents produced by inkjet printers must also be researched. A text-independent method for adequately describing source printers using deep visual Features has been applied [14]. Through transfer learning on a pre-trained CNN, the system could recognize 1200 papers from 20 different printers, including 13 laser and 7 inkjet printers. Solutions to learn discriminant-printing patterns directly from the provided data were found by Anselmo in [15]. This enabled him to reject any past beliefs about the distinctive printing artefacts of each printer. Results of the experiments demonstrated that the technique works better than its existing counterparts and is robust to noisy data. In [16], a novel technique is proposed based on SURF, Oriented Fast Rotated, and BRIEF feature descriptors. The Random Forest, Naive Bayes, k-NN, and other classifiers combinations were used for classification. The model could correctly classify the questioned papers and assign them to the relevant printer. The accuracy was 86.5% using a combination of Naive Bayes, k-NN, Random Forest classifiers, a straightforward majority voting system, and adaptive boosting techniques. A text-independent algorithm for detecting document forgeries based on source printer identification SPI is suggested by [30]. The image is divided into the top, middle, and bottom sections. The feature extraction algorithms HOG and LBP are employed. Classification approaches such as decision trees, k-NN, SVM, random forests, bagging, and boosting are considered for printer identification. The AdaBoost classifier achieves 96% classification accuracy, which is the highest.

III. Proposed Techniques

In this research, three distinct techniques are proposed for SPI and classifying the questioned document into one of the printer types. The proposed techniques are worked with the document as a whole and a small dataset. In the first technique, pre-trained CNN models with transfer learning for feature extraction are used. Feature maps can be extracted from any layer to train a classical classifier. It classifies the output using an SVM classifier, which means that the SoftMax layer of a CNN model is replaced with such an SVM. In the second technique, pre-trained CNN models are adjusted via transfer learning, which involves replacing the final fully connected or learnable layer of a CNN model with a new fully connected layer equal to the number of classes in the datasets. The third technique utilizes a convolutional neural network (CNN) model to resolve the SPI problem. The suggested framework (SPI-CNN) has the ability to dynamically learn and extract printer features. The SPI-CNN and a support vector machine (SVM) classifier used in this work were trained using various datasets. The datasets description, pre-processing, and details of CNN models are covered in the subsections below.

A. Datasets Description

To test the models, three different datasets are employed. The public dataset by Khanna et al. [31] consists of 20 printers (13 laser printers and 7 inkjet printers). There are a total of 60 pages distributed to each printer. All of a printer's documents are unique. Contracts, invoices, and scientific publications are the three types of documents that are included in the dataset. The second dataset includes printed documents and extracted characters from 10 printers. English and Portuguese documents are printed on each printer. The dataset is freely available on [32]. The third dataset, which comprises 30 printers, was created by combining the first and second datasets. Details of three different datasets used in training and testing are shown in Table I.

TABLE I. Details of Three Different Datasets used in Training and Testing

	Dataset_1 (Khanna et al., 2007)	**Dataset_2 (Ferreira et al., 2015)**	**Dataset_3**
Name	Anselmo Ferreira dataset	Khanna dataset	Hyper dataset
Number of printers	10	20	30
Number of documents	1185	1200	2385
Resolution	4922x6530	3312x4677	3312x467 and 4922x6530
Format	.tiff	.png	.tiff and .png

B. Pre-Processing

The pre-processing phase is utilized in the training and testing phases. For the pre-processing step, there are three methods: Histogram Equalization (HE), Gamma Correction, and resizing image. Histogram equalization (HE) [33], [34], helps normalize image grey-scale values and improve brightness discrimination between foreground and background images. The histogram function is written as (1)

$$H(f) = \frac{C(f) - C(f)_{min}}{(W \times H) - C(f)_{min}} \times (G_L - 1) \quad (1)$$

Where, $H(f)$ signifies the histogram function of the image, $C(f)$ identifies the cumulative function, $C(f)_{min}$ denotes the minimum non-zero value of the cumulative distribution function, $W \times H$ gives the image's number of pixels, and G_L defines the number of grey levels utilized.

Gamma correction is a nonlinear process to manage an image's overall brightness. Translating the values of the input intensity image to new values, improves the image's contrast. The Gamma is obtained by (2),

$$N_i = G(\alpha) \times (O_i)^{\frac{1}{\gamma}} \qquad (2)$$

Where, N_i stands for the new intensity value, O_i for the old intensity value, $G(\alpha)$ stands for the gray stretch parameter utilized to linearly scale the outcome on the image of [0, 255], and γ stands for the positive constant. Gamma can have any value between 0 and 1; infinite mapping is linear when it is 1. When less than 1, Gamma is weighed in terms of greater output values. The mapping is weighted toward lower output values if Gamma exceeds 1. Fig. 1 shows three Different Gamma corrections. Finally, the input image is resized to match each model's input size because each CNN model has an input size.

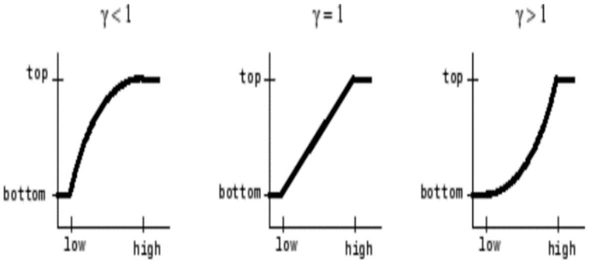

Fig. 1. Plots showing three different gamma correction settings.

C. The First Proposed Technique

Transfer learning (TL) for pre-trained models is a method that is suggested in this section for SPI. TL is used to prevent deep learning defects, which speeds up training and improves training outcomes. The pre-trained network with TL is considerably more comfortable and faster than the one trained from the start. Instead of building and training a new network, which requires millions of images, the system may quickly learn different jobs utilizing pre-trained deep networks. To transfer the learning capabilities to our application, transfer learning is employed rather than creating and training a deep learning model from scratch. 13 well-known pre-trained CNN models were used in this method to extract features (AlexNet, VGG-16, VGG-19, GoogleNet, DarkNet-19, DarkNet-53, ResNet-18, ResNet-50, ResNet101, SqueezeNet, XceptionNet, shuffleNet, inceptionv3). The obtained features are classified using SVM. In order to extract learned features from printer images, the pre-trained VGG-16 CNN model is used. The features are taken from one of the CNN layers and used to train an SVM classifier. Fig. 2 displays the model that extracts features using feature extraction and then classifies them using an SVM classifier.

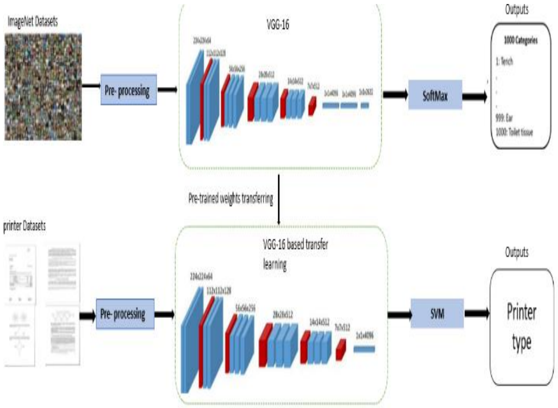

Fig. 2. Illustration of the first proposed SPI model based on transfer learning via extracting features and classifying using an SVM classifier.

D. The Second Proposed Technique

Transfer learning is based on using a CNN model that has been pre-trained and its weights that have been trained on enough data [35]. You can save time by using a pre-trained CNN model rather than creating a CNN from scratch, which requests a large, labeled dataset and lots of computational resources. While being preserved in other layers, the weights of the pre-trained CNN model are tuned in some. The higher layers of a pre-trained CNN (like DarkNet-53), initially designed for printer classification, are swapped out for the dense layer(s) in the proposed SPI approach to make the CNN compatible with SPI. In this technique, after the scanned documents for each dataset have been pre-processed. The number of classes in the current classification task is modified in every last FC layer neuron of pre-trained ConvNets ((AlexNet, VGG-16, VGG-19, GoogleNet, DarkNet-19, DarkNet-53, ResNet-18, ResNet-50, ResNet101, SqueezeNet, XceptionNet, shuffleNet, inceptionv3). With a very small learning rate of 0.0001 and 16 different batch sizes, the Adam Optimizer, also known as the Adaptive Learning Rate Algorithm, is employed to fine-tune the network. It is more efficient and less memory intensive. A model using transfer learning through fine-tuning is shown in Fig. 3.

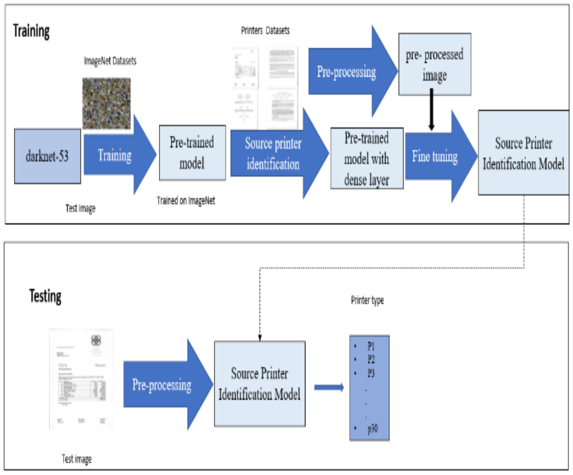

Fig. 3. Illustration of the second proposed SPI model based on transfer learning via fine-tuning in deep CNN.

E. The Third Proposed Technique (SPI_CNN)

The third technique suggests the CNN model as a solution to the SPI problem. The suggested framework (SPI-CNN) can dynamically learn and feature extraction for printers. This method uses a support vector machine (SVM) as the classifier and the SPI-CNN as the feature extraction technique.

1) SPI-CNN for features extraction: Four distinct models (7, 10, 13, and 17 layers) are used in SPI to choose the model with the highest degree of accuracy. Table II provides information about the various SPI-CNN models that were employed. Section B explains that all the dataset's scanned documents have been pre-processed. Following the pre-processing of all documents, the SPI-CNN model is applied, as shown in Fig. 4.

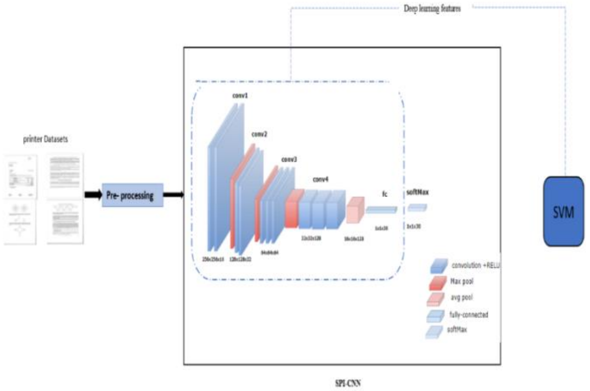

Fig. 4. The architecture of the third proposed SPI-CNN model.

TABLE II. DETAILS OF DIFFERENT MODELS OF CNN

Model_1	Model _2	Model _3	Model _4

			AvgPool4(2x2)
			Dropout Layer (0.5)
			Fully-Connected (num class)
			SoftMax Layer

The SPI-CNN is made up of layers arranged as follows:

- A multi-layer neural network is made up of different combinations of convolutional layers with a kernel size of 5 x 5 and (16,32,64,128) number of filters.
- A 2x2 kernel size average-pooling layer is used to aggregate the generated feature maps.
- Using a dropout layer with a probability of 0.5, we generate more robust features by randomly omitting various subsets throughout training.
- The final dense layer, which used a SoftMax function and various output neurons depending on the dataset, served as the classifier.
- ReLu was utilized as the activation function in each convolutional layer to learn complex functional mappings.

2) Classification with SVM: Although SoftMax succeeds in classification, current research has shown that the SVM classifier increases classification accuracy [36]. The SVM classifier in the current investigation replaced the SoftMax layer. To train the SVM, the outputs from the layer before (FC) are used as features. After training, it applies an SPI using the features gathered from the testing image.

IV. EXPERIMENTS AND DISCUSSIONS

This section describes the experimental technique and analyses the results. All of the earlier techniques were tested on three distinct data sets: the first with 10 printers and 1185 documents, the second with 20 printers and 1200 documents, and the third with 30 printers and 2385 documents. Evaluation of the first proposed technique's performance is discussed in Section 4.1, along with the performances of the second and third proposed techniques, which are considered in Sections 4.2 and 4.3, respectively. Finally, a discussion and comparison of the three methods to other techniques are provided.

The performance of the proposed techniques is estimated using accuracy metrics [37], [38], [39]. The accuracy is obtained using the following equation (3). It is defined as the percentage of perfectly classified images, where TP: True Positive, FN: False Negative, FP: False Positive, and TN: True Negative.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \qquad (3)$$

The suggested techniques were tested on a DELL PC using the following configuration implemented in MATLAB R2021b: Windows 11 64-bit, Intel(R) Core (TM) i7-11800H @ 2.30GHz, 6GHz GPU, 16GB RAM. Several tests were run to evaluate how well the suggested techniques worked.

F. Performance of the First Proposed Technique

The proposed technique is tested against 13 different pre-trained CNN models) AlexNet, VGG-16, VGG-19, GoogleNet, DarkNet-19, DarkNet-53, ResNet-18, ResNet-50, ResNet101, SqueezeNet, XceptionNet, shuffleNet, and inceptionv3 (with three distinct datasets. The number next to the model's name indicates its depth; thus, the models chosen are various, with varying depth sizes. The tests were carried out on both randomly selected 20% data as a test (i.e., 80% as the training set). When using pre-trained CNN as feature extractors and an SVM for classification, VGG-16 claims a maximum classification rate of 82.6% for dataset 1, 87.15% for dataset 2, and 86.67% for dataset 3. The accuracy of feature extraction and classification using pre-trained CNN and SVM with three different datasets is shown in Fig. 5.

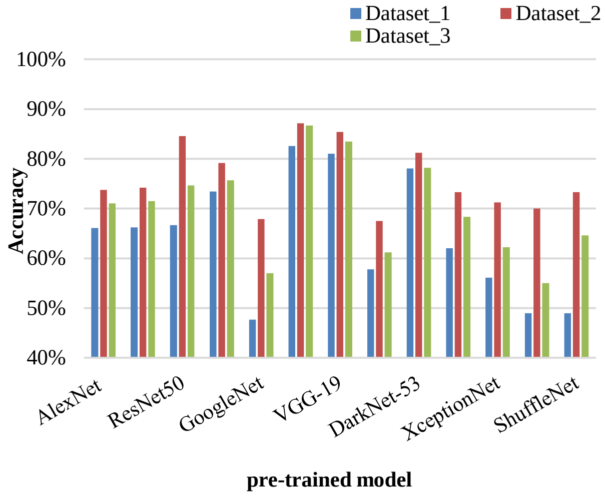

Fig. 5. The feature extraction and classification accuracy using pre-trained CNN and SVM with three different datasets (the first proposed model).

G. Performance of the Second Proposed Technique

As section D indicates, we use three separate datasets to fine-tune 11 pre-trained CNN models (AlexNet, VGG-16, VGG-19, GoogleNet, DarkNet-19, DarkNet-53, ResNet-18, ResNet-50, ResNet101, SqueezeNet, and shuffleNet). Deep transfer learning CNN architectures were used in this method to transfer learning weights, which reduced training time, mathematical calculations, and hardware resource utilization. Each dataset is split up into two parts: 20% for testing and 80% for training. The network architecture is as follows: The batch size for the 2D-CNN training was 16 samples. The Adam optimizer with a learning rate of 0.0001 was used. DarkNet-53 achieved a maximum classification rate of 98.31% for dataset 1, 97.5% for dataset 2, and 97.9% for dataset 3. Fig. 6 illustrates the performance of pre-trained CNN models during fine-tuning.

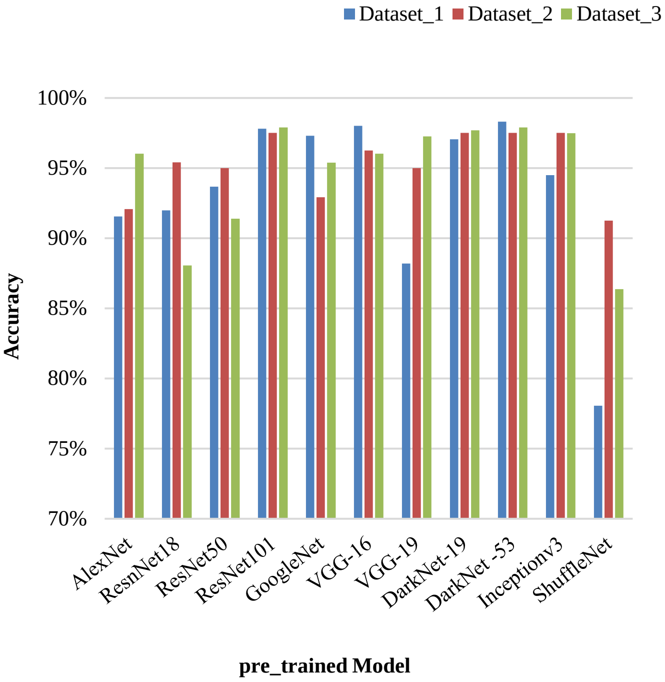

Fig. 6. The accuracy of pre-trained CNN via fine-tuning before and after pre-processing (the second proposed model).

H. Performance using the Third Proposed Technique

Three separate datasets were used to train the four CNN models that are shown in Table II. Neural network models with 1, 2, 3, and 4 convolutions were developed for comparison. Each dataset is split into 20% for testing and 80% for training. Following is the network architecture: 16 samples were used in the batch size for the 2D-CNN training. The Adam optimizer with a 0.0001 learning rate was employed. Four CNN models are used to train and classify each scanned document of a sample. Fig. 7 displays the accuracy attained by each SPI-CNN model using various datasets. Using model _4(SPI-CNN), which consists of four convolution layers, the average accuracy was 96.23% for dataset 3, 93.33% for dataset 2, and 96.2% for dataset 1. Fig. 8 displays the accuracy attained by each CNN+SVM model using a different dataset. Using model _4, which consists of four convolution layers, the average accuracy for datasets 1, 2, and 3 was 99.16%, 99.58%, and 98.32%, respectively. Results indicate that model 4 has the highest accuracy rate for SPI-CNN with SoftMax and SPI-CNN with SVM. Additionally, compared to its original configuration, the SVM classifier increased SPI-CNN accuracy by about 3%.

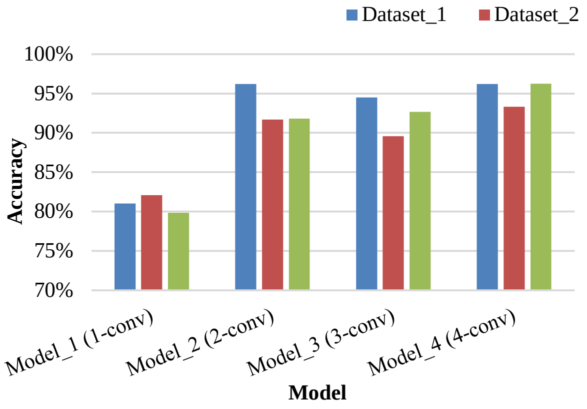

Fig. 7. Performance of SPI_CNN model.

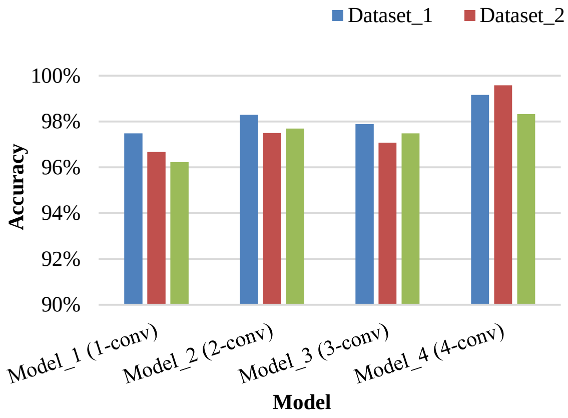

Fig. 8. Performance of SPI_CNN with SVM.

I. Discussion and Comparison

This section compares and discusses the results of three techniques using different datasets. Without dividing the document into letters, words, or patches and using only small datasets, three different CNN were trained to recognize the SPI. The first method was trained using SVM and used simply for feature extraction. The second had been trained in feature extraction and classification techniques. For feature extraction and classification, the third is trained completely from scratch. Because its parameters were tuned to extract features from printers document rather than other images, the third technique extracted features more effectively than the others. As illustrated in Fig. 9, our third proposed technique (SPI-CNN) outperforms [15], [40], [4], and [32] on both textural and deep learning features. As shown in Fig. 10, our third proposed technique (SPI-CNN) outperforms [37], [14], [12], [12], and [30] on dataset 2 of 20 printers and 1200 documents for both textural and deep-learned features. Fig. 11 compares the outcomes of the three proposed techniques for the data set 3 of 30 printers and 2385 documents. The prior outcomes lead us to the conclusion that the third model performs better than any previous method.

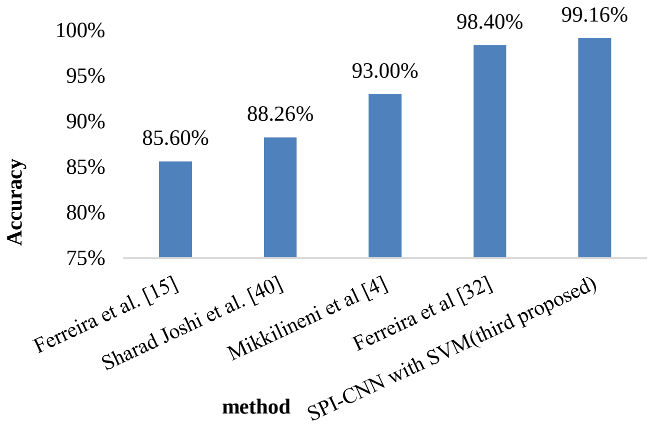

Fig. 9. Comparison of the third proposed technique with previous work on the dataset _1 of 10 printers.

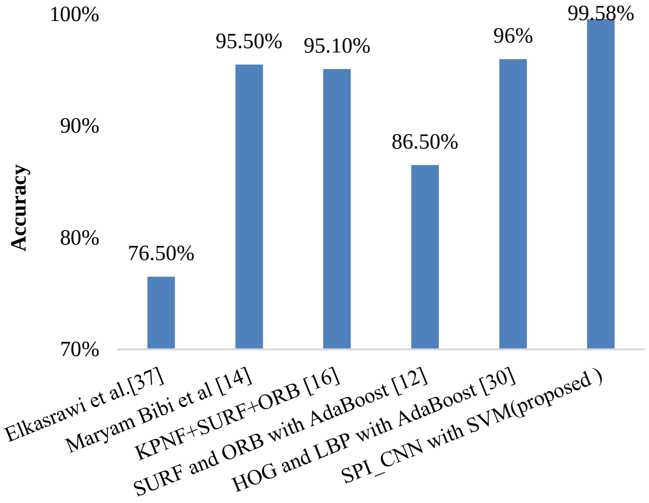

Fig. 10. Comparison of the third proposed technique with previous work on the dataset _2 of 20 printers.

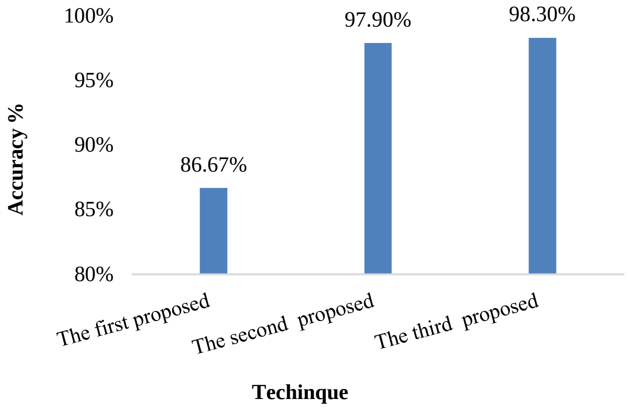

Fig. 11. Comparison of the three proposed techniques on the dataset _3 of 30 printers.

V. Conclusion

Three different techniques with CNN are proposed in this research to determine the printer's source. Although much research on source printer identification has been proposed, they have all been analyzed using distinct datasets and experimental setups. As earlier mentioned, several researchers use isolated characters in a text-dependent framework for experimental purposes. This paper uses CNNs to identify the source printer without segmenting the document into characters, words, or patches and with small datasets. An efficient pre-processing stage that combined histogram equalization and gamma correction was implemented, significantly improving the model's performance and increasing accuracy. The techniques are tested on a large number of 30 printers, whereas all previous studies only used a maximum of 20 printers. This paper trains three different CNN models on three separate datasets to determine the most accurate model. Transfer learning is used in the first technique for 13 pre-trained CNN models. These models serve as feature extractors, while SVM serves as a classifier. VGG-16 with SVM produces the best results. We tried 11 pre-trained models in the second technique but fine-tuned them by retraining each model and altering the last fully connected (The learning) layer. The fine-tuned DarkNet-53 achieves maximum classification rates. New CNN (SPI-CNN) from scratch adapted to this application in the third technique. The trained model was then used for feature extraction instead of SoftMax, and SVM was utilized as a classifier. Despite their simplicity, neural networks have proven to be extremely successful in producing good results across all datasets. The accuracy of the SPI-CNN model was 96.2%, 93.33%, and 96.23% for datasets 1, 2, and 3, respectively. For datasets 1, dataset 2, and dataset 3, the SPI-CNN-SVM model achieved 99.16%, 99.58%, and 98.3% accuracy, respectively. Based on the outcomes of the three techniques, we find that SPI-CNN with SVM is more accurate than the other two models. Additionally, the SVM classifier increased SPI-CNN accuracy by about 3% compared to its original configuration. With some previously published papers, the three techniques found that the third technique gives better results.

VI. Future Work

Future work will focus on discovering novel techniques to increase the accuracy of printer source identification. Try k-fold cross-validation as well rather than 20-80 validation. Identify forgeries in handwritten documents by looking at the type of ink used and the signature.

The Cross-Cultural Teaching Model of Foreign Literature Under the Application of Machine Learning Technology

Jing Lv
School of Humanities and International Education, Xi’an Peihua University,
Xi’an 710125, Shaanxi, China

***Abstract*—As globalization spreads, so does the world's ethnic makeup, leading to a surge in cultural diversity that has become a major issue for the educational systems of all countries. Many western countries advocate for cross-cultural education (CCE) as a means of dealing with cultural variety and promoting trust, tolerance, and interaction between individuals of different backgrounds. The way to achieve this goal is to work toward solving the issue while also fostering greater national unity. One of the newest developments in international education is the concept of CCE, which has also given rise to a whole new area of research within the subject of education. Too much time has passed since students were actively engaged in the learning process, and the new curriculum reform has seriously harmed the traditional approaches to teaching foreign literature. As a result, the proposed research has shown that around half of all education is dedicated to the FL cross-cultural teaching paradigm. Chinese students' data were first gathered for this study and divided into two groups: Control Class (CC) and Experimental Class (EC). The performance of the students in both groups is then forecasted using the extreme gradient boosting (XGBoost) technique, which is based on machine learning. Then, we use an optimization method known as the Flower Pollination Algorithm (FPA) to improve XGBoost's prediction performance. According to the descriptive findings, students who adhere to the suggested teaching strategy show more learning interest than those who adhere to existing strategies.**

Keywords—Cross cultural education; foreign literature; extreme gradient boosting (XGBoost) algorithm; flower pollination algorithm (FPA); control class (CC)

I. Introduction

In order for Chinese students to achieve the English proficiency levels needed by their curriculum, a totally new piece of software known as the English displaying mode was developed [1]. It is possible that pupils' own levels of originality and academic success would rise if they were given extended periods of time on the computer to engage in speaking and listening activities [2]. It is possible that teachers might aid pupils in learning a language by introducing them to online reading, writing, and translation materials. Educators and students alike may anticipate an increase in opportunities to use multimedia in class as more and more resources become available for this purpose [3]. Multimedia courses in community nursing that make use of a digital library of teaching resources may improve students' interest in and recall of course content. There is strong evidence that incorporating YouTube into the classroom enhances students' ability to jhioijjj/iooooooooklglhk[poiuyt86867 6 565eeryyyyyyyyyyyyyyr7fdhjrfjtttkttt9tyeerse v sASZ z zjunderstand and remember what they read [4]. Students who saw the video on YouTube fared better than those who did not. The author learns why high school students study English online via a survey she administers to them. What makes an activity effective in meeting the requirements of the learner and fostering development is the "input and interaction" process. Here the author explores how music education might benefit from "smart classrooms" and other types of multimedia instruction. Today's multimedia productions rely significantly on the composition, editing, and synthesis capabilities of music software [5]. Since technology advancement has made it possible for students of any age and from any location to build their own learning plans, teachers need to rethink their responsibilities in the classroom. Additionally, students should be confident presenting and defending their views in class utilizing a number of methods [6]. Teachers may adapt their classes to their students' needs with the use of multimedia resources. As part of their education, students are expected to do their own study on topics that pique their curiosity or puzzle them, and to provide their own unique takes on the ideas they unearth. To some extent, computers may one day be used in lieu of human teachers because of the individualized attention they can provide to each student. Because not all pupils at a given school will have the same linguistic or cultural background, it is essential that schools have access to materials like this one [7]. A student like A may learn the same amount in three days whereas it could take the teacher a whole week. Student B may solve the issue or review it by clicking the mouse many times if necessary [8].

Internet of Things (IoT) advances has allowed educators to provide students with more engaging and valuable online learning opportunities, many of which include collaborative software and assignments. While it's true that learning English might be difficult, each individual should first take stock of their unique situation and objectives before making any broad assumptions. It is typical practice to survey educators prior to making major purchases like new textbooks or sets of worksheets [9]. To accommodate today's diverse student populations and make up for the time that might have been spent together in class if all students had the same previous knowledge and skills, new textbooks are being developed. The most valuable function [10] is that users may set playback to begin at a time and location of their choosing. The high quality of the provided resources, the ease with which they may be communicated, and the possibility of presenting them all at once are just a few of the many benefits of this approach. As a means to better serve users with varying network speeds, service providers may provide customers granular control over which resources are duplicated, while researchers may look at normal resource flows simultaneously [11]. Multimedia lectures might be very helpful for college students engaged in a wide range of digital building projects. Students may watch and take part in the lectures from anywhere with an internet connections, and professors are freed up to focus on other aspects of the curriculum [12]. Since there are a lot of great learning resources available online, yet text-based materials might be monotonous, streaming media technologies may be useful in the self-study sector. Visitors from prestigious institutions in the academic or corporate sector often deliver talks on campus, and they are almost always streamed live online [13]. If there are too many people, it may become awkward. With the various multimedia education tools now accessible, professors may now reach students all over the globe in real time via online streaming of lectures. The school should explore recording extracurricular activities like sports and cultural presentations to make them available to students online [14]. In order to connect with people from all walks of life, a command of the English language is required. Speed is of the essence in today's globalized world [15]. Learning English might make people more educated, tolerant, and successful. Learners of English should make it a goal to improve their essay writing skills. A student's writing skills may be judged not just by their vocabulary and grammatical understanding, but also by their sentence structure, discourse, and ability to think coherently [16]. As a result, teachers need to pay close attention to their pupils' language abilities while crafting assessments of their progress. Perhaps this explains why today's pupils seem to be more attentive in class than ever before.

Educators' support of students' growth in written English proficiency is more important than ever [17]. Only a small number of the available short English works are appropriate for usage in a classroom where instructors physically check student work. This technique will be less effective and more prone to erroneous conclusions if stricter grading standards and longer essay lengths are used [18]. Manual grading is also very susceptible to prejudice since it's impossible to know how a reader from a different section of the globe or cultural background would interpret the same work. Due to technological developments, Automated Essay Scoring (AES) software is now often used in the classroom [19]. Though it has its constraints, this technology effectively probes and evaluates textual content. Computerized candidate evaluation is more efficient and cost-effective than human evaluation. Professors should focus more on actual teaching and cutting-edge research rather than spending time grading papers [20]. Machines excel at routine work. Students may either use the analysis results to methodically correct their own work (for things like spelling and grammar mistakes) or provide suggestions for further evaluation questions. Students may get inspiration for individual words, phrases, and even whole essays when perusing the study findings. The research findings have already been implemented in the design and analysis of AES systems. In spite of its lack of depth and precision, this study does touch on a number of important topics [21-24].

Contributions of the Study is as follows:

- To improve the effectiveness of foreign literature learning by Chinese students, this study presented Cross-Cultural Teaching Model (CCTM).
- Using the XGBoost prediction model, the perceptions and performance of Chinese students, provided with CCTM -based foreign literature learning, were intelligently predicted.
- To enhance the student evaluation performance of XGBoost model, Flower Pollination Algorithm was employed for XGBoost model optimization.
- The effectiveness of CCTM in foreign literature learning was compared with existing foreign literature teaching models to emphasize the potency of CCTM in foreign literature learning.

II. Related Works

Saeid Ghalehbani's (2022) research looked at how recasts and cues affected the vowel and consonant pronunciation accuracy of English as foreign language (EFL) students. Based on their scores on a pilot version of the KET, 89 primary school students were chosen to participate in the study and were randomly divided into three groups: the control group, the recast group, and the prompt group [25]. Before receiving treatment, each group took a custom-made pronunciation test developed by the researchers and tested with a sample group. The three groups were all given the same quantity of instruction time and content. People in the remake group were given recast, and those in the prompt group were given prompt. Participants in the control group, however, were not given any form of corrective input. Participants were given a post-treatment pronunciation test that was similar to the test they did before treatment. A multivariate analysis of covariance (ANCOVA) was performed. The outcomes showed that both recast and prompt greatly improved EFL students' consonant and vowel pronunciation accuracy. Furthermore, the findings revealed that the impact of recast and prompt on EFL students' consonant and vowel pronunciation accuracy was statistically indistinguishable.

The current research by Wei Zhang (2020) aimed to test how various types of corrective feedback (recasts and clarification requests) can differentially affect the suprasegmental development of English intonation [26]. A total of 102 EFL learners took part in the study. All participants, with the exception of the control group (n=34), got five treatment sessions intended to get them to focus on and practice the target feature in real-world discourse, and their untarget like output was corrected through recasts or clarification requests. Seven intonation features, including words/IP, pause, anacrusis, lengthing, pitch reset, improper tonicity, and tone selection, were analyzed acoustically using pre- and post-test measures of learned and untrained occurrences. The findings indicated that 1) recasts are more effective than clarification requests in helping EFL learners develop English intonation at a suprasegmental level, and that 2) recasts may lead learners to establish, reinforce, and generalize their new phonological knowledge of English intonation that they practiced during the treatments.

It is timely and prudent to provide a scholarly work that focuses on synthesizing and presenting the current state of affairs in the field of corrective feedback (CF) for the development of L2 pronunciation, as interest in this topic has been growing quickly in recent years. Existing descriptive studies show that both teachers and students value the provision of CF as an important part of L2 pronunciation development, particularly when the errors in question impede effective communication. In recent years, researchers in both classroom and laboratory contexts have begun to examine the pedagogical benefits of CF with a specific emphasis on pronunciation through the use of quasi-experimental studies employing a pretest-posttest design.

Even though the findings suggest that pronunciation-focused CF aids in the development of both segmental and suprasegmental accuracy, there appears to be a great deal of individual variability in how well such CF techniques work. [27] The potentials of CF for teaching pronunciation are greatest (a) when L2 learners have sufficient phonetic knowledge, conversational experience, and perceptual awareness of target sounds; (b) when CF provides model pronunciation forms (e.g., recasts rather than prompts); and (c) when the target of instruction concerns communicatively important and salient features.

Nearly half of the world's population uses a mobile phone regularly, a number that has grown by 20% in the past year compared to the last global population survey. Researchers performed a global survey to determine the average monthly data usage of mobile devices, and found that a single user generated 45 exabytes of data in just one month. Nowadays, e-commerce businesses are starting to see data consumption and analytics as one of their most essential requirements. Individuals' future signature or activity can be forecast with the help of such gathered data. The average calculation and quantity of data to be collected for five billion users looks to be much more challenging if 45 terabytes of data can be stored for a single user. It appears that a conventional computer system would have trouble processing this volume of input, even more so than the human working concept. For researchers in the fields of machine learning and artificial intelligence, accumulating enough data to make accurate predictions based on a user's behavior is a crucial first step. The expectations for academic assessment and the responsibilities of both teachers and students are laid out in this essay by Yang Q (2022). Most people were unaware of the online education paradigm even before the pandemic. Since it's difficult to hold traditional, in-person classes, internet education has been slow to catch on [28]. In an effort to increase student-teacher communication and provide more flexible learning options, nearly sixty percent of nations are attempting to transition their education systems to online models. Big data is one of the IT industry's technological revolutions that gained traction after the cloud computing disaster. In this paper, we suggest using a support vector machine (SVM) to analyze ESL pedagogy and then compare it to the more conventional method of fuzzy analysis. According to the findings, the suggested model is 5% more accurate than the current algorithm, at 98%. Farhad Tabandeh's (2019) research compared the effectiveness of two methods for teaching English lax vowels to Persian EFL students: focus-on-form (FonF; explicit instruction followed by focused tasks) and focus-on-forms (FonFS; explicit instruction followed by controlled exercises). Forty-eight students voluntarily participated in a 6-hour course, with 17 receiving FonF, 16 receiving FonFS, and 15 participating in theme-based talks without attention to the target vowels as the experimental group, comparison, and control, respectively. Auditory measurements of tongue position were used to determine the phonetic accuracy of learners' pronunciations elicited in controlled read-aloud and spontaneous image description tasks (i.e., formant 1 [F1] for the height and formant 2 [F2] for the backness of the tongue). While the results showed that both methods of instruction led to substantial gains in phonetic accuracy (i.e., adjusting F1/F2 values) in the controlled task, only the FonF methodology was successful in the spontaneous task, showing particularly large effects in the delayed posttest [29]. Nothing got better for the control group. Results suggest that there may be significant advantages to teaching FonF to EFL students, particularly in terms of helping them acquire more native-like pronunciations in spoken English. Finally, the article discusses how these results can be applied in the classroom.

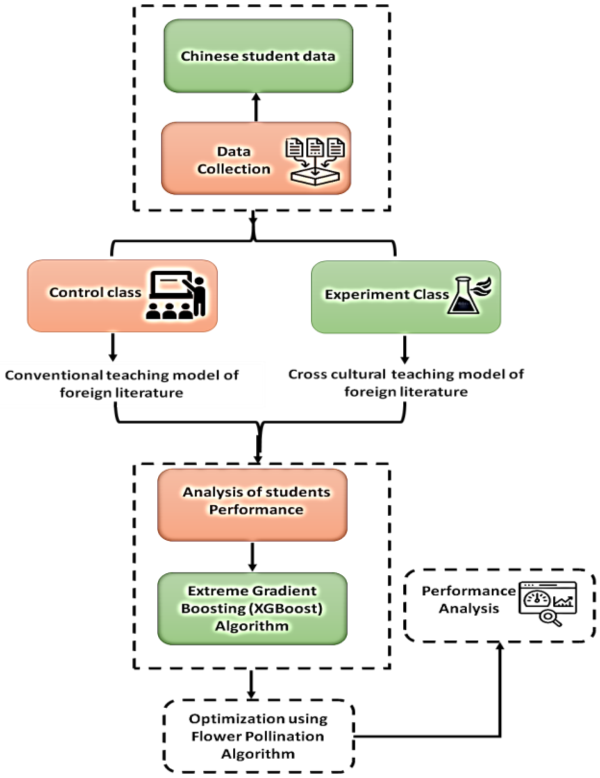
The purpose of this study by Siti Salina Mustakim was to better understand how teachers of the Contemporary Children's Literature Program at the upper primary level handle the subject. This paper uses classroom observations and interviews as research tools to compare and contrast the methods used by five ESL teachers of Year 5 students and to explore the various difficulties these educators encounter when instructing literature [30]. The preliminary results of the methods indicated that there was little effort made to incorporate literature concepts into the classroom. Educators lacked originality and relied heavily on the CDC's premade lessons. Because the school did not supply the necessary material, the Pre, While, and Post-Reading strategy was not fully implemented. Nonetheless, there is a lot of hope that the initiative will help students improve their language skills in the classroom. By analyzing how educator’s approach teaching and learning in the classroom, this research adds to the literature on authentic education.

The purpose of the study by Ruzbeh Babaee (2014) is to give credence to literature as a significant tool for training rudimentary linguistic abilities like speaking, listening, reading, and writing [31]. In order to make readers aware of the primary reasons why language instructors are suggested to use literary texts in their classrooms, it is important to emphasize the reasons for using literature in language classes and the major factors for choosing appropriate kinds of literary texts in such classes. The benefits of different types of literature to language instruction, as well as some of the challenges that teachers of languages encounter when using literature as a teaching tool, are also taken into account here.

Because of their potential to help students move beyond the referential and into the representational realms of language, reading diaries are commonly used in the instruction of foreign languages. In this article, Ochoa Delarriva (2015) presents findings from a qualitative study of reading logs created by upper-level students in an English language teacher education program in Argentina [32]. The students were required to keep the logs as part of their coursework in a literature course. The Authors were able to reflect on the usefulness and applicability of reading logs and the need to encourage diversity in literature teaching in English language teacher education by categorizing them according to the various literature teaching models used in the program.

III. Methodology

This section discusses in detail about the cross-cultural teaching model of foreign literature under the application of machine learning technology. Fig. 1 depicts the schematic representation of the proposed teaching model. 1307 Chinese students participated in the current research. All of the applicants are sophomores at one of three different Chinese high schools in Lu'an City. They may have been following a standardized curriculum and syllabus set out by the "People's Republic of China Ministry of Education" (Li 2020). Table I displays participant information in detail.



Chinese student data
Data Collection
Control class
Experiment Class
Conventional teaching model of foreign literature
Cross cultural teaching model of foreign literature

TABLE I. Participants Characteristics

School	Total participants	Male	Female	Mean Age
A	829	399	430	16.92
B	154	94	60	16.64
C	324	179	145	16.72
Total	1307	672	635	16.83

A. *Student Categorization*

Among 1307 participants, 50 percent of the participants i.e. 653 students were in the control group and the remaining students were in the experimental group. CC students follow conventional teaching method of foreign literature whereas EC students follow cross cultural teaching method of foreign literature.

B. *Conventional Teaching Method*

The most prevalent teaching style used in schools all around the globe is teacher-centered instruction and lectures. Teachers that use this style of instruction choose activities and provide resources that are suitable for the students' abilities in foreign literature learning. Here, a curriculum establishes the foreign literature material, and all students study the same subjects at the same time. Only a little amount of information on foreign literature, chosen by the instructor or the school library, is available to students. The majority of the time, academic subjects is discrete and unrelated to one another. These learners recite material exactly and sometimes engage in critical information analysis. A little amount of attention is paid to how to use ideas or facts in conventional teaching model based foreign literature learning. Foreign literature learning takes place in an often-quiet classroom according to conventional teaching (CT) model. This CT model can be efficient particularly for

- Disseminating information that is hard to get elsewhere.
- Quickly presenting the facts.

However, there are various difficulties with this kind of instruction in foreign literature learning, including:

- Not all students learn best by listening.
- Maintaining students' attention is often challenging.
- The strategy typically calls for little to no critical thinking.
- It assumes that all students learn in the same impersonal manner.

C. *Cross Cultural Teaching Method*

Since China joined the "World Trade Organization," there has been an uptick in demand for people with foreign language skills in all industries. At the same time, however, more strict and detailed requirements for English proficiency and diverse abilities have been imposed. As globalization has accelerated in recent years, China and other nations have cooperated and competed more often, and interactions between Chinese civilization and other cultures have been booming [25]. China desperately needs individuals with cross-cultural aptitude given the history of mutual learning between Chinese and other cultures. Most pupils cease to be really interested in conventional education. Therefore, in this study, we suggest a cross-cultural teaching strategy.

There are three definitions for cross-cultural education: first, it relates to the simultaneous teaching of foreign literature based on multiple cultures in the environment where various cultures coexist; second, foreign literature students who have exposed to a specific cultural background are exposed to another cultural environment with varied customs for foreign literature education. Third, it's about making an intentional effort to bring together people from different cultural backgrounds in the classroom so that students of literature from other countries may learn about other cultures' languages, traditions, and values. An understanding of English is frequently necessary when analyzing works written in other languages. From the perspective of a student's capacity for intercultural communication, CCTM-based foreign literature learning seeks to strengthen intercultural communication abilities and encourage both intercultural communication and cultural adaptation, thereby establishing a highly robust intercultural communication theory.

Multiculturalism's protection of the cultural rights of ethnic minorities enables cross-cultural education to embrace and comprehend cultural differences, which is essential for successfully addressing the problem of cultural diversity. The essential notions of intercultural education are understood and seen differently by different academics due to differences in language habits between nations and experts. As a result of its explosive growth, cross-cultural studies is now acknowledged as an interdisciplinary field of applied social science and cultural education research devoted to the examination of the causes and consequences of variation in social structures, institutions, and individuals in response to their context. To face the problems of this age, a new kind of education based on understanding and appreciating other cultures has emerged. Human rights, the end of discrimination, and the cultivation of talent are all areas where intercultural training and civic education overlap. The decline of connectedness and synchronization strategies grounded in local communities all contribute to the pressing need to include people of different ethnicities and backgrounds into the framework of cross-cultural civic community in the postmodern era. International political and economic relations sparked the idea of cross-cultural competency. Thus, intercultural competency studies continue to be conducted with a focus on implementation. As individuals continue to investigate cross-cultural encounters, the foundations of what it means to be culturally competent grow. From this, it develops its own theory of intercultural communication and a model of intercultural proficiency.

Teaching FL with a cross-cultural focus allows institutions to better prepare their students for the global workforce by helping them develop the critical thinking skills necessary to effectively communicate and collaborate across cultural boundaries. However, due to China's late entry into the area, numerous issues remain in the implementation of FL courses at the tertiary level. Teachers that use a speculative approach to FL education must alter their students' conceptual frameworks in order to successfully implement cross-cultural speculative FL instruction. First, the teacher needs to have a deep understanding of the significance of cross-cultural speculative ability, and base their teaching work on this understanding; second, the teacher needs to have a complete understanding and mastery of the connotation of cross-cultural thinking ability, and use this as the starting point and the foothold to do all types of teaching work effectively; third, the teacher needs to have a deep understanding of the significance of cross-cultural sensitivity, and base their teaching work on this understanding; Fourth, educators ought to abandon the notion of conventional opposites in time, stop seeing FL culture through "tinted glasses," assess it objectively, scientifically, and dialectically, and take advantage of what other nations have to offer.

IV. Analysis of Students' Performance

A. *Machine Learning based Extreme Gradient Boosting (Xgboost) Algorithm*

The "Extreme Gradient Boosting Method (XGBoost)" was used to analyze the students' performance in both groups. Given a collection of student information denoted by the notation V={(h_w, t_w)} where h_w represents the performance profile of students and t_w is their associated binary label, Assuming that the XGBoost model is made up of R decision trees, the objective function may be found by using the equation (1):

$$\hat{t}_w = \sum_{r=1}^{R} l_r(h_w), l_r \in L \quad (1)$$

Where L is the space of regression trees, and for each l_r there is a corresponding tree whose performance scores are also stored in L. Equation (2) describes the loss function used to forecast student performance.

$$F(l_r) = \sum f\,(\hat{t}_w, t_w) + \sum \Omega\left(l_y\right) \quad (2)$$

For predicting student performance, the first term is the derivative of a loss function, F, which measure the difference between the real output $\hat{t}_w$ and the anticipated output t_w. The second is a regularisation term, which devalues the prediction's complexity to prevent over-fitting. In the case where Ω and $\hat{t}_w$ can be represented as:

$$\hat{y}_w^{(y)} = \hat{y}_w^{(y-1)} + l_y(h_w) \quad (3)$$

$$\Omega(l) = \gamma Y + \frac{1}{2}\|w\|^2 \quad (4)$$

where, Y represents the total number of leaf nodes and w represents the performance grade. From this, we may derive that

$$F\left(l_y\right) \approx \sum_{g-1}^{Y}(g_w) i_g + \frac{1}{2}\left(\sum_{w \in w_g} x_w + \lambda\right) i_g^2] + \gamma Y (5)$$

where, g_w and x_w represent the first- and second-order gradient statistics of the loss function in predicting student performance, respectively. Parameters γ and λ are constants used to adjust the level of regularisation. They help prevent prediction models from becoming too specific.

B. *Optimization using Flower Pollination Algorithm (FPA)*

The "Flower Pollination Algorithm" (FPA) is used to enhance the performance of XGBoost in making predictions. The inspiration for the invention of it was taken by Xin-She Yang in 2012 from the flow pollination experienced by flowering plants. Multi-objective optimization is now a part of FPA's capabilities. In the sake of simplicity, we will employ the following four rules:

- It has been shown that pollen-carrying insects follow trajectories that are compatible with L'evy flights, suggesting that biotic and cross-pollination may be thought of as a kind of global pollination (Rule 1).

- For local pollination, abiotic pollination and self-pollination are used (Rule 2).
- "Flower constancy," which pollinators like insects may acquire, is equivalent to a reproduction probability that scales with the degree of similarity between two blooms (Rule 3).
- The interaction or switching between local and global pollination may be controlled by a switch probability p [0, 1], slightly slanted toward local pollination (Rule 4).

In order to improve the accuracy of the algorithm's prediction of students' performance, it first generates a random initial population and evaluates it. Before a new student's performance can be calculated, the pollination type must be established using a fixed probability p (K4). That is, we select a random number k between 0 and 1, and if k is less than u, then both global pollination and flower constancy (K1 and K3) may occur as follows:

$$h_w^{y+1} = h_w^y + \gamma F\left(h_w^y - gbest\right) \qquad (6)$$

Where student w's performance at time y is denoted by h_w^y, the current best performance is denoted by gbest, is a scaling factor, and F is a step size derived from Lévy flight, as follows:

$$F(a,s) \sim \frac{\lambda\Gamma(\lambda)sin\left(\frac{\pi\lambda}{2}\right)}{\pi}\frac{s}{a^{1+\lambda}}, |a| \to \infty \quad (7)$$

where () is the standard gamma distribution with index, s is a variable used to adjust the distribution's tail amplitude (s=1 in the proposed FPA), and a big step function (a>>a0>0) is built using the necessary nonlinear transformation as:

$$a = \frac{P}{|D|^{\lambda-1}} \qquad (8)$$

When P and D are two random student samples chosen from a Gaussian normal distribution with mean equals 0, and standard deviations σ_P and σ_d:

$$P \sim \left(0, \sigma_p^2\right), D \sim (0, \sigma_d^2) \qquad (9)$$

$$\sigma_P = \left[\frac{\Gamma(1+\lambda)}{\lambda\Gamma((1+\lambda)/2)} \cdot \frac{sin\left(\frac{\pi\lambda}{2}\right)}{2^{(\lambda-1)/2}}\right], \sigma_d = \qquad (10)$$

Since σ_P and σ_d cannot be selected individually for any value of, the standard deviation σ_d is fixed at 1. If, however, k is larger than u, then the local pollination and flower constancy (K2 and K3) are carried out as follows:

$$h_w^{y+1} = h_w^y + \varepsilon\left(h_g^y - h_r^y\right) \quad (11)$$

where h_w^y and h_r^y are two student results chosen at random and $\varepsilon \in [0,1]$ is a random integer. Next, the current best performance is updated, and the search iterations are restarted until the termination criterion is met.

V. Results and Discussions

The investigation of student's performance and perceptions regarding cross-cultural teaching model (CCTM) based foreign literature learning is conducted using machine learning algorithm. The learning performance and perceptions of students being exposed to the suggested CCTM was evaluated using XGBoost prediction model optimized by FPA (XGBoost-FPA). To state the effectiveness of CCTM based foreign literature learning, we compared the suggested model with existing teaching models in foreign literature learning. The existing teaching models in foreign literature learning considered for the comparative investigation are Conventional Teaching (CT) model, Zoom Web Conference System (Zoom WCS) [33], Translanguaging + Task-based Language Teaching (TL+TBLT) model [34], Content and language integrated learning (CLIL) model [35], Flipped Learning (FL) model [36]. This study aimed at exploring the Chinese students' perceptions of using cross-cultural Teaching model in foreign literature learning in terms of Perceived Usefulness, Perceived Ease of Use, and student acceptance [37]. In addition, the learning performance of students being exposed to the suggested CCTM was evaluated in terms of student's overall performance, learning ability, and student engagement.

A. *Perceived Usefulness*

The degree to which a student thinks that utilising CCTM for studying foreign literature would improve their academic performance is known as student's perceived usefulness. Fig. 2 shows the comparative investigation of student's perceived usefulness for various teaching models in foreign literature learning. It is noted that student's perceived usefulness for CCTM based foreign literature learning was higher than that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. Higher student's perceived usefulness, observed for CCTM, using XGBoost-FPA illustrates that CCTM is highly useful for Chinese students who are learning foreign literature.

B. *Perceived Ease of Use*

One of the most important variables in determining whether students would adopt CCTM-based foreign literature learning is student's perceived ease of use. It is defined as how simple it is for students to access CCTM-based instruction in foreign literature. Fig. 3 shows the comparative investigation of student's perceived ease of use for various teaching models in foreign literature learning. From Fig. 3 and Table II, it is observed that student's perceived ease of use for CCTM based foreign literature learning (predicted using XGBoost-FPA) was higher than that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. This indicates that CCTM is easily accessible by Chinese students for learning foreign literature.

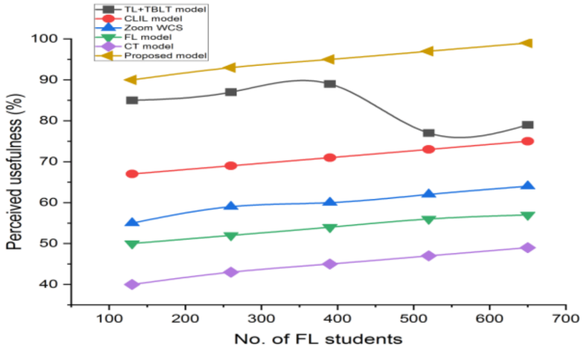

Fig. 2. Analysis of student's perceived usefulness for various foreign literature teaching models.

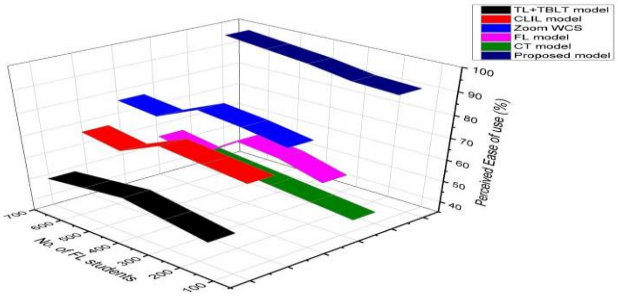

Fig. 3. Analysis of student’s perceived ease of use for various foreign literature teaching models.

TABLE II. COMPARATIVE EVALUATION OF STUDENT’S PERCEPTIONS REGARDING VARIOUS FOREIGN LITERATURE TEACHING MODELS

Student’s Perception Variables	TL+TBLT model	CLIL model	Zoom WCS	FL model	CT model (Control Group)	CCTM (Proposed model)
Perceived Usefulness (%)	79	75	64	57	49	99
Perceived Ease of Use (%)	52	69	79	58	45	97
Student’s Acceptance (%)	69	79	59	57	48	97

C. Student’s Acceptance

Student’s acceptance is defined as the degree to which a student is satisfied with the CCTM based foreign literature learning. Fig. 4 shows the comparative investigation of student’s acceptance for various teaching models in foreign literature learning. Chinese students receiving CCTM based foreign literature learning reported to have higher acceptance level compared to that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. The findings depict that Chinese students are highly satisfied with CCTM based foreign literature learning.

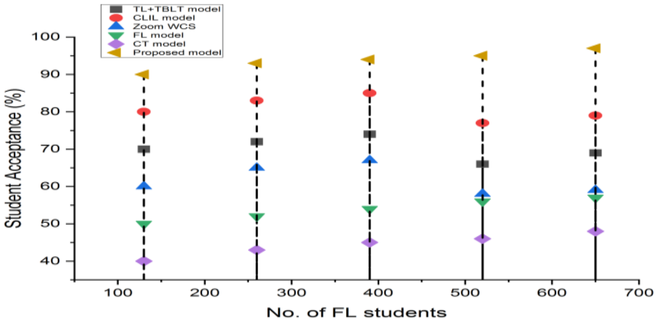

Fig. 4. Analysis of student’s acceptance for various foreign literature teaching models.

D. Student’s Academic Performance

Student’s academic performance means the extent to which a student has attained knowledge on foreign literature through CCTM. Fig. 5 shows the comparative investigation of student’s academic performance in various teaching models in foreign literature learning. It is noted from Table III that academic performance of students receiving CCTM based foreign literature learning was higher than that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. Higher student’s academic performance observed for CCTM (as predicted by XGBoost-FPA) shows that CCTM enhances the efficiency of foreign literature education.

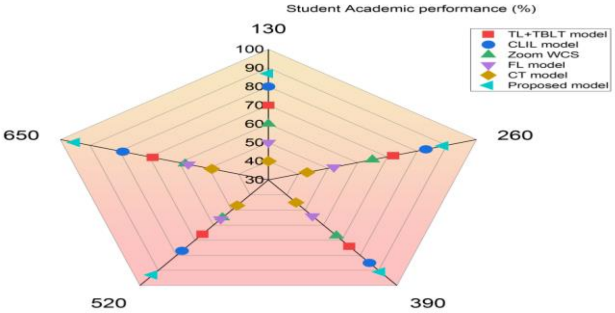

Fig. 5. Analysis of student’s academic performance in various foreign literature teaching models.

TABLE III. COMPARATIVE EVALUATION OF STUDENT’S PERFORMANCE REGARDING VARIOUS FOREIGN LITERATURE TEACHING MODELS

Student’s Performance Variables	TL+TBLT model	CLIL model	Zoom WCS	FL model	CT model (Control Group)	CCTM (Proposed model)
Student’s Academic Performance (%)	69	79	58	57	49	95
Student’s Engagement (%)	85	74	64	53	39	96
Student’s Learning Ability (%)	69	79	54	64	46	98

E. Student’s Engagement

The term "student engagement" refers to the extent to which a student participates in class discussions and other collaborative tasks. Fig. 6 shows the comparative investigation of student’s engagement in various teaching models in foreign literature learning. It is noted that student’s engagement in CCTM based foreign literature learning (predicted by XGBoost-FPA) was higher than that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. The results showed that Chinese students are highly engaged in CCTM based foreign literature classroom.

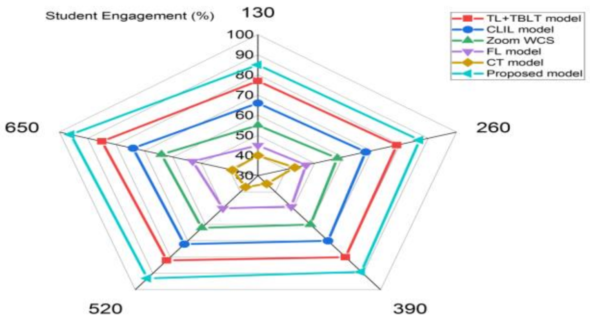

Fig. 6. Analysis of student's engagement in various foreign literature teaching models.

F. *Student's Learning Ability*

Student's learning ability is defined as the student's capacity to comprehend and understand foreign literature. Fig. 7 indicates the comparative investigation of student's learning ability in various teaching models in foreign literature learning. It is noted that student's learning ability in CCTM based foreign literature learning (predicted by XGBoost-FPA) was higher than that for existing teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. This proved that CCTM based foreign literature learning improves the ability of Chinese students to learn foreign literature.

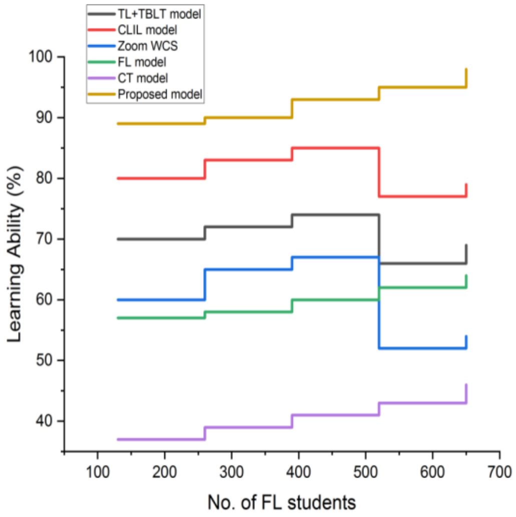

Fig. 7. Analysis of student's learning ability in various foreign literature teaching models.

VI. Conclusion

This research presents the cross-cultural teaching model (CCTM) for foreign literature learning by Chinese students. The performance and perceptions of Chinese students regarding CCTM based foreign literature learning were automatically estimated by XGBoost prediction model which was optimized by FPA (XGBoost-FPA). The effectiveness of CCTM in foreign literature learning was confirmed by comparing with existing foreign literature teaching models like CT model, TL+TBLT model, CLIL model, Zoom WCS, and FL model. The findings indicated that students exposed to CCTM based foreign literature learning are reported to have acceptance level of 97%, learning ability of 98%, academic performance of 95%, engagement level of 96%. Moreover, student's perceived usefulness and perceived ease of use for CCTM based foreign literature learning were found to be 99% and 97%. Chinese students are highly satisfied with the suggested CCTM based foreign literature learning. These results confirm that CCTM can improve student's foreign literature learning ability, make them involved in foreign literature learning. Future research may resolve the shortcomings of this study. First of all, the study's student sample size is small, which might restrict how broadly the findings can be applied to ensure the effectiveness of CCTM. Future research with a bigger sample size could provide results that add to the CCTM's potency in foreign literature learning.

***Abstract*—General cause of diabetes mellitus is Diabetic Retinopathy (DR), which outcomes in lesions on the retinas that impair vision. If it is not detected in time, the result is severe blindness issues. Regrettably, there is no treatment for DR. Early diagnosis and treatment of DR can greatly lower the risk of visual loss. In contrast to computer-aided diagnosis methods, the manual diagnosis of DR using retina fundus images is more time-consuming effort, and high cost as well, as it is highly prone to error. Deep learning has emerged as one of the most popular methods for improving performance, particularly in the classification and analysis of medical images. Therefore, a deep structure-based DR detection and severity classification has been demonstrated for treating the DR with the usage of fundus images. The major aim of this developed technique is to classify the severity level of the retinal region of the human eye from the fundus images. At first, the required retinal fundus images are collected from the standard benchmark data sources. Secondly, image enhancement techniques are applied to the collected fundus images to improve the quality of images. Thirdly, the abnormality segmentations are carried out by using the optic disc removal process using active contouring model and then, the regional segmentation is done via the Modified U-Net method. Finally, the segmented image is subjected to the hybrid classifier network named a Hybrid Soft Attention-based DenseNet with Multi-Scale Gated ResNet (HSADMGR Net) for classifying the retinal fundus images and finding the severity level of the retinal images with higher accuracy. Furthermore, the parameters present inside the hybrid classifier network are optimized with the help of implemented Multi-Armed Bandits Groundwater Flow Algorithm (MABGFA). The test results regarding the developed deep structure-based DR model are validated with the existing DR detection and classification approaches by using different performance measures.**

Keywords*—Diabetic retinopathy segmentation and classification model; multi-armed bandits groundwater flow algorithm; hybrid soft attention-based DenseNet with multi-scale gated ResNet; modified U-Net-based segmentation

I. INTRODUCTION

One of the major issues facing people nowadays is diabetes. DR is one of the blindness diseases and it is complicated by diabetes. It has varying degrees of severity and it is hard to predict the DR in its early condition [9]. The retina, which converts light into the electric signal that is processed to produce an image, is impacted by DR. A network of abnormalities found in the retina gives nutrients to the retina. Abnormalities are damaged as a result of diabetes [10]. At that time, the retina does not contain a blood supply. This has an impact on retinal health and ultimately skews a person's vision [11]. Background retinopathy refers to the initial DR stage. Diabetes affects the blood vessels in the early stage, which causes sight loss [12]. It's possible for the vessels to swell slightly and leak blood, fluid, or proteins. Ophthalmologists or skilled graders manually identify DR, which is costly [13]. Lesions caused by diabetic retinopathy are typically believed to be reversible and the illness can only grow more slowly [14].

Convolutional methods frequently use a DL architecture with millions of learnable parameters [15]. Train a large amount of data suffers from the over fitting issue. Although, very effective laser therapy does not completely cure vision impairment and highlights the necessity of an efficient screening model [16]. Despite this fact, the screening of diabetic retinopathy is successful. An unacceptable amount of diabetes patients do not have the annual eye exams that are advised by guidelines [17]. One of the most significant issues faced by ophthalmologists and diabetes providers today is identifying at-risk patients and enabling them to get therapeutic therapies in a timely manner [18]. DR continues to be the cause of acquired vision loss despite the availability of healthcare facilities and the development of several methods that improve early detection. Maintaining such a register will probably be difficult because of the difficulty in obtaining precise [19], frequently updated lists from primary care practitioners. Due to these difficulties as well as the anticipated size and breadth of such a project, federal funding would probably be needed and would be expensive [20] for the construction of a national diabetes registry that allows for broad population coverage. The long-term advantages must be underlined, however, as they are of the opinion that such a register would significantly lower the rate of blindness among diabetes patients [21].

Due to their capacity to extract and learn the most discriminative features at the pixel level, convolutional neural networks (CNNs), a subset of deep learning, produced effective deep models for DR grading [22,23]. In this study, we create a method for the automatic segmentation and classification of retinal fundus picture using a convolutional neural network based on the U-Net architecture. We use data sets with very high resolution images labeled pixel by pixel to train neural networks.

The performance of a model is strongly influenced by how it is optimized using a small set of fundus images [25].

The deep learning-based DR segmentation and classification system objectives are described below.

- To design a deep learning-based DR segmentation and classification system that effectively detects the DR disease at an early stage that is helpful for DR patients in the hospitals to prevent blindness effectively.
- To develop an effective Modified U-Net-based abnormality segmentation to effectively segment the DR disease abnormalities from the fundus images.
- To implement a MABGFA optimization to optimize the parameters from HSADMGR Net to maximize the classification performance of the suggested model in terms of accuracy and precision.
- To develop an effective HSADMGR Net-based classification with optimized parameters like resblock, hidden neuron count, activation function and to maximize precision and accuracy.
- To validate the performance of the developed deep learning-based DR segmentation and classification model with different performance metrics among various optimization strategies and baseline models.

The suggested deep learning-based DR segmentation and classification system is explained in the remaining sections. The explanation of conventional DR segmentation and classification algorithms and methods and their advantages and disadvantages are given in Section II. The research problem is stated in Section II. The developed DR segmentation and classification model developed algorithm, and dataset details are given in Section IV. The segmentation of the DR disease and the preprocessing explanations are given in Section V. Section VI explains the DR classification and the developed model's objective functions. The experimental setup and results are given in Section VII and Section VIII. The summarization of the conclusion is given in Section IX.

II. Literature Survey

In 2021 Saeed *et al.* [1] have proposed a new DR screening system using effective deep learning with fundus images. The low-to-high-level characteristics was taught through a deep learning model. Initially, the first layer of the deep learning model was re-initialized utilizing regions of lesions derived from fundus images. To extract discriminatory characteristics from the input of fundus images in an unsupervised way, they replaced the full layers that encoded features that were global in domain-specific. The model was adjusted, so the lower layers were easy to find the normal regions and local, regional features of the lesion. It reduces the over-fitting problem. A classification layer based on gradient boosting was added last. The 10-fold cross-analysis used to evaluate the suggested model on two difficult datasets showed higher performance than conventional techniques. It helped graders make quick decisions regarding to a therapist for therapy during the early screening of DR patients.

In 2020 Shankar *et al.* [2] have investigated a new DR classification and automatic detection system using a deep learning framework. The contrast level of the fundus image was enhanced during the pre processing stage by utilizing the new method. The required features from the segmented image were then extracted using the developed model and the classification was done by Multilayer Perceptron (MLP) model. To ensure the accuracy of the investigated technique, a number of experiments were conducted using the MESSIDOR DR Dataset. The results of these experiments showed the superiority of the suggested system to the conventional techniques.

In 2020 Qiao *et al.* [3] have designed a new hybrid CNN-based DR segmentation system. Using deep learning techniques that were accelerated by Graphics Processing Units (GPUs), it was possible to identify the DR disease in fundus images and segments them with high performance and little latency. It offered a computerized technique to help ophthalmologists classify the input of fundus images like severe, early, or moderate NPDR. A deep learning technique suggested for early diagnosis of DR is also capable of effectively segmenting the DR disease. Also, it showed high prediction accuracy.

In 2023 Wang *et al.* [4] have implemented a method for segmenting four different types of fundus lesions associated with DR simultaneously using Deep Convolution Neural Networks (DCNN) that was totally autonomous. They suggested a collaborative design consisting of a local branch and a contextual branch to take advantage of multi-scale image information. To efficiently and completely merge informative features from the two branches, new mechanism was suggested to fuse the maps. To further increase the accuracy of the lesion segmentation model, it needed to reduce the over fitting issue in the developed model. Three publicly available fundus datasets were used in extensive experiments, and their methodology yielded a mean AUC value for each dataset separately. The outcomes of the suggested model showed greater performance when compared to other exceeding competing strategies and other cutting-edge models.

In 2023 Zhang *et al.* [5] have suggested a new DR identification and classification using a deep learning approach by examining the correlations between unlabeled data. It was possible to see that the ability of the network to extract crucial features could be improved by a mechanism that fitted the information. Unlabeled data was just potentially valuable labeled data, and the samples could increase the system's effectiveness. In order to effectively use the vast amounts of unlabeled information for precise DR classification, they offered a new framework. They specifically suggested an attention approach to remove the incorrect regions and retrieve factors from various views of input images in the developed model. Additionally, depending on the chosen annotated samples, they developed model compared to execute unknown samples to enhance the possibility of unlabeled information. For two open datasets, the experimental results showed that their new framework achieved high effectiveness.

In 2019 Jebaseeli *et al.* [6] have investigated a new framework for retinal disease segmentation using a neural network. That framework recommended the neural network model for automatically creating vectors, deep learning was proposed for classification, and pre processing method was used to remove the unwanted details. The Firefly method was used to adjust the DLBSVM parameters. The suggested methods were evaluated using the DRIONS, DRIVE, STARE, REVIEW, and HRF fundus imaging datasets. The outcomes showed that the proposed methods given enhanced segmentation due to sensitivity, specificity and accuracy.

In 2022 Kushnure *et al.* [7] have implemented a new architecture for classifying the DR disease using the U-Net approach. It changed the skip pathways utilizing feature fusion mechanisms and local feature reconstruction that represent the specific information in features. To represent the rich spatial information in the low-level features, they used the new module in the bottleneck layer to represent multi-scale features with different receptive fields. These modifications improved segmentation efficiency while decreasing the complex problem of model compared to existing techniques. Furthermore, the independent results confirmed the investigated system's robustness.

In 2018 Mansour *et al.* [8] have investigated an effective DR disease prediction using neural network-based hybrid optimization. That was done in consideration of deep learning to solve very sophisticated segmentation issues. Pre-processing, Principle Component Analysis (PCA) connected component analysis-based localization, adaptive learning-based region segmentation, a high feature extraction, and Linear Discriminate and feature selection were included in the DR system. The proposed DR model performed better with LDA feature selection than with FC7 features or PCA, according to simulation results using common KAGGLE fundus datasets. It also performed more accurately among FC7 features than with LDA features. A comparison with the SIFT technique-based DR feature extraction demonstrated that deep learning-based DR works better than SIFT-based DR.

III. Problem Statement

Most of the conventional diabetic retinopathy classification and segmentation models do not detect the disease in its early stage. It takes more a lot of time while predict the DR disease and it provides more economic cost. Hence, it is unaffordable to many researchers. To overcome these problems, most existing approaches have been designed for the DR segmentation system and advantages and disadvantages are shown in Table I. CNN [1] provides high classification accuracy. Also, it reduces computational complexity. But, it is hard to segment the retinopathy disease because of the complicated structure, fewer voxel intensity variation and highly variable shape and also, it increases the economic cost. SVM [2] gives robustness. Also, it improves the accuracy of lesion segmentation. Yet, it takes a lot of time to classify the disease of DR and also it suffers from Class imbalance during the training. DCNN [3] avoids over fitting problems. Also, it maximizes specificity, accuracy and sensitivity. Yet, it is hard to predict the various lesions regardless of their complex texture, form and small scale and also, it gives very less quality input images and poor performance in the final outcome. DCNN [4] gives strong efficacy. Also, it avoids vision deterioration. But, it is hard to detect the dark spots in retinal images at the early stage and also, and it gives less classification accuracy. MASL [5] reduces the model complexity. Also, it gives more reliable results. Yet, it does not find the local structures of the lesion and also, and it needs a huge amount of data for effective segmentation. TPCNN [6] effectively reduces the cataract progression in the early stage. Also, it reduces the risk of vision loss. Yet, it does not generate the vectors to predict the DR disease and also, and it takes more time. UNet-CNN [7] effectively predicts the dark lesions also and it effectively classifies the DR disease. But, it is difficult to predict the fine vascular structures and causes of skin infections. CNN-DNN [8] effectively solves the intricate segmentation issue. Also, it effectively predicts the DR disease in its early stage. But, it is highly time-consuming while predicting the DR disease and also, and it suffers from over fitting issues. Hence, this disadvantage arises to design an efficient diabetic retinopathy classification and segmentation system with advanced deep-learning techniques.

TABLE I. FEATURES AND CHALLENGES OF EXISTING DR CLASSIFICATION MODELS UTILIZING DEEP LEARNING

Author [citation]	Methodology	Advantages	Disadvantages
Saeed et al. [1]	CNN	It provides high classification accuracy. It decreases computational complex issue.	It is hard to segment the retinopathy disease because of the complicated structure, fewer voxel intensity variations and highly variable shape. It increases the economic cost.
Shankar et al. [2]	SVM	It gives robustness. It improves the accuracy of lesion segmentation.	It takes a lot of time to classify the disease of DR. It suffers from Class imbalance during the training.
Qiao et al. [3]	DCNN	It avoids over fitting issues. It maximizes specificity, sensitivity and accuracy.	It is hard to predict the various lesions regardless of their complex texture, form and small scale. It gives very less contrast images and poor performance in the final outcome.
Wang et al. [4]	DCNN	It gives strong efficacy. It avoids vision deterioration.	It is hard to detect the dark spots in retinal images at the early stage. It gives less classification accuracy.
Zhang et al. [5]	MASL	It reduces the model's complexity. It gives more reliable results.	It does not find the local structures of the lesion. It needs a huge amount of data for effective segmentation.
Jebaseeli et al. [6]	TPCNN	It effectively reduces the cataract progression in the early stage. It reduces the risk of vision loss.	It does not generate the feature vectors at low level to detect the DR disease. It takes more time
Kushnure et al. [7]	UNet-CNN	It effectively predicts dark lesions also. It effectively classifies the DR disease.	It is difficult to predict fine vascular structures. It causes skin infections.
Mansour et al. [8]	CNN-DNN	It effectively solves the intricate segmentation issue. It effectively predicts the DR disease in its early stage.	It is highly time-consuming while predict DR disease. It suffers from the over fitting issue.

IV. Implementation of Diabetic Retinopathy Classification Framework using Hybrid Deep Learning Network

A. Proposed Diabetic Retinopathy Classification Framework

The main challenges with the DR detection models are it does not detect small-scale lesions, low-contrast images, and ambiguous boundaries. Successful segmentation also requires color information because lesions and healthy tissues can seem to be the same when they are of the same color. In the conventional models, they are suffered from the above segmentation issue. Low sensitivity is another problem with the previous segmentation models. The early detection of DR is still difficult, though, for a number of reasons. The current DR screening procedure takes more time. No baseline model used today produces findings that are satisfactory outcomes, because they are frequently very small micro aneurysms and they are susceptible to misdiagnosis or being mistakenly categorized as hemorrhages. For a significant portion of the retinal image collection, some of them were difficult to detect. Because of their resemblance in the color of blood arteries and their proximity to them in some research studies, micro aneurysms are challenging to segment. The abnormality intersection characteristic has been employed in some approaches to derive the optic disc. However, the interference from the blood vessels, they use the entire abnormality structure, which may produce inaccurate or inconclusive results. As a result, the majorities of studies using various image processing methods have not reached a high level of accuracy and fail to categorize the DR disease. The investigated deep learning-based disease of DR segmentation and classification model is shown in Fig. 1.

Fig. 1. Proposed deep learning-based DR segmentation and classification model.

The newly designed DR segmentation and classification model using new technique to predict the disease in its early stage. It helps in hospitals to prevent vision loss or blindness for patients. It effectively predicts the retinal thin outer structure. The retinal fundus images are collected using the internet resources. The collected fundus images are given to the next stage. Here, the pre processing can be done utilizing a contrast enhancement approach [36]. The pre-processed retinal images are given to the segmentation section. Here, the two types of segmentation process such as abnormality segmentation and regional segmentation can be segmenting the pre processed images. The abnormality segmentation can be performed using Adaptive contour-based optic disc removal process [24]. The regional segmentation can be performed using Modified U-Net method technique. After, the segmentation the images are undergoes the next stage. The classification can be done using HSADMGR Net technique. Here, the investigated MABGFA optimization used for optimizing the parameters that is activation function, hidden neuron count and resblock to maximize the precision and accuracy. The designed HSADMGR Net-based DR

Segmentation and classification system performance is validated to other traditional methods and heuristic algorithms in terms of a number of performance measures.

B. Dataset Details

The collected fundus images are gathered through the benchmark dataset using the below link "https://www.it.lut.fi/project/imageret/diaretdb1/. This dataset contains normal and diseased retinal images. It also contains 89 types of color fundus images. Here, the fundus images are gathered using 50 degree view of workable camera. This dataset give a better accurate solution during DR detection. The model's primary goal was to clearly describe a database and a testing procedure that can be used to compare various DR detection techniques. Hence, the collected retinal fundus images are denoted by A_q^{Np}, where $q = 1,2,\cdots,Q$. The total numbers of sample images are indicated by N. The collected fundus images adopted for the DR segmentation and classification system are shown in Fig. 2.

C. Proposed MABGFA

The developed MABGFA optimization is adopted to improve the effectiveness of the deep learning-based DR classification and segmentation model with the help of optimized the parameters such as hidden neuron count, activation function, and resblock for maximizing accuracy. The MABOS algorithm is simple to understand and simple to use. But, it continues to experience problems such as unequal exploitation, lack of diversity, and local optimum. It is simple to fall into an optimal local situation in high-dimensional space. The GFA algorithm increases computing effectiveness and control parameter resilience. But, the convergence rate is poor. That takes a huge amount of time to finish. The GFA algorithm suffers from processing vast amounts of data in order to produce superior results. The implementation is also very challenging. So, they developed MABGFA optimization is adapted to segment and classify the disease from fundus images. The MABGFA optimization is designed related to mean, worst and best fitness functions. Here, the random number to be distributed is indicated by rnd. In the traditional optimization, the term rnd is chosen in the interval of [0,1]. But, in the developed algorithm, it is estimated using Eq. (1).

$$rnd = \frac{\sqrt{worstfit} + \sqrt{meanfit}}{besfit} \tag{1}$$

The best fitness is represented as $besfit$ and the worst fitness value is indicated by $worstfit$. The term $meanfit$ indicates the mean fitness value. By using this newly estimated value, this algorithm converges very fast and gives superior optimization results in the solution space.

MABOS [26]: The balance between exploration and exploitation is crucial in the classic reinforcement learning problem known as Multi-Armed Bandits (MAB). Here, various utility qualities are used that are named armed bandits. Initially, there is no prior knowledge of bandits. The resource is fixed and limited, which can be seen in terms of computing time. When they provide the bandit's resources, the objective is to decrease the regret or increase the gain. The estimated parameter is denoted by R. The true-action parameter is denoted by r. The term b is the selected action. The expected reward is calculated using Eq. (2).

$$r(u,b) = F[S(u)B(u)] = b \tag{2}$$

Here, the iteration count is denoted by u. The term $B(u) = b$ indicates the selected action. The current reward is indicated by $S(u)$. The term $B^*(u)\arg\max_b R(u,b)$ indicates the greedy action. It is measured using $R(u,b)\alpha\, r(u,b)$. The optimal value is calculated using Eq. (3).

$$w^*(u) = r(b^*,u) = \max_{b\in B} r(b,u) \tag{3}$$

The opportunity loss is calculated by the total number of regret and it is given in Eq. (4).

$$M_U = F\left[\sum_{u=1}^{U}\left(w^*(u) - r(b(u),u)\right)\right] \tag{4}$$

Hence, regret is unavoidable because they can't always choose the best action. If the system changes to smooth, they anticipate the estimation to get more accurate results. Initially, the action is chosen for every time and, a reward is collected, the evaluation of the action value is updated. The term b is denoted by the action operator and it is chosen by using the number of times parameter $O_u(b)$. It is given in $g\left(S_1, S_2, \ldots, S_{O_u(b)}\right)$. The achieved rewards are measured by the term R and it is given in $R(u,b) = \sum_{j=1}^{O_u(b)} S_j / O_u(b)$. Using the non-stationary and stationary measures the updated increment is calculated using Eq. (5).

$$R(u+1,b) = (\beta)R(u,b) + (1-\beta)S(u) \tag{5}$$

Here, the term hyper parameter is denoted by β and it is selected using $(\beta \in [0,1])$. Smaller values of β are suitable for dynamic systems because they focus more on recent rewards. On the other hand, choosing a small value β relies on the present reward. Hence, choosing this parameter requires better balance. The experiments section includes the value of β and this value is utilized for this algorithm.

The main issues with this problem are known to be the most crucial part of MAB to maintain the balance between the exploration for improved estimates and unreliable estimates in exploitation. It is used to increase the regret with the low cost. In this algorithm, the action uncertainty is considered to determine the expected value. The term VDC is measured using Eq. (6).

$$VDC(u,b) = R(u,b) + dV(u,b) = R(u,b) + d\sqrt{\frac{L(u)}{M_u(b)}} \tag{6}$$

Here, the hyper parameter is denoted by d and it increases the confidence level of the upper bound in final validation. The non-negative real value is indicated by d and it decreases the uncertainties in the final validation. The term $soft\max$ is used for selecting the VDC action easily, and it is measured using in Eq. (7).

$$Q(B=b) = soft\max(VDC(b)) = \frac{\exp[VDC(b)]}{\Sigma_{b\in B}\exp[VDC(b)]} \tag{7}$$

The fitness value is increased using the term L. If the condition is $d = 0$ they do not change the final process. Balance is based on the selection of values. The term Q gives the best solution using the upper confidence actions and better-estimated value.

GFA [27]: In the suggested optimization technique and traveling multiple paths in search of a solution is the crucial issue. The dimension is indicated by E. The GFA gives the best solution. The GFA initialization is given in Eq. (8).

$$y_{jk} = mc_k(g) + rnd_k(1) \times (vc_k(g) - mc_k(g)) \tag{8}$$

The candidate solution is denoted by y_{jk}. The term rnd indicates the random number. Every candidate solution is determined by using the velocity. Every GFA velocity is assigned to 0 and it is given in Eq. (9).

$$w_j\left(\vec{0}\right) = 0 \tag{9}$$

Here, the initial velocity is indicated by $w_j\left(\vec{0}\right)$. The terms $E\vec{B}_j(u)$ and $M\vec{B}_j(u)$ are calculated using Eq. (10) and Eq. (11), respectively.

$$\begin{gathered} E\vec{B}_j(u) = rnd_j\left(E\vec{B}_1(u), E\vec{B}_1(u), \ldots, E\vec{B}_h(u)\right), \\ h = flr\left(\frac{Q\times o}{100}\right) \end{gathered} \tag{10}$$

$$M\vec{B}_j(u)=mean\left(y_k{}^{\rightarrow}(u)\right)\forall k \tag{11}$$

Here, the selected value of EB is indicated by $E\vec{B}_j(u)$. The term $M\vec{B}_j(u)$ denotes the local average value of GFA. The ratio calculations of Δi_{je} and Δi_{jm} are measured using Eq. (12) and Eq. (13), respectively.

$$\Delta i_{je}{}^{\rightarrow}(u)=E\vec{B}_j(u)-y_k{}^{\rightarrow}(u) \tag{12}$$

$$\Delta i_{jm}{}^{\rightarrow}(u)=M\vec{B}_j(u)-y_k{}^{\rightarrow}(u) \tag{13}$$

Here, the terms e and m represents the subscripts of EB and MB, respectively. The terms $M_{je}(u)$ and $M_{jm}(u)$ are measured using Eq. (14) and Eq. (15), respectively.

$$M_{je}(u)=\frac{\max_{k\neq j}\left|g\left(y_k{}^{\rightarrow}(u)\right)-g\left(y_k{}^{\rightarrow}(u)\right)\right|}{\left|g\left(EBy_k{}^{\rightarrow}(u)\right)-g\left(y_k{}^{\rightarrow}(u)\right)\right|} \tag{14}$$

$$M_{jm}(u)=\frac{\max_{k\neq j}\left|g\left(y_k{}^{\rightarrow}(u)\right)-g\left(y_k{}^{\rightarrow}(u)\right)\right|}{\left|g\left(MBy_k{}^{\rightarrow}(u)\right)-g\left(y_k{}^{\rightarrow}(u)\right)\right|} \tag{15}$$

Darcy's law calculates the velocity and it is directly proportional to the term IH and it is calculated by Eq. (16) and Eq. (17), respectively.

$$IH_{je}{}^{\rightarrow}(u)=\frac{\Delta i_{je}{}^{\rightarrow}(u)}{M_{je}{}^{\rightarrow}(u)} \tag{16}$$

$$IH_{jm}{}^{\rightarrow}(u)=\frac{\Delta i_{jm}{}^{\rightarrow}(u)}{M_{jm}{}^{\rightarrow}(u)} \tag{17}$$

The term we is a discharge velocity. The coefficient factor is denoted by l. The discharge velocity is measured by Eq. (18) and Eq. (19), respectively.

$$we_{je}{}^{\rightarrow}(u)=l\times IH_{je}{}^{\rightarrow}(u) \tag{18}$$

$$we_{jm}{}^{\rightarrow}(u)=l\times IH_{jm}{}^{\rightarrow}(u) \tag{19}$$

Both discharge velocities of EB and MB are combined using Eq. (20).

$$we_j{}^{\rightarrow}(u)=\beta\times we_{je}{}^{\rightarrow}(u)+(1-\beta)\times we_{jm}{}^{\rightarrow}(u) \tag{20}$$

Here, the term β controls the water levels using the selected weight range in $[0,1]$. Water's discharge velocity is its speed when there is no barrier in its path. In general, groundwater travels via porous media called aquifers. Hence, the aquifers' pores are the only places where water can pass. The division of discharge velocity and the intermediate medium is known as velocity of seepage. The velocity of seepage is measured using Eq. (21).

$$wt_j{}^{\rightarrow}(u)=\frac{we_j{}^{\rightarrow}(u)}{\gamma_j} \tag{21}$$

The intermediate medium is denoted by γ. The dimension is updated using DG and it is indicated by e. The term DG is a controlling factor calculated by Eq. (22).

$$DG(u)=\left(1-\frac{u}{U}\right)\times E \tag{22}$$

Here, the term U is the maximum number of iterations. The randomly selected integer is indicated by e. The dimensions are updated by Eq. (23).

$$\gamma_j=\frac{e_j}{E} \tag{23}$$

The velocity of $w_j{}^{\rightarrow}(u)$ is measured using Eq. (24).

$$w_j{}^{\rightarrow}(u)=\alpha\times w_j\,(\overrightarrow{u-1})+\kappa\times wt_j{}^{\rightarrow}(u) \tag{24}$$

Finally, the velocity of any one GFA can be determined by adding its seepage velocity to its previous velocity. When all GFAs share the same fitness measures, the best solution can be found. The pseudo-code of the investigated MABGFA is given in Algorithm 1.

Algorithm 1: Designed MABGFA

```
Initialize the iterations $U$ and population $y_j$
Load the initial positions
Calculate the initial fitness value
  **Update the parameter $rnd$ with the adaptive concept**
  While $(u \le U)$
      For
    $(j = 1 to Maxiter)$
    For $(k = 1 to pop)$
        If $(rnd < 0.5)$
                        Update the parameter using MABOS in Eq. (9).
                        Evaluate the seepage velocity
        Else:
                        Update the parameter using GFA in Eq. (23).
        End if
        Calculate the discharge velocity
     End For
    Select the value using softmax sampled by Eq. (7).
    Validate the best fitness solution
  End while
  Return the parameters
End
```

V. Abnormality Segmentation and Regional Segmentation for Diabetic Retinopathy Classification using Fundus Images

A. Preprocessing of Fundus Images

The collected fundus images are given to the pre processing stage indicated by A_q^{Np}. Image enhancement is the technique of enhancing the original data images and details. Typical techniques add the density slicing, contrast enhancement and spatial filtering,. By applying a linear transformation, the original range of grey levels is expanded, resulting in contrast enhancement. The natural linear factors such as shear zones, lineaments and fault are improved by contrast enhancement. In order to indicate various aspects, density slicing breaks up the continuous intervals, each designated by a different color. The preprocessed image is denoted by A_m^{pre}.

B. Active Contour-based Optic Disc Removal

The preprocessed image A_m^{pre} is given in the segmentation section. The optical disk is eliminated from the inverted equalization image before it is given to element. It is used to open the edge-improved image based on curvelets in order to remove it. For the purpose of removing the optic disc, the morphological procedure is applied, which is used for the complete removal of the optic disk. The term $Dj - Tf$ defines the erosion process and it is calculated using Eq. (25).

$$Dj - Tf = \{W \in F / Ty \subseteq Dj\} \tag{25}$$

Here, the initial input is indicated by Dj. As a result, the term Ty is measured using Eq. (26).

$$Ty = \{g + y / g \in Tf\}, \forall_y \in F \tag{26}$$

The active contour is a recent method that divides the further analysis and processing using energy forces and challenges. The approach of collecting deteriorated structures from an image with respect to issues and energy forces for the segmentation of blood arteries is known as active contouring. The bounds of the image elements are decided by the contour model to produce a contour. Using a variety of approaches that include both internal and external forces, the structure's curvature is determined. The energy function is determined in order to acquire the required structure. To define contour deformations, a group of points that define a contour are used. As a result, the segmented image produced by active contouring is represented by KR_r^{out}.

C. Modified U-Net-based Abnormality Segmentation

The input given to the regional segmentation section is indicated by KR_r^{out}. The modified U-Net-based segmentation procedure will receive as its input. It is used to encode the fundus image using the Modified U-net encoder. The decoder contains number of U-Net blocks to given the output of the model. The output of the previous block is to be up sampled and activation features are sent from an intermediary layer of the encoder to each U-Net block.

Encoder and Decoder: The decoder and encoder are the two components that make up the modified U-Net. The encoder utilizes ResNet architecture that has already been trained. The residual network is primarily used because, when compared to other pre-trained models, it has a higher accuracy in image classification issues. It contains four blocks ReLu, decoder, encoder and batch normalization. There are four U-Net blocks in the decoder. The up sampling mechanism in the improved images convolution initialized to convolution block. The model's deconvolution layer has been swapped out for a sub-pixel convolution layer. Therefore, the segmented image produced by modified U-Net is represented by OT_s^{Bld}. The basic diagram of the Modified U-Net-based segmentation system is shown in Fig. 3.

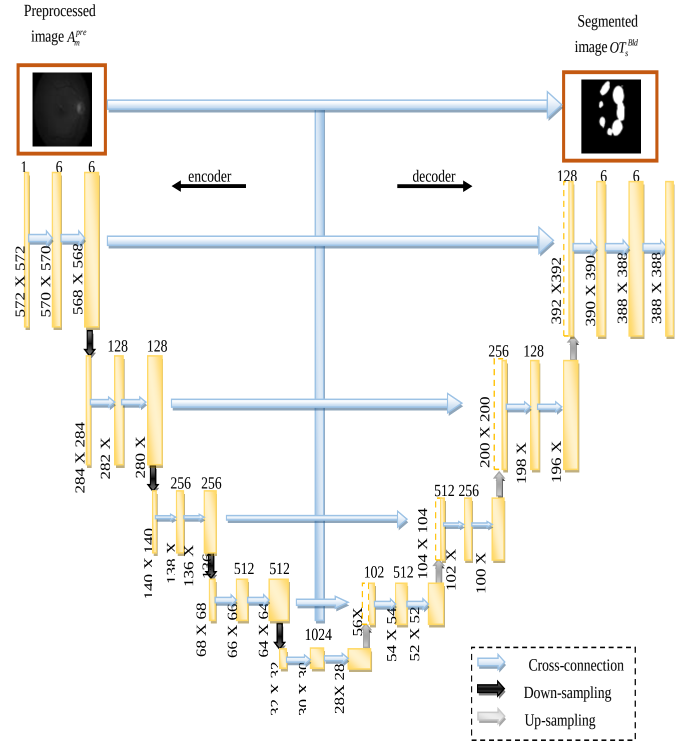

Fig. 3. Modified U-Net-based segmentation system.

VI. Classification of Diabetic Retinopathy using Hybridization of Soft Attention-based Densenet and Multi-Scale Gated Resnet

A. Soft Attention-based DenseNet

The segmented image given to the classification section is denoted by OT_s^{Bld}. The classification process is a one of the supervised learning technique. It adopted a data into different classes. It trained the models and predicts the groups.

DenseNet [29]: Transition and dense blocks are used to build the DenseNet model. The pooling layer is part of the Convolution unit in the transition block. The transition block is employed to eliminate the complexity of computation. The bottleneck layer used in the convolution reduces the input feature map sizes. Therefore, it minimizes the feature mappings at transition layers. The transition stage receives the output.

Soft attention block: Soft attention increases the robust ssystem. It favors the most pertinent input while allowing a portion of the other data to influence the system's judgment. It is based on the precise location determined by the feature map that was extracted. The term T is a soft attention score and it is indicated by Eq. (27).

$$T = \sum_{L=1}^{L} \frac{\exp\left(g_{3e_{jk}}\right)}{\sum_{j=1}^{x^y}\sum_{k=1}^{i^y}\exp\left(g_{3e_{jk}}\right)},\ g_{3e} = I\left(g^{y}\right) \tag{27}$$

$$\beta_z = g^{y} + zg_t^{y} \tag{28}$$

This model is assisted in choosing the precise positions of the feature map's relevant properties by the finished soft attention layer.

B. Multi-Scale Gated ResNet

Multi-scale Gated model [32]: They develop an attention-gating module for the top-down adaptive fusion as opposed to the typical method of feature concatenation from several layers or multi-scale inputs. It directs the second level's learning through the gating operation, the fusion process begins. The hierarchical fusion operation is calculated using Eq. (29).

$$B_j = \beta\left(X^{7\times7}\left(\left[AvgPl\left(G_j\right); MaxPl\left(G_j\right)\right]\right)\right) \tag{29}$$

$$G^{`}_{j+1} = up\left(B_j\right)\circ C\left(G_{j+1}\right)\left(j = 1,2,3\right) \tag{30}$$

Finally, the gated feature at the top level includes both high-level semantic knowledge and high-resolution spatial data. The saliency map is normalized using a sigmoid activation function.

ResNet: The DR is primarily classified with the resnet technique. The block of the resnet is used to determine the direct residual output. The term $J(z)$ is a target output. The degradation happens much more quickly when there are multiple convolutional layers. The resnet has a lot of small connections that allow us to identify the mapping process indirectly by skipping one or two tiers. The residual mapping function is given in Eq. (31).

$$H = B_2\gamma\left(B_1 z\right) \tag{31}$$

Here, the term γ indicates the Relu activation function.

$$a = H\left(z,\{B_k\}\right) + z \tag{32}$$

Here, the term a is a representation of the second Relu's shortcut connection. Finally, they effectively predict the DR disease and also increase the performance of classification using res net.

C. Proposed HSADMGRNet-based Diabetic Retinopathy Classification

The HSADMGR Net-based system enhances the classification effectiveness over the segmentation and classification of DR with high accuracy. The designed MABGFA optimization is utilized for optimizing the parameters like res block, hidden neuron count and activation function. The HSADMGR Net model with MABGFA optimization maximizes the accuracy and precision of the designed DR segmentation and classification model. The Soft Attention-based DenseNet method improves classification accuracy. It takes less time to segment the DR disease. DenseNet replicates the data numerous times and splices the feature maps of each layer with the layer before. Sometimes it makes misdiagnosis results. A Multi-Scale Gated ResNet approach considerably reduces the error rate below a certain threshold, further enhancing the network. But, it takes weeks of segmentation, which makes it practically impossible to use in real-time. The computational density of the ResNet method is one of its main disadvantages. To resolve these problems, the suggested MABGFA-HSADMGR Net-based DR classification model is developed to enhance the classification results. The developed MABGFA-HSADMGR Net-based DR classification model gives better fitness in terms of maximization of accuracy and precision and it is given in Eq. (33).

$$Ob_j = \underset{\left\{\begin{array}{l} SA_{DesNet}^{Linear}, SA_{DesNet}^{sigmoid}, SA_{DesNet}^{\tanh}, SA_{DesNet}^{\mathrm{Re}Lu} \\ KJ_{\mathrm{Re}sNet}^{Linear}, KJ_{\mathrm{Re}sNet}^{sigmoid}, KJ_{\mathrm{Re}sNet}^{\tanh}, KJ_{\mathrm{Re}sNet}^{\mathrm{Re}Lu}, \\ KJ_{\mathrm{Re}sNet}^{Hidden}, KJ_{\mathrm{Re}sNet}^{resbk} \end{array}\right\}}{\arg\min}\left(\frac{1}{Ac} + \frac{1}{\mathrm{Pr}}\right) \tag{33}$$

Here, the optimized ReLu, linear, tanh and sigmoid activation functions from the DenseNet are denoted by $SA_{DesNet}^{\mathrm{Re}Lu}$, SA_{DesNet}^{Linear}, $SA_{DesNet}^{\tanh}$ and $SA_{DesNet}^{sigmoid}$ in the interval of $[0,3]$, respectively. The optimized ReLu, linear, tanh and sigmoid activation functions from the ResNet are indicated by $KJ_{\mathrm{Re}sNet}^{\mathrm{Re}Lu}$, $KJ_{\mathrm{Re}sNet}^{Linear}$, $KJ_{\mathrm{Re}sNet}^{\tanh}$ and $KJ_{\mathrm{Re}sNet}^{sigmoid}$ in the interval of $[0,3]$, respectively. The hidden neuron count from ResNet is indicated by $KJ_{\mathrm{Re}sNet}^{Hidden}$ and it is selected in the interval of $[5,255]$. The optimized res block in the ResNet is indicated by $KJ_{\mathrm{Re}sNet}^{resbk}$ and it is selected in the interval of $[3,15]$. The precision parameter is calculated using Eq. (34).

$$PR = \frac{UO_f}{UO_T + UF_m} \tag{34}$$

The accuracy is measured using Eq. (35).

$$A = \frac{\left(UO_T + UF_p\right)}{\left(UO_T + UF_p + UO_f + UF_m\right)} \tag{35}$$

The true positive and negative values are denoted by UO_T and UO_f, respectively. The false positives and false negatives are indicated by UF_p and RU_s, respectively. A diagrammatic representation of the developed MABGFA-HSADMGR Net-based DR classification is shown in Fig. 4.

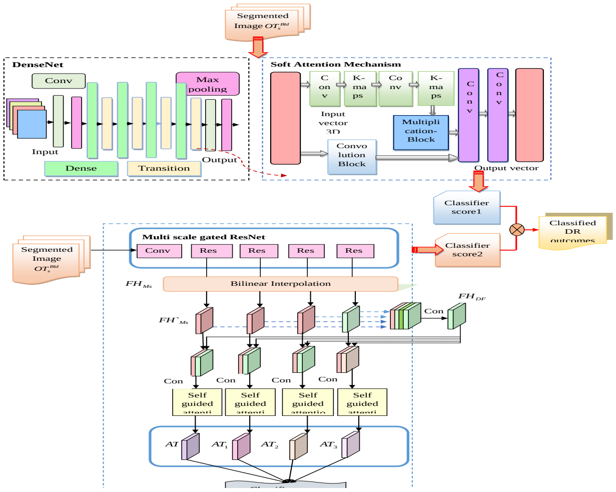

Fig. 4. MABGFA-HSADMGR Net-based DR classification system.

VII. Results and Discussions

A. Experimental Setup

The developed MABGFA-HSADMGR Net-based DR segmentation and classification model was developed by using Python environment. The performance of the DR segmentation and classification model was validated over different classification methods and hybrid algorithms via many evaluation measures. The analysis was conducted using a population rate of 10, an iteration gap of 10 and a chromosomal length of 5. For validation, classifiers including Mobile Net [28], Dense net [29], VGG16 [30], XGBOOST [31], MG_Res Net [32], and RN-Bi-LSTM [33] were considered and several optimization algorithms like Harris hawks optimization (HHO) [34], Salp Swarm Algorithm (SSA) [35], MABOS [26], and GFA [27] were utilized.

B. Pre-Processing and DR Segmentation Output

The outputs of the Modified U-Net-based DR disease segmentation system are given in Fig. 5. The segmentation performed utilizing the Modified U-Net approach.

Description	Sample1	Sample 2	Sample 3	Sample 4	Sample 5
Original retinal images					Pre-processed retinal images					Modified U-Net-based Segmented retinal images					
Fig. 5. Outcomes of the designed Modified U-Net-based DR segmentation.

C. Evaluation Measures

The effectiveness measures used for the implemented DR segmentation and classification model are described as below.

a) FNR: The FNR is measured by Eq. (36).

$$FNR = \frac{UO_T}{UF_p + UF_m} \quad (36)$$

b) NPV: It is measured using Eq. (37).

$$NPV = \frac{UF_p}{UF_p + UO_m} \quad (37)$$

c) Sensitivity: It is validated using Eq. (38).

$$SEN = \frac{UF_m}{UF_m + UO_f} \quad (38)$$

d) FPR: The FPR is calculated using Eq. (39).

$$FPR = \frac{UF_p}{UF_p + UO_f} \quad (39)$$

e) F1-score: The F1-score value is measured using Eq. (40).

$$F1 = \frac{2 \times UF_m}{2UF_m + UO_f + UO_T} \quad (40)$$

f) MCC: The MCC value is calculated by Eq. (41).

$$MCC = \frac{UO_T \times UO_f - UF_m \times UF_p}{\sqrt{(UO_T + UF_m)(UO_T + UF_p)(UO_f + UF_m)(UO_f + UF_p)}} \quad (41)$$

g) FDR: it is measured by Eq. (42).

$$FDR = \frac{UF_p}{UF_p + UO_T} \quad (42)$$

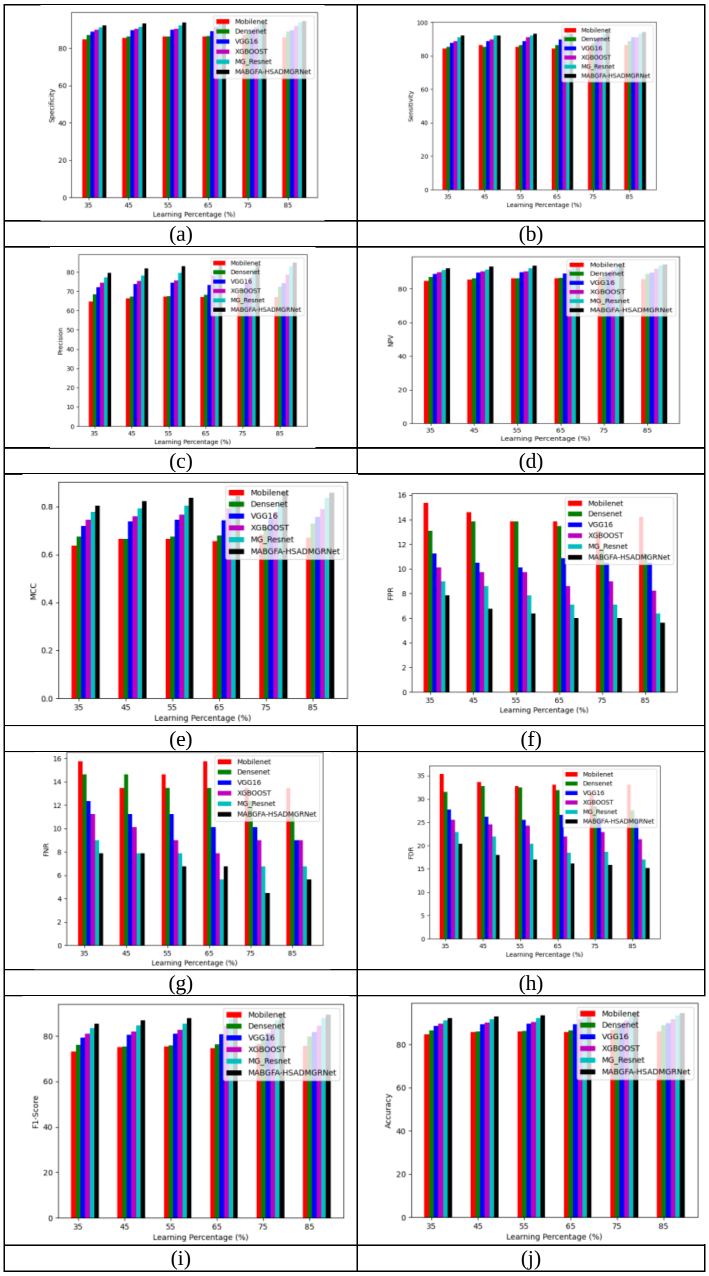
h) Specificity: The specificity is measured by Eq. (43).

$$SP = \frac{UO_f}{UO_f + UF_m} \quad (43)$$

VIII. Result Analysis

A. Performance Analysis of the Developed DR Segmentation and Classification Model with respect to Learning Percentage

Performance comparison of the developed MABGFA-HSADMGR Net-based DR segmentation and classification system to conventional techniques and hybrid algorithms is shown in Fig. 6 and Fig. 7, respectively. Then, the developed MABGFA-HSADMGR Net-based DR segmentation and classification system improved with a high sensitivity of 18% more than Mobile Net, 16.6% more than Dense Net, 15.2% more than VGG16, 12.6% than XGBOOST, 8.8% than MG_Res Net and 7.6% than RN-Bi-LSTM with the value of learning percentage is 35. As a result, the designed MABGFA-HSADMGR Net-based DR segmentation and classification model has achieved better classification rates when compared to conventional techniques and heuristic strategies.

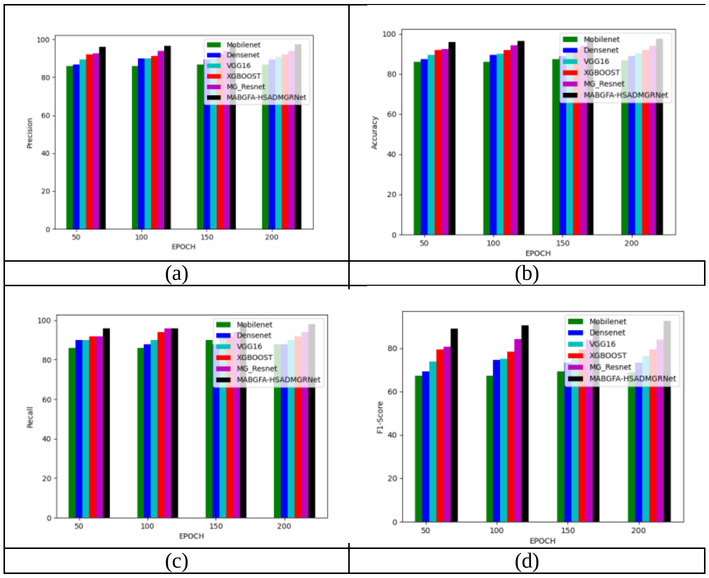


(a) (b) (c) (d) (e) (f) (g) (h) (i) (j)

Fig. 6. Performance validation of various heuristic algorithms in terms of “(a) Specificity, (b) Sensitivity, (c) Precision, (d) NPV, (e) MCC, (f) FPR, (g) FNR, (h) FDR, (i) F1-Score, and (j) Accuracy”.

B. *Performance Analysis of the Developed Model with respect to Epochs*

A performance comparison of the developed MABGFA-HSADMGR Net-based DR segmentation and classification model to existing techniques and algorithms to existing techniques and algorithms in terms of epoch analysis is shown in Fig. 8, and Fig. 9, respectively. In the Epoch value of 100, the developed MABGFA-HSADMGR Net-based DR segmentation and classification showed a high precision of 18.6% more than Mobile Net, 18.1% more than Dense Net, 18.1% than VGG16, 15% than XGBOOST, 13% than MG_Res Net and 12% than RN-Bi-LSTM. Therefore, the designed MABGFA-HSADMGR Net-based DR segmentation and classifications system has achieved high efficacy due to accuracy.



(a) (b) (c) (d)

Fig. 8. Performance analysis of over different heuristic algorithms in terms of “(a) Precision, (b) Accuracy, (c) Recall, (d) F1-Score”.

C. *Cost Function Analysis of the Developed DR Classification and Segmentation System*

A performances comparison of the developed MABGFA-HSADMGR Net-based DR segmentation and classification system to previous classification techniques and hybrid algorithms to existing techniques and algorithms in terms of cost function analysis is shown in Fig. 6. In the value of 5, The developed MABGFA-HSADMGR Net-based DR segmentation and classification showed with cost function of 4.4% than HHO-HSADMGR Net, 4.2% than SSA-HSADMGR Net, 3.8% than MABOS-HSADMGR Net, 4.1% than GFA-HSADMGR Net. Therefore, the designed MABGFA-HSADMGR Net-based DR segmentation and classification model has showed high efficacy.

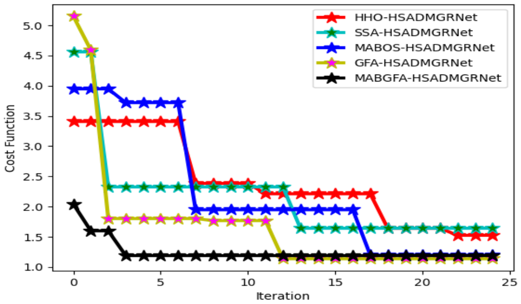

Fig. 9. Cost function analysis of suggested DR classification and segmentation model among different heuristic algorithm.

D. Overall Validation of the Implemented DR Segmentation and Classification System

The newly designed MABGFA-HSADMGR Net-based DR segmentation and classification model performance is analyzed using various heuristic algorithms and existing methods, shown in Table II and Table III, respectively. The developed DR classification and segmentation model has improved the f1-score of 3.4% than HHO-HSADMGR Net, 7.2% than SSA-HSADMGR Net, 9.8% than MABOS-HSADMGR Net, 14.1% than GFA-HSADMGR Net. The developed model performed more accurately and efficiently over previous hybrid algorithms and existing methods.

TABLE II. PERFORMANCE ANALYSIS OF DR SEGMENTATION AND CLASSIFICATION SYSTEM WITH HEURISTIC ALGORITHM

Terms	HHO-HSADMGR Net [28]	SSA-HSADMGR Net[29]	MABOS-HSADMGR Net[30]	GFA-HSADMGR Net[31]	MABGFA HSADMGR Net

IX. CONCLUSION

A newly developed DR segmentation and classification system is used to detect the DR in the early stage with high accuracy. The retinal fundus images were gathered through resources in internet. The gathered fundus images were given to first stage of pre processing step. Here, the fundus images would be performed by contrast enhancement technique. Then, the pre processed images undergoes to the segmentation section. Here, the pre processed images were segmented by two types of segmentation such as abnormality segmentation and regional segmentation. The abnormality segmentation could be performed using an Adaptive contour-based optic disc removal technique. The regional segmentation could be performed using the Modified U-Net method technique. Then, the segmented images were given to the classification stage. The classification could be done using the HSADMGR Net model. Here, the implemented MABGFA optimization was adapted to optimize the values such as activation function, hidden neuron count and resblock to maximize the precision and accuracy. The suggested MABGFA-HSADMGR Net-based DR classification and segmentation model achieved high performance in terms of F1-score of 13.6% than Mobile Net, 16.1% than Dense net, 14.1% than VGG16, 16% than XGBOOST, 17% than MG_Res net and 15% than RN-Bi-LSTM. The designed HSADMGR Net-based DR segmentation and classification system efficacy was validated among different traditional methods and hybrid algorithms in terms of accuracy and it showed greater performance.

Legal Entity Extraction: An Experimental Study of NER Approach for Legal Documents

Varsha Naik[1], Purvang Patel[2], Rajeswari Kannan[3]
Pimpri Chinchwad College of Engineering, Pune, India[1, 3]
Dr. Vishwanath Karad MIT World Peace University, Pune, India[1, 2]

***Abstract*—In legal domain Name Entity Recognition serves as the basis for subsequent stages of legal artificial intelligence. In this paper, the authors have developed a dataset for training Name Entity Recognition (NER) in the Indian legal domain. As a first step of the research methodology study is done to identify and establish more legal entities than commonly used named entities such as person, organization, location, and so on. The annotators can make use of these entities to annotate different types of legal documents. Variety of text annotation tools are in existence finding the best one is a difficult task, so authors have experimented with various tools before settling on the best one for this research work. The resulting annotations from unstructured text can be stored into a JavaScript Object Notation (JSON) format which improves data readability and manipulation simple. After annotation, the resulting dataset contains approximately 30 documents and approximately 5000 sentences. This data further used to train a spacy pre-trained pipeline to predict accurate legal name entities. The accuracy of legal names can be increased further if the pre-trained models are fine-tuned using legal texts.**

Keywords—Named Entity Recognition; NER; legal domain; text annotation; annotation tools

I. Introduction

Artificial Intelligence (AI) has the potential to improve both the efficiency and accessibility of numerous legal processes [1]. In the current digital era, online document collections are growing rapidly. Technology and automation can help to extract information from these collections. As the amount of data continuously increasing, it is more and more necessary to access and process these data. The use of natural language processing is significant. NER, one of Natural Language Processing's (NLP) fundamental building blocks, can be used to develop AI applications in the legal domain [2]. Name entity recognition is a process of locating and classifying named entities in an unstructured text into predefined categories.

Name entity recognition is used to find a link to rigid notations in text that are related to well-known semantic classes like person, place, organization, etc. NER is used not only as a standalone tool for information extraction (IE) [3], but also in a variety of natural language processing (NLP) applications such as text understanding, information retrieval, automatic text summarization, question answering, machine translation, and knowledge base construction, and many others. Information retrieval, question-and-answer systems, machine translation, and many more applications use NER as a crucial pre-processing step [4].

To achieve high performance in NER, large amounts of knowledge in the form of feature engineering and lexicons have traditionally been required [5]. Also, there is great advancement in machine learning algorithms and deep learning algorithms in natural language processing and more specifically name entity recognition and information extraction [6]. Depending on the problem, such methods typically require a large set of manually annotated data,[5] whereas some machine learning algorithms rely on unsupervised techniques that do not require a large set of annotated data. There is an active learning-based clustering technique that is a subset of the semi-supervised technique and is used to reduce manual annotation time [7].

Annotation is a practice of adding linguistic and interpretive information to an electronic corpus of spoken or written linguistic data. Basically, annotation means adding a note to the input data. Annotation of words and characters are quite common for exactly distinctive medical specialty entities, resembling genes, proteins, and diseases [8]. In previous work, Jackson M.Steinkamp, Abhinav Sharma has annotated the unstructured clinical notes to identify the symptoms within the electronic health records. In another work related to the medical name entity recognition have prepared their dataset by annotating notes of pneumonia patients [2]. And, annotation between two words or phrases are also done for syntactic dependencies or identifying relation between two words in a sentence. For new annotation project or for doing annotation from scratch, typically includes a variety of activities including defining annotation schemas [9], developing guideline for annotations and defining entity type assembling appropriate collections of documents, and properly pre-processing those documents and create the final corpus [10].

One of the important tasks while annotation is selecting appropriate annotation tool given the large number of tools available and the lack of an up-to-date list of annotation tools and their respective pros and cons [11]. Therefore, extensive review of available tools must be done to avoid poor decision of selecting tools. Weak decision can lead to the unnecessary wastage of time of installing and converting document to the specific format for tools.

In this task, an extensive review of annotation tools for manual annotation of documents has been presented. The basic requirements for selecting the annotation tools have been defined. To gain a better understanding of name entity recognition, an ER-system for the legal domain has been created. The first step in creating a corpus of annotated judgment papers is to define relevant entities, which can mainly be categorized into two: domain-specific named entities like legal terms, Act, legal institutes, etc., and general named entities like person, location, date, etc. An ER-system built with a spacy pre-trained model is then presented.

Following contributions were made in this paper:

- An extensive review was conducted on manual annotation tools for creating NER training corpus.
- A corpus for legal name entity recognition was created, consisting of 5000 judgment papers with 8 legal named entities.
- An Entity-Relation model was developed based on spacy pretrained model.

II. Literature Review

NER is regarded as a crucial activity in the information extraction process. While numerous studies on name entity recognition have been conducted. Several datasets have been offered over a long period of time. CoNLL' 03 [12], which was taken from a German newspaper and is regarded as a language independent NER dataset, is one of the more well- known datasets. Many datasets from many fields, including medical, law, archaeology, and many more, are afterwards proposed [13].

Early NER systems relied on rules that were created by humans. A rule-based NER system is thought to take a long time to design. Researchers have created a NER System based on a machine learning algorithm to solve this issue. They used a few learning techniques, including supervised learning, semi-supervised learning, and unsupervised training. Alex Brandsen et al. [9] have used machine learning approach for predicting name entities from Dutch Excavation reports. Not only machine learning algorithms, but also satisfactory research on NER systems using deep learning algorithms and neural networks, are being conducted. A study conducted by Franck Dernoncourt et al. [14] successfully performs NER using ANN and obtain satisfactory result out of it. Thomas AF Green et al. [15] have included a benchmark CRF-based Entity recognition model of a manually created corpus of job description and achieve accuracy of approx. 60-65 %.

While many type of research on NER is carried out using deep learning and machine learning approach. Very Few studies have been done using pre-trained model like BERT [16]. Mugisha et al. [2] have published a detailed comparison of the neuro-linguistic modelling pipeline for predicting outcomes from medical text notes using patients with pneumonia. Li, Jianfu, et al. [17] in their study, they have fine-tuned pre- trained contextual language models to support the NER task on clinical trial eligibility criteria. They have systematically explored four pre-trained contextual embedding models for biomedical domain (i.e., BioBERT, BlueBERT, PubMedBERT, and SciBERT).

Table I summarizes the literature survey conducted during this study.

TABLE I. Summary of Literature Review

Year	Paper No.	Domain of study	Comments
2019	[6]	Symptom extraction with unstructured clinical notes	To create clinically useful information extraction tools, a task definition, dataset and simple supervised NLP model were used.
2022	[2]	Outcome Prediction from medical notes	A deep comparison of natural language modelling pipelines from outcome prediction from unstructured medical text notes.
2020	[9]	NER in Archaeological domain	Developed a training dataset for name entity recognition in archaeology domain, for which Doccano tool was used for annotation.
2022	[15]	Entity recognition in job descriptions	Created a benchmark suite for entity recognition in job description which includes annotation schema, baseline model, and training of corpus.
2020	[18]	Dataset for legal name entity recognition	A dataset created for NER in German federal court decisions
2022	[19]	NER on Indian judgment paper	Created a training corpus of Indian court judgment and developed a transformer-based legal NER baseline model.

III. Research Methodology

A systematic review of literature on various annotation tools used for NER was conducted. In this paper, the standard SLR procedures as described by the authors Chitu Okoli and Kira Schabram [20] were taken under consideration. This methodology demonstrates a detailed examination of the NER system across multiple domains, as well as a manual annotation tool and various annotation methods.

A. Research Question

One of the crucial steps in a systematic review is the research question. In order to maintain focus at the start of the study, we write research questions (RQ) that will adhere to the review procedure. Table II show the lists of research questions.

B. Search Method

1) Choose keyword: Table III shows a list of keywords used in the search for the paper from the online library.

2) Inclusion and exclusion criteria: Only conference and journal papers published in English language within the last five years were considered, and any papers currently under review were excluded. Table IV show the inclusion and exclusion criteria.

IV. Review of Text Annotation Tools

The formal description of the text annotation problem and annotation tools was presented, followed by a detailed discussion of the selection criteria for annotation tools. Next, an introduction was provided on the commonly used annotation tools.

A. Annotation Tools

Data annotation tools are software used to create high-quality annotated machine learning training data such as text, images, and videos. There are wide variety of annotation tools from open-source tools that developers can modify accordingly to freeware applications that are free to use. Let us first discuss what is text annotation, what is the need of it and discuss some type of text annotation.

B. Text Annotation: Needs and Type

1) Labelling procedures: Adding labels entails putting a word in a sentence that explains its type. It can be explained using emotions, technical terms, etc. For instance, the phrase “I am satisfied with this product, it is amazing” could be given a label like “happy”.

2) Adding matadata: Similar to this, relevant information can be added to the statement “Mahadevapura police have fled charge sheet against the accused alleging that he has committed an offence punishable under Section 354C of I.P.C R/w sec.66(E) of Information Technology Act” to help the learning algorithm priorities and concentrate on particular terms. One might write something like, “Mahadevapura (Location) police have fled charge sheet against the accused alleging that he has committed an offence punishable under Section 354C (Legal) of I.P.C. (Act) R/w sec.66(E) of Information Technology Act (Act)”.

3) Now let us discuss in brief some of the types of data annotation: Sentiment Annotation: Sentiment annotation is nothing more than the assignment of labels to feelings like sadness, happiness, anger, positivity, negativity, and neutrality. Any activity involving sentiment analysis can benefit from sentiment annotation. (For example, in retail, facial expressions can be used to assess customer satisfaction.)

a) Intent annotation: The intent annotation also identifies the sentences but emphasises the purpose or motivation behind the statement. A message such as “I need to talk to Sam” in a customer service situation, for example, may direct the call to Sam by himself, or a message such as ”I have a problem with the credit card” could direct the call to the team handling credit card issues.

b) Named entity recognition: The goal of named entity recognition (NER) is to find and categorise special expressions or predefined named entities in a sentence [21]. It is used to look up words based on what they mean, such as names of people or places. Information can be extracted using NER, together with information classification and categorization.

c) Semantic annotation: It can be also known as meaningful annotation, semantic annotation is the addition of metadata, supplementary data, or tags to text that contains concepts and entities, such as persons, places, or themes.

C. Selection of Tools

Tools that are known and have been mentioned in previous studies were listed. Google, Google Scholar, Scopus, and other online databases were searched for tools mentioned in annotation tool-related publications. There are a wide range of annotation tools available, but for this survey, the tools selected are the most widely used in any domain and meet the criteria.

There are a few requirements that have been studied and presented for an annotation tool. In this research, total 22 criteria are considered to evaluate annotating tools which are further divided into different groups such as input-output, publication, system criteria, and function. For these categories important features of tools are considered such as accessibility, usability, and cost. All these mention categories are listed in Table V along with the associated criteria.

The input-output or data criteria address the input-output format of document, schema for annotation, and input format for multi-media file. Publication criteria include the year of last publications, number of citations, and number of publications in last five years. System criteria indicate installations architecture and simplicity of installations, quality and quantity of documents, license of tools and OS support. And the last set of criteria is functional criteria which contains multimedia annotation support, support of multiple language other than English, automatic text annotation, pre-annotation support and data security.

TABLE II. LIST OF RESEARCH QUESTION

Sr. No.	Research Question
1.	Domains where Name entity recognition is used?
2.	Dataset related to Name entity recognition?
3.	Which annotation tool is used for creating corpus?
4.	What are challenges and issue faced wile manual annotating dataset using tool?
5.	What are various techniques used for annotating dataset for NER?

TABLE III. LIST OF KEYWORDS

Sr. No.	Keyword	No of Articles
1	Name Entity Recognition Corpus and Annotation tools	3
2	Name Entity Recognition Dataset and Manual Annotation	2
3	Manual Text Annotation and annotation tools	4
4	Name entity recognition and (Deep learning or Machine learning)	32
5	legal name entity recognition or medical name entity recognition	14
6	Text annotation tool or lighttag or Doccano or brat or label Studio	45
	Total	100

TABLE IV. LIST OF INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria	Last five-year publication: 2017-2021
	All Open Access
	Only Conference Paper and Journal Paper
	Only considered the ER system for text dataset
Exclusion Criteria	Unpublished paper
	Literature other than English language

The features with which the tools must comply are listed below:

- It should be freely available.
- It should be a web application that can be downloaded or used online.
- It should be able to installed easily.
- It should be approachable.
- It should support multiple file format and export annotation in multiple formats.

To satisfy the availability criteria a tool must be instantly accessible, either for direct online usage (via a web user interface) or to download at the time of writing, without requiring consumers to get in touch with the developers. The availability also depends on whether the tool is free or licensed.

The tool must be a web application, which means that it must either be easily accessible online or may be downloaded and installed as a web application. The requirement that annotations be web-based ensures that annotators can focus completely on their annotation tasks without having to fight with tool installation. Manual annotation is a labor-intensive and difficult task in and of itself, and additional work may annoy the annotators and jeopardise the annotation process.

The survey requires the tool to function properly, and it is a requirement for practical experiments. A minimal set of features, as described by the criteria (as defined in Table V), should be accessible regardless of whether the tool is locally installable or accessible online for use. Therefore, there is no need to contact the developers for help because the tool should be simple to use or the documentation should be thorough enough.

Few more additional features are considered in this research other than the functionalities listed above which makes annotation process much easier such as the smallest unit of annotation (character or token), built-in domain-specific named entity extraction, and quick annotations such as keyboard shortcuts, pre-annotations, or ontology.

Some additional feature which are not compulsory for the annotation tools are listed below but they might be useful for most of the NLP based task:

- It can support multimedia.
- It can support multiple language.
- Integration with AI model for automatic annotation tools.
- Good and simple User Interface.

D. Selected Tools

In this section total eight tools are studied and selected for the research work are listed in Table VI, detailed discussion is done for the selected tools with respect to their features.

1) BRAT (Browser based rapid annotation tool): One of the most well-liked tools for manually annotating documents, it has been employed in the creation of numerous corpora. BRAT is a browser-based free online annotation tool for collaborative text annotation [22]. BRAT is not accessible online and must be installed locally. Documents are imported in the same format as the plain text file that contains the schema configuration. It was designed for rich structured annotation for a range of NLP activities. BRAT was created to enhance manual curation efforts and boost annotator productivity using NLP approaches. It is possible to highlight entities and relations as well as normalize data to pre-established terminology. It has a rich range of features such as integration with external resources such as Wikipedia, support for automatic text annotation tools, and built-in annotation comparison.

BRAT is more suitable for annotating expressions and the relationship between them, because annotating longer texts like paragraphs is really inconvenient. It only accepts text files as input documents, and text files are not presented in their original format in the user interface. Despite the fact that the last version was issued in 2012, the product is still readily accessible and well-liked in the industry. Recent upgrades include, among other things, integrating with external TM tools and embedding visualizations in HTML pages.

TABLE V. CRITERIA FOR SELECTION OF ANNOTATION TOOLS

Criteria Categories	Criteria
Input & Output (data)	Input format for document
	Input for multi-format file
	Format for annotation
	Output format for annotation
Publication	Number of citations
System Criteria	Installation Design (Web, standalone, plugin)
	Simplicity of installation
	Quality and Quantity of documentation
	Licence of Tool
	Operating System Support
	Availability (Free/ Paid)
Function	Multimedia or Multimodal Support
	Multilingual Support
	Interactive UI
	Support of Fast Annotation
	Full Text Support
	Inter-annotator agreement
	Pre-annotation Support
	Integration with external sources
	Automatic text annotation
	Annotation Relationship
	Data Security

TABLE VI. LIST OF SELECTED TOOLS

Tools	Installation	Input Format	Output Format	License
BRAT	Web	TXT	brat standoff format	CC BY3.0
Djangology	Web	DB	DB	-
Doccano	Web	TXT	JSON, CSV	MIT
GATE teamware	Web/ SA	TXT	XML, DB	GPL
Label Studio	Web/SA	TXT, JSON, CSV	CSV, JSON, CONLL	-
Lighttag	Web	TXT	JSON	-
Prodigy	SA	TXT	JSON, txt	-
UBIAI	SA	TXT, JOSN, PDF, HTML	JSON, Amazon Comprehend, Stanford CoreNLP	-

a) Doccano: Doccano is an open-source web-based annotation tool for text files only [23]. It is an open-source tool that supports a variety of job types, such as tasks involving the annotation of text sequences or text classification, which may be applied to a variety of problems, such as the annotation of text for sentiment analysis, text summarization, NER, etc. [9] It has a more modern and attractive user interface, and all configuration is done in the web user inter- face. It also generates a basic overview of tagging statistics. All of these make Doccano more beginner-friendly and user- friendly in general. It supports multiple users, but there are no additional features for collaborative annotation.

b) GATE: Gate team-ware is a web-based open-source collaborative annotation and curation tool [24] and is freely available. Gate teamware is an extension of an annotation tool GATE, which is an annotation management tool. GATE teamware offers user automatic annotation which reduces the manual annotation tool. It offers the interface which can be used to create corpus, to define annotation schema, to load pre-annotated data. As it is collaborative tool, it allows the users to monitor the annotation process i.e., number of annotated document and remaining document to be annotated. It is also use to monitor statistics like time spent on a document, inter annotator agreement.

c) Light tag: Another browser-based text labelling tool is LightTag [25], however it’s not completely free. No local installation is required for annotation using lighttag. It offers a free edition with 5,000 annotations each month for its essential features. It supports working with different languages (like Arabic, Hebrew and CJK among others), document level, multi-word, nesting, relationship annotations, etc. Additionally, it uses machine learning to learn from active annotators and suggest possible annotations for hidden text. It assigns tasks to annotators and ensures that there is enough overlap and duplication to maintain a high degree of accuracy and consistency.

d) Prodigy: It is a paid tool, and the only free version is a demo. Prodigy is an active learning-based annotation tool that is also connected with the Spacy library. This annotation tool’s active learning feature allows you to only annotate cases for which the model does not yet have an answer, greatly accelerating the annotation process. By using transfer learning technology and a more flexible approach to data gathering, you can train models of production quality with a minimal number of samples. Prodigy allows you to annotate images, videos, and audio in addition to text. When exporting your files, you can select among the JSONL, JSON, and txt formats.

e) UBIAI: UBIAI is a powerful labelling platform for training and deploying custom NLP models. UBIAI is a tool for data labelling as a service category in the technology stack [26] . It offers free and paid plans, OCR annotation tools, document classification, auto-tagging for team collaboration, and more. Widely used in the corporate world to convey important information, this is a must, especially for businesses and organizations that need to create high-quality annotations to PDFs, but difficult to edit there is. With UBIAI you can easily annotate native his PDF documents, scanned images, images, invoices or contracts in over 20 languages including Japanese, Spanish, Arabic, Russian and Hebrew can be attached. Per- form named entity recognition (NER), relationship extraction, and document classification in the same interface. Export annotations in multiple formats including Spacy, IOB, and Amazon Comprehend. Supports various input formats such as native PDF, TXT, CSV, PNG, JPG, HTML, DOCX, JSON. It also offers team management features that allow you to track progress. Measurement of text annotations, performance of assigned projects, and agreement among annotators.

f) Label studio: Label Studio is an open-source data labeller that allows you to label and explore a variety of data written in Python. You can make different entries with several data formats. You can also integrate Label Studio with machine learning models to provide label predictions (examples) or perform continuous active learning. Label Studio is also available in Enterprise and Cloud versions with additional features. Simplicity of label studio is that it has no complicated configurations, and ease of integration into Machine Learning pipelines. Label Studio can be used in different places, depending on different use-cases. It is quickly configurable for many data types. The tool gets ready in a few minutes. There is an easy way to switch between labelling texts, audios or images, or even annotating all three types at the same time. Many existing labelling frameworks accept only one data type, and it becomes tedious to learn a new app each time whereas Label Studio works with Texts, Images, Audios, HTML documents and any imaginable combination of annotation tasks like classification, regression, tagging, spanning, pairwise comparison, object detection, segmentation and so on. After configuring what the labelling interfaces should look like, you can import your data. The web import supports multiple formats: JSON, CSV, TSV, and archives consisting of those.

V. Experiment and Results

A. *Annotation of Dataset*

The following section describes the premise for dataset annotation, including the defining of annotation setups, various entity types, and annotation method (Annotation guidelines).

1) Selecting suitable input documents for annotation: In order to construct a robust dataset for legal named entity recognition, a comprehensive effort was undertaken to collect a diverse range of case documents from the Indian Supreme Court and several High Courts throughout India. The documents were sourced from a multitude of publicly available repositories on the web, including the official websites of these courts and prominent legal databases such as https://www.indianka noon.org, as well as numerous other legal repositories. The dataset was made sure to represent a wide range of court cases accurately and thoroughly from various jurisdictions through a long and complex process of data collection.

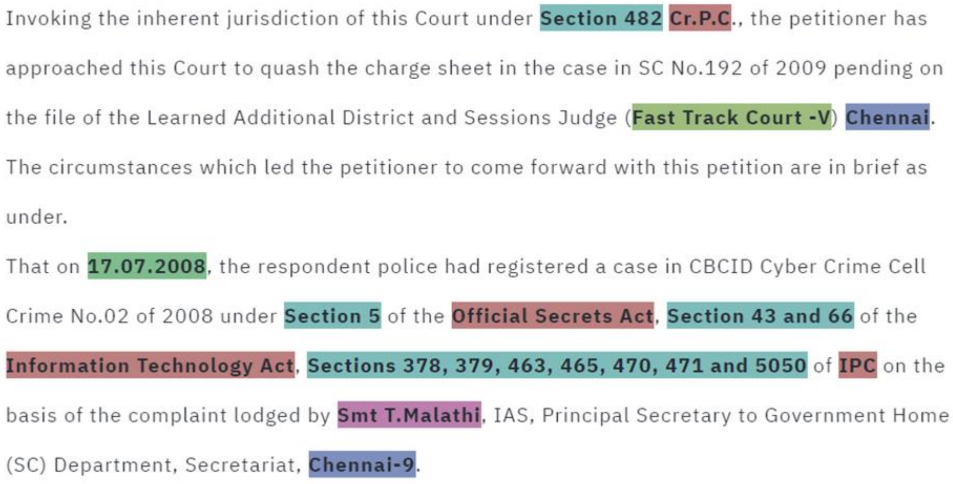
2) Annotation setup: Open-source data labeller Label Studio was used as an annotation tool. After comparing the system to other tools (as previously indicated), it was discovered that this was the most straightforward, user-friendly, and effective tool for our experimentation. There are several methods for installing label studio, including installing with pip, installing with docker, and installing from source, whether you are installing it locally or in the cloud. The only need for label- studio is that Python 3.6 or later must be installed on a machine running Linux, Windows, or MacOSX. Port 8080 is expected to be open by default in Label Studio. Label Studio installation needs SQLite 3.35 or later and PostgreSQL version11.5 or above. After installing Label Studio using pip, data was uploaded and entity types were defined in the tool after the system was downloaded and launched on a local machine.

3) Entity type: The targeted entities are listed in the Table VII, along with a brief description and an example for each category. After talking with legal experts on the pertinent information that may be gleaned from court rulings, the entity kinds were established.

Fig. 1 explain sample example of document to be annotated. The highlighted part of the text indicates the name entity to be annotated. The name entities that can be extracted from above text are given in Table VIII.

TABLE VII. List of Entities of the Legal Judgments

Name Entity	Descriptions	Example
PERSON	Name of the person	Praveen Kumar Wadi, Guruanna Vedi, B.L. Gupta
LOC	Locations which include name of states, cities, villages	Pune, Haryana, Gujarat, Mumbai
DATE	Any Date mentioned in judgment	10 April, 2001
ORG	Name of organization mentioned in text apart from the court.	General Insurance Co. Ltd.
Court	Name of the court which has delivered the judgment.	Supreme Court, Andhra Pradesh High Court, Bombay High Court
LEGAL	sections, Sub-sections, articles orders etc.	Section 110-A, Section 95(2)(d)
ACT	It includes Act name in constitution	Motor Vehicles Act, IT Act, Official Secret Act, IPC
CASE_NO	It indicates the particular case no. of court judgments	C.C. No. 3286 / 2019



Invoking the inherent jurisdiction of this Court under Section 482 Cr.P.C., the petitioner has approached this Court to quash the charge sheet in the case in SC No.192 of 2009 pending on the file of the Learned Additional District and Sessions Judge (Fast Track Court -V) Chennai. The circumstances which led the petitioner to come forward with this petition are in brief as under.

That on 17.07.2008, the respondent police had registered a case in CBCID Cyber Crime Cell Crime No.02 of 2008 under Section 5 of the Official Secrets Act, Section 43 and 66 of the Information Technology Act, Sections 378, 379, 463, 465, 470, 471 and 5050 of IPC on the basis of the complaint lodged by Smt T.Malathi, IAS, Principal Secretary to Government Home (SC) Department, Secretariat, Chennai-9.

Fig. 1. Example of annotated document.

TABLE VIII. NAMED ENTITY EXTRACTED FROM SAMPLE PARAGRAPH

Name Entity	Text
ACT	CrPC, Information Technology Act, Official Secret Act, IPC
LEGAL	Section 482, Section 5, Section 43 and 66, Sections 378, 379, 463, 465, 470, 471 and 5050.
PERSON	Smt. T. Malathi
LOC	Chennai
DATE	17.07.2008
COURT	Fast track court

4) Manual annotation process: The annotation for the judgment text was done at the sentence level, therefore each judgment sentence was given separately from the annota- tion without document-level context. In the event that extra background information is required for annotation, the whole judgment text is also available. The indiankannon URL was used to obtain the whole judgment text.

To Label and annotate data we have use the open-source data labelling tool, i.e., Label Studio. After importing your data, you can start labelling and annotating your data. Fig. 2 conceptualised name entity recognition using machine learning algorithm and manual annotation.

a) Open a project in Label Studio and optionally.

b) Click Label All Tasks to start labelling.

c) Use keyboard shortcuts or your mouse to label the data and submit your annotations.

d) Follow the project instructions for labelling and deciding whether to skip tasks.

e) Click the project name to return to the data manager.

5) Annotated corpus statistics: In this paper, a dataset of annotated judgment text with seven entities has been created. A dataset of almost 5000 Indian judicial judgment sentences with seven entities has been created. The Table IX lists the number of documents, sentences, and tokens in the annotated corpus as well as other general statistics.

TABLE IX. ANNOTATED CORPUS STATISTICS

No. of Documents	30
No. of Sentences	~5196
Average no. of sentences per document	173
No. of tokens (without stop words)	63155
Annotated tokens	~5286

B. NER Model

Several well-known NER model architectures were explored to identify legal named entities in judgment papers. Initially, spacy's pre-trained NER model was used to implement Legal NER. Two of spacy's pre-trained pipelines, namely en_core_web_trf and en_core_sci_sm, were integrated with unique rules created specifically for the legal domain to improve the accuracy of predictions.

During the training phase, the model's predictions were iteratively compared to the reference annotations to calculate the gradient of the loss as shown in Fig. 3. Backpropagation was then used to determine the gradient of the weights using the gradient of the loss. This approach enabled us to determine how to adjust the weight values so that the model's predictions gradually resembled the reference labels, hence enhancing the model's accuracy.

To make sure that our Legal NER model was optimized for the needs of legal named entity identification, we used a strict and systematic methodology. Our algorithm is capable of accurately identifying many different types of legal entities, such as court names and legal terms.

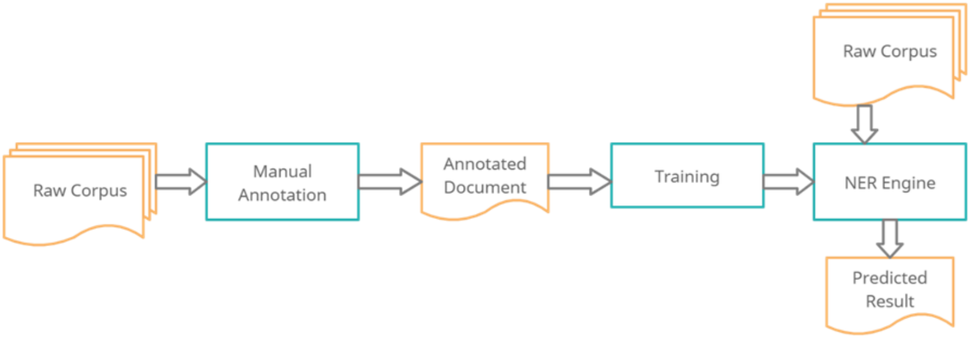


Fig. 2. Manual annotated data and NER system.

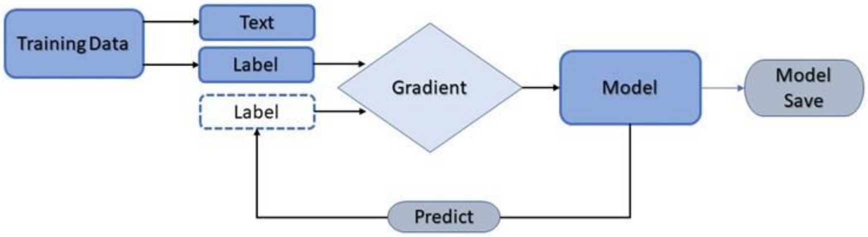

Fig. 3. Spacy pretrained pipeline.

C. Results

Various evaluation matrices were used, such as the F1 score, recall, and precision, to evaluate the model's efficiency. These metrics provide important information about how well the model can identify and categorize data points. The F1 score represents the harmonic mean of accuracy and recall, where recall represents the proportion of true positive values that the model correctly identified and precision represents the percentage of true positive values that the model correctly recognized. A variety of measurements can be utilized to better understand the model's advantages and disadvantages, which will help in deciding how to enhance its performance.

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$F1\ Score = \frac{2*Precision*Recall}{Precision+Recall} \quad (3)$$

where,

TP = True Positive   FP = False Positive

TN = True Negative   FN = False Negative

NER model's aggregate F1 score of 0.62 indicates that the quality of our training data is higher than average. Precision, Recall, and F1scores on judgment sentences are used to assess the model. Table X displays the results of various tests and experiments.

TABLE X. RESULT OF SPACY TRAINED PIPELINE

Spacy Trained Pipeline	Precision	Recall	F1 Score
en_core_web_trf	0.6	0.41	0.48
en_core_sci_sm	0.51	0.4	0.45

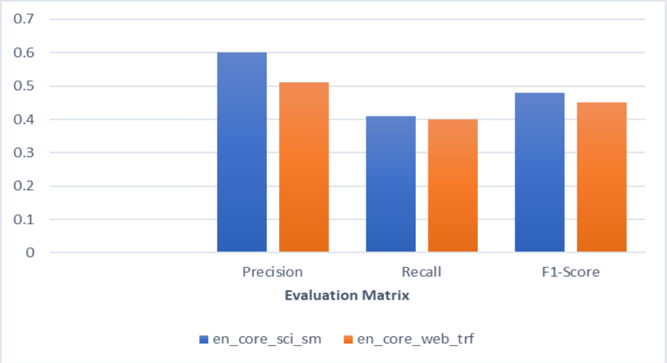

Fig. 4. Analysis of results of trained spacy models.

The Fig. 4 shows the comparison of the performance of the model on individual entities. Since the dataset is completely unbalanced, precision, recall, and F1 score have been calculated for comparison. Precision and recall are defined in terms of true positive, false positive and false negatives, whereas the F1 score is defined as the harmonic mean of precision and recall. The weighted average of precision, recall, and F1 score for spacy en_core_web_trf pipeline are 0.60, 0.41, and 0.48 respectively, and for spacy en_core_sci_sm are 0.51, 0.40, and 0.45 respectively. Good results have been obtained from the experiments and evaluations, and the Legal NER model can be a valuable tool for a variety of legal applications such as legal information retrieval, document summarization, and more.

VI. DISCUSSION

In the legal domain, NER is typically used for tasks such as document classification, contract analysis, and case law research [27]. The accuracy of NER is crucial in the legal domain, as incorrect recognition of entities can lead to incorrect legal decisions [28].

There are several challenges in NER for the legal domain compared to other domains [29]. Firstly, the language used in legal documents is often complex and technical, which might be difficult to identify with traditional NER models. Secondly, legal named entities can have multiple forms and variations, such as acronyms, abbreviations, and synonyms, requiring NER systems to have a comprehensive understanding of legal terminology. To solve this issue, NER models in the legal domain are frequently fine-tuned using massive annotated legal corpora, which can increase the accuracy of legal entity recognition [30].

Another challenge in NER in the legal domain is the presence of named entities with several mentions, such as the names of legal parties. These entities may be referred to by multiple names or titles in different places of the document, making proper identification difficult. To overcome this problem, NER models in the legal sector typically include named entity disambiguation approaches, which assist in the identification and resolution of ambiguity in named entities.

Despite these challenges, NER has proven to be a valuable tool in the legal domain. By automating the process of identifying named entities [31], NER can significantly reduce the time and effort required for legal research and analysis. This can result in increased efficiency and productivity for legal professionals, as well as improved accuracy and consistency in the analysis of legal data. Overall, NER in the legal domain is a critical tool for facilitating legal research, analysis, and decision-making. With advances in machine learning and NLP techniques [32], NER models in the legal domain are becoming more accurate and efficient, helping to make the legal process faster and more effective.

Name Entity Recognition has great potential to improve the process of legal research and analysis, but it faces significant challenges in the legal domain due to the complexity and technical nature of legal language [33]. Further development and refinement of NER systems for the legal domain will likely result in even greater benefits for legal professionals in the future. Once these entities have been extracted and tagged, they can be used for research and analysis of legal texts. Furthermore, policy-making can be informed by the knowledge gained by Legal NER. Overall, the use of LNER in legal research and text analysis can enhance legal research, inform policy decisions, and result in more efficient and fair legal systems.

VII. Conclusion and Future Work

In this paper, a corpus of Indian judgment papers is presented that is annotated with 7 distinct types of entities and can be used to identify legal named entities. In order to create the annotated dataset, a variety of annotation tools were reviewed. 30 court documents that are available publicly were manually annotated. With the dataset, a spacy model was also trained utilizing the trained NER pipelines en_core_sci_sm and en_core_web_trf. The model displays an F1-score of almost 60%, indicating that the dataset has better quality. It is believed that the dataset will be useful for additional NLP tasks on Indian judicial material, such as relationship extraction, knowledge graph modelling, extractive summarization, etc.

In terms of future work, the author will explore approaches for extending and further optimizing the dataset. They will also perform additional experiments with more recent state-of-the-art approaches. The researchers plan to produce a CSV version of the dataset, which will simplify the data format, enhance compatibility, facilitate data pre-processing, and enable data analysis.

Research on the Model of Preventing Corporate Financial Fraud under the Combination of Deep Learning and SHAP

Yanzhao Wang*
Henan Institute of Economics and Trade, College of Finance,
Zhengzhou, 450000, China

***Abstract*—Preventing financial fraud in listed companies is conducive to improving the healthy development of China's accounting industry and the securities market, is conducive to promoting the improvement of the internal control system of China's enterprises, and is conducive to promoting stability. Based on the combination of SHAP (Shapley Additive explanation), a prediction and identification model should be built to determine the possibility of financial fraud and the risk of fraud for the company. The research model has effectively improved the identification accuracy of financial fraud in listed companies, and the research model has effectively dealt with the gray sample problem that is common in the forecasting model through the LOF algorithm and the IF algorithm. When conducting comparative experiments on the models, the overall accuracy rate of the research model is over 85%, the recall rate is 78.5%, the precision rate is 42%, the AUC reaches 0.896, the discrimination degree KS reaches 0.652, and the model stability PSI is 0.088, compared with traditional financial fraud Forecasting models FS model and CS model has a higher predictive effect. In the empirical analysis, selecting a company's fraud cases in 2020 can effectively analyze the characteristic contribution in the fraud process and the focus on fraud risks. The established model can effectively monitor the company's finance and prevent fraud.**

Keywords—Financial fraud; deep learning; ensemble algorithm; feature selection

I. Introduction

With the rapid development of China's social economy, listed companies also occupy the majority of the market economy, and the quality of financial information of listed companies has an important impact on the efficiency of the capital market. The frequent occurrence of financial fraud in listed companies has seriously hindered the healthy development of the capital market, leading to the weakening of the company's control structure, reducing the effectiveness of corporate governance, and deteriorating the quality of its audit function [1-3]. At present, traditional financial fraud prevention and prediction systems are gradually unable to meet the needs of the market economy, and financial fraud prediction models are not yet sound. Relevant institutions and enterprises are difficult to effectively evaluate financial fraud phenomena, resulting in difficulties in effectively improving the financial risks of listed companies. How to enable different institutions and relevant enterprises to avoid financial fraud is the key to improving social economy and improving the market system. XGBoost integrated learning algorithm can more effectively predict financial fraud, which is currently an excellent classification algorithm. Therefore, in order to more accurately predict the existence of fraud in enterprises, a model based on deep learning combined with SHAP to prevent financial fraud in enterprises was studied, enabling regulators to conduct regulatory early warning for listed companies, creating a good ecological environment for the healthy growth of the capital market [4-6]. The research proposed combining ratio scaling with XGBoost model. The financial fraud prediction model can be quantitatively evaluated, and the design of a scoring card can not only have high prediction accuracy, but also have a negative sample capture rate. Derivative screening of the financial fraud risk indicator system, dimensionality reduction processing features make the model easy to use, combining different corporate governance perspectives with financial data as indicator variables. Reduce the cost of manual investigation, reasonably assess audit risks, and determine a more efficient audit scope. Reasonably evaluate the potential value and future growth space of different enterprises. At the same time, the model can be used to evaluate the potential fraud risks of debt companies, providing a more favorable analysis of the security of borrowing funds.

II. Related Works

Financial fraud means that the managers of the enterprise cover up the real financial status and cash flow of the enterprise by changing or falsifying the accounting information, so as to bring huge economic benefits to the fraudsters. How to predict or detect financial fraud has been researched and analyzed by various scholars. HWA et al. constructed a thinking map based on the relationship between enterprises and audit firms, and used the method of feature extraction to build a thinking framework to analyze whether enterprises have financial fraud [7]. Houssou et al. use homogeneous and non-homogeneous Poisson processes to detect financial fraud in imbalanced datasets. Experimental results show that applying the model to financial datasets shows better predictive ability than baseline methods especially in the case of high data imbalance [8].

The XGBoost algorithm is an integrated learning method, which is widely used in all walks of life, and is also deeply researched and developed by different professionals. C Zhao et al. established a prediction model of speed estimation and distance between other vehicles during vehicle operation by mixing neural network and limit gradient, and found that the model can help drivers effectively predict the speed and distance of other vehicles when changing lanes in different scenarios, with good prediction effect [9]. W niu et al. integrated a gradient lifting algorithm into computer traffic monitoring to protect computer security and monitor hacker attacks. XGBoost is mainly used to distinguish whether there is malicious traffic. The performance of the established model can effectively distinguish between malware traffic and normal traffic from normal data sets in actual use, and the false alarm rate is less than 1% [10]. Bao et al. combined AdaBoost ensemble learning with under sampling data processing methods, and introduced a model evaluation index that is more suitable for fraud prediction tasks. Experimental results prove that the model is superior to the financial ratio-based regression model and single-core support vector machine model in predicting financial fraud [11].

To sum up, in the research on the prediction and detection of financial fraud, there is relatively more research on the detection of financial fraud. However, there is little research on the prediction of financial fraud and economic fraud. The SGBoost algorithm is widely used in engineering, Internet security, data set classification, and system modeling, but there are relatively few related studies on the application of the XGBoost algorithm to predict financial fraud. Therefore, research on deep learning combined with SHAP to prevent corporate financial fraud models, Using Benford’s law, LOF local anomaly detection, and isolated forest detection method to eliminate gray samples in the prediction model, establish a financial fraud prediction model for listed companies based on machine learning methods, and create a good and healthy ecological environment for the capital market.

III. Construction of Financial Fraud Prevention Model based on Deep Learning and SHAP

A. Fraud Prediction Model Index Construction

Financial fraud hides or changes the relevant financial status, operating conditions and capital flow of the enterprise through forgery, omission, fabrication, etc., which can bring huge economic benefits to the fraudsters. Therefore, choose the appropriate financial fraud early warning indicators to establish a suitable model foundation. In the process of selecting indicators, follow the principles of reference, systematization, operability, and loose before tightening to make the model have good versatility [12-14]. The premise of an efficient and accurate deep learning model is to select good financial fraud characteristic variables, and the index selection is shown in Fig. 1.

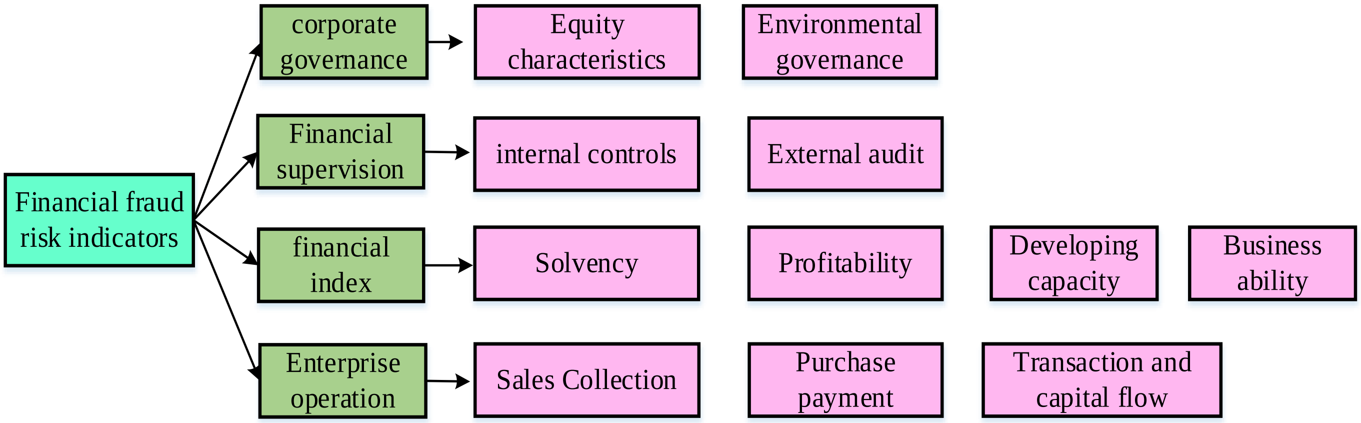

Fig. 1. Financial fraud risk indicator system.

Fig. 1 shows the financial fraud risk indicator system. Corporate governance indicators reflect the level of managers within the company and the degree of internal checks and balances. The secondary indicators are divided into equity characteristics and environmental governance. Financial and accounting supervision indicators divide supervision into internal control and external audit. Financial fraud is more likely to occur in companies that lack effective internal control systems. External audit indicators, such as firm size, auditors and other external factors, examine the factors affecting financial fraud. Financial indicators reflect the development of the company’s economy, solvency reflects an important indicator of the company’s long-term operation and development, and profitability is an indicator for evaluating the company’s created value and company value. Operating ability reflects the turnover of different assets of the company and the level of management. Development ability is the basis for measuring whether the company has good growth potential in the future. The cash flow cycle is a risk indicator that reflects whether the company has abnormal operations. The sales collection indicator reflects whether the company’s revenue is normal, the purchase payment indicator reflects whether the credit purchase and cash purchase at the purchasing end of the enterprise are normal, and the transaction and capital flow reflect whether the company has engaged in financial fraud through related transactions. After determining the financial fraud risk indicator system, research and select appropriate financial fraud samples. The financial fraud samples for this research are selected from the CSMAR China listed company financial annual report database and the violation information summary table of the violation event database, and select the handling documents issued by the regulatory agency. The data of illegal companies involving "fictitious profits" and "fictitious assets" between 2010 and 2021 are used as financial fraud samples in this paper. The financial fraud sample noun is divided into three different training sets before building the model: training samples, test samples, and out-of-time samples. The ratio of training samples to testing samples is 7:3. The out-of-time samples are the last samples of the time slice among all the samples. The training samples are used to train the model, while the test and out-of-time samples are utilized to evaluate the model's capability, stability, and generality [15]. In order to make the model more flexible and stable, and avoid the impact of extreme data values on the model, feature discretization is selected. The discretization formula is shown in formula [16-18] (1).

$$woe_i = \ln(\frac{p_{y_i}}{p_{n_i}}) \tag{1}$$

In formula (1), p_{y_i} is the ratio of fraudulent samples in the current group to all fraudulent samples in the sample, is the ratio p_{n_i} of all non-fraudulent samples in the current group to non-fraudulent samples in all samples, and woe is the difference between the two ratios, the difference Expressed logarithmically. Ensure the operational efficiency of the model and avoid overfitting, the overall features are screened. In the preliminary screening process, after determining the feature missing rate, the distribution difference of the sample labels with different values of the feature is measured. The calculation formula is shown in formula (2).

$$IV = \sum iv_i \tag{2}$$

In formula (2), iv_i the expression of is shown in formula (3).

$$iv_i = (p_{y_i} - p_{n_i}) woe_i \tag{3}$$

In formulas (2) and (3), it IV represents the amount of feature information, which can reflect the contribution of a single feature to label distinction. When the amount of feature information is too large, it means that the model simulation effect is excellent. The characteristic correlation calculation between two characteristic variables is measured by the Spearman correlation coefficient. The measurement formula is as follows.

$$r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)} \tag{4}$$

In formula (4), it n represents the quantity of data, which d_i is the difference between the order of two feature data. In feature correlation screening, feature indicators with a correlation greater than 0.7 are eliminated. The calculation formula for calculating the distribution difference of the same index on different data sets, measuring characteristics and model stability is shown in formula (5).

$$PSI = \sum_i (p^i_{t\arg et} - p^i_{base}) * \ln(\frac{p^i_{t\arg et}}{p^i_{base}}) \tag{5}$$

In formula (5), PSI is the characteristic stability, $p^i_{t\arg et}$ is the ratio of the samples in the first box of the target set to the i total samples, and is the total proportion of samples in the p^i_{base} first box of the basic distribution i. In the characteristic stable value, the characteristic items less than 0.02 are eliminated. After screening the information quality of the features, Use Chichi information criterion and Bayesian information criterion to select the characteristics of the model to ensure that the model has sufficient complexity and data set description. The calculation formula of AIC is as follows.

$$AIC = 2k - 2\ln L \tag{6}$$

The calculation formula of BIC is as follows.

$$BIC = 2\ln n - 2\ln L \tag{7}$$

In formula (6) and formula (7), k is the number of model parameters, n is the number of samples and L is the likelihood function. The fraudulent companies in the non-fraudulent samples are called "gray samples". Eliminating gray samples can ensure the quality of training data of the deep speech learning model and improve the reliability of the model; balance problem. The study uses Binford’s law, LOF local anomaly factor method and isolated forest algorithm (IF) to eliminate gray samples.

The calculation formula of probability distribution and correlation coefficient in Binford’s law is shown in formula (8).

$$r(X,Y) = \frac{Cov(X,Y)}{\sqrt{Var(X) \cdot Var(Y)}} \tag{8}$$

In formula (8), $\mathrm{Cov(X,Y)}$ is the covariance, $Var(X)$ and $Var(Y)$ is the variance respectively. In Binford’s hypothesis test, the chi-square test is selected to test the degree of conformity of the numerical distribution of the observed samples. The calculation formula of statistics is shown in formula (9).

$$\chi_n^2 = \sum_{i=0}^{9} \frac{(F_n(i) - F_0(i))^2}{F_0(i)} \tag{9}$$

In formula (9), $F_n(i)$ is the actual observed value, and $F_0(i)$ is the theoretical distribution value of the law. The LOF anomaly detection method introduces local reachability density to measure the degree of sample anomaly, which can output anomaly scores very well and has strong interpretability. The calculation formula is shown in formula (10).

$$lrd_k(p) = \frac{1}{\frac{\sum_{o \in N_{k(p)}} reach\_dis_k(p,o)}{|N_k(p)|}} \quad (10)$$

In formula (10), p and o are two different sample points, and the reachable distance is $reach\_dis_k(p,o)$, which $N_k(p)$ means that the distance between the sample points is less than or equal to the k distance between the nearest point and the sample point. The local anomaly factor is calculated using the following formula.

$$LOF_k(p) = \frac{\frac{\sum_{o \in N_{k(p)}} lrd(o)}{|N_k(p)|}}{lrd(p)} \quad (11)$$

The IF algorithm is an integrated algorithm is based on the idea of random partitioning of space. The principle of a single isolated tree in the two-dimensional space of the IF algorithm is shown in Fig. 2.

The blue point in Fig. 2 means normal sample, and the outlier point is indicated by red. The straight lines that divide the space are randomly selected along the two coordinates respectively. The probability of the red dot being isolated before the blue dot is much greater than that of the blue dot. The probability of being isolated before the red point is uncertain, however, the presence of a single tree can increase the chance. Therefore, the combination of multiple isolated trees can enhance the stability of the model, leading to the final IF model. The final IF abnormal score is defined as formula (12).

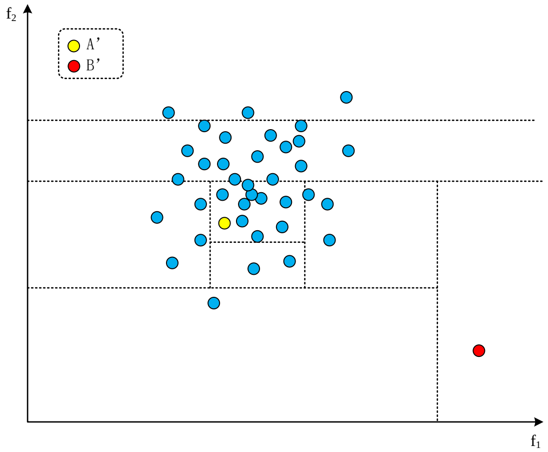

Fig. 2. Schematic diagram of IF algorithm.

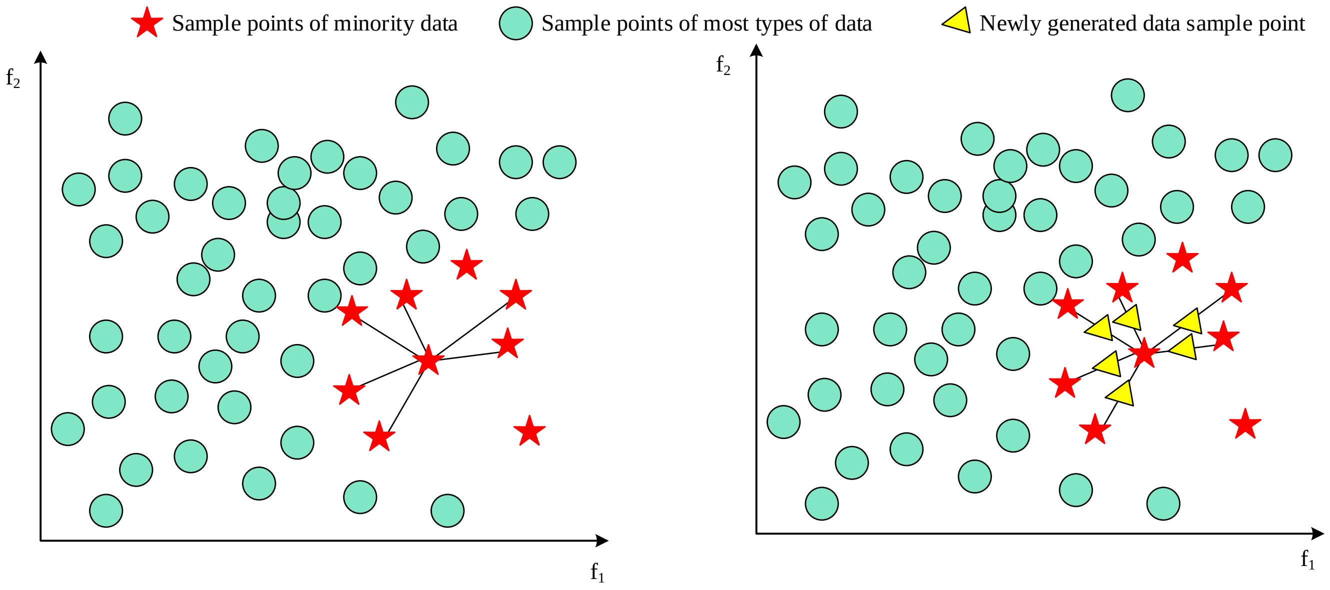
$$Score(x_i) = 2^{\frac{E(h(x_i))}{C(n)}} \quad (12)$$

In the formula (12), it $E(h(x_i))$ represents the average path length of the blue point on the isolated tree, n is the number of training samples, and $C(n)$ is n the average path length of the binary tree trained by samples. After the gray sample is proposed, SMOTE is selected for oversampling. The basic principle of SMOTE is retracted as shown in the Fig. 3 below.



Sample points of minority data
Sample points of most types of data
Newly generated data sample point
f2
f1
f2
f1

Fig. 3. Schematic diagram of SMOTE algorithm.

SMOTE algorithm interpolates and synthesizes existing minority samples by analyzing minority samples, and then adds the samples to the dataset for training. The Light GBM algorithm was selected in this study to clean the samples. This was achieved by reducing the weight of samples with poor head and tail prediction results, so that they would not participate in the interpolation process of the SMOTE algorithm. The SMOTE algorithm has a high reliability for classification and oversamples the samples. Finally, the sampling results are combined.

B. Construction of Financial Anti-Fraud Model based on Deep Learning

After preprocessing the data, establish an anti-fraud model, and use the XGBoost model to improve the gradient boosting regression tree (GBRT) algorithm. The XGBoost model can support CART trees and linear classifiers at the same time. The study method is based on the forward distribution algorithm to achieve the integration of the additive model. The iterative process of the traditional GBRT algorithm is shown in formula (13).

$$\hat{y}^{(T)} = v\sum_{j=1}^{T} f_j(x;\Theta_j) = \hat{y}^{(T-1)} + vf_T(x;\Theta_T) \tag{13}$$

In formula (13), T is the number of basic regression trees, Θ_j is the corresponding regression tree structure, v is the scaling weight factor, $\hat{y}^{(T)}$ is the prediction result of the regression tree, and $f_j(x;\Theta_j)$ is the output result when the scaling weight is not considered.

The gradient boosting process of the XGBoost model is shown in Fig. 4.

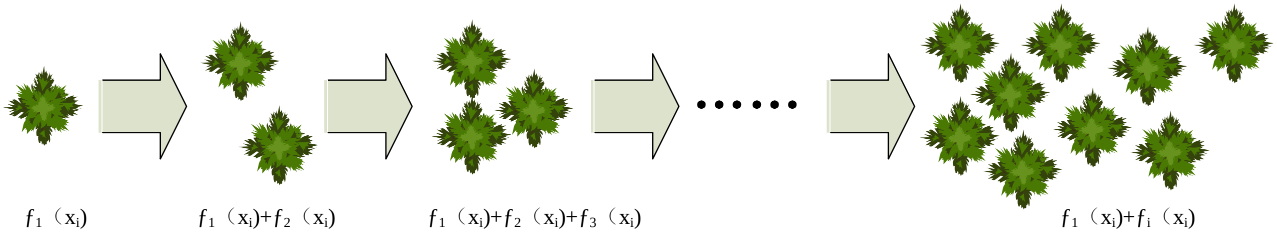


Fig. 4. XGBoost model principle.

The principle of a regression or classification model based on gradient lifting is shown in Fig. 4: First, establish a tree, and then gradually iterate. Each iteration process adds a tree, gradually forming a strong evaluator that integrates multiple tree models. The XGBoost model based on the tree model approximates the negative gradient of the model through the second-order Taylor expansion of the loss function, and learns it as the residual of the previous model. A higher learning weight is assigned to the samples with insufficient accuracy during the previous training process to improve the model accuracy, and serial iterations of multiple different models are implemented to gradually correct the deviation until the loss meets the convergence condition. The objective function after introducing the second-order Taylor expansion of the loss function is shown in Formula (14).

$$\hat{\Theta}_J \approx \arg\min_{\Theta_J}\left\{\sum_{i=1}^{N}\left[\hat{y}_j^{(j-1)} - y_i + vf_j(x_i;\Theta_j)\right]^2 + \Omega(\Theta_j)\right\} \tag{14}$$

In formula (14), N is the sample size, y is the minimum loss per additional node branch, and y_i is the given sample, and $\hat{y}^{(j-1)}$ has been determined. Therefore, $L(y_i,\hat{y}_j^{(j-1)})$ can be considered as a constant term to offset, and it is the regular term of the $\Omega(\Theta_j)$ th regression tree of j. After finding all the optimal single regression trees, the training is completed for enterprise fraud prevention prediction. The principle of $\Omega(\Theta_j)$ is shown in Formula (15).

$$\Omega(\Theta_j) = \gamma M_j + \frac{1}{2}\lambda\sum_{k=1}^{M_j}(w_k^{(j)})^2 \tag{15}$$

IV. Model Analysis and Empirical Application of Preventing Corporate Financial Fraud under Deep Learning

A. Model Prediction Effect Analysis

Effectively evaluate the actual put-to-use influence of the research model, the Fscore (FS) model and the Cscore (CS) model were selected to carry out a control experiment with the research model (RS), and the out-of-time samples were selected to test the model to test the stability of the model. In the control experiment, the application effects of different methods are compared by matrix. The matrix results are shown in the Table I.

TABLE I. Research Model Prediction Results

/	RS		CS		FS	
	Forecast		Forecast		Forecast	
Actual	Negative	Positive	Negative	Positive	Negative	Positive
FALSE	3146	513	2004	1763	1265	2574
TRUE	130	457	169	310	155	252

The research model correctly predicted 3146 cases of non-fraud samples and 457 cases of fraud samples, which is the model with the most correct prediction rate among the three models. The CS model correctly predicted only 2004 cases of non-fraud samples. Only 310 fraud samples were predicted, the FS model has the lowest prediction accuracy, only 1265 non-fraud samples were correctly predicted, and only 379 fraud samples were correctly predicted. The overall accuracy of the research model reaches 85%, the overall accuracy of the CS model reaches 54.5%, the prediction accuracy of FS model is relatively lower, reaching 36%. When analyzing the confusion matrix, we need to pay attention to the accuracy of the model, but also need to comprehensively evaluate the recall rate and accuracy rate of the model. The recall rate indicates the proportion of all companies that the model correctly predicts fraudulent companies, and the precision rate reflects the credibility of the model. The recall rate-precision rate results are shown in Fig. 5.

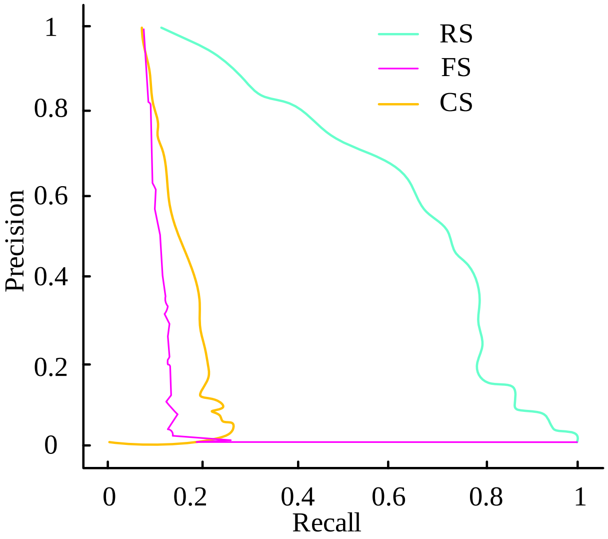

Fig. 5. PR curves of three models.

From the recall rate-precision rate result graph, it can be seen that the PR curve of the research model is the best, and the AP area is the largest, reaching 0.64. The precision rate and recall rate of the research model on samples out of time are higher than those of the CS model and the FS model. The indicators are superior, the AP area of the CS model is 0.16, and the AP area of the FS model is the smallest, which is 0.11, and the FS model is a commonly used forecasting model in the western capital market, and it has the worst forecasting effect on Chinese companies. The ROC curve can simply and intuitively observe the accuracy of different experimental models and make judgments through illustrations. This curve can accurately reflect the internal specificity relationship of the model and is a comprehensive representation to ensure the accuracy of the model. The results of the ROC experiment are shown in Fig. 6.

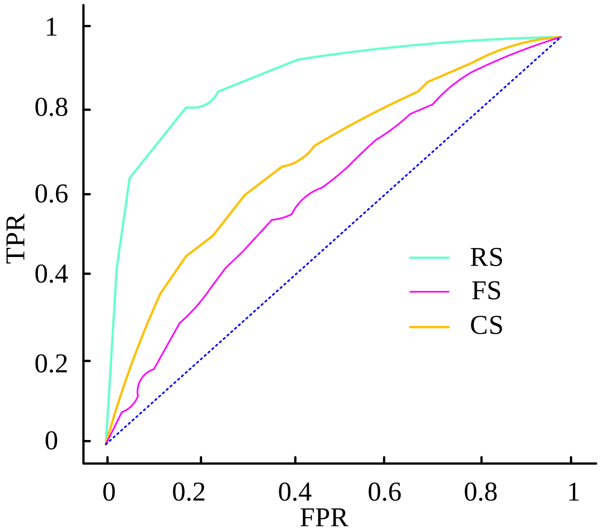

Fig. 6. ROC curves of different models.

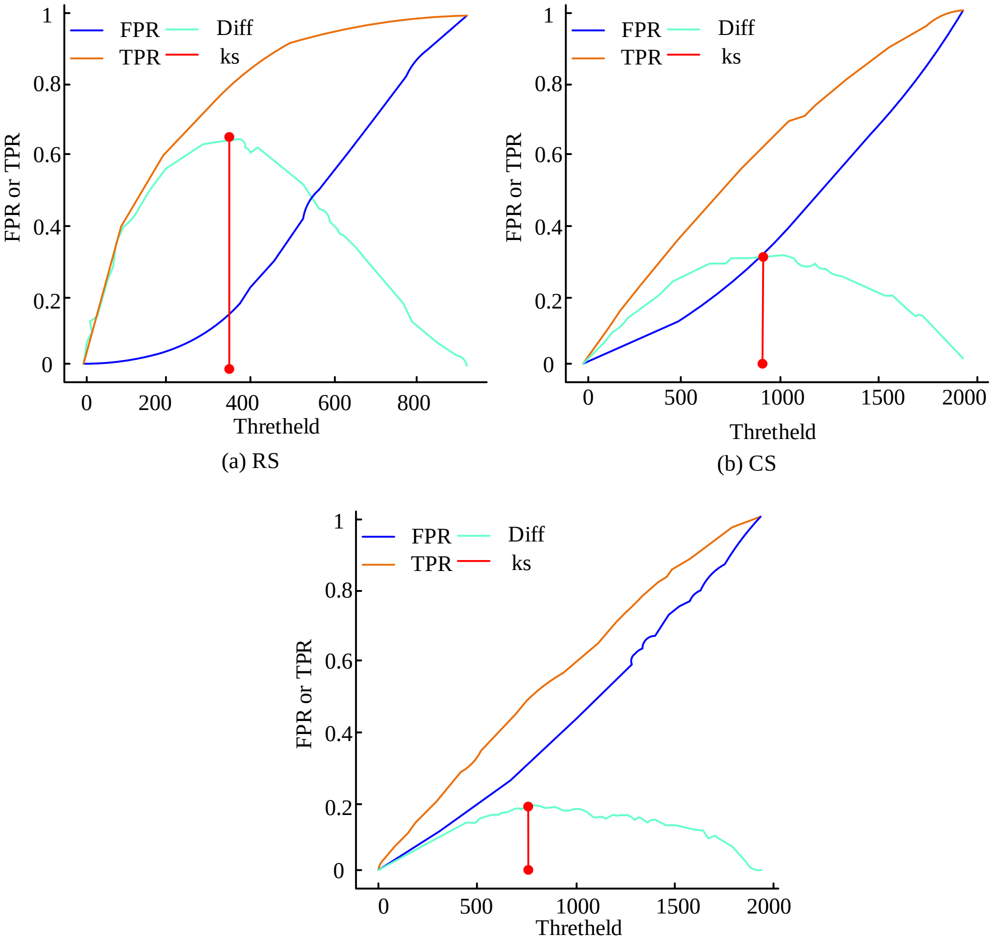
When the area under the curve of the pure random classifier is 0.5, the larger the area under the ROC curve, the more realistic the fitting effect of the model. The research model's ROC curve performs best among the three models, with the largest area under the curve reaching 0.9. The ROC curve of the CS model is lower than that of the research model, and the area under the curve is only 0.7. The FS model had the lowest curve magnitude and the smallest area under the curve, reaching a value of 0.62. Combining Fig. 5 and Fig. 6, the research model can achieve a high accuracy rate when predicting fraud samples. The KS curve reflects the distinguishing ability of the model. After the model predicts the scores of all samples, it is divided into different parts according to TPR and FPR, and the distribution of the scores of different sample groups is tested by KS statistics. The KS curves of the three models are shown in Fig. 7.



(a) RS

(b) CS

(c) FS

Fig. 7. KS curves of three models.

Fig. 7 shows the comparison of KS curves for different models. The abscissa is arranged in descending order with thresholds of 1-0, and the ordinate is the difference between TPR and FPR under different thresholds. The higher the KS value is, the stronger the distinguishing ability of the model is. However, if it is too large, there is the problem of over-fitting. It can be seen from the above figure that the KS value of the research model is 0.65, which is within the range of the ideal model and has excellent positive and negative sample differentiation ability. Although the KS value of the CS model is in the ideal state, it is 0.35 lower than the KS value of the research model. The FS model has the worst ability to distinguish positive and negative samples among the three samples, only 0.18, and has a lower prediction effect on Chinese companies. The out-of-time sample test results of the three models combined with different evaluation indicators are summarized in Table II.

TABLE II. COMPREHENSIVE TEST RESULTS OF DIFFERENT MODELS

Model	**Accuracy**	**AUC**	**Recall**	**Precision**	**AP**	**KS**	**PSI**
RS	0.859	0.896	0.785	0.422	0.641	0.6 52	0.088
CS	0.545	0.697	0.564	0.143	0.159	0.30 5	0.115
FS	0.357	0.619	0.564	0.102	0.11 5	0.18 2	0.116

From the comprehensive test results in Table II, the accuracy of the research model reaches 0.859, the accuracy of the CS model is only 0.545, and the accuracy of the FS model is only 0.357. In AUC, the research model reaches 0.896, while the AUC of CS and FS Both are lower than the research model, reaching 0.697 and 0.619 respectively. In terms of recall rate, the recall rate of the research model reaches 0.785, the recall rate of the CS model is only 0.697, and the recall rate of the FS model is only 0.619. In terms of accuracy, the two models compared in the experiment are lower than the research model, the research model reaches 0.422, the CS model is only 0.142, and the FS model is only 0.102. In the PR curve comparison, the research model has the highest AP among the three models, which is 0.641, the CS model is only 0.159, and the FS model is only 0.115. Also in the KS value comparison, the research model reached 0.652, which has a good discrimination ability, the KS value of the CS model is only 0.305, and the FS model is only 0.182. PSI measures the distribution difference between test samples and model training samples. When PSI is less than 0.1, it can be considered that the model stability is very high. When PSI is 0.1-0.2, the stability of the model is average. When PSI is greater than 0.2, the model is stable. It can be seen that the PSI of the research model is the lowest among the three models, only 0.0883, and the stability is the highest, while the PSI of the CS model and the FS model are both higher than 0.1, and the stability is average, so the research model has a strong generalization ability.

B. Practical Application and Analysis of the Model

In the practical application and analysis of the research model, the SHAP method is used to explain the research model by using the SHAP library of Python, and a real fraud case in the training set is selected for analysis and prediction. The prediction results of the research model can be visualized with a single-sample SHAP graph. In the SHAP diagram, blue indicates that the contribution of the feature is negative, and orange indicates that the contribution of the feature is positive. The longer the orange color, the higher the probability of the predicted result being fraud. The specific results are shown in Fig. 8.

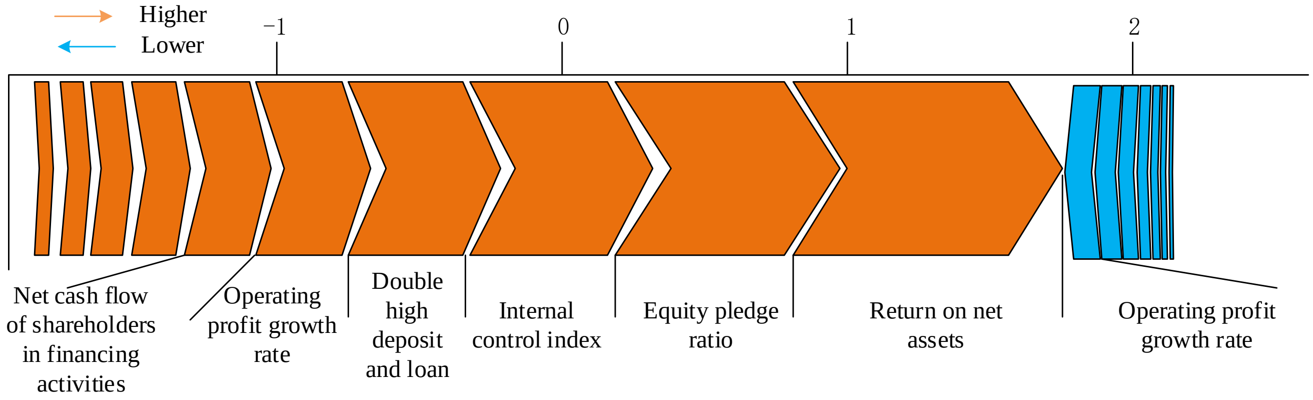


Fig. 8. SHAP chart of X enterprise’s research model forecast in 2020.

Fig. 8 shows the prediction results of the financial fraud scorecard. To improve the usability of the research and prediction model, a credit scoring mechanism is introduced into the model, and the model output is normalized through a unified scoring map to make the financial fraud risk readable. Among them, the high-risk score is ranked according to the feature contribution degree from high to low. To analyze the degree of dependence on related transactions, etc. In the prediction results of Company X in 2020, the important contributing variables are the proportion of equity pledges, internal control index, and high deposit and loan ratios, which reflect that Company X has risks in funding sources, risks in financial and accounting supervision, and abnormal business operations. The annual financial report disclosed by Company X contains major false information. First, there is a false increase in deposits. When there is a huge amount of monetary funds in the financial statements, there is a shortage of funds at the same time, and there is a phenomenon of high deposits and loans. Secondly, the forged business certificates lead to an inflated rate of return on net assets; in addition, part of the funds is transferred to the accounts of related parties for stock transactions, reflecting the illusion of a closed-loop capital flow. In addition, in terms of financial and accounting supervision, in the annual report, Company X reported that the company had major deficiencies in internal control, and its internal control audit agency maintained a negative audit opinion on the company’s internal control in 2020 [19-22].

V. CONCLUSION

With the development of the social economy, the quality of financial information in market information is more and more important to the efficiency of the market economy, but the problem of financial fraud is the most serious problem affecting the social economy. How to accurately predict financial fraud for listed companies is becoming more and more important. In this study, the integrated learning in deep learning is used to construct a risk warning model with more complete identification, more accurate and more robust, to score the financial fraud risk of listed companies, and to judge the prediction model of the company’s financial fraud possibility. The results show that the research model effectively solves the gray sample problem commonly faced when machine learning is applied to financial fraud identification research. The research model can improve the prediction effect of the model prediction. The overall accuracy rate of the research model is over 85%, and the recall rate is 78.5%. The accuracy rate reached 42%, AUC reached 0.896, the discrimination KS reached 0.652, and the model stability PSI was 0.088. Compared with the traditional financial fraud prediction models FS model and CS model, it has a higher prediction effect. In the empirical analysis, choose a certain company. The analysis of fraud cases in 2020 can effectively analyze the characteristic contribution in the fraud process and the focus of fraud risks. The research model is more suitable for the financial fraud prediction of listed companies in my country. However, in view of the availability of data, the research model does not sufficiently screen text analysis variables, there may be missing variables, and no specific analysis is carried out for the characteristics of different industries. The model also has a certain room for improvement, hoping to provide direction for future research.

Conjugate Symmetric Data Transmission Control Method based on Machine Learning

Yao Wang
Chongqing City Vocational College, College of Creative Design,
Chongqing, 402160, China

***Abstract*—In conjugate symmetric data transmission, due to insufficient judgment of congestion during transmission, the amount of data is large and the transmission rate is low. In order to improve the data transmission rate, a conjugate symmetric data transmission control method based on machine learning is designed. Firstly, the data to be transmitted is tracked and determined, and then conjugate symmetric data fusion is completed according to the calculation result of the best tracking signal. According to the fusion results, the framework of the conjugate symmetric data coding system is established, and the data coding is completed. The average congestion mark value is calculated by the machine learning method, and the congestion judgment of data transmission is completed. On the basis of congestion determination, the efficient transmission control of conjugate symmetric data is realized by specifying the conjugate symmetric data transmission protocol. Experimental results show that compared with traditional control methods, this control method has the advantages of a high delivery rate, low message transmission overhead and low data transmission delay. Compared to the traditional two-way path model, the scheduling method proposed in this study increases the transmission delivery rate by 5%, while reducing the transmission cost and delay by 0.7 cost index and 1.1 min delay, respectively. In comparison with the performance of accurate error tracking equalization, the transmission delivery rate of the research method increased by 21%, and in transmission cost index and delay analysis, it also decreased by 3.1 and 2.9 minutes. Based on the above performance comparison analysis, it can be concluded that the machine learning method has more superior transmission control performance.**

Keywords—Machine learning; conjugate symmetric data; transmission control; data coding; transmission delivery rate

I. INTRODUCTION

In the transmission process of conjugate symmetric data, the energy and storage resources of data nodes are limited, and the mobility of nodes and other practical application conditions are limited. At the same time, most of the nodes in the data transmission channel are in motion, and their physical positions often change. The data transmission link is not a very reliable wireless connection, which will also increase the difficulty of conjugate data transmission [1]. Due to the limited communication distance, low connection bandwidth, insufficient energy resources of nodes and other factors, the network connection is frequently interrupted, which cannot guarantee a constant end-to-end connection, which increases the difficulty of conjugate data transmission. At present, the research on data transmission control methods mainly includes two methods, one is based on the two-way path data transmission congestion control method, and the other is based on accurate error tracking equalization data transmission control method.

The congestion control method of data transmission based on a bidirectional path is mainly based on conjugate symmetric data transmission protocol. The congestion control mechanism can well avoid data loss caused by congestion. In this method, the connection is established through three handshakes, and then the congestion control algorithm is started. The application layer data is divided into data packets which are transmitted to the opposite end one by one. Each packet is composed of a byte sequence number and a message size, both of which are little in size. Each time the receiving terminal receives a data message, it will generate a corresponding response message to control the data transmission [2]. The data transmission control method is based on precise error tracking equalization, by constructing the historical record tracking process, adopting the way of threshold control to equalize the sensor data, and reducing the cost of fusion. Then the recursive flow is constructed to control the data transmission by packet tracking [3]. However, due to the large number of conjugate symmetric data that need to be transmitted at present, there are some problems such as transmission delay, low delivery rate and high transmission cost. Yi LA et al. used artificial bee colony algorithm to obtain the shortest path analysis of each cluster head node in the transmission of the Internet of Things. Experiments have shown that this algorithm can effectively reduce the amount of data that sensor nodes transmit to the sink through cluster head node fusion, improve data collection efficiency, energy consumption balance, and network reliability, and extend the network life cycle [4]. Mu et al. reconstructed routing problems such as the limitations of routing protocols under the condition of rapid data growth into a Markov decision process, combining deep reinforcement learning to solve the high blocking probability problem caused by increased data volume. Experiments show that this method can significantly reduce the probability of data congestion and improve network throughput [5]. In order to fully utilize multi-channel video transmission, Li H et al. proposed a joint optimization method for conversational high-definition video services, taking into account the connection between video coding and transmission. Experiments show that this method is superior to existing schemes in terms of data transmission and playback quality [6]. Pyeon D et al. proposed an efficient multipath pipeline transmission (EMP) to support low latency and high energy efficiency large data transmission under various network conditions. Experiments have shown that EMP outperforms existing protocols in terms of transmission time and energy efficiency, and can maintain improved EMP performance regardless of network environment (such as link quality, hop count, and network density) [7]. WANG Zhan Yu et al. designed a distributed communication platform based on P2P network technology to achieve concurrent path transmission on the internet. Experiments have shown that the effectiveness of this method has been verified by actual experiments on a simulation platform [8].

Therefore, a control method of conjugate symmetric data transmission based on machine learning is designed. Machine learning is an interdisciplinary subject, involving probability theory, statistics, approximation theory, convex analysis, algorithm complexity theory and other disciplines. The purpose of this paper is to study how a computer can simulate or realize human learning behavior, acquire new knowledge or skills, and reorganize the existing knowledge structure to improve its performance. Therefore, machine learning is applied to the transmission control of conjugate symmetric data. The conjugate symmetric data is used to provide some information to the learning part of the machine learning system. The machine learning part uses this information to modify the knowledge base, so as to improve the performance of the executive part of the system to complete the task. Firstly, the conjugate symmetric data are tracked, confirmed and fused, and the conjugate symmetric data coding architecture is constructed to code the data. Then, the data transmission congestion value is calculated by the machine learning method, which realizes the accurate judgment of data transmission congestion and provides the basis for the high-speed transmission of conjugate symmetric data. By formulating a conjugate symmetric data transmission protocol, the transmission control of conjugate symmetric data is realized, and the data loss caused by congestion is avoided.

This study conducted performance analysis experiments on delivery rate, transmission cost, and transmission delay for the constructed model. Firstly, the delivery rate compares the machine learning method used in this study with the traditional two-way path method and the accurate error tracking and balancing method. In the experiment, the model built in this study was in the delivery rate range of 0.76-0.83 after 6400 simulations, while the delivery rate of two-way paths was in the range of 0.77-0.71. Traditional accurate error tracking and balancing methods have the worst effect, with the highest delivery rate of only 0.52. In the second step of the experiment, the transmission cost was compared, and machine learning methods were also compared with traditional two-way path methods, as well as accurate error tracking and balancing methods. The results show that the cost index of the machine learning method is stable below 1.4, lower than other models. Finally, in the performance analysis of transmission delay, the delay of the machine learning method is controlled below 1.3 minutes, which is lower than other models. The experimental results can prove that the machine learning conjugate symmetric data transmission model constructed in this study has good transmission delivery rates, as well as excellent features such as low latency and low cost. The main purpose of this time is to provide a high-performance transmission scheduling control method for conjugate symmetric links of big data transmission. The proposed conjugate symmetric data transmission scheduling algorithm based on machine learning calculates data transmission congestion values, achieving accurate judgment of data transmission congestion. Therefore, the main contribution of this method is to simultaneously reduce information loss during transmission and increase the performance of transmitted information.

II. Conjugate Symmetric Data Fusion

Before controlling the transmission of the conjugate symmetric data, the conjugate symmetric data to be transmitted is first tracked and confirmed, because the signal strength of the conjugate symmetric data and the strength distribution proportion between the corresponding nodes need to be considered comprehensively in the node tracking. The tracking signal strength of the whole network node has a strong correlation proportion with the communication distance of the node. Therefore, by comprehensively judging the energy threshold and recursively measuring the threshold based on the intensity value, the best tracking signal can be obtained from the signal strength of other nodes. Therefore, the initial tracking of the node can be realized in this way. Assuming that the conjugate symmetric data to be transmitted is q, the preliminary tracking formula is as follows:

$$q = \frac{r}{W} / i \qquad (1)$$

In the formula, W is the joint quadratic probability function, r is the error estimation parameter, i represents the coordinates of the conjugate symmetric data nodes to be tested.

Due to the strong information interaction between the tracking node and the surrounding node, if a node is fully tracked, its tracking is related to the tracking connectivity factor of the node and the surrounding node. By comprehensively considering the tracking connectivity factor of the surrounding node and the node, the chaos inference based on the signal RF strength can effectively achieve the precision of the conjugate symmetric data node Make sure to track. Firstly, the nodes with the best energy surplus are selected as the tracking reference nodes, and the nodes to be tracked are tracked accurately through these nodes. While the nodes to be tracked are connected to other nodes through the broadcast mechanism, they are sorted according to the RF intensity threshold of other nodes. The expression is as follows:

$$y = \frac{qu}{t} * \sqrt{o} \qquad (2)$$

In the formula, t represents the maximum number of data tracking cycles of the tracking node, u is the probability that the node to be tracked can work normally at the next time, o is the coordinate accuracy of the current data to be transmitted.

On the basis of the above transmission data tracking, half of the output data in the conjugate symmetric sequence can be approximately 0. All the data to be transmitted are fused, and butterfly operation is carried out based on frequency decimation 2FFT. The two data with conjugate symmetric values are transformed into imaginary and real numbers at multiple levels, which reduces the computational complexity. The conjugate symmetric transmission data is fused by butterfly operation, and the calculation formula is as follows:

$$P = y \cdot F\left(M\right) / \frac{1}{C} \qquad (3)$$

In the formula, P represents all data to be transmitted, F represents the fusion error of the coordinates to be tracked, M represents data fusion parameters, C is the number of data traces.

According to the above process, the conjugate symmetric transmission data fusion is completed.

III. Conjugate Symmetric Data Coding

On the basis of the above-mentioned data fusion of conjugate symmetric transmission, the fused conjugate symmetric data is encoded, and the network coding technology is adopted. In order to realize the application of network coding technology in conjugate symmetric data transmission, a new strategy should be used to realize the anti-entropy transmission of data after two nodes establish a connection. Most existing link prediction studies originate from the resource transmission process of network evolution. Unfortunately, they ignore the impact of the topological stability of the structure around the path on the effectiveness of resource transmission on the path during the resource transmission process. The path topology stability in link prediction refers to the ability of the destination node to receive more resources from the originating node during resource transmission through the path. The stability of the structure around the path can reduce resource losses on the path, making both nodes receive more resources, and making both nodes more similar. The possibility of connecting edges between nodes is analyzed from the perspective of effective path topology stability. Therefore, this study will start with machine learning methods, analyze the transmission stability of conjugate symmetric data links, and conduct control optimization. First of all, we should establish the index of an encoded message rather than a simple message ID; secondly, we should increase the judgment of the value of the encoded message to ensure that the receiving node does not receive too many invalid messages, resulting in waste of storage resources and extra transmission load. The process of coding message anti-entropy transmission is shown in Fig. 1.

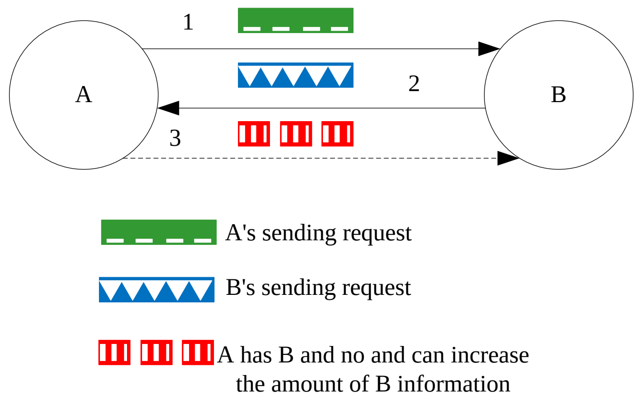

Fig. 1. Anti-entropy transmission process of encoded message.

The anti-entropy transmission process of encoded messages is shown in the figure above. When two nodes A and B establish a connection, in the first step, one node A sends the digest vector ACSV of the encoded message in its cache to another B; the second step node B performs an inverse operation on the digest vector of the encoded message in its own cache, and determines that the message is beneficial to increase the amount of information. Through the above process, the conjugate symmetric data is encoded. After the conjugated symmetric data is encoded, the amount of information contained in it differs from the source message. Multiple conjugate symmetric data encoded messages compare with multiple source messages. The amount of information is also different. The conjugate symmetric data encoding node evaluates the amount of information contained in the encoded message in its cache and determines whether it is necessary to encode a new message. This can greatly reduce the burden of node encoding calculation in the implementation of encoding. At the same time, it can avoid unnecessary "redundant" interference of encoded messages in the network, and can reduce the complexity of final decoding.

In order to evaluate the amount of information contained in the coded generation message and whether the new message contributes to the increase in the amount of information in the coded generation, it is proposed to use the concept of redundancy to characterize the number of coded sources messages and the number of generated coded messages in the coded generation. The relationship between them, and through this relationship to determine whether the newly received message can increase the amount of information in the current encoding generation, thereby determining whether it is necessary to encode the information, which can increase the effectiveness of the encoding result. From the perspective of whether the message in the encoding generation is sufficient to decode, consider the relationship between the dimension of the encoding generation (the number of messages in the generation) and the number of source messages (the number of messages originally generated in the encoded message contained in the generation before the encoding). The redundancy of an encoding generation is defined as the ratio between the dimension of the encoding generation and the number of source messages, and the calculation formula is:

$$w = P\frac{S}{D+Z} \quad (4)$$

In the formula, w represents the relationship between the number of initially generated and the number of messages contained in the encoded message, D represents the redundancy of an encoding generation, Z represents the number of messages, S represents the number of copies.

Redundancy can represent the relationship between the number of dimensions in a coding generation and the number of source messages. It can control the number of effective copies of messages in a coding generation. From a mathematical point of view, it is the relationship between the number of equations and the number of unknowns in a multivariate linear system. Mathematically, if the individual equations in the system of equations are linearly independent, only the unknown number of equations can be used to solve all the unknowns; and in the delay-tolerant network with network coding, the message is encoded through multiple paths. Sent to the target node, on one of the paths, the intermediate node does not need to obtain enough messages to reach the decodable condition. On the other hand, the message is stored with a new id after encoding. Under the infection routing strategy, another node will request this new message after seeing the message with this new id. Degree control can solve this problem. In order to realize the application of the network coding technology, this paper refers to the implementation method of the constrained protocol, and proposes an implementation method of inserting the "network coding layer" as the "overlay layer" between the application layer and the transmission layer. The framework of the conjugate symmetric data encoding system is shown in Fig. 2.

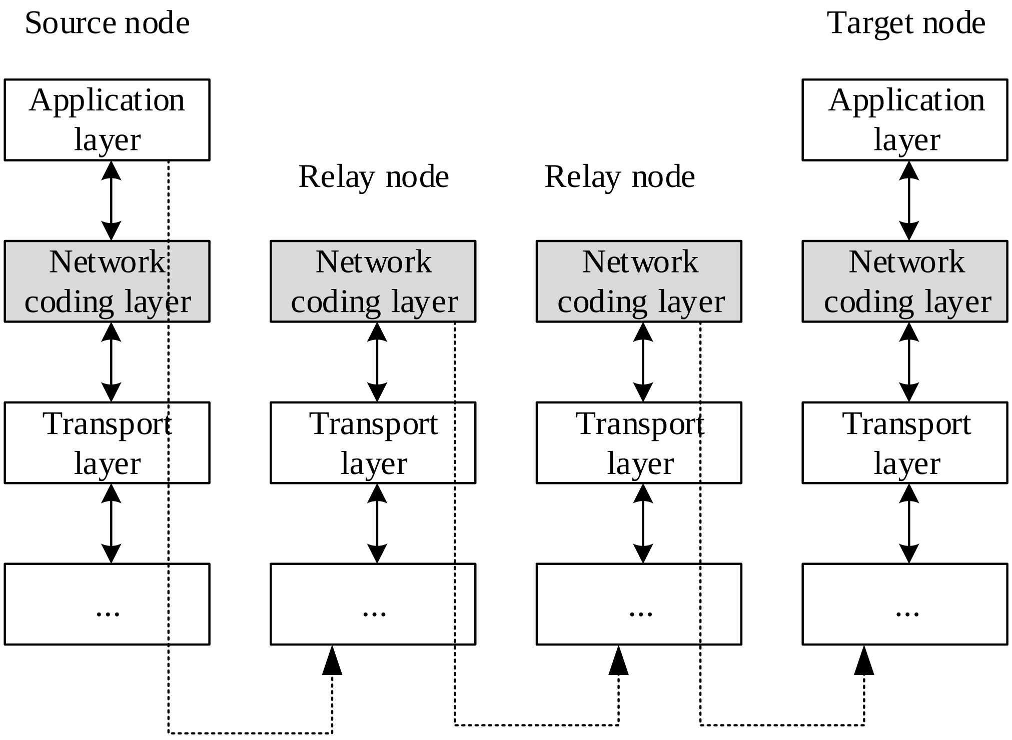

Fig. 2. Framework of conjugate symmetric data encoding system.

Regardless of the heterogeneous network environment, the relay node only needs to consider the transmission layer of a single mode, and does not need to consider compatibility with multiple network structures. For the source node, the conjugate symmetric data generated by the application layer is sent to the network coding layer. The network coding layer encodes the conjugate symmetric data and hands it to the bottom layer to complete the data transmission. The relay node uploads the message to the network coding layer after receiving the message. The network coding layer stores the message and encodes the conjugate symmetric data at the appropriate time. The network coding layer judges whether the remaining space of the current coding matrix is greater than zero when it receives the data packet sent to the receiving end by the transmission control protocol TCP layer. If so, it puts the data packet into the current coding matrix and performs linear coding to generate a linear-coded combined packet. The header of the combined packet includes the coefficient of this linear coding, the index number of the coding matrix and the serial number of the data packet. When the current node establishes a connection with other nodes, the encoded message is handed over to the bottom layer to complete the transmission of the conjugate symmetric data encoded data. The receiving node is the target node of the message. After receiving the encoded message, the network encoding layer of the target node stores the message in the local cache and uploads the successfully decoded message to the application layer to complete the encoding of conjugate symmetric data.

IV. Congestion Determination of Conjugate Symmetric Data Transmission Channel based on Machine Learning

Based on the above data fusion and data coding, machine learning methods are used to determine the congestion of the conjugate symmetric data transmission channel. In the research of multi-rate congestion control mechanisms, a key question is how to judge the current transmission path congestion [9].

Random early detection is performed first. Early detection means that the router detects congestion by monitoring the average queue length of the output queue. When congestion is found to be approaching, it randomly discards the data packets arriving at the queue to indicate that the terminal is congested and causes the source to overflow the queue the sending rate was reduced before to ease network congestion. The expression of random early detection is:

$$J = w\sqrt{e}\,/\,q + b \qquad (5)$$

In the formula, e represents the probability of dropping the packet, q represents the weight of the current queue length, b represents the actual queue length when sampling and measuring.

Through early detection, "filter" out the short-term queue length changes caused by data bursts, and try to reflect the long-term congestion. The relationship between drop probability and average queue length is shown in Fig. 3.

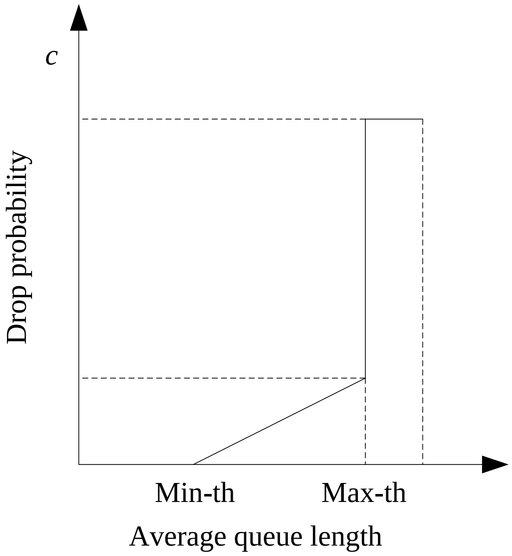

Fig. 3. Relationship between drop probability and average queue length.

In Fig. 3, c represents the probability of packet loss, and Min-th and Max-th respectively represent the thresholds related to queue length.

According to the relationship between the obtained drop probability and the average queue length, a deep learning algorithm is used to calculate the initial judgment weight:

$$\alpha = \frac{1}{2}\ln\left(\frac{1-\varepsilon}{\varepsilon}\right)J \qquad (6)$$

In the formula, ε represents the normalized judgment factor.

The calculation formula for weight update is:

$$conf\,(i) = \sum_{i=1}^{I} \alpha\gamma(i) \qquad (7)$$

In the formula, $\gamma(i)$ represents the weight update training function.

On this basis, the available bandwidth is estimated. In multi-rate congestion control, each receiver needs to determine whether the current subscription level conforms to the available bandwidth of the transmission path, so estimating the available bandwidth is an important part of multi-rate congestion control. For the congestion mark statistical value marking, the receiving end only counts the congestion mark values collected in the synchronization interval after receiving the synchronization mark packet, considering that the mark value carried by the recent packet can better reflect the current network congestion status, So a machine learning algorithm is used to calculate the average congestion marker value, First, calculate the window value decline ratio. When packet loss occurs in congestion, three repeated ACK are received continuously, and the window threshold will drop by a certain ratio. Different congestion algorithms adopt different ratios, for example, RENO is 0.5, while CUBIC is 0.8. According to the ratio of congestion window values before and after the packet loss point, the window value reduction ratio can be determined. Then calculate the congestion avoidance window growth function. In the stage of congestion avoidance, for the functional characteristics of window growth, the difference between the window values at two-time points in this stage and the starting point window value in the stage of congestion avoidance is used, and the relative value is used to express the function curve characteristics in this stage. Then, the fast recovery window growth function is calculated. In the fast recovery stage, when the server receives three DUPACK in succession, different algorithms process differently, such as waiting for retransmission after the timeout, or constantly increasing the window value until the retransmitted packet is received. In this paper, this feature is expressed by the difference between the window value and the starting point value at a certain time point in this stage. As shown in the following formula:

$$k\left(a\right) = conf\,(i)\left(1-d\right) * R \qquad (8)$$

In the formula, $k\left(a\right)$ represents the congestion mark value carried by the a packet, d represents the statistical value of the congestion mark, R represents the weight of the congestion mark value carried by the packet. When the statistics are completed, the congestion mark value collected in the synchronization interval is cleared to avoid interference with the statistics of the next synchronization period [10].

Determine the transmission channel congestion according to the average congestion flag value obtained. When $k(a) > 0$, it means that the transmission channel is in a congested state. When $k(a) < 0$, it means that the transmission channel is in a non-congested state. When $k(a) = 0$, it means that the transmission channel at this time is just saturated.

V. Formulation of Conjugate Symmetric Data Transmission Protocol

Because the data collected by the transmission data itself has high redundancy, the direct communication between the single node and the cluster head in the cluster has little effect on the reliability of the data communication of the entire network, and consumes a lot of resources to maintain the data collected by the node is not worth the gains. Due to the limited communication range of the conjugate symmetric data cluster head, the cluster head can only forward the request message to the base station through the adjacent cluster head. This data packet can record the node information traversed during the forwarding process and the reception at each node for signal strength parameters, when the data packet reaches the base station, the base station analyzes and calculates the information recorded in the data packet to perform path generation. Convert all the data request messages that need to be transmitted, the expression is:

$$L = \beta / I + \frac{\lambda}{O} k(a) \quad (9)$$

In the formula, β represents the set of the head node and base station node of the transmission data cluster, I is the set of communication links between any two transmission data cluster heads, which can also be considered as the edge set corresponding to the node set, O is the signal strength received by the node, λ A is the transmitted signal strength of the parent node when forwarding the packet, the signal strength is related to the transmission power and the communication distance.

In order to maximize the multi-path routing from a node to the base station, the idea of breadth-first algorithm is applied in the path generation process. The algorithm process is as follows:

step1: Initialization, input all cluster head and base station node sets into the transmission data set;

step2: Calculate the number of all neighbor nodes of this node;

step3: If the number of neighbor nodes is empty, go to step1, otherwise go to the next step;

step4: Input all neighbor nodes into the set to make the following judgment: if there is a node and it is the same as the parent node of the input node, delete it; if there is a node and the energy has been excessively consumed, delete it; if there is a node Export the path.

The above process generates a transmission path, but due to the limitation of the transmission channel energy, the stored energy is also limited, and the output power of the sensor node increases exponentially with the increase of wireless coverage. At the same end-to-end distance, if each link uses limited transmission power, the power consumption of multi-link transmission is lower than the power consumption of directly transmitting information on a long link. In order to verify the survival time of the entire transmission channel, the multi-hop method is used when the long-distance transmission is required.

Based on the above analysis, the conjugate symmetric data transmission path is optimized. In the actual data transmission process, the energy consumption between the same distance and different links will be different due to the influence of objective factors, so energy-based the path optimization method adds transmission consumption weights to each link, so that the network can better integrate with the objective environment in which it is located, thereby better improving the reliability of data transmission [11-14]. The transmission consumption weight matrix is as follows:

$$H = \sqrt{L} * \frac{x}{K} \quad (10)$$

In the formula, K represents the set of transmission link, x represents the number of nodes transmitted in conjugate symmetric data.

It is also known that the relationship between energy consumption and communication distance during data transmission is:

$$U = \frac{i}{I} / \frac{l}{H} \quad (11)$$

In the formula, l represents the signal attenuation coefficient.

Combining the above two formulas, a link energy consumption matrix consisting of transmission energy on the corresponding link is obtained:

$$T = z(V) / n \quad (12)$$

In the formula, T represents the transmission energy consumption, z represents the signal strength parameter, V represents the transmission consumption weights, n represents the number of nodes.

Calculate and sequence the energy consumption of all available paths, and the transmission path with the lowest energy consumption is taken as the optimal path, followed by the other paths. If there are paths with equal transmission energy consumption, they are sorted according to the sum of the consumption weights of the entire path. The smaller T is, the better the transmission environment is, that is, the higher the transmission reliability, so the higher the priority of this path.

Through the above process, the route optimization is completed. Since the data transmission workload undertaken by each cluster head is different, the data transmission workload of the cluster head close to the base station is much larger than the workload of the cluster head far from the base station, so the network the energy consumption rate of the cluster head is different. At the same time, because the network will consume a large amount of node energy consumption and generate a large number of redundant data packets during large-scale reselection, frequent reselection requires a lot of networks running time. The efficiency of the network in collecting and transmitting data is reduced, so multi-path updates and transaction processing are required in time. The remaining energy of the cluster head is low, and it cannot continue to assume the current role. The number of nodes in the area under the jurisdiction of the cluster head is exhausted. In order to facilitate routing updates and effectively handle network transactions, the following standards are set. Ordinary nodes indicate to the cluster head that their remaining energy is below the threshold and cannot continue to work. Calculate the total number of energy-depleted nodes at the same time as the base station, and then perform data transmission [15-20].

VI. Experimental Comparison

In order to verify the application performance of the proposed conjugate symmetric data transmission control method based on machine learning, a comparative experiment was carried out. This experiment was carried out on the ONE simulation platform. The ONE simulation platform is a very widely used simulator in tolerant network simulation. It can effectively simulate the routing and transmission of messages in the tolerant network and give detailed results reports. In addition to generating statistical message status reports and node connection status reports after the simulation is completed, it also supports separate reports on message generation, relaying, successful transmission, abnormal interruption, and connection time between nodes. The experimental platform is graphical. The real-time monitoring and event display interface are shown in Fig. 4.

The main parameter settings of the simulated scene are shown in Table I.

Error	1:52:16 PM	hv02.demo.veeam.local		Failed to load VM configuration	2

Alarm details

Description

Fired by event: 16300 Microsoft-Windows-Hyper-V-VMMS
Event description: Cannot load a virtual machine configuration: The system cannot find the path specified. (0x80070003)
(Virtual machine ID 46BEA23C-5C55-4F37-8C0B-16606D40E93C)
Initiated by: NT AUTHORITY\SYSTEM

Knowledge

Cannot load a virtual machine configuration.

Cause

Virtual machine configuration file is set with incorrect parameters or VMMS service cannot access it.

Resolution

Ensure that the virtual machine configuration file is set with the right parameters. Additionally, ensure that the configuration file has the right permissions set so that the VMMS service can access it. Then, retry the operation that failed.

TABLE I. MAIN PARAMETER SETTINGS OF EXPERIMENTAL SIMULATION SCENARIOS

Classification	Main content	Specification
Simulation scene	Simulation space size	5000 m×5000 m
	Number of nodes	20
	Data transfer model	Infection routing/NTC
	Nodal motion model	Random Way Point
Common node parameters	Movement speed	Random change between5m/s-10m/s
	Communication bandwidth	2Mbps
	Cache size	5M
	Communication distance	100 m
Message parameters	Size	500K–1M
	Number	200
	Production methods	Randomly generated within 1000 seconds
Datasets	IMDBDatasets	52.4MB

The experimental environment configuration for this study is as follows: The experiment was completed using the MATLAB platform, with a running memory of 16g, a computer operating system of WIN10, and a CPU of AMD Ryzen 7 4800U. The following points need to be explained about the parameter setting:

First: 20 nodes are evenly distributed and randomly move in a 5000m×5000m plane space. The communication distance of the nodes is 100m, so the network connection rate is low and belongs to sparse network.

Second: Only when the two nodes reach the communication distance of each other can the connection be established, and then the information exchange can be carried out.

Third: It is convenient for comparative analysis. The message event adopts a fixed configuration, and 200 unicast messages are randomly generated in 1000 seconds with a tool in advance. Each node has 10 messages sent to other nodes. The messages are random sizes of 500K to 1M. Since the node cache is only 5M, the network load is heavy.

A. Evaluation Index of Conjugate Symmetrical Data Transmission

The experimental comparison methods are the conjugate symmetric data transmission control method based on machine learning, the data transmission congestion control method based on the bidirectional path and the data transmission control method based on accurate error tracking equalization. From the perspective of the message delivery rate, three indicators are used to measure the data transmission effect of the tolerant network, including the message delivery rate, message transmission overhead, and average message transmission delay.

The delivery rate refers to the ratio of the number of successfully delivered messages to the total number of messages generated by the network. The expression is:

$$deliverRatio = \frac{N}{E} \quad (13)$$

In the formula, E represents the total number of messages generated in the experiment, N represents the number of successfully delivered messages.

In the case of multiple copies, the number of the same message is recorded as 1, regardless of the number of copies. The delivery rate indicates how many messages can be sent by the entire delay-tolerant network, and can measure the network data transmission capability. Increasing this value is the main goal of the delay-tolerant network data transmission problem.

Transmission overhead refers to the ratio of the total number of message transmissions in the network to the number of successfully transmitted messages. The expression is:

$$deliverOverhead = \frac{n_i}{\partial} \quad (14)$$

In the formula, $deliverOverhead$ represents the transmission overhead, ∂ represents the number of successfully transmitted messages, n_i represents how many times the message i has been transmitted during the transmission process. In the case of multiple copies, the transmission of each message copy must be included.

The average transmission delay represents the statistical average of the transmission delays of all successfully transmitted messages. The expression is:

$$AverageDelay = \frac{\varphi}{t_Q} \quad (15)$$

In the formula, t_Q represents the transmission delay of the message, φ represents a successfully transmitted message. The average transmission delay is a statistical average value that characterizes the efficiency of the network to transmit messages.

B. Delivery Rate Comparison

The results of the three methods of delivery rate comparison are as Fig. 5.

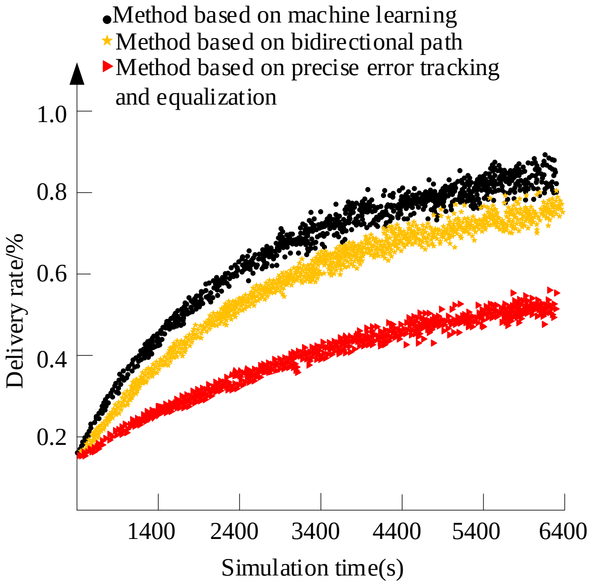

Fig. 5. Delivery rate comparison results.

It can be seen from the above figure that the application of conjugate symmetric data transmission control method based on machine learning to data transmission is beneficial to improve the delivery rate of the message, because the method designed this time applies the encoding technology to encode the transmission rate of the transmission data. It is very close to the infection route, and sometimes even lower than the infection route. This is mainly because the target node has not collected enough messages to complete the decoding when the time is short, which shows that the delivery rate is slightly lower; when the simulation reaches a certain time, the delivery rate of the method no longer changes significantly with time. At this time, the target node can decode the source message with a sufficient number of encoded messages. Therefore, as the time continues to increase, the message delivery rate in the strategy of applying network encoding continues to increase. The delivery rate of the traditional data transmission congestion control method based on the two-way path and the data transmission control method based on accurate error tracking equalization is lower than the method designed this time, mainly because the traditional method cannot store more information. Even if there is a connection opportunity between the nodes of the transmission network, more messages cannot be transmitted, thereby reducing the data delivery rate.

C. Transmission Cost Comparison

The transmission cost comparison results of the conjugate symmetric data transmission control method based on machine learning, the data transmission congestion control method based on the bidirectional path and the data transmission control method based on accurate error tracking equalization are as Fig. 6.

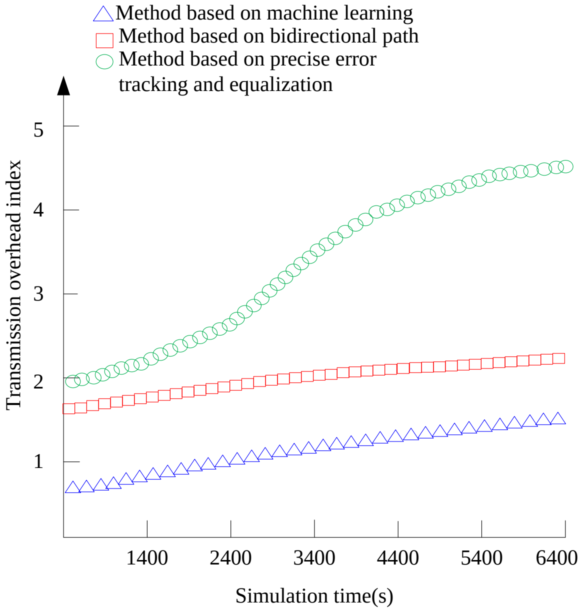

Fig. 6. Comparison of transmission overhead.

As can be seen from the above figure, from the comparison of the transmission costs of the three methods, in the initial data transmission, the transmission overhead of the three methods is lower, and as the time increases and the number of messages increases, the messages transmitted between the nodes also change. However, the message transmission overhead is closely related to the number of network transmissions. Therefore, in the later stage of simulation, the message transmission overhead becomes very large. However, it can be seen from the comparison that the transmission cost of the traditional two methods is much higher than the proposed method.

D. Comparison of Average Propagation Delay

The comparison results of the data transmission congestion control method based on the bidirectional path and the data transmission control method based on accurate error tracking equalization and the conjugate symmetric data transmission control method based on machine learning designed this time are shown in Fig. 7:

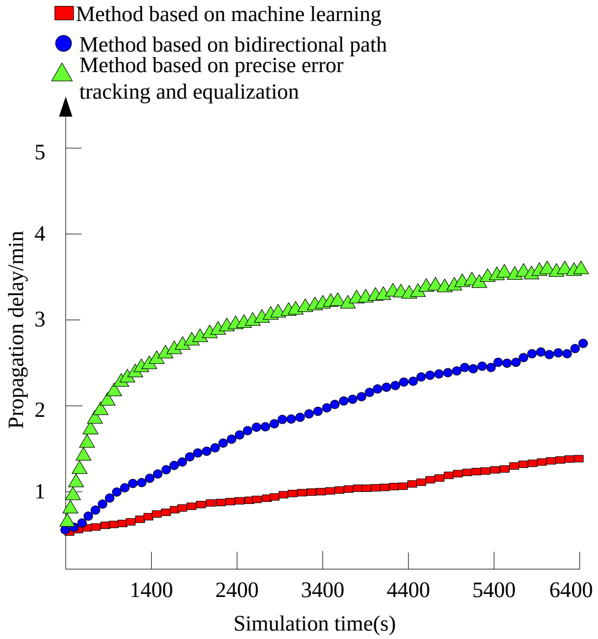

Fig. 7. Comparison of average transmission delay.

It can be seen from the above transmission delay curve that the transmission delay of the data transmission congestion control method based on the bidirectional path and the data transmission control method based on accurate error tracking equalization are higher than the transmission method designed this time. The reason for the low transmission delay of this design method is that the designed method can identify the congestion degree of the transmission channel and can encode the data, thereby improving the transmission efficiency of the message.

VII. Conclusion

In conjugate symmetric data transmission, the transmission path will be congested when the amount of transmitted data is large. This paper studies a conjugate symmetric data transmission control method based on machine learning, which tracks the target data, fuses conjugate symmetric data according to the calculation result of the best tracking signal, encodes the data, calculates the average congestion mark value by machine learning, and judges the congestion of data transmission. Transmission control of conjugate symmetric data is realized by transmission protocol. Experimental results show that the proposed method has low transmission cost, low transmission overhead and short transmission delay. The research method can identify the congestion degree of transmission channel and realize the efficient transmission of conjugate symmetric data.

The research on conjugate symmetric data transmission control is still in its preliminary stage, and there is still much work to be discussed and carried out. Further work mainly includes:

First: In the current congestion control algorithm based on asymmetric links, the fairness of data packets in bidirectional data transmission is still a problem that needs further research.

Second: Establish a reasonable data transmission model to theoretically analyze the characteristics of data transmission between nodes. The movement of nodes in the network is very random, and the connections between nodes are also opportunistic. The modelling of the entire network is very complicated, but the data transmission model between nodes can be mathematically modeled using random processes and probability theory, the mathematical description of the problem, and then theoretically evaluate the data transmission.

Third: Study the security problem of data transmission based on network coding. The transmission mechanism of this study is only applicable to the process of node "storing-carrying-forwarding" messages. It fails to consider how to ensure the security of messages in data transmission using network coding technology Transmission problems. If malicious messages are involved in the encoding, all subsequent encoded messages based on this message will carry the malicious message information. The spread of such malicious messages poses challenges to the security requirements of system data integrity. The security mechanism should contain guarantee mechanisms against such attacks.

Fourth: In-depth study of the problem of code generation management using network coding in the Rongchi network. Separate airspace coding is the preferred organization strategy when the network is small in scale, short in running time, and has few message events. However, when the large-scale network runs for a long time and there are many message events, it will bring about the problem of expansion of the coding generation space, so you need to consider "Time domain" encoding. That is, when the coding generation is divided, the message is divided into different generations according to a certain period of time. Although the time-domain coding is simple and looks like the superposition of several spatial coding processes, there are many problems that are very different from the simple superposition analysis, especially the problems of cache management and message receipt caused by multiple time-domain coding generations. The time-domain coding of messages also needs further study.

Towards Finding the Impact of Deep Learning in Educational Time Series Datasets – A Systematic Literature Review

Vanitha.S[1], Jayashree.R[2*]
Department of Computer Applications-College of Science and Humanities,
SRM Institute of Science and Technology, Kattankulathur, Tamilnadu, India

***Abstract*—Besides teaching in the education system, instructors do a bunch of background processes such as preparing study material, question paper setting, managing attendance, log book entry, student assessment, and the result analysis of the class. Moreover, Learning Management System(LMS) is mandatory if the course is online. The Massive Open Online Course (MOOC) is an example of the worldwide online education system. Nowadays, educators are using Google to efficiently formulate study material, question papers, and especially for self-preparation. Also, student assessment and result analysis tools are available to get instant results by feeding student data. Artificial Intelligence (AI) is driving behind these applications to deliver the most precise outcome. To accomplish that, AI requires historical data to train the model, and this sequential (year-wise, month-wise, etc) information is called time series data. This Systematic Literature Review (SLR) is conducted to find the contribution of time series algorithms in Education. There are enormous changes in algorithm architecture analogized to the traditional neural network to endure all kinds of data. Though it significantly raises the performance, it expands the complexity, resources, and execution time as well. Due to this, comprehending the algorithm architecture and the method of the execution process is a challenging phase before creating the model. But it is essential to have enough knowledge to select the suitable technique for the right solution. The first part reviews the time series problems in educational datasets using Deep Learning(DL). The second part describes the architecture of the time series model, such as the Recurrent Neural Network (RNN) and its variants called Long-Short Term Memory (LSTM) and Gated Recurrent Unit (GRU), the differences between each other, and the classification of performance metrics. Finally, the factors affecting the time series model accuracy and the significance of this work are summarized to incite the people who desire to initiate the research in educational time series problems.**

Keywords*—Deep learning; education; gated recurrent unit; long-short term memory; recurrent neural network; time series

ABBREVIATIONS

SLR	Systematic Literature Review
PRISMA	Preferred Reporting Items for Systematic Review and Meta-Analyses
LMS	Learning Management System
MOOC	Massive Open Online Courses
CNN	Convolutional Neural Network
AE	Auto Encoder
DBN	Deep Belief Network
GAN	Generative Adversarial Network
DRL	Deep Reinforcement Learning
FFNN	Feed Forward Neural Network
MLP	Multi Layer Perceptron
ERNN	Elman Recurrent Neural Network

TCN	Temporal Convolutional Network
LR	Linear Regression
NB	Naive Bayes
SVM	Support Vector Machine
DT	Decision Tree
RF	Random Forest
GBM	Gradient Boosting Machine
AUC	Area Under Curve
ADAM	Adaptive Moment Optimization algorithms
SGD	Stochastic Gradient Descent
SMOTE	Synthetic Minority Oversampling Technique
HMM	Hidden Markov Model

I. INTRODUCTION

Human education assists in automating massive work with less intervention of human resources. That education system itself automated with the help of AI. Machine Learning is a subset of AI. Likewise, Deep Learning (DL) is a division of broader machine learning based on the Neural Network (NN) designed to mimic the human brain. DL is becoming an imperative buzzword in data handling technology due to the potential of prediction using extensive data. However, the prediction system was enlightened only after the innovation of RNN. The RNN is chosen for this study due to its architecture to operate on sequential nature data. For example, Predicting learner dropout rate in MOOC using LMS interaction data (user click events, weekly assignments, etc). All educational institutions switched online to continue the classes during the corona lockdown period. Many online courses started and then boomed. The MOOC is one of the popular platforms for online education. But, the course completion rate is significantly lower than the number of registration due to being free of cost. RNN helps to predict the success and dropout rate of MOOC learners. RNN applications are unrestricted in all the fields, such as finance [1], [2], medicine [3], [4], [13], and nature-related forecasts, such as weather, rainfall, temperature, and wind speed [5]-[8]. Also, enough surveys are available to enrich the existing work on those domains. But in education, reviews still need to be conducted

*Corresponding Author, jayashrr@srmist.edu.in

to find the related work in sequential data collectively. Hernández et al.,[21] did the same job, but that did not focus on time series. This work fills this research gap with the time series model architecture, the difference from the conventional neural network, and the parameters influencing the model performance. The following are the research questions identified for this work:

RQ1: Finding the impact of Deep Learning in educational time series problem.

RQ2: Identify the architecture of time series model and how it differs from the traditional approach.

RQ3:Discover the significant factors affecting the time series model accuracy.

The remaining paper encloses five sections. Section II defines the methodology of this work, and Section III describes the review results including previous work using the deep learning model,working methodology of RNN, LSTM, and GRU, and metrics used for the model. Section IV outlines the contribution of this paper through discussion. Finally, Section V explains the conclusion and future work of this article.

II. Research Methodology

This section elucidates the research methodology followed in carrying out this review process and the filtration of the downloaded papers. The following research repositories are accessed: Google Scholar and IEEE Xplore. The keyword used for this work is the following: "Deep Learning", "RNN", “Time Series", "Student”, and “Education”. The google search result showed many research papers, and all are evaluated manually to select the suited one for this work. The selection process considers the journal articles using time series data in Education and valid conference papers. The inclusion and exclusion criteria of this study is mentioned in Table I.

The article selection process followed the PRISMA method to carry out this study. PRISMA is an abbreviation of the "Preferred Reporting Items for Systematic Review and Meta-Analyses". Fig. 1 explains the step-by-step article inclusion and elimination details through PRISMA 2020 flowchart.

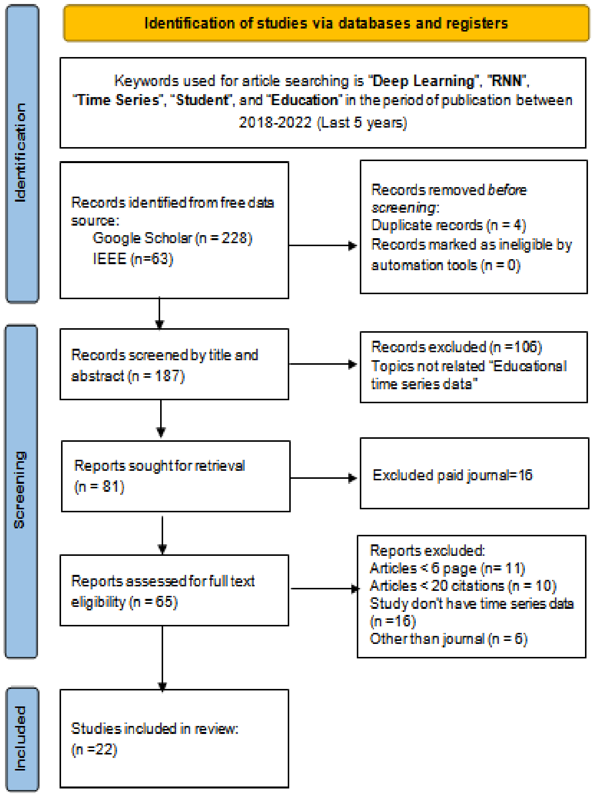
1) Identification: The initial search retrieved two hundred and ninety-one (n= 291) documents from Google scholar and the IEEE database. The filter is applied for the last five years (2018-2022) to restrict the search before 2018 and after 2022. Then removed, four duplicate records from various databases.

2) Screening: There are two screening steps to check the paper's eligibility. i) Preliminary check ii) Full-text analysis. Step 1 investigates the title and abstract to verify the document's relevance. It removed one hundred-six (n=106) reports and included eighty-one (n=81) articles for full-text retrieval. Then sixteen (n=16) documents are eliminated due to paid version. Step 2 inquiry prevents invalid articles, conferences, and other documents irrelevant to this context.

3) Included: The previous stage gives twenty-two reports (n=22), and the selected articles are used as a source for this Systematic Literature Review(SLR) or meta-analysis.

TABLE I. Selection and Rejection Criteria of the Study

Criteria	Inclusion	Exclusion
Year	Documents published between 2018 to 2022	Documents published before 2018 and after 2022
Language	Articles in English	Other language articles
Domain & Data	Educational time-series documents	Other domains and the data which are not using time-series
Article type	Journal and conference	- Articles less than 6 pages - Articles having less than 20 citation
Algorithm	Deep Learning	Machine Learning



Identification
Screening
Included
Identification of studies via databases and registers
Keywords used for article searching is "Deep Learning", "RNN", "Time Series", "Student", and "Education" in the period of publication between 2018-2022 (Last 5 years)
Records identified from free data source:
Google Scholar (n = 228)
IEEE (n=63)
Records removed before screening:
Duplicate records (n = 4)
Records marked as ineligible by automation tools (n = 0)
Records screened by title and abstract (n = 187)
Records excluded (n =106)
Topics not related "Educational time series data"
Reports sought for retrieval (n = 81)
Excluded paid journal=16
Reports assessed for full text eligibility (n = 65)
Reports excluded:
Articles < 6 page (n= 11)
Articles < 20 citations (n = 10)
Study don't have time series data (n =16)
Other than journal (n = 6)
Studies included in review: (n =22)

Fig. 1. PRISMA 2020 flow diagram of the study.

III. Results

This section describe the review results obtained through previous section. Fig. 2. depicts the publisher's contribution to this topic. It shows that most well-known publishers are involved, but springer published more articles than others.

Fig. 3. explains the number of publications year-wise. It depicted the growing trend from 2018 to 2021 and decreased in 2022. Due to corona, online education peaked in 2021, and most of the research was conducted on various dimensions using vast online data such as MOOC and other LMS platform.

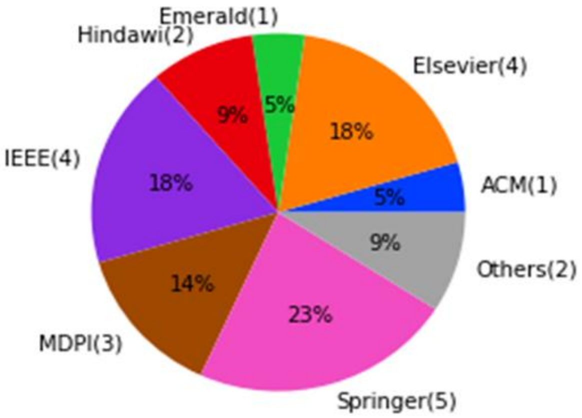


Fig. 2. Publisher contribution.

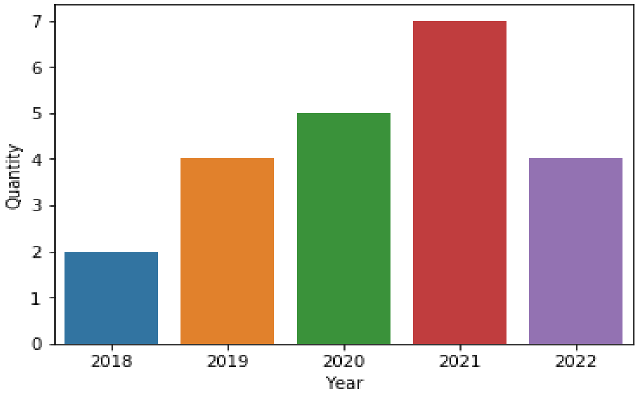

Fig. 3. Year wise publication.

A. Contribution of Deep Learning in Educational Time Series Data

Wang et al.,[24] proposed two novel methods to predict student learning status. The first one is to retrieve compelling features and performance using Conv-GRU. The second one, xNN (Explainable Neural Network) explains the relevance of student positive/negative results to improve the weak area. This approach helps to identify the hidden pattern of student behavior and early notification to improve the particular section.

Waheed et al., used the same dataset (OULAD) in both of their papers [25, 29], but followed different methodologies to predict the student category. The first work gives the highest accuracy (93%) than the second using DNN(84%), with a notable difference. The deep neural network(DNN) proves its power by providing the highest accuracy. Mubarak et al., [26] predict learner's weekly performance using video click stream for timely intervention. This model is created in such a way that it can adjust a variable window length routinely, which helps it to fit the RNN layer dimensions with different sizes of input data.

In studies [27, 28, 39, 42], all the authors used the same dataset (KDD cup 2015) to predict student dropout, and the result shows above 85% performance in all. It contains 39 courses and seven kinds of student behavioral information such as Access, video, wiki, discussion, navigate, page_close and problem. These multiple parameters allow applying a multi-variate time series approach. Though the dataset is the same, imbalanced data is handled only in [28, 39].

Zhang et al., [30] introduced a predictive model to pick the micro-level pattern from student learning behavior. To avoid data sparsity, the author divides the data into five clusters based on the nature of the student's learning behavior. Because, the author believes that every student's online learning behavior will change depending on their free time. An auto-encoder is used to encode time-series data. The significant difference between recall and accuracy values shows that classification errors need to fix in this model.

He and Gao [31] proposed a student performance predictive model by collecting student learning behavior information through terminal data acquisition tools to find the student concentration level in the classroom and explore the influencing factors of learning concentration. Aljaloud [32] suggested a model to predict student learning outcomes by selecting the number of essential features and evaluating the result by reducing the number of features. There are seven features(f1,f2,f3,f4,f5,f6,f7) and seven courses used in this LMS, and the final result shows the best accuracy in the more number of attribute combination.

Chen et al., [33] created an intelligent framework to handle imbalanced datasets and spatiotemporal information. This LMS contains eight learning features (F1-F8): assignment, file, forum, homepage, label, page, quiz, and URL. Course length is 16 weeks, but this model helps to warn the at-risk students much earlier than other models with higher accuracy.

Karim et al., [34] conducted ablation tests on time series data using LSTM. In this experiment the LSTM block is substituted by other techniques such as GRU, RNN, and Dense block. But LSTM-FCN performance was higher than others.

Chen et al., [35] provided a comparative study between deep learning and conventional machine learning using the data retrieved from the Learning Management System (LMS). This data tells the temporal behavior of the student activity in the form of time series. The author used classification and clustering techniques to predict early identification of at-risk students, and then compared the results using AUC.

Li et al., [36] also did a comparative study using higher education data such as student grades and levels to predict the performance. Prabowo et al., [37] tried dual input, the combination of categorical and numerical time series data. The proposed dual-input hybrid model combines MLP and LSTM networks and then compares the perrmance with the individual model.

Asish et al., [38] offered a comparative study using CNN, LSTM, and CNN-LSTM to classify the student distraction level using eye gaze data. The author collected the data through a Virtual Reality Environment. Wuet al., [39] proposed a hybrid model called CNN-Net to predict student dropout in MOOCs. Moreover, the author handled the class imbalance due to the massive dropout ratio of students.

Shin et al., [40] created a model to predict student performance using time series data by clustering the students using the k-shape technique. Each cluster helps to identify the student category to give a warning from the instructors. Bousnguar et al., [41] proposed a model for enrolment prediction using LSTM and statistical machine learning. The statistical model gives the highest accuracy than deep learning due to the insufficient data for training.

Qiu et al., [42] developed a model for dropout prediction using CNN. The author compares the results with baseline models, including LR, Naïve Bayes, Decision Tree, Random Forest, Gradient Tree Boosting, and SVM. Among those, CNN with windows size 10 showed better results than the others. Chen et al., [43] created a model for predicting course performance using an imbalanced dataset. The SMOTE sampling technique is applied to balance the minority data.The author used the KNN algorithm to fill in the arbitrary missing values.

Aljohani et al., [44] proposed a model to find the at-risk student in the early stage based on weekly performance sequence data. But it achieved the highest accuracy only after 38 weeks. He et al., [45] suggested a model for student performance prediction. The author used two fully connected neural networks for demographic information; RNN for handling student assessment and click stream time series data. The proposed method provided better performance than the baseline models.

Tables II provides the vital points of this review and Fig. 4 represent the classification of time series use case and workflow found in this review.

TABLE II. REVIEWS OF PREVIOUS WORK IN EDUCATIONAL TIME SERIES DATA

Source	Model	Dataset	Samples/Train-Test	Purpose/Findings	Individuality
[24]	ML, BPNN, RNN, GRU,LSTM, Conv-GRU-MaxP, Conv-GRU-AvgP	WorldUC, Liru Online Course Dataset	Datasets 1 - 7543 students, Dataset 2 - 347 students	Predictive model for student performance ML-75%, BPNN-76%, RNN-78%,LSTM-80%, GRU-81.3%, Conv-GRU-MaxP-81.8%, Conv-GRU-AvgP-82.2%	Weighted average pooling is used instead of max pooling in Conv-GRU to achive better performance.
[25]	LR,SVM,Deep ANN	Open University Learning Analytics Dataset (OULAD)	2014-2015 32,593 student log records. 70% - train 30% - test	The inclusion of legacy data and assessment-related data impact the model significantly. LR-85%, SVM - 89%, Deep ANN - 93%.	Instead of week- wise, at-risk students are identified in each quarter Q1,Q2,Q3, and Q4 along with distinction, pass, fail and withdrawal.
[26]	LR, SVM, Deep ANN, LSTM	MOOC - Stanford University Dataset	Student records for each dataset. course 1 - 5346 course 2 - 2135 course 3 - 3022 course 4- 2497 60%- training 30%- testing 10% - validation	Predicting learner performance and early dropout using video file click stream events and quiz score. LR=84%, SVM=85%, Deep ANN=85%, LSTM=93%	More than 90% accuracy in real time dataset.
[27]	CSLA(Hybrid model using CNN+Bi-LSTM+Attention Mechanism)	MOOC - KDD Cup 2015 dataset	2013-2014 79,186 students records 80% - training, 20%- testing	Predicting the student dropout rate based on learners' behavior data with accuracy - 87.6% and f1 score-86.9%.	Combined three different strategies to increase the performance over 2.8% . CNN - Feature selection LSTM - Time series Attention Mechanism- Assigning weight
[28]	LR, SVM, DNN, CONV-LSTM	MOOC- Dataset 1- Stanford University Dataset 2- KDD cup 2015.	Dataset 1- 78,623 records Dataset 2- 120,542 records 65% - training 20% - testing 15%-validation	Predicting Student Dropout using MOOC data with f1 score 89% and 90% for two datasets respectively.	Custom loss function applied to rectify classification error instead of SMOTE and other techniques used for imbalanced dataset.
[29]	LR, SVM, DT, GBT, KNN, ANN, LSTM	OLUAD	2014-2015 32,593 student log records. 75% - training 25% - testing	Predicting learners behavior using student online log data. LR-73%, SVM – 73%, DT-79%, GBT-78%, KNN-78%, ANN-83%, LSTM-84%.	Time series data(clickstream logs) converted into aggregated format for the purpose of applying classical machine learning.
[30]	LSTM - Encoder	Blackboard LMS	2014-2016 4706 students 3,625,619 log records	Predicting at-risk students using micro level behavioral pattern and time series clustering with accuracy-92%	Auto encoder used to extract best featuresStudent clustering based on the learning behavior
[31]	HMM, Machine Learning (ML), LSTM, CNN-LSTM	UCI - HAR dataset	10,299 data samples 70% - training 30 % - testing	Classroom attention behavior recognition using sensor data. HMM-72%, ML-78%, LSTM-89%, CNN-LSTM - 92%.	Identifying student concentration level through wearable device and mobile interaction data.
[32]	CNN, LSTM, CNN-LSTM	Blackboard LMS	35,000 students 1, 715, 000 records	Predicting student learning outcomes in LMS with fl	This study aims to find thedominate features called KPI

			70% - training 30%- testing	scoreLSTM - 90%, CNN - 92% CNN-LSTM - 93%	(Key Performance Indicator) to improve the model performance.
[33]	LR,SVM, LSTM, CNN-LSTM, Conv-LSTM	MOODLE-Gadjah Mada University	977 students 202,000 log records	Early prediction of at-risk students. LR-64%,SVM-80%,LSTM-85%, CNN-LSTM-88%, Conv-LSTM-91%	Hybrid SMOTE technique used for imbalance dataset More than 90% accuracy in predicting the first few weeks instead of final week.
[34]	LSTM-FCN, Attention LSTM-FCN, GRU, RNN, Dense block	University of California-Riverside (UCR) time series repository	Not specified due to the large number of experiment.	Z-normalization is recommended, if the training data having good representation of global population, Appling dimension shuffles before the LSTM block increases the performance.	Series of experiments(3627) using educational data, the State-of-Art performance for classifying the time series signal
[35]	NN,LR,NB, SVM,DT,RF, GBM,LSTM	Canadian university. (LMS log data- https://moodle.org/)	290 (semester 1)-train, validation, test data 311(semester 2)-Test data	Predicting the students' performance using LMS activity. LSTM (AUC: >60%) performs better than classical machine learning (AUC <60%).	SMOTE sampling technique is used to overcome the imbalanced dataset.
[36]	Linear Regression, LSTM	Multi-disciplinary university	2007-2016-training 2017-2019-testing	In Predicting student performance, deep learning offers the highest accuracy than the Linear model. MAE: 0.593 and RMSE: 0.785	Extracting informative data as a feature with corresponding weights. Multiple updated hidden layers were used for designing neural networks automatically
[37]	LSTM, MLP-LSTM	Bina Nusantara University	2011-2017 46,670 -univariate time-series and tabular data	Predicting student GPA using tabular and historical data. Hybrid model with dual input gives highest accuracy MSE:0.41, MAE:0.34, R-square:0.48.	Dual input to the hybrid model using tabular data and time series data
[38]	CNN, LSTM, CNN-LSTM	Student classroom data using Virtual Reality (VR) Environment	3.4 M data points 70%-Training 30%-Testing	Finding the student distraction level using Virtual Reality data by creating a deep learning model. The hybrid model achieves the highest accuracy at 89.8%	The large amount of data points were used for this experiment.
[39]	CNN-Net, CNN-LSTM,CNN-RNN, Classical Machine Learning	MOOC - KDD Cup 2015 dataset	79,186 students records 1,20,542 data points 80% - training, 20%- testing	Early prediction of student dropout in MOOC and Hybrid Model gives highest accuracy AUC: 91.5% than classical model.	The effort was given for pre-processing the data to handle categorical and imbalanced dataset.
[40]	RNN, LSTM, Deep LSTM	Dataset collected from Star Math-Formative Assessment tool	2017-2018, 10,107- records, 80% -training,10% test, 10% validation	Predicting student performance using previous test assessment. The short history (3 data points) prediction gives highest accuracy.	Student performance is predicted then categorized using clustering technique based on their performance.
[41]	ARIMA, LSTM, Exponential Smoothing, and Fuzzy Time Series algorithms	IBN ZOHR University	18 years data	Developed four different forecasting models using Time Series algorithms to predict the new student enrollment. Highest RMSE score Fuzzy Time Series: 211, ARIMA: 452,ES: 461, LSTM: 1152.	Comparison between Statistical and Deep Learning model.
[42]	CNN	MOOC - KDD Cup 2015 dataset	79,186 students records	Predicting student dropout in online courses.Precision: 86%, Recall: 87%, F1 score: 86%, AUC: 86%	CNN model is newly applied for student dropout prediction using click stream data.
[43]	NN, LR, NB, GBM SVM, DT, KNN, RF, and LSTM with SMOTE	Moodle LMS data –Canadian university	527 students 72% - training 28% - testing	Analyze student online temporal behavior using their LMS data for the early prediction of course performance. LSTM - AUC Score 80.1.	Separate models are created for 28, 48, 56, and 70 days data to evaluate the course performance for each semester.
[44]	LR, ANN, SVM, LSTM	Open University Learning Analytics Dataset (OULAD)	2014-2015 32,593 students with 20 different activity data.	Finding the at-risk students in the early stage using virtual learning environment video stream click event and demographic data. Recall score is LR=80, SVM=78, ANN=85, LSTM=95.	Student week-wise activities are stacked and given to the model for early prediction. The last week's data provides better performance.
[45]	RNN,GRU and LSTM	Open University Learning Analytics Dataset (OULAD)	2014-2015 32,593 student records.	Static and sequential informationswere combined for performance prediction. GRU gives better performance than LSTM due to minimal length data. The accuracy of the proposed model is above 80% in the last week.	The joint neural network is proposed to fit both static and sequential data, where the data completion mechanism is also adapted to fill the missing stream data.

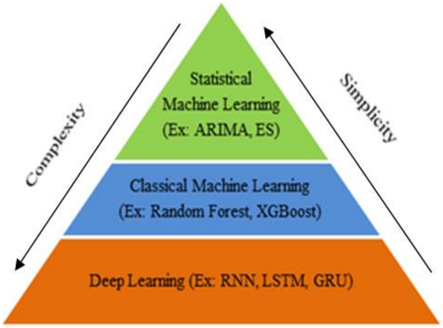
B. The Architecture of Time Series Model and the Difference between Traditional Approach

This section provides the history and technical background of Recurrent Neural Networks. Even though a few studies used other models (CNN and hybrid models) for time series problems, those are excluded and not specific to handle temporal data.



Statistical Machine Learning (Ex: ARIMA, ES)
Classical Machine Learning (Ex: Random Forest, XGBoost)
Deep Learning (Ex: RNN, LSTM, GRU)
Complexity
Simplicity

Fig. 5. Classification of time-series algorithms.

Initially, statistical methods are beneficial in predicting time series problems, but they are ineffective in handling nonlinear data. Therefore deep learning came into existence to overcome the liabilities of conventional time series algorithms such as ARIMA and Exponential smoothing techniques [9], [10], [20]. Similarly, few classical machine learning algorithms (XGBoost) apply to time series problems. Fig. 5 illustrates the complexity and the simplicity level of different time series algorithms.

The properties of time series data are Trend, Seasonal, Cyclic, and Irregular. Fig. 6 describes the pictorial representation of each property.

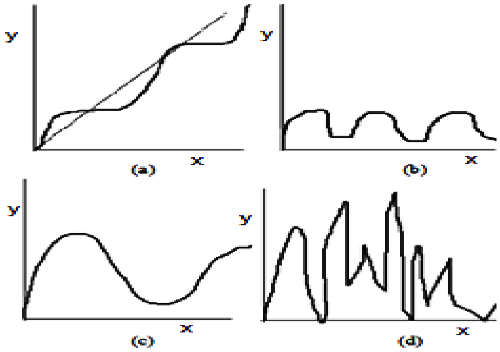


Fig. 6. Time series properties (a). Trend (b). Seasonal (c). Cyclic (d). Irregular.

Here ‘x’ denotes any time unit such as minutes, hours, months, years, etc. And the ‘y’ represents the numerical value such as weight, height, price, quantity, etc. Fig. 6 explains how the ‘y’ value is changed based on time. The appropriate algorithm has to prefer built on the type of the dataset. RNN has introduced around the 1980s. However, it got renowned after the invention of LSTM in 1990 to overcome the weaknesses of RNN. The most common use case for RNN is time series problems [11] and natural language processing [12]. Fig. 7 depicts the workflow difference between traditional Feed Forward Neural Networks (FFNN) and RNN.

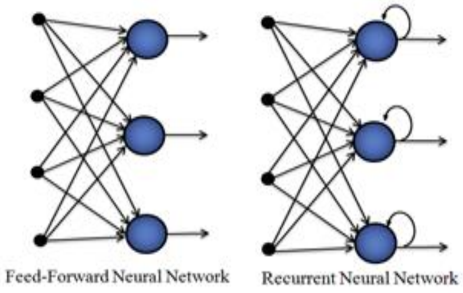

Fig. 7. FFNN vs RNN.

1) Recurrent Neural Network (RNN): RNN is a type of Artificial Neural Network (ANN) specially designed to capture sequential information with the aid of memory cells. This memory cell retains the previous report for further processing, and the decision is based on the prior and current state. RNN shares the same weight parameters within each layer, whereas the traditional neural network shares different weights. There are three crucial components in RNN Input, hidden neuron, and activation function, as described in Fig. 8 and 9.

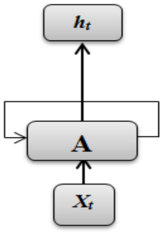

Fig. 8. Simple RNN.

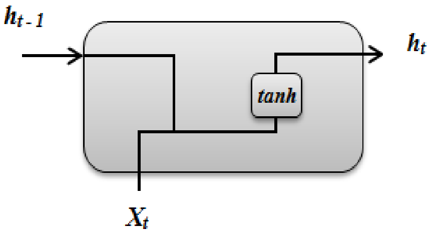

Fig. 9. Internal architecture of simple RNN.

$$h_t = tanh(\mathrm{U}.x_t + W.h_{t-1}) \tag{1}$$

Eq. (1) calculates the hidden state where h_t is a hidden neuron at time t, x_t is the input at time *t, U* is the weight of the hidden layer and *W* is the transition weight of the hidden layer. The input and previous state informations are combined to go through the *tanh*activation function to produce a new hidden state. RNN suffers from the vanishing gradient problem while handling long sequence data. But it is rectified by Long Short-Term Memory[19], another variant of RNN.

2) Long Short Term Memory (LSTM): LSTM is capable of processing long-term dependency data. It manages the previous context more effectively than RNN using three gates. They are the input gate, forget gate, and output gate, as depicted in Fig. 10. The input gate updates the memory cell, forget gate decides whether the information has to be kept or not. The output gate is responsible for determining the next hidden state.The loop structure of RNN and LSTM helps to choose the better weight parameter. The formula for each variable in LSTM is defined below:

$$f_t = \sigma(W_f.X_t + U_f.h_{t-1} + b_f) \tag{2}$$

$$i_t = \sigma(W_i.X_t + U_i.h_{t-1} + b_i) \tag{3}$$

$$S_t = tanh(W_c.X_t + U_c.h_{t-1} + b_c) \tag{4}$$

$$C_t = i_t * S_t + f_t * S_{t-1} \tag{5}$$

$$o_t = \sigma(W_o.X_t + U_o.h_{t-1} + V_o.C_t + b_o) \tag{6}$$

$$h_t = o_t * tanh(C_t) \tag{7}$$

where i_t, f_t, o_t refers to the input gate, forget gate, and out gate respectively. *W, U,* and *V* are the weight matrices, *b* is the bias vectors, X_t is the input vector to the memory cell at time t, h_t is the value of the memory cell at time t, and C_t, S_t are the candidate state and state of the memory cell at time *t*, respectively. Here sigmoid (*σ*) and *tanh* are the activation functions.

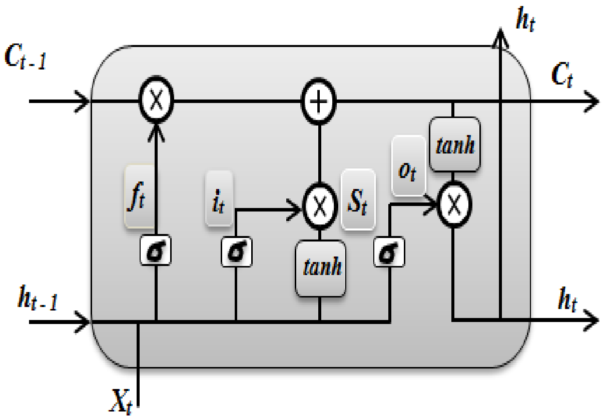

Fig. 10. LSTM architecture.

3) Gated Recurrent Unit (GRU): GRU is a simple version of RNN in terms of architecture. It is uncomplicated to implement and has a quick performance than LSTM, but the functionalities of both architectures are identical. GRU uses fewer parameters, so it requires less hardware and training time. Therefore, GRU attracts the user to involve in many applications. The three gates are reduced into two gates update and reset gate, defined in Fig. 11.

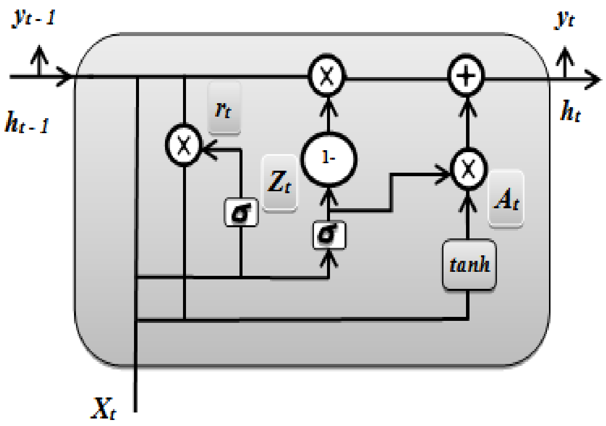

Fig. 11. GRU architecture.

The update gate is a combination of the input, and a forget gate in LSTM. It decides whether the particular information has to be kept or discarded. The reset gate will determine the amount of data that should forget. The following formula defines each variable in GRU:

$$r_t = \sigma(W_r . X_t + U_r . h_{t-1} + b_r) \quad (8)$$

$$Z_t = \sigma(W_z . X_t + U_z . h_{t-1} + b_z) \quad (9)$$

$$A_t = tanh(W_h . X_t + U_h . (r_t * h_{t-1}) + b_h) \quad (10)$$

$$h_t = (1 - Z_t) * h_{t-1} + Z_t * A_t \quad (11)$$

where r_t and Z_t are the two gates for reset and update respectively. A_t is memory content, h_t is the final memory of the current time step and the σ and *tanh* are the activation functions. The two gates have values between 0 and 1 through the sigmoid function (σ). While doing, the memory content (A_t), using the reset gate store the significant information from the previous value between the range −1 to 1 over *tanh*.

4) Metrics used for time-series data: Choosing the right metric is essential to evaluating the model's performance. All the decision, such as tuning the hyper-parameter and selecting the suitable model, is made on the result only. Here the notable thing is before deciding the metrics, need to check the following entities: the nature of the dataset, the values going to handle, and whether there is any need to compare other datasets. If so, are they all on the same scale or different ones? Table III and Table IV illustrate the various metrics available for the time series problem [14]-[18]. Fig. 12 shows the percentage of performance metrics reported in this study.

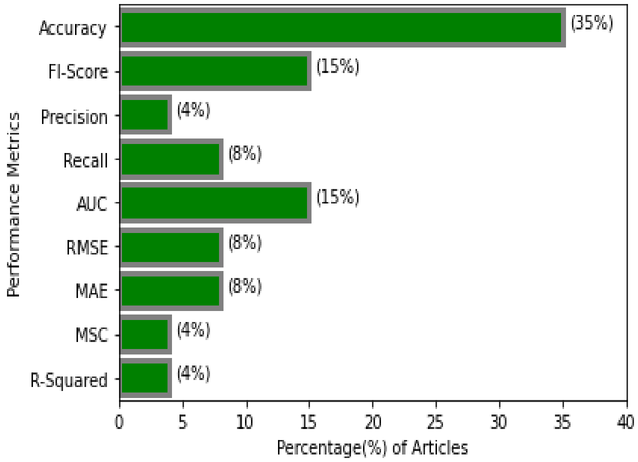

Fig. 12. Percentage of performance metrics applied in this review.

TABLE III. TYPES OF PERFORMANCE METRICS IN REGRESSION PROBLEM

Metrics for Regression			
Scale-Dependent	**Percentage-Error**	**Relative-Error**	**Scale-Free Error**
• Mean Absolute Error(MAE) • Mean Squared Error (MSE) • Root Mean SquaredError (RMSE)	• Mean Absolute Percentage Error(MAPE) • Symmetric Mean Absolute Percentage Error (SMAPE)	• Median Relative Absolute Error (MdRAE) • Geometric Mean Relative Absolute Error (GMRAE)	• Mean Absolute Scaled Error (MASE)
Description			
Error metrics are articulated in the units of the underlying data (Example: Dollars, Inches, etc.)	Scale independent and used to compare forecast performance between different time series	Compare your model's performance with the baseline or benchmark model**.**	Scale the error based on the in-sample MAE from a random walkforecast method
Advantage			
Easy to calculate and interpret	Scale- independency and easy interpretability	Scale-independence	Scale free and suitable metric for time series data with zeros
Disadvantage			
Scale dependency	- Infinite or undefined values for zero or close-to-zero actual values - Heavier penalty on negative than on positive errors - Cannot be used when using percentages make no sense.	When the calculated errors are small it leads to division by zero error.	Not to use when all historical observations are equal or all of the actual values during the in-sample period were zeros.

TABLE IV. TYPES OF PERFORMANCE METRICS IN CLASSIFICATION PROBLEM

Metrics for Classification			
Name	**Description**	**Advantage**	**Disadvantage**
AUC/ROC	The **AUC** measures the entire two-dimensional area under the curve at all possible classification thresholds.ROC is a plot to explain the true and false positive rates.	Using graph representation to show the trade-off between the TPR and FPR.	Not suitable for the highly imbalanced dataset and concentrates only on TPR and FPR.
Confusion Matrix	Identify the model correctness all the way. The Four elements of this table are TP, TN, FP, and FN, which helps to derive the following metrics.	Find the issue where the model failed to understand.	Interpreting the result is complex.
Accuracy	The degree of model correctness. ***Accuracy=(TP+TN)/(TP+FN+TN+FP)***	Easy to interpret	Misleading the result where the sample of minority class is very less.
Precision	Ability of the model to identify only the relevant data points. ***P=TP/(TP+FP)***	Identify the proportion of correct positive identifications	It doesn't consider the type II classification error.
Recall (Sensitivity)	Ability of the model to find all the relevant data points. ***R=TP/(TP+FN)***	Identify the proportion of correct actual positives.	It doesn't consider the type I classification error.
F1-Score	A single score that balances both the concerns of precision and recall in one number. ***F1-Score = 2 *(P*R)/(P+R)***	The harmonic mean of precision and recall value	It is a combined result of precision and recall, so a bit harder to interpret.

TABLE V. LIST OF HYPER-PARAMETERS

Hyper-Parameters	Description
Train/Test ratio	Splitting the dataset into train and test. (Example: 80:20)
Hidden Layer	The layer between input and output and it determines the depth of the neural network (Usually 1 or 2 layers).
Optimizer	It is an algorithm used to update the weight of each layer after each iteration (Example: Gradient descent, Adam [26,27,39,43,45,29,31,32,33])
Learning Rate	It defines how quickly the network updates its parameters (0.0-0.1)
Activation function	Allowing deep learning models to learn non-linear prediction boundaries [22] (Example: Sigmoid [28, 39], ReLU[24,28,32], Tanh[26,32], Leaky Relu[45])
Number of Epochs	Number of iterations to pass the whole dataset in training.
Batch-Size	Number of sample that the network used to update the weights
Momentum	It speeds up the learning process by preventing the oscillation in the convergence of the method.
Weight initialization	It defines the starting point of the optimization.
Dropout	It helps to avoid over-fitting by eliminating the randomly selected neurons in training [26, 27, 28, 41,43, 45].
Regularization	It prevents over-fitting by stopping the weights that are too high(L1,L2) [26]
Units	It determines the level of knowledge that is extracted by each layer.

C. Factors Affecting the Time Series Model Accuracy

There are several factors affecting the model performance which are the techniques used for pre-processing,train-test ratio, and the selection of model hyper-parameters. Table V represents the hyper-parameters that are affecting the model accuracy [23].

1) Pre-processing: Removing unwanted data and filling in the missing values are the initial step inpre-processing. Several methods are available for imputation, such as mean, median,mode, interpolation, weighted average [24], and k-nearest neighbor[43]. Mean and Weighted Average is the widelyused techniques. The first one returns the average value of the feature column, and the second substitute the average of the most frequent information.

The next step is to encode all the categorical information into numerical value for model understanding using any technique such as label encoding or one hot encoding [39]. Each method has merits and demerits of its own. After encoding, re-scaling the data (feature) is very important since it makes the model less sensitive to the scale of features and allows converging with better weights. There are two significant types of scaling: Standardization(z-score) and Normalization (min-max scalar). Standardization assumes that the values are in Gaussian distribution and centered on the zero mean with unit standard deviation. It is less sensitive to outliers, so Karim et al., [34] used z-score normalization to handle the outlier values, and Wang et al., used batch normalization for scaling in [24]. It is specific to each layer and batch of input in the neural network.

2) Train-test split: Normally, 80:20 is the suggested ratio for a train-test split if the samples are distributed evenly across the dataset. Wu et al., [27,39] split the dataset into 80:20 for training and testing. Shin et al., carry the exact ratio in [40], but 10 % for validation from test data. In researches [25,38, 31, 32], the percentage used for training/testing is 70:30; the remaining studies [43, 26, 28, 29] use slightly different ratios.

3) Imbalanced dataset: Most of the real-time dataset is imbalanced and should be handled appropriately to avoid classification errors. In studies [35, 39, 43, 33], the authors used synthetic samples (SMOTE) to balance the target class count. But Mubarak et al.,[28] introduced a cost-sensitive technique in the loss function to avoid type 2 classification error[28]. Dimension reduction is also another issue where the feature count is vast. Waheed et al.,[25] using Singular Value Decomposition (SVD) method to find the top 30 efficient features.

4) Hyper-parameters: The number of hidden layers is significant in deep learning because it shows the complexity of the problem. Bousnguar et al., [41] used three LSTM layers and 50 cells for each layer. Qiu et al.,[42] involved two convolutional and two fully connected layers for binary classification with the sigmoid activation function. Aljohani et al.,[44] applied three LSTM layers, and each layer is assigned 100 to 300 units of neurons. Deep ANN is appliedin [25,45] and uses a minimum of three layers and up to seven hidden layers. Next to hidden layers, select the suitable optimizer to update the weight for every iteration. The Adam optimizer is majorly used [39, 43, 45, 26, 27, 29, 31, 32, 33] among others, such as gradient descent, stochastic gradient descent, and RMSProp.

Then the learning rate (0.0-0.1) assigns the speed of the network parameter update. Frequently used values are 0.0025 [27], 0.001 [29, 32, 33], and 0.1 [31]. The activation function is another hyper-parameter that helps to predict complex non-linear data. This parameter differentiates neural networks compared with machine learning models. Relu, Leaky Relu, tanh, and sigmoid are the activation functions equally used in all the papers. After fitting these parameters training the model by mentioning the number of epochs is mandatory. Sometimes less training, such as 15, 20, and 25, gives better performance than massive iteration [27, 31]. The Dropout is the last layer of the neural network to avoid overfitting, so it is majorly used in all the experiments. The frequent values are 0.1, 0.2, 0.3, and a maximum of 0.5 by Mubarak et al., in [28].

Concerning batch size, the authors adjusted the value to improve the accuracy by doing several experiments. Waheed et al., found the batch size from the value of 64 increased the model performance for all the weeks, but when the batch size was increased additionally from 1364, the model performance degraded with AUC decreasing by a value of 0.04. Regularization is rarely used [26] in the experiment. The model setup does not explain the other parameters, such as Weight initialization and Momentum.

IV. Discussion

This section discuss the contribution of this paper referred to in the introduction.

A. *Finding the Impact of Deep Learning in Educational Time Series Problem*

To answer RQ1, this SLR proved the success of deep learning models in educational time series data retrieved from various sources. Hernández et al.,[21] also confirmed in their review the number of publications recently enriched after raising the application of the DL model. But the first publication commenced in 2015. Section III describes the previous work, and all the information is summarized in Table II to explain the types of models used, the paper's findings, individuality, and the dataset details. The CNN-LSTM is the majorly used hybrid technique, and the LSTM is the widely used single model in many research works. In Education, student performance prediction is the typical use case executed in multiple investigations. Moreover, clustering the time sequence data was also applied to categorize the students based on their performance. Due to its sequential nature, most of the work was done on MOOC online data than the offline mode to predict student dropout.

B. *Identify the Architecture of Time Series Model and How it Differs from the Traditional Approach*

To answer RQ2, Section IV describes the internal structure of RNN, LSTM, and GRU using the required diagrams and formulas. It represents the improvement and differences between each other. Numerous investigations involve LSTM rather than RNN and GRU though the architecture is intricate. Also, LSTM merged with CNN to retrieve spatiotemporal features effectively. Self-connected neurons helps to maintain the previous information, and this is different from feed-forward neural network.

C. *Discover the Significant Factors Affecting the Time Series Model Accuracy*

To answer RQ3, Table V provides information on the factors influencing the model accuracy. Tuning the Neural Network is necessary because it improves the model's performance. The number of hidden layers, epochs, batch size, dropout layer, and optimizers are the commonly used hyper-parameters due to their high impact on the outcome. Most authors use manual selection to pick the best hyperparameters instead of any optimization technique, such as grid search and Bayesian method.

V. Conclusion

Understanding the DL methodology and the previous work done in a particular domain is fundamental before implementing the research idea. This study is the first work that gives a background for young researchers who want to involve Deep Learning in the Education time series problem. Accessed Google Scholar and IEEE Xplore scientific websites to collect relevant research papers. Then the collected documents(n=291) are analyzed manually and selected twenty-two (n=22) papers for this SLR by following PRISMA methodology. The essence of this survey is deep learning applies widely, but the hybrid model gave the highest accuracy than the individual model. Student classification, clustering, forcasting the student enrolment/grade, and dropout prediction using online course log data are the normally used problem statement. Large sequential data are rarely used compared with other domains which helps to avoid complex models. Finally discussed the RNN architecture, types of metrics, and the factors influencing the model accuracy.

VI. Future Perspective

This deliberation clearly explains the previous work done in the educational domain using time series data and will involve all this learning in the implementation work to fill the research gap identified.

AI in Tourism: Leveraging Machine Learning in Predicting Tourist Arrivals in Philippines using Artificial Neural Network

Noelyn M. De Jesus[1], Benjie R. Samonte[2]
Assistant Professor, College of Informatics and Computing Sciences[1, 2]
Batangas State University ARASOF-Nasugbu, Nasugbu, Batangas, Philippines [1, 2]

***Abstract*—Tourism is one of the most prominent and rapidly expanding sectors that contribute significantly to the growth of a country's economy. However, the tourism industry has been most adversely affected during the coronavirus pandemic. Thus, a reliable and accurate time series prediction of tourist arrivals is necessary in making decisions and strategies to develop the competitiveness and economic growth of the tourism industry. In this sense, this research aims to examine the predictive capability of artificial neural networks model, a popular machine learning technique, using the actual tourism statistics of the Philippines from 2008-2022. The model was trained using three distinct data compositions and was evaluated utilizing different time series evaluation metrics, to identify the factors affecting the model performance and determine its accuracy in predicting arrivals. The findings revealed that the ANN model is reliable in predicting tourist arrivals, with an *R*-squared value and MAPE of 0.926 and 13.9%, respectively. Furthermore, it was determined that adding training sets that contain the unexpected phenomenon, like COVID-19 pandemic, increased the prediction model's accuracy and learning process. As the technique proves it prediction accuracy, it would be a useful tool for the government, tourism stakeholders, and investors among others, to enhance strategic and investment decisions.**

Keywords—Tourist arrivals; machine learning; predictive analytics; artificial neural network; ANN; time series prediction

I. Introduction

Big data has been utilized by many academics and industry professionals to make their own predictions and forecasting in a variety of fields, including the travel and tourism industries. Tourism is one of the most prominent and rapidly expanding sectors that contribute significantly to the growth of a country's economy. In the Philippines, travel and tourism contributed 12.7%, 5.4%, and 5.2% in the Gross Domestic Product (GDP) in 2019, 2020, and 2021, respectively [1]. This year, the tourism sector achieved another remarkable recognition when it won three significant awards at the 29th World Travel Awards (WTA). According to [2], the country was named "Asia's top tourist attraction," "dive destination," and "top beach destination" among Asian countries. The [3] names dive tourism as one of the important industries that can have a favorable impact on industry growth in terms of more visitors, longer stays, and increased tourism revenue.

However, the direct gross value contributed of the tourism industry has decreased by almost 50% over the last two years as a result of the closing of international borders and national lockdowns.

Thus, a reliable and accurate prediction of tourist arrival is necessary in making decisions and strategies to develop the competitiveness and economic growth of the tourism industry. In the previous study of [4], they investigated the connection between the tourist arrivals from the quantity of COVID-19 cases during summer. The analysis uses three models: the simple linear model, the negative binomial regression model, and the Cognitive Artificial Neural Network (ANN) model. The findings showed that tourism is a significant factor of the increase in Covid-19 cases. The researchers also concluded that the ANN model can make the most accurate predictions among the three models.

The random forest (RF), artificial neural networks (ANN) [5], and support vector machine are three of the most popular AI-based models for time-series prediction. However, many publications, including [6,7,8], claim that there is no one technique that consistently delivers the best tourism forecasts; rather, the results rely on the model and technique applied, the amount of observations, features of the data set, and predicted duration.

This study's objective is to forecast future tourist arrivals using historical data rather than to examine demand for tourist attractions. As has already been mentioned, seasonal times-series forecasting is crucial for making strategic decisions and organizing upcoming tasks. The researchers want to raise concerns about neural network models' capability for predicting seasonal tourist arrivals, which is a challenge that shows frequently in a variety of applications. In addition, this study aims to identify the factors affecting the model performance and determine its accuracy in tourist arrivals' prediction.

The following are the primary contributions of this study:

- An exploratory data analysis that delivers more meaningful data through visualization using a dataset that includes information about Philippine tourist arrivals.
- In contrast to other studies that concentrated on and employed a single data composition in training and testing sets, the researchers explore with several data

compositions to assess the predictive capability of ANN models.

- Leveraging machine learning, particularly artificial neural networks model in alternative with other popular data mining techniques like random forest and support vector machine, in predicting tourist arrivals in the Philippines and perform model performance evaluation using various time series evaluation metrics.

II. Related Works

Machine learning and data science researchers have been working on time series forecasting. There is a growing need for precise and effective forecasting techniques as time series data from numerous industries, including banking, healthcare, and energy, become more widely available. In this study, the researchers highlight a few recent developments in time series forecasting and talk about their advantages and disadvantages.

Deep learning is one of the most well-liked methods for time series forecasting and has demonstrated promising outcomes in a number of fields. In order to capture long-term relationships in the data, [9] introduced a unique deep learning architecture for time series forecasting dubbed Longformer-TS. This design makes use of the self-attention mechanism. On numerous benchmark datasets, they showed that Longformer-TS outperformed a number of cutting-edge models.

The introduction of probabilistic forecasting techniques, which offer a distribution of potential future values rather than a single point estimate, is another new development in time series forecasting. This might be helpful when making decisions that call for quantifying uncertainty and assessing risk. In order to model the uncertainty in the data, [10] for instance suggested a deep probabilistic forecasting framework that makes use of a Bayesian neural network. On real-world electrical load forecasting tests, they demonstrated that their system beat numerous conventional and deep learning approaches.

There has been an increase in interest in applying meta-learning techniques for time series forecasting in addition to deep learning and probabilistic approaches. By utilizing prior experience on related tasks, meta-learning seeks to discover the best algorithm or hyperparameters for a current task. Using a neural network to train a set of hyperparameters that can adapt to various forms of time series data, [11] suggested a meta-learning framework for time series forecasting, for instance. On a number of benchmark datasets, they showed that their method delivered state-of-the-art performance.

For predicting tourist arrivals, [12] introduced a neural network model termed the Deep Travel Demand Forecasting Network (DTDNet). A prediction module and a feature learning module make up the model's two primary parts. While the prediction module employs a Long Short-Term Memory (LSTM) network to identify temporal connections and generate predictions, the feature learning module employs a deep convolutional neural network (CNN) to extract pertinent features from the raw data. On three tourism datasets from various areas, the authors examined the DTDNet model and found that it beat other cutting-edge models, including ARIMA, SARIMA, and VAR.

A hybrid neural network model that combines a convolutional neural network (CNN) and a recurrent neural network (RNN) for forecasting tourist arrivals was proposed by [13]. The data is processed using the CNN to extract spatial features, and the RNN to identify temporal connections. The model was tested on a Chinese tourism dataset, and the results demonstrated that it beat numerous conventional models like ARIMA and exponential smoothing.

Another study, [14] suggested a neural network model for anticipating tourist arrivals termed the Multivariate Attention-based Temporal Convolutional Network (MATCN). The model combines a temporal convolutional network (TCN) and an attention mechanism to identify both short- and long-term dependencies in the input. On a Thai tourist dataset, the authors tested the MATCN model and found that it performed better than numerous conventional models, including ARIMA and Holt-Winters.

III. Methodology

Datasets for the study are mainly collected from three Philippines government organizations, i.e., the Tourism Department and Development Planning of Department of Tourism, Research and Information Management, and Statistics, Economic Analysis, and Information Management Division. The data collected from Philippines's tourism demand statistics include the annual number of inbound tourists' arrivals to Philippines from January 2008 to October 2022 [15].

A. Descriptive Analysis

Inbound travel to the Philippines increased dramatically between 2008 and 2021 (Fig. 1). From 3.14 million in 2008 to 8.26 million in 2019, there were more than twice as many foreign and overseas Filipino tourists visiting the country [16].

Despite the fact that the graph indicates an increase in inbound tourists' arrivals to the Philippines over the past years, as forecast indicate, there were notable drops in tourist arrival in 2009, 2014 and 2020. In 2009, there was a decrease in the number of arrivals by 1.5% compared to 2008 [17]. Several upsetting incidents occurred in the global tourism industry in 2014, such as the emergence of SARS, avian influenza, Ebola, and MERS-CoV infections [18]. Evidently, a sudden decline in tourist arrivals and subsequent drop in tourism demand of the country caused by coronavirus pandemic in the year 2020, which led to the loss of millions of jobs, severe economic hardship, and the demise of many enterprises [19]. Several jobs and businesses, particularly the micro small, and medium-sized ones that catered to tourists or were related industries, were at risk due to the border closures, main entry points, and hotels as well as mass gatherings restrictions, land travel, and related services worldwide.

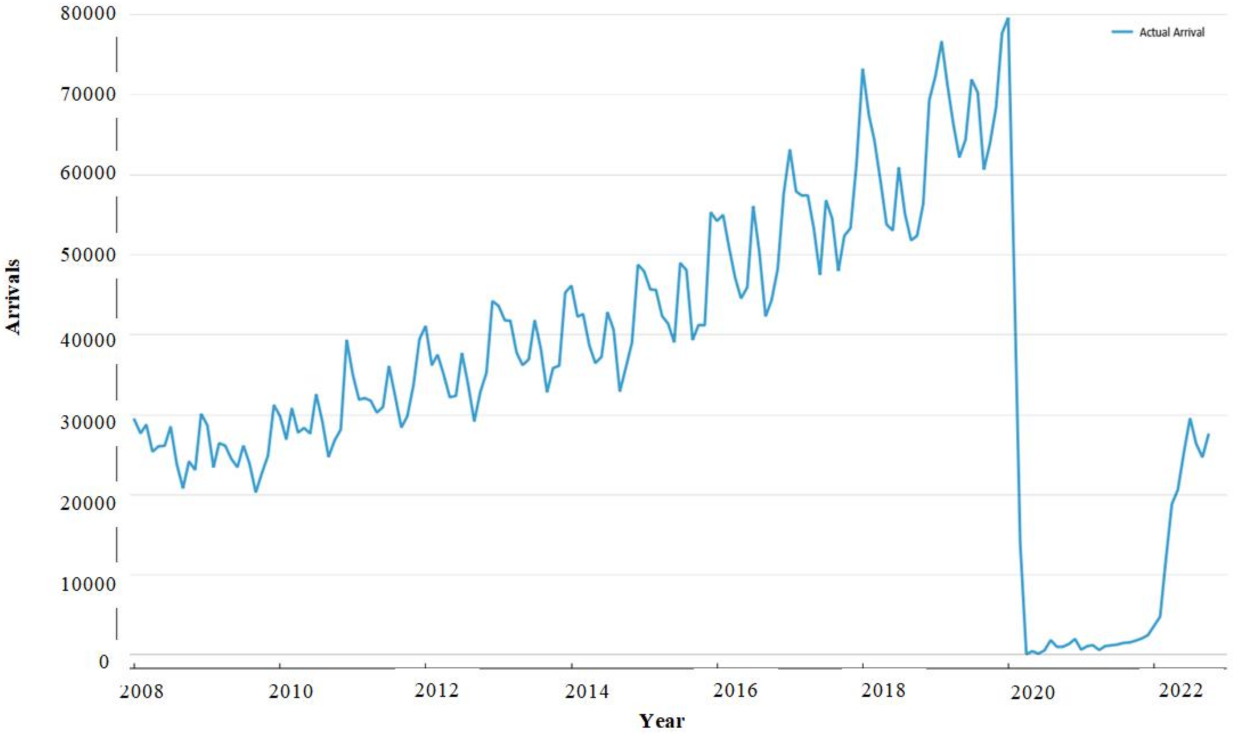

Fig. 1. Number of inbound tourists' arrivals to Philippines and annual grow rate in arrivals (2008-2022). Source: Statistics, Economic Analysis and Information Management Division (SEAIMD) and Department of Tourism (DoT).

Travel and tourism competitiveness in the Philippines continues to rise globally, continuing a trend that has been present for the past eleven years [20]. In 2019, 8.3 million tourists (including non-resident overseas Filipinos) visited the country, primarily from Korea, China, the USA, Japan, and Taiwan. These made up 70% of all visitors during the year. Tourist arrivals in the Philippines, however, fell by 80% in the first quarter of 2020 and by about 90% in 2021 for both foreign and overseas Filipinos, these are the periods when most countries started implementing travel restrictions and lockdowns [21].

B. Methodology

Fig. 2 shows the adapted and modified research framework of the study [22]. It involves collection and preprocessing of data, feature extraction, model development, and its performance evaluation. The researchers first gathered tourist arrival statistics from the Department of Tourism's website. Then, the data was preprocessed in the second phase to extract valuable and target information. Third, train and test the time series machine learning model, and finally, evaluate the model performance.

1) Data collection: To perform this study, the researchers collected the actual inbound tourist arrivals to Philippines between 2008-2022 from the Department of Tourism's official website. The datasets were analyzed and visualized using exploratory data analysis in Python programming. This was done to determine what the tourism data could reveal beyond the formal modeling [23]. Table I presents the descriptive statistics of annual inbound tourist arrivals in the Philippines from 2008 to 2022.

TABLE I. DESCRIPTIVE STATISTICS OF THE DATASETS

Variable	Year	Mean	Std. Dev.	Min	Max
Tourist arrivals	2008	261,618.50	28,386.64	208,167	301,175
	2009	251,424.92	28,750.71	202,822	312,132
	2010	293,372.58	37,521.50	247,191	393,585
	2011	326,454.50	30,288.81	284,040	394,567
	2012	356,067.58	41,311.19	291,637	442,088
	2013	390,108.92	37,505.80	328,114	452,650
	2014	402,780.67	45,120.36	328,981	487,654
	2015	446,723.50	48,193.41	390,486	553,002
	2016	497,250.42	51,174.38	422,943	576,638
	2017	552,489.58	47,494.22	474,854	631,639
	2018	597,372.25	73,046.16	518,041	732,506
	2019	688,409.42	55,021.46	606,553	776,798
	2020	123,544.58	249,612.96	948	796,164
	2021	13,656.58	5,339.33	6,036	24,353
	2022	157,918.67	117,900.48	-	295,650

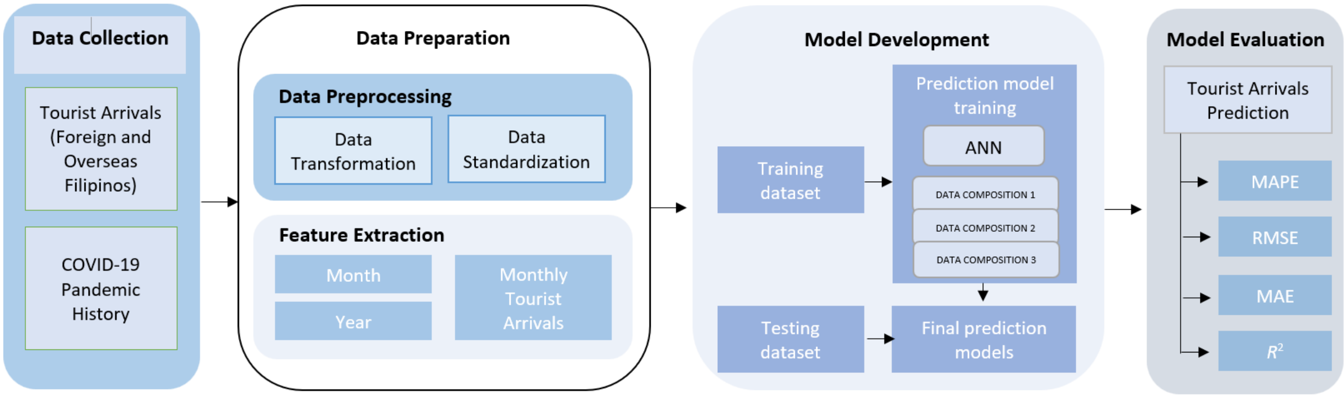

Fig. 2. Adapted research framework of the study.

2) Data preparation: Two temporal features were extracted in the preprocessing stage: month and year. The extracted data was pre-processed using Long-Short-Term Memory (LSTM) as the extraction feature technique, capturing the complex dependencies between the past and current tourist arrivals. The study conducted the time series analysis following the theory of Autoregressive model (Equation 1). The model uses observations to predict a value based on prior time steps as an input. The order of the model is determined by the number of samples utilized for prediction, n_r [24].

$$x\,[k] = e[k] \sum_{r=1}^{n_r} a_r x[k = r] \tag{1}$$

AR model was translated into a neural network, where there is a need of inputs that are lagged. In order to that, the data set was pre-processed, in such as a way that input values was created as lagged values. From the original dataset having a month and tourist arrivals column, the last 12 months was taken from the seasonal time series of the dataset and was used as lags. It will be used as inputs to predict the current month. The first twelve months, January through December 2008, were eliminated, and a new dataset that began in January 2009 and ended in October 2022 was established with twelve additional dummy variables. Then, a traditional neural network was formed, where there are twelve features and the target variable which is the number of tourist arrivals.

3) Model development: To build and develop the model, train and test sets were split into two parts. The criteria for data decomposition in this study is the trend where the tourist arrivals show an upward and downward movements, particularly during the COVID-19 pandemic. In the training process, the segments of the training dataset were decomposed into three partitions such as: (a) January 2008 – January 2020 with 82% as the training data, and 18% as the testing data, (b) January 2008 – March 2020 with 83% as the training data, and 17% as the testing data, and (c) January 2008 – December 2020 with 88% as the training data, and 12% as the testing data (Fig. 3):

- January 2020 (*the period when the government confirmed the first case of new coronavirus*)

In the middle of January 2020, the Philippines reported its first coronavirus case [25] [26].

- March 2020 (*the period when the government implemented suspension of arrivals*)

According to the Bureau of Immigration (BI), entry into the Philippines is prohibited as of March 22, 2020, with the exception of foreign spouses and children of Filipino citizens, diplomats, international organizations' employees and officials [27].

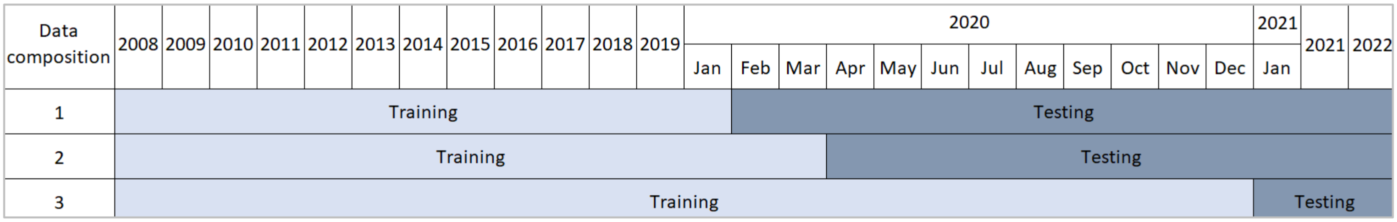
- December 2020 (*the period when the restrictions to main entry point amid new COVID-19 strain was implemented by the government*).

The prohibition on travelers from 20 countries was made public by the Bureau of Immigration (BI) on December 29, 2020, as an additional step to stop the spread of the COVID-19 virus's alleged new strain [28].

The datasets were loaded into Orange Data Mining tool for time series prediction using artificial neural network model based on the architecture of a MLP network. Orange is an open-source data mining toolkit which provides a platform for data visualization and predictive modeling [29].

The researchers adapted the architecture of multi-layer perceptron (MLP), which serve as a supplement to the feed forward neural network. As depicted in Fig. 4, it has three distinct types of layers such as input, hidden, and output layers; receiving the input signal for processing takes place at the input layer. The output layer completes the necessary task, such as classification and prediction [30].

The multilayer perceptron is a feedforward-style design that is based on the perceptron neuron model, which is one of the most popular topologies for forecasting time series [31].



Data composition	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020												2021	2021	2022
													Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan		
1	Training													Testing													
2	Training															Testing											
3	Training																								Testing		

Fig. 3. Composition of fixed training and test sets.

4) Model evaluation: The trained network's predictions were compared against the test forecast set to assess the error. On the test dataset, the network was then simulated.

Evaluation of the Artificial Neural Networks model with three distinct data composition is shown in this section. Each model's prediction accuracy was assessed using mean absolute percentage error (MAPE: Equation (2)), coefficient of determination (R^2: Equation (3)), mean absolute error (MAE: Equation (4)), and root mean squared error (RMSE: Equation (5)) [32, 33]. The MAPE is used to check how close estimates or forecasts are to actual values. Both RMSE and MAE calculate the size of a set of predictions' errors. The primary purpose of the R^2 is to assess how similar the predicted and actual time series are [34].

$$\text{MAPE} = \frac{100}{n}\sum_{t=1}^{n}\left|\frac{A_t - F_t}{A_t}\right| \quad (2)$$

$$R^2 = 1 - \frac{SS_{res}}{SS_{tot}} \quad (3)$$

$$\text{MAE} = \frac{\sum_{i=1}^{n}|Y_i - X_i|}{n} \quad (4)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(Y_i - Y_i)^2} \quad (5)$$

The MSE, RMSE, MAE, MAPE and R^2 determined with the predicted values over the test set are presented for the three data compositions. Furthermore, the selections are based on the best R^2 and lowest MAPE because it shows whether or not the model is a good fit for the observed values, as well as how good of a fit is.

IV. Results and Discussions

Considering the results presented in Table II, the adapted Artificial Neural Networks (ANN) model with the third data composition was the best performing model for predicting tourist arrivals across different data compositions, which clearly shows that ANN is a reliable model in time series prediction [35].

The results show that the prediction models trained with the third training set have the highest coefficient of determination of 0.926 and the lowest MAPE with 13.9%, meaning the forecasted value is closer to the actual one [36]. These results show that the models that were trained with enough data to cover unexpected events like corona virus pandemic, will improve the model accuracy. [37] As the last study pointed out, researchers need to come up with predicting models that can take into account of unplanned scenarios [38]. Overall, the best predictor is the ANN model that uses the data composition which consists of the data of COVID-19 pandemic period.

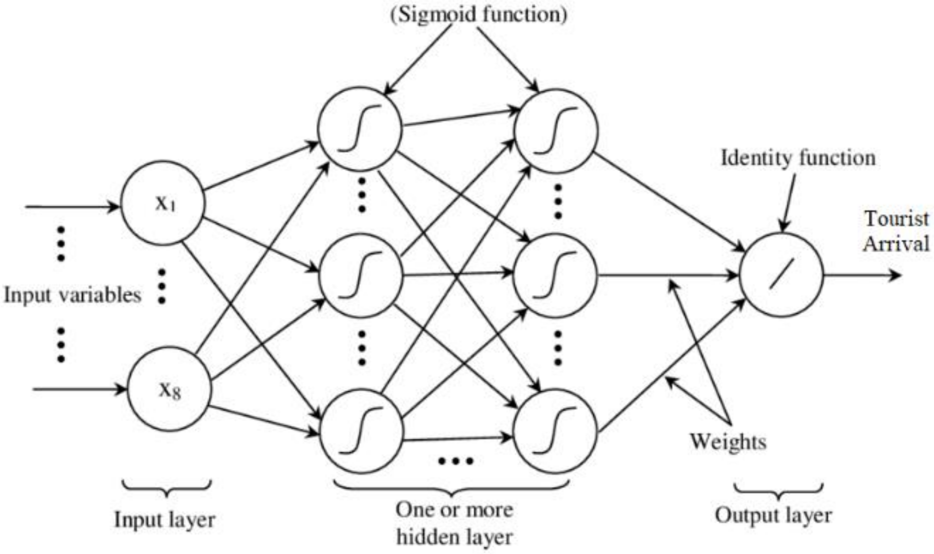


Fig. 4. Multilayer perceptron – artificial neural networks architecture.

TABLE II. COMPARISON OF THE ANN MODEL PERFORMANCE USING DISTINCT DATA COMPOSITIONS

Data Composition	RMSE	MAE	MAPE	R^2
Data Composition 1	333,830.43	255,944.55	543.8%	-6.857
Data Composition 2	156,101.00	113,327.23	250.2%	-1.414
Data Composition 3*	29,814.31	25,254.74	*13.9%*	*0.926*

Note(s): The italicized figures show the results with the best fit across various data compositions, and the * denotes the model with the best performance across various data compositions.

Fig. 5 to 7 portrays the comparison of actual and predicted values of monthly number of inbound tourist arrivals with all data compositions using Artificial Neural Networks model.

The blue line represents the actual tourist arrival, while the predicted value is represented by a red line. Similar to the result in the study of [39], the outputs portrayed in Fig. 7 confirm the competence of ANN model in predicting tourist arrivals in the Philippines. Another researcher conforms that the ANN model has the capacity to outperform other time series machine learning techniques, like ARIMA models [40, 41], Box-Jenkins and Exponential Smoothing models [42].

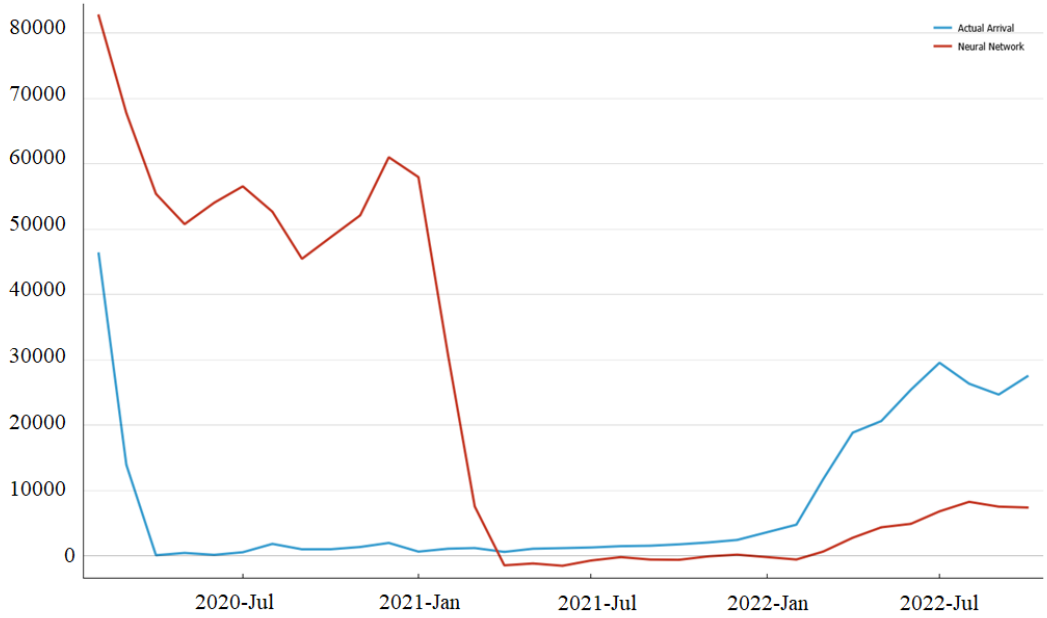

Fig. 5. The actual and predicted values of tourists' arrivals using ANN of first data composition. Source: Author's elaboration.

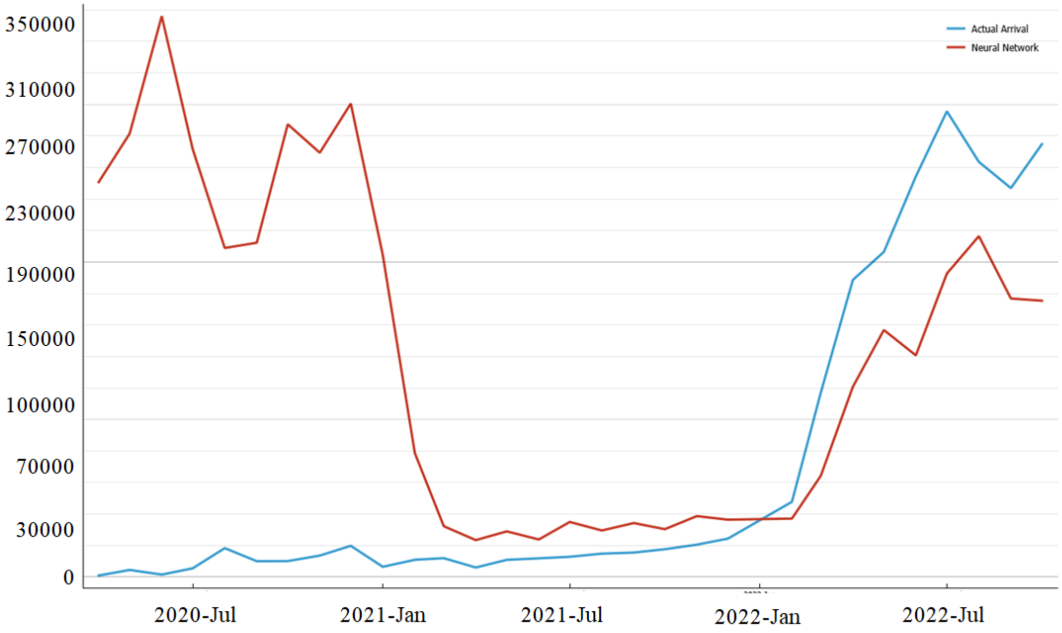

Fig. 6. The actual and predicted values of tourists' arrivals using ANN of second data composition. Source: Author's elaboration .

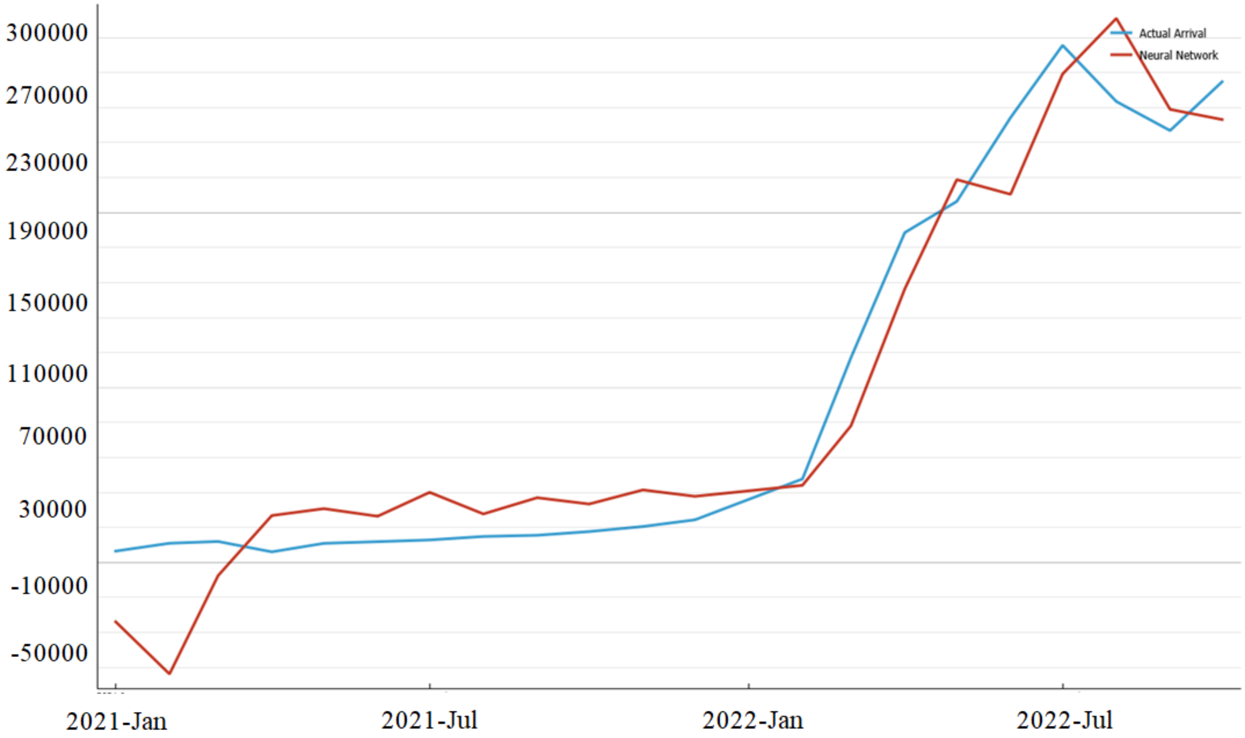

Fig. 7. The actual and predicted values of tourists' arrivals using ANN of third data composition. Source: Author's elaboration.

V. Conclusion

This study compares three distinct data composition in training data sets of Philippines' tourism demand from 2008-2022 using Artificial Neural Network model. The first training set consists of the period when the government confirmed the first case of new coronavirus; the second set is the period when the government implemented suspension of arrivals, and finally, the period when the restrictions to main entry point amid new COVID-19 strain was implemented by the government. To determine the best model and to see whether or not the model is a good fit for the observed values, as well as how good of a fit is in predicting and forecasting the arrivals, it was evaluated utilizing different time series evaluation metrics namely, mean absolute percentage error (MAPE), coefficient of determination (R^2), mean absolute error (MAE), and root mean squared error (RMSE).

The findings showed that the ANN model is reliable in predicting tourist arrivals, with an R-squared value and MAPE of 0.926 and 13.9%, respectively. Furthermore, it was determined that adding training sets that contain the unexpected phenomenon, like COVID-19 pandemic, increased the prediction model's accuracy and learning process. As the technique proves it prediction accuracy, it would be a useful tool for the government, tourism stakeholders, and investors among others, to enhance strategic and investment decisions.

VI. Future Work

To further the study, a combination of neural networks with fuzzy logic or other time series forecasting models for more reliable and accurate results. In addition, other external factors like online forums, reviews in travel Apps, and social media posts, can be added to further enrich the dataset.

Acknowledgment

The authors would like to extend their profound gratitude and sincere appreciation to the Editors and anonymous reviewers for their valuable and constructive feedbacks to further improve the study.

***Abstract*—In recent years, smart cities have gained in popularity due to their potential to improve the quality of life for urban residents. In many smart city services, particularly those in the field of smart healthcare, big healthcare data is analyzed, processed, and shared in real time. Products and services related to healthcare are essential to the industry's current state, which increases its viability for all parties involved. With the increasing popularity of cloud-based services, it is imperative to develop new approaches for discovering and selecting these services. This paper follows a two-stage process. The first step involves designing and implementing an Internet-enabled healthcare system incorporating wearable devices. A new load-balancing algorithm is presented in the second stage, based on Ant Colony Optimization (ACO). ACO distributes tasks across virtual machines to maximize resource utilization and minimize makespan time. In terms of both makespan time and processing time, the proposed method appears to be more efficient than previous approaches based on statistical analysis.**

Keywords—Internet of things; cloud computing; healthcare; load balancing

I. INTRODUCTION

Recent advancements in Internet of Things (IoT) [1, 2], Blockchain [3], 5G connectivity [4, 5], cloud computing [6], smart grids [7], optical networks [8, 9], machine learning [10], and artificial intelligence [11, 12] have resulted in exponential growth in data usage across a wide variety of engineering and commerce fields. Embedded systems and Internet-enabled devices have given rise to a new technology called the IoT [13]. IoT allows physical objects, data, and virtual environments to interact. In a prosperous digital society, IoT is used in various applications for data acquisition, such as smart communications, smart healthcare, and smart cities [14]. IoT-enabled medical sensors and tools pose several potential research opportunities in medical and health care [15]. There is a mutual dependency between IoT and cloud computing. By combining both, they provide real-time health data to medical professionals and caregivers at the remote site [16]. Cloud resources and capabilities enable IoT to overcome technological limitations. In contrast, IoT can benefit the cloud by adding real-life items to its scope and distributing and dynamically delivering many new services [17].

Smart environments can be extended to develop new applications and services using IoT-centric-cloud architectures. Combining cloud computing with IoT technology is far more efficient than regular cloud-based applications. This combination of technologies can be used in emerging medical, military, and banking applications [18]. Cloud-based IoT is particularly useful in medical applications that require tracking and remote access to records [19]. IoT-driven healthcare applications collect data on frequent changes in health parameters and continuously update their severity. The IoT devices and sensor readings associated with medical parameters will also be used to diagnose diseases on time before they become severe [20]. There is an increasing amount of data being created and stored for a long period of time today [21].

IoT plays a vital role in healthcare applications. Three phases are included in this criterion: treatment, monitoring remotely, and awareness of context. Patients in the hospital, especially those in intensive care, require constant monitoring and close attention to respond to potential crises and save lives. Physiological data is collected using sensors, analyzed in the cloud, and sent to caregivers (parents, nurses) for further analysis [22]. The sensors collect and analyze the flow of data collected by many health professionals to examine patients according to their specialties. This makes identifying the emergency conditions of patients at risk (Urgent or emergent surgery patients, cardiac patients, etc.) much easier [23]. Many real-world applications rely on remote monitoring. People worldwide are currently suffering from the lack of effective healthcare monitoring. People with chronic illnesses, such as the elderly and children, must be examined almost daily. Remote monitoring eliminates the need to make rounds to the hospital for checkups. Caregivers can diagnose early and intervene earlier with remote access sensors. Healthcare IoT applications require context awareness as a key criterion. As it can determine the condition of the patient and the environment, this technology is extremely useful in comprehending changes in the health status of these patients. Furthermore, changing the patient's physical state could increase his/her vulnerability to diseases and lead to health deterioration [24].

The paper is divided into two stages. In the first stage, an Internet-based healthcare model is designed and implemented, which involves wearable devices attached to the patients' bodies. The second stage proposes a new method based on Ant Colony Optimization (ACO) algorithm to solve the load balancing problem. In order to maximize resource utilization and minimize makespan time, the ACO distributes tasks over the available virtual machines. IoT provides a basis for next-generation applications and services by supporting and developing foundational technologies. Likewise, cloud computing provides the potential to support these applications, allowing for broad network connectivity, distributed computation, and real-time data sharing. Using cloud computing and IoT together provides enhanced performance and security. Still, they could also be used to develop innovative new applications. Cloud computing allocates tasks to virtual machines (VMs) with varying lengths, launch times, and processing times. A key factor in this process is balancing the loads among VMs. Cloud computing presents a number of challenges concerning load balancing. Since cloud workloads can fluctuate depending on users' requirements, it is difficult to arrange these resources in the cloud. By using task scheduling, load balancing allows the requests to be split between different machines so that more jobs are processed in less time, and the VMs' performance can be monitored. A key goal of load balancing is to reduce makespan times and increase cloud resource utilization. The rest of the paper is arranged in the following manner. Related works are reviewed in Section II. Section III gives a background of the problem. Section IV presents the proposed method. Section V concludes the paper.

II. Related Works

Hassan, El Desouky [25] has developed an intelligent and context-aware hybrid model for assisting patients at home under close supervision. Cloud-based systems monitor chronic illness patients at home and store and process massive amounts of data generated by ambient assisted living systems. The local component monitors patients in the event of a cloud system failure or internet disconnect. Real-time health status can be determined using context-aware methods that continuously monitor ambient conditions, physiological signals, and patient behavior. The effectiveness of the model for monitoring and identifying emergencies in an unbalanced dataset has been demonstrated in an experimental case study, including patients with blood pressure disorders. However, the case study only included a small sample size of patients. In order to truly be effective, the local component would need to be tested on a larger, more diverse group of patients.

Kumar, Lokesh [26] propose a mobile healthcare IoT and cloud-based application. By combining the medical sensors with the UCI repository dataset, the researchers have created diabetes datasets for predicting people with severe diabetes. Additionally, a new algorithm has been developed that diagnoses and estimates the severity of diseases using fuzzy rule-based neural classifiers. Health records from various hospitals and UCI Repository datasets were used for some experiments. Compared to existing disease prediction systems, the proposed mechanism is more effective. However, there are some potential drawbacks to this system. First, it is reliant on accurate and up-to-date data from both the medical sensors and the UCI repository. If either of these sources is inaccurate or out-of-date, the predictions made by the system will be less accurate. Additionally, the system is only as effective as the algorithms used to make the predictions. If the algorithms are not accurate, the predictions will also be inaccurate.

Using edge-cognitive computing, Chen, Li [27] have developed an intelligent healthcare system. This system monitors and assesses users' physical health using cognitive computing. Using a health risk assessment table, a user's health risk grade is determined under various health statuses and then distributed across the entire edge computing network based on the user's health risk grade. As a result, the network has a deeper cognitive intelligence that is application-aware. Experiments show the proposed method increases patient survival rates in an emergency while improving user experience and maximizing computing resource utilization. However, there are also potential risks associated with this health risk assessment table. For example, if the health risk grade is incorrectly determined, it could lead to devastating consequences for the user. In addition, if the table is not updated frequently, it may not be accurate in predicting health risks.

In addition, Garbhapu and Gopalan [28] have created a device using the IoT to monitor patients simultaneously while wirelessly transmitting data to physicians across the globe. Hub and spoke diagrams illustrate the interaction between the sensor nodes in the instrument, which include a microprocessor MSP430 and a wireless transceiver nRF24L01. The wristband has a sensor that continuously monitors the user's vital signs. Data collected by the MSP430 is stored and wirelessly transmitted for future treatment by doctors. However, there are also potential risks associated with using such technology. For example, if the data collected by the wristband is not properly encrypted, it could be hacked and used to exploit the user's personal information. Additionally, if the wristband malfunctions, it could give false readings that could lead to incorrect diagnosis and treatment by doctors.

An IoT-based mechanism for authenticating health monitoring signals was developed by Hossain and Muhammad [29]. Since ECG monitoring is an essential evaluation tool, it was used as a case study. ECG signals can be constantly monitored by a medical expert to detect illness and prescribe medications to minimize avoidable deaths. ECG signals are captured by a portable ECG recording device and sent via Bluetooth to a smartphone or computer. To ensure security and authentication, the recorded signal is processed with a simple algorithm to remove unwanted noise. After extracting and classifying the temporal and spectral features of the watermarked ECG signal, a one-class support vector machine classifier is used. A suitable healthcare expert evaluates the watermarked ECG and classification decision. The expert then enters a prescription and a conclusion into the cloud server. Eventually, the patient is notified by the cloud. Cloud-based ECG health monitoring experiments and simulations has demonstrated the applicability of this method. However, while this system may be convenient for some, there are also potential privacy concerns that come with storing this sensitive information in the cloud. There is also the potential for system failure or human error that could lead to misdiagnosis or delayed diagnosis.

An overview of ubiquitous and intelligent healthcare systems is provided by Motwani, Shukla [30]. A novel mechanism to monitor and recommend smart patients was developed using deep learning and cloud-based analytics. The proposed mechanism monitors and forecasts patients' health status using vital signs and activity context, generated by ambient assisted living devices and calls for assistance. The experimental study used an unbalanced dataset compiled from a case study of blood pressure patients and predicted the patients' actual health status. Preventive and therapeutic care can be provided in real-time without Internet access or cloud services. However, the accuracy of the predictions made by the mechanism may not be accurate enough to provide reliable preventive or therapeutic care to patients in real-time.

Using blockchain technology and attribute-based encryption Mubarakali [31] has proposed a method for securely transmitting healthcare data in cloud environments by addressing privacy and security concerns. A centralized healthcare system collects patient data using wearable devices. Patient conditions are observed while sleeping, hearing heartbeats, and walking. Servers in the cloud receive the gathered data. Doctors review the patient's observation report, genetic information, and clinical test results before prescribing the appropriate medicine and precautions to speed up recovery. Based on experimental results, the approach has shown better success rates, execution times, and delay times than previous methods. However, there are also potential privacy concerns that come along with this method of data collection and storage. If patient data is not properly secured, there is a risk that it could be accessed and used without the patient's consent or knowledge. There is also the potential for security breaches that could lead to the release of sensitive patient information.

III. Backgrounds

With the rapid growth of the IoT and the popularity of wearable devices, the relationship between healthcare and technology has significantly changed in recent years. This results in personalized healthcare, increasing access to healthcare like never and allowing for customization like never before. IoT-enabled healthcare models require an intensive collaboration with cutting-edge technologies to build a flexible, efficient and secure platform for developing new services. A major objective of IoT in healthcare is to replace the traditional approach with an electronic approach, which means linking the patient and doctor in real-time via a smartphone so that doctors can continuously track the patient's health and provide him with recommendations.

Cloud computing provides a cost-effectively scalable and resilient computing resources, enabling large-scale applications to be deployed quickly and efficiently. Large-scale applications handle a large volume of work. There are three types of cloud computing services: infrastructure as a service (IaaS), software as a service (SaaS), and platform as a service (PaaS). SaaS cooperative models allow users to access cloud applications via web browsers on desktops or workstations. Using PaaS, developers can improve, evaluate, and accommodate their applications. The IaaS model enables large-scale applications to be run on an elastic and scalable computing platform.

VMs offer users’ preconfigured CPU processors, bandwidth, memory, and storage capacities in a virtualized computing environment. Virtualization solutions are available at various prices to meet customers' varied needs, allowing them to manage computer resources efficiently. IaaS offers end users three primary benefits. Users pay for the infrastructure usage as they would for essential services. Resources can be contracted or increased depending on the needs of the application. Additionally, IaaS cloud computing improves application development by providing direct access to resources. Lastly, according to users' requirements, renting resources is possible anytime and anywhere. In IaaS clouds, finding enough resources to handle a wide range of massive-scale tasks is still an open and well-known challenge. The healthcare field can benefit from cloud computing techniques for maintaining patients' records and monitoring health outcomes more efficiently and effectively. Healthcare systems can benefit from cloud computing in the following ways:

- Cost reductions: Hardware and operating systems do not have to be monopolized by healthcare systems.
- Security and privacy: Cloud providers must meet several privacy requirements, including the Health Insurance Law and Issue.
- Exchange of health information: Healthcare organizations can exchange information through cloud computing.
- Telemedicine: As technology disperses and technologically advanced devices spread, telemedicine encompasses teleoperations, electronic health records, video conferences, and the provision of health care at home.
- Speed: Patients and healthcare providers can access confidential information quickly via cloud services.

As the number of cloud providers grows and the load on the cloud servers also increases, the scheduling problem in this environment becomes a key issue. Scheduling tasks on VMs may result in some VMs needing more utilization while others are underutilized. An efficient scheduler is needed to organize the scheduling process and balance the server loads. Load balancing has been an efficient way to distribute a system's load among the involved VMs. CPU, memory, and network loads are all possible types of loads. Cloud computing environments rely on the following metrics for load balancing.

- Resource utilization refers to the mechanism's effectiveness in employing resources for the given tasks.
- Throughput: It indicates the number of customer requests handled per unit of time.
- Makespan: It represents the time when the last submitted task was completed.
- Performance: It measures system efficiency after executing a load-balancing algorithm.
- Response time refers to the combined arrival and waiting time in a task queue.

IV. Proposed Mechanism

Ant Colony Optimization (ACO) is a meta-heuristic used to solve complex combinatorial optimization problems. The basic ACO algorithm relies on laying pheromone trails inspired by how biological ants communicate using pheromones. Artificial ants communicate with each other via artificial pheromones within a colony, similar to the biological example. Pheromone bands induce indirect communication between simple agents called artificial ants. Pheromone traces act as digital and distributed information in ACO that ants use to create solutions to problems to be solved and to adapt to them as a reflection of their search experience during the execution of the algorithm, which is why ACO differs from other construction heuristics in many ways [32, 33]. The ACO key steps are described in the following.

A. *Initialization*

All pheromone variables and parameters are set in this step.

B. *Constructing and Solutions*

The ants use the pheromone values and other information to solve the problem. Depending on the particular construction mechanism, a partial solution may not be extended and still be feasible, or a complete solution may be constructed that is impossible. If an infeasible solution violates constraint requirements to a greater or lesser extent, it may be penalized. Each step of the construction process involves selecting a solution component based on probabilities. Probability distributions are defined in various ways. The most commonly used rule is described by Eq. 1.

$$p\left(c_i^j \middle| S_p\right) = \frac{\mathcal{T}_{ij}^{a}.\left[\eta(C_i^j)\right]^{\beta}}{\sum_{C_i^l \in N(S_p)} \mathcal{T}_{il}^{a}.\left[\eta(C_i^l)\right]^{\beta}}, \forall c_i^j \in N(S_p) \tag{1}$$

C. *Local Search*

Using local search algorithms, completed candidate solutions can be further improved. ACO algorithms perform best when coupled with local search algorithms to solve combinatorial optimization problems. The local search operation can be viewed as a daemon activity that performs centralized or problem-specific functions that cannot be handled by an ant individually.

D. *Global Pheromone Update*

As pheromones are updated, subsequent iterations will be more attracted to good solutions. This goal can be achieved through two mechanisms. Firstly, pheromone deposits boost the pheromone level in selected solution components. It led to making these solution items more appealing to ants in subsequent iterations. Another mechanism is pheromone trail evaporation, which causes the pheromones left behind by previous ants to diminish over time. Practically, pheromone evaporation is necessary to prevent too rapid convergence of the algorithm towards a suboptimal region. It facilitates exploring new search spaces by implementing an effective form of forgetting. Pheromone updates are implemented by Eq. 2.

$$\mathcal{T}_{ij} = (1-\rho)_{\mathcal{T}_{ij}} + \sum_{s \in S_{upd} \middle| c_i^j \in s} g(s) \tag{2}$$

As illustrated in Fig. 1, two stages are involved in the proposed mechanism: developing an IoT-based healthcare system and solving the cloud load balancing problem using the ACO algorithm. The idea behind it in healthcare is moving from a conventional way of monitoring to a modern way called real-time remote monitoring. To build the health care system, wearable devices (medical sensors) connect to patients' bodies. These devices transfer data throughout the day through a wireless network attached to the patient's body. Servers in a cloud centre have characteristics, and virtual machines with similar characteristics surround them. A key challenge in cloud computing is load balancing, and a new algorithm is proposed to resolve it. In this design, rapid response reduces costs and improves patient care. This mechanism includes the following components:

- Doctors: They monitor patients, perform diagnoses and treatments, and prescribe medications for patients.
- VMs: Cloud resources are provisioned to customers through VMs.
- ACO algorithm: It chooses optimal VMs based on their fitness values for load distribution.
- Cloud broker: In a nutshell, it is an intermediary between the ACO algorithm and the VM manager that assigns the VMs to different loads.
- VM manager: The tool extracts tasks from the queue and provides relevant data regarding the machines regarding their activities, efficiency, number of hosts, number of virtual machines, and task counts and lengths.
- Task queue: It is utilized to keep track of the number of tasks that need to be completed by the manager.
- IoT gateway: This device bridges the sensor and the task queue. Gateways transfer data from on-premises to the cloud and vice versa.
- Patients: There are several diseases afflicting a group of patients. Data such as heart rate and temperature are sent to an IoT gateway by sensors attached to patients' bodies.

The gateway receives tasks from sensor devices and sends them to the task queue. The VM manager collects queued tasks and forwards them to the cloud broker once sufficient VMs are available. As a load balancer, the cloud broker allocates tasks to virtual machines based on their fitness values using the ACO algorithm. Each VM is given a fitness value based on the three following criteria:

E. *Execution Time*

It refers to the amount of time a VM takes to complete the execution of a given task, calculated by Eq. 3, in which U denotes the CPU utilization and V stands for the VM load. The VM load is calculated using Eq. 4, in which M refers to MIPS for the VM, L indicates the task length, and N reflects the number of tasks.

$$E = {}^{V}\!/_{U} \tag{3}$$

$$V = {}^{(N \times L)}/_{M} \qquad (4)$$

F. *Storage Utilization*

It is the proportion of occupied storage space versus total storage space, calculated by Eq. 5, in which T, A, and R stand for the total memory of VM, available memory, and the amount of memory remaining before implementing a task in the VM, respectively.

$$S = R + ({}^{A}/_{T}) \times 100\% \qquad (5)$$

G. *CPU Utilization*

It refers to the amount of work that a CPU handle using its processing resources, calculated by Eq. 6, where U indicates the CPU usage of a task.

$$C = 100 - ({}^{U}/_{N}) \qquad (6)$$

The past state of VMs and the task's duration are considered during load distribution. The search space's starting point is the matrix's centre, where each position represents a VM. In each iteration, an ant calculates the fitness value of its present position and neighbors and moves on to the next hope with the highest fitness value.

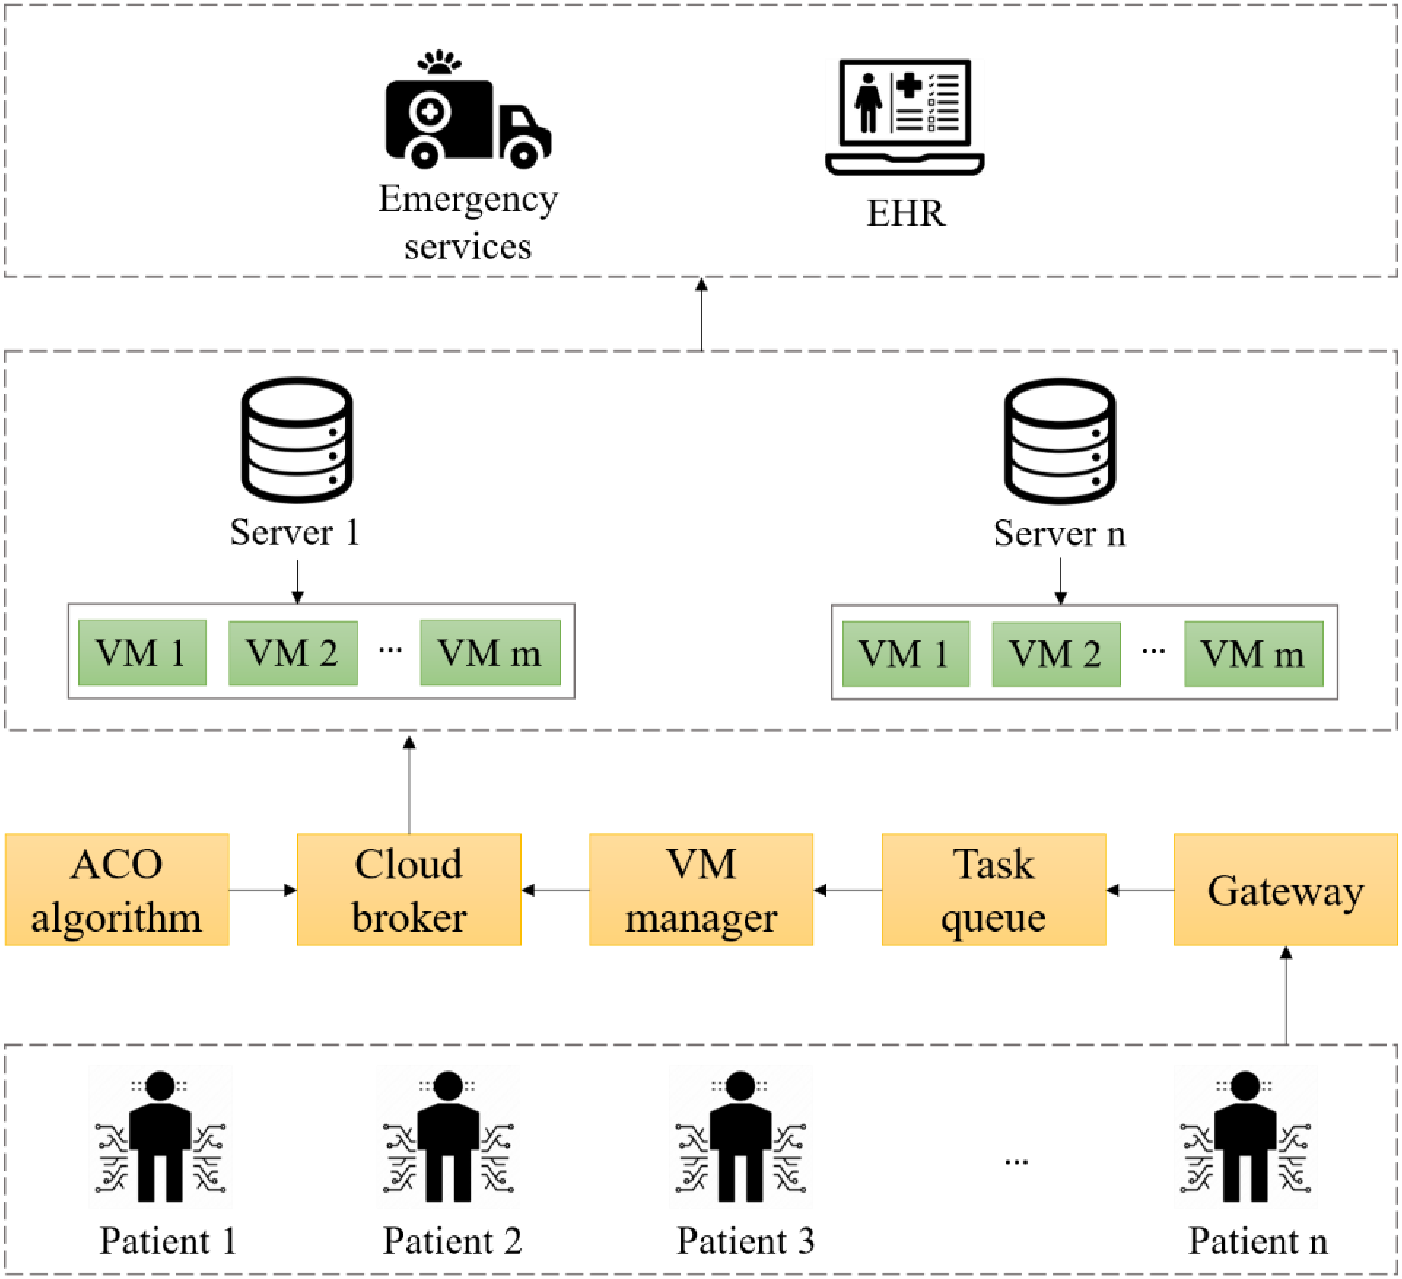

Fig. 1. Structure of proposed mechanism.

V. Experimental Results

The proposed system was evaluated experimentally and estimated using the CloudSim simulator. Parameters and assumptions are summarized in Table I. VMs differ in their ability (fitness) to execute tasks (Table II). Different VMs and tasks were used to compare the proposed mechanism with other approaches. Fitness (capability) varies from VM to VM. In this situation, load balancing is necessary to achieve the preferred performance. Thus, the ACO algorithm divides workload among virtual machines according to their capability (fitness) and task length, in which longer tasks are assigned to VMs with a high fitness level. VMs selected by the ACO are shown in Fig. 2, along with the shape of their movements, with red representing the ants' starting points and green representing the VMs selected. Table III and Fig. 3 illustrate the VMs selected and the fineness.

For each iteration, the time elapsed can be seen in Table IV. Increasing the number of iterations leads to an increase in time, as shown in Fig. 4. The ACO chooses optimal VMs for the given task based on the VM's status and length in the cloud environment. The ACO reduces makespan time as well as balances the whole system load. Table V compares the makespan time of our mechanism with those of other heuristic algorithms. When the number of tasks increases, the suggested mechanism performs faster than others; this proves that it is more effective than its competitors. As shown in Fig. 5, the proposed algorithm has a shorter makespan time. Eq. 7 calculates the processing time of an algorithm to perform a given task, in which Np represents the number of processors within the current virtual machine. A comparison of the total processing time of the proposed mechanism and recent ones are presented in Table VI. According to Fig. 6, our mechanism outperforms others regarding processing time.

$$Processing\ time = {}^{TL}\!/_{(Vm * Np)} \tag{7}$$

The implementation of a healthcare system to enhance the interactivity between patients and physicians has been enhanced with the integration of IoT with wearable devices. Specifically, the ACO algorithm has been applied to load balance in cloud computing, which assigns tasks based on their length and fitness values to the appropriate VMs. By assigning tasks to the most efficient VMs, the ACO algorithm can ensure that the tasks are completed in a timely manner, while also reducing latency and improving the overall user experience. Furthermore, the use of wearables enables the collection of data that can be used to track and monitor patient progress over time, allowing for more accurate diagnosis and treatment. A primary aim of load balancing is to eliminate the overloaded tasks from VMs and allocate them to underloaded VMs, improve the runtime of loads (tasks), decrease the overall makespan time, maximize resource utilization, and balance the load in each VM.

This study demonstrated that the ACO algorithm is more effective than other meta-heuristic algorithms in providing strong optimal results. In most cases, it provides better solutions, is faster in convergence, and is more computationally efficient than other approaches. When compared to prior work, this work is effective in reducing the makespan time and the processing time. In all cases, resource utilization increases when the number of tasks increases. Furthermore, the degree of imbalance is measured in order to assess the effectiveness of the proposed method. The measurements indicate that the proposed method performs better for a large number of cloudlets, estimated at 177.767.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Number of hosts	10
VMs memory	512-2048
VMs MIPS	500-2000
Number of VMs	100
Length of tasks	1000-5000 MI
Number of tasks	100

TABLE II. VMS AND FITNESS VALUES

VI. CONCLUSION

A healthcare system has been implemented by connecting IoT with wearable devices and cloud computing to enhance patient-doctor interaction. Cloud computing load balancing is solved with the ACO algorithm, which assigns tasks to suitable virtual machines based on fitness values and lengths of tasks. Load balancing focuses on eliminating overloaded tasks from the VMs, reallocating them to underloaded VMs, increasing load time (tasks), reducing makespan times, and increasing resource utilization. In comparison to other meta-heuristic algorithms, the ACO algorithm provides strong optimal results, provides better solutions, is faster in convergence than other methods, and is more computationally efficient than previous ones. The proposed method may be improved or enhanced in the future by improving the ACO algorithm in order to reduce the search time for candidate VMs and solve the local optimization problem. Moreover, the performance and efficiency of the system can be enhanced by integrating or utilizing other intelligent algorithms. Messages can be given priority based on their importance. Additionally, the proposed method could be extended to incorporate additional constraints such as cost, availability, or energy efficiency. Furthermore, the proposed method could be adapted to work with different types of clouds, such as public, private, and hybrid clouds, to offer even greater scalability and flexibility.

***Abstract*—Developing a license plate recognition system that can cope with unconstrained real-time scenarios is very challenging. Additional cues, such as the color and dimensions of the plate, and font of the text, can be useful in improving the system's accuracy. This paper presents a deep learning-based plate recognition system that can take advantage of the bilingual text in the license plates, as used in many countries, including Saudi Arabia. We train and test the model using a custom dataset generated from real-time traffic videos in Saudi Arabia. Using the English alphanumeric alone, the accuracy of our system was on par with the existing state-of-the-art algorithms. However, it increased significantly when the additional information from the detection of Arabic text was utilized. We propose a new algorithm to restore noise-affected missing or misidentified characters in the plate. We generated a new test dataset of license plates to test how the proposed system performs in challenging scenarios. The results show a clear advantage of the proposed system over several commercially available solutions, including Open ALPR, Plate Recognizer, and Sighthound.**

Keywords—Automatic License Plate Recognition (ALPR); Intelligent Transportation System (ITS); Optical Character Recognition (OCR); Deep Convolutional Neural Network; You Only Look Once (YOLO)

I. INTRODUCTION

In recent times, smart cities have been a popular trend, resulting in the pacing of the development of several enabling technologies. One of them is robust automatic license plate recognition (ALPR) [1], which offers a computer vision based solution for intelligent transportation systems (ITS) [2]. In this regard, a passive mesh of cameras is generally installed at road intersections and other suitable locations to observe vehicle routing through urban environments [3]. ITS can improve safety and mobility and help law enforcement agencies monitor traffic effectively. There have been several systems proposed to detect and recognize license plates (LPs) for various applications like toll fees collection [4], monitoring for the speed of a car on the road [5], traffic volume estimation on [6], detection of illegal parking [7], highway surveillance [8], and border control [9]. However, most systems tackling any of these aspects often work well only when operated in a restricted environment where camera distance and angle are fixed [10]. In an unconstrained environment, factors like low image resolution, dynamic background, motion blur [11], and variable lighting conditions, can degrade the image quality. This makes recognizing LP characters in unconstrained environments a very challenging task.

Some solutions that have been proposed to address these variabilities include Laplacian gradient-based partial character segmentation [12], Generative Adversarial Network (GAN) [13], super-resolution (SR) image reconstruction using maximum a posteriori (MAP) [14], SR reconstruction [15], and Recurrent Neural Network (RNN) [16]. Although these approaches can help restore the deteriorated or missed characters within LP, they do it at the expense of higher computational complexity due to the additional machine learning model used for the restoration task. Similarly, methods like multiscale adaptive thresholding [17] and matrix edge information based adaptive thresholding [18] depend on edge information. They can produce false positives due to weak edges, especially in the presence of high noise.

We propose a simple and fast technique for detecting and recognizing the contents of LP in unconstrained environments. You Only Look Once Version 5 (YOLOv5) network is used for detection, while a custom-built convolutional neural network (CNN) recognizes the contents in the detected LP. We collected a custom dataset from real-time traffic in Saudi Arabia, where the number plates are bilingual, using Arabic text on top and English at the bottom. The unique feature of the proposed method compared to the existing works is that it tries to recognize alphanumerics in both languages and then combines both results to improve the overall accuracy of LP recognition. We propose a new algorithm, which can address several scenarios of unrecognized and wrongly recognized alphanumerics. It uses computationally simple and efficient techniques, implemented without using a separate deep learning model, and does not depend on the deteriorated character's edge information either to restore the noise-affected missed character. Our results show that the proposed model outperforms commercially available server-based ALPR systems of Sighthound [19], Plate Recognizer [20], and Open ALPR [21].

The rest of the paper is organized as follows. Section II gives an overview of the related work. Section III describes training dataset preparation steps, including extracting LP from the captured video streams and synthetically generating and augmenting more plates to add to the data. The steps of detecting LP, recognizing Arabic and English alphanumeric characters, and restoration of missed and wrongly recognized characters are discussed in Section IV. Experimental evaluation is reported in Section V, while some conclusions and future research directions are given in Section VI.

II. Related Work

Over the years, numerous designs based on different architecture and technologies have been proposed to solve the detection and recognition problems of ALPR. For the detection of LPs, some works use image processing-based solutions. Chen and Luo [22] proposed an LP localization method using an improved version of the Prewitt arithmetic operator. It extracts the exact location from vertical and horizontal projections. However, the method requires prior knowledge of all the characters' textures which become difficult to obtain while working in an unconstrained real-time environment. Vijeta et al. [12] used stroke pair candidate detection by using Laplacian and gradient information. They find pixels that represent the stroke width of characters on a given LP. However, this method usually fails while dealing with complex backgrounds in real time due to unsymmetrical features within the captured frames.

YOLO models have been used to detect LPs in more recent works. Alghyaline [11] used a modified YOLOv3 model. Since the LP size is much smaller than the captured frame, they used only 15 layers instead of the original 75. It made the process fast but at the expense of low accuracy when detecting smaller characters within LPs. Ju-Yeong Sung [23] used YOLOv4, which can detect smaller objects, both LP and the characters within it, but at the expense of higher training costs. Khan et al. [24] used the YOLOv5 model to detect LP and its characters in a real-time environment. The YOLOv5 model uses path aggregators to speed up the detection process in real time. It also uses the mosaic data augmentation technique, which helps detect very small objects in challenging environments. Moreover, it also uses auto-learning bounding box anchors, which help make bounding boxes around objects despite the challenging backgrounds within a frame.

Some works use image processing-based techniques to reconstruct deteriorated or missed characters for the recognition task. Vijeta [12] proposed partial character reconstruction with the Tesseract optical character recognition (OCR) library, which uses the characteristics of stroke widths in the Laplacian and gradient domains. The method first enhances high-contrast information at the edges using symmetrical features of incomplete characters by suppressing background information. Then it uses stroke width properties to reconstruct the complete shape of the deteriorated characters. This method, however, proves to be not very effective for restoring completely deteriorated characters. Khoshki et al. [17] proposed a multiscale adaptive thresholding method for ALPR, which is used to find the candidates matching the LP characters affected by noise. However, the effectivity of this method lessens under varying illumination conditions. Moreover, it is computationally intensive and requires significant time to process input images. Mokji et al. [18] proposed an algorithm that incorporates matrix edge information, which enhances foreground objects in relation to the neighborhood pixels. This method does not work well when the edges of objects are weak and disconnected. Moreover, in an extremely degraded image, strong interfering patterns can generate false edges.

Some works used SR algorithms along with machine learning models. Lin et al. [13] proposed an SR image reconstruction method using GAN, an unsupervised learning model. It preprocesses the affected input image and extracts image features using a residual dense network. The method then uses sampling to restore more information using a larger receptive field. A Markovian discriminator is used to accurately guide the generator to reconstruct high-quality restored images. Despite good results, the method increases the difficulty level of training such a highly complex model. Moreover, it shows edge artifacts as well. Zhan et al. [14] proposed a MAP-based SR image reconstruction approach. It helps to estimate distribution and model parameters that best explain an observed dataset. It then uses a Huber Markov random field (HMRF) along with an ALPR system to measure image smoothness. The technique improves the recognition rate by restoring and improving the quality of LP image. However, quality enhancement is limited to single-frame reconstruction instead of a sequence of video frames.

Chen et al. [15] proposed an SR reconstruction algorithm. It uses the mechanism of attention along with a feature map to reconstruct multiscale SR images from original low-resolution images. It uses a combined feature map of multiple channels before applying a reconstruction module. It also uses interdependence to adaptively adjust the characteristics of the channel to restore details before generating high-resolution images at different scales. Despite reconstructing images, it increases weight parameters which eventually increases training time. Hui Li et al. [16] extracted and recognized the sequential features from the whole LP using a recurrent neural network with long short-term memory. However, a large number of labeled LPs are required for training. Duan et al. [25] used inception structure, which utilizes computational resources effectively by image dimensionality reduction, in an end-to-end CNN. However, this can affect the recognition accuracy of noisy images taken in real-time scenarios. Ergun et al. [26] used a statistical method in which refined characters are stretched/reduced to a given size and matched in a labeled database. This method has a limitation as it requires exact correspondence. Moreover, a slight deterioration of characters can affect the recognition accuracy.

There are several commercial ALPR solutions also available. OpenALPR [21], PlateRecognizer [20], and Sighthound[19] are open-source systems that can recognize LPs in a given input frame. These systems can be accessed using their cloud API services that predominantly use OpenCV and Tesseract OCR libraries. Moreover, reconstruction algorithms are also part of these available systems, but they require incomplete strokes of digits or characters in a noiseless background for good performance. Otherwise, these APIs fail to restore the completely missing alphanumerics in noise effected license plates.

III. The Proposed Method

The proposed system uses several steps, including extraction of frames from the videos of traffic, annotating the frames, augmenting the dataset, training the network, and testing its performance. The complete pipeline is shown in Fig. 1, and its different modules are explained in this section.

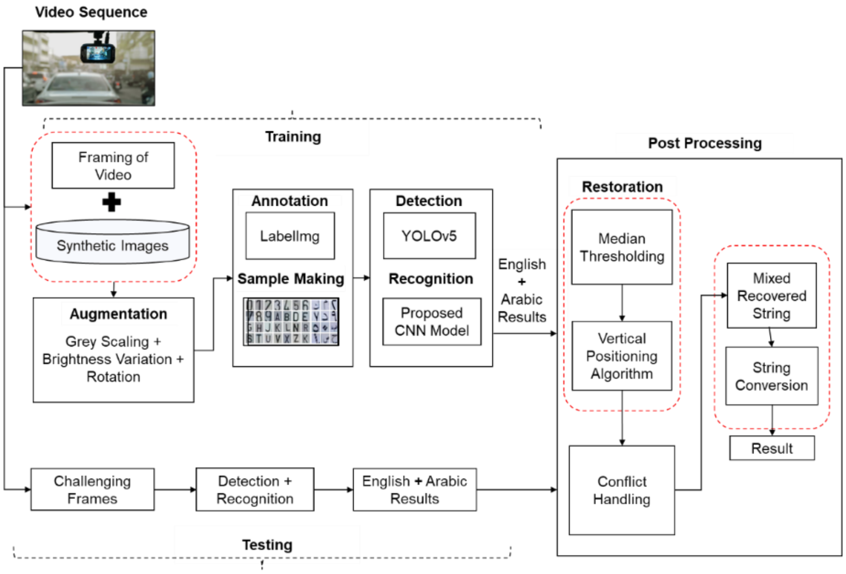

Fig. 1. The pipeline of proposed multi-string ALPR system.

A. Preparation of Dataset

1) Data acquisition: Designs of the most commonly used LPs in Saudi Arabia are shown in Fig. 2. The standard size of these plates is 32 cm in width and 16 cm in height. The color schemes indicate the usage of vehicles. We captured many videos of live traffic, with a sufficient number of samples of each type. We examined each frame of these videos manually and extracted 2600 frames in total. The rest of the frames that had no vehicle or were very similar to one of the previously selected frames were discarded. The frames were stored as color images in PNG format at FHD resolution (1920×1080 pixels).

2) Synthetic Saudi Arabian LP Generation: No Saudi LP dataset is available in the literature with sufficient size (number of images) and variety of scenarios to support robust training of LP detection and recognition models. Moreover, dataset preparation is a very time-consuming process. Hence, we increased the size of our dataset by adding some synthetically generated license plates. For this, our algorithm first generates random but mutually mapping strings of officially used English and Arabic alphanumerics. These random texts are then appended on synthetically generated layouts. The synthetic layouts contain immutable elements such as the country name, the grid, and other official symbols on the right side of every plate. The mapping coordinates are determined based on the positional analysis of different characters in the actual plates. A total of 200 synthetic images were generated this way and included in the dataset. Some examples are shown in Fig. 3. In a real-world scenario, the license plates may be dirty and less readable than the synthetically generated plates. Thus, to create more realistic data, noise is added. Afterward, all these plates are appended on some selective frames of actual data, as shown in Fig. 4.

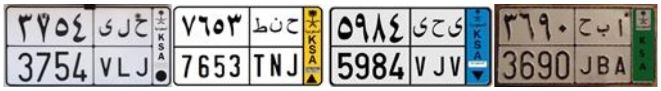

Fig. 2. Types of Saudi Arabian license plates [27].

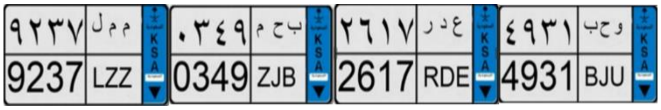

Fig. 3. Examples of synthetically generated Saudi Arabian license plates.

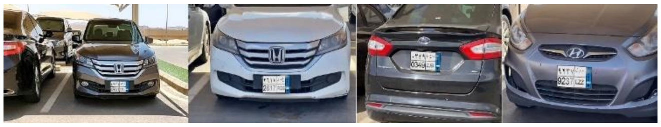

Fig. 4. Examples of appending synthetically generated plates in different video frames.

B. Training Samples Generation

All Saudi Arabian LPs have three alphabet and four digits in English and Arabic both. For training of the custom CNN model, samples for each English and Arabic Alphanumeric glyph are required. For this, an algorithm was designed to automate certain steps of this process, avoiding human intervention. YOLOv5 [28] model initially trained on the available custom dataset is used to detect LP in each frame along with all Arabic and English alphanumerics in it. Coordinates of the detected bounding boxes are used to extract the alphanumerics from the LP automatically. As the training of the network is improved, more samples can be extracted more accurately with minimal manual supervision. The process is depicted in Fig. 5.

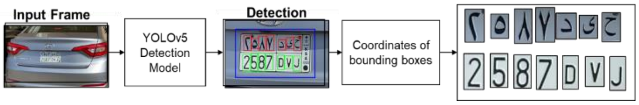

Fig. 5. Generation of training samples.

Each extracted sample is saved in its respective folder. There are 54 classes in total, including ten numerical digits (0-9) and 17 alphabets among (A-Z) that are officially used in LPs, and another 27 Arabic counterparts, containing ten digits (٠ – ٩) and 17 alphabets among (ا – ى).

C. Data Augmentation

Deep learning models require large datasets for increased accuracy. In comparison, our proprietary data is relatively limited, having 2800 frames in total, including 2600 frames extracted from the actual traffic videos and 200 generated synthetically. We split them into training and testing sets containing 2600 and 200 frames, respectively. The testing set includes challenging situations of deteriorated and completely missed alphanumeric characters in Arabic and English strings.

To increase the training dataset and its variability, data augmentation techniques were used, including gray scaling, brightness variation, and rotation. As a result, we got 6500 frames and 15000 alphanumeric characters in total. They vary considerably in size and cannot be used for training without preprocessing. We scale each of them 128x128 pixels. Through augmentation, we could increase the variability in the dataset, which helps in better training of networks, improving their accuracies, and avoiding overfitting. The numbers of frames and samples are shown in Table I.

TABLE I. SUMMARY OF THE TRAINING DATASET

Dataset	Real	Real + Augmented
Frames	2600	6500
Arabic + English Characters	9000	15000

D. Data Annotation

We used a graphical image annotation tool, LabelImg [29], to label the dataset. The coordinates of plates as well as the individual characters, are marked, as shown in Fig. 6. Since we are using YOLOv5 for detection, which accepts annotations in extensible markup language (XML) files, we save the annotations in this format.

E. Detection of License Plates

Due to their high efficiency, the detectors in the YOLO family are often used to work in real-time scenarios [30] [31] [32]. Since the release of its first version, many updates and new versions of YOLO have been developed. The most recent is YOLOv5 [28] [33], which outperforms its predecessors in terms of computational complexity and accuracy of detection. The structure of the YOLOv5 model, a relatively new family member, is shown in Fig. 7.

YOLOv5 is pre-trained on a large dataset; therefore, we use transfer learning [34] using our proprietary dataset. Transfer learning is a well-known technique to fine-tune a previously trained neural network to perform a new task. In our case, YOLOv5 is trained to perform general object detection, and we tune it for LPs. This process prevents the need to complete network training from scratch, which would have required an extensive dataset. For training YOLOv5, our training dataset is split at a ratio of 70 to 30 as shown in Table II.

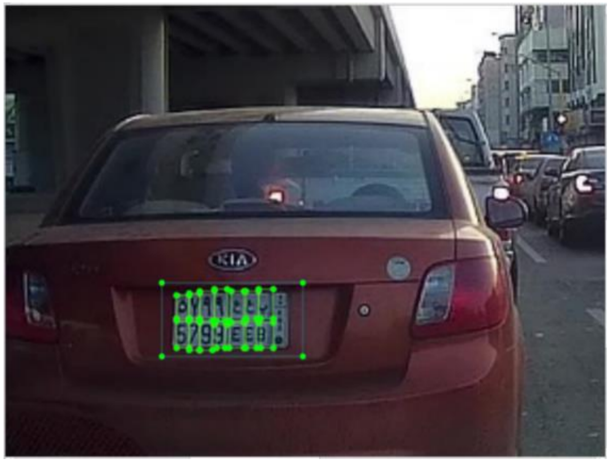

Fig. 6. Annotation of the LP and Arabic and English alphanumeric in an LP using LabelImg software tool.

TABLE II. DATASET SPLIT FOR DETECTION MODEL

Dataset	Split Percentage	Number of Frames
Training	70%	4550
Validation	30%	1950

For the training of YOLOv5, we use Google Collab notebook [28], which provides free access to powerful GPUs. The trained model takes an input frame at the dimensions of 416x416x3 and detects LP in it. The detected LP is cropped automatically, resized to the same input dimensions of 416x416x3, and fed again to the YOLOv5 model to detect its alphanumerics. Since the original frame had an FHD resolution of 1920 x 1080 pixels, the coordinates of the bounding boxes are upscaled to find the exact locations in the original frame. Some results of the extracted LPs are shown in Fig. 8 by marking the bounding boxes with red colored rectangles.

F. Custom Network for Recognition of Arabic and English Alphanumerics

The architecture of the proposed CNN for the recognition phase is shown in Fig. 9. The input of this network is the bounding box detected by the YOLOv5 in the previous step. The proposed CNN's first layer is a convolution layer with dimensions of 224x224x3; the output of YOLOv5 is resized to match it. A maxpool layer after each convolution layer uses 2x2 pixels for pooling. The convolution layers have different filter sizes (64, 128, 256, 512), and the convolution kernel size is 3x3. There are two fully connected (FC) layers, in the end, to keep the model end-to-end trainable. "Same Padding" is used to handle the convolution near the boundaries of the image, and the stride size is 1. Adam optimizer alpha is used for its desirable characteristics in non-convex optimization problems [35].

Alternating convolutional and non-linear activation layers extract rich features of given alphanumerics. The activation function of Rectified Linear Unit (ReLU) with a stride size of 1 pixel for convolutional layers and 2 pixels for the maxpool layers is used. Each of the output FC layers contains 1000 neurons. The final decision is made by using SoftMax about the recognition (classification) of alphanumeric characters.

Fig. 9. The complete achitecture of the proposed pipeline.

We use 15000 alphanumeric characters, including those taken from original plates and others obtained by augmentation. These are split into training, validation, and testing sets, as given in Table III.

TABLE III. DATASET SPLIT OF ARABIC AND ENGLISH ALPHANUMERIC CHARACTERS

Dataset	Split Percentage	Number of Samples
Training	70%	4550
Validation	20%	1950
Testing	10%	1500

G. Post Processing

The dataset used for testing includes some challenging scenarios. In some instances, characters are badly affected by noise, or the plate has a poor condition. Some examples are shown in Fig. 10.

The reconstruction techniques in the existing literature, as discussed earlier, can be used to restore missing and noise-affected individual characters either in English or Arabic string. However, using a separate trained restoration model will increase the whole system's computational cost. We propose a fast and simple solution based on the fact that there is redundant information available in the form of Arabic and English text, and correct recognition of the individual alphanumerics in either of them can lead to overall correct recognition of the LP.

The first step for restoration is to find the location of missing characters in Arabic and English text, and we use a median thresholding based approach for this. It measures the position of each alphanumeric bounding box in both strings relative to the extreme left of the LP and calculates the difference between the successive bounding boxes. If a character is missing, the difference between its left and right detected neighboring boxes would be large. Due to the different shapes of characters, the distance between each pair of neighbors is not the same; however, a missing character makes it much large. We calculate the median value of the distance between detected neighboring boxes and set a threshold of 1.5 times the median distance to detect the missing characters. If the distance is more than 2.5 times the median distance, we assume two characters are missing. However, to explain the algorithm, we assume that only one character is missing between two successfully detected characters. For this case, different steps involved in the restoration process are explained in Fig. 11.

The next step is to restore the missing digit or letter on the spots identified by the median thresholding algorithms above. The exact location of the missing character is assumed to be in the middle of the neighboring characters as shown in Fig. 12.

Step 4
Threshold = median*1.5
Step 5
Xn > Threshold → character is missing

Fig. 11. Working of median threshold-based algorithm for locating missing characters.

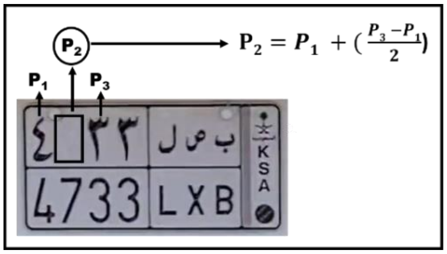

Fig. 12. Finding position of the missing character.

This way, we get seven bounding boxes in each string, regardless the character is detected or missing. The empty boxes are filled by the corresponding vertically mapping characters in the other string. Except for a rare scenario where the same character is missing in both English and Arabic strings, the algorithm can successfully recognize the plate quite accurately, as shown in the experimental results in the next section.

1) Handling conflicts between two strings: Arabic and English alphanumerics have one-to-one matches. To have recognition results with greater precision, we pick the alphanumeric, which is recognized with a higher confidence level by CNN. The string obtained this way is a mix of Arabic and English characters as shown in Table IV. We convert the entire string to the desired language, which is English in our case as shown in the table.

TABLE IV. EXAMPLES OF IMPROVED RECOGNITION RESULTS OF THE PROPOSED ALGORITHM

License Plates			
Mixed Strings	١٠٣٨TKA	1٨٠٦XHJ	21٨٢XDD
Converted Strings	1038TKA	1806XHJ	2182XDD

2) Handling misrecognition due to bolts on the lp: Among many challenging scenarios we encountered in our dataset, one worth mentioning is the wrong recognition of alphanumerics due to the bolts used to attach the plate to the car. There are two bolts used on the top-right and top-left regions of the plate. The location of the right bolt is such that if there is the Arabic character "Alif" (Equivalent of English character A) in the rightmost position, it is read as English "9", as shown in Fig. 13. This is, however, easy to correct, knowing that the rightmost alphanumeric cannot be a digit and it must be a character. So, if a nine is detected at this position, there is a good chance it should be "Alif". If the English string does not detect anything at the rightmost location, we take it as "Alif" or "A". However, if the English string detects something different, we include that in the final result.

Correcting the left bolt is not that straightforward, which happens to be between the first two characters in the Arabic text. If a "9" is detected as the second digit from the left, it could be actually "9" or "1". We examined several cases and found that the head of true "9" has a hollow space, whereas the head formed by the bolt is solid black. We have shown both cases side by side in Fig. 14. Our algorithm crops the head when a "9" is detected at the second place from the left and examines it further. A simple count of black pixels in the binarised image of the head can reveal if it was all filled with back pixels or had a hollow white space.

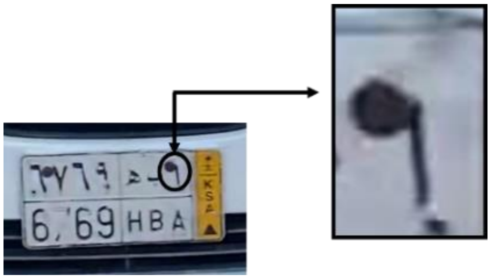

Fig. 13. Bolt Overlapping onto Arabic corresponding character of A.

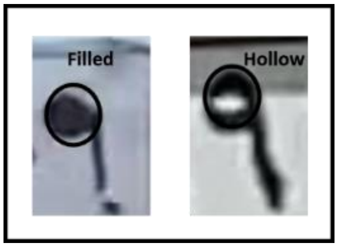

Fig. 14. One misread as nine, shown on the left, and a true 9 in Arabic shown on the right.

IV. Experimental Evaluation

Training and validation are done using the official notebook repository of YOLOv5, which provides a powerful GPU for fast processing. The YOLOv5 model has 476 layers. The batch size and epoch values were set to 35 and 100, respectively. The accuracy of detection can be determined by the overlap between the annotated (ground truth) mask and detected plates. The ratio is called Intersection Over Union (IOU). We considered different values of IOU and the optimal detection results are achieved at IOU>0.5. The rectangles predicted by the YOLOv5 model below this value are discarded.

For training the proposed CNN model, a computer with moderate specifications – GPU GeForce GTX 1080 GPU, 8 GB memory – running on the Linux operating system of Ubuntu 20.04.3 LTS was used. The learning rate was set to 0.001.

The proposed system achieved significantly higher accuracy when both Arabic and English alphanumerics of the LPs were used as discussed above, compared to the accuracy of either string recognized individually. We tested a few commercially available tools as well. On good quality images, all of them achieved high accuracy. However, on challenging cases consisting of real traffic scenarios in different conditions, commercially available tools performed very poorly, and our proposed model outperformed them by a clear margin. We show some results in Tables V to VII. In the shown LP text, the red color shows a wrongly recognized character, the black color shows a correctly read character, and the blue color shows a successfully restored character.

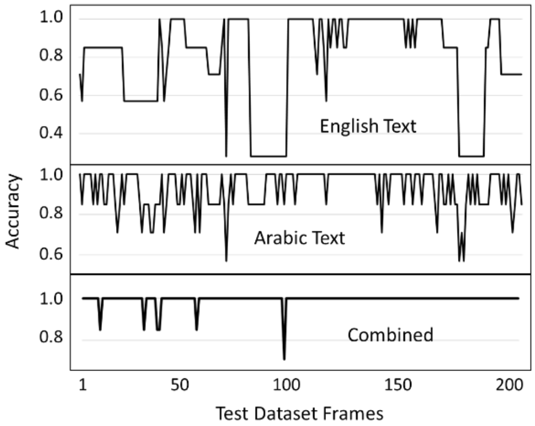

Fig. 15. Accuracy of English and Arabic strings recognition and the combined results for each LP in our test dataset.

A. *Plates with Extremely Poor Visibility*

This test dataset consists of cases where visibility of alphanumeric in the LP plate was poor due to shadows or glare. Many of the alphanumerics were wrongly recognized, but when we considered both resultant strings, the actual LP text was successfully restored. Some examples are shown in Table V A and V B. Note that all three commercial software failed in all these cases, whereas the proposed successfully recognized all plates.

TABLE V. A. Results of Extremely Poor Visibility Cases

Model				Sighthound	7172LA	8302KEJ	3636NHB	4810VVA
OpenALPR	71727LA	6302KEJ	3636NHB	4810VA

Proposed	7170DLA	5802KEJ	8636NHB	4210NVA

TABLE V. B. MORE RESULTS OF EXTREMELY POOR VISIBILITY CASES

Model			Sighthound	5941G1	7779KXJ	3864B
OpenALPR	594LG1	7778KXJ	386B
Plate Recognizer	584LG1	7779XXJ	8664JB
Proposed	5943LGJ	7779XXJ	8864ZJB

B. Deteriorated Alphanumeric Characters

Our dataset contains some cases where alphanumerics are degraded partially or fully causing missing a few alphanumerics at the recognition stage. We show some such cases in Table VI. Again, the proposed system outperforms the commercial systems. The missing characters are marked by an asterisk in red color.

C. Mud Affected Plates

There are certain LPs badly affected due to aging or covered by mud, and plate detection becomes challenging in such cases. We show some examples in Table VII. Our system not only detects these plates but also recognizes the text. Only in the last plate, which is challenging even for the human eye, our system made one mistake out of seven characters. The other methods could not even detect that plate.

It would be interesting to see the performance of our system on English and Arabic parts of the LPs separately and combined. Fig. 15 shows the accuracy in all three scenarios for each of the 200 plates in the test dataset. Note that one plate has seven alphanumerics. If all of them are correctly recognized, we consider the accuracy to be 1. If 6 of them are recognized correctly, the accuracy is 6/7, and so on. It can be seen in the figure that the combined results, except for a few cases, could recognize all the characters correctly.

We also present the results of the individual alphanumeric recognition in Table VIII. The first column shows the method used for recognition. In 200 plates in our test dataset, there are 1400 characters in total. The second column shows how many of these were recognized correctly. The third column shows the number of cases when all seven alphanumerics in the plate were correctly recognized. This also gives the system accuracy in perfectly recognizing plates, which is shown in the last column as a percentage. The rest of the columns further break down the cases when less than seven alphanumerics were recognized correctly. It can be seen that the proposed system identified 194 plates out of 200 perfectly while making one mistake in five plates and two mistakes in one plate. The other methods performed much poorly in comparison. The closest competitor Sighthound could recognize only 110 plates.

Sighthound	1015	**72.5**	110	55%

V. CONCLUSION

This paper proposed a CNN model that can recognize English and Arabic text in the license plates used in Saudi Arabia. The two were combined using a proposed algorithm to correctly restore missing or wrongly read alphanumerics in either of the strings. These methods successfully recognized the license plates where commercially available solutions OpenALPR, Plate Recognizer, and Sighthound failed. The proposed system is computationally efficient and works in real-world unconstrained situations.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number MoE-IF-G-20-12.

***Abstract*—Cardiovascular diseases (CVDs) are a leading cause of death worldwide. Early detection and diagnosis of these diseases can greatly reduce complications and improve outcomes for high-risk individuals. One method for detecting CVDs is through the use of electrocardiogram (ECG) monitoring systems, which use various technologies such as the Internet of Things (IoT), mobile applications, wireless sensor networks (WSN), and wearable devices to acquire and analyze ECG data for early diagnosis. However, despite the prevalence of these systems in the literature, there is a need for further optimization and improvement of their classification accuracy. In an effort to address this challenge, a novel heterogeneous unsupervised learning model for real-time ECG classification was proposed. The main goal of this work was to reduce the error rate and improve the classification accuracy of the system. This study presents a framework for the classification of multi-class abnormalities in electrocardiograms (ECGs) using an ensemble feature extraction technique and unsupervised learning. The framework utilizes a real-time electrocardiogram-cardiotocography (ECG-CTG) system to extract features from the ECG signal, and then employs an ensemble of feature extraction techniques to enhance the discrimination of the extracted features. The extracted features are then used in an unsupervised learning-based classification algorithm to classify the ECG signals into different classes of abnormalities. The proposed framework is evaluated on a dataset of ECG signals and the results show that it can effectively classify ECG signals with high accuracy and low computational complexity.**

Keywords—Ensemble; feature ranking; improved inter quartile range; outlier detection; heterogeneous optimized k-nearest neighbor; unsupervised learning

I. Introduction

According to research data from the National Family Health Survey, people living in rural areas of India are disproportionately affected by cardiovascular diseases (CVDs) compared to those in urban areas. This is due to factors such as lower income and lack of access to healthcare infrastructure. To address this issue, there is growing interest in developing low-cost tools and techniques for detecting CVDs in a timely and accurate manner. The utilization of IoT and machine learning in healthcare presents a promising solution, enabling remote diagnosis of patients and identifying patterns in vast amounts of medical data. Nonetheless, there is still room for improvement in accurately diagnosing patients by classifying ECG signals. This research aims to address this issue by developing a reliable ECG monitoring system that utilizes IoT and signal classification to enhance diagnosis rates. The system utilizes an AD8232 biopotential sensor to capture real-time ECG data, which is then transmitted to an AWS IoT core through a NodeMCU ESP8266 gateway and MQTT protocol. In monitoring fetal well-being during pregnancy, fetal cardiotocogram (CTG) and fetal electrocardiogram (FECG) are two critical tools. CTG, a non-invasive technique, measures fetal heart rate (FHR) and uterine contractions through the use of a tocodynamometer and an ultrasound transducer placed on the mother's abdomen. It is typically performed during the latter part of pregnancy to evaluate fetal well-being and detect abnormalities, such as fetuses at risk for distress, which can lead to poor outcomes such as stillbirth or neonatal death. On the other hand, FECG is an invasive technique that records the electrical activity of the fetal heart and is usually performed during the third trimester of pregnancy [1]. The process of fetal electrocardiogram (FECG) involves inserting a small electrode into the amniotic fluid surrounding the fetus, which records the electrical activity of the fetal heart to detect any abnormalities in the fetal heart rate (FHR). Compared to cardiotocogram (CTG), FECG is considered to be a more accurate method of assessing fetal well-being as it can detect subtle changes in the FHR that may not be visible on a CTG trace. Both CTG and FECG have their own advantages and limitations. While CTG is a non-invasive technique that is easy to perform and does not pose any risks to the mother or fetus, it is not as accurate as FECG in detecting fetal distress. FECG, on the other hand, is a more accurate method of assessing fetal well-being, but it is invasive and carries a small risk of infection or bleeding.

In conclusion, CTG and FECG are two important tools used in the monitoring of fetal well-being during pregnancy. CTG is a non-invasive technique that is easy to perform and does not pose any risks to the mother or fetus, while FECG is a more accurate method of assessing fetal well-being, but it is invasive and carries a small risk of infection or bleeding. Both techniques play an important role in the assessment of fetal well-being, and when used together, they can provide a more comprehensive picture of the fetus's health [2].

The collected data is preprocessed to remove outliers, and features are extracted using statistical and advanced filtering techniques. An ensemble learning model is then employed to optimize the prediction rate on the segmented classes. Regarding the research approach, different methods such as deductive or inductive, qualitative and quantitative can be used. Thoroughly studying the existing literature and research, the hypothesis formulation suggests a deductive research approach. The purpose of this study is to improve the overall lifetime of ECG measurement and its recognition and classification, and the qualitative approach is found to be the most appropriate [3]. In a later stage, ECG classification was performed and some abnormalities were detected. A test was conducted on 50 ECG signals with a duration of 2.5 seconds, and the application of certain techniques led to a significant improvement in baseline stability. ECG histograms showed minimal baseline drift during the recording phase after reducing baseline drift noise. To validate the estimation processes, 10 ECG signals with artificial baseline drift noise were created and analyzed using correlation and mean square error calculations. Farrell et al. [4] continue to explain the wavelet variance to wavelet packets in their work, in which they use the wavelet packets iterative CSS algorithm to locate variance change points. As a result, their method can be applied to a large variety of processes. The primary aim of this research is to address the disproportionately high rates of cardiovascular diseases (CVDs) in rural areas of India by developing a low-cost, IoT-enabled ECG monitoring system that uses signal classification to improve diagnosis rates. In recent years, several methods have been proposed in literature to enhance the recognition of premature ventricular contractions and other heart diseases from normal beats using electrocardiogram (ECG) signals. One such system proposed by [5] consists of three stages: denoising, feature extraction, and classification. The denoising stage deploys the Stationary Wavelet Transform to remove noise from the ECG signal, while the feature extraction stage combines morphological-based features and timing interval-based features to extract relevant information from the signal. Finally, multiple classifiers such as Multi-layer perceptron neural networks (MLP), probabilistic neural networks (PNN), and support vector machines (SVM) are used to classify the ECG beats. Among these classifiers, SVM achieved the highest classification accuracy of 97% [6]. Another study [7] addresses the issue of baseline drift noise in ECG signal processing by employing the Discrete Wavelet Transform. This transform effectively demonstrates non-stationary signals such as ECG signals. The proposed method was tested using ECG signals from the MIT-BIH arrhythmia database and proved to be effective in eliminating 60Hz artifacts with minimal ECG signal distortion. Other methods have also been proposed in literature to reduce noise and improve the quality of ECG signals, including the use of multirate architecture with a linear phase lowpass filter, Butterworth and Chebyshev I filters, wavelet transform method and a neural network based on adaptive filters, artificial neural network for automated noise removal, IIR Zero phase filtering, FIR and IIR filters, particle swarm optimization and support vector machine classifier for wavelet-based representation of ECG beats, an algorithm using a discrete wavelet transform, extreme learning machine and support vector machine for classifying four different types of heart beats, automated medical diagnostic tool using the cross-spectral density approach and least square support vector machine classification algorithm, and a power spectral-based hybrid support vector machine-genetic algorithm to categorize five different types of ECG beats [8].

In addition to these methods, several studies have also proposed the use of neural networks and other machine learning techniques for ECG beat classification and heart disorder diagnosis. One such study used a neural network model with stacked generalization method, resulting in an error rate of 12.41%. Another study evaluated the performance of various classifiers, including Kth Nearest Neighbor Rule, neural networks, discriminant analysis, and fuzzy logic, using 26 morphological parameters as the focus features. A third study proposed an Artificial Neural Network (ANN) based system for the diagnosis of cardiac arrhythmia using standard 12-lead ECG signal recordings. In all of these studies, the MITBIH database was used to evaluate performance, and the results were found to be satisfactory [9].

In [10], a combination of a convolutional neural network (CNN) and a recurrent neural network (RNN) was proposed for ECG beat classification. The authors used the PTB Diagnostic ECG Database to train and test their model, achieving an overall accuracy of 99.2%. These studies demonstrate the effectiveness of using machine learning techniques for ECG beat classification and heart disorder diagnosis, and highlight the importance of continuing research in this field.

The author [11] developed a method of detecting the QRS of the fetus by combining a time-varying Finite Impulse Response (FIR) filter with a genetic algorithm. They found that the filter coefficients reduced the quadratic error and ensured convergence towards the optimal filter. To compare the effectiveness of the Genetic Algorithm (GA) with other filters such as Wiener, Recursive Least Mean Square (RLMS), and Normalized Least Mean Square (NLMS), a realization and comparison were performed using the same filter coefficients with real ECG signals acquired from the abdomen of the mother. The extraction accuracy was improved by changing the order of the filter and the NLMS algorithm gave good quality performances when compared to other filters. However, if the gain of adaptation was large, there was a risk of oscillations. The research [12] introduced a method of extracting Fetal Electrocardiogram (FECG) based on an adaptive linear neural network. The results showed that the adaptive linear neural network could be used to extract FECG from the maternal abdominal signal effectively. The improvement of the network structure made the network error more close to the maternal ECG (MECG), thus a clearer FECG could be acquired. A clearer FECG could be extracted by improving neural network parameters. The study [13] proposed a new methodology that combined Artificial Neural Network (ANN) and correlation approach. Nonlinear and time-varying features of the ECG signal had to be adapted using an Artificial Neural Network. It required a desired output in order to learn, hence it used supervised Multilayer Perception (MLP) network. Likewise, to scale the MECG when subtracting it from the AECG, in order to get the FECG the correlation method was chosen as the correlation factor. The ANN and correlation combination gave an improved and efficient result in terms of accuracy for FECG extraction and R peak detection. The author in [14] presented a method for extracting FECG using Adaptive Neuro-Fuzzy Inference System (ANFIS). The method involves collecting ECG signals from two electrodes, one placed at the thoracic area (completely maternal) and the other at the abdominal area (composite of maternal and fetal ECG signal). Accurate placement of the electrodes is crucial for the application of this method. ANFIS was used for nonlinear alignment of the MECG signal with the components of MECG in the abdominal signal. Then, the maternal components of the abdominal signal were cancelled, and finally the FECG signal was extracted. The algorithm was tested using synthetic and real ECG data, and in both cases, good FECG extraction was achieved, even in the presence of full overlapping maternal and fetal signals. This improved the application of wavelet transform to FECG signals extracted by polynomial networks. Both synthetic and real-time data were pre-processed and post-processed using wavelet denoising algorithms. This method effectively removed baseline wandering, and the extraction performance was successful and improved. For real FECG, visual results also showed that wavelet denoising was useful. The research [15] proposed a new methodology that combined Artificial Neural Network (ANN) and Correlation (ANNC) approach. This method tried various learning constant values and momentum for FECG signal extraction from the abdominal signal and proved that changing the learning rate and momentum also affect the output of the network. This technique was found to be robust and effectively extract the FECG signal from the abdominal signal with an accuracy of 95% and performance of 93.75%. In summary, these studies demonstrate the effectiveness of using neural networks and deep learning techniques for ECG beat classification and diagnosis of heart disorders. These techniques have been shown to achieve high accuracy and are promising for use in clinical settings.

A. *Research Gap*

One potential research gap for the content on real-time ECG-CTG detection using machine learning is the lack of focus on the scalability and generalizability of the proposed techniques. Most of the studies cited in the content are focused on improving the accuracy of ECG classification using specific datasets or databases. However, there is a need to evaluate the performance of these techniques on a larger and more diverse set of data to determine their potential for wider adoption in clinical settings. Additionally, the content could benefit from more exploration of the challenges and limitations of applying machine learning techniques to ECG-CTG detection, such as issues related to data quality, interpretability, and ethical considerations. Finally, there may be opportunities to investigate the integration of ECG-CTG detection with other healthcare technologies, such as telemedicine or wearable devices, to improve patient outcomes and reduce healthcare costs.

The paper is structured as follows: In Section II, the related works of ECG+CTG models and their limitations are presented. Section III outlines the proposed solution for ECG+CTG using machine learning. Section IV provides details on the experimental results and analysis. Finally, in Section V, the paper is concluded.

II. Related Works

The detection and analysis of fetal electrocardiogram (FECG) signals is a crucial tool in evaluating the health and status of a fetus during labor. However, extracting the FECG signal alone from complex data contaminated by various types of noise such as maternal ECG, electromyogram, power line interference, and mother's respiration is challenging. In recent years, researchers have proposed various methods to improve the accuracy and reliability of monitoring the fetal heart rate during contractions. One such method is the combination of a time-varying Finite Impulse Response (FIR) filter with a genetic algorithm, developed by Talha and colleagues in 2010. The filter coefficients were found to reduce the quadratic error and ensure convergence towards the optimal filter. Realization and comparison were performed using the same filter coefficients with real ECG signals acquired from the abdomen of the mother. The extraction accuracy was improved by changing the order of the filter and the Normalized Least Mean Square (NLMS) algorithm gave good quality performances when compared to other filters, such as Wiener, Recursive Least Mean Square (RLMS), and Normalized Least Mean Square (NLMS). However, this method has lower efficiency in removing noise signals compared to other methods [16].

Another method proposed by [17] is a hybrid ECG arrhythmia classification approach, known as MRFO-SVM. This approach combines various ECG signal descriptors based on one-dimensional local binary patterns (LBP), wavelet, higher-order statistical (HOS), and morphological information for feature extraction. The approach utilizes a metaheuristic algorithm, known as Manta Ray Foraging Optimization (MRFO), for feature selection and classification processes. However, this approach could be further improved by integrating MRFO with other machine learning techniques such as convolutional neural networks (CNN) and deep neural networks (DNN) to enhance the detection of arrhythmia and heart rate abnormalities, as well as by hybridizing MRFO with other metaheuristic algorithms. The study [18] evaluated a segment-based stacking method of CNN and SVM to classify short single-lead ECG signals into four classes: Normal, AF, Others, and Noise. Landry et al. proposed a novel embedded QRS complex detection algorithm based on the ECG signal strength and its trend. Mourad et al. used wavelet transforms to detect QRS complexes, and Rahul et al. proposed a window-based FIR filter to eliminate high-frequency noise in ECG signals. Yang et al. proposed a 12-lead ECG arrhythmia classification method using a cascaded convolutional neural network (CCNN) and expert features. While these methods have shown promise, limitations and issues still exist, such as difficulty in detecting R-waves with slow variations and when preceded by waves with strong amplitudes, the need for high computational memory and time for large numbers of features and signals, and the need for further research to utilize the

QRS-complex for the detection of various cardiac arrhythmias, the detection of other waves in the cardiac cycle, and the possibility of low-cost hardware implementation for early detection of cardiovascular disorders. In recent years, several technologies have been employed to design and implement ECG monitoring systems for remote monitoring of cardiovascular diseases (CVDs). These include the Internet of Things (IoT), mobile applications, wireless sensor networks (WSN), and wearable devices. For example, Serhani et al. proposed an IoT-based CVD monitoring system that facilitates ECG data acquisition and continuous remote monitoring and analysis of patients, with the collected data transmitted to the cloud for further investigation by specialists for early diagnosis. Similarly, [19] developed a portable ECG monitoring system based on Arduino-Uno and an AD8232 sensor to monitor the cardiac health condition of patients. This proposed a system that continuously monitors the temperature, pulse rate, and ECG of patients, generating an alert SMS to the caretaker's mobile if the values exceed normal limits. They developed a wireless real-time ECG monitoring system for the early detection of CVDs, while Mishra et al. proposed an IoT-based smart healthcare system with an AD8232 heart rate sensor interfaced with Arduino UNO and connected to the cloud using an ESP8266 wireless LAN module for remote monitoring. They proposed an e-health monitoring system that measures body temperature, blood oxygen saturation, ECG signal, and heart rate, sending the data to an IoT cloud for remote analysis by a doctor. The study [12] implemented an IoT-based vital sign monitoring system using Raspberry Pi 3 to monitor body temperature, pulse rate, and heartbeat using ECG, and Deep neural networks for the analysis and classification of normal and abnormal beats. Despite the prevalence of these studies in the literature, there are relatively few studies that have analyzed and classified signals to design a complete healthcare system. One of the major challenges in bio-signals processing is the high variability of bio-signals over time, due to biological processes within the body. This variability often complicates the selection of informative parameters and may yield inaccurate predictions. Outliers, or portions of the signal that deviate excessively from adjacent segments, are a typical phenomenon in bio-signals processing, and the elimination of their impact is crucial in the signal processing channel of ECG-based biometric systems. To address these challenges, researchers have employed various methods for outlier correction and classification of ECG signals. For example, Jun et al. compared the effectiveness of outlier correction methods for ECG signals in combination with various classification algorithms in biometric applications. Aqeel et al. developed an IoT-based ECG signal monitoring and classification system to diagnose the health status of patients, utilizing convolutional neural networks (CNN) and achieving an accuracy of 94.94%. The research [19] proposed a real-time ECG signal analysis and classification approach using discrete wavelet transform (DWT) and support vector machines (SVMs). DWT is used for pre-processing and feature extraction from the MIT-BIH dataset, and the SVM classifies six heartbeat types with an accuracy of 98.61%.Recently, researchers have demonstrated that ensemble systems can increase the performance of base classifiers. Ensemble learning is the process of integrating various base models to improve the overall performance of the system. Ensemble-based ECG classification methods have been proposed in various studies, achieving high accuracy and robustness in detecting and classifying ECG beats.

III. Proposed Model

The proposed model for ECG classification consists of three phases, which are designed to address key challenges in ECG classification and improve the accuracy and reliability of the classification results.

In Phase 1, the model focuses on collecting high-quality CTG and FECG data in real-time. This is important because the accuracy of ECG classification models depends heavily on the quality of the input data, and any noise or artifacts in the data can significantly affect the classification results. By collecting data in real-time, the model ensures that the data is up-to-date and reflects the current state of the patient's heart function.

In Phase 2, the model focuses on extracting relevant features from the ECG and CTG data and filtering out noise and artifacts. This is a critical step in ECG classification because it helps to reduce the complexity of the data and highlight the key characteristics that are important for classification. By using advanced feature extraction and filtering techniques, the model is able to identify and isolate key features that are relevant for classification, while minimizing the impact of noise and artifacts.

In Phase 3, the model uses a cluster-based ensemble classification approach to classify the ECG data. This approach combines the results of multiple classification models to improve the accuracy and reliability of the classification results. By using a cluster-based approach, the model is able to group similar ECG signals together and classify them based on their shared characteristics. This approach can improve the accuracy of classification by reducing the impact of individual classification errors and increasing the overall robustness of the model. The proposed model is implemented in three phases shown in Fig. 1.

- Phase 1: Realtime CTG and FECG data collection.
- Phase 2: ECG+CTG Feature extraction measures and filtering.
- Phase 3: Proposed cluster based ensemble classification.

As depicted in Fig. 1, the data is initially collected from a real-time ECG sensor. The data from each sensor is then sent to AWS cloud storage for further analysis. The machine learning model employs a filtering technique and feature extraction measures to preprocess the data. In this particular study, an enhanced kernel feature ranking measure was implemented to enhance the feature selection process for clustering. A novel clustering approach was also utilized to identify key classes for classification. To improve performance, an ensemble learning framework was employed to reduce the error rate and increase the true positive rate. As depicted in Fig. 1, the data is initially collected from a real-time ECG sensor. The data from each sensor is then sent to

AWS cloud storage for further analysis. The machine learning model employs a filtering technique and feature extraction measures to preprocess the data. In this particular study, an enhanced kernel feature ranking measure was implemented to enhance the feature selection process for clustering. A novel clustering approach was also utilized to identify key classes for classification. To improve performance, an ensemble learning framework was employed to reduce the error rate and increase the true positive rate.

1) Phase 1: Realtime CTG and FECG data collection: CTG is a non-invasive test that uses ultrasound to measure the fetal heart rate and uterine contractions, while FECG is an invasive test that uses electrodes to measure the electrical activity of the fetal heart. Both tests are used to detect any potential problems that may arise during pregnancy, such as fetal distress or abnormal fetal heart rate patterns.Real-time data acquisition for CTG and FECG is essential for data processing. This involves the collection and analysis of data in real-time, as opposed to after the fact. Real-time data acquisition allows for the early detection of any potential problems, which can lead to prompt intervention and better outcomes for both the mother and the fetus.One of the most important aspects of real-time data acquisition for CTG and FECG is the use of advanced technology. High-quality ultrasound machines, specialized software, and sophisticated electrodes are used to collect and analyze data. This technology is able to detect even the slightest changes in the fetal heart rate and contractions, which can indicate potential problems. In addition to advanced technology, real-time data acquisition for CTG and FECG also requires trained professionals to operate the equipment and interpret the results. Obstetricians and gynecologists, as well as specialized nurses and technologists, are responsible for monitoring the data and interpreting the results. They must be able to recognize any abnormal patterns or changes in the data, and take appropriate action to address any potential problems. Data processing is also an important aspect of real-time data acquisition for CTG and FECG. This involves the analysis of the data collected by the equipment, and the identification of any patterns or trends that may indicate potential problems. Data processing is typically done using specialized software, which can analyze the data in real-time and identify any potential issues.

Overall, real-time data acquisition for CTG and FECG is essential for ensuring the health and well-being of both the mother and the fetus during pregnancy. Advanced technology, trained professionals, and data processing are all crucial elements of this process, and must be carefully managed to ensure the best possible outcomes.

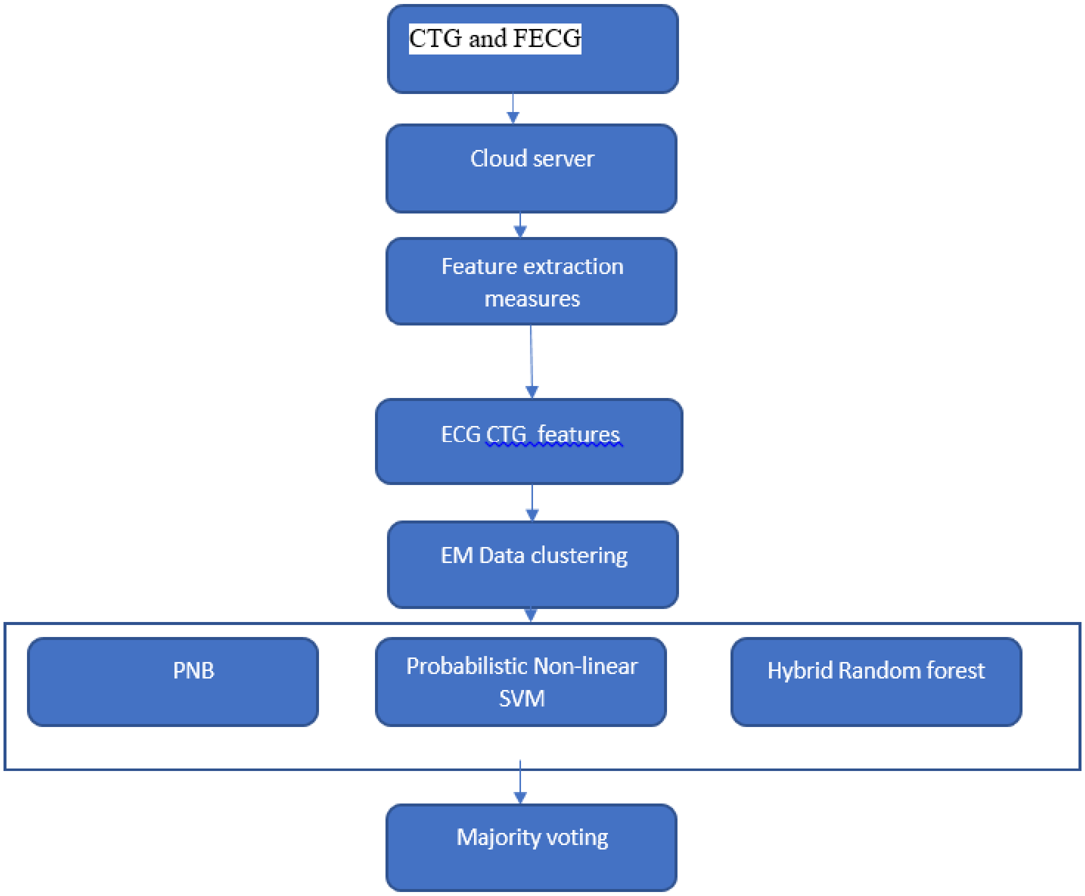

Fig. 1. Proposed framework.

2) Phase 2: Feature extraction measures and filtering: QRS peak detection is an important step in the analysis of electrocardiogram (ECG) signals as it helps to identify the locations of the Q, R, and S waves, which are indicative of the electrical activity of the heart. The following are the steps of a typical QRS peak detection algorithm:

Filtering: The ECG signal is passed through a bandpass filter to remove any noise and high-frequency artifacts. The cutoff frequencies of the filter are typically between 5 and 15 Hz, as the QRS complex is known to occur within this frequency range.

Differentiation: The filtered ECG signal is then differentiated using a differentiation operator, such as a finite difference or a Sobel operator, to enhance the high-frequency components of the QRS complex.

Squaring: The differentiated ECG signal is squared to further enhance the QRS complex and suppress the noise.

Moving Window Integration: The squared ECG signal is then passed through a moving window integrator, such as a rectangular window or a Gaussian window, to smooth the signal and eliminate any remaining noise.

Thresholding: A threshold is set to detect the QRS peaks. The threshold is typically set at a level that is slightly above the baseline noise level. Any sample that exceeds this threshold is considered a QRS peak.

The above described steps are mathematical derivation:

Filtering:

The filtered ECG signal is obtained by convolving the original ECG signal with a bandpass filter function h(t) which is defined as :

$$h(t)= (1/T) * rect((t-T/2)/T) * (sin(2\pi fct)/(\pi fct)) \quad (1)$$

where rect(x) = 1 for |x|<0.5 and 0 otherwise,

Differentiation:

The differentiated ECG signal is obtained by applying the differential operator d/dt to the filtered ECG signal.

Squaring:

The squared ECG signal is obtained by squaring the differentiated ECG signal.

Moving Window Integration:

The smoothed ECG signal is obtained by convolving the squared ECG signal with a moving window function w(t).

Thresholding:

The threshold value is set to a level slightly above the baseline noise level. Any sample that exceeds this threshold is considered a QRS peak.

3) Phase 3: Proposed Cluster based Ensemble classification framework: The Probabilistic Expectation-Maximization (PEM) algorithm is a popular method for clustering data, including ECG signal data. The algorithm consists of two main steps: the Expectation step (E-step) and the Maximization step (M-step). The steps are repeated until convergence, at which point the algorithm has found the maximum likelihood estimates for the parameters of the underlying mixture model.

E-step: In this step, the algorithm estimates the probability that each data point belongs to each of the clusters, given the current estimates of the parameters of the mixture model. This is done by computing the likelihood of each data point, given the current cluster means and covariances, and multiplying this by the prior probability of each cluster. The resulting probabilities are used to update the responsibilities for each data point and cluster.

Mathematically, the E-step is represented by the following equation:

r_{n,k} = P(z_n = k | x_n, mu, Sigma) = frac{P(x_n | z_n = k, mu, Sigma) * P(z_n = k)}{P(x_n)} (2)

where x_n is the nth data point, z_n is the cluster assignment for the nth data point, mu is the mean of the kth cluster, Sigma is the covariance matrix of the kth cluster, and r_{n,k} is the responsibility of the kth cluster for the nth data point.

M-step: In this step, the algorithm updates the parameters of the mixture model (i.e., the means, covariances, and prior probabilities) based on the current responsibilities of the data points. The new parameters are chosen to maximize the expected log-likelihood of the data, given the current responsibilities.

Mathematically, the M-step is represented by the following equations:

mu_k = frac{1}{N_k} sum_{n=1}^{N} r_{n,k} x_n

Sigma_k = frac{1}{N_k} sum_{n=1}^{N} r_{n,k} (x_n - mu_k)(x_n - mu_k)^T

P(z_n = k) = frac{N_k}{N} (3)

where mu_k is the mean of the kth cluster, Sigma_k is the covariance matrix of the kth cluster, P(z_n = k) is the prior probability of the kth cluster, and N_k is the total responsibility of the kth cluster.

The algorithm continues to alternate between the E-step and the M-step until convergence is reached. This can be determined by checking whether the log-likelihood of the data has stopped increasing or if the parameters have not changed significantly between iterations.

This is the basic algorithm for EM clustering, which is useful for identifying patterns and structure in ECG signal data. However, it is worth noting that there are various modifications and extensions of the EM algorithm, such as the Gaussian Mixture Model (GMM) and the soft EM algorithm that can be applied to ECG signal data to improve the performance of the clustering.

A. Proposed Ensemble Classification Learning Model

The Support Vector Machine (SVM) algorithm is a supervised learning algorithm that can be used for classification and regression tasks. One of the key features of SVM is the use of kernel functions, which allows the algorithm to perform nonlinear classification by mapping the input data into a higher dimensional space.

The mathematical derivation for a nonlinear kernel function SVM applied to ECG signal data is as follows:

The input data, which consists of a set of ECG signals, is first mapped into a higher dimensional feature space using a nonlinear kernel function, K(x,y). Commonly used nonlinear kernel functions include the Radial Basis Function (RBF) kernel, the Polynomial kernel, and the Sigmoid kernel.

The equation for the RBF kernel function is: K(x,y) = exp(-γ||x-y||^2)

The equation for the Polynomial kernel function is: K(x,y) = (x.y + c)^d

The equation for the Sigmoid kernel function is: K(x,y) = tanh(γx.y + c) (4)

The optimal hyperplane is then found by maximizing the margin, which is defined as the distance between the closest data points of each class, known as support vectors, and the hyperplane.

The equation for the optimal hyperplane is: wx + b = 0

The decision boundary is given by the equation: f(x) = sign(wx + b).

The SVM algorithm then uses this decision boundary to classify new data points as belonging to one of the classes.

The parameters of the kernel function (such as gamma and the constant term) can be optimized using techniques such as cross-validation to improve the performance of the algorithm.

Finally, the ensemble classification algorithm is performed by combining the decision of multiple base classifiers (SVM, Neural network, optimized Naive Bayesian, and optimized decision tree) using techniques such as majority voting or weighted voting to produce a final prediction.

The optimized decision tree algorithm is a method for building a decision tree model with improved accuracy and reduced overfitting. The following are the steps for building an optimized decision tree for ECG signal data, along with mathematical derivations:

Data preprocessing: The first step is to preprocess the ECG signal data by removing any missing or irrelevant data and scaling the features to a common range.

Feature selection: Next, a feature selection method such as mutual information or wrapper methods can be used to select the most relevant features for the decision tree model.

Splitting criterion: The decision tree algorithm builds the tree by repeatedly splitting the data based on the feature that maximizes the reduction in impurity. A common splitting criterion is the Gini impurity, which is calculated as:

Gini = 1 - Σ(p_i)^2

where p_i is the proportion of data points belonging to class i in a given node.

Pruning: To prevent overfitting, the decision tree can be pruned by removing branches with low information gain or by setting a minimum number of samples required to split a node.

Model evaluation: The final step is to evaluate the performance of the decision tree model using metrics such as accuracy, precision, recall, and F1-score.

Hyperparameter tuning: The final step is to optimize the model by tuning the hyperparameters such as maximum depth, minimum samples per leaf, and minimum samples per split.

Ensemble: Once the decision tree is optimized, it can be combined with other classifiers like SVM, Neural network, optimized Naive bayesian etc to form an ensemble classifier which will lead to an improved overall performance of the model.

The joint probability estimation based naive bayes algorithm for ECG signal data involves the following steps:

Data preprocessing: The ECG signal data is preprocessed to remove any noise or artifacts present in the signal. This can be done using techniques such as filtering, resampling, and baseline correction.

Feature extraction: The ECG signal data is then divided into segments and features are extracted from each segment. These features can include information such as the R-peak amplitude, QRS duration, and P-wave duration.

Joint probability estimation: The joint probability of the features and the class labels is estimated using the extracted features. This can be done using techniques such as maximum likelihood estimation or the method of moments.

Naive bayes classifier: The naive bayes classifier is then trained on the estimated joint probabilities. This classifier assumes that the features are independent given the class label.

Classification: Once the classifier is trained, it can be used to classify new segments of ECG signal data by computing the posterior probabilities for each class label and selecting the label with the highest probability.

Mathematical derivation:

Let's suppose we have D = {(x1,y1),(x2,y2),...,(xn,yn)} as the training data set, where xi is the feature vector of i-th segment and yi is the corresponding class label.

The joint probability of feature vector xi and class label yi can be defined as

P(x,y) = P(x|y)P(y)

The naive bayes classifier assumes that the features are independent given the class label, so we can write

P(x|y) = Πi=1n P(xi|y)

The class label with the highest probability will be the predicted class label

P(y|x) = P(x|y)P(y) / P(x) = P(x|y)P(y) / Σy' P(x|y')P(y') (5)

where y' is a class label

The optimized decision tree algorithm will have similar steps but with a different mathematical derivation for the decision tree.

IV. Experimetnal Results

Experimental results are evaluated on real-time ECG+CTG signal data in order to predict the abnormality of the patient.

CTG Data:

Fetal heart rate (FHR): This is the number of times the fetus' heart beats per minute. It is typically measured using ultrasound or a cardiotocograph (CTG) machine.

Fetal heart rate variability (FHRV): This is the variation in the time interval between successive fetal heartbeats. It can be measured using ultrasound or a CTG machine.

Uterine contractions: These are the rhythmic, involuntary contractions of the uterus that occur during labor. They can be measured using a tocodynamometer.

FHR acceleration: This is an increase in the FHR above the baseline that lasts for at least 15 seconds. It can be measured using ultrasound or a CTG machine.

FECG Data:

Fetal ECG: This is the electrical activity of the fetus' heart. It can be measured using electrodes placed on the mother's abdomen.

Fetal heart rate: Same as above

Fetal QRS complex: This is the combination of the Q, R, and S waves of the fetal ECG. It can be used to assess the fetal cardiac function.

Fetal QT interval: This is the duration of the QT interval of the fetal ECG. It can be used to assess the fetal cardiac function.

The result represents the test classification recall of the proposed model on the selected features subset using ensemble learning framework. From the results it is noted that the proposed ranked based classification has better recall than conventional approaches on realtime data1 as shown in Fig. 2.

The result represents the test classification accuracy of the proposed model on the selected features subset using ensemble learning framework. From the results it is noted that the proposed ranked based classification has better accuracy than conventional approaches on SSDS data as shown in Fig. 3.

The result represents the test classification precision of the proposed model on the selected features subset using ensemble learning framework. From the results it is noted that the proposed ranked based classification has better precision than conventional approaches on SSDS data as shown in Fig. 4.

Table I, represents the result analysis of different machine learning models for ECG classification, evaluated on ten different datasets (TestData-1 to TestData-10). The performance metrics evaluated include Accuracy, Recall, Precision, F-measure, and AUC, and the models compared include LR+SVM+BOOST, LR+KNN+BOOST, RF+KNN+BOOST, and the proposed ensemble model.

Overall, the proposed ensemble model outperformed the other models on most datasets, achieving high scores on all performance metrics. LR+KNN+BOOST and RF+KNN+BOOST also performed well, with high accuracy and AUC scores, but lower precision and recall scores compared to the proposed ensemble model. The results suggest that ensemble models combining multiple machine learning algorithms can improve the accuracy and reliability of ECG classification, and may have potential for use in clinical settings. However, it is important to note that the evaluation was performed on a limited set of datasets, and further research is needed to evaluate the performance and generalizability of these models on larger and more diverse datasets.

V. Conclusion

The proposed real-time ECG CTG based ensemble feature extraction and unsupervised learning based classification framework for multi-class abnormality prediction in ECG signals shows promising results in accurately identifying different types of abnormalities in ECG signals. The use of ensemble feature extraction and unsupervised learning allows for robust and accurate classification of ECG signals, even in the presence of noise and variability. Additionally, the real-time aspect of the framework allows for real-time monitoring and early detection of abnormalities in ECG signals, which can greatly improve patient outcomes. Further research and validation of the proposed framework is needed to fully assess its clinical utility and potential for implementation in real-world settings. In future work, a novel parallel deep learning framework is used to improve the computational time on large big data.

***Abstract*—With the technological progress of human beings, more and more animal and bird species are being endangered and sometimes even going to the verge of extinction. However, the existence of birds is highly beneficial for human civilization as birds help in pollination, destroying harmful insects for crops, etc. To ensure the healthy co-existence of all species along with human beings, almost all advanced countries have taken up some conservation measures for endangered species. To ensure conservation, the first step is to identify the species of birds found in different locations. Deep learning-based techniques are best suited for the automated identification of bird species from the captured images. In this paper, a Convolutional Neural Network based bird image identification methodology has been proposed. Four different transfer learning-based architectures, namely Resnet152V2, Inception V3, Densenet201, and MobileNetV2 have been used for bird image classification and identification. The models have been trained using 58388 images belonging to 400 species of birds, and the models have been tested using 2000 images belonging to 400 species of birds. Out of these four models, Resnet152V2 and DenseNet201 performed comparatively well. The accuracy of Resnet152V2 was highest at 95.45%, but it faced a large loss of 0.8835. But based on the results, even though DenseNet201 had an accuracy of 95.05%, it faced less loss i.e., of 0.6854. The results show that the DenseNet201 model can further be used for real-life bird image classification.**

***Keywords*—Deep learning; CNN; Image classification; DenseNet201; ResNet152V2; InceptionV3; MobileNetV2**

I. Introduction

Biodiversity around us is quite important for human civilization as it helps maintain a balance in the ecosystems. Birds are one of the most important resources, which help us in various ways like pollination, protecting crops from harmful pests destroying the crops, etc. However, with rapid industrialization, more and more bird species are becoming endangered and sometimes on the verge of extinction. Bringing more forestland and wetland under modernization is also fueling the extinction process. Therefore, almost all countries have taken one or more conservation projects to preserve biodiversity and conserve endangered species [1][2].

To preserve a species, the first important step is to identify the species correctly followed by the appropriate steps to preserve it. Deep learning-based approaches are best suited for the automated identification of bird species because deep learning enables us to extract the features of birds and provide higher accuracy while predicting. Deep learning can identify the species of a bird based on data in the form of audio, video, and image. In the case of real life, audio and video are not that suitable as the overlapping of chirping of multiple birds can't be ruled out, and those noises may tamper with the essential features of the bird. Thus, in this paper, a deep learning-based approach trained with bird images has been proposed. There are some papers which proposed the use of images for bird species identification [9][20][21]. But the novelty of our study is that we have included 400 species for identification which has expanded the application of our study.

As there are hundreds of deep learning algorithms available, it is necessary to investigate with the test data set to understand which algorithm generates the best accuracy and minimizes the loss. In this paper, four different transfer learning-based models namely Resnet152v2, InceptionV3, Densenet201, and MobileNetV2 are tested and compared for bird image classification. The transfer learning models are used to extract the features of the birds. The dataset used contains a total of 58388 images of birds. The total number of species included in the dataset is 400 [31]. The output and input layer are added to the transfer learning model with dense connection. The output layer is generating results by using SoftMax. Given that SoftMax is employed for multiclass classification, it serves as the activation function.

The major research objectives of this paper are as follows: (a) To compare various transfer learning models for bird species identification from bird image datasets. (b) To build a system of automatic identification of bird species with maximum accuracy using the transfer learning model which is most suited for the given dataset. (c) To put forth a web-based system which will help photographers to build their portfolio by identifying the bird species from the image they captured.

A. *Contribution of the Paper*

- A comprehensive study of existing deep learning/ transfer learning-based systems for bird species identification and pinpointing the drawbacks of those existing systems.
- Identification of an intricate dataset for bird species identification by studying various related datasets.
- Implementation of different transfer leaning models such as InceptionV3, ResNet152V2, DenseNet201 and MobileNetV2 on the identified dataset.
- Selection of the most efficient and accurate model suited for image classification of birds and the measures that can be incorporated to increase the performance.

Section II of this paper presents the literature review to find the gap in the existing approaches; Section III presents the proposed architecture and methodology; Section IV shows the experimental results and, finally Section V concludes the paper.

II. Literature Review

Many researchers have used Deep Learning and Convolutional Neural Network based approaches for image classifications, especially for identifying diseases from image datasets, but not much work is done for identifying bird species from the image datasets of birds. In this section, the existing approaches of image classification using transfer learning techniques are explored.

A recent paper [3] explaining the deep learning architecture for the detection of birds from the images captured by the webcam was published. For the pre-processing of data, deep learning algorithm's capability for the detection of birds inside the images is checked first. Then the authors used two CNN models i.e., single-shot detectors (SSD) and Quicker R-CNN as a combination with Inception ResNet152V2, ResNet50, ResNet152, ResNet101, and MobileNet-V2 features. By combining a faster R-CNN, they got high precision, and the SSD with MobileNetV2 was selected as the best model in terms of speed and smaller memory consumption.

Transfer learning model was used with six different CNN architectures such as DenseNet201, MobileNetV2, ResNet50, InceptionResNetV2, ResNet152V2, and Exception in a paper [4]. After calculating the evaluation matrix, the authors found that MobileNetV2 performed better than the other transfer learning approaches in terms of evaluation matrices. However, they could classify the bird images in only eight categories.

A paper was published in which [5] the authors worked to find a suitable model for transfer learning. After comparison of results, the authors showed that the training Inception-v3 on the CIFAR-10 dataset provided better results. The authors also explained that the basic to advanced use of transfer learning may be used not only for the model presented but also for other deep neural networks for image classification.

A paper [6] implementing the CNN algorithm to extract information from bird images was published. The CNN model was developed entirely from scratch. The model was then trained to test its efficiency. The developed application had a high accuracy of about 93.19% on the training set and 84.9% on the testing set.

The image classification models MobileNetV2 and Inception-v3 were proposed to be used in a paper [7]. The authors used four approaches—Inception-v3 with and without transfer learning and MobileNetV2 with and without transfer learning—to accomplish the task. Among the four approaches, MobileNetV2 with transfer learning performed better, with an accuracy of about 91.00%.

In a paper published in 2021[8], the authors tried to identify the habitat elements from the bird elements using a deep convolutional neural network and ResNet152 dependent models, which gave the test accuracy that was best. It has been proven that a deep convolutional neural network could be effective for automatically identifying habitat elements from images of birds. The author concluded that the actual implementation of this technology would be extremely useful in understanding the relationship between habitat elements and birds.

The paper [9] proposed a VGG-16 network model-based solution to extract bird image features. The authors used different classification methods, each with different results. Support Vector Machine (SVM), when compared to other categorization techniques like random forest and K-Nearest Neighbor (KNN), provided the highest accuracy of 89%.

The authors of a paper which was published in 2019 [10] developed a cloud-based mobile phone app that makes use of deep learning for image processing to find the species of birds from the various digital images that are transferred by the user over a mobile phone. Convolutional Neural Network was trained using bird images to limit the outstanding image features. The Convolutional Neural Network model with bound connections gave high accuracy, which is 99.00%, as compared to the CNN with 93.98% and the SVM with 89.00% for the image training.

A pose-normalized deep convolutional nets approach was proposed in a paper published [11]. The proposed method depends on a detection part, and the Convolutional Neural Network features are extracted from various regions that are pose-normalized. Its execution was better for the usage of Convolutional Neural Network features, which were fine-tuned upon CUB-200-2011 for every region. It also was effective for the usage of various Convolutional Neural Network layers for numerous alignment levels; and the usage of a similar warping function that's estimated to use a larger number for detecting key points. They introduced an innovative method for studying a group of various pose-regions that clearly curtails the alignment of pixel error. Then it works on complicated pose-warping operations.

Another paper [12] proposed a deep learning model which can identify individual birds from the input image. The authors proposed two different models and showed that the proposed pre-trained ResNet model has achieved better accuracy than the based model. The best model showed 97.98% accuracy in identifying bird species.

The paper proposed in 2020 [13] used deep learning models to detect pneumonia based on chest x-ray images. The author used four models: two pretrained models (ResNet152V2 and MobileNetV2), CNN, and long-short-term memory (LSTM). The result showed that the ResNet152V2 performed better and the MobileNetV2, CNN, LSTM accuracy, recall, F1-score, precision, and AUC were higher than 91%.

An author published a paper based on declining the North American avifauna [14] represented that by using the multiple and independent monitoring networks author represented the loss of population of the North American avifauna which includes the common species.

The paper proposed in 2021 describes the declining of the forest bird species [15] where the author studied birds in six land types in the oak forest biome of Himalaya. The richness of the species was west in pine and built-up sites as compared to natural oak. The forest specialist and insectivores are reduced up to 60 - 80% in the modified forests.

The loss found in biodiversity in the European Union is described in a paper [16] by the author by studying the extensive dataset. The author evaluated that there is a decline of around 17-19 % in the overall bird abundance. The authors are suggesting that we should preserve the bird species and that it is beneficial to nature and human beings.

In the paper that was published in 2021 [17], the authors tried to explain that there is a huge amount of decrease in the bird species, some have vanished, some are endangered. As a result, it has a negative impact on both biodiversity and human lives. So, it's our responsibility to preserve them.

A paper that uses a deep convolutional neural network [18] to identify birds' images was published. The author used habitat elements of bird images. Author used the model based on the ResNet152 algorithm, given 95.52% validation and AlexNet given the lowest test accuracy as 89.48%. It is proved that a deep convolutional neural network is efficient and useful for bird image classification.

A paper was published which explained that ecological resources are important for the survival of human beings [19]. The author has used ecological research. The author first developed the relationship between the theory of deep learning and ecological research. It is expected that participation and preparing cross-disciplinary abilities may advance standardization. Deep learning is used for nonlinear feature extraction for scientific and industrial data processing.

A paper that was published in 2019 [20], used the VGG 16 network to extract features of birds. The author used a dataset of bird species of Bangladesh. The author used different classification methods, like random forest, K-nearest neighbor (KNN) but the support vector machine (SVM) gave the max accuracy of 89%.

A paper that uses a deep learning platform to identify bird species images [21] using the mobile app Internet of birds. The author used convolutional neural network (CNN) to find different features in images. To improve feature extraction, the skip connection method is used. Then the SoftMax function is used to get a probability distribution of the features of birds. 93.98 % was convolutional neural network (CNN) accuracy and support vector machine (SVM) got 89.00% accuracy. Both accuracies are less than 99.00%, which is the highest accuracy of the proposed model convolutional neural network (CNN) with skip connection.

The paper published in 2014[22] proposed architecture which first finds the pose of a bird. For bird feature extraction Deep Convolutional Neural network is used. To find the compact pose the author proposed a novel graph- based clustering algorithm. Author got great classification accuracy that is 75% vs. 55-65%.

A paper that was published in 2020 [23] proposed a deep learning model to identify bird species. The author used the ResNet model as a pre-trained convolutional neural network (CNN) with a base model to identify the images. The author got a high accuracy of 97.98% on the bird classifications.

A paper [24] for predicting breast cancer was published in 2021 that used a dataset of QIN-Brest for breast cancer detection that is divided into the ratio 7: 3 for training and testing. The authors used two deep transfer learning models, DenseNet201, ResNet152v2 and an ensemble model with concatenation of two models, trained and tested using a dataset of CT images. The ensemble model has been given 100% accuracy on the test data. The authors concluded that ensemble models are better at predicting breast cancer than those of DenseNet201 and ResNet152v2 models.

A paper published in 2019 [25] explaining that there is a loss in abundance of bird species that leads to the changes in the ecosystem. Authors studied the bird population of North American avifauna for over 48 years. It is found that there is a loss in the population of birds, around 29% of 1970 bird population. This population loss needs to be addressed for the future of biodiversity.

In the paper that was published in 2021 [26], it is said that because of the land use change, there is a loss of biodiversity in different countries. That is responsible for changing the forest ecosystem. It is very important to know these things to avoid biodiversity loss. The author carried out a semantic breeding-season survey in six different land use types. The author's study shows that there is moderate to drastic species loss in all-the changed land uses compared to natural oak forests.

The Global Assessment Report on Biodiversity and Ecosystem Services is a thorough and evidence-based analysis of the state of biodiversity worldwide [27]. It pinpoints the causes of loss and the impacts on food security, health, and livelihoods. With recommendations for policy action, it provides a comprehensive understanding of the risks and opportunities associated with ecosystem degradation. Despite its strengths, future work is needed to address data gaps, regional limitations, implementation challenges, and the integration of other global challenges, requiring ongoing monitoring and evaluation.

The paper ‘Abundance decline in the avifauna of the European Union’ [28] reveals cross-continental similarities in biodiversity change" analyzes the changes in bird abundance in the European Union (EU) between 1980 and 2015. The study found that bird abundance has decreased by 22.5% in the EU during this period, and that the decline was most pronounced in farmland and grassland bird species. The decline in bird populations was found to be similar to trends observed in North America, suggesting cross-continental similarities in biodiversity change. The paper highlights the need for conservation efforts to reverse the decline in bird populations and prevent further biodiversity loss.

In a paper named ‘Birds in Decline’ [29], Youth H. takes us on a soaring journey through the troubling topic of declining bird populations. With a keen eye for detail and a passion for avian conservation, Youth H. paints a vivid picture of the challenges faced by birds and the ecosystems they inhabit. Through a mix of data analysis and personal observations, the author sheds light on the alarming trend of bird decline and highlights the urgent need for action. The result is a thought-provoking and informative piece that will leave readers with a renewed appreciation for the feathered friends that share our planet.

The paper ‘Applications for deep learning in ecology’ [30] provides an overview of the use of deep learning in ecology. It explains how deep learning, a branch of machine learning, has become popular due to its flexibility and performance. The paper reviews existing implementations and demonstrates how deep learning has been used successfully to identify species, classify animal behavior, and estimate biodiversity in large datasets like camera-trap images, audio recordings, and videos. It also provides guidelines, recommendations, and useful resources to help ecologists get started with deep learning. The authors argue that deep learning can become a powerful reference tool for ecologists, especially at a time when automatic monitoring of populations and ecosystems generates vast amounts of data that cannot be effectively processed by humans anymore.

The papers studied during the survey included bird image classification approaches, but the results were provided for only a few numbers of bird species. The dataset used for comparison of the transfer learning models in our study included 400 species of birds and the size was also large enough which ensured proper training and testing of the models to provide the maximum output from the models. A detailed comparative study of the discussed papers is presented in Table I.

TABLE I. COMPARATIVE STUDY OF EXISTING APPROACHES

Paper id	Dataset	Approach	Advantages	Limitations / Future work
[3]	Live bird feed watchers came from Cornell Lab of Ornithology at 6 different locations.	Single-shot detector and faster R-CNN with ResNet50, MobileNet-V2, ResNet152, ResNet101, and Inception ResNet-V2 feature extractors.	Faster R-CNN combined with ResNet152 feature extractor was best for achieving high precision.	The SSD with MobileNetV2 was best for fast speed and low memory consumption but lacked high precision like Faster R-CNN with ResNet152.
[4]	500 images of each bird class of 7 species of Bangladesh birds with a total of 2800 training images and 700 testing images	Transfer learning used in 6 different CNN architectures DenseNet201, InceptionResNetV2, MobileNetV2, ResNet50, ResNet152V2, and Xception.	MobileNetV2 outperforms all the other transfer learning models.	There is no support for using the live bird feed of the cam for identification.
[5]	CIFAR-10 and Caltech Faces dataset	Inception- v3 via transfer learning.	Transfer learning models are better than custom CNN.	Accuracy can be improved by increasing the epoch sizes and size of the dataset and combining CNN with Long-short Term Memory (LSTM).
[6]	Custom dataset using Microsoft’s Bing Image Search API v7.	Used a deep learning model to extract the information images of birds using CNN.	Developed a smaller and more portable version of VGGNet and achieved an accuracy of 93.19% on the training dataset.	The testing dataset accuracy is 84.91% which is very low.
[7]	700 testing images and 2800 training images of 7 local birds in Bangladesh.	Used 4 approaches inception - v3 with and without transfer learning, MobileNet with and without transfer learning.	MobileNet performed better than the Inception model.	Only 7 bird species are used to generate the output.
[8]	Custom dataset obtained from BirdFans in China containing 20000 images.	Implemented proposed method with 4 types of deep CNN.	DCNN gave a high accuracy of 97.76% on the testing dataset.	Further research is needed to improve the DCNN for performing well in real-world scenarios.
[9]	1600 images of 27 species of birds of Bangladesh.	Used machine learning approach using VGG-16 network as a model.	SVM gave the maximum accuracy of 89%.	KNN has less accuracy than SVM.
[10]	27 Taiwan endemic bird species.	Given bird images as an input to CNN which is used with the skip connection.	The Convolutional Neural Network model with bound connection gives high accuracy which is 99.00 %.	CNN and SVM have less accuracy than CNN with the skip connection.
[11]	CUB-200-2011	The bird's features are computed by CNN.	Performance was better for 1] usage of Convolutional Neural Network features which were fine-tuned upon CUB-200-2011 for every region, 2] usage of various Convolutional Neural Network layers for numerous alignment levels type, and 3] usage of a similar warping function that's estimated for using a larger number for detecting key points.	For future work, the proposed solution can be applied to other fine-grained datasets. Then they explore the custom-built CNN network structures and their training.
[12]	Data of bird species from various sources merged with the western dataset.	Pretrained CNN performs better on input images.	The proposed pre-trained ResNet model has better accuracy of 97.98% in identifying bird species.	The based model showed less accuracy than the proposed pre-trained ResNet model.

[13]	QIN-Breast Dataset	Two deep transfer learning models, ResNet152V2 and DenseNet201, and an ensemble model with a combination of 2 models, trained and tested by CT images.	The proposed model gained the maximum accuracy of 100 percent on the dataset which was tested and also high performance of 100% in f1-score, recall and precision value.	Both the models still have scope of improvement as considering various parameters.
[14]	529 bird species from the US and Canada.	Multiple and independent monitoring networks (radar networks)	Networks used in the paper are useful for getting the population loss across the North American avifauna.	As the birds are giving numerous benefits to the ecosystem, people should conserve them.
[15]	8549 bird observations.	The landscape is chosen and further it is divided into parts as per their use.	There should be conservation planning of bird species in human dominated landscapes.	Due to the use of land by humans affected the forest bird species in western Himalaya.
[16]	445 native bird species.	Bayesian models are used to check the change in abundance of the birds in the EU. The imputed model shrinks the uncertain indices of the species towards the group mean.	Using the models used in a paper, the author represented the biodiversity loss in native avifauna.	There is a decline of 17-19% in the overall breeding bird abundance
[17]	Worldwide different bird species.	Different bird species were studied all over the world, and various vanished and endangered species were discovered.	Preserve the bird species.	There is a huge amount of decrease in the bird species, and it has a negative impact on both biodiversity and human lives.
[18]	Habitat Elements from Bird Images	Used habitat elements of bird image and model based on the ResNet - 152 algorithm, given 95.52% validation and AlexNet given the lowest test accuracy as 89.48%	ResNet basel model given highest validation accuracy is 95.52 %.	ResNet basel model given lowest test accuracy is 95.52 %.
[19]	Multi-source data	Used ecological resources that are important for the survival of human beings. Developed the relationship between deep learning and ecological research .Deep learning is used for nonlinear feature extraction	Understanding of ecological resources is beneficial for the sustainable development of human society.	-
[20]	Bird species of Bangladesh.	Used the VGG 16 network to extract features of birds. Different classification methods, like random forest, K-nearest neighbor(KNN) but the support vector machine(SVM) gave the max accuracy of 89%	Support Vector Machine (SVM) gave the max accuracy of 89%	Improve accuracy by increasing data
[21]	27 bird species endemic to Taiwan.	Mobile app is used to identify bird species images. Used CNN for features extraction. To improve feature extraction, the skip connection method is used.	99.00%, is the highest accuracy of the convolutional neural network (CNN)model with skip connection.	CNN has 93.98 %,SVM has 89.00% accuracy which is lesser than CNN with skip connection model.
[22]	Worldwide different bird species.	Finds the pose of a bird. Deep convolutional network is used for feature extraction. For compact poses a novel graph-based clustering algorithm is used.	Classification accuracy, is 75% vs 55-65% which is of old method.	-
[23]	Birds found in diverse scenarios worldwide.	Used resNet model as a pre-trained CNN network with a base model to identify the images.	High accuracy of 97.98%	Birds are found in diverse scenario with different size and shapes.
[24]	Public dataset QIN Breast	Used 2 deep transfer learning models, DenseNet201,ResNet152v2 and an ensemble model with concatenation of 2 models, trained and tested using a dataset of CT images.	Ensemble model has given 100% accuracy on the test data.	Ensemble models are better than DenseNet201 and ResNet152v2 models.
[25]	North American avifauna	Loss in abundance of bird species that leads to the changes in the ecosystem	Population loss is studied which is helpful for the future of biodiversity	American avifauna when studied it is found that a loss in the population of birds, around 29% of 1970 bird population.

[26]	Western Himalaya bird species.	Because of the land use change, there is a loss of biodiversity.	Studied land use change which will help in future to avoid biodiversity loss.	Because of the land use change there is decrease in the biodiversity.
[27]	-	It provides a comprehensive analysis that identifies the causes and impacts of biodiversity loss.	It provides policymakers with actionable recommendations, Integrated approach, Global perspective, Foundation for future research.	Areas for future work, such as data gaps, Limited regional focus and implementation challenges.
[28]	Extensive dataset of breeding bird abundance in the European Union.	The approach used in the paper was to analyze data from bird monitoring programs across the European Union to estimate population changes over time.	The authors estimated a decline of 17-19% in overall breeding bird abundance, equivalent to a loss of 560-620 million individual birds. The study highlights the high declines in bird numbers among species associated with agricultural land.	Limitations of the paper are that it did not include other aspects of biodiversity, only included bird populations in the European Union and did not consider populations in other regions, did not investigate the specific causes of bird population decline.
[29]	-	The paper examines senescence variation in multicellular organisms, particularly social species. It reviews senescence research, quantifies covariation between mortality and reproductive ageing, models social interaction effects on ageing, tests predictions in social species, and examines senescence in a cooperative breeder population.	This work can inform future research on the evolution of senescence and the dynamics of social species.	Future work for this paper could involve further testing and refinement of the social interaction model for senescence in social species.
[30]	-	The article discusses the potential applications of deep learning in ecology, including species identification, animal behavior classification, and biodiversity estimation. The authors provide guidelines, recommendations, and a reference flowchart for ecologists to get started with deep learning. They argue that as ecological datasets become larger and more complex, deep learning could become a powerful tool for ecologists.	It provides an overview of deep learning in ecology, demonstrates the usefulness of deep learning in ecology and highlights the potential of deep learning for automatic monitoring.	The paper does not provide an in-depth discussion of the limitations and potential biases of using deep learning in ecology.

III. Proposed Work

The principal aim is to implement various transfer learning models to compare their performance on the bird image classification dataset. The main transfer learning models used for comparison are InceptionV3, ResNet152V2, Densenet201, and MobilenetV2. The transfer learning models are used as feature extractors. The dataset used contains a total of 58388 images of birds. The total number of species included in the dataset is 400. The output and input layer are added to the transfer learning model with dense connection. The output layer is generating results by using SoftMax as the activation function. Given that SoftMax is employed for multiclass classification, it serves as the activation function. The proposed system architecture is depicted in Fig. 1 and described in detail thereafter.

A. Datasets

To complete the implementation of the comparison of these transfer learning models a dataset of bird images available on Kaggle [31] is used for both the training and testing purposes. There are a total of 58388 images belonging to 400 species of birds for training purposes and 2000 images each of testing and validation images belonging to 400 species of birds.

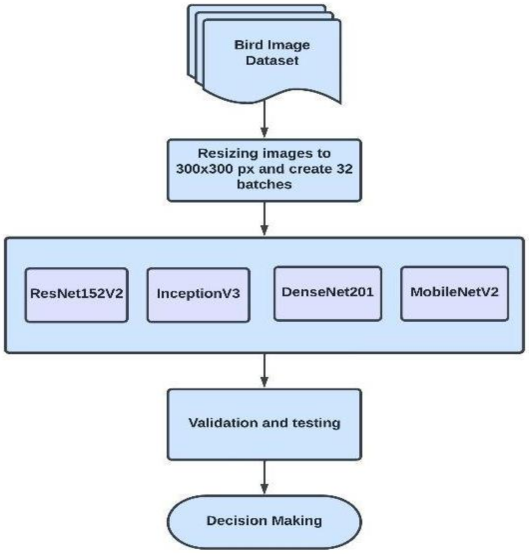

Fig. 1. System architecture.

B. Data Pre-processing

This mainly deals with preparing the data so that we can get maximum performance from the model after training the model using this data. All the images in the dataset must be in the same format for the model to be easier to train. For image pre-processing, we converted the images to 300x300px for standardizing the image dimensions. Then we created batches for training the model in batches. A batch size of 32 images was created. Batch size means the number of samples processed before the model is updated. This is needed because after training from batches expected results can be matched with actual results to calculate the error and this error is then used to update the algorithm to improve the model. All the images used are RGB images. So, the dimension of images used is (300,300,3).

C. Transfer Learning Models

Based on the literature survey, four transfer learning models are selected. These are ResNet152V2, InceptionV3, DenseNet201 and MobileNetV2. The ResNet152V2 and InceptionV3 models are selected because these are widely used and perform well. DenseNet201 is densely connected and thus takes more time to train but generally provides higher accuracy; and the MobileNetV2 is lightweight and has faster processing output.

1) DenseNet201: This is the feature extraction model. It is a convolutional neural network that is 201 layers deep. We can load millions of images to this pre-trained network which can classify the images into multiple object categories. Strong gradient flow, computational efficiency, and multiple different features are the advantages of this model.

2) ResNet152V2: This model is used for feature extraction. It is a pretrained model, so it gives higher accuracy in less time than traditional CNN. As the number of layers increases the training and testing rate also increases. To solve the problem of vanishing gradient residual block concept is introduced. The skip connection technique is used in this network. In this technique, it skips some layers in between. The advantage of this skip connection is if any layer in between changes the performance of architecture then this layer is skipped so performance increases. The ResNet model consists of a reshape layer, flattened layer, a dense layer having 128 neurons, a dropout layer, and the dense layer with SoftMax function which is used to classify the image.

3) InceptionV3: It is the deep learning model used for image classification which is based on CNN. It gives greater than 78.1% accuracy on the image datasets. It uses the transfer learning approach, so it gives good performance in classification. The model is made up of symmetric and asymmetric blocks which include convolutions, average pooling, max pooling, dropouts, concatenations, and fully connected layers.

4) MobileNetV2: It is a lightweight model for feature extraction which gives good performance on mobile devices. It is the convolutional neural network which is 53 layers deep. The model is based on residual structure. The model contains initial convolution layers with 32 filters followed by 19 residual bottleneck layers. The model can work in more than millions of images and the pre-trained network can classify images into about 1000 object categories.

D. Training

Each model is trained separately in a different notebook on Google Colab. An input layer and an output layer were added to the model for giving input and output along with a global average 2D pooling layer before the output layer. The Global Average 2D pooling layer takes a block of a tensor as input and calculates an average value of all the values across the tensor for each of the input channels. Pooling is necessary to reduce the dimensions, so it makes it easy for the model to train. The input layer accepts images of dimensions (300,300,3) and the output layer has 400 nodes for 400 species. The network is densely connected.

All the layers are frozen in the transfer learning model. The layers are frozen to reduce the training time and the activation function used is the same for all the models i.e., SoftMax as it is a multiclass classification. The learning rate is kept at 0.01. Based on the training time required to train the models and the size of the dataset used, 15 epochs were finalized to train the models. All these parameters are kept the same. This ensures that all the transfer learning models are fairly evaluated under similar conditions to give unbiased results.

E. Classification

A testing dataset of 2000 images is provided for testing the trained model. Accuracy is obtained to evaluate the performance of the models using the testing dataset. For prediction, the image which is to be classified is obtained from the user and it is first processed. It is converted into an image of 300x300px that is best suited for the model and then classification is done.

IV. Results

The results are checked based on the accuracy provided by each model. The accuracy and loss curves are also plotted to better understand the training process of the model. This gives an idea about the accuracy and loss of the model over each epoch. The maximum observed accuracy is of ResNet152V2 model i.e., 95.45%. The plots of each model are given below.

As the models were built on the same parameters, the results obtained from the comparison can be considered to fairly evaluate the performance of these transfer learning models. The MobileNetV2 took less training time, and the model size is also small. The DenseNet201 has the best performance out of all and the InceptionV3 and ResNet152V2 performed well. ResNet152V2 displayed maximum accuracy but was having a large loss. These models can be compared based on various factors. The results obtained because of those factors are given below.

A. Performance Metrics

Given below are the performance metrics based on which the models are compared.

1) Accuracy: Accuracy in model training refers to the ability of the model to correctly classify input data. In other words, accuracy is a measure of how often the model predicts the correct label for a given input. It is calculated as the ratio of correctly predicted samples to the total number of samples in the dataset. A higher accuracy score indicates that the model is better at predicting the correct output and is more reliable. However, it is important to note that accuracy is not the only measure of a model's performance.

2) Loss: Loss in model training refers to the difference between the predicted output of the model and the actual output. In other words, loss is a measure of how far off the model's predictions are from the true values. The goal of training a model is to minimize the loss function, which is typically a mathematical function that measures the difference between the predicted output and the actual output. This is done by adjusting the weights and biases of the network during the training process using techniques such as backpropagation. Lower loss values indicate that the model is better at predicting the correct output and is more accurate. However, it is important to find a balance between low loss values and overfitting, where the model becomes too specialized to the training data and performs poorly on new, unseen data.

3) Training time: Training time in model training refers to the amount of time it takes for the model to learn from the training data and adjust its weights and biases to minimize the loss function. The training time can depend on a variety of factors, such as the complexity of the model, the size of the training dataset, the available computational resources, and the hyperparameters used for training. The training process involves iterating through the training dataset multiple times (epochs) and adjusting the weights and biases of the network based on the feedback from the loss function. The goal is to find the optimal values for the weights and biases that minimize the loss and improve the accuracy of the model. In general, larger, and more complex models with larger datasets may require longer training times, while smaller and simpler models may converge faster. Efficient use of parallel processing resources can also help to reduce the training time.

B. Discussion

Given below are the accuracy graphs of the models.

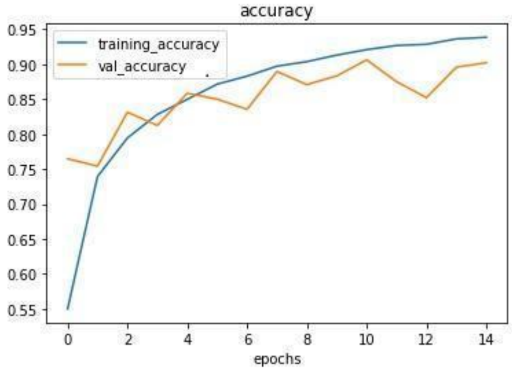

Fig. 2. InceptionV3 model training and validation accuracy.

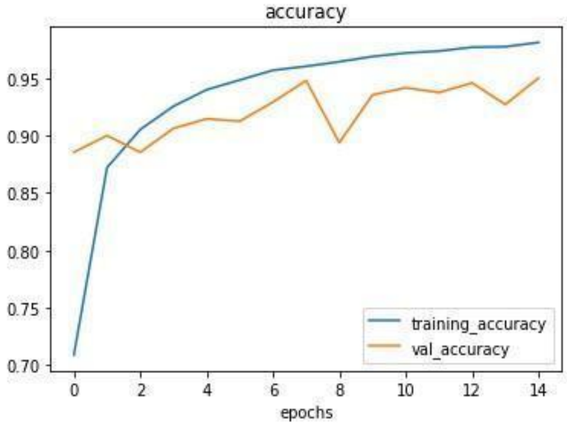

Fig. 3. ResNet152V2 model training and validation accuracy.

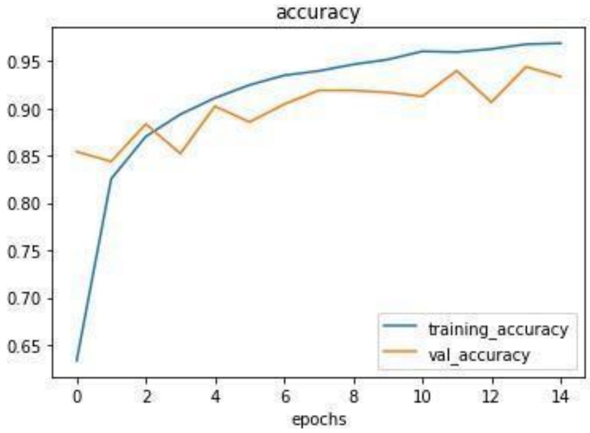

Fig. 4. DenseNet201 model training and validation accuracy.

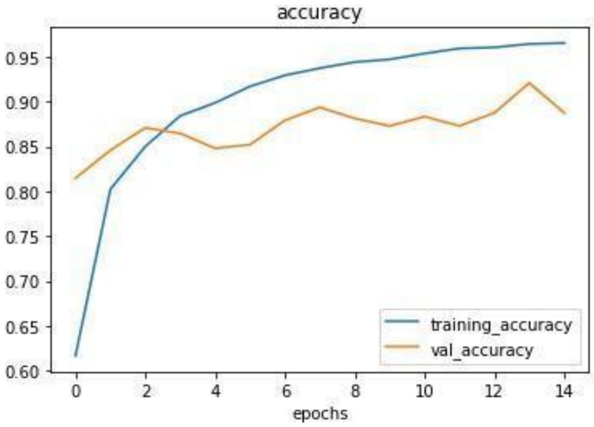

Fig. 5. MobileNetV2 model training and validation accuracy.

The steadiest training accuracy was observed in DenseNet201 from Fig. 4, and the other models performed almost similar in the training accuracy. The most stable validation accuracy was observed in DenseNet201 and the most unstable was observed in ResNet152V2 from Fig. 3 and InceptionV3 displayed in Fig. 2. From Fig. 5, it can be observed that the average training time of MobileNetV2 was 128 sec.

Given below are the loss graphs of the models.

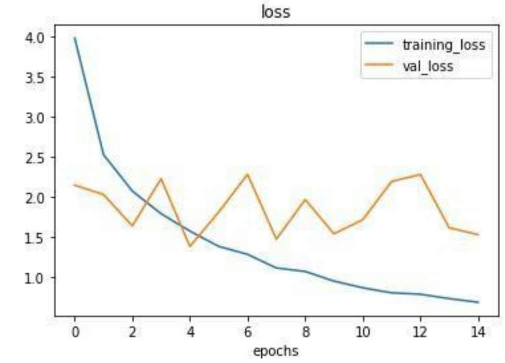

Fig. 6. InceptionV3 model training and validation loss.

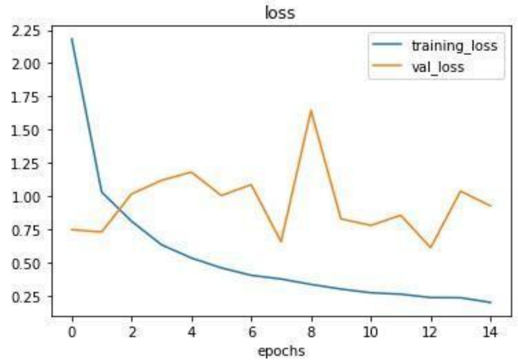

Fig. 7. ResNet152V2 model training and validation loss.

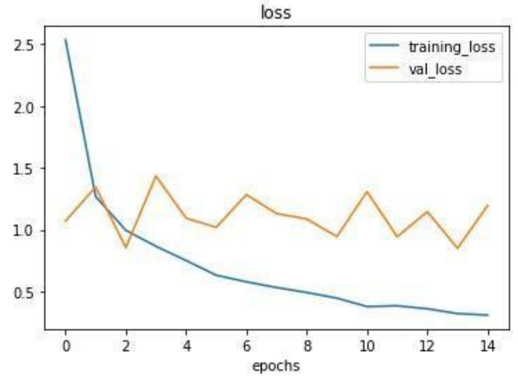

Fig. 8. DenseNet201 model training and validation loss.

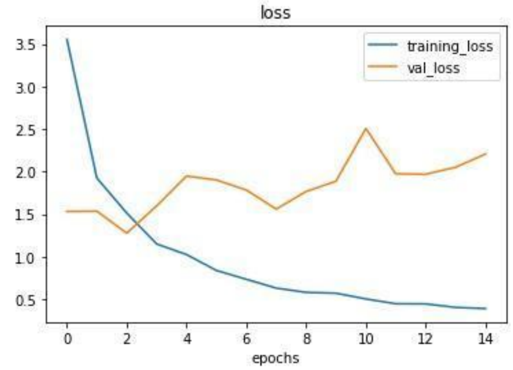

Fig. 9. MobileNetV2 model training and validation loss.

The models performed similarly on training data by reducing the training loss over epochs, but the loss fluctuated during the validation. The most fluctuation was observed in InceptionV3 validation loss from Fig. 6 and the most stable among the models was observed in DenseNet201 from Fig. 8. Fig. 9 depicted that the validation loss in MobileNetV2 increased over epochs instead of decreasing. The training and validation loss of Resnet152V2 can be observed from Fig. 7.

Fig. 10 displays the comparative graph of average training time required per epoch for training the models.

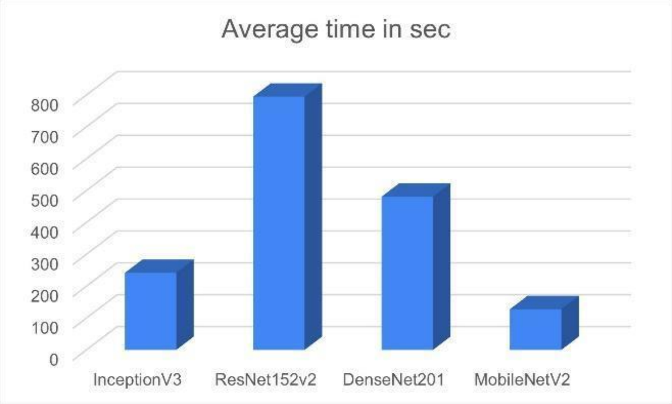

Fig. 10. Average training time per epoch comparison.

Fig. 10 compares the training time by taking the average of the time required by the model for each epoch. The ResNet152V2 required the highest training time with an average of 795 sec. It is more than the training time required by InceptionV3 and DenseNetV2 with average time 242 sec and 481 sec respectively. The MobileNetV2 is lighter and thus requires less time to train than the other transfer learning models compared in this study. The average training time of MobileNetV2 was 128 sec.

The overall result can be understood from the testing accuracy and the testing loss of the models as depicted in Table II.

Fig. 11 shows that ResNet152V2 provided the maximum accuracy with a loss of 0.883. But the DenseNet201 faced less loss than ResNet152V2 and provided accuracy like the ResNet152V2 model. Thus, DenseNet201 performed better than the other models on the bird image dataset with an accuracy of 95.09%.

TABLE II. COMPARISON OF PERFORMANCES OF TRANSFER LEARNING MODELS

Model Name	Accuracy	Loss
InceptionV3	90.2%	1.542
ResNet152v2	95.45%	0.883
DenseNet201	95.09%	0.685
MobileNetV2	91.1%	1.782

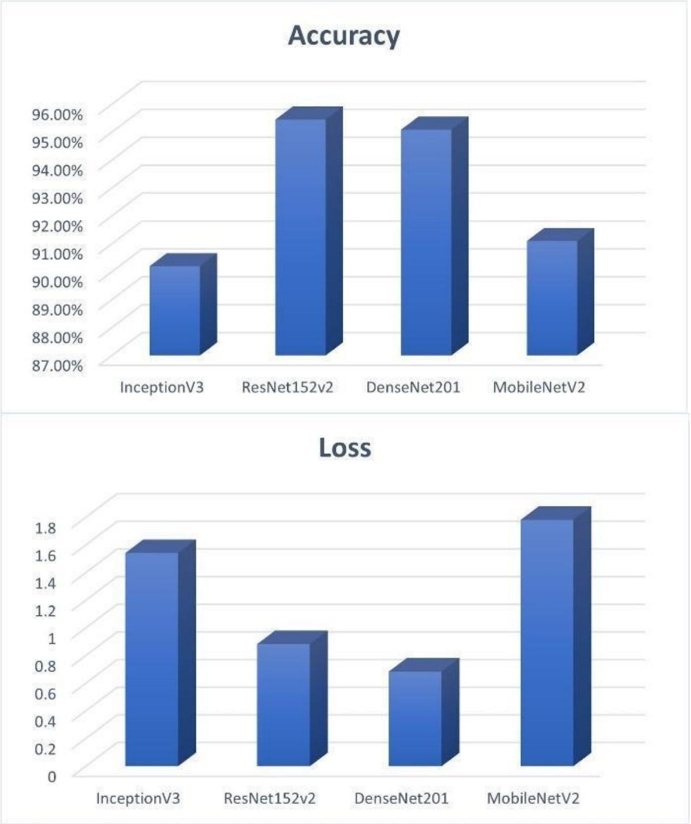

Fig. 11. Accuracy and loss curves for comparing the models on testing data.

V. Conclusion and Future Work

In this paper, various deep learning/ transfer learning models for bird species identification have been studied and compared. It has been understood that mostly the existing systems have used deep learning models or transfer learning models with smaller datasets. Therefore, an elaborate dataset consisting of 58388 [31] bird images of four hundred species has been identified for this work.

Four different transfer learning models namely InceptionV3, ResNet152V2, DenseNet201, and MobileNetV2 are implemented on the identified dataset. All these models were trained under similar conditions to get the best possible comparison between them. ResNet152V2 provided an accuracy of 95.45% which is more than the other 3 models. But it also faces more losses than DenseNet201. MobileNetV2 has the lowest training time, but the model accuracy is not as good as the other models. In conclusion, the best model among these models is DenseNet201. Even though its accuracy is a little less than the ResNet152V2 model, its loss is far less than other models. Thus, DenseNet201 is better than Resnet152V2.

Though the accuracy given by the implemented models are good, the models can be fine-tuned for better accuracy and better identification of birds. For fine-tuning, the number of epochs may be increased or some of the layers of the transfer learning models can be unfrozen. The same can be integrated with a mobile app, where common people would be able to upload captured images of birds and the app would provide details of the identified birds.

An Automated Framework to Detect Emotions from Contextual Corpus

Ravikumar Thallapalli[1], G. Narsimha[2]

Research Scholar, Faculty of Informatics-Department of CSE, Osmania University, Hyderabad, Telangana, India[1]
Professor, Department of Computer Science and Engineering, JNTUH University College of Engineering, Sultanpur, Sangareddy, Telangana, India[2]

***Abstract*—The emotion extraction or opinion mining is one of the key tasks for any text processing frameworks. In recent times, the use of opinion mining has gained a lot of potential due to the application of the potential customized aspects of the consumer relations and other customized applications. However, the application of sentiment analysis or opinion mining is highly challenging as the accuracy of the sentiment analysis depends on the input text corpus. The input text corpus can be highly fluctuating due to the inclusion of emojis or local language influences and finally the use of a wide variety of the regional languages. A good number of parallel research outcomes have aimed to solve these challenges in the recent time. However, most of the parallel research outcomes have primarily three challenges kept unsolved as firstly, the emojis in the text corpus is mainly removed but not translated into sentiment scores, secondly, the translation of the texts from various regional languages and the translation is mainly true translations rather than the contextual translation. Finally, the use of the dictionaries in the actual translation tasks takes a lot of time to process and must be reduced. Henceforth, in order to solve these challenges, this work proposed a framework to automate the weighted emoji-based sentiment analysis, Unicode based translation process to reduce the time complexity and finally use the collaborative sentiment analysis scores to build the final sentiment models. This work results into nearly 97% accuracy and nearly 50% reduction in the time complexity.**

Keywords*—Emoji translation; weighted annotation; text translation; reduced unicode based dictionary; relative sentiment score building; mean scoring technique; collaborative sentiment score building

I. Introduction

Weizenbaum created ELIZA in 1964–1966. The artificial intelligence system ELIZA fooled people into thinking it could grasp human language by imitating their speech patterns. The "DOCTOR" was asking random questions in an attempt to learn more about "patient-centered" care. The concept of giving machines emotions shocked Weizenbaum. A mute ELIZA was unable to say a thing [1].

Regular users of social networking sites are more likely to rely on text messaging than any other form of communication. The emotional state of both parties affects the quality of their relationships. Natural language processing has certain issues when dealing with tweets. Despite NLP's development, data was still necessary for earlier work on low-resource languages. The six native Arab taggers at ExaAEC tagged 20,000 tweets. Plutchik's emotional "paradigm" includes these 10 categories. LSTM and ELMO are used to categorize feelings. On the F1 scale, the agreement between our data and model is 0.65. The elimination of emotions changes [2]. The focus here is not on classifying or extracting emotions, but on understanding what sets them in action. Because we could not find any publicly accessible datasets, we opted to generate one using the Emotion Markup Language from the W3C. Here we detail how one may use a tree-based event representation framework to trace the roots of an emotional state. Under sampling-based bagging may be used to level out the training data's unequal distribution of events. The proposed approach can extract SVM features effectively with little training.

Natural language processing experts can decipher the underlying meaning of a written message by analyzing the writer's tone [3].

As it is, the problem is seen as a multi-label classification problem by the state of the art. These algorithms do not consider how a text makes the reader feel. Second, because diverse text fragments may predict different emotion labels, the model must gather effective attributes for each emotion. For this purpose, we use a topic-enhanced capsule network in conjunction with a variational autoencoder to classify a broad variety of emotions. The latent topic of a sentence is utilized to train a variational autoencoder, and a capsule module is employed for sentiment analysis. The proposed model outperforms the state-of-the-art [4].

Henceforth, after setting the context of this research in this section of the work, the rest of the work is furnished such as in the Section II, III and IV the foundational methods are discussed and based on the foundation methods, in the Section V the recent improvements are discussed. Further, in the Section VI and VII the identified problems and the proposed solutions are furnished. In the Section VIII, based on the proposed solutions, the algorithms and the frameworks are discussed. Furthermore, in the Section IX, the obtained results are discussed and compared with the existing research outcomes. Finally, the research conclusion is presented in the Section X.

II. Foundational Method for Emoji Detection

In this section of the work, the foundational method for the emoji detection is furnished. The detection of the emojis is one of the prime factors during any text processing tasks. The accuracy of any machine learning driven algorithms relies on the correctness of the input data and the datasets with emojis can deviate the accuracy of the machine learning methods to a greater extent.

Assuming that, the complete text corpus is T[] and the prime components in the dataset are the sequence number of the data items, n, and the actual text as t. This can be formulated as,

$$T[] = < n, t > \tag{1}$$

Further, the base line method indicates that, the set of uni-code characters, UC[], to be separated, t*[], from the actual text and must be handled separately, as,

$$t^*[] = \prod_{t[i]=UC} t[i] \tag{2}$$

Furthermore, the extracted Unicode characters must be validated against the specified range of the unicodes and must be assigned to the emoji collection as,

$$E[] = Iff\ \ t[] \subset UC[UC\_range] \tag{3}$$

Henceforth, the unicode removed text corpus, T1[], shall be presented as,

$$T1[] = T1[] - E[] \tag{4}$$

Further, in the next section of this work, the foundational method for the text translation is furnished.

III. Foundational Method for Text Translation

In this section of the work, the baseline method for the text translation is carried out. The text translation for the text processing projects plays a very important role. The translation of the text implies the verification of the text analysis process and majority of the text analyzers focus on the English dictionary. Hence, the translation of the text from other native languages is highly appreciated for any text mining applications.

Continuing from the Eq. (4), the text corpus, which is free from the emojis, must be further filtered to remove the numeric values as,

$$t[] = \prod_{T1[i] \notin Numeric\_Unicodes} T1[] \tag{5}$$

Also, the baseline method defines the use of the standard language dictionaries, D[], which contains the source language literals, s, and the destination language literals, d. This can be formulated as,

$$D[] = < s, d > \tag{6}$$

Further, the translated text, T2[] can be formulated as,

$$T2[] = \prod_{T2[i]==D[].s} D[].d \tag{7}$$

Henceforth, the final translated text, T2[] can be taken to the next phase of the process.

Further, in the next section of this work, the emotion detection foundational method is discussed.

IV. Foundational Method for Emotion Detection

In this section of the work, the baseline method for the emotion detection or opinion detection is analyzed.

Continuing from the Eq. (7), the text corpus further must be separated, T_X based on the stop words, connectors and finally based on the phases as,

$$T_X[] = \frac{d}{d(T2[])} T2[] \tag{8}$$

Also, the baseline method suggests to store all bag of words, B[], and further use the BoW to identify the set of sentiments with text phase, p, and sentiment score, sc. This can be realized as,

$$B[] = < p, sc > \tag{9}$$

Finally, based on the BoW, the sentiment collection, S[], must be designed. This can be formulated as,

$$S[] = \prod_{T_X[i] \approx B[].p} B[].sc \tag{10}$$

After the detailed analysis of the baseline methods in the previous sections of this work, in the next section of the work, the recent improvements over the baseline methods are discussed.

V. Recent Research Reviews

Extracting useful information from Twitter profiles is now trendy. From what you've stated, Twitter may infer how you feel about a topic. The newest graphs can detect your emotional state. It's only possible to utilize Western languages. The ability to recognize Indonesian speakers' emotions has been enhanced. Feelings of joy, sadness, fear, surprise, disgust, dread, and anticipation or fury (marah). As a result of its speakers' imbalanced emotions, Indonesian is imprecise. According to the findings, adjusting the pattern weight will help make the Indonesian data more comparable. The recommended strategy increases minority class accuracy (fear, surprise, and disgust) [5].

Emotional states impact the dynamics of interpersonal relationships. Text, speech, and body language all contribute to the communication of emotion, caring blogs and social media. Politics, both domestic and foreign, are discussed. The ability to evaluate the emotions described in books is helpful for success in social settings. The study of emotions in Bangla is quite new. Multi-class emotions are extracted from Bangla text using NB classifier, stemmer, POS tagger, n-grams, and word frequency-inverse document frequency analysis (tf-idf). [6] An overall accuracy of 78.6% was achieved in the final model.

Syntactically, NLP categorises expressions of emotion (NLP). When confronted with a classification issue with multiple labels, current methods perform well. This means that none of the methods can be used to demonstrate the model's ability to predict spatial correlations in sample data. In my opinion, a fantastic strategy to improve efficiency and productivity is to use contrastive learning. To maximize the positives and minimize the negatives, they apply a compound loss function on top of a tweaked version of the commonly used Cross Entropy loss function in training. My recommendations were successful [7].

Better computer-human interactions, monitoring mental health, and adapting corporate strategies are just a few examples of the many applications for emotion detection. Deep learning outperforms all other AI methods in every measurable way. Single-emotion and multi-emotion samples are used by all machine learning algorithms for emotion identification. Our research shows that these systems benefit more from single-emotion instances than from mixed-emotion ones. Single-emotion works are unusual. Inefficient procedures exist. We used all available information to create a dataset where each piece of text represents at least two different emotions. Since CNNs are so good at analyzing pictures, we modified their design to determine how readers would feel about a given passage. We used rapid text and GloVe to detect semantic and syntactic similarities between text and numerical expressions. There has to be more accuracy in the construction plans; excellent estimate [8].

The encoder is bidirectional. Both Transformers representations and the Universal Sentence Encoder make advantage of transfer learning. The problem of overfitting arises in language models trained using a classifier on a limited data set. The majority of current studies focus on generalizing deep language models to new fields. When it comes to determining how someone is feeling, DeepEmotex turns on transfer learning. Twitter's data on user sentiment is collected, analyzed, and utilized for further refinement. Twitter is vital to its users. DeepEmotex has a 91% accuracy rate. EmoInt and Stimulus both validate Deep-Emotex. An average level of emotional engagement is 73%. When compared to Bi-LSTM, DeepEmotex-BERT performs 23% better. Both the extent of the dataset and the effectiveness of the models are examined. Modeling the task at hand and refining it based on how the intended recipient is experiencing [9].

The ASR capabilities are used by EPD (DSFs). Decoding DSFs through ASR is a little pricey for embedded systems. Based on the word history of the whole ASR system, this study presents a language model (LM)-based end-of-utterance (EOU) predictor that does not need a decoding approach in the test phase. Using a novel full-stack EPD approach, audio and language modelling techniques based on predictive encoding (PE) and explicit outcome usage (EOU) predictors, respectively, are combined into a single RNN-based AFE-based EPD strategy. Ensemble RNNs trained with information from the LM-based EOU predictor, the acoustic model, and the AFE-based EPD for each target independently are used in the proposed EPD (AM). An ensemble of RNNs is linked to a DNN to create the EPD classifier. Following that, they get retraining in an effort to cut down on errors once they reach their ultimate destination. The EPD framework analyzed the proportion of incorrect CHiME-3 endpoint responses versus the proportion of responses that were right. There is an enhancement here compared to EPD [10].

Low resource - It is estimated that 230 million individuals worldwide have some level of fluency in Urdu. Researchers put together benchmark datasets in languages with limited resources. The English to Urdu language pair is one way of translation. Google Translate has recently been updated to include the ability to handle polarity shifts and other forms of natural language processing. The accuracy of sentiment analysis and emotion recognition suffers as a consequence. This study's primary objective is to categorize people's emotions in light of whether or not they have a lot of available resources to work with. We describe five classes of polarity-shifting nouns and verbs. It finds commonalities in the genesis of several languages. The accuracy of sentiment classification drops by 2% to 3% when transitioning from a language with a lot of resources to one with less [11].

Irony is the polar opposite of this. When analyzing text for sarcasm, emojis are seldom employed. This article discusses the use of satire on Weibo. After analyzing visual input, such as facial expressions, bi-LSTM networks next consult textual resources for more insight. Make your forecast using one of these three methods. Our comprehensive mining of sarcastic Weibo [12] was a smashing success.

The study of emotions is quite popular presently. Research on body language lags behind that on facial expressions and words. Surveys are designed to encourage participation from the general public. We take a look at the cultural and racial variations in body language. Human bodily movements are readable by our technology. Here, we investigate the use of RGB and 3D data for estimating body position. Current research on representation learning and emotion recognition in gestures is discussed. Similarly, speech and body multimodal techniques may be used. Massive scale data analysis of human identity, position assessment, and mood is now possible. The output spaces are inconsistent, and there are only simple representations [13].

Cyberbullying, especially among teenagers, has increased along with the development of new technologies. This article explores the role that emotions play in the identification of cyberbullying in India. We created BullySentEmo since there was no preexisting Twitter dataset that categorized bullying, sentiment, and emotion. Emoticons and short tweet-like text are encouraged to be embedded. In India, social media users often switch back and forth between the two languages. Multiple emoji manipulation is a feature of MT-MM-Bert+VecMap[14].

One way in which the prevalence of social media has altered the way we express ourselves verbally is by making us more likely to use strong language. Recognizing unsuitable content is a vital skill for anybody using the internet. The abundance of daily data has made automatic recognition a need. The effectiveness of hate speech detection algorithms is currently being studied. These methods are unable to detect polarity or tone in the language being studied. This is the first multi-task transformer-based technique for detecting hate speech in Spanish. Harassing communication that singles out certain groups often appeals to strong emotions or extreme opposites [15].

Opinion miners and researchers into human-computer interaction use different approaches to sentiment analysis. In this piece, we emphasize the importance of working across disciplines. In human-agent interactions, sentiment/opinion detection algorithms are often used for opinion mining rather than socio-affective interactions (timing constraint of the interaction, sentiment analysis as an input and an output of interaction strategies). To substantiate our arguments, we look at phenomena connected to emotions, sentiment recognition technology, and the goals of socio-affective human-agent strategies. The next steps that must be taken and the unanswered issues are discussed. For the purpose of providing a more precise sentiment analysis [16], we include the specified criteria into the Greta platform for humanoid conversational robots.

An approach of feature extraction is required for micro expressions. Multi-feature fusion may be used to detect micro-expressions. This technique establishes a connection between projection error and LBP features. In order to achieve rapid and precise identification, data utilized in the study was painstakingly extracted from specialized facial expression databases. In advanced learning environments, the novel method outperforms LBP; identification of objects in a photograph [17].

Recent research has shifted its emphasis from words to audio and video's non-verbal clues in order to make automated assessments of people's mental health. Textual content is as important as audio and video for depression detection systems. Comprehensively automated depression evaluation approaches need complex models of aural, visual, and textual elements. Anyone interested in learning more about depression may do so by perusing the audio, video, and textual materials provided here. A hybrid design consists of three main parts. a) A Deep Convolutional Neural Network (DCNN) and a Deep Neural Network (DNN) model for estimating the PHQ-8 based on audio-visual multi-modal depression recognition; b) a Paragraph Vector (PV) and a Support Vector Machine (SVM) model for inferring physical and mental conditions from interview transcripts; and c) a Random Forest (RF) model for depression classification using the estimated PHQ-8 sc. To identifying psychoanalytic symptoms, PV-SVM incorporates psychoanalytic questions pertaining to depression into fixed-length feature vectors and feeds them into SVM classifiers. Examining the PV drop for the first time. Identifying face characteristics in motion may be monitored in both time and space using HDR. The hybrid framework outperforms AVEC2016 in terms of depression estimates and classification on average by an F1 score of 0.746. (0.724). HDR outperforms BoW and MHH in identifying depressive episodes [18].

VI. Problem Formulation–Mathematical Model

Henceforth, after the detailed analysis of the existing systems in the previous sections of this work, in this section, the persisting research problems are furnished.

Firstly, the existing system is successful into detecting and separating the emojis, however the same detected emojis are not translated to sentiment scores.

Continuing from the Eq. (3) and Eq. (4), it is natural to realize that, the emojis collection, E[] is not been translated to emotion as,

$$E[] \not\subset T1[] \tag{11}$$

And Only,

$$T1[] \rightarrow S[] \tag{12}$$

Secondly, the baseline method recommends using the traditional dictionaries to convert the multi-lingual text corpuses to the standard text; however the text translating dictionary size can be overwhelming due to the fact that, the systems intended to translate a wide variety of the source languages.

Assuming that, the average size of the dictionary for one language is n and the diction, D[], is furnished for translating m number of languages. Hence, from the Eq. (7), the time complexity, T, can be furnished as,

$$T = n * m \tag{13}$$

Or,

$$T(n) = O(n^2) \mid n \approx m \tag{14}$$

Finally, the detection process for the emotion is not contextual.

As per the Eq. (10), the existing system builds the sentiment scores for text phases. Assuming that, the sentiment scores for two consecutive text phases are S[i] and S[j], then this can be furnished as,

$$S[i] \Leftarrow T_X[i] \tag{15}$$

And,

$$S[j] \Leftarrow T_X[j] \tag{16}$$

However, here the text corpuses are not inter-related as,

$$T_X[i] \not\subset T_X[j] \tag{17}$$

Thus, it is natural to realize that,

$$S[i] \not\subset S[j] \tag{18}$$

Henceforth, based on the identified challenges in the existing systems, in the next section of the work, the proposed solutions are furnished.

VII. Proposed Solutions

After the detailed analysis of the existing methodologies and the persistent research problems, in this section of the work, the proposed solutions are furnished.

Firstly, the emoji detection and translation to the sentiment process is furnished here.

Assuming that, the extracted text from the corpus, EJ[], have two prime component as enumerated id, e, for each text corpus and the text as t. This can be presented as,

$$EJ[] = < e, t > \qquad (19)$$

Further, based on the baseline method, the emojis are separated from the actual text and kept in a separate collection, E1[]. This can be formulated as,

$$E1[] = \prod_{EJ[i]=UC} EJ[i].t \qquad (20)$$

Further, the collection of emojis, E_X, which is already pre-build with the emotion scores, sc. This can be presented as,

$$E_X[] = < e, sc > \qquad (21)$$

Now, the extracted emojis must be translated to the sentiment scores, ES[], and kept for further processing.

$$ES[] = \prod_{E1[i]\approx E_X[]} E_X[].SC \qquad (22)$$

Secondly, the process for the translation process using the unicode driven dictionary is furnished.

Continuing from the Eq. (6), assuming that the unicodes, UC[], for each source and destination language phase can be extracted using the following hypothetical function as,

$$UC[] = \lambda\{D[].s\} \qquad (23)$$

And,

$$UC[] = \lambda\{D[].d\} \qquad (24)$$

Henceforth, assuming that, for two dictionaries D1[] and D2[], the unicodes are extracted as UC1[] and UC2[]. Now it is natural to realize that, both the unicode collections must have number of similar unicodes and thus, based on this situation, the length of the final dictionary, FD[], can be configured as,

$$FD[] = \{UC1[] \bigcup UC2[]\} - \{UC1[] \bigcap UC2[]\} \qquad (25)$$

This process can be repeated for all the dictionaries to be included and still the complexity for processing the total dataset can be limited to O(n/2) during the average case complexity.

Finally, the process for the relative sentiment score analysis process is furnished.

Continuing from the Eq. (10), assuming that for two text phases, $T_X[i]$ and $T_X[j]$, the sentiment scores S[i] and S[j], which can be furnished as,

$$S[i] = \prod_{T_X[i]\approx B[].p} B[].sc \qquad (26)$$

And,

$$S[j] = \prod_{T_X[j]\approx B[].p} B[].sc \qquad (27)$$

Further, for the relative and collaborative sentiment score analysis, the following process is furnished as,

$$\begin{aligned}&Iff\ \ S[i] \neq S[j],\\ &Then\ S[j] = Mean\{S[i], S[j]\}\ and\ S[i] \bigcup S[j]\\ &Else\ S[i] \bigcup S[j]\end{aligned} \qquad (28)$$

Further, for building final collaborative scores, the following strategy can be applied to include the sentiment scores from the emojis as,

$$\begin{aligned}&Iff\ \ S[i] \neq S[j],\\ &Then\ S[j] = Mean\{S[i], S[j]\}\ and\ S[i] \bigcup S[j] \bigcup ES[]\\ &Else\ S[i] \bigcup S[j] \bigcup ES[]\end{aligned} \qquad (29)$$

Furthermore, based on the proposed mathematical models, in the next section of this work, the proposed algorithms are furnished.

VIII. Proposed Algorithms and Frameworks

After the detailed analysis of the existing system, challenges in the existing systems and the proposed mathematical models, in this section of the work, the implementable versions of the proposed algorithms are furnished.

Firstly, the Emoji Translation using Weighted Annotation (ET-WA) Algorithm is furnished.

Algorithm - I: Emoji Translation using Weighted Annotation (**ET-WA**) Algorithm

Input:
Text Corpus as EJ[]

Output:
Sentiment scores for the Emojis as ES[]
Emoji Reduced Text Corpus as TT[]

Process:

```
Step - 1.   Load the text corpus dataset as EJ[]
Step - 2.   For each member of the EJ[] collection as EJ[i]
                a.   Extract the text component as EJ[i].t
                b.   If EJ[i].t belongs to Ex[] Then,
                         i.   Extract the emotion score as ES[j] =
                              EJ[i].SC
                        ii.   Build the reduced text corpus as TT[i] =
                              EJ[i] - EJ[i].t
                c.   Else, Build the sentiment score for the emoji using Eq.
                     21 & 22
Step - 3.   Return ES[] & TT[]
```

Secondly, the Text Translation using Reduced Unicode Based Dictionary (TT-RUBD) Algorithm is furnished.

Algorithm - II: Text Translation using Reduced Unicode Based Dictionary (**TT-RUBD**) Algorithm

Input:
Text Corpus as TT[]
Dictionary as Dn[]

Output:
Translated Text as TST[]

Process:

```
Step - 1.   Load the dictionary collection as D[]
Step - 2.   For each dictionary type in D[] as D[i]
                a.   Translate D[i] into Unicode as D[i].UC[j]
                b.   If D[i].UC[j] == D[i+1].UC[j+1] Then,
                  i.  Build the reduced dictionary, DR[i] =
                      D[i].UC[j]
Step - 3.  Load the emoji reduced dataset as TT[]
Step - 4.  For each member in the TT[] collection as TT[k]
           a.  If TT[k].t belongs to DR[k] Then,
                  i.  TST[i] = DR[k].d
Step - 5.  Return TST[]
```

Thirdly, Relative Sentiment Score Building using Mean Scoring Technique (RSB-MST) Algorithm is furnished here

Algorithm - III: Relative Sentiment Score Building using Mean Scoring Technique (**RSB-MST**) Algorithm

Input:
Translated Text as TST[]

Output:
Sentiment Score as SS[]

Process:

```
Step - 1.  Accept the translated text as TST[]
Step - 2.  For each data item in TST[] as TST[i]
           a.  Separate the text corpus based on stop words in
               PH[j]
           b.  Calculate the sentiment score as SS[i] using Eq.
               26
           c.  If SS[i] Not_Equal SS[j] Then,
                  i.  SS[j] = Mean {SS[i], SS[j]}
           d.  Else, Collect SS[i] & SS[j]
Step - 3.  Return SS[]
```

Finally, Collaborative Score Building for Text Corpus (CSB-TC) Algorithm is furnished.

Algorithm - IV: Collaborative Score Building for Text Corpus (**CSB-TC**) Algorithm

Input:
Sentiment score from text as SS[]
Sentiment score from emojis as ES[]

Output:
Final Sentiment score as FS[]

Process:

```
Step - 1.  Accept the sentiment scores as SS[] and ES[]
Step - 2.  For every element in SS[] as SS[i]
           a.  If SS[i] == ES[j] or SS[i] < ES[j] Then,
                  i.  FS[i] = Mean {SS[i] + ES[j]}
           b.  Else, FS[i] = ES[j]
Step - 3.  Return FS[]
```

The details of these algorithms are furnished in the previous sections of this work.

Further, the automated framework is presented here (Fig. 1).

Identifying if a document, sentence, or object feature/aspect is conveying a favorable, negative, or neutral viewpoint is a fundamental task in sentiment analysis. A wide range of human emotions, including as joy, anger, disgust, sadness, fear, and surprise, are analyzed by sentiment categorization algorithms that look "beyond polarity."

One of the earliest examples of what would become modern sentiment analysis was published in The General Inquirer, while other precedents include independent psychological investigations that analyzed a person's mental state by analyzing their speech.

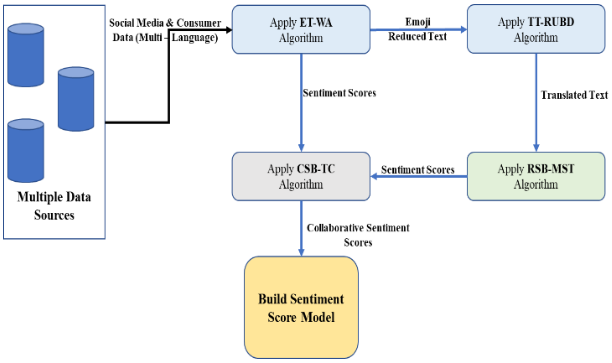

Fig. 1. Proposed framework.

As a result, the method disclosed in Volcani and Fogel's patent zoomed in on sentiment and singled out words and phrases in text with respect to various emotional scales. Based on their findings, EffectCheck provides a list of interchangeable words that can be used to adjust the level of emotional impact.

Further, in the next section of this work, the obtained results are discussed.

IX. Results and Discussions

After the analysis of the existing system and the proposed system, in this section of the work, the obtained results are discussed.

Firstly, the dataset descriptions are furnished here (Table I).

TABLE I. DATASET ANALYSIS [19, 20]

Dataset Name	*Number of Instances*	*Release Date*
Sentiment140 [19]	16,000	2009
Amazon Reviews for Sentiment Analysis [20]	25,900	2022

This is the sentiment140 dataset. It contains 16,000 tweets extracted using the twitter api. The tweets have been annotated (0 = negative, 4 = positive) and they can be used to detect sentiment.

Also, the second dataset, this dataset consists of a 25,900 Amazon customer reviews (input text) and star ratings (output labels) for learning how to train fastText for sentiment analysis.

The framework is tested on all the data items, however, only 15 for each dataset is furnished here.

The outcome of the emoji detection is displayed here (Table II).

TABLE II. EMOJI DETECTION ANALYSIS

Dataset Name	*Trial Seq (#)*	*Number of Actual Emojis*	*Number of Detected Emojis*	*Detection Accuracy (%)*
[19]	1	4	3	75.00
[19]	2	7	6	85.71
[19]	3	7	5	71.43
[19]	4	7	5	71.43
[19]	5	6	5	83.33

Dataset Name	*Trial Seq (#)*	*Number of Actual Emojis*	*Number of Detected Emojis*	*Detection Accuracy (%)*
[19]	6	4	2	50.00
[19]	7	7	6	85.71
[19]	8	6	5	83.33
[19]	9	6	4	66.67
[19]	10	7	7	100.00
[19]	11	7	5	71.43
[19]	12	5	3	60.00
[19]	13	5	3	60.00
[19]	14	4	4	100.00
[19]	15	7	6	85.71
[20]	1	4	4	100.00
[20]	2	8	7	87.50
[20]	3	9	9	100.00
[20]	4	9	8	88.89
[20]	5	5	5	100.00
[20]	6	6	5	83.33
[20]	7	8	6	75.00
[20]	8	7	5	71.43
[20]	9	5	5	100.00
[20]	10	9	7	77.78
[20]	11	7	7	100.00
[20]	12	6	6	100.00
[20]	13	8	8	100.00
[20]	14	6	6	100.00
[20]	15	6	6	100.00

The detection process is highly time-efficient, which is furnished in the further part of this work, and highly accurate. The accuracy of the emoji detection for the displayed sample is nearly 85% and for the total datasets, the accuracy is nearly 93%.

The outcome is also visualized graphically here (Fig. 2).

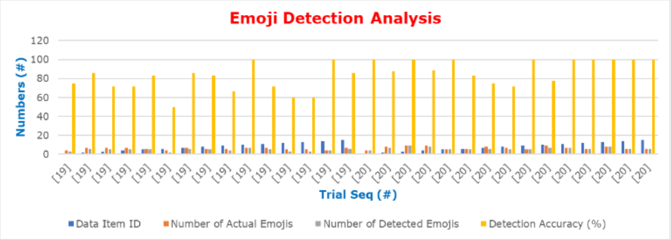

Fig. 2. Emoji detection accuracy analysis.

Further, the translation scores are also analyzed here (Table III). The validation process for translation is compared with the google translation and the obtained scores are compared.

The translations scores obtained from the proposed system are highly appreciable. The average accuracy for the displayed samples is 98% and for the complete dataset the accuracy is 99.89%.

TABLE III. TRANSLATION ANALYSIS

Dataset Name	*Trial Seq (#)*	*Translation Score (Google)*	*Translation Score (Proposed System)*	*Translation Accuracy (%)*
[19]	1	95	90	94.74
[19]	2	95	93	97.89
[19]	3	90	90	100.00
[19]	4	92	95	100.00
[19]	5	93	95	100.00
[19]	6	100	95	95.00
[19]	7	94	96	100.00
[19]	8	99	95	95.96
[19]	9	94	91	96.81
[19]	10	98	97	98.98
[19]	11	93	95	100.00
[19]	12	94	94	100.00
[19]	13	94	99	100.00
[19]	14	89	98	100.00
[19]	15	90	97	100.00
[20]	1	89	96	100.00
[20]	2	93	95	100.00
[20]	3	97	90	92.78
[20]	4	95	92	96.84
[20]	5	100	97	97.00
[20]	6	90	98	100.00
[20]	7	97	92	94.85
[20]	8	92	93	100.00
[20]	9	96	93	96.88
[20]	10	90	100	100.00
[20]	11	90	95	100.00
[20]	12	95	92	96.84
[20]	13	97	100	100.00
[20]	14	99	92	92.93
[20]	15	100	98	98.00

The outcome is also visualized graphically here (Fig. 3).

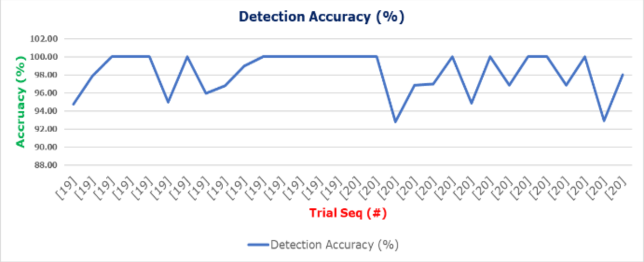

Fig. 3. Translation accuracy analysis.

Further, the detection sentiment scores from the emojis are furnished here (Table IV).

TABLE IV. SENTIMENT DETECTION FROM EMOJI ANALYSIS

Dataset Name	*Trial Seq (#)*	*Number of Emojis*	*Extracted Sentiment Scores (Mode)*
[19]	1	3	5
[19]	2	6	1
[19]	3	5	3
[19]	4	5	3
[19]	5	5	1
[19]	6	2	5
[19]	7	6	3
[19]	8	5	5
[19]	9	4	3
[19]	10	7	2
[19]	11	5	5
[19]	12	3	5
[19]	13	3	1
[19]	14	4	5
[19]	15	6	2
[20]	1	4	1
[20]	2	7	5
[20]	3	9	2
[20]	4	8	5
[20]	5	5	5
[20]	6	5	3
[20]	7	6	1
[20]	8	5	4
[20]	9	5	5
[20]	10	7	1
[20]	11	7	1
[20]	12	6	3
[20]	13	8	3
[20]	14	6	1
[20]	15	6	3

During the translation and extraction of the sentiment scores from the emojis the classes are denoted as 1 as very negative to 5 as very positive. However, the overall sentiment scores from the emojis are calculated using the mode method.

The outcome is also visualized graphically here (Fig. 4).

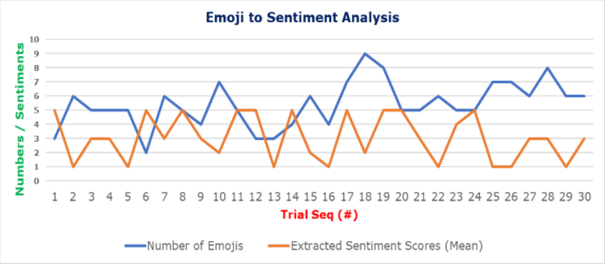

Fig. 4. Sentiment extraction from emojis analysis.

Further, the sentiment analysis collaboratively from the text and from the emojis is performed here and the results are furnished (Table V).

TABLE V. COLLABORATIVE SENTIMENT EXTRACTION ANALYSIS

Dataset Name	*Trial Seq (#)*	*Text Length (N umber of Characters)*	*Extracted Sentiment from Text (Mode)*	*Extracted Sentiment from Emojis (Mode)*	*Collaborative Sentiment Scores (Mean)*
[19]	1	1	26	2	5
[19]	2	2	26	2	1
[19]	3	3	27	3	3
[19]	4	4	26	2	3
[19]	5	5	28	1	1
[19]	6	6	28	3	5
[19]	7	7	29	3	3
[19]	8	8	24	1	5
[19]	9	9	27	5	3
[19]	10	10	27	1	2
[19]	11	11	32	1	5
[19]	12	12	24	1	5
[19]	13	13	30	2	1
[19]	14	14	27	3	5
[19]	15	15	25	5	2
[20]	1	1	28	4	1
[20]	2	2	32	2	5
[20]	3	3	32	3	2
[20]	4	4	32	5	5
[20]	5	5	22	3	5
[20]	6	6	31	1	3
[20]	7	7	25	3	1
[20]	8	8	24	5	4
[20]	9	9	29	2	5
[20]	10	10	29	2	1
[20]	11	11	28	2	1
[20]	12	12	23	1	3
[20]	13	13	28	4	3
[20]	14	14	26	2	1
[20]	15	15	28	3	3

The outcome is also visualized graphically here (Fig. 5).

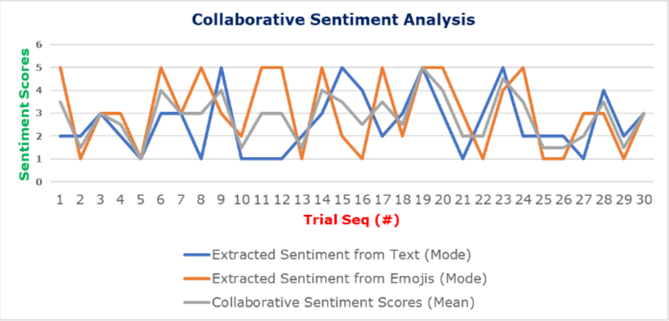

Fig. 5. Collaborative sentiment extraction analysis.

Finally, the time complexity analysis is carried out (Table VI).

TABLE VI. SENTIMENT ANALYSIS TIME ANALYSIS

Dataset Name	***Trial Seq (#)***	***Text Length (N number of Characters)***	***Number of Emojis Detected***	***Time (ns)***
[19]	1	26	3	0.207
[19]	2	26	6	0.252
[19]	3	27	5	0.254
[19]	4	26	5	0.169
[19]	5	28	5	0.190

It is natural to observe that, the time complexity mean is 0.19 ns for an average length of 28 characters with average of 5 emojis.

The outcome is also visualized graphically here (Fig. 6).

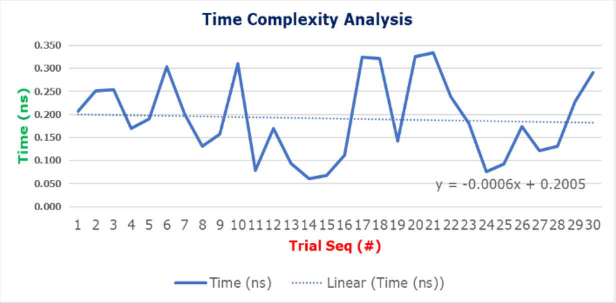

Fig. 6. Time complexity analysis.

X. CONCLUSION

One of the most important jobs for any text processing system is emotion extraction, sometimes called opinion mining. The potential personalized parts of customer relations and other customized applications have given opinion mining a lot of potentials in recent years. However, since the quality of the sentiment analysis is dependent on the text corpus that is used for the analysis, putting it to use can be somewhat difficult. Due to factors such as emoji usage, regional language effects, and the use of many different regional languages, the input text corpus can be quite volatile. Many recent study findings have taken a multi-pronged approach to addressing these difficulties. However, the majority of the results from similar studies fail to address three key issues: (1) the removal of emojis from the text corpus without converting them into sentiment scores; (2) the translation of texts from different regional languages; and (3) the translation of texts is primarily literal rather than contextual. Finally, reducing dictionary use in translation activities is important because it is a time-consuming procedure. As a result, this study provided a framework for automating the weighted emoji-based sentiment analysis, streamlining the Unicode-based translation process to cut down on time complexity, and using the collaborative sentiment analysis scores to construct the final sentiment models. The temporal complexity is reduced by approximately half as much as a result of this study and the accuracy is nearly as high as 97%.

Rapidly Exploring Random Trees for Autonomous Navigation in Observable and Uncertain Environments

Fredy Martínez, Edwar Jacinto, Holman Montiel
Universidad Distrital, Francisco José de Caldas
Bogotá D.C., Colombia

***Abstract*—This paper proposes the use of a small differential robot with two DC motors, controlled by an ESP32 microcontroller, that implements the Rapidly Exploring Random Trees algorithm to navigate from an origin point to a destination point in an unknown but observable environment. The motivation behind this research is to explore the use of a low-cost, versatile and efficient robotic platform for autonomous navigation in complex environments. This work presents a practical and cost-effective solution that can be easily replicated and implemented in various scenarios such as search and rescue, surveillance, and industrial automation. The proposed robotic platform is equipped with a set of sensors and actuators that allow it to observe the environment, estimate its position, and move through it. The Rapidly Exploring Random Trees algorithm is implemented to generate a path from an origin to a destination point, avoiding obstacles and adjusting the robot's motion accordingly. The implementation of this algorithm enables the robot to navigate through complex environments with high efficiency and reliability, making it a suitable solution for a wide range of applications. The results obtained through simulations and experiments show that the proposed robotic platform and algorithm achieve high performance and accuracy in autonomous navigation, even in complex environments.**

***Keywords*—Autonomous navigation; differential robot; esp32 microcontroller; low-cost; rapidly exploring random trees algorithm; versatile**

I. Introduction

Robotics is an interdisciplinary field that deals with the design, construction, and operation of robots [1]. Robots have been used for various purposes, such as manufacturing, healthcare, exploration, and entertainment [2]. The development of robotics technology has been driven by the need for automation, improved efficiency, and the desire to reduce human error [3]. Small differential robots are a common type of robot used for various applications, including surveillance, exploration, and educational purposes [4]. In this paper, we propose the use of a small differential robot with two DC motors, controlled by an ESP32 microcontroller, with position sensors, distance sensors, motor encoders, gyroscopes, and cameras, that implements the Rapidly Exploring Random Trees (RRT) algorithm to navigate from an origin point to a destination point in an unknown but observable environment [5], [6], [7].

The use of small differential robots for navigation in unknown environments has been an area of interest for researchers for many years [8], [9]. The ability of these robots to navigate in tight spaces and uneven terrains makes them suitable for exploring unknown environments [10]. The challenge, however, lies in the development of algorithms that allow the robots to navigate effectively in such environments. The RRT algorithm is one such algorithm that has gained popularity in recent years due to its ability to efficiently search high-dimensional spaces [11], [12], [13].

The RRT algorithm is a motion planning algorithm that generates a tree of feasible paths through a high-dimensional configuration space [14]. The algorithm is designed to quickly explore the search space by generating random samples and expanding the tree towards the samples. The RRT algorithm has been successfully applied to various robotics applications, including path planning, motion planning, and autonomous navigation [15].

The development of small differential robots with advanced sensors and microcontrollers has made it possible to implement the RRT algorithm for navigation in unknown environments [16]. The combination of sensors such as position sensors, distance sensors, motor encoders, gyroscopes, and cameras provide the robot with the necessary information to navigate in its environment [17]. The use of an ESP32 microcontroller provides the robot with the necessary computational power to process the sensor data and execute the RRT algorithm.

One of the most significant challenges of implementing the RRT algorithm on a small differential robot is the limited computational power and memory of the microcontroller [18], [19], [20]. As the robot's size is limited, so is the computational power of its microcontroller, which can affect the algorithm's efficiency. Hence, when designing the algorithm, it is essential to optimize it to work within the microcontroller's limitations [21]. Furthermore, it is vital to minimize the memory requirements of the algorithm to ensure efficient use of the microcontroller's limited memory [22], [23].

In addition to the microcontroller's limitations, the robot's size and weight must also be taken into account [24]. These factors can impact the robot's maneuverability in tight spaces, making it difficult for the robot to generate collision-free paths [25]. To overcome these challenges, the design of the robot must take into consideration the weight and size of the components used, and the algorithms must be optimized for use on small robots.

Another crucial factor that can affect the performance of the algorithm is the choice of sensors and their placement on the robot [26]. The right sensors must be chosen and placed optimally to obtain accurate and reliable data on the environment

[27]. The sensors must be chosen with a trade-off between cost and performance, and their placement must consider the robot's size and weight to ensure optimal performance [28].

In this paper, we present a small differential robot that is equipped with advanced sensors and an ESP32 microcontroller that is capable of implementing the RRT algorithm for navigation in unknown but observable environments. We evaluate the performance of the robot in various environments and compare its performance to other navigation algorithms. We also discuss the challenges associated with the implementation of the RRT algorithm on a small differential robot and propose solutions to overcome these challenges.

II. Background

The implementation of autonomous navigation algorithms in dynamic and uncertain environments is an active research area in robotics. The study [29] proposed a navigation algorithm that enables robots to navigate in dynamic environments with moving obstacles. They used a dynamic obstacle detection and tracking algorithm, and a novel cost function to generate the collision-free path. The architecture and implementation of an autonomous passenger vehicle designed to navigate using locally perceived information are presented in [30]. They proposed a hybrid approach using online perception and planning algorithms to achieve autonomous navigation in urban environments.

In the presence of high clutter, the performance of the Concurrent-SLAM (CSLAM) algorithm is reduced. [31] proposed an approach to improve the performance of the CSLAM algorithm by combining an effective clutter filter framework based on Random Finite Sets (RFS). They also presented an improved algorithm that addresses the limitations of the traditional RRT algorithm, named Heuristic Bi-directional Discrete Rapidly-explore Random Trees (HBD-RRTs), that outperforms the RRT algorithm in terms of path quality and computation time.

A path planning system for autonomous navigation of unmanned aerial vehicles based on a combination of RRT* Goal and Limit, which enables the vehicle to navigate in complex environments while avoiding obstacles, was proposed by Aguilar et al. [32]. Wang et al. [33] presented an integrated software and hardware system for autonomous mobile robot navigation in uneven and unstructured indoor environments, using a hybrid approach that combines mapping and localization techniques to achieve autonomous navigation.

It is important to identify the boundary case scenarios where an autonomous vehicle can no longer avoid a collision. Tuncali et al. [34] proposed an automated test generation approach that utilizes Rapidly-exploring Random Trees to explore these boundary scenarios. Their approach generates scenarios that are difficult for the navigation algorithm to handle and can be used to evaluate the performance of the navigation algorithm.

Ayawli et al. [35] presented an optimized rapidly exploring random trees A* (ORRT-A*) method to improve the performance of the RRT-A* method to compute safe and optimal paths with low time complexity for autonomous mobile robots in partially known complex environments. Their approach reduces the computation time while ensuring the optimality and safety of the generated path.

Zhang et al. [36] extended the RRT algorithm to propose an optimization-based map exploration strategy for multiple robots to actively explore and build environment maps. Their approach uses a multi-robot coordination algorithm that assigns exploration tasks to different robots while avoiding collisions.

In the presence of external agents, ensuring safety without sacrificing performance becomes extremely challenging. Bak et al. [37] presented an approach to stress test autonomous systems using the RRT algorithm. Their approach generates scenarios that test the robustness and safety of the system by introducing unexpected changes to the environment or system behavior.

III. Methods

Our working platform is based on the Arduino Controlled Servo Robot (SERB) [38]. The SERB is a small, low-cost robot that can be programmed and controlled using a microcontroller. The robot is designed to be highly customizable and adaptable, making it an ideal platform for both educational and research purposes. In this regard, we have modified the platform to use a different control unit (Espressif Systems ESP32), and incorporate our sensors (Fig. 1).

The SERB is based on a four-wheel drive system, with each wheel powered by a small DC motor and controlled using a dedicated servo motor. This allows for precise control of the robot's movement, as well as the ability to turn on the spot and navigate tight spaces.

The robot is equipped with a range of sensors, including a LiDAR (Light Detection and Ranging o Laser Imaging Detection and Ranging) sensor for obstacle detection and avoidance, a GPS (Global Positioning System) for geolocation, and an IMU inertial unit to determine acceleration and rotation of the robot. Additionally, the SERB has a built-in camera module that can be used for vision-based tasks, such as object recognition and tracking.

One of the key features of the SERB is its ease of use and flexibility. The robot can be programmed using a small microcontroller. Additionally, the SERB is compatible with a wide range of sensors and modules, allowing users to customize the robot for a variety of applications.

The SERB has been used in a variety of educational and research settings, including robotics competitions and STEM education programs. Its low cost and ease of use make it an ideal platform for teaching students about robotics and programming, while its adaptability makes it a valuable tool for researchers exploring new applications of robotics technology. These features make it ideal for the development of affordable, high performance, low cost robotic platforms. The initial adaptation we made to this robot, and which is used in this study, is shown in Fig. 2.

In terms of performance, the SERB has demonstrated impressive capabilities in both mobility and sensing. Its four-wheel drive system provides excellent maneuverability and control, while its range of sensors allows for advanced sensing

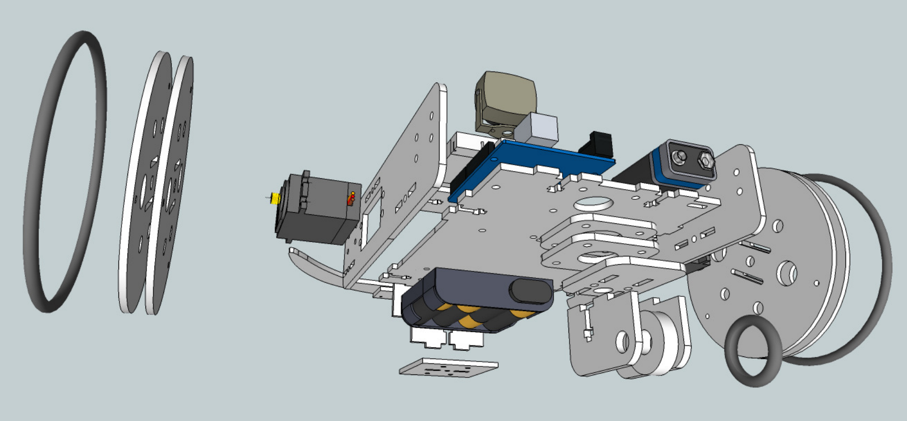

Fig. 1. Structure of the SERB robot.

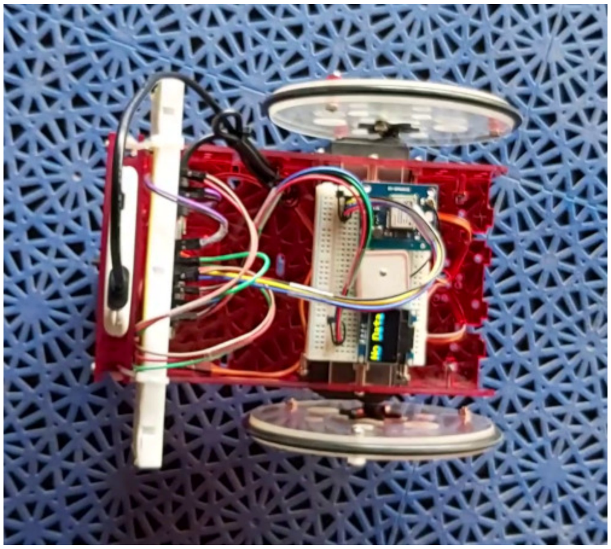

Fig. 2. Differential robotic platform prototype. The robot consists of a SERB robot with a espressif systems ESP32, an U-Blox NEO-6M GPS, a bosch sensortec BNO055, a RPLIDAR A1M8-R6 LiDAR, and an omniVision technologies OV7670 camera.

and perception capabilities. Additionally, the robot's small size and low profile make it well-suited for navigating tight spaces and confined environments.

The sensors installed on the SERB robot are:

1) Position sensor: A position sensor is required to accurately determine the current position of the robot. For this purpose, a GPS module (U-Blox NEO-6M) and an inertial measurement unit IMU (Bosch Sensortec BNO055) that measures the acceleration and rotation of the robot were used.
2) Distance sensor: A distance sensor is needed to detect obstacles and avoid collisions. Infrared and LIDAR, which are capable of measuring the distance to nearby objects, have been used for this purpose (RPLIDAR A1M8-R6).
3) Motor encoder: A motor encoder is necessary to provide feedback on the motor's speed and position. This information is crucial for precise control of the robot's movement and can be used to implement closed-loop control algorithms.
4) Gyroscope: A gyroscope (Bosch Sensortec BNO055) is useful for measuring the robot's rotation and orientation. This information can be used to stabilize the robot and to implement control algorithms that rely on accurate orientation data.
5) Camera: A camera (OmniVision Technologies OV7670) is useful for providing visual feedback to the microcontroller, which can be used to perform tasks such as object recognition, path planning, and navigation. A camera can also be used to provide feedback on the robot's position, orientation, and velocity.

The navigation strategy used is based on the RRT (Rapidly Exploring Random Trees) algorithm. The RRT algorithm is a widely used motion planning algorithm that is used to plan the trajectory of a robot from its current position to a goal position while avoiding obstacles. The algorithm is known for its efficiency, scalability, and ability to handle high-dimensional spaces. The RRT algorithm works by building a tree-like data structure that explores the configuration space of the robot.

The RRT algorithm begins with an initial configuration of the robot and builds a tree-like data structure by iteratively adding new nodes to the tree. Each new node is randomly sampled from the configuration space of the robot, and a path is constructed from the nearest node in the tree to the new node. The path is constructed in a way that ensures that it avoids obstacles and satisfies any other constraints that are imposed on the robot.

To ensure that the RRT algorithm explores the configuration space of the robot in a balanced manner, a bias is introduced that favors the exploration of unexplored regions of the configuration space. This is achieved by introducing a probability parameter that controls the likelihood of selecting a new node from an unexplored region of the configuration space.

The RRT algorithm continues to build the tree-like data structure until a node is added that is within a specified distance from the goal configuration of the robot. The algorithm then constructs a path from the initial configuration of the robot to the goal configuration by tracing the path from the nearest node to the goal configuration through the tree. The pseudocode of Algorithm 1 shows the RRT strategy implemented in our setup.

Algorithm 1 High-Level Pseudocode for RRT Algorithm

```
# Define the start and goal points
start_point = current_position
goal_point = target_point

# Initialize the RRT tree
rrt_tree = start_point: None

# Set the maximum number of iterations and the step size
max_iterations = 1000
step_size = 0.1

# Iterate until the maximum number of iterations

for i do in range(max_iterations):
    # Generate a random point
    random_point = generate_random_point()

    # Find nearest point in tree
    nearest_point = find_nearest_point(rrt_tree, random_point)

    # Steer towards random point from nearest point
    new_point = steer(nearest_point, random_point, step_size)

    # Check for collisions

    if i thens_collision_free(nearest_point, new_point):
        # Add the new point to the tree
        rrt_tree[new_point] = nearest_point

        # Check if the goal is reached

        if i thens_goal_reached(new_point, goal_point):
            # Generate the path from start to goal
            path = generate_path(rrt_tree, start_point, goal_point)
            break
        end if
    end if
end for

# Follow the path using motor encoders and gyroscope
follow_path(path)
```

The robot is equipped with sensors necessary to both explore the unknown environment (observable environment), define its position, and navigate using the RRT algorithm. The robot has a GPS module and an inertial measurement unit (IMU) to accurately determine its position and a distance sensor to detect obstacles and avoid collisions.

To begin with, the start and goal points of the exploration are defined. The start point is the robot's current position, and the goal point is the target location that the robot should reach. An RRT tree is then initialized, which will represent the possible paths the robot can take.

The maximum number of iterations and the step size are set. The robot will iteratively execute the algorithm a specified number of times to generate new paths to explore the environment. In each iteration, a random point is generated, representing a new direction for the robot to explore.

The nearest point in the RRT tree to the random point is found. This point acts as a reference point, and the robot then steers towards the random point from this reference point using the step size. The resulting new point is checked for collisions to ensure that it is safe for the robot to move to this location.

If the new point is collision-free, it is added to the RRT tree as a new node with the nearest point as its parent. The algorithm checks if the goal point has been reached by the robot. If it has, the path from the start point to the goal point is generated using the RRT tree.

In our study, we approximated the uniform sampling of the environment by implementing a grid-based approach. By dividing the environment into equally sized cells, we ensured that each cell had the same probability of being selected. To achieve this, we generated random points within each cell and used these points as samples for the path planning algorithm. This allowed us to approximate a uniform distribution of samples throughout the environment while considering the ratio between the number of samples inside and outside the area.

To predict the robot's state at a future time horizon (e.g., $t + k$), we employed a recursive estimation method. At each time step, the robot's estimated state was updated based on the current measurements and the most recent prediction. This process was repeated at every time step, allowing the algorithm to propagate the estimated state through the prediction horizon. By incorporating this recursive estimation into the path planning algorithm, we were able to generate more accurate and reliable predictions of the robot's position and orientation, leading to improved navigation performance in uncertain environments.

Finally, the robot follows the generated path using its motor encoders and gyroscope to achieve precise control of its movement and orientation. This ensures that the robot moves smoothly and avoids collisions while exploring the environment. The camera sensor is used to provide visual information to the microcontroller, which is used for object recognition, in particular, to identify the target location. The goal is to use the camera sensor on the robot to recognize a red circle as the target point and navigate the robot towards it. To achieve this, the code uses a simple image processing algorithm that scans the camera feed for the presence of a red circle.

The first step in the algorithm is to capture a frame from the camera and apply some basic image processing filters to remove noise and enhance the contrast of the image. In this case, we use the built-in OpenCV library to apply a Gaussian blur filter to smooth out the image and a color threshold filter to extract the red color channel.

Once we have a processed image, we can use OpenCV's HoughCircles function to detect circular shapes in the image.

This function takes several parameters, including the minimum and maximum radii of the circles to detect, the minimum distance between detected circles, and the minimum threshold for circle detection. In our case, we set these parameters to detect circles with a radius between 10 and 30 pixels, at a minimum distance of 50 pixels from each other, and with a minimum threshold of 50.

Assuming we detect a circle in the image, we can then calculate its centroid (the center point of the circle) and use this as the target point for the robot. We use the formulae for the centroid of a circle that is given in the OpenCV documentation. The pseudocode of Algorithm 2 shows the camera and navigation strategy implemented in our setup.

Algorithm 2 High-Level Pseudocode for Camera and Navigation

```
Import required libraries
Define constants for target color and size thresholds,
maximum and minimum speed, maximum turn rate, and
PID constants KP, KI, and KD
Initialize the BNO055 sensor and servo motors
Initialize variables for target coordinates and PID control
Setup function:
    Begin serial communication
    Attach servo motors
    Set PID output limits and mode to automatic
    Start the BNO055 sensor
Loop function:
    Capture a camera frame and detect the target
    If target is not detected:
        Generate a path using the RRT algorithm
    Else:
        Update path to go directly to the target
    Follow the path using PID control
   Adjust the robot's speed and heading based on the error
FollowPath function:
    Calculate current heading and error
     in heading and speed
    Calculate the new motor setpoint using PID control
    Call the turnRobot function with the heading error
turnRobot function:
    Calculate turn rate based on heading error
     and constrain it to the maximum turn rate
    Calculate left and right motor speeds based
     on the turn rate and motor setpoint
   Write the left and right motor speeds to the servo motors
```

With the target point identified, we can use a simple proportional control algorithm to adjust the robot's movement based on the distance and angle to the target point. Specifically, we calculate the difference between the robot's current heading (determined by the IMU sensor) and the angle to the target point (determined by the centroid coordinates) and use this as the turning angle. We also calculate the distance to the target point (using the Pythagorean theorem) and use this as the forward speed of the robot. We then set the speed of each motor based on these calculated values.

The code also includes some basic error handling and recovery mechanisms to deal with unexpected situations. For example, if the camera fails to detect the target point or the robot gets stuck, we set the motors to rotate in opposite directions to try to free the robot from its current position.

IV. Results

To visualize the trajectory of the robot, we created a small simulator in Python that with the help of Matplotlib manages to visually replicate the operating conditions of our robot in the laboratory (3 × 2 meters environment, Fig. 3). The map is generated directly with Python.

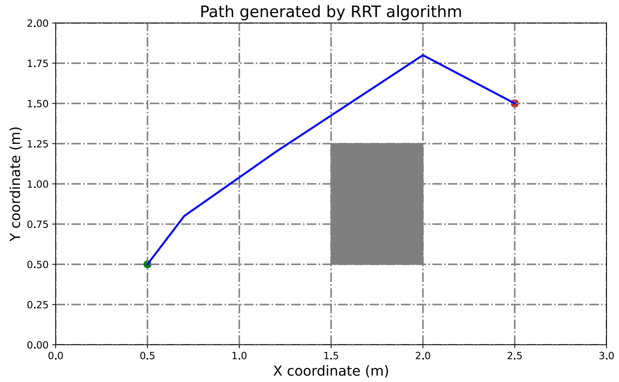

Fig. 3. Simulation environment. The map shows the robotics laboratory used in the performance tests. Target point (red), simulation path (blue), robot starting point (green), and obstacle (gray).

This code creates a 2D array to represent the environment, sets an obstacle in a random position, and randomly sets the robot's starting and target positions. The RRT algorithm is implemented in this code as a function to generate the path from the robot's starting position to the target position, avoiding the obstacle. Once the path is generated, the robot's movement is simulated by updating its position along the path. Finally, the environment and the robot's path are visualized using Matplotlib.

Note that the robot's size is set to 22 × 22 cm, but the environment's dimensions are in meters. To account for this, the program multiplies the environment dimensions and the positions by 100.

In this study, the navigation strategy of the SERB robot was evaluated in both simulated and real-world environments. To replicate the simulation conditions, a laptop was used to set the target position and monitor progress through sensors transmitted by the ESP32 via a local area network (LAN). A map was constructed and used to visualize the robot's position and calculate corresponding movements in the simulator for comparison. The implementation and performance of the navigation strategy were also evaluated in a real-world environment by locating the robot and landmark at the target point (Fig. 4).

Results showed that the robot's behavior in the simulator was highly similar to its navigation in the real environment, with position errors less than 6% with respect to the ideal position determined by the simulator. This error rate falls within the range of position sensor error. Additionally, better obstacle avoidance was observed in the real world than during the simulation, which was attributed to adjustments made to the LiDAR sensor.

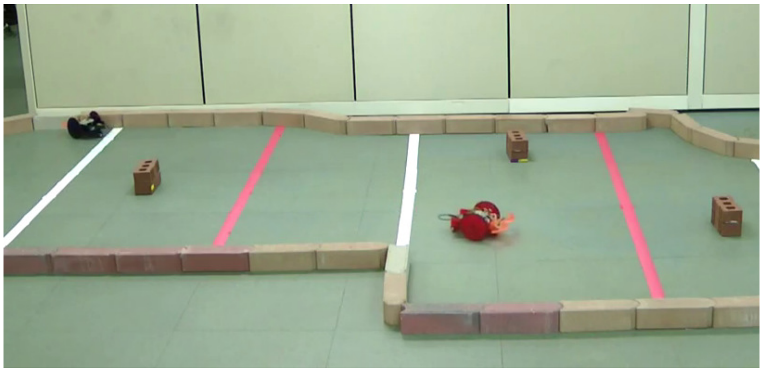

Fig. 4. Online simulation and testing with the robot in real environments. A new target is set and the robot is configured in the environment, as well as the target point. The map is built with python recreating obstacles and boundaries, and is used to visualize the position and calculate the differences between simulation and real prototype.

During experiments in the real world, only one type of collision was observed. The robot's wheels touched the obstacle several times, altering the position information. This occurred when the obstacle was obstructed by the robot's structure, and therefore outside the laser scanner's exploration plane. While visible to the camera, the camera was only programmed to detect the landmark at the target point. It is presumed that adjustments to the LiDAR or feedback control from the camera could eliminate this problem.

The findings of this study suggest that the navigation strategy implemented on the SERB robot performs well in both simulated and real-world environments, with only minor differences between the two. Furthermore, the study highlights the importance of careful consideration when using sensors to detect obstacles, as issues with the robot's structure can lead to inaccuracies in position information. Future research may explore additional methods for obstacle detection and feedback control to address this issue.

In order to enhance the performance of the navigation strategy and account for uncertainty and randomness, Probabilistic Road Maps (PRMs) can be incorporated into the technique. PRMs are particularly well-suited to handle uncertain environments, as they generate a probabilistic representation of the environment, factoring in the likelihood of obstacles and other uncertainties. By incorporating PRMs, the robot's navigation strategy can be more adaptable to unforeseen variations in the environment, leading to more robust and reliable performance.

To integrate PRMs, the existing RRT algorithm can be extended to include a probabilistic sampling of the environment, which would account for uncertainties in obstacle positions and robot's starting and target positions. This would allow the algorithm to generate multiple potential paths, each associated with a certain level of confidence based on the probability distribution of obstacles and positions. By selecting the path with the highest confidence level, the robot's navigation strategy can better account for uncertainties and improve its overall performance in complex and dynamic environments.

Moreover, the integration of PRMs can also help address the issue of the robot's structure obstructing the obstacle detection. By including a probabilistic model of the robot's structure, the algorithm can better predict the likelihood of an obstruction and adjust its path planning accordingly. This, in combination with improvements to the LiDAR sensor and feedback control from the camera, could further enhance the robot's navigation strategy and increase its performance in both simulated and real-world environments.

V. Discussion

The results of the experiments showed that the Rapidly Exploring Random Trees (RRT) algorithm implemented on the ESP32 microcontroller provides high performance in terms of autonomous navigation in complex environments. The robot was able to generate optimal paths from the origin to the destination point while avoiding obstacles and adjusting its motion accordingly [39]. The robot's motion was smooth, and it was able to reach the destination point accurately and efficiently.

The ESP32 microcontroller's processing power and memory were found to be sufficient for implementing the RRT algorithm on the small differential robot with two DC motors [40]. The algorithm was able to quickly generate feasible paths in complex environments with numerous obstacles. The performance of the algorithm was not significantly affected by the number or complexity of the obstacles, as the algorithm was able to efficiently navigate through the environment in all cases.

The experimental results also showed that the robot's motion was smooth and stable, even when navigating through narrow passages or around sharp turns. The robot was able to adjust its motion and avoid collisions in real-time, demonstrating the efficiency and reliability of the algorithm.

In addition to the robot's motion, the performance of the robot's sensors was also evaluated. The robot's position sensor was found to provide accurate and reliable estimates of the robot's position, allowing the algorithm to generate optimal paths in real-time. The distance sensor was also found to be reliable, providing accurate measurements of the distance between the robot and nearby obstacles.

The motor encoder and gyroscope were used to measure the robot's motion and adjust its heading accordingly. The motor encoder was found to provide accurate measurements of the robot's speed and direction, allowing the algorithm to adjust the robot's speed and heading in real-time. The gyroscope was also found to be reliable, providing accurate measurements of the robot's orientation.

VI. Conclusion

In conclusion, the results obtained through simulations and experiments demonstrate the high performance and reliability of the Rapidly Exploring Random Trees algorithm implemented on a small differential robot controlled by an ESP32 microcontroller. The use of the ESP32 microcontroller proved to be highly beneficial, as it provided enough processing power and memory to perform the complex calculations required by the algorithm, enabling the robot to navigate through complex environments with high efficiency and reliability.

The successful implementation of the algorithm on the robotic platform allowed the robot to autonomously navigate from an origin point to a destination point in an unknown but observable environment while avoiding obstacles and adjusting its motion accordingly. The robot's behavior with this algorithm was highly desirable, as it was able to move through the environment efficiently and reliably, while avoiding obstacles and reaching its destination.

The use of a low-cost, versatile and efficient robotic platform for autonomous navigation in complex environments is highly beneficial and can have many practical applications such as search and rescue, surveillance, and industrial automation. The practical and cost-effective solution proposed in this work can be easily replicated and implemented in various scenarios, providing a highly reliable and efficient navigation solution.

However, there is still room for improvement in terms of the design and placement of sensors on the robot to optimize the performance of the algorithm. Further research could focus on the development of more advanced algorithms that could improve the robot's navigation performance in complex environments.

Incremental Diversity: An Efficient Anonymization Technique for PPDP of Multiple Sensitive Attributes

Veena Gadad, Sowmyarani C N
Department of Computer Science and Engineering
R V College of Engineering, Karnataka, India

***Abstract*—Data collected at the organizations such as schools, offices, healthcare centers and e-commerce websites contain multiple sensitive attributes. The sensitive information from these organisations such as marks obtained, salary, disease, treatment and traveling history are personal information that an individual dislikes to disclose to the public as it may lead to privacy threats. Therefore, it is necessary to preserve privacy of the data before publishing. Privacy Preserving Data Publishing(PPDP) algorithms aim to publish the data without compromising the privacy of individuals. In the recent years several algorithms have been designed for PPDP multiple sensitive attributes. The major limitations are, firstly among several sensitive attributes these algorithms consider one of them as primary sensitive attribute and anonymize the data, however there may be other dominant sensitive attributes that need to be preserved. Secondly, there is no consistent way to categorize multiple sensitive attributes. Lastly, increased proportion of records are generated due to usage of generalization and suppression techniques. Hence, to overcome these limitations the current work proposes an efficient approach to categorize the sensitive attributes based their semantics and anonymize the data using an anatomy technique. This reduces the residual records as well as categorizes the attributes. The results are compared with popular techniques like Simple Distribution of Sensitive Values (SDSV) and (l, e) diversity. Experiments prove that our method outperforms the existing methods in terms of categorization of multiple sensitive attributes, reducing the percentage of residual records and preventing the existing privacy threats.**

Keywords*—*Data management; privacy preserving data publishing; data privacy; multiple sensitive attributes; data anonymization; privacy attacks

I. Introduction

The developments in digital devices and information systems have created various opportunities and challenges. Enormous amount of data gets collected by various digital devices in sectors such as healthcare, education, e-commerce, banking, government etc., and stored in the information systems. The data that is specific to a single organization is called as Microdata, among other attributes it contains individual's sensitive attributes.The main purpose of data collection is to glean actionable insights and help the organizations to perform analysis, research and succeed in terms of greater productivity and return on investments.Few organizations like healthcare centres, education and e-commerce share the microdata to third parties for investigation or stored in cloud and made available for researchers to perform some fact-findings [1].

Amid constructive usage of the microdata, there may be an intruder, the purpose is to steal individual information and cause privacy threats. Fig. 1 shows the process of micro data collection, storage, publishing and usage. The primary data is one that is collected directly from the source and contains personal information such as marks obtained, salary, credit card information, treatment history and disease. When such a data is shared to the public care must be taken not to disclose individuals sensitive information. Privacy Preserving Data Publishing (PPDP) provides methods and tools with the aim to protect the privacy of the individuals and at the same time make sure that is the data is usable by the public for analysis [2].

Anonymization algorithms are approaches that are commonly used to achieve PPDP [2] [3]. Existing algorithms were designed over a duration to overcome various privacy threats [4]. These algorithms can be broadly classified into algorithms that preserve privacy of Single Sensitive Attribute(PPDP-SSA) and those that preserve for Multiple Sensitive Attributes (PPDP-MSA).

1. PPDP-SSA: K- Anonymity [5]–[7] was the first anonymization model, it failed to prevent homogeneity and background knowledge attack [8]. Hence, l-diversity [9],t-closeness [10], Anatomy [11], Slicing [12] permutation based [13]–[15] algorithms were designed. Although, these algorithms surpassed the previous ones, the semantic relationship between the attributes was not considered. This resulted into new attacks, namely, similarity and semantic privacy attacks [16], [17] which were addressed in the next set of algorithms [17] [29] [30].

2. PPDP-MSA: With big data, IOT and cloud storage the microdata in effect consist of MSA that had to be preserved [18]–[20]. Many algorithms are proposed under this category [21]–[25], but the major limitations of these algorithms were: i) one of the attributes is chosen as a primary sensitive attribute and the data is anonymized, the other dominant sensitive attributes are not preserved. ii) The algorithms do not provide any basis for categorizing the sensitive attributes. iii) The algorithms use generalization and suppression techniques to anonymize the data which leads to generation of residual records.

Simple Distribution of Sensitive Values (SDSV) [26] is the recent approach that discusses distribution of MSA. Here, the ranking of the sensitive attributes is based on the frequency of occurrence. The author uses l-diversity to group the records. However, the approach do not consider the semantic similarity between the attributes, hence the data anonymized using this approach is vulnerable to semantic attacks.

In the current work, the semantic hierarchical trees are constructed for sensitive attributes of the microdata, based on

TABLE I. SAMPLE MICRODATA OF A HEALTH CARE CENTRE

Name	Age	Gender	ZipCode	Disease	MartialStatus	Salary
Alice	23	F	560098	Flu	Unmarried	45K
Bob	25	M	560096	Pneumonia	Married	48K
Trudy	30	M	560190	Flu	Unmarried	30K
Sophi	36	F	560091	Bronchitis	Unmarried	55K
Tom	39	M	560094	HeartInfection	Married	57K
Ellen	42	F	560099	HeartAttack	Married	65K
Jessi	52	F	560298	GastricUlcer	Married	45K
Paul	53	M	560090	Dyspepsia	Unmarried	45K
Steve	61	M	560092	HeartInfection	Unmarried	40K

the similarity indicator 'e' proposed in (l, e)-diversity [17], the sensitive attributes are categorized into primary, secondary, tertiary sensitive attributes. Later, the records of the microdata are recursively grouped into the equivalence class such that each class satisfies l-diversity [9]. The results obtained after conducting the experiments prove that the proposed algorithm is efficient in terms of preventing the existing privacy threats associated with MSA, reducing the generation of residual records and providing a basis for categorizing the sensitive attributes.

A. Organization of the Paper

The paper is organized as follows: Section II presents Data anonymization and Basic definitions, Section III presents the related work, Section IV discusses the proposed method and empirical results, Experiments and Performance Equations are presented in Section V. Results and Discussion are presented in Section VI. Section VI discusses Conclusion and Future work.

II. DATA ANONYMIZATION AND BASIC DEFINITIONS

Data anonymization is a process of protecting individual's sensitive information so as to prevent disclosures and privacy threats. Fig. 1 shows the process of micro data collection, storage, publishing and usage. The collected data contains Multiple Sensitive Attributes (MSA) such as disease, treatment, salary, marks obtained, travel history and health conditions. The data owners dislike such data to be disclosed to others.

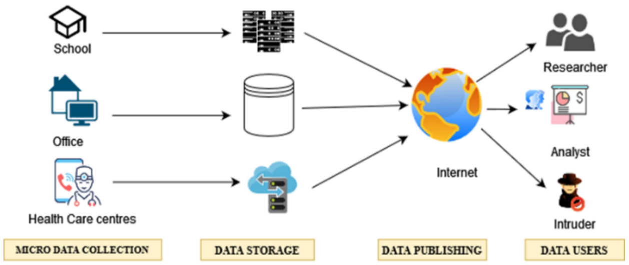

Fig. 1. Process of microdata collection, storage, publishing and usage.

Consider Table I, that is a sample microdata of a health care data center(M). From literature, the microdata attributes are classified as identifiers, quasi identifiers, sensitive and non sensitive attributes.

These attributes are defined as follows:

Identifiers (ID) – Directly identifying attributes are called as identifiers. For example: Name, Patient ID, Social Security number etc. Such attributes are removed be-fore publishing the micro data.

Quasi Identifiers (QID) – These attributes are used to indirectly identify a particular person. For example: Age, Gender and ZipCode. In any anonymization algorithms, the QID's are treated to different values to prevent disclosures.

Sensitive Attributes (SA) – The attributes that provide valuable information to the researchers/analyst and are used in data analysis. For example: Disease, Salary and Marital Status.

The following are the definitions of the terms that are used throughout the paper.

Definition 1: Equivalence class – Let a microdata M =(A1, A2, A3.. An) be the collection of records. The attributes are combinations of QID's and SA. 'n' is number of attributes. The equivalence class(EQ) is a group of records with indistinguishable mapping of QID values.

Definition 2: (e-Similar) - Let a1 and a2 be the levels of two sensitive values v1,v2 in their semantic tree respectively. A0 be the closest common ancestor. e= [(a1-a0)+(a2-a0)]/2. v1 and v2 are now said to be e-similar. In other words, the similarity between v1 and v2 is 'e'.

Definition 3: (l, e) Diversity - A data set is said to satisfy (l,e) diversity[14] if every EQ is l-diverse and the similarity among any two values in an EQ is equal to or more than 'e'.

Definition 4: Anatomy – An Anatomy [8] is anonymization technique, it disassociates the sensitive at-tributes and quasi identifier attributes into two tables. These tables increases utility when compared to k-anonymity because the attribute values are published in its original form. The anatomy breaks the correlation between the SA and QID's, this increases the privacy.

Definition 5: Residue Records - Those records that do not fit into any equivalence classes as they do not satisfy the constraints of the equivalence class are called as residues. When any anonymization algorithms is applied care must be taken to ensure that the residue percentage is as less as possible.

III. RELATED WORK

The datasets used in technologies such as BigData, IOT and cloud computing contain multiple sensitive attributes that need to be preserved [18]. Fig. 2 shows the advancement of the anonymization algorithms.

Initially, the algorithms were designed for SSA for example: k- anonymity [5], [7], [27], l-diversity [9], t-closensess [10], anatomy [11],slicing [12], failed to consider semantics between the sensitive atributes. Similarity and semantic similarity attacks [17] occur when the anonymization algorithms do not consider the semantics between the sensitive attributes. For example, Gastritis, Gastric Ulcer and Gastroparesis are diseases related to stomach. An intruder who has some background knowledge about the person can get to know that he is suffering from stomach infection.

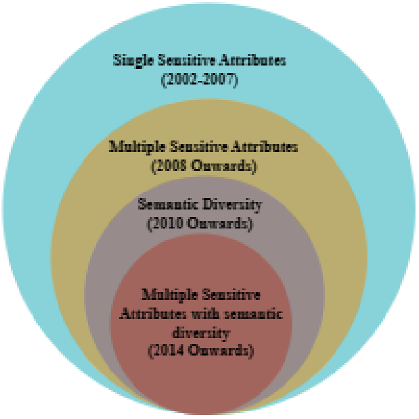

Fig. 2. Advancement of anonymization algorithms based on number of sensitive attributes and their semantics.

Later, algorithms like p-sensitive k-anonymity [28], (p+, α) sensitive k-anonymity [29], (p+, α, t) anonymity [30] were proposed. These algorithms,though considered the semantic relationship between the attributes, failed miserably when applied for dataset with MSA. Therefore, new set of algorithms were proposed to protect MSA.

The algorithms such as Rating [31], p-cover k- anonymity [32],Decomposition [33], Decomposition+ [34], KC slice [35], KCi slice [36] were designed to prevent privacy threats that occured on data with multiple sensitive attributes such as association attacks [37], semantic similarity attacks [16].In these algorithms, one of the attributes was considered as a primary sensitive attribute and other as secondary attribute. l-diversity, Anatomy or Slicing methods were used to group the records and anonymize the data. These algorithms did not discuss any method on how to select the sensitive attributes.

Simple Distribution of Sensitive Values for MSA (SDSV) [26] is a recent approach to distribute the MSA. In this method, two sensitivity levels are considered- High Sensitive Value (HSV) and Low Sensitive Value (LSV). Those sensitive attributes that have more than HSV is considered to be Primary Sensitive Attribute (PSA) and others are called as Contributory Sensitive Attributes (CSA). To understand this approach let us see basic definitions.

A. SDSV Approach to Select and Distribute the Multiple Sensitive Attributes

The user first selects the High Sensitive Values(HSV's) that he wants to preserve. Consider Table I, let the selected HSV be 'Heart Infection", ”$> 50K$” and 'Unmarried' for Disease, Salary and Marital Status attributes respectively. The occurrences of these values is II, III and IV in the table. Since the attribute value 'Unmarried' occurrence is high, the attribute Marital Status is considered as Primary Sensitive Attribute (PSA) and Disease, Salary are treated as Contributory Sensitive At-tribute(CSA). The table is anonymized as per anatomy [9]and it is published. The resulting tables are Table II, Table III , Table IV and Table V. Table II contains the QID's of the Microdata, these are grouped and assigned the GroupID. Table III contains the Marital Status as PSA that is grouped such that within each EQ there is equal diversity of the attribute value. Similarly, Table IV and Table V contains the grouping for Salary and Disease attributes. The groupID is assigned for the EQ's that are created in the tables.

TABLE II. QID TABLE

Age	Gender	Zip code	GroupID
23	F	560098	1
25	M	560096	1
30	M	560190	1
36	F	560091	2
39	M	560094	3
42	F	560099	2
52	F	560298	3
53	M	560090	2
61	M	560092	3

TABLE III. SAT 1 TABLE CONSIDERING MARITAL STATUS AS A PSA

GroupID	MaritalStatus	Count
1	Unmarried	2
1	Married	1
1	Unmarried	2
2	Unmarried	2
3	Married	2
2	Married	1
3	Married	2
2	Unmarried	2
3	Unmarried	1

TABLE IV. SAT 2 TABLE CONSIDERING SALARY AS A CSA

GroupID	Salary
1	45K
1	48K
1	30K
2	55K
3	57K
2	65K
3	45K
2	45K
3	40K

TABLE V. SAT 3 TABLE CONSIDERING DISEASE AS A CSA

GroupID	Disease
1	Flu
1	Pneumonia
1	Flu
2	Bronchitis
3	Heart Infection
2	Heart Attack
3	Gastric Ulcer
2	Dyspepsia
3	Heart Infection

From the generated tables it can be observed that marital status is considered to be HAS and the distribution of all the records was done based on this attribute. In Table III, the first EQ contains two occurrences of attribute value ” Unmarried” and one occurrence of “Married”. In Table V, the diseases in the EQ1, 'flu' and 'pneumonia' belong to chest infection and the intruder with some background knowledge(age, gender and zip code) can easily get to know the sensitive information. For example, if a person is neighbor of Alice and knows her

QID's , on getting access to the published Tables II, III, IV and V, he concludes that the Alice record belong to EQ1 and that she is suffering from some chest infections. This happened because in EQ1, all diseases are semantically similar.
It can be seen that the PSA is chosen based on number of occurrences. However, when the equivalence classes are created the attributes may be grouped such that they are semantically similar, this leads to semantic attacks and also due to multiple sensitive attributes there are every possibility that there could also be association attacks.

The following are the research gaps observed from the background study:

- Among the existing PPDP algorithms for MSA very few discuss how to select the Primary/Secondary/Tertiary sensitive attributes.
- Most of the algorithms do not deal with the residue records- those records that are skewed and do not fit into any of the equivalence classes.

B. Main Contribution of the Article

The main contributions of this work are:

- To provide an efficient method to select the sensitive attributes.
- Distributing the records within the EQ groups based on parameter 'e'.
- Applying incremental diversity so as to distribute the records appropriately within EQ with minimal residue records and preventing semantic attacks.
- Comparing the performance of the proposed algorithm (changing the primary sensitive attributes) against various parameters like residue percentage, diversity parameter (e) and computation time.

IV. Proposed Method and Empirical Results

Initially, the semantic hierarchy tree is constructed for all the selected sensitive attributes. For example, if disease, marital status and relationships are considered as sensitive attributes, the semantic hierarchical tree for all these is shown in Fig. 3,4 and 5 respectively.The semantic hierarchical tree for disease attribute, with Disease labelled as root node is at Level 0, the childrens namely Respiratory Disease and Digestive System diseases are at Level 1 and the attributes under these diseases are at level 3 and so on. Similarly, for attribute Marital Status there are 3 levels(0,1 and 2) and for Relationship there are 2 levels. Once the semantic hierarchy trees are constructed, those attributes with trees having more number of levels and with more number of child nodes can be selected as Initial Sensitive Attributes(ISA). This selection is essential to achieve optimal diversity of sensitive attributes in each equivalence classes. For example, if Disease is chosen as a ISA, if the equivalence class consist of sensitive values "Flu", "Heart Infection" and "Jaundice", the class satisfies (3, 2) diversity. Here, the equivalence class contains different values as well as the values are semantically far from each other. If Marital status is chosen as a ISA, then it is difficult to achieve (3,2) diversity, we can achieve only (3,1) diversity by repeating one of the values in each equivalence class. If Relationship is chosen as the ISA then it is possible to achieve only 'l' diversity and achieving (l,e) is not viable. A (3, 1) diversity table is shown in Table VI. Here, Disease sensitive attribute is chosen as the ISA

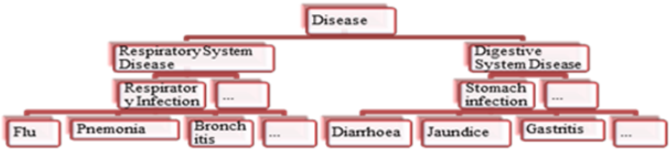

Fig. 3. Semantic hierarchical tree for disease attribute (Height=3).

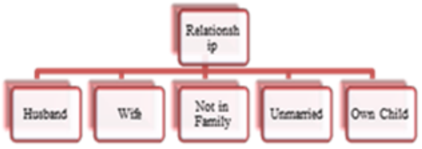

Fig. 5. Semantic hierarchical tree for disease attribute (Height=1).

TABLE VI. QID Table of Table I

Age	Gender	Zip code	GroupID
23	F	560098	1
25	M	560096	1
39	M	560094	1
36	F	560091	2
30	M	560190	2
61	F	560092	3
53	M	560090	3
52	F	560298	3
42	M	560099	2

TABLE VII. SA(Disease) Satisfying (3, 1) Diversity

Disease	Salary	MaritalStatus	Group ID
Flu	45K	Unmarried	1
Pneumonia	48K	Married	1
HeartInfection	57K	Married	1
Bronchitis	55K	Unmarried	2
Flu	30K	Unmarried	2
Heart Attack	65K	Married	2
GastricUlcer	45K	Married	3
Dyspepsia	45K	Unmarried	3
HeartInfection	40K	Married	3

After choosing the ISA, it is necessary to choose secondary sensitive attribute, ternary sensitive attribute and so on. This is necessary because if the Table 6 and 7 are published as they are, it may lead to association attack. For example, consider equivalence class 3, here even though the disease attribute satisfies (3, 1) diversity, the other associated attributes are predictable. If the intruder knows that a woman is more than 50 years and she is married, he well be easily be able to get to know that the lady belongs to group 3 and suffering from gastric ulcer. Such an attack is known as association attack [34]. These attacks happen in data set with multiple sensitive attributes.

A. Choosing Secondary and Tertiary Sensitive Attributes

From previous discussions it is clear that as a primary phase of data anonymization it is necessary to assign certain ranks to sensitive attributes. The attributes can be ranked based on the structure of the semantic tree. Those attribute values for which parents are more can be chosen as ISA and marked as rank 1. The next attributes are those with lesser parents as in case of Marital Status these attributes are termed as Subsequent Sensitive attributes (SSA) with rank 2 . Those sensitive attributes for which there are no many unique values and also are numerical in nature, for such attribute's values within each equivalence classes, they can be replaced with the mean of the values. For example, salary attribute, can be replaced with it mean value in each equivalence class The resulting tables generated based on the categorization of multiple sensitive attributes is shown in Table VIII and IX.

TABLE VIII. QID TABLE OF TABLE 1

Age	Gender	ZipCode	Group ID
52	F	560298	1
25	M	560096	1
39	M	560094	1
36	F	560091	2
30	M	560190	2
61	F	560092	3
53	M	560090	3
23	F	560098	3
42	M	560099	2

TABLE IX. ANONYMIZED TABLE BASED ON RANKS OF THE SENSITIVE ATTRIBUTES

Disease	Salary	MaritalStatus	GroupID
Disease	Salary	Marital Status	Group ID
Dyspepsia Pneumonia HeartInfection	41K	Unmarried Married Married	1 1 1
Bronchitis HeartInfection Gastritis	59K	Unmarried Unmarried Unmarried	2 2 2
Gastric Ulcer HeartAttack Flu	43.3K	Married Married Unmarried	3 3 3

When implementing the algorithm, the records are recursively reordered to make sure that in every EQ there is high diversity between the ISA values, average diversity between SSA and so on. That is, there will be incremental diversity achieved over the ranks of the sensitive attributes. The algorithm proposed next, takes the microdata table with identifiers, quasi identifiers and sensitive attributes as input. I, Q and S represents the number of identifiers, quasi identifiers and sensitive attributes respectively. The output of the algorithm is the separate QID table and SA table. The algorithm is implemented in Python language, the results obtained with varying k, number of records, 'l' and choosing different sensitive attributes. This is discussed in the next section.

```
Algorithm 1 Proposed Algorithm
  Input :
  1)  Microdata M(
          $i_1, i_2..i_I, q_1, q_2, \dots q_Q, s_1, s_2, s_3 \dots s_S)$
      ).
  2)  The diversity parameters 'l' and 'e'.
  3)  Equivalence group size 'k'.
  Output :
  1)  QIT(q1, q2..qn2 )
  2)  SA( s1,s2,s3. . . sn3)
 1: Classify the attributes within M into identifiers (i1,i2..in1)
    quasiidentifiers q1, q2,. . . qn2 ) and sensitive attributes
    (s1,s2,s3. . . sn3)
 2: Generate the semantic hierarchy tree for the sensitive
    attributes T( T1,T2..Tn3).
 3: Sort T in ascending order based on the depth of the tree.
 4: Select the Sensitive attribute with maximum depth as
    Initial Sensitive Attribute(ISA), the next as Secondary
    Sensitive Attribute(SSA) and so on.
 5: Initialize the groups EG ( G1,G2. . . Gm), K=k, QIT= $\Phi$
    and SA=$\Phi$
 6: Place all the records in the temporary dictionary TD.
 7: while $T \neq Empty$ do
        1)  Place ti into EG such that the ISA of ti when
            placed in EG satisfies 'l','e' defined before.
        2)  Increment value of K for that EG.
        3)  If not satisfied, place the tuples into Residue
            Dictionary RD and select next tuple.
        4)  If size of EG ¿ K break and place ti in next EG.
 8: end while
 9: while $RD \neq Empty$ do
        1)  reiterate the above steps (9-13) to reduce the
            residual records.
        2)  If the SA is numerical, within each EG, replace
            all the values by the mean.
        3)  Separate the SA's and QID's into separate table.
            Assign the Group ID's for the groups generated.
10: end while
```

V. EXPERIMENTS AND PERFORMANCE EQUATIONS

The algorithm is implemented in Python language using native python data types tuples, dictionary and lists. The use of external libraries such as NumPy and Pandas is avoided since it increases time complexity of the algorithm. The iteration through the tuples is pretty faster when dictionaries are used. The implemented algorithm is tested on the demographic data set obtained from University of California (UCI) machine learning repository [38]. This microdata contains 30162 records. Occupation, Education, Marital Status, Work Class

TABLE X. NUMBER OF UNIQUE VALUES IN EACH OF MSA'S

Attribute	Occupation	Education	MaritalStatus	Relationship	Race
No. of unique values	14	16	7	7	5

and Race are chosen as MSA's. Age, gender and Zipcode are chosen as QID's. The number of unique values for each of these is shown in Table X.

The following equations are used to compute various performance parameters. The residue percentage is computed as per equation 1.

$$RP = \frac{TotalNumberofRecordsinRD}{TotalNumberOfRecordsinM} * 100 \qquad (1)$$

Where RP- Residue Percentage.
RD- Residue Directory.
M- Original Microdata.

The computation time needed to run the code is obtained using equation 2.

$$Computationtime = (endtime - startime) * 1000 \qquad (2)$$

Where end time and star time are initialized at the beginning and end of the program respectively with the function time. time( ) that returns number of seconds elapsed since epoch.

$$DiversityOfEachAttributeWithinAnEQDEA = \frac{Numberofuniquevaluesofattribute}{Totalnumberofvaluesofattributes} \qquad (3)$$

The diversity percentage of the entire table is computed using equation 4.

$$DiversityPercentage = \frac{\sum_{EQ=1}^{n} \frac{\sum_{DEA}}{m}}{n} \qquad (4)$$

Where n- Total number of EQ's constructed. m- Total number of attributes

VI. RESULTS AND DISCUSSIONS

The results obtained after performing the experiments is presented in this section. The first three experiments are by varying the primary sensitive attributes and k, observing the residue percentage, computation time and diversity. The next set of experiments discusses the performance of the proposed algorithm with (l, e) diversity algorithm, in terms of residue percentage and computation time. Finally the comparison is done with proposed method, (l, e) diversity [17] and SDSV algorithm [29].

A. Performance of the Proposed Algorithm

1) Percentage of residue records based on choosing different primary sensitive attributes: The main objective is to reduce the residue percentage. Choosing k=3, and records 1000-5000, each line indicates number of residue records left out when a particular attribute is chosen as a ISA. It can be observed in Fig. 6, that if race is chosen as ISA, the percentage of residue records is highest and it is lowest when education is chosen as the ISA. The percentage of residue records is computed as per equation 1.

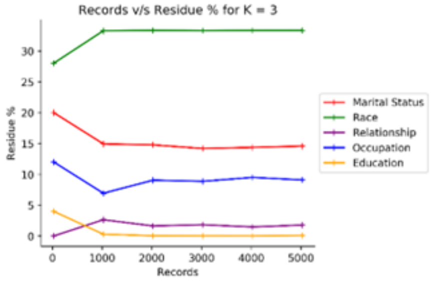

Fig. 6. Percentage of residue records vs parameter K.

2) Computation time: The computation time is the time required to generate the final QID and SAT tables. For this, on the chosen number of records, the equivalence classes are to be created choosing the diversity parameter 'l', of l-diversity [12] the levels of sensitive attributes and group size k as defined in [8]. On experimentation it is observed that, when Education is chosen as a ISA it consumes more time than Occupation or Race. This is obvious because the unique values are more for education attribute. The time performance choosing different attributes is shown in Fig. 7. The computation time is as per equation 2.

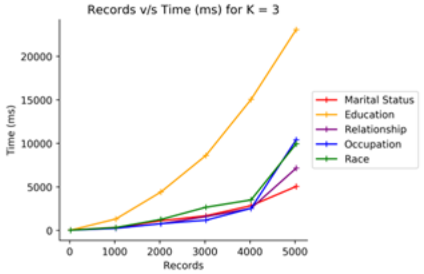

Fig. 7. Time performance for various attributes.

3) Diversity among the attribute values within the equivalence class: The diversity is computed as per (l,e) diversity discussed previously. From the experiments it can be observed in Fig. 8, that the attribute with more unique values (Education) achieves better diversity among the attributes within the equivalence classes. With the value of 'k' from 5 to 8, the performance of achieving more diversity can be seen with "education" attribute. The diversity percentage is computed according to equation given in 3 and 4.

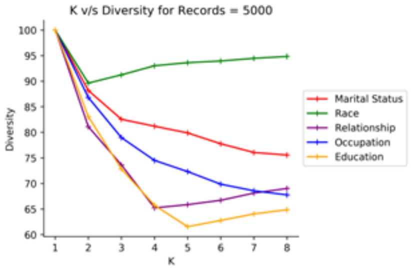

Fig. 8. Diversity of records within each EQ's.

B. Comparing with (l,e) Diversity Algorithm

The performance of our proposed algorithm is compared with the existing (l,e) diversity algorithm. The (l,e) diversity chooses only one sensitive attribute i.e Education. On observation it can be seen that choosing multiple sensitive attributes and then diversifying records achieves better performance in terms of reducing residue percentage. However, the time taken is more since multiple attributes are considered.

1) Residual percentage: The comparison is done for No.of records vs residue records and value of k. It can be observed from Fig. 9 that our proposed algorithm- choosing the attributes based on the ranks and then anonymizing results in reduction of residue records. Since (l,e) diversity uses generalization for anonymization it leads to more number of residue records.

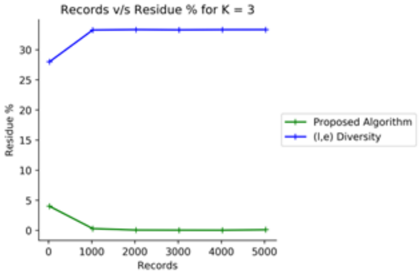

Fig. 9. Reduced residual records in proposed method vs (l, e) diversity.

2) Computational time: As shown in Fig. 10, the time taken by the proposed algorithm is slightly higher than (l, e) diversity because the algorithm considers MSA where as (l,e) preserves privacy of SSA.

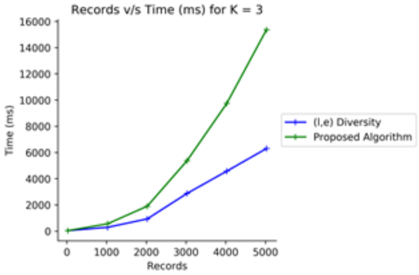

Fig. 10. Computation time in proposed algorithm vs (l, e) diversity.

3) Diversity percentage: The diversity percentage achieved in the proposed method with multiple sensitive attributes is much better when compared with (l,e) diversity. This is mainly because the attributes are selected based on their semantics and every EQ has diversified primary sensitive attribute. This is shown in . 11.

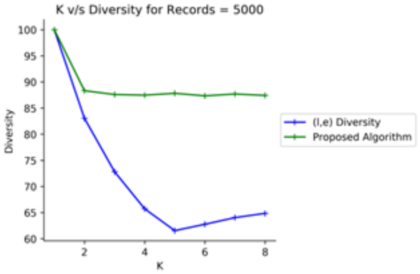

Fig. 11. Diversity percentage in proposed algorithm vs (l,e) diversity.

C. Comparision of Incremental Diversity, SDSV and (l,e) Diversity

As discussed in related work section, one recent algorithm that discusses the distribution of sensitive attributes is SDSV algorithm. However, the algorithm doesn't consider the semantic similarity between the attributes within an EQ. This leads to semantic diversity attack and weaker diversity among the attributes within an EQ's. It can be seen from Fig. 12, that, (l, e) diversity has highest diversity among the attributes within an EQ, since it considers single sensitive attributes. The diversity percentage for the proposed algorithm is average considering the multiple sensitive attributes and their semantic.

D. Security Evaluations

As mentioned before the privacy attacks considered in this work are semantic attacks, similarity attacks and association attacks that are predominant in data set with MSA. The proposed algorithm overcomes all these threats since the semantics of the sensitive attributes is addressed. Consider Table II, III, IV and V that were generated by SDSV algorithm. The algorithm did not consider the semantic relationship between the sensitive attributes there were semantically similar attribute values for disease within an equivalence class. Also, the algorithm generates multiple tables and this increases as the number of sensitive attributes increases.

The proposed algorithm overcomes the semantic and similarity attacks. Consider Tables VI and VII that are generated using the proposed algorithm. Every equivalence class has diversity of the sensitive attributes, which becomes difficult for the intruder to cause privacy threats. Even though the intruder knows one of the sensitive attribute and a quasi identifier it is difficult to cause association attack. For example, if the intruder is neighbour of Trudy (from Table I), he knows that he is unmarried and also the Zip Code. The intruder wants to determine other sensitive attributes like disease. On observing the published table, he gets to know that his record belongs to group 2 of Table VII. Here, since there are 2 records that have "Unmarried" as attribute value of Martial Status, he cannot predict Trudy's disease. Form the above experiments

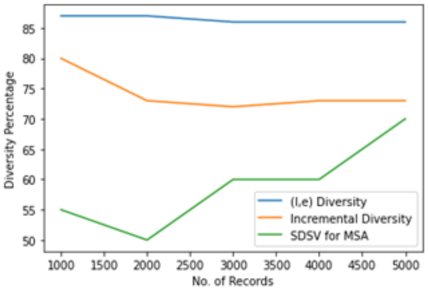

Fig. 12. Diversity percentage of (l, e) diversity, proposed method and SDSV for MSA.

and results it can be concluded that the proposed algorithm is efficient in terms of reducing the residual records, computation time at the same time achieving optimal diversity considering multiple sensitive attributes. Also, as discussed,the proposed algorithm overcomes the privacy threats that exists for MSA.

VII. Conclusion and Future Work

Concern to data privacy is increased with the increase in the digital technology. The personal data is collected at various places that contain multiple sensitive attributes (MSA). These attributes must be treated well to prevent privacy threats when the data set is published to outside world. Many algorithms have been proposed to preserve privacy of MSA in the literature. In these algorithms one of the attribute is chosen as a primary sensitive attribute and the microdata is anonymized. These algorithms do not discuss how to rank the sensitive attributes. This is the essential step in anonymizing the data. In this paper we discuss an efficient approach to rank the sensitive attributes and then anonymize the data. Experiments along with performance parameters, prove that our algorithm outperforms the existing methods and can be efficiently used to anonymize the data. As a part of future work we would propose an infrastructure framework where in the tables can be published.

Demand Forecasting Models for Food Industry by Utilizing Machine Learning Approaches

Nouran Nassibi[1], Heba Fasihuddin[2], Lobna Hsairi[3]
Department of Computer Science and Artificial Intelligence[1]
Department of Information Systems and Technology[2,3]
University of Jeddah, Jeddah 23443, Saudi Arabia[1,2,3]

***Abstract*—Continued global economic instability and uncertainty is causing difficulties in predicting sales. As a result, many sectors and decision-makers are facing new, pressing challenges. In supply chain management, the food industry is a key sector in which sales movement and the demand forecasting for food products are more difficult to predict. Accurate sales forecasting helps to minimize stored and expired items across individual stores and, thus, reduces the potential loss of these expired products. To help food companies adapt to rapid changes and manage their supply chain more effectively, it is a necessary to utilize machine learning (ML) approaches because of ML's ability to process and evaluate large amounts of data efficiently. This research compares two forecasting models for confectionery products from one of the largest distribution companies in Saudi Arabia in order to improve the company's ability to predict demand for their products using machine learning algorithms. To achieve this goal, Support Vectors Machine (SVM) and Long Short-Term Memory (LSTM) algorithms were utilized. In addition, the models were evaluated based on their performance in forecasting quarterly time series. Both algorithms provided strong results when measured against the demand forecasting model, but overall the LSTM outperformed the SVM.**

I. Introduction

Supply Chain Management (SCM) has been a key area of study and professional practice since the 1980s. However, in recent years, supply chains have come under increased scrutiny due to their critical role in business success or failure. A supply chain relies on a coordinated network of companies and sectors.Within this network, materials are obtained and processed into intermediate or final products so that the final products can be sent to users [1]. SCM has four main processes: plan, source, execute and deliver as shown in Fig. 1. Demand forecasting is one of the main axes of SCM [1]. In a changing world, forecasting has increased in importance across many sectors and forecasting has a particular relevance to supply chain management: accurate forecasting allows a company to ensure that supply exists to meet demand. Demand forecasting involves utilizing a probabilistic assessment of the available data, for aims to quantify and forecast future consumer demand for a good or service [2]. A corporation can improve it's supply decisions by using demand forecasting to predict possible sales volume and profitability. By estimating future sales from analyzing historical consumer trends, a business can use demand forecasting to make the most of their inventory [3]. Machine learning (ML) algorithms can forecast food sales by analysing the wealth of historical sales data and adapting to changes within it. ML models have greater predictive power than linear models with progressive parameter selection. Furthermore, the use of ML algorithms in the forecasting process provides adaptive capabilities to members of the supply chain. The system can be considered adaptable through its flexibility in improving the agreement between supply and demand. As a result, it improves the inventory balance throughout the chain by avoiding overstocking of products that are not in high demand [4]. The main focus of this research was forecasting demand within supply chains in the food industry. Although demand forecasting is important for the success of all supply chain processes, it has a critical role in the food industry because products are perishable. Thus, in this case demand forecasting directly contributes to resource preservation and sustainability. More specifically, this study focuses on using ML on long-shelf-life products, especially confectionery (such as chocolates). Such a model may support distribution companies in demand forecasting and stakeholder management with manufacturers and retailers. LSTM and SVM models were built to forecast demand of individual features for each city, or distribution channel, and product.

The remaining sections of this paper are as follows: Section II offers a brief literature review of research concerning demand forecasting in the food industry, Section III presents the research methodology, Section IV outlines the confectionery distribution company's data set, and Section V analyses the results of the forecasting model. Finally, Section VI shares the conclusion of this research and discusses directions which future research could undertake to further the field.

II. Literature Review: Demand Forecasting Models in the Food Industry

Demand forecasting plays crucial role in supply chain management. Using machine-learning algorithms in demand forecasting aids decision-makers in making effective and prescient choices. Accurate demand forecasting leads to increases in company revenue and stock value. Therefore, over the last decade, significant research has been conducted on sales demand forecasting in the food industry. A general overview of forecasting models for sales demand in food industry is provided in systematic review of [6]. This demonstrates the benefits of using ML techniques in the food industry especially for forecasting sales across several types of outlets including confectionery stores, grocer's shops and restaurants. ML techniques have greater predictive power than conventional approaches, which are subject to human error: the

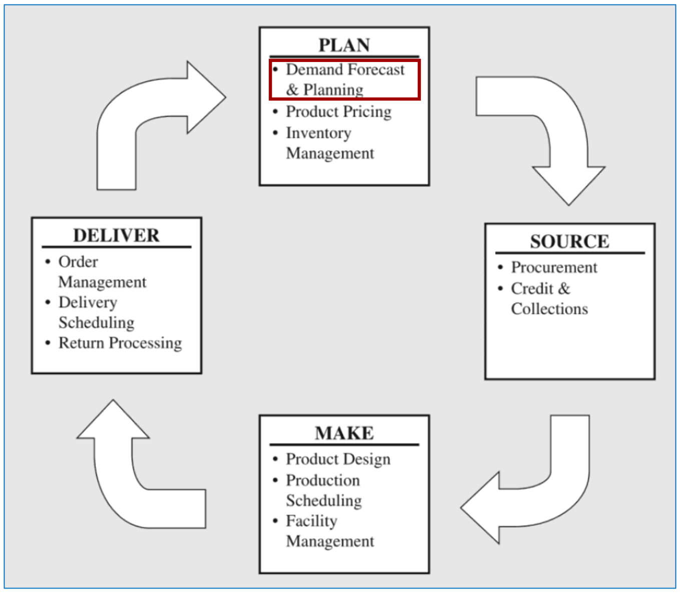

Fig. 1. SCM's four phases. [5]

main advantages of accurate forecasting are that it allows stores to dispose of expired products and minimize stock levels [6]. "Shelf-life" refers to the length of time a given foodstuff remains viable for purchase as a quality product and determines how long products remain on sale [7]. The paradox of having to throw away excessive amounts of products is a significant challenge for retailers. This is especially the case when selling items with a short shelf-life, such as fruits and vegetables. Researchers have made continuous efforts to improve demand forecasting for short shelf-life products. For instance, [3] estimated the sales demand for an Austrian retailer operating in the food industry, specifically with regards perishable products. The researchers used two different models Seasonal Autoregressive Integrated Moving Average (SARIMA) and Long Short-Term Memory (LSTM) and historical daily sales from January 2017 to December 2019 of four perishable products sold in over 90 stores. Both models produced useful outcomes, however, LSTM outperformed SARIMA for products with stable demand, while SARIMA outperformed LSTM for seasonal products. Furthermore, the researchers compared results with SARIMAX after including the external factors such as promotions sales and discovered that SARIMAX performed significantly better for products with external variables. Similarly, [8] used a neural networks approach to construct a forecasting model to predict annual import fruit for the following year. Moreover, [7] used various forecasting models such as LSTM networks, Support Vector Regression (SVR), Random Forest Regression (RFR), Gradient Boosting Regression (GBR), Extreme GBR (XGBoost/XGBR) and Autoregressive Integrated Moving Average (ARIMA) to attain the daily optimal order quantity of fresh produce and to avoid specific vegetables becoming out-of-stock. The study was conducted on the fresh vegetables section of a retail outlet of a college campus. They selected a range of products to fit the categories of low, moderate and long shelf-life (tomatoes, onions and potatoes, respectively). The results indicated that ML algorithms, namely, LSTM and SVR, produced better results as compared with other demand forecasting models. In another study [9], the forecast demand for a Portuguese company's sales was obtained by comparing various statistical methods (moving average, exponential smoothing and ARIMA). In this case, historical weekly sales of delicatessen products from 2013–2017 were used as the data. The author in [9] combined different forecasting techniques to produce consistently good results. Moreover, they used a simple average to combine the three different results of forecasts. In addition to previous studies, [10] proposed a model of Long Short-Term Memory (LSTM) to forecast daily consumer demand using Moroccan supermarket data from a period of six months. In this study, multi-layer neural was found to be the best neural network framework for demand forecasting. Forecasting future products sales enables stores and companies to avoid food waste. Therefore, [11] presented a case study of several ML models using real-time sales data from a restaurant. They applied data by using over 20 models to demonstrate the impact of creating stationary data-sets on the pre-processing of the feature and model training processes. The results showed that Recurrent Neural Network (RNN) models outperformed other models. The author in [12] also studied the efficacy of ML techniques in forecasting daily customer demand for beer in a restaurant setting. Their predictions were based on combining two different kind of data: internal data (such as point-of-sale (POS) transaction data) and external data (such as weather conditions). Demand forecasting models are not only employed within the food industry, but can also be applied to many other sectors. In e-commerce settings, some products are interconnected, and can be categorized into one subcategory; thus, they have correlated sales and demand patterns. Therefore, [13] suggested that better predictions would arise from using historical data from related products to forecast product demand. They applied an LSTM model by using historical data of interconnected products from Walmart.com in order to forecast the demand of other products within the same category, and achieved more accurate results by using LSTM model. To date, the field has seen a significant amount of research in demand forecasting. However, none of this deals with multi-faceted nature of the supply chain for such products, including channel distributions and city. The present study aims to apply some of these insights to the confectionery distribution industry. Table I summarizes previous studies that are related to the current research. There are two important attributes to consider when making comparisons:

Attribute 1: That the study considers sales by city to forecast demand.

Attribute 2: That the study examines the geographic distribution of products across different channels, such as larger stores, mini-markets and wholesale retailers.

This presence of these criteria are indicated in Table I as:

Y: Yes, this criterion is applied or considered.

N: No, this criterion is not applied or considered.

III. Methodology

This section reviews the methodology applied to build the forecasting model. The research methodology is based on artificial intelligence (AI) in food supply chains, taking into account a number of factors which significantly affect sales,

TABLE I. Comparison with Previous Research using the Proposed Models

Ref.No	Year	Products Type	Demand Type	Methodology	Attribute 1 (City)	Attribute 2 (Channel)
[10]	2017	Moroccan supermarket products	Daily sales	LSTM	N	N
[7]	2019	Vegetables	Daily order quantity	LSTM networks, SVR, RFR, GBR, XGBoost and ARIMA	N	N

such as city distribution channels and actual sales revenue. The methodology is based on a ML algorithm in order to map between input and output data and to discover the underlying rules governing the movement of the time chain so that realistic future predictions can be made. Fig. 2 outlines the methodology for the proposed model.

The proposed model comprises three major phases:

A. Data Pre-Processing

After collecting data from the chosen confectionery company in the Kingdom of Saudi Arabia, it was processed through noise removal. Effective pre-processing of data is essential for network input, it is better to convert raw time-series data into indicators which represent basic information more clearly. Therefore, features were classified as follows:

- **Three types of product sales are considered:**
  - ○ Actual sales revenue during regular periods, which represents the income the company or factory generates from the sale of its products.
  - ○ Sales promotions refers to sales records during offer periods (such as those occasioned by holidays, back-to-school offers and special events). Such promotions play a crucial role in demand forecasting as they can skew the results.
  - ○ Returns of products.

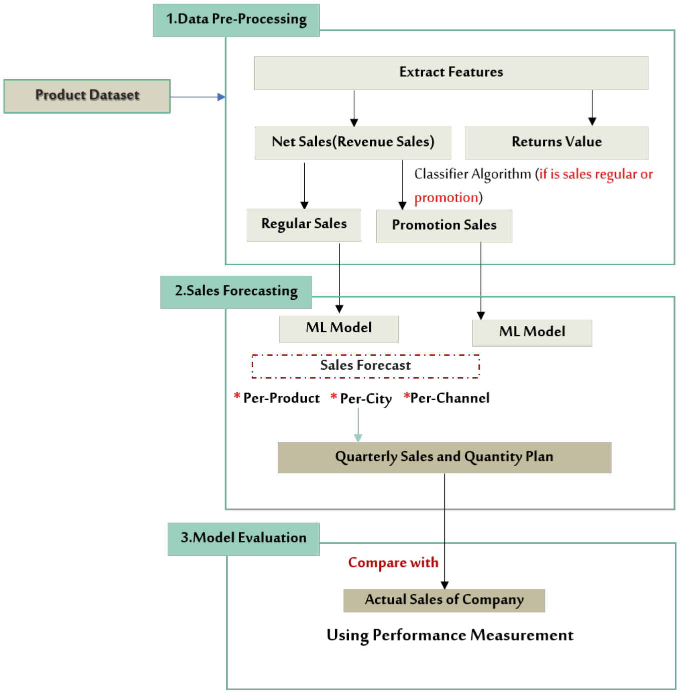

Fig. 2. Methodology for the proposed model.

- City.
- Distribution Channel.

B. Applying ML Algorithms in Forecasting Models

Based on the pre-processing phase, the appropriate model was chosen and applied to forecast quarterly sales volume and the required quantities of the product based on various factors such as city and distribution channel. Two machine learning algorithms were used in this study to determine the optimal order quantity of different chocolate products. This section describes each algorithm in overview.

1) Support vector machine (SVM): One of the supervised learning methods used to solve classification and regression problems is the Support Vector Machine (SVM). SVM is best suited to forecasting products with high dimensional margins, where the number of features exceeds the number of inputs [14]. SVM has often been used as the solution to demand forecasting in the food industry due to the need to solve regression problems. A key advantage of the SVM method over more conventional prediction techniques is that it does not require any previous information regarding the link between the input and the output [16].

[18] obtained more robust results using the SVM algorithm when forecasting demand for perishable foods. Furthermore, [7] produced good results with low forecast error when using the SVM algorithm to predict daily sales of vegetables. The findings from studies which have used this method, indicate that SVM produces strong results [10]. Therefore, SVM was selected for making predictions in the current study.

2) Long short-term memory (LSTM): Recurrent Neural Networks (RNNs) are a popular method for modelling time series data. However, RNN has some limitations. Firstly, all inputs must be the same size. Secondly, RNN suffers from the disappearing gradient problem. Due to these limitations a Long Short-Term Memory (LSTM) algorithm can be used to solve this problem. LSTM can save information from inferences in sequential data in long memory. This algorithm describes data properties without requiring previous knowledge of parameters or distribution of features [15].

C. Model Evaluation

To evaluate each model, the sales it predicted were compared with the actual sales data. The accuracy of the forecasting model was measured using two common performance measures:

- **Mean Absolute Percentage Error (MAPE).**
- **Root Mean Square Error (RMSE).**

IV. Confectionery Dataset

A large dataset describing customer transactions with the distribution company was provided by a chocolate distribution company in the Kingdom of Saudi Arabia. This dataset was obtained from the company's SAP platform [17], which saves detailed transaction records. This dataset provided more than ten attributes, including those most common to the food sales field as well as factors which might be useful in forecasting product sales. These were factors such as distribution channel, product code, date, plant, returns value, net quantity, and sales in Saudi Riyal (SAR). The target variable is forecasted sales quantities. Table II outlines the dataset dictionary.

Net value and quantity features are the units used by the company to measure the sales of their products. A returns value is represented by a negative value of net value. The data was in the form of daily transactions for 200 products in 11 cities and 6 distribution channels across 3 years (January 1 2018 - December 31 2020). This led to dataset with almost quarter of a million data rows. Table III shows the description of six distribution channels feature that are used in the dataset.

TABLE II. Dataset Dictionary

No.	Feature Name	Description
1	Product Code	A unique 6-digit number referring to an individual product with name of product.
2	Posting Date	Date of transaction sales.
3	City	Location of stores.
4	Distribution Channel	The way of distribute products in stores (6 chanels are available).
5	Net Value	Actual sales of product in Saudi Riyal (SAR).
6	Net Quantity	Actual quantities of product per transaction.
7	Returns Value	Value of purchased products returned to stores in Saudi Riyal (SAR).
8	Returns quantity	Quantity of purchased products returned to stores.

TABLE III. Description of Distribution Channel Feature

No.	Name of channel	Description
1	Key Account	Important major and big-sized main stores i.e (hyper market.)
2	Wholesale	Stores buying large quantities of products from distribution company.
3	Mini Markets	Small stores such as corner shops or newsagents.
4	Convenience Stores	Small stores located in gas stations (for example NAFT, SASCO).
5	New Channel	Stores whose main product line is different, such as Toys "R" Us, Sky sales (Saudi Airline).
6	Cash Van	A car with products in the custody of the company's salesman. The customer pays via cash.

V. Analysing Forecasting Model Performance

Forecasting demand for a company with several different products, across multiple cities and distribution channels is a challenging task. Creating one model which covers all products, cities and channels might not be accurate, because each of these factors affects the inputs and is subject to changing circumstances. The main objective of this study was to enhance predictive ability for sales, thus minimizing food wastage and supply chain issues by forecasting supply and demand, and improving the efficiency of the whole system by minimizing errors like data loss in traditional ways. As such, the developed model aims to forecast demand of products for next year's quarters, while the inputs for the models comprised city, distribution channel and sales quantities of products by quarter for the previous year. Therefore, the dataset was split into different time steps. The training dataset consisted of daily sales transactions during 2018 for products and the testing dataset used 2019 data. For model testing, we chose sales data for the top five products (product 1, product 2, product 3, product 4, and product 5) across the ten cities (Riyadh, Jeddah, Taif, Dammam, Qassim, Makkah, Eisha, Madina, Tabuk, Jizan, and Khamis).

The above-mentioned cities were mapped along the x-axis with product demand along the y-axis. With regards the distribution channel, only one channel was used in testing which was the key account channel. This channel represents the most significant markets in Saudi Arabian cities.

A model validation method was implemented in order to compare the performance of the models. After identifying and developing all of the forecasting models, the performance measures for validating and comparing these models was implemented by applying the following equations, using Python:

- $\sum$: Symbol means "sum", **E** = Actual value – Forecast value and **n** = sample size.
- Mean absolute percentage error, MAPE = $\frac{\sum_{i=1}^{n}|E|*100/A}{n}$ [7], where the actual demand value is indicated by A.
- Root mean squared error, RMSE = $\sqrt{\frac{\sum_{i=1}^{n}|E|^2}{n}}$ [7].

Several features potentially play a significant role in forecasting product sales. Separating the sales by channel and city revealed that each of them has unique purchasing trends. This justifies the need for separating out these factors and showing the results of the models for each product by city and by channel. The results of models for multiple cities across one channel using the **LSTM** model are presented in Section 5.1, while Section 5.2 describes the results when the **SVM** model was applied. Section 5.3 discusses the results for both models.

A. LSTM

As explained, time is an important factor in prediction models. Each year's data was split into quarters to observe the accuracy of the forecasting models' output in relation to actual sales. Each algorithm was executed separately to predict sales of the top five products in the given year.

Fig. 3 shows the actual values (coloured full lines) and the predicted values (dotted lines) respectively. Chocolate product demand is shown in the below graph for these cities. The actual values and predicted values by our models are almost identical, indicating the accuracy of the models' output. The LSTM model shows that **Product 2** saw the highest demand in the capital city RUH **(Riyadh)** during **quarter-1, quarter-2 and quarter-4**, as shown in Fig. 3 during **quarter-3**, however, **Product 2** saw the highest demand in the city of **(Dammam)**. Noteworth, **Product 4** not buy any items in **(Tabuk)** city during **quarter-2**.

B. SVM

The second model used for sales demand forecasting in this study was SVM. Fig. 4 shows the sales forecasting for products per quarter. Fig. 4 shows that **Product-2** had the most demand in **(Dammam)** during **quarter-4**. During **quarter-2 and quarter-3**, **Product 2** saw the most demand in the capital city of **Riyadh (RUH)**. The graph indicates that the SVM model is less accurate because the predicted values are higher than the actual values during **quarter-3**.

C. Discussion

The key research question for this study concerned which algorithm could better forecast demand, LSTM or SVM. A Support Vector Machine (SVM) is a classification algorithm used for a small amount of data, and it is less accurate than the LTSM. A Long Short-Term Model (LSTM) is used as a deep learning algorithm that performs effectively when used for a large amount of data. The overall results show that the LSTM model is more accurate than the SVM model, because of LSTM's ability to remember the data more efficiently than the SVM. The LSTM algorithm performed best when used for a large amount of data. Overall, LSTM performs better than SVM across all scenarios. However, both algorithms are useful in forecasting demand and when used together provide a more comprehensive picture.

Performance statistics like MAPE and RMSE enable the forecasting models to be evaluated. For this study, the algorithms resulting in the lowest RMSE and MAPE are the most effective. As explained above, the city and distribution channel destination is an important variable and a significant factor in the forecasting sales models. Therefore, Fig. 5 shows a comparison between LSTM and SVM models by city. Fig. 5 indicates that the LSTM forecasting is better than the SVM model's because the MAPE and RMSE values are lower for the LSTM model than for the SVM model. Additionally, Table IV shows all the results of the MAPE and RMSE values. Riyadh and Jeddah have the lowest MAPE and RMSE values as compared with other cities (blue line). This is because Riyadh is the capital and largest city of the Kingdom of Saudi Arabia, and Jeddah is also among the largest cities. Due to their geographical size, the demand for products is higher when

compared with other cities, the number of sales transactions in these two cities creates significant data and both cities had daily sales in the dataset. Since the forecasting model were trained to look for trends in large numbers of sales, this might have influenced their ability to reduce the rate of forecast error in these cities. The values shown in Fig. 5 were obtained by taking values of all four quarters for each city. In order to evaluate the performance of this study's LSTM and SVM models, a comparison against previously studies was undertaken. Table V illustrates those previous studies (in blue) which used similar factors to this study, such as store location. Other studies used general sales with category of products as the main factor for the LSTM and SVM models. This study obtained lower MAPE values compared with previous studies using LSTM (in green). However, this study's results using the SVM model (in yellow) are comparable with [7]. This study selected the most commonly-used algorithms for predictions [10]. Looking at the sequence of charts depicting the results, predicted and actual values agree more closely. Accurately predicting demand will help businesses to make better decisions and consequently save food, generate increased revenue, and solve food supply issues. This study shows that the implementation of LSTM and SVM models for real-life food items and the retail market helps to reduce forecast error, improve daily retail inventory and increase product sales. This will help small businesses to reduce the risk of particular items falling out-of-stock and optimize their sales.

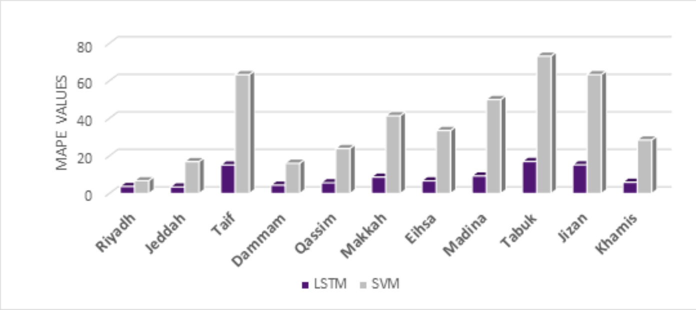

Fig. 5. A comparison of LSTM and SVM city forecasting.

TABLE IV. A COMPARISON OF MAPE AND RMSE VALUES USING LSTM AND SVM

	MAPE		RMSE	
City	LSTM	SVM	LSTM	SVM
Riyadh	3.78	6.8	2.24	7.69
Jeddah	3.48	15.9	2.26	8.21
Taif	15.20	63.3	2.37	10.26

VI. Conclusion and Future Work

In an era where information and data are increasingly available, ML is an important tool from which industries can greatly benefit to future-proof their supply chains. The ability to accurately forecast demand assists distribution companies to manage their supply chains more effectively. This study presents two models for a distribution company in the food industry by using the LSTM and SVM algorithms to forecast demand for products across a variety of factors. In particular, the demand forecasting models here were applied to the individual level of factors such as city and distribution channel. The evaluation of the experiment showed that the LSTM model outperformed SVM. In general, the findings demonstrate that the LSTM model reduces forecasting errors up to **77%** compared to the SVM model. This study has generated key insights concerning the sales of chocolate products within different cities of Saudi Arabia. Sales promotions are one of the most common phenomena in the retail industry. Special events such as marketing campaigns or holiday promotions are examples of valuable retail data that are often not incorporated into single-variable statistical forecasting models. Currently, this study only takes standard sales patterns into account when forecasting demand, so future work needs to examine promotion sales as an independent factor. Furthermore, the dataset used here was the company's sales record for 2020, a year in which the COVID-19 pandemic had a significant negative impact on almost all industries. Future work will extend the sales analysis depicted here to understand how the pandemic affected standard sales behaviour.

Acknowledgment

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-21-DR-138). The authors, therefore, acknowledge with thanks the University of Jeddah technical and financial support.

Unified Teaching Center of Piaui[3], Brazil

Abstract—**Machine learning is a suitable pattern recognition technique for detecting correlations between data. In the case of unsupervised learning, the groups formed from these correlations can receive a label, which consists of describing them in terms of their most relevant attributes and their respective ranges of values so that they are understood automatically. In this research work, this process is called labeling. However, a challenge for researchers is establishing the optimal number of clusters that best represent the underlying structure of the data subjected to clustering. This optimal number may vary depending on the data set and the grouping method used and influences the data clustering process and, consequently, the interpretability of the generated groups. Therefore, this research aims to provide an inference approach to the number of clusters to be used in the grouping based on the range of attribute values, followed by automatic data labeling based on the standard deviation to maximize the understanding of the groups obtained. This methodology was applied to four databases. The results show that it contributes to the interpretation of the groups since it generates more accurate labels without any overlap between ranges of values, considering the same attribute in different groups.**

Keywords—Inference approach; range of attribute values; labeling; standard deviation; interpretation of the groups

I. Introduction

The rapid popularization of computers in many sectors of society has resulted in significant data volume growth [1]. The researchers then began to use pattern recognition techniques by detecting correlations between the data, which could bring to light relevant and valuable knowledge potentially contained in these databases [2].

One of these pattern recognition techniques is machine learning (ML), which emerged from the realization of creating computer programs that learn a particular behavior or pattern automatically from examples or observations. The idea behind learning is that after looking at some data, a computer builds a model based on that data and uses that model as a hypothesis about the world and a piece of software that can solve problems [3].

Machine learning can consist of two main paradigms: supervised and unsupervised. For supervised learning, the aim is to create an accurate model for predicting values for new data. As for unsupervised learning, the objective is to find characteristics that can summarize the data. Other paradigms exist, such as reinforcement learning, multitasking, and semi-supervised.

As one of the best-known techniques in the area of unsupervised learning, grouping or clustering of data consists of defining a set of groups or clusters in which the elements of the same group are as similar as possible to each other, and the elements of different groups are as distinct as possible [4]. Because it is subjective, it does not provide clear information that allows inferring the characteristics of each cluster formed [5] due to the algorithms' limitations.

Establishing the optimal number of groups in a clustering algorithm is one of the most challenging and fundamental tasks for researchers since different amounts of clusters cause different results, influencing the performance of the clustering process [6], [7], [8]. For example, Cobweb [9] is a hierarchical algorithm whose order of factors affects the grouping and is very sensitive to data input. K-means [10] is an algorithm based on Euclidean distance dependent on the initial partition generated by the random choice of centroids, requiring the number K of groups to be informed in advance.

Labeling seeks to synthesize its definition, describing the groups' most relevant attributes and respective value ranges to understand the specialist better. Due to some limitations resulting from the grouping, auxiliary techniques can infer characteristics that identify the formed groups. Among these techniques are dispersion metrics, such as standard deviation. Therefore, the resulting clusters are labeled to be understood automatically. In this research work, this process is called automatic data labeling, which aims to identify the characteristics of each group and, later, allow the complete interpretation of the generated clusters.

In this sense, this research aims to provide an inference approach to the number of groups to be used in the clustering process, based on the range of attribute values, with subsequent automatic data labeling from the standard deviation to maximize the understanding of the groups obtained, without overlapping any range of values in the same dataset, considering the same attribute. It consists of calculating the standard deviation according to the value of each attribute. When necessary, the value of this deviation is increased to the lowest value of each attribute in the dataset or decreased by the highest value of each attribute, or both steps have been performed. This methodology was applied to four databases of different sizes.

The results show that it contributes to the interpretation of groups, as it generates more accurate labels since the algorithm developed to choose the optimal number of groups performs better when compared to other isolated methods, such as Elbow, Silhouette Coefficient, and Calinski-Harabasz, for example. Furthermore, the labels obtained do not overlap between ranges of values considering the same attribute in different groups. It contributes to better interpretability of the generated clusters.

In addition to the Introduction, the rest of this article is organized as follows. Section II presents the theoretical framework used in this model, Section III addresses influence studies for this research, Section IV displays the methodology used, Section V presents the results obtained and, finally, Section VI describes the conclusion of the research work.

II. Theoretical Reference

In this session, the selection processes of relevant attributes and measures of dispersion of data used in this research will be presented, followed by clustering, in addition to the labeling problem.

A. Dispersion Measures

According to [10], a measure of dispersion for a quantitative variable indicates the degree of spread of sample values around the centrality measure, indicating how much the elements differ from the mean of the data set. Greater dispersions exhibit less representativeness of the central values. One of the advantages of using these metrics is that they observe the data set as a whole and assess the degree of homogeneity or dispersion of this set, favoring a reduced computational cost. Next, a relevant metric used in data labeling will be presented to understand the *clusters* formed.

1) Standard Deviation: Mathematically, the standard deviation (SD) is a measure of dispersion used to quantify the variation or dispersion of a set of data values [11]. Equation 2 shows how the standard deviation calculation is performed.

$$DP = \sqrt{\frac{\sum_{i=1}^{n}(x_{\mathrm{i}} - MA)^2}{n}} \tag{1}$$

For clarification:

- SD: standard deviation;
- $\mathrm{x_i}$: value at position i in the data set;
- MA: arithmetic mean of the data;
- n: the amount of data.

A low standard deviation means that the data points tend to be close to the mean of the set, while a high standard deviation indicates that the data points are spread over a wide range of values.

B. Clustering

The basic idea of clustering is those elements that make up the same *cluster* must show high similarity (i.e. be very similar elements and follow a similar pattern). Still, it must be very dissimilar from objects in other groups. In other words, all clustering is done to maximize homogeneity within each *cluster* and maximize heterogeneity between groups.

K-means is one of the most popular clustering algorithms. The result of the K-means [12] method is generally influenced by the K-partition chosen in the initial step. If K is too small, there will be distinct elements in the same cluster. On the other hand, if K is very high, similar elements will be in different clusters. For this reason, it is recommended to validate the result of the cluster analysis based on inference criteria of the optimal number of groups in a data set, bearing in mind that different amounts of *clusters* generate different results, influencing the performance of clustering and consequently in understanding the *clusters* formed.

C. Labeling Problem

The task of interpreting clusters is commonly assigned to a specialist in the field under study who examines each group with respect to its objects to label them, describing the nature of the group. This process tends to be too laborious concerning time and resources, considering the amount of data and subjectivity of the task.

In view of this, [14] proposed a method for automatic extraction of characteristics from the groups, providing specialists a label with a selection of the most relevant characteristics of the elements of each group. These features are composed of attribute values range, so the labeling problem is defined as:

Given a set of clusters C $=\{\mathrm{c_1, ..., c_k} \mid \mathrm{k}\geq 1\}$, so that each cluster contains a set of elements $\mathrm{c_i} = \{\vec{e}_1, ..., \vec{e}_{\mathrm{n(c_i)}} | \mathrm{n}^{(\mathrm{c_i})}\geq 1\}$ which can be represented by a vector of attributes defined in $\mathrm{R^m}$ and expressed by $\vec{e}_{\mathrm{j}}^{\,(\mathrm{c_i})}$ = ($\mathrm{a_1}$, ..., $\mathrm{a_m}$) and even though $c_1 \cap c_{1'} = \emptyset$ with 1 $\geq$ i, i '$\geq$ K and i $\neq$i'; it aims to present a set of labels R $=\{\mathrm{r_{c_i}}, ..., \mathrm{r_{c_k}}\}$ in which each specific label is given by a set of pairs of values, attributes and their respective range $r_{(\mathrm{c_i})} = (a_1, [p_1, q_1]), ..., (a_{\mathrm{m(c_i)}},]p_{\mathrm{m(c_i)}}, q_{\mathrm{m(c_i)}}])$ able to better express the associated $\mathrm{c_i}$ cluster.

In order to clarify:

- K is the number of clusters;
- $\mathrm{c_i}$ is any cluster;
- $n^{(c_{\mathrm{i}})}$ is the number of elements in cluster $\mathrm{c_i}$;
- $\vec{e}_{\mathrm{j}}^{\,(c_{\mathrm{i}})}$ refers to the j-th element belonging to cluster $\mathrm{c_i}$;
- m is the dimension of the problem;
- $\mathrm{r_{(c_i)}}$ is the label for cluster $\mathrm{c_i}$;
- $]\mathrm{p_{m(c_i)}},\mathrm{q_{m(c_i)}}]$ represents the values range of attribute $\mathrm{a_{m(c_i)}}$ where $\mathrm{p_{m(c_i)}}$ is lower limit and $\mathrm{q_{m(c_i)}}$ is upper limit;
- $m^{(c_{\mathrm{i}})}$ is the number of attributes present in a label for cluster $\mathrm{c_i}$.

Finally, the method has as input a set of clusters and must present as output a specific label for each group that best defines it, according to the specifications already presented.

III. Related Work

This section addresses some methods for inferring the number of groups in the data clustering process, as well as automatic cluster labeling models that influenced this research, presenting its methodologies and results obtained.

In [15], a model was proposed that can be applied to the segmentation of products for inventory management based on the analysis of three basic principles, which are: history (recency (R)), frequency (F), and money spent (monetary (M)) from the K-means algorithm. Meanwhile, the determination of the optimal number of clusters was evaluated using eight validation indices, namely, Elbow Method, Silhouette Index, Calinski-Harabasz Index, Davies-Bouldin Index, Ratkowski Index, Hubert Index, Ball-Hall and Krzanowski-Lai Index to improve objectivity and accuracy in product segmentation compared to using only one method. The result obtained in all these criteria was 3 clusters, the optimal number of groups, with a low variance between the intra-cluster data, resulting in a high similarity between the elements of the same group.

According to [16], a method was presented to classify the egg production of laying hens in Indonesia based on the K-Means clustering algorithm. The survey data was taken from the National Statistics Center of Indonesia and corresponded to the period from 2018 to 2020 from 34 provinces. To validate the number of groups to be used, the researcher evaluated the Davies Bouldin Index (DBI) criterion for each number of existing clusters, which consists of the ratio between the intra-cluster and inter-cluster distances. In this study, 8 clusters were used, and the DBI value was calculated for each. It was observed that the optimal number of groups is four since it has the lowest DBI value.

A model proposed by [14] groups data based on the centroids of the clusters and uses Artificial Neural Networks (ANN) to generate labels for each of them. Initially, a dataset was provided as input to the model. To obtain better performance for continuous values, a discretization process was performed, in which different possible values for each attribute were divided into intervals, which represent the range of values. In the second stage, the clustering process was carried out using an unsupervised algorithm (K-means). Once the groups were generated, a supervised algorithm (ANN) was applied to each of them, using the discretized base to detect which attributes were relevant in the formation of each generated group. This methodology was applied to three databases (Glass, Seeds, and Iris), and the results were obtained with an average more excellent than 88.79% of correctly labeled elements.

The work of [1] used unsupervised and supervised machine learning methods for data clustering and labeling tasks. To group the data, the DAta MIning COde REpository (DAMICORE) algorithm was used, and to label, the Automated Labeling Method (ALM) based on Artificial Neural Networks (ANN) was used. Before data grouping, the data sets were submitted to the discretization step, and the continuous attributes were discretized by the EWD and EFD methods. The results were compared with those presented in the [13] model, and the analysis showed that applying the ALM method generated better results. The groups formed by DAMICORE are more accurate than those obtained by applying the K-Means cluster, with an average accuracy above 90%.

IV. Proposed Method

This research aims to provide an approach for inferring the number of groups to be used in the grouping process, based on a range of attribute values, with subsequent automatic data labeling from standard deviation to maximize the understanding of the groups obtained. Initially, the new method was validated based on a model already proposed in the literature, that of [14], which developed an algorithm for automatic extraction of the characteristics of the groups, contributing to the interpretability of these clusters.

The algorithm K-means in the proposed model used Python's sklearn library, and the ease and robustness of the environment could provide tests that led to a better understanding of the problem addressed.

Table I presents the four databases used, starting from the UCI Repository[1], including Wine, Breast Cancer, Quality White Wine, and Credit Card.

TABLE I. Databases Obtained from the UCI Repository

Databases	Amount of Data	Attributes
Wine	178	13
Breast Cancer	699	10
Wine Quality White	4.898	12
Credit Card	30.000	24

The methodology used by [14] to aid this task of interpreting clusters is illustrated in Fig. 1.

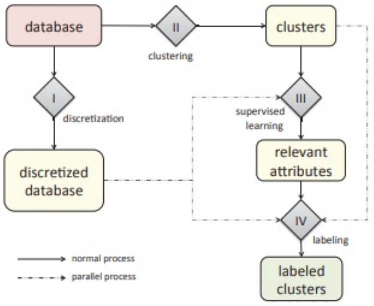

Fig. 1. Labeling template flowchart from [14].

At first, this model receives a database as an input parameter. This base can contain different types of data - discrete or continuous. In some cases, it will be necessary to apply a discretization method (I), which consists of assigning discrete values to attributes that can assume a wide variety of values within a given domain. Thus, the supervised learning algorithm used in step III will be able to identify a possible relationship between attributes with less complexity, showing better results when dealing with the classification problem involving such attributes. According to [17] and [18], there may be an increase in accuracy and speed during the training stage when using a discretization method. In addition, this discretization process allows the inference of a value range, which happens in step IV.

[1] https://archive.ics.uci.edu/ml/index.php

The discretization process starts with selecting which attributes should be discretized and which type to use. Therefore, for this model, the number of ranges of values was defined as FX, and the discretization technique used was by equal frequencies (EFD) to avoid an inadequate distribution of the values of an attribute due to identical elements and consequently cause an imbalance in the distribution of these elements about the ranges of values. In EFD, the number of components with different values between the cut-off points remains constant.

The second step (II) corresponds to using an unsupervised algorithm that receives as input a set of elements (in this case, the database) and presents as output the association of each component to a respective created cluster. The discretized database is not used in this step, but the initially provided database. The algorithm used was K-means, but any other algorithm with unsupervised learning capable of dealing with the clustering problem can be used.

Then step (III), an algorithm with supervised learning is applied to detect the relevant attributes for the definition of each group once the clusters are appropriately formed and the data to be worked on, if necessary, are already discretized. Then, the actual labeling work begins. Each label referring to any group is based on a set of attributes and their respective ranges of values. Therefore, this step has as input a set of clusters and presents as output a set of attributes for each generated group that will be used in its labeling. For this, artificial neural networks of the Multi-Layer Perceptron (MLP) type were used. However, in principle, any other algorithm with supervised learning capable of detecting relationships between variables or any other technique capable of selecting attributes could be chosen. In this case, each neural network presents a hit rate for its learning, performed only with the elements of their respective clusters.

Finally step (IV), a strategy that selects the value (for discrete attributes) or value range (for continuous attributes) for each chosen relevant attribute is applied to generate labels. This strategy seeks to represent the majority of the group so that the selected values for each attribute are those with the highest frequency in the group. The neural network chose the most relevant attributes in step III.

It was noticed, therefore, that the [14] model did not use any inference criteria to optimize the number of groups in the clustering process and did not verify the best amount of range of values for the composition of the labels.

Thus, this research work has the initial intention of providing a method for inferring the optimal number of groups considering different ranges of attribute values, since in the [14] model, as the number of ranges increases of values for the same group K, the hit rate of this model decreases. This fact was found in the four databases used, as shown in Table II.

Based on Table II, this research work developed the method *Optimization of the Number of Clusters Based on a Range of Values* according to the performance analysis (hit rate) of the [14] model to find the optimal number of groups and range of values to be used in the grouping step.

TABLE II. PERFORMANCE ANALYSIS (HIT RATE (%)) FOR VARIATIONS OF K AND VALUE RANGE (FX) ACCORDING TO THE [14] MODEL

WINE	**K=2**	**K=3**	**K=4**	**K=5**	**K=6**
FX=2	95.51	98.96	97.17	98.84	98.90
FX=3	87.29	90.78	96.06	98.21	98.59
FX=4	78.93	86.23	85.07	91.24	92.71
FX=5	71.41	75.36	82.06	87.22	91.88
FX=6	67.27	70.48	73.16	85.84	87.96

BREAST_CANCER	**K=2**	**K=3**	**K=4**	**K=5**	**K=6**
FX=2	91.34	93.41	92.55	92.04	91.58
FX=3	90.48	86.44	91.05	91.86	90.96
FX=4	86.28	82.17	87.67	91.05	89.95
FX=5	77.39	79.98	75.40	80.01	78.70
FX=6	76.90	74.31	74.50	79.17	78.25

WINE QUALITY WHITE	**K=2**	**K=3**	**K=4**	**K=5**	**K=6**
FX=2	99.90	99.98	100	100	100
FX=3	99.50	99.80	99.94	99.96	99.97
FX=4	98.51	98.66	99.10	99.38	99.61
FX=5	97.24	98.14	97.90	98.38	98.74
FX=6	94.34	94.63	96.06	96.98	97.12

CREDIT CARD	**K=2**	**K=3**	**K=4**	**K=5**	**K=6**
FX=2	92.60	99.94	99.96	99.97	99.98
FX=3	91.50	98.80	98.94	98.90	98.92
FX=4	90.51	97.66	97.10	96.96	97.01
FX=5	87.24	94.14	95.90	95.38	95.12
FX=6	85.34	93.63	94.06	93.98	93.06

1) The starting point of the method was to consider the initial K as the element with the highest frequency among the three inference criteria used (Elbow, Silhouette Coefficient, and Calinski-Harabasz) for the same database, which we call fashion. Table III displays the found values.

   Therefore, the initial K for each of the databases was the following: Wine (3), Breast Cancer (2), Wine Quality White (2), and Credit Card (2).

TABLE III. CRITERIA FOR GROUP INFERENCE

Database	**Elbow**	**Silhouette Coefficient**	**Calinski-Harabasz**
Wine	3	2	3
Breast Cancer	2	2	2
Wine Quality White	2	2	2
Credit Card	2	2	3

2) Next, the range of initial value (FX) equal to the chosen K value was selected, that is, FX = K. For example, the Wine database results will be displayed initially. Therefore, K=3 and FX=3;
3) The model's hits rates for K-1 to K+1 were shown, according to Table IV.

TABLE IV. HIT RATE (%) FOR WINE BASE WITH K BETWEEN K-1 AND K+1

WINE	K=2	K=3	K=4
FX=2			
FX=3	87.29	90.78	96.06
FX=4			

4) The highest hit rate among those displayed in the previous step was verified. In this case, the highest rate is 96.06% for K=4 and FX=3.
5) Next, the model's hit rate for FX-1 and FX+1 were presented, as shown in Table V.
6) Finally, there was the highest hit rate among the last ones calculated. In this case, for K=4 and FX=2, it was 97.17% hit, and for K=4 and FX=4, it corresponded to 85.07%. Therefore, for this database, the

TABLE V. HIT RATE (%) FOR WINE BASE WITH FX BETWEEN FX-1 AND FX+1

WINE	K=2	K=3	K=4
FX=2			97.17
FX=3	87.29	90.78	96.06
FX=4			85.07

optimal number of groups and range of values would be K=4 and FX=2 since it was the one that presented the best hit rate. However, in this [13] model, it was found that for this value of K and FX considered optimal, there was partial or complete overlapping of labels in at least two different groups of the same base, considering the same attribute. Therefore, this hit rate is disregarded when such situations occur, and the immediately lower one calculated so far is considered. Therefore, the optimal number of groups and hit rate for the Wine database becomes K=4 and FX=3. Table VI presents what this overlapping is.

TABLE VI. RESULT OF THE GROUP LABELING OF THE [14] MODEL FOR THE WINE DATABASE WITH K=4 AND FX=2

Grupo	Elementos	Rótulo		Análise
		Atributos	Faixa	Êxito (%)
0	66	Proline	276.6∼979.0	100
1	23	Alcohol Malic.Acid OD Proline	12.93∼14.83 0.73∼3.27 2.63∼4.0 979.0∼1680.0	100
2	57	Proline	276.6∼979.0	100
3	32	Malic.acid	0.73∼3.27	88.70

According to Table VI, for the [14] model, considering the Wine base with K=4 and FX=2, the following overlaps were found.

- r_{c_0} = (Proline, [276.6∼979.0]) e r_{c_2} = (Proline, [276.6∼979.0]);
- r_{c_1} = (Malic.Acid, [0.73∼3.27]) e r_{c_3} = (Malic.Acid, [0.73∼3.27]).

It means the proline attribute, in *clusters* 0 and 2, and the malic.acid attribute, in *clusters* 1 and 3, have the same range of values. Therefore, these values overlap and no longer represent a single group, making it difficult to interpret the label.

This method was performed for four databases of different sizes and quantities of attributes. It was found that the optimal number of K groups varies between the mode (referring to values from the Elbow, Silhouette, and Calinski-Harabasz methods) and the mode+1. The range of values varies from K-2 to K-1, according to Table VII. The Algorithm 1 summarizes this proposal in pseudocode.

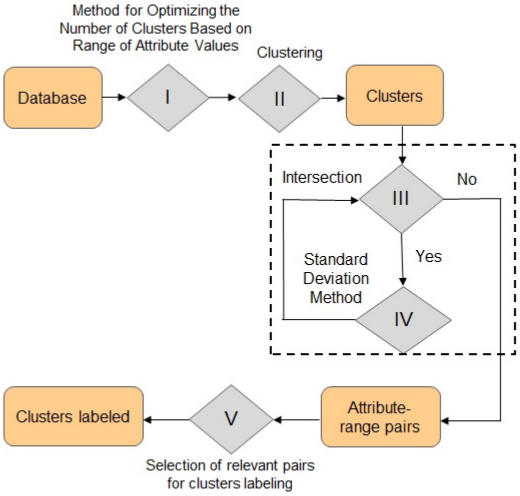
TABLE VII. OPTIMAL NUMBER OF GROUPS AND RANGE OF VALUES

	Optimal Number	
Database	Clusters	Range of Values
Wine	4	3
Breast Cancer	3	2
Wine Quality White	3	2
Credit Card	3	2

Algoritmo 1: Method for Optimizing the Number of Clusters based on the Range of Attribute Values

```
Select initial K by the mode of group inference criteria (Elbow, Silhouette, and
    Calinski-Harabasz);
Make FX = K;
Display the average hit rate of [14]'s method for K between K-1 and K+1;
Display the average method hit rate of [14] for FX between FX-1 and FX+1;
Consider the pair (K, FX) with the highest hit rate of the method among those
    displayed;
while not finding optimal K and FX do
    if complete overlapping of labels in at least two groups of the same base
      then
        Discard the pair (K, FX);
        Search for the next pair (K, FX) whose hit rate is the second highest
    end
    else
        Set the value of K and FX, whose method hit rate is the highest.
    end
end
until Até encontrar K e FX ótimos.
```

Therefore, to develop a more optimized model about the interpretability of the group hit rate and the specificity of the generated labels, considering that no [14] model was found to overlap between ranges of values, assuming the same attribute in different groups, this research work presented a method based on dispersion metrics to solve this limitation of the overlap between ranges of values. The methodology used in this research work went through the following steps, as shown in Fig. 2:



Method for Optimizing the Number of Clusters Based on Range of Attribute Values
Clustering
Database

No
Standard Deviation Method
Yes
IV
Clusters labeled
V
Attribute-range pairs
Selection of relevant pairs for clusters labeling

Fig. 2. Flowchart of the proposed labeling model.

A. Step 1 - Using the Value Range-Based Cluster Quantity Optimization Method

This step consists of using the proposed method based on the mode of the criteria found in the literature (Elbow, Silhouette Coefficient, and Calinski-Harabasz criterion) for the same data set to find the optimal number of clusters based on a range of values to be used in the data grouping and applied to four original databases of different sizes and quantities of attributes (Wine, Breast Cancer, Wine Quality White, and Credit Card), whose result can be seen in Table VII.

B. Step 2 - Clustering Data

After using the proposed method, the next step corresponds to the grouping of the data, which consists of submitting the original database composed of unlabeled examples to an algorithmic solution of unsupervised machine learning for the formation of groups. The basic idea is that elements that comprise the same group must present high similarity but are very dissimilar from objects in other clusters. The K-means algorithm was used for clustering, but any different clustering algorithm can be used.

C. Step 3 - Standard Deviation Method

Mathematically, standard deviation (SD) is a dispersion measure that is used to quantify the amount of variation or dispersion of a set of data values [11]. A low standard deviation value signifies that data points tend to be close to the mean of the set, while a high standard deviation indicates that data points are spread out over a wide range. Equations 2 show how standard deviation calculation is performed.

$$SD = \sqrt{\frac{\sum_{i=1}^{n}(x_{\mathrm{i}} - M_{\mathrm{A}})^2}{n}} \tag{2}$$

For clarification:

- $\mathrm{x_i}$: value at the i position in the dataset.
- $\mathrm{M_A}$: arithmetic mean of the data.
- n: the amount of data.

Based on the use of standard deviation, a formal definition of the method for automatic cluster labeling is presented below:

Given a set of clusters $\mathrm{C_1}$, $\mathrm{C_2}$, $\mathrm{C_3}$...$\mathrm{C_k}$ and $\mathrm{A_1}$, $\mathrm{A_2}$, $\mathrm{A_3}$...$\mathrm{A_n}$ the attributes of this subset, the attribute's values distribution $\mathrm{A_1}$ in group $\mathrm{C_1}$ was represented by $\mathrm{A_1C_1(v_i,\ v_j)}$, where i indicates the minimum value and j the maximum value. The technique updates values by applying $\mathrm{v_i}$+SD, $\mathrm{v_j}$-SD, when necessary, considering as a condition exists or not of an intersection between values that $\mathrm{A_1}$ represents, observing the other groups.

Thus, after grouping performed by K-means, attribute values, observing their representation in each group, are organized into temporary structures in which indexes corresponding to the lowest and highest value are identified (Table VIII). Values contained in this table are random for purposes of the understanding method.

TABLE VIII. Indexing of Attribute Values

Attribute Values	8	5	10	6	7
Indexes	0	1	2	3	4
		min.	max.		
		Range: 5 ∼10			

At that moment, it was necessary to check possible overlapping values range in the same dataset, considering the same attribute.

D. Step 4 - Intersection Check

For each attribute, the existence or not of an intersection between values range is verified. If any overlap is found, the standard deviation of the segment under analysis is then calculated based on the arithmetic mean of distances between smallest and largest values, as seen in Table VIII. The updating of these values that identify the ends is applied, observing the need to increase the lowest value or decrease the highest value or even both procedures that, when performed, count as interactions. This process is carried out until there is no longer any intersection between the labels, considering the same attribute in all clusters in the dataset. Fig. 3 contains a representation of values the update applies to until they no longer overlap.

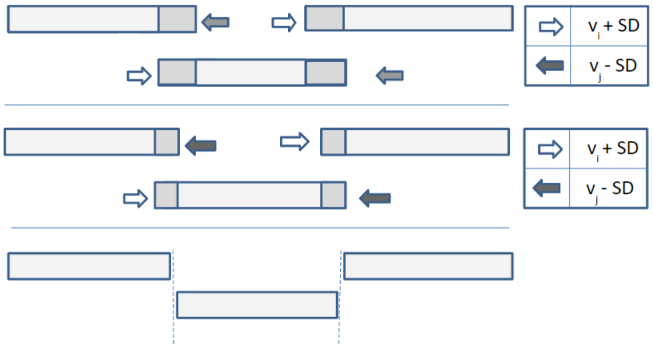

Fig. 3. Sequence of proposed updates.

Considering, for example, the $Petal\_length$ attribute of the Iris dataset, Table IX presents initial values range that represents this characteristic in different groups. In column 1 of this table, groups are identified, column 2 shows the range obtained with grouping, and in columns 3 and 4, operations must be performed when the intersection is found. For this purpose, the standard deviation value found in the respective distribution is applied as an updating factor.

TABLE IX. First SD Iteration for the $Petal\_length$ Attribute of the Iris Dataset

Clusters	Range	Decrement	Increment	SD
C0	3.0 ∼ 5.1	true	false	0.5
C1	1.0 ∼ 1.9	false	false	0.17
C2	4.9 ∼ 6.9	false	true	0.48

This same scenario is also illustrated in Fig. 4. Note that the analyzed attribute overlapped when considering its ranges, which justifies the decrement and increment in $C0$ and $C2$, respectively.

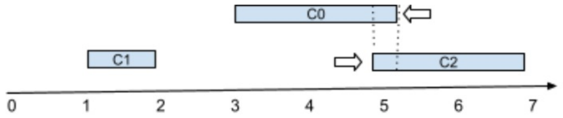

Fig. 4. Scenario described in table IV.

After performing this first iteration, Table X presents the new values resulting from the previous necessary update, also shown in Fig. 5.

TABLE X. SECOND SD ITERATION FOR THE $Petal\_length$ ATTRIBUTE OF THE IRIS DATASET

Clusters	Range	Decrement	Increment	SD
C0	3.0 ∼ 5.0	true	false	0.46
C1	1.0 ∼ 1.9	false	false	0.17
C2	5.0 ∼ 6.9	false	false	0.47

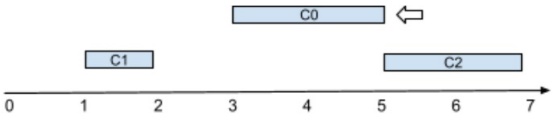

Fig. 5. Scenario described in table V.

Table XI presents data from this update process and verification of possible coincidences in interval segments. As described, it appears that the representation of attribute is distinct in observation of groups formed, thus dispensing with additional iterations. This process can be seen in Fig. 6.

TABLE XI. FINAL RESULT OF THE SD ITERATION FOR THE $Petal\_length$ ATTRIBUTE OF THE IRIS DATASET

Clusters	Range	Decrement	Increment	SD
C0	3.0 ∼ 4.9	false	false	2
C1	1.0 ∼ 1.9	false	false	0
C2	5.0 ∼ 6.9	false	false	1

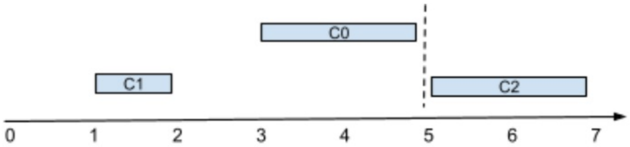

Fig. 6. Scenario described in Table VI.

Algorithm 2 summarizes this Cluster Labeling Proposal in pseudocode, where n is the number of attributes in the dataset, k is the number of groups, and C corresponds to a cluster.

Algoritmo 2: Pseudocode of Cluster Labeling Model Proposed

```
Input: K clusters
for attrA ← 1 until n do
    while there is an intersection of $att_A$ between two groups do
        $C_i \leftarrow 1$
        for $C_j \leftarrow 2$ until k do
            if max. of attrA in $C_i \geq$ min. of attrA in $C_j$ and max. of attrA in
              $C_i \leq$ max. of attrA in $C_j$ then
                decrement max. of $attr_A$ applying standard deviation of
                  $att_A$ distribution
            end
            if if min of attrA in $C_i \geq$ min attrA in $C_j$ and min. of $att_A$ in $C_i$
              $\leq$ max. $att_A$ in $C_j$ then
                increment min. of $att_A$ applying standard deviation of $att_A$
                  distribution
            end
        end
    end
end
```

E. Step 5 - Selection of the Relevant Attribute-Range Pair

This final step of labeling process consists of selecting relevant attribute–range pair for cluster labels composition, ensuring that each label represents specifically and exclusively one cluster. This selection was based on following measure:

1) Correlation Coefficient: Pearson's association [19] reflects direct relationship between two components, i.e. how much variables are associated, and reach out from +1 to - 1. An association of +1 suggests that there is an extraordinary positive direct relationship between elements, while an association of -1 demonstrates that elements have negative relationship. Table XII presents a categorization for Pearson's correlation coefficient values.

TABLE XII. CATEGORIZING FOR PEARSON'S CORRELATION COEFFICIENT VALUES

Correlation Coefficient	Classification
0	Null
0.01 - 0.19	Very weak
0.2 - 0.39	Weak
0.4 - 0.69	Moderate
0.7 - 0.89	Strong
0.9 - 0.99	Very Strong
1	Perfect

Therefore, the pair(s) of attributes that are most positively correlated in each data set are used in the composition of the final labels of the model.

V. RESULTS AND DISCUSSIONS

The results of applying the proposed method are presented with subsequent cluster labeling based on the correlation coefficient for the selection of the most relevant attributes and on the standard deviation metric to improve the specificity of the range of values of each selected attribute to eliminate overlaps between ranges of values, considering the same attribute in different groups.

In addition, the results obtained were compared with other methods proposed in the literature to show that the model guarantees an improvement in the specificity of the labels, reducing the computational effort to generate them.

A. Iris Dataset

Table XIII presents the analysis result for automatic rotation of the Iris database, for K=4 and FX=2 according to the proposed method. A label describes each cluster with a pair of attribute-value ranges, according to Pearson's association [19].

TABLE XIII. ANALYSIS FOR IRIS DATABASE LABELING

Cluster	Elements	Label		Analysis	Iterations
		Attributes	Range	Hits (%)	
0	28	SL	4.3∼6.1	98	2
		SW	2∼3.2	94	6
1	50	PL	0.99∼3.95	100	0
		PW	0.1∼1.3	100	0
2	32	SL	6.1∼7.9	95	5
		PW	1.3∼2.5	100	0
3	40	PL	3.95∼6.9	99	1
		SW	3.2∼4.4	94	6

Iterations correspond to steps to remove, when necessary, an intersection between clusters in the same dataset, considering the same attribute. It means that the number of iterations of the proposed method for each attribute can differ in each cluster, as it will depend on the dispersion of the group's elements about the mean of the data set. For cluster 0 and the SL attribute, for example, two iterations were necessary to obtain the result, while six iterations for the SW attribute of the same cluster were necessary.

The attribute pairs displayed are the ones that best correlate according to Pearson's correlation. The label obtained provides, as an aid to the specialist, the interpretation that:

- Cluster 0 is composed of plants whose sepal length (SL) varies between 4.3 cm and 6.1 cm, and the sepal width (SW) varies between 2 cm and 3.2 cm;
- Cluster 1 is formed by plants whose petal length (PL) varies between 0.99 cm and 3.95 cm, and petal width (PW) varies between 0.1 cm and 1.3 cm;
- Cluster 2 is composed of plants whose sepal length (SL) varies between 6.1 cm and 7.9 cm and petal width (SW) varies between 1.3 cm and 2.5 cm;
- Cluster 3 is composed of plants whose petal length (PL) varies between 3.95 cm and 6.9 cm and sepal width (SW) varies between 3.2 cm and 4.4 cm;

It was verified, therefore, that after executing the proposed method, fewer values are included as the range of values decreases, resulting in a non-overlap between labels generated by the same attribute in different clusters. This fact also occurred with the other data sets used.

The Table XIV displays the result of labeling the method of [20] for the Iris dataset. It was observed that the result was generated after 568 iterations of the method based on degrees of membership, which corresponds to a very high computational cost, in addition to having 12 database elements that could not be labeled. This model, proposed in this research, generated a maximum of six iterations to form labels, corroborating and reducing the computational effort. No criteria were used to infer the optimal number of groups in [20], so the author used K=3 for clustering.

TABLE XIV. Rótulos Gerados Por [20], Considerando a Base De Dados Iris

Cluster	Elements	Label		Analysis
		Attributes	Range	Hits(%)
1	50	PW	0.1 ∼0.6	100
		PL	1 ∼1.9	100
2	52	PL	3.5 ∼5.0	82.69
3	36	PL	5.1 ∼6.9	91.66

Table XV compares the models for the Iris dataset, considering the average hit rate of the labels, the number of attribute-value range pairs, and the maximum number of iterations that compose them.

TABLE XV. Comparison between the Labeling Models, Considering the Iris Database

Model	(%)	Attribute-Range Pairs	Maximum Iterations
Model of [20]	91.45	4	568
Proposed Model	97.5	8	6

In this proposed model, it was observed that the computational cost spent on forming the labels was extremely low, favoring a minimum number of iterations, compared to the [20] model, which presented a lower rate than this research model. Using the proposed method for inferring the optimal amount of *clusters* favored the obtained result. Also, in both methods, no range of attribute values overlapped for the same cluster when considering the same attribute.

B. Wine Dataset

Table XVI displays the analysis result for the Wine data set labeling for K=4 and FX=3 according to the proposed method. The clusters were labeled by alcohol and proline for clusters 0, 1, and 2 and by total phenols and flavanoids for cluster 3, as they are the attributes that best correlate according to the correlation coefficient, with a value of 0.86 for alcohol and proline and 0.64 for WK and LK.

TABLE XVI. Wine Database Labeling Analysis

Cluster	Elements	Label		Analysis	Iterations
		Attributes	Range	(%)	
0	66	Alcohol	12.72 ∼13.5	86.76	8
		Proline	690 ∼937	100	0
1	23	Alcohol	13.51 ∼14.83	86.60	13
		Proline	970 ∼1680	100	0
2	57	Alcohol	11.03 ∼12.7	91.22	7
		Proline	278 ∼590	100	0
3	32	Total phenols	0.98∼1.42	100	0
		Flavanoids	0.34∼1.25	100	0

The clusters were labeled by the attributes Alcohol and Proline and also Total phenols and Flavanoids, as they are the ones that best correlate according to the correlation coefficient and also have the highest rates. The interpretation given by the labels is that:

- Cluster 0 is composed of alcohol between 12.72 and 13.5 and proline between 690 and 937;
- Cluster 1 is composed of alcohol between 13.51 and 14.83 and proline between 970 and 1680;
- Cluster 2 is composed of alcohol between 11.03 and 12.7 and proline between 278 and 590;
- Cluster 3 comprises total phenols between 0.98 and 1.42 and flavanoids between 0.34 and 1.25.

The Table XVII shows the result of labeling the method of [14] for the Wine dataset. No criteria were used to infer the optimal number of groups in lopes, so the author used K=3 for clustering and FX=3 for data labeling.

TABLE XVII. Labels Generated by [14], Considering the Wine Database

Cluster	Elements	Label		Analysis
		Attributes	Range	(%)
0	62	Proline	628.5∼979	85.48
1	47	Proline	979∼1680	97.87
2	69	Proline	278∼628.5	100

Table XVIII compares the models in the Wine dataset, considering the average hit rate and the number of attribute-value range pairs that compose them.

It was found that the proposed model has a higher average hit rate than the [14] model, in addition to not having any overlap between ranges of values. This result was favored using the proposed method to infer the optimal number of *clusters*.

TABLE XVIII. COMPARISON BETWEEN THE LABELING MODELS, CONSIDERING THE WINE DATASET

Template	Wine	
	Average Hit Rate (%)	Attribute-Value Range Pairs
Model of [14]	94.45	3
Proposed Model	95.57	6

C. Seeds Dataset

Table XIX shows the analysis result for labeling the Seeds dataset for K=3 and FX=2 according to the proposed method. The clusters were labeled by perimeter (P) and area (A) for clusters 0 and 1 and by seed width (WK) and seed length (LK) for cluster 2, as these are the attributes that best correlate accordingly, with the correlation coefficient, with a value of 0.99 for P and A and 0.86 for WK and LK.

TABLE XIX. SEED DATABASE LABELING ANALYSIS

Cluster	Elements	Label		Analysis	Iterations
		Attributes	Range	(%)	
0	72	P	12.41 ∼13.78	91.04	7
		A	10.59 ∼13.07	89.56	9
1	61	P	13.82 ∼15.33	87.80	8
		A	13.19 ∼16.44	87.80	9
2	77	WK	3.465∼4.033	100	0
		LK	5.826∼6.675	100	0

The attribute pairs displayed are the ones that best correlate according to Pearson's correlation. The following interpretations can be drawn from the dataset labels:

- In cluster 0, elements have a perimeter (P) from 12.41 cm to 13.78 cm and an area (H) from 10.59 cm^2 to 13.07 cm^2;
- In cluster 1, the elements have a perimeter (W) from 13.82 cm to 15.33 cm and an area (H) from 13.19 cm^2 to 16.44 cm^2;
- In cluster 2, elements have seed width (WK) from 3465 to 4033 and seed length (LK) from 5826 to 6675.

The Table XX presents the result of labeling the method of [14] for the Seeds dataset. No criteria were used to infer the optimal number of groups in [14], so the author used K=3 for clustering and FX=3 for data labeling.

TABLE XX. LABELS GENERATED BY [14], CONSIDERING THE SEEDS DATABASE

Cluster	Elements	Label		Analysis
		Attributes	Range	Hits (%)
0	67	A	12.78 ∼16.14	87.30
		P	13.73 ∼15.18	
1	82	P	12.41 ∼13.73	86.58
		A	10.59 ∼12.18	
2	61	P	15.18 ∼17.25	98.34
		A	16.14 ∼21.18	
		LK	5.826 ∼6.675	
		WK	3.465 ∼4.033	

Table XXI addresses a comparison between models for the Seeds dataset, considering the average hit rate and the number of attribute-value range pairs that compose them.

The average hit rate of this proposed model is higher than the [14] method. No overlapping of the range of attribute values was verified in this model under analysis, in addition to having generated more accurate labels. It was observed that this result was favored due to the proposed method for inferring the optimal number of *clusters*.

TABLE XXI. COMPARISON BETWEEN THE LABELING MODELS, CONSIDERING THE SEEDS DATABASE

Model	Iris	
	Average Hit Rate(%)	Attribute-Range Pairs
Model of [14]	90.74	8
Proposed Model	92.70	6

D. Breast Cancer Dataset

Table XXII presents the analysis result for labeling the Breast Cancer data set for K=3 and FX=2 according to the proposed method. The clusters were labeled by Uniformity of Cell Size (UCS) and Uniformity of Cell Shape (UCSH) for cluster 0, Brand Chromatin (BC) and Uniformity of Cell Size (UCS) for cluster 1 and Brand Chromatin (BC) and Uniformity of Cell Shape (UCSH) for cluster 2, as they are the attributes that best correlate according to the correlation coefficient, with a value of 0.91 for UCSH and UCS, 0.76 for BC and UCS and 0.74 for BC and UCSH.

TABLE XXII. BREAST CANCER DATABASE DATA LABELING ANALYSIS

Cluster	Elements	Label		Analysis	Iterations
		Attributes	Range	Hits (%)	
0	455	UCSH	1 ∼4	97.40	4
		UCS	1 ∼2	82.18	3
1	108	BC	1 ∼4	100	0
		UCS	3 ∼10	98.68	2
2	120	BC	5∼10	100	0
		UCSH	5∼10	96.51	5

Although it is a large database with many attributes, the dispersion of the group elements about the dataset's average is small, which generated a few iterations about the Iris, Wine, and Seeds datasets. The label obtained provides the interpretation that:

- Cluster 0 is composed of elements whose Cell Shape Uniformity (UCSH) varies between 1 and 4 and Cell Size Uniformity (UCS) varies between 1 and 2;
- Cluster 1 is composed of elements whose Soft Chromatin (BC) varies between 1 and 4, and Cell Size Uniformity (UCS) varies between 3 and 10;
- Cluster 2 is made up of elements whose Soft Chromatin (BC) ranges from 5 to 10 and Cell Shape Uniformity (UCSH) ranges from 5 to 10.

The Table XXIII shows the result of labeling the method of [21] for the Breast Cancer dataset. No criteria were used to infer the optimal number of groups in [21], so the author used K=2 for clustering.

TABLE XXIII. LABELS GENERATED BY [21], CONSIDERING THE BREAST CANCER DATABASE

Cluster	Elements	Label		Analysis
		Attributes	Range	Hits(%)
0	232	UCS	1 ∼ 5	99.14
		MA	1 ∼ 10	99.14
		BN	1 ∼ 5.97	99.14
1	451	SECS	2 ∼ 10	99.11
		UCS	1.9 ∼ 10	99.11

Table XXIV presents a comparison between the models of the Breast Cancer data set, considering the average hit rate of the labels and the number of attribute-value range pairs that compose them.

TABLE XXIV. Comparison between the Labeling Models, Considering the Breast Cancer Database

Model	Iris	
	Average Hit Rate(%)	**Attribute-Range Pairs**
Model of [21]	99.13	5
Proposed Model	95.79	6

Despite a slightly lower average hit rate, the proposed model does not have overlapping labels, considering the same attribute. It was observed that in the model proposed by [21], there is an overlapping range of values, which compromises the interpretation of the label since the same label referring to the UCS attribute belongs to more than one *cluster*, that is is, UCS(c_1=[1∼5]) and UCS(c_2=[1.9∼10]).

Considering the four sets of data presented, it was verified that the proposed labeling approach does not offer any overlap between ranges of values of the same data set, considering the same attribute. In addition, the number of iterations was greatly reduced, favoring a low computational cost. It was also found in this proposed model that some ranges of values of certain attributes did not require iterations, given the lack of overlap between labels, when considering the same attribute. In three (Iris, Wine, Seeds) of the four data sets compared, the hit rate for the proposed labeling was higher, considering the use of the proposed method for inferring the optimal amount of *clusters* favored this result. The method considered in this paper is free of errors or biases.

VI. Conclusion

The group inference method developed in this research work proved to be satisfactory, considering that it was able to display an optimal number of clusters correlating the value of K to the range of attribute values, contributing to improving the data grouping process about other criteria existing in the literature separately, such as Elbow, Silhouette Coefficient, and Calinski-Harabasz Criterion.

Through labeling, this work provided an improved approach for group interpretation capable of automatically labeling data without overlapping any range of values in the same dataset, considering the same attribute and still with a reduced computational effort. This study initially used four data sets obtained from the UCI Repository, including Iris, Wine, Seeds, and Breast Cancer.

The results obtained in the experiments showed that the approach contributes to the groups' interpretation. The standard deviation-based labeling model also generated satisfactory results, with an average hit rate above 92% for the data sets. The model guarantees an improvement in the specificity of the labels, reducing the computational effort to generate them compared to other methods proposed in the literature.

Heart Disease Classification and Recommendation by Optimized Features and Adaptive Boost Learning

Pardeep Kumar, Ankit Kumar
Computer Science and Applications, Baba Mastnath University
Asthal Bohar, Rohtak, India

***Abstract*—In recent decades, cardiovascular diseases have eclipsed all others as the main reason for death in both low and middle income countries. Early identification and continuous clinical monitoring can reduce the death rate associated with heart disorders. Neither service is yet accessible, as it requires more intellect, time, and skill to effectively detect cardiac disorders in all circumstances and to advise a patient for 24 hours. In this study, researchers suggested a Machine Learning-based approach to forecast the development of cardiac disease. For precise identification of cardiac disease, an efficient ML technique is required. The proposed method works on five classes, one normal and four diseases. In the research, all classes were assigned a primary task, and recommendations were made based on that. The proposed method optimises feature weighting and selects efficient features. Following feature optimization, adaptive boost learning using tree and KNN bases is used. In the trial, sensitivity improved by 3-4%, specificity by 4-5%, and accuracy by 3-4% compared to the previous approach.**

Keywords*—*Heart disease prediction; heart disease; machine learning; optimization; multi-objective features

I. Introduction

The cardiovascular system, which also includes the lungs, is powered by the heart, a muscular organ which circulates blood throughout the body. The cardiovascular system includes a blood vessel network in addition to arteries, veins, and capillaries. Blood is distributed by these blood vessels all over the body. Cardiac disorders, also known as heart illnesses, are defined by deviations in the normal blood circulation of heart. The leading causes of death globally are heart disorders. Based on a survey conducted by the World Health Organization (WHO), strokes and heart attacks are responsible for 17.5 million deaths worldwide. Over 75% of deaths from heart disease happen in middle-income and low-income countries. In addition, strokes and heart attacks account for 80% of CVD-related mortality [1], [2]. In light of this, the mortality rate from cardiovascular problems can be reduced with the use of early recognition of cardiac abnormalities and prediction tools. Predictive models for cardiovascular disorders can now be developed with the help of the vast amounts of patient data that are readily available thanks to the expansion of modern healthcare infrastructure (i.e. Big Data inside the Electronic Health Records System). Machine learning is a technique for finding new information by analysing large datasets from several angles. Numerous records on patients' health, disease diagnoses, and other topics are created every day in the modern healthcare sector [3], [4], [5]. Many methods for unearthing similarities or hidden patterns in data can be found using machine learning [6], [7], [8], [9]. Machine learning has proved to be beneficial when it comes to making predictions and judgments based on the massive amounts of data collected by businesses in the healthcare industry [7], [8], [9], [10], [11]. Machine learning allows computers to automatically learn from data sets and improve their performance based on past experiences with little to no human input. Each time a ML algorithm makes a good call, it gets smarter. Consequently, in this research, we present a ML algorithm for the development of a cardiovascular disease forecasting tool.

A. GAP in Previous Work

The fundamental challenge with heart disease classification is that there is a limited dataset and just five classifications, thus learning efficiently is critical. In prior work, the following problem was discovered:

- Previous research has ignored feature overlaps and increased noise during learning [1], [2].
- Formerly, the emphasis was mostly on accuracy, which ranged from 40-50% in the case of five classes [4], [5].
- Do not improve the features based on their classification capacity [8], [9].
- Learning with a single classifier that is highly polynomial and increases over fitting [11].
- The majority of research is focused on binary categorization, yet this is not a true condition [12], [13].

B. Contribution of Research

- Apply entropy and information gain constraints to optimize features.
- Optimize feature selection and feature weights by using a genetic algorithm to maximize the Pareto surface.
- Work on feature-by-feature and weighted-features analysis of several performance metrics.
- In brief, optimize feature space and learning through optimizing classifiers.
- Focusing on five classes with high accuracy, sensitivity, and specificity.

II. Related Work

The paper gives an in-depth analysis of how ML can be used to treat cardiovascular disease. We also examine numerous popular literature on predicting the course of heart disease.

Ali et al. (2021) determines which machine learning classifiers provide the most accurate performance for diagnostic applications. Several supervised ML methods were implemented and compared in the prediction of heart disease. For all deployed algorithms except KNN and MLP, feature significance scores were assessed for each feature. All of the features were sorted based on their importance score to identify which ones offer the most reliable predictions of heart illness. Using a heart illness database from Kaggle and three-classification algorithms depending on KNN, DT, and RF, the analysis revealed that the RF method achieved 100% sensitivity, specificity, and accuracy. In this study, Katarya et al. (2021) summarized a portion of the expertise automated processes. Prediction and Feature selection are key components of every automated process. By selecting features effectively, one can attain improved heart disease prediction outcomes. The researchers have demonstrated useful methods for selecting attributes, including the hybrid grid search method and random search algorithm. As per Princy et al. (2020), a cardiac database is classified utilizing multiple cutting-edge Supervised ML algorithms for disease prediction. The findings show that the DT classifying model accurately diagnosed cardiovascular problems more so than the LR, NB, SVM, RF, and KNN approaches. 73% of the time, the Decision Tree produced the best outcome. This strategy could aid physicians in predicting the onset of heart problems and providing adequate treatment. Shah et al. (2020) offers several heart disease-related variables and a model based on supervised learning techniques like DT, NB, KNN, and RF. It utilizes the current database from the Cleveland dataset of UCI's heart disease patient repository. There are 76 attributes and 303 instances in the collection. For the purpose of verifying the efficacy of different approaches, only 14 of these 76 attributes are chosen for testing. The purpose of this report is to illustrate the occurrence of heart disease among patients. As per the results, K-nearest neighbour provides the highest accuracy. Sharma et al. (2020) makes a ML model that uses the relevant parameters to predict heart disease. The scholars used a standard UCI Heart disease prediction database for this research. This database has 14 key factors that are related to heart disease. For the creation of the model, ML techniques such as RF, SVM, DT, and NB, have been utilized. The research has also attempted to identify correlations between the numerous qualities present in the dataset by employing standard ML techniques and then employing these correlations to accurately forecast the likelihood of heart disease. When compared to other ML algorithms, the RF technique provides superior prediction accuracy and processing speed. The use of this system to aid in making decisions, this model may be beneficial to medical professionals in their clinic. Krishnan et al. (2019) used two supervised algorithms for data mining on a dataset to determine the likelihood of a patients experiencing heart disease, which were analyzed using classification models such as DT Classification and NB Classifier. These two algorithms were compared on a similar dataset to evaluate which one was the most accurate. The Decision Tree model accurately predicted the cardiovascular disease patient 91% of the time, while the Nave Bayes classifier correctly guessed the heart disease patient 87% of the time. Mohan et al. (2019) strategies and related cardiovascular disease prediction via hybrid ML techniques, with the purpose of discovering essential aspects by applying ML hence boosting the accuracy in the detection of cardiovascular illness. The expectation model consists of common feature groupings and their numerous permutations. The predictive model for cardiovascular illness with hybrid RF using a linear model allows the research teams to produce an improved exhibition level with a precision level of 88.7 percent (Table I). Individuals also informed about various data mining methods and assumption methods, for example, LR, KNN, NN, SVM, and Vote, which have recently been fairly popular in distinguishing and predicting heart disease. Santhana et al. (2019) detect cardiovascular disease in male patients using categorization approaches. This document offers exhaustive information on Cardiac Heart Diseases, including Risk Factors, Facts, and Frequent Type. WEKA seems to be the Data Mining tool used, and it is a great Computational Tool for Bioinformatics Fields. All three WEKA interfaces are used here; NB, ANNs, and DT are the main methods of data mining employed in this system to forecast heart disease. DTs such as C4.5, CART, CHAID, ID3, and J48 Algorithms, and NBs Techniques are commonly used for prediction. Gavhane et al. (2018) trained and examined the dataset using the multi-layer perceptron (MLP) neural network algorithm. Any number of input layers, output layers, and hidden units may be present in this algorithm. To achieve their desired effect, these hidden layers connect all input nodes to all output nodes. This bond is allocated weights. To achieve equilibrium in the perceptron, a second identity input, bias, with weight b, would indeed be introduced into the node. The nature of the nodes' connections to one another (feedforward or feedback) is determined by the task being performed. Li et al. (2018) have created an efficient ML-based approach for the diagnosis of cardiac disease. System design utilizes ML classifiers including ANN, K-NN, NB, SVM, and DT. Four classic feature selection methods, comprising MRMR, Relief, LLBFS, and LASSO, in addition, the issue of feature selection was addressed by employing a unique feature selection method. The system uses the LOSO cross-validation approach to select the optimal hyperparameters. The system is evaluated utilizing the Cleveland cardiovascular disease database.

III. Proposed System

A. Dataset

In experiment use ‘‘https://archive.ics.uci.edu/ml/datasets/heart+disease” data set for classification and recommendation in which total 303 instances, five classes and thirteen features (see Fig. 1 and 2).

Steps for Analysis

Entropy=$\sum_{j=1}^{N} P_i ly_s P_i$ .... (1)

ly_srepresent classes

$P_i$probability of Instance

Information gain=1-Entropy.................(2)

Step 1: Input heart disease dataset with features and labels.

Step 2: Features optimize by multi-objective optimization by this process given the efficient weight to features. In equation (3), E represent Entropy IG represent Information gain

Step 3: After crossover finish go to efficient Pareto space using following activation function or fitness function.

$$d\left(C_i, C_J\right) = \sum_{i=1}^{M} \left(W_i X_{i,J} - W_i X_i\right| \ldots\ldots\ldots\ldots..(4)$$

It finds the two-class distance and according to it finds Pareto space, here C_i, C_J are the classes, W_i are the weights as per the features.

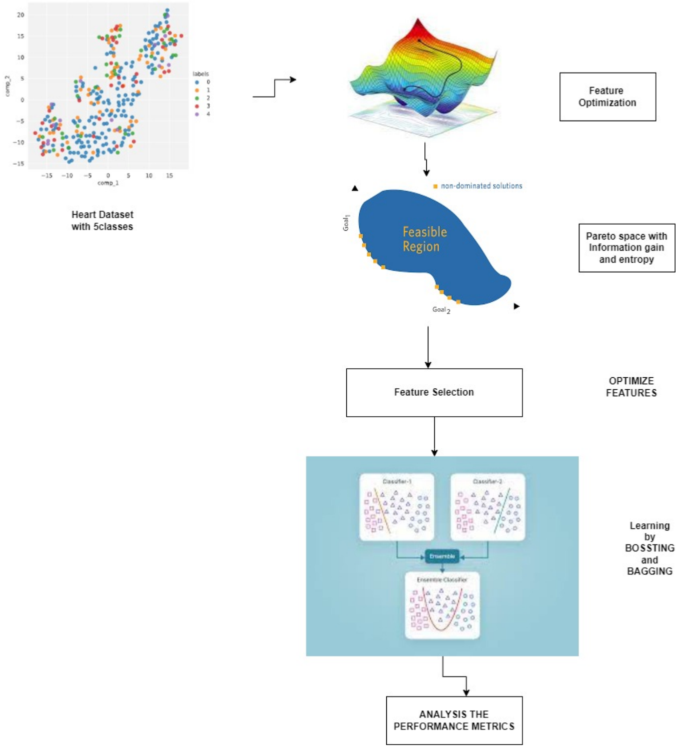

Fig. 2. Proposed classification approach.

Step 4: After finding the Pareto space optimize weight.

$$\delta^z = \frac{(\delta^z|^T.1}{\sum_{i=1}^{M}(\delta^K|^T.1} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..(5)$$

By equation (5) find the optimal solution in space of δ^z then

Step 5:

$$z = \underset{k}{max} \delta^k \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots...(6)$$

$$w = argmax\ (z) \ldots\ldots\ldots\ldots\ldots\ldots\ldots....(7)$$

By this find the maximize optimal weights o features

Step 6: After optimizing the weights of the weighted feature learn by classifier.

$$C_N\,(.) = \sum_{i=1}^{N} C_N * W_N\,(.) \ldots\ldots\ldots\ldots.(8)$$

$C_N\,(.)$Boosting Classifier

C_NN number of weak classifier

$W_N\,(.)$weight of features

After boosting all the possibilities send it to Bagging approach

$$B = \sum_{i=1}^{K} C_K\,(.) * \sum_{i=1}^{K} W_i \ldots\ldots\ldots\ldots.(9)$$

CM=$\alpha C_N\,(.)$+1-$\alpha\,(\delta_K) \ldots\ldots\ldots\ldots.(10)$

By (9) use bagging and use (10) for combining both develop a classification model. Here α is the learning parameter $\alpha[0,1]$

Step7: After step 6 recommendation part, according to Fig. 1, test one instance and according to predict class recommend the suggestion

IV. Experimental Results and Discussion

. Adaptive Boosting KNN with 60% accuracy outperforms Adaptive Boosting-Tree (54.34%), Adaptive Boosting (45.34%), KNN (40.2%), and SVM (40.11%) while using 5 features. Adaptive Boosting KNN with 70% accuracy outperforms Adaptive Boosting-Tree (50.12%), SVM (41.2%), Adaptive Boosting (40.12%) [2], and KNN (34.34%) [3] when using 6 features. With 8 features, however, Adaptive Boosting KNN (67.34%) achieves the highest accuracy, followed by Adaptive Boosting (47.44%), Adaptive Boosting-Tree (45.23%), KNN (42.12%), and SVM (40.34%). Similarly, with 10 features, Adaptive Boosting KNN (65%) achieves the highest accuracy, followed by Adaptive Boosting (48.12%), Adaptive Boosting-Tree (47.34%), SVM (39.5%), and KNN (36.44%). Adaptive Boosting KNN delivers superior accuracy with 12 and 13 features compared to previous approaches (Table II).

The comparison of the various features depending on their degrees of accuracy is shown in Fig. 3. When compared to other approaches, the accuracy that Adaptive Boosting KNN provides is far superior (Table III).

13	56.12	40.12	58.12	60.12	62

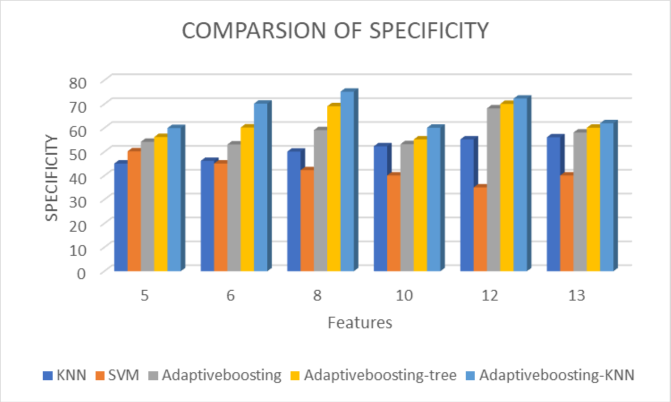

Fig. 5. Specificity-based comparison.

V. Observation of Results

- In the results, we compared existing and proposed adaptive boost approaches. There are three variants of adaptive boost in the results: one is basic adaptive boost, another is hybridized with tree, and the third is hybridized with KNN.
- Using multi–objective genetic optimization, features are given the appropriate weighting in all of the proposed methods. It makes sure that features don't overlap and boosts performance, as shown in the figures above.
- Adaptive boost tree improves all measures of performance because entropy and information gain map well on tree-based approaches.
- By maximizing performance improvement in sensitivity, the proposed model's recall value is raised.

VI. Conclusion

The long-term preservation of people's existence and the early detection of irregularities in heart problems will be made possible by recognizing the processing of primary health records of heart data. In order to process the raw data and deliver a new and unique insight towards heart disease, methods based on machine learning were applied in this study. Prediction of heart disease is difficult and crucial in the medical industry. However, if the disease is discovered in its initial stages and preventive measures are implemented as soon as feasible, the fatality rate can be significantly reduced. The proposed approach employs a five-class classification system to improve the diagnosis of specific heart disease and the subsequent recommendation. As a result, improving classification sensitivity is a significant task. Sensitivity is improved through feature optimization, and ensemble learning is enhanced through bagging and boosting. In comparison to traditional SVM and KNN methods, a 5% gain in sensitivity is highly significant.

In future, we enhance this work using non-linear mapping by deep learning approach and make optimize latent space for reducing overlapping between classes

***Abstract*—Hand Gesture Recognition (HGR) refers to identifying various hand postures used in Sign Language Recognition (SLR) and Human Computer Interaction (HCI) applications. Complex background in uncontrolled environmental condition is the major challenging issue which impacts the recognition accuracy of HGR system. This can be effectively addressed by discarding the background using suitable semantic segmentation method, where it predicts the hand region pixels into foreground and rest of the pixels into background. In this paper, we have analyzed and evaluated well known semantic segmentation architectures for hand region segmentation using both RGB and depth data. Further, ensemble of segmented RGB and depth stream is used for hand gesture classification through probability score fusion. Experimental results shows that the proposed novel framework of Semantic Segmentation and Ensemble Classification (SSEC) is suitable for static hand gesture recognition and achieved F1-score of 88.91% on OUHANDS test dataset.**

Keywords*—*Hand gesture recognition; semantic segmentation; ensemble classification; score fusion

I. Introduction

Hand gestures plays significant role in many real time applications like robotics control, gaming, 3D modeling, virtual environment etc,. Various methods are used to detect and recognize the hand gestures depending on the data acquisition and processing system [1] [2]. Hand gesture recognition systems can be broadly classified into sensor based and vision based systems.

In sensor based systems, data is captured using the sensor modules connected to the hand which converts the hand movements into varying time series signal. These devices captures the hand movement data very precisely but not ease for usage as it impose the constraint to wear the device and not supporting the contact less operation [3] [4].

In vision based systems, RGB cameras are widely used to capture the hand pose data as color images. Vision based systems involve hand detection or segmentation as one of the important pre-processing step involved in gesture recognition pipeline to localize the hand region and discard the background in the image [5]. Feature extraction methods are used on the segmented hand data to obtain its characteristic representation which are used in classification stage to effectively recognize the various hand gestures. Current state-of-the-art recognition systems based on the color image data face many challenges in hand segmentation and recognition due to the complex background and varying illumination conditions. Gestures performed by various subjects differing in their hand size and color is difficult to identify due to large intra-class and inter-class variations. Addressing these issues is difficult by using the color modality data. Hence recent systems are developed on dual modality using RGB and Depth data known as RGB-D data. In these systems, data is simultaneously captured using both color and depth sensor to obtain the RGB-D aligned data pair registered on the same view of camera coordinate system [6].

Depth map can be obtained using various techniques like stereo, time-of-flight of IR etc., where it provides the distance information between depth sensor and the object scene [7]. Kinect device sensor uses time-of-flight between the emitted IR light and the reflected light on projector to provide raw depth map in which each pixel location represents the distance in millimeter. Depth modality can be effectively used to discard the far away background based on depth distance range. It helps in effective hand segmentation to group hand region pixels into foreground and rest of the image pixels into background [8]. Also in case of low light scenarios RGB sensors fails to capture the data, this issue can be resolved using Kinect depth sensor as it captures the data using IR light.

Various image processing and computer vision algorithms are discussed in literature for hand region segmentation. According to recent studies, CNN architectures are widely used to address various real time problems and segmentation is one of the majorly studied area. CNN based semantic segmentation networks performs pixel level localization of region of interest where it classifies each pixel into its corresponding segmentation class. It provides the fine boundary of each distinct region mapped to the unique segmentation class.

In this paper, we analyzed various segmentation methods on RGB and depth data and provided comparative analysis to identify the best suitable method for hand segmentation.

The organization of the paper is as follows. In Section II, a brief review of different methods that exist in vision based hand gesture recognition is presented. In Section III, problem statement and the proposed method is discussed. In Section IV, detailed experimental results is presented. Experimental outcomes are briefly discussed in Section V. Finally, conclusion is drawn in Section VI mentioning the limitation of current work and scope of future work.

II. Literature Review

In this section, we discuss on the state-of-the-art methods for hand region segmentation and gesture classification along with their advantages and limitations.

Earlier approaches of hand segmentation in color image were based on color intensity thresholding in RGB, HSV, YCbCr and other color spaces [9]. In these methods suitable color range was identified based on the experimentation to segment the skin region. Limitation of this approach is difficulty in selecting the threshold range to segment all variation of skin color and the lighting variations which significantly affect the segmentation accuracy.

Hand region segmentation based on human skin tones was proposed in [10] using an MLP network to learn the skin color tones and classify the pixels of image which belongs to the skin color sets.

User independent recognition system using low-cost Microsoft Kinect depth sensor was proposed in [11] to overcome illumination and background variations issue in color-based sign language recognition. Here hand region was segmented by using a pre-processing algorithm on depth image. Features are extracted from hand segmented data using CNN based unsupervised Principal Component Analysis Network (PCANet) and classified using Support Vector Machine (SVM) classifier.

Real-time hand gesture recognition method was put forth in [12] using light-weight semantic segmentation method (FASSD-Net) to produce hand segmentation masks which are combined with RGB frames in gesture classification using Temporal Segment Networks (TSN) and Temporal Shift Modules (TSM) tested on IPN Hand dataset.

Various interactive methods like Graph cut, Random walker, geodesic star convexity etc., were analyzed in [13] for hand region segmentation. Five distinct types of hand motions in various backdrops were tested using the Expectation Maximum technique to learn the parameters of the Gaussian Mixture Model and the Gibbs random field to image segmentation by minimising the Gibbs Energy using the Mincut theorem. According to experimental findings, utilising manually segmented photos improves recognition accuracy when compared to unsegmented images.

Bin et. al [14] proposed a fine-tuned Inception V3 RGB-D static gesture recognition method. This framework eliminates the gesture segmentation and feature extraction steps in traditional algorithms. The proposed framework consists of a CNN architecture in which feature concatenate layer concatenates the features of RGB and depth images. Compared with general CNN, the Inception V3 based gesture recognition resulted in improved accuracy.

D Kumar et. al [15] proposed a two stage approach for static hand gesture recognition using RGB-D data. In first stage k-means clustering algorithm is applied on the depth image to cluster the foreground and background depth pixels based on the distance. Depth threshold is computed as the mean of cluster centers and using this dynamic threshold background is discarded. In classification stage, segmented RGB-D data is stacked to form the input to data layer of custom CNN network.

Coarse to fine segmentation approach using depth map was proposed in [8] where pre-trained YOLO-v3 model was used to detect and localize the hand region at coarse level. The hand detected bounding region was used to initialize the foreground in graph cut segmentation algorithm which refines the hand region boundary and discards the background. Hand segmented RGB-D data was further used in classification stage to recognize the hand gestures.

The hand region in the depth map was segmented using the depth thresholding approach in [16]. Additionally, a two stream network with AlexNet and VGG16 was employed using score-level fusion technique to recognise the static hand gestures from the datasets from Massey University (MU) and HUST American Sign Language (HUST-ASL) with accuracy of 98.14 % and 64.55 % respectively.

Hand Gesture Recognition Approach called HGRA on RGB data using two stream was proposed by [17], in first branch U-Net combined with Multi-Scale Attention module is used to segment the hand region and extracting shape features. In second branch, Multi-Scale Fusion (MSF) and Light-Weight Multi-Scale (LWMS) modules are used to extract multi-scale appearance and color features. This method was evaluated on OUHANDS and HGR1 datasets and achieved the accuracy of 90.9% and 83.8% respectively.

Three stage spatial attention-based neural network was proposed in [18]. First two stages include generation of feature vector and attention map with the feature extraction architecture and self-attention technique. Final feature is generated after multiplying the features and attention map and feed to classification module in third stage to predict the label of hand gesture. This model achieved 99.75%, 99.46% and 99.67% accuracy in Kinematic, NTU and senz3D datasets respectively.

Dual-stream dense residual fusion network(DeReFNet) was proposed in [19] which utilizes the strength of global features and spatial information from the residual stream and other stream. Both the streams are fused using the feature concatenation module. Subject-independent cross-validation technique is used to validate DeReFNet four publicly available benchmark datasets.

Kinect sensor device is used to capture hand gesture depth images. Serial binary image extraction is used in [20] to eliminate the undesired shadow region in depth image and improve the recognition accuracy using VGG-type CNN. Emergence of industry 4.0 with need of natural human-robot interaction in manufacturing using vision-based and wearable-based approaches for gesture-based interaction is discussed in [21]. Position data from Microsoft Kinect RGB-D cameras and acceleration data from inertial measurement units (IMUs) is compared to evaluate the recognition accuracy.

Based on the brief literature review it can be observed that most of the recent research in hand gesture recognition use RGB-D data. Early methods of hand region segmentation used skin color based segmentation in different color space, later CNN based semantic segmentation methods gained much attention due to its efficiency and robustness even in complex scene. Depth modality can be used both in segmentation and classification, hence active research is being carried out in state-of-the art methods to evaluate various ensembling and fusion techniques of RGB and Depth modalities [22]. In further section, we discuss about the details of proposed method and experimental analysis.

III. Proposed Method

Based on the literature review, it is evident that hand gesture recognition is still an active area of research trying to solve the challenges of gesture recognition is real scenarios with complex background scene and varying lighting conditions. Current research methods have also showed that multi-modal RGB and depth stream data is effective than uni-modal RGB data for hand gesture recognition.

In this paper, we analyze various semantic segmentation methods to effectively segment the hand region using RGB and Depth stream data. Hand segmented RGB and Depth data are further used to train custom CNN model for gesture classification. Suitable approach for fusing the probability scores from both the models are analyzed and proposed ensemble classification framework for static hand gesture recognition.

The main contributions of this paper are:

1) Analysis of semantic segmentation model accuracy using RGB data, depth data and combined RGB-D data.
2) Proposed the ensemble approach of score fusion for static HGR classification on RGB and Depth data.

A. Semantic Segmentation

Semantic segmentation is a pixel-based classification in which each pixel of an image is classified to its corresponding class. Here the class labels of all the pixels of image are predicted, hence segmentation is also termed as dense prediction. Hand region segmentation is a binary case of segmentation which has two output class and provides the pixel level mapping into required foreground and background regions as in Fig. 1. In this work, we evaluate various CNN architectures like UNet, ResUNet and DeeplabV3-Plus for semantic segmentation of hand region on both RGB and Depth data.

B. UNet

U-Net architecture [23] adopts auto-encoder framework which consists of two components known as encoder and decoder as in Fig. 1. Encoder generates the compressed feature representation of the image using down sampling and strided convolution, these features contribute in classifying the pixels into its corresponding segmentation class. The encoder and decoder layers are symmetrical to each other. Decoder includes up-sampling and transpose convolution which generates the output segmentation map which has the same resolution as the input image to segmentation model. The least squares reconstruction error is back propagated from the decoder to encoder using which the weights are updated to obtain optimal feature representation.

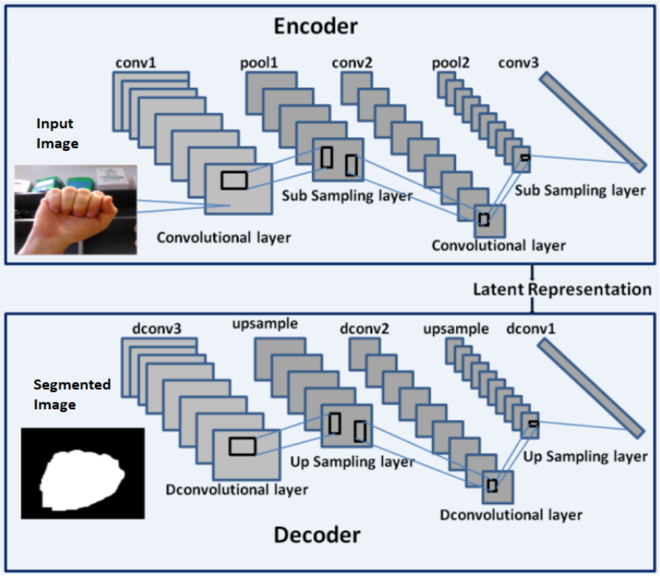

Fig. 1. Auto-encoder based segmentation network.

Encoder generally have the following sub layers, Convolution layer, Relu activation layer and pooling layer. The input image is fed in to the data layer followed by convolution layer which consists of filter of size 3x3 followed by Relu activation to add non-linearity. In the subsequent layers the number of kernels is doubled with constant kernel size and the max pooling layer is used to reduce or down sample the feature map and to maintain the local dominant features in the image patch. Here we have modified original architecture by removing last block of convolution layers and used only three blocks which consists of two convolution layers in each block for model convergence.

Decoder is used to reconstruct the input image using the reduced representation from encoder layer. Encoded input images are decoded by a series of up sampling and de-convolution block. The up-sampling operation of the decoder layers use the max-pooling indices of the corresponding encoder layers. The decoder architecture follows certain pattern based on its encoder design, where the decoder is mirror replica of encoder. The decoded image is evaluated against the input image while self learning the feature representation.

C. ResUNet

Residual U-Net [24] is a semantic segmentation network in which the residual blocks are used in encoder and decoder block of U-Net architecture. This residual learning helps to improve the U-Net results and only with fewer parameters. Fig. 3 shows the basic unit blocks of U-Net (a) and ResUnet (b). Each residual unit can be mathematically shown as in Eq.1.

$$\begin{aligned} y_l = h(X_l) + F(X_l, W_l), \\ X_l + 1 = f(y_l) \end{aligned} \tag{1}$$

where X_l and $X_l + 1$ are the input and output of the l^{th} residual unit, F is the residual function, $f(y_l)$ is activation function and $h(X_l)$ is a identity mapping function, where $h(X_l) = X_l$.

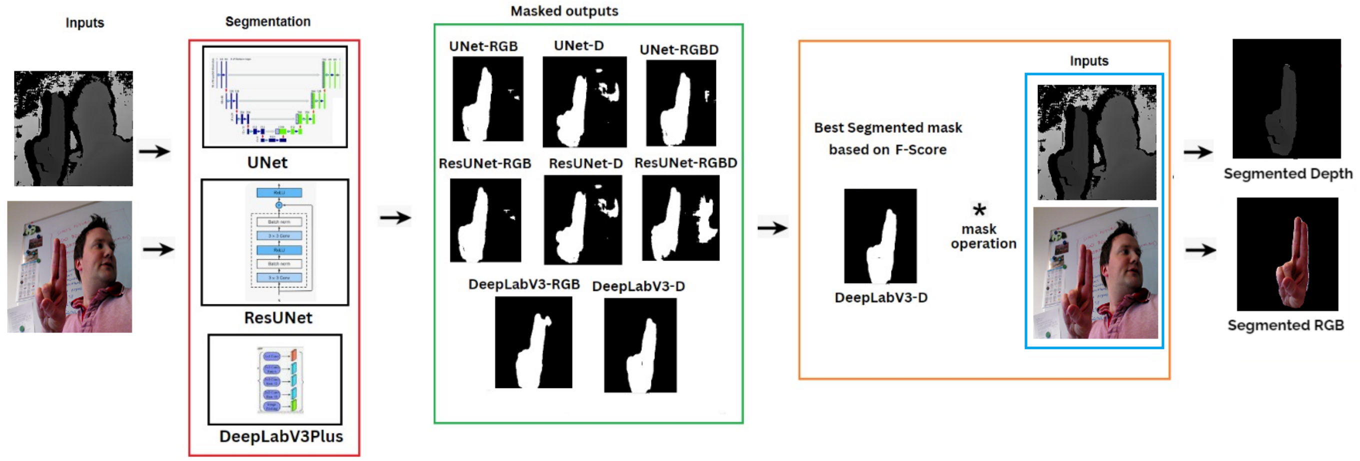

Fig. 2. Block diagram of RGB-D semantic segmentation analysis.

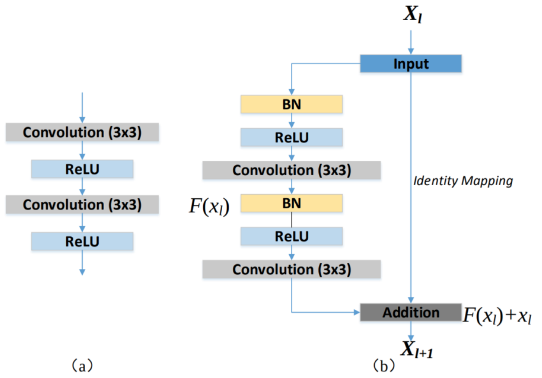

Fig. 3. (a) U-Net unit block and (b) ResUnet unit block.

ResUnet comprises of three parts built with residual units, encoding, bridge and decoding. The first part encodes the input image into latent feature representation. Second part forms a bridge connecting the encoding and decoding paths. Third part of decoding provides the semantic labels to each pixel by pixel-wise classification. Each residual units consists identity mapping and two 3 × 3 convolution blocks with BN layer and ReLU activation layer. The identity mapping connects the inputs and outputs of the unit. Decoding path consists of three residual units and concatenated with the feature maps from the corresponding encoding path. After the last level of decoding path, a 1 × 1 convolution and a sigmoid activation to obtain desired segmentation.

D. DeepLab-V3+

DeepLabv3+ [25] is the extended version of DeepLabv3 segmentation architecture. It follows encoder-decoder structure with Atrous Spatial Pyramid Pooling (ASPP) module in the encoder block. Hence encoder module processes multi-scale contextual information at multiple rates and multiple effective fields-of-view by applying dilated convolution at multiple scales. The decoder module with depthwise separable convolution refines the segmentation results along object boundaries by gradually recovering the spatial information.

Fig. 2 shows the block diagram of segmentation architecture analysis. UNet and ResUnet models are trained on RGB, Depth and stacked RGB-D data, DeepLabv3+ is trained on RGB and Depth data. All these models are trained separately and results are analyzed using mean IoU (Intersection over Union), average F1-score metrics. DeepLabv3+ trained on depth data gave better accuracy with comparatively less parameters, hence this model is selected as the best model for hand region segmentation. Predicted binary segmentation mask from this model is combined with RGB and depth data to obtain segmented RGB and segmented Depth data, this data is further used as input to the classification model.

E. Ensemble Classification

Classification block diagram is depicted in Fig. 4, where two classification models using segmented RGB and segmented depth data stream are trained independently using the custom CNN network as shown in Table I. Further, the classification probability of segmented RGB and depth model are analyzed and fused using max and average operator to select the best classification model.

Custom CNN-Net architecture in Table I consists of four groups with two layers of convolution CONV2D and RELU activation, Batch normalization and Max pooling. The number of kernels is increased as [16, 32, 64, 128] in subsequent groups. Global average pooling layer is used to get final feature map, two fully connected layers are used followed by Softmax activation to get the probability output of each class.

Model is trained using Adam optimizer with learning rate of 0.001 and categorical cross-entropy is used as loss function. Batch normalization and drop out layers are used avoid the model from over-fitting. RGB and depth data from OUHANDS dataset is resized to 320 x 320 and segmented using the binary mask obtained from Deeplabv3+ depth segmentation model.

Two classification models are trained using the segmented RGB and depth data, these models are evaluated on the test data and the miss-classified images are analyzed. It is observed that some of the images that were wrongly classified in the RGB stream are detected properly in the depth stream and

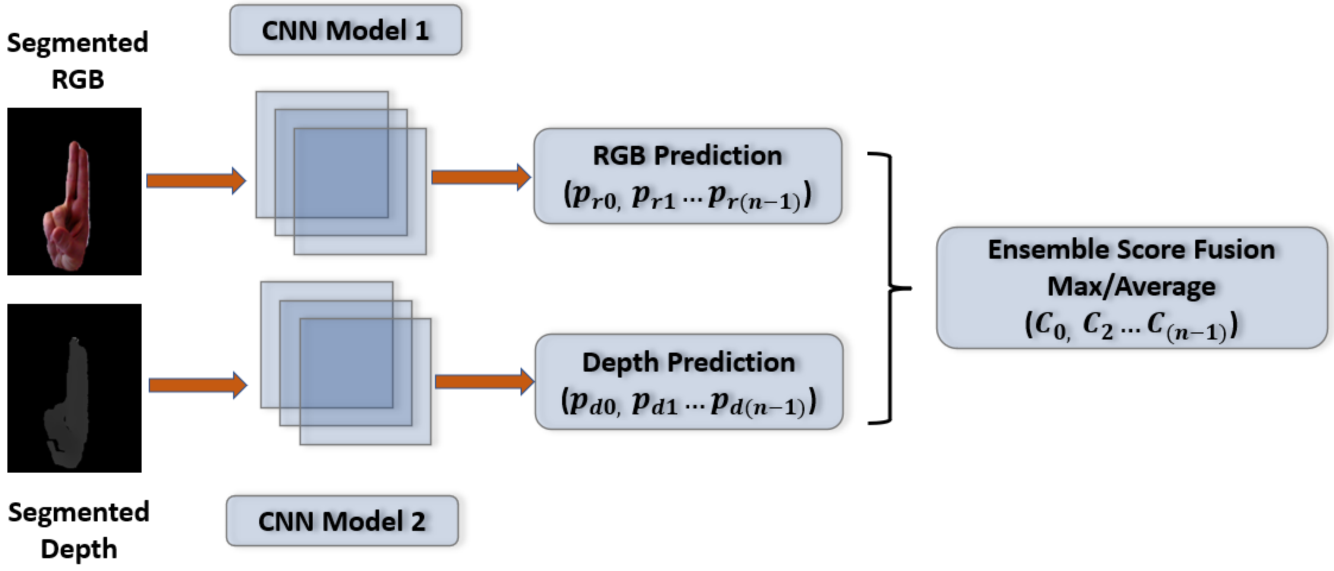

Fig. 4. Block diagram of ensemble score fusion for hand gesture classification.

Global average pooling	gap2d_1	(128)
Dense	dense_1	(64)
RELU	activation_1	(64)
Dropout (0.5)	dropout_1	(64)
Dense	dense_2	(10)
Softmax Activation	activation_2	(10)

vice versa, hence this forms the basis to build a score fusion ensemble model with both RGB and depth stream which gives better accuracy as compared to the uni-modal results.

Let $P_R = (p_{r0}, p_{r1}, p_{r2} \ldots . p_{r(n-1)})$ and $P_D = (p_{d0}, p_{d1}, p_{d2} \ldots . p_{d(n-1)})$ be the probability vectors obtained from RGB stream and depth stream respectively, where $n = 10$ represents the number of class.

$$P_{E_{(max)}} = (max(p_{r0}, p_{d0}), max(p_{r1}, p_{d1}), \\ max(p_{r2}, p_{d2}) \ldots . max(p_{r(n-1)}, p_{d(n-1)})) \tag{2}$$

$$P_{E_{(avg)}} = 0.5 * ((p_{r0} + p_{d0}), (p_{r1} + p_{d1}), \\ (p_{r2} + p_{d2}) \ldots . (p_{r(n-1)} + p_{d(n-1)})) \tag{3}$$

Probability score fusion of max and average methods is mathematically shown in Eq. 2 and Eq. 3. In max fusion, maximum value of RGB and depth probability is considered for each class, where in average fusion mean probability is taken. Further, max of these fused probability is taken to decide the class label of ensemble classification model. From the experiments, it is found the average fusion gives better results as compared to max fusion.

F. Evaluation Metrics

Most commonly used principal measures to evaluate semantic segmentation and classification performance are briefly explained below.

Intersection over Union (IoU) - It is computed as intersection of the pixels from a given class in the predicted results with the ground truth divided by their union. IoU is computed class wise in case of multi-class segmentation. In our work, it is binary case of foreground hand region and the background hence only the class of pixels belonging to foreground is considered.

$$IoU = \frac{T_p}{T_p + F_p + F_n} = \frac{c_{jj}}{c_{ij} + c_{ji} + c_{jj}} i \neq j \tag{4}$$

where, c_{jj} = T_p is the number of pixels which are labeled as class j in ground truth and also predicted as class j, c_{ij} = F_p is the number of pixels which are labeled as class i, but classified as class j that is False Positives class for class j. Similarly, c_{ji} = F_n , the total number of pixels labeled as class j, but classified as class i are the False Negatives (misses) for class j.

Mean Intersection over Union (mIoU): mIoU is the class-averaged IoU across all the images, where k is the number of class.

$$mIoU = \frac{1}{k} \sum_{j=1}^{k} \frac{c_{jj}}{c_{ij} + c_{ji} + c_{jj}} \tag{5}$$

Precision - It is the ratio of hits over summation of hits and false alarms. It indicates total positive cases predicted correctly, over all the predicted positive cases.

$$Precision = \frac{T_p}{T_p + F_p} = \frac{c_{jj}}{c_{ij} + c_{jj}} i \neq j \quad (6)$$

Recall - It is the ratio of hits over summation of hits and misses. It indicates total positive cases predicted correctly, over all the actual positive cases.

$$Recall = \frac{T_p}{T_p + F_n} = \frac{c_{jj}}{c_{ji} + c_{jj}} i \neq j \quad (7)$$

F1score - This measure also known as the dice coefficient, computed as harmonic mean of the precision and recall.

$$F1_{score} = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (8)$$

In this work precision, recall and F1-score are computed for both segmentation and classification models. In segmentation predicted pixel class is considered whereas in classification predicted image class label. Additionally IoU metrics are used to evaluate segmentation models.

IV. Experimental Results

The appraise the proposed semantic segmentation and ensemble classification framework, experiments are conducted on widely used benchmark OUHANDS [26] dataset for static hand gesture recognition. The experiments are performed using TensorFlow2.0 Keras deep learning library in Google Colab environment with NVIDIA GPU.

OUHANDS dataset [26] - contains RGB, raw depth data and segmentation ground truth images. It consists of 10 unique gestures captured in complex backgrounds and lighting changes from 23 subjects with different hand gesture sizes and shapes. Training dataset consists of 2000 images split into 1600 for training, 400 for validation. Test dataset contains 1000 images of the unseen individuals in the training set. All images in the training and test datasets are resized to 320 x 320 image resolution and used in segmentation and classification.

As depicted in Fig. 2, We have chosen three well known segmentation networks namely: UNet, ResUNet and DeepLabV3+. RGB and Depth images are used as input into these networks, which outcomes the hand region segmented mask. We trained these networks with various type of input data like RGB, Depth and the stacked RGBD data. Out of these 3 combination Depth data based model gave better accuracy with fine segmented hand region mask.

As shown in Table II, it can be observed that DeepLabV3+ segmentation results are better than UNet and ResUNet models. Also it can be observed that, the Depth data based based models provide better F1-score as compared to RGB data and stacked RGBD data. The DeepLabV3+ depth segmentation model resulted in the highest F1 score of 0.9235 compared to other networks.

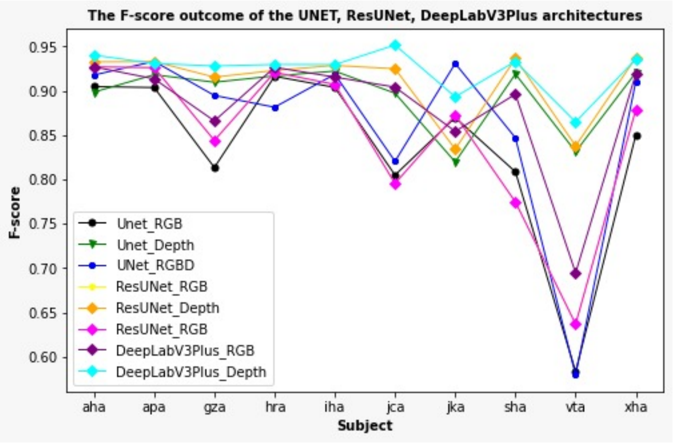

Fig. 5. Analysis of segmentation F1-score outcome by various networks specific to each subject.

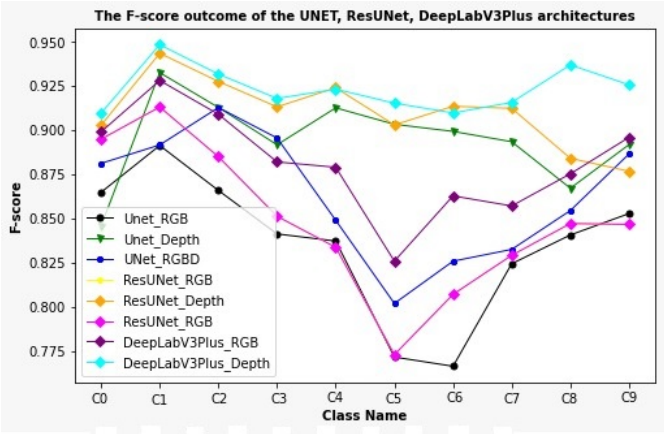

Fig. 6. Analysis of segmentation F1-score outcome by various networks specific to each class.

We have analyzed the segmentation accuracy for each subject performing various gestures under different lighting conditions as shown in Fig. 5. As it can be observed, Deeplabv3+ depth segmentation model gave better accuracy for all the subjects.

Segmentation results were analyzed over each gesture class as shown in Fig. 6. From the plot it is evident that Deeplabv3+ model gives better segmentation accuracy over UNet and ResUNet models. Hence we can conclude that DeepLabV3+ segmentation model trained with Depth data is suitable for efficiently segmenting the hand region in complex scenarios.

Based on experimental results DeepLabV3+ is selected as best segmentation model, predicted binary segmentation mask is used for masking to discard the background by bitwise AND operation on the input RGB and depth image. This results in fine segmented foreground hand region in RGB and Depth image constituting to segmented RGB and Segmented Depth images.

Table III shows the classification results on OUHANDS test dataset from the models trained on segmented RGB and Segmented Depth training data using custom CNN network

sRGB = Segmented RGB
sDepth = Segmented Depth
sMask = Segmented Binary Mask

shown in Table I. Accuracy of these two models are analyzed and found that few miss-classified images are detected complementary, hence score fusion is performed using max and average operations to get ensembled gesture classification results. It can be observed that average ensemble gives the best result of 88.91%. It is also evident from Fig. 7, average ensemble provides best accuracy over all models for all the gesture class.

Proposed framework of semantic segmentation and ensemble classification (SSEC), is compared with the state of the art methods as shown in Table IV. Deeplabv3+ depth segmentation model followed by classification using average score fusion gives the best F1 score accuracy on OUHANDS test dataset.

V. Discussion

Comprehensive experiments using RGB and Depth data stream are conducted in both segmentation and classification stage. As in Fig 2, hand region segmentation is performed using three segmentation networks UNet, ResUNet and Deeplab V3+ with RGB, Depth and stacked RGBD data. Corresponding experimental result is shown in Table II which indicates Deeplab V3+ with Depth data gives the better segmentation accuracy. This is also evident from the plots in Fig. 5 and Fig. 6, where segmentation accuracy is analyzed for each subject and each class respectively (both in aqua color plot).

Segmented RGB and Depth data is used to train the classification model as depicted in Fig. 4. Corresponding experimental results in Table III and plot in Fig. 7. shows that average ensemble (blue color plot) gives the better classification accuracy.

Proposed SSEC framework of Deeplab V3+ based semantic segmentation and average score ensemble classification is evaluated on OUHANDS benchmark dataset and compared the accuracy with existing methods as in Table IV. Experimental results shows that proposed methods gives the highest F1-score of 0.8891 and proved to be better than state-of-the-art methods.

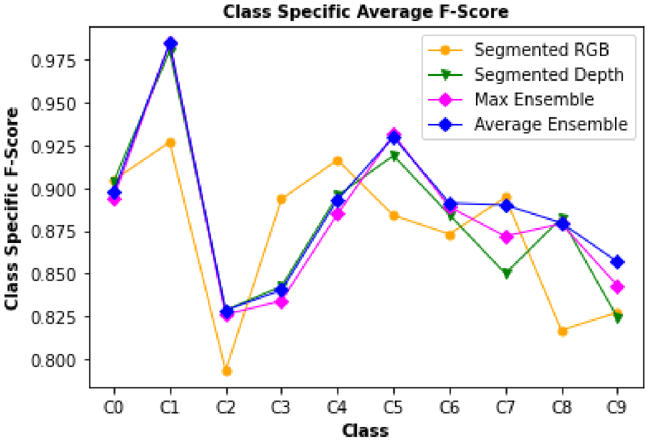

Fig. 7. Analysis of classification F1-score results of each class using segmented RGB, depth data models and various score fusion techniques.

VI. Conclusion

In this paper, we introduce SSEC, a novel semantic segmentation and ensemble classification framework on RGB-D Data for Static Hand Gesture Recognition. Specifically, we have analyzed three segmentation networks UNet, ResUNet and Deeplab V3+ with RGB, Depth and stacked RGBD data. Deeplab V3+ with Depth data gave higher F1 Score, the prediction outcome of this model is used as segmentation mask to discard background in RGB and depth data. In classification stage, custom CNN network was trained with segmented depth and segmented RGB data individually. Experimental results shows that, average score ensemble of these models can give better accuracy as compared to individual models. Hence it is inferred that RGB-D is with score fusion model ensembling is suitable for hand gesture classification as compare to the stat-of-the art methods.

Limitation of current approach is the usage of same network in both the RGB-D stream which may not give the diverse features, this can be further improved by using different CNN architectures in both streams to extract complimentary features.

In future work, we intend to develop a framework for dynamic hand gesture recognition considering the temporal sequence of RGB-D data for word and sentence level classification.

***Abstract*—In this paper, a COVID-19 dataset is analyzed using a combination of K-Means and Expectation-Maximization (EM) algorithms to cluster the data. The purpose of this method is to gain insight into and interpret the various components of the data. The study focuses on tracking the evolution of confirmed, death, and recovered cases from March to October 2020, using a two-dimensional dataset approach. K-Means is used to group the data into three categories: "Confirmed-Recovered", "Confirmed-Death", and "Recovered-Death", and each category is modeled using a bivariate Gaussian density. The optimal value for k, which represents the number of groups, is determined using the Elbow method. The results indicate that the clusters generated by K-Means provide limited information, whereas the EM algorithm reveals the correlation between "Confirmed-Recovered", "Confirmed-Death", and "Recovered-Death". The advantages of using the EM algorithm include stability in computation and improved clustering through the Gaussian Mixture Model (GMM).**

Keywords*—*COVID-19; clustering; k-means; EM algorithm; GMM

I. Introduction

Cluster analysis involves organizing data into meaningful and valid groups [1], which are homogeneous and similar. This technique involves classifying each data point into a specific set using clustering algorithms [2], [3]. A method proposed by the authors in [4] determines the optimal number of clusters, k, which represents the inherent significant clustering structures of the dataset. K-Means and Expectation Maximization (EM) algorithms are commonly used for clustering [5]. The proposed EM algorithm, initially designed for finding maximum likelihood parameters of a statistical model, has been applied to various domains such as speech recognition [6], interactive systems [7], etc.

On the other hand, the researchers in [8] have proposed a new epidemiological mathematical model for the spread of the COVID-19 disease with a special focus on the transmissibility of individuals with severe symptoms. Recently an important report using C++ can be used to "track" the daily evolution of new confirmed cases of the COVID-19 epidemic [9]. Rizvi et al. [10] have described K-Means clustering of 79 countries has been performed for COVID-19 confirmed cases and COVID-19 death cases based on 18 feature variables.

This study presents a fresh approach to analyzing the COVID-19 dataset using clustering techniques. Specifically, we apply a standard version of K-Means and EM algorithms based on GMM to partition the local COVID-19 Moroccan dataset into three sets: "Confirmed-Recovered", "Confirmed-Death", and "Recovered-Death", with varying cluster numbers. Our primary objective is to identify the optimal classification for each data cluster.

This paper is organized as follows: Section II gives the Literature Review. The K-Means and EM algorithms is introduced in Section III. The COVID-19 pandemic is presented in Section IV. Section V describes the COVID-19 dataset. Section VI exposes the results and discussion. Finally, in Section VII we conclude this work and gives perspectives.

II. Literature Review

The COVID-19 pandemic has led to an increase in the use of data mining and machine learning techniques to understand and analyze the spread of the virus. Clustering is a popular technique used to group similar data points together. K-Means, EM Algorithm and GMM are three commonly used clustering algorithms in machine learning. Several clustering methods have been developed with the objective to find the correct number of clusters [11], [12], [13], [14], [15]. In [16] the authors focus on utilizing Probabilistic Graphical Models for detecting COVID-19, resulting in excellent detection of the disease. One potential use of the EM algorithm is to estimate the parameters of a mixture model in cases where the data is incomplete. This technique is sometimes referred to as finding the parameters of Gaussian mixture densities [17], [18]. Eva and Dharmende [19] conducted a comparison between K-Means and GMM to assess their effectiveness in representing clusters of heterogeneous resource usage in Cloud workloads. Their experiments, which utilized Google cluster trace and business critical workloads by Bitbrains, revealed that K-Means provided a more generalized representation, whereas GMM resulted in better clustering with clearly defined usage boundaries. Despite Gaussian Mixture Model's longer computation time compared to K-Means, it is preferred for more detailed workload analysis and characterization.

Appiah et al. [20] proposed a study that utilizes the EM algorithm, which is initialized by a semi-supervised K-Means clustering approach based on geodesic distance classification of crime dataset. The aim is to track changes in cluster centroids (mean), shape and orientation, volume, and predictive trends of criminal activities. In this approach, the cluster assignment obtained from K-means is assumed as the distribution of GMM. The model-based clustering algorithm is then used to estimate the parameters of the mixed model while maintaining the probabilistic assignment and multivariate nature of the

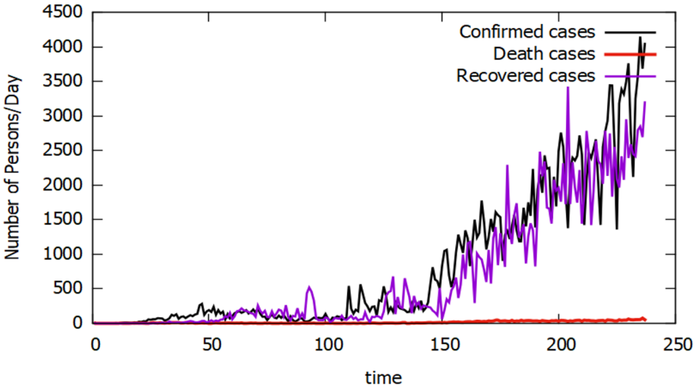

Fig. 1. COVID-19 confirmed-recovered and death cases in Morocco.

model. On the other hand, Zarikas et al. [21] developed a clustering algorithm designed specifically for grouping countries based on COVID-19 active cases, active cases per population, and per area. The results showed that countries facing similar impacts of COVID-19 also shared similar societal, economic, and other factors.

Aungkulanon et al. [22] clustered different regions of Thailand based on financial conditions and mortality differentials, revealing super-locale that are mainly urban and have a low all-cause normalized mortality proportion but a high colorectal disease-specific death rate. The study also found that deaths caused by liver cancer, diabetes, and renal diseases are common in low economic super-regions. Malav et al. [23] conducted a study to predict coronary heart disease using K-means and artificial neural networks. The combined approach led to a system with a very high accuracy rate. Another work by Singh et al. [24] used clustering and classification techniques to forecast heart diseases with high accuracy.

Isikhan et al. [25] clustered countries based on causes of deaths, health profiles, and risk factors using unsupervised K-means. The study analyzed clusters based on some financial and socio-demographic indicators and found that climate and ethnicity were more significant factors for clustering than socio-economic factors. These studies demonstrate the importance of COVID-19 dataset clustering in identifying patterns and trends associated with the virus, which can aid in developing effective strategies to combat its spread.

Death	0	0	0	3	10	2	2	2	...	50

III. K-MEANS AND EM ALGORITHMS

Given a set of observations $Y = (Y_1, ..., Y_N)$, independent and identically distributed (i.i.d) where each observation $Y_t = (y_{t1}, ..., y_{tj}, ..., y_{td}) \in R^d$ is a d-dimensional real vector. The objectives of K-Means and EM are to partition N observations into G clusters [26].

A. K-Means Algorithm

In this part, the objective is to find values for z_{tk} and μ_k the mean so as to minimize D. Let $\Phi = \mu = \{\mu_1, ..., \mu_G\}$ be the set represents the mean of each cluster c_k, where $C_k \in \{C_1, ..., C_G\}$ the set of G clusters, and let $Z = (z_1, z_2, ..., z_N)$ the set of binary indicator variables.

$$D(\Phi, Z) = \sum_{t=1}^{N} \sum_{k=1}^{G} z_{tk} \|Y_t - \mu_k\|^2 \qquad (1)$$

Where $z_{tk} = 1$ when Y_t is a member of C_k , otherwise $z_{tk} = 0$. Or more exactly $\arg\min_k D(\Phi, Z)$. when D achieved minimal value, sum of $\|Y_t - \mu_k\|^2$ is minimal [27].

$$d(Y_t, \mu_k) = \sqrt{\sum_{j=1}^{d} (y_{tj} - \mu_{kj})^2} \qquad (2)$$

by Euclidean distance. We can do this through an iterative procedure in which each iteration involves two successive steps corresponding to successive optimizations with respect to z_{tk} and μ_k. We initialize the class centers $\left\{\mu_1^{(0)}, ..., \mu_G^{(0)}\right\}$ for the $\{C_1, ..., C_G\}$ set of clusters; by some initial values called seed-points, using methodically sampling.

Step 1:

We minimize D and we update z_{tk}, keeping the μ_k fixed.

Step 2:

We minimize D and we update μ_k, keeping the z_{tk} fixed.

$$\mu_k^{(m+1)} = \frac{\sum_{t=1}^{N} z_{tk}^{(m)}.Y_t}{\sum_{t=1}^{N} z_{tk}^{(m)}} \qquad (3)$$

(m) being the current iteration. This two-stage optimization is then repeated until convergence.

B. Expectation Maximization Algorithm

In this work, EM algorithm is used to complete the missing COVID-19 data. We introduce the latent variable Z. Y_t can describe the mix “Confirmed cases-Recovered cases”. The same study for the mixture of confirmed cases - death cases and recovered cases - death cases. We will assume that the observations Y_t are i.i.d and the observations from different clusters have correlated Bivariate Gaussian Density. If data t belongs to cluster C_k (denoted by $t \in C_k$) then:

$$Y_t \setminus t \in C_k \sim f(y_t/\mu_k, \Sigma_k) \qquad (4)$$

$$f(y_t/\mu_k, \Sigma_k) = \frac{1}{2\Pi^{\frac{d}{2}} \sqrt{|\Sigma_k|}}$$
$$\exp \frac{-1}{2}[(y_t - \mu_k)^t \Sigma_k^{-1} (y_t - \mu_k)] \qquad (5)$$

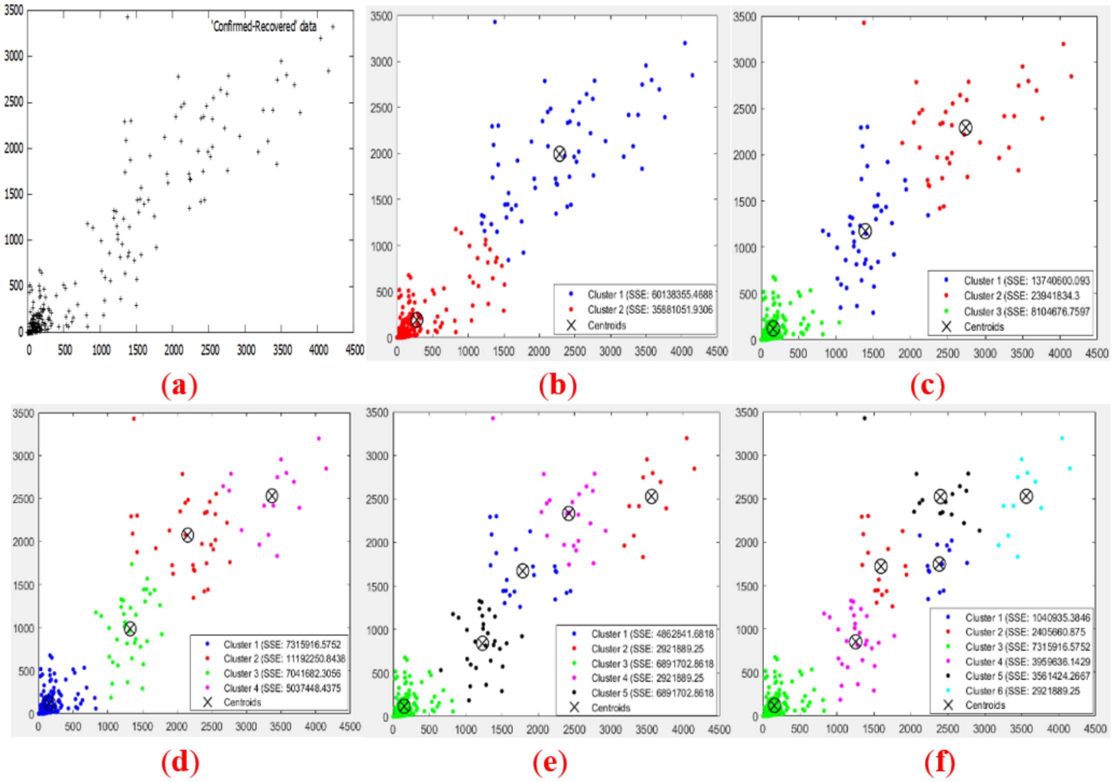

Fig. 2. (a) Two-dimensional input “Confirmed-Recovered” data; with no clustering. (b), (c), (d), (e) and (f) K-means partitions, respectively with k = 2, k = 3, k = 4, k = 5 and k = 6. The centroids are marked with a cross.

μ_k and Σ_k denote the mean vector and covariance matrix. Assign a data point to a nearest cluster, with calculate the following likelihood [28].:

$$\begin{aligned}\gamma(z_{tk}) &= \mathbf{E}(z_{tk}) = \mathbf{P}(z_{tk} = 1/y)\\ &= \frac{\mathbf{P}(z_{tk} = 1)\mathbf{P}(y_t/z)}{\mathbf{P}(y)}\end{aligned} \tag{6}$$

Where $\mathbf{P}(z_{tk} = 1/y)$ is a posterior probability of $y_t \in C_k$ the k^{th} – classes and z_t correspond to the Gaussian identity which generated an entry y_t.

Step 1 (Expectation): Given the current estimates, $[\boldsymbol{\mu_k}, \boldsymbol{\Sigma_k}, \boldsymbol{\Pi_k}]$

$$\gamma(\boldsymbol{z_{tk}}) = \frac{\boldsymbol{\Pi_k f_k(y_t/\mu_k, \Sigma_k)}}{\sum_{j=1}^{G} \boldsymbol{\Pi_j f_j(y_t/\mu_j, \Sigma_j)}} \tag{7}$$

Step 2 (Maximization): Compute the parameters that maximize the likelihood of the data set $\mathbf{P}(\boldsymbol{Y/\mu_k, \Sigma_k, \Pi_k, z_{tk}})$ which is the probability of all of the data under the GMM. Find the probability $\mathbf{P}(\boldsymbol{Y})$ that generated the COVID-19 dataset. Maximizing this with respect to each of the parameters can be done in closed form:

$$\boldsymbol{\Pi_k^{new\ ite}} = \frac{\sum_{t=1}^{N} \gamma(\boldsymbol{z_{tk}})}{\boldsymbol{N}} \tag{8}$$

$$\boldsymbol{\mu_k^{new\ ite}} = \frac{\sum_{t=1}^{N} \gamma(\boldsymbol{z_{tk}})\boldsymbol{y_t}}{\sum_{t=1}^{N} \gamma(\boldsymbol{z_{tk}})} \tag{9}$$

$$\boldsymbol{\Sigma_k^{new\ ite}} = \frac{\sum_{t=1}^{N} \gamma(\boldsymbol{z_{tk}})((\boldsymbol{y_t} - \boldsymbol{\mu_k^{new\ ite}}) \otimes (\boldsymbol{y_t} - \boldsymbol{\mu_k^{new\ \ ite}})^{\boldsymbol{t}}}{\sum_{t=1}^{N} \gamma(\boldsymbol{z_{tk}})} \tag{10}$$

1) Re-estimation of mixed weights: To find the parameter we using a Lagrange multipliers [29] with constraint $\sum_{i=1}^{G} \boldsymbol{\Pi_i} = \boldsymbol{1}$ and maximizing the following quantity:

$$\boldsymbol{L(l(\Phi), \lambda) = l(\Phi) + \lambda(\sum_{k=1}^{G} \Pi_k - 1)} \tag{11}$$

$$\boldsymbol{Where \frac{\partial L(l(\Phi), \lambda)}{\partial \Pi_k} = 0}$$

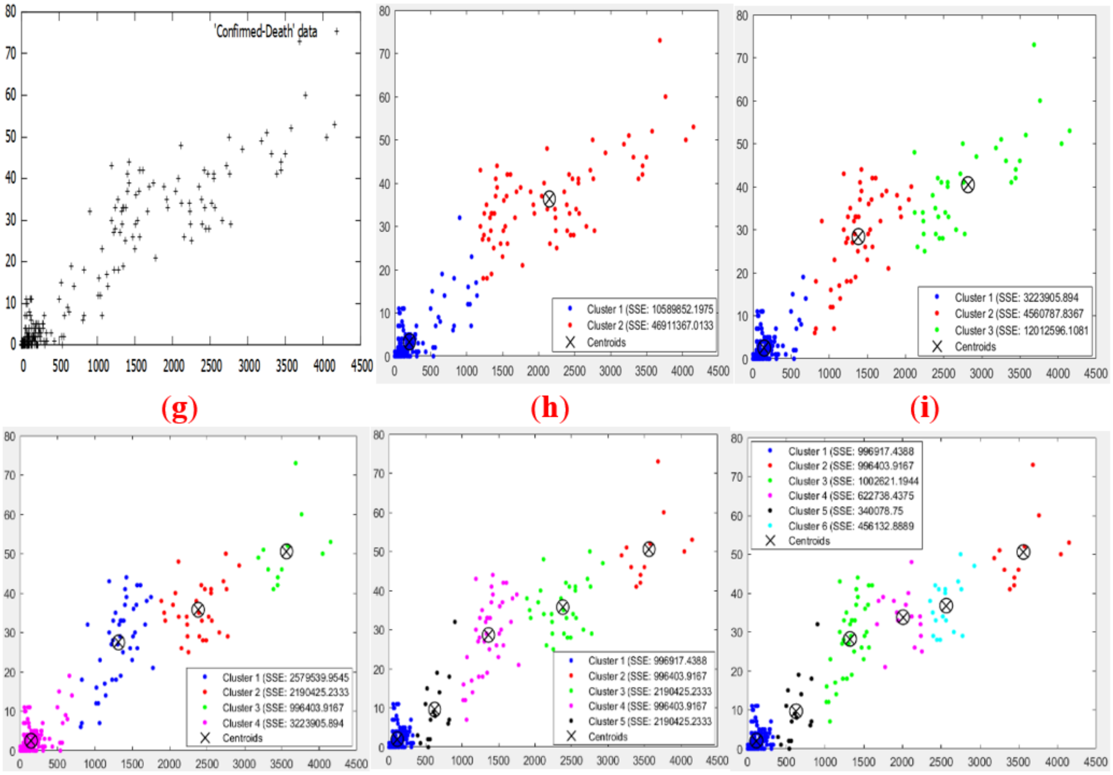
Then we obtain

$$\boldsymbol{\sum_{t=1}^{N} \frac{\Pi_k f(y_t/\mu_k, \Sigma_k)]}{\sum_j [\Pi_j f(y_t/\mu_j, \Sigma_j)]} + \lambda \Pi_k = 0}$$

and we have new estimation for $\boldsymbol{\Pi_k}$ (see Eq. 8).

2) Re-estimation of the means vectors: We assume $\gamma(\boldsymbol{z_{tk}})$ fixed. We derive this equation with respect to the means $\boldsymbol{\mu_k}$ at zero, we obtain:

$$\begin{aligned}\boldsymbol{l(\Phi)} &= \boldsymbol{\sum_{t=1}^{N} \ln[\sum_{k=1}^{G} \frac{\Pi_k}{2\Pi\sqrt{|\Sigma_k|}}}\\ &\boldsymbol{\exp \frac{-1}{2}[(y_t - \mu_k)^t \Sigma_k^{-1}(y_t - \mu_k)]]}\end{aligned} \tag{12}$$



(g) (h) (i)

(j) (l) (m)

Fig. 3. (g) Two-dimensional input “Confirmed-Death” data; with no clustering. (h), (i), (j), (l) and (m) K-means partitions, respectively with k = 2, k = 3, k = 4, k = 5 and k = 6. The centroids are marked with a cross.

$\boldsymbol{Where}\ \frac{\partial l(\Phi)}{\partial \mu_k} = \mathbf{0}$, Then we find:

$$\sum_{t=1}^{N} \frac{\Pi_k f(y_t/\mu_k, \Sigma_k)]}{\sum_j [\Pi_j f(y_t/\mu_j, \Sigma_j)]} \Sigma_k^{-1}(y_t - \mu_k) = 0$$

The new μ_k is gives in (Eq. 9)

3) Re-estimation of the covariance matrix: In the same way we derive $l(\Phi)$ with respect to Σ_k Where $\frac{\partial l(\Phi)}{\partial \Sigma_k} = \mathbf{0}$, then we obtain new values of covariance matrix (see Eq. 10).

IV. COVID-19 Pandemic

Later in 2019, in the city of Wuhan, in China, a new discovered version of coronavirus was detected as the principal reason for a strange aspect of pneumonia cluster. Local scientists react by isolating the SARS-CoV-2 into a patient on the earlier of January 2020, which led to the genome sequence of the SARS-CoV-2 [30].

According to the authors of sequencing, phylogenetic analysis this genome has made it possible to establish that the initial host of this virus is an animal sold on the market in Wuhan. Several studies have suggested bats could be at the origin of SARS-CoV-2 [31]. The virus was referred to as 2019-nCoV before the COVID-19 name. It is defined as a severe acute respiratory syndrome coronavirus number 2 (SARS-CoV-2). The WHO declares that the first the infection as a pandemic on March 11, 2020. It rapidly spread, followed by an increase in the number of infected cases around the globe. To this disease of August 16, 2020, the world has had 21.294.845 total confirmed cases, and 761.779 total deaths cases [32].

V. COVID- 19 Dataset Description

In the present study, we use public data from the COVID-19 outbreak in Morocco to estimate the evolution of this epidemic. The data is received through the official website created by the Moroccan Ministry of Health. For this disease, Morocco has had 194461 total confirmed cases, said the Director of epidemiology and disease control at the Ministry of Health as of October 24,2020 the total number of deaths has increased to 3255; and 160372 total cured cases (see Fig. 1) [33].

The training dataset is composed of the real COVID-19 cases daily collected Confirmed, Recovered, and Death patterns. The clustering is done with two-dimensional dataset “Confirmed – Recovered”, “Confirmed – Death” and “Recovered – Death” features of 237 samples. The Table I below shows a part of the complete data.

The recording of the $\mathbf{237^{th}}$ COVID-19 cases are store in the Table I. Each feature is a combination of two parameters, the Confirmed recorder and the Death cases, then the Confirmed recorder and the Recovered cases and the Recovered recorder and the Death cases, respectively.

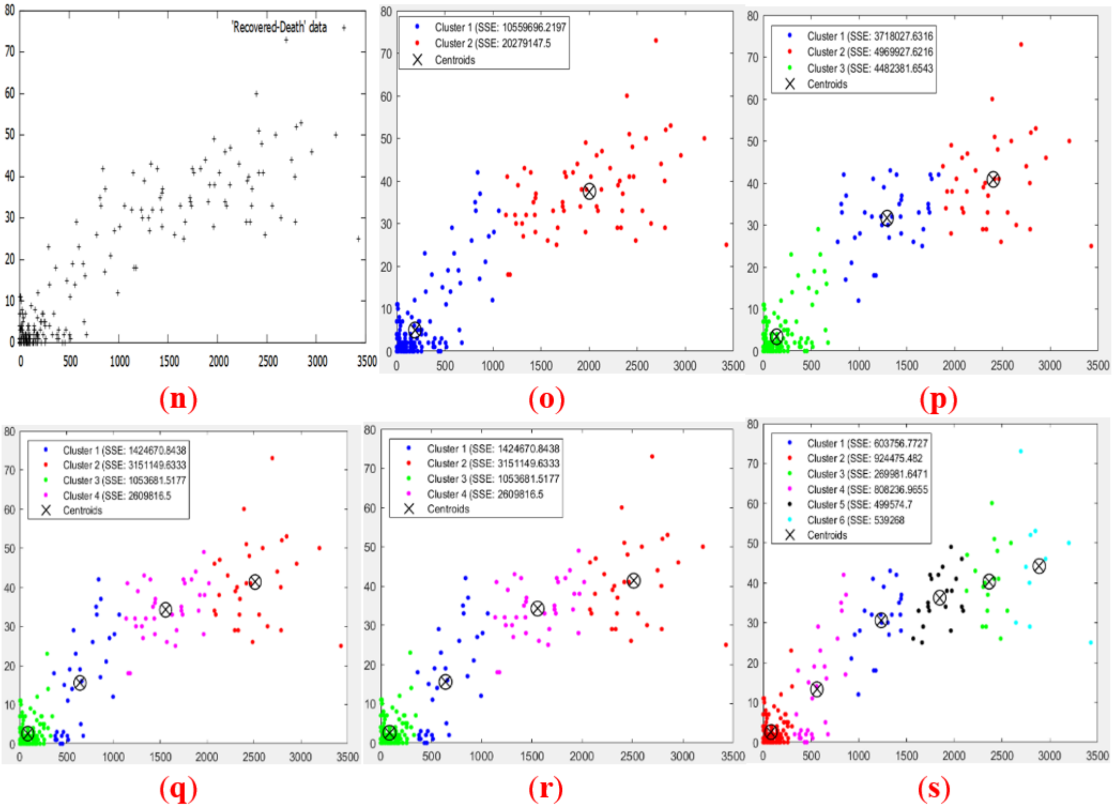


Fig. 4. (n) Two-dimensional input "Recovered - Death" data; with no clustering. Data to illustrate the K-means procedure. (o), (p), (q), (r) and (s) K-Means partitions, respectively with k = 2, k = 3, k = 4, k = 5 and k = 6. The red dots represent the centroid of each cluster.

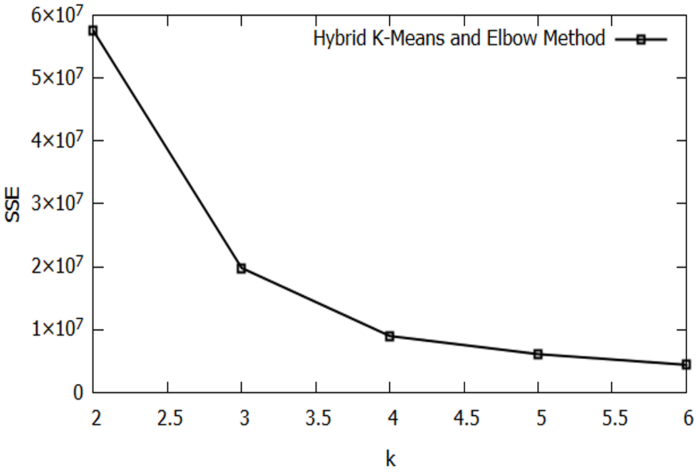

Fig. 6. Graph of sum square error depending on the number k for 'Confirmed-Death' data.

VI. Results and Discussion

In this work, we selected k-points as the primary group ranks as the points are calculated in order. The total number of initial points c_k is $237/k$ for all groups, then we define the initial centroids μ_k. The test data consists of three groups, "Confirmed – Recovered" (see Fig. 2), "Confirmed – Death" (see Fig. 3) and "Recovered– Death" (see Fig. 4). After divided each group into $k = 2$ to $k = 6$. The hybrid of K-Means algorithm and the Elbow method is been used to determine the best clustering as in [34].

Each data point is classified by computing the distance between that point and each group center, and then classifying the point to be in group whose center is closest to it. The results of sum square error calculations of each cluster have experienced the greatest decrease in k = 4 for groups "Confirmed-Recovered" and "Confirmed-Death", k=3

TABLE II. The Initial Values

‘Confirmed-Recovered’ data				
	K-Means	EM GMM		
C_1	$\mu_1 = [73.24, 15.73]^t$	$\mu_1 = [73.24, 15.73]^t$	$\Sigma_1 =$	$\begin{matrix} 4974.83 & 763.34 \\ 763.34 & 729.72 \end{matrix}$

C_3	$\mu_3 = [1724.95, 35.56]^t$	$\mu_3 = [1724.95, 35.56]^t$	$\Sigma_3 =$	$\begin{matrix} 485690.30 & 3820.91 \\ 3820.91 & 102.70 \end{matrix}$

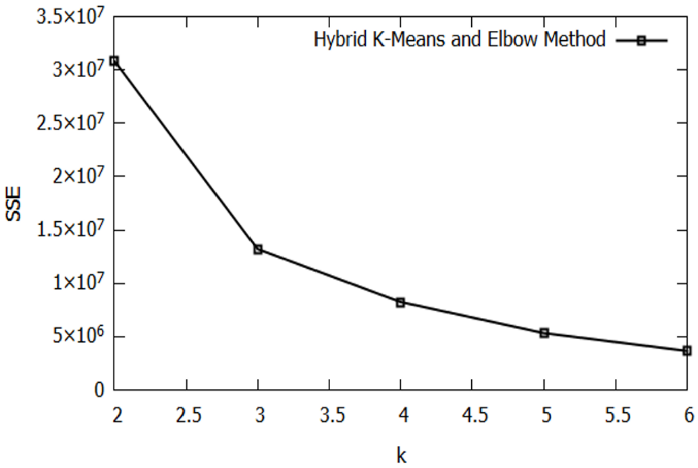

Fig. 7. Graph of sum square error depending on the number k for ’Recovered-Death’ data.

for “Recovered-Death” data can be seen in (Fig. 5), (Fig. 6) and (Fig. 7).

We used the hybrid K-Means algorithm and Elbow method, which gave best clustering with 4 and 3 clusters. This result is exploited in the EM classification based on GMM, we notice that the “Confirmed-Recovered”, “Confirmed-Death” and “Recovered-Death” can be divided into 4, 4 and 3 subsets, respectively. We analyze the correlation of feature variables for COVID-19, Correlation matrix is used to find the relationship between two variables “Confirmed-Recovered”, “Confirmed-Death” and “Recovered-Death”. Correlation Coefficient r is used to calculate the strength of this relationship between two quantitative variables $\boldsymbol{Y_i}$ and $\boldsymbol{Y_j}$ by using the formula given in (Eq. 13):

$$\boldsymbol{r} = \frac{(\boldsymbol{Y_i} - \boldsymbol{\mu_i})^{\boldsymbol{t}}(\boldsymbol{Y_j} - \boldsymbol{\mu_j})}{\sqrt{\|\boldsymbol{Y_i} - \boldsymbol{\mu_i}\|^2 \|\boldsymbol{Y_j} - \boldsymbol{\mu_j}\|^2}} \tag{13}$$

$\boldsymbol{i}$ and $\boldsymbol{j} =$ Confirmed, Recovered , Death r, the correlation coefficient is a unitless value between -1 and 1.

In Table II, we have the initial parameters of the different groups. To start the K-Means and EM algorithms, we use the same means values and the same coefficients of the found covariance matrix.

In this part, we aim to implement selected $\boldsymbol{C^{++}}$ object from [35] using K-Means algorithm is to partition the first, the second and the third group into four, four and three

(see Fig. 8, 9), ‘Confirmed – Death’ (see Fig. 10, 11), and ‘Confirmed – Recovered’ (see Fig. 12, 13).

We obtain values at convergence by using K-Means algorithm and EM algorithm (see Table III).

The correlation matrix of the initial values (see Table IV), and values at convergences (see Table V) for features "Confirmed – Recovered – Death" cases using (Eq. 13):

Positive values of r indicate a positive correlation, as the values of the two variables tend to increase together. Negative values of r indicate a negative correlation when the values of one variable tend to increase and the values of the other variable decrease. In the data mining of COVID-19 in Morocco, K-Means is a simple and fast algorithm for solving clustering issues, but it requires clarification in advance the exact number of clusters k, which is often difficult.

The "Confirmed – Recovered", "Confirmed – Death" and "Recovered – Death" groups are Mixtures Models of four and three two-dimensional Gaussians. K-Means algorithm only considers the mean to update the new centroids nevertheless EM based GMM takes into account the mean value as well as the covariance matrix of this data groups. We use this partitioning to start K-Means and EM. We start from a real model with correlated covariance matrices, the values at convergence are of the same nature. It can be interpreted that high positive correlation exists, in the third phase of the epidemic's spread, between Confirmed cases and Recovered cases (0.70), Confirmed cases and Death cases (0.67) and Recovered cases and Death cases (0.85) [10]. To evaluate clusters "Confirmed – Recovered" and "Recovered – Death"; values are in forms four categories (low, lower-middle, uppermiddle, and high), on the order hand "Confirmed – Death" data is in forms three phase (low, medium, and high).

We notice a clear difference between means of the K-Means algorithm and the means of the GMM. The EM based GMM has higher computation time than K-Means; because K-Means does not account for variance. The findings are in according with those of [19]. The Data membership points to clusters in GMM is probabilistic as versus the non-probabilistic, hard clustering K-Means process, thus resolving the membership vagueness that may appear in overlapping clusters. The analysis exposes a more meaningful workloads clustering with GMM than with K-Means, enabling a detailed characterization of resource usage needs of Cloud workload. As a comparison, the clustering by using K-Means algorithm is faster than Gaussian Mixture Models method.

K-Means clustering faces a major challenge in determining the optimal number of clusters, especially when working with COVID-19 data. Depending on the type of data being analyzed, the number of clusters may vary, and selecting the correct number of clusters is crucial for obtaining meaningful results. Furthermore, K-Means clustering relies on the Euclidean distance metric, which may not be suitable for all COVID-19 data. Other distance metrics, such as cosine distance, may be necessary to accurately capture the similarity between data points. Another clustering algorithm, EM clustering, is also sensitive to the initial conditions of the algorithm. Different initial conditions may result in different cluster assignments, leading to inconsistent results. Additionally, EM clustering may struggle to converge to a solution when working with high-dimensional data or complex probability distributions. Preprocessing and tuning of the algorithm may be necessary to ensure reliable results.

VII. Conclusion

This study focuses on analyzing the COVID-19 situation in Morocco using K-Means and EM clustering algorithms. The dataset includes daily Confirmed, Death, and Recovered cases from March 2 to October 24, 2020. For the k-means algorithm, discovering intra-cluster similarity in complex nonlinear models using Euclidean distance is difficult. The EM algorithm is more computationally intensive and requires larger sample sizes for accurate parameter estimates. The results indicate that the EM-based GMM method is the preferred clustering method as it yields smaller classification error rates. The K-Means generated clusters provide limited information, and the best clustering was found with four and three clusters. Furthermore, the EM algorithm demonstrates the correlation between "Confirmed-Recovered", "Confirmed-Death", and "Recovered-Death". The number of clusters corresponds to the number of phases of the epidemic propagation, as determined by the process of identifying the optimal number of clusters. In the future work, we will be focused on the enhancement of our model clustering for multi-dimensional datasets with several features.

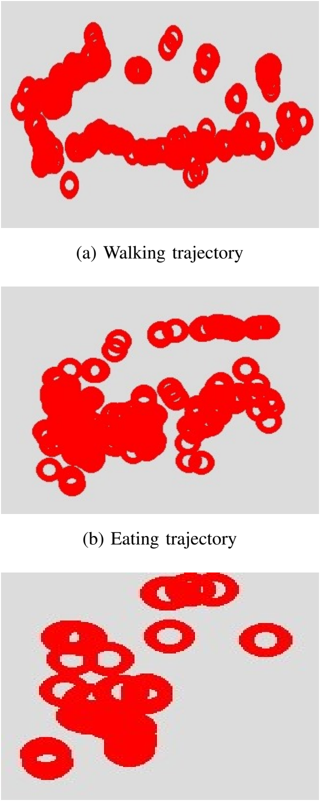
***Abstract*—Poultry farming is an important industry that provides food for a growing population. However, the welfare of the birds is a major concern, as poor living conditions leads to abnormal behavior that affects the health and productivity of the flock. In order to monitor and improve the welfare of the birds, it is important to have a surveillance system in place that monitors the behavior of the chickens and alert farmers to potential issues. This paper reviews the current state of the art in behavior analysis for surveillance in poultry farms and discuss potential future directions for research in this area. This paper presents a computer-vision-based system that detects and monitors the behaviors of the chickens in poultry farms. The system classifies three behaviors which are eating, walking and sleeping. The system takes videos as input and then classifies the behavior of the chicken. The proposed system produces an accuracy of 94.7% using Light Gradient Boosting Machine on a collected data-set of chickens, and a 98.4% accuracy on a benchmarked Human Activity Recognition data-set.**

Keywords*—*Chicken; poultry; abnormal; behavior; birds

I. Introduction

The study of chicken behavior plays a critical role in the poultry industry, as it provides valuable insights into the health and welfare of the birds. Farmers can detect any abnormal patterns that indicate illness, stress, or discomfort by analyzing chicken behaviors. This information is then used to improve their health condition, and ultimately, enhance production efficiency and profitability. In addition, an effective system for detecting and analyzing chicken behavior contributes in early disease detection, preventing outbreaks [1], ensuring food safety, protecting public health [2], and ensuring the quality of poultry production [3]. Hence, having a reliable system for monitoring chicken behavior is essential for sustainable poultry farming and ensuring the well-being of the birds.

The Food Standards Agency (FSA) reported that 1.35 million chickens die prior to being slaughtered, primarily due to diseases and illnesses [4]. This conclusion was drawn from a 15-month study conducted between 2016 and 2017. Ensuring the health of chickens is achieved by monitoring their behavior. Monitoring chicken behaviors by extracting, and analyzing their trajectories (as shown in Fig. 1), is used as an indicator to ensure their health and well-being. Although the chickens seem fine, sudden death occurs quickly if specific behaviors are displayed, leaving no chance for intervention [5].



(a) Walking trajectory

(b) Eating trajectory

(c) Sleeping trajectory

Fig. 1. Different chicken behavior trajectories.

Different methods for analyzing chicken behavior are utilized (as shown in Fig. 2), one such approach involves using pose estimation as used by Fang et al. [10], where the key points of the chickens are identified and utilized to monitor their behavior. Another method is to analyze the collective behavior of chickens within a farm environment. The manner in which chickens move as a group provides insights into their behaviors. The proposed system (as shown in Fig. 3) primarily concentrates on the third and final approach, which involves tracking the movements of each chicken trajectory individually. The individual actions of the chickens serve as an indicator of their behavior. Fig. 2 shows the previously mentioned methods.

Previous researches that tackled this problem mostly utilized image processing and machine learning to detect and classify chicken behaviors. As illustrated in Table I, Neethira-

TABLE I. Previous Deep Learning-based Approaches for Animal Detection

Algorithm	Application	Dataset Size	Dataset Availability	Accuracy	Reference

jan [6] put forward a system for detecting and counting chickens using Yolov5 and Kalman Filter. Siriani [7] also employed Yolov4 and Kalman filter to monitor chickens' movements in low light conditions. Meanwhile, Fang et al. proposed a system that classifies chicken behavior by analyzing their poses using DeepLabCut [12] and ResNet50 [13].

Table I presents a GAP analysis, which compares the proposed system work with previous studies on animal (chicken) detection and tracking. The table compares the algorithms, applications, data-set sizes, data-set availability, and achieved accuracies used in each previous work. Evaluating the strengths and limitation of each existing approach is achieved by comparing the mentioned factors.

The main contribution of this paper is to investigate the use of chicken's trajectories in order to classify its behavior using classical machine learning models. The proposed system (as shown in Fig. 3) aims to classify three chicken behaviors using their trajectories: walking (as shown in Fig. 1a), eating (as shown in Fig. 1b), and sleeping (as shown in Fig. 1c) (Fig. 4 also shows practical examples of the aforementioned behaviors). This paper utilizes a collected data-set of 90 records split evenly among the three mentioned behaviors. The data-set is to be further explained in the Data Collection section. The proposed model is also evaluated on a benchmarked data-set which is the Human Activity Recognition data-set [14] in order to evaluate its efficiency. Furthermore, a comparison between different classical machine learning models is also conducted in order to determine the highest performing model.

The rest of the paper is organized as follows: Section II discusses the literature review and previous related work, Section III outlines the proposed system's methodology, data collection, and how the system works, Section IV presents the setup and results of the two conducted experiments, Section V discusses the analysis and results produced by the classical machine learning models, Section VI presents the limitation of existing approaches and potential future work ideas, and Section VII states the conclusion of the paper.

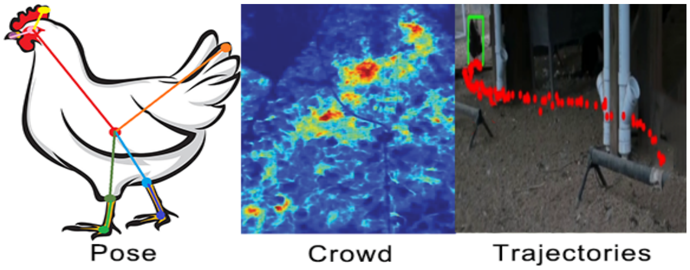

Fig. 2. Methods of chickens behavior classification.

II. Related Work

In recent years, many studies have focused on detecting and tracking animal behavior with the aim of further understanding the animals and detecting their behavior. The aim of these studies is to develop deep learning models for detecting and tracking animal behaviors. In this section, some of the previous work in this area is presented.

Neethirajan proposed a model which detects chickens, counts them, and extracts each chicken's movement from their bounding box [6]. Neethirajan's model detected chickens from various backgrounds using YOLOv5, and then gave each chicken an ID associated with the bounding box. As a result, the model was able to count and track chickens. To detect each chicken's direction, the proposed system stored the centroid of each bounding box. A challenge this model faced was occlusion, where a chicken disappears in one frame and return in the next frame, resulting in the chicken being given a new ID. To solve this challenge, a Kalman filter was used to compute the distance between each centroid and the old one, in order to check if the chicken had been tracked before.

Siriani et al. proposed a model to detect and track chickens in low light [7]. The proposed model used YOLOv4 in order to detect chickens from input frames in addition to returning the bounding box positions to store in CSV files for the tracking process. Kalman filter was used to predict the next position of each chicken depending on it's last positions. This model scored a very high accuracy of 99.9%. However the data-set used was to small in addition to using 10,000 epochs which

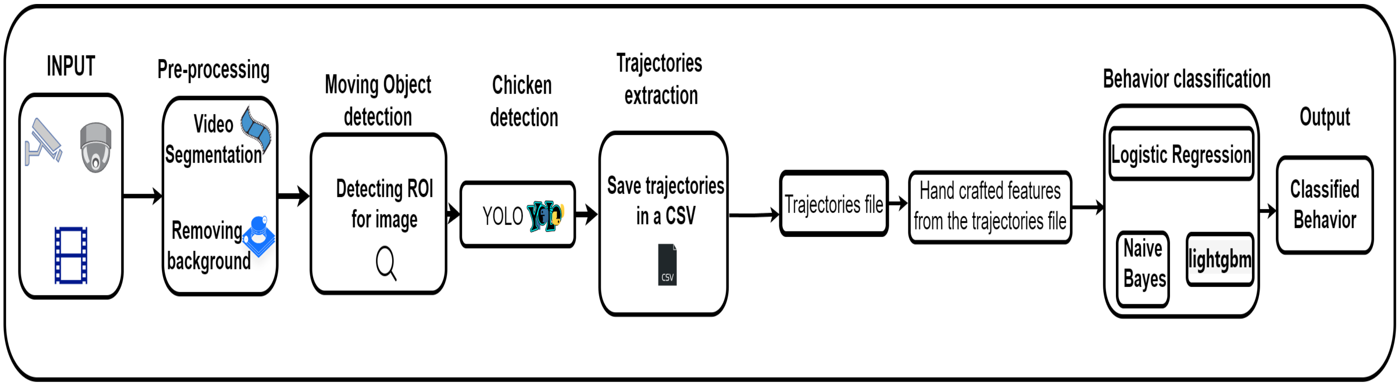

Fig. 3. System architecture.

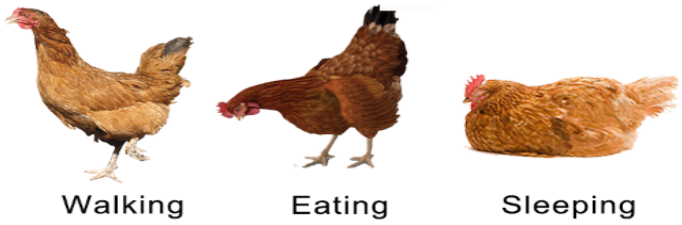

Fig. 4. Different chickens behaviors.

probably led to over-fitting for their model.

Evangelista et al. proposed a model for detecting quails using YOLOv5 and Detectron2 [8]. The proposed system combined YOLOv5 and Detectron2 to create a faster model for training and validation. However, the model failed to attain a high accuracy and detected touching quails as a single quail.

Zuerl et al. proposed a model for monitoring polar bear behavior using YOLOv5 and ResNet18 [9]. The suggested system consisted of four stages: object detection, classification, coordinate mapping, and analysis and user interface. In the first stage, YOLOv5 was used to detect polar bears. In the second stage, the image was cropped to only include the detected animal, and then ResNet18 was used to classify the animal type. After that, the center of one of the edges in the bounding box was used as the position of the polar bear. Following that, the extracted position was evaluated with respect to the map of the zoo to determine its location. The final stage was the user interface, which displayed the bear's location in the form of a heat map or trajectory, the distance covered in a selected time frame, and the bear's activity. Their model failed to achieve high accuracy. Furthermore, the mapping stage of their approach is difficult to implement, as a map of the farm is required.

The previous work mentioned methods primarily focused on detecting animals and determining their trajectories, without considering any behaviors. In contrast, Fang et al. proposed a model for chicken behavior classification, along with the estimation of chicken poses, using DeepLabCut and a pre-trained ResNet50 model [10]. As the first step, they created a basic skeletal map of the stance of broiler chickens. The ResNet-50 was then trained on the data-set, and DeepLabCut was used to predict the chicken's body position. Afterward, the chicken's posture was fed into a Naive Bayes model to determine the behavior to which it belongs. However, the limitations of this approach were the low accuracy scores in detecting running and walking behaviors, as the postures for these two classes are similar and difficult to separate.

Okinda et al. presented a distinct approach from the work discussed earlier [11]. This approach employed a support vector machine (SVM) to predict broiler diseases. Unlike the previous methods, this model detects chickens by analyzing images from the perspective of shape representation. To predict the disease, six models were experimented with, and the SVM scored the highest results. However, the model also missclassified some inputs as incorrect days.

However, to date, there has been no published study on behavior detection using chicken trajectories. This paper presents a novel approach for detecting chickens, extracting their trajectories, and classifying those trajectories according to their respective behaviors.

III. Methodology

The system proposed in this paper consists of six stages: pre-processing, background subtraction and ROI detection, chicken filtering, trajectory extraction, behavior classification, and output Fig. 3. In this section, a comprehensive explanation of each stage is provided.

A. Data Collection

The data-set used in this study was obtained from YouTube videos of chicken barns, totaling 6 hours of video footage. To establish ground truth, the video footage was labeled and trajectories were created with labels such as walking, eating, and sleeping. Each class comprised 30 records, resulting in a total of 90 records. Each record contains the (x, y) positions of the chicken during the recorded clips. The data-set was then split, with 80% used for training and 20% for testing.

For validation purposes, a human activity recognition data-set [15] was used as a benchmark to validate the proposed model. The handcrafted features were calculated from the raw time domain data. The data-set was constructed from 270 records, which contained four behaviors: standing still, walking, jumping, and running, with each class having an equal number of records. The data-set was split in the same manner

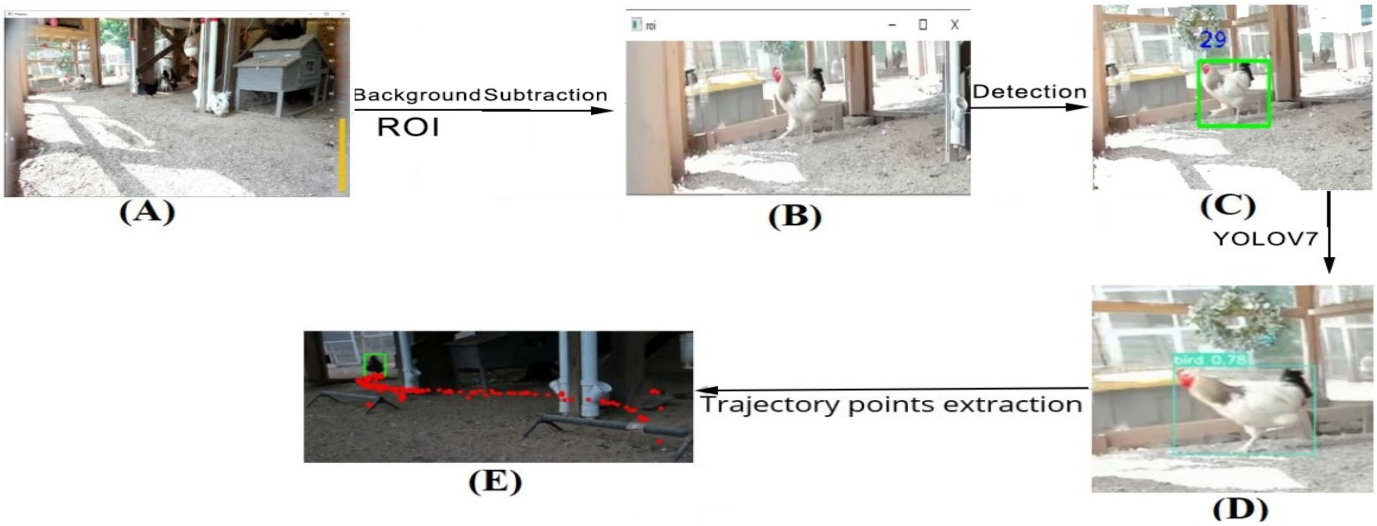

Fig. 5. System stages: (A) Input segmentation, (B) Background subtraction & ROI, (C) Moving object detection, (D) Chicken filtering, (E) Output.

as the constructed data-set, with 80% for training and 20% for testing.

B. Pre-Processing

The proposed system has a pre-processing stage, which requires video segmentation as its first step. The objective is to analyze the content of the video. To achieve the desired results, the video undergoes processing. The fundamental procedure for processing a video is video segmentation [16]. The input videos are segmented into intervals of 5, 10, and 15 seconds for processing. The results showed that the 10-second segmentation achieved the best outcome, as it was observed that chickens typically transition to a different behavior after 10 seconds.

C. Background Subtraction and ROI

After video segmentation, the next step is to apply background subtraction to the videos. Background subtraction is commonly used to isolate objects of interest in a scene by comparing an observed image to an estimated version of the image that does not contain any objects of interest [17], [18]. The purpose of applying background subtraction is to determine the trajectory of the chickens as shown in Fig. 5(B).

The process of applying the Region of Interest (ROI) to a moving object is utilized to eliminate any irrelevant data present in the image. In addition to detecting any moving object as demonstrated in Fig. 5(C).

D. Chicken Filtering

To detect any moving objects. The object detection stage is then performed to determine if the moving object is a chicken. This stage is conducted using YOLO, and if the object detected is a chicken, it is assigned an ID, as shown in Fig. 5(D).
Joseph Redmon and others first introduced YOLO in 2016 [19]. By partitioning an image into a grid and producing predictions for each cell in the grid, the algorithm is made to recognise objects in real-time. The distinctive feature of YOLO is that it only makes one forward pass over the network, enabling real-time image processing. Other object identification methods, on the other hand, call for many forward passes, which makes them slower and less suited for real-time applications. On a number of object detection benchmarks, YOLO has been demonstrated to attain state-of-the-art performance while also being computationally effective. Its widespread application in numerous computer vision tasks is a result of this. In addition to its benefits include quick deep learning network processing times, the capacity to handle larger data-sets, and real-time continuous detection [20], [21].

$$O = \sqrt{(Xnew - Xold)^2 + (Ynew - Yold)^2} \qquad (1)$$

Equation 1: Euclidean Distance Equation

The ID of a chicken changes in the case of occlusion and is assigned a new ID [6]. To overcome this challenge, the Euclidean distance is calculated between the chicken's previous location and its new location [22]. If the output of equation 1 is compared to the positions of all existing IDs and found to be less than 150, the chicken is assigned the same ID and the ID's position is updated.

E. Trajectories Extraction

The first step in trajectories extraction stage is to detect ROI(region of interest) from the image. The ROI is determined by the boundary box added in the previous stage by YOLO.

Next, the location of the chickens is assumed to be at the right edge of the bounding box, and a trajectory point is added every 10 frames. As previously mentioned, processing every frame is a challenging task, and thus trajectory extraction is only performed once every 10 frames [23].Finally, the trajectories are saved in a CSV (Comma-Separated Values) file to calculate features from it.

$$A = \frac{1}{n}\sum_{i=1}^{n} a_i = \frac{a_1 + a_2 + \cdots + a_n}{n} \tag{2}$$

Equation 2: Mean equation

$$\sigma = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_i - \mu)^2} \tag{3}$$

Equation 3: Standard deviation equation

$$M = \frac{1}{n}\sum_{i=1}^{n} x_i \tag{4}$$

Equation 4: Median equation

F. Hand Crafted features

Since the trajectories are considered time series data [24], several time series features are calculated, such as the mean, median, standard deviation, minimum, and maximum. Mean is used to calculate the average distance covered as shown in equation 2 where a1, a2, ... and is calculated using the euclidean distance mentioned in equation 1. Median is used to extract the center element from a list of numbers using equation 4. In this case median is used to achieve the medium distance from all distances calculated. Standard deviation is used to determine how close the values are to the average (mean) value. The standard deviation is calculated using the equation 3.

$$DC = \sum_{i=1}^{n} \sqrt{(Xnew - Xold)^2 + (Ynew - Yold)^2} \tag{5}$$

Equation 5: Distance Covered equation

$$\begin{cases} SS+ = 1 & \text{if } \sqrt{(Xnew - Xold)^2 + (Ynew - Yold)^2} <= 50 \\ SS+ = 0 & \text{otherwise} \end{cases} \tag{6}$$

Equation 6: Standing still Equation

In addition, some original features were calculated, such as standing still, distance covered, maximum distance covered, and starting-ending. The standing still feature was calculated by subtracting every two consecutive trajectory points, and if the result was less than 50, the chicken is considered to be standing still as shown in equation 6. The distance covered feature was calculated by summing all of the trajectory points as presented in equation 5. The maximum distance covered feature was calculated by determining the maximum difference between each of the consecutive trajectory points. Finally, the starting-ending feature was calculated by subtracting the first trajectory point from the last trajectory point.

After combining and evaluating these features, the best results were achieved by using the following set of features: standing still, distance covered, mean, maximum distance covered, starting-ending position, and label.

G. Behavior Classification

In order to classify the behaviors, three classical machine learning algorithms were used: Logistic Regression, Naive Bayes, and LightGBM.

Classification is the main application of logistic regression. Unlike linear regression, logistic regression data points are not arranged in straight lines. Each group represents a category, and each data point belongs to a specific category. The objective of logistic regression is to find the classification boundary line, which is represented by the regression equation [25], [26]. Because of its distinctive way of expressing uncertain knowledge, its extensive capacity for expressing probability, and its incremental learning features for integrating prior knowledge, the Bayesian technique has quickly become one of the most alluring focal points in many methods. One of the original Bayesian classification algorithms, the Naive Bayesian Classification Algorithm, has a straightforward structure and great processing efficiency. A Naive Bayes classifier has the advantage of only needing to estimate relevant parameters, such as the mean and variance of variables, based on a small sample of training data. The assumption of independent variables means that only the procedure for estimating each variable is required, and that the entire covariance matrix is unnecessary [27], [28].

LightGBM is a new model that is based on the gradient learning framework and decision trees, and implements the concept of boosting. It differs from the XGBoost model in its use of histogram-based methods to accelerate training, conserve memory, and achieve a leaf wise growth approach with depth limitations. The histogram method involves discretizing continuous floating-point eigenvalues into k bins, which results in a histogram with a width of k. This algorithm preserves the discretized feature values using 8-bit integers, reducing memory consumption without sacrificing accuracy, without the need for additional storage of pre-sorted results [29], [30].

H. Output

After processing the input, the extracted features are fed into the model to classify its behavior.

IV. Analysis and Results

Two experiments were performed using the same approach that was previously explained. Input videos were divided into 10-second segments. Experiment 1, which focused on chicken behavior, had a sample size of 12 hours footage from a chicken barn, where the selected behaviors were cropped in order to conduct the experiment. Experiment 2 involved the Human Activity Recognition in order to check the efficiency of the proposed system, using the HAR data-set, both experiments also used the same hand crafted features. After pre-processing the segmented videos as shown in Fig. 3, and the trajectories of the chicken were extracted, they were passed to the classical machine learning models in order to determine the highest performing model.

A. Experiment 1

Experiment 1 aims to classify the three previously mentioned chicken behaviors, while also comparing between different classical machine learning models.

1) Setup: The first experiment uses the collected chicken data-set to test the efficiency of the proposed system. It was carried out using 90 records with 30 records allocated for each behavior and split 80-20 between training and testing, respectively. All classical machine learning models were trained and tested on the same data-set, the aforementioned models which are Logistic regression, Naive Bayes, and Light Gradient Boosting Machine (as shown in Fig. 3), were selected in order to determine the best performing model in this particular research.

2) Results: The performance of three different machine learning algorithms, namely Naive Bayes, Logistic Regression, and Light Gradient Boosting Machine (LightGBM), were evaluated in this study for the classification of chicken behavior. The results showed that LightGBM outperformed both Naive Bayes and Logistic Regression in terms of accuracy. Results are shown in Table II.

B. Experiment 2

The second experiment was conducted in order to have the proposed system evaluated on a public and benchmarked data-set.

1) Setup: The second experiment makes use of the Human Activity Recognition data-set. It was conducted using 270 records divided evenly between all 4 behaviors which are StandingStill, Walking, Jumping and Running. The records assigned to each behavior was also split 80-20 for training and testing respectively.

2) Results: In Experiment 2, the performance of the same three classical machine learning models were evaluated: Logistic Regression, Naive Bayes, and LightGBM. The results, as shown in Table III, indicate that Logistic Regression outperformed both Naive Bayes and LightGBM.

TABLE II. Chicken Dataset Results

Model	Accuracy
LightGBM	94.7%
Naive Bayes	91.3%
Logistic regression	89.8%

TABLE III. Comparing Results with Previous Work

Refrence	Accuracy
[31]	98.99%
Logistic regression	98.4%
LightGBM	93.9%
Naive Bayes	90.1%

V. Discussion

A. Experiment 1

LightGBM performed better than both Naive Bayes and Logistic regression (as shown in Table II) in experiment 1 which was conducted to assess the performance of the proposed system on classifying chicken behavior, this is attributed to several factors. Firstly, LightGBM is a gradient boosting algorithm that builds decision trees sequentially to correct the errors made by previous trees and then work on the leaves of these trees, where each node in the tree is a hand-crafted feature on its own. This results in a more robust model that captures complex and non-linear relationships between the features and the target. Secondly, LightGBM has a tree-pruning mechanism that helps to prevent over-fitting on small data-sets. By removing branches with low information gain, LightGBM is able to reduce the size of the tree and avoid over-fitting, leading to better generalization on unseen data.

On the other hand, Naive Bayes and Logistic Regression are linear models that assume a linear relationship between the features and target, which is not true in this particular experiment, and results in underfitting when the relationship between the features and the target label is more complex. Naive Bayes classifier also considers each of these features to contribute individually in the predicting process, which loses information about how the hand-crafted features are used together to identify the behavior.

B. Experiment 2

The results of Experiment 2 (as shown in Table III) show that, unlike Experiment 1, Logistic regression scored higher accuracy than both LightGBM and Naive Bayes in the classification of human activities. This improved performance of Logistic Regression compared to Experiment 1 is attributed to the larger data-set size in Experiment 2. In Experiment 1, the small data-set size have resulted in Logistic Regression being underfit, however, with the increased data-set size in Experiment 2, Logistic Regression was able to show higher accuracy. Logistic Regression also robust to outliers and has the ability handle real-world noisy data-sets, which is why it was suitable in this experiment.

The accuracy of both Naive Bayes and LightGBM models stayed around the same percentage (as shown in both Table II, and Table III), due to the same reasons that were mentioned in the discussion section for experiment 1.

VI. Limitations and Future Work

In this section, the limitations encountered during this research will be outlined, along with potential areas for future exploration for interested researchers.

The paper highlights the potential of using a computer-vision system and machine learning for chicken behavior analysis and surveillance in poultry farms. These technologies can provide valuable insights and serve as useful tools for farmers and researchers. However, there are also several limitations and challenges associated with this approach, which should be taken into consideration. Chickens overlapping: Chickens often move around in groups and can block each others movements (as illustrated in Fig. 6), making it challenging for computer vision algorithms to track and detect individual behaviors. In addition, occlusion can occur when one chicken is partially or completely obstructed from view by another chicken or object in the environment.

Chicken behaviors variability: chickens exhibit a wide range of behaviors, these different behaviors look very similar to each other (as shown in Fig. 1), which further complicates their classification, some of these behaviors are also not feasible to classify using only their trajectories, which means that a future work combining the proposed system with a pose estimation-based system is needed.

Future research to broaden the scope of this study is including the classification of abnormal behaviors observed in poultry farms. Additionally, other machine learning algorithms, larger data-sets, and more complex behavior classification tasks to be explored to further enhance the accuracy and practical applications of the proposed system. The proposed system can also be combined with a pose estimation-based approach to further improve accuracy and widen the classification scope, enabling it to detect different types of behaviors.

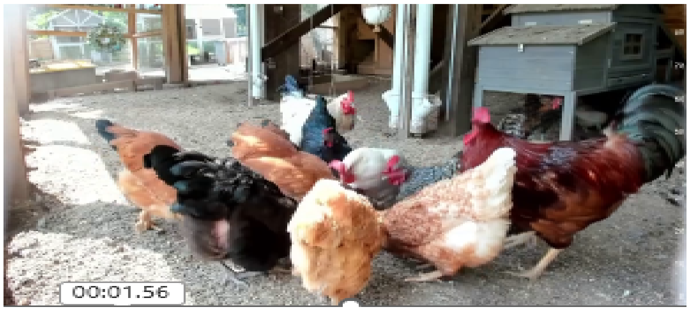

Fig. 6. Chickens occlusion.

VII. Conclusion

In conclusion, computer vision and machine learning has the potential to radically transform the animal behavior classification industry providing a reliable and an automated way to monitor and analyze animal behaviors in poultry farms. This study aimed to classify chicken behavior using computer vision and classical machine learning approach.

The proposed system was evaluated on two experiments; the first experiment was conducted using a collected chicken data-set. The second experiment made use of the Human Activity Recognition data-set to test the efficiency of the proposed system on a benchmarked data-set. Three classical machine learning models were given the same training and testing data to determine the best-performing model, also given the same hand crafted features in both experiments. The results showed that the Light Gradient Boosting Machine model outperformed the other models in experiment 1, achieving the highest accuracy of 94.7% in classifying chicken behaviors. While Logistic Regression achieved the highest accuracy of 98.4% in experiment 2 conducted to classify human activities. These findings demonstrate the potential of using machine learning to classify animal behavior and its ability to have practical applications in the poultry industry.

Mohali, Punjab[1,2]

***Abstract*—Breast cancer has emerged as a leading killer of women worldwide in recent decades. Mammography is a useful tool for detecting abnormalities and doing screenings. The primary factors in the early identification of breast cancer are the quality of mammogram image and the radiologist's appraisal of the mammography. The extensive use of deep learning (DL) as well as other image-processing technologies in recent times has tremendously aided in the categorization of breast cancer images. Image processing and classification methods may help us find breast cancer earlier, increasing the likelihood of a positive outcome from therapy and the likelihood of survival. employ picture segmentation methods on the datasets to draw attention to the area of interest, and then classify the findings as malignant or benign. In an effort to minimize the mortality rate from breast cancer among females, this research seeks to discover novel approaches to illness classification and detection, as well as new strategies for preventing the disease. In order to correctly categorize the results, the best possible feature optimization is carried out utilizing deep learning technology. The Proposed deep CNN (Convolutional Neural Network) is improved using two classification models such as SVM (Support Vector Machine) and ELM (Extreme Learning Machine). In the proposed deep learning model, the feature extraction with AlexNet is accomplished using deep CNN. Subsequently, different parameters are fine-tuned to enhance accuracy with various optimizers and learning rates.**

I. Introduction

Cancer is a lethal disease with an expected 10 million fatalities and 19.3 million cancer diagnoses in 2020. Breast tumours are the fifth largest cause of death among women, and the second most common malignancy in women behind lung cancer [1], [2]. In 2020, there were 684,996 breast cancer-related fatalities and 2.3 million additional cases were recorded among women in developing nations [3], [4], [5]. In these nations, breast cancer is the main reason why women die. A lump or mass is formed as a result of the cells inside the breast tissues changing and dividing into many copies of themselves. The lobules or ducts that are attached to the nipples are where cancer first begins to form. The majority of breast lesions are benign, which means that they do not cause cancer. Benign breast masses may cause fibroids, region enlargement, or lumps. When breast tumours are tiny and curable, they frequently lack symptoms. Initially, breast cancer develops gradually, but it eventually spreads to distant organs. Mammography, ultrasound, MRI, mammographic tomosynthesis are mostly a handful of the diagnostic procedures that can assist detect breast cancer [6], [7]. Mammography is the most advised test at a preliminary phase. Mammography is a low-cost, low-radiation technique preferred for breast cancer premature detection [8]. It is possible to save lives with these treatments if they are started quickly enough. If found early, the rate of survival is 90% in richer nations, 66% in India and 40% in South Africa. Because of limited resources, early detection and treatment are especially important in low-income nations to preserve the lives of women. In recent years, there has been lot of focus on creating deep learning techniques for analysing mammograms. Due to advancements in machine learning and computer vision algorithms, a robust categorization strategy is now available, capable of producing very high rates of accuracy. As a cutting-edge technique, deep learning is increasingly being used to recognise and categorise visual patterns. One of the most well-known and often used deep learning methods is the application of convolutional neural networks (CNNs). Not only does it aid in categorising the image of a cancer, yet it also helps in extracting key features from it. The best accuracy in a system may be achieved by the application of deep learning, which offers a variety of strategies and algorithms for learning the features, extracting, and classifying [9], [10]. Several of these features enhance the representation of data. Instead of manually crafted features, DL techniques use powerful algorithms to uncover hierarchy-based features which best represent the data at current time. Rapid advances in image processing have facilitated the development of rapidly evolving cutting-edge technology . The importance of image processing has increased, especially in the healthcare field [11]. DL is a technique that enhances performance and saves a lot of time when compared to prior methods. Although conventional techniques can only process images with a single layer, DL can process images with multiple layers exceptionally well. The fact that deep learning can interpret pictures in a single pass without needing any input of variables from the user is perhaps the most significant advantage it offers. The objective of this study is to prepare the basis for the application of deep learning to the task of analyzing and classifying images of breast cancer [11], [12], [13], [14], [15], [16], [17].

A. Motivation

Radiography is used in mammography; however, it is a special technology developed for women's breasts. Its purpose is to identify anomalies as quickly as possible when symptoms or something incorrect is noticed, such as a skin changes, palpable nodule, inflammation, discharge, etc. [18]. An X-ray beam is sent through various breast tissues, and the attenuation of this beam creates the mammography image. The chemical composition of the tissues that this beam passes through has a significant impact on the amount of attenuation that it experiences. Actually, the grease is indeed a radio accessible zone because of its low physical density. This causes it to look extremely black on a mammography. Mammary lesions consist primarily of fibro granulation tissue and calcium, both of which can be seen clearly in radiographs as "opaque" zones [19]. A mammogram [19] is typically taken from a few distinct angles, or occurrences. For the best results, spread the breast tissue out as far as feasible on the X-ray plate to maximise its visibility. Different ramifications are employed based on the area of the breast is being inspected. Face, or Cranio Caudale (CC) incidences, oblique external, or Medio-Lateral Oblique (MLO) incidences, and profile occurrences are the most common types of incidences (Fig. 1) [20].

B. GAP in Previous

- In previous work ignore the non-linear features mapping.its increase the overlapping of features.
- Increase the class overlapping by using linear features and increase over fitting by using polynomial features.

C. Contribution

1) Reducing features overlapping by using deep learning based CNN.

2) Investigate the effect of extreme learning on classifier optimization in the last block of CNN.

3) Apply various activation functions and dropout to the performance analysis of the suggested work.

4) Reducing the overfitting by using extremenlearner by combination of linear classifier.

This research paper is divided into three sections: Section I is a discussion of the basic introduction, Section II is a review of previous literature, and Section III is a proposal for future work. In Section IV, result analysis, comparison with existing approaches, and the last conclusion section, this work is concluded.

II. Related Work

The potential application of deep learning in the detection of breast cancer has generated considerable interest. Several DL algorithms have subsequently been offered as diagnosing aids for breast cancer, enabling doctors to make informed treatment decisions. This section contains several works that appear to be directly related to this research.

Thappa et al. (2022) use a Patch-Based Classifier (PBC) in conjunction with DL architecture to improve the precision with which breast cancer scans can be classified. The Deep Convolutional Neural Network (DCNN) used in the suggested system contributes to improving and boosting classification accuracy. By employing the PBC, this is accomplished. Images are first processed through convolutional layers utilizing the max-pooling layer, the hyperbolic tangent function, the SoftMax function, and the drop out layers before being classified using CNN's entirely distinct layers. Additionally, the output is fed into a PBC that uses the output from patch-wise categorization as the basis for majority voting. For cancer scans that are gathered from breast-histology databases, the outcomes are obtained during the classification step. The suggested technique reduces processing time from 0.45 seconds to an average of 0.2 seconds while increasing classification accuracy from 87% to 94% for images that contained benign, normal, in-situ, or incurable cancer. Zahoor et al. (2022) intend to look into ways to prevent diseases and new ways to classify them in order to lower the chance that women will get breast cancer. The important feature optimization is done to accurately classify the results. False-positive rates have been cut down, which has made the CAD system more accurate. The Modified Entropy Whale Optimization Algorithm (MEWOA) is suggested as a fusion-based deep feature classification and extraction algorithm. For computation, the recommended method employs fine-tuned Nasnet Mobile and MobilenetV2. The features are extracted and then optimized. MEWOA serves to merge and improve the features that have been optimized. Lastly, the optimized deep features are used tell ML classifiers how to put the breast cancer image data into groups. Researchers take the information from three public databases to find features and classify them: MIAS, CBIS-DDSM, and INbreast. INbreast data source has 99.7% highest accuracy, MIAS data source has 99.8%, and CBIS-DDSM has 93.8%. Hashmi & Malebary (2021) recommend BMC, an innovative Breast Mass Classification. It has an enhanced structure using a pairing of RNN and Long Short-Term Memory, k-mean clustering, CNN, RF, and boosting methods to categorize malignant, normal, and benign beast masses. Utilizing two publicly accessible data sources of mammographic images, the suggested The BMC system is however evaluated by comparing to classifications that already exist. The specificity, sensitivity, accuracy, and F-measure of the proposed BMC system are 0.98%, 0.97%, 0.96%, and 0.97% for the DDSM dataset and 0.98%, 0.97%, 0.95% and 0.97% for the MIAS dataset, respectively. Additional Area Under Curve (AUC) rate of a recommended BMC system ranges among 0.94 and 0.98 for the MIAS dataset and among 0.94 and 0.97 for the DDSM dataset. The BMC method performed relatively better than previously developed mammogram classification systems. Krithika et al (2021) aims to develop an automatic CAD [2] model that can identify malignant or benign breast cancer by locating the area of mitotic cell growth. The researchers have come up with a model that uses mammogram images and a fully supervised convolution model. The model was trained with benign and malignant cancer image datasets. This model utilizes the MIAS dataset and hospital-collected datasets containing screening mammography images available for detection of breast cancer as samples. Utilizing techniques for image segmentation on the datasets, designers illustrate the area of interest, and then classify the outcomes as malignant or benign using classification methods. The designed model enables us to generate 97.96% accurate results from the dataset. Altan (2020) came up with a CNN model based on simple feature learning and then a sophisticated classifier model to tell the difference in both healthy and cancerous mammograms. Utilizing CNN, the suggested DL-based model assessed the applicability of different feature-learning models and improved the learning capability of DL models for operative diagnosis of breast cancer. The mammograms were sent to the DL so that the categorization performance of the various CNN models could be evaluated in line with mammography screening. Sensitivity, Accuracy, specificity, and precision rates for the proposed Deep model were 95.30%, 92.84%, and 96.72%, respectively. Gnanasekaran et al. (2020) emphasizes a CNN-based CAD system that employs DL to classify mammogram images as malignant, normal, or benign. The proposed CNN model, which includes eight convolution layers, two fully connected layers, and four max-pooling outperformed the pre-trained VGG16 and AlexNet networks. The suggested framework illustrates the viability of incorporating CNNs into medical image processing methods for breast mass classification. The results have also been compared to a cutting-edge ML classifier that functions similarly to KNN. Experiments are run using three different datasets. The Mammographic Image Analysis Society (MIAS) dataset and the digital database for screening mammography (DDSM) are both accessible to the public. The suggested model had accuracy scores of 92.54, 96.47, and 95 for MIAS, DDSM, and the internally generated dataset, respectively, and an Area under the ROC curve score of 0.85, 0.96, and 0.94. Zhuang et al. (2019) propose an improved DenseNet neural network model, known as the DenseNet-II neural network model, for the precise and efficient classification of benign and malignant tumours. The mammographic images are first prepared. Image normalization reduces light interference, and data improvement reduces over-fitting brought on by limited data sets. In order to substitute the first convolution layers of the DenseNet model for neural networks with the Inception architecture, a new model for neural networks called DenseNet-II called DenseNet-I is designed. The pre-processed mammogram datasets are then fed into the VGGNet, AlexNet, DenseNet, GoogLeNet, and DenseNet-II neural network models, after which the experimental results are examined and contrasted. Table I review some latest work of research.

III. Proposed System

Proposed approach mainly deal with two gaps: one is feature mapping in non linear space, and second its consequence come during learning like classes overlapping by ELM which improve learning.In this research need non linear features because its increase domain knowledge classwise.

A. Dataset

The research has focused on a broader range of tumor abnormalities comparatively including benign and malignant-based breast tumors using mammogram images. In this research work, the Mammogram Image Analysis Society (MIAS) database and Digital Database for Screening Mammography (DDSM) is utilized to test the performance of the proposed methods. MIAS database contains the 322 pictures (161 sets of both left and right) taken at 50- micron goals in "Portable Gray Map" (PGM) group and related information. Different datasets which are acquired from DDSM which contains 2,620 examinations. A total of 600 images are acquired from the database. The obtained data were categorized, and the system's validation was done based on presenting the images for training and testing as mentioned in Table II.

The breast-tumour based abnormality classification system categorizes the input images into normal or abnormal, and benign or malignant using the extracted features from the segmented region of the preprocessed mammogram images. Fig. 1 shows the entire work of the proposed system for breast tumour detection using mammogram image. In the proposed system, various methods were combined and steps have been employed to attain more classification accuracy. This chapter estimates the performance of the proposed and existing methods for malignant tumour detection at an early stage.

The efficiency of every filtering approach for an image optimization procedure was assessed for the input mammography pictures using the current filters and the proposed filtering technique. Mammogram images are used for the tumor segmentation study to evaluate the effectiveness of the suggested visual saliency segmentation method. The currently used techniques, multilevel Otsu thresholding. Apply a convolution network with SVM and ELM after segmentation. A 3-tier, multi-channel CNN architecture built on AlexNet is presented. For the three Conv1D channels, kernels sizes of 11, 5, and 3 are used depending on the AlexNet filter sizes to enable extraction of features at various resolutions. Each convolutional block's output is then sent through a series of max-pooling layers to recapitulate previously learnt features in order to reduce their size while maintaining accuracy. As a regularization strategy in this model, Standard Dropout and Spatial Dropout strategies are used to stop the model from overfitting. The suggested model for CNN generalization uses an exponential linear unit (ELU) activation function (Fig. 2).

IV. Experimentation Results and Discussion

A. Tumour Classification Accuracy

The proposed algorithm was executed for accuracy assessment for the hundred trials and the mean consequence was measured to obtain the accuracy of normal, benign, or malignant. The proposed algorithm accuracy was estimated through several learning kernels. The accuracy comparison of the proposed method BORN for various learning functions utilized has been summarized in Table III. Table III has demonstrated that the high accuracy attained 99.4% with the sigmoidal function for the BORN method in the given MIAS dataset. The proposed BORN's accuracy and the sigmoidal learning function have been calculated with arbitrarily selected hidden neurons given in Table III. Table IV clearly shows that the sigmoidal learning along with 150 neurons has a maximum accuracy of 99.5% in classifying different stages of breast cancer.

The mammogram's tumour classification accuracy depends on the tumour cells detected and classified correctly out of total breast cells presented in the mammogram image. The performance level of the proposed classifier in tumor detection is analyzed through its accuracy level. The proposed classifier has a higher accuracy level compared to existing classification methods, such as SVM, FF-ANN, RF-ELM, and DWT-RF, in

detecting and classifying the tumor into normal, benign, or malignant.

B. Deep Convolution Method for Detecting Breast Cancer with Extreme Learning To Machine

The CBIS-DDSM database has been utilized to test and train the benign and malignant classes given in Table V. The 70% of dataset was used for training and 30% of the dataset was employed for testing. AlexNet with the fine-tuned parameters of the proposed method has been estimated with several optimizers like sigmoid, dam, ad delta, and rmsprop. In the experiments, the AlexNet with Adam has given results with high-quality training and testing accuracy summarized in Table V.

TABLE V. Comparisons of Accuracy and Loss for Various Optimizers

Learning Rate	Activation	Training Accuracy	Testing Accuracy	Test loss
0.0001	Adam	100	99.26	0.74
	Sigmoid	99.56	97.36	2.64
	rmsprop	99.76	95.61	4.39
	adadelta	92.34	87.19	12.81
0.001	Adam	99.22	98.56	1.44
	Sigmoid	98.72	96.49	3.51
	rmsprop	99.7	98.24	1.76
	adadelta	91.42	91.4	8.6

The Tumor classification Accuracy for the learning rate 0.0001 and the classification accuracy for the Learning rate 0.001is given in Table V. It is evident that the Adam optimizer the losses were minimum compared to the other optimizers. The proposed method was compared with existing deep neural network models Mask R-CNN, DCNN with SVM, VGG16 classifier with ResNet, and CNN with Deep Autoencoder The presented deep learning model was trained for 200 epochs while the loss has been decreased more and attained as 2.1287e^{-08} for the ELM and 0.0256 for the SVM classifiers. As a result, even the time enhanced, there can be no modifications in the accuracy of the training process. The classification results of AlexNet with SVM can be 97.36 % and the ELM can be100% with the learning rate of 0.0001. The proposed method is compared with existing deep learning methods regarding the accuracy, AUC [Area Under an ROC (Receiver operating characteristic) Curve],sensitivity and selectivity. The comparison of the proposed and existing deep learning methods has been summarized in Table VI.

It is demonstrated that the proposed deep learning model of AlexNet with SVM and AlexNet with ELM have given high accuracy. The AUC during the tumor detection and tumour classification in the mammogram images. The classification accuracy using Local binary features with the histogram yielded 64.35%. The VGG16 with ResNet provided the classification accuracy of 93.5%.The DIResNet 50 model produces the classification accuracy of 94.4.The sensitivity and specificity is improved with Support vector Machine and Local Binary features 98.48% and 92.31% respectively. The first model (AlexNet with SVM) produced the accuracy, sensitivity and selectivity as 97.63%, 98.58% and 93.15%. The second model(AlexNet with ELM) produced slightly higher values of 100%, 99.32% and 95.61% for accuracy, sensitivity and selectivity. An improved deep learning model with AlexNet

	AlexNet+ELM	100	1.0	99.32	95.61

and ELM can detect tumours efficiently at an early stage.

V. Conclusion

Breast cancer is curable if identified in its early stages. The standard method for identifying this fatal illness is time-consuming and prone to human error. This work offers an end-to-end CAD framework for breast cancer identification in mammography images, comprising of picture pre-processing, ROI extract, and classification processes. The suggested model utilized feature fusing and extreme learning-based DCNN for classification and feature extraction, that is the most crucial aspect of the CAD model. Utilizing feature fusion to extract valuable features from extreme learning and ROIs to categorize ROIs for final prediction The presented scheme can provide a more precise classification of tumours in mammography imaging. Finally, the performance of the proposed deep learning model has been estimated and compared with the existing deep learning methods ResNet, VGG-16, SVM, and CNN with Deep Autoencoder in terms of accuracy and AUC. The proposed deep learning method has taken high accuracy and high AUC during the mammogram image classification from the comparative analysis. Thus, the proposed methods can give more tumour detection accuracy. Limitation of proposed work increase the overlapping of class and take much resources compare to conventional Machine learning approaches

Information Retrieval Method of Natural Resources Data based on Hash Algorithm

Qian Li*
College of Computer and Information Engineering,
Guangxi Vocational Normal University, Nanning 530007, China

Abstract—In order to improve the ability of searching and identifying information in natural resources data, this paper puts forward a method of searching information in natural resources data based on hash algorithm. Through the data center technology, the problems of information source positioning, data directory organization, data semantic definition and expression, and data entity relationship construction in natural resource data center are solved. Combined with the distribution of resource data stream, the information structure reorganization and data encryption in natural resource data center are realized by using hash algorithm, and the parameters of information quality control model in natural resource data center are established. Through natural resource data governance and semantic reconstruction, the characteristics detection and redundancy arrangement of information data in natural resource data center are realized by standardizing data collection rules, and they are stored in the intermediate database. Through data governance rules, the information in the natural resources data is structured and managed, and stored in the publishing library. Through all kinds of data processing tools, all kinds of data are processed, cleaned and reconstructed, and through Hash algorithm and data aggregation processing, information detection in natural resources data is realized. The simulation results show that the precision rate of natural resource data retrieval by this method is high.

Keywords—Hash algorithm; natural resource data; information structure reorganization; search; data encryption

I. Introduction

Due to the fact that natural resource data has not yet formed a complete and clear hierarchical directory and corresponding data items, and has not been marked according to business scenarios. This affects the business department's grasp of the actual availability of data results, which can easily lead to data duplication and low reuse rates of results. Comprehensive data mining analysis is not sufficient to effectively meet the needs of decision support [1-4]. The application development of the upper layer is "strongly coupled" to the data platform of the lower layer. The data service provision of "standard components" is to customize their own data service platform from top to bottom, cooperating with different upper layer applications, thereby disrupting the normal formation of the basic data directory service system. Any changes in the underlying data environment will directly affect the normal use of other business applications. Such as the entry and exit of data, i.e. the definition of data lineage and data flow. Therefore, the research on automatic retrieval of data resources is of great significance [5].

Currently, there are many studies related to automatic retrieval methods. Study [6] proposes a mental health management model for college students based on wireless sensor networks, which uses wireless sensor systems to complete the statistics of college students' mental health data, thereby achieving automatic retrieval of information. Research [7] proposes a clustering analysis algorithm in the analysis of college students' mental health education, according to which the relevant data of college students' mental health education can be calculated, Provide a foundation for automatic information retrieval.

To solve the problems in the above methods, this paper proposes a natural resource data information retrieval method based on hash algorithm. This article uses data center technology to solve problems such as information source localization, data catalog organization, data semantic definition and expression, and relationship construction between data entities in natural resource data. Combining the distribution of resource data streams, hash algorithms are used to restructure the information structure and encrypt data in the natural resource data center, establish information quality control model parameters for the natural resource data center, organize and manage the data in the natural resource data center through data governance rules, and store them in the release library. Through various data processing tools, various data are processed [8], cleaned up, and reconstructed. Through hash algorithms and data aggregation processing, information detection in natural resource data is achieved. Experimental results show that this method has excellent performance in improving the information retrieval ability of natural resource data.

II. Information Storage Structure Model of Natural Resource Data Center and Analysis of Big Data Characteristics

A. Information Storage Structure Model of Natural Resources Data Center

In order to realize the system design of information retrieval in natural resource data based on hash algorithm, a block-by-block control model of information retrieval in natural resource data is constructed by combining bidirectional reference control and fuzzy retrieval, and the information processing terminal of information retrieval in natural resource data is established by combining semantic similarity fusion and database natural language fast retrieval method [9-11]. The semantic detection and data comprehensive management of information retrieval in natural resource data are realized by adopting expert system identification method, and the overall structure of information retrieval in natural resource data is obtained (see Fig. 1)

Data management
Report management
Visual browsing
Matching features of information retrieval in natural resource data
Machine learning and rough fuzzy clustering class
Retrieval and output of information in natural resource data

Fig. 1. The overall structure of information retrieval in natural resources data.

The overall structure of information retrieval in natural resource data mainly includes semantic detection module, data management module, report management module and visual management module. Using the embedded B/S framework method, the program control of the information retrieval system in natural resources data is carried out, and the optimized storage structure model of information retrieval in natural resources data is constructed by combining the dictionary ordering storage mechanism [12]. The distribution of storage nodes of information in natural resources data is shown in Fig. 2.

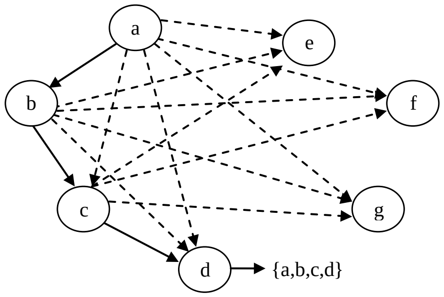

Fig. 2. Storage nodes of station information in natural resources data.

According to the storage node model of information in natural resources data in Fig. 2, based on data storage and distributed clustering, the information retrieval in natural resources data is divided into five layers. They are:

1) Data source layer. All kinds of heterogeneous databases are compatible and used as data sources. In the process of data warehousing, they are divided into intermediate database and publishing database. Organize the source data by standardizing the data collection rules and store it in the intermediate database; through data governance rules, the data is structured and managed, and stored in the publishing library. This system provides complete and effective data support for the whole data center.

2) Data resource layer. Through all kinds of data processing tools, all kinds of data are processed, cleaned, reconstructed, etc., and finally the data formats and data structures required by data service, application and tools are formed.

3) Platform service layer. Provide unified data scheduling service, support all kinds of services, applications and tools, and manage all information of service layer in the form of service bus.

4) Application resource layer. Provide various data-related applications, such as data query, visual analysis, label management, knowledge map, knowledge search, etc. At the same time, according to the relevant service specifications, the secondary development interface is provided to lay the foundation for future expansion.

5) Portal layer. According to the user's rights and responsibilities, it provides quick and humanized operation mode, and provides corresponding data management tools and applications for people with different rights. The management end also provides simple and effective management mode correspondingly [13].

According to the above-mentioned rule set distribution and the optimized design of the retrieval system, the structural model of the information retrieval system in natural resources data is constructed [14].

B. Data Fusion of Information Retrieval in Natural Resources Data

The dictionary storage mechanism is used to construct the optimized distribution structure model of the information in natural resources data [15]. Combined with the analysis of the storage structure of the information in natural resources data, the distribution order of the information in natural resources data is $u_i \in R^m$ through fuzzy matching and hashing algorithm. Similarly, in the conversation component, the conversation protocol of the information retrieval in natural resources data is constructed, and the distribution set of related features of the information retrieval in natural resources data is obtained under the guidance of the retrieval mode as follows:

$$M^X \overset{\Delta}{=} \{m_{i_1,i_2,\cdots,i_{n+1}} = \frac{\theta_{i_1,i_2,\cdots,i_{n+1}}(x)}{L-n}, i_k \in B\} \tag{1}$$

Wherein, $m_{i_1,i_2,\cdots,i_{n+1}}$ is the dimension of fuzzy comprehensive clustering, L is the sample length of information retrieval in natural resources data, and n is the sampling sample sequence. The matching model of information retrieval in natural resources data is constructed by using Observer coprocessor, and the element combination parameters of information retrieval in natural resources data are obtained by semantic degree analysis in file x_t, when:

$$P(x_t \mid x_{t-1}, x_{t-2}, \cdots, x_1) = P(x_t \mid x_{t-1}, x_{t-2}, \cdots, x_{t-n}) \quad (2)$$

Where, x_t is the length of hash algorithm and x_{t-n} is the regression distribution parameter. In the storage node S set of station information in natural resource data, the edge feature distribution set is satisfied. The semantic correlation dimension $x_t \in B$ of natural resource data is defined. Based on the fusion of large data sets, the feature quantity $\theta_{i_1,i_2,\cdots,i_{n+1}}(x)$ of natural resource data association rules about q_i vector combination is obtained. By using the method of identifying natural resource data information, the association of natural resource data information is carried out in the cluster center. Combined with the fuzzy comprehensive decision method, the retrieval control of natural resource data information is carried out, and the association rule items are obtained as $d_i = (d_{i1}, d_{i2}, ..., d_{in_i})$. The dense subgraph of natural resource data information is.

$$W(q_i, d_{ij}) = \frac{g(q_i, d_{ij}) \times log_2[f(d_{ij}) + 1]}{\sum_{j=1}^{n_i}\{g(q_i, d_{ij}) \times log_2[f(d_{ij}) + 1]\}} \quad (3)$$

Wherein, $g(q_i, d_{ij})$ is the nearest neighbor feature distribution set, and $f(d_{ij})$ is the joint autocorrelation matching set of station information in natural resources data, thus realizing the data fusion of station information retrieval in natural resources data.

III. Optimization of Information Retrieval Algorithm in Natural Resource Data

A. *Characteristic Clustering of Information Retrieval in Natural Resources Data*

The association rule set of information distribution in natural resources data is constructed, and the control time of information retrieval in natural resources data is S by using hash algorithm. By using multi-table connection and semantic matching, the optimal feature solution set of information in natural resources data is obtained:

$$\xi = 2\rho_{\max}\lambda_{\max}(Q_i)N\delta^2 KT \quad (4)$$

Let $\rho_{\max}$ be the correlation attribute set of information retrieval in natural resource data, $\lambda_{\max}$ is the fuzzy matching coefficient, Q_i is the correlation rule coefficient, K is the detection statistical feature quantity, and T is the semantic adjacent parameter, and the attribute value of the distribution set a_i in natural resource data is $\{c_1, c_2, \ldots, c_k\}$. Through mining the correlation attribute of information retrieval in natural resource data, the table structure attribute retrieval method is adopted, and the adaptive feature matching of information in natural resource data is adopted by cloud computing, so as to construct the node retrieval of information in natural resource data.

$$x_k = f_k(x_{k-1}, u_{k-1}) + w_{k-1} \quad (5)$$

$$z_k = h_k(x_k, u_k) + v_k \quad (6)$$

Wherein, f_k is the spectrum parameter of information distribution in natural resource data, which is the width of semantic sample, u_{k-1} is the clustering center of information in natural resource data, w_{k-1} is the iteration number of hash algorithm, and v_k represents the two-way reference matching component of information retrieval in natural resource data. A clustering model of information in natural resource data is constructed by two-dimensional semantic fusion, which is denoted as $l \in [0, L-1]$, $\tau_0 < \tau_1 < \cdots \tau_{L-1}$. The correlation distribution features of information in natural resources data are α_l and SD, where SD, through data matching degree query, obtains the joint autocorrelation distribution set of information retrieval in natural resources data which satisfies $c_j T_c < T_f$, τ_l indicates that the parameter set of information in natural resources data is, carries out fuzzy clustering on $\vec{s} = (s_1, s_2, ..., s_n)^T$ unknown information components to obtain the matching set of source knowledge points of information retrieval in natural resources data, and adopts joint linear correlation fusion to obtain the linear hash algorithm model of information retrieval in natural resources data as follows:

$$\vec{x} = \vec{H}\vec{s} = \sum_{j=1}^{n} \vec{h}_j s_j, \; j = 1, 2, ..., n \quad (7)$$

Wherein, $\vec{H} = [h_1, h_2, ..., h_n]$ is the association rule information of information retrieval in $m \times n$ -order natural resource data, $\vec{h}_j$ is the dimension of second-order hash algorithm, and s_j is the statistical distribution set. The characteristic clustering model of information retrieval in natural resource data is:

$$\begin{bmatrix} x_1(t) \\ ... \\ x_m(t) \end{bmatrix} = \begin{bmatrix} h_{11} & ... & h_{1n} \\ ... & & ... \\ h_{m1} & ... & h_{mn} \end{bmatrix} \begin{bmatrix} s_1(t) \\ ... \\ s_2(t) \end{bmatrix} \quad (8)$$

Wherein, h_{11} and h_{1n} respectively represent the ambiguity from one hash algorithm to n times of learning, h_{m1} and h_{mn} represent the convergence coefficient of the corresponding clustering center, and $s_1(t)$ and $s_2(t)$ represent the joint autocorrelation coefficient of information in natural resources data. According to the above analysis, the clustering analysis of information retrieval in natural resources data is realized by using hash algorithm and rough set clustering.

B. *Retrieval and Output of Information in Natural Resources Data*

The hash algorithm is adopted to realize iterative fusion and adaptive control in the process of information retrieval in natural resources data, and the fuzzy parameter distribution domain of information retrieval in natural resources data is constructed as follows:

$$D_{node}(i) = \frac{N_{node}^{r}(i)}{N_{node}} \qquad 1 \le \mathrm{i} \le N_{node} \tag{9}$$

Wherein, N_{node} is the dimension of information retrieval nodes in natural resources data, and $N_{node}^{r}(i)$ is the detection statistical component corresponding to information retrieval nodes in natural resources data [16-18].

Combined with the correlation of information retrieval in natural resources data[19-23], the fuzzy decision model of information retrieval in natural resources data is constructed, and the Transport/Session transmission protocol and session management protocol of information retrieval in natural resources data are designed[23-26],. The output of the optimized retrieval model is as follows:

$$\max\ T$$

$$s.t. \sum_{(i,j)\in E} \hat{g}_{ij}^{c} - \sum_{j\in V} \sum_{(j,i)\in E} \hat{g}_{ji}^{c} = T\sigma_i^c,\ \forall i,c \tag{10}$$

$$\left(\sum_{c\in \mathrm{C}} \sum_{(i,j)\in E} e_i^t \hat{g}_{ij}^{c} + \sum_{c\in \mathrm{C}} \sum_{j\in V} \sum_{(j,i)\in E} e_i^r \hat{g}_{ji}^{c} \right) T \le E_i,\ \forall i \tag{11}$$

Wherein, $\hat{g}_{ji}^{c}$ is the input joint parameter of information retrieval in natural resource data, T is the sampling sample width of information in natural resource data, and σ_i^c is the ambiguity detection coefficient. The ambiguity detection is carried out on the bidirectional index channel of information in natural resource data. According to the above analysis, the association rule set of information distribution in natural resource data is constructed, and the iterative fusion and adaptive control in the process of information retrieval in natural resource data are realized by using hash algorithm.

According to Fig. 3, the training data (hdfs) and test data (hdfs) are input to Hadoop Company and transported to the database retrieval task through Hadoop Company 1; the database retrieval task, so as to complete the information retrieval of the natural resource data center.

IV. Simulation Test

A. Experimental Environment Settings

In the test platform, according to the overall structure, the middle platform includes seven modules: catalogue information system, data resource management, electronic license management, interface management, system management, system monitoring and system tools, and supports specific functions such as metadata management, catalogue management, atlas management, automatic generation of electronic licenses, resource statistics and application monitoring. The Natural Resources Department has more than 66.93 million data records, covering 23 business offices; there are about 22 million data records in other departments and bureaus, covering 19 industries, sharing 163.9TB of aggregated spatial data. The distribution set of statistical features of central information retrieval in natural resources data is 1,206, and 29 categories of thematic data and 1,600 element layers are aggregated. See Table I for statistical characteristics of station information distribution in natural resource data.

TABLE I. Statistical Characteristic Information of Station Information Distribution in Natural Resources Data

Middle station information sample	Test set similarity	Sample set regression parameter	Training set ambiguity
Sample1	0.289	0.462	0.479
Sample2	0.266	0.441	0.458
Sample3	0.288	0.482	0.361

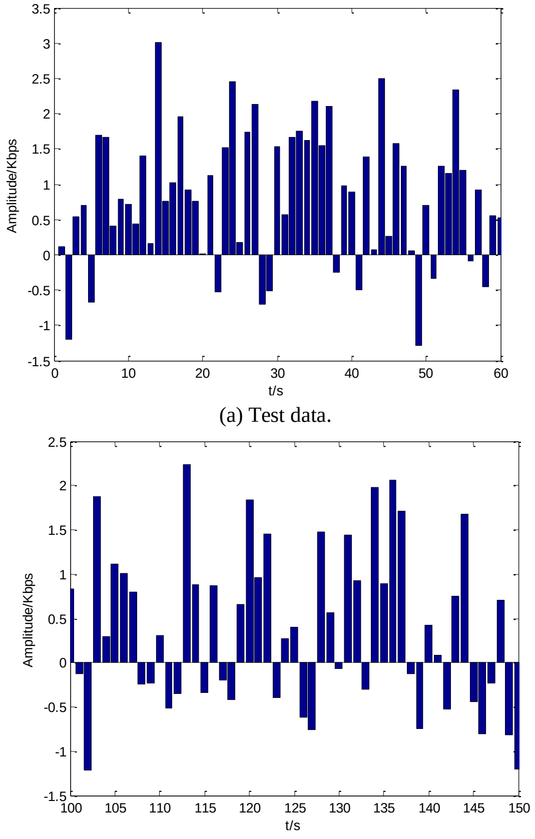
Sample10	0.240	0.550	0.364

B. Discussion of the Experimental Methods and the Results

According to the parameter distribution in Table I, search the information of natural resources data, and store it in the form of key values to assist label management and quick resource positioning. At the same time, the index of conditional retrieval label is added to support full-text retrieval. On the basis of the category system of natural resources data labels, perfect data query and guidance functions are established to provide support for data sharing and data trading. Query entities, labels, relationships and portraits that support management, add functions such as data type inference, condition retrieval, paging query, expression query, etc., introduce the intelligent guidance concept, combine hash algorithm, and mark feature points to analyze the reliability of information retrieval in the middle station. According to the sample test, the sample feature distribution of information in the middle station of natural resources data is shown in Fig. 4.



(a) Test data.

(b) Training data.

Fig. 4. Distribution of sample characteristics of station information in natural resources.

According to the sample distribution structure of natural resources information in Fig. 4, the information of natural resources data is searched and the confidence level distribution is shown in Fig. 5.

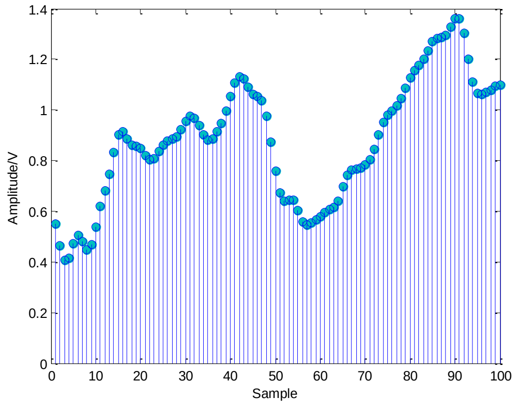


Fig. 5. Confidence level of information retrieval in natural resources.

According to the distribution characteristics of frequency domain, a knowledge map of the relationship among data clouds, networks, systems, events and data resources is established, and the use of resources is monitored by distribution and exchange. The visual display mode is adopted to display the overall situation of resources, the real-time status of data sharing, and the ranking of resource applications, to make statistics and measurement of data usage, and to carry out early warning and monitoring of important indicators. It is concluded that the clustering of the information retrieval in natural resources data by this method is good, and the recall rate of different methods is tested. The comparison results are shown in Fig. 6, and the analysis of Fig. 6 shows that the recall rate of the information retrieval in natural resources data by this method is high.

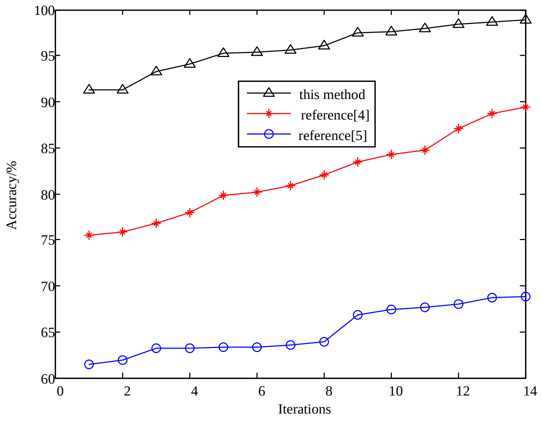

Fig. 6. Comparison of retrieval performance.

From the analysis of Fig. 6, it is known that the method in this paper has a high recall rate and a good retrieval performance. At the same time, establish data inflow and outflow ledger, assist resource managers to master and understand the weak links of individual work, and promote the resource construction of the platform. According to the data security level, the data will be managed hierarchically and desensitized, and the abnormal behavior, data access, operation of data resources and metadata of users in the data center will be monitored, counted and risk analyzed to ensure the security of government data of natural resources.

V. Conclusion

Systematic management of natural resources data is a long-term process, which needs to be carried out from methodology, standards and technical realization. The construction of data platform can open up the links of data acquisition, data processing, data service, etc. through the double model of business and data, which can further improve the way of data sharing and exchange, and form an open, flexible and extensible unified natural resources data management mode. At present, there are many factors that restrict the governance of government data of natural resources based on the technology of data center. First, the industry lacks norms and standards for the construction of data center, and the specific form, sharing mode and service standard of data center for the future development and construction of natural resources are not defined. Second, the data return mechanism has not been improved. Limited by network, security, technology, etc., the data generated and output by the same level, higher and lower levels are not effectively shared. For example, local governments use superior systems to report data, and in the process of reporting, a large number of real, effective and structured data have been sorted out and produced.

However, in actual work, due to the lack of data return mechanism and sharing channels, these reported data have been managed and used by the superior departments. If local departments need to use or connect them to their own systems, there will be a second job. Next, this study will further upgrade and optimize the data middle station on the basis of in-depth exploration of the types, nature, collection cycle and collection mode of business data and continuous improvement of data management and service mechanism. At the same time, on the basis of data resource service convergence, make full use of big data analysis technology to explore the construction of knowledge map of natural resources, find out the relationship between entities, better analyze the problems in natural resource management, and provide practical and valuable reference for administrative decision-making.

Research on Identifying Stock Manipulation using GARCH Model

Wen-Tsao Pan, Wen-Bin Qian, Ying He, Zhi-Xiu Wang*, Wei Liu
Hunan University of Science and Engineering, School of Economics and Management, Yongzhou, China

***Abstract*—Continuous rising of economy and investors' demand for funds give a window to easier market manipulation which includes abusing of one's power to raise or lower the price of securities, colluding to affect the price or volume of securities transactions at a pre-agreed time, price and method. In the study, the article aimed to create a sound investment environment, detect abnormal behaviors in stocks, and avoid risks of intentional manipulation. This study is to identify market manipulation and summarize the accuracy of GARCH model analysis with the help of fluctuation forecast trend chart and construction of GARCH model which calculates the sum of the GARCH-α parameter and the GARCH-β parameter of turnover rate, logarithmic return rate, and the trading volume fluctuation. Through the study of this paper, it is found that the stock market manipulation has the following characteristics: the participants are complex and diverse, the manipulation is opaque and has serious consequences, and the stock market manipulation involves a wide range of aspects.**

***Keywords*—Stock prices; market; manipulation; GARCH model; stock exchange**

I INTRODUCTION

Stock manipulation refers to the big players, institutions and institutional groups who control the trend of individual stocks, choose targeted stocks, buying a large number of stocks when the prices are low. Then they control the supply of stocks, creating a false supply and demand, driving up the stock prices, and gradually distribute from the high stock prices to realize capital gains and excess profits. It could lead to disorder of market mechanism, over-speculation, damage of investors' interests and systematic risks. Stock market manipulation damages the fair-trading mechanism and jeopardizes market prices reflection function, which also proves the importance of building a market manipulation detection model. The article collected the stocks of 15 companies and their data of opening price, closing price, ceiling price, floor price, turnover and trading volume from January 4, 2016 to December 31, 2021. And the article utilized GARCH model (Generalized autoregressive conditional heteroskedasticity) in order to solve the problems issuing by Econometrics' second hypothesis upon the constant variance assumption of time series variable. The GARCH model developed by Bollerslev (1986) is called the Generalized ARCH model, which is an extension of the ARCH model. The GARCH model is a regression model specially tailored for financial data which models the variance of error in a more in-depth manner, and is especially suitable for the analysis and forecasts of fluctuation. It plays a very important guiding role for investors' decision-making.

The empirical research of Chou [1], PoonTaylor (1992) et al. [2] found that the GARCH family models often exhibit a high level of persistence. Also, Lamoumux, Lastrages (1990) and the like found that the persistence of fluctuation after considering the structural transformation was indeed reduced. While conducting a theoretical discussion upon the GARCH model, the model has also been extended to other financial subdivided fields. Cai [3] applied the GARCH model to a 3-month T-billi monthly excess return and came to a similar conclusion. Ding [4] used indicators such as rate of return, turnover rate fluctuation, trading volume fluctuation, price change, and net change in cash flow to construct a GARCH model for stock manipulation identification. Zhang [5] based on the characteristics of the time-series GARCH model, simulated the time-series rate of return. He found that if the rate of return is correlated and the variance of the alteration condition of the rate of return is unstable, it is considered that the stock is likely to be at a non-speculative price. Fluctuation of the time-series rate of return could indicate whether the stock is under manipulation. Jiang [6] found the large fluctuations of time series in some sections, while the fluctuations in other sections are relatively small. Therefore, the heteroskedasticity of the time series needs to be taken into consideration. Introducing GARCH model solves the problem of heteroskedasticity in residuals of cointegration equation. Also, the time-varying standard deviation is introduced to more accurately reflect the real changes of fluctuation, and thereby optimizes the trade signals. Guo [7] stated that China Stock Markets has been in operation for 20 years. Index return of China Stock Markets encompasses heteroskedasticity and leptokurtic with fat-tail in financial time series. With purposes of deeply analyzing the nature of the index return, the GARCH model is used for the Market index for empirical analysis. Geng and Liu proposed that the GARCH model is effective to describe the fluctuation of financial data [8]. It is the most commonly used and most convenient time-series heteroscedastic fitting model. Building up GARCH model and later predicting the rate of return and stock prices, could produce results that provide some references for investors' decision making.

Wang and Wu [9] used the GARCH model to conduct empirical research on the fluctuation and rate of return of the CSI 300 Index. They also achieved good results in accomplishment of fitting and prediction of the time series. Nie and Hu concluded the applications of the GARCH model in 10 fields [10], namely, finance, macroeconomic management and sustainable development, investment, securities, mathematics, market research and information, trade economy, industrial economy, agricultural economy industry, oil and natural gas industry, among which, the GARCH model accounts for the largest proportion in researches of the financial field, and further guides the research on realistic financial issues. Li and Xin [11] pointed out that the GARCH model can not only describe the heteroskedasticity of the time-series rate of return, but also, together with other financial analysis theories, make a more important contribution to the study of practical financial problems. Pan et al. used the GARCH model to fit a line to dynamic data of gold prices [12]. And the outcome which has practical significance for the future prediction and risk control of the market is remarkable.

In Liu’s (2004) study [13], two types of models, GARCH model and asymmetric GARCH model, were used to study actual data. He found that Shanghai stock market doesn’t have the characteristics of high risk and high return, but the asymmetric GARCH model shows that when the risk is higher than a certain level, there is a positive correlation between the rate of return and the risks. According to the dataset 1 and the penalty bulletins, it is possible to analyze the market manipulation, identifying its characteristics and judge its existence. Also, it can better assist the CSRC (China Securities Regulatory Commission) to supervise, creating a good investment environment, and maintain market orders. So, and TSE use the GARCH model to discover the phenomenon of volatility interaction with the Hong Kong Hang Seng Index and the Hang Seng Index futures market [14]. In terms of linked analysis between the markets, Sibel (2012) believes that financial infection is important for monetary policy [15], risk measurement, asset pricing and investment portfolio allocation. Therefore, the impact of the US subprime mortgage crisis on emerging markets is necessary. The Garch model is used to test the existence of financial infection between foreign exchange markets during the US subprime mortgage crisis. This model has certain advantages than other methods. Sabiruzzaman et al. believes that in addition to considering modeling of stock price fluctuations [16], we must also consider modeling transaction volume fluctuations, and transaction volume plays a key role in the financial market. Among them, they studied the fluctuation of the Hong Kong Stock Exchange’s daily transaction volume index, using the GARCH model to simulate the volatility of the transaction volume, and found that the GARCH model was well fitted with the data. BURNS [17] proposes that these commonly used multi-GARCH models are too high at estimates, so they improve the model and propose the PC-Garch model. This model reduces the calculation amount, can better fit the data, enables relevant estimates to be more stable, and better applies to the stock market. Prateek et al. compared the Realized Garch model and GARCH model [18], Egarch model in the prediction of the stock market volatility in 2020, Eric [19] et al. using the Garch-Midas model to use the monthly data of the macroeconomic variables. It proves that China’s stock market has speculation characteristics. At the same time, it shows that the volatility of the macroeconomic aspect in the stock market has played a larger and larger role, especially CPI inflation. When modeling the asset income, this article can use the Garch model (GARCH) model with a broad sense. This problem, so more and more scholars consider improving the distribution of model conditions. In order to further describe the nature of financial asset income, different types of partial -state thick tail distribution is in the GARCH model in the application, Mighri, SU, and PHERSbuilt the Garch-SKT model based on SKT distribution [20, 21, 22]. Robert In the discussion on the Garch model [23], the data detection, the number of samples and volume of the data, they analyzed the data within one year of the daily stock trading of an Australian company, and found that Garch corresponds to the corresponding correspondence The analysis results are closely related to the number of samples and the number of transactions. Cathy and Mike proposed a harem difference model [24], It combines the GARCH model and non -linear clusors to study the average and variance volatility of the model of the financial market. The research results show that when the average volatility is high, or when the fluctuations are more lasting, the negative effects will come. Visser [25] proposes the concept of scale model and volatility replacement, combining high -frequency data with the GARCH model within one day to analyze the factors that affect the stock market.

II METHODOLOGY AND SCHEMES

A Methodology

Literature research methodology: in this study, this article summarized the methods and characteristics of stock market price manipulation and gained a comprehensive and in-depth understanding of its behavior.

Case study: in this study, this article analyzed cases of stock price manipulation in recent years.

Empirical analysis: in this study, this article conducted empirical analysis using data from stock price manipulation cases published by the CSRC (China Securities Regulatory Commission) in recent years.

Quantitative data analysis:

Theoretically, the annual rate of return of the CSI 300 Index acts as the benchmark rate of return. And the annual return of individual stocks is the strategic rate of return.

$$B_r = (\frac{B_{end}}{B_{start}})^{(250/n)} - 1 \tag{1}$$

Bend = ending benchmark, Bustard initial benchmark, n= trading days for back testing.

Measuring the systematic risks in the investment process through the β value, reflects the investors’ strategic sensitivity to benchmark changes.

$$\beta = \frac{\operatorname{cov}(P_{n,} B_n)}{\sigma^2} \tag{2}$$

P_n = strategic benchmark return, B_n = daily benchmark return, σ^2 = variance of daily benchmark return, $\operatorname{cov}(P_n, B_n)$ = covariance of strategic benchmark return and daily benchmark return

α refers to excess returns irrelevant to the market, that is, non-systematic risk which can make indirect judgment upon market manipulation. Formula as follows:

$$\alpha = R_p -（R_f + \beta_p (R_m - R_f)）\quad (3)$$

R_p= strategic annualized return

R_m= benchmark annualized return

R_f= risk-free rate

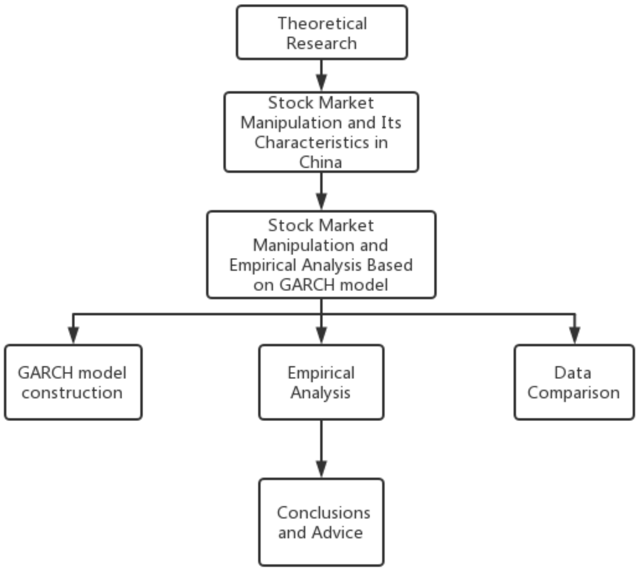
β _p= strategic beta value

α >0,when R_p exceeds risks, excess returns gained, manipulation existed.

α =0,when R_p almost equals risks, appropriate returns gained, no manipulation.

α <0,when R_p is less than risks, a small quantity of returns gained, manipulation existed.

Quantitative data analysis: in this study, this article mainly calculated the data of the opening price, closing price, trading volume, and transaction amount, so as to obtain turnover rate, trading volume fluctuation and logarithmic return rate. Eventually this article obtained GARCH-α parameter and GARCH-β parameter in order to carry out data analysis and comparison with actual data. Model schemes are as follows (Fig. 1).



Theoretical Research
Stock Market Manipulation and Its Characteristics in China
Stock Market Manipulation and Empirical Analysis Based on GARCH model
GARCH model construction
Empirical Analysis
Data Comparison
Conclusions and Advice

Fig. 1. Model schemes.

Model analysis: In this study, this article utilized GARCH model as identification model of stock price manipulation.

Building up ARCH model is defined of the form:

$$y_t = \gamma_0 + \sum_{i=1}^{k} \gamma_i X_{it} + \mu_t \quad (4)$$

$$\sigma_t{}^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i \mu^2{}_{t-1} \quad (5)$$

The Premise is that $\mu_t \sim (o, \sigma_t{}^2)$. ARCH model laid out solid foundations for subsequent analysis, which can better deal with heteroskedasticity and explain changes in market price fluctuations.

Building up GARCH model is defined as:

$$y_t = X_t \pi + \in_t \quad (6)$$

$$\sigma_t{}^2 = \omega + \alpha \varepsilon_{t-1}^2 + \beta \alpha_{t-1}^2 \quad (7)$$

Variance σ_t^2 is subjective to the former residual ε_{t-1}^2 and the former variance α_{t-1}^2 while the sum of α and β is constantly the root of autoregressive model which determines the continuity of fluctuation shock. In many occasions, the root is very close to 1.

GARCH (p,q) is defined in the form as follows:

$$\sigma_t^2 = \omega + \alpha \sum_{i=1}^{q} \in_{t-1}^2 + \beta \sum_{j=1}^{p} \sigma_{t-j}^2 \quad (8)$$

P refers to the maximum lag of GARCH model while q refers to the maximum lag of ARCH model. In this study, independent testing will be carried out to predict price manipulation using GARCH model. Judgment will be made through the followings:

no manipulation: α + β ≦1

manipulation existed: α + β >1

Research schemes

input stock price data

calculate logarithmic return rate, turnover rate and trading volume fluctuation

draw sequence diagrams

descriptive statistic

stationary test (unit root test)

autocorrelation test

ARCH effect test

GARCH parameter estimation: this study conducted indicators like turnover fluctuation, trading volume fluctuation, prices fluctuation, GARCHA α parameter and GARCHA β parameter. Through comparative analysis, it is verified that GARCHA α parameter and GARCHA β parameter are effective in judging stock market price manipulation.

Calculate the GARCH fluctuation rate, conduct a comparative analysis with former data, and judge time points of manipulation with practical data of the stock.

III Analysis of Empirical Results

A Indicator Analysis

In terms of forecasting model construction, this study collected fifteen stock price data in dataset 1, seven of which had market manipulation, and eight had none. On that data basis this article constructed GARCH model to identify market manipulation. Finally, whether the sum of GARCH-α and

GARCH-β is greater than 1 using logarithmic return rate, trading volume fluctuation, turnover rate along with their fluctuation forecast trend charts will be set as judging standards of manipulation’s existence.

Logarithmic return rate formula as follows:

R=ln(closing price on a day)-ln(closing price of the former day)

Trading volume fluctuation formula as follows:

TVF = turnover on a day- turnover of the former day

Turnover rate formula as follows:

TR = turnover/sum of issuing stocks *100%

Abbreviations

R: Logarithmic return rate

TVF: Trading volume fluctuation

TR: Turnover rate

B Trend Chart Analysis

Fig. 2 to 8 shows the four indicator trend comparison.

In the study, closing price, R, TVF, and TR in seven stocks with market manipulation in dataset 1 are compared using EViews software. It is found that during the manipulation, closing price, R, TVF, and TR all showed a sharp rise while they experienced an obvious slump after the manipulation. Besides that, there was data loss before and after manipulation. Take Tianjin Futong Information Science& Technology Co., Ltd. (stock code: 000836), its data went missing from May 24, 2017 to November 24, 2017.

By comparing the trend chart and the data analysis of the China Securities Regulatory Commission announcement, it can be seen that the market manipulation has the following characteristics:

The participants in stock market manipulation are complex and diverse.

From the announcement data, this article can know that the main body of the stock manipulation are those who hold significant authority and social status including the the chairman of the board, insiders, legal representatives, general managers, shareholders, the actual controller, managing partners and other administrative seniors.

Manipulation holds characteristics of zero transparency and severe consequences.

To evade the supervision of the China Securities Regulatory Commission, insiders usually adopt relatively covert methods. Specifically, insiders use other people’s accounts instead of their own when manipulating. Huang Xiaodiao as one of insiders borrowed other people’s accounts and trade stocks of Neoglory Prosperity Inc. (stock code: 002147). The China Securities Regulatory Commission imposes heavy fines on stock market manipulation, and adopts measures to ban the parties from entering the stock market within a specified period, with serious penalties.

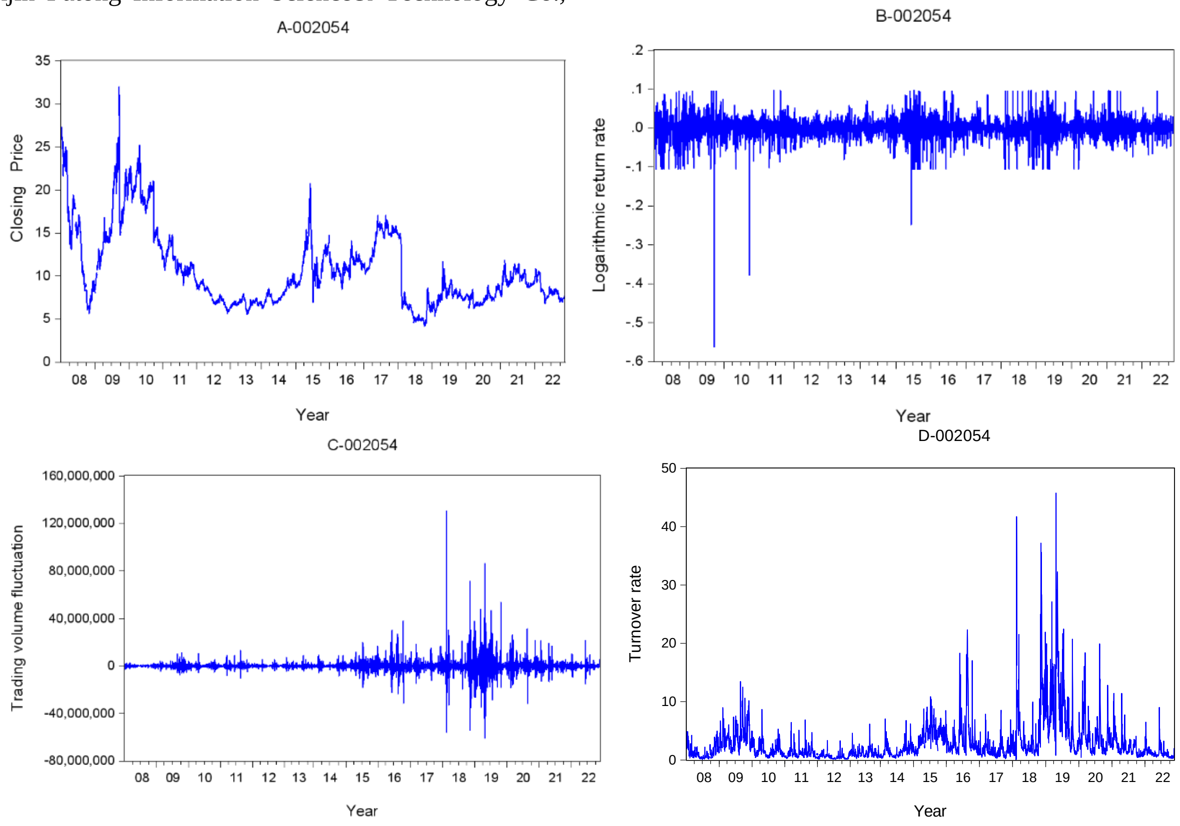


Fig. 2. Stock 002054 four indicator trend comparison.

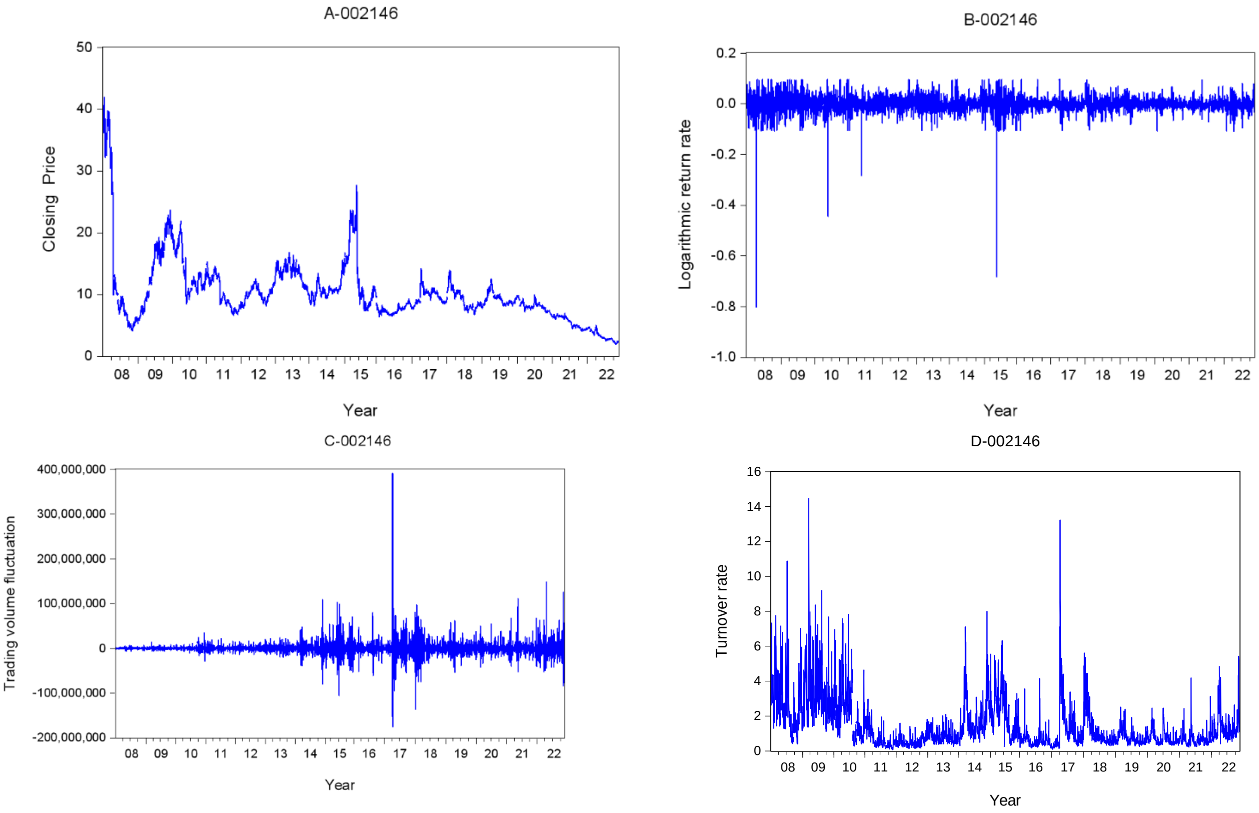

Fig. 3. Stock 002146 four indicator trend comparison.

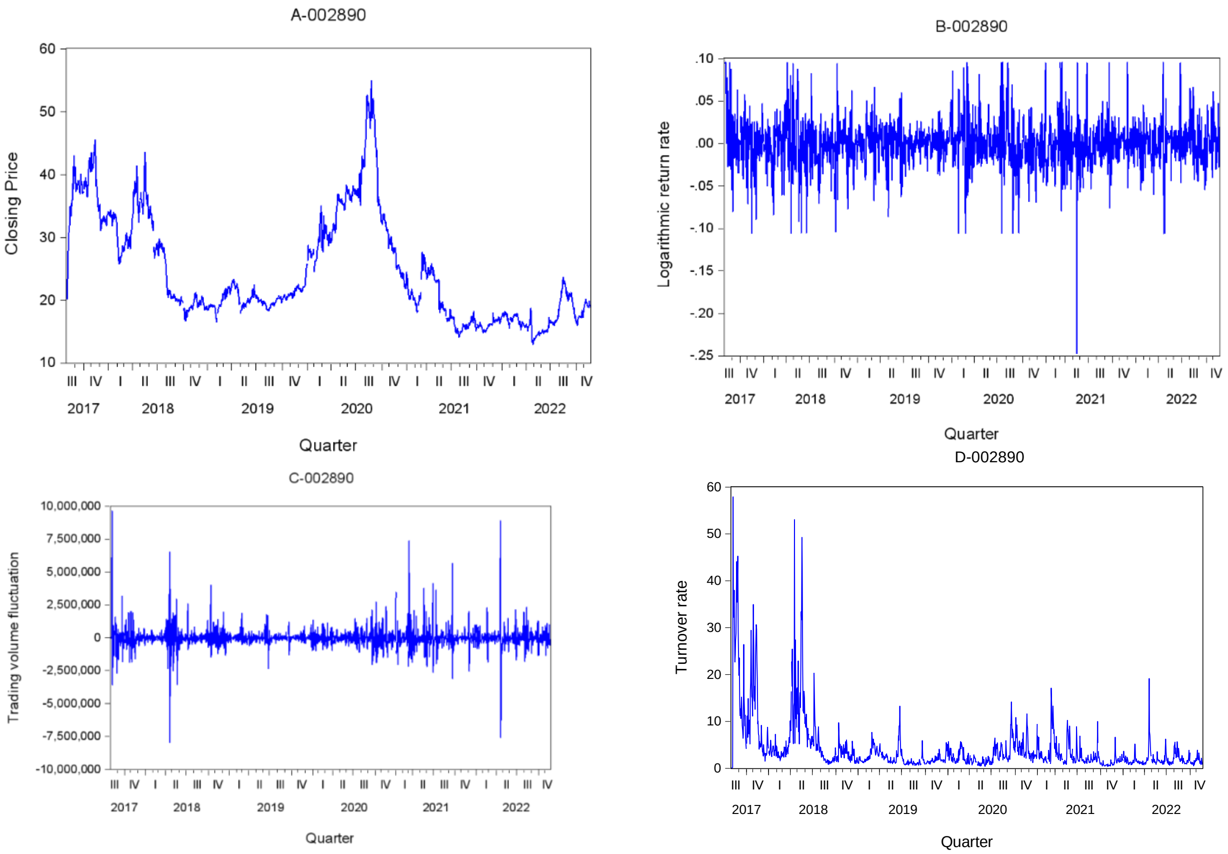

Fig. 4. Stock 002890 four indicator trend comparison.

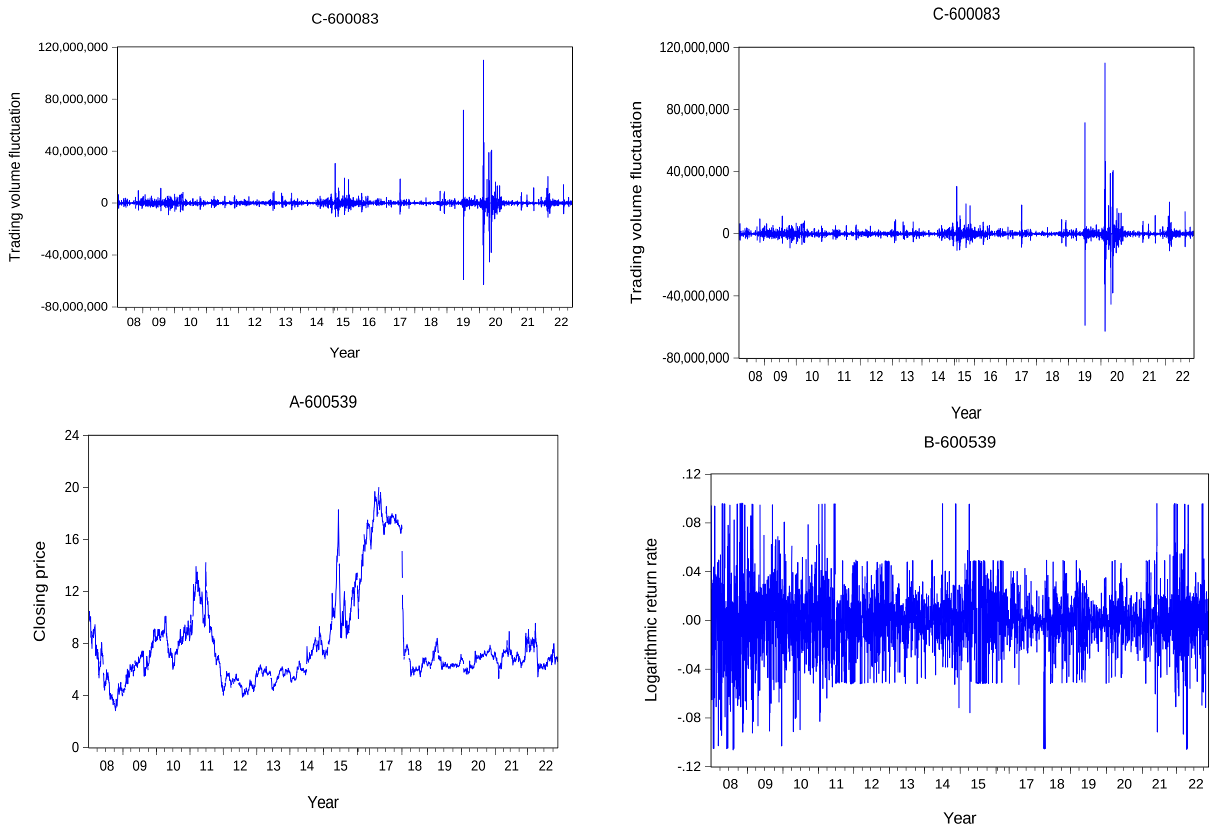

Fig. 5. Stock 600083 four indicator trend comparison.

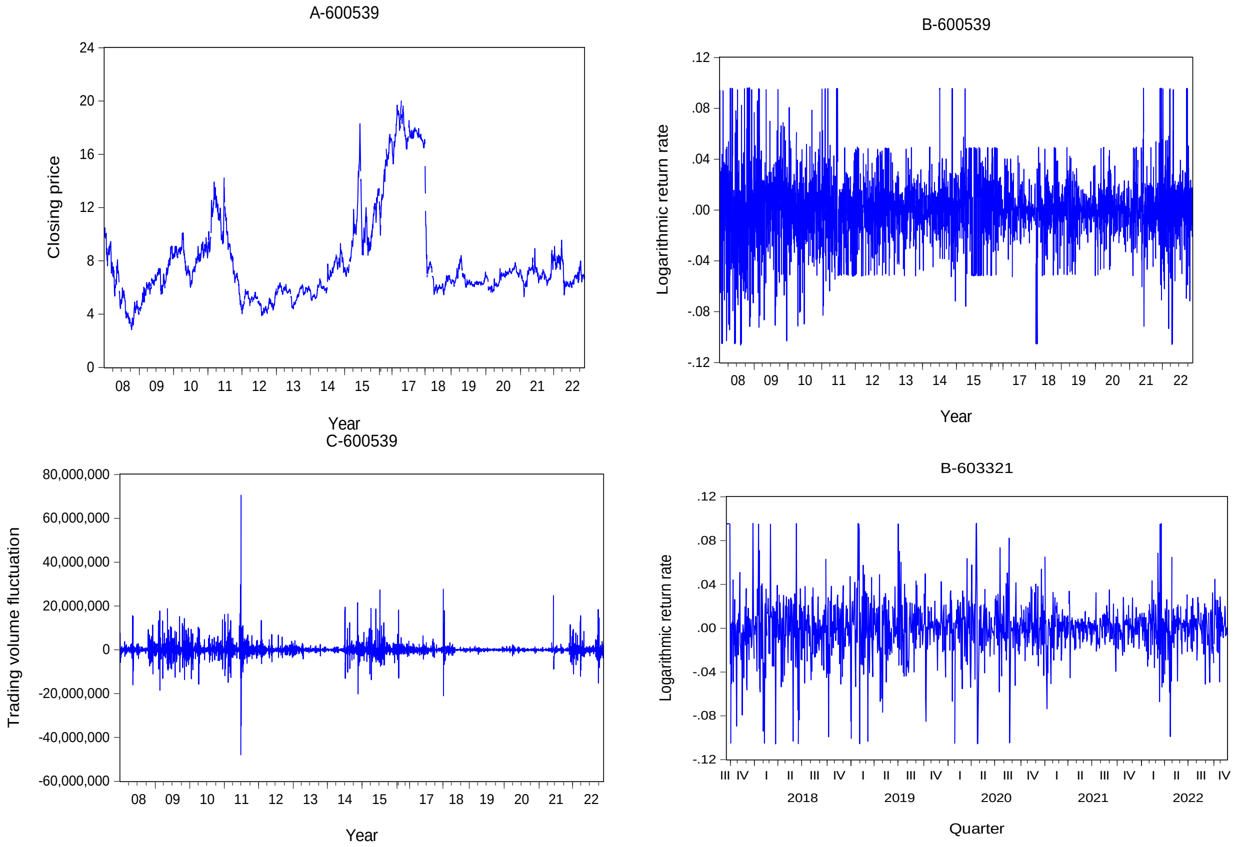

Fig. 6. Stock 600539 four indicator trend comparison.

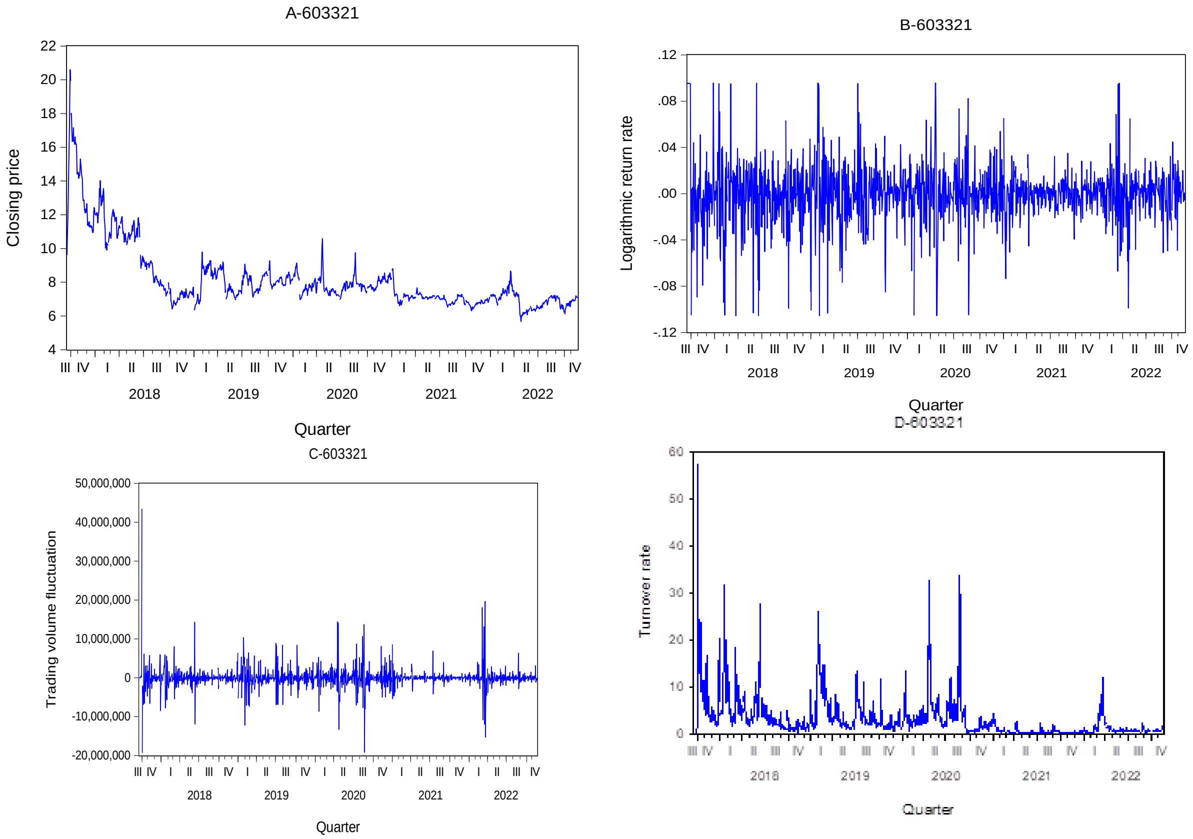

Fig. 7. Stock 603321 four indicator trend comparison.

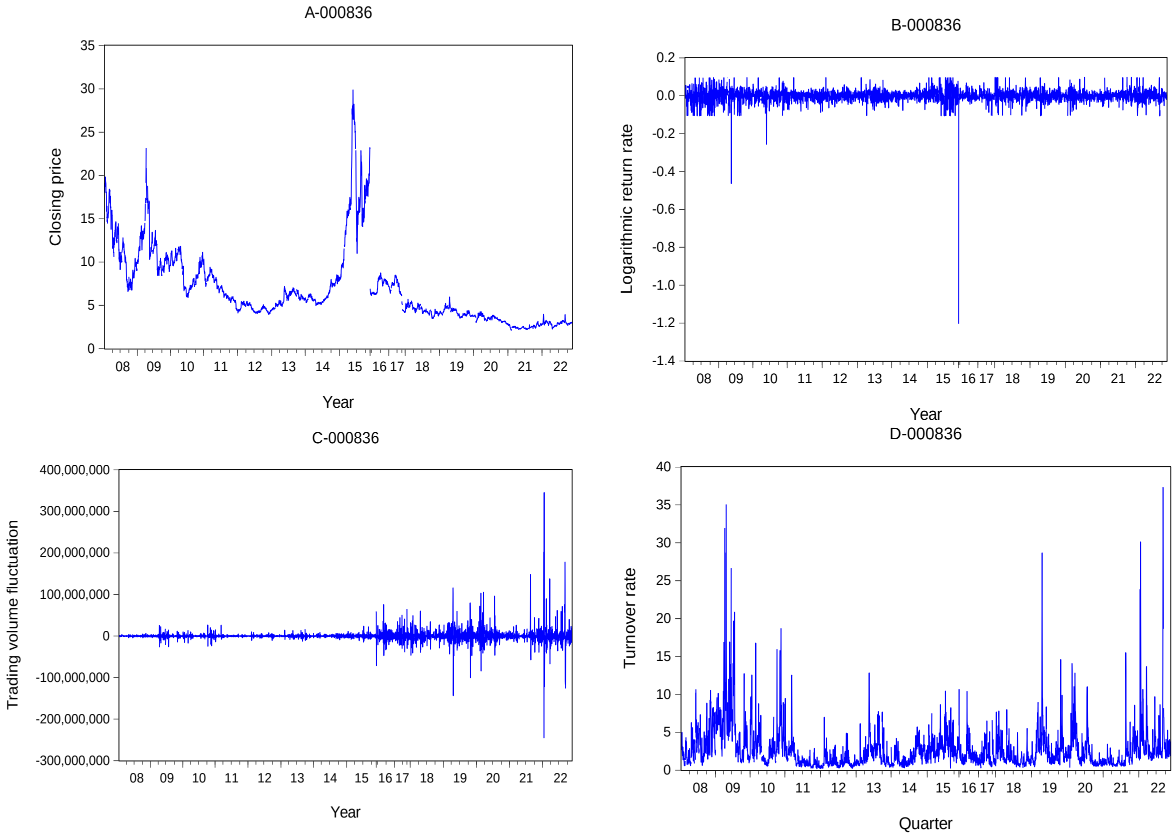

Fig. 8. Stock 000836 four indicator trend comparison.

Stock market manipulation is widespread in many industries.

Based on the stock data of dataset 1 and the China Securities Regulatory Commission’s penalty announcement, stock market manipulation can be seen in the tourism real estate industry and machinery manufacturing industry (Neoglory Prosperity Inc. stock code: 002147), in optical fibre and cable industry and quartz-fibre manometer ware industry(Tianjin Futong Information Science& Technology Co., Ltd, stock code: 000836), in elevator industry (Zhejiang Meilun Elevator Co.,Ltd, stock code: 603321), in real estate industry (RiseSun Real Estate Development Co., Ltd, stock code: 002146), in main business of shipping and terminal operation(COSCO SHIPPING Holdings Co., Ltd, stock code: 601919), in construction and building materials industry (Taiyuan Lionhead Cement Co., Ltd, stock code: 600539). They are the lively examples indicating wide ranges of manipulation.

Stock market manipulation takes various forms:

By controlling the account information and accounts that in full charge to engage in securities transactions. Liu Xiaodong from Dymatic Chemicals,Inc (stock code:002054) colluded with Hu Kan from Zhejiang Meilun Elevator Co.,Ltd. (stock code:603321) using multiple securities accounts to buy in a concentrated manner, and apply for large orders to drive up the stock prices.

C Empirical Analysis

From Table I, this article can conclude that in two stocks, the sum of GARCH-α and GARCH-β in R, TVF and TR was all greater than 1. While in four stocks, the sum of GARCH-α and GARCH-β in TVF and TR was greater than 1 altogether with the sum of GARCH-α and GARCH-β in R greater than 0.97. The results proved that the model is marvelous in manipulation identification.

From Table II, this article can conclude that in two stocks, the sum of GARCH-α and GARCH-β in R, TVF and TR was less than 1. While in two stocks the sum of GARCH-α and GARCH-β in R and TR was less than 1. And in other two stocks the sum of GARCH-α and GARCH-β in R and TVF was less than 1.

D Model Checking

This study collects five stocks in dataset 2, and conducted GARCH model detection and identification on R and TVF, so as to predict and judge the existence of manipulation along with its time points and characteristics.

With identification and detection of GARCH model, evaluation results of two indicators for five stocks in dataset 2 were showed in Table III. From the table above, this article can conclude that in the first and third stocks, the sum of GARCH-α and GARCH-β in R and TVF was less than 1. In other 3 stocks, the sum of GARCH-α and GARCH-β in R was less than 1 while the sum of GARCH-α and GARCH-β in TVF was greater than 1. To improve the accuracy of the model, this study splits the six-year stock data of five stocks into annual data for re-testing. The evaluation results are as follows (see Tables IV-VIII).

TABLE I. EVALUATION RESULTS OF THREE INDICATORS FOR SEVEN STOCKS WITH MANIPULATION

	000836	**600083**	**2054**	**2146**	**2890**	**600539**	**603321**

After the test, this article found that the sum of GARCH-α and GARCH-β of some indicators was greater than 1 in stock 1 and stock 3. But this article still believed both has no manipulation, considering the total time was less than 1, and fluctuations of indicators could arise from company's thriving development. In all the five years (Table III), the sum of GARCH-α and GARCH-β of R in stock 4 was less than 1 while the sum of GARCH-α and GARCH-β of TVF was greater than 1. However, the sum of GARCH-α and GARCH-β of R and TVF was less than one annually. Therefore, this article believed that there was no manipulation in stock 4.

Besides, the sum of GARCH-α and GARCH-β of R and TVF in 2020 of stock 2 was greater than 1. While the sum of GARCH-α and GARCH-β of TVF in the 5 years (Table III) was greater than 1. Data was abnormal. The sum of GARCH-α and GARCH-β of TVF in 2018 of stock 5 was way greater than 1 while the sum of GARCH-α and GARCH-β of R and TVF was less than 1. Therefore, this article analyzed on stock 2 and stock 5 with the following Fig. 9 and 10.

From Fig. 9, R and TVF of stock 2 was asymmetric in mid-October. However, its TVF had a significant surge in mid-October. Therefore, this article believes manipulation took place in mid-October 2020. R and TVF of stock 5 showing a great opposite trend from mid-March to April could also be the prove that manipulation happened from mid-March to around April in 2018.

Characteristics of the trend charts are as follows:

Opposite trends took place in two indicators' prediction value.

The R prediction value is rather low while the TVF prediction value promptly rises.

The closing price, R and TVF snowballed during the manipulation.

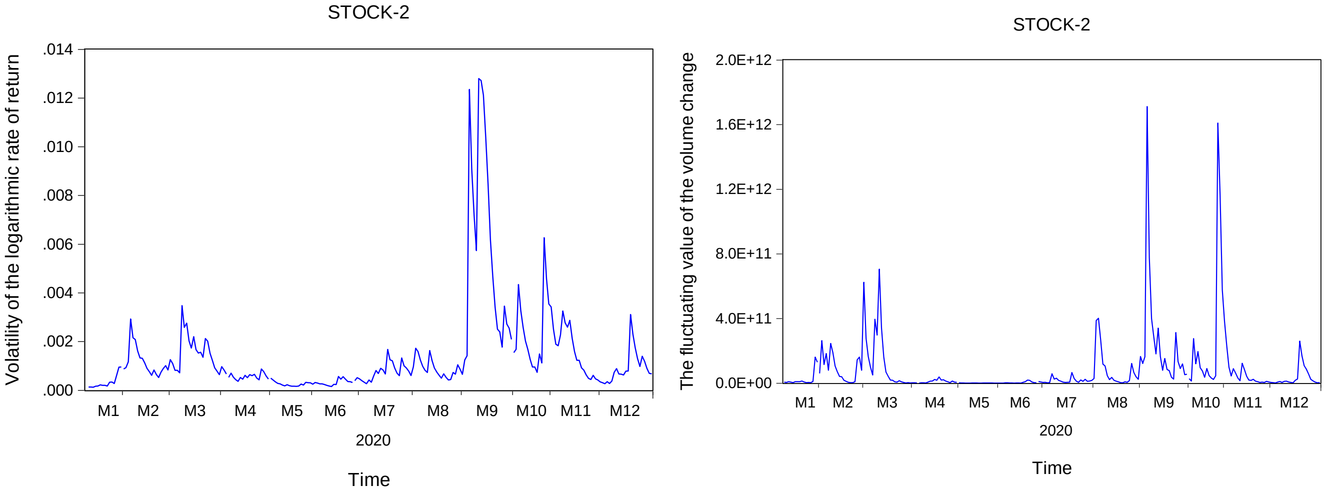

Fig. 9. R and TVF in 2020 of stock 2.

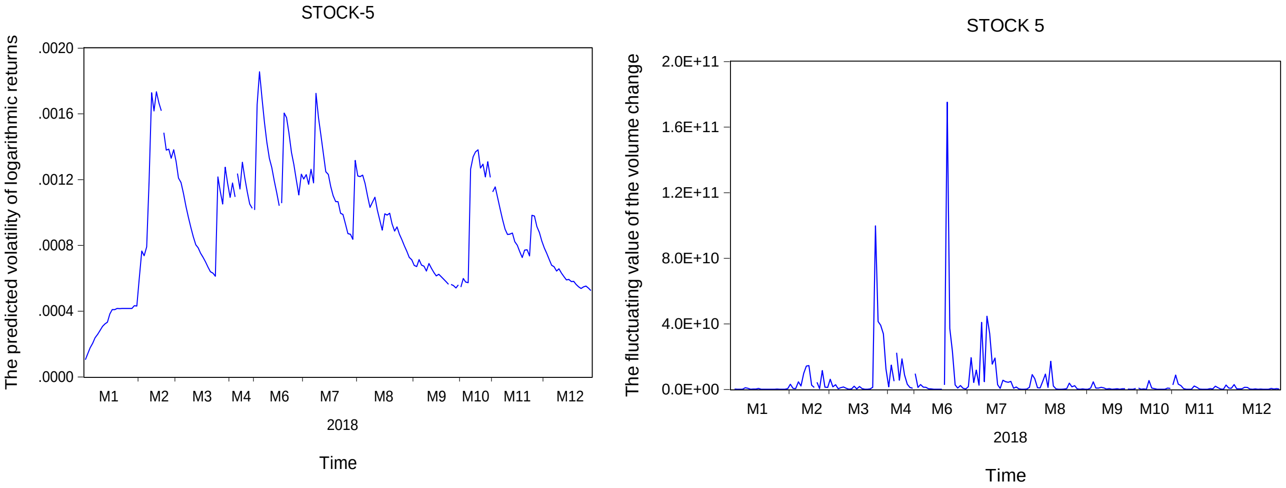

Fig. 10. R and TVF in 2018 of stock 5.

IV CONCLUSIONS AND ADVICE

A Conclusions

This paper analyzes the manipulation behavior of the stock market based on relevant theories and GARCH model. On the basis of GARCH model, data analysis is carried out by using EViews software. Meanwhile, indexes such as logarithmic rate of return, turnover rate change, turnover change, GARCH-α and GARCH-β are constructed for manipulation behavior identification.

Analysis of the data obtained in this study shows that when the closing price, logarithmic return rate, trading volume change and turnover rate increase sharply, the market manipulation probability of individual stocks increases significantly, and after the manipulation, the indexes all show a precipitous decline, in which the Fortis information (stock code: 000836) represented by May 24, 2017 to November 24, 2017. This is basically consistent with the empirical analysis of this study. At the same time, Ding (2019) constructed GARCH model, Zhang (2015) based on the GARCH model of time series, Jiang (2022) eliminated the influencing factors of adding heteroskedasticity to time series, and Liu Ning (2004), Wang Wu (2011), Geng, Liu (2019), Nie and Hu (2020) et al. learned from relevant GARCH model construction that the characteristics of high risk and high return in Shanghai stock market do not exist in the basic view of finance. However, according to the asymmetric GARCH model, the above researches show that when the risk is higher than a certain level for a period of time, there is a direct proportional relationship between return rate and risk. This is consistent with the analysis results in this study. Based on the scholars' literature on the application of relevant GARCH model in stock price manipulation analysis and the summary of this paper, it is known that: There are risks in the market, but when the relevant indicators of the stock price fundamentals fluctuate too much, the relevant GARCH model can be used for analysis and research, and the probability risk of stock price manipulation can be obtained, so as to carry out reasonable position planning and market management, and guide managers and investors to make more optimal decisions.

It is known from the empirical results that the prediction accuracy rate is 85.71%, but due to the small number of samples, the reliability of such data analysis results is low. In the subsequent improvement, the sample size can be increased to reduce the error value. 4. The index studied in this paper is mainly based on the price index. In addition to controlling trading volume and changing stock prices, manipulation in the actual market is often filled with information differentiation, which increases the difficulty in detecting market manipulation. Therefore, based on this model, other dimensional models should be added to monitor market stocks combined with multidimensional models, which can effectively enhance the early warning system of advance indicators and achieve better results for regulatory departments to maintain market orderly and regularized.

B Advice

The regulatory authorities should further classify the market manipulation behaviors and establish the benchmark values of various indicators, which is conducive to the faster and more accurate detection of illegal market behaviors in the follow-up monitoring.

The increase of sample size can more effectively reduce errors caused by model data, make model monitoring more accurate, reduce fault tolerance rate and improve accuracy.

The competent authorities should put forward the requirements of strengthening education for all investors in the market, at the same time improve relevant systems and regulations, improve anti-manipulation supervision methods, make the market more legal and systematic, and provide a healthy and green investment environment for market investors.

***Abstract*—With cloud computing, resources can be networked globally and shared easily between users. A range of heterogeneous needs are met on demand by software, hardware, storage, and networking. Dynamic resource allocation and load distribution pose challenges for cloud servers. In this regard, task scheduling plays a significant role in enhancing the performance of cloud computing. With the increase in the number of users and the capability of cloud computing, cloud data centers are experiencing concerns regarding energy consumption. To leverage cloud resources energy efficiently and provide real-time services to users, a viable cloud task scheduling solution is required. To address these problems, this paper proposes a new hybrid task scheduling algorithm based on squirrel search and improved genetic algorithms for cloud environments. The proposed scheduling algorithm surpasses existing scheduling algorithms across multiple parameters, including makespan, energy consumption, and execution time.**

Keywords—Cloud computing; energy efficiency; task scheduling; genetic algorithm

I. Introduction

Recent technological and scientific advances in Complementary Metal-Oxide Semiconductor (CMOS) [1, 2], machine learning [3], cloud computing [4], 5G connectivity [5, 6], Blockchain [7], artificial intelligence [8, 9], smart grids [10], Internet of Things (IoT) [11, 12], and optical networks [13, 14] are bringing numerous benefits to society. Schedulers (brokers) in cloud computing determine potential solutions for assigning constrained resources to requests in order to achieve multiple goals (e.g., energy consumption, response time, resource utilization, reliability) [15-17]. It is believed that the study conducted in [18] laid the foundation for modern scheduling techniques. Schedules are used in many applications today, including power system control, multi-media data object scheduling on the Internet, and manufacturing printed circuit boards [19]. Over the past three decades, distributed computing systems have become one of the most important aspects of modern scheduling [20]. In recent years, various standalone computers have been combined with working together as a cluster system. By integrating heterogeneous resources from geographically dispersed areas, grid systems overcome the shortcomings of cluster systems by using more resources [21]. Cloud computing has recently become popular, combining the strengths of clusters and grids [22].

Due to the wide solution space, most scheduling problems are NP-hard and require a long period of time to be resolved within a minimal period [23]. The scheduling of limited resources in modern computing systems cannot be optimized using a polynomial time-scheduling algorithm [24]. The researchers of [25] illustrated the dilemma posed in this case by giving a simple example: approximately 0.02 percent of the possible solutions consume up to 1.01 the necessary amount of time to reach the optimal result. It is proven that a complex problem can be extremely challenging to solve. Therefore, researchers have been motivated to develop effective algorithms to solve such scheduling problems. Scheduling techniques can be static or dynamic [26]. Due to the dynamic nature of cloud environments, more dynamic algorithms must be incorporated to achieve breathtaking results. In contrast, static algorithms are only used when workloads vary only slightly. Thus, deterministic methods cannot solve the task scheduling problem. This problem has been solved significantly in polynomial time by meta-heuristic algorithms, which are non-deterministic methods [27].

Virtualization technology and dynamic task scheduling techniques can benefit cloud service providers and users. By scheduling tasks effectively, resources are conserved (the resource utilization ratio is increased), and incoming tasks are also completed in the shortest possible time (the makespan is minimized) [28]. With the growing workloads in cloud data centers, task scheduling has become increasingly critical due to the scarcity of resources. In order to improve QoS criteria and the mapping of incoming tasks to available resources, cloud task scheduling needs further study. In scheduling, the goal is to determine optimal resources for executing incoming tasks, thereby enabling a scheduling algorithm to enhance various QoS factors such as response time, energy consumption, resource utilization, and makespan [29]. The rest of the paper is organized as follows. The next section reviews the previous works. Section III describes the proposed method. Experimental results are reported in Section IV. The conclusion is provided in Section V.

II. Related Work

A QoS-aware cloud task scheduling algorithm was proposed by Wu, et al. [30]. In the proposed algorithm, tasks are first prioritized using their special attributes, then sorted according to their priority. Second, the algorithm schedules tasks based on the sorted task queue according to the completion time for each task on different services. Based on CloudSim experiments, the algorithm can achieve good load balancing and performance by using priority and completion time to determine QoS. An improved sunflower optimization algorithm was introduced by Emami [31] for optimizing existing task scheduling algorithms. The algorithm schedules tasks in polynomial time. Experimental results have shown that the algorithm outperforms its competitors. Makespan and energy consumption have improved by 0.74% and 3%, respectively, compared to the best counterpart.

Yang, et al. [32] developed a simplified cloud computing task scheduling model. This paper uses game theory to simplify cloud computing task scheduling algorithms as opposed to previous studies. This algorithm considers the reliability of a balanced task when scheduling tasks with game theory. A task scheduling model for computing nodes is developed based on the balanced scheduling algorithm. The rate allocation strategy is calculated using game strategy in the cooperative game model. Experimental results indicate that the proposed algorithm performs better than others.

Srichandan, Kumar [6] developed an approach to task scheduling that combined the advantages of two widely used biologically-inspired algorithms: genetic and bacterial foraging. This article makes two main contributions. In the first place, the scheduling algorithm minimizes the time between tasks, and in the second place, it reduces energy consumption economically and environmentally. According to experimental results, the proposed algorithm provides superior performance for convergence, stability, and solution diversity.

Abd Elaziz, et al. [33] presented a method for scheduling cloud tasks to minimize the time consumed scheduling different tasks across different virtual machines. This method uses Differential Evolution (DE) to improve the Moth Search Algorithm (MSA). The MSA mimics moth movements in nature using Levy flights and phototaxis as indicators of the ability to explore and exploit resources. The exploitation ability still needs to be improved so that DE can be used for local searches. Three experimental series are conducted to evaluate the proposed algorithm. An analysis of twenty global optimization problems is carried out using the traditional MSA and the proposed method in the first experiment. The proposed algorithm was compared to other meta-heuristic and heuristic algorithms on synthetic and real trace data in the second and third experimental series. Performance measurements in both experiments demonstrate that the proposed algorithm outperforms competitors.

Using cat swarm optimization algorithm, Mangalampalli, et al. [34] addressed data center-specific parameters, such as power consumption, migration time, and makespan. VM mapping was performed by calculating the priorities of tasks at the task level. Based on the cloudsim simulator, this algorithm generates random inputs for total power costs. HPC2N and NASA workload archives are used as inputs to the algorithm. The proposed algorithm is compared to existing algorithms such as PSO and CS. Using HPC2N and NASA workloads, significant improvements are observed in different parameters.

Various meta-heuristic algorithms have been used in the works discussed above. These approaches share the common characteristic of using random population to initialize the metaheuristics and hybrid metaheuristics. The initial population has a significant impact on metaheuristic algorithms. Randomness is a fundamental requirement for avoiding local minimum traps. However, the algorithm convergence can be improved if some particles are assisted heuristically in selecting effective or near optimum starting points. The proposed algorithm utilizes heuristic algorithms for initializing the papulation in order to significantly improve the algorithm's performance.

III. Proposed Method

There are many scheduling algorithms to minimize the tasks' completion time in distributed systems. These types of scheduling systems find the most proper resources to assign to the tasks. Minimizing the tasks' completion time does not lead to minimizing each task's execution time. Task scheduling goals in cloud computing are to propose optimal scheduling of the tasks with load balancing guarantee and guarantee Quality of Service (QoS) criteria like response time, execution time, system throughput, cost, reliability, and availability. A new method is proposed for scheduling cloud tasks.

A. *Formulating the Problem*

The utilized method has four main parts, including the network information server, the network resource broker, the tasks, and the resources that act in the following manner. Users send requests to process tasks. The information about the task is embedded in the request, including the required CPU time for each task, the size of each task, and the total number of tasks. The network resource broker starts calculating the program parameters after the received message from the user. Moreover, the information server provides the resources information for the network resource broker. The proposed method will be used to select the input for processing the resource. The local update of the nodes is performed after assigning a task to a resource. The global update of the nodes is performed after executing a task by a reference. Fig. 1 shows the flowchart of the proposed algorithm.

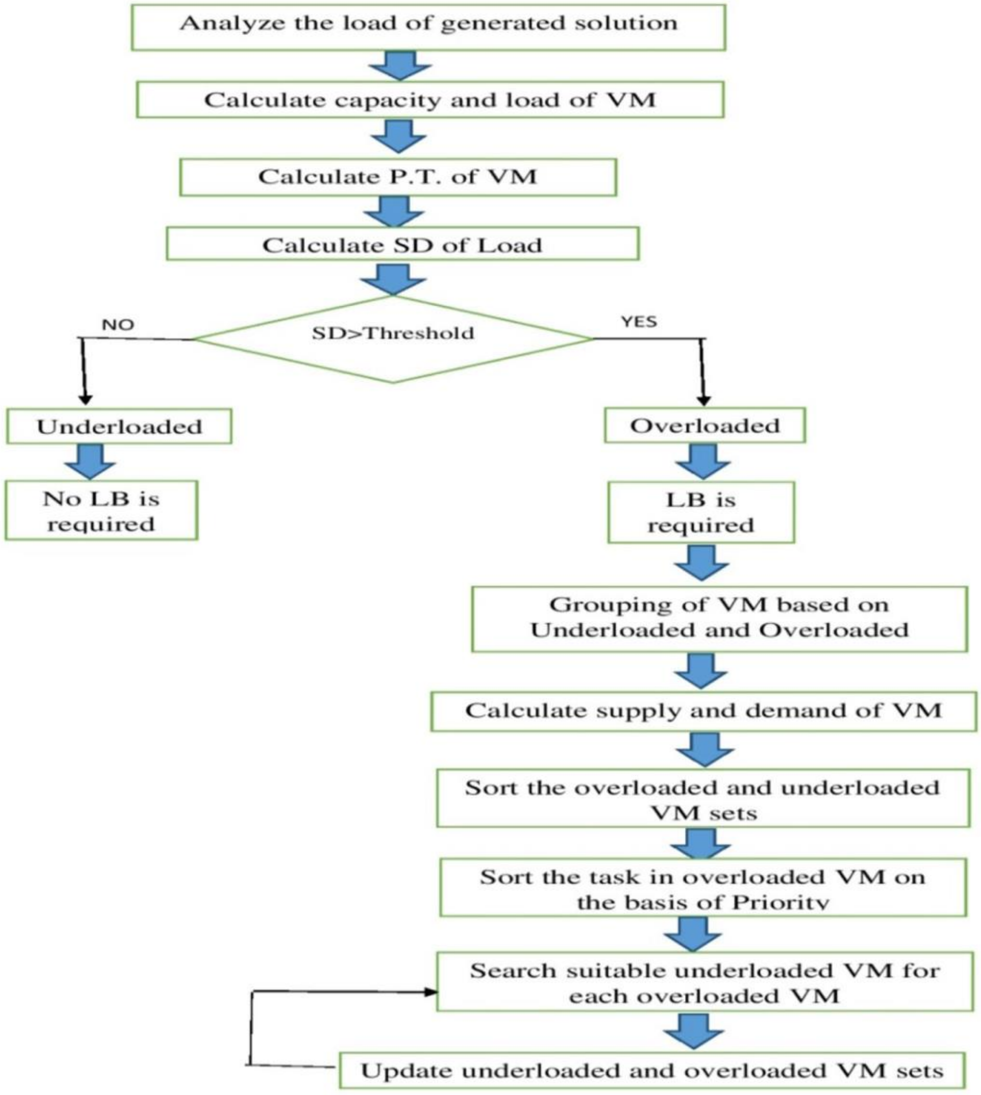
The execution results are transmitted to the user. The fitness function is the function that receives a candidate solution for a problem as input and provides an output that determines a good amount of the solution. The key characteristic of the optimization algorithms is determining the fitness value of each solution. The algorithm tries to schedule K tasks to M virtual machines in each repetition. Virtual machines are optimally scheduled in accordance with their processing capacity, given by Eq. (1).

$$Capacityvm_j = Mipsvm_j \times PesNumvm_j \quad (1)$$

where $pesNumbervmj$ is the number of processors in the vmj virtual machine and MIPSVMJ is the number of million instructions per second of all processors on VMJ virtual machine. Task scheduling reduces the execution time of virtual machine tasks. The execution time is estimated by Eq. (2).

$$ExecutionTime_j = \frac{TaskLength_j}{Capacityvm_j} \quad (2)$$

where $TaskLengthj$ denotes the length of the jth request on the queue, and Capacityvmj refers to the processing capacity of the virtual machine on the jth location of the solution (J=1, 2, ..., K).



Analyze the load of generated solution
Calculate capacity and load of VM
Calculate P.T. of VM
Calculate SD of Load
SD>Threshold
NO
YES

Sort the task in overloaded VM on the basis of Priority
Search suitable underloaded VM for each overloaded VM
Update underloaded and overloaded VM sets

Fig. 1. Flowchart of the proposed algorithm.

The amount of load on the virtual machine and the amount of load resulting from accepting a new request are considered for load balancing in virtual machines. Hence the virtual machine load is defined as Eq. (3).

$$Loadvm_j = CurrentLoadvm_j + TaskLength_j \qquad (3)$$

where $CurrentLoadVMj$ signifies the virtual machine load on the jth location of the solution (J=1, 2, ..., K). During task assignment, the standard deviation of the solution's virtual machine should be minimized for load balancing.

B. *The Steps of the Proposed Method*

Two main steps of the proposed method for task scheduling in this paper include:

- First step: GA to select the tasks and prioritize them for execution.
- Second step: using the Squirrel Search Algorithm (SSA) to map tasks to the virtual machines and their duration to reduce energy and fair load distribution.

1) Task selection for execution based on GA: First, in this section, general information is expressed about GA, and then the use of this algorithm to select the best task is explained. John Holland invented the main idea of GA from the evolutional theory of Darvin in 1967. Generally, GAs includes the following parts:

- Chromosome: Chromosomes in GAs show points in the search area and possible solutions to the considered problem. The number of genes (variables) on each chromosome (solution) is constant. Binary coding (binary strings) is used to present the chromosomes. A chromosome in this research shows a list of assigned resources for each task.
- Population: A population includes a set of chromosomes. A new population is generated with the same count of chromosomes using the impact of genetic operators on the population.

- Fitness function: First, a fitness function is provided to solve a problem using GAs. The fitness function in this research is based on the last task completion time duration, meaning that it is considered from the start time of the tasks to the last task completion in a parallel manner.
- Selection operator: This operator reproduces some chromosomes among the existing chromosomes in a population. Fitter chromosomes are more likely to reproduce. Elitist Selection is used in this research.
- Crossover operator: The crossover operator generates a new pair of chromosomes from a pair of chromosomes from the productive generation. Uniform crossover is used in this paper, and a random matrix is generated, namely a mask including 0 and 1 and the same length as the existing chromosomes. The mask chromosome determines which genes are transferred to the child from the first parent and which one from the second parent.
- Mutation operator: A mutation operator is applied to the chromosomes after crossover. This operator changes the content of a gene by randomly selecting an operator of a chromosome's gene.

Mapping the tasks of the application workflow to the distributed resources may have many objectives. The focus of this research is on minimizing the sum of the calculation time of the application workflow. The parallel workflow allows each task to have subtasks, and the subtasks are distributed among different resources in order to minimize the total completion time. so that each task can have some subtasks, and the subtasks are distributed among different resources to minimize the total time of the project completion. This system has two main parts:

- Task: it is the work performed in the cloud environment based on the user's request. Each task also is divided into some subtasks.
- Resource: each service in the cloud environment can assign one or some virtual machine and web services to each resource. These resources may have different processor powers and perform the service in different time durations and costs. A cloud computing system faces the challenge of selecting the resources for each task with the least amount of time and cost.

2) Machine selection by the SSA: Squirrel search is a memetic metaheuristic algorithm to find the optimal global solution via heuristic functions. This algorithm is based on memes evolution carried by interactive people and the global exchange of information among the population. In the SSA, the squirrels are transformed due to memetic evolution. In this algorithm, the squirrels are considered the hosts for the memes and are presented as a memetic vector. Each meme includes memo types showing a feature on the chromosome, like genes in GA. The squirrels can exchange their information and correct their memes. The amount of each squirrel search is adjusted by the memes improvement, and each squirrel's position is changed. SSA combines deterministic and random approaches. The deterministic approach makes it possible to use the response-level information efficiently to direct the heuristic search and the random components guarantee the flexibility and strength of the search.

The squirrel search is started with the primary population of P squirrels that are generated randomly from the problem area of Ω. In the Di-dimensional problems, the position of the ith squirrel is presented as (xi1, xi2, …, xiD). Then the merit of each squirrel is calculated based on its position, and the squirrels are sorted decreasingly based on their merits. In the next step, the total population is divided into m groups. This division is performed so that each group includes n squirrels (P=m×n). During the division process, the first squirrel is located in the first group, the second one in the second group, the mth one in the mth group, and the (m+1)th one in the first group again. The squirrels with the best and the worst merit values are presented as Xb and Xw in each group, respectively. Moreover, the squirrels with the best merit among the population are presented as Xg. Then using an evolutional process, the worst existing squirrels' merit on each cycle of the algorithm is corrected.

3) Selecting the best machine by SSA: In this section, SSA is used to execute the tasks globally. In this method, each squirrel is considered a response to the problem, and the squirrels are distributed randomly. There are some sets with an equal number of squirrels. In order to assign tasks to virtual machines, three main measures should be considered, namely the task size, the machine processing power, and makespan.

The input tasks and the virtual machines are presented as $TaskLsit=\{t1,t2,\ldots,tn\}$ and $VM=\{vm1,vm2,\ldots,vmm\}$ respectively. The squirrel hybrid mutation evolutional approach maps the tasks to the local virtual machine. The algorithm steps are presented in the following.

4) Generating the First Generation: Like other evolutional algorithms, the primary population is generated randomly. In the proposed method, each virtual machine is considered a squirrel to perform the tasks. In each repetition of the algorithm, it tries to schedule K tasks by M virtual machines. The processing capacity of the virtual machines can affect the optimal scheduling of tasks to the virtual machines. Before assigning the squirrels to the sets, the fitting function value of each squirrel should be calculated using Eq. (4).

$$F = \frac{\text{Processing\_power}}{makespan} \qquad (4)$$

This fitting function is calculated based on the machine processor and makespan. The lower the makespan, the better situation the machine has. Hence, the above equation results in the highest fitting function value for the most powerful machines.

After calculating the fitting function for all the squirrels' populations, they are sorted decreasingly, and there is a list of empty sets. The total population of the squirrels is divided into M sets. The division is performed so that each set has N squirrels. For the division, the first squirrel belongs to the first set, the second one belongs to the second set, the Mth one belongs to the Mth set, and the (M+1)th belongs to the first set again. It is repeated until the last squirrel. Each M sets include N squirrels. Since the squirrels are sorted decreasingly based on the fitness function, the first and the last assigned squirrels to the set are the best and the worst solutions, respectively. Hence, the order of entering the squirrels into the sets is important. Locality and makespan criteria are considered to find the best answer by the squirrel algorithm, which are explained in the following. The processing capacity of each virtual machine is calculated using Eq. (5):

$$\text{Processing\_power} = \text{powerj} \times \text{PCount} \quad (5)$$

where power is the processing power of the virtual machine and Pcount is the number of empty processors. The execution time of each task on the virtual machine is estimated by Eq. (6):

$$\text{ExeTime} = \text{TaskTime} \times \text{Processing\_power} \quad (6)$$

where TaskTime is the size of the task which wants to be executed. The execution time of each virtual machine is different. Less execution time of a task on the virtual machine makes less makespan on the machine. In order to accomplish this, the following algorithm is applied.

The worst squirrel's location in each set of the local search based on the fitting function is improved according to the best answer location on that set or even the best answer of all sets. Hence the average of the squirrel fitting increases. The following algorithm is used for this aim:

- Step 1: the best and the worst squirrels of each set based on the fitting value are called $Xbest$ and $Xworst$, respectively.
- Step 2: the worst squirrel of each set ($Xworst$) tries to improve itself by exchanging its information rather than the best squirrel ($Xbest$). In order to reduce the makespan value achieved when all virtual machines are processing the same amount of data, the following improvement is performed.
- Step 3: two $Xbest$ and $Xw\quad rst$ squirrels are selected so that their fitting function has the most difference, and this value should apply to all. Thus, the number of tasks of Xworst is transferred to Xbest. This transfer is performed until both fitting functions are equal.
- Step 4: after duplication of these two values, the list of squirrels in the set is sorted again. This process is performed for the next Xbest and Xworst.
- Step 5: this process is continued until the fitting function value of all squirrels is equal to the set fitting function average value.
- Step 6: all the sets are combined and sorted based on the fitting value, decreasingly, after internal evolution in each set. Then they are divided into some sets, and the evolution continues until the stop condition.

Usually, the stop condition of the algorithm is selected based on the constant variations of the best answer fitting or the algorithm repetition up to a determined number. In this problem, the considered stop condition is the determined value, $globalit$.

IV. Simulation

The proposed algorithm for task scheduling is implemented using Cloudsim. Moreover, the proposed method is simulated on the San Diego dataset. The San Diego dataset is a widely used benchmark dataset for task scheduling simulations. By using Cloudsim to simulate the proposed algorithm on the San Diego dataset, it allows researchers to compare their results with the existing literature on task scheduling and measure the performance of their proposed algorithm. This section compares the proposed method with [9] and [8] methods based on comparable criteria, including makespan, energy consumption, and execution time. This comparison allows for a clear assessment of the relative merits of the proposed method compared to the existing literature, highlighting the advantages in terms of performance and energy efficiency. Makespan determines the maximum time that each machine is active. If the distributions are not fair, this criterion is for different machines. It is the maximum time of the machine that works more than all other machines. The less general average of this criterion makes the better performance of the scheduling algorithm.

The proposed method is compared in the first experiment with the method presented in [35]. According to the results obtained in this experiment, the proposed method showed better results with regard to makespan, as shown in Fig. 1. This is because the proposed method is able to more efficiently distribute the tasks among the different machines, resulting in a lower makespan. Additionally, the proposed method is able to better account for the different capabilities of the machines, leading to a more even distribution of the tasks and better machine utilization. The proposed method is compared in the second experiment with the method presented in [34]. HPC2N and NASA workloads were used in this experiment to evaluate the proposed method. As shown in Fig. 2 and Fig. 3, the proposed method outperforms previous approaches regarding makespan time. The proposed method is able to better utilize the machines by accounting for the differences in the machines' capabilities. This means that it can better distribute the tasks to the machines, leading to a shorter makespan time, as seen in the results of the second experiment.

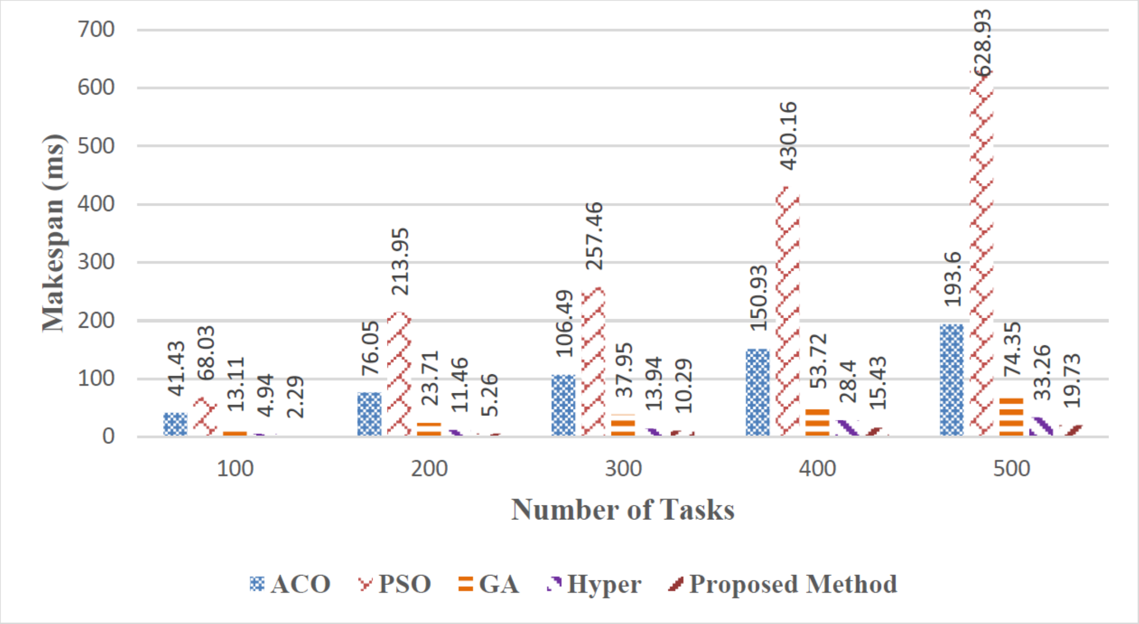

Fig. 2. Makespan comparison

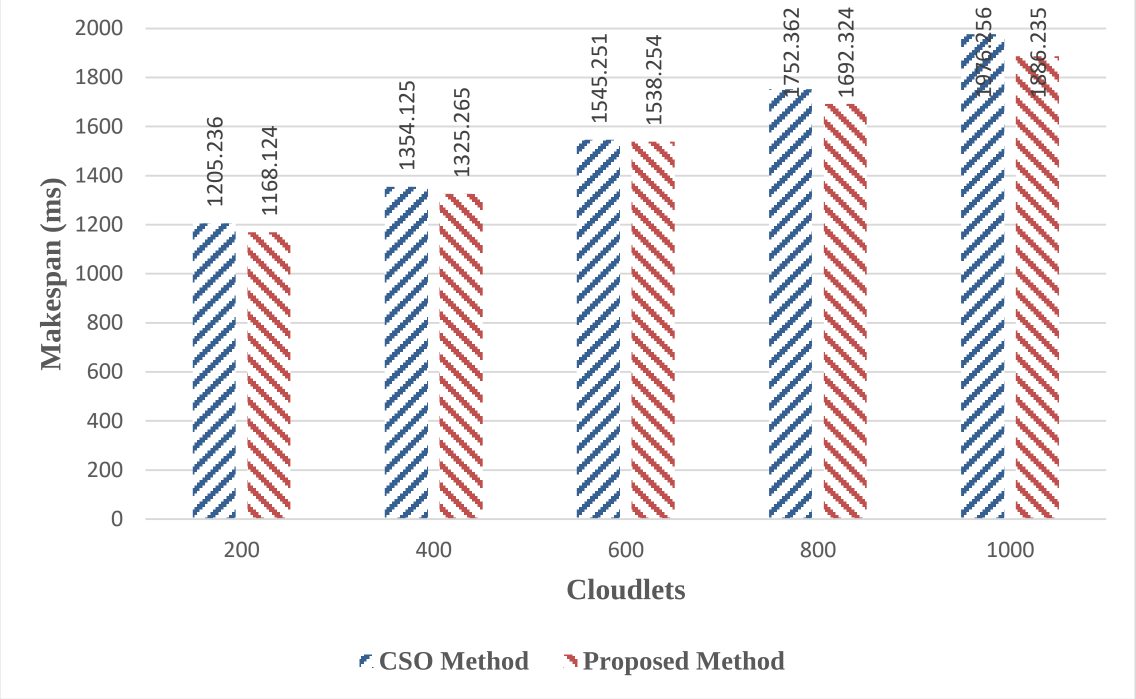

Fig. 3. Makespan comparison based on HP2CN workload.

Energy consumption criterion shows the amount of consumed energy for the execution of the tasks on the machines simulated in two different scenarios. In the first scenario, the number of machines is constant, and the number of tasks increases in each step. It is assumed that each task unit consumes one energy unit. In this scenario, the proposed method's performance is better. The cause of the increasing trend of the consumed energy diagram is the constant number of machines and the increasing number of tasks in each step. Execution time is the average time the tasks reach the resources. The less time, the better the scheduling algorithm. In the third experiment, the energy consumption and execution time of the proposed method is compared according to the data of the article [36]. This experiment uses five physical machines, 20 virtual machines, and 50 to 400 tasks. The obtained results are shown in Fig. 4. In the fourth experiment, the power consumption and execution time are evaluated based [37] dataset. Four physical machines and 5 - 50 virtual machines are used in this experiment. The obtained results are shown in Fig. 5 to 7.

V. Conclusion

In this paper, by applying efficient scheduling to virtual machines, the efficiency of the system is enhanced, resulting in a shorter response time. It makes quick calculations and reduces energy consumption. This problem aims to apply an efficient scheduling method on virtual machines on a cloud system to meet all operational requests, and each performance criterion is optimized. Hence, metaheuristic algorithms are used. This algorithm is used by mathematical modeling of the political-social evolutional process to solve many optimization problems. This optimization evolutional strategy performance in convergence rate and reaching the global optimal is very high. While integrating multiple meta-heuristic methods may provide a hybrid heuristic with good performance, some meta-heuristics are not complementary, so combining them may not improve or even degrade performance. Performance is also affected by the integration strategy. In order to improve the performance of distributed systems on a wide range of aspects, we will study the complementarity of multiple meta-heuristics and develop an efficient integration strategy for the hybrid of multiple meta-heuristics.

Bisayan Dialect Short-time Fourier Transform Audio Recognition System using Convolutional and Recurrent Neural Network

Patrick D. Cerna, Rhodessa J. Cascaro, Khian Orland S. Juan, Bon Jovi C. Montes, Aldrei O. Caballero
College of Computer and Information Science, MAPUA Malayan College Mindanao, Davao City, Philippines

***Abstract*—Speech is a form of oral communication that reinforces thoughts and ideas that have general purpose and meaning. In the Philippines, Filipinos can speak at least three languages. English, Filipino, native language. The Philippine government says the Philippines has more than 150 regional native languages, one of which he says is Cebuano. This research aims to implement automatic speech recognition (ASR) specifically for the Bisayan dialect, and researchers use machine learning techniques to create and operate the system. ASR has served its purpose in recent years not only in the official language of the Philippines, but also in various foreign languages. The required datasets were collected throughout the study to train and build the models selected for the speech recognition engine. Audio files are recorded in waveform file format and contain Visayan phrases and sentences. Audio was captured through hours of recorded audio and process using Tensorflow short time Fourier transform (STFT) algorithm to ensure the accurate representation. In order to analyze the audio data, the recordings were specially converted to digital format, specifically .wav and making it sure all records are uncorrupted with only one channel, and finally have a sample rate of 22050kHz. A data mining process was carried out by integrating CNN layers, dense layers, and RNNs to predict the transcription of speech input using multiple layers that determine the output of the speech data. The researchers used the JiWER Python library, which was used in parallel when evaluating WER. This is because the trained scripted data set contains at least 500 time recordings totaling 61.78 minutes. Overall, the WER output is at best 99.53% and the percentage of records used is acceptable.**

***Keywords*—Bisayan dialect; speech recognition; dense layer; CNN; RNN**

I. INTRODUCTION

Automatic speech recognition (ASR) systems use algorithms to convert spoken words into text. Companies like Google Cloud, Microsoft Azure, IBM Watson, and YouTube use ASR systems for education, transcription, and disability support. All of these can provide high quality transcripts. A study showed that YouTube was able to transcribe with a word error rate of 28% compared to manual transcription with a word error rate of 17.4% [1]. However, for this study, we only used high quality FLAC files with little background noise. Poor recording quality and high background noise will result in a high word error rate. Since video data is resistant to audio noise, it can be used for speech recognition. Automatic Speech Recognition (ASR), also known as Automatic Speech Recognition, is the process of converting speech signals into text. The text can be in the form of words, phrases, syllables, or any subword unit [2]. ASR is a subset of Natural Language Processing (NLP) in the knowledge domain of artificial intelligence (AI) and aims to make communication between humans and computers as natural as possible. Its ultimate goal is to make human-computer communication indistinguishable from human-human conversation. A deep neural network (DNN) is a neural network with two or more levels of complexity that uses mathematical modeling to process data, and was used in speech recognition in 2010. DNNs have had great success with automatic speech recognition. However, due to differences in speaking styles and attitudes, models that can account for small changes or perturbations in the feature space lead to overfitting and poor generalization, which is desirable [3].

Accent can be defined as a style of pronunciation in a language. In a Filipino setup, a speaker's accent can be heavily influenced by other speakers in their approximate geographic location. This allows people to speak the same language with different accents, resulting in languages (such as Filipino) that are used with multiple accents. Extensive analysis of this provides information on speaker status, age, gender, dialect, and ethnicity [4]. Recently, the value of recognizing a speaker's accent has begun to be noticed in the field of computers. Its influence has been recognized as a basis for the development of various large-scale speech applications such as automatic speech recognition [5]. However, automatic detection of accents is a challenging research topic because languages can have multiple pronunciation styles. Automatic accent detection (also known as accent identification) is based on the consistency of acoustic patterns that can be identified in speaking styles to identify pronunciations in the same accent cluster.

Previous studies on ASR used hidden Markovs, but some focused only on vowel recognition in Tagalog [6]. Another study by Fajardo et al. [7] Automatic Filipino speech recognition is done using a convolutional neural network (CNN) model with SqueezeNet architecture for Filipino. Meanwhile, E developed continuous speech recognition for Bicol and Kapampangan using the CMU Sphinx Toolkit. The speech corpus was collected by the researcher and consists of seven hours of recordings from 150 native speakers of Kapampangan and Bicolano [8]. A hardware-based speech recognition system [9] is built with circuits incorporating neural networks, including passive and active filters to drive microphones, input/output ports, EEPROM memory, and other components. Advantages of this type of system include speed, accuracy, and lower cost than software-based speech recognition products.

Cebuano is a native language of Cebu City, of which the Visayan dialect is part. This has been extended not only to the Visayas but also to many places in Mindanao due to its growth and usefulness. There was no formal training in the Visayan dialect during the author's primary and secondary education. However, it is learned through the life stages and experiences of the community and relatives. When the K-12 Enhanced Basic Education was signed into law in the Philippines in 2013, native language subjects were included as part of the language classes for kindergarten and primary school. This gave children insight, depth of knowledge, and understanding of their mother tongue, as well as exposure to English and Filipino from an early age. Just as the Visayan dialect has evolved over the years, like other native languages that have been taught in primary school for almost a decade, these languages may one day gain the upper hand for some reason.

However, not all languages are being supported by this technology due to a very large amount of languages existing in our world, and only a few people are working on it. Thus, the researchers were able to implement Automatic Speech Recognition (ASR) in the Bisaya dialect. By doing so, the researchers would be able to provide a new path for the Bisaya dialect in the implementation of technologies alongside the expanding community in our country. In addition, the researchers would also be able to promote the use of their language in technologies, thus making it popular among the people to reduce the risk of being lost in the future. However, not all languages are being supported by this technology due to a very large amount of languages existing in our world, and only a few people are working on it. Thus, the researchers are planning to incorporate Automatic Speech Recognition (ASR) in the Bisaya dialect. By doing so, the researchers would be able to provide a new path for the Bisaya dialect in the implementation of technologies alongside the expanding community in our country. In addition, the researchers would also be able to promote the use of their language in technologies, thus making it popular among the people to reduce the risk of being lost in the future.

II. Related Works

Raval and Gajjar [10] conducted a study in an effort towards filling the gap between differently-abled people like deaf and dumb and the other people. The obtained results after extracting background were used for forming data that contained 24 alphabets of the English language. The Convolutional Neural Network proposed here is tested on both a custom-made dataset and also with real-time hand gestures performed by people of different skin tones. The accuracy obtained by the proposed algorithm is 83%. To develop a system that can read and interpret a sign like Amrutha and Prabu [11], one must train it using a large dataset and the best algorithm. As a basic SLR system, an isolated recognition model is developed. The model is based on vision-based isolated hand gesture detection and recognition. Assessment of ML-based SLR model was conducted with the help of four candidates under a controlled environment. The model made use of a convex hull for feature extraction and KNN for classification that yielded 65% accuracy.

On the other hand, Adithya and Rajesh [12] presents an efficient convolutional neural network (CNN) based model for automatically recognizing fingerspellings in sign languages. The model has been tested on a novel Indian sign language (ISL) fingerspelling dataset as well as a publicly available hand posture dataset, and has obtained promising results. Similary, Qin et al. [13] construct a lightweight sign language translation network. We construct the dataset called CSL_BS (Chinese Sign Language-Bank and Station) and two-way VTN to train isolated sign language and compares it with I3D (Inflated three Dimension). Then I3D and VTN are respectively used as feature extraction modules to extract the features of continuous sign language sequences, which are used as the input of the continuous sign language translation decoding network (seq2seq). Based on CSL-BS, two-way VTN achieves 87.9% accuracy while two-way I3D is 84.2%. Finally, Suardi et al. [14] created a trial of combining CNN models using the Ensemble method has been successfully carried out with the results being able to increase the accuracy value to 99.4%. and proved that using Ensemble can increase the higher accuracy value.

In the Philipines, Bautista and Yoon-Joong [15] describe the development of speech recognition using the Hidden Markov Model Toolkit (HTK) in Filipino only. Modifications were made to some datasets to remove unwanted background noise that is not needed for speech recognition. Therefore, removing these noises may improve the model's performance. A variety of experiments with the models are specified in the author's study, and the accuracies can be compared to conclude which model is the most effective to use in the study. Finally, Laguna and Guevara [16] used a language identification (LID) system in their approach. LID can recognize languages of unknown languages, Tagalog (TGL), Cebuano (CEB), Hiligaynon (HIL), Kapampangan (KAP), Bicolano (BCL), Warai (WAR), Tausugu (TSG) based on their research. Among these languages were pairwise and hierarchical LIDs, yielding average accuracies of 48.07% for seven languages, 72.64% for pairwise and 53.99% for hierarchical. The researchers say the LID system works best for a small number of target languages that are closely related to Filipino.

III. Materials and Methods

A. Research Design

The study intends to implement and create automatic speech recognition for Bisayan dialect. To be more specific, the study will produce an output of the transcribed text from the input audio. But, to do so, the researchers had to collect the necessary datasets that will be used throughout the study to train and build the selected models for the speech recognition engine. Researchers adapted the Knowledge Discovery in Databases (KDD) framework to manipulate data in their research. This data mining (DM) framework was adopted for the research, which consists of six distinct phases as shown in Fig. 1, based on the research goal. This will help researchers identify and collect valuable datasets for developing their own neural network models to achieve her Bisayan speech recognition. Therefore, researchers also use various techniques to help create and develop useful datasets for training models.

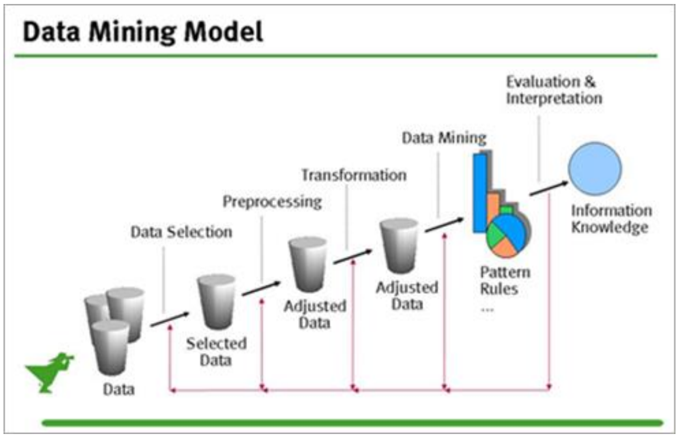

Fig. 1. KDD framework [17].

B. Data Sources and Selection

This study selects research participants who are fluent in the Visayan dialect of the Davao area and collects the required datasets through voice recordings. This helps the authors collect real, authentic data to use in their experiments and analysis throughout the study. These datasets consist of audio files containing unedited recordings of participants' natural voices. This is the raw audio output from the recording device where data collection starts with voice and text data. Audio files are recorded in waveform file format and contain Visayan phrases and sentences. When capturing audio data, hours of recorded audio must be captured to ensure the process is more accurate. During text data collection, everything is controlled and thoroughly researched by researchers to ensure quality and accurate data for research. A phrase or sentence script is provided by the researcher for text data collection (Table I). All these collections are handled according to requirements model and evaluation. So before the actual audio data processing he needs a powerful GPU such as the Nvidia RTX series to process large datasets efficiently and the latest generation of his GTX series performs well I can do it.

Researchers collected speech recognition data from public and private premises with the consent of the participants in Davao City and Mati City, as shown in Fig. 2. Respondents were provided with a script containing random Bisaya phrases of hers. The list of phrases in the Visayan dialect contains hundreds of sentences structured as scripted phrases. Some of these phrases are informal conversations by researchers affiliated with privacy and other illegal matters, but they do not infringe. The recorded phrases are long and short as they provide random topics and fiction for conversation. As shown in Table I, some examples of the following Visayan dialect phrases are read by participating speakers.

C. Methods of Data Processing

The refine input recording audio from raspberry pi powered device which contains waveform file format and this will contain Bisayan phrases or sentences. The captured audio were processed for training and testing through Tensorflow STFT algorithm will use to analyze, synthesize, transform and describe audio signals and JiWER plugins fo Similarity measures. PRAAT application tool for speech/voice feature extraction will also be utilized as the need arises.

Fig. 2. Audio recording of bisayan speakers.

TABLE I. LIST OF BISAYAN SENTENCES

English	Visayan / Cebuano
How are you?	Kamusta Ka?(Ka-mu-sta ka)
Do you speak english?	Kabolo ka mo sultiogenglish? (ka-ba-lo ka mo salty ogenglish?)
A little	Gamay ra (ga-m(eye) ra)
I speak a little Visayan	Makasulti ko gamay (ma-ka-salty ko ga-may)
I don't understand	Wala ko sabot (wa-la ko sa-bot)
Please speak slowly	Hinaya lang ogstorya (Hi-n(eye)-yah lang og story-ya)
What is you name?	Unsay imongngalan? (Un-s(eye)ee-mongnga-lan)
Thank you	Salamat (Sa-la-mat)
Where can I buy… (item)?	Asa ko makapalit ani (item) e.g shoes (ah-sa ko ma-ka-pa-lit ah-ni)
I would like to buy souvenirs	Ganahan ko mopalit pasalubong (Ga-na-han ko mo-pa-lit pa-sa-loo-bong)
Where is…(place)?	Asa ang lugar (place) e.g CR (term used for bathroom) (ah-sa ang loo-gar)
What places can one visit here?	Unsay ma suroyansainyonglugar? (Oon-s(eye) ma soo-roy-yansaee-mong loo-gar)
How much?	Tag pila? (tag-pi-la)
Good Morning	MayongBuntag (m(eye)-yong bun-tug)
Good Afternoon	MayongHapon (m(eye)-yong hah-pon)
Good Evening	MayongGabii (m(eye)-yong gah-bee-e)
See You Later	Kita ta unya (ki-ta ta oon-ya)
Yes	O-o (oh oh)
No	Dili (Di-li)
What?	Unsa? (oon-sa?)
When?	Kan-usa? (kan-oosa?)
Please	Palihug (Pa-lee-hoog)

The CNN Layer, Dense Layer, and RNN will be used is to predict the transcription of the audio input using several layers that would determine the output of the audio. It is expected that the output of this research will then evaluate the accuracy of the speech recognition by using Word Error Rate (WER), accuracy, precision and recall. Fig. 3 shows the separate steps of a process in sequential order, this is known as Flowchart. The process will start by processing the dataset and getting their audio and text data, which will be used for the training of the model. The audio data shall be used as the input data for the model, while the textual data shall be used as the target data of the model's prediction. While in training, the model shall compare its prediction to the target data, and shall evaluate its errors to modify its weight parameters. During testing, it shall compare its prediction to the target data so that it could compute the Word Error Rate of its output. Thus, the value of the Word Error Rate will serve as its evaluation in transcribing Bisaya Dialect.

To analyze the audio data, the recording was converted into a digital format specifically using audacity in particular into a .wav format. According to Frosch [18], digital audio is presented in many formats, and one of them can also compress audio which is termed as the lossy audio compression format. Lossy sound files compression attempts to reduce the amount of data. In simpler meaning, it allows for even more file size reductions by eliminating certain audio information and simplifying the data. At the same time, the frequency has audio features that are also audio signals that can be used to develop statistical or Machine Learning models. Audio files for this study will contain unedited recordings in a lossy format which will significantly benefit for data compression of the study. All audio recorded was set by 22,050 Hz of Project Rate and Mono Recording Channel to lessen file size and let the model train faster. If some of the recordings do not follow the rule or forgot to set, a code in the Programming section will automatically do it for convenience as shown in Fig. 4.

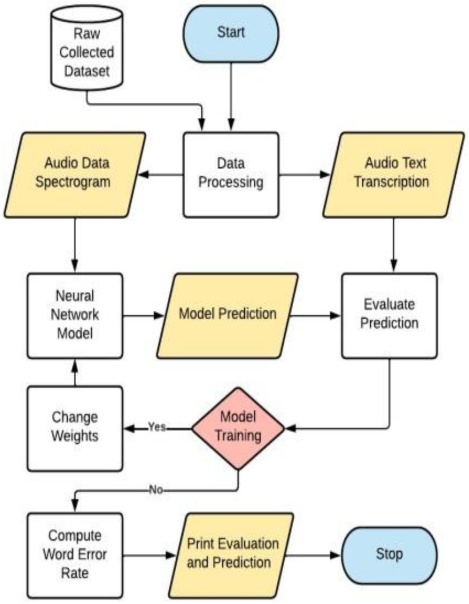

Fig. 3. Flowchart of dialect recognition system.

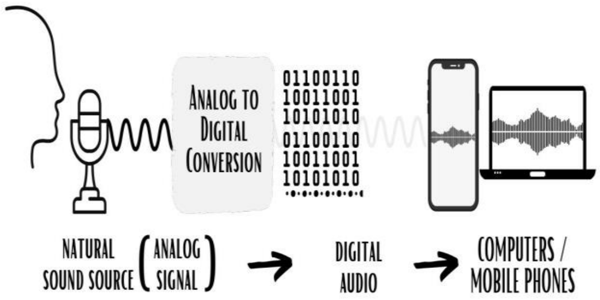

Fig. 4. Analog to digital conversion.

IV. Data Experimentation and Analysis

A. Audio Conversion to Datasets

After gathering the necessary data for the experimentation, the researchers had to optimize and clean the collected data. Thus, the researchers utilized Python packages to easily optimize and clean their audio dataset so that it would be used for the training of the model. The process was done to ensure that all of their datasets are not corrupted, must be in a .wav format, must not be over 10 seconds, should only have 1 channel, and finally, it should have a sample rate of 22050 kHz. If this would not be followed, it would affect the efficiency of the training process, which would further burden the researchers to do their experimentations. Based on Table II, the researchers had gathered a total amount of 68.76 minutes of audio data that consists of 563 recordings. Each recording contains one phrase out of the 500 phrases that were prepared by the researchers to the participants. The list of created phrases or sentences can be found in Bisaya Dialect Phrases.

TABLE II. Datasets Gathered after the Conversion

Group Dataset	No. of Times (mins)	No. of Files
Collected Datasets	68.76	563
Train Datasets	61.78	506
Test Datasets	6.97	57
Augmented Datasets	123.57	1012
Train + Augmented	185.35	1518
Overall	192.33	1575

After optimizing and cleaning the audio datasets, they would be separated into two folders which will be called "train_wav" and "test_wav". These folders shall be the basis for the train datasets and test datasets of the experimentation. After processing the required audio data, the researchers had to create a CSV file for the train and test datasets that would be used to fit the model as shown in Fig. 5. There would be two CSV files that would be generated which are called "train.csv" and "test.csv". These CSVs shall contain the file directory of the audios while also having the text transcription of it. In order for the neural network model (CNN and RNN) to train, the researchers had to extract the audio data and its transcription so that it would be given to the model. The necessary data that needs to be processed is the input and target data for the model. By getting the input data, the researchers use a Python package that is capable of reading the signal from the audio and transforming it into input data for the model. For the target data, the characters in the transcription of the audio shall be converted into numbers which will be the target data that the model should have after computing the input data as shown in Fig. 5.

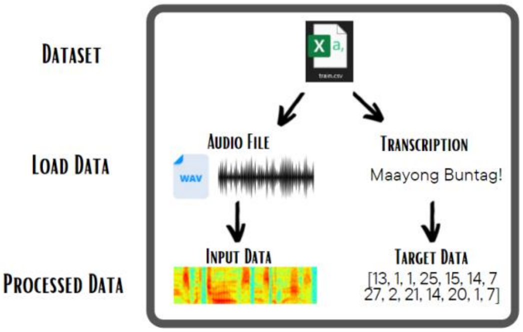

Fig. 5. Audio conversion to target data.

B. Prediction using CNN, RNN and Dense Layer

The CNN Layer, Dense Layer, and RNN were used to predict the transcription of the audio input using several layers that would determine the output of the audio. Based on the figure below, the structure of the neural network model used in this study contains several layers as shown in Fig. 6. The layers within the models consist of several layers. Furthermore, the researchers will use some other underlying layers that are used to optimize the training performance of the model, such as dropouts and normalizations. With this kind of network model structure, the researchers believe that it will be able to perform its purpose and provide results from the given input audio. The researcher will then evaluate the accuracy of the speech recognition by using Word Error Rate (WER), accuracy, precision and recall.

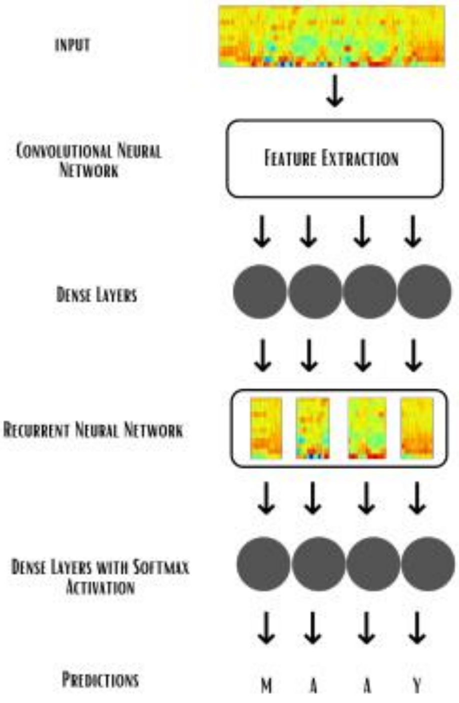

Fig. 6. Prediction of recognition using CNN, RNN and dense layer.

C. Result of Data Analysis

Based on the results of experimentations as reflected in Table III, the researchers believed that adding augmented data would provide better model predictions. Furthermore, having additional RNN layers would also provide positive training results but would make the model predictions perform slower than having a few layers. Thus, depending on the target development and dataset would determine how many layers would be necessary to have better results in the training and deployment. However, since the researchers had only a few datasets to train the model, they had to provide alternative solutions based.

TABLE III. RESULT OF AUDIO RECOGNITION USING CNN AND RNN

Row Number	Audio Dataset	RNN Layers	Optimal Epochs	Word Error Rate
1	11.95 minutes (conversation)	2 layers	100 Epochs	99.53 %
2	11.97 minutes (scripted)	2 layers	92 Epochs	96.37 %
3	11.95 minutes + 11.97 + Noise	2 layers	64 Epochs	98.48 %
4	39.13	5 layers	81 Epochs	76.79 %
5	61.78 Minutes + 123.57 minutes (Augmented)	5 layers	30 Epochs	66.82 %

Furthermore, having additional RNN layers would also provide positive training results but would make the model predictions perform slower than having a few layers. Thus, depending on the target development and dataset would determine how many layers would be necessary to have better results in the training and deployment. However, since the researchers had only a few datasets to train the model, they had to provide alternative based on their experimentations shown in the table above. In the Word Error Rate (WER), this is the standard evaluation of how accurate an Automatic Speech Recognition (ASR) system is. It calculates the number of found "errors" in an ASR transcription text. This has been used by different researchers and big companies worldwide to also measure and identify the accuracy of their machine learning. In this study, the researchers used JiWER Python Library and is used alongside in evaluating WER. Since the trained scripted datasets contains at least 500 and a total of 61.78 minutes' time recording. The WER output shows 99.53% (as reflected in Table III) at best which results to acceptable percentage for the number of datasets used.

V. CONCLUSION AND RECOMMENDATIONS

Overall, the study was able to create and train a neural network model that would be used for Speech Recognition System in Bisaya Dialect. The result of the data experimentation reveals the best results of analysis through 99.53% Word Error Rate for their trained model. The researcher therefore recommends that it would be best to seek ways to address the biggest limitation of the study which is to acquire a large amount of dataset for the training of the model. By doing so, the trained model would be able to have a better prediction and performance, since it has been exposed to a large amount of different data for its training. Aside from that, others should also be thoughtful when it comes to their hardware specifications, as the training of the model would require a heavy amount of processing power which would put a lot of stress onto your hardware. Thus, it would be recommended to have better hardware when training a neural network model with a very large amount of datasets, so that it would lessen the amount of time to train the model.
