Fig. 6. Performance analysis-BraTS 2018 dataset by varying training percentage, a) accuracy, b) F1-score, c) precision, d) recall.

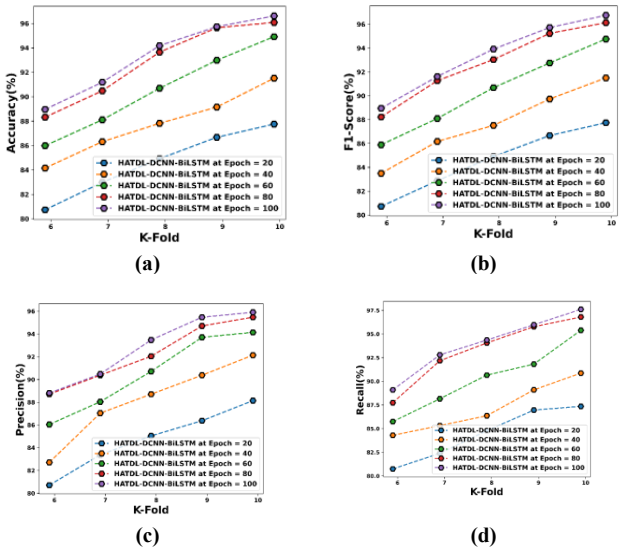

Fig. 7. Performance analysis with BraTS 2018 dataset by varying k-fold, a) accuracy, b) F1-score, c) precision, d) recall.

2) Analysis based on BraTS 2019 dataset: Fig. 8 illustrates the performance analysis carried out with BraTS 2019 dataset varying by training data. Fig. 8 (a) illustrates accuracy measure. Accuracy obtained by HATDL-DCNN-BiLSTM for 80% training data by varying the epoch 20 to 100 is 86.38%, 89.44%, 91.88%, 94.14%, and 98.93%. Fig. 8 (b) depicts F1-score

metric. The F1-score obtained by proposed HATDL-DCNN-BiLSTM with 80% training data for epoch 20 is 86.36%, epoch 40 is 89.43%, epoch 60 is 91.87%, epoch 80 is 94.13%, and epoch 100 is 97.67%. The precision used to analyze the performance is illustrated in Fig. 8 (c). With 80% training data, the precision of HATDL-DCNN-BiLSTM by varying the epoch from 20 to 100 is 85.51%, 89.04%, 91.89%, 93.53%, and 96.17%. Fig. 8 (d) illustrates the recall measure. The recall of proposed HATDL-DCNN-BiLSTM at 80% training data for epoch 20, 40, 60, 80, and 100 is 87.24%, 89.82%, 91.84%, 94.74%, and 99.21%.

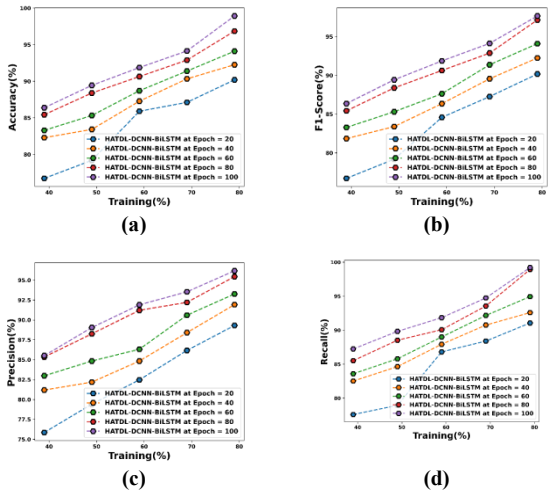

Fig. 8. Performance analysis with BraTS 2019 dataset by varying training data, a) accuracy, b) F1-score, c) precision, d) recall.

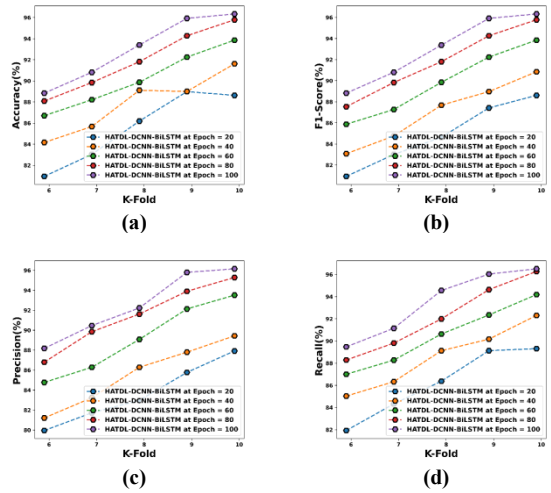

Fig. 9. Performance analysis with BraTS 2019 dataset by varying k-fold, a) accuracy, b) F1-score, c) precision, d) recall.

Fig. 9 shows the performance analysis done withBraTS 2019 dataset with k-fold. Fig. 9 (a) depicts accuracy measure. At k-fold 10, the accuracy observed by HATDL-DCNN-BiLSTM for epoch 20 is 88.84%, 90.81%, 93.40%, 95.93%, and 96.34%. Analysis done by varying F1-score is depicted in Fig. 9 (b). For k-fold 10, the F1-score measured by HATDL-DCNN-BiLSTM by varying the epoch from 20 to 100 is 88.82%, 90.80%, 93.38%, 95.92%, and 96.33%. The precision used to analyze the performance is shown in Fig. 9 (c). The precision obtained by proposed HATDL-DCNN-BiLSTM for k-fold 10 with epoch 20 is 88.18%, epoch 40 is 90.46%, epoch 60 is 92.23%, epoch 80 is 95.80%, and epoch 100 is 96.15%. Fig. 9 (d) illustrates the recall measure. With 10 k-fold value, the recall computed by HATDL-DCNN-BiLSTM by varying the epoch from 20 to 100 is 89.47%, 91.15%, 94.55%, 96.03%, and 96.51%.

F. Comparative Methods

To evaluate the performance, the proposed HATDL-DCNN-BiLSTM is compared with the existing techniques, like parallel deep convolutional neural network (PDCNN) [11], unified deep learning model (TumorDetNet) [17], Semi-Supervised Brain Tumor Classification Network (SSBTCNet) [10], Ensemble Deep Neural Support Vector Machine (EDN-SVM), and DCNN-BiLSTM [36] [37].

V. Discussion

This section elaborates the comparative discussion of proposed HATDL-DCNN-BiLSTM model with two different datasets.

1) Analysis with BraTS 2018 dataset: Fig. 10 illustrates the comparative analysis of proposed HATDL-DCNN-BiLSTM model with existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods using BraTS 2018 dataset in terms of training percentage. For training percentage of 80%, the proposed HATDL-DCNN-BiLSTM model obtained the accuracy of 97.55%, which is superior than existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods by 12.80%, 18.59%, 8.38%, 16.06% and 6.45% respectively. The F1-Score of the proposed HATDL-DCNN-BiLSTM model achieves the result of 12.73%, 18.61%, 9.34%, 16.05%, and 6.44% higher than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM approaches for 80% of training percentage. The precision of the HATDL-DCNN-BiLSTM model attains the result of 96.70%, which is improved over the existing PDCNN, by 11.41%, EDN-SVM by 16.33%, TumorDetNet by 5.74%, SSBTCNet by 14.62%, and DCNN-BiLSTM by 4.70% for 80% training data. Finally, the recall of the HATDL-DCNN-BiLSTM model is 98.38%, which is improved to 14.05% with PDCNN, 20.80% with EDN-SVM, 12.74% with TumorDetNet, 17.46% with SSBTCNet, and 8.16% with DCNN-BiLSTM with 80% training data.

Fig. 11 show the comparative results of the proposed HATDL-DCNN-BiLSTM model with existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods using BraTS 2018 dataset in terms of k-fold. The HATDL-DCNN-BiLSTM model achieves the accuracy of 96.62%, which shows that the accuracy is superior over the existing PDCNN by 5.46%, EDN-SVM by 12.71%, TumorDetNet by 3.75%, SSBTCNet by 7.01%, and DCNN-BiLSTM by 2.09% for k-fold of 10 respectively. The HATDL-DCNN-BiLSTM model achieves the F1-score of 96.75%, which shows that the F1-score of the HATDL-DCNN-BiLSTM model is 6.07%, 12.84%, 3.90%, 7.32%, and 2.24% advanced

than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM approaches respectively. The precision of the HATDL-DCNN-BiLSTM model for k-fold of 10 is 95.91%, which increased 4.62% with PDCNN, 11.91% ith EDN-SVM, 2.53% with TumorDetNet, 5.66% with SSBTCNet, and 1.14% with DCNN-BiLSTM. Moreover, for k-fold of 10, recall of the HATDL-DCNN-BiLSTM model is 97.61%, which is higher than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods by 7.50%, 13.77%, 5.26%, 8.95%, and 3.34% respectively.

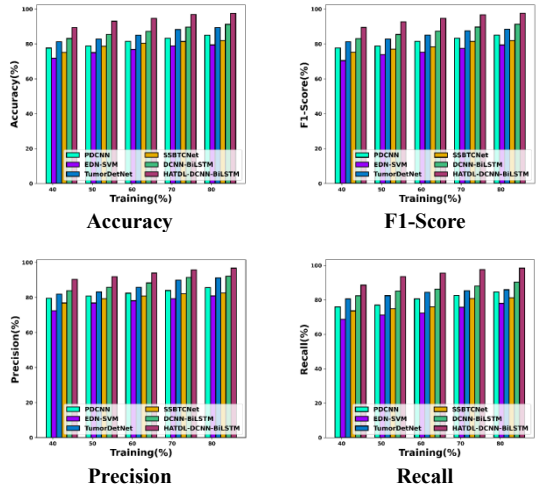

Fig. 10. Comparative analysis of HATDL-DCNN-BiLSTM with training percentage using BraTS 2018 dataset.

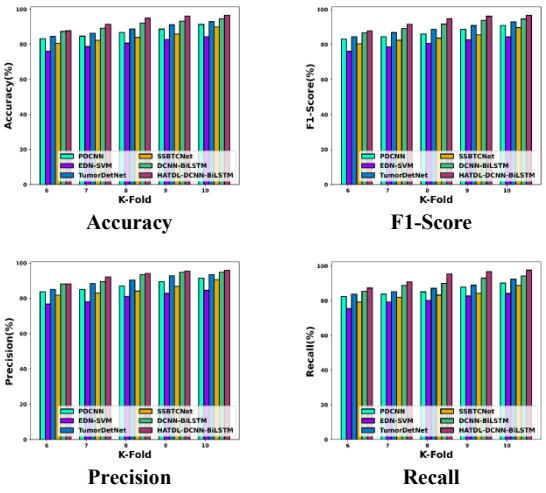

Fig. 11. Comparative analysis of HATDL-DCNN-BiLSTM with k-fold using BraTS 2018 dataset.

2) Analysis with BraTS2019 dataset: Comparative analysis of proposed HATDL-DCNN-BiLSTM model with existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods using BraTS 2019 dataset in terms of training percentage is shown in Fig. 12. The accuracy of the proposed HATDL-DCNN-BiLSTM model for 80% of training percentage is 98.93 which is compared with existing schemes, that reveals the improvement of 12.63% with PDCNN, 17.78% with EDN-SVM, 11.31% with TumorDetNet, 13.82% with SSBTCNet, and 6.39% with DCNN-BiLSTM respectively. The F1-Score of the HATDL-DCNN-BiLSTM model at 80% training percentage is 97.67%, which is higher than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM techniques by 11.52%, 16.75%, 10.18%, 12.76%, and 6.25% respectively. The HATDL-DCNN-BiLSTM model attains the precision of 96.17%, which depicts that it is higher than the conventional PDCNN by 9.48%, EDN-SVM by 14.19%, TumorDetNet by 8.44%, SSBTCNet by 10.52%, and DCNN-BiLSTM by 3.53% for training percentage of 80%. Finally, the recall of the proposed HATDL-DCNN-BiLSTM model is 13.53%, 19.24%, 11.91%, 14.96% and 8.91% superior than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM approaches respectively.

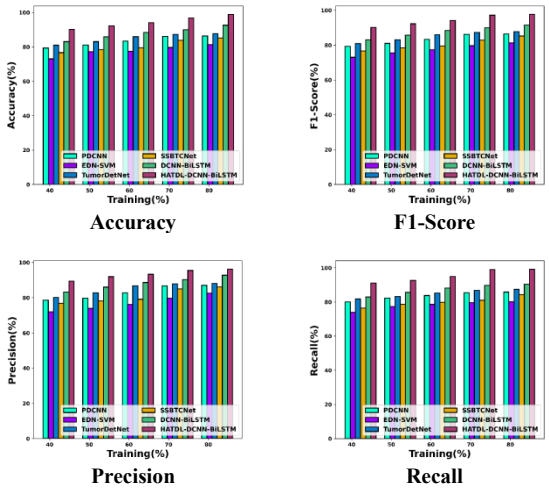

Fig. 12. Comparative analysis of HATDL-DCNN-BiLSTM with training percentage using BraTS 2019 dataset.

Fig. 13 illustrates the comparative outcomes of proposed HATDL-DCNN-BiLSTM model with existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods using BraTS 2019 dataset in terms of k-fold. For k-fold 10, accuracy of HATDL-DCNN-BiLSTM model is 96.34%, which is higher than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM methods by 7.31%, 14.71%, 3.93%, 10.20%, and 1.69% respectively. The HATDL-DCNN-BiLSTM model attains the F1-Score of 96.33%, which shows it is superior than the existing PDCNN by 7.31%, EDN-SVM by 14.72%, TumorDetNet by 3.93%, SSBTCNet by 10.21%, and DCNN-BiLSTM by 1.69% for k-fold 10 respectively. The precision of proposed HATDL-DCNN-BiLSTM is 7.27%, 14.15%, 3.56%, 10.71% and 1.19% advanced than the existing PDCNN, EDN-SVM, TumorDetNet, SSBTCNet, and DCNN-BiLSTM approaches respectively. The recall of the HATDL-DCNN-BiLSTM model for k-fold of 10 is 96.51%, which increased 7.36% with PDCNN, 15.28% with EDN-SVM, 4.30% with TumorDetNet, 9.70% with SSBTCNet, and 2.19% with DCNN-BiLSTM respectively.

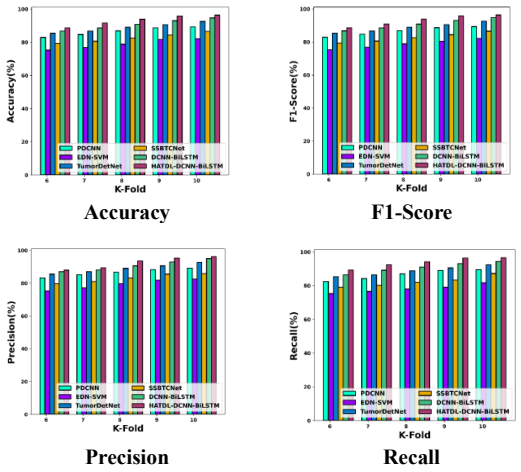

Fig. 13. Comparative analysis of HATDL-DCNN-BiLSTM with k-fold using BraTS 2019 dataset.

3) Comparative discussion: Table I illustrates the comparative discussion of HATDL-DCNN-BiLSTM with other existing methods using BraTS 2018 dataset. The existing methods evaluated for BT classification obtains inaccurate results with less accuracy. The PDCNN method [11] failed to use the model with 3D structure for identifying the tumors. Also, the TumorDetNet designed in [17] higher accuracy measure, but failed to identify the tumor grades. The SSBTCNet for BT classification failed to detect the tumor types exactly [10]. The EDN-SVM developed for the tumor classification provide higher performance but results computational complexity issues. The above stated issues are resolved through the proposed HATDL-DCNN-BiLSTM using the distributed learning mechanism of deep neural network model. The model effectively reduces the overfitting issues and offers higher performance in terms of the evaluation measures. The proposed HATDL-DCNN-BiLSTM framework minimizes the computational issues globally through the extraction of optimal features. The features extracted through different models have varying dimensions and these varying dimensional features are resized to have same dimension for all the features such that this process minimizes the computational complexity issues effectively. The proposed HATDL-DCNN-BiLSTM value is measured by altering the training percentage and k-fold value. With training percentage, the proposed obtained higher value of 97.55%, 97.54%, 96.70%, and 98.38% for accuracy, F1-score, precision, and recall. The proposed HATDL-DCNN-BiLSTM showed 96.62%, 96.75%, 95.91%, and 97.61% for accuracy, F1-score, precision, and recall and these values are measured byBraTS 2018 dataset.

Table II illustrates the comparative discussion of HATDL-DCNN-BiLSTM with other existing methods using BraTS 2019 dataset. With this dataset, the proposed HATDL-DCNN-BiLSTM obtained the accuracy, F1-score, precision, and recall as 98.93%, 97.67%, 96.17%, and 99.21 by changing the training percentage. On the other hand, proposed HATDL-DCNN-BiLSTM obtained accuracy, F1-score, precision, and recall as 96.34%, 96.33%, 96.15%, and 96.51% with k-fold value.

TABLE I. COMPARATIVE DISCUSSION OF HATDL-DCNN-BILSTM WITH BRATS 2018 DATASET

Methods		PDCNN	EDN-SVM	TumorDetNet	SSBTCNet	DCNN-BiLSTM	Proposed HATDL-DCNN-BiLSTM

VI. CONCLUSION

This research designs a proposed framework named HATDL-DCNN-BiLSTM for detection and classification of BT with MRI. This method uniquely addresses the issues in BT classification through the extraction of important and essential features by applying the attention mechanisms. It shows considerable advancements in efficiency and contrast for differentiating the tumor grades. The extracted features enable the model to increase the training speed that in turn enable to generate more reliable classification results. The transfer learning model introduced in the mechanism provides more beneficial activities, like faster training, less data requirements, higher learning rate, less training time and enhanced generalization. Due to the pre-trained models located in the transfer learning, the tasks to be executed are quickly learned and prevents the overfitting issues. It showed outstanding performance using the metrics, like accuracy, recall, F1-score, and precision of 98.93%, 99.21%, 97.67%, and 96.17% with training data. Also, the proposed scheme measured higher performance in terms of accuracy, recall, F1-score, and precision of 96.34%, 96.51%, 96.33%, and 96.15% using k-fold by considering the BraTS 2019 dataset. However, the proposed method has some limitations. Model performance is dependent on data quality and size, so further improvements can be brought about by using larger diverse datasets for better generalization.

The future direction of research would be the consideration of a hybrid optimization algorithm to improve efficiency in the network so as to give better classification results during BT classification. For example, combining genetic algorithm and particle swarm optimization can enhance the feature selection and the optimization of parameters for achieving an even more accurate and stable classification result.

A Distributed Framework for Indoor Product Design Using VR and Intelligent Algorithms

Yaoben Gong*, Zhenyu Gao
College of Art and Media Design, Nanchang Institute of Technology, Nanchang 330108, Jiangxi, China

***Abstract*—This paper presents an innovative approach to the digital design of indoor home products by integrating virtual reality (VR) technology with intelligent algorithms to enhance design accuracy and efficiency. A model combining the Red deer Optimization Algorithm with a Simple Recurrent Unit (SRU) network is proposed to evaluate and optimize the design process. The study develops a digital design framework that incorporates key evaluation factors, optimizing the SRU network through the Red deer Optimization Algorithm to achieve higher precision in design applications. The model's performance is validated through extensive experiments using metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE). Results show that the RDA-SRU model outperforms other methods, with the smallest MAE of 0.133, RMSE of 0.02, and MAPE of 0.015. Additionally, the model achieved an R^2 value of 0.968 and the shortest evaluation time of 0.028 seconds, demonstrating its superior performance in predicting and evaluating digital design applications for home products. These findings indicate that the integration of VR with intelligent algorithms significantly improves user experience, customizability, and the overall accuracy of digital design processes. This approach offers a robust solution for designers to create more efficient and user-centric home product designs, meeting growing customer demands for immersive and interactive design experiences.**

I. INTRODUCTION

With the development and popularization of Internet technology and artificial intelligence (AI) algorithms, the design field is diversifying, especially in the direction of digital applications, which has become the trend of the times and has unlimited development potential [1]. Virtual reality (VR) technology as the development of active new technology, constantly integrated into people's lives, especially in the field of scene visualization is widely used [2]. The combination of VR technology and realistic real interior home product design, constructing an interior home design scene close to the real world, promoting the design of interior home products, improving the degree of tacit understanding between the product and the user to a certain extent, and improving the user's experience of the product [3]. With the arrival of the product experience-oriented consumer design era, indoor home product design needs to adapt to the needs of humanization, combined with VR technology has become one of the ways to solve the problem of meeting the needs of users in home product design [3]. Based on VR technology indoor home products digital design method from the visual can improve the sense of interesting online home operation experience, while improving the efficiency of product design [4]. The accurate evaluation of digital design technology as a combination of VR technology in the home product design process feedback is an important link to help improve the accuracy of customer-oriented demand indoor home product design, but also improve the integrity of the home product design process [5]. The research direction of the digital design of indoor home products under the VR scene mainly focuses on the construction of scenes in virtual home product design, product virtualization design, product interaction design, digital application test analysis and other aspects of the research [6]. Scholars have made many contributions. Basha et al. [7] optimized the method and scene of secondary modeling and proposes a rapid modeling system based on VR technology; Sobhy and Abouelnaga [8] studied the value of the integration of VR technology and indoor home product design and introduces the stage-by-stage method of integration design; Wei et al. [9] analyzed the development trend of VR technology and combines with the characteristics of the experiential display design, and analyzes the characteristics of the experiential display design from a variety of perspectives VR technology in indoor home design application characteristics; Ye and Li [10] puts forward a virtual scene optimization layout strategy that can adapt to the real-time interactive display of different cell phone devices, and realizes the virtual scene of indoor home product design; Hewitt et al. [11] researched the design and implementation of a three-dimensional product interactive display website using computer language; Rangaswamy et al. [12] built a digital design based on VR technology process, and extracted relevant digital design evaluation indexes, and used hierarchical analysis to solve the problem of digital design evaluation of indoor furniture products.

With the development of AI algorithms, digital design application methods based on machine learning algorithms and deep learning algorithms enter the field experts and scholars [13]. Currently, design application evaluation methods based on intelligent algorithms include k-means clustering algorithm, support vector machine, decision tree, neural network, deep learning and so on [14]. At present, the research on the method of digital design of indoor home products based on intelligent algorithms combined with VR technology is less, in its infancy, and the effect and accuracy of the application formed cannot meet the needs of customers [15, 16]. For this reason, this paper proposes a digital design method for indoor home products based on the Red deer Optimization Algorithm to improve the simple recurrent unit neural network [17, 18]. Focusing on the digitalization of indoor home products, the digital design framework of indoor home products is constructed by analyzing

*Corresponding Author.

the digital design process, and the key technologies of digital design are illustrated and introduced; for the evaluation of the digital design application of indoor home products in combination with VR technology, the simple recurrent unit network is trained and optimized using Red deer Optimization Algorithm, and the digital design evaluation model based on RDA-SRU network is constructed; the digital design application evaluation model is verified through experiments. The digital design application evaluation model based on RDA-SRU network is constructed by using the Red deer optimization algorithm; the application feasibility and computational efficiency of the method proposed in this paper are proved through experimental verification.

II. Digital Design Framework for Interior Home Products

A. Virtual Reality

VR technology is through the comprehensive use of computer graphics science on the seeming, multimedia teaching science on the seeming, human-computer interaction science and technology, Internet information, sensors and check measurement technology, three-dimensional performance technology and simulation technology and other types of disciplines and technologies, to create a real audio-visual, touch one of the artificial virtual environment [19], specifically as shown in Fig. 1. In the virtual environment, the user with the help of professional technical equipment, the most natural way to interact with the objects in life, so as to achieve a stronger sense of immersion and real feelings.

The key components of VR technology include headset devices, intrusion devices, 3D audio and sound technologies, and simulated environment modeling and rendering [19] (Fig. 2), which are mainly used in the fields of gaming, education, healthcare, industrial design, entertainment, and military [20] (Fig. 3).

B. Digital Design Process

1) Definitions and key techniques, tools: Digital design of interior home products is the process of designing, simulating, optimizing and manufacturing home products using advanced computer technology, information technology and digital tools. This design methodology improves design efficiency, reduces errors, lowers costs, and allows for better customization and service. Digital design can also help companies achieve scale customization, flexible production, and networked services, thus improving competitiveness and market responsiveness [21].

The key technologies and tools used for the digital design of interior home products include CAD/CAE/CAPP/CAM/PDM integration software, parametric modeling technology, VR (VR)/augmented reality (AR) technology, product lifecycle management (PLM), and enterprise resource planning (ERP) systems, etc., as shown in Fig. 4.

The process of digital design for interior home products is shown in Fig. 5, with the following steps: a) Demand analysis: collecting information on customers' individual needs and market trends; b) Conceptual design: based on the results of the demand analysis, preliminary design ideas; c) Detailed design: using digital tools to carry out accurate product design, including dimensions, materials, colours, etc.; d) Simulation and testing: by computer simulation to verify the feasibility and performance of the design; e) Prototyping: making samples based on the design drawings for actual testing and evaluation; f) Production preparation: after completing the design, preparing the documents and processes required for production; g) Production and quality control: monitoring the product quality during the production process to ensure compliance with the design; and h) Feedback services: providing installation guidance, maintenance services and customer support [22].

Technology can help designers and clients preview and experience design solutions in three-dimensional space, improving the interactivity and realism of design, and is mainly used in the c) detailed design phase.

Fig. 1. Virtual reality technology.

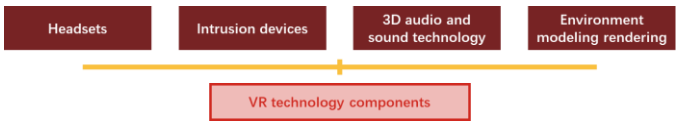

Fig. 2. VR technology components.

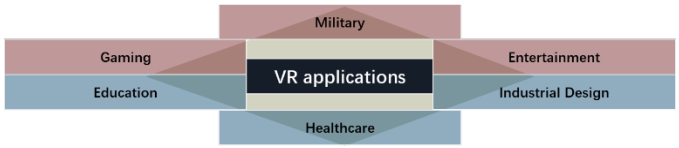

Fig. 3. Application areas of VR technology.

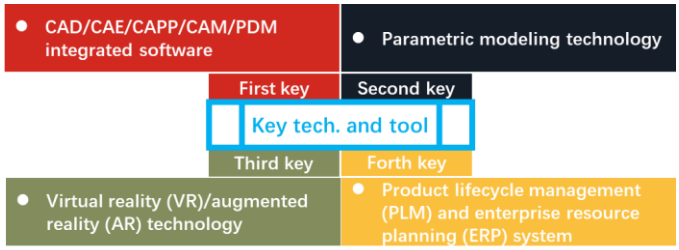

Fig. 4. Key technologies and tools for digital design of interior home products.

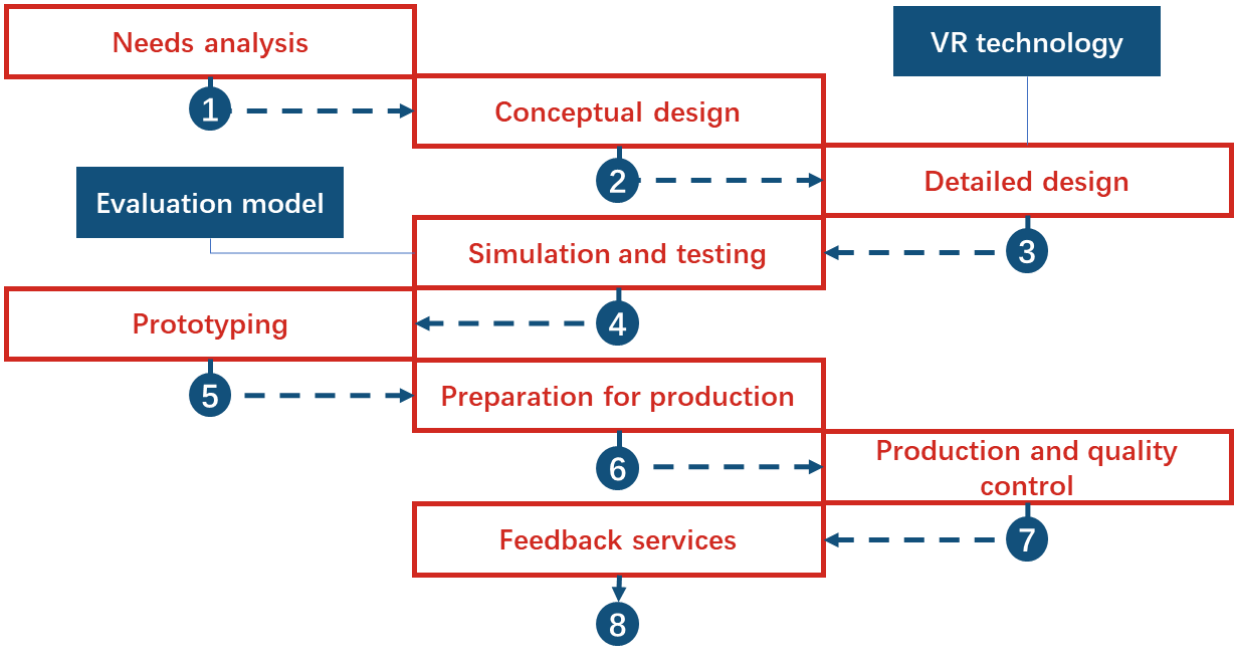

Fig. 5. Process of digital design for interior home products.

Digital design application evaluation can help designers quantify the suitability of interior home products and accelerate the improvement of the efficiency of digital design of interior home products, which is mainly used in the d) simulation and testing phases.

C. Digital Design Framework and Key Technology Analysis

1) Digital design framework: In order to improve the efficiency of digital design of indoor home products based on VR technology and enhance the evaluation accuracy of digital design application of indoor home products, this paper combines the intelligent optimization algorithm (Red deer Optimization Algorithm) and the deep learning algorithm (Simple Recurrent Unit Network) to propose a digital design method of indoor home products based on the RDA-SRU model, and the specific framework is shown in Fig. 6.

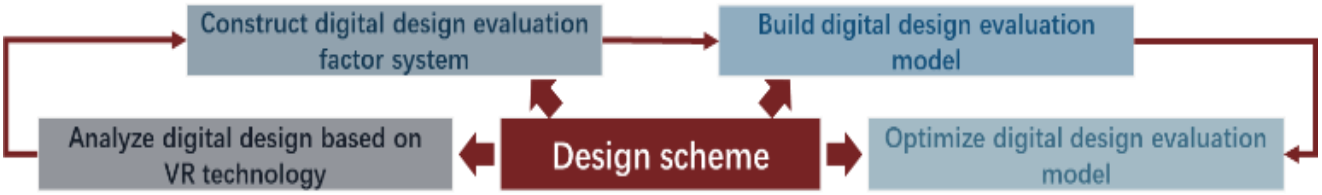

Fig. 6. Digital design framework for interior home products.

According to the analysis of the digital design framework, the digital design method of indoor home products based on RDA-SRU model by combining VR technology mainly consists of subsystems such as evaluation factor set construction, data preprocessing, digital design evaluation model construction optimization, evaluation performance analysis, etc., which are shown in Fig. 7.

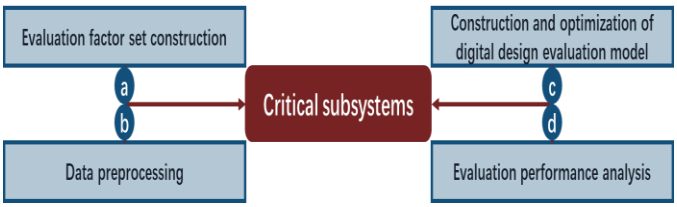

Fig. 7. Key subsystems for digital design of indoor home products.

2) Analysis of key technologies

a) Evaluation factor set construction: In the evaluation factor set construction subsystem, the digital design process of indoor home products combined with VR technology is analyzed to extract the digital design evaluation feature indicators and construct the evaluation factor set, and the specific subsystem inputs, outputs, and structures are shown in Fig. 8.

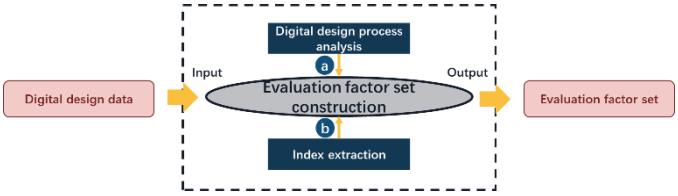

Fig. 8. Subsystem for constructing the factor set for digital design evaluation.

According to the principles of factor selection, such as demand orientation, objective scientificity, and quantitative comparability, the evaluation factors of digital design of indoor home products combined with VR technology are extracted from the phases of environment design F, 3D modeling S, and human-computer interaction T, and the evaluation factor set shown in Fig. 9 is constructed.

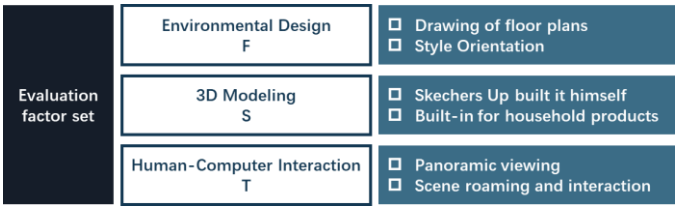

Fig. 9. Evaluation factor set construction.

b) Data pre-processing: In the data preprocessing subsystem of evaluation indexes for the digital design process of indoor home products, the data set used for training the evaluation model is obtained in a regular way through the outlier elimination technique, missing value regression filling technique, normalization processing technique, and dimensionality reduction technique [23], and the specific subsystem inputs, outputs, methods, and structures are shown in Fig. 10.

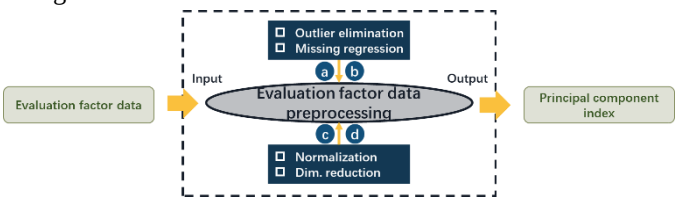

Fig. 10. Schematic diagram of the digital design evaluation data preprocessing subsystem.

c) Optimization of digital design evaluation model construction: In the optimization subsystem of evaluation model construction, the Red deer optimization algorithm is used to learn and train the weights and biases of the simple cyclic unit network, and to construct the digital design evaluation model based on the Red deer optimization algorithm-simple cyclic unit network, and the specific subsystem inputs, outputs, methods, and structures are shown in Fig. 11.

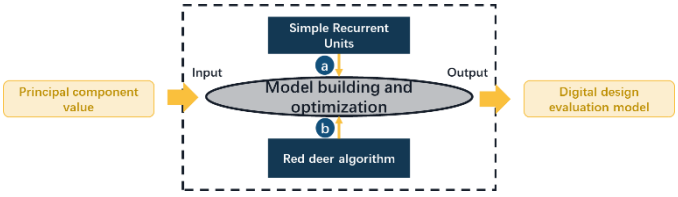

Fig. 11. Schematic diagram of the optimization subsystem for digital design evaluation model construction.

d) Evaluation performance analysis: In the digital design evaluation model performance analysis subsystem, MAE, RMSE, MAPE, R2, and evaluation time [24] are used as the performance evaluation indexes of the digital design evaluation model, as shown in Fig. 12.

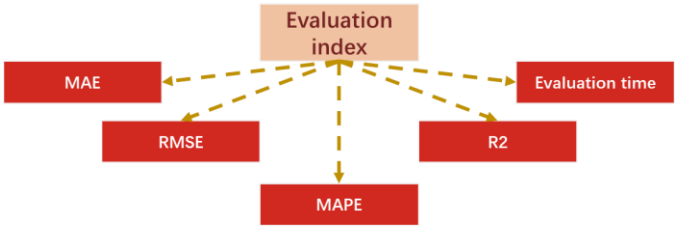

Fig. 12. Performance evaluation indicators.

III. Red Deer Optimization Algorithm for Interior Home Products

A. Simple Cyclic Unit Networks

1) Fundamentals: SRU (Simple Recurrent Units) [25] is a simplified recurrent neural network (RNN) architecture designed to increase the training speed of RNNs and allow for more efficient parallel computation. SRUs enable the network to be trained faster on modern GPUs by reducing the dependencies between time steps. SRUs are designed with the concept of optimizing the main portion of the computation is optimized to be a complete computation that does not depend on previous time steps, thus enabling an easily parallelizable network structure, the structure of which is shown in Fig. 13.

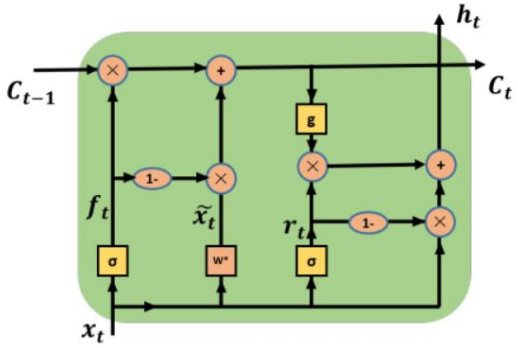

Fig. 13. Structure of SRU network model.

$$\tilde{x}_t = W x_t \tag{1}$$

$$f_t = \sigma\left(W_f x_t + b_f\right) \tag{2}$$

$$r_t = \sigma\left(W_r x_t + b_r\right) \tag{3}$$

$$c_t = f_t \odot c_{t-1} + \left(1 - f_t\right) \odot \tilde{x}_t \tag{4}$$

$$h_t = r_t \odot g\left(c_t\right) + \left(1 - r_t\right) \odot x_t \tag{5}$$

Where f_t is the forget gate and r_t is the reset gate.

2) Characteristics of SRU: The SRU network is characterized by the following features: 1) parallelization capability, 2) reduced computational complexity, and 3) gradient propagation improvement [26], as shown in Fig. 14.

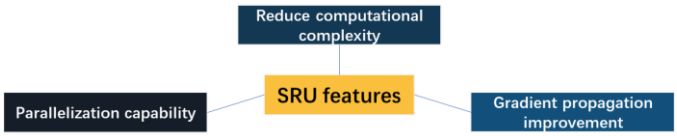

Fig. 14. SRU network characteristics.

3) SRU applications: SRU networks are suitable for a variety of deep learning tasks that require the processing of sequential data, including but not limited to the fields of natural language processing, speech recognition, and time series analysis, due to their improved training speeds and parallel computing capabilities [26] (Fig. 15).

Fig. 15. SRU web application.

B. The Redouble Optimization Algorithm

1) Algorithmic principles: The Red deer optimization algorithm (RDA) [27] was inspired by observing the mating activity of the horse deer species living in the UK during the breeding season. The population of horse deer is divided into four main species: male deer (Male), female deer (Hind), commander deer (Com), and stag (Stag). The RDA algorithm simulates the behaviors of roaring, fighting, and mating in a group of horse deer to solve the optimization problem, and demonstrates a better performance in complex problems.

a) Generation of initialized horse deer populations: In the RDA algorithm, the optimization object is a horse deer and each horse deer is represented as follows:

$$X_i = \left[x_1, x_2, x_3, \cdots, x_n\right] \tag{6}$$

Where, X_i is the i^{th} individual horse deer and n is the dimension of the RDA problem to be optimized.

In order to evaluate the merit of individual horse deer, it is necessary to introduce a fitness function:

$$f\left(X_i\right) = f\left(x_1, x_2, x_3, \cdots, x_n\right) \tag{7}$$

where $f\left(X_i\right)$ is the value of X_i fitness function.

Based on the size of the fitness value, the better N_{male} stags were selected as males and the remaining stags as females ($N_{hind} = N_{pop} - N_{male}$), the size of N_{male} denotes the algorithmic elite criterion, which maintains the augmentation properties of the algorithm, and N_{hind} takes into account the diversification phase of the algorithm.

b) Roaring stage between male deer: The roaring phase (Fig. 16) is searching the neighborhood space, and if a better Red deer is found in the neighborhood, the previous Red deer is replaced by the better one, as modeled below:

$$New_{male} = \begin{cases} Old_{male} + a_1\left(\left(UB - LB\right) \times a_2 + LB\right) & a_3 \geq 0.5 \\ Old_{male} - a_1\left(\left(UB - LB\right) \times a_2 + LB\right) & a_3 < 0.5 \end{cases} \tag{8}$$

Among them, Old_{male} is the current position of male deer, New_{male} is the updated position of male deer, UB and LB are the upper and lower bounds of the search space, respectively, and a_1 , a_2 and a_3 are randomly generated numbers.

a) Commander deer selection: The division of males into Commander Deer (Com) and Stag (Stag), primarily to differentiate between stags that are more powerful in combat and more successful in expanding their territories, is calculated as follows:

$$N_{Com} = round\left\{\gamma \cdot N_{male}\right\} \tag{9}$$

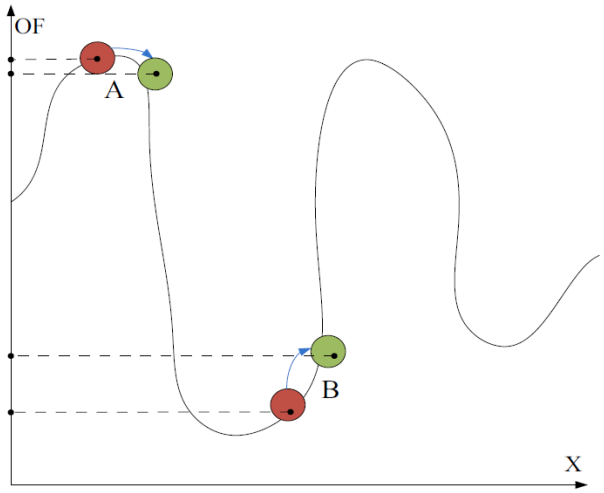

Fig. 16. The process of yelling.

Where, N_{Com} is the number of commander deer, γ is the initial value of the algorithm model, the value range is 0 to 1, the number of stags is $N_{Stag} = N_{male} - N_{Com}$, the specific distribution of the horse deer population is shown in Fig. 17.

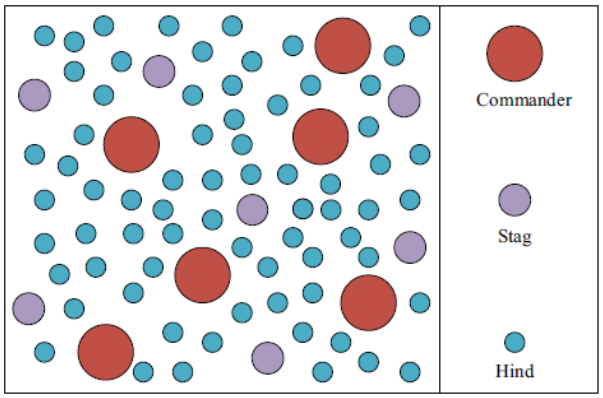

Fig. 17. Distribution of red deer populations.

b) Combat phase: From Fig. 18, Each commander deer will randomly fight a stag by approaching the other, causing a change in position, comparing fitness values, and replacing the commander deer with the superior stag individual, as calculated below:

$$New1 = \frac{(Com + Stag)}{2} + b_1 \times \left((UB - LB) \times b_2 + LB\right) \quad (10)$$

$$New2 = \frac{(Com + Stag)}{2} - b_1 \times \left((UB - LB) \times b_2 + LB\right) \quad (11)$$

Where $New1$ and $New2$ are two solutions generated by the combat process, Com and $Stag$ are commander deer and stag respectively, and b_1 and b_2 are uniformly distributed random numbers.

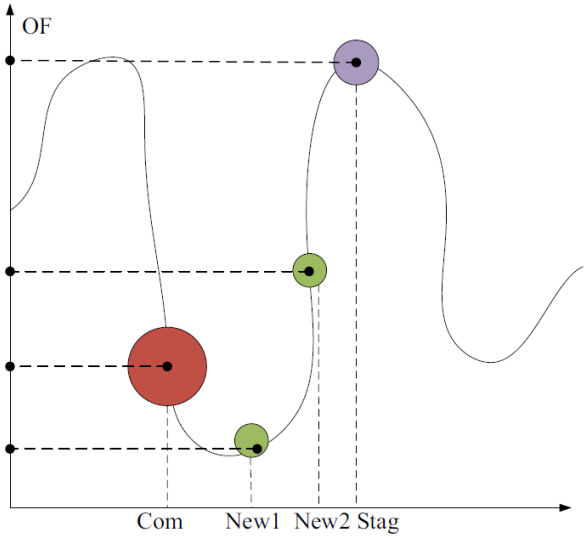

Fig. 18. Fighting process.

c) Formation of polygamy: The formation of polygamy can be referred to as the formation of a harem (Fig. 19), which is a group of female deer captured by a single commander deer. The number of female deer in the harem depends on the commander deer combat effectiveness. Forming a harem requires defining the commander deer standardized cost, which is modeled as follows:

$$V_n = v_n - \max_i \{v_i\} \quad (12)$$

$$P_n = \left| \frac{V_n}{\sum_{i=1}^{N_{Com}} V_i} \right| \quad (13)$$

$$N.harem_n = round\{P_n.N_{hind}\} \quad (14)$$

Where v_n is the fighting strength of the nth commander deer, $\max_i \{v_i\}$ denotes the maximum value of the fitness function for all stags, V_n is the standardized fighting strength, P_n is the standardized fighting strength, and N_{Com} denotes the commander deer. The standardized fighting power of commander deer includes a part of female deer, then the number of female deer in the harem is $N.harem_n$.

a) Mating stage: Commander deer mated with α% females, calculated as follows:

$$N.harem_n^{mate} = round\{\alpha.N.harem_n\} \quad (15)$$

Where, $N.harem_n^{mate}$ is the number of females in the nth harem that mated with the commander deer, and α is the value of the initial parameters of the RDA model. The locations of the next generation of mating-produced Red deer were as follows:

$$offs = \frac{(Com + Hind)}{2} + (UB - LB) \times c \quad (16)$$

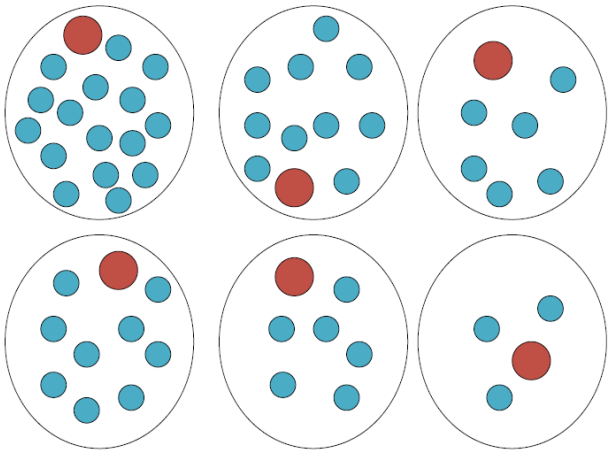

Fig. 19. Polygamy.

where $offs$ denotes a new problem-solving individual horse deer and c denotes a random number.

In the mating of a commander deer with a β% female, a harem is randomly selected and the commander road is allowed to mate with its β% female, mainly to exaggerate territory, calculated as follows:

$$N.harem_k^{mate} = round\{\beta.N.harem_k\} \quad (17)$$

where $N.harem_k^{mate}$ is the number of female deer in the k^{th} harem and β is the initial parameter that produces new individuals.

Male deer mated with the most recent female deer, calculated as follows:

$$d_i = \sqrt{\sum_{j \in J} \left(stag_j - hind_j^i\right)^2} \quad (18)$$

$$offs = \frac{(Stag + Hind)}{2} + (UB - LB) \times c \tag{19}$$

where d_i is the distance between the i^{th} female deer and the stag.

b) Choosing the next generation: In order to speed up convergence and avoid falling into local optimality, the RDA algorithm chooses two different strategies. The first strategy is to retain all male deer; the second strategy is to select among the fitness values and the offspring produced by the mating process using a roulette mechanism.

2) Algorithm flowchart: According to the optimization strategy and principle of Red deer's optimization algorithm, the flow of RDA algorithm is shown in Fig. 20.

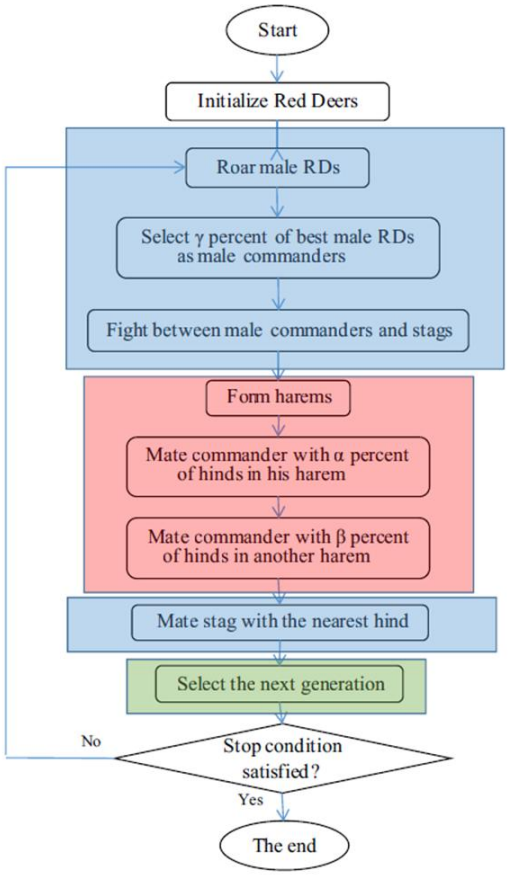

Fig. 20. Flowchart of the redouble optimization algorithm.

C. Digital Design Application Method Based on RDA-SRU Network

The application of RDA-SRU network for digital design of indoor home products is analyzed in three main aspects, i.e., decision variables, fitness function, and optimization steps.

In terms of decision variables, the optimized variables are W ,W_f ,W_r ,b_f ,b_r of the SRU network; in terms of the fitness function, the chosen function is the MAE value; the steps of the application of the RDA-SRU network model in the problem are shown in Fig. 21.

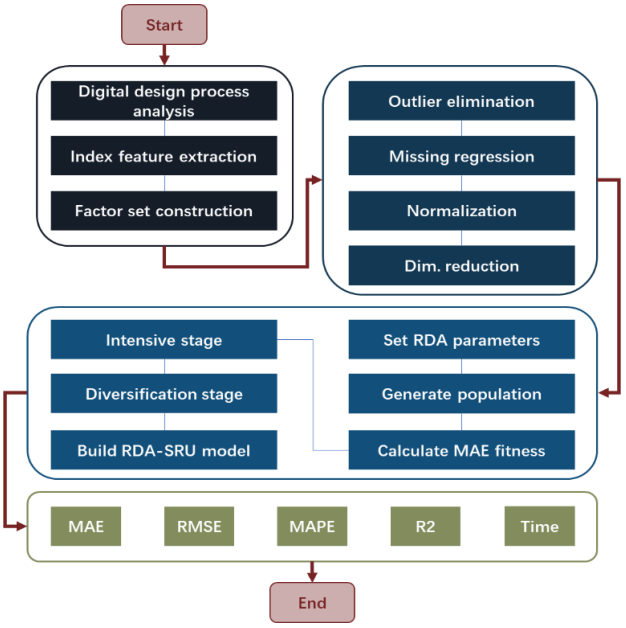

Fig. 21. Flowchart of RDA-SRU model application.

IV. Experimental Analysis

A. Experimental Setup

Digital design software includes CAD, Photoshop, Sketch up and Unity 3D engine; the computer processor is Intel7 Core Quad Core i7-7700HQ 2.8GHz with NVIDIA GeForce GTX10708GB discrete video memory, and the VR headset device is Xiaomi headset.

Using the MIVR headset device in conjunction with the NOLO interactive positioning device, the built-in sensors go out to receive signals and transmit them to Unity3D for processing.

B. Analysis of Experimental Results

With the help of drawing tool AutoCAD, the indoor scene plan is drawn as shown in Fig. 22. After being processed by Photoshop software, it is imported into Sketch up software to get the 3D model, as shown in Fig. 23. Through the VR software, build the virtual furniture scene, as shown in Fig. 24. The virtual scene is refined to get the VR realization effect as shown in Fig. 25.

In order to evaluate the effect of digital design of indoor home products based on VR technology, RNN, LSTM, GRU, SRU, RDA-SRU and other evaluation models are used to compare and analyze the design methods, and the specific results are shown in Fig. 26, 27 and 28.

The MAE, RMSE, MAPE, R2, and evaluation time performance comparison of different algorithms is given in Fig. 26. In terms of MAE, the RDA-SRU model has the smallest MAE value of 0.133, followed by SRU, GRU, LSTM, and RNN; in terms of RMSE, the RDA-SRU model has the smallest value of 0.02; in terms of MAPE, the RDA-SRU model has the smallest value of 0.015, followed by GRU, LSTM, SRU, and RNN; in terms of R2 , the RDA-SRU model is the largest with 0.968, followed by GRU, SRU, LSTM, and RNN; in terms of evaluation time, RDA-SRU model takes the shortest time with 0.028.

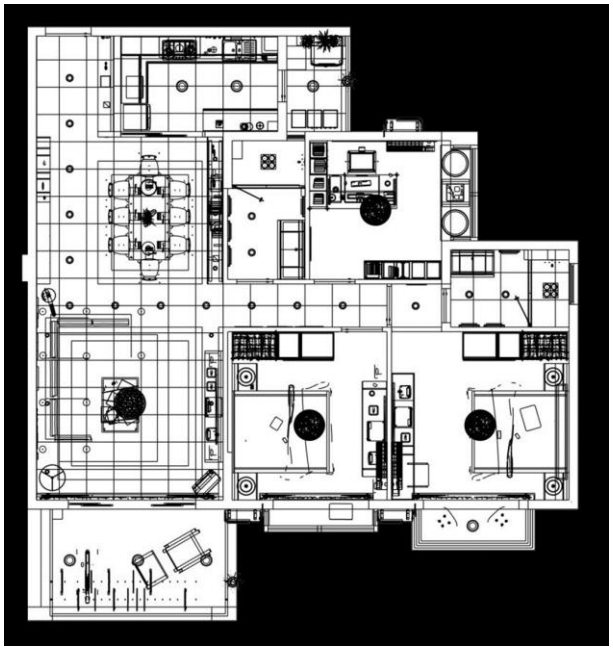

Fig. 22. Indoor scene floor plan.

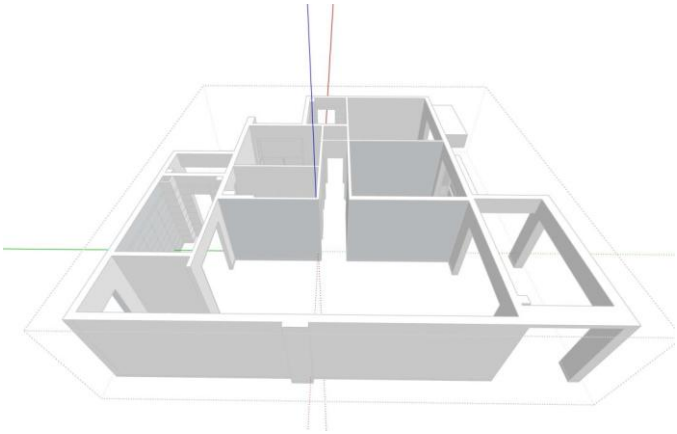

Fig. 23. Schematic diagram of 3D model.

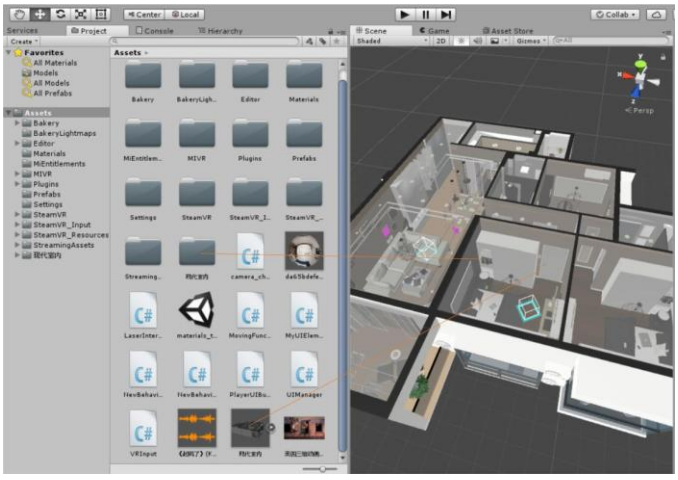

Fig. 24. Virtual engine scene.

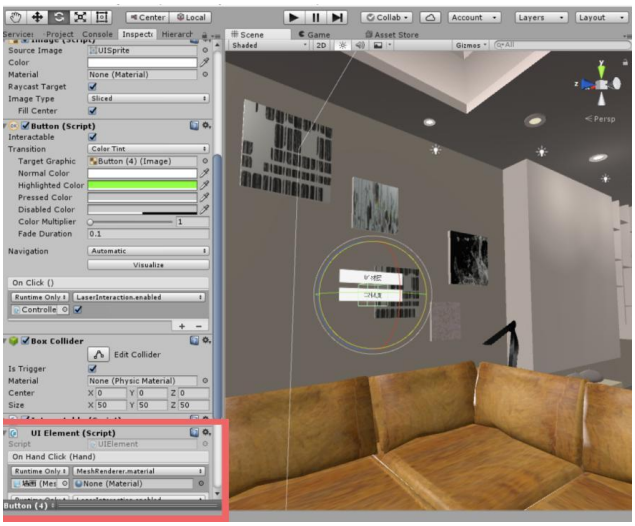

Fig. 25. Virtual reality interactive interface.

No.	Evaluation models	MAE	RMSE	MAPE	R2	Time/s
1	RNN	0.554	0.066	0.070	0.799	0.122
2	LSTM	0.480	0.045	0.042	0.846	0.089
3	GRU	0.443	0.058	0.017	0.956	0.085
4	SRU	0.257	0.044	0.066	0.881	0.036
5	RDA-SRU	0.133	0.02	0.015	0.968	0.028

Fig. 26. Comparison of performance metrics of the contrasting algorithms.

Fig. 27 gives the evaluation error of digital design application effectiveness of different comparison algorithms. From Fig. 27, it can be seen that the RDA-SRU model has the smallest RMSE value of 0.02 for evaluating the effectiveness of digital design application, followed by SRU, LSTM, GRU, and RNN.

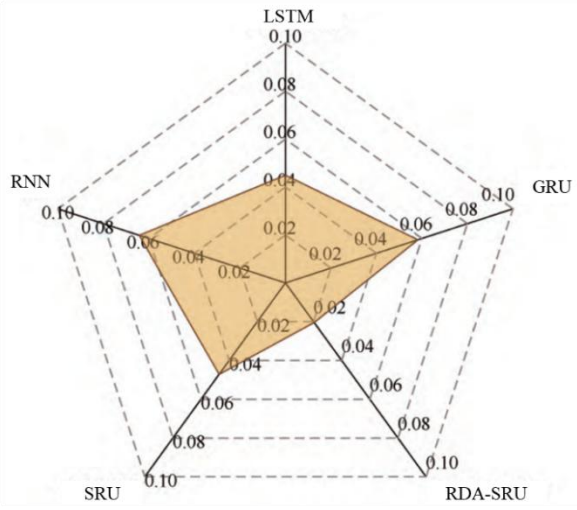

Fig. 27. Comparison of root mean square error of evaluation for contrasting algorithms.

Fig. 28 gives the convergence curve of the digital design evaluation of interior home products based on the RDA-SRU model. In Fig. 28, as the number of iterations increases, the value of the fitness function decreases until the RDA fitness value converges to about 0.184 at 50 iterations.

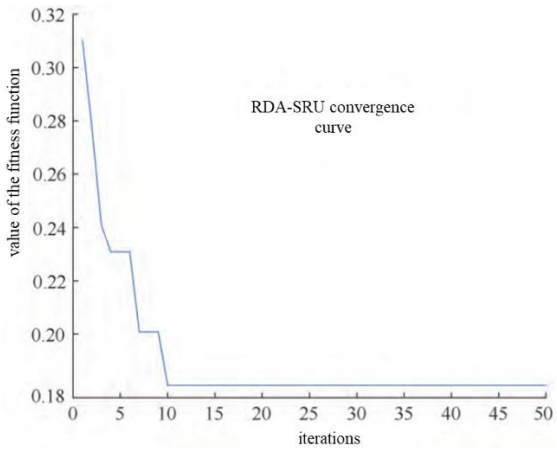

Fig. 28. Convergence curves based on RDA-SRU models.

V. CONCLUSION

In this paper, for predicting and evaluating the effect of digital design application combined with VR technology, firstly, according to the digitization process, we designed the evaluation framework of digital application effect, extracted the digital design evaluation factor set, and optimized the W , W_f , W_r , b_f , b_r of the Red Deer Optimization Algorithm degree SRU model to improve the performance of the digital design evaluation model; and then, through the experiment of digital design process of indoor home products, we chose to use the design process evaluation factor data set for training through pre-processing input into the RDA-SRU model. Then through the indoor home products digital design process experiment, the design evaluation factor dataset is selected to be input into the RDA-SRU model for training through preprocessing, and compared with the other four algorithms, and the results show that the RDA-SRU model proposed in this paper possesses a better accuracy, and good evaluation prediction results have been achieved.

***Abstract*—Mammography and ultrasound are the main medical imaging modalities for identifying breast lesions. Computer-assisted diagnosis (CAD) is an important tool for radiologists, helping them differentiate benign and malignant lesions more quickly and objectively. The use of appropriate features in mammography and ultrasound is one of the key factors determining the success of computer-assisted diagnosis (CAD) results for breast cancer systems. The diversity of feature forms and extraction techniques is a challenge. Additionally, the use of a single classification algorithm often causes noise, bias, and is not robust. We propose a convolutional layer-based feature extraction technique in the ensemble learning model for the classification of breast cancer. This study uses 439 mammography images (203 benign, 236 malignant) and 421 ultrasound images (244 benign, 177 malignant). This research consists of several stages, including data pre-processing, feature extraction, classification, and performance evaluation. We used four convolution layer-based feature extraction techniques: simple convolution (SC), feature fusion convolution (FFC), feature fusion depthwise convolution (FFDC), and feature fusion depthwise separable convolution (FFDSC). The model uses five machine learning algorithms (support vector machine, random forest, k nearest neighbours, decision tree, and logistic regression) that are part of ensemble learning. The experimental results show that the use of the FFC convolution layer in ensemble learning has the best performance for both datasets. In the ultrasound data set, the FFC achieved a value of 0.90 in each of the accuracy, precision, recall, specificity, and F1 score metrics. In the mammography data set, the FFC achieved a value of 0.98 on each of the same metrics. These results show the effectiveness of feature fusion in improving classification performance in the soft voting classifier for ensemble learning.**

I. INTRODUCTION

Breast cancer is the main cause of cancer-related mortality in women. Early detection of cancer, especially breast cancer, will contribute to the treatment process [1]. Currently, computerised tomography (CT), magnetic resonance imaging (MRI), mammography, thermal imaging, and ultrasound are common screening for breast cancer. These methods have their own unique approaches and tools, and the expected results of these methods depend on different factors, so it is recommended to validate the results using multiple methods. Although mammography is considered by many physicians and specialists the gold standard method for the detection of breast cancer, the demand for more reliable methods is increasing. Mammography and ultrasound are critical tools in breast cancer screening, but they have different applications, effectiveness, and limitations. Mammography, a form of X-ray imaging, is considered the gold standard for breast cancer screening in high-income countries because of its ability to detect cancer at an early stage. However, its effectiveness may be limited by the radiographic density of the breasts; In dense breasts, noncalcified cancers are more likely to be missed [2]. This limitation is particularly significant because the diagnostic accuracy is largely dependent on breast density and denser breasts, which pose a challenge for clear imaging [3]. Ultrasound, on the other hand, uses sound waves to create images of breast tissue [4]. It has been shown to have a high detection sensitivity, especially in younger women and those with dense breasts, where mammography may not be as effective.

Computer-assisted diagnosis (CAD) systems have shown significant achievements in improving breast cancer detection and provide complementary tools to traditional diagnostic methods [5]. The effectiveness of the CAD system is emphasized by its ability to detect and classify breast cancer with high precision, sensitivity, and specificity, as demonstrated in various studies. Recent research has shown that the precision of breast cancer detection is greatly influenced by the characteristics of mammography and ultrasound. Although mammography is widely used, its sensitivity is limited, especially in dense breast tissue, which can conceal the presence of tumours [6]. Contrast-enhanced mammography (CEM) is introduced to address some of these limitations, introducing a similar performance in the detection of mammography-occult diseases with higher sensitivity than conventional mammography and higher specificity than ultrasound [7].

The development and application of computer-aided diagnosis (CAD) systems in the detection and classification of breast cancer by mammography and ultrasound have significantly benefitted from various feature extraction methods. In mammography, several feature extraction techniques have been used in different studies. For example, an approach involves the extraction of 16 geometrical

characteristics from regions of interest (ROI) in mammograms, which are then analysed using machine learning algorithms to classify mammograms into four classes [8]. Another mammography method was to calculate 271 characteristics in various categories, including shapes, textures, contrasts, and other characteristics, and to calculate additional characteristics derived from the dilated segment [9]. Some methods have been used in ultrasound. A study extracted 855 characteristics, including shapes, contours, and texture, from breast ultrasound images [10]. Another method uses the pyramid of orientated gradient descriptor histograms to obtain a characteristic vector without prior processing of tumour region selection [11]. Automated contouring and morphological analysis were used to calculate 19 practical morphological characteristics [12]. The various forms of features used affect the performance of a classification model.

Some cases that often occur in the learning process using a single classification algorithm are noise, bias, and low accuracy. This is due to the use of non-uniform data samples and the presence of overlapping classes [13]. One method of reducing these issues is to implement the concept of ensemble learning, which is designed to improve the stability and accuracy of machine learning algorithms. The concept of ensemble learning is a paradigm of learning that uses a combination of several models synergistically to improve the quality of predictions collectively [14], [15]. The objective of Ensemble learning is to reduce the bias, variance, or error that often occurs in individual models [16], [17], [18]. The main goal is to achieve predictive results that are more accurate, stable, and generally better than the results of a single model.

Furthermore, one of the keys to successful learning is the use of the right features. Feature extraction techniques have evolved [19]. In general, features consist of colour, shape, texture, and others. Some previous research related to medical imaging, especially breast cancer, uses features of colour and texture [20]. Deep feature extraction uses pre-trained convolutional neural networks such as VGG-19, SqueezeNet, ResNet-18, and GoogLeNet to distinguish between benign and malignant tumour types in ultrasound images [21],[22] Therefore, it is necessary to experiment with the use of several image feature extraction schemes using convolutional layers.

We propose the use of an ensemble learning concept for breast cancer classification using two medical images, namely mammography and ultrasound. This ensemble learning model uses five machine learning algorithms, including a supervised vector machine, random forest, nearest neighbours k, decision tree, and logistic regression. The ensemble learning model was trained using mammography and ultrasound images that have been feature extracted using four different convolution layers, including simple convolution, feature fusion convolution, feature fusion depthwise convolution, and feature fusion depthwise separable convolution. The four model schemes were evaluated for accuracy, precision, recall, ROC curve, specificity, F1 score, kappa and Matthews correlation coefficient. Some of the main contributions of this research are summarised in the following.

- We propose a novel ensemble learning model for breast cancer classification using mammography and ultrasound.
- The feature extraction technique uses four different convolution layers, namely, simple convolution (SC), feature fusion convolution (FFC), feature fusion depthwise convolution (FFDC), and feature fusion depthwise separable convolution (FFDSC).
- The ensemble learning model uses soft voting with five machine learning algorithms, namely the support vector machine, the random forest, the k closest neighbours, the decision tree, and logistic regression.
- We investigate the use of different feature extraction techniques in the ensemble learning model by evaluating its performance.

The structure of this paper consists of several sections; after the introduction in Section I, Section II describes the proposed method, for Sections III and IV explain the results and discussion on the use of the proposed method. Section V explains the conclusions and future research and ends with acknowledgments.

II. METHODS

A. Datasets

This study used primary data from Sardjito Hospital and Kotabaru Yogyakarta Cancer Clinic that have been identified and diagnosed by radiologists. The approval for the private data set was obtained from the Ethics Committee (Ref. No.: KE/FK/1229/EC/2023). The results of the image reading were initially classified into five class categories in BIRADS. The researchers grouped the data from the BIRADS standard into two classes, namely benign and malignant. BIRADS 2 and BIRADS 3 are benign classes, while BIRADS 4 and BIRADS 5 are malignant classes. Details of the amount of data in each benign and malignant class for both types of images can be seen in Table I.

TABLE I. THE INITIAL DATA SET (BEFORE AUGMENTATION)

Dataset	Class		Total
	Malignant	***Benign***	
Ultrasound	177	244	421
Mammography	236	203	439

B. Proposed Method

We propose an ensemble learning model using two different modes of mammography and ultrasound data with four convolution layer schemes for feature extraction. In the classification process, five machine learning algorithms (support vector machine, random forest, KNN, decision tree, and logistic regression) are run together in one iteration by voting. In general, we propose a model that consists of four main processes: data preprocessing, feature extraction, classification, and performance evaluation. The use of the model aims to compare the use of four convolutional layer schemes as feature extraction using voting on the determination of classification results. Details can be seen in Fig. 1.

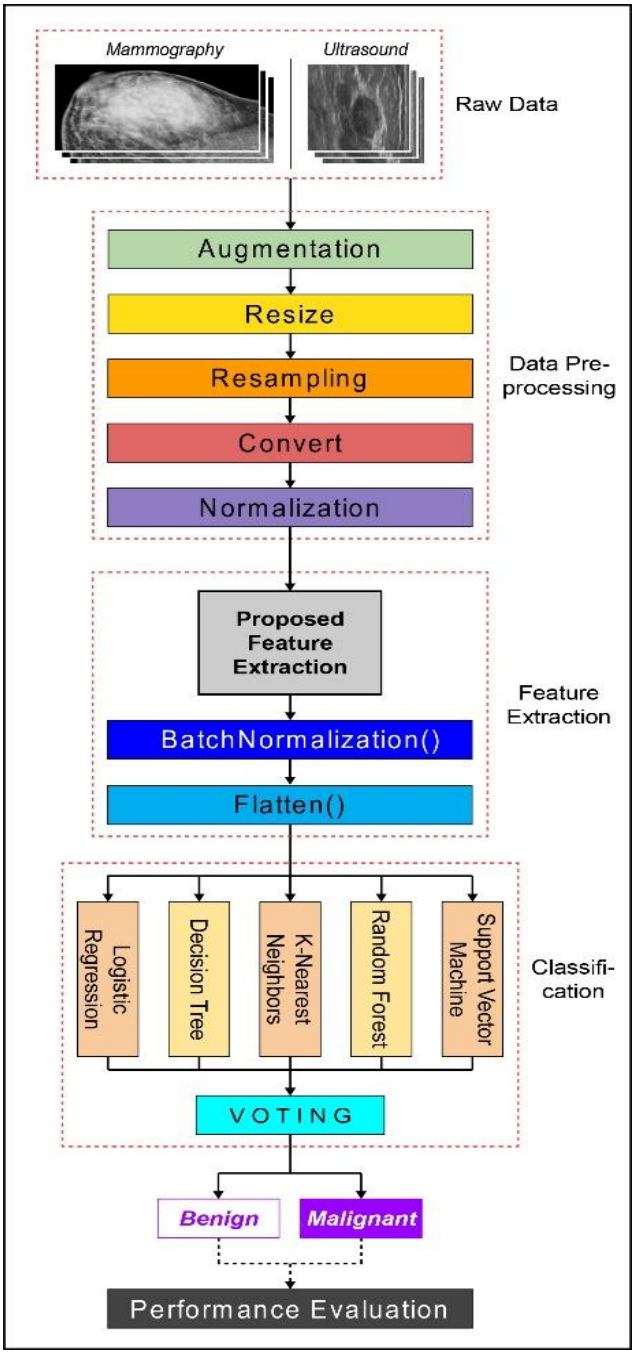

Fig. 1. Proposed ensemble learning model with four different feature extraction schemes.

Details of the convolution layers for feature extraction for the four schemes are shown in Fig. 2. The first scheme uses four convolution layers. The second scheme uses feature-fusion convolution in feature extraction with the same layer configuration as in the first scheme. Feature fusion is a technique that combines predictions from multiple machine learning models to create a combination of more than one feature that is used to generate the final prediction [19], [20]. The third scheme uses a depth-wise convolution of the feature fusion, and the last scheme uses a separable depth-wise feature fusion convolution.

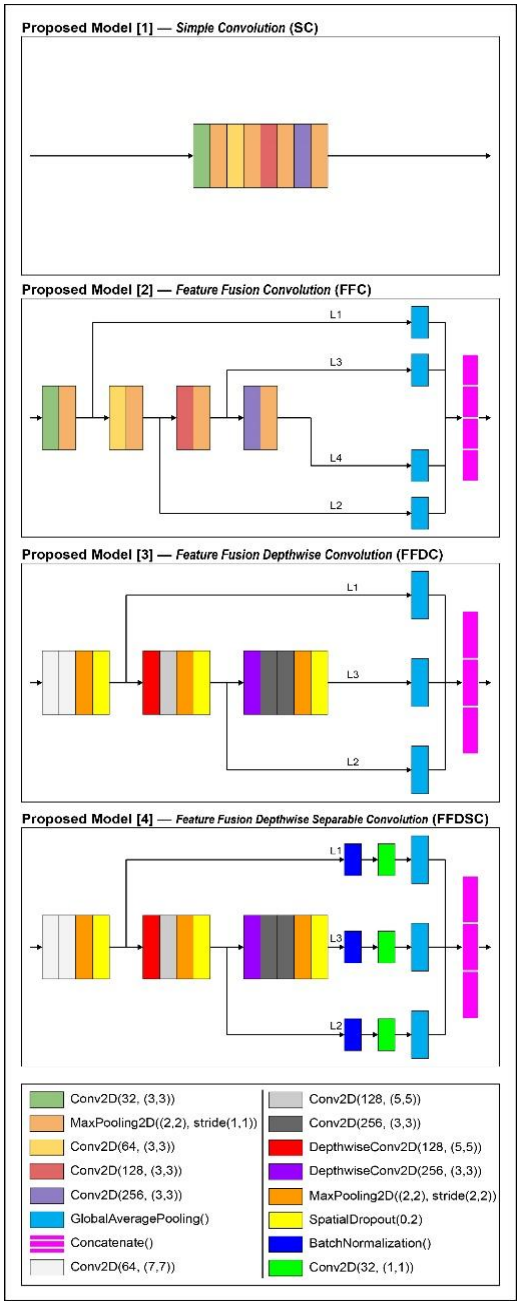

Fig. 2. Convolution layer scheme as feature extraction.

1) Pre-processing: This preprocessing stage consists of five image improvement techniques before feature extraction, including: augmentation, resize, resampling, convert, and normalisation. Some augmentation techniques in medical images that have been shown to improve classification accuracy are translation, shear, and rotation [5]. Translation is done by shifting the image by a maximum of 15 pixels either towards the positive or negative poles of the x-axis and the y-axis with a probability of 1. Shear is done by shearing the image by a maximum of 15 degrees toward the positive or negative poles of the x-axis and y-axis with a probability of 1. Rotation is done by rotating the image by a maximum of 25 degrees clockwise or counterclockwise. After image

enhancement, resize the ultrasound image to 224×224 pixels and the mammography image to 448 x 224 pixels so that the entire data set has a uniform resolution. The total data amounted to 1,000 images for each modal image with various predefined parameters. After that, the data are converted into a numpy array to convert the colour data in the image into numerical data using the numpy library. Labels or classes are extracted using numpy by taking the folder name used in each class. The purpose of converting data into numeric form is to allow the model to recognise the data to be trained. The last step in preprocessing is image normalisation using a rescaling technique with a normalisation factor of 1/255 to change the range from 1-255 to 0-1. The preprocessing data are shown in Table II.

TABLE II. DATASET AFTER IMAGE PRE-PROCESSING

Dataset	Class		Size [Height×Width] (pixel)	Total
	Malignant	*Benign.Benign.*		
Ultrasound	500	500	224 × 224	1.000
Mammography	500	500	448 × 224	1.000

2) Feature extraction: This research uses four different CNN architecture schemes in the convolution layer in the feature extraction stage, namely: simple convolution (SC), feature fusion convolution (FFC) [23], feature fusion depthwise convolution (FFDC), and feature fusion depthwise separable convolution (FFDSC). The first scheme with simple convolution consists of four layers of convolution or Conv2D and 32 filters in the first layer, 64 filters in the second layer, 128 filters in the third layer, and 256 filters in the fourth layer. The kernel size used in the convolution layer is 3x3. The pooling process in each layer uses a kernel pool of the maximum value of MaxPooling2D pixels with a size of 2x2. Each convolution layer, Conv2D, uses the Rectified Linear Activation (ReLU) activation function and the 'same' value in the padding parameter so that the output image is the same size and does not cut at the edges. The pooling layer, MaxPooling2D, also uses the 'same' value for the padding parameter.

The second scheme with FFC, consists of four convolution blocks that are run cumulatively. The first block consists of a Conv2D layer with 32 filters and a kernel size of 3×3. Then a Maxpooling2D layer with a kernel size of 2×2 and standard strides of 1×1 pixels. The second block consists of the layers of the first block plus Conv2D with filter 64 and kernel size 3×3. Then a Maxpooling2D layer with a kernel size of 2×2 and standard strides of 1×1 pixels. The third block consists of the layers of the second block plus Conv2D with filter 128 and kernel size 3×3. Then the Maxpooling2D layer with a kernel size of 2×2 and standard strides of 1×1 pixels. The fourth block consists of the layers of the third block plus Conv2D with filter 256 and kernel size 3×3. Then a Maxpooling2D layer with a kernel size of 2×2 and standard strides of 1×1 pixels. Each Conv2D convolution layer uses the Rectified Linear Activation (ReLU) activation function and the 'same' value in the padding parameter so that the output image is the same size and not cut at the edges. The pooling layer, MaxPooling2D, also uses the 'same' value for the padding parameter.

The third scheme, FFDC, consists of three convolution blocks that are run cumulatively. The first block consists of two Conv2D layers with 64 filters and a kernel size of 7×7. Then a Maxpooling2D layer with a kernel size of 2×2 and strides of 2×2 pixels. Next, we have the SpatialDropout2D layer with a probability of 0.2. The second block consists of the layers of the first block plus DepthwiseConv2D with a kernel size of 3×3. Then two Conv2D layers with 256 filters and 3×3 kernel size. Next, we have a Maxpooling2D layer with a kernel size of 2×2 and a shift of 2×2 pixels. Then comes the SpatialDropout2D layer with a probability of 0.2. The third block consists of the layers of the second block plus DepthwiseConv2D with a kernel size of 5×5. Then Conv2D with filter 128 and kernel size 5×5. Next, we have the Maxpooling2D layer with a kernel size of 2×2 and a shift of 2×2 pixels. Subsequently, the SpatialDropout2D layer was populated with a probability of 0.2. Each Conv2D and Depthwise2D uses the Rectified Linear Activation (ReLU) activation function and the 'same' value in the padding parameter so that the output image is the same size and does not cut the edges. In layer-pooling, MaxPooling2D also uses the 'same' value for the padding parameter.

The fourth scheme with FFDSC has the same architecture as FFDC. The difference between the two types of architecture lies at the end of the process of each block; for the FFDSC architecture, a batch normalisation layer is added, then Conv2D with a 32 filter and a kernel size of 1×1 which is often referred to as Pointwise Convolution. In the first scheme, after passing through the data convolution layer, a batch normalisation layer is added to overcome problems caused by changes in input distribution that occur during the training process.

The results of the training process are entered into the flatten layer to change the data dimension from three dimensions to one dimension to facilitate the classification process. However, in the second, third, and fourth schemes before the BatchNormalization and Flatten layers, the GlobalAveragePooling2D (GAP) layer is added with the aim of reducing dimensions, accelerating computation, and reducing overfitting. After passing through the convolution layer in each block, the data are merged in the concatenate layer. The next stage is the process of compiling the model with Adam parameters in the optimiser and binary cross-entropy in loss.

3) Classification: In this research, the ensemble learning used is voting on the classifier. Voting is a technique in which various predictive models vote or weigh their predictions, and the final result is taken based on the majority of these votes or weights [24]. The classification process using five algorithms, namely: SVM [25], Random Forest [26], KNN, Decision Tree, and Logistic Regression are used as voting-based classifiers in the designed model. The hyperparameters used for each classifier are the result of a series of experiments that have been carried out to optimise model performance. The SVM

used is the SupportVectorClassifier with a linear kernel and a penalty value of 3.0. Random Forest uses an estimator of 100. KNN uses a neighbour count value of 3, uses distance as a weight assessment scheme, and cosine as a distance metric value. Decision Tree uses the entropy value as a criterion to measure split quality. Logistic regression uses L1 as penalty value, liblinear as optimisation algorithm, and a maximum iteration value of 750. In voting classifiers, SVM, regression are trained together in one iteration. The "soft" parameter is used in voting with the aim that the classification results used later are based on the average probability of each classifier, not on the number of dominant classifiers.

4) Perfomance evaluation: We used 5-fold cross-validation for training and model evaluation to calculate the average over five iterations. Some common indicators to determine classification system performance include true positive (TP), true negative (TN), false positive (FP), and false negative (FN). These four basic indicators can be used to determine eight other metrics such as accuracy, precision (TPR), recall, ROC curve, specivicity, F1 score, kappa and matthews correlation coefficient (MCC), which are defined in Eq. (1)-Eq. (8):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} * 100\% \quad (1)$$

$$Precision = \frac{TP}{TP+FP} * 100\% \quad (2)$$

$$Recall = \frac{TP}{TP+FN} * 100\% \quad (3)$$

$$ROC\ Curve\ (FPR) = \frac{FP}{(FP+TN)} \quad (4)$$

$$Specificity = \frac{TN}{(TN+FP)} \quad (5)$$

$$\text{F1 Score} = \frac{2x(\text{PrecisionxRecall})}{(\text{Precision}+\text{Recall})} \quad (6)$$

$$Kappa = \frac{p_o - p_e}{1-p_e} \quad (7)$$

$$Kappa = \frac{TN\ x\ TN - FP\ x\ FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (8)$$

III. RESULTS

Ultrasound and mammography data were trained separately using a cross-validation fold selection model, KFold, with five data folds. Training data are evaluated by testing the label of the predicted results against the label of the actual data using a confusion matrix. The confusion matrix results for both modal data show that the model has fairly accurate results characterised by the match between the predicted data label and the actual data label having a very dominant data membership in each class. The validation process of the training data is also analysed using several metrics such as accuracy, precision, recall, RoC curve, specificity, F1 score, Cohen's Kappa (Kappa) and Matthews correlation coefficient (MCC). Information about the data metric: The values of the training validation results can be seen in Table III.

Both graphs in Fig. 3 show the accuracy graph using Eq. (1). Both graphs compare the performance of the four feature extraction schemes. The FFC scheme consistently has the most superior feature extraction capability in ultrasound and mammography images. This is reflected in the higher average validated accuracy compared to the other feature extraction schemes, which is 89.90% on the ultrasound image and 98.20% on the mammography image. Meanwhile, Fig. 4 shows that the FFC scheme has the lowest loss among others for mammography and ultrasound, 3.6404 and 0.6488, respectively.

The Receiver Operating Characteristics (ROC) curve serves to evaluate the performance of binary classification models with a focus on the trade-off between sensitivity (recall) and specificity. Both graphs in Fig. 5 show that the FFC scheme performs better than the other three schemes with AUC values of 0.90 and 0.98 on ultrasound and mammography images, respectively. The precision recall curve serves to evaluate the performance of binary classification models, especially in unbalanced data. Fig. 6. shows the results of using four feature extraction schemes for both images. Similarly to the RoC curve, the AUC value also shows that the FFC scheme has the best feature extraction capability of 0.93 and 0.98 in ultrasound and mammography images. The results of the comparison of feature extraction techniques with four different schemes show that scheme 2 (FFC) has the best performance in ensemble models using five machine learning classification algorithms. SVM, Random Forest, KNN, Decision Tree, and Logistic Regression. The feature extraction process with scheme 4 (FFDSC) is designed to reduce the number of parameters and increase the efficiency of deep learning so that it is not optimally applied to classification algorithms using conventional machine learning (non-deep learning).

TABLE III. THE RESULTS OF THE MEAN METRICS FOR 5-FOLD OF EACH MODAL

IV. Discussion

Several studies focus on the classification of breast cancer using several types of medical imaging. The limited number of data sets in medical images, especially hispatological images, is a challenge for deep learning techniques for feature extraction. The use of deep convolutional neural networks (DCNN) and SVM techniques for classification [27]Techniques to overcome the imbalance in the amount of data in a particular class are a challenge in itself, and there are several ways to overcome these limitations, one of which is the use of image enhancement techniques. Image augmentation techniques have been shown to improve classification system performance compared to the original dataset [28]. It has also performed feature extraction using deep learning with several types of CNN architectures (ResNet-18, ResNet-34, ResNet-50, and EfficientNet-B0). The study used mammography images and the classification process based on multiple instances learning [29] In contrast to what was done by [30] with other types of images, namely thermal imaging with classification based on convolutional neural networks. The collaborative use of two image models has also been done by [31] using hispatology and ultrasound images based on transfer learning.

This research has conducted eight different scenarios with four different feature extraction techniques. The test results show that the use of the feature extraction technique of the feature fusion convolution type has been shown to give the best performance compared to the other three feature extraction techniques. For the classification stage, this research uses five machine learning algorithms that are combined into one unit in an ensemble machine learning system with a soft voting classifier. Table IV compares the results of the proposed method with those of other methods from previous studies for the classification of breast cancer.

V. CONCLUSIONS AND FUTURE WORK

This study has compared ensemble learning models with four convolution layer schemes for feature extraction in breast cancer classification using ultrasound and mammography images separately. The four convolution layer schemes used are simple convolution (SC), feature fusion convolution (FFC), feature fusion depthwise convolution (FFDC), and feature fusion depthwise separable convolution (FFDSC). Classification is performed using an ensemble learning soft voting classifier with SVM, Random Forest, KNN, Decision Tree, and Logistic Regression algorithms. The experimental results show that the FFC convolutional layer scheme achieves the best performance for both datasets. In the ultrasound data set, FFC achieved a value of 0.90 in each of the Val-Acc, TPR, Recall, TNR and F1-Score metrics. In the mammography data set, the FFC reached a value of 0.98 on each of the same metrics. These results emphasize the effectiveness of feature fusion in improving classification performance. Future research can focus on exploring more complex fusion techniques, such as using multimodal data or combining classification with deep learning.

Design and Application of a TOPSIS-Based Fuzzy Algorithm

A Case Study from Tourism Attraction Evaluation

Fei Liu
School of Humanities and Tourism, Zhejiang Institute of Economics and Trade, Hangzhou, 310018 Zhejiang, China

***Abstract*—The study aims to evaluate the tourism attractiveness of different tourist attractions in the same region through the TOPSIS model in the perspective of culture and tourism integration, so as to provide theoretical and practical support for the tourism development of the region. On the basis of the concept of culture and tourism integration and its importance in tourism development, the evaluation index system of tourism attraction is constructed, including the indicators of tourism resources, tourism infrastructure, etc. Finally, the entropy weighting method and TOPSIS model are used for the comprehensive evaluation of these indicators, and the weight of each indicator and the comprehensive score of the tourism attraction of a certain place are derived through calculation. The results show that through the analysis of the TOPSIS model, the advantages and shortcomings of the region in terms of tourism resources and cultural characteristics can be clearly understood, and recommendations can be targeted, including strengthening tourism infrastructure construction, excavating and protecting cultural characteristics, and so on. These suggestions can help to further improve and enhance the tourism attractiveness of a certain place, so as to attract more tourists and promote the development of the local economy. Meanwhile, the methodology and framework of this study also provide reference and reference for other regions to carry out similar tourism attractiveness evaluation. In the context of cultural and tourism integration, this study expands the perspective of tourism evaluation and provides new ideas and methods for local tourism development.**

***Keywords*—Cultural and tourism integration; attractiveness; TOPSIS; entropy weight method**

I. INTRODUCTION

The integration of culture and tourism refers to the deep integration of culture and tourism, through the excavation and use of local cultural resources, to create a destination with cultural charm and tourism attraction [1]. In order to achieve a win-win situation of cultural heritage and tourism in today's society, the integration of culture and tourism has become a hot topic in the development of the tourism industry, for the evaluation of tourism attraction under the integration of culture and tourism, academics and the tourism industry have carried out a lot of research [2, 3].

In the study of tourism attractiveness evaluation under the perspective of culture and tourism integration, scholars are committed to constructing the evaluation index system, determining the weights of the indexes and selecting the comprehensive evaluation method, so as to comprehensively consider the impact of culture and tourism integration on tourism attractiveness [4, 5]. First of all, in terms of the evaluation index system, the index system usually includes indicators of tourism resources, infrastructure, service quality, cultural characteristics and other aspects, in order to comprehensively evaluate the tourism attractiveness of the destination [6, 7]. For example, the indicators of tourism resources can include natural landscape, historical sites, folk customs, etc.; the indicators of infrastructure can include the degree of accessibility, accommodation facilities, catering services, etc.; the indicators of service quality can include the attitude of tourism services, the quality of tour guides, and tourism safety [8]. Meanwhile, in order to accurately evaluate tourism attractiveness [9], it is necessary to determine the weight of each indicator, and under the perspective of cultural and tourism integration, the importance of different indicators may change, so it is necessary to determine the weight by appropriate methods [10]. Researchers usually adopt methods such as hierarchical analysis (AHP) [11] or principal component analysis (PCA) [12,13] in order to determine the weights of the indicators so as to reflect the importance of each indicator more accurately in the comprehensive evaluation. Meanwhile, evaluation method is an important part of the evaluation model, and different scholars have tried different methods to evaluate the attractiveness, such as fuzzy theory-based tourism attractiveness evaluation [14.15], MBO method [16], the integrated method of MDS and ANP method [17], and many other evaluation methods [18, 19].

Under the perspective of culture and tourism integration, the evaluation of tourism attractiveness not only needs to build a good indicator system, but also for the selection of the evaluation model is also crucial, while the increase in the number of tourists in recent years shows that how to choose good tourist attractions for travellers has become a point of concern, and the use of fuzzy comprehensive evaluation and other methods of selection of multiple attractions is a little bit of heavy workload, and computationally redundant [20]. The TOPSIS model, as a commonly used multi-indicator comprehensive evaluation method, has been widely used in various fields of evaluation, the model can be used in the evaluation and selection of tourist destinations through the comprehensive calculation of the scores and weights of the indicators to arrive at a comprehensive evaluation of tourism attractiveness of the destination [21, 23]. Therefore, this paper builds the evaluation index system on the accumulation of literature, and at the same time adopts the entropy weight method and the improved TOPSIS method to construct the evaluation model, which is used to study the evaluation of tourist attractiveness of tourist attractions under the perspective of

culture and tourism fusion, with a view to providing an in-depth exploration and expansion of the concept of culture and tourism fusion, promoting the continuous improvement and innovation of the theory of culture and tourism fusion, and at the same time, providing the scientific evaluation method and decision-making reference for the development of local tourism.

II. Evaluation Model Construction

A. Cultural and Tourism Integration

Culture and tourism integration refers to the in-depth integration of the two industries of culture and tourism to achieve the goal of mutual promotion and common development. In the integration of culture and tourism, several key points can be summarised as follows through relevant research:

- Cultural inheritance and innovation: The integration of culture and tourism requires that traditional culture be inherited and protected, while also focusing on innovation and giving traditional culture modern connotations to make it more in line with the aesthetics and needs of contemporary people.
- Integration and development of tourism resources: Fully integrate local tourism resources such as natural scenery and humanistic landscapes, carry out planning and development, and create distinctive and quality tourism products and services.
- Integration of cultural and tourism projects: Through cultural and artistic performances, cultural and creative bazaars, and cultural themed exhibitions, culture and tourism projects are combined to enrich the experience and feelings of tourists.
- Cultural and tourism industry linkage: Encouraging the in-depth integration of the cultural industry with the tourism industry, promoting the interactive development of cultural and creative products and tourism products, and forming an industry linkage effect.
- Culture and tourism branding: With the help of cultural resources and tourist attractions, create a culture and tourism brand with local characteristics and cultural connotations, and enhance the image and popularity of the place.
- Cultural and tourism marketing and promotion: Use new media and social platforms to promote cultural and tourism products and attract more tourists and cultural enthusiasts.
- Public services for culture and tourism: Upgrading cultural and tourism service facilities and public services to provide visitors and residents with a better cultural experience and tourism environment.

Many studies consider the above seven key points to be effectively integrated and implemented, and the integration of culture and tourism will be able to realise the complementary advantages of culture and tourism and promote the sustainable development of local economy and society. The author's research believes that the evaluation of attractiveness of tourist attractions is closely related to the integration of culture and tourism, and that cultural heritage and tourism experience directly affect the attractiveness of tourist attractions; excellent cultural heritage and rich tourism experience can enhance the attractiveness of attractions and attract more tourists to come to visit them, while creative design and sustainable development can add new charms to attractions and make them stand out in the highly competitive tourism market. Therefore, the key points of cultural and tourism integration are closely linked to the relationship between the attractiveness evaluation of tourist attractions, which promotes the enhancement of the cultural value and attractiveness of tourist destinations and injects new vitality into the development of the tourism industry. Therefore, this paper will carry out the tourism attractiveness evaluation based on cultural and tourism integration through different tourist attractions, to explore the important influencing factors of cultural and tourism integration and their degree of influence on the attractions.

B. Constructing the Evaluation Index System

Existing studies believe that the construction of tourism attraction evaluation index system under the perspective of culture and tourism integration should contain multiple dimensions, such as natural environment, cultural heritage, tourism infrastructure, service quality, etc., in order to comprehensively assess tourism attraction. At the same time, the evaluation indicators should be comparable to facilitate comparison between different regions or attractions, and the meaning of the indicators should also take into account the regional characteristics and differences; in view of the fact that the current indicators are more subjective, the evaluation indicators should be quantifiable, so that it is easy to collect and analyse the data, based on which to ensure the objectivity of the evaluation results.

Through reviewing the literature, this paper argues that the indicator system needs to take into account the cultural, natural environment and historical characteristics of different regions, i.e., the evaluation indicators should have a certain degree of geographical adaptability, avoiding the simple application of standard indicators. Given that most of the research objects become attractions have been solidified, the index referentiality needs to be sufficient, and should be based on the status quo more easily accessible data and information, to avoid difficult to obtain or inaccurate data. At the same time, taking into account that the tourism market serves the market, so the evaluation index system should adapt to the changes in the tourism market and environment. Finally, this paper considers that the evaluation indexes should be operable, so that managers and decision-makers can take corresponding management measures according to the evaluation results. Based on this, this paper finally constructs the indicator system as shown in Table I.

TABLE I. TOURISM ATTRACTION EVALUATION INDEX SYSTEM BASED ON THE CONCEPT OF CULTURAL AND TOURISM INTEGRATION

Level 1 indicators	Secondary indicators	Indicator assessment content
Indicators of cultural content	Number of cultural heritages	Measures the amount of important cultural heritage, such as historical buildings, monuments and artefacts that a destination possesses.
	Status of protection of cultural heritage	Assessment of the protection and restoration of cultural heritage at the destination, including restoration work, regulatory measures, etc.
	Richness of cultural activities	Measure the number and quality of cultural festivals, exhibitions, performances and other events organized by the destination.
	Development of cultural industries	Assess the scale and contribution of the destination's cultural industries, including cultural and creative products, cultural and artistic performances, and so on.
Tourism infrastructure indicators	Accessibility	Evaluate how well the destination is connected to the transport network, including accessibility by road, rail and air.
	Accommodation facilities	Measures the number and quality level of accommodation facilities such as hotels, B&Bs and resorts in the destination.
	Tourism reception capacity	Evaluate the destination's capacity and level of service to tourists, including guides, interpreters, reception facilities, etc.
	Service level of guided tours	Measure the professionalism and service attitude of the destination guide.
Natural landscape indicators	Quality of the natural environment	Measurement of natural environmental indicators such as air quality, water quality and environmental cleanliness of the destination.
	Natural landscape features	Evaluate the unique natural landscape features of the destination, such as mountains, lakes and forests.
	Ecotourism resources	Measures the richness of the destination's ecotourism resources, including wildlife, eco-farms, etc.
Indicators for cultural and tourism integration projects	Development of Cultural and Creative Industries	Assess the extent and impact of the cultural and creative industries in the destination.
	Culture and Tourism Integration Construction	To measure the construction of demonstration projects and demonstration areas in the field of cultural and tourism integration in destinations.
	Cultural and Tourism Integration Activities Organised	To assess the number and quality of cultural and tourism integration activities organised by the destination, such as cultural and arts festivals and cultural and creative bazaars.
Indicators of tourist satisfaction	Traveller's comment	Gather travellers' ratings and opinions about the destination, including attractions, services, transport and more.
	Tourist return rate	To assess the proportion of tourists who choose the destination again to travel, reflecting the return and loyalty of the destination's visitors.
	Word-of-mouth communication	Evaluate the destination's word-of-mouth and user experience through online and social media channels.

It can be seen that in the evaluation of the attractiveness of tourism regions, the indicator system based on the integration of culture and tourism is considered more comprehensively, and as we all know, the concept of integration of culture and tourism refers to the integration of culture and tourism to create attractions or projects with cultural connotations and tourism attractiveness. Therefore, it can be seen that the following characteristics are presented when constructing tourism attraction indicators:

1) Cultural connotation: Whether the attraction or project has rich cultural connotation, such as historical heritage, folk customs, artistic performance, etc., which can be reflected by indicators of cultural heritage, history and culture, folk customs, etc., and is compatible with the first-level indicator of cultural connotation indicators.

2) Tourism facilities: Whether the attraction or project provides perfect tourism facilities and services, such as convenient transport, accommodation and catering, and guided tour services. This can be reflected through the indicators of convenient transportation, accommodation and catering support, which corresponds to the tourism infrastructure indicator in this paper.

3) Experience and interaction: Whether the attraction or project provides rich experience and interactive projects, such as cultural experience, handicraft production, interactive performances, etc., which can be reflected through the indicators of experiential projects and interactive activities, which corresponds to the indicator of cultural and tourism integration projects in this paper.

4) Visitors' perception: Whether the attraction or project is innovative and sustainable, such as the innovative application of the concept of cultural and tourism integration, the richness of tourism resources, and the follow-up evaluation of tourists, etc. This point is mirrored by the indicators of natural landscape and the indicators of tourists' satisfaction in this paper, and this paper considers that although there is a little bit of linkage between the two, there is also a certain degree of discrepancy, so they are listed separately to be analysed.

C. Coefficient of Variation Method

Entropy weighting method is a multi-indicator decision-making method to determine the importance of each indicator in decision-making by calculating the entropy value and weight of each indicator [24]. Entropy weighting method can consider the correlation and importance between indicators by calculating the information entropy of the indicators, so as to reflect more accurately the influence of each indicator on the decision-making, and at the same time, compared with the traditional method of subjective assignment, the entropy weighting method does not require subjective evaluation, but rather, it determines the weights through the amount of information of the data itself, which has the objectivity and scientific nature [25].

This paper considers that the entropy weight method can consider the importance of multiple indicators comprehensively, which can well reflect the multiple factors and indicators involved in the evaluation of tourism attractiveness under the concept of cultural-tourism fusion, and at the same time, the process of adopting the entropy weight method to use information entropy to measure the differences and uncertainties between indicators and to determine the weights of the indicators can better reflect the correlations and influences among the factors of tourism attractiveness under the concept of cultural-tourism fusion. In general, the entropy weight method is comprehensive, objective and widely applicable in the evaluation of tourism attractiveness under the concept of cultural and tourism integration, and can effectively calculate the weights and reflect the impact of cultural and tourism integration on tourism attractiveness. The calculation steps are as follows.

1) Indicator data forwarding: Considering that the indicator weight data in this paper all belong to the larger and more important indicators, therefore, this kind of indicator data does not need to be forwarded.

$$x'_{ij} = x_{ij} \tag{1}$$

Where: x'_{ij} - Data matrix elements after normalisation;

x_{ij} -Initial element of the data matrix.

2) Data standardisation

$$r_{ij} = \frac{x'_{ij} - min\left(x'_j\right)}{max\left(x'_j\right) - min\left(x'_j\right)} \tag{2}$$

Where: r_{ij} - Normalised data matrix elements;

x'_{ij} -After normalisation the data matrix elements in this paper are the initial matrix elements.

3) Calculating information entropy: Noting the matrix obtained from the normalised post-processing as $R = \left(r_{ij}\right)_{m\times n}$, the information entropy is E_j for a given indicator r_j.

$$E_j = -\frac{1}{lnm}\sum_{i=1}^{m} p_{ij} lnp_{ij} \tag{3}$$

Included among these:

$$p_{ij} = \frac{r_{ij}}{\sum_{j=1}^{n} r_{ij}} \tag{4}$$

Where: E_j - information entropy;

r_{ij} -Normalised data matrix elements.

If the information entropy of an indicator is smaller, it indicates that the degree of variation of its indicator value is larger, and the amount of information provided is also larger, and it can be considered that the indicator plays a greater role in the comprehensive evaluation.

4) Calculation of weights

$$\omega_{ij} = \frac{1 - E_j}{\sum_{j=1}^{n}\left(1 - E_j\right)} \tag{5}$$

Where: E_j - information entropy.

D. Improvement of the TOPSIS Model

Based on Table I of this paper, it can be seen that the evaluation of tourism attractiveness based on culture and tourism integration is a process that involves a wide range of indicators, and at the same time the assessment content is redundant, while the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) model can comprehensively consider a number of indicators, including culture, tourism, economy and other indicators, so as to more comprehensively evaluate the tourism attractiveness. The TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) model can consider multiple indicators, including cultural, tourism, economic and other indicators, to evaluate tourism attractiveness in a more comprehensive way. At the same time, the TOPSIS model is applicable to different types of indicators and different ranges of data, and can be flexibly adjusted and applied according to the characteristics of cultural and tourism resources in different regions. In addition, the advantage of the TOPSIS model is that it can compare the evaluation object with the ideal solution and the negative ideal solution, so as to determine the optimal solution, which is conducive to the improvement of the objectivity and accuracy of the evaluation results. The purpose of this paper is that through the evaluation of TOPSIS model, the advantages and shortcomings of cultural and tourism integration can be better found, and provide scientific basis for the development of cultural and tourism integration, of course, there are some limitations of TOPSIS method, such as the determination of the weights is more subjective, taking this into account, this paper adopts the objective weighting method - entropy weighting method for the determination of weights, and at the same time, considering that the TOPSIS model is lower than the perception of the evaluation results, so it is improved. At the same time, considering that the TOPSIS model has a low perception of the evaluation results in the evaluation, it is improved to carry out the evaluation of tourism attractiveness based on the improved TOPSIS model, and its calculation process is as follows.

1) Calculate the weighted data matrix

$$e_{ij} = \omega_j r_{ij} \tag{6}$$

Where: e_{ij} - weighted matrix elements;

ω_{ij} -weight vector;

r_{ij} -Normalised data matrix elements.

2) Calculate the distance between the weighting matrix and the most value

After processing you can form a data matrix

$$M = \left(e_{ij}\right)_{m\times n} \tag{7}$$

Define the maximum value of each indicator, i.e., each column, ase_j^+

$$e_j^+ = max\left(e_{1j}\cdots e_{nj}\right) \tag{8}$$

Define the maximum value of each indicator, i.e., each column, ase_j^-

$$e_j^- = max\left(e_{1j}\cdots e_{nj}\right) \tag{9}$$

Define the ith object to be at a distance from the maximum asd_i^+ (positive ideal solution)

$$d_i^+ = \sqrt{\sum_{j=1}^{n}\left(e_j^+ - r_{ij}\right)^2} \tag{10}$$

Define the distance of the ith object from the maximum asd_i^- (negative ideal solution)

$$d_i^- = \sqrt{\sum_{j=1}^{n}\left(e_j^- - r_{ij}\right)^2} \tag{11}$$

3) Calculation of scores

$$S_i = \frac{d_i^-}{d_i^- + d_i^+} \tag{12}$$

$$Score_i = \frac{S_i}{maxS_i + 0.1} \tag{13}$$

Where: S_i -TOPSIS calculations;

$Score_i$ -Evaluation score.

III. Example Validation of Tourism Attractiveness Evaluation in the Perspective of Culture and Tourism Integration based on TOPSIS Model

A. Overview of the Study Area

The study area belongs to Mabian County in Sichuan Province, which is located under the jurisdiction of Leshan City, a county full of history, culture and natural scenery. At present, tourism in Mabian County is in a rapid development stage, attracting more and more tourists for sightseeing, holiday and leisure. First of all, Mabian County has rich historical and cultural resources, including ancient religious buildings and traditional folk culture. Guanyin Yan, Chongtianlou, Taiping, Ma'er Mountain Forest Park, and the First Walled City of Liangshan Mountain in the county attract a large number of tourists. In addition, there are some traditional folk activities in the county, such as Sichuan Opera, Sichuan Cuisine and Sichuan Tea, which attract culture lovers to experience. Secondly, Mabian County is blessed with natural scenery resources, beautiful scenery, with excellent outdoor sports and adventure environment, such as hiking, rock climbing, rafting and other projects are highly favoured by tourists. In addition, it is understood that Mabian County is also actively developing rural tourism, combining local farming culture and idyllic scenery with tourism, providing tourists with a richer tourism experience. In general, the current status of tourism development in Mabian County is good, with abundant tourism resources, attracting a large number of tourists, but how attractive the attractions are based on the view of cultural and tourism integration is still an unknown, so this paper will evaluate and analyse the five tourism zones in Mabian County (Guanyinyan, Chongtianlou, Taiping, Ma'er Mountain Forest Park, and the First Walled Village of Liangshan Mountain, which is hereinafter represented by Attractions 1 - Attractions 5).

B. Entropy Weight Method Weight Calculation

In this paper, the above research object to collect data is shown in Table II, while based on the collection of data according to the Eq. (1-5) calculated to get the entropy weight method of the relevant values and weights are shown in Table III.

C. Analysis of Weighting Results

In this paper, according to the results of weight calculation in Table III, the comprehensive single-indicator weight analysis chart and the analysis chart of hierarchical weight results are drawn by sorting as shown below Fig. 1 and Fig. 2.

Combined with the Fig. 1 and Fig. 2 , it can be seen that for the first-level indicators, cultural connotation indicators and natural landscape indicators accounted for 25.97% and 20.59% respectively, which shows that in the evaluation of tourism attractiveness of culture and tourism integration, the tilt towards culture is obvious, and the reason why cultural connotation indicators and natural landscape indicators are more important is that they represent the history of the people and the environment, which are the two important components of the tourism resources respectively. First of all, the cultural connotation indicator represents the richness of a place's history, traditions, arts and customs, etc. Places with rich cultural connotations tend to attract the interest of tourists, who want to feel and experience the local cultural charms by visiting cultural monuments, participating in traditional festivals, tasting local cuisine, etc. Therefore, the cultural connotation indicator is crucial to the attractiveness of culture and tourism integration tourism. The natural landscape indicator represents the attractiveness of a place's natural environment, geographical landscape and ecological resources, etc. Places with beautiful natural landscape can often make tourists feel the wonder and beauty of nature, and they want to enjoy the beauty of nature through viewing natural scenery, participating in outdoor activities, experiencing ecological farming, etc. Therefore, the natural landscape indicator is also very important for the attractiveness of the integrated tourism of culture and tourism. Therefore, the natural landscape indicator is also very important for the attraction of cultural tourism integration. This also shows that when a place has both rich cultural connotations and

beautiful natural landscapes, it tends to attract more tourists to come to experience and explore.

TABLE II. DATA ON THE STUDY POPULATION

Secondary indicators	Attractions 1	Attractions 2	Attractions 3	Attractions 4	Attractions 5
Number of cultural heritages	85	82	81	70	78
Status of protection of cultural heritage	90	87	86	76	87
Richness of cultural activities	75	70	73	80	70

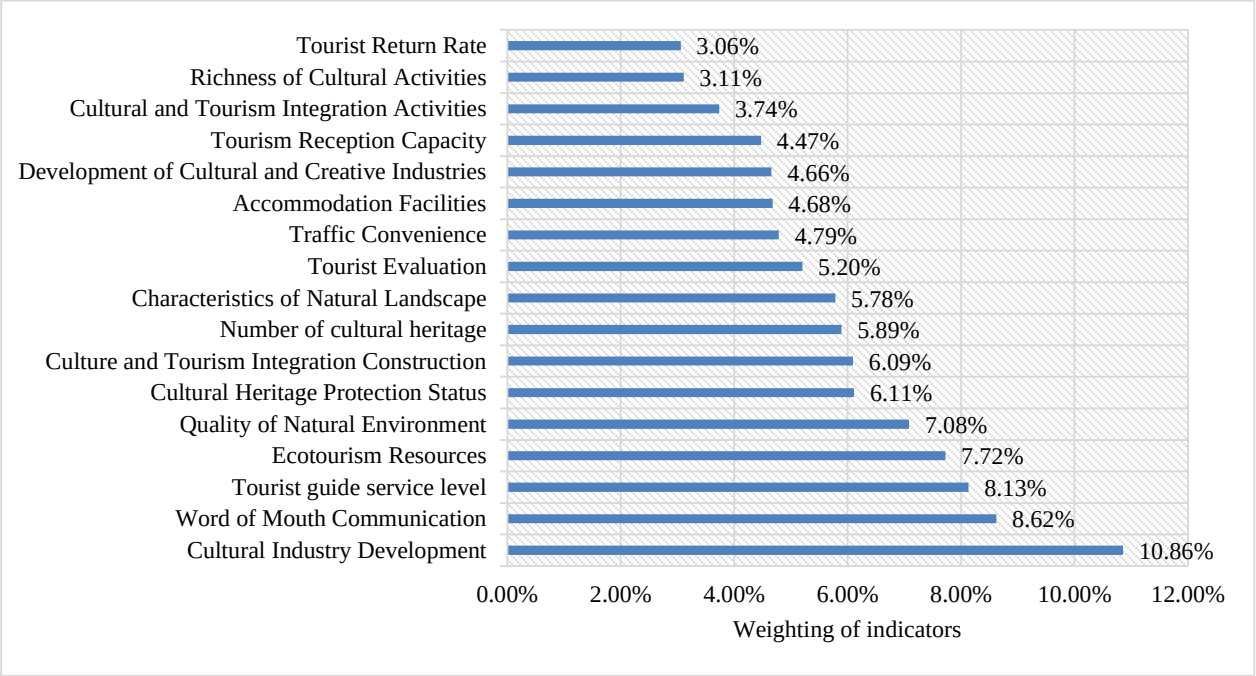

Fig. 1. Histogram of the ranking of weighting results.

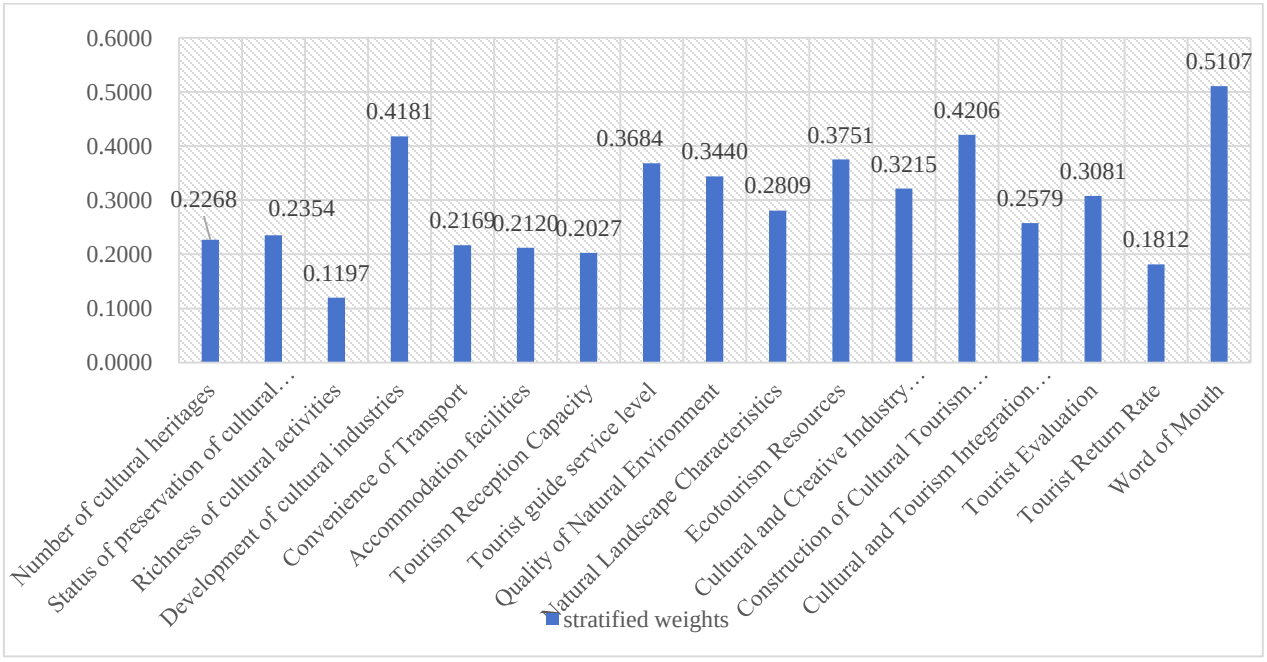

Fig. 2. Histogram of stratified weights.

And according to the calculation results of single indicators and bar charts, it can be seen that the development of cultural industry, word-of-mouth communication, tour guide service level, eco-tourism resources, and the quality of the natural environment are in the forefront, accounting for 10.86 %, 8.62 %, 8.13 %, 7.72 %, 7.08 %, which can be seen to belong to the indicators of cultural connotation, tourists' satisfaction, tourism infrastructure, and the natural landscape, respectively. This shows that even though the first-level indicators are not considered, the single indicator weights still indicate the importance of the indicators under the first-level indicators, which are analysed as follows: in the evaluation of tourism attractiveness of culture and tourism integration, the cultural industry development, word-of-mouth transmission, tour guide service level, ecotourism resources and natural environment quality indicators are all more important because they each represent different aspects of tourism purposes, and play an important role in enhancing the tourist The reason is that they represent different aspects of tourism purposes and play an important role in enhancing tourist experience and attracting tourists. Firstly, the cultural industry development indicator represents the development level of a place in terms of cultural

creative industries, cultural festivals and cultural product development. A place with rich cultural industries can provide tourists with diversified cultural experiences and cultural products, enhance their sense of participation and interactivity, and thus improve tourism attractiveness. Secondly, word-of-mouth (WOM) indicators represent tourists' satisfaction and experience of a destination. Good WOM means that tourists praise and recommend the destination, which can attract more tourists to come. Word-of-mouth communication is especially important in today's social media era, and tourists' favourable comments and sharing can directly influence other potential tourists' choices. The tour guide service level indicator represents the level of tourism service and the quality of tourists' experience in the destination. Quality tour guide service can provide tourists with a better travelling experience and enhance their knowledge and understanding of the destination, thus increasing their satisfaction and loyalty to the destination. Finally, the ecotourism resources indicator and the natural environment quality indicator represent the natural environment and ecological protection of the destination. In today's context of environmental protection and sustainable development [22], rich ecotourism resources and good quality of the natural environment can attract more tourists who are concerned about environmental protection, and also meet the contemporary demand for healthy, leisure and environmentally friendly tourism.

The results of the above weighting analyses show that important factors need to be considered comprehensively in tourism development and evaluation in order to enhance the competitiveness and attractiveness of tourism destinations.

D. The TOPSIS Model

1) Model evaluation: The TOPSIS model evaluation of the study area was carried out according to the Eq. (6)-Eq. (13), and the results of the calculation of the first-level indicators of the five study objects and their attractiveness evaluation are now presented in Table IV.

TABLE IV. EVALUATION RESULTS FOR THE STUDY AREA

place of interest (tourism)	Indicators of cultural content			Tourism infrastructure indicators		
	d+vector	*d-vector*	*score*	*d+vector*	*d-vector*	*score*
Attractions 1	0.0297	0.0288	68.3038	0.0152	0.0391	69.0666
Attractions 2	0.0427	0.0205	44.9665	0.0089	0.0468	80.6586
Attractions 3	0.0378	0.0195	47.1028	0.0029	0.0476	90.4069
Attractions 4	0.0258	0.0423	86.1356	0.0315	0.0231	40.5971
Attractions 5	0.0296	0.0225	59.8747	0.0448	0.0160	25.2612
place of interest (tourism)	**Natural landscape indicators**			**Indicators for cultural and tourism integration projects**		
	d+vector	*d-vector*	*score*	*d+vector*	*d-vector*	*score*
Attractions 1	0.0198	0.0364	72.0567	0.0306	0.0295	54.3214
Attractions 2	0.0343	0.0221	43.5494	0.0444	0.0086	89.3314
Attractions 3	0.0335	0.0181	38.9272	0.0269	0.0294	51.0423
Attractions 4	0.0118	0.0470	88.8821	0.0072	0.0446	14.8057
Attractions 5	0.0463	0.0043	36.2356	0.0177	0.0337	36.7036
place of interest (tourism)	**Indicators of tourist satisfaction**			**attractiveness rating**		
	d+vector	*d-vector*	*score*	*d+vector*	*d-vector*	*score*
Attractions 1	0.0413	0.0102	19.0468	0.0117	0.0146	80.6141
Attractions 2	0.0321	0.0249	41.8058	0.0154	0.0140	69.3502
Attractions 3	0.0249	0.0264	49.2807	0.0130	0.0144	76.3585
Attractions 4	0.0027	0.0461	90.4190	0.0119	0.0170	85.4721
Attractions 5	0.0206	0.0314	57.8215	0.0166	0.0097	53.6475

2) Analysis of results: Guanyinyan, Chongtianlou, Taiping, Maer Mountain Forest Park, Liangshan First Walled City scored 80.6141, 69.3502, 76.3585, 85.4721, 53.6475 in this evaluation, it can be seen that Chongtianlou and Liangshan First Walled City scored relatively low, based on the results of the attractiveness evaluation, based on the rating results of the two attractions mentioned above, this paper carries out the secondary survey analysed after the visit. First of all, the main reason for Chongtianlou is that the cultural connotation is not deep enough and there are certain problems in dissemination, Chongtianlou as a cultural attraction, its history, traditions, folklore and other aspects of cultural connotation is not rich enough and insufficient publicity, through the evaluation of the first level of indicators can be seen, its cultural connotation indicators score is very low, so it is necessary to strengthen the publicity and properly enrich their own advantages as a cultural classic. Mabian County Liangshan First Walled City attractions scored low mainly because of the scenic area's infrastructure is not perfect, the level of service is not high, including car parks, toilets, guide services, transportation, etc., and at the same time, the scenic area's cultural and tourism integration projects are not diversified enough and innovative enough, and are more conventional, if the Liangshan First Walled City continues to lack of innovative projects with local culture, traditional industries and other fusion, will affect the attractiveness of the scenic area to tourists, therefore, it is necessary to improve the

cultural connotation indicators. Attractive to tourists, so to improve the rating of the scenic area, it is necessary to improve the infrastructure, the introduction of innovative cultural and tourism integration projects.

IV. CONCLUSION

This study evaluates the tourism attractiveness in the perspective of culture and tourism integration based on the TOPSIS model, and the results show that the model can effectively assess the attractiveness of tourism destinations and provide a scientific basis for tourism development, and the results of the evaluation of tourism attractiveness through the perspective of culture and tourism integration show that the integration of culture and tourism resources plays an important role in enhancing the attractiveness of tourism destinations, which provides a It provides theoretical support for the development of culture and tourism integration. At the same time, this study also found that under the perspective of culture and tourism integration, the evaluation of tourism attractiveness needs to consider the integration of cultural heritage and tourism experience, in order to achieve the sustainable development of tourism destinations to further improve the attractiveness of existing tourism resources, and at the same time, it is necessary to strengthen the cultural and artistic activities of attractions with cultural heritage, and to make a unique tourism area.

In view of the demand for the development of cultural and tourism integration, more field research and case analyses can be considered in the future to explore the evaluation methods of tourism attractiveness in different regions and cultural backgrounds, so as to enrich the research results. At the same time, we can also combine big data and artificial intelligence technology to build a more accurate tourism attractiveness evaluation model under the perspective of culture and tourism integration, so as to achieve dynamic data collection and dynamic real-time evaluation, and to provide more scientific support for tourism development as well as suggestions for development decisions.

Enhanced Butterfly Optimization Algorithm for Task Scheduling in Cloud Computing Environments

Yue ZHAO
College of Computer, Cangzhou Jiaotong College, Cangzhou 061199, China

***Abstract*—Cloud computing is transforming the provision of elastic and adaptable capabilities on demand. A scalable infrastructure and a wide range of offerings make cloud computing essential to today's computing ecosystem. Cloud resources enable users and various companies to utilize data maintained in a distant location. Generally, cloud vendors provide services within the limitations of Service Level Agreement (SLA) terms. SLAs consist of various Quality of Service (QoS) requirements the supplier promises. Task scheduling is critical to maintaining higher QoS and lower SLAs. In simple terms, task scheduling aims to schedule tasks to limit wasted time and optimize performance. Considering the NP-hard character of cloud task scheduling, metaheuristic algorithms are widely applied to handle this optimization problem. This study presents a novel approach using the Butterfly Optimization Algorithm (BOA) for scheduling cloud-based tasks across diverse resources. BOA performs well on non-constrained and non-biased mathematical functions. However, its search capacity is limited to shifted, rotated, and/or constrained optimization problems. This deficiency is addressed by incorporating a virtual butterfly and improved fuzzy decision processes into the conventional BOA. The suggested methodology improves throughput and resource utilization while reducing the makespan. Regardless of the number of tasks, better results are consistently produced, indicating greater scalability.**

***Keywords*—Cloud computing; resource utilization; task scheduling; Butterfly Optimization Algorithm; fuzzy decision strategy**

I. INTRODUCTION

The Internet of Things (IoT) has evolved from the exponential proliferation of smart sensors in recent years and the demand for inter/interconnections between devices [1, 2]. IoT opens up broad medical, manufacturing, and logistics opportunities, necessitating high reliability, durability, flexibility, adaptability, and control levels [3]. Furthermore, IoT devices are limited in resources and equipped with specialized chips configured with various rules [4]. In this way, conventional networks become more complex owing to the specific requirements of IoT applications. Software-Defined IoT (SD-IoT) aims to apply Software-Defined Networking (SDN) to IoT to bring elasticity to managing resources and networks in traditional networks. SDN is regarded as a critical paradigm for next-generation networking [5].

A group of networked computers with several shared computing resources is referred to as the cloud. Recently, cloud computing has developed rapidly, enabling globally distributed data centers to develop and scale up to provide high-quality and reliable services [6]. Cloud computing has emerged as an effective model for providing computational resources on a "pay-per-use" basis. It brings uniformity and transformation to IT enterprises [7]. Cloud computing has significant prospects and poses several problems in conventional IT evolution due to its expanding uses and promotion [8]. In recent years, cloud computing has become an alternative online strategy to empower users. It offers access to shareable and customizable resources on demand, quickly allocated and released with little management or collaboration from the cloud provider [9]. This invention offers several advantages, including enhanced economic benefits related to time, cost, inventory management, and storage. This breakthrough enables all programs to operate on a virtual platform, with resources allocated across Virtual Machines (VMs) [10].

An effective and dynamic task scheduler is essential when multiple users simultaneously request services from the cloud environment, particularly from diverse and heterogeneous resources [11]. An optimal and adaptable task scheduler is critical in the cloud paradigm. Moreover, it must function under the workload submitted to the cloud platform [12]. An inefficient scheduling process in the cloud environment causes diminished service quality from cloud service providers, eroding confidence and adversely affecting corporate operations [13]. Hardware virtualization is the basis for distributing cloud resources. Numerous VMs are hosted on an individual computing server to support multiple users executing concurrent processes. VMs running in cloud data centers are given thousands of tasks. Consequently, employing an effective scheduler inside the cloud framework is advantageous for cloud providers and customers, allowing mutual benefits.

Task scheduling assigns cloud tasks to VMs to shorten makespan and enhance resource usage. Due to the NP-hard characteristics of this issue, conventional scheduling techniques have challenges regarding scalability and efficiency, especially in dynamic cloud settings [14]. Metaheuristic algorithms, such as the Butterfly Optimization Algorithm (BOA), have been shown to help tackle complicated optimization problems [15]. These algorithms leverage techniques like random walks and graph-based embeddings to improve search efficiency and adaptability in diverse optimization contexts [16]. BOA is suitable for such tasks due to its simplicity, excellent balance between exploration and exploitation, and adaptability to diverse optimization landscapes. Besides, its computational efficiency and the ability to converge on high-quality solutions make it a competitive choice for improving cloud task scheduling. This study presents an improved BOA, including a fuzzy decision method and an innovative virtual butterfly idea to maximize the algorithm's search efficacy and flexibility in

cloud job scheduling. As a summary, this study made the following contributions:

- A novel variant of the BOA is introduced, incorporating a fuzzy logic model and a virtual butterfly design to improve the algorithm's search efficiency and adaptability in cloud computing environments.
- A fuzzy logic model is implemented to continuously alter the balance between BOA's exploration and exploitation phases, allowing for better adaptation to varying optimization conditions.
- A virtual butterfly agent is developed that aggregates information from all butterflies, directing the swarm to promising areas in the search area, thereby avoiding premature convergence and improving the overall solution quality.
- The enhanced algorithm is evaluated using CloudSim with GoCJ and HCSP datasets, demonstrating its superior performance in minimizing makespan, improving resource utilization, and enhancing throughput compared to other metaheuristic methods like PSO and standard BOA.

The remaining portion of the paper is laid out in the following arrangement. Section II summarizes related research on cloud-based task scheduling. Section III defines the task scheduling problem and presents the challenges in optimizing makespan and resource utilization. Section IV introduces the proposed enhanced BOA, detailing its fuzzy decision strategy and virtual butterfly concept. Section V reports the findings and analyzes the efficiency of the developed algorithm. Section VI discusses key findings and outlines the limitations of current work. Lastly, Section VII offers a conclusion and recommends areas for further research.

II. Literature Review

Metaheuristic algorithms have been extensively adopted for scheduling tasks in cloud computing. Recent research efforts have focused on improving these algorithms to address local optima and poor convergence challenges. Some research studies emphasize the importance of parallel calculations in maximizing task scheduling efficiency. The need to balance exploration with exploitation has resulted in hybrid and adaptable methodologies. Nevertheless, several current methodologies encounter constraints when used in extensive, diverse cloud settings.

Dubey and Sharma [17] proposed the Chemical Reaction Partial Swarm Optimization (CR-PSO) method for distributing several independent jobs among VMs in a cloud computing context. This hybrid methodology integrates the merits of Chemical Reaction Optimization (CRO) and Particle Swarm Optimization (PSO), producing an optimum task scheduling sequence that accounts for both job requirements and deadlines. Hybridization optimizes makespan, decreases costs, and diminishes energy use. Comprehensive simulations were performed with the CloudSim tools, illustrating the algorithm's efficacy. The comparative examination of several scenarios, varying quantities of VMs and tasks, demonstrates a decrease in execution time between 1–6% and, at times, exceeding 10%. Furthermore, the CR-PSO algorithm boosted makespan by 5–12%, decreased costs by 2–10%, and improved energy efficiency by 1–9%. These findings validate the algorithm's capacity for enhanced resource management and scheduling in cloud systems.

Mangalampalli, et al. [18] developed a task scheduling system using Firefly Optimization, prioritizing jobs and VMs to guarantee precise scheduling. This methodology utilizes synthetic datasets with diverse distributions and workloads from NASA and HPC2N for assessment. This methodology, implemented in the CloudSim simulation environment, is contrasted with baseline methods like genetic, Ant Colony Optimization (ACO), and PSO algorithms. The simulation outcomes indicate that the firefly-based method substantially surpasses these benchmarks in minimizing makespan, augmenting resource availability, increasing the success rate, and decreasing turnaround time, thus producing a more dependable and effective scheduling solution for cloud environments.

Bezdan, et al. [19] suggested an enhanced bat algorithm to tackle multi-objective job scheduling in cloud settings. The strategy seeks to optimize efficiency while minimizing search duration. The methodology was assessed with the CloudSim toolbox on both regular and synthetic parallel workloads. The findings revealed that the hybridized bat algorithm surpasses conventional metaheuristic methods, highlighting its significant potential for enhancing job scheduling effectiveness.

Wu and Xiong [20] created an innovative job scheduling approach for cloud computing with PSO algorithm. Initially, the resource scheduling issue in a cloud computing ecosystem is simulated, and a task execution duration function is established. The updated PSO approach is then implemented to coordinate application activities and improve load distribution. It relies on the Copula algorithm to explore the correlation between variables and probability while defining the attractor component to prevent the objective function from being ensnared in local optimums. The analysis indicates that the proposed resource allocation and scheduling methodology may enhance cloud computing resource usage and decrease job completion time.

Mangalampalli, et al. [21] offered a multiple-objective task scheduling method based on the Grey Wolf Optimization (MOTSGWO) algorithm by optimizing scheduling options dynamically depending on resource availability and anticipated demand requirements. This approach allocates resources to meet customer budgets and work priorities. The MOTSGWO methodology is executed through the Cloudsim toolkit, with workloads generated via the development of datasets with varied task distributions and sequences sourced from NASA and HPC2N distributed repositories. The comprehensive evaluation findings reveal that MOTSGWO is superior to previous benchmark strategies and improves critical metrics.

Saif, et al. [22] presented a multi-goal GWO algorithm aimed at minimizing the QoS targets of latency and energy usage implemented inside the fog broker, which is crucial to job distribution. The experimental observations confirm the efficacy of the MGWO algorithm relative to contemporary algorithms in minimizing delay and energy consumption.

III. PROBLEM DEFINITION

As shown in Fig. 1, a cloud data center comprises numerous Physical Machines (PMs), each capable of providing distinct end-user services. PMs can generate thousands of VMs dynamically. Alternatively, multiple host machines can collaborate to support a single VM. Cloud service providers offer VMs with different performance and pricing options, meeting a wide range of user requirements. This study explores the problem of allocating VMs to incoming, independent tasks. Each task is assumed to run exclusively on one VM and cannot be partitioned into smaller segments. Managing task scheduling in such an environment featuring varying capabilities is a complex challenge, represented by the sets of tasks and VMs in Eq. (1) and Eq. (2).

$$T = \{t_1, t_2, t_3, \dots, t_n\} \quad (1)$$

$$VM = \{vm_1, vm_2, vm_3, \dots, vm_m\} \quad (2)$$

The set T represents tasks, each defined by a specific number of instructions. At the same time, VM denotes a set of VMs, each with defined computational power determined by Millions of Instructions Per Second (MIPS). In most cases, the workload volume surpasses the available VMs. These arrays act as inputs to the scheduling algorithm, which seeks to derive an optimal mapping of tasks to VMs. This mapping outlines the assignment of tasks to VMs, as expressed in Eq. (3).

$$Map = \{(t_2, vm_1), (t_1, vm_3), (t_3, vm_2), \dots, (t_n, vm_m)\} \quad (3)$$

In the mapping solution, each task (represented as the first element of a tuple) is assigned uniquely to a VM, while a VM can be associated with multiple tasks. This implies that each task is allocated to a particular VM, while a VM may handle several assignments. The execution time (ET) for a specific task t_i on a VM vm_j is calculated using Eq. (4).

$$ET_{task_i vm_j} = Number\ of\ instruction\ in\ t_i\ /vm_j\ MIPS \quad (4)$$

It is assumed that each VM processes multiple tasks sequentially without interruption. Eq. (5) defines the overall completion time (CT) for all tasks allocated to a particular VM. Notably, faster VMs will complete their assigned tasks faster than slower ones.

$$CT_{vm_j} = \sum_{i=1}^{n} number\ of\ instrucions\ in\ t_i\ /vm_j\ MIPS \quad (5)$$

In metaheuristic algorithms, the arrangement of tasks on VMs is continuously adjusted to optimize their fitness values. As such, the task assignments on each VM may change during the algorithm's execution. If task t_x is replaced with task t_y on a VM, the completion time for multiple tasks executed in the VM is computed using Eq. (6).

$$CT_{vm_j} = CT_{vm_j} - (number\ of\ instrucions\ in\ t_x\ /vm_j\ MIPS) + (number\ of\ instrucions\ in\ t_y\ /vm_j\ MIPS) \quad (6)$$

A critical metric in task scheduling is the makespan, which refers to the total time required to complete all tasks across the available VMs. The makespan is determined using Eq. (7), representing the maximum completion time among all VMs involved in the scheduling process.

$$Makespan = \max\left(CT_{vm_j}\right)\ \forall j \epsilon 1,2, \dots, k \quad (7)$$

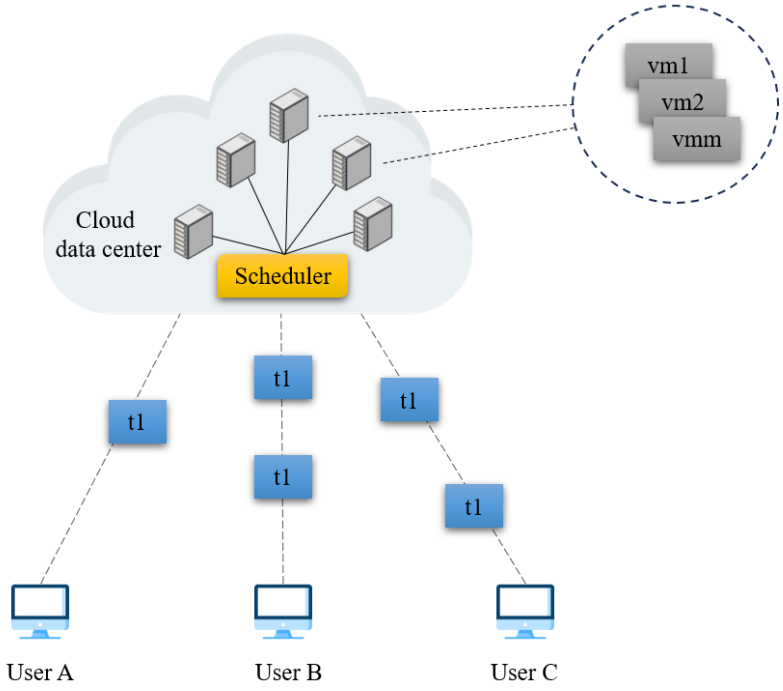

Fig. 1. Task scheduling process in cloud computing.

Throughout this study, makespan, completion time, and execution time are measured in seconds. Maximizing resource utilization during task scheduling is advantageous, ensuring a resource is fully utilized before allocating another instance on the cloud. Eq. (8) calculates the Average Resource Utilization (ARU) for PMs. This involves summing up the completion times of all VMs and dividing by the total number of VMs (m), followed by dividing the result by the makespan.

$$ARU = \left(\sum_{i=1}^{m} CT_{vm_j}/m\right)/makespan \quad (8)$$

System efficiency is further assessed through throughput, defined as the number of tasks processed per unit of time, calculated using Eq. (9). It is determined by dividing the total number of tasks by the makespan, resulting in a throughput value measured in terms of tasks accomplished per second.

$$Throughout = Total\ number\ of\ tasks /makespan \quad (9)$$

Additionally, Response Time (RT) is a key metric representing the duration between the scheduling decision and the initiation of task execution on a VM. Multiple VMs may operate on the identical PM, and a single VM may perform several tasks. Eq. (10) describes the mean response time for all tasks across multiple VMs. This calculation involves dividing the total initiation intervals for multiple tasks into the overall task count to determine the mean response time for each VM. The overall average response time is then obtained by averaging the response times across all VMs.

$$RT = \left(\sum_{j=1}^{m}\sum_{i=1}^{n} RT_i\right)/m \quad (10)$$

IV. PROPOSED METHOD

BOA mimics the foraging behavior of butterflies, driven by their sense of smell (olfaction). It aims to resemble how butterflies locate food sources (flowers) by navigating their environment using global and local search capabilities. In cloud computing and task scheduling, BOA facilitates allocating tasks to VMs by finding near-optimal solutions through iterative improvements. BOA is characterized by three central concepts: olfactory modality, global and local search, and scent intensity.

In BOA, butterflies are represented as solutions, and their sense of smell is modeled to guide their movement. Each butterfly (solution) is attracted to the most promising areas (best solutions), allowing for effective exploitation and exploration of the search area. The algorithm alternates between global search (exploration) and local search (exploitation). Global search occurs when butterflies move towards a global highest-quality solution. The solution space can thus be explored in new ways. Local search is triggered when butterflies move toward other butterflies nearby, allowing solutions to be fine-tuned.

The effectiveness of butterflies' movement depends on the intensity of the scent, which changes based on their position in the search space. The scent is calculated using fitness functions, which assess how effective a given solution is concerning the objective by cutting down makespan or optimizing resource utilization. The scent intensity S_i of each butterfly i is calculated using Eq. (11):

$$S_i = c.f_i^a \quad (11)$$

where c represents a sensory modality that affects scent strength, f_i^a stands for the fitness value of butterfly i, and a controls the nonlinearity of scent. The movement of a butterfly i towards a global best solution (global search) is given by:

$$x_i^{t+1} = x_i^t + r.S_g.(g^t - x_i^t) \quad (12)$$

Where x_i^t is the position of the butterfly i at iteration t, r stands for random number in the range [0, 1], S_g refers to the scent intensity of the best solution found so far (global best), and g^t specifies the global best position at iteration t. The movement of a butterfly towards another butterfly (local search) is represented as:

$$x_i^{t+1} = x_i^t + r.S_j.\left(x_j^t - x_i^t\right) \quad (13)$$

where S_j is the scent intensity of butterfly j, and x_j^t is its position at iteration t. The balance between global and local search is controlled using a probability parameter p. A random number $r \in [0,1]$ is compared to p to determine whether a butterfly moves towards the global best or another butterfly as follows:

- If $r<p$, the butterfly follows the global search strategy.
- If $r \geq p$, it engages in local search.

The task scheduling problem is treated as an optimization challenge in cloud computing. The objective is to reduce makespan, minimize energy consumption, and improve resource utilization by finding the best allocation of tasks to VMs. Each butterfly represents a potential solution, where:

- A solution is a specific mapping of tasks to VMs.
- The fitness of a solution is rated in terms of makespan, energy consumption, and other QoS metrics.

During each iteration, BOA adjusts butterflies' positions according to their scent intensities and the best solutions determined so far. Continuous iterations allow the algorithm to converge towards an optimal or near-optimal task allocation strategy.

The conventional BOA faces three primary challenges: (1) a fixed exploration-to-exploitation ratio controlled by the parameter p, leading to rigidity in the search process; (2) the possibility of being stuck in local optima due to a fixed global best attraction; and (3) pairwise interaction between butterflies, which limits search efficiency in complex optimization problems. The Fuzzy Butterfly Optimization Algorithm FBOA) overcomes these drawbacks by introducing (a virtual butterfly and fuzzy decision-making strategy. Fig. 2 compares conventional BOA and FBOA in terms of their exploration and exploitation strategies. FBOA integrates fuzzy logic to adjust the transition between these strategies.

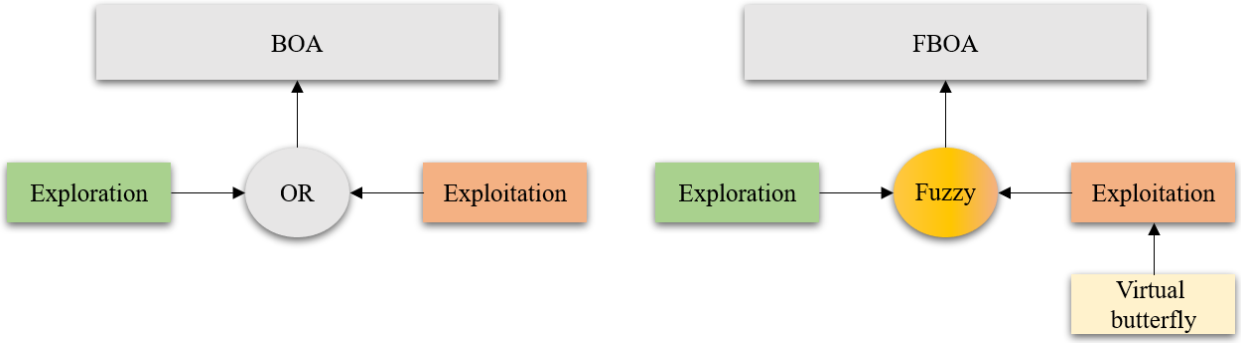

Fig. 2. Structure of BOA and FBOA.

To improve the adaptability of the BOA, FBOA employs a nine-rule fuzzy decision-making strategy. This strategy dynamically adjusts the tendency factor τi for each butterfly, which dictates its balance between exploitation and exploration based on the current optimization context. A novel concept called the virtual butterfly X^v is introduced, which serves as a guiding agent in navigation. Unlike the standard BOA's random pairwise interactions, the virtual butterfly uses the information from the best solutions and adjusts its direction based on the current problem's objective function. The Normalized Objective Function (NOF) is calculated to estimate the relative effectiveness of each butterfly's position:

$$NOF_i = \frac{f(X_i) - f(g^*)}{f(X^{worst}) - f(g^*) + \mu}, \quad i = 1,2,\dots,M \qquad (14)$$

Where $f(X_i)$ is the objective function value of the i^{th} butterfly, $f(g^*)$ is the fitness value of the current global best butterfly, $f(X^{worst})$ is the fitness value of the worst butterfly, μ is a small positive scalar to avoid division by zero, and M is the population size. The fuzzy decision system updates the tendency factor τi using the NOF and predefined fuzzy rules.

$$\tau_i = \omega_\tau + \Delta\tau_i \qquad (15)$$

where ω_τ indicates the origin of the tendency factor, $\Delta\tau_i$ is the adjustment value derived through the fuzzy inference process. Membership functions (as shown in Fig. 3) are used to categorize NOF into linguistic variables such as Small (S), Medium (M), and Large (L). The output values are adjusted based on the rules provided in Table I.

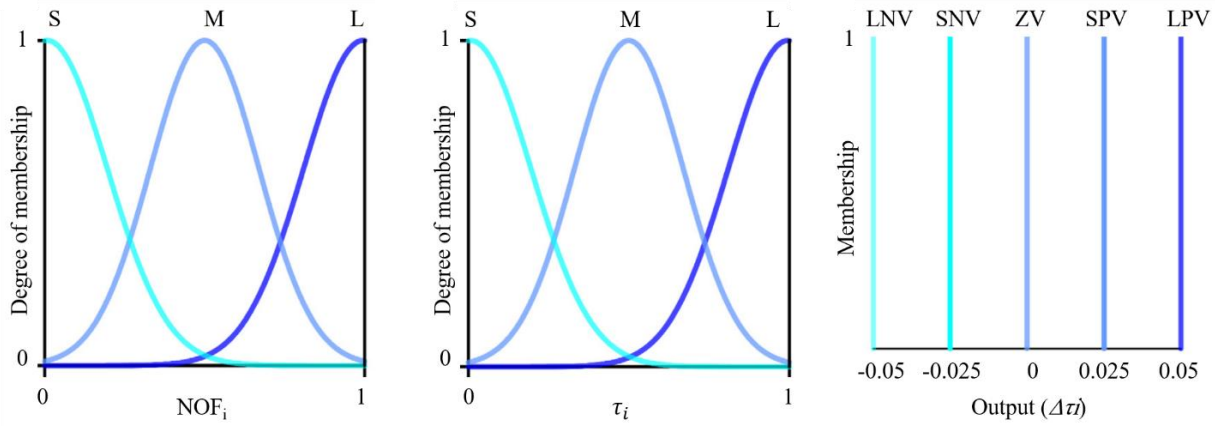

Fig. 3. Membership functions.

TABLE I. FUZZY RULES

Rules	Inputs		Output
	τi	NOF_i	
1	L	L	LNV
2	M	L	ZV
3	S	L	LPV
4	L	M	SNV
5	M	M	ZV
6	S	M	SPV
7	L	S	ZV
8	M	S	SPV
9	S	S	SNV

The updated movement rule in FBOA is formulated to incorporate the virtual butterfly and the fuzzy-adjusted tendency factor:

$$X_i^{t+1} = X_i^t + q.(\tau_i^2.g^* - X_i^t) + a.r.(\tau_i^2.X^v - X_i^t) \quad (16)$$

where g^* is the global best position, X^v is the position of the virtual butterfly, q is a random number in the range [0, 1], and α is the coefficient determining the impact of the virtual butterfly. The value of α is determined by the fitness comparison between X^v and X_i:

$$a=1 \quad if\, f(X^v) < f(X_i), \quad a = -1 \;\; if\; f(X^v) \geq f(X_i) \quad (17)$$

The virtual butterfly X^v aggregates information from the entire population using the weighted average of butterfly positions:

$$X^v = \sum_{i=1}^{M} X_i^v c_i^v \quad (18)$$

where c_i^v is a normalized weight defined as:

$$c_i^v = \frac{exp(\xi_i^v)}{\sum_{j=1}^{M} exp(\xi_j^v)} \quad (19)$$

ξ_i^v is the normalized fitness difference for butterfly i:

$$\xi_j^v = \frac{f(X_i^v) - f(X^{worst})}{f(X^{worst}) - f(g^*) + \mu} \quad (20)$$

FBOA addresses the task scheduling challenge in cloud computing environments by dynamically balancing exploration and exploitation through a fuzzy decision-making system. By adjusting the tendency factor for each butterfly using fuzzy logic, FBOA adapts its search behavior to optimize the allocation of tasks to VMs. This adaptability ensures that FBOA can efficiently handle the complex solution area of task scheduling, improving resource utilization, shortening makespan, and reducing energy usage. The integration of a virtual butterfly concept further enhances the algorithm's potential to overcome local optima, leading to more effective and balanced scheduling solutions. Through iterative adjustments, FBOA ensures that cloud resources are optimally allocated, providing better service quality and meeting the diverse demands of cloud users.

V. Performance Evaluation

The tests were performed on an Intel Core i5-12400 system featuring a 2.50 GHz processor and 16 GB of RAM. The effectiveness of the suggested FBOA was examined using the CloudSim 3.0.3 simulation toolkit and datasets from the Heterogeneous Computing Scheduling Problem (HCSP) and Google Cloud Jobs (GoCJ). The data center comprises a single entity equipped with 12000 MIPS processing capacity. It hosts three types of machines, each with varying cores, quad-core, hexa-core, and octa-core, and supports a memory range of 512 MB to 14436 MB. For the GoCJ dataset, the configuration includes ten VMs with MIPS capacities ranging from 400 to 12000 MIPS. For the HCSP instances, 32 VMs are distributed. This setup allows for a comprehensive analysis of task scheduling performance across diverse resource capacities and task complexities.

In cloud computing, makespan is a critical metric as it measures the total time required to complete all tasks on a set of VMs. A lower makespan indicates more efficient scheduling, allowing servers to process workloads quickly. As shown in Fig. 4, FBOA effectively minimizes makespan, particularly as the number of tasks increases, through its optimized task-to-VM mapping strategy. Compared with other methods such as Whale Optimization Algorithm (WOA) [23], Random Matrix Particle Swarm Optimization (RMPSO) [24], Security- and Energy-Aware (SAEA) [25], and Genetic Algorithm with MapReduce (GAMR) [26], FBOA demonstrates the smallest average increase in makespan (4.3%), illustrating its superior scalability in handling the rising number of tasks across 19 GoCJ instances. This makes FBOA highly suitable for dynamic cloud environments where workload demands fluctuate. For HCSP tasks, a similar trend was observed, with FBOA consistently achieving a reduced makespan across varying instances, as depicted in Fig. 5. This indicates that the algorithm adapts well to heterogeneous task categories, achieving efficient resource allocation.

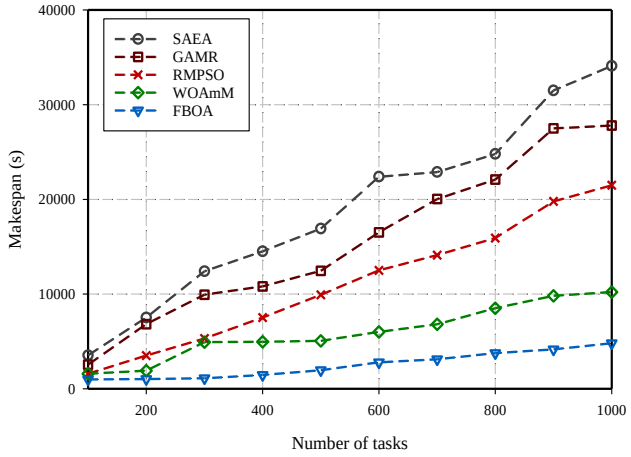

Fig. 4. Makespan for GoCJ dataset.

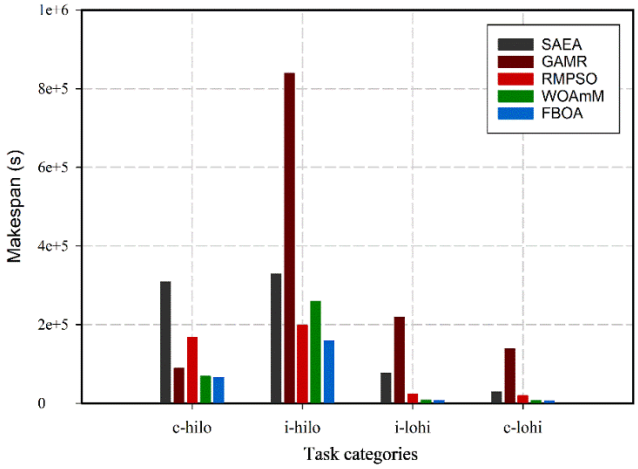

Fig. 5. Makespan for HCSP dataset.

Effective resource utilization ensures that the cloud infrastructure makes the most efficient use of available resources. FBOA achieved the best resource utilization over

other algorithms benchmarked, such as WOA, MRMPSO, and GAMR, as illustrated in Fig. 6 and Fig. 7. By dynamically adjusting its search mechanisms, FBOA efficiently managed VMs, reducing idle time and enhancing overall resource allocation. This is crucial in cloud environments where minimizing waste and optimizing VM usage can save significant costs. Among all methods, FBOA stood out for its ability to balance the workload, resulting in consistent resource usage, even with complex task distributions.

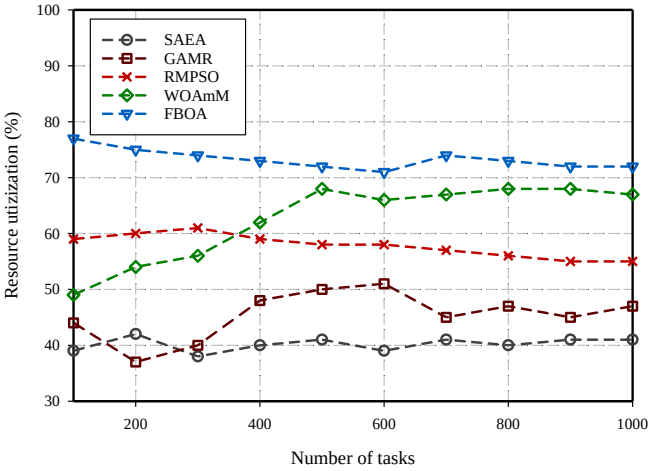

Fig. 6. Resource utilization for GoCJ dataset.

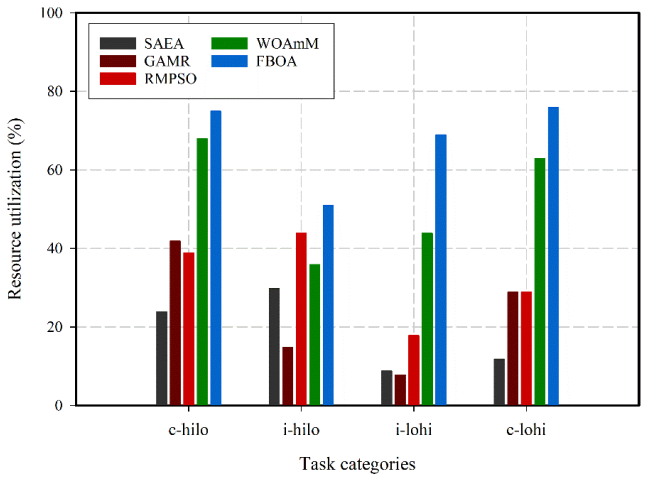

Fig. 7. Resource utilization for HCSP dataset.

Throughput, representing the number of tasks accomplished in a given period of time, serves as a measure of system efficiency. The results showed that FBOA achieved the highest throughput, which can be attributed to its parallel processing capabilities and refined task scheduling mechanism. Fig. 8 and Fig. 9 show a marked improvement in throughput for FBOA, especially when handling tasks with varying complexities. The enhanced throughput rates indicate that FBOA can efficiently manage large-scale task scheduling, making it well-suited for cloud infrastructures with fluctuating demands.

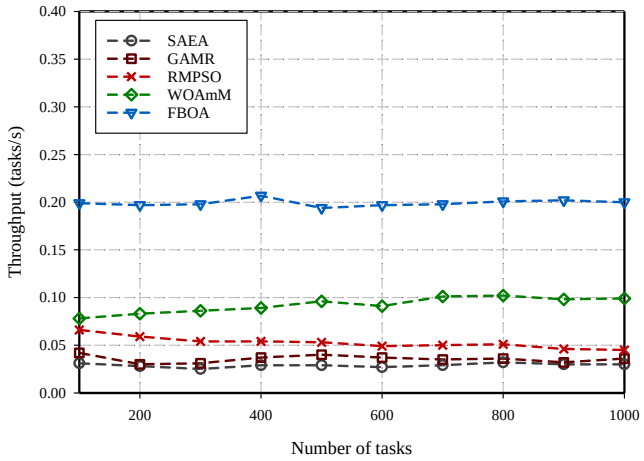

Fig. 8. Throughput utilization for GoCJ dataset.

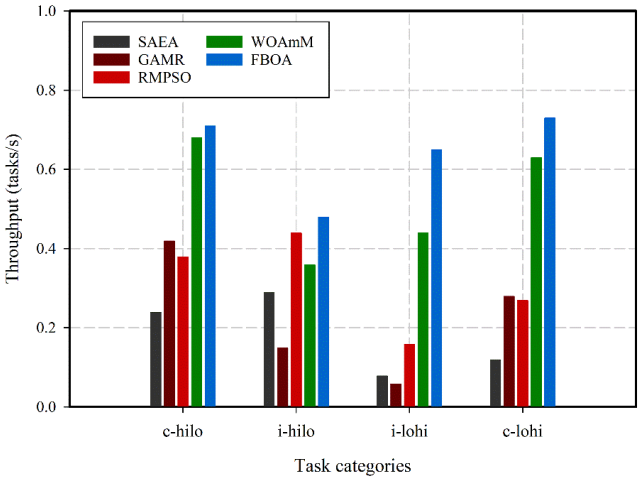

Fig. 9. Throughput utilization for HCSP dataset.

VI. Discussion

Compared to existing alternatives, the suggested FBOA significantly improves task scheduling problems. This success in the FBOA highlights the novelties achieved in coupling enhancements, a fuzzy decision strategy, and the idea of a virtual butterfly when overcoming deficiencies in BOA.

The fuzzy decision-making mechanism dynamically balances the phases of exploration and exploitation. Such adaptability allows the algorithm to cope with complex search spaces and prevent it from converging too early, guaranteeing robust optimization even for more complicated tasks. A proper example is that FBOA improves the makespan results on both GoCJ and HCSP datasets, proving that it can efficiently map tasks into VMs with good scalability.

The introduction of the concept of the virtual butterfly enables the central agent to gather and disseminate information in the swarm regarding the ongoing search process, orienting the same toward the most promising regions. This feature enhances

the solution quality and convergence rates, which is evident in the superior performance of FBOA in terms of the minimization of resource wastage and higher throughput value. FBOA maximizes the efficiency of a cloud environment since it ensures equal workload distribution and optimal utilization of resources.

These results hold important implications for cloud computing. With reduced makespan, improved resource utilization, and higher throughput, FBOA can contribute to creating efficient and scalable task scheduling solutions. For instance, such enhancements in makespan, resource utilization, and throughput shall enable service providers to reduce costs and improve user reliability, rendering cloud computing infrastructures more viable and competitive.

Furthermore, the adaptiveness of FBOA towards dynamic workloads and heterogeneous resources makes it likely to enable dynamic and real-time applications such as IoT ecosystems and high-performance computing. Therefore, contributions in this paper open new paths for further research in advanced cloud management intelligence and thus set a roadmap for optimizations in this rapidly changing field.

These benefits of FBOA are partially outweighed by several shortcomings. First, the virtual butterfly mechanism may lead to a significant increase in computation overhead in scenarios with extremely high heterogeneity among tasks or VMs. Further, this algorithm has only been experimented with in simulations with certain datasets. The real implementation could bring in unforeseen challenges, as scalability and adaptability may arise in infrastructures that are more dynamic or involve multi-clouds.

VII. Conclusion

In this study, we proposed FBOA to cope with the complexity of task allocation in cloud computing setups. By integrating fuzzy logic into the standard BOA, FBOA dynamically balanced exploration and exploitation, adapting to varying workload demands and resource availability. This adaptability ensured tasks were scheduled efficiently across VMs, minimizing makespan, reducing resource wastage, and improving overall system performance. The effectiveness of the proposed FBOA was validated through comprehensive simulations using the CloudSim toolkit, employing diverse datasets. The results demonstrated that FBOA consistently outperformed other metaheuristic algorithms such as WOA, RMPSO, MRMPSO, SAEA, and GAMR across critical metrics, including execution time, response time, throughput, resource utilization, and makespan. Notably, FBOA achieved lower increases in makespan, better resource allocation, and higher throughput, making it a robust and scalable solution for cloud environments. The superior performance of FBOA results from its ability to adjust the search behavior using a fuzzy decision-making mechanism and the introduction of the virtual butterfly concept, which helps avoid premature convergence and improves solution diversity. These features allow FBOA to effectively respond to the varying demands of cloud computing workloads, ensuring efficient resource use while meeting SLAs. Future research could explore further enhancements to FBOA, such as hybridizing it with other optimization techniques or applying it to emerging cloud paradigms like edge and fog computing to extend its applicability and effectiveness further.

***Abstract*—Bug fixing, which is known as Automatic Program Repair (APR), is a significant area of research in the software engineering field. It aims to develop techniques and algorithms to automatically fix bugs and generate fixing patches in the source code. Researchers focus on developing many APR algorithms to enhance software reliability and increase the productivity of developers. In this paper, a novel model for automated bug fixing has been developed leveraging large language models. The proposed model accepts the bug type and the buggy method as inputs and outputs the repaired version of the method. The model can localize the buggy lines, debug the source code, generate the correct patches, and insert them in the correct locations. To evaluate the proposed model, a new dataset which contains 53 Java source code files from four bug classes which are Program Anomaly, GUI, Test-Code and Performance has been presented. The proposed model successfully fixed 49 out of 53 codes using gpt-3.5-turbo and all 53 using gpt-4-0125-preview. The results are notable, with the model achieving accuracies of 92.45% and 100% with gpt-3.5-turbo and gpt-4-0125-preview, respectively. Additionally, the proposed model outperforms several state-of-the-art APR models as it fixes all 40 buggy programs in QuixBugs benchmark dataset.**

***Keywords*—Bug fixing; automated program repair; large language models; software debugging; software maintenance; machine learning**

I. Introduction

Automated Program Repair (APR) is considered one of the most ideal tasks in automated software engineering, with the potential to reduce the costs associated with software development and maintenance [32]. APR refers to the automated fixing of bugs or defects in the source code by a software tool [31]. It aims to minimize human intervention in the debugging process through the development and implementation of intelligent algorithms capable of automatically detecting and fixing errors in the source code.

Historically, APR techniques have relied on a variety of approaches, ranging from genetic algorithms [12-14] to symbolic execution [37], each with its strengths and limitations. However, the advent of Large Language Models (LLMs) in artificial intelligence has opened new directions for research and application in software engineering tasks [18, 33, 34], offering promising prospects for enhancing the accuracy, efficiency, and scope of automated bug fixes.

This paper introduces a novel model for APR that leverages the capabilities of two state-of-the-art LLMs, gpt-3.5-turbo and gpt-4-0125-preview, to automate the bug-fixing process across various bug types. The proposed model distinguishes itself by not only localizing bugs with high accuracy but also generating and inserting the correct patches into the source code. Accordingly, it significantly reduces the time and resources traditionally required for bug fixing, thereby accelerating the software development lifecycle, and enhancing developer productivity.

To validate the effectiveness of the proposed model, a new dataset consisting of 53 Java source code files, categorized into four distinct bug classes: Program Anomaly, GUI, Test-Code, and Performance was constructed. The performance of the proposed model was evaluated against this dataset to reveal its capability in bugs repair, with results indicating an impressive accuracy rate. These findings not only support the potential of integrating LLMs into the APR process but also open new directions for future research in the field.

The proposed model distinguishes itself from other APR models due to its ability to successfully debug code, localize buggy lines, generate correct patches, and insert them in the appropriate locations. It achieves this by only requiring the buggy code and the bug type, without needing additional user input, information about test cases, or prior knowledge of patch attempts. This makes it a more efficient, practical, and novel model.

The main contributions of this paper are as follows:

- Presenting a novelty in the use of gpt-4-0125-preview for APR: To the best of our knowledge, we present the first-of-its-kind model that leverages gpt-4-0125-preview for automated program repair, enabling the repair of multi-hunk and multi-fault bugs simultaneously. This significantly extends the capabilities of current APR models.
- Presenting a self-contained repair mechanism: Our approach does not rely on external test cases, prior patch knowledge, or feedback loops. Instead, it operates only with the buggy method and bug type, making it more efficient and less resource-intensive than traditional APR techniques.

- Illustrating an advanced fault localization: The proposed model identifies and fix buggy lines of code without requiring identification of a statement-level bug localization, reducing the manual effort typically needed in bug fixing.
- Building a new dataset: A new dataset comprising 53 Java programs across four bug categories: Program Anomaly, GUI, Test-Code, and Performance has been generated in this research.
- Presenting a comparison with state-of-the-art models: This paper has demonstrated that the proposed model not only achieves a higher bug fix rate than state-of-the-art APR models, but also it achieved this with fewer dependencies on external tools and inputs, making it a more scalable and practical solution for real-world use.

The rest of this paper is structured as follows: Section II outlines the motivation behind this research; Section III reviews existing literature on automated bug fixing algorithms; Section IV describes the proposed model; Section V details the experimental study; Section VI presents the experimental results; Section VII discusses the implications of these results; and Section VIII concludes the paper.

II. Motivation

To fix a bug in a software program, the location of the bug must first be identified. This includes the buggy class, the buggy method, and the buggy statement. Our previously proposed bug localization model [22] employs an information-retrieval-based approach to identify the buggy class and method within the class; however, it does not localize the buggy statement. On the other hand, spectrum-based fault localization (SBFL) can identify more precise locations, such as the buggy statement [19]. However, it requires a large number of passing and failing test cases with test oracles, which poses some limitations [19]. Furthermore, the performance of APR is influenced more by the quality of test cases than their quantity [19]. LLMs have shown significant improvements in software engineering, demonstrating exceptional performance in tasks such as code and document generation [6]. Consequently, this research proposes an automated bug fixing model that leverages a specific model of large language models, the gpt-4-0125-preview model. The main novelty in the proposed approach that it does not require test cases or oracles, nor does it require prior statement-level bug localization. It utilizes our previously proposed bug prediction model [23] to detect the bug type, identifies the buggy method via our localization model [22], and outputs the fixed version of the method, enhancing the accuracy of existing bug fixing models. The overall bug management system is presented in Fig. 1.

III. Related Work

Automated bug fixing, also known as automated program repair (APR), is a prominent research topic that has attracted significant interest from many researchers in the field. The literature includes many existing studies that present algorithms for automated bug repair. As illustrated in Fig. 2, these studies can be classified into four main categories: bug reports-based APR, constraint-based APR, search-based APR, and learning-based APR. More details about each category will be presented in the following paragraphs.

A. Bug reports-Based APR

Liu et al. [1] proposed R2Fix model for automatically generating bug-fixing patches using bug reports. Their model uses machine learning techniques, semantic patch generation techniques, and past fix patterns to automatic bug fixing. They evaluated their model for three bug types which are buffer overflows, null pointer bugs, and memory leaks. In the evaluation, they used three projects, the Linux kernel, Mozilla, and Apache. Their model generated 57 correct patches.

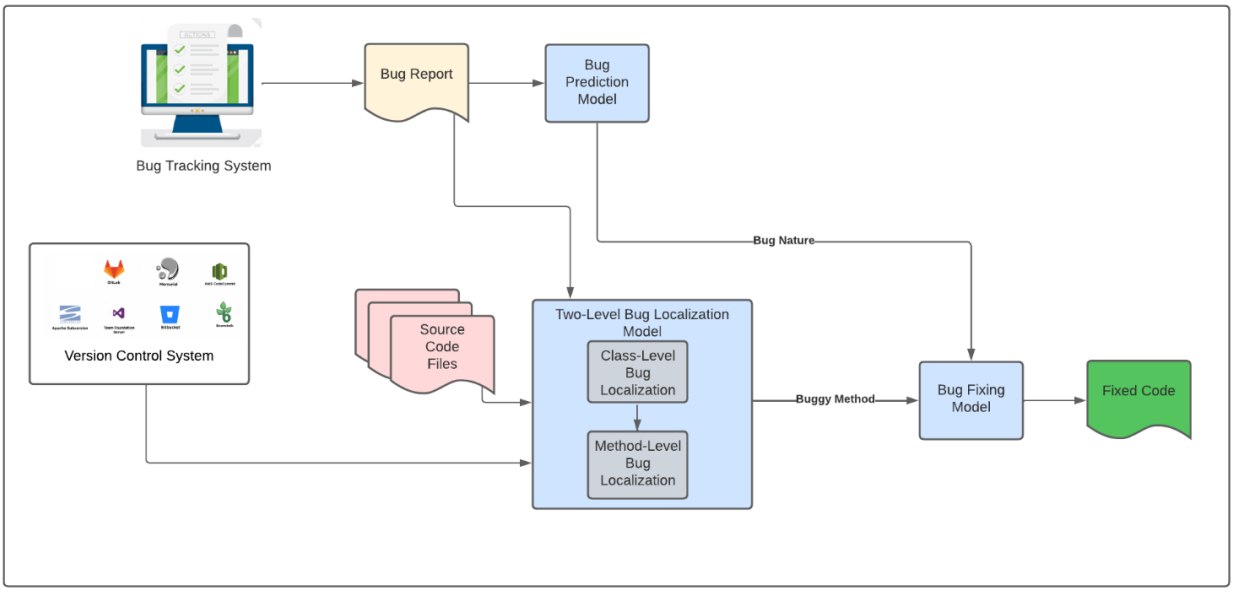

Fig. 1. Overall architecture of the bug management system.

Koyuncu et al. [2] proposed a novel model, namely iFixR, for bug localization and repair. In fact, their model is a bug repair system driven by bug reports. Their model uses bug reports as input. The main steps in their model are as follow: first, the bugs reports are fed to an information retrieval-based bug localizer; second, using fix pattern, patches are generated and validated by regression testing; third, patches are ordered by their priority for the developers. Their model did not have any assumption on the availability of test cases. To evaluate their model, they use and re-organize De-fects4J benchmark dataset and found that their proposed model can generate and recommend priority correct (and more plausible) patches for a wide range of issues reported by users.

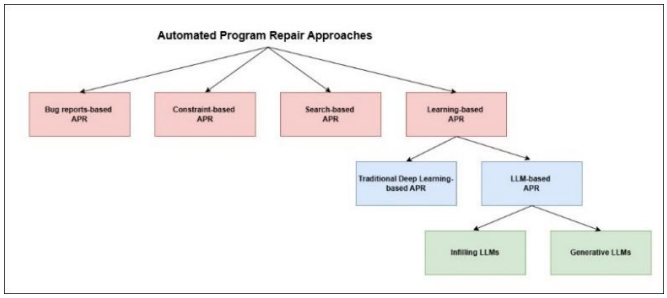

Fig. 2. Categories of existing APR approaches.

B. Constraint-Based APR

Constraint-based APR techniques use formal specifications and constraint solvers to transform the program repair problem into a constraint satisfaction problem. By focusing on expression-level variations and quickly pruning infeasible parts of the search space, these techniques can efficiently generate patches that satisfy the desired program behavior as specified by test cases or formal constraint [15].

Xuan et al. [3] proposed Nopol, a model for repairing faulty conditional statements, their model uses test cases as implicit program specifications. It generates patches by identifying expression-level changes that satisfy the constraints derived from the test cases.

Nguyen et al [4] introduced SemFix, a constraint-based method for APR, their method uses test cases to guide the patch synthesis process. The key features of SemFix include the use of symbolic execution and constraint solving to generate patches that ensure the program meets the desired behavior as specified by the test cases.

C. Search-Based APR

Goues et al. [14] presented GenProg, a generic and automated method for software repair, utilizing Genetic Programming to evolve and generate effective patches for a wide range of software defects. In the experiment, their method successfully fixed bugs in 16 programs written in C language which contain eight types of bugs. In their method, they presented three main novel ideas: Firstly, their method searches, in the program, at the statement level of the abstract syntax tree (AST). Secondly, to repair the bugs, their method does not introduce new code and uses only statements from the program. Lastly, genetic operators are localized to statements that are executed on the failing test case. However, their method does not support multi-hunk or multi-language program repair [15].

Yuan et al. [12] presented ARJA, a genetic programming-based approach for automated program repair in Java. ARJA suggests a new way of approaching automated program repair by treating it as a multi-objective optimization problem. They used a multi-objective optimization approach to minimize the weighted failure rate and patch size simultaneously, employing a multi-objective genetic algorithm (NSGA-II) to search for simpler repairs. The key innovation lies in designing a more detailed representation of patches, where the search spaces for likely-faulty locations, operation types, and ingredient statements are separated. This separation is intended to enhance the effectiveness of the genetic programming algorithm in finding appropriate solutions for fixing bugs in Java programs. The authors conducted a large-scale experimental study on both seeded and real-world bugs, demonstrating the effectiveness of ARJA in generating correct patches for a significant number of bugs compared to other repair approaches.

Yang et al. [13] presented a novel approach that uses similar bug fix information to automatic bug repair based on Genetic programming (GP). In their model, the candidate patches are generated by applying GP utilizing similar bug repair information. Then, the candidate patches are verified, by using a fitness function based on given test cases, if they are adoptable or not. Finally, the model generates the patch to fix the buggy code.

D. Learning-Based APR

Learning-based APR can be categorized further into two subcategories which are traditional deep learning-based APR, and Large Language Models-based (LLMs-based) APR.

1) Traditional deep learning-Based APR: Li et. al. [10] used deep learning algorithms in APR and proposed a two-level model, DLFix, which is based on deep learning algorithm that applies code transformation learning which learns from prior bug repairs and the surrounding code contexts of the fixes. The first tier contains an RNN model that is used to learn the context of bug fixes and the second tire uses the result from the previous tire as an additional weighting input learn the code transformations of the bug-fixing.

Lutellier et al. [16] presented a novel model, CoCoNuT, utilizes a new context-aware neural machine translation (NMT) architecture and an ensemble deep learning model which consists of combination of convolutional neural networks (CNNs) to automatically fix defects in multiple languages. The faulty source code and its surrounding context is separately represented using NMT. Their model utilizes CNNs in the hierarchical features extraction. However, their model cannot be used for multi-hunk bug fixing.

Huq et al. [17] proposed a novel sequence-to sequence model, Review4Repair, a deep learning-based approach that uses a neural machine translation (NMT) in APR. Their model uses the code review information to increase the performance of the automated bug fixing process.

DLFix, CoCoNuT, and Review4Repair all utilize context-aware strategies for patch generation and have the ability to fix multi-type bugs. However, all of them do not concern with the design of fault localization and work with the help of existing fault localization tools, and all do not have the capability of multi-hunk and multi-fault repair [15].

2) LLMs-Based APR: Recent advancements in large pre-trained LLMs offer a new direction for developing novel program repair models that do not rely on historical bug fixes [9]. Recently, some researchers proposed APR models based on LLMs. These models can be divided further into two sub-categories Infilling LLM-based APR, and Generative LLM-based APR.

Xia et al. [8] utilized CodeBERT [7], a pre-trained bimodal model designed for both programming languages (PL) and natural languages (NL), to propose a novel model for automated program repair (APR) called AlphaRepair. This model, which does not require retraining or fine-tuning on historical bug fixes datasets, represents the first cloze-style APR approach. Unlike traditional NMT tasks, AlphaRepair handles repair tasks as cloze tasks [15], aiming to predict the correct code based on its surrounding context [9]. Evaluation results showed that AlphaRepair can outperform state-of-the-art APR approaches. Mashhadi and H. Hemmati [20] presented a novel APR model which used CodeBERT [7] and fine-tuned it on ManySStuBs4J small and large datasets to generate fix patches for the buggy code. Evaluation results showed that their model can generate correct fixes in 19-72% of the cases.

Prenner & Robbes [21] presented a study which investigates the performance of Codex [11], a GPT language model that fine-tuned on GitHub code, in bug localization and fixing tasks. They used a dataset of 40 bugs in Java and Python and found that although Codex is not specifically trained for automated program repair task, it is effective for this task. Their observations also found that it is more effective at fixing Python bugs than Java bugs.

Xia and Zhang [5] presented ChatRepair, a conversational approach to automatically fixing bugs using ChatGPT. Their model takes as input relevant test failure information, enhancing bug-fixing capabilities of ChatGPT by learning from the failures and successes of previous patching attempts on the same bug. The model successfully fixed 162 out of 337 bugs from the Defects4j dataset.

Sobania et al. [18] presented an analysis of using ChatGPT for automated bug repair. In their study, they utilized 40 programs written in the Python programming language from the publicly available QuixBugs dataset to explore capabilities of ChatGPT in the bug fixing process. They found that providing ChatGPT with additional information (i.e., hints) about the bugs significantly improved its performance, resulting in a success rate that reached fixing 31 out of 40 bugs from the QuixBugs dataset. This performance outperforms several state-of-the-art APR models.

Despite the extensive development of various APR approaches, the field still faces significant challenges in improving the precision and generalizability of bug fixes across various programming environments. Existing models often rely heavily on extensive test suites, historical bug fixes, or detailed bug reports, which may not always be available or sufficiently comprehensive. Furthermore, many of these models struggle with complex bug fixes that require understanding detailed programming contexts or generating comprehensive patches. This paper aims to overcome some of current limitations by implementing a novel APR model that utilizes the advanced capabilities of LLMs such as gpt-3.5-trubo and gpt-4-0125-preview. Our approach reduces dependency on traditional inputs like test suites and historical fixes by directly interpreting the context of buggy code and generating appropriate fixes. By achieving this, the proposed model not only aims to enhance the accuracy and applicability of automated bug fixes but also to improve the repair process, making it more efficient and less reliant on extensive manual inputs. Thus, this paper aims to provide a foundation for future research in employing large language models to refine and expand automated repair algorithms.

IV. METHODOLOGY

This section illustrates the methodology that applied to develop the bug fixing model.

A. The Architecture of the Proposed Model

The architecture of the proposed model is illustrated in Fig. 3. This model takes the bug type and the buggy method as input and outputs the fixed version of the method. The bug types include Program Anomaly, GUI, Test-Code, and Performance. Program Anomaly bug refers to bugs in the source code files that occurs due to problems in the code [35] such as logical and syntax errors [28], GUI category refers to any bugs in the code that are related to the design of graphical user interface design or event handling [35], Test-Code bugs are occurs due to any problem which are related to the test code [35], while Performance bugs are related to the problem in the source code that are affect performance issues such as memory usage and memory leaks [35]. The two inputs are fed into the LLM using the prompt which is presented in the next subsection. In this research, two LLMs were tested to determine which one produces the highest accuracy in bug fixing for the generated dataset. These LLMs are gpt-3.5-turbo [24] and gpt-4-0125-preview [25]. As will be detailed in Section VI, gpt-4-0125-preview proved to be more accurate than gpt-3.5-turbo in terms of bug fixing and was therefore chosen for the proposed model.

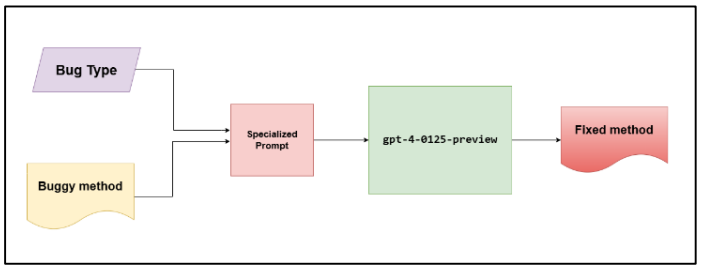

Fig. 3. High-level architecture of the proposed bug fixing model.

B. Large Language Models

LLMs are advanced deep learning algorithms capable of understanding, summarizing, translating, predicting, and generating content by leveraging large datasets [36]. In this research two LLMs from GPT family are used: the gpt-3.5-trubo model from GPT-3.5 and gpt-4-0125-preview model from GPT-4.

gpt-3.5-turbo [24]: is a variant of the GPT-3.5 language model. It is designed for enhanced performance and efficiency. This model is a group of models that improves upon GPT-3.5, enhances the ability to understand and generate both natural language and code.

gpt-4-0125-preview [25]: is a variant of the GPT-4 model. It is designed to give users a preview of the capabilities of the GPT-4 architecture. gpt-4-0125-preview performs tasks such as code generation more thoroughly than previous preview models. Additionally, this model is intended to reduce instances of "laziness" where the model does not fully complete a task [30].

C. Prompt Engineering

Models based on GPT utilize the paradigm of learning through prompts [26]. A prompt can be defined as a set of instructions that are given to the LLM, such as gpt-4-0125-preview, that program it by customizing it and/or improving or refining its capabilities [26]. Additionally, it is used to instruct the LLM to automate process or enforce rules [27]. Prompt engineering involves crafting clear, specific, and bias-mitigated prompts to guide the behaviour and output of AI models like GPT. It requires defining tasks, providing examples, and iterating on prompt design based on feedback to optimize results. Domain-specific knowledge may be necessary, and evaluation metrics help evaluate the effectiveness of the designed prompt.

The main contribution of this work lies in the application of LLMs for APR, and prompt engineering is an essential part of this process. The design of the prompt significantly influences the performance of the utilized LLM [6]. In the proposed model, the prompt is structured to instruct the LLM to accurately fix a buggy method. This prompt explicitly informs the LLM of the buggy method and categorizes the bug type. In the proposed model for automated bug fixing, a specific prompt template is utilized to guide LLMs, like gpt-3.5-turbo and gpt-4-0125-preview, to generate fixed versions of buggy Java methods. The template consists of several components: an objective statement, a placeholder for the incorrect Java function ({buggy_function}), and a detailed reason description placeholder ({reason_description}) that provides context about the type of bug, including categories such as GUI, Program Anomaly, Test-Code, and Performance. This context helps the model to better understand the issue and generate an appropriate fix. The template is structured as follows:

- **Objective Statement**: "Your goal is to correct the given Java function. The function will have a Javadoc that describes the function's purpose, parameters, and return value."
- **Function Placeholder**: {buggy_function}, which includes the buggy method which may has a Javadoc. The proposed model works effectively regardless of whether the method includes a Javadoc description.
- **Reason Description Placeholder:** {reason_description}, which explains the specific bug type, such as GUI issues related to layout problems or program anomaly involving logical errors.

The final prompt ends with "The correct Java function is:" prompting the model to generate the fixed function based on the provided details. This structured approach helps in automating the repair of code by leveraging the advanced capabilities of LLMs, thus enhancing the accuracy and efficiency of APR without requiring additional user input or test cases. This template plays a critical rule in achieving high accuracy rates in bug fixing, as demonstrated in the experiments conducted in this study.

V. Experimental Details

This section outlines the experimental setup and describes the implementation of the proposed bug fixing model. The experiments were conducted on a computer equipped with an x64 Intel® Core™ i7-10510U CPU @ 1.80GHz and 16.0 GB of RAM, running a 64-bit Windows Operating System. The model was developed using the Python programming language on Google Colab.

A. Dataset

To demonstrate the effectiveness of the proposed model, it is evaluated through two experiments. The first experiment involves evaluating of the proposed model using a new dataset. While in the second experiment, the proposed model is evaluated using a publicly available dataset to compare its performance against several state-of-the-art APR models.

1) Data collection and labeling: There are many reasons behind generating a new dataset in our research. First, there is no available dataset that contains source code files labeled in the same bug categories that are predicted by our bug prediction model. Secondly, we want to accurately evaluate our proposed model in a way that avoids information leakage from an existing dataset that might have already been seen by the LLM.

The presented dataset contains 53 Java source code files. These source code files were classified into four categories: Program Anomaly, GUI, Test-Code, and Performance. The Program Anomaly category contains bugs in the source code that occur due to logical and syntax errors. The GUI category refers to any bugs related to the design of graphical user interfaces or event handling. Test-Code bugs occur due to problems related to the test code. Performance bugs are related to issues in the source code that affect performance, such as memory usage, memory leaks, and missed performance improvements. The source code snippets used in this study were generated or collected from various sources available online. This involved identifying, collecting, and inspecting code snippets that contained bugs. The primary focus was on extracting examples that clearly demonstrated typical software

defects across different categories. These sources included open-source projects, coding forums, and educational resources. To ensure the quality and relevance of the dataset, each code snippet was carefully reviewed and categorized into one of the four main bug types mentioned above. This labeling process involved a detailed examination of each code snippet to identify the specific type of bug it represented. For instance, snippets involving inefficient coding practices or resource management issues were labeled as Performance Bugs, while those affecting the visual or functional aspects of the user interface were categorized as GUI Bugs. Similarly, errors within the test cases themselves were classified as Test-Code Bugs, and various coding errors leading to abnormal behavior or crashes were labeled as Program Anomaly Bugs.

This collaborative effort in data collection and labeling ensured a comprehensive and well-organized dataset, providing a solid foundation for analyzing common patterns and implications of different bug types in software engineering. Table I shows the number of Java source code files in each category. The Program Anomaly category contains 22 Java source code files, the GUI category contains 10 Java source code files, the Test-Code category includes 10 Java source code files, and the Performance category includes 11 Java source code files.

2) Analysis of the generated the dataset: The generated dataset consists of faulty source code files categorized into four main bug types: Performance, GUI, Test-Code, and Program Anomaly. Each category has distinct characteristics and common issues that are significant in understanding software bugs. A detailed analysis is presented for each bug type, their common patterns, and their effects in the following subsections.

a) Performance bugs: Performance bugs are mostly related to inefficient coding practices that reduce the runtime performance of applications. In the generated dataset, common issues include:

- **Inefficient String Operations:** Examples include using += in loops for string concatenation and creating new String objects unnecessarily.
- **Resource Management Issues**: Such as memory leaks from not clearing lists and inefficient use of wrapper classes leading to unnecessary boxing.
- **Control Flow Issues:** Infinite loops and concurrent modification exceptions which can cause applications to hang or crash.
- **Recursion Problems**: Recursive methods without proper termination can lead to stack overflow errors.
- **Other Issues:** Incorrect access patterns that can severely impact performance.

Effects: Performance bugs can cause significant degradation in application efficiency, leading to higher resource consumption and potential application failure. Identifying and optimizing these areas is crucial for enhancing software performance.

b) GUI Bugs: GUI bugs affect the usability and visual consistency of the application interface. Common GUI issues in the generated dataset include:

- **Visibility and Layout Problems:** Issues such as frames not being visible when they should be, incorrect component placements, and duplicate buttons in layouts.
- **Event Handling and Updates:** Bugs like missing initialization of components leading to null pointer exceptions, and incomplete status bar updates.
- **Drawing and Redrawing Inefficiencies**: Inefficient methods for redrawing components and missing drawing code.

Effects: GUI bugs can lead to poor user experience by making the interface confusing or non-functional. Proper testing and validation of the user interface components are essential to ensure smooth user interaction.

c) Test-Code Bugs

Test-Code bugs are errors within the test cases themselves which reduce the reliability of testing. Common issues in the generated dataset include:

- **Duplicate and Incorrect Test Methods:** Duplicate methods and logical errors in the methods being tested.
- **Uninitialized Variables:** Leading to compilation errors or incorrect test execution.
- **Incorrect Assertions:** Logical errors in assertions which lead to incorrect test outcomes.

Effects: Bugs in test code can lead to false positives or negatives, giving a misleading picture of the software quality. Ensuring the correctness of test code is as important as the application code itself.

d) Program anomaly bugs: Program Anomaly bugs involve a wide range of coding errors that result in abnormal behaviour or crashes. Common issues include:

- **Programming Errors:** Syntax errors and logical errors.
- **Control Flow Issues:** Infinite loops and incorrect loop conditions leading to unexpected behaviour.
- **Null Pointer and Type Safety Issues:** Potential null pointer exceptions and type mismatches.
- **Algorithmic and Recursive Errors:** Issues in algorithm implementation causing incorrect results or infinite recursion.

Effects: Program Anomaly bugs are critical as they often lead to crashes or incorrect program behaviour, significantly affecting the reliability and correctness of the software code. Comprehensive code review and rigorous testing are necessary to detect and fix these issues.

TABLE I. STATISTICS OF THE GENERATED DATASET

Bug Type Category	Total Number of Java Source Code Files in the category
GUI	10
Program Anomaly	22
Test-Code	10
Performance	11

3) QuixBugs benchmark dataset: The second experiment evaluates the proposed model using a publicly available benchmark dataset, QuixBugs[40], a collection of programs, each containing a specific bug, designed to test and evaluate the effectiveness of APR tools. The dataset includes 40 distinct algorithmic problems, such as sorting, graph traversal, and dynamic programming, implemented in both Java and Python. By providing a standardized set of challenges, QuixBugs allows researchers to consistently compare the performance of different APR methods. This dataset is widely used in academic research to advance the field of automated bug fixing. In the experiment, we use source code files written in Java only.

B. Evaluation Metrics

To evaluate the performance of the proposed model, the following evaluation metrics have been used.

- **Number of Repaired Defects**: It counts the defects which were successfully fixed by the repair algorithm. This metric is useful for demonstrating the capability of the algorithm. The diversity of defect classes in benchmark programs are crucial for the accuracy of this metric [29].
- **Repaired Defect Class:** Identifies specific classes of defects that the repair algorithm can successfully address. This helps in understanding the scope and specialization of the repair algorithm [29].
- **Success Rate (%):** The Success Rate of an automated program repair algorithm is quantitatively defined as the percentage of buggy programs that were successfully repaired by the algorithm out of the total number of buggy programs subjected to repair attempts. It is calculated using the Formula (1).

$$Success\ Rate\ (\%) = \left(\frac{Total\ Number\ of\ Successfully\ Fixed\ Programs}{Total\ Number\ of\ Buggy\ Programs}\right) \times 100 \quad (1)$$

VI. RESULTS

This section shows the results of the two experiments of the proposed bug fixing model on the generated dataset and on the benchmark, QuixBugs, dataset.

A. Results of the Proposed Model on the Generated Dataset

In the first experiment, the investigation of the achieved results by the proposed model explored the effectiveness of leveraging advanced language models, gpt-3.5- turbo and gpt-4-0125-preview, in automatically identifying and fixing bugs in software code. The analysis was structured around four main categories of bugs: GUI, Program Anomaly, Test-Code, and Performance. Table II shows the effectiveness of the proposed model in accurately repairing code from the used dataset.

The performance of the proposed model was evaluated based on its ability to correctly identify and fix these bugs. The proposed model can effectively localize the buggy lines, generate the correct patches, and insert them in the correct locations. The total accuracy of the proposed models (Success Rate) was calculated as follows: For the gpt-3.5-turbo model, the accuracy was 92.45%, while the gpt-4-0125-preview model achieved an accuracy of 100%. Fig. 4 shows an overview of the bug fixing results achieved by the proposed model.

TABLE II. RESULTS OF THE PROPOSED BUG FIXING MODEL

Bug Type	Correct Fixes by the Proposed Model (leveraging gpt-3.5-turbo)	Correct Fixes by the Proposed Model (leveraging gpt-4-0125-preview)
GUI	10 out of 10 (100%)	10 out of 10 (100%)
Program Anomaly	21 out of 22 (95.45%)	22 out of 22 (100%)
Test-Code	10 out of 10 (100%)	10 out of 10 (100%)
Performance	8 out of 11 (72.73%)	11 out of 11 (100%)
Total Fixes (Success Rate)	49 out of 53 (92.45%)	53 Out of 53 (100%)

B. Results of the Proposed Model on the QuixBugs Dataset

The proposed model that leverages gpt-4-0125-preview model has been evaluated using QuixBugs dataset. In more detail, the model achieved significant success, effectively repairing all 40 programs. This assessment covered a range of algorithmic problems, such as sorting, graph traversal, and dynamic programming. Utilizing advanced language model, gpt-4-0125-preview, our proposed APR model accurately detected and fixed bugs, demonstrating its robustness and efficiency.

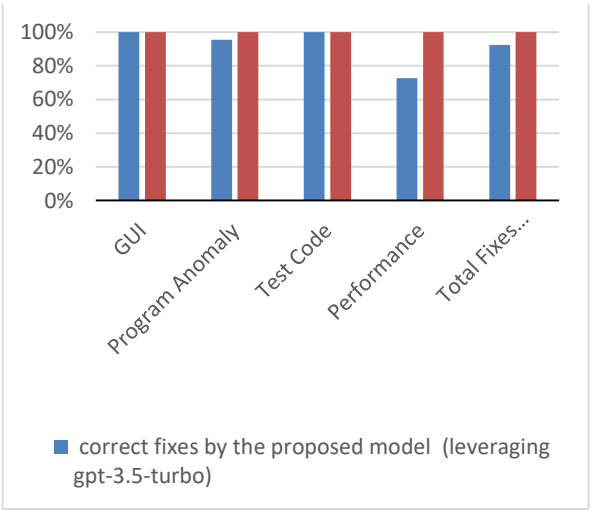

Fig. 4. An overview of the bug-fixing results achieved by the proposed model on the generated dataset.

VII. Analysis and Discussion

This section presents a comprehensive analysis and discussion of the results achieved by the proposed bug-fixing model in both experiments. Additionally, in this section, we answer the following research questions that address the improvements made by the proposed model in APR field.

- **Research Question 1**: What is the effect of different LLMs on the proposed bug fixing model on fixing different categories of programming bugs?
- **Research Question 2:** How does the proposed bug fixing model compare to several state-of-the-art APR models?
- **Research Question 3**: What are the practical improvements of integrating LLMs into the software development lifecycle for bug fixing?

A. Discussion of the First Experiment

To answer the first research question, we analyze the results of the first experiment.

Research Question 1: What is the effect of different LLMs on the proposed bug fixing model on fixing different categories of programming bugs?

Observations: Overall, the proposed model which leverages gpt-4-0125-preview demonstrates a 100% success rate, correctly fixing all 53 buggy source code files in the dataset. In contrast, the proposed model which leverages gpt-3.5-turbo achieves a 92.45% accuracy, successfully repairing 49 out of 53 buggy source code files. In the Program Anomaly category, the proposed model that leverages gpt-3.5-turbo fixed 21 out of 22 buggy source code files, while the proposed model that leverages gpt-4-0125-preview fixed all 22. The slight improvement with the latter model might be attributed to enhanced understanding or processing capabilities of gpt-4-0125-preview, possibly due to larger training data or improved algorithms. The most notable difference is observed in the performance category, where the proposed model that leverages gpt-3.5-turbo fixed 8 out of 11 bugs, whereas the proposed model that leverages gpt-4-0125-preview fixed all 11. This improvement may reflect advancements in the ability of gpt-4-0125-preview model to understand and optimize code for performance, a complex task that often requires deep under-standing and nuanced changes. Both models perform equally well in fixing GUI and Test-Code bugs, achieving a 100% success rate. This indicates robust capabilities in addressing issues within these specific categories, suggesting that the models have effectively learned patterns or solutions relevant to these types of bugs. Fig. 5 shows a buggy method in the dataset which is from GUI category. Fig. 6 and Fig. 7 show the fixed versions of this method using the proposed model (leveraging gpt-3.5-turbo model and gpt-4-0125-Preview model, respectively).

From this example, it is clear that both proposed models aim to address the issues found in the original code of the buggy method, but they do so with different ways. The buggy method has a bug in the loop that results in displaying incorrect keypad layout (i.e. it displays numbers from 1 to 12 instead of numbers from 1 to 9).

```
/**
 * This method  for GUI that resembles a telephone keypad.
 *
 *
 */

public void telephone() {
   JFrame frame = new JFrame();
   frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
   frame.setSize(new Dimension(250, 200));
   frame.setTitle("Telephone");

   frame.setLayout(new BorderLayout());

   // main phone buttons
   JPanel centerPanel = new JPanel(new GridLayout(4, 3));
   for (int i = 1; i <= 12; i++) {
   centerPanel.add(new JButton("" + i));
   }
   centerPanel.add(new JButton("0"));
   centerPanel.add(new JButton("0"));
   centerPanel.add(new JButton("0"));
   frame.add(centerPanel, BorderLayout.CENTER);

   // south status panel
   JPanel southPanel = new JPanel(new FlowLayout());
   southPanel.add(new JLabel("Number to dial: "));
   southPanel.add(new JTextField(10));
   frame.add(southPanel, BorderLayout.SOUTH);
  frame.setVisible(true);
   }
```

Fig. 5. Buggy method from GUI category.

```
/**
 * This method creates a GUI that resembles a telephone keypad.
 *
 * @param none
 * @return void
 */
public void createTelephoneGUI() {
    JFrame frame = new JFrame();
    frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    frame.setSize(new Dimension(250, 200));
    frame.setTitle("Telephone");

    frame.setLayout(new BorderLayout());

    // main phone buttons
    JPanel centerPanel = new JPanel(new GridLayout(4, 3));
    for (int i = 1; i <= 9; i++) {
        centerPanel.add(new JButton("" + i));
    }
    centerPanel.add(new JButton("0"));
    centerPanel.add(new JButton("*"));
    centerPanel.add(new JButton("#"));
    frame.add(centerPanel, BorderLayout.CENTER);

    // south status panel
    JPanel southPanel = new JPanel(new FlowLayout());
    southPanel.add(new JLabel("Number to dial: "));
    southPanel.add(new JTextField(10));
    frame.add(southPanel, BorderLayout.SOUTH);

    frame.setVisible(true);
}
```

Fig. 6. Fixed method from GUI using the proposed model (leveraging gpt-3.5-turbo model).

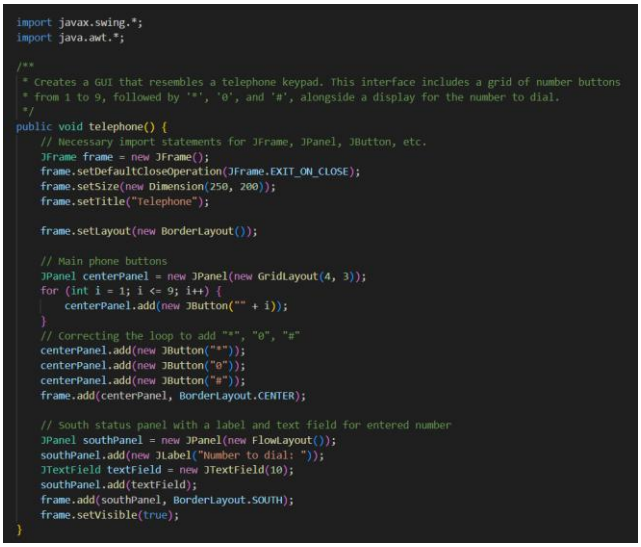

Fig. 7. Fixed method from GUI using the proposed model (leveraging gpt-4-0125-preview model).

Additionally, it incorrectly adds three "0" buttons instead of the conventional "*", "0", and "#" buttons found on a telephone keypad. Fig. 6 shows that the proposed model that leverages gpt-3.5-turbo model modifies the name of method to create TelephoneGUI, aligning with Java naming conventions by clearly describing the action performed by the method. This change emphasizes the importance of readability and maintainability in code. Additionally, it fixes the keypad layout to include "1" through "9", followed by "0", "*", and "#". Although the bug in the telephone keypad GUI has been successfully resolved, the arrangement of the buttons on the bottom row remains incorrect. The expected order of the buttons is * 0 #; however, the current implementation places them in the order 0 * #. Additionally, this model lacks the inclusion of import statements necessary for a standalone application, assuming prior context or placement within a larger source code. This approach addresses the discovered bugs and improves the naming of the method for better clarity. However, it fails to make the code independently usable by omitting necessary import statements. Fig. 7 shows the fixing code of the same buggy method using the proposed model that leverages gpt-4-0125-preview model which offers a comprehensive repairing by not only fixing the keypad layout but also adding essential import statements and a javadoc comment at the beginning of the method. This fixing assumes no prior context, aiming to make the code snippet independently compliable and understandable. The fixed version of the code follows best practices by including a detailed method description and fixing the keypad issue, which matches the standard layout of a telephone keypad. This model provides a more thorough fixing by ensuring that the code is both correct and self-sufficient. It addresses not only the initial logical issues but also enhances the readability and reusability of the code by adding documentation and necessary technical details for compilation.

Another example of bug fixing ability of the proposed model can be illustrated by Fig. 8-10. Fig. 8 presents a buggy code from the Test-Code category. The original buggy code presents a simple divide method intended to perform division operations while handling a potential division-by-zero error through an exception. However, the accompanying test cases contain several issues: incorrect assertions that do not match the expected outcomes of the division operation, duplication of test method names (which is not allowed in Java), and lack of a test case to explicitly check for the division by zero scenario.

Fig. 9 and Fig. 10 present the fixed versions of the buggy code by the proposed model in the two experiments, the first one when proposed fixing model leveraging gpt-3.5-turbo model and the second one when the proposed fixing model leveraging gpt-4-0125-preview model. Both models address the core issues in the original code, but they do so with varying levels of detail and adherence to best practices in software testing and documentation. Fig. 9 shows that leveraging gpt-3.5-turbo model in the proposed model fixes the logical bugs in the test cases and suggests a structured approach to handle different test scenarios, including dividing by zero. It provides clear, separate test methods with descriptive names that reflect their purpose: one for a successful division operation and another for testing division by zero. Improves readability and maintenance of the test suite by clearly separating test cases. Additionally, it correctly identifies the need for and implements a test case for division by zero, enhancing the robustness of the tests. However, in comparison with Fig. 10, the fixing is somewhat basic and does not explicitly address best practices in exception handling within test methods (e.g., using the expected annotation attribute).

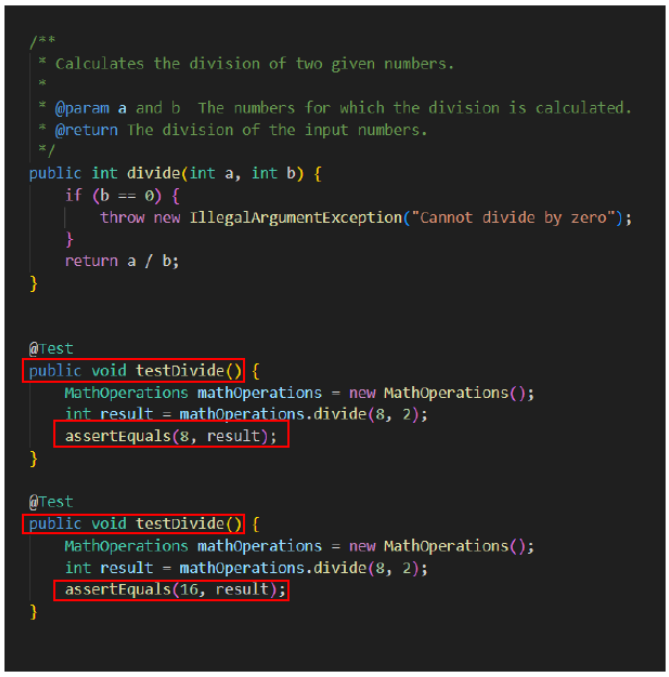

Fig. 8. Buggy code from Test-Code category.

Fig. 10 shows that leveraging gpt-4-0125-preview model in the proposed model offers a comprehensive fixing by not only repairing the test cases but also refining the testing approach to align with best practices. It fixes the bugs,

addresses method name duplication, and includes a detailed approach to testing exceptions using the expected attribute of the *@Test* annotation. This enhances the readability and maintainability of the test suite by demonstrating advanced testing techniques. However, the fixing assumes familiarity with the expected attribute for testing exceptions, which may require additional context for less experienced Java developers.

```java
/**
 * Calculates the division of two given numbers.
 *
 * @param a The numerator of the division.
 * @param b The denominator of the division.
 * @return The division of the input numbers.
 * @throws IllegalArgumentException if the denominator is zero.
 */
public int divide(int a, int b) {
    if (b == 0) {
        throw new IllegalArgumentException("Cannot divide by zero");
    }
    return a / b;
}

@Test
public void testDivide() {
    MathOperations mathOperations = new MathOperations();
    int result = mathOperations.divide(8, 2);
    assertEquals(4, result);
}

@Test
public void testDivideByZero() {
    MathOperations mathOperations = new MathOperations();
    assertThrows(IllegalArgumentException.class, () -> {
        mathOperations.divide(8, 0);
    });
}
```

Fig. 9. Fixed code from Test-Code category using the proposed model (leveraging gpt-3.5-turbo model).

```java
import static org.junit.Assert.assertEquals;
import org.junit.Test;

public class MathOperationsTest {

    /**
     * Calculates the division of two given numbers.
     *
     * @param a The dividend.
     * @param b The divisor.
     * @return The quotient from dividing a by b.
     */
    public int divide(int a, int b) {
        if (b == 0) {
            throw new IllegalArgumentException("Cannot divide by zero");
        }
        return a / b;
    }

    @Test
    public void testDivide_SuccessfulDivision() {
        MathOperations mathOperations = new MathOperations();
        int result = mathOperations.divide(8, 2);
        assertEquals(4, result); // Correcting the expected result to match 8 divided by 2.
    }

    // Example of how to test for division by zero scenario, if needed.
    @Test(expected = IllegalArgumentException.class)
    public void testDivisionByZero_ThrowsException() {
        MathOperations mathOperations = new MathOperations();
        mathOperations.divide(8, 0); // This should throw an IllegalArgumentException.
    }
}
```

Fig. 10. Fixed code from Test-Code category using the proposed model (leveraging gpt-4-0125-preview model).

The overall evaluation results provide a high-level view of the effectiveness of each model in the experiment in automated program repair. The best score achieved by the proposed model that leverages gpt-4-0125-preview is particularly significant, suggesting a notable advancement in the capability of the proposed model in understanding and fixing a wide range of software bugs.

The difference in accuracy between the two models (92.45% for the model leveraging gpt-3.5-turbo vs. 100% for the model leveraging gpt-4-0125-preview) could be attributed to several factors inherent to the evolution of generative pre-trained transformer models, such as increased model size, more diverse and extensive training data, or refined training techniques that improve understanding and generation capabilities.

B. *Discussion of the Second Experiment*

To answer the second research question, we analyze the results of the second experiment.

Research Question 2: How does the proposed bug fixing model compare to several state-of-the-art APR models?

Observations: To indicate the effectiveness of the proposed model, a comparison with the performance of several state-of-the-art APR models using the same dataset is crucial. Therefore, the achieved results of the proposed model on the QuixBugs dataset are compared to four studies which are:

- The results of the study presented by authors in the paper [39], involve an empirical study on automated bug repair using QuixBugs benchmark dataset.
- AlphaRepair [8] represents the first cloze-style APR approach, and it handles repair tasks as cloze tasks to predict the correct code based on its surrounding context.
- CoCoNut [16] which utilizes a new context-aware neural machine translation architecture and an ensemble deep learning model to fix buggy code.
- CURE [38] which is a novel APR tool that focuses on resolving software bugs through a sophisticated, context-aware neural machine translation (NMT) approach. Its main goal is to enhance the accuracy and effectiveness of bug fixes by utilizing detailed contextual information and robust neural network models. This allows CURE to generate more accurate patches by understanding not only the buggy code but also the surrounding context, significantly improving the quality and reliability of the fixes.

Table III illustrates the total number of QuixBugs programs out of 40 that are correctly fixed by the mentioned state of the art APR models and our proposed bug fixing model which leverages gpt-4-0125-preview model.

TABLE III. COMPARISON BETWEEN SEVERAL APR ON QUIXBUGS DATASET

Reference	Total Number of Correctly Fixed Programs	Success Rate
Ye et al. [39]	16 out of 40	40%
AlphaRepair [8]	28 out of 40	70%
CoCoNut [16]	13 out of 40	32.5%
CURE [38]	26 out of 40	65%
The Proposed Model	**40 out of 40**	**100%**

As observed from this table, our proposed model achieves the best results, successfully fixing all buggy programs in the dataset. Additionally, our proposed model does not need additional information about test cases, previous knowledge of patch attempts, nor additional follow up conversations which make it more efficient, practical and has its own novelty among other APR models as it only needs the buggy code and the bug type to debug the code, localized the buggy lines, generate the correct patches, and insert them in the right locations. Therefore, our proposed model outperforms all these state-of-the art APR models.

Furthermore, it was observed from this experiment that the proposed model not only fixed the identified bug, but also effectively enhanced the code by addressing the edge cases, aligning with Java naming conventions, and following better programming practices. In more details, Fig. 11 and Fig. 12 show the buggy version of TO_BASE.java program of QuixBugs dataset and its fixed version by the proposed model. Fig. 11 shows the buggy version of this program. The purpose of this Java program is to convert a given integer (num) into a string representation of that number in a specified base (b). The base can range from 2 to 36, allowing for conversion to binary, octal, decimal, hexadecimal, and other bases up to base 36, which includes digits 0-9 and letters A-Z. The main bug in this program is related to how the result string is constructed. In more detail, the code appends each new digit to the end of the result string, which results in the digits being in reverse order. Furthermore, there is no handling for the edge case where the input number is zero. From Fig. 12, the improvements made by the proposed model can be observed, which are:

- It fixes the bug; the fixed method reverses the resulting string ensuring the digits are in the correct order.
- It adds base validation; the fixed method includes a validation check to ensure the base is between 2 and 36. If the base is invalid, it returns an empty string.
- It adds zero handling; the fixed method correctly handles the case when num is zero, returning "0".
- It uses StringBuilder for efficiency; the fixed method uses StringBuilder for string concatenation, which is more efficient than repeatedly creating new string objects.
- It increases the clarity of the code; the fixed method is well-documented, explaining the purpose, parameters, and return value, making it easier to understand and maintain.

Therefore, the proposed model has significantly improved the original buggy method by adding necessary validations, handling edge cases, and improving performance through efficient string manipulation. These changes enhance the robustness of the method, efficiency, and readability, ensuring it works correctly across a wide range of inputs.

Furthermore, it was observed that the proposed model has the ability of multi-hunk and multi-fault repair. In more detail, the proposed model shows an ability for multi-hunk and multi-fault repair in software code. It can navigate and rectify issues spread across different parts of the source code (multi-hunk) and address several distinct types of faults within a single execution (multi-fault).

```java
import java.util.*;

/*

 * and open the template in the editor.
 */

/**
 *
 * @author derricklin
 */
public class TO_BASE {
    public static String to_base(int num, int b) {
        String result = "";
        String alphabet = "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ";
        int i;
        while (num > 0) {
            i = num % b;
            num = num / b; // floor division?
            result = String.valueOf(alphabet.charAt(i))+result;
        }

        return result;
    }
}
```

Fig. 11. Buggy TO_BASE.java from QuixBugs.

```java
/**
 * Converts an integer to its representation in a specified base.
 *
 * @param num The number to convert.
 * @param base The base of the target number system (must be between 2 and 36 inclusive).
 * @return A string representation of the number in the specified base, or an empty string if the base is out of the valid range.
 */
public class TO_BASE {
    public static String to_base(int num, int base) {
        // Validate the base
        if(base < 2 || base > 36) {
            return "";  // Return an empty string for invalid base values
        }

        // Handle the case when num is 0
        if (num == 0) {
            return "0";
        }

        StringBuilder result = new StringBuilder();
        String alphabet = "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ";

        while (num > 0) {
            int remainder = num % base;
            num = num / base;
            result.append(alphabet.charAt(remainder));
        }

        // Since the conversion process builds the result string in reverse order,
        // we need to reverse it before returning.
        return result.reverse().toString();
    }
}
```

The proposed model that leverages gpt-4-0125-preview model, in particular, demonstrates a higher level of sophistication in applying best practices, suggesting an advanced understanding and capability in handling complex repair scenarios efficiently. This analysis supports the

utilization of LLMs in automating comprehensive code repair tasks, highlighting their role in supporting and enhancing software development and maintenance processes.

Research Question 3: What are the practical improvements of integrating LLMs into the software development lifecycle for bug-fixing?

Observations: Integrating LLMs into the software development lifecycle for bug fixing has several practical improvements include:

- **Increased Productivity:** Developers can focus on higher-level tasks, as LLMs handle routine bug fixing, leading to increased productivity and efficiency.
- **Improved Code Quality:** Automated bug fixing can lead to more consistent and reliable code quality, as LLMs can systematically apply best practices and coding standards.
- **Reduced Time-to-Market:** Faster bug detection and fixing reduce the overall development cycle time, enabling faster releases and update**s.**
- **Enhanced Collaboration:** LLMs can help in bridging the gap between different team members (e.g., developers and testers) by providing clear and actionable bug debugging and fixes.

VIII. CONCLUSION

This paper introduced a novel approach to APR, utilizing LLMs to automate the bug-fixing process. Through the leveraging of gpt-3.5-turbo and gpt-4-0125-preview models, a significant leap forward in the field of software engineering has been demonstrated, particularly in enhancing software reliability and developer productivity. The proposed model presents an ability to accurately localize bugs across various code segments, debug the source code, generate correct patches, and integrate these fixes into the appropriate locations within the source code. The evaluation of the proposed model, conducted on a diverse dataset comprising 53 Java source code files categorized into four distinct bug categories, confirms the efficiency of the proposed model. The results show that the gpt-3.5-turbo model achieved an impressive success rate, successfully repairing 49 out of 53 source code files, equivalent to an accuracy of 92.45%. In contrast, the gpt-4-0125-preview model exhibited an exceptional performance, achieving 100% success rate in bug fixing. Additionally, the proposed model was evaluated using the QuixBugs benchmark dataset, and it can correctly fix all its Java buggy programs. The proposed model was compared to several state-of-the-art APR models and outperformed them. Such outcomes not only highlight the robustness of the proposed model in handling many types of bugs but also, reflect the advancements in large language-based program repair techniques. Furthermore, the comparative analysis offers valuable insights into the evolution of AI capabilities, particularly in the context of software debugging and maintenance. The superior performance of the gpt-4-0125-preview model, characterized by its ability to execute multi-hunk and multi-fault repairs with a higher degree of accuracy, points towards a promising future where the boundaries of automated software engineering can be expanded significantly. As the field continues to evolve, future research can uncover more advanced models and methodologies, further enhancing the scope and accuracy of automated bug fixing.

ACKNOWLEDGMENT

Deanship of Scientific Research (DSR) at King Abdulaziz University (KAU), Jeddah, Saudi Arabia, funded this project under grant no. (KEP-PhD-102-611-1443). The authors, therefore, acknowledge DSR for the financial support.

Towards Secure Internet of Things Communication Through Trustworthy RPL Routing Protocols

Rui LI
Shaanxi Technical College of Finance and Economics, Xianyang 712000, China

***Abstract*—The Internet of Things (IoT) refers to a network of connected objects for autonomous data exchange and processing. With the increasing growth in IoT, ensuring data transmission integrity and security is essential, as data is subject to many attacks. Currently, the routing protocol for low-power lossy networks is RPL and finds wide deployment in IoT deployments. It also provides a framework to define characteristics related to low-power consumption and resilience to specific routing attacks. RPL trust-based routing protocols improve RPL security by introducing a threshold for Minimum Acceptable Trust, permitting only trusted nodes with a sufficient level of obtained trust to participate in routing. This mechanism is designed to reduce malicious activities and to establish secure communications. This paper will provide an overall review of trustworthy RPL routing methods in IoT and discuss the trust metrics of these approaches and their limitations. To the best of our knowledge, this is the first survey focusing on trust-based RPL protocols in IoT, offering valuable insights into the performance of protocols and possible improvements.**

***Keywords*—Internet of Things; routing; trust; data transmission**

I. Introduction

A. Context

The Internet of Things (IoT) is one of the main transformative technological developments experienced today, involving billions of devices connected, communicating, and exchanging data over different networks [1]. As it has been implemented into daily life, IoT involves general applications and particular industries, including healthcare, transportation, agriculture, and manufacturing [2]. This interdependence has forged unparalleled motivation for efficiency and innovation, where devices can analyze the collected data and make decisions in real-time [3]. On the inverse side, however, the rapid proliferation of IoT networks and billions of devices operating today motivated numerous problems, not least of which pertain to security and data privacy. This sets up a situation in which exponential growth in connected devices makes the need for integrity and safety within IoT environments increasingly central [4].

Routing protocols constitute the central heart of IoT networks, facilitating efficient and reliable data delivery across various connected devices [5]. Considering the challenge posed by the diversity of IoT deployment scenarios, which often involve several resource-constrained devices, such protocols are expected to choose optimal paths for communication while keeping energy consumption as low as possible but preserving network performance [6]. Scalability for large and dynamic networks, energy efficiency to prolong the operable life of battery-powered devices, secure communications that protect data from possible threats, and, above all, autonomy to enable them to self-manage without constant outside control are some of the critical design elements for IoT routing protocols. The Routing Protocol for Low-power and Lossy Networks (RPL) has since become the de-facto solution to these issues due to a solid framework and suitability to meet low-power and lossy network requirements. By prioritizing energy efficiency, adaptability has confidence in RPL as a significant enabler of smooth and secure operations for IoT networks, mainly in applications that feature resource scarcity [7].

B. Problem Statement

RPL is specifically designed to meet the peculiar needs of IoT networks, mainly those constrained by limited power, processing capability, and unreliable communication links [8]. RPL organizes the network into a hierarchical framework called a Destination-Oriented Directed Acyclic Graph (DODAG), wherein nodes establish paths to a common destination, typically an Internet gateway or a data sink [9]. Each node in DODAG receives a rank, reflecting its relation to others. The lower this rank, the closer the node is to the study [10]. RPL makes efficient routing decisions since rank computation is based on routing metrics like link quality, throughput, and latency. Technical adaptability and energy efficiency make the RPL useful in innumerable critical domains, ranging from healthcare monitoring systems to smart city infrastructure and industrial automation. Each of these domains needs reliable data transmission with optimum utilization.

Despite RPL's efficiency and adaptability, it is subjected to various security threats like blackhole, rank, and wormhole attacks. Under the Blackhole attack, any malicious node advertises itself with an optimum path to intercept and drop packets to disrupt communications. In Rank attacks, an adversary can alter its rank to change network topology, which might lead to inefficient routing or partitioning of the network. The wormhole attack establishes a virtual tunnel between two distant parts of the network to deceive nodes, which may result in the interception or modification of data. This attack on RPL is critical, as such vulnerabilities can compromise essential IoT applications, such as healthcare and smart city systems, leading to data loss, service disruption, or even risks to human safety. Proper security can protect data integrity, preserve smooth communication, and maintain users' confidence in such IoT systems.

C. Motivation and Contribution

Trust-based RPL routing protocols have emerged as promising to enhance RPL security. These protocols incorporate

mechanisms that evaluate the trustworthiness of network nodes based on their behavior, record of communications, or reliability. By assigning a trust score, only nodes that meet predefined trust thresholds can participate in the routing process, thereby reducing the possibility of malicious activities. Essential trust metrics include packet forwarding ratios, energy consumption, and reputation scores distinguishing trusted and compromised nodes. Based on these trust metrics, the trust-based RPL protocols monitor for attacks, including blackhole or rank manipulation, to ensure data is forwarded to reliable nodes. This approach significantly improves the integrity, trust, and reliability of communications in IoT and enhances general network resilience against diverse security threats.

Kamgueu, et al. [11] presented various RPL protocol enhancements, emphasizing security and mobility. They classified existing solutions and discussed their effectiveness in mitigating RPL's inherent vulnerabilities. However, they have not discussed trust-based security mechanisms for RPL. Yang, et al. [12] presented an overview of possible RPL security vulnerabilities in RPL-based IoT networks and a discussion about possible countermeasures. While this study addresses most security-related issues, it provides only a limited discussion on trust-based routing protocols and lacks a critical analysis of trust metrics and their implementation mechanisms.

Sobral, et al. [13] presented a detailed survey of the routing protocol for Low-Power and Lossy Networks. This paper considers the evaluation of different protocols with various performance metrics like energy efficiency and scalability. The security issues are briefly discussed, but a detailed study on trust-based approaches has not been drawn. Bang, et al. [14], on the other hand, presented a thorough analysis of enhancements in security, scalability, and energy efficiency to RPL. They also discussed various attacks on RPL and their respective mitigation strategies. However, the trust-based routing protocol discussion falls short and thus demands more research into trust metrics and their impact on network performance. Shah, et al. [15] addressed the challenges and solutions of routing protocols in mobile IoT environments. They emphasized the challenges in mobility management and energy constraints but gave little attention to trust-based routing mechanisms, specifically on RPL.

Although much research has been done on RPL and its security challenges, a literature gap regarding the need for comprehensive surveys on trust-based RPL routing protocols is evident. Most related works are contributed piecemeal, leaving room for comprehensive analysis and comparison among those trust-based mechanisms. This, therefore, requires a review of the same protocols; indeed, trust-based approaches have promised a solution for improving IoT network security and preventing malicious activities while ensuring reliable communication. Such a review will shed light on the strengths and limitations of the current trust-based methods and highlight areas for further improvements to guide future research. This gap gives us a reduced understanding of the potentials available with the trust-based RPL protocols and retardation in further development of secured and resilient IoT systems.

This study primarily attempts to evaluate trust-based RPL routing protocols, examine the various trust measures used, and outline their limits and issues. Additionally, the study aims to identify and propose potential future research avenues to address existing shortcomings and increase security in IoT networks. This study is distinctive as it represents the inaugural comprehensive survey focused on trust-based RPL protocols. It offers a thorough analysis that addresses a significant gap in the literature and establishes a foundation for researchers and practitioners aiming to develop secure and efficient IoT communication systems.

II. Background

This section describes the basic principles of IoT and routing protocols, including the general architecture and operation based on the protocol RPL and the principle of trust-based routing in IoT networks.

A. Definition and Impact of IoT

IoT is ubiquitous across virtually every aspect of human activity in modern life because of intelligent gadgets or interconnected systems. Companies, governments, and organizations increasingly employ independent devices to increase productivity, enhance quality of service, and spur economic growth [16]. IoT, in return, with its rapid advancement in various fields of health and energy management for military purposes, agriculture, and smart city infrastructure, among others, is trying to make the world much more useful and linked. It has been described by many as the "system of systems" or even a "network of networks," with IoT communication protocols capable of making devices self-configuring and strictly limiting access to authorized and trusted users [17].

However, as IoT networks scale to billions of devices, the issues of security, scalability, and resource consumption become critical. Each IoT service model differs in security, architecture, and implementation, making standardization and integration of new services even more challenging [18]. Fig. 1 illustrates the complexity of the ecosystem that needs to be managed, starting with exceptionally diverse applications and network models and proceeding to considerations about security and privacy. Security remains a significant barrier to IoT's expansion, especially given the resource limitations of many IoT devices, making them vulnerable to various threats. These include Intrusion Detection Systems (IDS), trust-based models, and cryptographic techniques. The general idea of adapting to various IoT applications while implementing routing algorithms is highly trust-based models, which can support detecting and isolating malicious nodes.

B. Overview of the RPL Protocol

RPL stands for Routing Protocol for Low-power and Lossy Networks, designed to meet the unique requirements of IoT networks, which, in turn, feature limited power, processing capabilities, and unreliable communication links. The RPL protocol is one of the proactive protocols, which immediately establishes routing paths once the network becomes operative. It organizes the network into a DODAG structure, illustrated in Fig. 2. This structure has one root node that coordinates network communication. Due to such a structure, RPL can efficiently decide routing paths by ranking each node, as illustrated in Fig. 2. For the computation of the ranks, local metrics and constraints are considered so that the network has no cycle and performance is optimized.

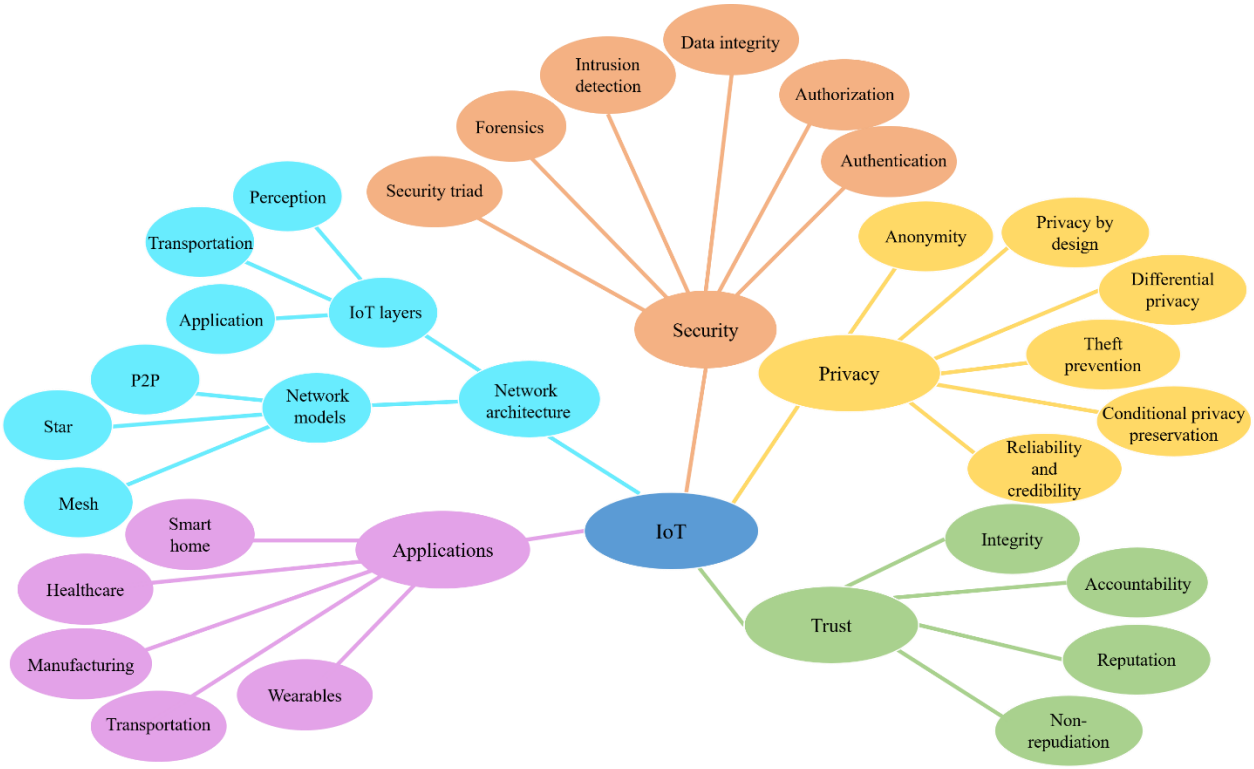

Fig. 1. An overview of IoT paradigm.

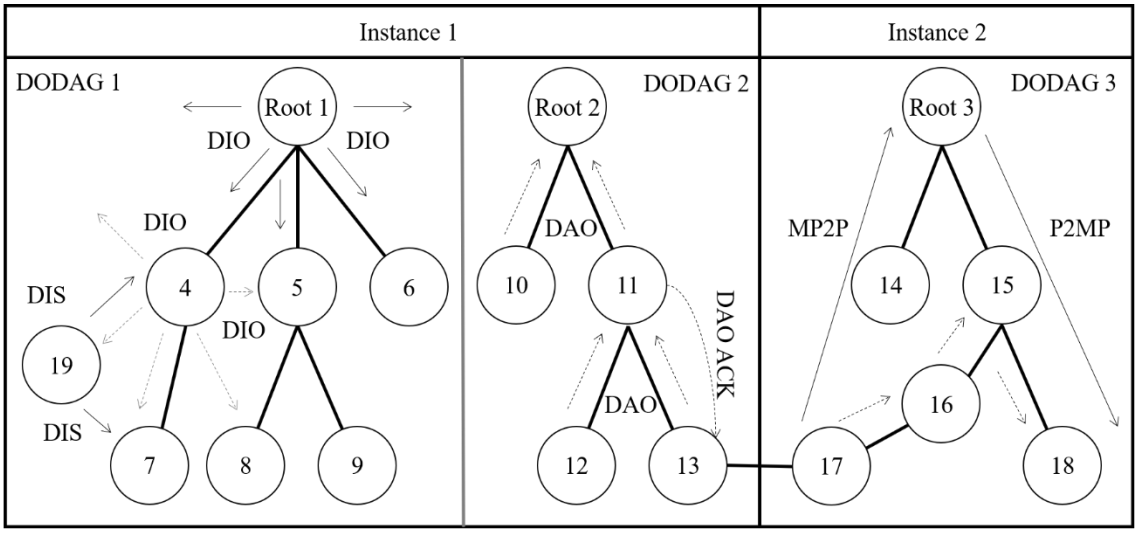

Fig. 2. DODAG structure.

The formation of DODAG in RPL starts with the root node broadcasting DIO messages. The nodes hear these messages, calculate their rank, and choose a parent node based on routing metrics. The nodes ensure the acyclicity of the DODAG by ensuring that the rank of its parent is less than that of itself. Techniques like trickle timers prevent extra overhead by controlling message traffic. The nodes can join the network by sending the DODAG Information Solicitation message. RPL also has different modes of operation for root to upward routes and downward routes based on Destination Advertisement Object (DAO) messages to communicate efficiently in the network.

C. Trust-based Routing in IoT

The widespread deployment of IoT devices in diverse environments increases the risk of security breaches, such as attacks that drain a device's energy or disrupt network operations. Given these threats, designing adequate safeguards is crucial, particularly considering the limited resources of many IoT devices. A promising approach is trust-based routing, which detects and isolates malicious nodes using appropriate trust assessment strategies. Trust among network nodes builds up over time, allowing the system to discriminate effectively between honest and malicious participants. However, attackers

can manipulate trust metrics either by falsely downgrading reliable nodes or by falsely promoting threatening ones, undermining the effectiveness of trust-based solutions and disrupting the stability of networks.

In other words, trust-based routing protocols ensure participation in route formation and data exchange through nodes that can be adjudged trusted depending on their behavior and past interactions. Isolation strategies will be applied to protect the network against malicious or selfish behavior by nodes. Trust attributes assessment is one of the most challenging barriers at the network level. Thus, trust-based approaches are recommended for several IoT applications.

D. Performance Metrics

This section presents some of the most essential metrics considered in the literature to evaluate the performance and security of RPL-based IoT networks. Each metric is briefly explained, and the relevant equations are presented.

Malicious node containment: This evaluates the protocol's effectiveness in isolating malicious nodes, expressed as follows.

$$Acc = \frac{No.of\ detected\ malicious\ nodes}{Total\ no.of\ malicious\ nodes} \quad (1)$$

Where Acc represents the detection accuracy of the proposed solution.

Network throughput: Measured in kilobits per second, indicates the data transmission rate over a given period.

$$Throughput = \frac{Total\ data\ transmitted\ (in\ kilobits)}{Total\ time\ (in\ seconds)} \quad (2)$$

Where Total Data Transmitted is the amount of data successfully sent over the network, and Total Time is the duration over which the data transmission occurs. This formula provides the data transmission rate in kilobits per second (kbps).

Storage cost: Nodes maintain lists of neighbors' behaviors, increasing storage requirements at the node level.

$$SC = N \times S_b \quad (3)$$

Where N represents the number of neighboring nodes for which behavior information is maintained, and S_b is the storage size required (in bytes) to store the behavior information of a single node.

Median packets dropped: This metric indicates the percentage of packets dropped during attacks, calculated as:

$$D_r = \frac{Drop_r}{\sum_{k=1}^{n} TAk} \quad (4)$$

$$E[Dpkt] = Median\ (D) \quad (5)$$

Packet Delivery Ratio (PDR): PDR is the median value of the packet delivery ratio across multiple repetitions, calculated as:

$$S_r = \frac{Rcvd}{\sum_{k=1}^{n} P_k} \quad (6)$$

$$E[DRpkt] = Median\ (S) \quad (7)$$

Communication overhead: This metric assesses the additional communication costs due to control messages exchanged during security events.

$$CO = \frac{CM}{TD} \times 100 \quad (8)$$

Where *CM* is the number of control messages transmitted during security events, and *TD* denotes the total data packets transmitted over the network.

Misdetection rate: This rate measures the error in detecting malicious nodes, accounting for false positives and negatives.

$$MR = \frac{FP + FN}{TP + TN + FP + FN} \quad (9)$$

Where *FP* denotes the number of false positives (benign nodes incorrectly identified as malicious), *FN* represents the number of false negatives (malicious nodes incorrectly identified as benign), *TP* is the number of true positives (malicious nodes correctly identified), and *TN* is the number of true negatives (benign nodes correctly identified).

Trust values: A trust value is a feeling of confidence in a node's predictable behavior and honesty. Trust values are essential for routing to ensure that only trustworthy nodes participate in packet forwarding, especially faraway nodes. The trust can be computed as follows:

$$RT(N_i, N_m) = DT(N_i, N_j) \times DT(N_j, N_m) \quad (10)$$

Where $RT(N_i, N_m)$ is the recommended trust value from node *i* to node *m*, and $DT(N_i, N_j)$ and $DT(N_j, N_m)$ are the direct trust values between nodes.

Reliability: Reliability is based on a predefined trust threshold. It assesses the trustworthiness and dependability of nodes, ensuring only reliable nodes participate in routing. Trust ratings are similar to assigning ranks to nodes based on trust indices.

$$R = \frac{N_t}{N} \quad (11)$$

Where *R* is the Reliability of the network, N_t represents the number of nodes with trust values above the trust threshold, and *N* is the total number of nodes in the network.

Key generation time: It calculates the time a key is generated for secure data transmission. High key generation times cause IoT devices to consume extra resources and experience delays. Thus, reducing them is critical for efficient data communication.

$$KGT = E_t - S_t \quad (12)$$

Where E_t denotes the end time when the key generation process is completed and S_t represents the start time when the key generation process begins.

Energy consumption: This metric quantifies the energy used during data transmission in the network. It is determined by the difference between the total energy T_e and the remaining energy R_e, given by:

$$EC = T_e - R_e \quad (13)$$

Delay: It refers to the time taken for data packets to travel from the source nodes to the root destination node in the network. Thus, it can be measured as a difference between packet transmission time, $P_{r,t}$, and packet received time, $P_{t,t}$, given as:

$$D = \sum_{i=0}^{n} \left(P_{r,t} - P_{t,t}\right) \quad (14)$$

III. TRUST-BASED RPL ROUTING PROTOCOLS

The taxonomy of trust-based RPL protocols can be divided into: 1) Trust-based detection and isolation mechanisms, which primarily detect and isolate malicious nodes by relying on trust scores generated from node behavior and recorded communications; 2) Energy-efficient and lightweight models of trust, which essentially reduce computational and energy overhead due to trust evaluations-small enough for resource-constrained IoT devices; 3) Advanced models of trust for dynamic environments for the adaptation of trust mechanisms to the respective mobility, heterogeneity, and time-varying conditions in IoT networks; 4) Attack-specific mitigation strategies that aim to identify unique trust metrics coupled with countermeasures developed for particular threats, such as blackhole, rank, and wormhole attacks. Together, these categories provide solutions for crucial challenges to RPL security by enhancing detection, reducing resource consumption, and improving network resilience against various threats.

A. Trust-Based Detection and Isolation Mechanisms

Airehrour, et al. [19] proposed SecTrust-RPL, which uses trust assessments to segregate malicious nodes from the network while determining optimal routing paths. Successful packet exchanges thus contribute to node reliability and build-up throughput. However, complex attacks like combinations of rank, blackhole, and Sybil would not be defended, and the integration of trustworthy nodes into the network needs to be addressed. Airehrour, et al. [20] developed a trust-based routing protocol for low-power networks whose efficiency was checked with RPL classic through Minimum Rank with Hysteresis Objective Function (MRHOF).

Rakesh [21] introduced the concept of SecRPL-MS to secure RPL-based IoT networks through authentication and security measures. This minimizes energy consumption in rank, Sybil, blackhole, and man-in-the-middle attacks. However, it also has some disadvantages since it neglects DoS/DDoS threats entirely and provides no satisfactory trust-based verification process. Ioulianou, et al. [22] presented SRF-IoT, which was developed by integrating external IDS and trust-based methods against rank and blackhole attacks. Decreasing the extra parent switches to the minimum will provide higher network efficiency, though it suffers from limitations in identifying unidentified attacks and indentation.

Patel, et al. [23] proposed a trust-based intrusion detection solution, FSTIDS, to reduce the impact of topology-based selective forwarding attacks against RPL networks. Selective forwarding is a hard attack to detect because it manifests by merely dropping control or data packets. FSTIDS performs computation at the sink node for trust values to reduce overhead, embedding a threshold and uncertainty factor to maintain accuracy.

Airehrour, et al. [24] proposed a trust-based routing protocol that efficiently protected against blackhole attacks and improved network efficiency without extra traffic overhead. This scheme addresses the challenge caused by compromised sensor nodes in IoT networks. Compromised nodes affect routing integrity by issuing false control information, dropping packets, and even introducing false data during aggregation or obstructing data forwarding.

Djedjig, et al. [25] analyzed the problem of trust management in RPL networks, illustrating that trusting only the Trusted Platform Module (TPM) is not enough to make nodes reliable. They pointed out that nodes may be infected internally or selfishly and thus still build the RPL topology. Their solution proposes trust values as a main routing criterion derived from a node's behavior to create a robust trust mechanism. Airehrour, et al. [26] proposed a comprehensive trust-based RPL protocol that could efficiently prevent black hole attacks. The authors evaluated the performance of the proposed protocol with standard RPL using the MRHOF and IETF's Contiki RPL implementation to analyze its capability in mitigating black hole threats.

These protocols enhance the security of RPL networks, which expose malicious nodes through trust evaluations and isolate them. Some protocols, such as SecTrust-RPL and SecRPL-MS, as shown in Table I, detect dangerous nodes based on trust metrics for their isolation to perform secure routing. However, their procedures are different when various types of attacks need to be handled.

Though SecTrust-RPL is efficient at threat node isolation without dealing with sophisticated attacks, SecRPL-MS detects many threats but cannot mitigate DDoS attacks. Similarly, RPL SRF-IoT maintains an external IDS to provide additional security features against rank and blackhole attacks. However, again, it fails to identify undetected threats. In addition, protocols like FSTIDS and TrustedRPL are more focused on efficient computation of trust and self-organization, ignoring factors related to node mobility and energy consumption in IoT.

B. Energy-Efficient and Lightweight Trust Models

Subramanian, et al. [27] has proposed HTmRPL++, which enhances the trust between fog nodes without compromising network speed. Though effective against BSA, it does not consider node mobility and addresses only one attack type. Mehta and Parmar [28] have proposed an energy-efficient strategy against wormhole and gray hole attacks using lightweight trust mechanisms. The technique is practical, yet extra or combined attacks are not considered.

Ul Hassan, et al. [29] suggested CTrust-RLP, which introduced a control layer that detects and isolates blackhole attacks with efficient energy conservation. Still, it reduces the processing overhead without scalability and cannot cope with multiple threats, such as Sybil and rank attacks.

TABLE I. AN OVERVIEW OF TRUST-BASED DETECTION AND ISOLATION MECHANISMS

Reference	Key features	Strengths	Limitations
[19]	Uses trust to isolate malicious nodes and optimize routing by examining successful packet exchanges	High throughput, effective at detecting and isolating suspicious nodes	Does not account for complex collusive attacks (e.g., rank/blackhole, rank/Sybil) and lacks strategies for integrating trustworthy nodes
[20]	Secures against black hole and selective forwarding attacks without adding traffic overhead	Effective against critical attacks and maintains network efficiency	Ignores energy consumption and does not address a broader range of attacks
[21]	Employs authentication and security to mitigate rank, Sybil, blackhole, and man-in-the-middle attacks, with a focus on delay and energy reduction	Comprehensive attack defense reduces packet loss and delay	Overlooks DDoS/DoS threats and lacks a robust trust verification mechanism
[22]	Combines external IDS and trust-based mechanisms to counter rank and blackhole attacks	Reduces parent switches and enhances network efficiency	Limited in detecting additional threats and lacks a solution for indentation attacks
[23]	Uses trust-based intrusion detection for selective forwarding attacks, computing trust at the sink node to reduce overhead	Efficient in minimizing processing load and precise trust computation	Does not consider mobility scenarios, restricting effectiveness in dynamic environments
[24]	Protects against black hole attacks without increasing network traffic using a trust-based mechanism	Secures against compromised nodes and maintains traffic efficiency	Does not consider energy criteria or other types of attacks
[25]	Uses trust values as the primary routing criterion to create a self-organized network	Focuses on internal threats and enables trust-based self-organization	Lacks simulation for empirical validation and does not analyze energy or routing overhead
[26]	Compares trust-based RPL to standard RPL and IETF Contiki RPL, focusing on mitigating black hole attacks	Strong protection against black hole attacks, validated through comparison	Insufficient focus on selective forwarding, ranking, and Sybil attacks; does not address energy and network lifespan

Djedjig, et al. [30] developed a Management Trust Scheme (MRTS) to enhance the security of RPL networks through a distributed and collaborative trust model. This model evaluates nodes' behavior to compute a trust-based value called the Extended RPL Node Trustworthiness (ERNT) measure. MRTS leverages these trust assessments to ensure that only reliable nodes participate in routing, enabling the self-organization of a secure network based on trust status.

Sisodiya, et al. [31] proposed a multicast trust-based RPL management scheme to enhance network security. This approach achieves its goal by continuously monitoring and isolating untrusted nodes that would destroy data integrity or delay and corrupt messages in the protocol. The protocol enables nodes to infer the degree of trust of neighboring nodes in establishing a network topology. It is more effective than broadcast-based transmissions. It provides greater energy efficiency, high throughput, and low dead node ratios. This schema detects malicious nodes before route establishment, allowing only trustworthy nodes to participate in secure multicast.

All these protocols target the optimization of the RPL security mechanism, not to compromise network performance for energy conservation. Most protocols listed in Table II, such as HTmRPL++ and CTrust-RPL, target lightweight design and will be suitable for application in resource-constrained environments. HTmRPL++ addresses specific attacks, such as Ballot Stuffing Attacks, without considering the node's mobility. As a result, it presents robust mutual trust among fog nodes. CTrust-RPL detects a suspicious node or source that can create an attack by using a control layer to reduce overhead processing efficiently; this technique has poor scalability and resistance against sophisticated threats.

TABLE II. AN OVERVIEW OF ENERGY-EFFICIENT AND LIGHTWEIGHT TRUST MODELS

Reference	Key features	Strengths	Limitations
[27]	Trust mechanism tailored for fog nodes, designed to maintain network speed and performance; tested for reliability, delay, and ballot stuffing attacks	Efficient communication for resource-constrained fog nodes and lightweight design	Does not account for node mobility, limited to testing against a single attack
[28]	Defends against wormhole and grayhole attacks using an energy-efficient trust-based approach	Reduces packet loss, isolates rogue nodes and improves performance	Fails to address combined or additional attacks beyond wormhole and grayhole
[29]	Control layer-based trust mechanism that conserves energy while stopping black hole attacks; calculates trust based on packet exchanges	Low processing and storage overhead, improved network longevity, and effective against black hole attacks	Not scalable or distributed, lacks defenses against threats like Sybil and ranking attacks, and limited evaluation of trust mechanism
[30]	Distributed trust model using extended RPL node trustworthiness for secure routing; allows self-organization based on trust status	Enables secure, self-organized network, and behavior-based trust evaluation	Overlooks energy consumption and routing/security overhead, not tested with Cooja-Contiki simulator
[31]	Uses a trust-based approach to identify and isolate malicious nodes, enabling efficient multicast transmission	More energy-efficient and reliable compared to Broadcast RPL, enhances network longevity and throughput	Does not address performance under various attack types, limited platform testing restricts versatility

C. Advanced Trust Models for Dynamic Environments

Muzammal, et al. [32] offered SMTrust, a mobility-based trust model that mitigates attacks such as black holes, rank, and gray holes. It provides optimization of routing in both static and mobile environments but needs to address energy consumption and other potential threats comprehensively. Al-Jumeily, et al. [33] came up with a hybrid trust approach against Sybil attacks, which they called THC-RPL. While this can help with network longevity, reducing packet loss significantly, this protocol has yet to be tested in practical situations, the relevance of which is thus limited.

Addressing one of the biggest challenges in military usage of COTS IoT devices, Thulasiraman and Wang [34] produced a lightweight trust-based per-node secure data transmission architecture based on routing in mobile IoT networks. This design enhanced security for the RPL IoT routing algorithm by bringing in nonce identity values, timestamps, and whitelisting. The modified protocol selects routing paths based on computed node trust values and the Average Received Signal Strength Indicator (ARSSI).

Hassan, et al. [35] introduced the Jini Index approach, a trust-based security framework designed to effectively detect and manage Sybil attacks, one of the most challenging internal threats in IoT networks. Their architecture employs a tiered design comprising layers of devices and fog nodes, enhancing overall network security and energy efficiency by offloading processing tasks from individual nodes. This approach significantly improves Sybil attack detection, reducing latency and energy consumption.

Savitha and Basarkod [36] introduced TEMGTO-RPL, which applies Gorilla Forces Optimization for node selection while balancing trust and energy efficiency. According to the simulation results, the protocol performs well but needs to consider various attack methods. Therefore, the TEMGTO-RPL protocol has an improvement space.

Muzammal, et al. [37] proposed the SMTrust model, which involves an extension of RPL with a trust factor criterion based on mobility in IoT networks. The SMTrust approach resists general RPL attacks such as Blackhole, grey hole, rank, and version number attacks. It considers the sink and sensor node mobility and only allows trustworthy nodes to participate in the network. It is designed for sensor nodes to provide confidentiality, integrity, and availability during routing and communicating data.

Jiang and Liu [38] proposed a defensive technique that effectively addresses sophisticated selective forwarding attacks in RPL-based IoT networks. They design and implement a set of energy-efficient attacks that can flexibly select the type and proportion of packets to be broadcast to maximize the impact, increasing the number of missed packets while keeping stealthy. They brought the right to neutralize these threats, a simple trust-based security mechanism using a beta trust model with asymmetric forgetting rates and decaying trust values.

The protocols reviewed address securing RPL networks in highly mobile or dynamic scenarios. According to Table III, protocols like SMTrust and THC-RPL integrate mobility-based trust metrics into their trust computations to ensure both fixed and mobile nodes. SMTrust can protect against various RPL attacks and perform better than the existing schemes. The significant drawbacks of this protocol lie in its failure to focus on energy consumption and protection against a wide range of threats. THC-RPL adopts a hybrid approach to Sybil attack detection to extend the network lifetime, yet it is waiting for validation in a natural environment.

In Thulasiraman and Wang's Lightweight Security Architecture, countermeasures against DoS and Sybil attacks are robustly provided in mobile IoT networks. Energy efficiency problems may be shown when the number of mobile nodes increases. The proposed Jini Index method by Hassan and Tariq detects Sybil attacks with minimum latency and energy utilization efficiently. However, more is needed to cover broader recognition of attacks using machine learning. TEMGTO-RPL proposes a trust model based on optimization that strikes a balance between energy and trust considerations without concerns about multiple attack vectors. These models show how trust mechanisms will adapt to IoT environments, which will be dynamic and balance mobility, energy efficiency, and security.

D. Attack-Specific Mitigation Strategies

Kim, et al. [39] proposed PITrust, which utilizes the RSSI and a centralized mechanism for trust to enhance the detection accuracy of Sybil attacks. While this method is effective, it targets only one type of attack with no extensive security scope. Lahbib, et al. [40] have proposed LT-RPL, which secures RPL networks under blackhole and grayhole attacks while still assured QoS guarantees. While this is efficient, it does not consider other types of attacks and protocol testing in various application settings. Karkazis, et al. [41] contributed to TXPFI by enhancing the routing with minimal transmission to enhance efficiency.

These approaches focus their contribution on protocols developed for targeted threats to optimize security measures against certain kinds of attacks in RPL networks. As summarized in Table IV, PITrust uses RSSI and a centralized trust mechanism to find Sybil attacks with high accuracy, but it does not cover other attack types. LT-RPL uses an ETX-based trust model to prevent black and gray hole attacks and ensure efficient and energy-conscious routing.

However, it is not validated in diverse application scenarios and does not cancel additional threats. TXPFI proposes a metric that minimizes message transmissions, considering retransmissions and lost links, and significantly reduces communication overhead. It provides a deficiency in performance evaluation during an attack and does not provide comprehensive security.

TABLE III. AN OVERVIEW OF ADVANCED TRUST MODELS FOR DYNAMIC ENVIRONMENTS

Reference	Key features	Strengths	Limitations
[32]	Incorporates mobility-based trust metrics for both fixed and mobile nodes; defends against blackhole, rank, and version number attacks	Outperforms MRHOF, SecTrust, and MRTS; improves performance for mobile and static nodes	Does not address energy efficiency or consider additional attack types
[33]	Hybrid trust model that uses Direct Trust (DT) and Indirect Trust (IDT) to detect Sybil nodes; relays trust data to the root node	Reduces packet loss, extends network lifespan, effective against Sybil attacks	Not tested in real-world environments, limiting practical applicability
[34]	Trust-based routing for mobile IoT using nonce, timestamp, and ARSSI; designed for COTS IoT devices	Protects against DoS and Sybil attacks, high PDR, lightweight and efficient	Does not consider energy consumption or handle a large number of mobile nodes efficiently
[35]	Layered trust model using fog devices to manage Sybil attacks; reduces detection latency and energy consumption	Effectively detects Sybil attacks, reduces energy use and latency	Does not integrate ML algorithms for broader attack mitigation, limited to Sybil attack recognition
[36]	Uses Gorilla Forces Optimization (GTO) for trust and energy-efficient routing; considers trust value, energy ratio, node distance, and PDR	Balances trust and energy efficiency, selects optimal nodes for routing	Does not address multiple attack types, lacks comprehensive security measures
[37]	Focuses on mobility and trust criteria to secure RPL networks against blackhole, greyhole, and rank attacks	Ensures confidentiality, integrity, and availability of sensor nodes; energy-efficient design	Limited in addressing combined attacks, needs efficiency improvements in detection and data transfer
[38]	Uses a beta trust model with asymmetric forgetting rates to detect and mitigate selective forwarding attacks	Efficient against selective forwarding, energy-efficient attack model	Ignores mobile node dynamics, does not address other attack vectors

IV. FUTURE RESEARCH DIRECTIONS

Although several trust-based RPL routing protocols have recently been developed for securing IoT networks, several research gaps and challenges remain to be addressed. Below are future research directions to enhance these protocols' effectiveness, scalability, and robustness.

Most protocols proposed to date target specific attacks, like black holes, Sybil, and rank attacks. Sophisticated and combined attack strategies will attack IoT networks. Future research should develop comprehensive solutions to guard against multiple and simultaneous attack types, such as DDoS, wormhole, and other advanced collusive attacks. Hybrid approaches using machine learning-based anomaly detection and trust evaluation mechanisms may be promising.

These trust-based protocols should take advantage of energy consumption in IoT environments when the resources are constrained. Novel approaches to be explored that tend to minimize energy consumption while sustaining a high level of security. Adaptive computation of trust, energy-aware routing decisions, and lightweight cryptographic methods may lead to less energy-consuming solutions. The protocol design should embed energy consumption models so that a careful evaluation of trade-offs involving security against resource management can be estimated.

IoT networks are highly dynamic, with nodes frequently joining and leaving a network. Most protocols still lack adaptiveness in large-scale or high-mobility scenarios. Trust mechanisms to handle node mobility, changing network topology, and variable device densities using scalable and efficient methods need more research attention. The development of distributed systems for trust management or decentralized usage of blockchain might allow increased scalability and resilience of RPL networks.

Most proposed protocols have been tested only with simulations with minimal scenarios or synthetic datasets. Implementation and testing in diverse and realistic real-world environments are essential in studying practical applicability and effectiveness. Field tests and experiments in intelligent cities or industrial automation based on these solutions may reveal unforeseen challenges and performance issues that might not become evident at a simulation level.

The selection and computation of appropriate trust metrics are critical factors in accurately detecting malicious nodes. In the future, refinement in trust evaluation methods should incorporate context-aware metrics, analysis of historical data, and adaptive trust thresholds. Machine learning algorithms improve trust evaluations by recognizing complex patterns and making better decisions in trust-based routing, making even more enhancement possible.

TABLE IV. AN OVERVIEW OF ATTACK-SPECIFIC MITIGATION STRATEGIES

Reference	Key features	Strengths	Limitations
[39]	Trust-based mechanism using RSSI and a centralized trust model for Sybil attack detection	High detection accuracy, improved routing performance compared to conventional protocols	Limited to addressing only Sybil attacks; does not consider other types of security threats
[40]	Trust management method integrated with ETX-based MRHOF to secure routing topology from black hole and gray hole attacks	Effective at identifying and isolating malicious nodes, provides QoS for energy-efficient routing	Does not address other attack types, lacks validation across various application scenarios and platforms
[41]	Routing metric that minimizes message transmissions by considering frame retransmissions and authenticating lost links	Reduces the number of messages transfers, improves efficiency in data delivery	Does not evaluate protocol under attack conditions, lacks comprehensive security measures and analysis of network lifetime impact

Limited computing and storage resources characterize most IoT devices. Thus, lightweight, efficient security architecture developments are of prime importance. Future research should investigate novel architectures that combine low overhead with solid security features. For example, offloading trust-related intensive computational tasks to fog or edge computing could achieve a good trade-off between performance and security in resource-constrained environments.

Integrating the IoT with blockchain, edge computing, and AI opens a new avenue for IoT network security. Blockchain will offer trust management in a decentralized and tamper-proof way, whereas AI can enhance features related to anomaly detection and adaptive security responses. The research study will focus on integrating such emerging technologies with trust-based RPL protocols to achieve secure and intelligent IoT ecosystems.

In light of the diverse IoT devices and networks, interoperability within the variant trust-based protocols poses a challenge. Any future work, therefore, should seek to develop standardized frameworks and protocols for easy interoperability across different platforms and communication standards. Industry, academia, and standardization bodies are encouraged to work together to enable the adoption of secure and interoperable mechanisms of trust.

Finally, there are issues regarding user data, which could raise some privacy concerns. It is essential to consider techniques during the design of research that will maintain users' privacy while still allowing trust evaluations. This might be a balance between security, trust management, and data privacy using techniques like differential privacy, homomorphic encryption, or federated learning.

Future protocols can adapt to changes in network conditions, such as varying device behavior, environmental factors, or application-specific requirements. Adaptive trust models will adjust the parameters of trust computation on the fly and enhance the robustness of RPL Networks. In this regard, context-aware security mechanisms can ensure that protection is appropriate for the current network state and the criticality of the data transmitted.

V. Conclusion

Despite increasing and diversifying cyber threats, IoT network security remains an open challenge. This review has presented a critical analysis of several trust-based RPL routing protocols proposed to enhance network security. The protocols discussed in this study utilize trust-based mechanisms to detect and isolate malicious nodes to ensure data integrity and optimize routing efficiency. Whereas some have been quite effective in eliminating specific attacks, such as blackhole, Sybil, and rank attacks, there are significant lacunae concerning their comprehensively addressing complex, multifaced threats and adaptation issues related to dynamic network environments. The evaluation of performance metrics across protocols presented a variety of tradeoffs between security and energy efficiency versus network performance. For example, some have high detection accuracy with low communication overhead; however, energy consumption and scalability in large networks should be considered. While designed for energy efficiency, others do not offer protection against complex or combined attacks. These observations clearly dictate why future research should concentrate on holistic and adaptive solutions, including performance and resource constraints. Others pertain to real-world validation and the introduction of cutting-edge technologies such as AI, blockchain, and edge computing. When the IoT network becomes widely adopted, most challenges in energy management, scalability, and user privacy will be resolved.

***Abstract*—This systematic literature review examines cybersecurity awareness in schools, focusing on effective practices, challenges, and future directions. Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, peer-reviewed publications in English were sourced from ACM Digital Library, IEEE Xplore, ScienceDirect, SpringerLink, and Emerald, covering the period from 2019 to 2024. Studies were included if they focused on cybersecurity awareness in primary and secondary educational settings, excluding those unrelated to educational contexts or published before 2019. A total of 816 records were identified, of which 220 were duplicates and removed. After screening and eligibility assessments, 14 studies met the inclusion criteria. Risk of bias was minimized by adhering to strict inclusion criteria, such as limiting the review to high-quality, peer-reviewed studies, and ensuring consistency in the data extraction process. The review highlights effective practices such as using serious games, mobile apps, and tailored programs to enhance cybersecurity awareness. Challenges include inconsistent curricula, insufficient parental involvement, and resource limitations. These results emphasize integrating cybersecurity education across school curricula and regularly updating content to reflect evolving threats. Limitations include the exclusion of non-English and non-peer-reviewed studies. Future research should consider broader contexts and additional sources.**

Keywords*—*Cybersecurity awareness; threats; awareness programs; education; school security

I. Introduction

In the digital age, educational institutions have progressively embraced technology, integrating it extensively into classroom instruction and administrative management. While this integration offers numerous advantages, it also significantly increases schools' exposure to cybersecurity risks, threatening the integrity of educational delivery and the privacy of student and teacher data [1,2]. The vulnerability of schools to cyber threats is particularly exacerbated by limited resources, which leave educational networks open to unauthorized access and data theft [3]. Additionally, the swift transition to e-learning platforms, particularly during the COVID-19 pandemic, has expanded the attack surface, providing cybercriminals with more opportunities to exploit outdated or unpatched systems [1,4].

Historically, responses to cybersecurity threats within educational settings have tended to be reactive rather than proactive. There is now a critical and urgent need to enhance cybersecurity awareness and improve practices across all stakeholders, particularly as the Internet becomes an indispensable part of educational infrastructure [5,6]. Effective cybersecurity awareness programs must encompass a wide audience, including students, who require adequate guidance and supervision to navigate online risks safely [7]. The current systematic literature review aims to meticulously examine the state of cybersecurity awareness in schools, delineating effective practices and identifying ongoing challenges. The review addresses the growing complexity and scale of cyber threats and underscores the necessity for comprehensive strategies that integrate public education, technology updates, and community involvement [8,9]. The outcomes of this review are designed to inform educational policymakers, school IT administrators, and educators, providing them with strategic insights to develop and implement robust, effective cybersecurity education and awareness programs.

Research Questions:

1) What are effective practices for improving cybersecurity awareness in schools?

2) What are schools' current problems and challenges in implementing cybersecurity awareness programs?

3) Who is the target audience for the current cybersecurity awareness assessment?

By addressing these questions, the research aims to contribute significantly to the body of knowledge on cybersecurity in education, facilitating the development of secure learning environments that effectively leverage digital technologies.

II. Literature Review

Cybersecurity awareness has become an essential aspect of contemporary education systems, driven by the widespread

integration of digital technologies in schools. As students, educators, and administrators increasingly depend on digital platforms, educational institutions face heightened exposure to cyber threats. This literature review examines the practices, challenges, and target audiences in fostering cybersecurity awareness in school environments.

Yuliana (2022) underscores the importance of raising cybersecurity awareness among children, particularly in the context of online schooling, which increases their vulnerability to cyberattacks and malware. The study demonstrates that digital literacy training can significantly enhance children's awareness of cybersecurity. It advocates teaching children how to avoid risky online behaviour, such as falling victim to phishing scams, pornography, cyberbullying, identity theft, and privacy breaches. Additionally, it stresses the importance of educating children on password security and fostering caution when engaging in online gaming [10].

Ondrušková and Pospíšil (2023) argue that the increasing use of the Internet necessitates adequate cybersecurity awareness to mitigate the risks and dangers associated with the online environment. Their findings reveal only a moderate level of cybersecurity awareness during initial testing and show that one-off training sessions have an insignificant impact on improving online behavior. The study concludes that one-time interventions are insufficient and recommends integrating cybersecurity awareness education throughout the entire educational process to effectively enhance online safety skills [11].

Nehrar and Deepanshi (2023) highlight the critical role of cybersecurity awareness and education programs in an era characterized by pervasive digital connectivity and cyber threats. They emphasize that such programs are effective in enhancing knowledge, fostering behavioral changes, and ensuring long-term impact on cybersecurity practices [12].

Prümmer et al. (2024) emphasize the growing significance of cybersecurity in mitigating financial losses, productivity disruptions, and reputational damage caused by cyberattacks. Their research highlights the pivotal role of end-user behavior in achieving robust cybersecurity within organizational settings. Comprehensive training programs are identified as an effective means of improving cybersecurity behavior, with most studies reporting positive outcomes regardless of the training method or topic. Notably, game-based training methods are frequently employed, demonstrating their effectiveness in engaging participants and enhancing cybersecurity practices [13].

The integration of technology into education has brought both opportunities and challenges, particularly in the realm of cybersecurity. Buyu & Ogange (2021) notes that the rapid adoption of digital tools in schools has introduced significant cybersecurity risks, including malware, ransomware, phishing, and denial-of-service attacks, which disrupt teaching, compromise data security, delay assessments, and erode trust between teachers and students. These challenges are exacerbated in developing countries, where schools often lack the funding, infrastructure, and expertise to effectively address these threats. Moreover, teachers frequently lack the necessary cybersecurity knowledge to protect themselves and their students, while young learners remain particularly vulnerable due to limited awareness of online risks and poor adherence to safe practices [14].

The transition to online education, particularly during the COVID-19 pandemic, has further amplified these challenges. Al-Fatlawi (2024) highlights how the rapid shift to digital learning exposed vulnerabilities, as many educators lacked the skills and resources to secure online environments. Students with low cybersecurity awareness became frequent targets of phishing, malware, and data breaches. The lack of structured training for teachers has compounded these issues, preventing them from adequately guiding students in safe online behaviours. Additionally, disparities in motivations and levels of understanding between different demographics, including educators and students, complicate the development of comprehensive and effective cybersecurity strategies [15].

Efforts to incorporate cybersecurity awareness into school curriculums face significant hurdles. According to Triplett (2023), while methods such as game-based learning show promise in engaging students and raising awareness, they often fall short of addressing the full range of skills and knowledge required to tackle real-world cybersecurity threats. A shortage of trained mentors and educators specializing in cybersecurity further diminishes the effectiveness of these initiatives. This gap underscores the need for sustained investment in teacher training and the integration of cybersecurity education across all levels of schooling [16].

The growing reliance on the Internet in education has also led to an increase in cyber-related issues such as cyberbullying, online fraud, racial abuse, pornography, and gambling, as noted by Sareen and Jasaiwal (2021). These problems arise from a lack of awareness among internet users and disproportionately affect children, especially in the context of online education. Limited teacher expertise, inadequate funding, and insufficient resources hinder schools' ability to implement robust cybersecurity education programs. Addressing these challenges requires a collaborative effort among educators, parents, policymakers, and media platforms to cultivate a culture of cybersecurity awareness from an early age [17].

The literature review underscores the critical need for robust cybersecurity awareness initiatives in contemporary education systems. As digital technologies become integral to learning, schools face escalating cyber threats that compromise safety, disrupt teaching, and erode trust. Studies highlight the importance of integrating comprehensive and sustained cybersecurity education across all levels of schooling to address vulnerabilities among students and educators. Effective approaches, such as digital literacy training and game-based learning, show promise but require adequate resources, skilled mentors, and long-term strategies to ensure meaningful impact. Addressing these challenges necessitates collaboration among educators, parents, policymakers, and media, fostering a culture of cyber safety that empowers learners and mitigates the risks of an increasingly connected educational landscape.

III. METHODOLOGY

To deliver an exhaustive review of cybersecurity awareness within school and educational settings and to bridge identified research gaps, this study is grounded in the PRISMA ("Preferred

Reporting Items for Systematic Reviews and Meta-Analyses") framework [18].

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement is an authoritative and updated guideline that enhances transparency in the reporting of systematic reviews. It addresses the rationale, methods, and outcomes of reviews [19]. The choice of the PRISMA framework was driven by its standardization, which ensures consistency and reliability in the systematic review process; and its comprehensiveness [20], which is crucial to addressing the multi-faceted issues of cybersecurity comprehensively and practically in the education sector [21]. The review process was initiated using the PRISMA framework, which consists of four phases: identification, screening, eligibility, and inclusion. The flow diagram, providing detailed information and statistics, is shown in Fig. 1. The four phases are explained in detail below. Data collection was conducted by a single reviewer to maintain consistency in the extraction process. Four instructors provided guidance and oversight, ensuring the integrity and accuracy of the data collection.

A. Identification Phase

1) Selecting database: In the initial phase of the literature review for a systematic review of cybersecurity awareness in schools, a range of scholarly and normative databases were carefully selected to ensure comprehensive coverage of the relevant literature. Selected databases include ACM Digital Library, IEEE Xplore, ScienceDirect; SpringerLink, and Emerald .These platforms were strategically selected to access diverse, high-quality academic resources essential for the comprehensive exploration of current studies.

2) Selecting keywords: In the keyword selection phase of the Systematic Literature Review (SLR) on cybersecurity awareness in schools, specific research questions were identified to guide the research process.

- To explore practices for improving cybersecurity awareness in schools, (“cybersecurity” OR “security” OR “cybersecurity”) AND (“awareness” OR “learning”) AND (“framework” OR “model”), and Added Educational Context More detailed (“Education Sector”, “Academy”, “School” or “Educational Institution”) were used.
- Regarding the current problems and challenges that schools face in implementing cybersecurity awareness programs, the keywords (“challenges of cybersecurity education” OR “barriers to cybersecurity training” OR “cyber threats”) and (“education sector”) were used.
- For the target audience in cybersecurity awareness assessments, the keywords (“cybersecurity” OR “security” OR “cybersecurity”) AND (“awareness” OR “learning”) AND (“assessment” OR “evaluation”) were used.

These keywords were carefully selected to ensure comprehensive coverage and relevance to the study's specific areas of investigation.

3) Initial search :In the initial search stage of the systematic literature review (SLR) following the PRISMA framework, a comprehensive search was conducted across the selected databases. This search, based on the keywords identified in the previous stage, aimed to retrieve relevant scientific papers and yielded a total of 816 records.

4) Inclusion/exclusion criteria: To maintain the integrity and relevance of the systematic review, rigorous inclusion and exclusion criteria have been applied focused on impurity removal. The review is confined to studies published within the past five years (from 2019 to 2024), ensuring the data's freshness and pertinence to current contexts. Sources have been restricted to peer-reviewed articles which are critical for upholding high research standards and credibility. Additionally, all studies included in the review are published in English, setting a necessary linguistic criterion that aids in uniform comprehension and analysis. Furthermore, only studies classified as Q1 or Q2 are included to ensure the inclusion of high-quality research. On the exclusion front, any studies published before 2019 are omitted to reinforce the recency of the included research. Non-peer-reviewed materials are also excluded to preserve the scientific integrity and quality of the review. Studies not available in English or not meeting the quality classification are systematically excluded.

5) Duplicate removal: All the duplicate records were eliminated, which summed up to 220. It resulted in many duplicate records. Finally, the total remaining articles after the identification phase was .596

B. Screening Phase

Following the identification phase, the screening phase involved a detailed review of the title and abstract of each selected article 5 96articles met the criteria during this phase and were advanced to the subsequent eligibility phase. The screening was conducted using new inclusion and exclusion criteria specifically tailored for this stage, as outlined below.

Inclusion and Exclusion Criteria: During this phase of the PRISMA systematic review, criteria to refine the selection of articles were applied. Only studies that specifically focused on cybersecurity awareness within educational settings were included, as articles that did not directly focus on cybersecurity awareness within educational settings were excluded. For example, the study by Renaud & Ophoff, which explored cybersecurity implementation in SMEs rather than educational institutions, was excluded [22]. Additional exclusions included works such as those reported in Reference, Although it presents a cybersecurity awareness framework based on the behaviour change wheel, did not specifically target educational settings [23]. When information was missing or unclear, assumptions were made based on the available data. For instance, if a study did not specify the age range of students but was conducted in primary schools, it was assumed that the participants were aged 5–12 years, based on common educational structures. Similarly, for studies with incomplete intervention details, those elements were excluded from the analysis unless sufficient information justified their inclusion. This criterion led to the exclusion of 252 records that solely addressed information security awareness,

cybersecurity awareness, or other general security issues without a direct educational context.

C. Eligibility Phase

A total of 344 articles that successfully passed the second screening stage were chosen for in-depth full-text review during the eligibility stage. All articles were accessed, and the established filtering criteria were applied to evaluate each article at this stage.

Inclusion and Exclusion Criteria: During the eligibility phase of the PRISMA systematic review, stringent criteria were applied to refine the selection of articles, focusing on studies specifically within the context of schools to ensure alignment with the research aim. For example, the framework proposed in [24] for assessing cybersecurity maturity in higher education institutes (HEIs) in the UK, despite its comprehensive approach and use of recognized Capability Maturity Model (CMM) methodology, was excluded due to its specific focus on higher education. Rather than the specific educational context (schools), this careful selection process resulted in a significant reduction in eligible articles. This drastic decline stems from the overwhelming number of studies focusing on cybersecurity in educational settings, particularly schools, highlighting the challenge of finding research that focuses exclusively on the educational context, especially in schools. A careful selection and exclusion process ensures that the final set of articles strongly represents the most relevant and up-to-date research regarding cybersecurity awareness in schools, thus providing a solid foundation for identifying effective strategies and challenges specific to this educational context. In addition, a group of articles was excluded due to a lack of access to the full text, which will be illustrated in Fig. 1. Given that the studies evaluated during the Q1-2 phases are peer-reviewed, validated articles that have been thoroughly evaluated and reviewed by referees, issues of bias due to missing data were not encountered. This rigorous selection process ensures the reliability and integrity of the systematic review findings, providing a solid foundation for identifying effective strategies and challenges specific to cybersecurity awareness in schools.

D. Included Phase

All articles that successfully passed the third eligibility stage were carried forward into the final in-depth analysis of this study. Consequently, 14 articles that met all the criteria of this search were included for detailed examination.

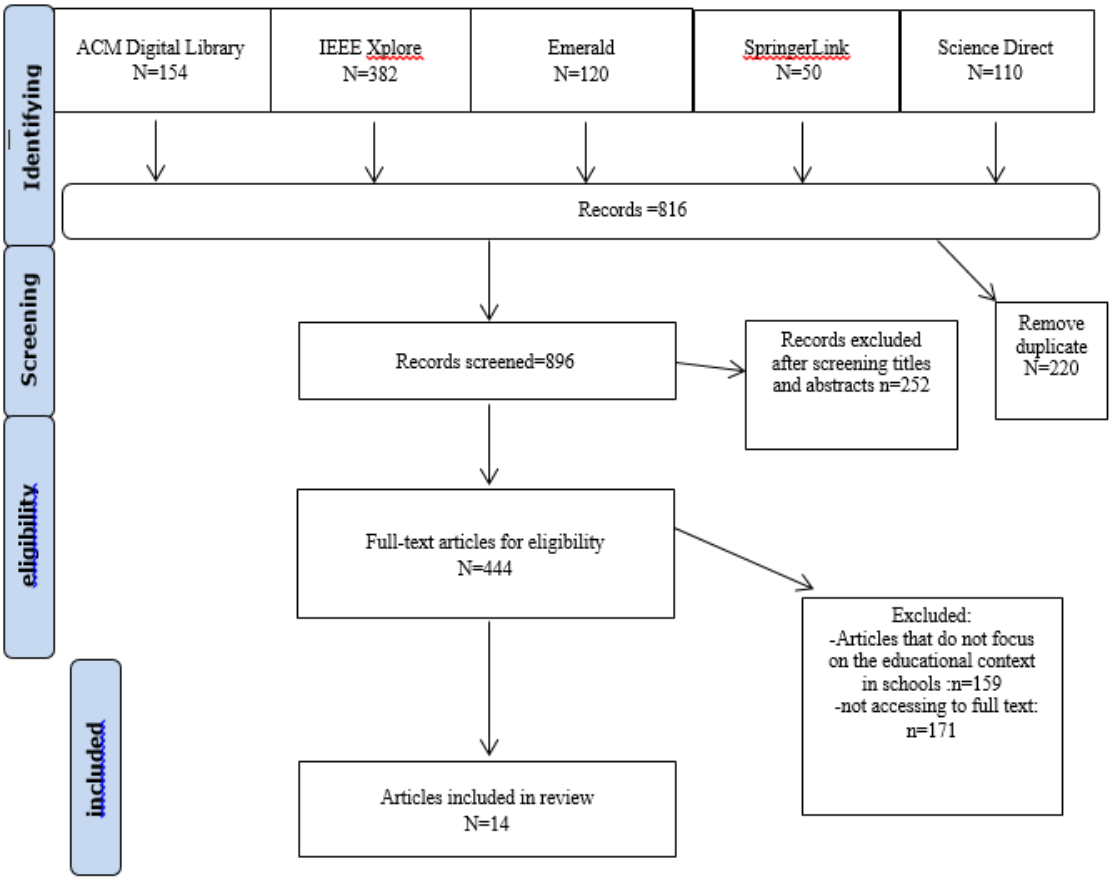

Fig. 1. Prisma flow chart.

IV. Results and Analysis

The results of this systematic review are presented based on the research questions through the analysis of the included studies (n = 14). Fig. 2 shows the distribution of the studied articles over the years in which they were published, these studies span from 2020 to 2024.

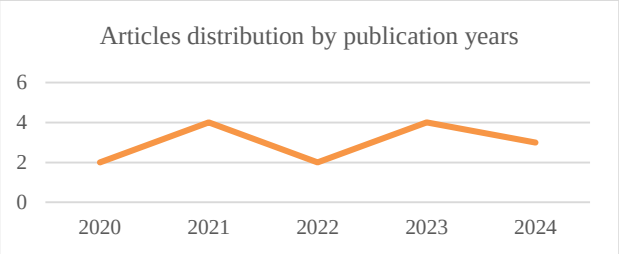

Fig. 2. Articles distribution by publication years.

While Fig. 3 shows the classification of the types of studied articles:

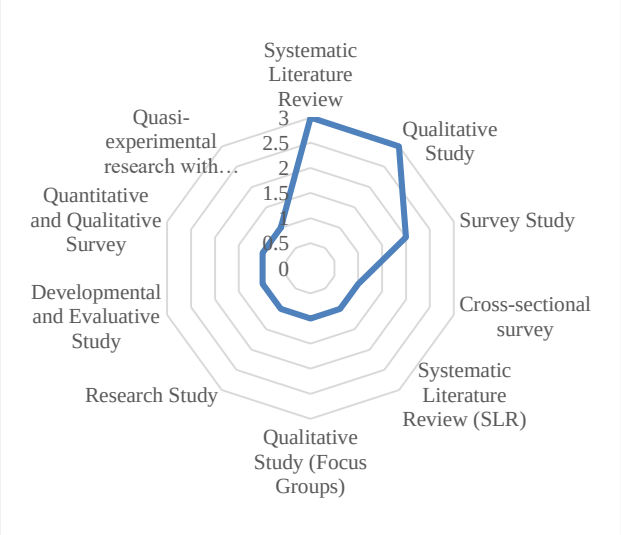

Fig. 3. The classification of the types of studied articles.

Addressing bias in systematic reviews

- Consultation with Experts: Collaboration with experts in the field of cybersecurity education was done to uncover any overlooked or insufficiently reported elements of cybersecurity awareness initiatives.
- The comprehensiveness of Reporting: Each study's reporting thoroughness was meticulously evaluated. Any discrepancies were looked for where expected results or data were absent and unaccounted for in the reports.

RQ1: what are effective practices to improve Cybersecurity awareness in schools?

Digital comics, serious games, and mobile applications are extensively used to foster engaging and interactive cybersecurity education, enhancing learning experiences by employing real-world scenarios and relevant challenges. This approach is particularly effective in engaging children and enhancing their understanding of cybersecurity concepts [25].Techniques such as the use of a web-based Learning Content Management System (LCMS) and mobile apps provide game-based cybersecurity education that captivates students' interest through interactive gameplay, which is crucial in maintaining student engagement and reinforcing cybersecurity [26]. Additionally, the gamified framework "Cyber-Hero" incorporates narrative techniques with serious games to offer an immersive learning experience that emphasizes critical cybersecurity skills, such as creating robust passwords and understanding online threats [27].

Tailored educational programs and comprehensive integration of cybersecurity into curricula are fundamental to creating a robust educational foundation. Segmented educational programs cater to specific demographic groups such as students, teachers, and parents, ensuring that each group receives relevant and effective cybersecurity knowledge [28]. Furthermore, the integration of cybersecurity topics throughout all K-12 levels ensures that students develop a comprehensive understanding from an early age, which is crucial for building a solid cybersecurity foundation [29].

Comprehensive cybersecurity education also involves the integration of national cybersecurity strategies into school curricula to align educational efforts with broader national security objectives [30]. Narrative-based learning techniques, which use storytelling and problem-solving to enhance engagement and understanding, are also highlighted as effective methods in making cybersecurity education more relatable and effective [11] [31].

Enhanced training programs for teachers and parents are critical to equipping them with the necessary skills to effectively impart cybersecurity knowledge and oversee children's online activities. These training programs not only enhance teachers' ability to teach cybersecurity effectively but also empower parents to supervise their children's online interactions more effectively [29]. Regular training sessions for both educators and parents help to ensure that children are adequately supervised and educated about the risks and safety measures associated with cyber activities [31] [32]. Additionally, the development of E-Safety frameworks that address ICT risks and the incorporation of feedback mechanisms into cyber wellness programs help monitor and control the effectiveness of cybersecurity education, adapting to new challenges and ensuring the safety of learners [33] [28]. Curriculum content that is framed around broad categories and uses innovative teaching methods like gamification not only enhances learning but also encourages active participation from students, making the learning process both enjoyable and educational [34]. Finally, the recommendations for interactive and practical teaching methods aim to engage students effectively and ensure that cybersecurity education evolves in response to new cybersecurity challenges, thus maintaining its relevance and effectiveness in educating young learners [11]

TABLE I. ANALYSIS OF PRACTICES OF CYBERSECURITY AWARENESS IN SCHOOL

Ref	Authors & year	study appraisal	Study type	Practices
[25]	Farzana Quayyum , Daniela S. Cruzes, Letizia Jaccheri (2021)	Q1	Systematic Literature Review	The review highlights multiple approaches to raising cybersecurity awareness among children. These include digital comics, serious games, and mobile apps focused on cybersecurity education. It emphasizes engaging children through interactive learning that covers internet fundamentals, privacy awareness, and risk management strategies.
[28]	T€urkera, Mıhcı and C¸akmakb, Ebru Kılıc¸ (2020)	Q2	Cross-sectional survey	The research utilizes detailed surveys to identify specific gaps in cyber wellness knowledge among students, teachers, and parents. Based on survey results, it recommends tailored educational interventions that address these specific knowledge gaps. Key practices include 1. Segmented Educational Programs: Developing age and role-specific educational materials that cater specifically to students, teachers, or parents. 2. Interactive Learning Modules: Implementing interactive and engaging learning modules that cover key topics like netiquette, cyberbullying, and online privacy practices. 3. Awareness Campaigns: Running targeted awareness campaigns that encourage safe and responsible internet use, focusing on the risks of internet addiction and the importance of copyright laws. 4. Feedback Mechanisms: Incorporating feedback mechanisms to continuously assess and improve the effectiveness of cyber wellness programs.
[29]	Ahmed Ibrahim, Marnie McKee, Leslie F. Sikos, Nicola F. Johnson (2022)	Q1	Systematic Literature Review (SLR)	The review suggests several targeted practices to enhance cybersecurity awareness: 1. Development of clear and consistent terminology across cybersecurity education to standardize teaching materials. 2. Incorporation of cybersecurity topics into curricula at all K-12 levels, ensuring a comprehensive understanding from a young age. 3. Enhanced teacher training programs to provide educators with the necessary skills and knowledge to effectively teach cybersecurity. 4. Use of interactive and practical learning modules to engage students and reinforce cybersecurity concepts
[32]	Stephanie Bannon, Tracy McGlynn, Karen McKenzie, Ethel Quayle (2024)	Q1	Qualitative Study (Focus Groups)	Inclusive Education Programs: Implement specialized cybersecurity education programs that account for the diverse needs of ASN students, emphasizing practical strategies to manage online risks. Parent and Teacher Training: Provide training for parents and teachers on how to support ASN students in navigating online spaces safely. Development of Tailored Online Safety Rules: Create school policies that address the specific online safety needs of ASN students, ensuring that they are comprehensible and enforceable.
[31]	Mohamed Ayyash, Tariq Alsboi, Omar Alshaikh, Isa Inuwa-Dutse, Saad Khan, and Simon Parkinson (2024)	Q1	Survey Study	Integration of Cybersecurity in Curriculum: Implement comprehensive cybersecurity education in schools. Narrative-based Learning: Emphasize storytelling, problem-solving, and video-based teaching methods to enhance engagement and understanding. Parent and Teacher Workshops: Organize regular training for parents and teachers to equip them with effective strategies to supervise and educate children on cybersecurity.
[35]	Ana Kovačević, Nenad Putnik, Oliver Tošković (2020)	Q1	Survey Study	Curriculum Improvement: Based on the study's findings, schools can enhance their curriculum to include more comprehensive cybersecurity education, focusing on practical knowledge and secure behaviors. Educational Programs: Development of targeted educational programs that address identified gaps in student knowledge and behaviors.
[34]	Rahime Belen Sağlam, Vincent Miller, Virginia N. L. Franqueira (2023)	Q1	Systematic Literature Review	- Curriculum content framed around six broad categories -Innovative teaching methods like gamification for a 'hands-on' experience. - Engaging students in curriculum design - Incorporating a 'bottom-up' approach listening to children's views.
[36]	Abel Moyo, Theo Tsokota, Caroline Ruvinga, Colletor T. Chipfumbu Kangara(2021)	Q1	Qualitative Research	- Development of an E-Safety framework to teach and safeguard learners from ICT-related risks. - Integration of cybersecurity knowledge into school curricula. - Continuous education, monitoring, and control of ICT use.
[37]	Farzana Quayyum, Jonas Bueie, Daniela S. Cruzes, Letizia Jaccheri, Juan Carlos Torrado Vida (2021)	Q1	Qualitative Study	- The study found that parents often discuss online security with their children at home, using real-world incidents reported in the media as teachable moments. - Schools in Norway enhance cybersecurity awareness by collaborating with organizations like Barnevakten, Bruk Hue, and Medietilsynet. These organizations assist in providing targeted cybersecurity training and lectures, not just for students but also for teachers and parents, fostering a comprehensive educational environment.
[27]	Hani Qusa, Jumana Tarazi (2021)	Q1	Research Study	- A new educational method is presented, the Gamification Framework (Cyber-Hero), which utilizes a specially designed gamified framework to boost early cybersecurity training in high schools. - This framework incorporates narrative instruction into serious games, which are strategically used to teach critical cybersecurity concepts, such as creating strong passwords. This method aims to make learning both engaging and effective.

				- The framework emphasizes two main dimensions—motivation and deployment. Motivational strategies include invoking emotions like fear to encourage proactive learning behaviors, while deployment strategies involve periodic gameplay and iterative learning, ensuring students can see their progress and are motivated to improve.
[30]	Saleh AlDaajeha , Heba Saleousa , Saed Alrabaeea, , Ezedin Barkaa , Frank Breitingerb , Kim-Kwang Raymond Chooc (2022)	Q1	Qualitative Analysis	- The study emphasizes the importance of integrating national cybersecurity strategies (NCSP) into educational curricula. - It suggests developing and aligning cybersecurity educational practices to meet the strategic objectives laid out by national policies.
[26]	Filippos Giannakas, Andreas Papasalouros, Georgios Kambourakis, Stefanos Gritzalis, 2023	Q2	developmental and evaluative study	- Utilization of a web-based Learning Content Management System (LCMS) and mobile application to deliver engaging, game-based cybersecurity education. - Application of the ARCS model of motivation to ensure the educational content is engaging and effective. - Flexible learning modes (standalone or client/server) to accommodate different learning environments and scenarios.
[13]	Julia Prümmer, Tommy van Steen, Bibi van den Berg (2024)	Q1	Systematic Literature Review	- Incorporate game-based training methods which were most frequently used and shown to be effective. - Employ a variety of training approaches, including simulation and presentation-based, to cater to different learning preferences and enhance effectiveness. - Use multi-method training campaigns to cover a broader range of cybersecurity topics effectively. - Ensure training includes interactive and engaging content to maintain participant interest and improve learning outcomes.
[11]	Dana Ondrušková, Richard Pospíšil, (2023)	Q2	Quasi-experimental research using time-series data to evaluate the impact of cyber security training on the online behavior of school children.	- Recommends integrating cybersecurity education into the ongoing educational curriculum rather than relying on one-off interventions. - Suggests using interactive and practical teaching methods to engage students effectively. - Recommends ongoing assessments and adaptations of educational content to ensure it meets the evolving challenges of cybersecurity.

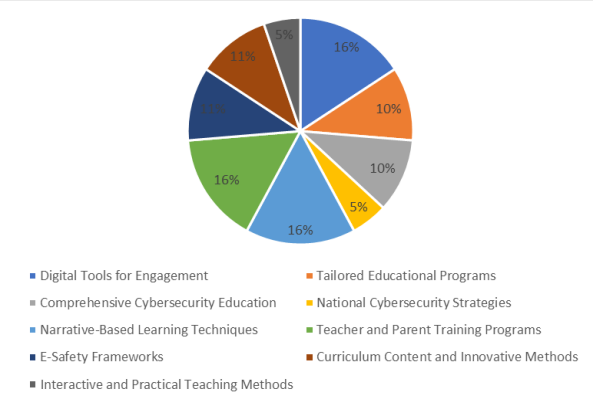

Fig. 4. Effective cybersecurity awareness practices in schools.

RQ2: What are the current issues and challenges that schools face in implementing cybersecurity awareness programs?

- Comprehensive Curriculum and Effective Educational Approaches*:*

The development of a comprehensive, consistent curriculum is critical yet challenging, necessitating curricula that not only cover a broad range of cybersecurity topics but are also adaptable to various learning needs, including those of students with Additional Support Needs (ASN). The challenge is compounded by often inconsistent educational content across different programs, which can lead to gaps in student knowledge and preparedness. Furthermore, traditional training methods have shown limitations in effectively engaging and educating students, highlighting the need for innovative approaches that cater effectively to today's diverse student bodies [25] [34] [26]. Fig. 4 shows effective cybersecurity awareness practices in schools.

- Parental Involvement and Supervision:

The role of parents in reinforcing cybersecurity education at home is crucial, yet many parents lack adequate cybersecurity awareness, which undermines their ability to support their children's learning and enforce safe online practices. Schools face the challenge of empowering parents with the necessary tools and knowledge to better manage and monitor their children's online activities. This includes providing parents with training and regular updates on cybersecurity practices and potential threats, thereby extending the learning environment beyond the classroom and fostering a holistic approach to cybersecurity education [31] [37]

- Knowledge and Awareness Gaps:

A major barrier to effective cybersecurity education is the lack of clarity in cybersecurity terminology and the absence of systematic teaching methods, particularly at the K-12 level. These gaps not only affect students but also impact educators and parents, complicating the task of achieving a comprehensive

understanding of cybersecurity across all stakeholders. The disparities in awareness based on demographic factors such as gender, class, and daily internet usage necessitate tailored educational efforts to ensure that all students, regardless of background, receive adequate and effective cybersecurity training [28] [29] [35].

- Human and Resource Limitations:

Human error is identified as a significant vulnerability in cybersecurity, exacerbated by a shortage of trained specialists within the educational sector. This shortage hampers the ability of schools to develop and deliver effective cybersecurity education, further strained by inadequate resources. Addressing these limitations requires not only more specialized training for educators but also sufficient funding to ensure that schools can afford to implement robust cybersecurity programs [27] [30].

- Engagement and Methodology Effectiveness:

Keeping students engaged in cybersecurity learning is a major challenge, particularly for younger audiences who may find traditional methods unappealing. The effectiveness of various training methodologies varies widely, and contradictory findings in research on optimal training methods create confusion about the best approaches to take. This situation calls for continuous experimentation and adaptation of teaching strategies to find what works best in different educational contexts [26] [13]

- Monitoring and Control Difficulties:

Implementing effective digital monitoring in schools involves navigating complex privacy issues and technical challenges. Schools must balance the need to monitor students' online activities to ensure their safety with the need to respect privacy rights. Effective policies and tools are needed to navigate these waters successfully, which requires ongoing dialogue among educators, parents, and policymakers [33]

- Intervention and Training Impact:

The impact of cybersecurity interventions and training programs varies widely, with some interventions showing limited effects on long-term behavioural changes and awareness among children. The success of these interventions often hinges on their duration and intensity. Well-designed, sustained programs that are integrated into the regular curriculum are more likely to have a lasting impact, highlighting the need for continuous evaluation and adaptation of these programs to meet evolving educational needs [11].

Intervention and Training Impact	[11]

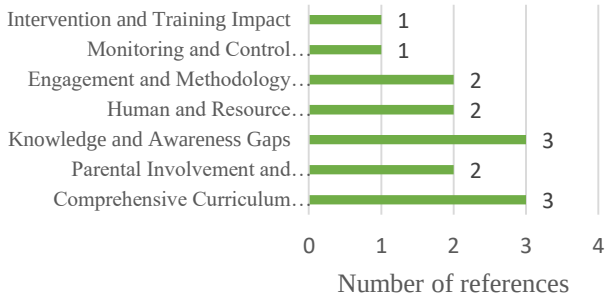

Fig. 5. Challenges of cybersecurity awareness.

RQ3: Who is the target audience in the current assessment of cybersecurity awareness?

The current assessment of cybersecurity awareness (Fig. 5) comprehensively addresses a diverse array of target audiences, each identified as critical in the ongoing efforts to enhance cybersecurity education. Primary school students are among the youngest learners, and their engagement is facilitated through digital tools such as comics, serious games, and mobile applications. These tools are essential in introducing foundational cybersecurity concepts in an age-appropriate and engaging manner, fostering early awareness and safe online behaviours [26] [25]. Secondary and high school students represent a slightly older demographic that faces more complex online risks, including cyberbullying, online privacy issues, and password security. For these students, educational programs often incorporate interactive and gamified learning experiences designed to maintain their engagement while reinforcing critical cybersecurity skills. These approaches are tailored to address the developmental and cognitive abilities of this age group, ensuring that the learning is both relevant and effective [28][33][27][30]. Teachers are a pivotal audience in this context, as they are the primary facilitators of cybersecurity education within schools. Training programs for teachers are therefore crucial, providing them with the necessary knowledge and pedagogical tools to effectively deliver cybersecurity education. Such programs also emphasize the importance of continuous professional development, enabling teachers to stay updated with the latest cybersecurity trends and threats [28][31][33]. Meanwhile, parents are recognized as the first line of defense in a child's online life. However, many parents lack the requisite knowledge and tools to effectively monitor and guide their children's online activities. Studies recommend targeted training for parents to improve their understanding of cybersecurity risks and how to communicate these risks effectively to their children, thereby extending cybersecurity education from the classroom to the home environment [31][37]

Curriculum designers and policymakers play a strategic role in shaping the educational landscape to include comprehensive cybersecurity education. Their responsibility involves integrating cybersecurity topics into the broader educational curriculum, ensuring that these efforts are aligned with national security objectives and are adaptable to the rapidly evolving digital threats [29] [11]. Additionally, in the corporate sector, corporate trainers and HR professionals are identified as key

audiences for cybersecurity training. These professionals are tasked with implementing training programs that not only educate employees about cybersecurity risks but also engage them through innovative methods such as game-based learning, which has been shown to enhance the effectiveness of these programs[13]. Finally, cybersecurity professionals are a crucial audience, as they are directly involved in protecting organizations from cyber threats.

The studies underscore the need for advanced educational frameworks tailored to these professionals, focusing on developing their skills to address the dynamic and complex nature of cyber threats. These frameworks are designed to enhance the preparedness of cybersecurity teams, ensuring they are equipped to handle real-world challenges effectively [30][13].

This comprehensive, multi-audience approach to cybersecurity awareness is critical in creating a resilient educational ecosystem that prepares all relevant stakeholders to navigate the digital world safely and responsibly.

TABLE III. ANALYSIS OF TARGET AUDIENCES

Category	Reference Numbers
Primary School Students	[26][25]
Secondary School Students	[28] [34] [36] [27]
K-12 Students	[29]
Children Aged 13-15	[11]
Special Needs Students	[32]
Teachers	[28] [36] [31]
Parents	[31] [37]
Curriculum Designers and Policymakers	[26] [29] [11]

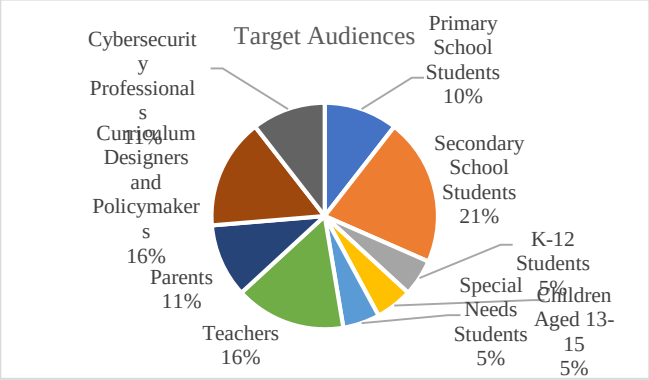

Fig. 6. Target audiences for cybersecurity awareness.

This systematic review systematically explores key practices, challenges, and target audiences (Fig. 6) in advancing cybersecurity awareness within educational institutions. The findings demonstrate that strategies such as the integration of digital tools, embedding cybersecurity within K-12 curricula, and targeted training for educators and parents significantly enhance student engagement and comprehension. However, challenges such as inconsistencies in curricular content, insufficient parental involvement, and resource constraints persist as significant barriers. The review underscores the necessity of tailoring cybersecurity practices to diverse target groups, including students, teachers, parents, and policymakers, to develop a comprehensive and resilient cybersecurity education framework. Crucially, the practices identified in the literature varied substantially depending on the target audience, leading to a wide range of specific outcomes for each group. The certainty of the evidence was evaluated, with particular attention to directness, ensuring that the findings closely aligned with the research questions and provided a robust foundation for the recommendations, despite some variations in study design and reporting rigor.

V. DISCUSSION

The findings from this systematic literature review reveal several dimensions of cybersecurity awareness in schools, emphasizing both effective practices and persistent challenges. The necessity for comprehensive and adaptable cybersecurity curricula is underscored, reflecting a critical need to bridge the gap between the evolving demands of the digital world and current educational offerings. This aligns with Blažič & Blažič, 2022 [38], who highlight the disconnect between educational content and the realities of digital threats, suggesting a pressing need for curriculum updates that mirror current technological landscapes. Innovative teaching methods, particularly those incorporating interactive tools like serious games and mobile apps, have proven effective. These methods resonate with findings from Jin et al., 2018, who confirm the efficacy of game-based learning in engaging students and enhancing their understanding of complex cybersecurity concepts [39]. However, the review also points to significant barriers in the development and implementation of such curricula, notably the inconsistency across educational programs which leads to gaps in cybersecurity knowledge and preparedness, as discussed by Lehto, 2022, this inconsistency can leave students underprepared for the cybersecurity challenges they face [40]. Furthermore, the review brings attention to the necessity of inclusive education strategies, particularly for students with Additional Support Needs (ASN). Ensuring that cybersecurity education is accessible to all students is crucial, a sentiment echoed by Ondrušková & Pospíšil, 2023 , who stress the importance of tailored approaches for students with special needs to safely navigate the digital world [11]. Parental engagement emerges as another vital component. The effectiveness of cybersecurity education often hinges on the support and knowledge of parents, yet many lack the necessary skills to guide their children in safe online behaviors, a gap highlighted by Al-Naser et al., 2019 emphasizes the need for programs that not only educate students but also empower parents with the necessary cybersecurity knowledge[41].

Additionally, the review identifies widespread gaps in knowledge among students, teachers, and parents, exacerbated by unclear cybersecurity terminology and a lack of systematic teaching approaches. This challenge is supported by O'Brien, 2019, who notes that the absence of standardized cybersecurity curricula in public schools underscores a widespread educational deficiency [42].

Demographic factors such as age, gender, and internet usage habits also influence cybersecurity awareness, necessitating more personalized educational interventions to address these disparities, as noted by Fatokun et al., 2019, this approach ensures that cybersecurity education is effective and inclusive, catering to the diverse needs of all students [43].

Moreover, the scarcity of trained cybersecurity specialists and adequate funding further constrains the ability of schools to offer effective cybersecurity education, a situation highlighted by Catota et al., 2019 argue for increased investment in both human resources and financial support to enable the development of comprehensive cybersecurity programs [44]. Issues of privacy and the need for effective digital monitoring are also discussed, pointing out the increasing complexity of maintaining privacy in an age of widespread digital surveillance[45]. This complexity necessitates clear policies and careful decision-making to balance safety and privacy rights effectively. Lastly, the variable impact of cybersecurity interventions is noted, with some programs significantly enhancing awareness and behavior, while others show limited long-term effects. Nasir, 2023 supports this observation, suggesting that the effectiveness of cybersecurity education programs can vary greatly depending on their design and implementation, highlighting the need for well-structured, sustainable initiatives[46].

Based on the discussion, this systematic literature review outlines strategies to boost cybersecurity awareness across educational levels through adaptable curricula incorporating key cybersecurity concepts and evolving through expert collaboration. It emphasizes creating targeted programs to enhance parental awareness, designing inclusive curricula with interactive tools like comics and games, and engaging the community through regular outreach. Recommendations include ongoing professional development for teachers, regular curriculum assessments, and partnerships with cybersecurity organizations to keep educational content current. Additionally, establishing clear online safety policies is advocated to ensure a secure learning environment. These measures aim to prepare students, teachers, and parents to confidently navigate digital challenges, underscoring the need for continuous research to keep educational practices up-to-date with the digital landscape.

VI. Conclusion

The systematic literature review on cybersecurity awareness in schools reveals critical issues and effective practices necessary for improving cybersecurity education. Key challenges include the lack of a consistent and comprehensive curriculum, inadequate parental supervision and knowledge, and the diverse needs of students, especially those with additional support needs (ASN). Effective practices identified include using interactive educational tools, tailored interventions, gamification, and narrative-based learning. Additionally, community involvement and continuous improvement of cybersecurity programs are essential. Recommendations include developing standardized curricula, enhancing parental education, tailoring programs for diverse needs, using interactive tools, implementing innovative teaching methods, fostering community involvement, providing ongoing professional development for educators, conducting regular assessments, establishing partnerships with cybersecurity organizations, and promoting safe online practices. Implementing these recommendations can significantly enhance cybersecurity awareness among students, educators, and parents, creating a safer online environment.

VII. Study Limitations

Despite the comprehensive approach taken in this systematic literature review, several limitations must be acknowledged. The scope was confined to studies published in the past five years and limited to peer-reviewed articles in English, potentially excluding valuable insights from earlier research, non-English publications, and grey literature. The selected databases, although extensive, may not encompass all relevant studies, especially those in lesser-known journals or emerging sources, leading to an incomplete representation of the current state of cybersecurity awareness in schools. The PRISMA framework relies heavily on the quality and reporting standards of included studies, so any deficiencies directly impact the reliability and generalizability of the findings. Additionally, the exclusion of articles due to lack of full-text access or lower quality thresholds might have omitted pertinent studies. Potential bias introduced by the subjective nature of the inclusion and exclusion criteria, despite consistent application efforts, could influence the final selection of articles. Furthermore, the review did not deeply analyze the diverse educational contexts and varying levels of technological infrastructure across different regions and countries, which means the applicability of certain findings and recommendations may be limited or require adaptation to fit specific local contexts. Addressing these limitations in future research will be essential to developing a more comprehensive and nuanced understanding of cybersecurity awareness in schools, enhancing the effectiveness of educational strategies and interventions across diverse settings.

- Funding statement:

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. All resources utilized were provided by the authors' own efforts.

- Registration Information:

The review was not registered in any systematic review protocol registry.

- Review Protocol Access:

No protocol was prepared for this systematic review.

- Amendments to Protocol or Registration:

As no protocol was prepared or registered, there were no amendments related to registration or protocol.

- Competing Interests

There are no competing interests to declare. No financial, personal, or professional conflicts influenced the conduct, results, or reporting of this systematic review.

- Availability of Data, Code, and Other Materials:

This systematic review exclusively involves the inclusion and analysis of previously published studies. No new data,

analytic code, or other materials were generated for this review. Therefore, there are no additional materials available for public access. All relevant data have been extracted from the included studies and are presented within the manuscript.

Integrating Multi-Agent System and Case-Based Reasoning for Flood Early Warning and Response System

Nor Aimuni Md Rashid[1]*, Zaheera Zainal Abidin[2], Zuraida Abal Abas[3]
Faculty of Information and Communication Technology, Universiti Teknikal Malaysia Melaka (UTeM)[1, 2, 3]
College of Computing, Informatics and Mathematics, Universiti Teknologi Mara, Malacca Branch, Malacca, Malaysia[1]

***Abstract*—This research addresses the limitations of current Multi-Agent Systems (MAS) in Flood Early Warning and Response Systems (FEWRS), focusing on gaps in risk knowledge, monitoring, forecasting, warning dissemination, and response capabilities. These shortcomings reduce the system's reliability and public trust, highlighting the need for better flood preparedness and learning mechanisms. To tackle these issues, this study proposes a new conceptual framework combining Case-Based Reasoning (CBR) with MAS, aimed at enhancing flood prediction, learning, and decision-making. CBR enables the system to learn from past flood events by retrieving and adapting cases to improve future predictions and responses, while MAS allows for decentralized and collaborative decision-making among various agents within the system. This integration fosters a dynamic, real-time system that adapts to changing conditions and improves over time through continuous feedback. The framework's effectiveness is evaluated using the quadruple helix model, addressing social, economic, environmental, and governance aspects. Socially, the system increases community resilience through improved early warnings. Economically, it reduces flood impacts by enabling faster and more accurate responses. Environmentally, it enhances monitoring and preservation of ecosystems. In governance, the framework improves coordination between agencies and the public. The CBR-MAS framework significantly improves intelligent detection, decision-making speed, and community resilience, offering substantial improvements over traditional FEWRS. This adaptive approach promises to build a more reliable, trust-worthy system capable of handling the complexities of flood risks in the future.**

***Keywords*—Flood; multi-agent system; flood early warning system; case-based reasoning; quadruple helix; flood risk**

I. Introduction

Floods are a prevalent natural phenomenon that can significantly impact human settlements and the surrounding ecosystem, often resulting in substantial socio-economic consequences. These impacts include property destruction, infrastructure impairment, and the interruption of vital services [1]. As flood risks grow more severe due to climate change and other factors, there has been a notable shift towards flood risk mitigation strategies, especially when traditional flood defense methods are perceived as ineffective or impractical [2]. Therefore, understanding the vulnerability of communities to flood impacts and developing comprehensive strategies for prevention, mitigation, and management is crucial [3].

Flood disaster management requires a multi-faceted approach that spans across different stages of a flood event. This is typically divided into three main categories: pre-disaster, during the disaster, and post-disaster, encompassing four phases: (i) prevention/mitigation, (ii) preparedness, (iii) response, and (iv) recovery [4], [5], [6] as shown in Fig. 1. A key component of flood preparedness is the Flood Early Warning System (FEWRS), which provides prompt and reliable data on potential flood occurrences. A well-designed FEWRS allows authorities to proactively monitor and detect potential hazards, enabling early intervention and preparation to mitigate the flood's impact [5].

According to the United Nations Office for Disaster Risk Reduction (UNDRR), a comprehensive early warning system integrates hazard monitoring, forecasting, disaster risk assessment, communication, and preparedness activities [7]. This enables communities, governments, businesses, and other entities to take timely action before a hazardous event occurs. As described by the World Meteorological Organization (WMO) in 2011 [8], flood forecasting and warning systems serve as a bridge between accurate rainfall forecasting, hydrometric data collection, real-time flood forecasting models, and issuing early warnings.

The Sendai Framework for Disaster Risk Reduction (SFDRR) [9] also identifies FEWRS as a high-priority tool for flood risk management, essential for mitigating the increasing flood risks posed by climate change in both industrialized and developing countries [10]. A comprehensive FEWRS as shown in Fig. 2, includes four key components: (i) risk knowledge, (ii) monitoring and forecasting, (iii) warning dissemination and communication, and (iv) response capabilities [11]. Each component plays a critical role in ensuring the effectiveness of early warning systems. For instance, risk knowledge encompasses understanding exposure, hazard, and vulnerability, while monitoring and forecasting address the uncertainties of hydrodynamic and meteorological factors. Any deficiency in these components can jeopardize the entire system's functionality [10], [12].

In recent years, Multi-Agent Systems (MAS) have emerged as a valuable tool in flood management. MAS offers a dynamic approach to modeling complex and distributed domains, improving decision-making, flood forecasting, risk assessment, and response capabilities [13]. MAS has been successfully applied in various areas, including reservoir flood control

optimization [14], traffic simulation during floods [15], and assessing flood losses and household responses [16]. By integrating physical and social aspects of flood risk, agent-based models and MAS provide a promising approach to address the complexities of flood management [17].

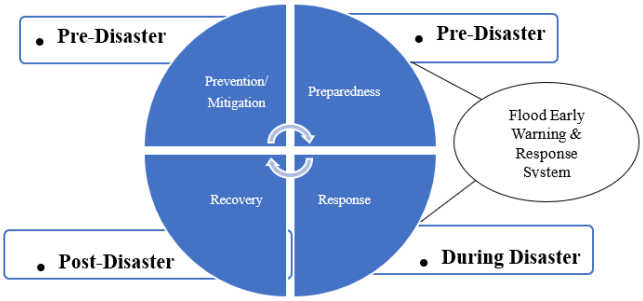

Fig. 1. Flood disaster management phases.

Fig. 2. FEWRS main components.

Current flood warning systems confront issues such as limited flexibility, a lack of collaborative behavior, and insufficient utilization of real-time input, all of which impede efficient crisis decision-making. The research seeks to answer key questions: How can CBR and MAS enhance the adaptability and accuracy of flood warning systems? What role does stakeholder collaboration, through the quadruple helix model in social, economic, environmental, and governance perspectives play in improving disaster management? How can the proposed framework address real-world challenges in flood response? This study tackles these difficulties by investigating how to combine Case-Based Reasoning (CBR) with Multi-Agent Systems (MAS) to develop a more flexible and collaborative framework for flood control. The goal is to improve forecast accuracy and decision-making by incorporating important stakeholders in the quadruple helix model in the area of social, economic, environmental, and governance perspectives. This research explores the application of MAS in addressing flood-related hydrological issues and systematically classifies MAS approaches in hydrologic modeling and prediction. It aims to demonstrate how these sophisticated techniques can enhance flood early warning systems and decision-making processes.

The paper is structured as follows: Section II focuses on materials and methods which discuss on the flood-related MAS modelling and reviewing various methods. Section III introduces a conceptual framework for MAS-FEWRS, while Section IV analyzes and evaluates the research findings. Finally, Section V concludes by summarizing the main findings and highlighting the significance of MAS-FEWRS in improving flood disaster management practices.

II. Material and Methods

Given the gradual increase in complexity of the contemporary world, it is imperative to acknowledge that flood prediction processes are also becoming increasingly intricate in tandem with the changing global climate. Consequently, it is imperative to develop, examine, and construct models that exhibit higher levels of complexity to effectively capture the interactions between the system and its growing complexity [13]. The escalation of complexity on a global scale may suggest that traditional models may not be sufficient in accurately depicting these intricate transformations. Hence, the utilization of MAS can effectively address complex problems that may prove challenging or unfeasible for a single agent or a monolithic system to resolve. Therefore, intelligence can encompass systematic, functional, procedural, or algorithmic methods for searching, discovering, and processing information [18].

A. Data Collection

Our research methodology involved a literature review to identify relevant articles for this study on developing a flood early warning system using multi-agent approaches. Initially, we collected a total of 76 articles from Scopus, Web of Science (WOS), and Institute of Electrical and Electronics Engineers (IEEE) databases. To refine our selection, we first removed any duplicate articles, resulting in 61 unique articles. Next, we scanned the titles and abstracts of these articles to assess their relevance to this research topic. By excluding 20 articles that did not align with our research objectives or did not address flood early warning systems or agent-based approaches, we were left with 41 articles.

Moving forward, we obtained the full texts of the 41 selected articles and performed a thorough reading and analysis. During this process, we carefully evaluated each article based on predefined inclusion criteria. After a comprehensive assessment, we excluded 26 articles that did not meet these criteria, leaving us with a final set of 15 articles that are directly pertinent to our research topic. The 15 relevant articles will serve as the foundation for the methods section of our research paper. They will contribute valuable insights into existing methodologies, techniques, and findings on flood early warning systems and agent-based/multi-agent approaches. By leveraging the knowledge gained from these articles, we will be able to propose and develop our own flood early warning system using multi-agent techniques, building upon the existing literature in the field. Fig. 3 depicts the review process.

B. Review Analysis

Based on the 15 articles, a comparative analysis was conducted. The relevant research papers were reviewed, and a comparison was made based on three criteria. The first criterion

focuses on the components of the FEWRS. This includes risk knowledge, monitoring and forecasting, warning dissemination, and response capabilities. Consequently, the second criterion examines the basic features of MAS, such as leadership, decision function, heterogeneity, agreement parameter, delay consideration, data transmission frequency, mobility, reasoning, perception, communication, and negotiation methods. The third criterion is based on key aspects of designing MAS models, including coordination control, Multi-Agent Learning System (MAL), fault detection, task allocation, localization, organization, and security.

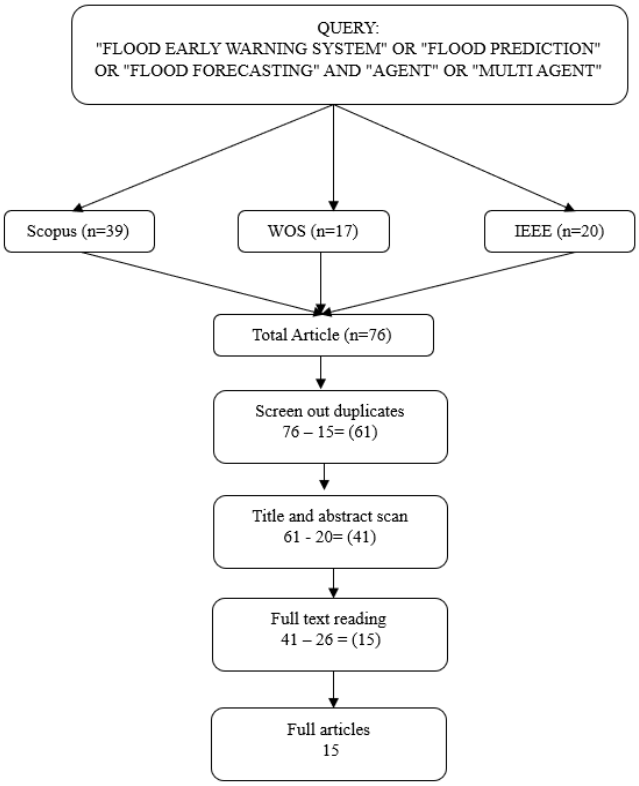

Fig. 3. Review analysis.

Through this comparative analysis, the strengths and limitations of existing approaches in flood early warning systems using agent-based techniques are evaluated, and potential areas for improvement in the design of such systems are identified. Table I depicts the mapping of existing MAS-based flood-related modeling with FEWRS components. In contrast, Tables II compare the existing MAS-based flood modeling with the basic features and key aspects of designing a MAS-based model in complex systems.

Fig. 4 illustrates the observed trends in FEWRS components implementation over the years. Between 2003 and 2009, there was a consistent presence of two key themes: "Risk Knowledge" and "Monitoring & Forecasting." This indicates an initial focus on comprehending risks and monitoring procedures. Nevertheless, it appears that the activities related to "Warning Dissemination" and "Response Capabilities" were relatively inactive during this timeframe, suggesting a potential emphasis on acquiring information rather than the prompt implementation of measures. The year 2011 witnessed a notable transition characterized by an increase in the practice of "Monitoring & Forecasting" and the emergence of "Warning Dissemination," indicating a proactive stance towards mitigating potential risks. By 2014, the domain of "Monitoring & Forecasting" had established a firm position, whereas the domain of "Risk Knowledge" experienced a decline in its level of prominence. However, there has been a noticeable shift towards prioritizing the dissemination of warnings and occasional displays of response capabilities, indicating an increasing emphasis on prompt and efficient responses.

The years 2015 and 2021 demonstrated significant advancements, as evidenced by the consistent prevalence of "Warning Dissemination" and "Risk Knowledge" and the emerging recognition of the importance of "Response Capabilities." By 2022, the domains of "Monitoring & Forecasting," "Warning Dissemination," and "Response Capabilities" had attained a state of strong establishment, thereby highlighting the adoption of a comprehensive and proactive strategy for the development of the system. The capabilities of the MAL System have demonstrated significant advancement over time. Initially, the system relied on the collaborative ANYTIME Multi-Agent System (AMAS) theory. However, it has since progressed to more sophisticated methodologies such as Deep Q-Network (DQN) and Twin Delayed-Deep Deterministic Policy Gradient. In general, the observed patterns suggest a gradual and flexible evolution within the system, demonstrating a continuous dedication to enhancing its capacities and ability to withstand potential obstacles.

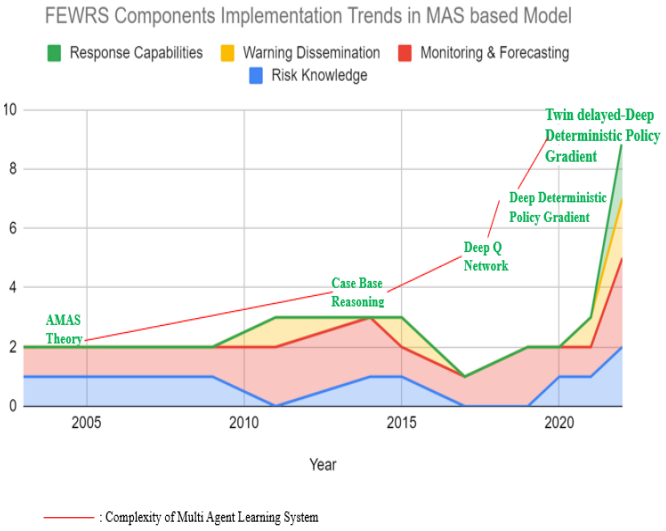

Fig. 4. FEWRS observed trends of MAL implementation.

TABLE I. EXISTING MODEL ANALYSIS

Research/ Existing model	Year	FEWRS Components				Input Parameter	Output Parameter
		Risk Knowledge	Monitoring & Forecasting	Warning Dissemination	Response Capabilities		
[20]	2003	/	/	X	X	Rainfall Level, River Level	Hourly Water Level
[21]	2009	/	/	X	X	Rainfall Level, River Level	Hourly Water Level
[22]	2011	X	/	X	X	River flow, River level, Precipitation	River flow, Warning code
[23]	2011	X	/	/	X	Rainfall, Water level	River water level, Flood alert (mild, critical, dangerous)
[24]	2014	X	/	X	X	Rainfall, Flow velocity, Water level	Sensor data classification to valid and invalid
[18]	2014	/	/	X	X	Rainfall	Water Level
[25]	2015	/	/	/	X	Rainfall, Runoff, Water Level	Estimate time for flood
[26]	2017	X	/	X	X	Rainfall, Flow velocity, Water level	Sensor data classification to valid and invalid
[27]	2019	X	/	X	X	Rainfall	Flood prone area
[28]	2019	X	/	X	X	Processed optical image, local state of the swarm	Flood prone area
[29]	2020	/	/	X	X	Rainfall	Water level
[30]	2021	/	/	/	X	Rainfall, Runoff, Water Level	Estimate time for flood
[31]	2022	X	/	/	/	Satellite photos, Meteorological data	Flood status (yes/no)
[32]	2022	/	/	X	X	Rainfall, flow rate	Discharge rate of the dam
[33]	2022	/	/	/	X	Rainfall, Water level, streamflow	Flood status (yes/no)

TABLE II. EXSITING MODEL ANALYSIS BASED ON MAS DESIGN ASPECT

Research/ Existing Model	MAS Design Key Aspects Consideration						
	Coordination Control	Multi-Agent Learning (MAL) System	Fault Detection	Task Allocation	Localization	Organization	Security

III. RESULT

The conceptual framework presented in this research paper (Fig. 5) is derived from a combination of previous concepts related to FEWRS, MAS design principles, and a thorough review of existing models. By building upon these foundations, our framework aims to improve the effectiveness and efficiency of FEWRS in mitigating flood hazards. The framework's development starts with examining FEWRS, serving as the basis for understanding the core components and requirements of flood early warning systems. Hence, by analyzing the strengths and limitations of existing FEWRS models, our framework incorporates advancements and novel approaches to address critical challenges in flood management.

Drawing on the principles of MAS, our framework introduces a multi-agent architecture comprising different specialized agents. These agents, including the Monitoring Agent, Forecasting Agent, Warning Dissemination Agent, Response Agent, and Learning Agent, work collaboratively to enhance the overall performance of the flood early warning system. Additionally, this framework incorporates active learning and inference techniques within a Reasoning/Inference Agent. This agent leverages data and information the system collects to make informed decisions and predictions regarding flood events. Thus, this active learning approach enhances the system's adaptability and predictive capabilities.

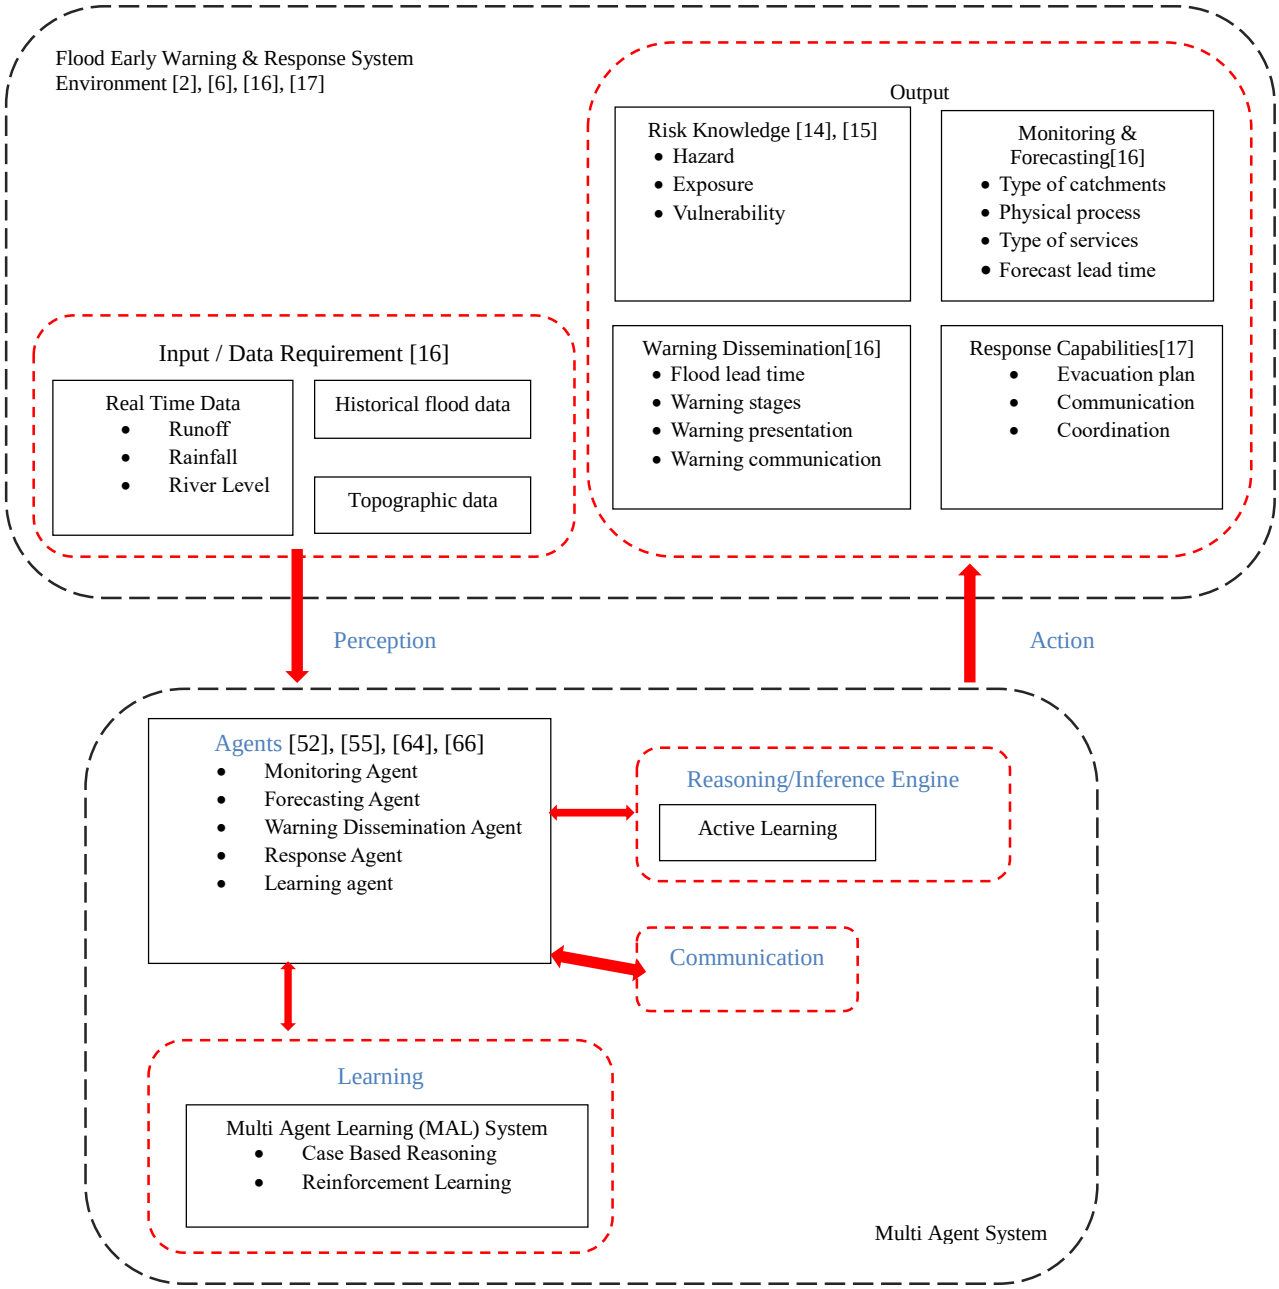

Fig. 5. Proposed MAS-FEWRS conceptual framework.

Other than that, communication is another integral component of the framework. It enables seamless information exchange among the agents, ensuring coordination and synchronization in decision-making. Effective communication mechanisms are designed to facilitate real-time data sharing, forecast dissemination, warning communication, and response coordination. Furthermore, the Perception component acts as a bridge between the MAS and the FEWRS environment. It encompasses collecting various data types, such as real-time data (river level, runoff, rainfall), historical data, and topographic data. These inputs are fed into the system for analysis, modeling, and decision-making processes.

The action component represents the output of the MAS, directed toward the FEWRS environment. It encompasses the four key components of FEWRS: Risk Knowledge, Monitoring and Forecasting, Warning Dissemination, and Response Capabilities. The framework provides a comprehensive approach to flood management by integrating these components. Moreover, this framework introduces a MAL System: Case-Based Reasoning (CBR) technique. This learning system enhances the overall adaptability of the agents by leveraging past experiences.

In summary, our conceptual framework is derived from previous concepts related to FEWRS, MAS design principles, and a review of existing models. By combining these elements, our framework introduces a comprehensive approach to flood early warning systems, emphasizing collaboration among agents, active learning, effective communication, and a past experience learning system. It emphasizes the importance of data collection, analysis, communication, and coordinated response for effective flood management.

IV. Discussion

Our discussion is structured into four main components, each addressing a distinct aspect of our research; (i) Understanding FEWRS and Identifying Key Challenges, (ii) Comparative Analysis of Existing Flood Early Warning System Models, (iii) Conceptual Framework: Building upon the insights gained from the comparative analysis and (iv) Impact of the Conceptual Framework using Quadruple Helix Model.

A. Understanding Flood Early Warning Systems (FEWRS) and Identifying Key Challenges

FEWRS is crucial in minimizing the damage and casualties caused by floods [34, 35, 36]. However, the efficiency of FEWRS in flood disasters is limited by various factors. Factors such as system quality, information quality, user satisfaction, service quality, use, perceived usefulness, intention to use, net benefits, perceived ease of use, compatibility, user experience, relative advantage, complexity, perceived risks, educational quality, and confirmation have been identified as significant factors affecting the effectiveness of FEWRS. Moreover, accurate intelligence is essential for issuing early warnings and responding effectively to floods. A structured review of the FEWRS literature identified twenty-seven types of key intelligence required in the flood cycle. This intelligence can be captured using technological solutions at various stages of a flood event to support decision-making for early warnings and response.

Implementing effective FEWRS is crucial in reducing losses and casualties caused by floods. The SFDRR emphasizes the need for multi-hazard warning systems and disaster risk information, including FEWRS, to be available to the community by 2030. The increased losses from floods can be attributed to population growth and rapid urbanization. To improve the effectiveness of FEWRS, it is important to enhance the employment performance of government agencies through technological innovation. FEWRS should have effective usability features and strategic information access and display to provide accurate and timely information to stakeholders. However, existing FEWRS often fail to effectively provide information on flood disasters, highlighting the need for improvement.

B. Comparative Analysis of Existing Flood Early Warning System Models

In this comparative discussion, we analyze and compare the information presented in three different areas: FEWRS components, MAS features, and key aspects for designing MAS models. These areas provide insights into developing and implementing flood early warning systems and MAS. By examining the details within each area, we can better understand the advancements, variations, and considerations in these domains.

The first area of analysis is FEWRS components. This highlights the research and existing models, the year of development, and the specific components involved in these systems. The components include risk knowledge, monitoring and forecasting, warning dissemination, and response capabilities. Furthermore, the input parameters vary from rainfall and river levels to river flow, precipitation, flow velocity, and sensor data. The output parameters also differ, ranging from hourly water levels to flood alerts and estimated times for flooding. This highlights the importance of collecting comprehensive data and providing timely warnings for effective flood management.

The second area of analysis is MAS features, which play a crucial role in the design and functioning of MAS models. The review provides insights into various features, including leadership, decision function, heterogeneity, agreement parameter, delay consideration, data transmission frequency, mobility, reasoning, perception, communication, and negotiation method. Moreover, these features reflect the diversity and flexibility of MAS models in adapting to different contexts and objectives. The variations observed in MAS features compatibility demonstrate the range of strategies employed to facilitate coordination, decision-making, information exchange, and negotiation among agents within the system.

The third area of analysis focuses on the key aspects of designing MAS models. This review explores coordination control, MAL systems, fault detection, task allocation, localization, organization, and security. Coordination control mechanisms can be centralized or decentralized, depending on the distribution of decision-making authority. Hence, the choice of coordination control mechanism directly influences the dynamics and efficiency of multi-agent collaboration. MAL systems encompass various theories and algorithms, enabling

agents to learn and improve their performance through environmental interactions. Fault detection mechanisms ensure system robustness, while task allocation strategies optimize overall performance. Localization techniques enhance agents' awareness, organization mechanisms define system structure, and security measures protect system integrity.

Comparing these three areas reveals the interconnectedness and interdependence of flood early warning systems and MAS models. The MAS features and key aspects of designing MAS models directly contribute to the effectiveness and efficiency of flood early warning systems. Moreover, MAS models provide a framework for integrating and coordinating the diverse components of flood early warning systems, enabling real-time monitoring, accurate forecasting, efficient warning dissemination, and prompt response capabilities.

Furthermore, the variations observed in MAS features and key aspects highlight the need for adaptive and context-specific approaches. Depending on their unique environmental, social, and organizational factors, different flood-prone regions may require different coordination control mechanisms, learning algorithms, fault detection strategies, and localization techniques.

By considering these insights, researchers and practitioners can enhance the design and implementation of flood early warning systems by incorporating MAS principles and utilizing suitable MAS features. Therefore, this holistic approach can lead to improved risk management, effective coordination, and timely response in mitigating the impact of floods and other natural disasters.

C. *Conceptual Framework: Building upon the Insights Gained from the Comparative Analysis*

Developing an effective conceptual framework for flood early warning systems requires a deep understanding of the underlying principles, existing models, and innovative approaches. In this regard, our research is guided by four key hypotheses supported by compelling evidence and critical analysis. These hypotheses serve as the foundation for our conceptual framework, enabling us to address the limitations and challenges identified in existing models and enhance the effectiveness of flood management practices.

Hypothesis 1 suggests that the integration of a MAS architecture within the FEWRS environment enhances the overall effectiveness and efficiency of flood management. The evidence supporting this hypothesis lies in the specialized agents involved, such as the Monitoring Agent, Forecasting Agent, Warning Dissemination Agent, Response Agent, and Learning Agent. By incorporating these agents, the system benefits from improved coordination and task distribution, leading to more informed decision-making and response capabilities. MAS design principles, which emphasize collaboration, adaptability, and distributed intelligence, are well-suited to address the complexity and uncertainty associated with flood events.

Hypothesis 2 proposes that active learning and inference techniques within the Reasoning/Inference Agent enhance the accuracy and reliability of flood predictions and decision-making. The evidence supporting this hypothesis lies in the capability of active learning techniques to continuously update the system's knowledge and models based on incoming data. This continuous learning process leads to improved predictive capabilities. Additionally, integrating inference techniques allows for extracting meaningful insights from various data sources, facilitating more informed real-time decision-making.

Hypothesis 3 asserts that effective communication mechanisms among the agents within the MAS contribute to the timely and accurate dissemination of flood warnings and response coordination. The evidence supporting this hypothesis lies in the seamless communication facilitated by the MAS architecture. Hence, real-time data sharing, forecast dissemination, and coordinated response actions are made possible, ensuring stakeholders receive timely and relevant information for informed decision-making. This robust communication mechanism enables efficient resource allocation, evacuation procedures, and overall flood management.

Hypothesis 4 suggests that the use of the MAL System, which is the CBR technique, enhances the adaptability and learning capabilities of the agents in response to changing flood conditions. CBR is a problem-solving approach involving solving new problems by retrieving and adapting solutions from similar cases. In the context of flood prediction, CBR can be utilized to improve the accuracy and reliability of flood forecasts by leveraging historical flood events and their associated data. Several experiments demonstrate the performance of CBR in various domains. For example, in the field of childhood disease diagnosis, a study compared rule-based reasoning and CBR and discovered that CBR had the best accuracy, achieving 92% accuracy [19].

By considering and validating these four hypotheses, our conceptual framework aims to address the limitations and challenges identified in existing models, enhance the effectiveness of flood early warning systems, and contribute to more efficient flood management practices. Through rigorous analysis, testing, and the integration of compelling evidence, we seek to provide practical insights and innovative solutions for real-world flood scenarios.

D. *Impact of the Conceptual Framework using Quadruple Helix Model*

The conceptual framework we have developed, which integrates a MAS architecture, active learning, effective communication, and a hybrid learning system, holds great potential for significantly impacting flood management practices. To analyze the impact of our framework, we will utilize the Quadruple Helix model, emphasizing the collaboration and interaction among academia, industry, government, and society. Fig. 6 illustrates the basic Quadruple Helix model that we are referring to.

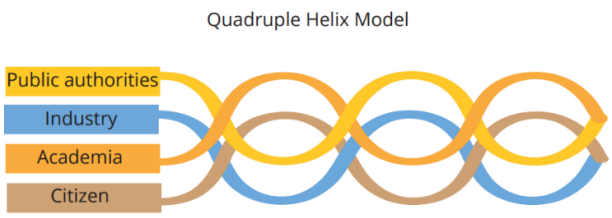

Fig. 6. Quadruple helix model.

1) Academia: In the context of academia, our conceptual framework offers an opportunity for further research and academic advancement. By exploring the integration of MAS architecture, active learning, and hybrid learning systems, we contribute to the theoretical understanding of flood management and the development of innovative approaches. As a result, the findings and insights from our research can enrich the academic literature and serve as a foundation for future studies in the field of flood early warning systems.

2) Industry: Implementing our conceptual framework has practical implications, particularly in developing and improving flood early warning systems. Integrating specialized agents within the MAS architecture enhances coordination and task distribution, improving decision-making and response capabilities. Furthermore, incorporating active learning and inference techniques improves the accuracy and reliability of flood predictions. Effective communication mechanisms ensure the timely dissemination of flood warnings and facilitate response coordination. Moreover, combining CBR and RL, the hybrid learning system enhances adaptability and learning capabilities. These advancements can potentially revolutionize the industry's approach to flood management, resulting in more effective and efficient systems.

3) Government: Our conceptual framework offers valuable insights for government agencies responsible for managing and mitigating flood risks. By adopting the MAS architecture, government entities can enhance their coordination and response capabilities in flood events. Moreover, integrating active learning and inference techniques improves the accuracy of flood predictions, enabling more informed decision-making in real-time. In addition, effective communication mechanisms ensure timely dissemination of warnings and support coordinated response actions. The learning system enables government agencies to adapt their strategies and responses to changing flood conditions, leading to improved flood management practices. Implementing our framework can enhance the government's ability to safeguard lives and property, reduce flood impacts, and ensure the overall resilience of communities.

4) Society: The ultimate impact of our conceptual framework is on society as a whole. By incorporating advanced technologies and methodologies, we aim to enhance the effectiveness of flood early warning systems, ultimately reducing the negative impacts of floods on society. The timely dissemination of accurate flood warnings can help individuals and communities make informed decisions, evacuate if necessary, and prepare for potential flood events. Note that effective communication mechanisms facilitate the coordination of response actions, ensuring that resources are allocated efficiently and evacuation procedures are well-coordinated. Hence, adopting our framework can improve public safety, reduce property damage, and increase resilience in the face of flood events.

By considering the impact of our conceptual framework through the Quadruple Helix model, we recognize the collaborative efforts and interactions among academia, industry, government, and society. The framework's implementation has the potential to drive positive change, transform flood management practices, and create a significant impact on the well-being and safety of individuals and communities affected by floods.

V. CONCLUSION

This research paper has explored the integration of MAS and MAL techniques to enhance FEWRS. By conducting a comprehensive review and comparative analysis of existing MAS models related to flood early warning systems, we have gained valuable insights into the system components, basic features of MAS, and key aspects of designing MAS models.

Our findings highlight the potential of MAS in addressing the complexity and dynamism associated with flood early warning systems. Other than that, the comparative analysis revealed the strengths and limitations of different MAS approaches, providing a basis for developing an improved conceptual framework. This framework combines the FEWRS components with MAL techniques, particularly CBR.

The proposed conceptual framework offers several advantages, including enhanced adaptability, scalability, and the ability to learn from past experiences. By incorporating CBR-RL, the framework enables the system to reason and make decisions based on historical cases, further improving the accuracy and timeliness of FEWRS.

The theoretical contribution of this study lies in its integration of MAS and MAL within the FEWRS framework, providing a novel approach that bridges technological advancements and disaster management. By incorporating the quadruple helix model, the framework fosters collaboration between academia, industry, government, and society, ensuring a comprehensive and stakeholder-driven approach to flood management. This integration not only advances theoretical understanding but also lays the groundwork for practical, scalable solutions.

However, this research has limitations that warrant future exploration. The framework's evaluation relied on historical data and simulated feedback, which may not fully capture real-world complexities. Future research should prioritize real-world deployment and validation in diverse geographical and climatic conditions. Additionally, exploring its applicability to other disaster types can provide insights into the framework's scalability and versatility.

In conclusion, this research paper contributes to the field of disaster management by presenting a comparative analysis of MAS models related to flood early warning systems and proposing a conceptual framework that integrates MAS, FEWRS components, and MAL techniques. The proposed framework can potentially advance the accuracy, efficiency, and adaptability of flood early warning systems, ultimately improving disaster preparedness and response. Correspondingly, further research and implementation efforts are encouraged to validate and refine the proposed framework, leading to real-world applications and positive outcomes in flood-prone regions.

Abstract*—How making full use of the multiple measured information sources obtained from the sucker-rod pumping wells based on deep learning is crucial for precisely recognizing the operating conditions. However, the existing deep learning-based operating condition recognition technology has the disadvantages of low accuracy and weak practicality owing to the limitations of methods for handling single-source or multi-source data, high demand for sufficient labeled data, and inability to make use of massive unknown operating condition data resources. To solve these problems, here we design a semi-supervised operating condition recognition method based on multi-source consistency deep learning. Specifically, on the basis of the framework of WideResNet28-2 convolutional neural network (CNN), the multi-head self-attention mechanism and feedforward neural network are first used to extract the deeper features of the measured dynamometer cards and the measured electrical power cards, respectively. Then, the consistency constraint loss based on cosine similarity measurement is introduced to ensure the maximum similarity of the final features expressed by different information sources. Next, the optimal global feature representation of multi-source fusion is obtained by learning the weights of the feature representations of different information sources through the adaptive attention mechanism. Finally, the fused multi-source feature combined with the multi-source semi-supervised class-aware contrastive learning is exploited to yield the operating condition recognition model. We test the proposed model with a dataset produced from an oilfield in China with a high-pressure and low permeability thin oil reservoir block. Experiments show that the method proposed can better learn the critical features of multiple measured information sources of oil wells, and further improve the operating condition identification performance by making full use of unknown operating condition data with a small amount of labeled data.

Keywords*—Operating condition recognition of sucker-rod pumping wells; multi-source consistency learning; semi-supervised learning; CNN; attention mechanism

I. INTRODUCTION

In the process of oil production, the sucker-rod pumping well production system can obtain a large amount of operating condition data from multiple information sources, such as dynamometer cards, electrical parameters, etc. Meanwhile, massive unknown operating condition data can also be obtained. It is crucial to timely and accurately recognize the operating conditions by effectively using and processing these different high-dimensional heterogeneous information sources. Recently, deep learning has become a research hotspot in oil production engineering and information technology due to its powerful ability to handle complex data structures and extract deep hidden features, thus improving the accuracy of model classification [1-2]. However, deep learning usually relies mainly on a great amount of labeled data for model training in order to maintain high accuracy. But the acquisition of such a large number of labeled data is impractical, and this will also cause a serious waste of massive unlabeled data resources. Therefore, exploring the integration of multiple information sources, massive unlabeled operating condition data, and deep learning to optimize the operating condition recognition with few labeled data is much of important for further improving the accuracy and extending the application of operating condition identification.

Existing deep learning-based sucker-rod pumping well operating condition recognition technology is mainly achieved by dynamometer cards or electrical parameters alone [3-4], or the effective combination of the two kinds of information as well as the oil well production information with artificial intelligence methods [5-6]. These studies have achieved good results, but also hold some limitations: (1) Relying on a single data source, which may easily cause false positives in electromechanical hydraulic coupling complex systems. (2) Poor fusion strategy and low robustness when integrating multiple information sources, which can degrade the performance and lower the robustness due to the uncertainty of production statistical data [7]. (3) Massive labeled samples requirement [8-9] and few unlabeled samples considered [10-11] during model training, which can greatly weaken the practical value of operating condition recognition technologies. (4) The feature extraction strategy is mainly realized by combining mechanism analysis [12-14], which will cause precision errors in the calculation of model feature parameter values and affect the recognition effect. Besides, the problems of "zero division" (appears during the electrical parameter timing signal recognition) and damping coefficient (appears during the pump dynamometer card recognition) will also increase the accuracy error.

Multi-source information fusion [15] is an information integration technology that can achieve more comprehensive and accurate feature representation by integrating features from

different information sources. By combining the unique advantages of each data source, it overcomes the limitation of a single data source, reduces the prediction error, and therefore significantly improves the robustness. Compared with traditional multi-feature connection strategy [16], multi-source information fusion can smartly integrate multi-source features and effectively address the challenge caused by simple connection fusion, such as higher feature dimension, information redundancy and inability to capture complex relationships among features. In the fusion process, following the consistency principle [17], multi-source information fusion can keep the logical consistency of the fused features and reduce information redundancy and conflict. Further, taking the cosine similarity measure [18] as a consistency measure, a more accurate measurement instead of the traditional Euclidean distance, can further improve the reliability and effectiveness of fusion results. In order to realize efficient multi-source information fusion, a powerful feature extractor is also needed to capture the key features of each information source. With wide network structure, WideResNet28-2 (WRN28-2) [19] can capture more abundant and diversified feature information, thus providing basic support for subsequent fusion. Referring to the encoder design in Transformer architecture [20], the introduction of multi-head self-attention mechanism and feedforward neural network can facilitate the deep interaction between multi-source features, significantly enhance the representation capability of multi-source features, and provide more abundant feature information for the fusion process. Studies have shown [21] that the introduction of an attention mechanism can further improve the effect of feature fusion. The attention mechanism can automatically learn and dynamically adjust the weights of features of various data sources and focus its attention on more critical information in the classification task, thus effectively improving the classification performance and overall effect.

Semi-supervised deep learning [22] trains the model by using a few labeled data and lots of unlabeled data, with the aim of enhancing the generalization ability of the model. It has four main learning strategies: pseudo-label learning [23], consistency regularization [24], deep learning-based generation [25], and graph-based strategy [26]. In pseudo-label learning, the model uses its own predictions of unlabeled samples to expand the training data. Compared with other methods, it has high flexibility and strong generalization, making it applicable for a variety of practical application scenarios, therefore is widely used in semi-supervised deep learning. Contrastive learning [27] is an effective unsupervised learning method. It learns distinguishing feature representations by comparing sample pairs, therefore the learned features achieve improved generalization on unlabeled data. Studies have shown that the combination of class-aware contrastive learning, pseudo-label learning and consistency regularization learning [28] can effectively solve the common confirmation bias problem in semi-supervised deep learning and improve accuracy. By minimizing the distance of samples of the same category in feature space and maximizing the distance between samples of different categories, this combination strategy can not only enhance differentiation between categories, but also significantly improve the accuracy of semi-supervised learning for tasks such as image recognition.

As described above, to solve the limitations of existing deep learning-based operating condition recognition research, this paper proposes a semi-supervised sucker-rod pumping well operating condition recognition method based on multi-source consistency deep learning. Specifically, in order to avoid damping coefficient, "division by zero" and statistical data uncertainty, we select the measured dynamometer cards and the measured electrical power cards (both of which are high-dimensional binary images) as multi-source data. We adopt the framework of WRN28-2 convolutional neural network, and achieve the maximum consistency interactive learning based on features complements of different information sources through the combination of multi-head self-attention mechanism, feedforward neural network and cosine similarity measurement. Then, we apply the adaptive attention mechanism to achieve the optimal global feature representation of multi-source fusion by learning the weights of feature representations of different information sources, thus improving the existing operating condition feature extraction technology by capitalizing on all the multi-source information. The combination of multi-source fusion features and semi-supervised class-aware contrastive learning can further utilize the massive unlabeled data and a few multi-source labeled data to improve the operating condition recognition accuracy and extend its applications.

The contributions of this paper are as follows:

1) An efficient multi-source feature fusion deep learning algorithm for the operating condition is proposed. Based on the framework of the WRN28-2 convolutional neural network, the algorithm uses a multi-head self-attention mechanism and feedforward neural network to extract the deep image features of each measured information source respectively, and introduces consistency constraint loss based on cosine similarity measurement to ensure the maximum similarity of the final feature representations from different information sources. Then, the optimal global feature representation of multi-source fusion is obtained by using an adaptive attention mechanism to learn the weights of feature representations of different information sources.

2) A multi-source semi-supervised class-aware contrastive learning operating condition recognition method is proposed, which effectively integrates the multi-source feature fusion deep learning algorithm with the semi-supervised class-aware contrastive algorithm. Its objective function consists of four parts: supervised loss function, multi-source information consistency constraint loss function, unsupervised loss function and class-aware contrastive loss function. The recognition bias of the same category in multi-source feature space is reduced by class-aware contrastive learning, and the discriminant ability of the semi-supervised deep learning model is highly enhanced.

3) The effectiveness and practicability of the proposed method is verified experimentally. Compared with state-of-the-art multi-source semi-supervised learning recognition methods, traditional single-source recognition methods or multi-feature connection recognition methods, different attention mechanism learning recognition methods, and different contrastive learning

recognition methods, the proposed method exhibits improved recognition accuracy in different proportions of labeled training data, especially with 10\% increase. In addition, key hyperparameter analysis and ablation experiments further verify the effectiveness and practicability of the proposed method.

II. Related Works

In this part, we first give a short introduction to the information sources of the sucker-rod pumping well production system in terms of the operating principle of the system, and then we present the related works on operating condition recognition research respectively, using dynamometer cards, electrical parameters and multiple information sources.

A. Information Source Analysis of the Sucker-Rod Pumping Well Production System

The architecture diagram of the sucker-rod pumping well production system [29] is shown in Fig. 1.

It can be observed that the system is composed of 15 parts: (1) Standing valve; (2) Pump barrel; (3) Traveling valve; (4) Plunger; (5) Dynamic fluid level; (6) Sucker rod; (7) Casing; (8) Tubing; (9) Beam hanger; (10) Horse head; (11) Beam; (12) Link rod; (13) Crank; (14) Induction motor; (15) Electronic control cabinet.

The operating principle of the system is as follows: First, the high-speed rotating motion of the induction motor will be converted into the mechanical up-and-down swing of the beam by the crank connecting to the link rod. Then, the sucker rod connected to the beam hanger suspended from the horse head drives the pump plunger in the underground wellbore to move up and down through the mechanical swing of the beam. Finally, the mixed fluid in the wellbore is pumped to the surface through the tubing.

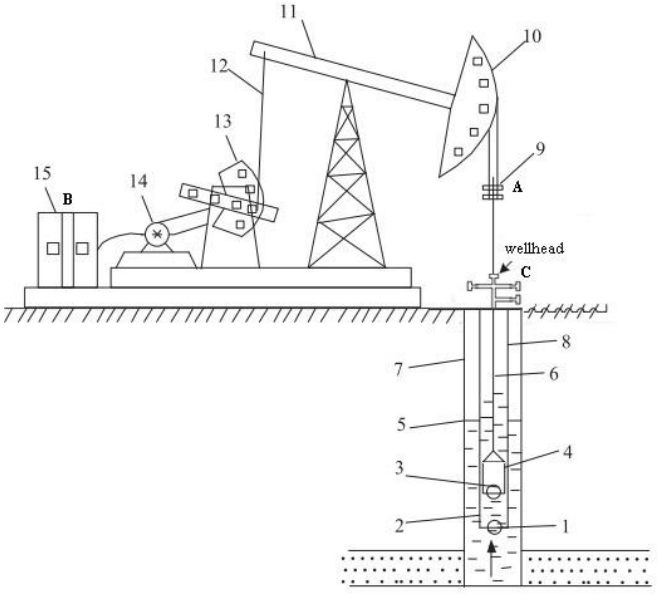

Fig. 1. The architecture diagram of the sucker-rod pumping well production system.

As the key downhole production equipment, the oil well pump mainly consists of three parts: pump barrel, plunger, and valves (see (1) and (3) in Fig. 1). One operation of the oil well pump includes valves opening and closing during one stroke.

In the sucker-rod pumping well production system, the measured information mainly comes from three sources: dynamometer cards (see A in Fig. 1), electronic parameters (see B in Fig. 1), wellhead data (wellhead temperature, wellhead pressure, etc., see C in Fig. 1). The measured dynamometer cards are binary images composed of the displacement and load of the polish rod (see (9) in Fig. 1), which are usually with high dimension and strong noise, and can reflect the situation of the wellbore and the stratum in real-time. The existing operating condition recognition technology using dynamometer cards mainly uses the pump dynamometer card data (transformed from the measured dynamometer card data after denoising, but may occur the damping coefficient problem). The measured electrical parameters are time-series signals, which can reflect the situation of the ground and the stratum in real-time. It is worth mentioning that the "division by zero" problem may occur when using the electronic parameters for operating condition recognition.

In the production process, there are also some non-measured information sources, such as dynamic fluid level (see (5) in Fig. 1), liquid-producing capacity, working time, etc. These statistical production data can also be regarded as information sources. However, the present research on operating condition recognition usually focuses on effectively utilizing the aforementioned two types of information sources.

B. The Operating Condition Recognition Technology Review

In general, the research on the operating condition recognition technology of the sucker-rod pumping well production system is mainly focused on three aspects: dynamometer card-based, electronic parameter-based and multi-source-based.

1) The dynamometer card-based recognition technology: The dynamometer card-based recognition method is the most widely used one, which is mainly implemented by ground or pump dynamometer cards combined with some artificial intelligence technology. For example, Li et al. [30] employed the moment feature and the “four-point method” to extract pump dynamometer card features and used SVM combined with particle swarm optimization to recognize working conditions. Zheng et al. [31] used the moment feature and the astr polygon decomposition centroid localization algorithm to extract ground dynamometer card features and used HMM combined with clonal selection optimization to recognize working conditions. Zhang et al. [32] extracted the feature of dynamometer cards by the fast discrete curvelet transform and utilized a sparse multi-graph regularized extreme-learning machine to recognize working conditions. The above working condition recognition methods involve a large number of complex feature parameter calculation and need a large amount of labeled data for training, thus greatly affecting the working

condition recognition performance. To this end, recently, deep learning is applied to extract the features in order to improve the recognition performance. Ye et al. [3] proposed an improved CNN to automatically obtain the deep feature expression of the dynamometer card data, overcoming the limitations of traditional feature extraction methods and achieving better recognition accuracy. But this method requires lots of labeled working condition data for model training. In the case of few-shot learning, He et al. [10] proposed to compress the raw working condition data through a 4-dimensional time-frequency feature extraction method, and then optimize parameters of the convolutional shrinkage neural network through meta-learning. This method overcomes the limitation of a large number of labeled data requirements for training, but it reveals the neglect of the massive unknown working condition data. In addition, there are some precision errors in the calculation of the characteristic data value based on the mechanism analysis.

2) The electrical parameter-based recognition technology: The electronic parameter-based operating condition recognition technology works with lower cost and higher reliability. Zheng et al. [33] proposed to extract feature data of the measured electric power signal based on mechanism analysis and accomplish the operating condition recognition by HMM. In addition, Chen et al. [34] deduced the electric power card model by considering the angular velocity of the crank and the friction and inertia of the 4-bar linkage and implemented the operating condition recognition by establishing a feature atlas of electric power cards. In order to further improve the working condition recognition effect based on electrical parameter sequence signals, researchers also introduced deep learning technology to extract deeper features of electrical parameter data. Wei et al. [4] realized a deep and broad learning system by motor power data, utilizing CNN to extract features of the electric power signal and employing the broad learning system to recognize the operating condition. However, because of " division by zero", the recognition accuracy based on electronic parameters is far from satisfactory. In addition, the current deep learning-based working condition recognition technology using electrical parameter data also needs a lot of labeled working condition training data.

3) The multiple information source-based recognition technology: Although it is easy to classify operating conditions using single-source data, it is also prone to error. Therefore, researchers started to develop operating condition recognition models based on multiple information sources. Zheng et al. [35] applied seven feature data such as sucker-rod specifications, pump diameter, stroke, speed, moisture content, gas-liquid ratio and working condition to a HMM model. Zhang et al. [36] adopted feature data such as dynamometer cards, power, dynamic fluid level, and liquid-producing capacity. Liu et al. [37] selected feature data such as dynamometer cards, work day time, and liquid-producing capacity. However, all the above operating condition recognition methods use non-measured production statistics data, which will affect the robustness of the recognition model. Zhou et al. [38] put forward a semi-supervised operating condition recognition technology integrating four measured data, namely, ground dynamometer cards, electric power signal, wellhead temperature, and wellhead pressure. The technical model has good performance and wide application, but the recognition accuracy of multi-classification conditions needs to be improved. Deep learning technology can improve model performance by deeply mining multi-source fusion feature expressions. Li et al. [5] developed an improved deep learning-based operating condition recognition method by the fusion of Fourier descriptor features and graphic features based on dynamometer cards. Abdurakipov et al. [7] used pump dynamometer cards, pump inlet pressure and temperature production data to establish an operating condition identification model with transformer. In summary, at present, the multi-source operating condition recognition technology based on deep learning mostly relies on lots of labeled data, and the multi-source fusion technology is mostly traditional. Recently, in the multi-source semi-supervised deep learning classification recognition research, Wu et al. [39] proposed a multi-view semi-supervised learning method based on graph convolutional network to improve model performance under label-scarce situations. This method maps data from multiple views into a low-dimensional space and uses Laplacian embedding technology to preserve the structural information between data, thereby achieving the fusion and representation learning of multi-view data. In addition, this method implies that we can try to explore the best consistent connection relationship between multiple views to obtain better recognition effects.

To sum up, the research on the operating condition recognition technology has achieved remarkable results, especially with the introduction of deep learning technology, which overcomes the limitations of traditional manual design features. However, in order to establish an efficient and practical operating condition recognition model based on deep learning, limitations such as the requirement of lots of labeled data, the neglect of massive unknown data, and the improvement of the multi-source fusion strategy remain for further handling.

III. Multi-Source Consistency for Semi-Supervised Deep Learning

This section introduces our proposed multi-source consistency deep learning for semi-supervised operating condition recognition method from sucker-rod pumping wells, emphasizing the integration of a multi-source consistency strategy, which includes WRN28-2 convolutional neural network backbone, multi-head self-attention mechanism, feedforward neural network, and an adaptive attention-based feature fusion strategy. Furthermore, this section describes how our model employs the semi-supervised learning technique to make efficient use of limited labeled data alongside a large number of unlabeled data, thereby enhancing recognition performance.

A. Problem Definition

Before introducing our method, the key symbols and variables used in this paper are clearly described in Table I.

TABLE I. NOTATION DESCRIPTION

Notation	Description
$\mathcal{V}$	the number of information sources
D	multi-source data set
L^v	labeled data set of the v^{th} data source
U^v	unlabeled data set of the v^{th} data source
l	the number of labeled data
m	the number of unlabeled data
A_w	weak data enhancement method
A_s	strong data enhancement method
F	backbone network model
G	global feature after multi-source feature fusion
H	multi-source data feature representation after multi-source information consistency learning
ω^v	the attention weight of the data feature of the v^{th} data source
S^v	cosine similarity of data from the v^{th} data source
$\|\cdot\|_2$	the l_2 norm

Here, we study a semi-supervised operating condition recognition task based on multi-source data. Suppose there are $\mathcal{V}$ different data sources, and each data source contains the C class. Multi-source data set D consists of labeled data set L and unlabeled data set U, i.e. $D = \{L, U\}$. For labeled data set L, it is defined as $L = \{L^v | v = 1,2,\dots,\mathcal{V}\} = \{(x_i^v, y_i) | i = 1,2,\dots,l\}$, where L^v is the labeled data set of the v^{th} data source, x_i^v is the i^{th} labeled image of the v^{th} data source, $y_i \in \{1,2,\dots,C\}$ is the label corresponding to the i^{th} image, and l is the number of labeled data. Unlabeled data set U is defined as $U = \{U^v | v = 1,2,\dots,\mathcal{V}\} = \{u_i^v | i = l+1, l+2,\dots,l+m\}$, where U^v is the unlabeled data set of the v^{th} data source, u_i^v is the i^{th} unlabeled image of the v^{th} data source, m is the number of unlabeled data. In order to increase the data diversity and improve the accuracy of semi-supervised learning, this paper adopts two data enhancement methods: weak enhancement $A_w(\cdot)$ and strong enhancement $A_s(\cdot)$. Weak enhancement usually includes small-angle rotation, translation, scaling, etc. Strong enhancement includes cropping, color transformation, etc. For labeled data set L and unlabeled data set U, the weak enhanced data are represented as $A_w(L)$ and $A_w(U)$, and the strong enhanced data are represented as $A_s(L)$ and $A_s(U)$, respectively. In this paper, WRN28-2 model is used as backbone network $F(\cdot)$ to learn feature representations of multi-source data, which are used for subsequent consistency learning and semi-supervised learning tasks.

B. Model Overview

This paper proposes a semi-supervised sucker-rod pumping well operating condition classification method based on multi-source information consistency deep learning. The model structure is shown in Fig. 2. The algorithm consists of the following two key steps: multi-source information consistency learning and multi-source semi-supervised learning. In multi-source information consistency learning, firstly, the WRN28-2 convolutional neural network is used to extract the feature representation of multi-source data. For the multi-source feature representation of the same sample, the dependence relationship in the feature representation is captured by multi-head self-attention mechanism, and the deeper feature is extracted by non-linear transformation with feedforward neural network. In order to ensure the consistency of multi-source information, this paper introduces a multi-source consistency constraint loss function based on the cosine similarity to strengthen the correlation among different information sources. In addition, the attention mechanism is used to learn the weights of feature representations from different information sources to achieve an effective fusion of multi-source feature representations, so as to obtain the optimal global feature representation of each sample. In multi-source semi-supervised learning, two enhancement strategies, weak enhancement and strong enhancement, are applied to the unlabeled data respectively, and the corresponding predicted values are generated, and the unlabeled data with high confidence are selected to generate pseudo labels. To improve the prediction accuracy, consistency regularization is used to calculate the cross-entropy loss of the predicted value corresponding to the strong enhancement and the pseudo-label corresponding to the weak enhancement. In view of the possibility of pseudo label method being affected by confirmation bias in the training process, this paper introduces the class-aware contrastive learning method [28], aggregates samples of the same category in feature space, and disperses samples of different categories to reduce confirmation bias and improve the discriminant ability.

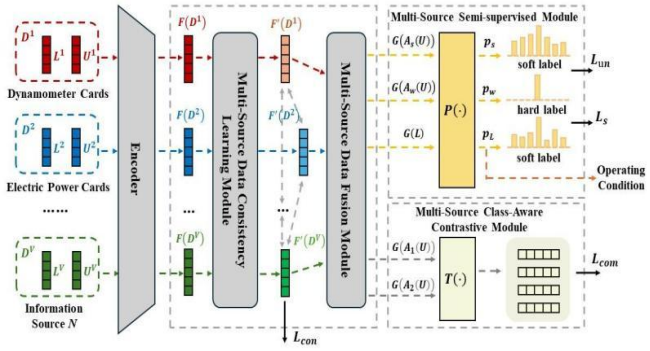

Fig. 2. Model structure diagram.

C. Consistency Learning of Multi-source Information

In this paper, the WRN28-2 backbone network is used to learn the feature representation $F(D)$ of multi-source data set D, where $F(D) = \{F(L), F(U)\}$, and the expressive power of the feature representation is enhanced by multi-head self-attention mechanism. Then, the multi-source consistency constraint loss function based on cosine similarity is used to ensure that the feature representation of the multi-source data is consistent in the feature space, thereby improving the generalization ability. The multi-source information consistency learning model structure is shown in Fig. 3.

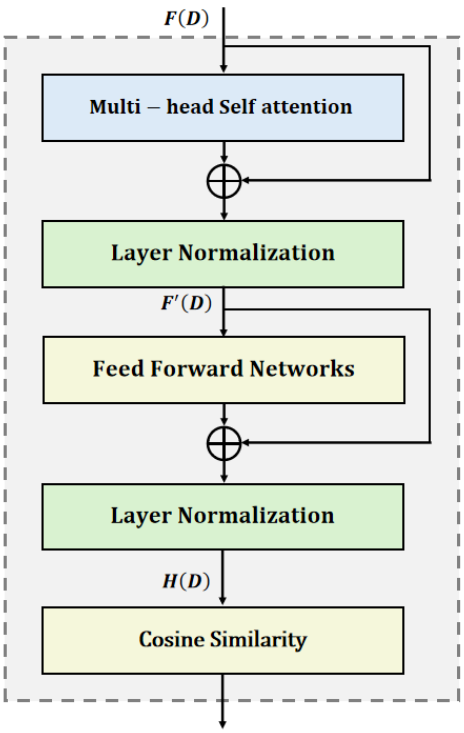

Fig. 3. Structure diagram of multi-source information consistency learning model.

Firstly, the feature representation of the multi-source data is sent into the multi-head self-attention module (MHSAM), and the feature representation ability of the multi-source data is enhanced by capturing the information of the input feature representation in their respective subspaces. Then, we implement residual connections between the input feature $F(D)$ and output feature $F'(D)$ of the MHSAM and carry out Layer Normalization (LN), as shown in Eq. (1):

$$F'(D) = LN\left(F(D) + MHSAM\left(F(D)\right)\right) \quad (1)$$

Then, the deeper features are extracted by nonlinear transformation through the feedforward network module (FFNM). Similarly, the residual connections and layer normalization are used to stabilize the training process, as shown in Eq. (2):

$$H(D) = LN\left(F'(D) + FFNM\left(F'(D)\right)\right) \quad (2)$$

where the FFNM consists of two linear mapping layers and Relu activation function, the former of which is $FFNM(x) = Relu(W_1 * W_2 * x)$, W_1 and W_2 are the weights of the linear mapping layer. $H(D)$ is the feature representation of multi-source data D after consistency learning of multi-source information. The above multi-source information consistency learning method is inspired by the Transformer network structure, and the Transformer coding layer is used to realize the relevant calculation.

There is an intrinsic consistency between different feature representations of multi-source data. To make full use of the consistency and improve the generalization of the model, we design a multi-source consistency constraint loss function based on cosine similarity to maximize the cosine similarity between feature representations of different sources, so as to ensure their consistency in feature space.

Specifically, for the multi-source feature representation $H(D)$ of the same sample, the l_2 norm ($\|\cdot\|_2$) is first converted into the standard feature representation $\|H(D)\|_2$ to eliminate the influence caused by the magnitude difference between the multi-source feature representation vectors. Then, the cosine similarity between the multi-source feature representation vectors is calculated to obtain the degree of consistency between the multi-source feature representations, which is calculated as in Eq. (3):

$$S^v = \|H(D^v)\|_2 \cdot \|H(D^v)\|_2^T \quad (3)$$

where S^v represents the cosine similarity of the v^{th} data source, and $(\cdot)^T$ represents the transpose of the vector.

Then, to ensure the consistency of feature representations from different data sources in feature space and enhance the generalization ability of the model, the difference matrix between any two data source similarity matrices is calculated, and the square of the norm of the difference matrix is calculated as the constraint loss function of multi-source information consistency learning, as shown in Eq. (4):

$$L_{con} = \sum_{i,j \in v} \left\| S^i - S^j \right\|_2^2 \quad (4)$$

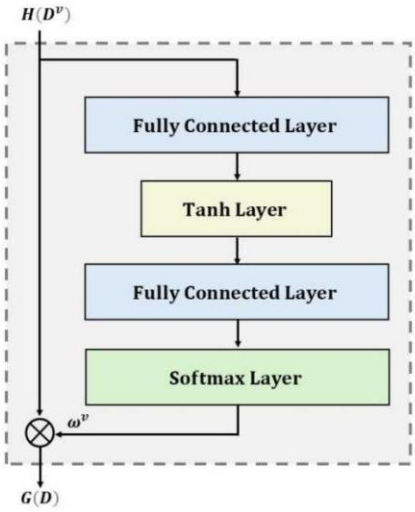

Fig. 4. Structure diagram of multi-source feature fusion model.

To further improve the performance, we further apply a multi-source feature fusion method based on adaptive attention mechanism, the model structure diagram is shown in Fig. 4. The adaptive attention mechanism is used to learn the weights of different data source feature representations, and the multi-source feature representations are then fused into a unified global feature representation to obtain the optimal global characteristics of each sample. Specifically, for the v^{th} data source, the data feature is represented as $H(D^v)$. In this paper, a network structure consisting of fully connected layer, followed by $tanh$ activation function and then by fully connected layer is adopted. The nonlinear combination of $H(D^v)$ is obtained by the network structure learning and the

corresponding attention score W_{out}^{v} is generated, as shown in Eq. (5):

$$W_{out}^{v} = W_2 \cdot [tanh(W_1 \cdot H(D^v) + b_1)] + b_2 \quad (5)$$

where W_1 and W_2 represent the weight of the two fully connected layers respectively, b_1 and b_2 are the corresponding bias vectors.

Then, the SoftMax function is used to normalize the attention score W_{out}^{v} , and the attention weight ω^v of each data source feature representation is obtained. The calculation is shown in Eq. (6):

$$\omega^v = softmax(W_{out}^{v}) = \frac{exp(W_{out}^{v})}{\sum_{n=1}^{N} exp(W_{out}^{v})} \quad (6)$$

where exp is the natural exponential function, and $\sum_{v=1}^{\mathcal{V}} \omega^v = 1$.

Finally, according to the normalized attention weight ω^v, the feature representation of each data source is fused into a unified global feature representation, and the fusion process is achieved by weighted summation, as shown in Eq. (7):

$$G(D) = \sum_{v=1}^{\mathcal{V}} \omega^v \cdot H(D^v) \quad (7)$$

where $G(D)$ is the global feature representation after fusion, and $G(D) = \{G(L), G(U)\}$.

D. Multi-Source Data Semi-supervise Module

After completing the multi-source information consistency learning and the multi-source feature fusion, this paper implements pseudo-label-based semi-supervised learning of multi-source data by referring to Fix-Match [40]. Two enhancement strategies, weak enhancement $G\big(A_w(U)\big)$ and strong enhancement $G\big(A_s(U)\big)$, are applied to unlabeled data, respectively. Then, corresponding predicted values p_w and p_s are generated using a fully connected layer $P(\cdot)$, which are calculated as shown in Eq. (8):

$$p_w = P\left(G\big(A_w(U)\big)\right)$$
$$p_s = P\left(G\big(A_s(U)\big)\right) \quad (8)$$

Then, weakly enhanced unlabeled data with high confidence predicted value are screened out, and the corresponding pseudo-label q_w are obtained using $argmax$ function, as shown in Eq. (9) :

$$q_w = argmax(\hat{p}_w) \quad (9)$$

where $\hat{p}_w$ represents the part of p_w, $\max(\hat{p}_w) > t$, $\max(\cdot)$ is the maximum function and t is the confidence threshold.

Finally, to increase the prediction accuracy, the consistency regularization is adopted to compute the cross-entropy loss between the predicted value of the strong enhancement and the pseudo-label of the weak enhancement. The detailed calculation of the semi-supervised loss L_{un} is shown in Eq. (10):

$$L_{un} = -\sum_{c=1}^{C} q_w^c \log(p_s^c) \quad (10)$$

where c represents the c^{th} class, and C is the total number of sample classes.

The supervised loss function L_s uses the cross-entropy loss of multi-source labeled data L, which is calculated as shown in Eq. (11):

$$L_s = -\sum_{c=1}^{C} y^c \log(p_L) \quad (11)$$

where p_L is the predicted value of labeled samples generated by $P(\cdot)$, $p_L = P\big(G(L)\big)$.

Pseudo-label based semi-supervised learning methods need to generate pseudo-labels independently in the process of semi-supervised learning, and are susceptible to confirmation bias in the training process. To solve this, this paper introduces a multi-source data class-aware contrastive learning method, aggregates samples of the same category in feature space, and drives samples of different categories away from each other. By the contrastive learning, the robustness of the model is increased and the impact of confirmation bias is reduced.

First, the unlabeled data are enhanced by two different data enhancement methods $A_1(\cdot)$ and $A_2(\cdot)$ respectively, obtaining $A(U) = [A_1(U), A_2(U)]$, and then the high-dimensional feature representation is mapped to a low-dimensional embedding vector through the projection layer $T[\cdot]$ composed of two fully connected layers. The specific calculation is shown in Eq. (12):

$$T[G(A(U))] = \{T[G(A_1(U))], T[G(A_2(U))]\} \quad (12)$$

The class-aware contrastive learning loss consists of two parts: narrowing the aggregation distance of enhanced data from the same category samples and widening the aggregation distance of enhanced data from the different category samples. The specific calculation is shown in Eq. (13):

$$L_{com} = \sum_{i \in I} \left[log \sum_{a \in O(i)} \left(exp\left(\frac{T\left[G\left(A^i(U)\right)\right] \cdot T\left[G\left(A^a(U)\right)\right]}{\tau} \right) - exp\left(\frac{T\left[G\left(A_1^i(U)\right)\right] \cdot T\left[G\left(A_2^i(U)\right)\right]}{\tau} \right) \right) \right] \quad (13)$$

where $I = \{1,2,\dots,M\}$, M is the number of unlabeled samples. $O(i)$ is the index of $M-1$ unlabeled samples except the index i. $T\left[G(A_1^i(U))\right]$ and $T\left[G(A_2^i(U))\right]$ are a set of positive sample pairs that are output from the i^{th} unlabeled sample after two data enhancement transformations and then through the projection layer. $T[G(A^i(U))]$ and $T[G(A^a(U))]$ are the corresponding negative sample pairs. τ is the temperature coefficient.

E. Objective Function

The loss function set includes four parts: supervised loss function L_s of labeled data, multi-source information consistency constraint loss function L_{con}, unsupervised loss function L_{un} and class-aware contrastive loss function L_{com}. The total loss function L is calculated using Eq. (14):

$$L = L_s + \lambda_{con} L_{con} + \lambda_{un} L_{un} + \lambda_{com} L_{com} \quad (14)$$

where λ_{con}、λ_{un} and λ_{com} are the weights of multi-source information consistency constraint loss, unsupervised loss and class-aware contrastive loss, respectively.

IV. Experimental Results

The experimental dataset is obtained from an oilfield in China with a high-pressure and low-permeability thin oil reservoir block. The operating condition samples used in the experiment are selected strictly according to the operation records of the oil wells. The measured dynamometer cards (binary images composed of polish rod displacement and load) and measured electric power cards (binary images composed of polish rod displacement and motor power) are included in each operating condition sample. The measured dynamometer card data and electric power card data are composed of the data points collected at the actual corresponding acquisition time on the production site. The sample set is built by the accumulation of operating condition samples of 60 sucker-rod pumping wells for 3 years and includes 11 typical operating conditions, each operating condition has 150 samples, for a total of 1650 samples. The 11 typical operating conditions include normal, assist-blowing, lack of supply liquid, rod cutting, stuck pump, traveling valve failing, wax precipitation, pump leakage, tubing leakage, standing valve leakage, traveling valve leakage.

The experiment is run on Python 3.8.10/pytorch 1.10.0 and Linux 5.4.0/24 GB NVIDIA RTX3090 GPU. The training set and the test set each have 825 samples, of which each operating condition contains 75 samples. The experimental results are averaged 10 times.

To verify the effectiveness and practicability, experiments are carried out from five aspects: (1) The verification of the superiority of the basic model. The learning models based on the classical residual network are compared in the case of full labeled training samples. (2) The verification of the effectiveness of the proposed method. On the basis of the first part of the experiment, different operating condition recognition methods are compared in terms of the operating condition recognition effect with full labeled training samples. (3) The verification of the practicability. On the basis of the second part of the experiment, different operating condition recognition methods are compared in terms of the operating condition recognition effect with different proportions labeled training samples. (4) Hyperparameter analysis. The impact of the four main hyperparameters of the objective function λ_{con}、λ_{un}、λ_{com} and the number of heads of the multi-head attention mechanism are analyzed, respectively. (5) Ablation test.

A. The Basic Model Analysis

To verify the superiority of the designed infrastructure, in the case of full labeled training samples, based on the two main learning models of the depth and width of the classical residual network combined with class-aware contrastive learning (CCL), we compare the results of various operating condition recognition methods based on traditional single-source operating condition recognition methods (WRN28-2/10_CCL, Resnet18/34/50/101/152_CCL,), traditional multi-source connection operating condition recognition methods (MCWRN28-2/1_CCL, MCResnet18/34/50/101/152_CCL), multi-source interactive consistent learning operating condition recognition methods (MIWRN28-2/10_CCL), and multi-source data online augmented interactive consistent learning operating condition recognition methods (MAIWRN28-2_CCL (the proposed method in this paper), MAIWRN28-10_CCL). In the proposed method, the pseudo-label threshold τ is 0.95; the learning rate is 0.02; the number of heads of the multiple self-attention mechanisms in the transformer encoder layer is 2; the middle layer dimension of FFNM is set to 512; λ_{un} and λ_{com} are set to 1, and λ_{con} is set to 10. The comparison results of various operating condition recognition methods based on the classical residual network combined with CCL are shown in Table II.

TABLE II. The Comparison Results of Various Operating Condition Recognition Methods based on the Classical Residual Network Combined with CCL (Average Accuracy, %)

Operating condition recognition methods	Measured dynamometer cards	Measured electrical power cards	Measured dynamometer cards and electrical power cards
Resnet18_CCL	93.67	95.83	--
Resnet34_CCL	92.87	95.25	--
Resnet50_CCL	88.55	94.71	--
Resnet101_CCL	84.09	94.27	--
Resnet152_CCL	89.79	95.27	--
WRN28-2_CCL	93.72	**95.93**	--
WRN28-10_CCL	**94.34**	95.67	--
MCResnet18_CCL	--	--	96.55
MCResnet34_CCL	--	--	96.46
MCResnet50_CCL	--	--	95.39
MCResnet101_CCL	--	--	95.03
MCResnet152_CCL	--	--	94.18
MCWRN28-2_CCL	--	--	97.55
MCWRN28-10_CCL	--	--	97.23
MIWRN28-2_CCL	--	--	97.96
MIWRN28-10_CCL	--	--	97.41
MAIWRN28-2_CCL(Ours)	--	--	**98.79**
MAIWRN28-10_CCL	--	--	98.34

From Table II:

1) Among the operating condition recognition methods based on the classical residual network combined with CCL, recognition methods based on WideResNet have significantly better effects than those based on Resnet, which reflects that WideResNet can obtain better performance by increasing network width and reducing network depth.

2) Among the traditional single-source operating condition recognition methods, in terms of recognition effects, recognition methods based on the measured electrical power cards are obviously superior to those based on the measured dynamometer cards, which shows that the measured electrical power cards adopted in this paper can better overcome the influence of "zero division" on the operating condition recognition accuracy. In addition, the traditional single-source

operating condition recognition methods based on WideResNet are more accurate than those based on ResNet. Meanwhile for the measured dynamometer cards, WRN28-10_CCL has the best recognition effect, and for the measured electrical power cards, WRN28-2_CCL has the best recognition accuracy.

3) Among the traditional multi-source connection operating condition recognition methods, MCWRN28-2/10_CCL, MCResnet18/34_CCL have better recognition accuracy than those based on traditional single-source methods, but MCResnet50/101/152_CCL are the opposite, which indicates the technology limitations of the traditional multi-source connection operating condition recognition methods. In addition, MCWRN28-2/10_CCL have better recognition effects than MCResnet18/34_CCL.

4) Among the operating condition recognition methods based on multi-source consistency learning, MIWRN28-2/10_CCL are more accurate than those recognition methods based on traditional single source and traditional multi-source connection, which reflects the advantage of the multi-source consistency learning method proposed in this paper. Further, this paper carries out the online augmented processing on the multi-source consistency learning to further improve the recognition accuracy. MAIWRN28-2/10_CCL well reflect this strategy for the operating condition recognition, of which MAIWRN28-2_CCL performs best and is selected and used in subsequent experiments in this paper.

B. Multi-Source Learning Operating Condition Recognition with Full Labeled Training Samples

To verify the effectiveness, on the basis of the first part of the experiment, the method proposed in this paper is compared with the interpretable multi-view graph convolutional network recognition method (IMvGCN) [39], and the multi-source consistency learning operating condition recognition methods based on different contrastive learning (MAIWRN28-2_InfoCL), based on different attention mechanism fusion (MAIWRN28-2_SELF_CCL, MAIWRN28-2_SE_CCL). The comparison results of different multi-source learning operating condition recognition methods with full labeled training samples are shown in Table III.

From Table III:

1) Compared with the multi-source learning operating condition recognition method based on InfoNCE contrastive learning, our method improves the recognition accuracy by about 1.2%, showing the superiority of CCL adopted in this paper.

2) Compared with the multi-source learning operating condition recognition methods based on SE attention mechanism and self-attention mechanism fusion, the proposed method improves the recognition accuracy by about 0.5% and 0.6%, respectively, showing the advantage of fusion learning of the attention mechanism adopted in this paper.

3) Compared with IMvGCN, our method improves the recognition accuracy by about 2.2%, showing the superiority of the multi-source consistency learning adopted in this paper.

4) Compared with the multi-source learning operating condition recognition methods based on different multi-source learning algorithms, different contrastive learning algorithms and different attention mechanism fusion algorithms, our method has higher recognition accuracy, thus verifying the effectiveness of the proposed method.

TABLE III. THE COMPARISON RESULTS OF VARIOUS OPERATING CONDITION RECOGNITION METHODS BASED ON THE CLASSICAL RESIDUAL NETWORK COMBINED WITH CCL (AVERAGE ACCURACY, %)

Methods	Measured dynamometer cards and measured electrical power cards
MAIWRN28-2_InfoCL	97.63
MAIWRN28-2_SELF_CCL	98.17
MAIWRN28-2_SE_CCL	98.32
IMvGCN	96.57
MAIWRN28-2_CCL(Ours)	**98.79**

C. Multi-Source Learning Operating Condition Recognition with Different Proportions of Labeled Training Samples

To verify the practicability, on the basis of the two parts of the experiment, we add the multi-source consistency learning semi-supervised CCL recognition method based on CoMatch [41] (MAIWRN28-2_CoMatch_CCL), and compare the recognition results in 5 groups of labeled training samples with different proportions (1%, 10%, 30%, 50%, 70%). The comparison results of different multi-source learning operating condition recognition methods with different proportions of labeled training samples are shown in Table IV.

TABLE IV. COMPARISON RESULTS OF DIFFERENT MULTI-SOURCE LEARNING OPERATING CONDITION RECOGNITION METHODS WITH DIFFERENT PROPORTIONS OF LABELED TRAINING SAMPLES (AVERAGE ACCURACY, %)

Methods	1% (n=11)	10% (n=88)	30% (n=25)	50% (n=41)	70% (n=58)
MAIWRN28-2_InfoCL	80.64	91.03	93.64	95.45	96.86
MAIWRN28-2_SELF_CCL	81.17	92.45	95.55	96.08	97.18
MAIWRN28-2_SE_CCL	81.45	92.85	94.81	96.53	97.52
MAIWRN28-2_CoMatch_CCL	79.88	91.12	94.34	95.84	97.56
IMvGCN	**83.79**	92.68	93.65	95.81	96.35
MAIWRN28-2_CCL(Ours)	82.98	**94.13**	**96.18**	**97.20**	**98.25**

From Table IV:

1) In five groups of different proportions labeled training samples, compared with various multi-source semi-supervised learning recognition methods (MAIWRN28-2_SE_CCL, MAIWRN28-2_CoMatch_CCL, MAIWRN28-2_SELF_CCL, MAIWRN28-2_InfoCL, IMvGCN), our method has obtained higher accuracy (except 1%), reflecting the advantage of the semi-supervised learning algorithm adopted.

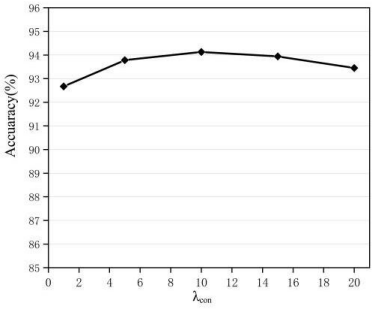
2) Among the recognition results of five groups of labeled training samples with different proportions, 10% (8 labeled training samples for each class) has a particularly significant recognition effect, which shows that our method can effectively

use a large number of unlabeled training samples to further improve the recognition accuracy, thus verifying the practicability of our method.

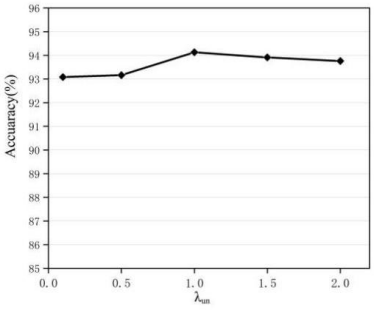
D. Key Hyperparameter Analysis

To explore the influence of hyperparameters on the performance of the operating condition recognition model, an extensive hyperparameter analysis of the proposed method is carried out with 10% proportion labeled training samples. We focus on four major hyperparameters: multi-source information consistency constraint loss weight λ_{con}, unsupervised loss weight λ_{un}, class-aware contrastive loss weight λ_{com}, and the number of heads of multi-head attention in Transformer coding layer. The value range of λ_{con} is [1,5,10,15,20], the value range of λ_{un} is [0.1, 0.5, 1,1.5, 2], the value range of λ_{com} is [0.1, 0.5, 1,1.3, 1.5], the value range of the head number of multi-head attention is [1,2,4,8,16].

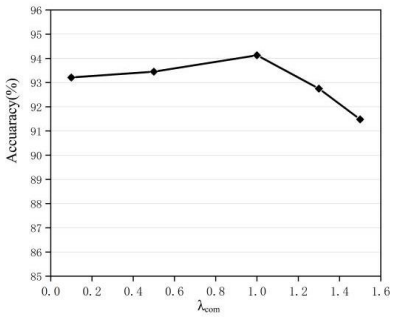
Fig. 5 shows the classification accuracy on the selected data set in different hyperparameter settings. It can be seen from Fig. 5 (a) and (b) that our method shows high stability within certain parameter ranges of λ_{con} and λ_{un}, that is, when λ_{con} , λ_{un} change within a certain ranges, the model accuracy fluctuates only slightly. It can be seen from Fig. 5(c), with the increase of λ_{com}, the impact on the model gradually increases. It can be seen from Fig. 5(d), when the number of heads of attention varies within the value range, the accuracy shows a trend of first increasing and then decreasing, and when the head=2, the accuracy is optimal. By selecting the optimal hyperparameter configuration, the overall performance of our proposed method can be effectively improved.



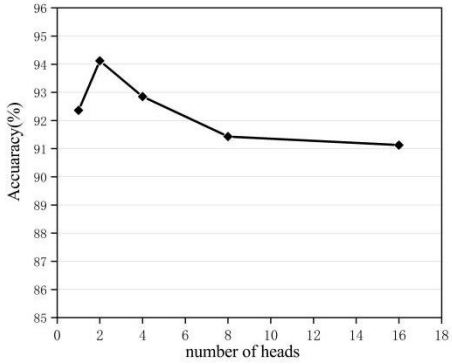
(a) Accuracy with different λ_{con}, λ_{un}=1.0, λ_{com}=1.0, multi-head attention with 2 heads.



(b) Accuracy with different λ_{un} , λ_{con}=10, λ_{com}=1.0, multi-head attention with 2 heads.



(c) Accuracy with different λ_{com} , λ_{con}=10, λ_{un}=1.0, multi-head attention with 2 heads.



(d) Accuracy with different heads of multi-head attention, λ_{com}=1.0, λ_{con}=10, λ_{un}=1.0.

Fig. 5. Key hyperparameter analysis of the proposed method in 10% proportion labeled training samples.

E. Ablation Experiments

Ablation experiments are conducted from three aspects with 10% proportion of labeled training samples: (1) the verification of the effectiveness of the multi-feature fusion algorithm based on attention mechanism. We compare the operating condition recognition results with the pooling learning multi-feature fusion method (MAIWRN28-2_Pooling_CCL) and the fixed-weight multi-feature fusion method (MAIWRN28-2_Fixed-weight_CCL). (2) the verification of the effectiveness of the contrastive learning algorithm. We compare with the multi-feature fusion method based on non-contrastive learning (MAIWRN28-2). (3) the verification of the effectiveness of online augmented data processing. We compare with the multi-feature fusion method without online augmented data processing (MIWRN28-2_CCL). The comparison results of ablation experiments are shown in Table V.

TABLE V. THE COMPARISON RESULTS OF VARIOUS OPERATING CONDITION RECOGNITION METHODS BASED ON THE CLASSICAL RESIDUAL NETWORK COMBINED WITH CCL (AVERAGE ACCURACY, %)

Methods	10% labeled (n=88)
MIWRN28-2_CCL	91.27
MAIWRN28-2	90.18
MAIWRN28-2_Fixed-weight_CCL	90.46
MAIWRN28-2_Pooling_CCL	92.18
MAIWRN28-2_CCL(Ours)	**94.13**

From Table V:

1) Compared with the multi-feature fusion method based on pooling learning and fixed weights, the multi-feature fusion method proposed in this paper can obtain better global feature representation by adaptive adjustment of the feature weights of different information sources through the attention mechanism, thus improving the condition recognition effect.

2) Compared with the multi-feature fusion method based on non-contrastive learning, the proposed method can effectively solve the common confirmation bias problem in semi-supervised deep learning through class-aware contrastive learning, thus further improving the model performance.

3) By using the augmented technique based on geometry operations such as rotation, scaling and expansion, our method can significantly expand the size and diversity of the training set without the need for collecting additional data, thereby improving the model's performance on unknown data.

V. Conclusion and Future Work

In order to solve the limitations of operating condition recognition in the context of big data oil production, such as the bottleneck of traditional single or multi-source operating condition recognition technology, high demand for lots of labeled operating condition data, and inability to make use of massive unknown operating condition data resources, we propose a semi-supervised sucker-rod pumping well operating condition recognition method based on multi-source consistency deep learning. The proposed approach first draws on the design idea of the Transformer coding layer and extracts the deep features of the measured dynamometer cards and the measured electrical power cards, respectively, through a multi-head self-attention mechanism and feedforward neural network. Then, combined with cosine similarity measurement, it realizes the maximum consistency of interactive learning on the complementary feature information of different information sources. Further, the optimal global feature representation of multi-source fusion is obtained by self-learning the weights of the feature representations of different information sources by the attention mechanism. Finally, the multi-source fusion feature is combined with the multi-source semi-supervised class-aware contrastive learning to build the operating condition recognition model and carry out the operating condition recognition. A large number of operating condition recognition comparison experiments show our method can not only mine the deep characteristics of multiple measured information source data but also effectively utilize massive unknown operating condition data in a small amount of labeled operating condition data to further improve the recognition effect and engineering practicability. Key hyperparameter analysis and ablation experiments further verify the effectiveness of the proposed method.

Future Work

The future directions of this paper worth further exploration are: (1) The study of the influence of heterogeneous data from multiple sources on the universality and generalization of the operating condition recognition model. In this paper, two kinds of image information sources, dynamometer cards and electrical power cards, are used to carry out research by combining the adaptive interactive learning fusion method based on the attention mechanism. The sucker-rod pumping well production system is a complex nonlinear system with mechanical-electrical-hydraulic coupling, and operating conditions are complex and changeable. Therefore, it is worth studying more comprehensive and appropriate information sources and more effective fusion learning methods. (2) The exploration of more efficient semi-supervised deep learning methods to further optimize the operating condition recognition model performance in insufficient labeled samples.

***Abstract*—In this project, we develop and apply a Smart Water Dispenser system, which is combined with object recognition and fluid level control supported by Ultrasonic Sensors, Raspberry Pi, and also DC Motors. The essence of this system is to develop a system using the Raspberry Pi 4 Model B with other components that have been integrated and interrelated Hardware and programming using OpenCV, YOLO V8, and other components, the point is that the cup can be detected, and water filling is done precisely and automatically. The process carried out is the detection of cups automatically using Raspberry Pi which is in charge of controlling the DC Motor and also the Ultrasonic sensor (HC-SR04) and detecting based on the volume of water with precision. The dispenser functions to pump water based on the condition of the volume of water in the glass and stop pumping if the volume of the glass has been fulfilled, aka not spilling with a percentage of 90%. In the scenario process, the cup search process is first carried out by scanning three times until a cup is found, if a cup is found, then the sensor component and the valve for the release of water in the hose will stop right at the position of the cup and the water will fill the cup automatically. Otherwise, the system will move backward and the system will be turned off. The first testing process has been successful and shows the effectiveness of the system in the process of finding cups and managing water levels. This innovation shows hope for improving user comfort, especially for disabilities, utilizing advanced technology in object recognition, and of course, saving water usage. In the testing process obtained 95% to 97% accuracy in object detection with different types of cups.**

Keywords*—Smart water dispenser; object recognition; Raspberry Pi 4; YOLO VB; ultrasonic sensor

I. Introduction

The demand for automation solutions has significantly increased in recent years, driven by advancements in Internet of Things (IoT) technologies and smart devices. IoT-based systems enable the interaction of interconnected electronic devices that can be automatically controlled and monitored, transforming various sectors, including smart homes, industries, and offices, toward enhanced convenience and efficient resource use. One of the promising applications of smart technology is in the development of automated water dispenser systems, which provide water efficiently and accurately, reducing the need for manual methods that are prone to wastage and contamination [1].

Traditional water dispensers rely heavily on manual operation, which often leads to inefficient water usage. These conventional systems cannot detect the user's needs or monitor the fluid level, which presents several limitations, particularly in environments that demand precise control of water use. Consequently, the integration of smart water dispensers equipped with sensors and object recognition technology has become an ideal solution. These systems can automatically detect the presence of objects like cups and dispense the appropriate amount of water, minimizing direct contact and saving users time. Research conducted by Raspberry Pi (2023) demonstrates that an automatic water bottle filling system using Raspberry Pi can detect bottles and adjust the water flow according to the object's needs, showcasing the practical potential of such technology [2]. In addition, the important conclusions of this research are: a) the importance of this study: the development of this research will be able to automate the process of filling water, especially cups. And can be applied to patients with disabilities and can be applied for other purposes according to their needs and development using sophisticated technology following novelty research. b) Recent advances in technologies applied to this research are how to use object recognition technology using artificial intelligence using the Convolutional Neural Network (CNN) method and a combination with other methods in Machine Learning and Deep Learning. Technology is evolving rapidly with various approaches such as Image Recognition [25-30] and Convolution Neural Network (CNN). Some studies use Image Recognition with various approach methods [31-40] and also hardware and Raspberry Pi 4 b Microprocessor as a processor.

II. Literature Review

A. Object Recognition Technology in Water Dispensers

Object recognition has emerged as a core element in the development of smart devices, especially for systems such as water dispensers that require accurate detection of specific objects before initiating any action. Object recognition technology enables the system to "see" and interpret the surrounding environment so that water is dispensed only when a suitable object, like a cup, is detected. This feature not only reduces water waste but also contributes to better user convenience and hygiene. One of the widely used frameworks for object recognition is OpenCV, paired with YOLO (You Only Look Once) to enhance detection accuracy and speed in real-time applications [3], [4]. In the context of water dispensers, a camera connected to the Raspberry Pi leverages these algorithms to detect the presence of a cup accurately and in a short time, allowing for efficient control of water flow [5].

B. The Role of Raspberry Pi in IoT Applications

Raspberry Pi, particularly the Raspberry Pi 4 model, has become a popular choice in developing IoT applications due to its affordability, compact size, and adequate processing capabilities. The Raspberry Pi 4 is capable of handling image processing and real-time object detection operations, which are critical for applications such as smart water dispensers that must respond promptly to the presence of objects. For applications that require object detection, the Raspberry Pi can be programmed to process inputs from the camera and send signals to other devices, such as water pumps and motors, to control fluid dispensing automatically [6]. This capability is particularly valuable in smart water dispenser systems, as it enables the device to function autonomously with minimal user intervention.

C. Sensor Technology and Fluid Dispensing Control

In addition to object recognition, sensor technology plays an essential role in the functionality of smart water dispensers. Sensors are used to detect the presence of objects, monitor fluid levels, or gauge environmental conditions surrounding the device. A recent article on Instructables (2023) explored a water level monitoring system using Raspberry Pi, which could be integrated into smart water dispensers to control water flow. This setup allows for controlled water dispensing according to the capacity of the container or cup being used, thereby reducing the risk of spills or underfilled containers [7]. While traditional dispensers may release excess water or require manual monitoring, sensors in smart dispensers ensure the precise amount of water is dispensed every time, supporting both user convenience and sustainability.

D. The Need for Automation in Daily Life

Automation has become increasingly relevant in modern households, primarily through smart home devices that enable a range of tasks to be conducted without manual intervention. Automation also promotes environmental sustainability by optimizing resource use, such as water. Smart water dispenser systems are designed to address two main concerns: efficient water usage and enhanced user convenience. These systems also reduce direct contact with the device, making them a hygienic solution in both public and private settings. A fully automated water dispenser that uses object recognition technology exemplifies the extent to which IoT and sensor-based automation can improve daily life by conserving resources and minimizing the risk of contamination [8].

E. Benefits of the Study and Contributions to Smart Home Technology

This research contributes to the field of smart home technology by developing a device that not only functions automatically but also interacts intelligently with the user. A system utilizing Raspberry Pi and object recognition technology can expand the capabilities of smart homes in terms of automation, providing a sustainable solution for water usage. The implementation of this technology is not only beneficial for household users but can also be applied in offices, schools, and public facilities where efficiency and reduced physical contact are priorities. By offering a self-contained water dispensing solution, this study bridges the gap between basic automated dispensers and advanced IoT-integrated devices that respond to specific user needs [9].

III. METHOD

This study employs an experimental method to design, implement, and test a smart water dispenser system utilizing object recognition technology and automated control. Below are the methodology steps applied in this research, complemented with relevant references.

A. System Design

1) Component selection: This study uses the Raspberry Pi 4 Model B as the main controller, the Raspberry Pi Camera V2 for object recognition, and a DC motor to drive the water flow mechanism. Other key components include a water pump and relay to control water flow as needed [10], [11].

2) Object recognition integration with OpenCV and YOLO: The system employs the OpenCV library and YOLO (You Only Look Once) algorithm for real-time object detection. YOLO allows high-speed and accurate object detection, making it suitable for detecting the presence of glass in the filling area in real-time [12], [13].

3) Sensor setup and water flow control: The DC motor and relay are connected to the Raspberry Pi to automatically control water flow. When a glass is detected, the Raspberry Pi activates the water pump through the relay and drives the motor to fill the glass to the desired level [14]. The Raspberry Pi controls the movement of the DC motor, which carries a camera to scan for the presence of a glass. When a glass is detected, the Raspberry Pi then checks the water level using an ultrasonic sensor. If the glass is empty or the water level is insufficient, the water pump is activated to fill the glass until the desired level is reached.

B. Implementation Phase

1) Raspberry Pi programming: The Raspberry Pi is programmed using Python to run the OpenCV and YOLO V8 libraries. The program processes the image input from the camera to detect the presence of a glass. When a glass is detected, the Raspberry Pi sends a signal to the relay to activate the water pump and control the DC motor [15], and The water level using an ultrasonic sensor.

2) Camera configuration and object detection algorithm: The Raspberry Pi Camera V2 is positioned at a specific angle to scan the dispenser area. The YOLO algorithm is implemented in Python on the Raspberry Pi for real-time object detection. A threshold setting in YOLO is applied to ensure that only objects meeting certain criteria (such as the shape and size of glass) and Moved by a DC motor are identified as targets [16].

3) Initial testing and system calibration: After the hardware and software integration is complete, initial testing is conducted to ensure all components function as designed. Testing includes camera calibration or positioning to detect objects accurately and setting the Pump activation timing based on the measurement of the water level based on ultrasonic sensor readings [17]. Pump activation timing based on

measurement of the water level based on ultrasonic sensor readings.

C. Testing and Data Collection Phase

1) Object detection accuracy testing: The system is tested to detect the presence of glasses of various shapes and sizes. This test aims to ensure that the YOLO and OpenCV algorithms can detect objects accurately under different lighting conditions and positions [18].

2) Reliability testing of automatic water dispensing: The system is tested with different glass sizes to ensure the automatic water dispensing matches the glass's capacity. Data is collected to evaluate the system's reliability in stopping the water flow once the desired volume is reached [19].

3) System stability testing: Stability testing is performed to ensure the system can operate consistently over a long period without failure. This test includes monitoring power consumption, sensor durability, and detection accuracy over multiple usage cycles [20].

D. Data Analysis

1) Object detection accuracy analysis: The object detection test results are analyzed based on the success rate of detection relative to the number of trials. This analysis aims to determine the system's accuracy level in recognizing the presence of a glass under various conditions [21].

2) Automatic water dispensing effectiveness analysis: The effectiveness of automatic water dispensing is analyzed by measuring the precision of the dispensed water volume according to the glass size. The error percentage in the dispensed water volume is calculated to evaluate the system's precision [22].

3) Overall system evaluation: An overall evaluation of the system is conducted by considering data from object detection accuracy testing, water dispensing reliability, and system stability. The analysis results will demonstrate the system's effectiveness in reducing water waste and enhancing user convenience [23].

E. Conclusion and Development Recommendations

The data analysis results will be summarized to conclude the success of implementing this smart water dispenser system. Recommendations for further development will also be included, particularly in improving detection accuracy and water dispensing efficiency [24].

This diagram provides a visual representation of the workflow and integration of each component, helping readers understand the process from start to finish within the system.

F. Flowchart Smart Water Dispenser

The smart water dispenser flowchart and explanation are depicted in Fig. 1.

Explanation of Components in the Block Diagram

1) Raspberry Pi 4 Model B:

- Serves as the main controller, handling both object recognition and control of hardware.
- Integrates with the Raspberry Pi Camera V2 using OpenCV and YOLO v8 for real-time glass detection.
- Controls the DC Motor with L298N Motor Driver to move the conveyor.

2) Camera and Detection:

- The Raspberry Pi Camera scans for the presence of a glass as it moves on the conveyor.
- If a glass is detected, Raspberry Pi stops the motor, aligns the spout, and activates the pump.

3) Water Pump and Ultrasonic Sensor:

- Raspberry Pi activates the relay to start the water pump and then uses the Ultrasonic Sensor HC-SR04 to monitor the water level in the glass.
- Once the water level reaches 90% of the glass height, the relay turns off the pump. And then activate the relay to start the water pump.

4) Process Flow:

- The DC motor moves the conveyor for glass detection.
- When the glass is detected, the motor stops, the water pump is activated, and the water level is monitored by the ultrasonic sensor.
- Once the required water level is reached, the pump stops, and the motor returns to its initial position.

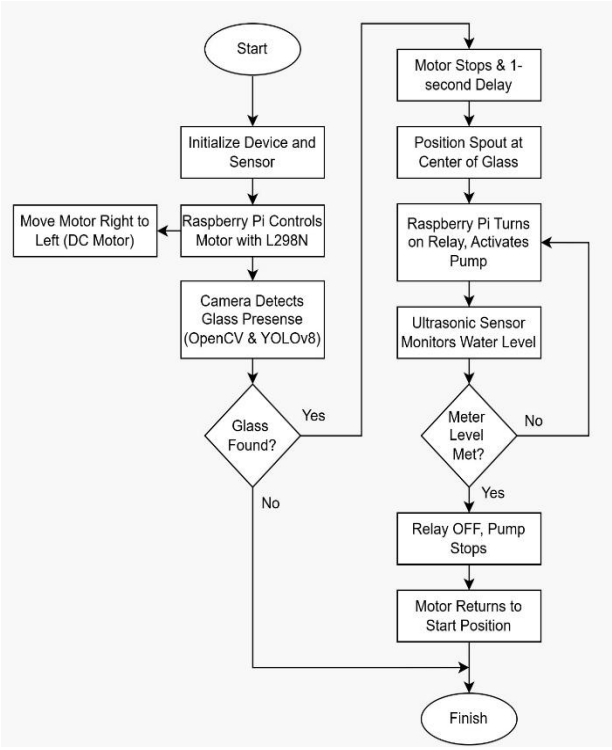

Fig. 1. Flowchart smart water dispensers.

Moreover, Fig. 3, 4, and 5 are a frame of hardware that outlines the efficient workflow of the smart dispenser system controlled entirely by Raspberry Pi, handling both the detection and water dispensing process.

Moreover, The Hardware and Software Design:

1) Raspberry Pi 4 model B: Used for object recognition programs utilizing the Raspberry Pi Camera V2. The Raspberry Pi Camera V2 is programmed with the OpenCV application and YOLO V8 algorithm.

2) Control system: Control Systems include a 17-stepper motor, L298N motor driver, HC-SR04 ultrasonic sensor, and a relay for turning the water pump on and off. The ultrasonic sensor, camera, and water hose are mounted together on a conveyor system, whose movement is synchronized with the rotation of the stepper motor.

Fig. 2 shows the system configuration built in this research. There are several sets of hardware and software installed and placed according to their functions and uses. Moreover. The method taken in this research is Object Detection and retrieval and equalization on the dataset side, such as Convolutional Neural Network (CNN) by utilizing a smart camera as hardware connected to a Raspberry Pi 4b and also the Python programming language, such as the YOLO and OpenCV platforms. The goal is to build a smart system on the dispenser Therefore, it can fill water automatically.

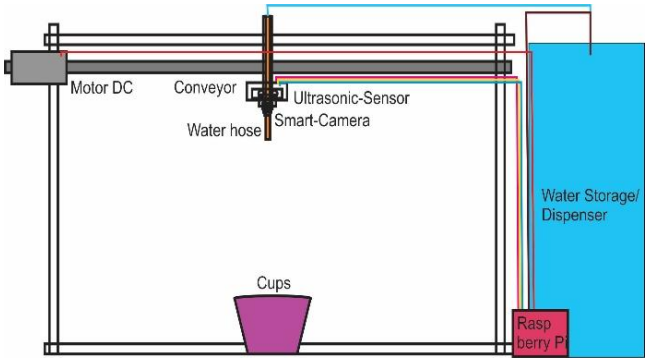

Fig. 2. Configuration of the built tool.

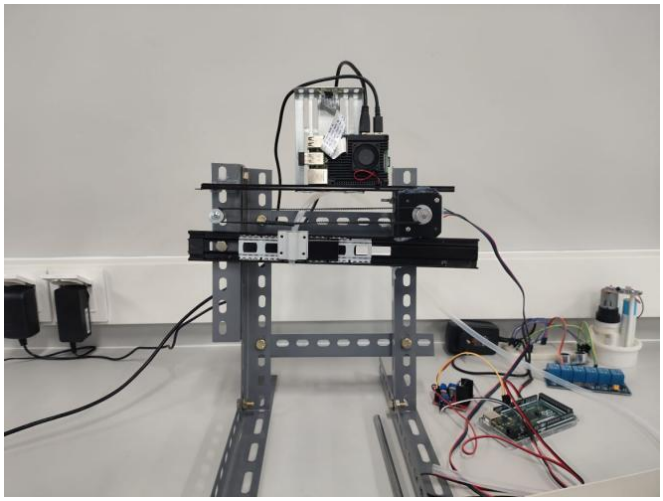

Fig. 3. A series of hardware in this system.

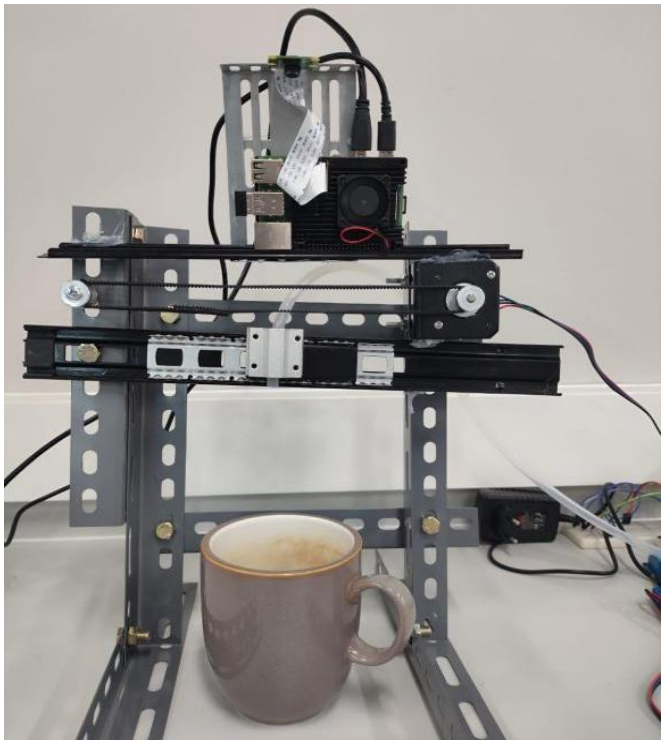

Fig. 4. Frame of hardware.

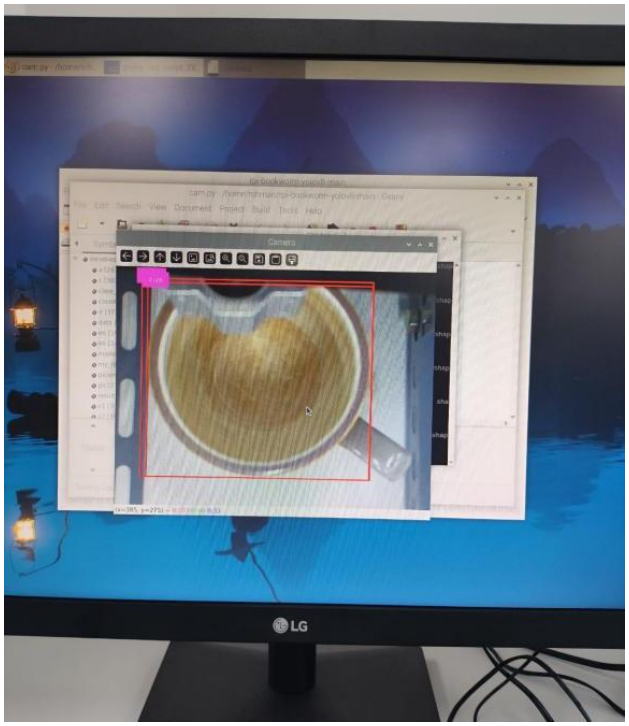

Fig. 5. Glass object detection system.

The configuration system is also carried out on the DC Motor in running the Conveyor so that the camera and other devices such as the Ultrasonic Sensor and the Mini Pump can work precisely.

IV. Result and Discussion

This section presents the outcomes of testing conducted to evaluate the performance of the smart water dispenser system in terms of object detection accuracy, reliability of automatic water dispensing, and overall system stability. The discussion is based on data obtained from various testing scenarios to assess system effectiveness and identify potential improvements. The innovation proposed in this research is how to produce an invention that can have intelligence in terms of automatic water filling, specifically in terms of detecting glass objects and classifying them. The camera moves to detect the presence of a glass. Once a glass is detected, water will flow, and the level is monitored using an ultrasonic sensor. When the water level reaches the desired point, the filling process stops, and the motor returns to its initial position. If the camera does not detect a glass by the end of its path, it will return and continue scanning until a glass is found, or the user turns off the device.

Steps of Operation:

1) Initialization and Conveyor Movement: When the device is powered on, the Arduino Mega commands the motor to move the conveyor from right to left. This movement shifts the camera's position to scan for the presence of a glass.

2) Object Detection by the Camera: The Raspberry Pi Camera V2, running an OpenCV and YOLO V8 program, detects objects. When a glass (cup) is identified, the motor stops after a 1-second delay. This delay ensures that the water hose is positioned directly above the center of the glass.

3) Water Pump Activation: When the motor halts (assuming the hose is centered over the glass), the Arduino Mega triggers the relay to turn on the water pump, starting the filling process.

Monitoring Water Level: The ultrasonic sensor monitors the water level until it reaches a predetermined height (e.g., 90% of the glass height). Once the desired level is reached, the relay is turned off, and the pump stops. Return to Initial Position The motor moves back to the initial position (left side) after completing the filling process. Moreover, the Pseudocode 1 will explain in detail how this system works.

A. Test Results

1) Object detection accuracy: The initial test focused on the system's ability to detect the presence of glass using the YOLO algorithm integrated with OpenCV. Tests were conducted with glasses of different sizes and shapes under various lighting conditions. The results showed that the system achieved an accuracy rate of 94% under optimal lighting and 89% in low-light conditions. Some inaccuracies were observed with objects that had high reflectivity, such as metal or transparent glasses, which affected detection accuracy.

1. **Import library**, GPIO, Camera, OpenCV, YOLO
2. Setup GPIO
3. Function definition (motor movement, Ultrasonic distance reading, water filling)
4. The motor starts moving forward
- Record start moving time (initial time set) 4.

5. LOOP for True:
- Take a picture from the Pi camera
- Object detection using YOLO on the image

A. If the detected object is a "*cup*":
- Stop the motor
- Record the time after the motor stops (set stop time)
- Call the water fill () function to start filling the water
- Calculate the rewind duration (stop time - start time)
- Rewind the motor for the calculated duration
- Stop the motor

B. If the motor runs for more than 20 seconds without detecting the glass:
- Stop the motor
- Rewind the motor for 20 seconds (to return to the starting position)
- Stop the motor
- Display the detection result image

--------- *Pseudocode 1*----------

2) Reliability of automatic water dispensing: The second test assessed the system's reliability in filling glasses to their respective capacities. The system was tested with three different glass sizes (small, medium, and large). Results indicated that the system consistently dispensed water with a margin of error of ±5% from the target capacity. Automatic filling stopped precisely when the volume matched the glass capacity, demonstrating the system's effectiveness in preventing water spillage and overuse. +10% and -16%. With a target water level of 5cm, the water level varies between 4.2 to 5.5cm. error range + 0,5cm and - 0,8cm. This is due to the uneven water surface when filling the water.

3) System stability: Stability tests were conducted to evaluate the system's ability to operate consistently over multiple cycles. The system was tested across 50 continuous usage cycles without a reset, and results showed no performance degradation or component failure. This test demonstrated that both the hardware and software components of the system are stable and reliable for long-term use.

B. Discussion

The test result and analysis are explained in Table I.

1) Analysis of object detection accuracy: Test results revealed that high detection accuracy can be achieved with the YOLO algorithm running on a Raspberry Pi, especially under well-lit conditions. However, accuracy slightly decreased in low-light scenarios, highlighting the importance of lighting in detection performance. To improve accuracy for reflective or transparent objects, additional techniques such as image preprocessing or adjusting the camera angle to reduce reflection effects can be considered.

2) Evaluation of automatic water dispensing reliability: The system's success in filling glasses accurately demonstrates the effectiveness of its automated control mechanisms. A small margin of error indicates that the system provides precise control over water volume, which is crucial for water conservation and spill prevention. The use of relays and DC motors controlled by the Raspberry Pi proved capable of

delivering rapid and stable responses for automatic water dispensing. For applications requiring higher precision, additional sensors to measure water levels within the glass could enhance control accuracy.

3) System stability evaluation: Stability testing indicated that the system operates consistently over extended periods without failure. This highlights the durability of the hardware, including the Raspberry Pi, camera, and control components. Such reliability is critical for household or industrial applications where repeated use is expected. The stability test also demonstrated that the system functions efficiently with minimal power consumption, avoiding overheating or technical issues.

4) Implications and potential for further development: The test results suggest that the smart water dispenser system holds significant potential for household or public applications. With reliable object detection, precise water dispensing, and high system stability, it offers an effective solution for water conservation and user convenience. Potential improvements include integrating additional sensors for water level detection, employing enhanced filters for transparent object detection, and optimizing the algorithm to improve accuracy under diverse lighting conditions.

TABLE I. TESTING RESULT FOR SMART WATER DISPENSER SYSTEM

No.	Test Type	Parameter	Test Result	Description
1.	Object Detection Accuracy	Optimal Lighting Condition	94 % Object detection accuracy	High accuracy under optimal lighting conditions
		Low Lighting Condition	89 % Object detection accuracy	Reduced accuracy in low-lighting
		Transparent/Reflective Objects	75 % Object detection accuracy	Transparent and reflective objects are harder to detect
2.	Automatic Water Dispensing Reliability	Small Glass (150 ml)	95% accuracy (±5 % margin of error)	Accurate dispensing for small glass capacity
		Medium Glass (250 ml)	97% accuracy (±5 % margin of error)	Accurate dispensing for medium glass capacity
		Large Glass (500 ml)	96% accuracy (±4 % margin of error)	Accurate dispensing for large glass capacity
3.	System Stability	Continuous Operation Cycles	50 cycles without failure	The system operates stably over 50 cycles without interruptions
		Power Consumption	5V, 2.5 A (Rasberry Pi Standard)	The system operates with minimal power consumption
		Operating Temperature	40-45° (no overheating)	Temperature remains stable during prolonged operation

Explanation of the Table I Testing:

1) Object detection accuracy: Tests were conducted to measure the system's accuracy in detecting the presence of a glass under various conditions. Under optimal lighting, the system achieved 94% accuracy, while low lighting conditions slightly reduced accuracy to 89%. Transparent or reflective objects, such as glass, resulted in lower detection accuracy (75%). In optimal lighting conditions or less light, glass detection can still run well. but if the size of the glass used is not standard, it will affect the detection accuracy, especially if the glass is transparent without color, the accuracy will decrease even more.

2) Automatic Water Dispensing Reliability: This test measured the system's accuracy in dispensing water according to the glass capacity. Three different glass sizes were tested, showing a low margin of error across all sizes (small, medium, and large), indicating high accuracy in controlling the water volume dispensed.

3) System Stability testing: It was conducted to ensure the system could operate continuously over multiple cycles. The system showed consistent performance over 50 cycles without failure, maintained stable operating temperatures (40-45°C), and consumed minimal power (5V, 2.5A).

V. CONCLUSION

This study successfully developed and implemented a smart water dispenser system using Raspberry Pi and object recognition technology to automate water dispensing based on the detection of a glass. The system incorporates OpenCV and YOLO algorithms for real-time object detection and controls a DC motor and water pump to ensure precise and reliable water filling. Testing demonstrated that the system achieved a high detection accuracy of 94% under optimal lighting conditions and maintained stable performance over multiple cycles, with no operational failures observed.

The system's ability to accurately detect different glass sizes and automatically adjust the water volume demonstrates its effectiveness in reducing water waste and enhancing user convenience. Moreover, the stable operating temperature and minimal power consumption indicate that the system is suitable for continuous use in real-world applications, whether in household settings or public spaces.

In summary, the smart water dispenser system shows promising potential for improving the efficiency and sustainability of water use in smart homes and IoT applications. Future improvements, such as adding sensors for enhanced water level detection and optimizing algorithms for detecting transparent or reflective objects, could further enhance the system's robustness and broaden its range of applications.

The strength of this research is the process of filling water in the glass automatically, by involving the Convolutional Neural Network (CNN) method, so that the water filling process has its intelligence and can be applied to patients with disabilities, but this research has a weakness, namely still using a scanning system on the cup at point A to point B statically, not having a Degree of Freedom (DOF) like the Robot Arm.

ACKNOWLEDGMENT

Gratitude is extended to the National Research and Innovation Agency (BRIN) for their support, ideas, and guidance in the development of this research. Appreciation is also given to the research institution for providing facilities and technical assistance throughout the research process. Special thanks to the Faculty of Engineering and the Department of Electrical Engineering for providing funding, facilities, and necessary infrastructure. The support from all parties has been invaluable to the smooth conduct of this research. It is hoped that the results of this research will contribute to the advancement of science and technology in the future. Thanks also to other universities who helped collaborate in improving this manuscript until it was accepted.

FUTURE RESEARCH

The development of this Smart Water Dispenser is still static, so it is necessary to make changes to the side of the water filling hose and Degree of Freedom (DOF) as in the Robot Arm, so that the position of the cup that is anywhere in the X, Y, Z coordinates, can fill water with great precision.

Machine Learning as a Tool to Combat Ransomware in Resource-Constrained Business Environment

Luis Jesús Romero Castro, Piero Alexander Cruz Aquino, Fidel Eugenio Garcia Rojas
Department of Computer Science, Universidad Peruana de Ciencias Aplicadas, Lima, Perú

***Abstract*—Ransomware has emerged as one of the leading cybersecurity threats to microenterprises, which often lack the technological and financial resources to implement advanced protection systems. This study proposes a cybersecurity model based on machine learning, designed not only for the detection and mitigation of ransomware attacks but also as a scalable and adaptable solution that can be integrated into business infrastructures across various sectors. By leveraging advanced techniques to identify malicious behavior patterns, the system alerts businesses before significant damage occurs. Moreover, this approach provides complementary measures such as automated updates and backups, enhancing resilience against cyber threats in resource-constrained environments. This research aims not only to protect critical data but also to contribute to the development of accessible cybersecurity models, improving operational continuity and promoting sustainability in the digital landscape.**

Keywords*—Ransomware; cybersecurity; machine learning; microenterprise; threat detection

I. Introduction

The exponential growth of ransomware attacks poses a serious threat to the cybersecurity of various organizations, including microenterprises, which often lack the resources to implement advanced protection systems. These attacks, characterized by their ability to lock or encrypt critical data in exchange for a ransom, have evolved in complexity and frequency, significantly impacting the operational and financial stability of these businesses.

Recent reports project that ransomware attacks occur every 11 seconds, with associated costs potentially reaching $20 billion by 2021. These alarming figures underscore the urgent need to develop advanced detection and prevention strategies to mitigate these devastating attacks in the microenterprise sector [1], which is especially vulnerable due to its limited cybersecurity investment capacity.

The analysis of leaked ransomware source codes, such as the detailed study of the Conti ransomware [9], has provided valuable insights into the attack techniques employed by these threats. However, despite progress, many studies have primarily focused on identifying and characterizing attacks without offering comprehensive solutions addressing all stages of ransomware defense. While machine learning algorithms and advanced detection techniques have proven effective in identifying threats [1][2], these approaches often lack proactive and adaptive measures to anticipate and neutralize new, evolving attack vectors. Additionally, the lack of integration between detection solutions and mitigation strategies limits their effectiveness in real-world microenterprise environments. It is, therefore, crucial to develop a cybersecurity model that not only detects but also prevents and dynamically responds to ransomware attacks, ensuring more robust and sustainable protection for these businesses.

This study proposes implementing a cybersecurity model based on machine learning techniques specifically designed to strengthen the cybersecurity posture of microenterprises against ransomware. This model will integrate early detection and neutralization strategies inspired by recent research [3][4], aiming to develop a proactive system capable of identifying and mitigating threats before causing significant damage.

In addition to exploring advanced detection approaches, complementary measures such as automated backups and regular software updates will be considered to establish a comprehensive defense against ransomware attacks [5], [7]. This proposal aims not only to protect the critical data of microenterprises but also to lay the foundation for a holistic cybersecurity approach capable of adapting and effectively responding to emerging threats.

This study will provide a practical roadmap for implementing an advanced cybersecurity system in microenterprises, contributing to the effective protection of critical data and systems against the growing threats of ransomware. By integrating machine learning-based approaches for ransomware detection and response, as proposed by previous studies [1], [3], [4], this research aims to significantly enhance the ability of these businesses to anticipate and neutralize such attacks. Moreover, complementary strategies, such as neutralizing ransomware techniques through format-preserving encryption [6] and implementing dynamic and static analysis to identify and mitigate new ransomware variants [9], will be considered. These integrated measures will enable microenterprises to not only effectively respond to current threats but also adapt to future challenges in the field of cybersecurity.

This study is organized as follows: Section II presents prior research related to the topic. Section III focuses on the contribution of the proposed cybersecurity model and its key components, while Section IV discusses the results and their implications. Discussion is given in Section V. Finally, Section VI provides conclusions and recommendations for future work.

II. Related Work

Various studies on ransomware management and cybersecurity have been identified, offering a wide range of approaches and solutions to address these threats. For instance, [1] focuses on applying advanced machine learning algorithms

for ransomware detection and mitigation, while [2] emphasizes the importance of dynamic analysis combined with machine learning for early detection. Additionally, other works such as [3], [4], [5], and [6] explore different approaches, ranging from decision tree-based detection to ransomware neutralization through encryption techniques. The detailed analysis of leaked Conti ransomware source code, as described in study [9], also provides crucial insights into the attack techniques employed. These studies represent just a sample of the available research but demonstrate the diversity of approaches that can be applied in the context of microenterprises to strengthen their defenses against ransomware and effectively protect their data.

Most previous works on ransomware detection through machine learning have focused on specific aspects, such as initial threat detection and static behavior analysis, leaving aside an integrated approach that combines early detection, proactive mitigation, and adaptability to resource-constrained environments. For instance, recent studies like the analysis of Conti ransomware have provided valuable insights into attack techniques but failed to address how these solutions can be tailored to microenterprises with limited infrastructure.

This study proposes a comprehensive model that bridges the existing gap by combining:

- Adaptability in Resource-Constrained Environments: Designing a lightweight architecture that does not rely on expensive hardware or advanced technical expertise.
- Early Detection and Mitigation: Leveraging advanced machine learning algorithms to identify malicious patterns and act before irreversible damage occurs.
- Dynamic Updating: Incorporating a continuous learning system based on static and dynamic analysis to tackle new ransomware variants.

These proposals not only fill the gap in designing and implementing effective solutions for microenterprises but also highlight critical areas for future research, such as improving machine learning model interpretability and optimizing performance under real-world operating conditions.

In the field of cybersecurity and threat management, various studies and models have been developed to address the protection of critical data and the mitigation of risks associated with ransomware. These works provide a valuable framework for designing and implementing effective cybersecurity strategies in microenterprise environments. Table I shows related works on cybersecurity and ransomware detection.

TABLE I. RELATED WORKS ON CYBERSECURITY AND RANSOMWARE DETECTION

Method	Evaluation Method	Main Outcome	Source

Cybersecurity Impact on SMEs	Case analysis	SMEs in the Balearic Islands lose an average of €30,000 due to cyberattacks	[10]
Ransomware Growth Analysis	Case analysis	Study of the 81% increase in ransomware attacks	[11]

Relevant studies include research focused on ransomware detection using machine learning algorithms [3]. This approach offers an important perspective on detection techniques based on behavior analysis and specific characteristics of ransomware attacks. Additionally, investigations explore dynamic ransomware detection methods through behavior analysis and machine learning [4], highlighting the importance of proactive approaches to addressing these threats.

In the realm of enterprise architecture, a detailed analysis of Conti ransomware is proposed, emphasizing the importance of understanding leaked source codes to develop effective countermeasures [9]. This study underscores the necessity of applying multidisciplinary approaches that combine behavioral and forensic analysis techniques to strengthen microenterprise security against ransomware.

Furthermore, these studies provide a comprehensive perspective on anti-ransomware research strategies, outlining a roadmap for enhancing the impact of research in this field [7]. This investigation highlights the importance of tackling ransomware from multiple dimensions, including risk assessment, technological innovation, and best practices in cybersecurity.

These studies represent only a glimpse of the broad spectrum of available research on ransomware management and cybersecurity. Analyzing and applying these approaches in the context of microenterprises will offer valuable insights to strengthen their defenses and effectively protect sensitive data.

III. CONTRIBUTION

The aim of this research is to propose a cybersecurity model based on machine learning techniques to address ransomware in Peruvian microenterprises, which face resource limitations in implementing advanced protection systems. This model seeks to provide robust and efficient protection against cyber threats by enabling early ransomware detection using advanced machine learning algorithms, as employed in previous studies [3][4].

Behavioral analysis is performed in real-time to identify suspicious patterns and anomalous behaviors, complemented by an automated system response that isolates suspicious files and notifies security personnel to mitigate risks immediately. Additionally, the model incorporates continuous updates based on detailed analyses of ransomware source codes [9], enabling the adaptation and enhancement of defenses against new attack variants.

Finally, the system generates detailed and periodic reports on detected threats and actions taken, providing a comprehensive and up-to-date view of the security status, as suggested in related studies [6], [7]. This contribution represents a significant advancement in the protection of critical data for microenterprises, establishing a robust and adaptable standard for cybersecurity in this sector (see Fig. 1).

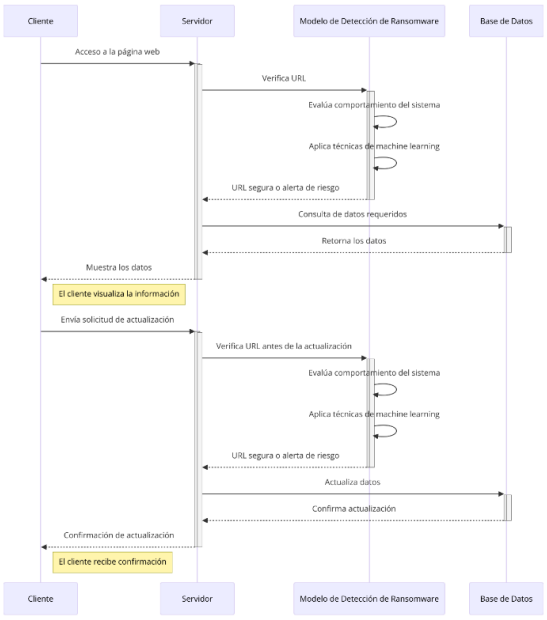

Fig. 1. Microenterprise client working within the company's web page.

A. Proposed Machine Learning Model for Ransomware

1) Continuous updates based on source codes: The objective of this strategy is to ensure that the model remains dynamic and adaptive, staying effective against new ransomware variants. To achieve this, source code mining is utilized, automating the extraction of unique features from new ransomware variants through both static and dynamic analysis. Static analysis identifies malware signatures by reviewing the source code, while dynamic analysis observes behavior in real-time by executing the ransomware in a controlled environment (sandbox). For instance, these techniques can be instrumental in detecting new file access paths or encryption methods used by modern variants such as LockBit or REvil.

Additionally, the model undergoes retraining using transfer learning. This approach allows the reuse of parts of the previously trained model, incorporating new patterns without losing acquired knowledge, thereby conserving computational resources by avoiding full retraining from scratch. Controlled simulations are also conducted using platforms like MITRE Caldera, where real attacks are replicated in secure environments. From these simulations, the model is adjusted to respond to observed tactics, such as data exfiltration or mass encryption. Synthetic data based on these attacks is also generated, reinforcing the model's training.

2) Model pipeline: Data collection will focus on capturing system logs that include access events, file modifications, network traffic, and security-related events tied to the applications used by microenterprises. These logs will be complemented with public and private datasets of known ransomware, such as WannaCry, Locky, and CryptoLocker, along with normal behavior data. During preprocessing, tasks such as data cleaning and normalization will be performed to remove duplicates, handle null values, and standardize formats. Additionally, feature engineering will be conducted to create key attributes, such as massive directory changes, unusual spikes in resource usage (CPU, network, or memory), and a high number of failed access attempts.

For model training, the data will be split into training (70%), validation (20%), and testing (10%) sets. The model will be validated using metrics such as precision, recall, F1-score, and a confusion matrix. These metrics will assess the model's performance, ensuring a balance between accurate detection and reduced false positives. Subsequently, the model will be deployed as a microservice integrated into the IT infrastructure of microenterprises, generating automatic alerts with details such as the affected file, detection time, and suggested actions.

The detection and response processes for ransomware in microenterprises were modeled and characterized, analyzing both their current state (AS-IS) and the desired future state (TO-BE). This analysis included threat identification, updating the machine learning model, and generating security reports. These steps ensure a clear and effective implementation of the proposed model, tailored to the specific needs of microenterprises and guaranteeing an efficient response to potential attacks (see Fig. 2 and Fig. 3).

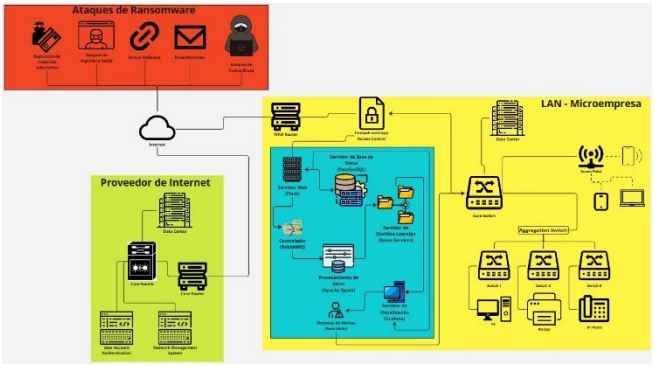

Fig. 2. Integrated architecture.

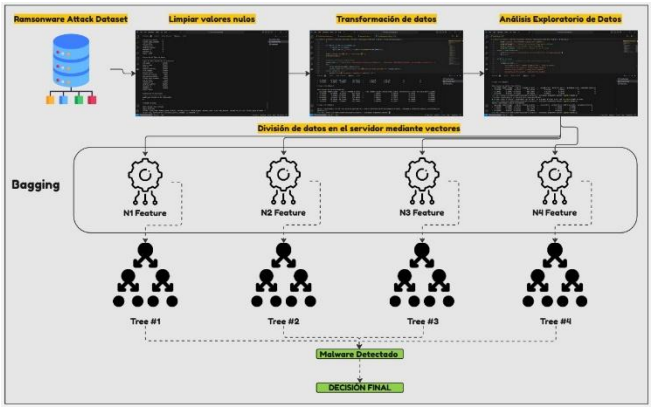

Fig. 3. Detection model.

3) Key features of the model: The designed model incorporates key features that ensure its effectiveness and adaptability to the dynamic environments of microenterprises.

a) Scalability: The model is designed to scale efficiently, enabling deployment across multiple microenterprises using shared infrastructure. Tools such as Apache Spark, which facilitates distributed data processing, and TensorFlow, which handles large data volumes without compromising performance, are employed. This ensures that the model can grow with the businesses' needs without losing effectiveness.

b) Efficiency: The model's hyperparameters, such as the number of trees in Random Forest algorithms or the kernel coefficient in Support Vector Machines (SVM), have been optimized. These optimizations minimize the occurrence of false positives and false negatives, increasing the accuracy of ransomware detection. This not only enhances the model's effectiveness but also strengthens user confidence in the implemented solution.

c) Portability: The model is designed to be highly portable, supporting deployment both on local servers and cloud solutions such as AWS, Azure, and Google Cloud. Furthermore, it is compatible with heterogeneous environments, eliminating the need for retraining when switching platforms. This guarantees flexible and adaptable implementation across various microenterprise infrastructures

4) Expected results: The proposed model aims to deliver tangible outcomes that significantly enhance microenterprises' ability to counter ransomware attacks, promoting effective and sustainable protection.

a) Reduction in response times: The model is expected to detect ransomware in real time, with response times measured in milliseconds. This capability will enable immediate actions, such as isolating malicious files or disconnecting affected devices from the network, minimizing the risk of propagation and additional damage.

b) Reduction in financial impact: The model will help reduce the financial impact associated with ransomware attacks by preventing the need for ransom payments and mitigating operational losses. These losses, currently estimated at millions of dollars annually for affected microenterprises, will be significantly reduced thanks to the system's preventive and reactive capabilities.

c) Increase in awareness: To foster greater user awareness, the model will provide clear and detailed visual reports. These reports will include information on the types of threats detected, the system's efficiency in protection tasks, and the automatic actions taken to mitigate risks. This transparency will help users better understand the system's functionality and its value in protecting against ransomware attacks.

B. System Requirements

This section outlines the components necessary for the development and implementation of the machine learning-based cybersecurity model for microenterprises. The requirements are divided into hardware and software (see Table II and Table III) to ensure a scalable and efficient infrastructure capable of supporting data processing and analysis demands.

TABLE II. HARDWARE REQUIREMENTS

Hardware	Description
Memoriy (RAM)	16 GB of RAM to handle large data volumes and perform complex analysis operations.
storage	500 GB SSD storage to ensure fast and efficient data access.
Processor	Intel Core i7 for optimal performance in data processing.
GPU	NVIDIA with CUDA support, required to accelerate the training of machine learning models.

Details: [1]: Programming Languages and Environments, [2]: Machine Learning Libraries and Frameworks, [3]: Databases and Storage, [4]: Infrastructure and Development Tools, [5]: Data Management and Visualization Tools.

TABLE III. SOFTWARE REQUIREMENTS

Details	Software	Description
[1]	Python, Jupyter Notebook	Development of the machine learning model.
[2]	Pandas, NumPy, Scikit-Learn, TensorFlow, PyTorch	Data manipulation and model development.
[3]	PostgreSQL, Redis, Apache Spark	Structured storage and distributed processing.
[4]	Docker, Flask, Visual Studio Code	Containerization and application development.
[5]	Elasticsearch, Kibana, Grafana, Tableau, Power BI	Visualization and monitoring of security data.

C. Model Implementation

The implementation follows a series of structured steps to ensure effectiveness in protecting the critical data of microenterprises:

Process (Table IV): [1]: Process Initiation, [2]: Data Retrieval, [3]: Command for Review, [4]: Data Processing, [5]: Machine Learning Data Analysis, [6]: Analysis Results, [7]: Visualization and Alerts, [8]: Real-Time Notifications, [9]: Process Completion.

TABLE IV. PROCESS DESCRIPTION FOR MICROENTERPRISE DETECTION SYSTEM

	Description
[1]	The worker accesses the interface through the Web Server (Flask) to interact with the system.
[2]	The Web Server (Flask) retrieves and stores data in the Database, ensuring that the data needed for analysis is properly retrieved and managed.
[3]	The Database sends a command to the Controller to initiate the processing of the retrieved data.
[4]	The Controller works with Apache Spark to extract and process the data, performing the necessary operations to handle large volumes of data.
[5]	The data processed by Apache Spark is sent to the Machine Learning (ML) module, where advanced algorithms analyze the data and generate results.
[6]	The results of the analysis are sent from the Machine Learning (ML) module to the Visualization and Alerts System.
[7]	The Visualization and Alerts System presents the results to the worker in real time and issues relevant notifications if necessary.
[8]	Real-time notifications are managed throughout the process to ensure that the worker is informed of any critical changes or events.
[9]	Once the tasks are completed and the results displayed, the system returns to the starting point to handle new requests.

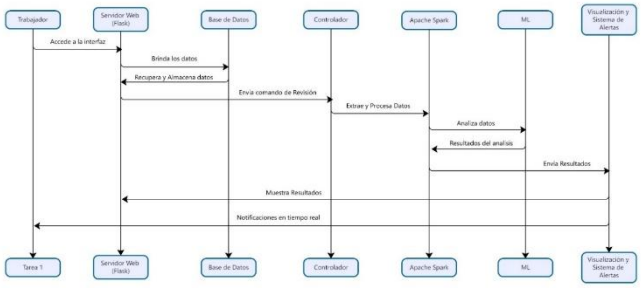

Fig. 4. Internal system usage process for the microenterprise.

IV. VALIDATION AND RESULTS

The validation of the proposed cybersecurity model is a critical stage to ensure its effectiveness and robustness in detecting and mitigating ransomware attacks in microenterprises. This process involves a series of tests and evaluations designed to verify the proper integration of system components, the accuracy of the machine learning model, and its performance under various operational conditions typical of microenterprises. Fig. 4 shows internal system usage process for the microenterprise.

Through integration testing, feature parameterization, load and performance testing, model training and evaluation, security testing, and continuous monitoring, the goal is to ensure that the system meets the security requirements of microenterprises and responds effectively to cyber threats. These validations enable the system to adapt to the infrastructure and resource limitations characteristic of microenterprises, ensuring efficient and effective implementation.

A. Validation Objective

The objective of this project is to develop an advanced ransomware detection and control model using machine learning algorithms and robust technologies to effectively protect microenterprises from cyber threats. This system will employ a comprehensive cybersecurity approach that not only detects malicious behaviors but also acts automatically to contain and mitigate the effects of attacks.

To achieve this objective, technologies such as Flask for web server development, RabbitMQ for message queue management, PostgreSQL as the database, Redis for caching, and Apache Spark for processing large volumes of data will be integrated. Additionally, machine learning models will be implemented using Scikit-learn, and data visualizations will be developed with Grafana to provide users with a clear and efficient interface.

The model validation will include a comprehensive process encompassing various types of tests to ensure the model's accuracy, efficiency, and security. These tests include:

- Unit Testing: Each system component will be verified to ensure the correct implementation of individual functions using tools like unittest in Python.
- Integration Testing: Different modules will be tested for correct interaction, validating integrations between services such as RabbitMQ and Apache Spark.
- Functional Testing: The system's compliance with functional requirements will be validated using tools like Selenium for user interface testing.
- Security Testing: Vulnerabilities will be identified, and system data and resources will be protected through vulnerability analysis and secure session management.
- Performance Testing: The system's capacity under various load conditions will be evaluated with Apache JMeter.
- Usability Testing: The system's ease of use by end users will be analyzed using heuristic evaluations and user testing.
- User Acceptance Testing (UAT): Scenarios reflecting real-world use cases will confirm that the system meets the end user's expectations.

Regarding the machine learning algorithms, a Support Vector Machine (SVM) model will be implemented, with data transformed and normalized to optimize performance. Multiple algorithms will be evaluated, and hyperparameters will be fine-tuned to enhance the system's accuracy in detecting ransomware. The MITRE Caldera framework will be employed to simulate cyberattacks, strengthening the system's response capabilities against real-world threats.

This comprehensive validation approach, combined with advanced algorithms, will ensure the system not only detects ransomware but also acts proactively to secure the operational continuity of microenterprises in a safe digital environment.

B. Evaluation Metrics for ML Model Performance

1) Area Under the ROC Curve (ROC AUC)

Definition: The Area Under the Receiver Operating Characteristic (ROC) Curve measures the model's ability to distinguish between positive and negative classes across different classification thresholds.

Formula: There is no closed-form formula to calculate the ROC AUC, as it is determined by integrating the ROC curve.

Interpretation:

- Value 0.5: The model has no discriminative ability, equivalent to random guessing.
- Value close to 1: The model has excellent ability to distinguish between classes.
- Value close to 0: The model misclassifies the classes entirely.

Observation: The ROC AUC is useful for evaluating models on imbalanced datasets, as it considers all possible classification thresholds and is unaffected by class distribution. However, it may be less informative when classes are extremely imbalanced, in which case metrics such as the Area Under the Precision-Recall Curve might be more appropriate.

2) Matthews Correlation Coefficient (MCC)

Definition: The Matthews Correlation Coefficient evaluates the quality of predictions in binary classification problems, considering true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN).

Formula:

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(\mathrm{TP}+\mathrm{FP})(\mathrm{TP}+\mathrm{FN})(\mathrm{TN}+\mathrm{FP})(\mathrm{TN}+\mathrm{FN})(\mathrm{TP}\times\mathrm{TN})}}$$

Interpretation:

- Value 1: Perfect prediction.
- Value 0: Predictions are equivalent to random guessing.
- Value -1: Perfect inverse prediction (all predictions are incorrect).

Observation: MCC is a balanced metric suitable for datasets with imbalanced classes. It provides a more comprehensive view of model performance compared to Accuracy, as it takes all components of the confusion matrix into account.

3) Balanced Accuracy

Definition: Balanced Accuracy is the mean of the true positive rate (Recall) and the true negative rate (Specificity).

Formula:

$$Balanced\ Accuracy = \frac{(Recall + Specificity)}{2}$$

Where:

$$Specificity = \frac{TN}{(TN + FP)}$$

Interpretation: Balanced Accuracy provides a measure that accounts for the model's ability to correctly detect both positive and negative classes, thus balancing the impact of imbalanced classes.

Observation: This metric is valuable for imbalanced datasets, offering an evaluation that does not favor the majority class. It is especially relevant in applications like medical diagnosis or fraud detection, where both classes are equally critical.

4) Logarithmic Loss (Log loss)

Definition: Logarithmic Loss measures the uncertainty of the model's predictions based on the probabilities assigned to the correct classes.

Formula:

$$\boldsymbol{Log\ Loss} = -\frac{\mathbf{1}}{\boldsymbol{N}}\sum_{\boldsymbol{i=1}}^{\boldsymbol{N}} = [\boldsymbol{y_i} log(pi) + (1 - y_i) log(1 - pi)]$$

Where:

- y_i is the true label (0 or 1).
- p_i is the predicted probability for the positive class.
- N is the number of instances.

Interpretation:

- Value 0: Perfect predictions.
- Higher values: Indicate greater errors in assigned probabilities.

Observation: Log Loss is particularly useful when class probabilities matter, such as in applications requiring confidence estimates for predictions. It penalizes incorrect but confident predictions more severely.

5) Cohen´s Kappa

Definition: Cohen's Kappa measures the agreement between the model's predictions and the actual observations, adjusting for agreement expected by chance.

Formula:

$$\kappa = \frac{po - pe}{1 - pe}$$

Where:

- po is the observed agreement proportion.
- pe is the expected agreement proportion by chance.

Interpretation:

- Value 1: Perfect agreement.
- Value 0: Agreement equal to random chance.
- Negative values: Agreement worse than random.

Observation: Cohen's Kappa is especially useful in multi-class classification tasks and in scenarios where accounting for random agreement is important. It is more robust than Accuracy in contexts where class imbalance might inflate perceived model performance.

6) Area Under the Precisión-Recall Curve (PR AUC)

Definition: PR AUC measures the trade-off between precision and recall across different classification thresholds, focusing on the positive class's performance.

Formula: Similar to ROC AUC, it does not have a closed formula and is computed by integrating the Precision-Recall curve.

Interpretation: A higher PR AUC indicates better model performance in terms of precision and recall. It is particularly useful for imbalanced datasets where the positive class is the primary focus of interest.

Observation: PR AUC is especially valuable in datasets with significant class imbalance, as it focuses on the performance of the minority (positive) class without being influenced by the majority class's abundance. It provides a more informative evaluation than ROC AUC in such scenarios. Table V shows evaluation metrics.

Metric: [1]: ROC AUC, [2]: MCC, [3]: Balanced Accuracy, [4]: Log Loss, [5]: Cohen´s Kappa, [6]: PR AUC.

TABLE V. EVALUATION METRICS

Metric	Ventajas	Desventajas
[1]	Considers all thresholds; useful for imbalanced datasets.	Less informative in cases of extreme class imbalance.
[2]	Considers all elements of the confusion matrix; balanced.	More complex to interpret compared to Accuracy.
[3]	Balances performance across classes; useful for imbalanced datasets.	May be less intuitive than traditional metrics.
[4]	Accounts for prediction confidence; penalizes incorrect predictions.	Harder to interpret compared to class-based metrics.
[5]	Adjusts agreement for chance; useful for multiple classes.	Can be less intuitive and more complex to calculate.
[6]	Focused on the positive class; useful for highly imbalanced datasets.	Does not account for the negative class, which may be a limitation.

C. Comparative Analysis of Ransomware Detection Algorithms

In this analysis, we compare three Machine Learning algorithms used to detect ransomware: Neural Networks, Random Forest, and Support Vector Machine (SVM). They will be evaluated in terms of accuracy, recall, F1-score, and performance in validation and test trials.

Algorithm: [A]: Accuracy (Training), [B]: Loss (Training), [C]: Accuracy (Validation), [D]: Loss (Validation).

TABLE VI. SUMMARY OF TRAINING AND VALIDATION

Algorithm	[A]	[B]	[C]	[D]
Neural Networks	99.94%	0.0033	100 %	0.0023
Random Forest	100%	-	100 %	-
(SVM)	100%	1.293939977335144e-05	100 %	1.293939977335144e-05

Table VI compares the accuracy and loss of the algorithms during training and validation. All models have shown perfect performance in validation. The low losses in Neural Networks and SVM indicate an excellent ability to minimize error during training.

Algorithm: [A]: Class, [B]: Precision (Validation), [C]: Recall (Validation), [D]: F1-Score (Validation), [E]: Support (Validation)

[A]: Class: 0: no ransonware, 1: ransonware

TABLE VII. VALIDATION RESULTS

Algorithm	[A]	[B]	[C]	[D]	[F]
Neural Networks	0	100%	100%	100%	1048326
	1	80%	80%	89%	1249
Random Forest	0	100%	100%	100%	209459
	1	100%	100%	100%	256
(SVM)	0	100%	100%	100%	209459
	1	100%	100%	100%	256

Table VII details the validation results for each class (No Ransomware and Ransomware) in terms of Precision, Recall, F1-Score, and Support. While both Random Forest and SVM achieved perfect results across all metrics, Neural Networks showed slightly lower precision in the Ransomware class, though they maintained excellent overall performance.

Algorithm: [A]: Class, [B]: True Positives (TP), [C]: False Positives (FP), [D]: False Negatives (FN), [E]: True Negatives (TN)

[A]: Class: 0: no ransonware, 1: ransonware

TABLE VIII. CONFUSION MATRIX (VALIDATION)

Algorithm	[A]	[B]	[C]	[D]	[E]
Neural Networks	0	1048326	0	0	1048326
	1	1249	0	159831	1249
Random Forest	0	209459	0	0	209459
	1	256	0	0	256
(SVM)	0	209459	0	0	209459
	1	256	0	0	256

This confusion matrix (Table VIII) illustrates each algorithm's ability to correctly classify ransomware and non-ransomware instances. Neural Networks exhibited some false negatives in the ransomware class, whereas Random Forest and

SVM achieved perfect classification with no false positives or false negatives.

Algorithm: [A]: Class, [B]: Precision (Test), [C]: Recall (Test), [D]: F1-Score, [E]: Support (Test). Table IX shows test results.

[A]: Class: 0: no ransonware, 1: ransonware

TABLE IX. TEST RESULTS

Algorithm	[A]	[B]	[C]	[D]	[E]
Neural Networks	0	100%	100%	100%	1048326
	1	80%	80%	89%	1249
Random Forest	0	100%	100%	100%	640000
	1	100%	100%	100%	100000
(SVM)	0	100%	100%	100%	799032
	1	100%	100%	100%	968

In the test results, both Random Forest and SVM maintained perfect precision and recall across both classes. Neural Networks, while highly accurate in the No Ransomware class, exhibited lower precision in the Ransomware class, suggesting potential challenges in detecting these instances.

Algorithm: [A]: Class, [B]: True Positives (TP), [C]: False Positives (FP), [D]: False Negatives (FN), [E]: True Negatives (TN)

[A]: Clase: 0: no ransonware, 1: ransonware

TABLE X. CONFUSION MATRIX (TEST)

Algorithm	[A]	[B]	[C]	[D]	[E]
Neural Networks	0	799032	0	0	799032
	1	968	0	0	968
Random Forest	0	639999	1	0	639999
	1	100000	0	0	100000
(SVM)	0	799032	0	0	799032
	1	968	0	0	968

The confusion matrix (Table X) for the test phase confirms the validation results, with both Random Forest and SVM demonstrating perfect classification. Neural Networks also showed no false positives or false negatives in the test phase, consistent with their high performance in prior validations.

V. DISCUSSION

The proposed ransomware detection model in this study relies on the analysis of both quantitative and qualitative data. Quantitative data includes statistics on the frequency and economic impact of ransomware attacks, while qualitative data encompasses descriptions of malicious behavior patterns and common technological limitations in microenterprises. These inputs informed the design of an approach tailored to the specific needs of this sector, based on principles of scalability, adaptability, and precision.

According to recent reports, ransomware attacks have increased by 81% over the past year, with estimated losses amounting to billions of dollars globally. This highlights the urgent need for proactive and accessible solutions to detect threats before they cause significant damage. The proposed model utilizes machine learning algorithms such as Random Forest and Support Vector Machine, which have demonstrated performance exceeding 90% in controlled environments. However, it is essential to consider the limitations of implementing these solutions in resource-constrained infrastructures.

The model's approach is mixed: quantitative in its ability to measure performance metrics such as accuracy, response time, and detection rates, and qualitative in evaluating ease of integration into microenterprises with non-technical staff. The goal is to provide a tool that is not only effective but also operationally and economically viable.

From a state-of-the-art perspective, most existing studies on ransomware detection focus on scenarios involving large corporations with advanced infrastructure. For example, research by Dobbertin and Leiva (2020) identified common attack patterns but did not address how to adapt these to microenterprises. This study bridges that gap by proposing a lightweight and adaptable model specifically designed for resource-constrained environments. Additionally, a dynamic updating system is incorporated based on the analysis of new ransomware variants, a feature frequently overlooked in prior research.

The goal of the model is to ensure the operational continuity of microenterprises, significantly reducing the financial and operational impact of cyberattacks. Complementary measures such as automated backups and an early warning system are included. In simulated tests, these features have shown promising results, achieving a 70% reduction in response time to simulated attacks.

This discussion highlights the integration of quantitative and qualitative data into the design of the proposed model, emphasizing its contribution to the state of the art in cybersecurity for microenterprises. Initial results are encouraging, but real-world testing is required to fully validate its effectiveness and adaptability. Additionally, the model presents opportunities for future research, such as exploring hybrid approaches that combine machine learning with emerging technologies like blockchain.

VI. CONCLUSION

The evaluation of cybersecurity technologies demonstrated that machine learning algorithms, such as Random Forest and Support Vector Machine, are effective in detecting ransomware, meeting the criteria of scalability and adaptability for resource-constrained microenterprises. The designed model, based on malicious behavior patterns and supported by an integrated architecture, achieved threat detection accuracy exceeding 90% in controlled environments. Controlled tests validated that the model and network structure are efficient, achieving rapid response times and precise ransomware detection in simulated scenarios.

However, it is important to acknowledge certain limitations and challenges encountered during the study. Although the results in controlled environments were promising, implementation in real-world scenarios may vary due to the diversity and complexity of microenterprise technological infrastructures. The model's adaptability to different configurations and its performance in operational conditions require further validation. Additionally, the performance of machine learning models heavily depends on the quality and quantity of available data; insufficient or poor-quality data can lead to ineffective models. The lack of interpretability in these models can cause distrust and hinder their adoption in certain contexts. Moreover, the cyber threat landscape is constantly evolving, with a significant increase in the frequency and sophistication of ransomware attacks. For instance, an 81% increase in ransomware attacks has been observed in the past year [10] implying that models must be continuously updated to remain effective. Finally, implementing machine learning-based solutions can be challenging for microenterprises due to a lack of technological and financial resources. Small and medium-sized enterprises (SMEs) have reported significant losses due to cyberattacks; for example, in the Balearic Islands, SMEs have lost an average of 30,000 euros due to cyberattacks [11].

Despite these limitations, the developed continuity plan includes clear protocols for incident management, automated backups, and regular model updates, ensuring operational resilience for microenterprises against cyber threats. It is recommended to conduct pilot tests in microenterprises across various sectors to assess the model's effectiveness and adaptability in operational conditions, implement a periodic model update process to incorporate new attack techniques and ensure its relevance against emerging threats, and develop training programs for microenterprise staff, focusing on identifying and responding to security incidents, thereby complementing the effectiveness of the technological model.

This study reaffirms the importance of investing in innovative and accessible technologies to safeguard critical data and improve the cybersecurity posture of microenterprises. While the proposed model has demonstrated effectiveness in controlled environments, future research should prioritize validating its performance in real-world scenarios. Pilot studies in microenterprises across various sectors are essential to assess its adaptability to conditions such as heterogeneous networks, limited technical expertise, and budget constraints. These tests will help identify necessary adjustments to maximize its effectiveness and usability.

Future work should also explore the integration of advanced machine learning techniques, such as recurrent neural networks (RNNs) and deep learning, to enhance the detection of complex malicious patterns and advanced ransomware variants designed to bypass traditional defenses. Additionally, the model's economic impact must be assessed by developing metrics to measure the cost-benefit ratio, balancing the savings from attack prevention against the implementation and maintenance costs.

Privacy and ethical considerations are crucial, given the need to access enterprise data for training and improving accuracy. Techniques like federated learning, which allows local model training without sharing sensitive data, could ensure data privacy. Furthermore, scalability and portability should be evaluated by testing the model's performance on cloud platforms to enable efficient implementation across diverse technological infrastructures, from local servers to distributed cloud environments.

The incorporation of emerging technologies, such as blockchain, represents another promising avenue. Blockchain could enhance the model by improving data integrity and traceability of security events, especially in managing real-time security alerts. These advancements, combined with continuous refinement to address emerging cyber threats, will ensure that microenterprises remain resilient in an evolving digital landscape. By focusing on these areas, future research can contribute to the development of more robust, efficient, and accessible solutions, advancing the field of cybersecurity for microenterprises.

Traffic Speed Prediction Based on Spatial-Temporal Dynamic and Static Graph Convolutional Recurrent Network

YANG Wenxi, WANG Ziling, CUI Tao, LU Yudong, QU Zhijian
School of Computer Science and Technology, Shandong University of Technology, Country Zibo, China

***Abstract*—Traffic speed prediction based on spatial-temporal data plays an important role in intelligent transportation. The time-varying dynamic spatial relationship and complex spatial-temporal dependence are still important problems to be considered in traffic prediction. In response to existing problems, a Dynamic and Static Graph Convolutional Recurrent Network (DASGCRN) model for traffic speed prediction is proposed to capture the spatial-temporal correlation in the road network. DASGCRN consists of Spatial Correlation Extraction Module (SCEM), Dynamic Graph Construction Module (DGCM), Dynamic Graph Convolution Recurrent Module (DGCRM) and residual decomposition. Firstly, the improved traditional static adjacency matrix captures the relationship between each time step node. Secondly, the graph convolution captures the overall spatial information between the road networks, and the dynamic graph isomorphic network captures the hidden dynamic dependencies between adjacent time series. Thirdly, spatial-temporal correlation of traffic data is captured based on dynamic graph convolution and gated recurrent unit. Finally, the residual mechanism and the phased learning strategy are introduced to enhance the performance of DASGCRN. We conducted extensive experiments on two real-world traffic speed datasets, and the experimental results show that the performance of DASGCRN is significantly better than all baselines.**

***Keywords*—Intelligent transportation; traffic speed prediction; spatial-temporal correlation; dynamic graph; graph convolution recurrent network**

I. INTRODUCTION

Traffic prediction is a crucial component of intelligent transportation systems, aiming to forecast future traffic conditions based on historical observational data. The systems optimize the use of traffic resource and enhance efficiency [1]. Traditional univariate time series prediction methods, including Historical Average (HA) [2], Vector Auto-Regression (VAR) [3], Support Vector Regression (SVR) [4] and Auto-Regressive Integrated Moving Average (ARIMA) [5], mainly focus on time dependence. There methods ignore the spatial-temporal correlation between nodes, resulting in poor prediction accuracy. Spatial-temporal feature fusion models involve data modeling across spatial and temporal dimensions, and have been widely used to solve traffic prediction challenges due to their significant versatility [6, 7].

In recent years, spatial-temporal graph neural networks have attracted the attention of researchers in the field of traffic prediction because of their excellent performance. Spatial-temporal graph neural network is a typical application of Graph Convolution Network (GCN) in spatial-temporal domain. At present, most popular traffic prediction methods are based on GCN, which uses predefined graph structure to capture spatial features between nodes, and uses Convolutional Neural Networks (CNN) [8] or Recurrent Neural Networks (RNN) [9,10] to extract temporal features [11, 12]. However, these methods rely heavily on predefined static graph structures, which directly affect the predictive performance of the model. To address the limitations of static graph structures, researchers have proposed a data-driven approach to adaptively generate adjacency matrices [13]. These methods improve the performance of the model by learning the parameters of the adjacency matrix in the training process and then calculating the similarity between the embeddings of learnable nodes [14].

However, the traffic prediction data show strong dynamic spatial-temporal correlation. The adjacency matrix generated by static adaptation is difficult to capture the complex dynamic characteristics of the road network. Researchers are increasingly interested in modeling dynamic nonlinear spatial-temporal correlations inherent in traffic data. Recent literature on STG-NCDE [15] combines adaptive graphs with neural controlled differential equations to further improve the performance of the model. STGODE [16] captures the dynamic spatial-temporal correlation of traffic flow through tensor-based ordinary differential equations, and combines semantic adjacency matrices and time-extended convolutional structures to capture long-distance spatial-temporal correlation. ST-GDN [17] uses multi-resolution traffic transformation information and local-global regional dependencies for prediction. DSTAGNN [18] directly mines historical traffic flow data to extract spatial-temporal correlations, and effectively capture the dynamic attributes of spatial associations between nodes. Traffic flow probability graphs [19] employ reinforcement learning to generate dynamic graph for extracting spatial-temporal features. DAGCRN [20] captures the spatial-temporal dependencies in traffic data through dynamic adjacency matrix and graph convolutional recurrent network, combined with spatial-temporal relationship extraction, adjacency matrix update and global temporal attention module. MHSRN [21] captures the moving features between timestamps through a hybrid convolution module, and designs a spatially aware multi-attention module to capture global and local spatial-temporal features. DSTGRNN [22] captures the spatial-temporal dependence in traffic data through the dynamic graph convolution module and generator, combines spatial-temporal relationship extraction, node embedding and dynamic feature

update, and integrates dynamic and static features to improve the accuracy of traffic flow prediction.

Considering the complex spatial-temporal correlation of traffic data, great progress has been made in traffic forecasting. However, there are still some challenges to be solved in the integration of dynamic spatial-temporal features. Firstly, the predefined adjacency matrix and adaptive adjacency matrix, which reflect the static structure of the traffic network, are static and cannot capture the dynamic characteristics of the actual traffic network over time. Therefore, this highlights the need for more sophisticated modeling of dynamic features in traffic prediction topologies. Secondly, the static distance graph and the dynamic attribute graph provide different perspectives on the topology of the traffic network. Their effective integration can provide more comprehensive and accurate topological information, to better capture spatial dependencies. Finally, most traffic forecasting methods generally do not distinguish between normal and abnormal traffic conditions, despite the prevalence of unexpected events such as accidents and traffic control measures. Therefore, a more in-depth exploration of anomalous traffic patterns is essential for enhancing the accuracy of traffic predictions.

In response to the identified challenges, a traffic speed prediction model that integrates spatial-temporal dynamic-static graph convolutional recurrent networks (DASGCRN) is proposed. Firstly, the learning aid self-recurrent unit matrix and trainable parametric matrix are added to the traditional adjacency matrix by the Spatial Correlation Extraction Module (SCEM). The pre-defined adjacency matrix is reconstructed to enhance the expressiveness of the traffic graph. Secondly, based on SCEM, the Dynamic Graph Construction Module (DGCM) introduces a hypernetwork based on gate control mechanism and sparse connection layer to construct dynamic adjacency matrices. Through dynamic node feature propagation, DGCM improves the stability and effectiveness of graph structures in dynamic environments. In addition, a dynamic graph generation method is proposed to capture the correlation between nodes while considering the periodic and dynamic changes of the traffic network. Furthermore, a dynamic graph convolutional recurrent model (DGCRM) based on RNNs integrates static and dynamic graphs to capture the spatial-temporal dependencies in traffic networks. Finally, in order to further improve the prediction performance of DASGCRN, a residual mechanism and a phased learning strategy are introduced.

The rest of this paper is organized as follows. The traffic prediction problem is formulated in Section II. Motivated by the challenges, we introduce the details of our solutions in Section III. After that, we evaluate our model by two real-world traffic datasets and derive the parameter studies and experimental results in Section IV. Studying the ablation experiments in Section V. Finally, we conclude our paper in Section VI.

II. Problem Formulation

Based on the connectivity of the actual road network among sensors in the given datasets, a corresponding road network topology graph $G = (V, E, A)$ can be generated. $V = \{v_1, \dots, v_N\}$ represents the set of all nodes in the network and N denotes the total number of nodes, with each node representing a traffic sensor deployed at the roadside responsible for recording traffic information at its location. E denotes the set of edges that represents the spatial connectivity between nodes. The adjacency matrix $A \in R^{N \times N}$ is employed to depict the spatial adjacency relationships between nodes, where a_{ij} is an element of matrix A indicating the spatial connection status between nodes v_i and v_j. If $v_i, v_j \in V$ is connected to $(v_i, v_j) \in E$, then $a_{ij} = 1$; otherwise $a_{ij} = 0$. The relationship between road connectivity and the road network topology is illustrated in Fig. 1.

In this context, $X_t = [x_t^1, \dots, x_t^N]^T \in R^{N \times L \times C}$ denote the traffic speed at the N nodes of topology graph G at time t, L represent the total length of each time series, and C indicate the total number of node feature types. The traffic speed prediction problem is defined as shown in Eq. (1): Given the speed sequence $X_{1:P} = [X_1, \dots, X_P]^T \in R^{P \times N \times L}$ and topology graph G, the objective is to learn a mapping function F to predict the future sequence $\tilde{X}_{(P+1)(P+Q)} = \left[\tilde{X}_{(P+1)}, \dots, \tilde{X}_{(P+Q)}\right]^T \in R^{Q \times N \times L}$. Here, P represents the length of the historical speed data sequence, and Q denotes the length of the speed sequence to be predicted.

$$[X_{1:P}, G] \xrightarrow{F} \tilde{X}_{(P+1)(P+Q)} \tag{1}$$

III. The Proposed DASGCRN Model

A. Model Architecture

The architecture and various modules of the proposed DASGCRN model are illustrated in Fig. 2. The model consists of four main modules: Spatial Correlation Extraction Module (SCEM), Dynamic Graph Construction Module (DGCM), Dynamic Graph Construction Recurrent Module (DGCRM), Residual Decomposition and Model Training Strategy. SCEM models the spatial relationship between nodes based on static adjacency matrix. DGCM module is responsible for modeling the dynamic spatial-temporal relationship between nodes and edges, effectively capturing the potential dynamic correlation in the traffic network, and generating the dynamic adjacency matrix. The DGCRM module integrates dynamic and static adjacency matrices to model long-term dependencies between historical and future time steps by focusing on connections between different nodes in the transportation network, capturing time dependencies from a global perspective. In addition, residual traffic improves the training process of the model by adding skip connections between different layers of the network. Finally, piecewise learning training strategy is used to promote model convergence.

B. Spatial Correlation Extraction Module (SCEM)

1) In traffic road networks, traditional static adjacency matrices are typically used to represent the static connectivity relationships between nodes, as shown in Eq. (2). Where A_{v_i,v_j} denotes the edge weight between sensors v_i and v_j, d_{v_i,v_j} represents the road network distance from node v_i to v_j. Additionally, σ indicates the standard deviation of the distance, and κ denotes the sparsity threshold.

$$A_{v_i,v_j} = \begin{cases} exp\left(-\frac{d_{v_i,v_j}}{\sigma^2}\right), v_i \neq v_j, d_{v_i,v_j} \leq \kappa \\ 0, otherwise \end{cases} \tag{2}$$

2) The static adjacency matrix reflects the static connection state of the road. While the central road node is restricted to processing only the information from neighboring nodes, thus ignoring the data from distant nodes with similar traffic flow patterns [23]. The static adjacency matrix only considers the spatial distance factor, ignoring the influence of time factor on the relationship between nodes. In the real traffic road network, the spatial relationship between nodes is affected by time change [24], which limits the representation of dynamic spatial relationship in the traditional static adjacency matrix. Inspired by DAGCRN [20], the improved static adjacency matrix incorporates an identity matrix and a parametric matrix, as shown in Eq. (3).

$$\tilde{A} = A + A_{par} + I_N \tag{3}$$

3) where $\tilde{A}$ represents the improved static adjacency matrix, A denotes the traditional static adjacency matrix, and I_N is the identity matrix with diagonal elements equal to 1, indicates that each node is connected to itself (self-recurrent). This mechanism.

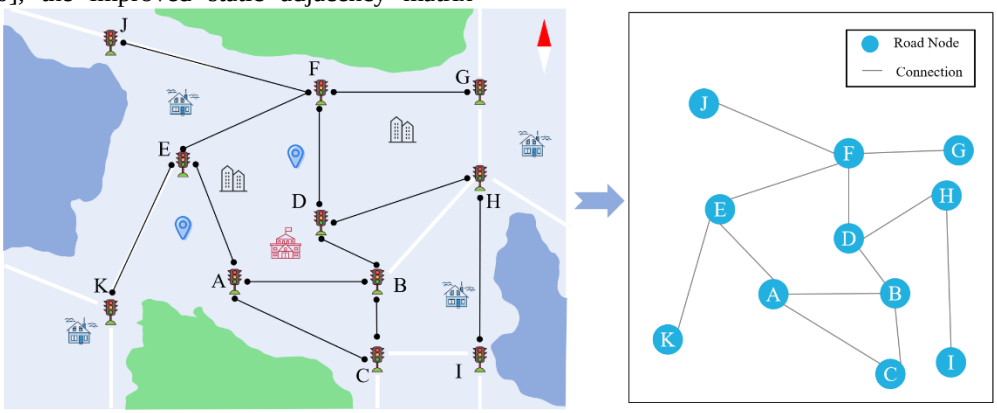

Fig. 1. The corresponding relationship between road connection and road network topology diagram.

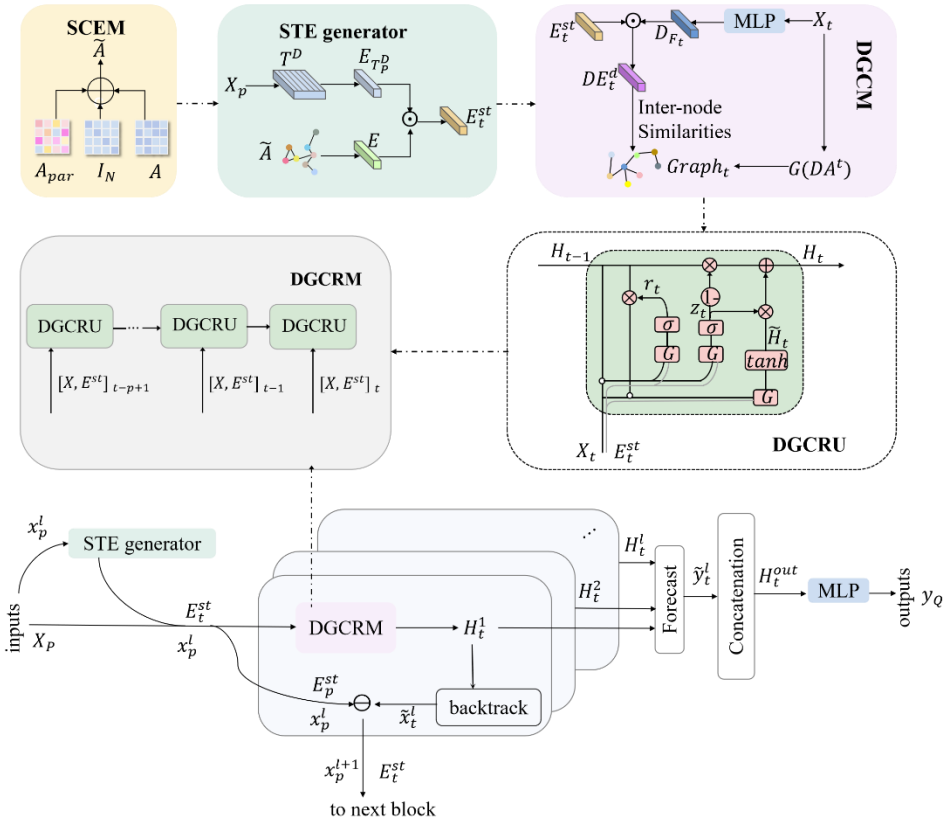

Fig. 2. The architecture and modules of DASGCRN.

4) It allows nodes to retain their own information while considering the impact of their state on neighboring nodes at each update step. The goal is to enhance the model's ability to capture long-term dependencies related to changes in traffic speed variations. A_{par} is the parametric matrix, initialized randomly and optimized through continuous iterations. As shown in Fig. 3, A_{par} enables the dynamic learning of the weight relationships between the central node (pink pentagon) and surrounding nodes (brown and beige circles). Allows adaptive adjustment of the connection based on these weights. This flexibility helps to explore the dynamic dependence of traffic speed over time in static network space. After A_{par} is optimized across all training samples, its combination with A and I_N forms $\tilde{A}$, enabling $\tilde{A}$ to more accurately represent the dynamic spatial relationships in the traffic network.

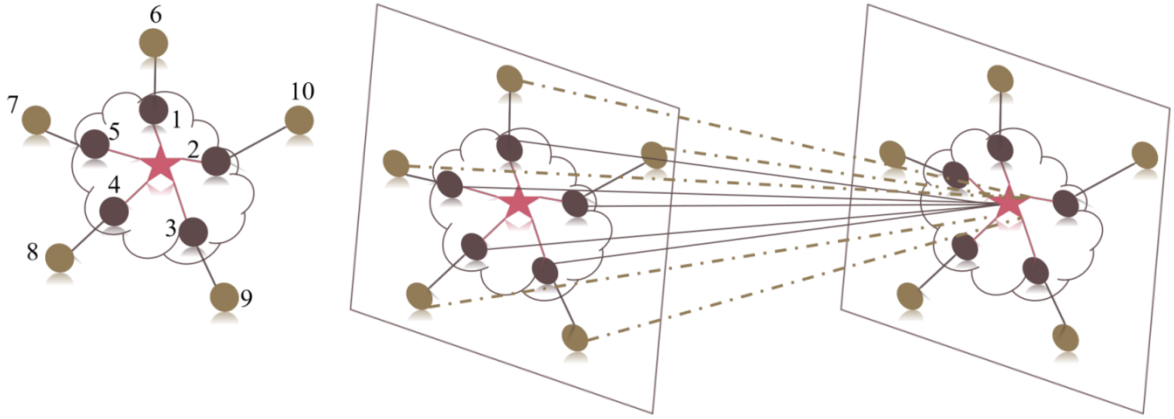

Fig. 3. Parametric matrix diagram.

C. Dynamic Graph Construction Module (DGCM)

The Dynamic Graph Construction Module (DGCM) has been carefully designed to efficiently capture spatial dependencies in traffic speed sequences, as well as temporal variations in these sequences. Specifically, the algorithm first builds a Spatial-Temporal Embedding generator (STE generator), which consists of two basic components: a spatial embedding generator and a temporal embedding generator. These components work together to extract and represent the spatial and temporal features present in the traffic speed sequence, thereby improving the overall understanding of its dynamics.

The core function of the spatial embedding generator is to learn the graph structure from input $\tilde{A}$, after which the learned node information is processed through two fully connected layers to produce the spatial embedding E. The primary task of the temporal embedding generator is to determine the daily encoding embedding $E_{T_P^D}$ that corresponds to the current traffic speed sequence X_P. Subsequently, $E_{T_P^D}$ and E are combined using an element-wise multiplication operation to obtain the new spatial-temporal embedding E_t^{st}. The implementation process of the spatial-temporal embedding is shown in Eq. (4).

$$E_t^{st} = E_{T_P^D} \odot E \tag{4}$$

where $E_{T_P^D} \in R^{P \times N \times D}$ is the daily embedding composed of consecutive time steps $P = [t - p + 1, \dots, t]$, and the p denotes the input sequence length. Additionally, $\odot$ signifies the element-wise multiplication operation. The input at the current time step x_t is processed through a multi-layer perceptron MLP to extract dynamic features, as shown in Eq. (5).

$$D_{F_t} = MLP(x_t) \tag{5}$$

where, $D_{F_t} \in R^{N \times D}$ represents the dynamic features of the current time step x_t after transformation. An element-wise multiplication operation is performed between D_{F_t} and E_t^{st}, and the resulting product is normalized to generate the dynamic graph embedding DE_t^d, as shown in Eq. (6).

$$DE_t^d = tanh\left(D_{F_t} \odot E_t^{st}\right) \tag{6}$$

The dynamic adjacency matrix DA^t at time t is calculated using the similarity between nodes, as shown in Eq. (7). This dynamic adjacency matrix expresses the evolving connectivity and changing trends among the network nodes. Furthermore, α is a hyperparameter used to control the saturation rate of the activation function.

$$DA^t = ReLU\left(tanh\left(\alpha\left(DE^d DE^{d^T}\right)\right)\right) \tag{7}$$

D. Dynamic Graph Convolutional Recurrent Module (DGCRM)

The Dynamic Graph Convolutional Recurrent Module (DGCRM) primarily integrates the improved static adjacency matrix $\tilde{A}$ with the generated dynamic adjacency matrix DA^t. This integration aggregates the information between the nodes of the traffic network and their neighbors, and effectively captures the dynamic spatial-temporal dependencies in the traffic network. Both $\tilde{A}$ and DA^t reflect the correlations among nodes from different perspectives. The DGCRM module effectively combines these matrices to provide a comprehensive view of the traffic road network for predictive modeling, accommodating the dynamic characteristics of the graph structure over time, as detailed in Eq. (8) to Eq. (12).

DGCRM utilizes X_P, $\tilde{A}$, and DA^t as inputs for the graph convolutional layer, and computes a weighted average to the outputs of the graph convolution.

$$\widetilde{H}_t^{(k)} = \alpha H_t^{in} + \beta H_t^{(k-1)} DA^t + \gamma H_t^{(k-1)} \tilde{A} \quad (8)$$

$$H_t^{(k)} = ReLU\left(\left(\mu H_t^{in} + (1-\mu)\widetilde{H}_t^{(k)}\right) W_P^{(k)}\right) \quad (9)$$

$$H_t^{out} = \sum_{i=0}^{K} H_t^{(k)} W^{(k)} \quad (10)$$

$$H_t^{(0)} = H_t^{in} \quad (11)$$

$$H_t^{out} = \Theta_{*G}\left(H_t^{in}, DA^t, \tilde{A}\right) \quad (12)$$

where α, β and γ are hyperparameters that adjust the weights of different components. $W_P^{(k)}$ denotes the k-th order parameter matrix. Hyperparameter μ is used to control the retention rate of the original node information in the process of information transmission, and deeper neighborhood exploration is carried out while preserving the local structure. H_t^{in} and H_t^{out} represent the input and output node states of the dynamic graph convolution at time step t, respectively. $W^{(k)} \in R^{k \times d_{in} \times d_{out}}$ is the learnable feature transformation matrix, and k denotes the model propagation depth. $H_t^{out} = \Theta_{*G}\left(H_t^{in}, DA^t, \tilde{A}\right)$ serves as a simplified representation of the dynamic graph convolution process, where Θ indicates dynamic graph generation, and $*G$ represents dynamic graph convolution. In the context of the DGCRU module diagram, G is used to denote dynamic graph convolution.

DGCRM is composed of Dynamic Graph Convolutional Gated Recurrent Unit (DGCRU), with the hidden state H_t^l of the final DGCRU serving as the output of the DGCRM. DGCRU is formulated by substituting the matrix multiplication operations in the GRU with dynamic graph convolution modules, as detailed in Eq. (13) to Eq. (16).

$$z_t = \sigma(\Theta_{*G}^z [X_t || H_{t-1}, E_t^{st}]) \quad (13)$$

$$r_t = \sigma(\Theta_{*G}^r [X_t || H_{t-1}, E_t^{st}]) \quad (14)$$

$$\widetilde{H}_t = tanh\left(\Theta_{*G}^h [X_t || r_t \odot H_{t-1}, E_t^{st}]\right) \quad (15)$$

$$H_t = (1 - z_t) \odot H_{t-1} + z_t \odot \widetilde{H}_t \quad (16)$$

where X_t and H_t represent the input and output at time step t, respectively. The symbol $\odot$ denotes the Hadamard product, while $||$ indicates concatenation operations. The function $\sigma(\cdot)$ refers to the sigmoid activation function. z_t and r_t are the update gate and reset gate at time t. Respectively, $\widetilde{H}_t$ represents the candidate state of the GRU unit. The symbol $*G$ signifies dynamic graph convolution, and Θ^z, Θ^h, and Θ^r correspond to the learnable parameters associated with the respective graph convolutions.

E. Residual Decomposition

To achieve multi-step predictions and sequence decomposition of traffic flow. An output sublayer consisting of linear layers is constructed after DGCRM. The mathematical expressions for the output sublayer are shown in Eq. (17) and Eq. (18).

$$\tilde{y}_t = Linear_{1:t}\left(H_t^l\right) \quad (17)$$

$$\tilde{x}_t = Linear_{1:t}\left(H_t^l\right) \quad (18)$$

where the predicted output $\tilde{y}_t^l \in R^{Q \times N \times C}$ denotes the prediction of y_t by the l-th block based on x_p^l, while the backward predicted output $\tilde{x}_t^l \in R^{P \times N \times C}$ represents the reverse prediction of x_p^l by the l-th block. The final output of the prediction model is given in Eq. (19) and Eq. (20).

$$y_Q = \sum_1^l \tilde{y}_t^l \quad (19)$$

$$x_p^{l+1} = x_p^l - \tilde{x}_t^l \quad (20)$$

Backward prediction can be understood as the decomposition process of traffic speed sequence. The aim is to eliminate the part of the information that the model has learned, while retaining the unlearned part for further processing by reconstructing the velocity sequence. Specifically, $\tilde{x}_t^l$ can be viewed as the reconstruction of the input speed sequence x_p^l, which incorporates the information that H_t^l has learned from x_p^l. By utilizing a residual decomposition mechanism, the learned information from x_p^l is removed, and the unlearned components of x_p^{l+1} are preserved for modeling in the subsequent block. The outputs from each block are then summed to produce the final prediction result.

F. Model Training

In order to improve the training efficiency of the model, a phased learning strategy is designed. In the initial phase of training, instead of training all blocks at the same time, only the first few blocks are trained. As the number of training layers increases, additional blocks are gradually incorporated into the training process. This approach significantly reduces the time and memory overhead required in the early stages of training. The training process is illustrated in Algorithm 1.

Algorithm 1: Training Algorithm of the DASGCRN Model.

Input: The static graph $G = (V, E, A)$, traffic speed sequence $X_p \in R^{P \times N \times D}$, current time step $X_t \in R^{T \times N \times D}$, time embedding T^D, spatial embedding E, training epochs $epochs$;

```
set turn = 1, i = 1
repeat
    initialize hidden state H_t^0, randomly select a batch (input X ∈ R^{P×N×D}, output Y ∈ R^{Q×N×D}, time of day T ∈ R^{Q×N×D}) from X_p;
    if turn%s == 0 and i < K then
        i = i + 1
    end if
        for p in 0,1,...,P − 1 do
            Calculate ỹ_t^l and x̃_t^l according to Eq.16, Eq.17 ;
    end for
        sum ỹ_Q = Σ_1^l ỹ_t^l
        Compute loss L = loss(ỹ_Q, y_Q)
        Back propagation and update parameters according to L;
        turn = turn + 1;
    Until the model reaches a stable state;
```

Output: the leaned DASGCRN model.

IV. EXPERIMENTS

A. Datasets

The experiment used two real-world traffic history datasets to verify the performance of different prediction models, as detailed in Table I.

- Los-loop Dataset

The dataset, from the City of Los Angeles, records speed information collected by loop detectors from March 1-7, 2012. It includes 207 road nodes and 1,313 road connections, collecting speed data every five minutes.

- SZ-taxi Dataset.
- The dataset comes from taxi tracks in Shenzhen City from January 1-31, 2015, covering 156 major roads in Luohu District, including 266 road connection relationships, with speed data collected every 15 minutes.

TABLE I. DETAILED INFORMATION OF TRAFFIC DATASETS FOR EXPERIMENT

Dataset	Number of Sensors	Edge	Time Interval	Time Range
SZ-taxi	156	266	15min	2015.1.1-2015.1.31
Los-loop	207	1313	5min	2012.3.1-2012.3.7

B. Parameter Settings

According existing methods, we split the datasets into training and testing sets in the same way as the baseline, i.e. 8:2 on the Los-loop and SZ-taxi datasets. Historical traffic speed data from the past hour is used to predict traffic speed in the future hour. The time step for the Los-loop dataset is set to 12 (sampling for 5 minutes), while the time step for the SZ-taxi dataset is set to 4 (sampling for 15 minutes). The experiment was repeated for 5 times and the average value of the evaluation index was reported.

The model employed the Adam optimizer with a learning rate of 0.003, 64 hidden units, an embedding dimension of 10, a batch size of 64, and an epoch value of 300. Mean Absolute Error (MAE) was used as the training loss function, along with an early stopping strategy to prevent overfitting.

C. Baseline Methods

HA: The Historical Average method (HA) predicts future speeds by analyzing the average values of historical speed data.

SVR: Support Vector Regression (SVR) is one of the classical time series analysis models that employs linear support vector machines to perform regression tasks.

Graph Convolutional Network (GCN): GCNs are capable of considering the spatial structural characteristics of graphs, extending convolution operations to graph structures.

Gated Recurrent Unit (GRU): GRUs can capture significant data dependencies over large gaps in time series.

T-GCN [11]: The T-GCN model simultaneously captures spatial and temporal dependencies using GCN and GRU.

A3T-GCN [25]: The A3T-GCN model introduces an attention mechanism to the T-GCN framework to extract weight information for each time step.

NA-DGRU [26]: The NA-DGRU model utilizes two GRUs to extract correlations between speed and time from both the original features and aggregated neighborhood features.

MTA-CN [27]: The MTA-CN model transforms long time single feature historical data into short time multi-feature data and incorporates a two-stage attention mechanism to capture the significance of features in different time periods and time steps.

FD-TGCN [28]: The spatial module introduces a novel Dynamic Convolution Matrix (DCM) to learn the characteristics of dynamic road structures, while the temporal module employs a Fast Temporal Convolution Network (FTCN) to model long-term temporal relationships.

D. Experimental Evaluation Metrics

The experiment employs five commonly used evaluation metrics to assess the performance of various prediction methods:

1) Mean Absolute Error (MAE): This index intuitively reflects the actual forecast error, as shown in Eq. (20).

2) Root Mean Squared Error (RMSE): RMSE is sensitive to outliers and is often used as a standard to measure the predictive performance of deep learning models, as shown in Eq. (21).

3) Accuracy (ACC): This measure describes the degree of fit between the predicted value and the true value; The closer the value is to 1, the better the prediction performance, as shown in Eq. (22).

4) Coefficient of Determination (R2): This statistic evaluates the goodness of fit of regression models; higher values indicate better predictive accuracy, as defined in Eq. (23).

5) Explained Variance Score (var): This score measures the model's ability to explain the variance in the data; values closer to 1 indicate a higher explanatory power of the model, as defined in Eq. (24).

$$MAE = \frac{1}{MN}\sum_{j=1}^{M}\sum_{i=1}^{N}\left|y_{ij} - \tilde{y}_{ij}\right| \tag{20}$$

$$RMSE = \sqrt{\frac{1}{MN}\sum_{j=1}^{M}\sum_{i=1}^{N}\left(y_{ij} - \tilde{y}_{ij}\right)^2} \tag{21}$$

$$ACC = 1 - \frac{Y - \tilde{Y}_F}{Y_F} \tag{22}$$

$$var = 1 - \frac{Var\{Y - \tilde{Y}\}}{Var\{Y\}} \tag{23}$$

$$R^2 = 1 - \frac{\sum_{j=1}^{M}\sum_{i=1}^{N}\left(y_{ij} - \tilde{y}_{ij}\right)^2}{\sum_{j=1}^{M}\sum_{i=1}^{N}\left(y_{ij} - \bar{Y}\right)^2} \tag{24}$$

In the above equations, y_{ij} and $\tilde{y}_{ij}$ represent the actual and predicted traffic speeds on road i-th at time t, respectively. M denotes the sample size of the traffic series, while N represents the set of roads. Y and $\tilde{Y}$ denote the sets of y_{ij} and $\tilde{y}_{ij}$, with $\bar{Y}$ being the average of Y. Both MAE and RMSE describe error

values, where smaller values indicate better model performance. On the contrary, the accuracy reflects the correctness of the prediction, and the higher the value, the better the prediction effect.

E. Experimental Results

Table II presents a comparison of the DASGCRN model with nine baseline models on the Los-loop and SZ-taxi datasets. The metrics underlined in the table indicate the best results, while the models in bold italic type denote those whose prediction results are directly referenced from the published papers. A "/" indicates that the baseline model did not provide that metric at the time of publication. It is evident from the experimental results that the proposed DASGCRN model outperforms all other models on all evaluation indicators of the two datasets. Statistical methods and traditional machine learning models have high requirements for data stationarity and usually focus only on temporal correlation. This leads to challenges in meeting these requirements for traffic data, resulting in poor predictive performance from traditional methods. In contrast, compared with GCN and GRU, the DASGCRN model improved on all evaluation measures. This shows that the model effectively captures the spatial topological features of urban road network and the temporal changes of traffic state. In addition, other baseline models also achieve better predictive performance compared to traditional methods, highlighting the strong spatial-temporal correlations in traffic data. Capturing these spatial-temporal features enhances traffic prediction accuracy.

The experiment further divided the data of one day from the Los-loop and SZ-taxi test sets. It drew the prediction curves of DASGCRN and T-GCN models within the interval of 5 minutes and 60 minutes, and compared them with the Ground Truth, as shown in Fig. 4. As can be seen from the dotted box in Fig. 4, the DASGCRN model is more sensitive to capturing data with sudden increases or decreases in speed than the T-GCN, so the predictions are more accurate. This improved performance is attributed to the integration of time series modeling in DASGCRN's dynamic graph structure, which enables the model to focus on specific patterns of dynamic change, resulting in faster and more accurate predictions. As highlighted by the pink dotted boxes in Fig. 4(c) and Fig. 4(d), DASGCRN showed superior performance in both short (5 minutes) and long (60 minutes) predictions.

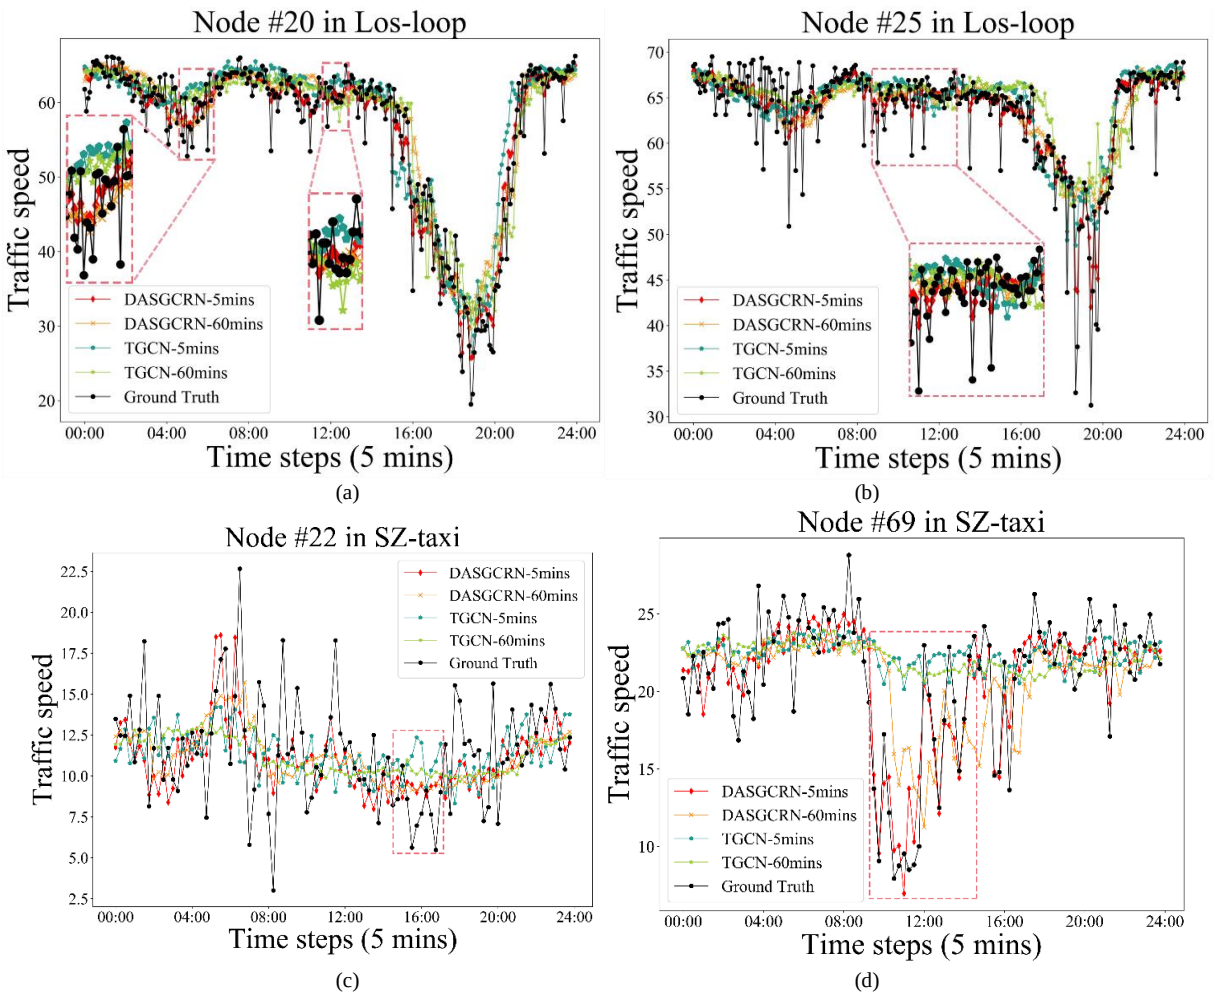

Fig. 4. The prediction curves of two datasets.

Fig. 5 illustrates the absolute error heatmaps of predicted values versus actual values for the DASGCRN model across two datasets. Due to the large size of the dataset, we selected only the first 60 time steps of the 12 roads in each dataset and generated heatmaps for each dataset with four different prediction ranges. Generally, the prediction performance of the model tends to decline with the increase of the prediction range. However, the heatmap shows that DASGCRN has maintained good performance across both the short-term and long-term forecast ranges. This is due to the dynamic graph convolution module used in the DASGCRN model, which replace the matrix multiplication in GRU. It can allow for more flexible control over feature information transmission and enhance the model's ability to capture long-term dependencies.

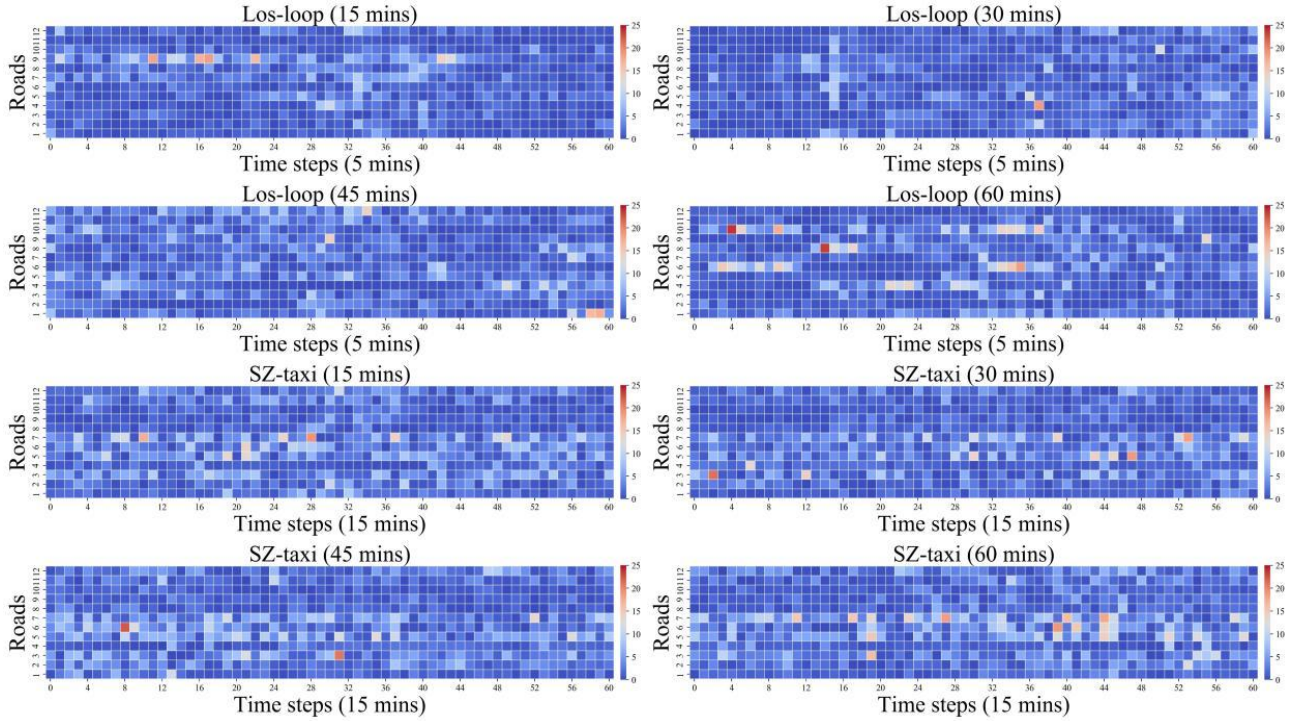

Fig. 5. The heatmaps of different forecasting granularity of DASGCRN two datasets.

V. Ablation Study

To validate the effectiveness of key components in the DASGCRN model, nine variants of the DASGCRN model were designed:

w/o I_N: DASGCRN without the self-loop adjacency matrix.

w/o A_{par}: DASGCRN without the learnable parameter matrix.

w/o DA_t: DASGCRN without the dynamic adjacency matrix.

w/o FCL: Replacing dynamic graph convolution with a simple fully connected layer in DASGCRN.

w/o T^D: DASGCRN without temporal embeddings, using only spatial embeddings to generate dynamic embeddings.

w/o DA_tI_N: DASGCRN without dynamic graph convolution and the self-loop adjacency matrix.

w/o DA_tA_{par}: DASGCRN without dynamic graph convolution and the learnable parameter matrix.

w/o Mix: DASGCRN without residual connections in dynamic graph convolution, using the last hop's output as the output of dynamic graph convolution.

w/o TS: DASGCRN without segmented training.

Table III presents the ablation study results for the DASGCRN variants on the Los-loop and SZ-taxi datasets, indicating that each design module performs as expected. To visually compare the performance of DASGCRN and its variants. Fig. 6 further illustrates the comparative results for both datasets. From the results, we can observe:

1) When the dynamic adjacency matrix DA_t is removed, the model's predictive performance declines sharply, demonstrating the necessity of capturing dynamic information within the road network.

2) The learnable parameter matrix A_{par} can adaptively explore potential spatial relationships between nodes, contributing to improved predictive performance.

3) The removal of temporal embeddings T^D results in a decrease in overall model performance. This indicates that temporal embeddings have a significant impact on the predictive capability of DASGCRN.

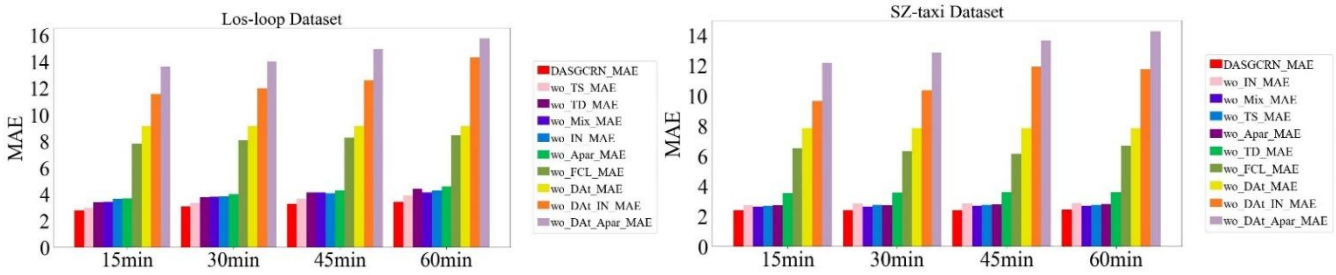

Fig. 6. Ablation experimental results on Los-loop and SZ-taxi

VI. Conclusion

A traffic speed prediction model DASGCRN based on dynamic spatial-temporal information is proposed. Firstly, the parameterized matrix and self-recurrent adjacency matrix are used to represent the spatial relationship between nodes effectively, which surpasses the traditional static adjacency matrix. Secondly, the dynamic graph is generated by using spatial-temporal feature embedding and traffic speed sequence, and the effective combination of dynamic graph and predefined graph is realized by step generation process. This method reduces the dependence on the prior knowledge of the road network and enhances the capture of the dynamic spatial-temporal dependence in the traffic network. Finally, the residual decomposition with skip connection is used to facilitate the transfer of feature information. It improves the training process of the model, and further improve the performance of the model.

In the future, we will further integrate more real-time datasets associated with traffic flow prediction, such as Internet of Things devices, autonomous vehicles, and mobile sensors, the model can capture the dynamic variations of the traffic network more accurately. Meanwhile, we will also enhance our attention to external factors such as weather and road conditions, and incorporate them as key features into the model, thereby enhancing the model's expressive capacity and predictive accuracy in a data-driven manner.

Enhanced Aquila Optimizer Algorithm for Efficient Stance Classification in Online Social Networks

Na LI
Department of Information Technology, ZhengZhou Vocational College of Finance and Taxation,
Zhengzhou, Henan, 450048, China

***Abstract*—Stance classification in Online Social Networks (OSNs) is essential to comprehend users' standpoints on various issues relating to social, political, and commercial aspects. However, traditional methods applied to large datasets and complex text structures usually face several challenges. This study introduces the Enhanced Aquila Optimizer (EAO), a metaheuristic algorithm designed to improve convergence and precision in stance classification tasks. EAO incorporates three new strategies: Opposition-Based Learning (OBL) to improve the exploration, Chaotic Local Search (CLS) to escape from the local optima, and a Restart Strategy (RS) to rejuvenate the search process. Experimental assessments on benchmark OSN datasets prove the superiority of EAO in terms of accuracy, precision, and computational efficiency compared to state-of-the-art methods. These findings position EAO as a potential revolution for stance classification and other large-scale text analysis tasks by offering a robust solution that can be used in real-time for complex OSN scenarios.**

***Keywords*—Stance classification; online social networks; opposition-based learning; chaotic local search; Aquila Optimizer**

I. Introduction

In the past couple of years, the rapid development and growth of Online Social Networks (OSNs) have been driven by the remarkable evolution of our economic and social lives due to the internet [1]. OSNs represent powerful communication platforms for sharing interests, exchanging ideas, or creating communities. Schneider, et al. [2] defined OSNs as networks of individuals with common interests in activities and mutual relationships. Most OSNs enable users to share messages, photos, and videos, rate objects, or discuss any topic, from health problems to political opinions [3]. Another social network is Facebook, estimated to have 2.38 billion monthly registered users as of March 2019, and Twitter has around 330 million monthly active users. These are dynamic and real-time sources of information wherein users actively post their views on certain topics. Thus, OSNs have become a significant means of understanding trends in public opinion and have valuable insights into how ideas originate and spread in complex social networks [4].

The challenges for position classification in OSNs are enormous, considering the immense volume and complexity of information exchanged daily. OSNs generate vast amounts of unstructured text data covering diverse subjects, from sixteen social issues to product reviews, often including various linguistic expressions, slang, abbreviations, and dialects of different regions [5]. This makes developing a model that can generalize for all types of content pretty tough. Moreover, the language used in OSNs is generally informal, with humor, sarcasm, and implicit cues included, making their correct classification challenging. Traditional machine learning techniques, including Neural Networks (NNs) and Support Vector Machines (SVM), often need to scale up efficiently for big dynamic data sets [6, 7]. These methods can only grab those subtle expressions reliant upon context and reduce the accuracy of finding users' positions. More advanced and scalable methods are needed to process the inherent complexity present in OSN data and improve the accuracy of position classification [8].

Metaheuristic optimization algorithms have gained considerable attention due to their efficiency in exploring large-sized search spaces associated with complex classification tasks [9]. Unlike the conventional methods of optimization, which suffer from high dimensionality and run the risk of getting trapped in local optima, metaheuristic algorithms have shown flexibility in navigating through such complex landscapes [10]. All these algorithms are population-based and explore a range of possible solutions at every iteration, with a better chance of converging to a global optimum. Their adaptability predisposes them to be good performers across various scenarios, especially in data-rich dynamic environments like OSNs. Metaheuristic algorithms explore the balance between exploration and exploitation in high-dimensional classification tasks and complex data to reach high accuracy while reducing computational costs [11]. This flexibility and strength of position makes metaheuristic optimization a valuable tool in solving the problems of position classification in OSNs.

Aquila Optimizer (AO) is a newly introduced metaheuristic algorithm. The algorithm is inspired by the hunting strategy of the Aquila bird, one of the best algorithms in balancing exploration and exploitation to find its prey. AO simulates four different phases of the hunting behavior of the Aquila bird for moving between diverse explorations to the search space and focused exploitation around promising solutions. So far, this approach has successfully solved several optimization tasks, positioning AO as one of the more promising choices for challenging high-dimensional problems. Like many other metaheuristics, however, AO has ample limitations. In complex problem spaces, convergence can be slow, and this method may get stuck in suboptimal regions. These all relate to the ability of the algorithm to balance the trade-off between exploration and exploitation, which is the central challenge in the efficient exploration of massive, complex Spatiotemporal data environments characterizing OSNs. This makes enhancements

of AO of paramount importance and assures better performance of such robust applications on classification.

The complexity of position classification in OSNs, marked by vast data volumes, high dimensionality, and nuanced language, demands highly efficient optimization methods. Although AO performed so well in optimization performance in many scenarios, the efficiency of the algorithms is crippled when dealing with the scale and intricacies of OSN data. Convergence to optimality can take a long time and sometimes even get stuck in local optima, which will make this algorithm deteriorate more for the performance of large-scale classification tasks where timely and proper analysis is required. Based on these findings, we will represent an Enhanced Aquila Optimizer (EAO) by implementing extra mechanisms into AO to enhance its capability.

Metaheuristic optimization algorithms have drawn much interest since they can handle high dimensions and the inherent complexity of OSN's stance classification tasks. It is still challenging to efficiently map these complicated data structures into user and linguistic patterns. Recent breakthroughs in graph-based embeddings, such as Subgraph2vec, confirmed the power of random walk-based methods for meaningful representation extraction from structured data, including knowledge graphs [12]. Motivated by such techniques, our study focuses on optimizing the exploration and exploitation of high-dimensional data with the EAO.

EAO unifies three central strategies, namely Opposition-Based Learning (OBL), Chaotic Local Search (CLS), and a Restart Strategy (RS). OBL enhances the exploration capability by considering the opposite solutions; hence, it increases the diversity in exploiting the search space for high possibilities of converging to global optima. CLS contributes controlled randomness to the search process, which helps the algorithm maintain its distance from local optima and promotes diversity in potential solution regions. Finally, it uses RS in its last stage to reset the stagnated solution and reinitialize the diverted search agents into suboptimal areas, rejuvenating the exploration process and accelerating the convergence speed.

II. Related Work

Several works have addressed position classification in OSNs using machine learning and optimization techniques. Parimi and Rout [13] envisaged a paradigm based on similarity to spread rival and counter-rumors. They introduced a probabilistic score-based system for determining whether a user should support a rumor or a counter-rumor. This paper uses a neighborhood analysis-based propagation methodology to examine the effects of rumor and counter-rumor cascades in OSNs. Determining the minimum user count that will start the counter-rumor and reducing communication costs in the application is another complex problem this study attempts to tackle.

A comprehensive Hybrid Clustered Shuffled Frog-Leaping Algorithm-Particle Swarm Optimization (HCSFLA-PSO) algorithm was proposed by Hu, et al. [14] to quickly and continuously suppress rumors spread in OSNs. First, a novel scheme for refuting rumors and an inventive depiction of trust levels are presented by dissecting social interactions and examining intimacy, independence, and credibility. Second, a thorough HCSFLA-PSO algorithm is developed, utilizing the PSO algorithm's quick convergence and the SFLA's local clustering to refute rumors. This comprises the CP-HCSFLA-PSO component for real-time rumor refutation during truth evolution and the CNP-HCSFLA-PSO sub-algorithm for timely rumor refutation, adapted to various social relationships with differing levels of trust.

Saeidi [15] provided a straightforward, uncomplicated, and efficient approach to determining trust relationships between different OSN members. Consequently, four novel approaches for assessing the trustworthiness of users are developed and evaluated with the Anderson-Darling statistical hypothesis and Kolmogorov-Smirnov analyses to choose and verify the most suitable model using 20,613 empirical data from 4,552 volunteers in social networks. A metaheuristic algorithm based on the Artificial Bee Colony (ABC) optimization approach was designed to address the temporal complexity of the issue and identify the optimal model fit.

Fatehi, et al. [16] have developed a hybrid model that integrates graph-based and artificial intelligence methodologies to enhance the coverage and precision of online social networks. This method uses a distributed learning automaton rather than established graph-based search methods like breadth-first search, which can identify all reliable associations without limitations. Simulation findings conducted on an actual dataset from Epinions.com show enhanced accuracy and coverage relative to leading algorithms. The suggested approach demonstrates an accuracy of 0.939, indicating a 6% improvement over similar algorithms.

Mallick, et al. [17] devised a collaborative deep-learning algorithm for detecting fake news. The suggested method employs user input to assess the trustworthiness of communications, with message ranking established according to these evaluations. Messages of lower rank are preserved for linguistic analysis to verify their authenticity, whereas highly ranked information is acknowledged as legitimate communications. A Convolutional Neural Network (CNN) transforms user input into rankings inside the deep learning framework. Messages with negative ratings are returned to the system for CNN model training.

Vaghefi, et al. [18] investigated personal disclosure and brand perception on online networks like Foursquare and Twitter. Based on social and hyper-personal information processing theories, relationships between peers, distance, and advertising messages are examined. An integrated dataset reveals that self-disclosure is significantly influenced by checking in with friends and their proximity. Especially when interacting with well-informed peers, individuals prefer to ignore inquiries that reflect poorly on their health.

Bangyal, et al. [19] investigated sentiment analyses and the detection of fake news using machine learning and deep learning in different challenges, and significant data volumes arose and became dynamic over Twitter. They presented for the first time an innovative proposed method of detecting COVID-19-related false information in deep learning models, particularly the BiGRU model, for which the obtained accuracy was scored very impressively at around 91%. Bangyal, et al.

[20] compared classical machine learning classifiers such as Support Vector Machines and Random Forests. The results proved efficient in the competition and improved the robustness of even simpler models. Bangyal, et al. [21] extended the work by including semantic models and the TF-IDF and compared eight machine-learning classifiers with four deep-learning classifiers. The valuable outcome provided a comparison between accuracy and computational cost. While an advance in sentiment analysis, these works pointed to the need for scalable algorithms of high precision that handle stance classification in large and complex datasets. This motivated the development of the EAO.

Position classification in OSNs is an attractive topic since there has been a high demand from users to make effective use of people's opinions and to control information dissemination effectively. Various state-of-the-art machine learning and optimization techniques have been studied for the works shown in Table I regarding rumor suppression, trust evaluation, sentiment analysis, and fake news detection. These works span classical machine learning model applications, leveraging the latest metaheuristics algorithms and deep learning frameworks, each with different advantages and limitations. Despite such advances, most previous approaches also either suffer from issues like scalability and computation efficiency or are very poorly applicable to OSN data, which by default is complex and time-variant. This extends earlier work and bridges previous gaps in the literature that resulted in the development of the proposed EAO, providing for a state-of-the-art scalable and efficient stance classifier.

TABLE I. AN OVERVIEW OF PREVIOUS STUDIES

Reference	Methodology/algorithm	Dataset	Key findings	Limitations
[13]	Neighborhood analysis-based propagation and multi-objective genetic algorithm	Actual datasets for rumor and counter-rumor analysis	Efficiently reduced communication costs and minimized counter-rumor users	Limited scalability for larger datasets
[14]	Hybrid clustered shuffled frog-leaping algorithm-particle swarm optimization	Simulated datasets for real-time and evolving rumor refutation	Effectively suppressed rumors, accounting for trust and timeliness	High computational complexity for real-time adaptation
[15]	Artificial bee colony optimization	Facebook dataset (20,613 data points from 4,552 users)	Identified optimal trust models with reduced temporal complexity	Requires significant computational resources
[16]	A graph-based and distributed learning automaton	Epinions.com dataset	Enhanced accuracy and coverage by 6% and 10%, respectively	Does not address dynamic changes in network topology
[17]	Collaborative deep learning with CNN	Simulated datasets for fake news detection	Achieved 98% accuracy in detecting fake news	Dependent on user input for initial rankings
[18]	Integrated social and hyper-personal information processing theories	Integrated dataset (Foursquare and Twitter)	Revealed self-disclosure influenced by peer proximity and advertising	Limited to health-related and brand perception studies
[19]	BiGRU deep learning model	COVID-19-related false information dataset	Achieved 91% accuracy in detecting COVID-19-related fake news	Focused only on COVID-19-related data
[20]	Classical machine learning classifiers (SVM, Random Forest)	Twitter datasets	Proved efficient for simpler models in sentiment analysis	Simpler models are less effective for nuanced stance classification
[21]	Semantic models with TF-IDF, multiple classifiers	Twitter datasets with semantic enrichment	Provided a trade-off comparison between accuracy and computational cost	Needs scalable algorithms for complex stance classification tasks

III. PROPOSED METHOD

A. Problem Definition

Position classification is a task aimed at estimating the stance of users concerning particular topics in OSNs, including opinion classification as favourable, unfavourable, or neutral towards various entities or topics. Unlike general sentiment analysis, which broadly adjectives text into positive, negative, or neutral areas, position classification is a closer sentiment analysis. It pinpoints users' opinions concerning clearly defined subjects, such as political figures, social problems, products, or happenings, offering a better perspective on public opinion. This fact renders this task especially hard due to the dynamism of the OSN data, which are often unstructured, different in linguistic styles, and very massive.

One of the big questions is how to classify user opinions efficiently and accurately from a large dataset with high precision. OSNs generate magnificent volumes of textual data daily, from explicit endorsement to subtle criticism or neutral observations. Such data is usually unstructured and informal, including colloquialisms, abbreviations, and context-dependent meanings, which make their correct classification challenging. Moreover, the data in OSN is typically full of mixed emotions,

sarcasm, and idiomatic expressions, complicating their classification.

This vast amount of data is bound together with complexity, and traditional machine learning with statistical methods faces scalability issues while handling this immense data. While the dataset grows, conventional models like support vector machines lose much of their accuracy and efficiency, or even simple neural networks take up much computational time and resources for training and inference. Moreover, these models must be revised to represent complicated relationships and subtleties specific to the context in the OSN language and limit generalization across a wide range of topics with users' expressions.

Metaheuristic optimization is one of the ways of taming this. Considering position classification as an optimization problem, metaheuristic algorithms will handle high-dimensional feature spaces to arrive at the uppermost solution, a highly performant classification with limited computational overhead. Within such a paradigm, the optimization algorithms must be solid and flexible enough to meet the peculiar demands of the data in OSNs. In this regard, it may likely involve the development of classical algorithms, such as Aquila Optimizer, for better exploration, adaptability, and higher accuracy regarding OSN position classification.

B. Enhanced Aquila Optimizer

AO is a newly formulated population-based optimization algorithm inspired by Aquila birds' predatory strategies proposed by Abualigah, et al. [22]. Aquila birds originate from the Northern Hemisphere and are considered one of the most famous predators, distinguished by their agility, strong talons, and strong feet. Thus, they may catch a wide range of prey, from squirrels and rabbits to marmots and hares. The proposed AO algorithm draws inspiration from four different foraging behaviors of Aquila birds that oscillate between exploration and exploitation during hunting. The AO algorithm starts with a randomly generated population of candidate solutions that can be mathematically expressed as follows:

$$X = \begin{bmatrix} X_{1,1} & X_{1,2} & \cdots & X_{1,j} & \cdots & X_{1,D} \\ X_{2,1} & X_{2,2} & \cdots & X_{2,j} & \cdots & X_{2,D} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ X_{n-1,1} & X_{n-1,2} & \cdots & X_{n-1,j} & \cdots & X_{n-1,D} \\ X_{n,1} & X_{n,2} & \cdots & X_{n,j} & \cdots & X_{n,D} \end{bmatrix} \quad (1)$$

Each element $X_{i,j}$ in this matrix represents the position of an agent, calculated as follows:

$$X_{i,j} = rand \times \left(UB_j - LB_j\right) + LB_j, \;\; i = 1, \dots, n, \;\; j = 1, \dots, D \quad (2)$$

Where *rand* represents a random number between 0 and 1, UB_j and LB_j are the upper and lower bounds for each dimension, *n* denotes the population size, and *D* is the number of decision variables. The AO algorithm consists of four unique stages, facilitating the balance between exploration and exploitation. These stages are triggered under the following conditions:

$$\begin{cases} Perform\ exploration, & if\ t \le \frac{2}{3} \times T \\ Perform\ exploitation, & otherwise \end{cases} \quad (3)$$

Where T refers to the total number of iterations and t is the current iteration.

1) Expanded exploration: At this stage, Aquila searches over a large area to find its prey by performing a high dive and then a soaring flight. In this phase, the position of each agent is updated using Eq. (4).

$$X_1(t+1) = X_{best}(t) \times \left(1 - \frac{t}{T}\right) + (X_M(t) - X_{best}(t) \times rand) \quad (4)$$

Xbest represents the best position, and XM(t) gives the average position of the current population generation.

2) Narrowed exploration: This process is Aquila's most commonly adopted hunting strategy. It involves a short gliding flight and contour-following maneuver. Eq. (5) updates the agent's position.

$$X_2(t+1) = X_{best}(t) \times Levy(D) + X_R(t) + (\gamma - x) \times rand \quad (5)$$

Where Levy(D) is a Levy flight distribution, D represents the number of dimensions, and XR indicates an agent's position at random. The Levy flight is defined by Eq. (6).

$$Levy(D) = s \times \frac{u \times \sigma}{|v|^{1/\beta}} \quad (6)$$

Where β=1.5, u, and v are random values, and s=0.01 is a scaling factor.

3) Expanded exploitation: In the third stage, the search scope is narrowed further; the agent is prepared for an attack through a low-flight preliminary assault. The position update is done as follows:

$$X_3(t+1) = \left(X_{best}(t) - X_M(t)\right) \times \alpha - rand + \left((UB - LB) \times rand + LB\right) \times \delta \quad (7)$$

Where α and δ are exploitation parameters set to 0.1.

4) Narrowed exploitation: In this final stage, Aquila chases and attacks the prey using an escape trajectory. Eq. (8) updates the agent's position.

$$X_t(t+1) = QF \times X_{best}(t) - (G_1 \times X(t) \times rand) - G_2 \times Levy(D) + rand \times G_1 \quad (8)$$

Here, QF represents the quality factor, where $QF(t) = \frac{t}{2 \times rand - 1} / (1 - r)^2$, and $G_1 = 2 \times rand - 1$ and $G_2 = 2 \times \left(1 - \frac{t}{T}\right)$ manage different motion and attack angle aspects.

C. Opposition-based Learning

The OBL strategy was first proposed by Tizhoosh [23], and since then, it has been implemented for several swarm optimization algorithms to improve their performance

significantly. Many researchers have practiced this technique on swarm optimization algorithms to enhance the exploration and convergence potential of the swarm optimization algorithm. For instance, OBL is combined with the SSA framework in [24] to avoid local optimization problems. In [25], the Harris Hawks Optimization (HHO) algorithm combines the OBL concept with a chaotic local search to substantially improve its exploration capability. Zhang, et al. [26] used OBL to enhance the algorithm's performance in arithmetic optimization. The OBL works based on comparing the original solution's fitness value with its opposition. The opposition solution of an integer x in the bounds $[lb, ub]$ can be computed using Eq. (9).

$$\bar{x} = ub + lb - x \tag{9}$$

For a vector x, the opposite value of each component can be determined as follows.

$$\bar{x_j} = ub_j + lb_j - x_j \tag{10}$$

Where lb_j and ub_j represent the lower and upper bounds for the j^{th} dimension.

D. Chaotic Local Search

CLS is one of the well-known algorithms applied to various swarm optimization techniques, such as the Jaya Algorithm [27], brainstorm optimization [28], and WOA [29]. The CLS approach is usually implemented by using a logistic map in the following:

$$o^{s+1} = Co^s(1 - o^s) \tag{11}$$

Where s denotes the iteration and C is a control parameter, typically set to 4. Values of o^1 can be initialized at 0.25, 0.50, or 0.75. CLS focuses on local searches around the optimal solution found so far, aiming to enhance accuracy within that neighborhood. The CLS-generated values C_s in iteration i are computed as follows:

$$C_s = (1 - \mu) \times T + \mu \hat{C_i}, \;\; i = 1,2, \dots, n \tag{12}$$

Where $\hat{C_i}$ is calculated as:

$$\hat{C_i} = LB + C_i \times (UB - LB) \tag{13}$$

Here, μ represents a shrinking factor, determined by:

$$\mu = \frac{T - t + 1}{T} \tag{14}$$

E. Restart Strategy

In the optimization process, some agents will be entrapped or stuck in a particular local optimal and fail to obtain the best performance. Such agents cannot contribute to improving the search but consume additional computing resources. Zhang, et al. [30] proposed RS that restarts or relocates such stagnant agents. The RS strategy traces the improvement frequency of each agent. If an agent does not find newer and better solutions, a trial will increase in value. When it reaches a certain threshold predefined, the position of the agent resets according to the following equations:

$$X(t + 1) = lb + \text{rand} \cdot (ub - lb) \tag{15}$$

$$X(t + 1) = \text{rand} \cdot (ub + lb) - X(t) \tag{16}$$

F. Proposed Algorithm

EAO, the improvisation proposed in this paper, tries to overcome its bottleneck with the help of standard AO by applying strategies like OBL, RS, and CLS. OBL applied during initialization and in the position updates ensures that the optimizer is initialized with a robust set of agents and explores a good amount of solution space. CLS fine-tunes the best solution in every iteration to ensure an enhanced search precision neighborhood. Finally, RS re-positions the stagnant agents, which stirs the exploration process. Fig. 1 shows the pseudocode of EAO. To obtain the computational complexity of EAO, one can focus on the three phases separately: initialization, assessment, and position update. This gives, in total, the complexity *O(EAO)*:

$$O(EAO) = O(\text{Initialization}) + O(\text{Assessment}) + O(\text{Position update}) + O(\text{CLS} + \text{OBL} + \text{RS}) \tag{17}$$

Assuming T as the total iterations, N as the population size, and D as the number of dimensions, each component has the following complexity:

- Initialization: *O(N)*
- Assessment: $O(N \times T)$
- Position update: $O(N \times D \times T)$
- RS and OBL: $O(N \times D \times T)$
- CLS: $O(N \times T)$

The overall complexity of the EAO can be expressed as follows:

$$O(EAO) = O(N) + O(N \times T) + O(N \times D \times T) + O(N \times D \times T) = O(N \times D \times T) \tag{18}$$

```
Initialize the population matrix X for the AO
Calculate the opposition-based set X̄ and select the top N solutions from X ∪ X̄
Set the initial parameters for the AO
while (iteration t < maximum iterations T) do
    Evaluate the objective function for each solution
    Identify the best agent X_best
    for each agent i from 1 to N do
        Update the mean position of the current solution set
        Compute the parameters y, x, G1, G2, and Levy(D)
        if current iteration t ≤ 2/3T then
            if (random value ≤ 0.5) then
                Update the current position using Eq. 4
                Compute the opposite position using Eq. 10
            else
                Update the current position using Eq. 5
                Compute the opposite position using Eq. 10
        else
            if (Fitness value rand ≤ 0.5) then
                Update the current position using Eq. 7
                Compute the opposite position using Eq. 10
            else
                Update the current position using Eq. 8
                Compute the opposite position using Eq. 10
        end if
    end for
Apply the restart strategy using Eqs. 15 and 16
Apply CLS strategy using Eq. 12
```

IV. Performance Evaluation

Stance detection involves an automated method for determining how a writer expresses support, opposition, or neutrality toward a particular argument or topic. The scope of analysis in this field is extensive and may include subjects such as individuals, organizations, governmental policies, social movements, or commercial products. For instance, a detailed examination of Barack Obama's speeches could be conducted to ascertain his position on regulating guns in the U.S. Individuals convey their opinions on various issues through various platforms, including Facebook, YouTube, Twitter, and online forums. This approach applies to several areas, such as stand-alone stance classification, information retrieval, automatic text summarization, and text inference. Over the past decade, significant research has focused on modeling stances in digital media. This study utilized four datasets from an existing database, comprising training and testing data derived from tweets. These datasets cover over two million stance expressions across four topics.

In this work, stance classification is analyzed as an optimization problem. The dataset is initially converted into structured data for analysis. Such datasets used to perform experimentation include Hillary Clinton, the Legalization of Abortion, Atheism, and the Feminist Movement, which constitute an optimization space. Firstly, documents are generated for each dataset after the preprocessing steps. Since the number of tweets is taken across rows in the document array, the total volume of words obtained by preprocessing defines the dimensionality of a single tweet. If a word from a set is featured in a given tweet, its column will be assigned a value equal to 1. In other cases, when some word from a set does not appear in the text of a certain tweet, the respective column will be recorded with 0. Consequently, the document matrix is only composed of zeros and ones.

A vector of word weights is also constructed based on word weights within documents. The "maximum word passes" denotes the highest quantity of records where a single word occurs. The weight for each word is then calculated as the ratio of the word's frequency to the maximum occurrence across all documents. These calculated weights collectively form the word weight vector used in the optimization analysis.

In this research, the similarities among the population participants (potential solutions) and the document structure are critical for constructing an effective classification system. Specifically, correlations between document matrix components and possible solutions are carefully evaluated. Various methods exist for measuring similarity, including Overlap, Dice, Jaccard, and Cosine. This study found that the Jaccard similarity measure yielded the best results, and a modified Jaccard similarity measure quantified correlations across texts. This approach determines standard features by calculating the proportion of shared features over the entire text.

Mathematically, for an individual $X_i = (X_{i1}, X_{i2}, \ldots, X_{iM})$ in the population and a corresponding line $D_j = (D_{j1}, D_{j2}, \ldots, D_{jM})$ Jaccard similarity is calculated as follows:

$$J(D_j, X_i) = \frac{X_i \cap D_j}{X_i \cup D_j} \quad (19)$$

The extended Jaccard similarity is computed using Eq. (20).

$$J(D_j, X_i) = \frac{\sum_{k=1}^{M} D_{jk} X_{ik}}{\sum_{k=1}^{M} (D_{jk}^2) + \sum_{k=1}^{M} (X_{ik}^2) - \sum_{k=1}^{M} D_{jk} X_{ik}} \quad (20)$$

Furthermore, to account for the significance of word frequency, tweet word counts relative to the total document word count were included. This ratio is calculated using Eq. (21).

$$ratio_j = \frac{No.of\ words\ in\ the\ j^{th}\ comment}{Total\ No.of\ words\ in\ the\ document} \quad (21)$$

This ratio helps assign appropriate word weights based on their occurrence within the preprocessed dataset. The new similarity measure, incorporating both the Jaccard similarity and the word frequency ratio, is defined as:

$$Similarity_{ij} = \alpha \times jaccard + \beta \times ratio_j \quad (22)$$

Where α and β are coefficients whose sum equals one, allowing for a balanced weighting scheme to optimize the model's performance.

The similarity of each X_i within the population was evaluated based on all tweets included in the dataset. Classification of tweets was conducted by comparing the similarity value to a predefined threshold: tweets were classified as either above or below this threshold. To determine an individual's fitness in similarity analysis, Eq. (23) was used:

$$F = \alpha \times \frac{TP}{length} + \beta \times \frac{TP}{FP+TP} + \gamma \times \frac{TN}{FP+TN} + \omega \times \frac{TP}{FN+TP} \quad (23)$$

Where False Negative (FN) refers to the number of instances in which the rule incorrectly identified as negative when they belong to the positive class, True Negative (TN) stands for the number of cases accurately recognized as negative by the rule, False Positive (FP) signifies the count of instances incorrectly labeled as positive by the rule, even though they belong to the negative class, and True Positive (TP) represents the number of cases correctly identified by the rule as belonging to the positive class.

The coefficients $\alpha, \beta, \gamma, and\ \omega$ are weight values that must collectively sum to one. These weights are customizable and can be adjusted to optimize the performance of the fitness function, allowing the algorithm to be tailored for the best possible results in a given context.

The proposed EAO algorithm's effectiveness in addressing the stance detection problem, a complex task in online social network analysis, was evaluated and compared against several classifiers. The experiments were performed using MATLAB R2018b on a system equipped with an Intel Core i5-12400F CPU running at 2.5 GHz and 8 GB of RAM. The comparative analysis of the algorithms' results was based on the following classification metrics.

$$F - measure = \frac{2TP}{FN+FP+2TP} \quad (24)$$

$$Recall = \frac{TP}{FN+TP} \quad (25)$$

$$Precision = \frac{TP}{FP+TP} \quad (26)$$

$$Correctly\ labaled\ data = \frac{TN+TP}{FN+TN+FP+TP} \quad (27)$$

Tables II to V present a comparative analysis of EAO, ACO, and AO algorithms applied to stance detection datasets on various social issues. Each table illustrates the performance of multiple classification algorithms, focusing on F-measure, recall, precision, accuracy, and correctly labeled data metrics. For the Feminist Movement dataset (Table II), EAO performs better than others, achieving an accuracy rate of 61.387%, while NaiveBayes and staking also show competitive results. Similarly, in the Atheism dataset (Table III), EAO achieves the highest accuracy of 64.593%, followed closely by random forest.

In the analysis of the Legalization of Abortion dataset (Table IV), EAO emerges as the top-performing classification algorithm with an impressive accuracy rate of 70.201%, significantly higher than the other contenders. Finally, for the Hillary Clinton dataset (Table V), EAO shows better accuracy at 83.921%, indicating enhanced performance than the other algorithms.

V. CONCLUSION

This paper proposed and evaluated EAO on the OSN stance detection problem, a complex high-dimensional classification problem. The performance of EAO was rigorously compared to ACO and classical AO on multiple datasets about social issues. In this regard, a comparative analysis was conducted, where the EAO outperforms its competitors on the classification accuracy of F-measure, recall, and precision for most of them, thus proving the more remarkable ability of EAO in exploring the search space in most cases. Our results suggest that embedding superior methodologies such as OBL and CLS contributes to robustness and efficiency while handling complex problems with EAO. EAO effectively resolves the challenges posed by stance detection in OSNs through improvements in convergence speed while sustaining diversity among solutions. This work may be extended by further optimization or hybridization strategies, including adaptation of EAO for other tasks related to social media analysis and deep learning frameworks for better performance. The proposed algorithm EAO has considerable potential for wild applications in dynamic and data-heavy settings, serving as a valid tool for large-scale social network data analysis.

***Abstract*—Due to the COVID-19 pandemic, schools in Malaysia have been physically closed for more than 40 weeks and the students have to learn online. As Malaysia transitions to endemicity, many younger students struggle to keep up with their education due to significant learning loss caused by school closures and the challenges of virtual classes, including distractions and reduced engagement. This study aims to address these issues by developing an educational application that integrates gaming elements, focusing on arithmetic for Year 6 primary school students. The application engages students through interactive gameplay, requiring them to solve math problems to progress, thereby promoting a fun and effective way to enhance their arithmetic skills and mitigate learning loss.**

***Keywords*—Lehmer's RNG algorithm; online educational; gamification**

I. Introduction

COVID-19 pandemic has changed to being endemic and become more common, students start to return to school and learn face-to-face in physical class. Before that, the schools are closed and students conducted their classes with online learning. Some teachers will ask the students to open the webcam but most of them did not know what the students doing behind the screen. After a long time of school closure, a huge problem was occurred and be discovered which is 'Learning Loss' [1]. Due to the lengthy summer break, when kids did not learn for a while and were unfamiliar, learning loss first occurred. Even though pupils had been learning online, there was still a problem with learning loss when the school closed. Numerous academics have provided compelling data and statistics to support their claims that this issue exists, showing that student test scores are lower than they were prior to the epidemic [2-5].

The issue of learning loss is crucial and demands attention since it has a significant negative impact on Malaysian students, particularly those from less-educated or ignorant parents. Some of the B40 (the bottom 40% of income earners) family's youngsters find it challenging to participate in online learning in Malaysia [1]. The goal of online learning is to help students finish their coursework on time, yet they learn less and find it difficult to make up on their learning after 40 weeks of break from class. One of the reasons is that it is difficult to maintain elementary school children' interest in online learning since they lack the capacity to seek out information on their own. Additionally, because they are not being watched, most pupils rarely study independently when under lockdown. The pupils in primary school may have not be able to achieve the desired outcomes, and this problem may continue to secondary school [5].

The objective of this paper is to create a learning game for Malaysian Year 6 primary school pupils. The application, which will be deployed on a personal computer (PC) platform, will concentrate on the math curriculum's arithmetic topic. The math for grade six comprises fraction and decimal multiplication and division. There are many degrees of difficulty for the application, and English is the in-game language. Playing the game and responding to the questions helps students gain arithmetic proficiency. A captivating tale will be created for the Role-Playing Game (RPG). In order to save the princess, students will take on the role of an explorer and attempt to rebel against the demon king. To harm foes, students must correctly respond to the question they are provided by the adversaries within the allotted time. Students will be attacked by the opponents if they fail to respond to the question or take too long. The student either wins the game by killing the final boss or loses the game when their health reaches 0. To get pupils to play the game, a compelling tale is necessary. The game is designed to integrate educational content seamlessly with engaging gameplay, ensuring students remain motivated to learn while having fun. Built-in feedback mechanisms will help students track their progress and identify areas for improvement. The adaptive difficulty levels ensure that the game challenges students based on their proficiency, promoting continuous learning. Java and the NetBeans IDE will be utilized in this study's application development. Additionally, usability testing will be conducted to evaluate the game's effectiveness in improving students' arithmetic skills.

II. Literature Review

A. Current Situation of Education

Today, every child must have access to education. Every element of life is inspired by education, which also provides the road for personal growth. From their education, students may assure a bright future, develop knowledge, and boost their confidence [6]. According to the United Nations International Children's Fund (UNICEF), the closing of schools across the world has an impact on, puts students at danger, or causes them to lag behind [7]. Additionally, more than 1.5 billion children were affected by the epidemic, and the most vulnerable kids suffered grave consequences, according to a United Nations

assessment [8]. The number of students worldwide who will be impacted by school closings in 2020 is shown in Fig. 1.

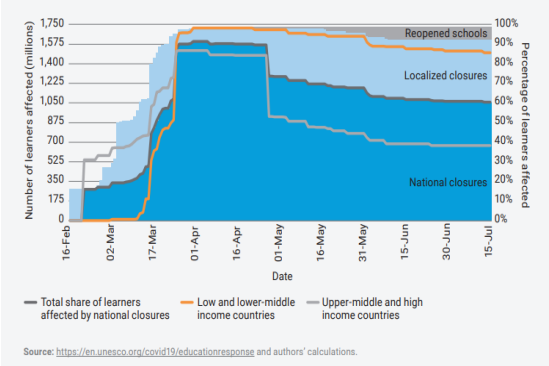

Fig. 1. Number of children affected by school closures globally.

In Malaysia, the government has mandated that students remain at home and do their coursework online [9]. The Malaysian government has made significant contributions to education by giving B40 families and students free internet connection so they may do their coursework online [10]. Although a great alternative to traditional classroom instruction, online learning still has several drawbacks, like restricted Internet accessibility, difficulty in interacting with others, a lack of learning materials, and more. These problems have an impact on students' educational experiences, particularly in some rural parts of Malaysia [11] brought the learning loss problem in result.

Although not a new issue, learning loss manifests itself more frequently in another way. Learning loss originally happened in the summer and was referred to as "Summer learning loss" since some countries, including the United States and Canada, have extensive summer vacations. The prolonged summer break disrupts the instructional pattern, and pupils risk forgetting what they have learned [12]. Despite the COVID-19 epidemic, students were still able to learn online, but there were still issues with learning loss. The next sections will cover several studies and publications that use a lot of statistics to support their arguments. Due to the closing of the schools, these two learning deficits have comparable features. Online learning needs self-discipline because pupils can't focus on the screens [13]. Additionally, it may be challenging for kids from low-income households to access the Internet, which has an impact on their ability to study [14]. The problem of learning loss during the pandemic was created by the closing of schools and a shift in the teaching approach.

Numerous studies using extensive data have found the impacts of learning loss. The majority of the researchers that analysed the test scores of pupils before and after the shutdown of the schools discovered evidence of student learning loss. Additionally, several research noted the rise in inequity, with some student groups suffering greater learning losses than others [15]. In order to evaluate the arithmetic, spelling, and reading exam results for primary students in grades 8 to 11 in the Netherlands, research was done, according to the Proceedings of the National Academy of Sciences of the United States of America (PNAS).

Despite learning remotely for eight weeks when schools were closed, the pupils' arithmetic and spelling test scores fell by 2.15 and 0.76 percentile points, respectively (Fig. 2). According to estimates based on the aforementioned finding, pupils generally underperformed by 3.16 percentiles, or 0.08 standard deviations (SDs). The impact of learning loss is 60% worse for pupils from less-educated parents where it is concentrated [2].

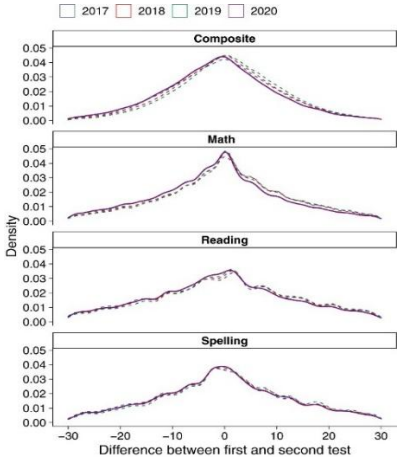

Fig. 2. Difference in test scores of years 2017 to 2020.

Additionally, another study used data from 5.4 million American kids in grades 3 through 8 who took arithmetic and reading tests during the first two years of the epidemic to conduct research. Between autumn 2021 and fall 2019, students' average math exam scores declined from 0.20 to 0.27 SDs. The reading test scores are 0.09 to 0.18 SDs lower (Fig. 3), and the difference in performance between kids attending primary schools with low and high levels of poverty has grown by 0.10-0.20 SDs [16].

Although the school closures took place in the early stages of the epidemic, this study did not take into account whether the pupils had engaged in remote learning. The arithmetic score has decreased for two years, while the reading score has decreased between the fall of 2020 and the fall of 2021 [3].

According to another news from UNICEF, school closures resulted in significant learning losses in math and reading plus the learning losses are roughly proportional to the length of closures in some countries. Students aged 10 to 15 has significant learning losses in math and reading from the results of two states in Mexico. Many other countries also faced this problem, for instance, South Africa, India, Pakistan and Brazil [8]. Since the schools have been closed for about 40 weeks in Malaysia, the learning loss on Malaysia students must be more serious [1].

The causes of learning loss might vary depending on the circumstances. It is clear from this experiment that the COVID-19 pandemic's propagation is its primary cause. To protect pupils from the pandemic's risks, the majority of governments have stated that schools would be closed. The solution is then put into place to allow the students to continue their education—remote learning or online learning. The aforementioned elements are closely related to one another. Zhdanov et al. (2022) categorized the factors impacting the learning losses as

the following themes: “change in teaching methods”, “opportunities to reach education”, “less time for learning”, “less control / feedback” and “emotional factors” (Fig. 4) [17].

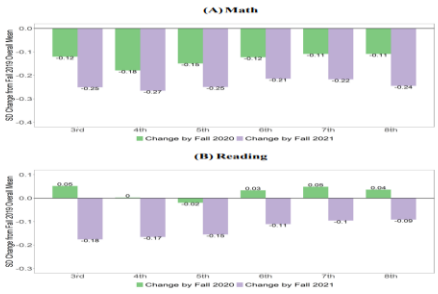

Fig. 3. Trends in test scores in fall 2020 and fall 2021 compared with fall 2019.

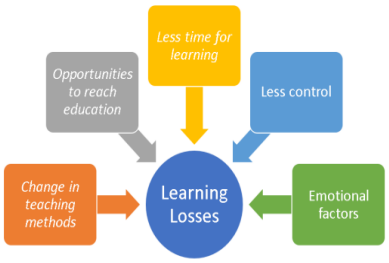

Fig. 4. Affecting factors to learning losses during COVID-19.

B. Maintaining the Integrity of the Specifications

Many schools, colleges, and universities have also begun to employ e-learning apps or platforms in the education in order to reduce the pandemic-related learning loss and improve the learning experiences. The students may always remain linked, from any location. As a result, its importance and utility have increased as a result of the COVID-19 epidemic.

Additionally, a lot of schools, colleges, and universities have started implementing e-learning platforms or applications in the classroom to reduce the learning loss caused by the epidemic and enhance the learning experiences. The students can always keep in touch, from any location. As a result, the COVID-19 pandemic's emergence made it more important and valuable. When it is discovered that the pupils are having academic difficulties, it will already be too late because there is no single evaluation to examine the students until form 5 since the two public examinations, Primary School Achievement Test (UPSR) and Form Three Assessment (PT3) have been abolishment [18].

Numbers and their operations are the subject of the scientific discipline known as mathematics [19]. Galileo defined mathematics as "the language in which God has written the cosmos" in his definition. He believes that learning math is necessary to comprehend the universe and that it is an essential language [20]. In addition, as previously noted, learning loss has a significant influence on the arithmetic subject in basic education. As a result, in the current context, minimizing and reversing the learning loss is crucial.

C. Gamification with Education

A game is a playing activity that is used for fun or learning. People are under stress as a result of the COVID-19 outbreak since they are unable to leave their homes. They begin playing a game for enjoyment and relaxation. Game and gamification are two distinct concepts. Gamification is the process of applying game concepts and components to non-game activities [21]. Combining education with games creates gamification in education, which mostly occurs in the context of online learning. As a result, it is an appropriate response to the current circumstance, and pupils are accustomed to this kind of instruction. Gamification in education may enhance the learning process, grab students' attention, and make the subject matter more entertaining [22].

In Indonesia, Udjaja, Guizot, and Chandra (2018) use gamification to enhance learning in elementary math. They develop an interactive learning game by fusing gaming aspects with math resources. They seek to make math learning more engaging so that children can readily comprehend the arithmetic information. Consequently, both teachers and students find the game-based learning approach to be engaging. Most pupils are now more interested in learning math, and they see the value in doing so [23].

D. Game Genres

Table I categorizes various game genres and provides a brief description of their key features. Each genre emphasizes different gameplay mechanics, offering unique player experiences. For example, action games focus on combat and intensity, while puzzle games emphasize critical thinking and problem-solving. Role-playing games immerse players in characters and storylines, while sandbox games allow open-world exploration and creativity. These genres highlight the diversity in game design, catering to a wide range of player preferences and objectives [24-25].

TABLE I. GENRES AND DESCRIPTION OF GAMES

Game Genres	Description
Action	Games with action intensity and combat as its main attraction.
Adventure	Games that focus on exploration and puzzle solving.
Multiplayer online battle area (MOBA)	Games that place the focus on player control, map and resource management.
Puzzle	Games with puzzles as its key game mechanic.
Real-time strategy (RTS)	Games that include real-time reasoning and problem solving.
Role-playing	Games that allow players to take control of a character and immerse in their situation.
Sandbox	Games that associate with player choice, open environments and non-linear gameplay.
Simulation	Games that focus on creating a game world and it is matching with the real-world situation.
Shooters	Games with different weapons for aiming and shooting at targets.
Survival	Games that focus on resource management to keep the player character alive.
Platformer	Games with 2D side-scrollers and simple controls.

However, in order to implement the gamification in education, it is important to know that not every game type is suitable to the teaching environment. Amory et al. (1999) have conducted research to discover the most suitable game type and game elements. They tested on the adventure, RTS, shooting and simulation games. They found out that the students prefer playing the adventure and RTS rather than the other two. This may be caused by the user interface and game play. The research also shown that login, memory, visualization, mathematics, reflexes and problem solving are the important game elements [26].

Instead, eleven game types identified by [24] and [25], role-playing game and sandbox game has been implemented in the education. Role-playing game has been used to teach vocabulary [27] and Japanese [28]. Also, it is proved that the role-playing games are able to improve the knowledge and encourage students to learn. The game was utilized as a learning material in the class, provide a good environment and experience to students. The example of the sandbox game is education edition of Minecraft. It allows the users to gather resource and use the resource to create anything they want. It motivates the creativity of students and can be used to teach various subject, for instance, math, history and visual arts. It is proved that the math ratings of 4th grade students in Australian schools have increased when using Minecraft for math's learning [29].

Furthermore, Hussein et al. (2019) conduct research of the past relevant literature between 2006 to 2017 years to find out the effects of educational gaming in teaching science of primary levels. They discovered that RPG is the most popular game genre. Students are able to control the game avatar and communicate with Non-Player Character (NPC) which allow the students immerse in the learning environment [30]. Another research also conducts research of the past relevant literature but from 2016 to 2020 finds out that adventure games is the most preferred game genre while sport and simulation, RPG and puzzle games are often used [31] (Fig. 5).

Hassan, Mailok and Hashim (2019) conducts research on the relationship between gender and game genres by collecting data from Diploma students in Malaysia. In overall, the most popular one is Adventure games. Adventure and puzzle games are the most popular game genre for female while action and strategy games are the most popular game genre for male. Male do not prefer music or dance games while female do not prefer cross genre games [32]. Fig. 6 shows the table of the game genres selection based on gender.

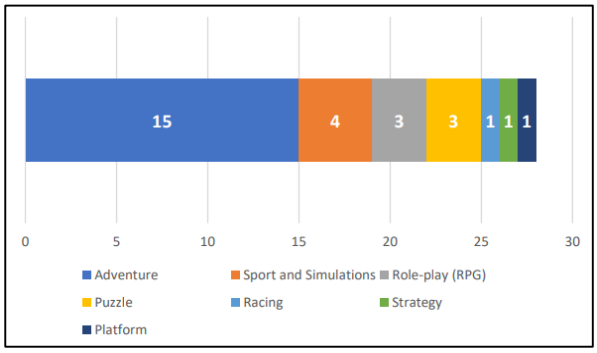

Fig. 5. Frequency of game genres.

No	Game Genres	Female	Percentages (%)	Male	Percentages (%)	Total	Percentages (%)
1	Adventure	26	63.4	57	76.0	83	71.6
2	Board/card	17	41.5	27	36.0	44	37.9
3	Puzzle	26	63.4	27	36.0	53	45.7
4	Platform	20	48.8	34	45.3	54	46.6
5	Strategy	23	56.1	58	77.3	81	69.8
6	Sport	15	36.6	42	56.0	57	49.1
7	Action	21	51.2	58	77.3	79	68.1
8	Shooting	24	58.5	51	68.0	74	64.7
9	Simulation	15	36.6	30	40	45	38.8
10	RPG	10	24.4	42	56.0	52	44.8
11	Music/Dance	23	56.1	22	29.3	45	38.8
12	Cross Genre	9	22.0	29	38.7	38	32.8

Fig. 6. Game genre selection based on gender.

To develop a gaming application, the problem statement, objective and scope must be clearly determined. Then, developer has to create the game design or prototype. Developer can start coding the application when all the details are finalized. The application will then test by the developers and external testers. Finally, the application can be released after testing [33]. On the other hand, [23] implement the game development life cycle (GDLC) to develop the math education game. It consists of initiation, pre-production, production, testing and release. Initiation phase is to create the game concept with simple description. Pre-production phase is to create and review the game design plus create a game prototype. Production phase is to produce the game assets and coding. Testing phase is to test the functionality and usability of game internally. Release phase is the final stage which the game is ready to be released to public. Tan and Suparjoh (2022) also implement GDLC to create the educational game for mobile but it has one more, beta phase before the application is published. After the internal testing, the game will be tested by third-party or external tester in beta phase [33-34].

E. Game Algorithm

Other than that, algorithms can be used in the production phase in order to make the gaming application more effective. Developers may use algorithms and implement them into the application. Candra et al. (2021) used A-star (A*) algorithm to design the pathfinding and develop a tree planting game. A* algorithm uses the heuristics function to plan a path between multiple nodes efficiently. It uses the best-first search and finds the shortest path by calculating the cost from initial node to destination node [35]. Galam et al. (2019) conduct research on the performance A* algorithm and Dijkstra's algorithm. Dijkstra's algorithm is also a pathfinding algorithm that use to search for the shortest path but it has to build the shortest paths to all other nodes in the graph which is not efficient. Therefore, 68 uses the simpler A* algorithm to create the tower-defence game because he or she thinks A* algorithm can be considered as a low-fill version of Dijkstra's algorithm. In conclusion, the A* algorithm is frequently used in game development [39].

Also, Lehmer's Random Number Generation (RNG) algorithm is used to generate a simplified initial world state in a role-playing game [36]. The researcher compares the RNG algorithm with the random number generators inside the C++ library and discover that the average speed of the algorithm is faster than the other methods (Fig. 7). Thus, it will be better to include the RNG algorithm in order to improve the software performance.

Lehmer's RNG algorithm is based on a general formula which is 'Xk+1 = a · Xk mod m'. The multiplier 'a' is an element

of high multiplicate order of modulo 'm' and the modulus 'm' should be a prime number or power of prime number. The seed 'X0' is coprime to 'm' and has to be set at the beginning along with other variables. Fig. 8 shows the code example of Lehmer's RNG algorithm in C#.

Alhassan et al. (2019) and da Silva and Villela (2016) use the breadth-first search (BFS) algorithm to generate and expand nodes of a tree data structure. It includes a simple first in first out (FIFO) queue which mean the parents of same level will be checked before moving to their children. All the node of level n will be expanded before any node of level n+1. Alhassan et al. (2019) uses it to create a puzzle game whereas da Silva and Villela (2016) uses it to create a mobile game [37-38].

Zain et al. (2020) uses Minimax search algorithm and Alpha-Beta pruning algorithm to develop a tic-tac-toe game. Minimax search algorithm is a backtracking algorithm based on the game theory, decision theory, statistics and philosophy [40]. It uses to find the optimal path and maximize the player's chance to win whereas minimize the opponent's chance to win. Alpha-Beta pruning algorithm is an optimization algorithm for the minimax algorithm [40]. It reduces the computation time by removing all the unnecessary bunches when it finds a better path. In minimax algorithm, it will continue evaluating all the nodes until it reaches the root node. Monte Carlo algorithm is used to develop card game and puzzle game [41-42]. Monte Carlo algorithm is a searching algorithm that conducts simulations to evaluate unknown patterns or unknown actions to know their values by using a rollout policy [41]. It requires a lot of information to make the simulation.

Method	Avg. Time
rand()	0.001160
std::random	0.067793
Lehmer	0.000269

Fig. 7. Average speed of RNG methods.

```
public class LehmerRng
{
  private const int a = 16807;
  private const int m = 2147483647;
  private const int q = 127773;
  private const int r = 2836;
  private int seed;
  public LehmerRng(int seed)
  {
    if (seed <= 0 || seed == int.MaxValue)
      throw new Exception("Bad seed");
    this.seed = seed;
  }
  public double Next()
  {
    int hi = seed / q;
    int lo = seed % q;
    seed = (a * lo) - (r * hi);
    if (seed <= 0)
      seed = seed + m;
    return (seed * 1.0) / m;
  }
}
```

Fig. 8. Code example of Lehmer's RNG algorithm.

Table II shows the summary of algorithms that can be used for game development. It includes the name and the basic function of the game development algorithms. Hence, specifically tailored to address key challenges in game development. These algorithms ensure efficiency, improve gameplay mechanics, and enhance user experience by solving complex problems like shortest path searches, and probabilistic outcomes in a structured and reliable manner.

TABLE II. USES OF ALGORITHMS IN GAME DEVELOPMENT

Game Development Algorithm	Description
A* algorithm	To search the shortest path between the initial and final state.
Lehmer's RNG algorithm	To get a random number by using the equation. ($X_{k+1} = a \cdot X_k \bmod m$)
Breadth-first search (BFS) algorithm	To search a node in the tree structure level by level.
Dijkstra's algorithm	To find the shortest path between nodes in a graph.
Minimax search algorithm	To find the optimal move by decision making and game theory.
Alpha-Beta pruning algorithm	To optimize the minimax algorithm by decrease the evaluation times.
Monte Carlo algorithm	To estimate the possible outcomes of an uncertain events.

III. METHODOLOGY

There are three phases in the game education application development. The first phase is on collecting data from the user stakeholders. Questionnaire will be used as quantitative research method to get the basic information. The target audiences for the questionnaire include the year 6 students, educators, parents and guardians in Malaysia. Moreover, interview will be conducted as qualitative research method with selected students to have in-depth understanding. The collected data will be used to identify the learning experience, learning performance, the needs of learning materials and more.

The second phase will be based on software development. Waterfall methodology will be used to develop the application. It consists of five phases which are requirements analysis, design, implementation, testing, deployment, and maintenance. The author will start analyzing the requirements after data collection and create an application design. Then, the author will code and test the application to ensure its performance. The application will then deploy to the target audience and be maintained.

The third phase is to test the application with both functional testing and usability testing. Functional testing is used to check the errors or bugs within the application by implementing the black box testing. The output will be compared with expected result and they must be same. Usability testing is used to test whether the application can help the students to improve their math skills. Testers will have to do a short math test before and after they play the game. Both testing will be conducted during the testing phase in waterfall methodology.

F. Phase 1 – Data Collection

Quantitative research is a type of research that uses to collect information that can be measured and analyzed. It focuses on data that is structured and can be represented numerically [43]. This study will use questionnaire as the research approach to collect data from the persons that related to the students, such as, educators, parents and guardians. The questionnaire is estimated to have 12 questions. Qualitative research is a type of research that aims to find out about people's experiences and help to understand what is important for people. It concerns with subjective 'meanings' rather than objective 'facts' [44]. This study will use interview method as the research approach and conduct interview with three Year 6 primary school students.

Different perspective can be gotten from the interviewees about the learning performance of students.

G. Phase 2 – Waterfall Methodology for Software Development

Waterfall methodology consists of five phases which are requirements analysis, design, implementation, testing, deployment and maintenance. It is one of the software development life cycle models that allow us to plan the development process in a systematic manner.

- Phase 1 – Requirements analysis focus on capturing the requirements or problems faced by the target audience. The objective is to understand all the requirements which includes scope, costs, timelines and limitation. This phase involves gathering input from stakeholders, teachers and students, to ensure the application meets their needs. Additionally, it identifies potential challenges, such as technical constraints or user accessibility, to ensure a clear development roadmap.
- Phase 2 – During design phase, programmer has to decide a plan for the solution. An application design will be created in this study.
- Phase 3 – Implementation is the phase that the coding start. Software design has been confirmed in the previous phase and programmer start to develop the application based on that design. The application use Java as the programming language and NetBeans IDE as the platform for development.
- Phase 4 – The aim of testing phase is to test the application so that it will achieve the expected result. Also, the application will be tested to find out there is any bug or not. Programmer has to debug if there are errors or bugs in the application.
- Phase 5 – The application must deploy to the target audience and need to be maintained in order to have improvement in the future if necessary.

H. Phase 3 – Software Testing

Functional testing is a type of software testing that use to verify and validate the functional requirements of the software. It involves black box testing and every function will be tested by entering the input and comparing the output with the expected result. The application should able to generate the question automatically and know the answer entered by the user is right or wrong. Usability testing is used to test whether the application can improve the knowledge. Hence, the target audience is Year 6 primary school student. If the students are unable to learn from the application, then the expected result of the study cannot be achieved.

IV. Design and Development

The target audience, users, and stakeholders were surveyed by the author to determine the needs and expectations for the system. The data gathered can be used to comprehend fundamental needs and identify potential issues. Functional requirements, non-functional requirements, and user requirements can all be improved after examining the replies. The design of the suggested educational gaming application is then displayed using UML diagrams, including use case diagrams, activity diagrams, sequence diagrams, and more.

Questionnaire and interview are conducted before the design and development. Four components make up the questionnaire. The target audience, year 6 primary school pupils, and stakeholders, such as teachers, parents, and guardians, were all included in the first section's demographic information gathering. In the second portion, the author discusses how pupils learn and how they perform before and after school closures. The third segment is where the student's experiences and facts regarding the gaming are gathered. Respondents are prompted to react with their thoughts on the educational gaming applications in the last section.

Besides that, like the questionnaire, the interview questions are divided into four pieces. The interviewees' demographic data is gathered in the first phase. It is intended to identify the interviewees' learning performance and experience in the second portion. The third piece asks the interviewers about their gaming history, while the last section collects their system needs and expectations. Initial requirements for the game education application are recognized and defined based on questionnaire and interview responses as well as the author's gaming history. Table III shows the functional requirements, non-functional requirements, and usability requirements.

TABLE III. Application Requirements

Functional Requirements	• Main menu with play, load, control and quit buttons • In-game setting menu with save game, control and exit game functions • Character control • Turn-based battle system with math arithmetic questions • Inventory system • Level-based progression with health point (HP) and experience point (XP) • Display game scenes • Difficulty levels • Game clearance timer • Random questions with random number generation (RNG) algorithm
Non-functional Requirements	• Provide accurate questions and examine the answers correctly • Provide fast response on player control • User-friendly
Usability Requirements	• Basic animation in combat scene • Basic examples of questions in menu

I. Design

(Fig. 9-11) illustrate aid in defining the gaming education application's architecture, features, and functionalities.

J. Development

There are many scenes in the game education application and the author uses state engine to differentiate them. The state engine includes ‘titlestate’, ‘playstate’, ‘optionstate’,

'dialoguestate', 'combatstate', 'characterstate', 'victorystate' and 'gameoverstate'.

Title screen is the first screen when the users open the application. Users can start a new game by pressing 'New Game' button, continue previous game by pressing 'Load Game' button, find out the game control and question examples by pressing 'How to Play' button and close the application by pressing 'Quit' button. The users require to select difficulty after pressing 'New Game' button. Difficulty levels will affect the question complexity and the time given for users to answer a question. 'Easy' is 90 seconds, 'Normal' is 135 seconds, and 'Hard' is 180 seconds.

After pressing the 'New Game' button or 'Load Game' button, the application will change to play state. In this state, the application will render and display the tile map, character, non-player character (NPC) and more. Option screen are shown when the state engine change to option state by pressing 'Esc' on keyboard. It will open the interface of options menu and allow the users to save, control the volume of music and sound effect, change difficulty level, read game story, game control, question examples and end game. When the users press the buttons of 'Difficulty Level', 'Game Story', 'Game Control' and 'Question Examples', it will open the same interfaces as the title screen.

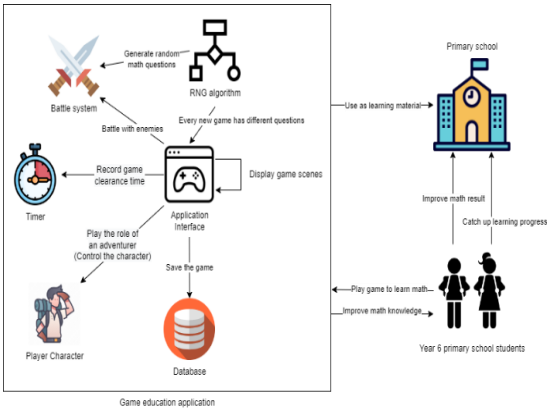

Fig. 9. Rich picture diagram.

```
public float uniform()
{
        System.out.println(r_seed);

    // highest and lowest for a rar
    long hi = r_seed / q;
    long lo = r_seed - q * hi;
      long lo = r_seed % q;

    // calculate random number
    long t = (a * lo) - (r * hi);

    // if positive
    if (t > 0)
    {
        r_seed = t;
    }
    else
    {
        r_seed = t + m;
    }

      System.out.println(r_seed);
    return r_seed;
}
```

Fig. 10. RNG algorithm.

Moreover, users can enter the dialogue screen by pressing 'E' on keyboard while the character is beside the NPC. The state engine will change to combat state when users can press 'Enter' on keyboard while the character is beside the enemy. The health points of enemy and character are shown in the combat screen. Users can choose to 'Attack', 'Skill', 'Item' or 'Run' in the combat. When the users press the 'Run' button, it will back to the map and change to the play state.

The RNG algorithm's Java code is seen in Fig. 10 The most crucial component of the application that enables it to produce unique numbers each time is this one. A variety of questions will be constructed using the generated numbers once they have been put in an array. Users will get the important objects after defeating the enemies. Users must keep answering the questions correctly until the health points of enemy goes to zero. Furthermore, users can enter the character screen by pressing 'Q' on keyboard in the play screen. The interface will display the level, health point, attack damage, current experience, experience to level up and inventory.

When the users clear the game, the state engine will change to victory state and show the interface of victory screen. The game clearance time will be displayed to let the users know how much time they spend to clear the game. Users can press the 'Quit' button to go back to the title screen. When the health point of character become zero because users did not answer the question correctly or overtime, the state engine will change to game over state and show the interface of game over screen. Users are able to press the 'Retry' button to go back to the play screen or press the 'Quit' button to go to the title screen.

In addition, the application is connected to the MySQL database with phpMyAdmin at localhost by using XAMPP. The application will store the data of current date, time, game clearance time, victory or game over, difficulty level, number of questions answered correctly, total number of questions generated in the game. The number of questions is separated according to the question types in the database. Fig. 11 depicted below shows the game interface of the application.

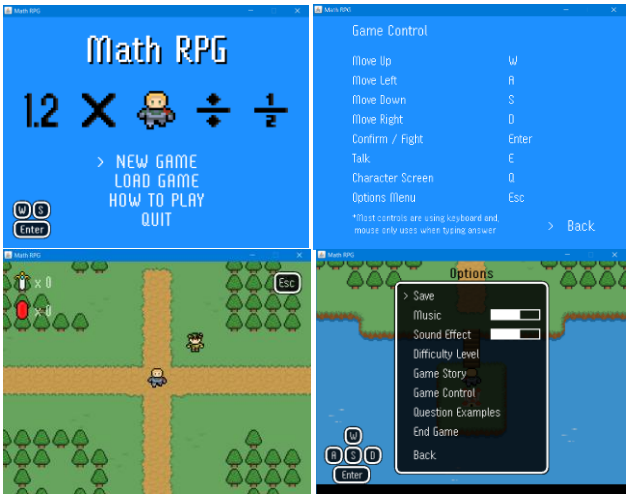

Fig. 11. Game interface.

V. TESTING

In order to make sure the game education application can fulfill the aim and criteria; the author will carry out functional and usability testing on it.

A. Functional Testing

Black box testing is used in functional testing to identify errors or bugs within the application, ensuring the predicted and actual outcomes match. Test cases enable developers to verify that various system features are functioning as expected and that the system meets the requirements. Table IV – VII presents the test cases conducted using the application, highlighting the thorough approach taken to ensure system reliability. This method ensures that critical features are tested rigorously, providing confidence in the system's performance. Additionally, the testing process helps in uncovering hidden issues that could impact user experience.

TABLE IV. TEST CASES

Tester	Chong Bin Yong
Test Date	11/20/2022
Application Developer	Chong Bin Yong

TABLE V. TEST CASE 1

Test Objective	Validate the 'Save' button in options menu
Potential Test Inputs	1. Press 'Save' button
Expected Test Outputs	Completion notification displayed
Test Procedures	1. Enter the game 2. Press 'Esc' to open options menu 3. Press 'Save' button 4. View the screen displayed
Actual Test Results	Completion notification displayed 
TABLE VI. TEST CASE 2

Test Objective	Validate the 'Load Game' button in title screen
Potential Test Inputs	1. Press 'Load Game' button
Expected Test Outputs	Enter the game with previous saved process
Test Procedures	1. Press 'Load Game' button 2. View the screen displayed
Actual Test Results	The saved process is loaded while entering the game 

TABLE VII. TEST CASE 3

Test Objective	To test the random questions generator
Potential Test Inputs	1. Press 'Attack' button in combat scene
Expected Test Outputs	Different questions are generated each time
Test Procedures	1. Enter the game 2. Combat with one of the enemies 3. Press 'Attack' button 4. View the screen displayed
Actual Test Results	The questions are different every time the user wants to attack First attack:  Second attack: 
B. Usability Testing

Usability testing is performed to determine whether a game-based educational application can assist students in developing their mathematical abilities. After playing the game, test subjects were asked to fill out a questionnaire, and some testers had to do a quick arithmetic exam both before and after playing the game. The usability testing involved four Year Six primary school children as participants. Each participant completed the questionnaire, and two of them conducted the short math test for both pre-test and post-test evaluations.

The questionnaire focused on assessing the user interface, engagement level, and overall game effectiveness in enhancing learning. The pre-test and post-test results were analyzed to determine the improvement in arithmetic skills after using the application. These results provided valuable insights into the application's impact on learning outcomes and highlighted areas for further refinement. Fig. 12 illustrates the usability testing process for Participant 1, showcasing the steps taken during the evaluation.

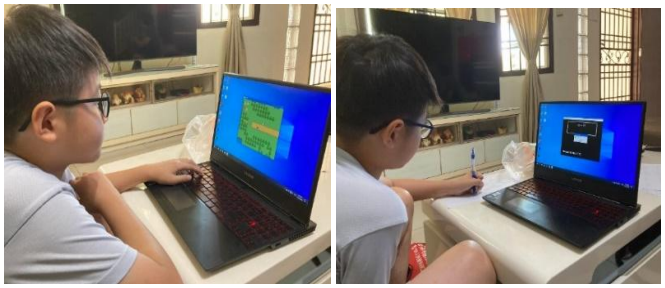

Fig. 12. Usability testing of participant 1.

The results of the post-test indicated an improvement in mathematical skills after interacting with the game. Table VIII – IX show the pre-test and post-test for the participants that have been using the application.

TABLE VIII. PRE-TEST

Questions	*Answers*	*Participant 1*	*Participant 2*
Q1. 5.2 × 2.7	A1. 14.04	14.04 (Correct)	14.04 (Correct)
Q2. 6.2 ÷ 9.8	A2. 0.63	No answer (Wrong)	No answer (Wrong)
Q3. $\frac{5}{9} \times \frac{1}{7}$	A3. $\frac{5}{63}$	$\frac{5}{63}$ (Correct)	No answer (Wrong)
Q4. $\frac{8}{9} \div \frac{3}{10}$	A4. $\frac{80}{27}$	$\frac{80}{27}$ (Correct)	No answer (Wrong)
Q5. 4.5 × 2.5 × 2.0	A5. 22.5	3.65 (Wrong)	No answer (Wrong)
Q6. 5.7 ÷ 4.6 ÷ 4.9	A6. 0.25	No answer (Wrong)	No answer (Wrong)
Q7. $\frac{5}{7} \times \frac{5}{4} \times \frac{9}{4}$	A7. $\frac{225}{112}$	No answer (Wrong)	No answer (Wrong)
Q8. $\frac{10}{9} \div \frac{1}{3} \div \frac{5}{8}$	A8. $\frac{16}{3}$	No answer (Wrong)	No answer (Wrong)

After the game, a brief arithmetic exam is administered to participants to determine their math proficiency. Eight arithmetic problems covering fraction and decimal multiplication and division were also included in the quick math test. Although the questions alter from the ones on the pre-test math test, the question format remains the same. The participant is given the same amount of time—5 minutes—to do the brief math test. Table IX shows the results of post-test.

TABLE IX. POST-TEST

Questions	Answers	Participant 1	Participant 2
Q1. 7.7 × 3.7	A1. 28.49	28.49 (Correct)	7.6 (Wrong)
Q2. 8.6 ÷ 2.2	A2. 3.91	4.0 (Wrong)	0.3 (Wrong)
Q3. $\frac{6}{4} \times \frac{5}{4}$	A3. $\frac{15}{8}$	$\frac{15}{8}$ (Correct)	$\frac{13}{12}$ (Wrong)
Q4. $\frac{1}{8} \div \frac{2}{4}$	A4. $\frac{1}{4}$	$\frac{1}{4}$ (Correct)	No answer (Wrong)
Q5. 7.5 × 4.1 × 10.0	A5. 307.5	347.5 (Wrong)	No answer (Wrong)
Q6. 6.6 ÷ 5.5 ÷ 1.5	A6. 0.8	0.8 (Correct)	No answer (Wrong)
Q7. $\frac{10}{3} \times \frac{4}{7} \times \frac{5}{10}$	A7. $\frac{20}{21}$	$\frac{20}{21}$ (Correct)	No answer (Wrong)
Q8. $\frac{3}{7} \div \frac{6}{1} \div \frac{9}{1}$	A8. $\frac{1}{126}$	$\frac{18}{7}$ (Wrong)	No answer (Wrong)

Participant 1 answered 5 out of 8 questions correctly and his answers of questions 2 and 5 are also similar with the correct answers. Participant 2 did not answer any questions correctly. For participant 1, he is able improve the arithmetic skill after playing the game. For participant 2, he will try to answer the question after playing even though the answers are wrong.

In the opinion of author, participant 1 has the basic arithmetic knowledge and know how to do the questions before playing the game but participant 2 did not know how to do because of poor math knowledge. Therefore, participant 1 improved a lot after playing whereas participant 2 did not have much improvements.

A questionnaire is given for the participants to answer after playing the game in order to get their opinion or feedback related to the application. There are 25 questions in the questionnaire which first 20 questions are scale questions (1-5) and last 5 questions are open-ended questions. For the scale questions, 1 means 'Strongly disagree', 2 means 'Disagree', 3 means 'Neutral', 4 means 'Agree' and 5 means 'Strongly agree' while question 20 uses the scale as the ratings for the game application. Table X shows the questions and Table XI shows the results of the questionnaire.

TABLE X. QUESTIONNAIRE

Question	Description
Q1	I think that I would like to use the application.
Q2	I found the application unnecessarily complex.
Q3	I thought the application was easy to use.
Q4	I think that I would need the support of a technical person to be able to use this application.
Q5	I found the various functions in the application were well integrated.
Q6	I found there was too much inconsistency in this application.
Q7	I would imagine that most people would learn to use this application very quickly.
Q8	I found the application very awkward to use.
Q9	I felt very confident using the application.
Q10	I needed to learn a lot of things before I could get going with this application.
Q11	I am able to learn math quickly using this application.
Q12	I believe I score high marks after using this application
Q13	The application tells me my weakness of math.
Q14	The information provided with this application is clear.
Q15	It is easy to learn math using this application.
Q16	The information provided with the application is effective in helping me learn the math.
Q17	The interface of this application is pleasant.
Q18	This application has all the functions and capabilities I expect it to have.
Q19	I am satisfied with this application.
Q20	Rate this application as learning material.
Q21	What was the best thing about this application?
Q22	What was the worst thing about this application?
Q23	Do you understand what the game story is talking about?
Q24	How long do you think a math question will take to complete?
Q25	How many math questions do you think you have to do to learn it?

TABLE XI. RESULTS OF QUESTIONNAIRE

Questions	Participant 1	Participant 2	Participant 3	Participant 4
Q1	4	2	3	3
Q2	2	2	3	4
Q3	4	5	5	4
Q4	2	3	2	3
Q5	3	4	5	5
Q6	2	2	1	1
Q7	4	4	5	3
Q8	3	1	2	3
Q9	3	1	4	4
Q10	4	3	3	3
Q11	3	4	4	3
Q12	4	4	4	3
Q13	4	1	5	4
Q14	3	3	4	3
Q15	3	5	4	4
Q16	4	4	4	4
Q17	3	5	4	3
Q18	3	3	5	4
Q19	4	3	4	4
Q20	4	5	4	4
Q21	No opinion	The interface is nice	The application is easy to understand	Fun to play
Q22	No opinion	Questions are difficult	No opinion	A little hard to learn to use the application
Q23	Yes, roughly understand	Do not know much	Yes, roughly understand	Yes, able to understand
Q24	Between 1 minute and 1 and a half minutes	Around 3 minutes	Around 2 minutes	Around 1 and a half minutes
Q25	4 – 6 questions	20 questions	12 questions	10 questions

Overall, the participants are eager to use the game-based learning tool. They consider the application to be well-designed and simple to use. The software received a 4.25 average rating. Most users also think they can improve their arithmetic skills and test scores after using the application. They may learn math with the aid of the application, which also identifies users' areas of difficulty. In this study, the participants have a favorable attitude toward the game-based educational application. The amount of time they estimate it will take to finish a math problem is directly related to how many problems they estimate it will take to master it. By looking at the results of the pre- and post-tests for participants 1 and 2, it can be seen that these features are likewise influenced by the participants' arithmetic proficiency.

VI. CONCLUSION AND FUTURE WORK

After the application development and testing, it has been discovered that the application is not good enough because it is not very effective if the student is not good on doing arithmetic questions. The limitation of the application can be considered as future work. The author has planned the future work of the game education application. It is important to have a plan for the application development so that the users will continue to use the application and more users will be attracted to use it.

The authors will include application programming interface (API) into the system so that it can be run on the web browser and students can play the game online. A registration and login system will be built for students and educators to create their accounts and each account has its own ID. Students can play the game whereas educators can check the results according to the ID number of students after logging in. Besides that, the functions of the application will be improved and more functions will be added into the application. For example, users are allowed to interact to more game scenes and items in order to make the game more interesting. The users will traverse in different maps and they will be allowed to control the character by using both mouse and keyboard controls since the application has mostly used the keyboard controls so far.

Furthermore, the authors will add more game settings so the users will have more controls on the application. They can choose how long they want to spend on the question by separating the required completion time from the difficulty levels. Better game teaching will be also added instead of showing the game control only. More save slots and full screen mode will be added for users to choose in the application. The author will find more participants to conduct the usability testing so as to get more data related to the application performance. Feedback will be collected from the users to improve the application whereas any bugs found will be fixed in the updates.

Moreover, better math teaching will be added into the application despite showing the question examples only. More detailed steps will be shown in order to give the users a better understanding of solving the arithmetic questions. Most math homework is calculated to allow students to multiply or divide exactly in primary school. Therefore, the users may be confused when doing the arithmetic questions with remainders especially division questions. It becomes important to let the user understand how to solve this kind of questions or allow the application to generate the question that can be calculated exactly.

The authors believes that the educational math role-playing game using Lehmer's RNG algorithm could provide a solution to students to assist their learning.

***Abstract*—Latest research in the field of cyber security concludes that a permanent monitoring of the network and its protection, based on various tools or solutions, are key aspects for protecting it against vulnerabilities. So, it is imperative that solutions such as firewall, antivirus, Intrusion Detection System, Intrusion Prevention System, Security Information and Event Management to be implemented for all networks used. However, if the attack has reached the network, it is necessary to identify and analyze it in order to be able to assess the damage, to prevent similar events from happening and to build an incident response adapted to the network used. This work analyzes the impact of malicious and benign files that have reached a network. Thus, during the work, various analysis methods (both static and dynamic) of real malicious software will be developed, in two different operating systems (Windows 10 and Ubuntu 22.04). Thereby, both the malware and benign files and their impact on various operating systems will be analyzed.**

***Keywords*—Cybersecurity; network security; network monitoring; incident analysis; incident response**

I. Introduction

Network security includes a large number of technologies and devices that must work together based on a predefined set of rules. These rules are primarily intended to protect sensitive information in a system. However, it must be considered that security aspects cannot work with the same set of rules indefinitely because the threat environment is constantly changing, attackers are always trying to find new vulnerabilities, and network architectures are increasingly complex and different. This is the main reason why network security management tools or applications are also constantly updated.

In this security context, malicious files are an extremely difficult aspect to ignore. So, they are represented by malicious software that is created to produce, according to study [1], various exfiltration of information or to cause various interruptions. Their general purpose is to obtain ideas, to damage the reputation of a company or a system, or material gains. Malicious files can achieve these aspects precisely because of the possibility of exploiting some vulnerabilities or due to the negligence of certain people who perform various actions unfavorable to the security context (disabling the antivirus, deactivating the firewall). From study [2], malicious files and cyber-attacks have expanded their action exponentially in recent years, being encountered more and more often both within companies and for ordinary users. Their greatest impact is given by affecting critical systems such as the health area, the financial-banking area, the area of government attacks or the industrial area. Although malicious files and new types of attacks appear daily, a main part of them are based on the skeletons of older malware to which various code improvements are added. Thus, it is imperative to analyze the existing malware and understand their characteristics because they can generate patterns of future attacks. To perform this type of analysis, it is important to distinguish between static and dynamic analysis of files. This differentiation is made considering various sources such as [3], [4] and [5]. Static analysis of a malicious file involves testing it without executing it. So, this involves the analysis of the source code and other aspects such as the magic number or the hash of the file in order to identify whether it is malicious or not. Dynamic analysis is how the file is analyzed after it is executed to observe how it affects various files or various system registries. Given the fact that this method also involves the execution of the file, it is necessary for this to be done in a closed and controlled environment. Following these two types of analysis, it will be determined whether the file is malicious. The most frequently encountered types of malware present in a system are those known as zero-day. However, the static and dynamic analysis methods cannot detect this type of attack if it does not have a known pattern. For all the other types of malicious files: ransomware, trojan, virus, worm, backdoor, this analysis can be performed for the purpose of documentation and for the purpose of identifying the main characteristics necessary to prevent a possible subsequent attack. These characteristics are also considered based on the literature in [6], [7], [8] and [9].

The purpose of this work is to perform a comparative analysis of how different types of files are executed within two different types of operating systems. For this purpose, a test environment is created, which includes both static and dynamic analysis methods. The contributions of this work consist in creating a test environment (which is similar to a regular user, within a company and does not rely on existing sandboxes), choosing the most recent files from a public malware database (that are not predefined and used in another labeled database), analyzing various events and logs (after the execution of the files) and making a comparison on the key characteristics of these files.

This paper is organized as follows. Section II provides an evaluation of the specialized literature and research related to the analysis of malicious files. Section III provides the area of background work. Experiments and results are presented in Table IV. Discussion is given in Section V and finally, Section VI concludes the paper.

II. Related Work

To perform a complete analysis of malware files, a thorough review of the research activity and tools required in the process is required. Through this section, a deeper understanding of the existing research in the field will be achieved, an aspect that will also lead to the framing of this work in the current security context.

Taking into consideration the paper [10], it is found that it introduces a study related to the dynamic analysis of malicious files, evaluating an open source SIEM (Security Information and Event Management) system called Elastic Stack. Thus, by capturing the event logging mode in Windows, a complete description of the events within the system could be achieved. Malware analysis included in the paper contains a Dynamic Analysis. This type of analysis is also used in the current paper, but compared to the work [10], this paper includes experiments within both Linux and Windows operating system.

The vulnerabilities of a system are an extremely sensitive subject for traditional detection methods because they contain extremely complex functions and algorithms, which cannot be interpreted by them. In the paper [11], detection of these vulnerabilities is carried out in a binary code, by means of neural network algorithms and by means of the NDSS18 database. This database contains CVEs (Common Vulnerabilities and Exposures) for both Windows and Linux operating systems. The results indicate a good performance of the model given by machine-learning algorithms. In this paper, both operating systems will be used to see the interaction of some malware files with the default processes of these operating systems.

In paper [12], a method for detecting the behavior of malicious Android activities is proposed through a hybrid, static and dynamic approach with automatic learning. The results of the work indicate an accuracy of 97% for the detection of anomalies. The advantages of the work would be the reduced use of some permission functions and the consumption of resources, which improve the efficiency of the system. In the present work, the absence of experiments in the area of the Android operating system is identified, as it is not a desktop environment. However, the work in [12] indicates various similarities between the operating modes of malicious files in the desktop area and in the mobile area, the static analysis being carried out identically.

According to study [13], IoT devices occupy a special place in the area of malware detection because they have different characteristics depending on the environment and the platform studied, making it extremely difficult to identify. The proposed analysis method includes both static analysis, against software shells, and dynamic analysis, through nine different sandboxes. The analysis method required the creation of a database and, for this, samples from the Padawan sandbox, VirusTotal [33] and other open-source areas were taken into account. The malware detection accuracy presented in the solution, evaluated using XGBoost, SHAP and Scikit-Learn exceeds 98%. In the current work, compared to the work [13], the sandbox used for dynamic analysis is not a commercial one, but is given by common virtual machines of common users of a company. Thus, the tools used for the experiments are also different, but the key aspects pursued are similar.

In the paper [14], a solution for detecting malicious files using the YARA tool is presented. Thus, during the work, five rules were developed for malware detection in the static analysis area. From the expressed results, it is stated that the presented solution reduces the identification time, improving the detection efficiency. In this work, Yara rules will be also used for static analysis.

Considering [15], the paper presents a way of detection and prevention of malicious files before they corrupt the test system. Thereby, a Virtual Box type environment is used in which a static analysis of malicious files is carried out. The experiments were carried out by means of IDAPro, a tool that will be used in this work as well, and the malicious files were of the type of Trojan horses. The results indicated various functions, strings, imports and exports made by the malware program, and their detection was done through Reverse Engineering.

Taking into account the experiments made in study [16], it is concluded that a static analysis is carried out on a malicious file, with the aim of detecting its behavior. The way to detect malicious files is by extracting the APIs and checking them, and the authors have developed a program that analyzes PE files. The files on which this test is performed are benign, Ransomware, Backdoor and Keylogger and this approach is also found in the present work.

From study [17], it can be concluded how ransomware works. Thus, through the specified paper, certain experiments are carried out through the Kaspersky ransomware signature database and a virtual environment. So, attacks are detected, based on rules based on the signatures of these files, and an analysis is made on their functionality and prevention. Therefore, all analyzed files are either restricted or sent to the detection area for further processing. The present work also addresses ransomware files within the experiments, but the files are different within the two papers.

In study [18], an analysis of the vulnerabilities of a software system is presented. During the work, both the main types of system vulnerabilities (from Buffer overflow to DOS or Memory Corruption) are highlighted, as well as the detection methods, which include, as in this work, static analysis, dynamic analysis and hybrid analysis. The experimental data used in the paper are the authors' own data and include historical vulnerability data. These are evaluated for vulnerability detection by means of machine-learning techniques. The essential difference between the work [18] and the current paper includes their motivation: one trains Machine Learning algorithms and the other only extracts and analyzes key features to form a complex database of malware files.

The previously cited literature sources highlight various aspects of the cyber security area and various approaches similar to the one in the present paper. A good part of them is based on machine-learning algorithms and the development of robust models through this technology. However, in the real security environment, within various companies, there is still quite a lot of skepticism regarding the area of artificial intelligence and the methods used by it. Although the advantages of these solutions are immense and solve a large part of repetitive tasks, knowledge of traditional methods is still imperative to ensure a complete and deep understanding of the field.

III. BACKGROUND WORK

In order to carry out a complete analysis of the behavior of a malicious file, both a static analysis and a dynamic analysis of it are necessary. Thus, during the experiments carried out in this work, both types of analysis will be performed on legitimate or malicious files from the Windows 10 and Ubuntu 22.04 operating systems. The goal is to identify the essential characteristics of various types of malware in order to create a complete database of characteristics. This will be able to serve, later, to create an automatic intrusion detection system within a computer network of various sizes. These types of analysis, both static and dynamic, will be implemented using various open-source tools, and the results of the study will be analyzed comparatively.

The analyzed files were downloaded from the MalwareBazaar Database [25] and include various types of files related to Windows and Linux operating systems. The method of choosing the malware samples used did not follow any specific algorithm but included the identification of similar types of malware for the two types of operating systems used. This need appeared after consulting the literature regarding similar, relevant articles in the field, finding a predilection for known or even outdated databases, which are permanently tested. Therefore, out of the desire to perform the experiments with real malware samples and not with pre-tagged databases, the MalwareBazaar Database [25] source was chosen.

Within this database there are many different malware samples, but the categories are represented by the main types of malware. Thereby, similar samples were chosen (from the same malware family, from the same category, appeared on the same day, etc.), both for Windows and for Linux. By means of this approach, the research can evaluate various ways of functioning of malicious files in its own way and can lead to unpredictable conclusions, which can contribute both in the literature and in the area of commercial applications.

A. Static Analysis

The static analysis of this work will be carried out using various open-source tools. These tools were chosen due to their popularity and effectiveness in detecting key characteristics of malicious files for both Windows and Linux operating systems.

- IDA Pro [19] is a tool that is able to disassemble the files and identify the way in which the instructions are executed in the assembly language. This tool is suitable for both Windows and Linux OS.
- PeStudio [20] is an integrated tool for static analysis of malicious software that indicates various information about files (file headers, file entropy, character strings or imported or exported functions). This tool is characteristic of the Windows operating system, but for Linux it will be an used an alternative named Malcat [26] and Detect-It-Easy [27].
- YARA rules [21] – methods of identifying malicious programs by means of commands written in a .txt program that include instructions for identifying similar sequences used or that have similar patterns.

B. Dynamic Analysis

Dynamic analysis of malicious files means executing them to be able to observe the actual behavior. So, it is found that for this aspect, it is necessary to create a safe and isolated sandbox environment. Except for this aspect, it is also necessary to introduce various tools that can be used to identify the described behavior at runtime. Also, tests will be carried out through which it will be possible to observe whether or not these types of files raise various alerts through the antiviruses specific to each OS.

The essential characteristics that must be monitored in a dynamic analysis are:

- Network traffic monitoring: To be able to track IPs and DNSs contacted for file downloads or data exfiltration.
- System file monitoring: Monitoring how certain registries are created, modified or deleted.
- CPU monitoring: To be able to observe if it becomes overloaded by certain unknown requests.
- Memory area monitoring: To be able to identify activities that are not visible.
- Code monitoring: If it can be decrypted, it provides important information about how the malicious file works.

This information can determine several aspects of the actual attack and whether the system in which it was identified is the target or only an intermediate step towards the final target.

It is mentioned that some of the tools used in the created sandboxes are characteristic of the operating system, and another part of them is common to both Windows and Linux. The chosen tools have the advantages of being open-source and, according to the literature, have increased efficiency in monitoring malicious activity.

- Regshot [22] is a dynamic analysis tool that performs a comparison of a created file with the status of registers and system keys before and after the execution of the malicious file. This tool identifies the changes made by the malicious file and is characteristic of the Windows operating system, but it can also be adapted for Linux, through a series of commands.
- Wireshark [23] is a tool that can be used to capture and analyze data packets from a network. In this work, this analyzer will be used to identify the exchange of messages between the malware file executed within the network and any IPs to which the request is made. Although this tool is normally used in the Windows operating system, adaptations can also be found for the Linux area.
- FakeNet-NG [24] is a tool that simulates Internet traffic, specially created for the malware analysis area. Thus, the malicious programs consider that the workstation is connected to the Internet and try to access various resources. These are later captured to be analyzed in the file behavior characteristics area. This tool can be implemented both in the Windows operating system area, as well as in the Linux OS area.

IV. Experiments and Results

As can be seen from the Fig. 1, the steps necessary to perform the two types of analysis are: choosing the file type, choosing the analysis method with the related implications (analyzing the file, without executing it, and analyzing it by executing it, in a sandbox environment) and choosing the appropriate tools for each analysis, separately. Considering the fact that, in the case of dynamic analysis, the execution of malicious files will involve affecting some registers or even the entire test environment, the experiments will be performed in a virtual work environment. This offers the possibility of returning to the previous settings through the Snapshot function.

This work approach will be preserved for both operating systems. In addition to the basic tools, which will be used to detect malware files, additional resources will be used, such as various functions from Microsoft or the detection of differences in the state of the CPU and memory during the attack. Also, in order to be able to analyze the involvement of anti-virus software in the experiments, this resource will also be used, and its involvement will be analyzed comparatively, depending on the operating system.

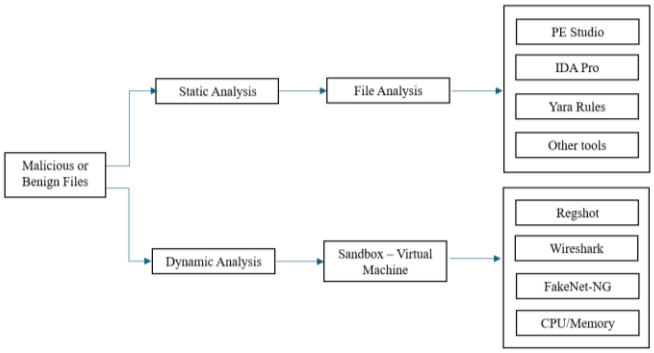

Fig. 1. Workflow diagram of the system.

A. Experiments in the Windows Operating System

a) Static analysis: In the framework of the static analysis present in the Windows operating system, all the tools that were previously presented, in Section III, will be used.

The files used for the experiments in this scenario are of different types, containing both non-malicious and malicious files downloaded from an online database or from public resources (for benign files). For the experiments carried out, the legitimate files are of various types – from executable files to document-type files, archived or photo-type files. The benign file that has .exe extension is the strings64.exe file from the Strings library [28]. Apart from benign files, several different types of malicious files were also chosen from MalwareBazaar Database [25]. Each of these was analyzed using PEStudio, strings64.exe, YARA Rules and IDA Pro. By means of these tools, it was possible to analyze the hash values of the files (MD5-Message Digest Method 5, SHA1-Secure Hash Algorithm 1, SHA256-Secure Hash Algorithm 256), their imphashes, entropy values, imported libraries or APIs. In Table I, you can find the values of file types, their imphash or MD5 hash and the entropy values for each one of them.

TABLE I. Static Analysis of Malicious files in the Windows Operating System

File Type	Characteristics	
	MD5/ Imphash	Entropy
Benign .exe	4d936b630620ff7c59da22b1206636e	6.42
Benign .doc	6698b2a4a15f86ddd4fc90ad65521cf7	7.76
Benign .txt	42631b1af161defcf4844fb1e26cfc70	4.40
Benign .jpg	2be5d32efb9c3f4b6acf94a1d1e707b4	7.96
Benign .mp4	37d7f751daa745beba4cf44b6373f2be	8.00
Benign .pdf	f9067cb2369fa0ec4e3753f67638fbca	7.34
Benign .zip	8273b4301f7a6d678c0523bb07fedd80	7.99
Benign .html	40c15f040bc8f4aeb81909fb36aa9905	4.29
Benign .iso	089a3a344f301a34dc40cc3702f2b873	7.93
Botnet .exe	5e146bf6c1ef160162ed271c0ddde908	3.54
Backdoor .dll	f34d5f2d4577ed6d9ceec516c1f5a744	4.42
Keylogger .exe	008a6a7f7e2610edadf3e2f26c73b646	7.63
Malware .exe	11ea24073ee65343ee563e3160c77fde	7.81
Ransomware .exe	914685b69f2ac2ff61b6b0f1883a054d	7.18
RAT .exe	8d5087ff5de35c3fbb9f212b47d63cad	6.59
Trojan .exe	d6d4965d7fe2d90a52736f0db331f81a	6.59
Worm .exe	2dfc2c74864b84f5530ab40a343c56d8	5.36

Imphash is, from study [31], the method by which a hash is calculated based on the libraries and APIs imported by the file. This is useful to determine if two apparently different files come from the same source or belong to the same family. Within the values presented in Table I, the imphash values are not similar and, therefore, the analyzed files are different and do not belong to the same malware family. Given the fact that the imphash value can only be calculated for executable files, for benign files, which also contain other types of files (except for .exe), the values related to the MD5 type string were added.

The entropy value gives, according to [30] the level of randomness of a file. Thus, the higher the value of the file, apart from the interval [0, 8], it can be concluded that the file is encrypted or packed and can be identified as malware. This aspect is not respected within the values in Table I because the benign files, which are also executable, have, sometimes, a higher value than malicious files such as backdoor or worm. In the case of benign files, the highest entropy values are recorded in the case of .doc, .jpg, .mp4, .pdf, .zip and .iso files.

The explanation for this phenomenon is that, in the case of .jpg or .zip files, the compression algorithms used increase the randomization of the data in order to compact them in a safe way. In the case of .mp4 type files, they encode various waveforms, which leads to a random appearance of the file. For files of type .doc or .pdf, the entropy can have a high value due to various images or text with different fonts. In the case of .iso files, they contain several types of smaller files (which can have various extensions), so its randomization index will be high.

Since the static analysis of a file, especially in the case of those considered malicious, includes aspects such as access and manipulation of memory resources, reading the source code or imported functions or libraries, a deeper look at these resources is necessary.

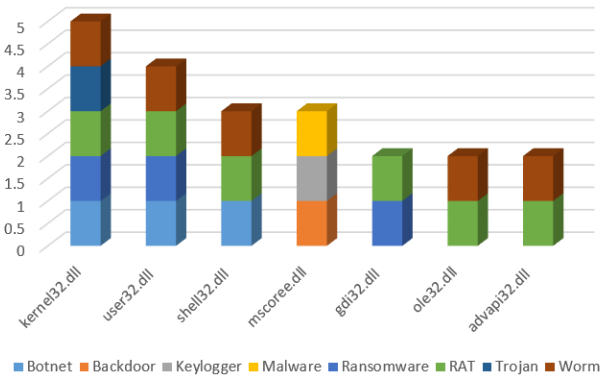

Fig. 2. DLLs imported by malicious files in Windows operating system.

Thus, bearing in mind that the files are of different types and, therefore, the imported functions are also diverse, a comparative analysis at their level would be extremely difficult to achieve. However, what can be analyzed is the domain of libraries imported by each individual file. For the current work scenario, this data can be found in Fig. 2. From this figure, you can see what type of libraries can be imported by the file, if it will be executed. All these libraries are considered legitimate libraries and compatible with the Windows operating system, having various specific functions. As an example, the kernel32.dll library deals with memory management and the control of various processes, while user32.dll considers the user interface and various inputs given by them. However, in the case of malicious files, these libraries have different functionalities. Basically, an attacker names a part of the malicious file identical to a known library but attaches it to a different directory within the file suite. This is also a direct way to detect if a library is legitimate or not. Moreover, even the fact that a file wants to create or overwrite a system library is a fairly solid indicator of the presence of malicious software.

Taking into account the fact that, through static analysis, the considered parameters can create confusion regarding the malware characteristics of a file, a dynamic analysis is also needed, which can clarify certain aspects. Therefore, the analysis of these files will have to be carried out in the next paragraph, in order to be able to observe how legitimate and malicious software functions in a real environment.

b) Dynamic analysis: Dynamic analysis is important because it allows evaluating the behavior of a software program during its execution. In the case of this scenario, the motivation for its realization is the more defined perspective on the key aspects of some legitimate files, compared to some malicious ones.

The aspects identified in the dynamic analysis will be related to the presence or absence of system changes. Thereby, by means of values in Table II, it will be identified if there are modified key values or registers (identified by the Regshot tool), if the connection to various Internet sources (Fake Net and Wireshark) is started, if there are changes to the CPU resources and memory and if the presence of the malware is identified by the antivirus.

TABLE II. DYNAMIC ANALYSIS OF MALICIOUS FILES IN THE WINDOWS OPERATING SYSTEM

File Type	Characteristics			
	Values/ Keys Modified	*Network Activity*	*CPU/ Memory*	*Detected by AV*
Benign .exe	√	X	X	X
Benign .doc	√	X	X	X
Benign .txt	√	X	X	X
Benign .jpg	√	X	X	X
Benign .mp4	√	X	√	X
Benign .pdf	√	X	√	X
Benign .zip	√	X	X	X
Benign .html	√	√	X	X
Benign .iso	√	X	X	X
Botnet .exe	√	√	√	√
Backdoor .dll	√	√	√	√
Keylogger .exe	√	√	√	√
Malware .exe	√	√	√	√
Ransomware .exe	√	√	√	√
RAT .exe	√	√	√	√
Trojan .exe	√	√	√	√
Worm .exe	√	√	√	√

During the experiments carried out in the Windows sandbox, all files were executed sequentially. After running each type of malware, the test environment needed to be replaced via the Snapshot function. This aspect was also valid for benign files, even if their execution does not endanger other files. However, it was desired that the execution of one of the files to not influence the execution of subsequent files in any way. The files that strongly affected the test environment were Worm and Ransomware. In the case of these two types of experiments, the results, given by running the malicious files, led to temporary interruptions of the virtual machines or even to the irretrievability of some data.

A slightly more atypical aspect, resulting from experiments, was in the case of the experiments carried out with the Worm type file, because the Fake Net area could not stop making recordings, having this behavior for a few minutes. During all this time, many HTTP (POST) or DNS related events were recorded, through which the malicious file tried to access ihcnogskt.biz or kkqypycm.biz multiple times.

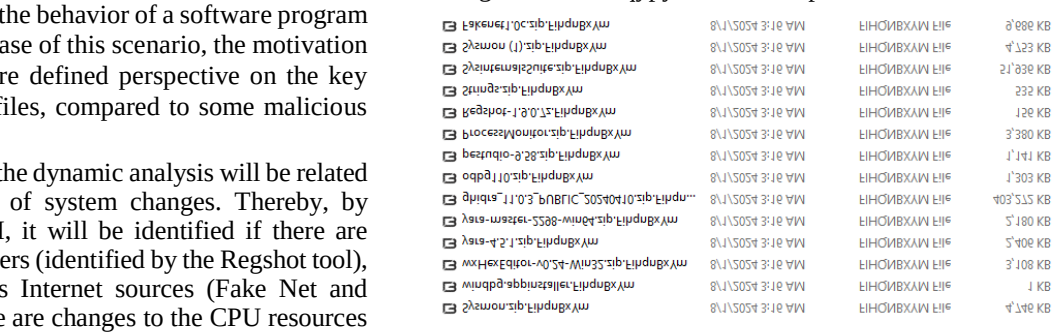

Fig. 3. Changing the file extension after conducting experiments with the malicious ransomware type file.

In the case of the experiments carried out with the Ransomware type file, after execution, it encrypted all the files of the working system, giving them a new type of file extension that can be seen in Fig. 3. As a result of this aspect, the virtual machine became inaccessible, and the files could no longer return to the previous extension type. Even after trying to return to the default settings of the virtual machine, the initial files could not be recovered. Thus, it was necessary to create another working environment.

It is mentioned that the duration of all the experiments done in the test environment did not last more than 5-10 minutes/experiment out of concern not to irreparably affecting the test environment.

B. *Experiments in the Ubuntu 22.04 Operating System*

a) Static analysis: In the case of the experiments carried out in this scenario, benign files, that are completely different from those used in Windows operating system, contain different file types, from a python executable called impelf.py [29], to some other file types corresponding to the Linux operating system. The malicious files are also different, but the way in which they were chosen was by comparing them with the previous chosen ones (be from the same malware family, be announced around the same time, etc.). Each of these files were analyzed using Malcat, Detect-it-Easy, readelf, md5sum, sha1sum, sha256sum. Since .elf and benign files have no information about their executable mode, the imphash hash could only be generated for Keylogger and Worm files, which were .exe. For the rest of the files, in Table III, their md5 hash was added.

Taking into consideration that a complete static analysis needs to include aspects related to various properties of the files (the imports made or file structures), it is also necessary to understand the malicious files in this scenario. Thus, an important amount of the files analyzed within the experiments have the extension .elf. From [32], these files are characteristic of the Linux systems, being executable files or libraries. This type of file is structurally divided into two parts: the header area and the segment area. The header contains various metadata, and the segments describe various memory operations, which are performed during execution. These segments are of various types, but the most common ones are those found in Fig. 4.

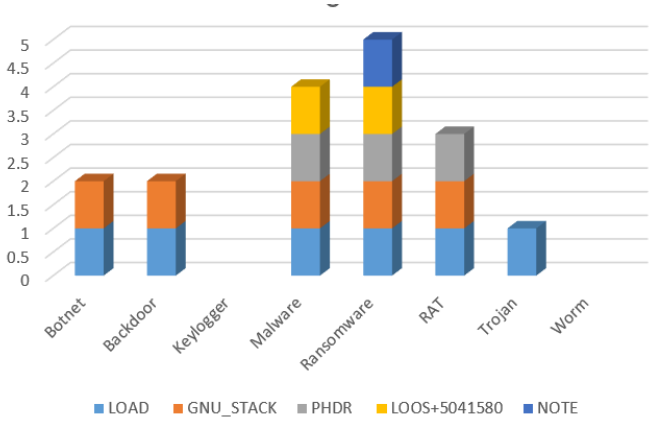

Fig. 4. Segments imported by the malicious files in the ubuntu 22.04 operating system.

Thus, as can be seen from the figure, the first type of segment is LOAD segment and it indicates the memory location where the file will be loaded and its various permissions, while the NOTE type segment includes information that can be used by the system kernel such as version, debug data, etc.

In the context of the analysis of some malicious files, although certain segments appear to be legitimate, being usually found in executable files, they can be modified to have the character of malware. Thereby, the malicious behavior can be hidden in "stuffing" segments in order to be able to pass undetected by various types of antiviruses. If these segments also have file modification or execution privileges, this behavior may indicate the presence of malware. Another detection index of these types of files is the atypically large size of some segments that are apparently legitimate.

In addition to the general segments, such as LOAD or GNU_STACK, which are present in almost all files of the .elf type, there are also segments that are a little more atypical for an ordinary file. Among these types of segments is LOOS+5041580. The fact that, even at the level of Internet resources, extremely little data about this type of segment can be identified, may indicate the presence of malware. It is emphasized that, even the searches based on the LOOS segment, without the numerical suffix, did not indicate details about a usual work segment.

Similar to the experiments carried out in the Windows operating system, the presence of malicious activity cannot be clearly defined to be able to conclude that one of the chosen files is truly legitimate or has malicious characteristics (entropy has different values, segment type files also have a legitimate character, etc.). Thus, the dynamic analysis of the files is also needed to be able to have a more explicit conclusion on the mode of operation and the influence they have on the Ubuntu 22.04 operating system.

TABLE III. STATIC ANALYSIS OF MALICIOUS FILES IN THE UBUNTU OPERATING SYSTEM

File Type	Characteristics	
	MD5/ Imphash	***Entropy***
Benign .py	b6014a53db0e1797301ec118f2625c45	4.53

Trojan .elf	1655222d44cfc33dcc3d10f8a4f2e2db	1.51
Worm .tar	5a46892a133f6e380a5a2acb389c5af6	6.93

b) Dynamic analysis: Following the experiments carried out, in the Ubuntu 22.04 operating system, the same structure found in the dynamic analysis in the Windows 10 sandbox was kept. So, both the benign files and the malicious files were run one by one.

The results of the experiments can be found in Table IV, where the key elements of the detection are reproduced. Thereby, it can be observed that for all types of files, there are modified values or registry keys, and different CPU and memory values recorded during the attack. However, the situation is different for the network activity when the file is executed and the files that are detected by the ClamAV antivirus indicators. Thus, although some files are declared as malware in public databases, in our experiments, it can easily pass the security system of the virtual machine. The less favorable aspects happened in the case of running two different types of files, the one with malware and the one with ransomware. So, after running the malware file, the message "Exporting key" is recorded, after which the workstation becomes unusable, performing a restart. After the execution of the ransomware file, not even this message is displayed, but after restarting the test environment, some files are unusable. For these experiments, recording the malicious behavior was quite difficult due to the continuous restart of the virtual machine. Thereby, in order to succeed in capturing the parameters for Table IV, it was necessary to repeat the tests several times.

It is mentioned that the recording duration of the malicious events was carried out in an interval of approximately 5-10 minutes after the execution of the malware file. The values presented in Table IV reveal only the aspects recorded within this interval. It is also mentioned that, even for the benign files, after each execution, the test environment was returned to the default settings, so that the experiments are not inter-influenced.

TABLE IV. DYNAMIC ANALYSIS OF MALICIOUS FILES IN THE UBUNTU OPERATING SYSTEM

V. DISCUSSION

Taking into account the aspects analyzed in the previous section, a comparative analysis of how the benign files and the malicious software affected the test systems is necessary. Although, in Fig. 1, these analyses are treated independently, in fact, an analysis of malware files is complete only by encompassing all aspects analyzed through all experiments performed and tools used. Thus, in the static analysis, carried out in the case of both analyzed operating systems, it is found that the test files have different entropies, included in the range [3.54-8.00] for Windows and [1.51-7.99] for Ubuntu. Although the initial expectations were that malicious files have a higher entropy value (corresponding to the way in which the malicious file is encrypted and packaged to avoid detection), it is observed that, in the case of both operating systems, some of the files that do not contain malware has a higher entropy value than some files containing malware. This aspect is caused by the randomization achieved by compressing certain files (archive type), by including certain metadata such as photos or different fonts (in the case of document type files) or by processing certain different waveforms (in the case of .mp4 files).

Regarding the hash part, for both operating systems it was necessary to discover various types of hashes. Although, initially, for the tests, the representation of the data by imphash was chosen, this aspect proved to be inconsistent for files that are not Portable Executable. This aspect had an impact in both operating systems because, given the fact that the construct part of some files is not executable or is a binary one, imphash cannot be represented. Therefore, it was chosen to complete the table with the MD5 value for these types of files. A good aspect that needs to be mentioned is the purpose for which it was necessary to find out the hash of a file. Basically, according to study [3], the hash of files within the tables had two directions of development. The first direction is given by the fact that a good part of the malicious files is recognized in some tools by hashes. The second direction, which derives from the first, is the fact that, depending on various hash values (MD5, SHA, SHA256, SHA512, imphash), the characteristics of malicious files can be found in various public databases. The most used example, in this case, is through the VirusTotal tool through which, after searching for a hash, it shows extremely relevant information about the respective file. This tool can also be included in the static analysis area, being an extremely useful aspect in discovering similar files or the characteristics of a certain type of malware.

However, this approach was not necessary in the case of benign files because these files could be represented by the actual name. Their values, that are, in Table I and III, also in the form of hash have the purpose of a unitary way of data representation.

Considering that a complete static analysis must also include aspects related to the actual content of the file, it is necessary for it to include various information such as the strings used, APIs or DLLs imported or the source code, as in study [3], [4] and [10]. Therefore, in the case of both scenarios, these aspects were also analyzed. Unfortunately, due to the difference in the structure of the analyzed files, they cannot be the basis of a comparative analysis, being also extremely different. Thus, the

approach consisted in delimiting the two scenarios and performing a comparative analysis only according to the malicious files within the respective scenario. Therefore, within the Windows operating system, the most frequently encountered imported DLLs were chosen, to be able to observe if there are common characteristics between the analyzed malware files and the intentions of each malicious file, separately. It was concluded that these files import both common libraries and independent libraries. Within Fig. 2, only the common ones were included, the most frequently encountered being kernel32.dll, user32.dll, shell32.dll and mscore.dll. These have as their main characteristics file operations, privilege escalation, avoid analysis, user interface or memory management operations. The importance of these DLLs imported by malicious files can lead to conclusions about the behavior of the malicious file (as in [16]), its inclusion in a certain family, the creation of similarities with other files known to be malicious or the creation of action patterns of certain types of files.

In the Ubuntu 22.04 operating system, the analyzed files, from a static point of view, imposed the analysis of some files with .elf extensions. These are, in essence, binary files and therefore it is quite difficult to extract some essential features, in a similar way to the previous scenario. The initial analysis of these files consisted of examining the file structure (the size of the headers, their number, etc.) or the strings used, but these characteristics could not define a comparative analysis that would indicate an atypical character of the file. Therefore, the chosen feature consisted of presenting the segments loaded in memory during execution. Considering Fig. 4, it is indicated that the most frequently used segments for malicious files were LOAD, GNU_STACK and PHDR. Their essential characteristics include indications on an executable code, on working with the memory stack or on various memory locations that need to be accessed or written. In the case of malicious files, these segments include the possibility of attacks that include self-modifying, returning addresses from the memory stack or escalation of privileges. Therefore, it is extremely important for these characteristics to be known, in order to get an overview of the behavior of the malicious files. Apart from the mentioned aspects, in Fig. 4 you can see the absence of segments for two types of files - Keylogger and Worm. This aspect is due to the fact that the two types of files are not of the .elf type, but of the .gz type. Thus, they must be characterized in a different way.

Considering the aspects mentioned for static analysis and papers [3], [4], [5] and [15], it is necessary to emphasize that they are quite insufficient for a complete characterization of a file type. Therefore, a dynamic analysis would complete the unknown aspects or for which the static analysis is insufficient and would offer the possibility of an overview of the malicious file's mode of action.

Dynamic event analysis involved conducting experiments on how file execution works in a sandbox environment. However, in order to distinguish between a malicious file and a benign one, it was necessary to establish some indicators of the presence of malicious software, similar to [4], [5], [10] and [17]. Therefore, detection by OS-specific antivirus was one of the main parameters that should be considered. Also, the steep increase in machine performance, given by the CPU and memory values, is one of the necessary indicators of the presence of non-compliant activity. Other important aspects were given by the monitoring of the traffic within the network and the values or keys changed at the level of the operating system registries.

Although analyzed independently, the performance parameters could be considered insufficient (CPU and memory values increase even when running a legitimate application), in the analysis, they work as a whole. The discrepancy in results between the two operating systems is due to both the way the malicious files work and the actual file type. Not having the same applicable file available for both operating systems leads to different experimental values.

Taking into consideration all this, it was found that, if at the level of the Windows operating system, aspects are more uniform, the malware files leaving positive traces for all the mentioned indicators, in Ubuntu operating system, things are less favorable because some malicious files are not even recognized by the antivirus. Thus, they can go unnoticed and can attack systems without being detected. The worst aspect is that ransomware and malware files that, after execution, lead to the temporary inaccessibility of the virtual machine, are, initially, undetected by the antivirus. This does not mean that keylogger or worm files cannot affect systems or perform various lateral movements. Therefore, in the case of the Linux-type operating system, the fact that the antivirus used fails to effectively identify certain malicious files is an important problem.

The importance of a preliminary analysis of a file is recalled here to avoid, as much as possible, the unfavorable aspects of executing a malicious file. Thus, considering the results presented in Fig. 3 and [17], attention is drawn to the fact that, for the execution of ransomware, the working environment or even the network may become unusable. And, if the file backup area is located within the same network, it will most likely be affected as well. In all experiments performed, the performance of the virtual machine was affected by running the malicious software, with related CPU values increasing instantly, certain processes stopping or becoming temporarily inaccessible.

For benign files, there was also an increase in CPU and memory values, especially for larger files. So, in the case of the experiments carried out through the Windows operating system, the CPU and memory values increased for the .pdf and .mp4 files, while, in the case of the Ubuntu 22.04 operating system, the same values increased for the .py type files, .txt, .mp4 and tar. The only common aspect is the fact that, in both cases, the CPU and memory values increased when executing the .mp4 file because they are quite resource consuming. No conclusions can be drawn for the rest of the files, as the CPU and memory values may also increase depending on the characteristics of the file itself (its size, the information contained, etc.).

As for the area of activity of the network resources, it is different within the analyzed operating systems. Thus, if in the first scenario all malicious files register the need for access outside the network (trying to access various resources from the Internet), in the case of the second scenario, this event was registered only for the keylogger type file.

For the benign files, they did not register the need to access additional resources from the Internet, with the exception of the

html file, in Windows operating system. Although, initially, its execution can be done in an offline mode, as additional aspects are opened within it, internet resources are needed. It is very likely that, in this case too, there will be changes to the system after the working time allocated to the realization of the experiments.

Regarding the Values/Keys Modified parameter, whose value is based on the Regshot tool, but also on various processing tools such as Process Monitor, it is observed that, for all types of files analyzed (both benign and the malicious ones), there are changes at the level of various registries or keys of the operating system, regardless of whether we consider the Windows or Ubuntu 22.04 platform.

Considering all these aspects, it is necessary to open a discussion about how the execution of these files affects the performance of the analyzed test systems. Thus, taking into account both the aspects mentioned in the static analysis and those in the dynamic analysis, it is appreciated that, if a file is unknown to a user, a simple check of its hash or entropy can be a sufficient index good to see if the file is, in fact, malicious software. These aspects can be done both individually and using various tools or resources from the Internet. It is particularly important that the unknown file is not executed, if no data is known about it, in order to protect both the system through which the file was received, and the network of which it is a part, if applicable.

If the file has been executed, the way in which the performance of a system is affected includes some effective evaluation indicators. Among them, the high CPU and memory values are counted because the malicious file requires various resources to be able to increase its coverage area or to access various types of sensitive information. An immediate effect would be longer response times for applications or even the impossibility of accessing them, various crashes or even restarts of the operating systems. Another performance parameter, taken into account in the case of this work, is the access area to unknown internet resources. As a result of this fact, Internet resources can become difficult to access, and latency can increase.

Other ways in which operating systems are affected include a slower boot, changes to registries or their keys, deletion of various information or files and even their full encryption. It needs to be mentioned that since a system is compromised, it can open various backdoors for further infections.

If, when running, the file is detected by the antivirus, it will block its effective execution and delete it. But, as was observed from the experiments, sometimes antiviruses can also let malicious files pass. Therefore, increased attention is required in the case of unknown files.

Even benign files can affect the performance of operating systems. Thus, although they do not cause the same damage as malicious files, the fact that they are large files or archives with many files of various types affects the operating system. Another way in which they can impact the performance of the operating system is if they contain outdated software. These not only affect the total performance, not having any updates, but they can also create many vulnerabilities, which facilitate various types of attacks. Also, if there are files that contain errors or have modified extensions, they can also corrupt other files, even from the installer area of the operating system.

Considering all this, it is imperative that the files be verified, especially when they come from unknown sources. The verification methods can be both simple (checking the hash and comparing it with the effective extension of the file), as well as complex (which can include reverse engineering). It is also necessary to keep in mind that even benign files can affect system performance. Therefore, increased attention is needed regarding the public sources for downloading them and the way of implementation, both within the respective system and in the case of various communication networks.

In this paper, certain limitations related to the field of cybersecurity are also admitted. Among these, the method of selecting malware samples is listed, since they focused only on executables from the Windows and Linux operating systems. Also, the selection method did not have a predefined set of rules, the files being chosen according to the malware family they come from, their category and the publication date (the aim being to perform experiments with the most recent files). Thus, it is possible that files with relevant characteristics were omitted from the study. Another important limitation is given by the isolated environment in which the experiments were performed, because it was not possible to record the working mode of the malicious files at the network level and the impact that it may have on other network resources. Mentioning these limitations is important for identifying how to perform future experiments.

VI. Conclusions

In this work, a comparative analysis was presented on the way of working of various operating systems with malicious or legitimate files. Therefore, for this aspect, it was necessary to download samples of malicious files from public resources and to choose various types of legitimate files, to be able to make a comparison between them. Later, they were analyzed at the level of the Windows and Ubuntu operating systems, both through static and dynamic analysis.

The static analysis was carried out by means of open-source tools and made an identification of the malicious and benign files, without them being executed. This type of analysis was based on the identification of file hashes, their entropy, the strings used within the system, the imported libraries and the APIs called. However, given the fact that they were quite diverse and ambiguously related, they could not be the basis of a comparative analysis between the two types of operating systems used. Thus, the aspects taken into account at the level of this work were the imphash or the MD5 hash, the entropy of the files and, depending on the operating system, the imported libraries and the structural segments of the file.

In the dynamic analysis area, two sandbox virtual machines were built, with two different operating systems (Windows 10 and Ubuntu 22.04). Within these virtual machines, an isolated file execution environment was created, and the network area was simulated by means of a public tool. The analysis required the execution of the files, and this aspect led, in some cases, to the temporary unavailability of the virtual machines or even to the corruption of all the files within it.

Taking into consideration all this analysis, a discussion was also carried out on the impact that various types of files have on operating systems, either from the perspective of legitimate files or from the perspective of malicious files. The conclusion of this discussion led to underlining the importance of preliminary verification of files received from unknown authors or downloaded from various less obscure public sources, in order to prevent damage to the actual operating system or the network of which it is a part.

The most surprising conclusions that can be drawn from the experiments are given by the way in which the ransomware file, run in the Windows operating system, led to the impossibility of accessing them and by the fact that some malicious files went unnoticed by the Linux operating system antivirus. These aspects may impact the academic and work environment to carry out similar experiments to try to make antiviruses more efficient or to analyze new methods for restoring files affected by ransomware attacks.

For future work, other types of malicious files will be taken into account (adware, rootkits, bots), and the analysis will also be performed at the level of other types of operating systems (MAC OS, for desktop area, and Android and iOS, for mobile area). The final goal is to create a robust database, which contains more recent malware samples and their key features, which can be adapted to current security systems and can be considered can be considered a working basis for other experiments that will be carried out in the literature.

A Malware Analysis Approach for Identifying Threat Actor Correlation Using Similarity Comparison Techniques

Ahmad Naim Irfan, Suriayati Chuprat, Mohd Naz'ri Mahrin, Aswami Ariffin
Universiti Teknologi Malaysia, Malaysia

***Abstract*—Cybersecurity is essential for organisations to protect critical assets from cyber threats in the increasingly digital and interconnected world. However, cybersecurity incidents are rising each year, leading to increased workloads. Current malware analysis approaches are often case-by-case, based on specific scenarios, and are typically limited to identifying malware. When cybersecurity incidents are not handled effectively due to these analytical limitations, operations are disrupted, and an organisation's brand and client trust are negatively impacted, often resulting in financial loss. The aim of this research is to enhance the analysis of Advanced Persistent Threat (APT) malware by correlating malware with its associated threat actors, such as APT groups, who are the perpetrators or authors of the malware. APT malware represents a highly dangerous threat, and gaining insight into the adversaries behind such attacks is crucial for preventing cyber incidents. This research proposes an advanced malware analysis approach that correlates APT malware with threat actors using a similarity comparison technique. By extracting features from APT malware and analysing the correlation with the threat actor, cybersecurity professionals can implement effective countermeasures to ensure that organisations are better prepared against these sophisticated cyber threats. The solution aims to assist cybersecurity practitioners and researchers in making informed decisions by providing actionable insights and a broader perspective on cyber-attacks, based on detailed information about malware tied to specific threat actors.**

***Keywords*—Malware analysis; APT group; threat actor correlation; CTI**

I. Introduction

The increasing number of cybersecurity incidents is a significant challenge faced by organisations worldwide. Throughout the year, many organisations must deal with cyber incidents involving malware. According to a report by Trend Micro, there has been a 382% increase in blocked malicious files, such as malware [1] deployed by threat actors, These threats are continuously adapting to organisations' cyber defences. Threat actors can bypass these defences due to their ever-improving modus operandi [2] [3] including the malware they use [1], which targets multiple devices, [4] such as computers and smartphones. [5] [6]. Threat actors aim to avoid detection by making it increasingly difficult to identify malicious files. This is particularly evident in cases of ransomware, where cyber-attacks are becoming more sophisticated [7]. As threat actors deploy new diversion and evasion techniques, they are able to avoid detection, highlighting the growing complexity of cyber threats [8].

Identifying malicious activities is crucial when dealing with malware found during cyber incidents, such as data breaches [12]. Cyber-attacks carried out by threat actors, particularly APT groups, are highly sophisticated and have a severe impact on victims. For example, the Lazarus Group, a state-sponsored threat actor, was reported to have attacked Automated Teller Machines (ATMs) and banks in India [13]. In addition to causing disruption, financial gain and espionage are common motivations for APT groups to execute cyber-attacks. These attacks are high-stakes because APT groups are highly motivated, skilled, and resourceful, with perpetrators often not stopping until they meet their objectives. Moreover, APT groups commonly employ stealth, anti-analysis techniques, and covert communication to evade detection, making malware analysis both difficult and time-consuming [14]. Dealing with APT groups also takes considerable time due to the scale of the cyber-attacks, which can affect targets across multiple organisations and countries.

The identification of malware, especially APT malware, is unique as it involves multiple factors and often depends on a case-by-case basis. Factors such as file type, extracted malware data, and the purpose of the malware analysis all play a role in shaping the malware analysis approach. As a result, many researchers have developed specific approaches based on these factors, such as classifying malware by type. However, current malware analysis approaches primarily focus on identifying malware itself. There is an opportunity to broaden the purpose of malware analysis by also identifying the threat actor responsible for developing the malware. Correlating malware with its associated threat actor is valuable for identifying shared features. The identification of similar features helps in discovering links between threat actors, where malware from the same actor can be correlated.

One of the factors contributing to the rising number of cybersecurity incidents is the complexity of malware analysis, which is unique and depends on a case-by-case basis. Previous research on malware analysis approaches typically focuses on factors such as the data used in experiments, features extracted, the purpose of the analysis, the medium of analysis, and how results are measured. However, current malware analysis approaches are often limited, as they primarily focus on identifying malware rather than the threat actor behind it.

Therefore, the aim of our research is to enhance an APT malware analysis approach using a similarity comparison technique to identify the threat actor.

II. Malware Analysis Approach Considerations

Malware is one of the key artefacts found in cyber-attacks and serves as a valuable source of Cyber Threat Intelligence (CTI) [9], [10], [11], data. It contains harmful code with unique signatures and behaviours [15]. Identifying these signatures and behaviours is challenging, as they are often unique to the design of the malware author. However, some malware is derived from known variants, where the signature and behavioural patterns have already been identified [16]. Current human capabilities and technologies, such as antivirus software, rely on predefined malware signature databases that require constant updates to detect new threats. The large volume of malware makes it impractical to analyse each piece manually, which is why automated technology is used to conduct these analyses.

A. Malware Group

Malware is commonly grouped by its type. Since there are many types of malware, categorising them in this way helps identify new variants within the same malware family or discover entirely new ones. Examples of common malware types include backdoors, botnets, ransomware, spyware, keyloggers, rootkits, viruses, and worms [17]. The advantage of classifying malware by type is that it enables the identification of malware families. Grouping malware in this manner improves detection accuracy, as similar types tend to share common traits. Malware type identification is achieved by analysing patterns in malware behaviour and grouping them based on these similarities.

Currently, there is a growing body of research focused on attributing malware, as it has become increasingly sophisticated. This requires analysing malware from different perspectives, such as identifying traits to group malware by platform. In addition to traditional Personal Computer (PC) malware, malware is now being developed for a wide range of platforms, including Android malware for mobile devices, Industrial Control Systems (ICS) malware for Operational Technology (OT) systems, and Internet of Things (IoT) malware for appliances connected to the internet. This approach allows malware to be grouped according to the platform it is designed to target. For example, IoT malware refers to any type of malware developed to compromise a network of connected devices, as well as the technology that facilitates communication between these devices, the cloud, and other devices within the network.

In addition to being grouped by platform, malware is also classified based on its authors, linking it to the respective threat actor. Connecting the malware to the threat actor helps gain insights into the objectives behind an attack and understand the motive of the threat actor [29]. This information is then used to build a profile of the threat actor, detailing the tools, targets, and preferred attack vectors. Having a profile of the threat actor aids in anticipating future attacks by enabling necessary preparations to enhance the organisation's cybersecurity posture. For example, incorporating known signatures and the behavioural traits of the malware into cybersecurity controls to detect or block possible threats identified [30].

The challenge in the current ecosystem is identifying specific malware groupings, rather than categorising by type, as some malware exhibits the functionalities of two or more types. For example, China Chopper is a piece of malware that displays the capabilities of a trojan, infostealer, and password brute-force attack tool, among others [18] [19]. This demonstrates that sophisticated malware has a range of functionalities, making it difficult to group strictly by type. However, despite this complexity, malware still exhibits attributes that are linked to specific threat actors, such as APT group [20]. Grouping malware by its authors enables malware analysts to attribute it to a specific threat actor group or link it to a particular threat campaign [31]. This practice enhances threat detection by providing critical insights into adversarial motives, which, in turn, facilitates proactive defence measures.

B. Malware Analysis Environment

There are various ways to build malware analysis environments, depending on the data being analysed and the specific experimental scenario. One option is to use a dedicated physical machine for performing the analysis. However, this approach is time-consuming and inflexible, as cleaning the machine and reinstalling tools after each analysis session is cumbersome. After each analysis, the machine must be cleaned, and tools need to be reinstalled. An alternative approach is to use hypervisors and preinstalled tools [21]. In this setup, the machine is simulated through virtual machines (VMs). VMs offer several advantages, including network configurations that allow for host-only connections, which prevent the machine from connecting to the internet. VMs also include a snapshot function, enabling users to capture the system's state once the machine and applications are properly configured. This snapshot is used to revert to the captured state whenever required.

C. Related Work

Related works on malware analysis approaches typically use either generic malware or APT malware for experiments. Research on APT malware often involves classification to identify APT attacks based on common features extracted from malware samples belonging to different APT groups. Additionally, features extracted from APT malware are used to distinguish between APT and non-APT malware. However, these studies do not specifically analyse PE format APT malware. Given that Windows OS is widely targeted in cyber-attacks, a dedicated extraction and analysis approach is required to gain a deeper understanding of PE-based APT malware. A comparison of related research works is presented in Table I.

TABLE I. MALWARE ANALYSIS APPROACH COMPARISON STUDY

Research Work	Malware Analysis Approach				
	Data used in Experiment	Features Extracted	Analysis Purpose	Analysis Medium	Result Measurement
Torabi, S., Dib, M., Bou-Harb, E., Assi, C., & Debbabi, M. (2021)[22]	IoT Malware (Collected using IoT-based honeypot)	Strings	Visualise Covid-related malware clusters based on strings attribute	Similarity Measurement Based on Strings Attribute to determine covid related IoT malware	Members, percentage, density
(Xu et al., 2021)[23]	APT Malware (cyber-research/APT Malware Github)	API calls	APT Malware Classification (If it is an APT malware)	Adaboost feature selection and LightGBM	Accuracy, precision, recall, F1 score
(Hu & Hsieh, 2021)[24]	APT Malware (cyber-research/APT Malware Github)	Hexadecimal and ASCII codes (APT PE samples were converted to PNG images with a fixed width of 256 pixels)	APT Malware Classification (If it is an APT malware)	Convolutional Neural Network	Avg. Train Accuracy and Max Train Accuracy
(X. Han et al., 2021)[25]	APT Malware (cyber-research/APT Malware Github)	Binary code collection and network behaviour (Grayscale image conversion)	APT Malware Classification (If it is an APT malware)	Convolutional Neural Network	Accuracy, precision, recall, F1 score
(Do Xuan & Huong, 2022)[26]	APT malware downloaded from Interactive Online Malware Sandbox (any run app)	Processes from Event ID	Classify an APT or non-APT malware	Graph Neural Network	Experimental Scenarios to measure to measure effectiveness, Accuracy, precision, recall, F1 score
Enhanced Malware Analysis Approach	Only PE file type of APT Malware (cyber-research/APT Malware Github) and vxunderground	Strings and Import Address Table	Determine features of APT malware and using similarity comparison technique to correlate with threat actor	Similarity Measurement based on strings and IAT attribute	Experiment Scenarios based on Similarity Concept

Table I presents the enhanced approach we propose, which uses the similarity comparison technique to correlate APT malware with its author. The enhanced approach is simulated through experimental scenarios designed to evaluate the results. Table I also highlights that this enhanced approach is specifically tailored for analysing PE file-type APT malware and expands the use of the similarity comparison technique, as well as the developed experimental scenarios. Therefore, this research aims to combine various techniques and methods to analyse APT malware and extract information for Cyber Threat Intelligence (CTI) purposes.

III. ENHANCED MALWARE ANALYSIS APPROACH

The enhanced approach to analysing APT malware follows the entire process flow, from feature extraction to data analysis. This approach is presented visually to demonstrate the process, which is replicable using the preferred tools and methods. The enhanced approach is illustrated in Fig. 1.

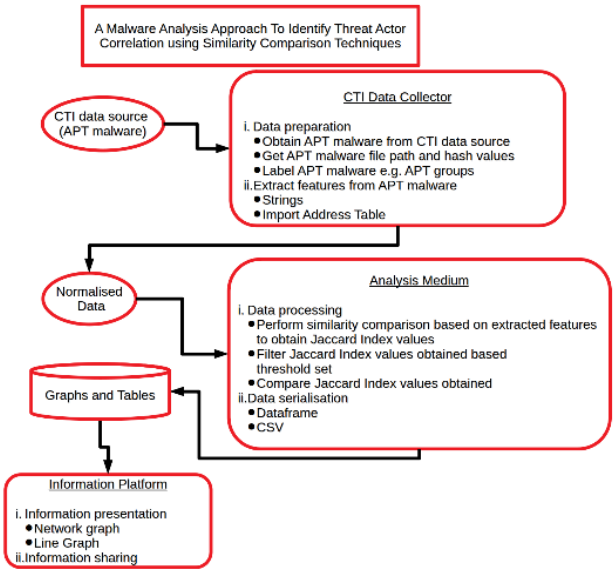

Fig. 1. Enhanced APT malware analysis approach.

Fig. 1 shows the enhanced approach for analysing APT malware to identify threat actor correlation using similarity comparison techniques. The approach takes APT malware files as input via the CTI data collector component, which performs data extraction and preparation. The normalised data is then processed and serialised by the analysis medium component. Finally, the graphs and tables generated by the analysis medium are presented and shared through the information platform component.

The first step in the approach for the CTI data collector component is to identify the APT malware source for data collection. CTI data sources are categorised into open-source, closed, or subscription-based categories. Open-source repositories, maintained by the community, include forums and websites that offer free access to content. However, the quality and availability of this content depend on how well the repository is maintained. Closed and subscription-based repositories, on the other hand, are accessible only to a select group, typically based on membership arrangements that may require payment or affiliation with an organisation. To ingest APT malware from a source, the repository typically provides a download feature to store data files locally or an API to pull data to an external storage location, such as a server or cloud.

Once APT malware is in the designated storage location, the contents of the files are extracted to obtain the relevant data. Data extraction is performed using specialised tools, which may be open-source or proprietary. Alternatively, a custom program can be written to perform the extraction process. This approach offers greater flexibility, as the features are not restricted by the limitations of open-source or proprietary data extraction tools. To develop a data extraction program, programming languages and scripting libraries typically include modules to read files and extract data based on the file format.

Initial analysis is performed on the extracted APT malware data. This step helps identify key content within the data and prepares it for subsequent processing. By reviewing the extracted data, relevant attributes are selected for analysis, and appropriate data structures are chosen based on these observations. Additionally, this step includes data labelling, which adds context to the content by tagging relevant data. Observing the data also provides an overview of its contents, allowing for the identification and removal of noise through sanitisation. Sanitisation involves filtering out irrelevant file types and removing empty rows to refine the data.

Once the data is prepared during the data collection phase, analysis mediums are used to transform it into meaningful information. At this point, the data is still in its raw format, and processing is necessary to derive actionable insights. Analysis mediums, typically built using programming languages, scripts, or available tools, perform the required processing and generate output results. Libraries and modules play a crucial role in this process, as they save time in developing the analysis mediums and allow the developer to focus more on the logic needed to process the data.

The first decision when starting data processing is to choose the appropriate algorithm for the task. In artificial intelligence, the two main options are machine learning and deep learning. The next decision is to select the data processing algorithm, which is based on the data preparation step completed earlier. A data processing algorithm is a series of instructions designed to process the data. Libraries are often used to incorporate common functions such as validation, sorting, summarising, and aggregation into the algorithm. These libraries vary across programming languages or scripts, and custom functions are written to perform tasks beyond the available scope. Pseudocode is frequently shared by the community to assist in building custom functions, and many libraries are specifically designed to support AI.

Once the data is processed, serialisation is performed to convert an object into a stream of bytes for storing the results. Common formats for storing results include CSV for tabular data and PNG for images. Serialised data are records kept for future reference when needed. Choosing the appropriate format for saving data is crucial to ensure that it is both preserved and easily shareable through the information platform.

All results obtained from the analysis are gathered on the information platform. Web-based platforms, such as blogs, wikis, and dashboards, are used to transmit and display these results. A web-based information platform is chosen because it allows for customisation in how information is presented and provides graphical tools to assist in visualising the data. Additionally, sharing features and APIs are available on web-based platforms to relay information to relevant parties.

Based on the results obtained, suitable ways to present the information include visuals such as graphs, histograms, bar charts, pie charts, and tables. These visuals help describe and interpret the data, assisting recipients in the decision-making process. Multiple visual options are available to present the information effectively, depending on the context. Key considerations when presenting information include the purpose, the recipient's background, and the structure of the information flow. To manage these visuals and considerations, a platform like a dashboard is often used to consolidate all the information in one view. A dashboard allows recipients to access information and make queries efficiently.

Before sharing information containing the analysis results, the parties who need to receive the information are identified. This step is crucial to prioritise information sharing based on the roles of personnel within the organisation. It functions as a call tree, alerting relevant personnel according to a layered, hierarchical communication model, ensuring the right people are notified of the threat. This enables the necessary preparations to be made in response to the threat. Communication methods include multiple channels, such as email, chat, SMS, and voice calls for emergencies. The information platform serves as a central medium, accessible to recipients, allowing them to pull the information when needed.

A. Malware Analysis Study

A malware analysis environment is established to experiment with and evaluate the proposed APT malware analysis approach. This environment integrates open-source tools and custom scripts to extract and compare malware features, facilitating the identification of similarities across various APT malware datasets. The environment is designed to align with the APT malware analysis methodology, simulating the analysis process using data derived from APT malware samples. The results of these experiments are assessed by reviewing the analysis outcomes. The APT malware analysis approach serves as the foundation for the environment's architecture, which is built using open-source technologies. Tools are integrated into the environment to perform similarity comparisons, offering valuable insights for

cybersecurity practitioners. These insights enable prompt actions, such as malware detection, as illustrated in Fig. 2.

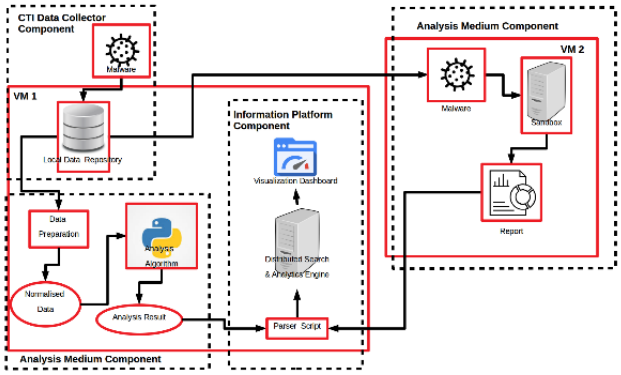

Fig. 2. Malware analysis environment.

Fig. 2 illustrates the architecture of the malware analysis environment, which implements the proposed APT malware analysis approach. Two Virtual Machines (VMs) are used in the environment to manage the integration of components separately. VM 2 runs Windows 10 for sandbox deployment, while VM 1 is used for tool installation and runs Ubuntu. The requirements and installation procedures for each tool or software used are documented on the respective tool websites. The suitability and functionality of the tools are evaluated in advance to avoid any installation or deployment issues that could hinder their operation. The tools used in the malware analysis environment are listed in Table II.

TABLE II. MALWARE ANALYSIS ENVIRONMENT

Malware Analysis Environment	Description
Host Hardware Specification	• CPU: Intel i7-13700F • RAM: 64GB (16GB assigned to VM1 and VM2)
Dataset 1 Publicly available dataset from https://github.com/cyber-research/APTMalware	The APT Malware Dataset contains over 3,500 malware samples in various file formats, such as .exe and .pdf, which are associated with 12 APT groups allegedly sponsored by five different nation-states. This dataset is primarily used for benchmarking different machine learning approaches in the context of authorship attribution. It can also serve as a valuable resource for future benchmarks or malware research.
Dataset 2 Publicly available dataset from VX Underground (https://vx-underground.org/)	The malware repository is regularly updated and maintained, with each sample properly attributed to specific cyber incidents and threat actors based on CTI reports. As such, malware from this repository serves as a suitable dataset for this research experiment. Additionally, this repository has been used as an experimental dataset in the research by Piskozub et al. (2021) [27]. The APT malware samples from 2022 and 2023 were used in this experiment.
Virtual Machine 1 (VM 1, Linux Machine)	The experiment tools installed on the virtual machine include Jupyter Lab is used to write the Python algorithms that is used for analysis durin the experiment. Elasticsearch which is a ditributed search and analysis engine is used to store experiment results obtained and the results are visualised on the Kibana (dashboard).The experiment tools installed on the virtual machine include Jupyter Lab, which is used to write the Python algorithms for analysis during the experiment, and Elasticsearch, a distributed search and analysis engine, which is used to store the experiment results. The results are then visualised on the Kibana dashboard.
Virtual Machine 2 (VM 2, Windows Machine)	Cuckoo Sandbox is a sandbox environment used for malware analysis and containment, designed to prevent outbreaks. It provides an analysis report on a given malware sample based on detection rules such as YARA (a tool commonly used in malware research and detection) to determine whether the sample is benign or malicious.

Table II describes the tools used in the malware analysis environment, which has been built according to the proposed APT malware analysis approach. This environment can be customised by replacing the existing data feeds, tools, or software with alternatives, as long as they offer the functionality outlined in the proposed approach. The tools employed in the development of the malware analysis environment are open-source and available for free download from their respective websites. Additionally, scripting is required to integrate the tools and perform tasks that require specific libraries or unique functionality. For instance, Python scripts are used to execute functions that are not provided by the selected technology providers.

B. Malware Analysis Experiment Design

The flow of the malware analysis experiment follows the enhanced malware analysis approach, which consists of six stages: data extraction from files, data preparation, data processing, data serialisation, information presentation, and information sharing. In the experiment using VM1, static analysis is performed to extract malware features such as strings and the import address table. These extracted features are then used for similarity comparison, which is conducted using the Jaccard Index, as shown in Fig. 3.

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|}$$

Fig. 3. Jaccard index.

Fig. 3 shows the Jaccard Index, which is used to gauge the similarity of sample sets by measuring the ratio of the intersection to the union of the two sets (Yang et al., 2023). The Jaccard Index between two sets is calculated by dividing the number of elements in their intersection by the number of elements in their union. The value of the Jaccard Index, denoted as J(A,B), lies between 0 and 1, where $0 \leq J(A,B) \leq 1$. For example, if the intersection of sets A and B is empty, then J(A,B)=0, indicating no similarity between the two sets of assembly code [28]. This is one of the similarity comparison techniques identified for assessing similarities in malware attributes.

Dataset 1, sourced from the GitHub link mentioned in Table II, contains 3,594 APT malware samples. During the data preparation step in the CTI data collector component, 2,887 PE files are filtered out of the 3,594 APT malware samples in the dataset. For Dataset 2, which is pulled from Vxunderground, 596 PE files from 2023 and 3,446 PE files from 2022 are filtered during the same data preparation step in the CTI data collector component.

Two attributes are selected from the observations during the data preparation step. These chosen attributes—strings and the Import Address Table (IAT)—are analysed during the experiment to identify similarities in APT malware. Based on these two attributes, three experiment scenarios are designed to help security professionals, researchers, and organisations understand how to identify similarities between different malware samples. Table III describes the role of these attributes and outlines the execution of the experiment scenarios.

TABLE III. EXPERIMENT SCENARIO IMPLEMENTATION

Experiment Scenarios	Implementation
String comparison	Strings are ASCII and Unicode printable sequences of characters embedded within a file. The strings attribute refers to the human-readable text embedded within a binary file, often revealing useful information such as URLs, file paths, error messages, and even internal function names. Malware analysts frequently examine these strings to gain insights from the malware, such as its behaviour and command-and-control (C2) information. The string comparison scenario is an experiment designed to analyse APT malware and calculate the Jaccard Index between combinations of the 2,888 PE files identified. In this scenario, only Dataset 1 is used to identify the similarity between two distinct samples based on string attribute.
IAT Comparison	The Import Address Table (IAT) is part of a Windows module—either an executable or a dynamic link library (DLL)—that records the addresses of functions imported from other DLLs. The IAT provides insight into the specific system resources and APIs used by the malware, which is valuable for identifying patterns across different samples.. The IAT comparison scenario is an experiment designed to analyse APT malware and calculate the Jaccard Index between combinations of the 2,888 PE files identified. In this scenario, only Dataset 1 is used to identify the similarity between two distinct samples based on the IAT attribute.
Similarity Comparison on Dataset 1 and Dataset 2	In this experiment scenario, the strings and IAT attributes are extracted from APT malware in both Dataset 1 and Dataset 2. The similarity comparison is then performed by calculating the Jaccard Index between the APT malware samples in Dataset 1 and Dataset 2 based on these two extracted attributes. The similarity comparison is performed to identify any correlation between the two different APT malware datasets based on the string and IAT attributes. The comparison between Dataset 1 and Dataset 2 begins with the year 2023, followed by the year 2022.

Table III illustrates the experiment flow, which includes three scenarios. These experiment scenarios are designed based on the dataset and the chosen attribute similarity comparisons, which include strings and IAT, as described in detail. The scenarios are executed to demonstrate how the normalised data are analysed and represented in graphs and tables. The sample data collected are shown in Table IV.

TABLE IV. SAMPLE DATA COLLECTED

Malware Hash	Malware Label	String Attributes	IAT Attributes
00be6858156b0be404b4fa4852ffc550c25565236beaa4cb13ffe288bcb48d8e	APT 1	Syntax error! Usage: getf/putf FileName <N> Mozilla/5.0 So long! exit Shell started,wait to terminate it..... 		Usage: start </p|/s> <filename|ServiceName>	

Table IV lists sample data extracted from the APT malware. The fields identified for analysis, which are relevant to the experiment, include Hash, Label, Strings, and IAT. The comparison is then performed by calculating the Jaccard index values for the Strings and IAT attributes. This comparison, using the Jaccard index, is based on the bag of features concept, as shown in Fig. 4.

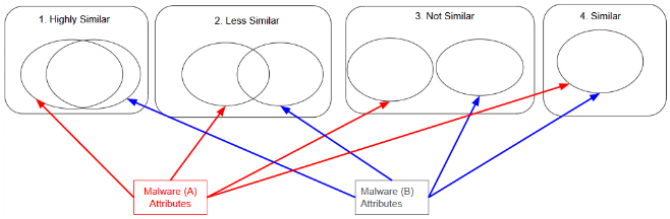

Fig. 4. Malware attributes similarity concept.

Fig. 4 illustrates the concept of attribute similarity used in malware analysis, where the similarity of malware attributes is calculated using a similarity coefficient, such as the Jaccard index. Based on the threshold of 0.8 for Jaccard index calculation: Diagram 1 represents an instance where the calculated Jaccard index value is greater than 0.8; Diagram 2 shows an instance where the Jaccard index value is less than 0.8; Diagram 3 depicts an instance where the Jaccard index value is 0. Finally, Diagram 4 illustrates an instance where the malware attributes exactly match, and the Jaccard index value is 1.

IV. Malware Analysis Results

Experiments are conducted to demonstrate the results obtained from the implementation of the enhanced approach. The results are based on three scenarios, using the malware attribute similarity concept described in Section 3B. Two distinct samples, identified by hash value, are obtained from the malware dataset and labelled as Malware 1 and Malware 2. For each comparison performed based on the designed scenario, the Jaccard Index value is calculated to identify the similarity between the compared samples.

A. Strings Similarity Comparison

The string comparison scenario in the experiment compares the string attributes of each APT malware sample. For each APT malware analysed, the string values are extracted and saved in a CSV file. A sample of the results from the similarity comparison of string attributes extracted from APT malware is presented in Table V.

TABLE V. Sample Jaccard Index Results for Strings Attribute

Malware 1 Hash	Malware 1 Label	Malware 2 Hash	Malware 2 Label	String Jaccard Index
0fbb47373b8bbefdfd9377dc2	AP	0fbb47373b8bbefdfd9377dc2	AP	1
6b6418d2738e6f688562885f4d2a1a049e4948e	T1	6b6418d2738e6f688562885f4d2a1a049e4948e copy	T1	
6c8eb3365b7fb7683b9b465817e5cb87574026e306c700f3d103eba056777720	AP T29	6c8eb3365b7fb7683b9b465817e5cb87574026e306c700f3d103eba056777720	AP T29	1

Table V shows sample Jaccard index results for the string attribute. The first row presents a sample where the Jaccard index value for the string attribute is 1. This result indicates that the malware is identical, as it represents the same sample with a similar hash value.

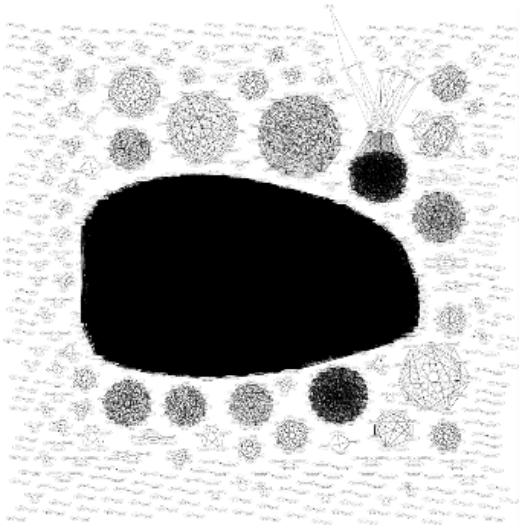

Fig. 5. Strings network graph.

Fig. 5 shows the results of the string attribute comparison between malware from different APT groups. Nodes without at least one edge are removed from the graph to reduce clutter.

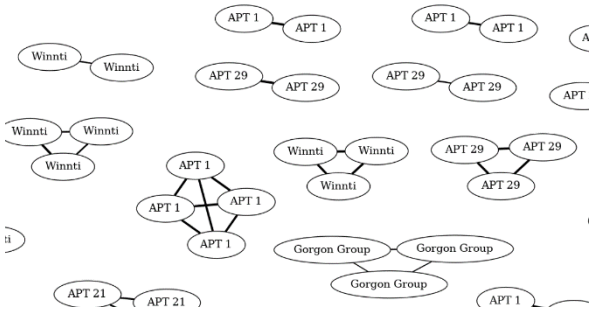

Fig. 6. Close up of strings network graph.

Fig. 6 provides a close-up of Fig. 5. The APT malware samples are grouped based on the string attribute. Observations of the results reveal that some malware, even from the same APT group, are not clustered together. Additionally, no malware from different APT groups shows any connections.

B. Imports Address Table Similarity Comparison

The IAT comparison scenario in the experiment compares the IAT attributes of each APT malware sample. For each APT malware analysed, the IAT values are extracted and saved in a CSV file. A sample of the results from the similarity comparison of IAT attributes extracted from APT malware is presented in Table VI.

TABLE VI. SAMPLE JACCARD INDEX RESULTS FOR IAT ATTRIBUTE

Malware 1 Hash	Malware 1 Label	Malware 2 Hash	Malware 2 Label	IAT Jaccard Index
0fbb47373b8bbefdfd9377dc26b6418d2738e6f688562885f4d2a1a049e4948e	APT1	0fbb47373b8bbefdfd9377dc26b6418d2738e6f68856285f4d2a1a049e4948e	APT1	1
1b3ee0274ae0ac0b83dba7f95f00e2381a5d3596d136eb1fac842a07d8d25262	APT1	6bb764f3a5ca57f9bcc72aa0c34dab64e870e22c6400f6b3f62d5986104dc68f	APT1	0.82828282828 2828
6c7e768e48b9b225b7b9f84528c53c2e6f9b639ce2e7919fe0dff9aad07ea4f5	APT29	6c8eb3365b7fb7683b9b465817e5cb87574026e306c700f3d103eba056777720	APT29	0.94845360824 7423
6c8eb3365b7fb7683b9b465817e5cb87574026e306c700f3d103eba056777720	APT29	6c8eb3365b7fb7683b9b465817e5cb87574026e306c700f3d103eba056777720	APT29	1

Table VI shows two identical samples in rows 1 and 4, which are malware from the same APT group with a Jaccard Index value of 1. Rows 2 and 3 show malware with different hashes but from the same APT group, with Jaccard Index values of 0.83 and 0.95, respectively. The closer the Jaccard Index values are to 1, the greater the similarity in the IAT attributes.

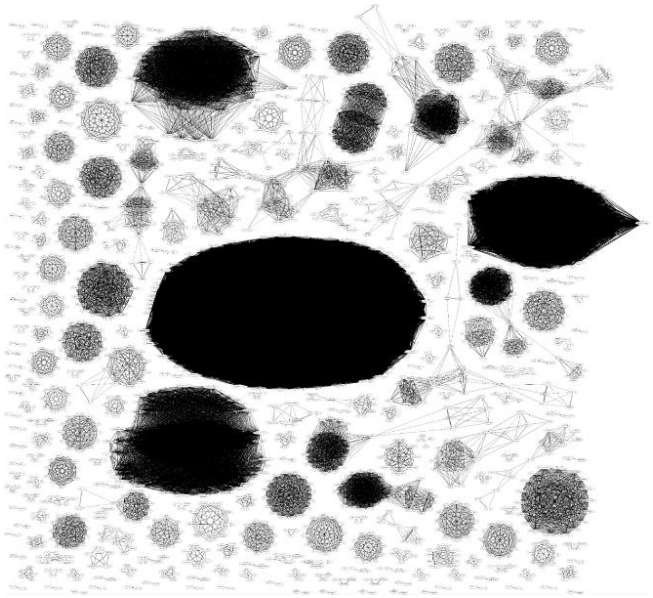

Fig. 7. IAT Network graph.

Fig. 7 shows the results of the IAT comparison between malware from different APT groups. The IAT network graph differs from the string network graph shown in Fig. 5. A close-up of the IAT network graph is presented in Fig. 8.

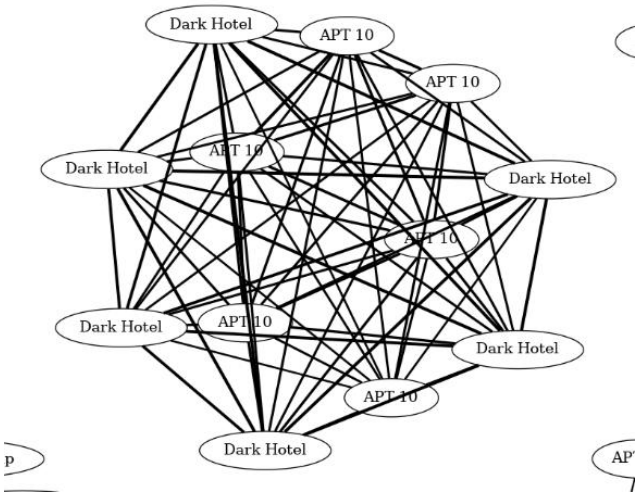

Fig. 8. Close up of IAT network graph.

In contrast to Fig. 6 from the string comparison experiment, Fig. 8 shows that in the IAT network graph, there are overlaps in IAT values for malware from different APT groups. This example demonstrates that there are overlapping attributes between malware from two different APT groups, which are grouped based on attributed threat actors.

C. Strings and Import Address Table Similarity Comparison

The similarity comparison scenario compares features from Dataset 2 (2023) and Dataset 2 (2022) with features collected from APT malware in Dataset 1. In this scenario, the strings and IAT attributes extracted from Dataset 2 are compared with the corresponding strings and IAT attributes extracted from malware samples of 12 APT groups in Dataset 1.

The similarity comparison of 596 samples from Dataset 2 (2023) with 2,887 samples from Dataset 1 took 24 minutes and 19 seconds, resulting in 1,720,652 similarity comparisons. A summary of the results is shown in Table VII.

TABLE VII. SUMMARY OF SIMILARITY COMPARISON RESULTS FOR DATASET 1 AND DATASET 2 (2023)

Similarity Comparison	Greater than 0.8	Greater than 0.5	Lower than 0.5	Lower than 0.2
Strings	0	121	1,720,531	1,715,434
IAT	9643	33673	1,684,723	1,472,266

The results of the string similarity comparison show that no Jaccard Index value exceeds 0.8. However, further examination of the results reveals that 28 samples have a Jaccard Index value greater than 0.6, with some samples exceeding 0.5. The outcome of the string similarity comparison is presented in Fig. 9.

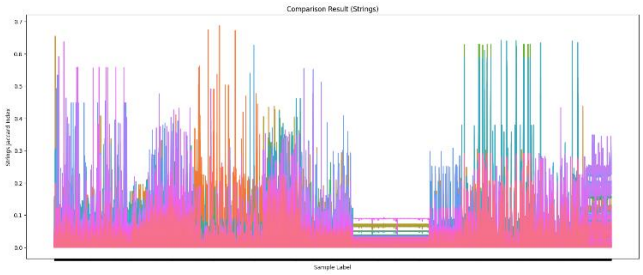

Fig. 9. Similarity comparison result line graph (Strings).

Fig. 9 provides an overview of the string similarity comparison results. The graph shows that, out of the 1,720,652 similarity comparisons performed, none of the Jaccard index values exceed 0.7. Since the Jaccard Index values in the results are below the set threshold, it is likely that there are no significant similarities between the malware in Dataset 2 (2023) and Dataset 1.

A different result was obtained for the IAT similarity comparison, with 9,643 samples having a Jaccard Index value greater than 0.8, as shown in Table VII and represented in Fig. 10.

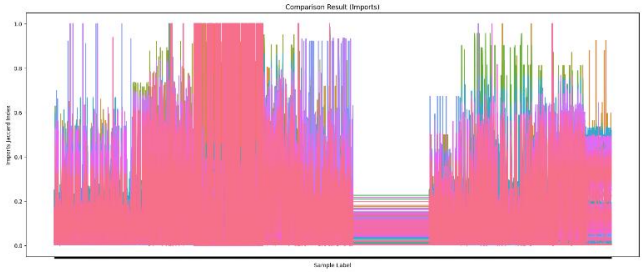

Fig. 10. Similarity comparison result line graph (IAT).

Fig. 10 provides an overview of the 1,720,652 IAT similarity comparison results. A correlation of 9,643 samples that scored a Jaccard Index higher than 0.8 is highlighted in the IAT network graph shown in Fig. 11.

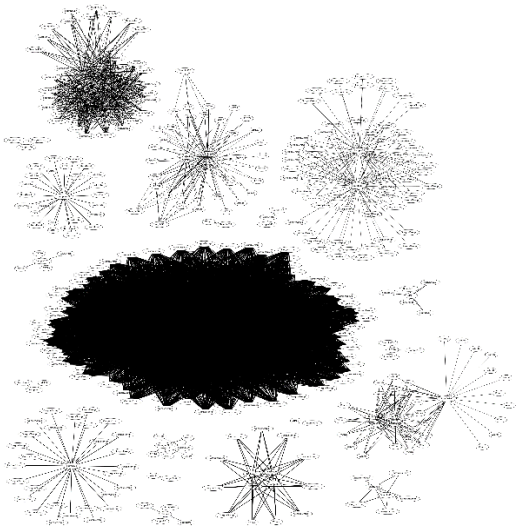

Fig. 11. IAT network graph.

Fig. 11 depicts the results of the IAT comparison between Dataset 2 (2023) and Dataset 1. The IAT network graph shows multiple correlations. One of the correlations identified is shown in Fig. 12, which provides a close-up of the IAT network graph from Fig. 11.

Fig. 12. Close up IAT network graph.

Fig. 12 shows that Sample 160, Sample 161, and Sample 162 are correlated with malware attributed to APT 10 and APT 28, based on the IAT similarity comparison. Additionally, Sample 368 and Sample 371 are correlated with malware identified as being used in APT 28 malicious operations. This suggests that, since the results scored higher than 0.8, the IAT attributes for these samples overlap with those of APT 10 and APT 28 malware.

The experiment continued with the similarity comparison of 3,446 samples from Dataset 2 (2022) with 2,887 samples from Dataset 1, which took 2 hours, 52 minutes, and 45 seconds. This resulted in 9,948,602 similarity comparisons. A summary of the results is shown in Table VIII.

TABLE VIII. SUMMARY OF SIMILARITY COMPARISON RESULTS FOR DATASET 1 AND DATASET 2 (2022)

Similarity Comparison	Greater than 0.8	Greater than 0.5	Lower than 0.5	Lower than 0.2
Strings	4	299	9,948,301	9,901,641
IAT	48,110	196,401	9,741,018	8,380,710

Table VIII shows that for the string similarity comparison, 299 samples scored above 0.5, and four samples scored above 0.8. The results of the string similarity comparison are represented in Fig. 13.

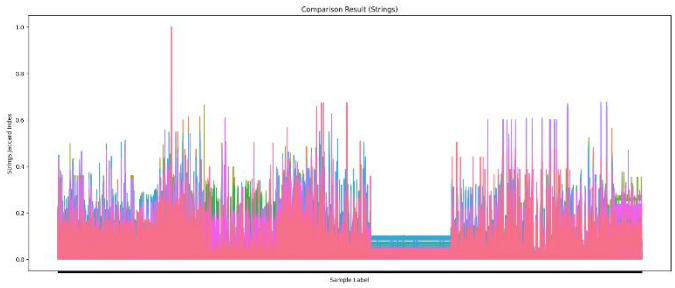

Fig. 13. Similarity comparison result line graph (Strings).

Based on Fig. 13, it is clear that there is a single instance where the Jaccard Index value is 1.0. The results of the line graph for the IAT similarity comparison are shown in Fig. 14.

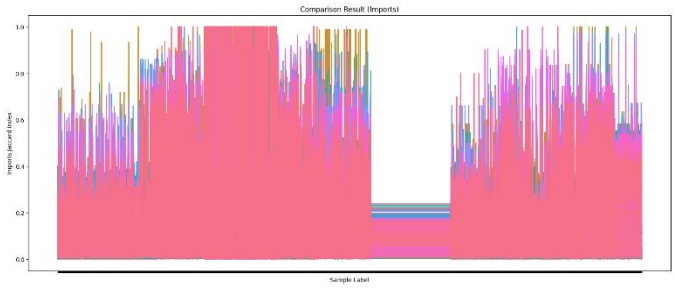

Fig. 14. Similarity comparison result line graph (IAT).

Fig. 14 depicts the visualisation of the results for 48,110 samples with Jaccard Index values greater than 0.8 in the IAT similarity comparison. We then further investigate the results from Table VIII and Fig. 13 to better understand the findings. The 4 samples with Jaccard Index values greater than 0.8 for the string similarity comparison are filtered from the others. The results for the string similarity comparison above 0.8 are shown in Table IX.

TABLE IX. STRINGS SIMILARITY COMPARISON RESULT FOR DATASET 1 AND DATASET 2 (2022)

c9d5dc956841e000bfd8762e2f0b48b66c79b79500e894b4efa7fb9ba17e4e9e	Sample3063	c9d5dc956841e000bfd8762e2f0b48b66c79b79500e894b4efa7fb9ba17e4e9e	APT10	1.0	1.0
c9d5dc956841e000bfd8762e2f0b48b66c79b79500e894b4efa7fb9ba17e4e9e	Sample3427	c9d5dc956841e000bfd8762e2f0b48b66c79b79500e894b4efa7fb9ba17e4e9e	APT10	1.0	1.0

Table IX lists the four samples for which the Jaccard Index values for strings are greater than 0.8. Observations from both the string and IAT similarity comparisons show that the Jaccard Index obtained is high, with a score of 1.0. This indicates that Sample 243, Sample 809, Sample 3063, and Sample 3427 exactly match APT10 malware, which has the hash"c9d5dc956841e000bfd8762e2f0b48b66c79b79500e894b4efa7fb9ba17e4e9e". This correlation is also reflected in the strings network graph shown in Fig. 15.

Fig. 15. Correlation identified in strings and imports network graph.

Based on the correlation shown in Fig. 15, a relationship between APT 10 malware and Sample 809, which has the hash "fa7eee6e322bfad1bb0487aa1275077d334f5681f0b4ede0ee784c0ec1567e01," is identified. Since Sample 243, Sample 3063, and Sample 3427 have the same hash as the APT 10 malware, they are not shown in the network graph in Fig. 15. This also explains the result obtained in Fig. 13, which indicates the similarity between APT 10 malware and those samples. Therefore, only the correlation of Sample 809 to APT 10 malware, based on the string similarity comparison, is shown, as only Sample 809 has a different hash. This suggests that the incident involving Sample 243, Sample 809, Sample 3063, and Sample 3427 is likely linked to APT 10, since these samples share similar attributes with malware already attributed to this APT group, which is believed to be linked to China.

Based on the information obtained, these findings can be used for CTI (Cyber Threat Intelligence) purposes. The report accompanying Dataset 2 from Vxunderground states that Sample 243 is Nbtscan, discovered by Avast; Sample 809 is NBTScan, discovered by Symantec; Sample 3063 is a NetBIOS scanner, discovered by Trend Micro; and Sample 3427 is F01A9A2D1E31332ED36C1A4D2839F412, discovered by Kaspersky, where only the MD5 value is provided in the IOC section. All of these reports attribute the samples to APT groups possibly linked to China, such as Mustang Panda and Earth Lusca. Therefore, the analysis and results obtained in this research provide a valid correlation.

By knowing that the malware found is possibly attributed to a specific APT group, organisations can better prepare to defend against the threat. For example, based on our results, if the sample found in an organisation is linked to APT 10, threat hunting efforts can focus on looking for IOCs (Indicators of Compromise) and activities associated with APT 10 or related APT groups, based on past incidents involving those groups. Our research demonstrates how string and IAT attributes can be used in similarity comparison scenarios, with extracted features being correlated to the threat actor through visual information presentation.

V. CONCLUSION

In general, the enhanced APT malware analysis approach extracts attributes from PE files and uses these to correlate with threat actors. This helps identify the origin of malware through the Jaccard Index, a similarity comparison technique used to establish threat actor correlations. The information

obtained can be leveraged to develop countermeasures against cyber threats. The development of additional malware analysis systems and experiments performed in this research includes technical discussions and examples to deepen understanding of the formulated APT malware analysis approach. This solution aims to assist cybersecurity practitioners and researchers in making informed decisions by providing actionable insights and a comprehensive perspective on cyber-attacks, based on the analysis of artefacts from APT groups.

Our experiment identified correlations between four samples and malware attributed to APT 10. Our analysis of the results also validates the findings obtained during the experiment. The enhanced APT malware analysis approach, the malware analysis environment, and the experimental scenarios developed in this research provide a foundation for discovering threat actor correlations. Our work provides a foundation for correlating malware with the threat actor, and the malware analysis approach can be used in designing other experimental scenarios.

Extending the experimental scenarios is one possible avenue for future work. Developing additional scenarios would uncover more insights from the APT malware dataset. Additionally, the malware analysis environment could be improved by using hardware with higher specifications, which would enable faster analysis, and by incorporating tools that are more preferred or offer better functionality.

Another direction for future work is refining the dataset used, or adopting a different dataset that is better suited to the experiment. Our research used Dataset 1, which, although relatively outdated, is well-structured, making it easier to label samples with the attributed threat actor. Moving forward, we plan to use Dataset 2, which is more recent but requires additional effort for labeling. If publicly available datasets were better structured or properly labeled, the sample analysis process would be much easier, and the labeling step would be significantly streamlined.

Apart from that, other similarity comparison techniques could be explored for future work, incorporating AI—such as machine learning or deep learning algorithms—into the approach. Our current work, using the Jaccard Similarity Index, aims to conduct a preliminary analysis of the dataset and obtain results that will help develop the malware analysis approach with similarity comparison techniques, as well as design the malware analysis environment. Both the enhanced approach and the malware analysis environment are integral for analysing APT malware to extract information for identifying the threat actor.

ACKNOWLEDGMENT

This research was fully funded by the Ministry of Higher Education (MOHE) through Fundamental Research Grant Scheme (5F511) awarded to Suriayati Chuprat, Universiti Teknologi Malaysia.

Usability Heuristic Evaluation of Mobile Learning Applications Based on the Usability Design Model for Adult Learners

Amy Ling Mei Yin[1], Ahmad Sobri B Hashim[2], Mazeyanti Bt M Ariffin[3]
Department of Computing and Information Technology, Tunku Abdul Rahman University of Management and Technology (Perak Branch), Perak, Malaysia[1]
Department of Computer & Information Science, Universiti Teknologi PETRONAS, Perak, Malaysia[2, 3]

***Abstract*—Adult ownership of mobile devices has exploded over the past few years, and smartphones and tablets have become vital for communication, productivity, entertainment, and learning. Some common problems adults face are that they find it difficult to use new technology-based apps because many devices are small. Tasks on new technology-based apps take longer to complete. Therefore, the usability design model for adult learners has been proposed. The objective of this study is to evaluate the usability design model for adult learners and whether the applications containing the model components will affect the satisfaction of adult learners. The evaluation was based on the heuristics guidelines by Nielsen and has been modified and mapped with the seven components in the model. Two existing mobile learning (m-learning) applications (Duolingo and Lingualia) from the Play Store have been chosen for this evaluation. The results indicate that Duolingo has an overall satisfaction mean score of 4.38 compared to Lingualia, where the score is only 2.43. Duolingo meets most of the model's criteria and can score a higher satisfaction mean score. This indicated that the seven components play important roles in contributing to satisfaction among adult learners.**

Keywords*—Usability design model; mobile learning; adult learners; heuristic evaluation

I. Introduction

Mobile learning (m-learning) is quite popular in today's educational world, and many scientists have recognized the potential of mobile technology to enhance learning. The continuous and rapid growth of mobile technology has transformed the traditional education setting into a more accessible, flexible, and personalized learning mode. Such learning benefits adult learners the most because they often face unique challenges, such as time constraints, where they need to balance their work and family commitments.

Moreover, m-learning applications can potentially enhance adult students' learning experience by providing timely, 'just-in-time' resources relevant to their particular needs and lifestyles. In the case of adult learners, the usability of these applications is critical to their design and development. If the applications are not easy to use, unintuitive, or inappropriate to their cognitive and physical needs, it can cause them to struggle to use m-learning. Adults face a number of challenges when using new technologies. People frequently lose various cognitive abilities as they age. Cognitive barriers, such as slower information processing and memory recall, cause difficulties with complex systems and unfamiliar digital interfaces. As a result, using technology or interfaces can be more difficult for older adults, especially when they require adjustments to their perception, movement, or thought processes [1]. Usability Heuristic Evaluation (HE), a recognized method in user-centred design, serves as an effective framework for evaluating and enhancing the user experience of m-learning applications.

The objective of this study is to evaluate the usability design model for adult learners and whether the applications containing the model components will affect the satisfaction of adult learners. The evaluation was based on the heuristics guidelines by Nielsen and has been modified and mapped with the seven components in the model. Two existing m-learning applications (Duolingo and Lingualia) from the Play Store have been chosen for this evaluation.

II. Literature Review

A. Mobile Learning

Note that m-learning describes education using a mobile device. The idea encompasses "gaining knowledge in various environments, through social and content interactions using personal electronic devices" [2]. Furthermore, m-learning lets learners join in informal learning anytime and anywhere. It gives students control over their learning by offering access to different multimedia materials and chances for group learning and research [3]. Other than that, m-learning allows learners to do many tasks at different places and times. It provides educational content to help learners learn outside the classroom and boost their advanced thinking abilities [4].

Abduljawad and Ahmad [5] study the evolution and integration of m-learning into educational practices. Mobile learning faces challenges wherein teachers do not understand how to utilize mobile technology; security and privacy issues might arise because of connectivity restrictions; and the perfection of teachers using mobile devices creates some technical deficiencies. More problems related to the need to detail the development of efficient pedagogical content strategies and create comprehensive user interfaces. Mobile applications are increasing day by day and the software that used to rule earlier is getting outdated which is leading to compatibility issues. In the end, the study depicts m-learning as

an innovative, accessible, and flexible way to advance learning opportunities in the education system.

Olga Viberg & Åke Grönlund [6] study focuses on the design requirements for mobile applications in second language learning within online distance education. It highlights that students frequently use personal mobile technologies for self-initiated learning. Besides that, the study includes the challenges and strategies students face when using technology for language learning in both formal and informal educational settings. Furthermore, it emphasizes the importance of technology in supporting successful language learning processes and the need to provide instructional materials that are compatible with students' technological habits. Overall, the study provides useful insights into the use of mobile technology in language learning, as well as its impact on course design and teaching methodologies.

B. Usability for Adult Learners

Finger gesture interaction with multi-touch surfaces has become more common. Frustrations with using touchscreen technologies are not only reported by older users, but younger groups also find difficulties, though they are typically better at adapting to technological changes [7]. Therefore, movements appropriate for older users may differ significantly from those designed for younger users [8]. Pointing and sliding (scrolling) tasks on the touchscreen, as well as the small size of the buttons, were more difficult for older adults than younger adults [9].

As they age, several people experience decreased ranges and levels of skills like vision, hearing, haptics, cognition, and adeptness, which may negatively impact their use and interaction with user interfaces [10]. Common user interface issues include misinterpretation of general icons, long task completion times, poor task efficiency, errors when reading text due to small font size and poor colour distinction, and confusion with output inputs [11-13]. Although this is usually the case, improving the design to enhance usability for older learners can also improve usability for other user groups [14].

C. Heuristic Evaluation

Nielsen and Molich developed HE, which involves a small group of experts reviewing an interface based on key usability principles. At least three to five evaluators are usually recommended, as this group can identify approximately 65% to 75% of usability issues [15, 16]. Heuristic tests are typically performed during development, but running them on an operational, deployed system can improve how well it detects usability issues [17-19]. According to Nielsen, HE is quick, cost-effective, and simple because it relies on knowledgeable domain experts who efficiently assess usability [19, 20].

D. Duolingo

In November 2011, Cambridge Mellon University's Luis Von Ahn and Severin Hacker released the free language learning app Duolingo. This app provides 68 different language courses in 23 languages, including French, German, Spanish, Dutch, and others, to help learners learn and acquire a foreign or second language. The learning interface is easy to use because it feels and looks like a game. In addition to dictation and written learning, Duolingo provides speaking practice for users who have attained a specific level. Applications for iOS, Android, and Windows Phone are made to improve users' ability to communicate anywhere, at any time. Furthermore, Google Play presented Duolingo with the esteemed Best of the Best 2013 award [21].

E. Lingualia

Lingualia-Learn Languages [22] is an educational app created in 2012 by Javier Sanchez, Roberto Zamora, and Sergio Blanco. Leaner has been able to download the APK since December 2013. Lingualia, a novel and cutting-edge language learning method based on artificial intelligence, adapts to students' interests, motivations, progress, and free time. In addition to all of this information, it can tailor students' learning to meet specific needs. Lingualia allows students at all skill levels (beginner, intermediate, and advanced) to learn Spanish or English. Using cutting-edge technology, educators developed all of the multimedia content. Lingualia contained more than 400 language lessons, 25,000 pronunciation audios, 10,000 vocabulary words, pronunciation guides, grammar, and 100 online language practice exercises.

III. Components in the Usability Design Model for Adult Learners

The usability design model for adult learners includes seven components, as shown in Fig 1: usability layout, navigation, content, a touch gesture, andragogy, and scaffolding.

Fig. 1. Usability design model for adult learners.

A. Usability

The concept of usability has been defined in several ways, and providing teaching and learning services through mobile devices is one of the required aspects. Usability focuses on how computer-related systems communicate with humans [23, 24]. In this study, usability refers to suitable usability for adult learners concerning inability and motor skills.

B. Layout

Application layout refers to the device structure that users see. The consistent page layout will allow users to quickly understand how the application works [23, 25]. Aside from that, all application interfaces must have a simple and consistent

layout that adapts to any smartphone or tablet screen size and is easy for the user to manage.

C. Navigation

Navigation is essential in managing the learner's mood while interacting with the program. Using the navigation feature, learners are able to easily move around the application, making it simpler for them to go from one page to another. Complicated navigation can present challenges for users when using the application. It is not advisable to use complex navigation systems [26]. By including clear navigation in the application, users will have an easier time learning the application process. Hence, having a fixed menu bar on every application interface is important.

D. Content

Learning activities would take place on mobile. The small screen size of mobile devices makes it difficult for users to read lengthy content [27]. Content should be compact, concise, and straightforward. Mobile devices have limited screen space, so a simple design allows learners to access information without scrolling or zooming excessively. Simplifying content can reduce cognitive load and allow learners to focus on learning objectives. Besides that, choose bright and colourful colours to create the content, making the icons appealing.

E. Touch Gesture

Pointing and sliding (scrolling) tasks on the touchscreen, as well as the small size of the buttons, were more difficult for older adults than younger adults. Older adults may find certain gestures, such as pressing and holding, sliding, pinching/spreading, and rotating, too difficult [8, 28, 29]. However, tap and swipe gestures are recommended for older users as they are easy to use and understand [28, 29]. Therefore, it is important to include appropriate touch gestures for adult learners within the application to ensure that they can use it without becoming stressed or demotivated.

F. Theory of Andragogy

In the late 1960s, Malcolm Knowles introduced the term "andragogy" to define his approach to adult education [30]. Adult learning theory is important in designing instructional material to ensure the model suits the adult learner. Andragogy theory has been applied in global studies, resulting in literature translations in multiple languages. This approach to andragogy is effective for individuals of all ages, genders, and nationalities [31].

1) The learner needs to know why they need to learn something: Adults need to understand why they are learning something. They will feel more driven when they know what they should pick up. It can help them grasp the point of the lesson by zeroing in on what they want to learn or how they plan to use it in their lives [32]. Therefore, it is important for the learners and facilitator to communicate with each other. To ensure learners understand why they need to learn something, facilitators must give feedback about how useful the ongoing learning is throughout the course.

2) The learner (self-concept): Adult learners learn new information and enhance their current knowledge more efficiently when motivated to investigate a subject independently. This could be in the form of individual or group projects that require only minimal input from the teacher. The self-concept learner plays a key role in determining performance in a distance learning setting [33]. Hence, collaborative activities that support and encourage adult learners are recommended. Collaborative activities allow adults to showcase their skills and are consistent with the principles of andragogy [34].

3) Adult learning experiences: Every adult has accumulated a lifetime of experiences and may desire to apply their expertise and receive recognition for their knowledge. Examples of learning activities like case studies, group projects, reflective tasks, and short writing exercises can help learners utilize their existing knowledge through sharing and reflection. They are more likely to remember what they have read when they connect it to their own experiences [32, 35]. When learners connect their lives to their reading, they are more likely to remember what they read. As a result, it is important to link assignments or projects to real-life experiences.

4) Readiness to learn: Knowles [30] states that adults need to learn to cope more satisfactorily with real-life tasks or problems. This showed that adults were willing to learn as long as it was connected to their social development. If they realize that certain new learning opportunities can enhance their skills, they are more inclined to push themselves to acquire additional knowledge. Social networking platforms and digital collaboration tools aid adults in integrating this belief into their final projects. Hence, designing tasks that prompt adult students to utilize blogs, wikis, or other social platforms can assist them in not just expanding their social circle but also in working together with individuals who have similar interests. Socializing is essential for connecting users to social networking platforms.

5) Orientation to learn: Adults focus on solving problems when they learn. Learning is based on real-life scenarios or job-related situations rather than specific academic topics. Highlighting how the topic will address issues commonly faced by adult learners in their personal or professional lives through the use of real-life situations is crucial [32]. Using real-life situations related to their life makes it more effective. Media is the most effective way to provide a tangible example or scenario that individuals may encounter in real life.

6) Motivation to learn: Knowles believed that adults were most motivated to achieve their educational goals when acknowledged and appreciated for their contributions to the class [36]. Increased job satisfaction, self-esteem, and quality of life are critical in motivating adults to learn [32]. To motivate adults to learn, the learning environment should encourage active participation. Games, quizzes, and multimedia have all been used effectively to boost learner motivation [35]. Recognizing learners' contributions to the course will boost their self-esteem, motivating them to succeed in their coursework [37]. Therefore, it is important to let them know a reason for every activity, assessment, or e-learning module they

need to complete and acknowledge them after they contribute their effort.

G. Scaffolding

Scaffolding divides complex tasks or competencies into smaller components that will be completed one at a time. This reduces the stress and difficulty of the task while also allowing adult learners to track their progress. Scaffolding is especially important for first-year adult students who may require additional assistance as they transition to an academic setting [38].

IV. Comparison of Mobile Learning Applications Based on the Usability Design Model

Duolingo and Lingualia, two different m-learning apps available on the Play Store, were compared. Both m-learning apps provide language courses based on the m-learning model's seven components: usability, layout, navigation, content, touch gesture, andragogy, and scaffolding for adult learners.

In this study, usability refers to how well the system works for adult learners. When developing m-learning, it is necessary to consider adult learners' motor skills and limitations. It is possible that movements designed for younger users will not work well for older users. The term layout refers to a m-learning interface that is simple and consistent. A simple and consistent layout is easier to control than a complicated layout, which confuses the user. Duolingo provided the user with guidance information that was simple, consistent, and understandable. Despite the fact that a simple and consistent layout is easier for users to control, Lingualia's mobile application is overly simple and lacks information.

Navigation is defined as simple, consistent, and stagnant. Duolingo's navigation design is straightforward, simple, consistent, and stagnant. Each application page has a fixed size, colour, and location. However, in Lingualia, the navigation was designed as a kebab menu (hidden menu), and not all pages included the menu. Aside from that, the Lingualia mobile app provides less navigation information. Duolingo offers simple, accessible, and concise content design. The bright and colourful colours used in the content design make for attractive icons. The information displayed on the screens is simple to view, read, and comprehend, unlike Lingualia, which uses plain colours and simple icons to design its content.

Touch gestures refer to using appropriate touch gestures with an adult learner. The majority of Duolingo and Lingualia's touch gestures are designed to allow users to interact with the mobile application by tapping. It is simple to use and consistent, and the button size is suitable for finger touch for adult learners. However, some of Lingualia's button designs are small compared to Duolingo's.

Andragogy is made up of six assumptions. For the first assumption, the learner needs to know why they need to learn something. Duolingo offers basic information about outline contents, whereas Lingualia does not. The second assumption is that learners are motivated to learn. Adult learners are motivated to learn when there is a clear connection between the information provided and their personal experiences. Using a game that is relevant to their lives and setting a reward for success can help the adult become more motivated. In contrast to Lingualia, Duolingo has set the reward if the user successfully completes the level. Even though Lingualia offers a learning game, the user does not receive any rewards.

The third assumption in andragogy theory is the learner (self-concept), which states that adult learners prioritize their learning and do not rely solely on their teachers. The use of mobile applications should be learner-focused. Both Duolingo and Lingualia were created to break down learning into manageable portions that can be completed in a short time, with logical stopping and starting points. The use of mobile applications is extremely convenient, especially in terms of timing, as adult learners can direct their learning from anywhere and at any time.

The next assumption is adult learning experiences, in which adult learners enjoy sharing their experiences with others. Duolingo provided a forum where users could share their experiences and connect with friends using their Facebook accounts or email addresses. In these terms, Lingualia did not provide a user interaction or sharing platform.

The fifth assumption is readiness to learn. To meet this assumption, a content syllabus relevant to real-world scenarios and an outline of the learning objectives would be useful. Both Duolingo and Lingualia offered activities that were applicable to real-world situations. The final assumption is an orientation to learn. Adults prefer problem-based learning relevant to real-world situations, such as connecting activities or tasks to real-life scenarios. Duolingo and Lingualia included a game inspired by a real-life situation in this section. Duolingo, unlike Lingualia, provides a simple explanation of how the learner will apply the course material in their daily lives.

Scaffolding is an instructional strategy in which the learner receives external support in person or through artifacts to achieve learning goals and tasks within the zone of proximal development until the learner is able to perform the task independently. Duolingo provided clear instructions and effectively conveyed information when using the mobile application, whereas Lingualia provided less instruction.

V. Methodology

This study applied HE based on the usability engineering methodology. The heuristics guidelines were modified and mapped to the seven components. The goal of this study is to evaluate the existing m-learning design using Nielsen's heuristics guidelines to determine whether the m-learning application containing the model's components is able to give satisfaction to adult learners.

A. Experts

In this study, seven experts are involved in evaluating the m-learning application, which is acceptable, as suggested by Nielsen [17], where the minimum number of experts can be three. Table I presents the details of the experts involved in the evaluation process. Fig. 2 illustrates the pie chart of the experts' total percentage of years of service experience.

TABLE I. EXPERT DETAILS INVOLVED IN THE EVALUATION

Experts	*Position*	*Expertise*	*Year of Experience*
Expert 1	Mobile App Developer	Mobile Application, Information Technology, Human-Computer Interactions	Less than 5
Expert 2	Lecturer	Mobile Learning / App; Information Technology	6 – 10 years
Expert 3	Lecturer	Information Technology	More than 11 years
Expert 4	Lecturer	Information Technology	6 – 10 years
Expert 5	Lecturer	Information Technology	More than 11 years
Expert 6	Lecturer	Mobile Learning / App; Information Technology; E-Learning & Education	More than 11 years
Expert 7	Lecturer	Mobile Learning / App; Data Science and Machine Learning	6 – 10 years

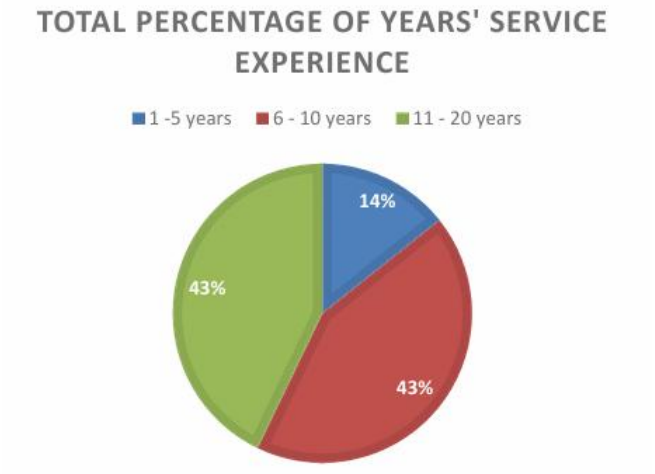

Fig. 2. Total percentage of years of service experience.

B. Questionnaire

The questionnaire for evaluating the m-learning application was based on HE. Nielsen's heuristics guidelines were chosen, modified, and mapped to the seven components based on how appropriate they are for this study to ensure that the m-learning application contains the model's components. Table II presents the heuristic rules mapped to the model's seven components. Questionnaires were designed to elicit responses using a five-point Likert Scale: 1 = strongly disagree, 2 = disagree, 3 = neutral, 4 = agree, and 5 = strongly agree.

TABLE II. HEURISTIC RULES MAPPED WITH THE COMPONENTS IN THE MODEL

No	*Heuristic Rules*	*Components*
1.	User control and freedom	Usability, Navigation, Content, Touch Gesture
2.	Error prevention	Scaffolding
3.	Consistency and standards	Layout, Navigation, Touch Gesture
4.	Aesthetic and minimal design	Layout, Navigation, Content, Touch Gesture
5.	Suitability	Usability, Layout, Navigation, content, touch gesture
6.	Help and Documentation	Andragogy
7.	User Satisfaction	

C. Evaluation Process

The first step in the evaluation process was to identify the number of the expert, which was then reached via email or phone call. An appointment was made with those who agreed to participate in the evaluation process. The experts entered their background information and began to evaluate the mobile application using the provided questionnaire and description of how the procedure was carried out. After the expert had completed the evaluation process, the researcher analyzed the findings and arrived at the results and conclusion.

VI. RESULT AND DISCUSSION

Duolingo has a mean score of 4.46 for user control and freedom, compared to Lingualia's 2.91. Duolingo's design enables adult learners to manage the application easily. Duolingo outperforms Lingualia in error prevention with clear and easy-to-understand instructions, where the mean score is 4.45 for Duolingo and 2.39 for Lingualia. Table III lists the result of the mean score for Duolingo and Lingualia.

TABLE III. RESULT OF THE MEAN SCORE FOR DUOLINGO AND LINGUALIA

No	*Heuristic Rules*	*Duolingo*	*Lingualia*
1.	User control and freedom	4.46	2.91
2.	Error prevention	4.45	2.39
3.	Consistency and standards	4.29	3.00
4.	Aesthetic and minimal design	4.48	2.45
5.	Suitability	4.20	2.43
6.	Help and Documentation	4.27	2.16
7.	User Satisfaction	4.38	2.43

Consistency and adherence to standards in application development help create user-friendly experiences, reducing confusion and improving the ease of learning. Duolingo's design is consistent and standard, and the bar chart portrays that Duolingo's mean score is higher than Lingualia's, where the mean score is 4.29, while Lingualia's score is 2.90. Aesthetics play an important role in the perception and memory of application designs.

In addition, for minimal, it maximizes utility and usability by allowing users to find what they need. In other words, interfaces should not include irrelevant or rarely used information. Duolingo scored 4.48 on aesthetic and minimal design, while Lingualia scored 3.00. Duolingo is better suited for adult learners, with a score of 4.2 versus Lingualia's 2.43. Duolingo earns a 4.27 rating for its comprehensive support and documentation resources. Lingualia has fewer guidelines and a lower score, with a mean score of 2.16. Fig. 3 shows that

Duolingo has a higher overall satisfaction mean score of 4.38 than Lingualia, which is 2.43. Duolingo meets most of the model's criteria and offers higher user satisfaction. According to the study's findings, it shows that the user satisfaction is higher with m-learning applications that include a greater number of these model components. Applications with fewer components, on the other hand, may fall short of meeting the diverse needs of adult learners. The findings also highlight the significance of including comprehensive model components during the design phase of m-learning applications.

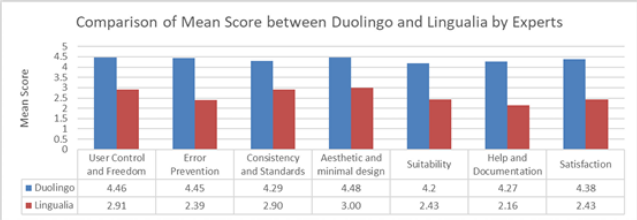

Fig. 3. Comparison of mean score between duolingo and lingualia.

VII. Conclusion

This study compares two different m-learnings available in the Play Store, Duolingo and Lingulia. The purpose of this study is to evaluate the existing m-learning design based on Nielsen's heuristics guidelines. The heuristics guidelines have been modified and mapped with the seven components in the model to validate whether the m-learning application containing the model's components can give adult learners satisfaction. Moreover, the results indicate that the m-learning application containing the component in the model is able to score higher satisfaction to adult learners compared to m-learning applications that contain fewer model components. This study will contribute to the growing body of work on m-learning by offering practical insights for design and development teams and educators who are trying to optimize usability with adult learners.

Acknowledgment

We want to thank Tunku Abdul Rahman University of Management & Technology and the experts for their willingness to be involved in this study. This research was funded by Tunku Abdul Rahman University of Management & Technology (TAR UMT).

Abstract*—The significant use of Unmanned Aerial Vehicles (UAVs) in commercial and civilian applications presents various cybersecurity challenges, particularly in detection and authentication. Unauthorized UAVs can be very harmful to the people on the ground, the infrastructure, the right to privacy, and other UAVs. Moreover, using the internet for UAV communication may expose authorized ones to attacks, causing a loss of confidentiality, integrity, and information availability. This paper introduces radar-based UAV detection and authentication using Micro-Doppler (MD) signal analysis. The study provides a unique dataset comprising radar signals from three distinct UAV models captured under varying operational conditions. The dataset enables the analysis of specific features and classification through machine learning models, including k-nearest Neighbor (k-NN), Random Forest, and Support Vector Machine (SVM). The approach leverages radar signal processing to extract MD signatures for accurate UAV identification, enhancing detection and authentication processes. The result indicates that Random Forest achieved the highest accuracy of 100%, with high classification accuracy and zero false alarms, demonstrating its suitability for real-time monitoring. This also highlights the potential of radar-based MD analysis for UAV detection, and it establishes a foundational approach for developing robust UAV monitoring systems, with potential applications in aviation military surveillance, public safety, and regulatory compliance. Future work will focus on expanding the dataset and integrating Remote Identification (RID) policy. A policy that mandates UAVs to disclose their identity upon approaching any territory, this will help to enhance security and scalability of the system.

Keywords*—Authentication; detection; cybersecurity; Micro-Doppler; radar; Unmanned Aerial Vehicle (UAV)

I. Introduction

Unmanned Aerial Vehicles (UAVs) are rapidly gaining momentum across various sectors where information technology is crucial in enhancing efficiency and operations [1]. The popularity of UAVs is due to their cost-effectiveness, ease of use, and potential to streamline business processes [1]. UAVs are being deployed in various industries, including transportation, agriculture, surveillance, and defense, offering unprecedented flexibility and operational efficiency. However, this widespread adoption is not without challenges, as UAVs increasingly face cybersecurity threats. These threats pose risks to the integrity of UAV operations and the safety of the data they collect and transmit [2].

Cybersecurity is critical for the safe operation of UAVs. A breach in security can endanger ground personnel, infrastructure, personal privacy, and the UAVs themselves. Since UAVs rely heavily on internet connectivity, they are vulnerable to threats compromising confidentiality, integrity, and availability [3]. Confidentiality may be violated through data interception, physical tampering, eavesdropping, or social engineering attacks. Integrity is at risk from data tampering and hacking, while availability can be disrupted by interference, jamming, denial-of-service attacks, or natural events [3].

UAV detection is identifying and tracking UAVs using various technologies, such as radar, cameras, or acoustic sensors among others. It plays a crucial role in ensuring the safety and security of airspace by monitoring unauthorized and potentially harmful UAV activity. The detection and classification of UAVs can be challenging, and various technological approaches offer unique advantages and limitations [4].

1) Radar detection: This approach works by emitting radio waves (signals) that reflect off UAVs, allowing it to gather detailed information about the UAV's distance, speed, and movement patterns [4]. Radar's ability to operate in all weather conditions and low-visibility environments, such as during rain, fog, or nighttime, makes it highly reliable [8]. It is particularly effective for long-range detection and can differentiate UAVs from other objects by analyzing their motion and size. This robustness and capability to detect small UAVs over large distances make radar an essential tool in security-critical environments [5].

2) Video detection: It relies on cameras and image processing algorithms to visually identify UAVs. It excels in clear visibility conditions, offering high-resolution images for accurate UAV identification and classification [4]. Video detection can work in real time, leveraging machine learning to enhance accuracy. However, its effectiveness diminishes in poor lighting conditions, such as nighttime or foggy environments, and it struggles to detect small UAVs at long distances [5]. Consequently, while video detection is valuable

in specific contexts, its dependence on favorable visibility limits its reliability.

3) Acoustic detection: It captures the unique sound signatures produced by UAVs, especially the noise from their propellers and motors [4]. The method uses microphones to monitor sound and can detect UAVs even when they are not visible. Acoustic detection is a cost-effective and straightforward solution for short-range detection, in quiet environments [5]. However, its range is limited, and it faces significant challenges in noisy environments, such as urban areas. In addition, it struggles to detect noiseless UAV models, making it less effective for comprehensive UAV detection over larger areas.

4) RF-Based detection: It monitors the communication signals transmitted between UAVs and their controllers [4]. This method is highly effective for detecting UAVs as soon as they begin transmitting signals, and it can provide valuable information about both the UAV and its operator [5]. However, RF-based detection is ineffective against fully autonomous UAVs that do not rely on RF signals or operate with encrypted communications. Moreover, its range is limited to the transmission distance of the UAV's signals, and it can be vulnerable to signal interference or jamming, reducing its reliability [5].

Among these methods, radar-based UAV detection is effective as it captures unique MD signatures generated by a UAV's rotating blades and motion. The radar signals analysis can detect, classify, and track UAVs in low visibility conditions, providing valuable information for security, surveillance, and air traffic management [5], [6]. Radar detection is preferred for its versatility and reliability. Unlike video, acoustic, or RF-based detection, radar is unaffected by visibility, background noise, or signal dependence. Its ability to detect UAVs over long distances and in all weather, conditions make it the most robust solution for UAV detection, in security and defense applications where continuous and reliable monitoring is essential [5], [6], [7]. Despites the radar's effectiveness, the existing systems struggle to identify specific UAV types using MD features or radar cross-section (RCS) characteristics. Furthermore, reliance on proprietary datasets limits the generalizability of findings and hinders benchmarking efforts. This shows the need for standard, and public available datasets to improve radar-based detection and authentication methods.

In light of this, this research focuses on developing an identity-based UAV detection and authentication system that leverages information on radar signal analysis. The system uses radar to analyze the UAV's signal through the MD effect, which reveals unique features of the UAV's rotor movements and structure. These unique MD radar features will help to authenticate the UAV's identity, ensuring that it matches the information and parameters of the known UAVs. Then, the proposed system employs the k-NN, Random Forest, and SVM to classify and authenticate UAVs based on the identified patterns in radar signal data. Furthermore, this research generates raw datasets for three distinct UAV models: DJI Matrice 600, DJI Matrice 300, and Phantom 4. The study offers an identity-based UAV detection, authentication, and classification model. The model handles detection and authentication in separate phases, while the combined model integrates both processes into a unified approach. The proposed model is compared with others to ascertain its efficiency and performance. This comparison underscores the advantages and limitations of each framework, demonstrating their applicability in real-world scenarios.

The research makes stride contributions to the field of UAV detection, classification, and authentication. These contributions include a novel radar-based dataset, generated through simulations of three UAV models (DJI Matrice 600, DJI Matrice 300, and Phantom 4), that can provide a foundation for advanced research in this domain. The study also develops a robust classification system employing machine learning algorithms (kNN, Random Forest, and SVM). The proposed model effectively detects and classifies UAVs and enhances authentication by comparing radar signal data with predefined UAV parameters. Furthermore, the performance of the proposed models is evaluated on the radar dataset, demonstrating improved detection accuracy and reliable classification and authentication.

B. Our Contributions

This research offers the following contributions:

1) A novel radar-based dataset is created through simulation using three UAV models (DJI Matrice 600, DJI Matrice 300, and Phantom 4). This dataset will be instrumental for future UAV detection, authentication, and classification research.

2) A classification system is developed using kNN, Random Forest, and SVM for UAV detection and classification. The framework compares radar signal data with the known UAV information and parameters for enhanced authentication.

3) The detection, classification, and authentication performances of the proposed frameworks are evaluated on the generated radar dataset. Detailed comparisons show that the proposed framework improves detection accuracy and achieves reliable classification and authentication.

II. Related Work

This section reviews the approaches and methodologies in UAV detection, emphasizing radar-based systems and machine-learning models for classification. A radar-based UAV detection method is proposed using the Empirical Mode Decomposition (EMD) algorithm to extract MD signals for identifying small UAVs [11]. The technique offers the advantage of isolating m-D features crucial for differentiating UAVs from other moving objects, decomposes signals into intrinsic mode functions (IMFs), and addresses mode-mixing challenges by analyzing the extrema distribution. The EMD algorithm distinguishes UAVs from birds or other objects based on their rotor blade signatures, making it highly effective even in noisy environments. In addition, the paper points that while the EMD algorithm effectively processes non-stationary signals, it also has limitations, such as susceptibility to noise and increased computational load, which may hinder its real-time application in practical UAV detection scenarios.

A. Radar Approaches, and Machine Learning Models UAV Classification

Ezuma et al. [9] presents a multistage system for detecting and classifying UAV controllers using radio frequency (RF) fingerprints in the 2.4 GHz band, even in environments with significant interference from Wi-Fi and Bluetooth devices. The system addresses the challenge of detecting UAV controllers in the presence of Wi-Fi and Bluetooth interference by first detecting RF signals using a Markov model-based Naïve Bayes algorithm, followed by interference detection and machine learning (ML) classification. The system extracts 15 statistical features from the UAV controller signals and achieves a classification accuracy of 98.13% using k-Nearest Neighbors (kNN) at 25 dB signal-to-noise ratio (SNR). Despite the effectiveness of the system, its limitation lies in distinguishing identical UAV controllers, such as pairs of DJI models, which slightly lowers accuracy due to signal similarity.

Meanwhile, a system proposes using Frequency Modulated Continuous Wave (FMCW) radar to detect and identify UAVs by analyzing their MD signatures [10]. It addresses the challenge of extracting MD signatures caused by the rapid rotation of UAV rotor blades, which introduces high-frequency variations in radar signals. The system proposes a new approach for studying MD signatures in UAVs and presents both simulation and experimental results to demonstrate the effectiveness of this method. The analysis showcases the ability of FMCW radar to capture fine-grained UAV motion details, allowing for more accurate UAV detection and identification. This work improves UAV detection in target-dense environments and shows the advantages of MD signature analysis for characterizing UAVs in real-time scenarios.

Similarly, a micro-motion model for detecting and identifying low-slow-small UAVs using radar systems is proposed [11]. The research focuses on the MD effects generated by the rotating blades of UAVs. It suggests a method to enhance detection performance by compensating for translational movement and employing an optimal demodulation operator for parameter estimation. The process improves the signal-to-noise ratio (SNR) and suppresses clutter, making it practical for detecting small UAVs even under challenging low-SNR conditions. The simulation and experimental results demonstrate the accuracy of the proposed technique in estimating MD parameters, which significantly aids in classifying UAVs based on their unique motion characteristics. This work is relevant for air defense systems identifying small, slow-flying UAVs based on radar signatures.

Besides, a study establishes a theoretical foundation linking the MD signatures and motion dynamics of small UAVs, focusing on analyzing the Doppler spectrum as a more efficient tool than joint time-frequency (JTF) images [12]. It explores how MD features, such as blade length, rotor rotation rate, and radial velocity, can be derived from the Doppler spectrum, aiding in detecting and classifying small UAVs. The study demonstrates the correlation between the spectral distribution and UAV physical specifications through simulation and measured data. Compared to JTF images, the Doppler spectrum provides significant computational and storage benefits while delivering accurate MD signatures. However, the study acknowledges challenges in detecting chopping frequencies and resolving smearing effects caused by multiple rotors, especially in practical scenarios with complex UAV dynamics. Future work will focus on refining algorithms to address these issues for more reliable UAV detection and classification.

In another development, a study explores the use of machine learning for drone classification based on radar signals [13]. It details the creation of datasets through simulation, considering radar specifications and SNR ranging from 0 to 20 dB. Each dataset, with 1000 spectrogram samples per class and smaller validation sets, was used to train a Convolutional Neural Network (CNN). The CNN architecture, comprising convolutional layers, SoftPlus activation, instance normalization, dropout, and linear layers, was adapted for different radar pulse repetition frequencies (PRFs). The performance of the model was evaluated using the macro-F1 score, with results showing the X-band 2 kHz PRF radar outperforming the W-band radar, especially at lower SNRs. The study revealed that while the X-band radar achieved an F1 score of 0.816±0.011, it struggled with false alarms, particularly with noise being confused with the DJI Matrice 300 RTK drone. The model exhibited robustness to varying blade pitch and SNR values, maintaining performance with different pitch values and showing reduced effectiveness at lower SNRs. Future work aims to investigate the impact of various wavelengths, explore more complex CNN architectures, and validate models with real-world data, addressing the current model's limitations and extending its applicability.

Furthermore, a novel lightweight architecture presents the development of an MD-based detection method called DIAT-RadSATNet, a deep CNN (DCNN) designed for the detection and classification of Small UAVs (SUAVs) using MD signatures [14]. The method addresses the growing need for efficient SUAV detection in both defense and civilian applications. The proposed architecture is lightweight, with 40 layers and only 0.45 million trainable parameters, achieving a high classification accuracy of 97.3%. The study indicates the radar system's ability to classify various SUAVs, such as quadcopters and bionic birds, through field experiments and ablation studies, demonstrating superior performance compared to existing models. The DIAT-RadSATNet's lightweight design allows for real-time implementation with reduced computational costs. However, the study acknowledges limitations, regarding the potential challenges in detecting SUAVs under complex environmental conditions and the need for further testing in diverse operational scenarios to validate the system's robustness and scalability.

Rojhani et al. [15] introduced a novel deterministic data augmentation method for UAV classification based on MD radar signatures. The technique generates synthetic training datasets using a physical radar backscattering model, reducing reliance on extensive measurement campaigns. Compared to conventional random signal processing augmentation, the deterministic approach produces datasets that maintain the physical integrity of features, resulting in better generalization and reducing classification bias. The study focuses on classifying UAVs based on their number of motors using CNN, achieving an accuracy of 78.68% and outperforming conventional augmentation methods, which resulted in 66.18%

accuracy with significant class bias. The results suggest that the deterministic augmenter provides more reliable and effective training datasets, for radar-based UAV classification, and can be extended to other scenarios, such as human recognition and medical imaging. The research indicates the potential for scaling this method to produce diverse datasets without costly and time-consuming measurement campaigns.

Further, a novel approach for UAV classification using radar digital twins is presented by generating full-wave electromagnetic simulations [16]. A Multiple-Input Multiple-Output (MIMO) radar system is simulated using CAD models of various UAVs to create radar datasets that include Range-Doppler and MD information. The datasets train a machine learning classifier, a one-versus-rest Support Vector Machine (SVM), for UAV detection and classification. The simulations allow for generating radar datasets without the need for expensive, time-consuming measurement campaigns. The study demonstrates high classification accuracy (minimum 97%) in multi-UAV scenarios, showing that the digital twin framework offers a flexible and cost-effective solution for UAV detection and classification in various operational conditions.

Moreover, a review of radar-based drone detection, tracking, and classification techniques focusing on real-world data from 25 drone trials using the Gamekeeper radar and over 55,000 trajectories and diverse drone types like the DJI Phantom 2 and DJI Inspire 2 is conducted [17]. The challenges established include differentiating drones from non-drones and managing varying SNRs. The performance metrics such as accuracy, F1 score, true positive confidence, false alarm rate, and classification time delay are discussed, with the false alarm rate remaining a significant hurdle. The study explores advancements in distributed and multi-static radar systems, quantum oscillators, advanced antennas, ML, and AI, emphasizing their role in improving automatic target classification (ATC). It suggests future directions, including leveraging cognitive radar systems, digital twins for rapid algorithm development, and integrating contextual and meta-level information to enhance performance. The study concludes that while radar systems have made significant progress, challenges remain, in complex environments, and suggests a multisensor approach for more robust detection and classification of drones.

Furthermore, a study proposes a fully convolutional network (FCN)-based approach for fast detection of UAVs using pulse Doppler radar. The traditional constant false alarm rate (CFAR) methods, effective for uniform backgrounds, struggle with low-small UAVs [18]. The proposed FCN operates on the entire range-Doppler map to enhance detection speed while maintaining high accuracy. The network leverages a bifurcated classification and regression architecture, reduces computational overhead, and integrates a post-processing mechanism for precise target location. The experimental results show the FCN-based method improves detection speed by up to 47 times compared to previous methods while ensuring high detection accuracy and reduced false alarms. Despite its achievements, it has difficulties detecting multiple UAVs in the same grid cell due to resolution constraints, with plans to address this via sampling in future research.

In another research, a study investigates the use of MATLAB simulations for analyzing MD signatures of rotating propeller blades and flapping wings using an S-band continuous-wave (CW) radar system [6]. The system demonstrates the effectiveness of the Short Time Fourier Transform (STFT) and Fast Fourier Transform (FFT) in distinguishing between the unique signatures of micro- UAVs and birds. It employed a 100 kHz sampling frequency and 700ms integration time, revealing significant Doppler shifts and frequency dispersion associated with different propeller blade lengths and flapping frequencies. The results show STFT's capability to provide detailed time-frequency analysis, contributing to improved detection and characterization of small UAVs and avian targets. This work supports the development of advanced radar systems for enhanced detection and tracking, aligning with the goals of optimizing UAV identification and authentication in the context of radar signal analysis.

B. Research Gap

Significant advancements in UAV detection, classification, and authentication are attained across various methods, as observed in literature and as depicted in Table I. Despite this strides, significant gaps remain, in datasets and radar-based detection approaches. The reviewed research often relies on proprietary datasets, limiting generalizability, which indicates the need for publicly available, standardized UAV/drone datasets to benchmark the systems. In addition, radar systems are adequate for general UAV detection but lack robust methods for identifying specific UAV types based on MD or RCS features. Further innovation is needed to improve radar detection capability and address environmental challenges in urban areas, such as noise and clutter. To address these gaps, our research aims to develop a novel raw dataset for UAV identification and authentication, leveraging unique features and employing three models, kNN, Random Forest, and SVM, to classify UAVs based on their MD signatures. This proposed approach will enhance the accuracy of radar-based systems and utilize MD signatures for identity-based detection and authentication of UAVs.

Achieves 100% accuracy with Random Forest.	kNN, and SVM are struggling in distinguishing some types of UAVs due to their similarities.	To integrate RID Policy in UAVs detection and authentication.

III. SIMULATION SETUP

This research presents a novel approach to generating a raw dataset of UAVs, focusing on three distinct types: the DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4. The dataset is designed to capture radar signals reflective of these UAVs' unique characteristics, facilitating a detailed analysis of their operational signatures. The radar system is configured to simulate detections of the UAVs at distances of up to 1 kilometer in both hovering and motion operations. This involves UAVs located 1 kilometer towards the radar and 1 kilometer away from it, with all the points between the intervals of 10 meters inclusive. The simulation considers various UAV operations, such as stationary hovering and different flying speeds, providing a robust dataset that reflects real-world operational conditions. The generated data, which encompasses detailed radar reflections and MD signatures unique to each UAV type, is used to train machine learning models utilizing kNN, Random Forest, and SVM algorithms. These models are employed to classify and detect UAVs based on their distinct radar signatures, enhancing the system's capability to differentiate between the DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4 across various operational modes. This research contributes to advancing more effective and precise UAV detection and classification systems.

The flowchart in Fig. 1 illustrates the detection and classification processes. Radar sends continuous signals to detect UAVs and collects return signals for analysis. The data is processed through the three models. In kNN, the Euclidean distance between the test data and training samples is calculated, and the UAV is classified based on the majority class among the five (5) nearest neighbors. While, Random Forest uses feature selection and bootstrapped datasets to train multiple decision trees, and combine their votes to classify the UAV. As SVM involves feature selection, kernel function selection (linear, polynomial, or RBF), hyperplane construction, and margin maximization to separate classes, and classify UAV based on a one-vs-all strategy. Then, the model with the highest accuracy is chosen to make the final classification decision. This ensures a systematic approach to UAV detection and classification using machine learning, and demonstrates the complementary work by the three integrated models.

A. UAV Parameters

The three simulated UAVs have the following parameters:

1) DJI Matrice 600: It is set to have $N_r^{M600} = 6\,rotors$, blades with a length $L_b^{M600} = 0.5\,m$, a rotor speed $\omega^{M600} = 2200\,RPM = 36.7\,Hz$, a propeller distance $D_p^{M600} = 1.13\,m$, and $N_a^{M600} = 6\,arms$.

2) DJI Matrice 300: It is set to have $N_r^{M300} = 4\,rotors$, blades with a length $L_b^{M300} = 0.4\,m$, a rotor speed $\omega^{M300} = 2400\,RPM = 40.0\,Hz$, a propeller distance $D_p^{M300} = 0.885\,m$, and $N_a^{M300} = 4\,arms$.

3) DJI Phantom 4: It is set to have $N_r^{M600} = 4\,rotors$, blades with a length $L_b^{P4} = 0.3\,m$, a rotor speed $\omega^{P4} = 3500\,RPM = 58.3\,Hz$, a propeller distance $D_p^{P4} = 0.35\,m$, and $N_a^{P4} = 4\,arms$.

These parameters are used to simulate the MD signatures generated by the rotor blades. The rotor speed (in Hz) and blade length define the periodic motion, while the propeller distance and number of arms influence the radar reflections. This level of detail is essential for modeling radar signals that differentiate between UAV types based on their distinct physical characteristics. The factors are significant in generating unique MD patterns that facilitate the classification and identification of the UAVs.

B. Radar Parameters

The radar system is simulated to operate in this research at a carrier frequency, $f_c = 77\,GHz$. It features a maximum range (detectable range), $R = 1200\,m$ and a range of resolutions, $\Delta R = 1\,m$. The radar's bandwidth is calculated as the speed of light divided by twice the range resolution, $B = \frac{c}{2\Delta R} = 150\,MHz$. The sweep time, $T_s = 5.5\,seconds$, while the chirp slope is derived from the bandwidth and sweep time, $\Upsilon = \frac{B}{T_s} = 2.27 \times 10^6\,Hzs^{-1}$. The radar's maximum beat frequency and range beat frequency, $f_{beat,max}$ are set to handle the operational parameters effectively. The system supports MD processing for velocities, $V_{max} = 50\,ms^{-1}$, with the maximum Doppler frequency set to accommodate these speeds, $f_{doppler} = \frac{2V_{max}f_c}{c} = 25.67\,kHz$. The radar simulation encompasses, $N_p = 10\,pulses$ each consisting of $N_c = 60\,chirps$ and $N_s = 80\,samples\,per\,chirps$. The pulse repetition frequency (PRF) is determined based on these parameters where Np, Nc, and Ns stand for number of pulses, number of chirps, and number of samples respectively.

1) Transmitted chirp signal: The transmitted chirp signal models how the radar transmits a signal over time. This chirp signal is essential for determining the range and Doppler characteristics of UAVs. The selected UAVs in this research are DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4. Hence, the chirp signal detects and measures their distance and movement by analyzing the returned signals as in Eq. (1),

$$S_r(n,t) = a_t rect\left(\frac{\hat{t} - t_d}{\tau}\right) e^{j[2\pi f_c t_d + \pi\Upsilon(\hat{t}-t_d)^2]} \qquad (1)$$

where $S_r(n,t)$, is the transmitted baseband signal from the radar at the time $\hat{t}$ for the nth pulse and a_t is the amplitude of the return signal, often defined by the radar range equation, and it depends on the transmitted power, target radar cross-section (RCS), and range. While $rect\left(\frac{\hat{t}-t_d}{\tau}\right)$ is the rectangular window function that represents the radar pulse shape. The function limits the signal to the time interval τ, which is the pulse width. It centers on the delayed time, t_d where t_d is the round-trip time delay is related to the range R of the target by $t_d = \frac{2R}{c}$. Meanwhile, $e^{j[2\pi f_c t_d + \pi\Upsilon(\hat{t}-t_d)^2]}$ is the complex exponential that describes the frequency modulation (FM) of the chirp signal and f_c is the radar's carrier frequency (center frequency of the transmitted signal). In addition, γ is the chirp rate or chirp slope, representing the rate of frequency change in the transmitted chirp signal and $(\hat{t} - t_d)^2$ represents the quadratic phase term, where $\hat{t}$ is the time within a pulse and t_d is the delay due to the target's range.

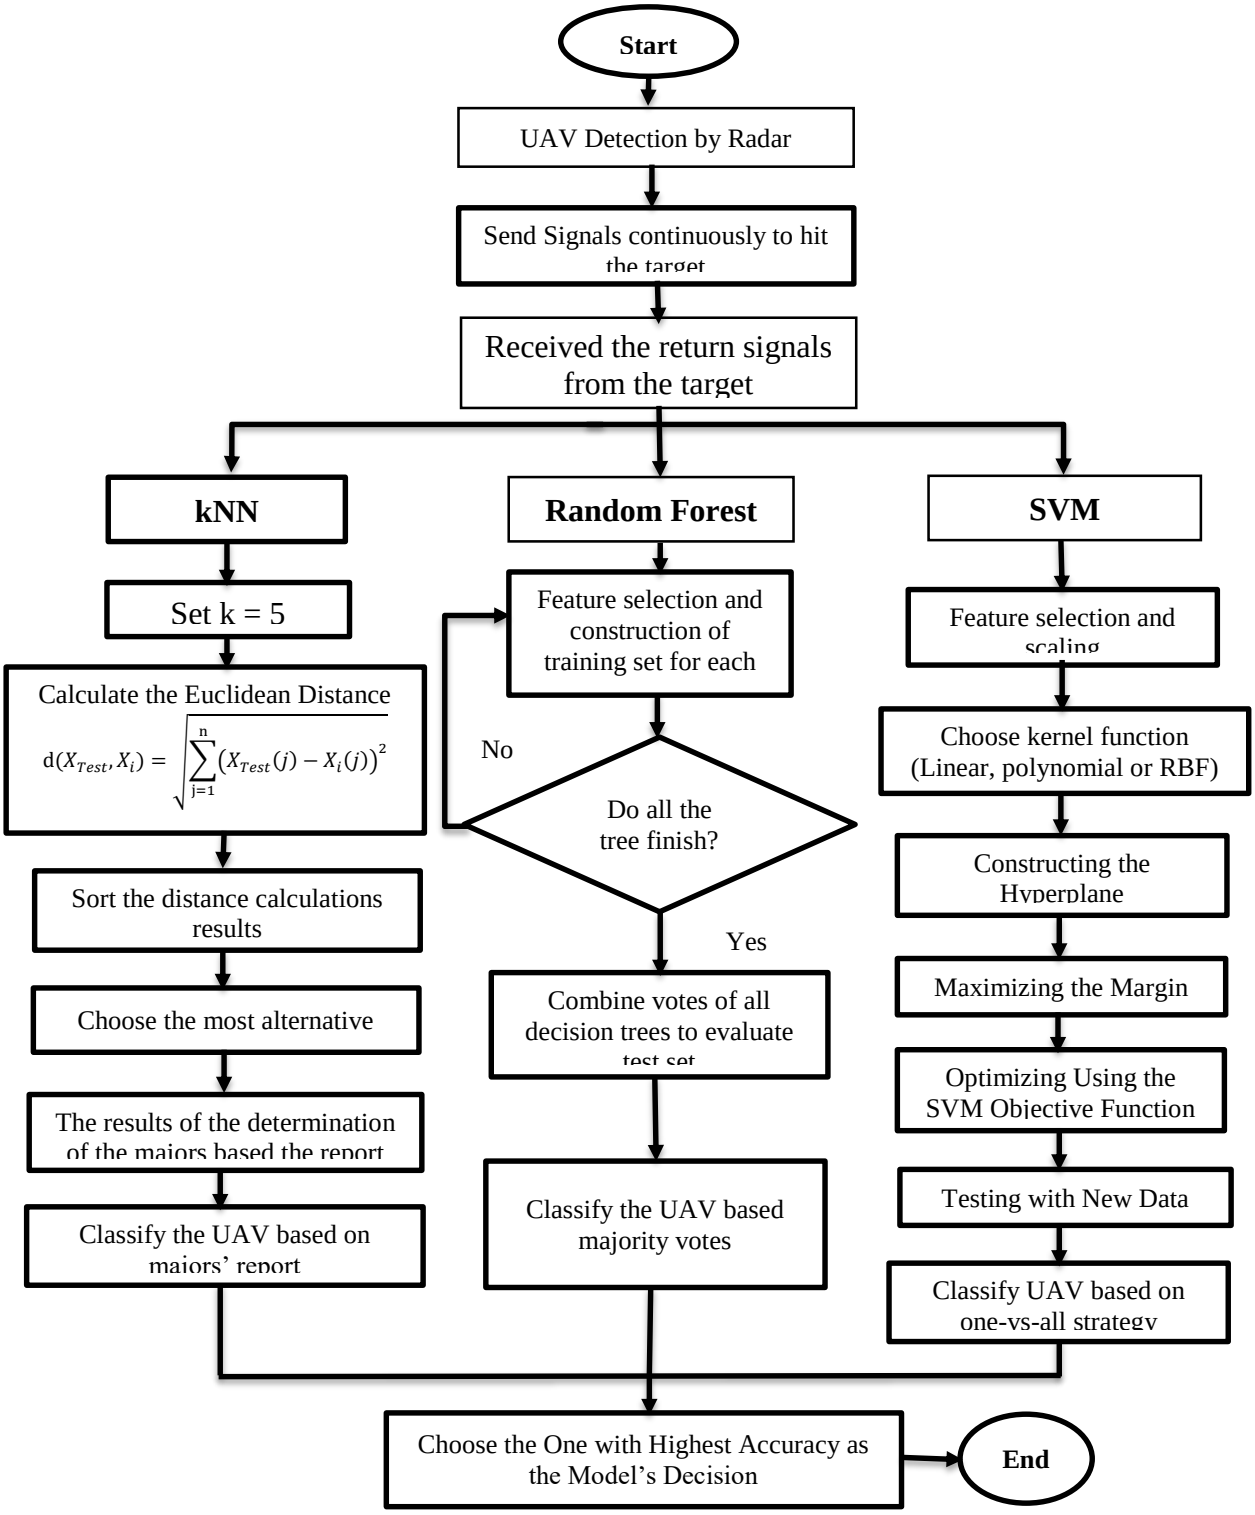

Fig. 1. Flowchart of the proposed model.

2) Received chirp signal: The received chirp signal $S_R(t)$ models the interaction between the radar and UAVs. The time delay τ =2r/c reflects the time it takes for the radar signal to travel to the UAV and back. This model is crucial for calculating the distance of the UAVs from the radar. Therefore, the received signal can be written as in Eq. (2),

$$S_{received}(n,t) = S_{UAV}(n,t) + S_{clutter}(n,t) + Noise(0,\sigma^2) \quad (2)$$

where $S_{UAV}(n,t)$ is the signal reflected by the target (UAV), $S_{clutter}(n,t)$ is the clutter signal, which is the sum of reflections from multiple clutter sources and $Noise(0,\sigma^2)$ is the additive noise in Gaussian distribution.

3) Dechirped intermediate frequency signal: The dechirping is the mixing (multiplying) of the received signal with a delayed version of the transmitted signal (reference chirp). This multiplication produces the Intermediate Frequency (IF) signal as described in Eq. (3), which contains the difference between the transmitted and received frequencies.

$$S_{IF}(n,t) = S_{received}(n,t) \times S_r^*(n,t) \tag{3}$$

$S_r^*(n,t)$ is the complex conjugate of the transmitted signal $S_{received}(n,t)$. When the received signal is mixed with the conjugate of the transmitted chirp, the high-frequency terms cancel out, leaving behind a low-frequency signal (beat signal) that encodes target information such as range and Doppler shifts. The resulting signal $S_{IF}(n,t)$ will have components related to the difference in time delay and Doppler shift between the transmitted and received signals. The UAV reflection of the IF signal is given by Eq. (4), where $f_{beat} = f_c(t_r - t_d)$ is the beat frequency proportional to the time delay, $(t_r - t_d)$, which relates to the range of the target. $\phi(t)$ is the phase component, which includes Doppler frequency information.

$$S_{IF,UAV}(n,t) = a_r rect\left(\frac{\hat{t} - t_r}{\tau}\right) e^{j[2\pi f_{beat}t + \phi(t)]} \tag{4}$$

The IF signal after dechirping contains beat frequency and phase modulation. The beat frequency is proportional to the range of the UAV (or other targets); the greater the range, the higher the beat frequency. Meanwhile, phase modulation is caused by Doppler shifts, which provide information about the relative velocity of the UAV.

4) Dechirped signal: The dechirped signal, $S_0(t,t_s)$ assists in analyzing the radar return signal by removing residual phase terms. This step is essential for accurately processing and analyzing the data collected from UAVs, ensuring that the range and Doppler measurements used for classification are precise. The dechirped signal would also include contributions from clutter and noise. Therefore, the IF signal after dechirping becomes Eq. (5), where, $S_{IF,UAV}(n,t)$ is the beat signal from the UAV, while $S_{IF,clutter}(n,t)$ represents the beat signals from clutter sources and $Noise(0,\sigma^2)$ is the noise (modeled as Gaussian noise).

$$S_{IF}(n,t) = S_{IF,UAV}(n,t) + S_{IF,clutter}(n,t) + Noise(0,\sigma^2) \tag{5}$$

5) MD effect: The MD effect is significant in detecting and identifying the UAVs' distinct features, such as rotor blades' motion. MD is a time-varying frequency shift caused by small periodic motions like the rotor blades of the UAV. It is modeled in Eq. (6) where, $v(t)$ is the instantaneous velocity of the rotating or moving part, λ is the wavelength of the radar signal, and $f_{mD}(t)$ represents the MD frequency shift.

$$f_{mD}(t) = \frac{2v(t)}{\lambda} \tag{6}$$

The overall received signal, including the MD effect, is represented in Eq. (7) where $2\pi f_c t_r$ is the bulk Doppler shift and the MD shift is $2\pi f_{mD}(t)t$.

$$S_r(n,t) = a_r rect\left(\frac{\hat{t} - t_r}{\tau}\right) e^{j[2\pi f_c t_r + 2\pi f_{mD}(t)t + \pi\Upsilon(\hat{t}-t_r)^2]} \tag{7}$$

6) Received Signal with MD and Noise: The total received radar signal, including the reflected signal from the UAV, clutter sources, MD effects, and noise, can be modeled in Eq. (8).

$$\begin{aligned} S_{received}(n,t) &= a_r rect\left(\frac{\hat{t} - t_r}{\tau}\right) e^{j[2\pi f_c t_r + 2\pi f_{mD}(t)t + \pi\Upsilon(\hat{t}-t_r)^2]} \\ &+ \sum_{i=1}^{N_c} a_{ci} rect\left(\frac{\hat{t} - t_{ci}}{\tau}\right) e^{j[2\pi f_c t_{ci} + 2\pi f_{mD}(t)t + \pi\Upsilon(\hat{t}-t_{ci})^2]} \\ &+ Noise(0,\sigma^2) \end{aligned} \tag{8}$$

C. File Format and Metadata

The data is stored in an Excel file and is organized into four sheets, each containing 8,120,601 samples of the three different UAVs (DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4). The data is captured as the UAVs move within a 3D space ranging from 1 km away towards the radar to 1 km towards the radar. The movement is recorded at 10-meter intervals in each direction. Each sheet includes the following data for every sample: Raw RX Data, UAV Type, UAV Features, and Location. The captured information is utilized to train the machine learning models kNN, Random Forest, and SVM for classification purposes.

D. UAV Classification

The classification of UAVs is an approach for identifying UAV types and their operational modes based on the received radar information, specifically range-Doppler maps. The method leverages the kNN, Random Forest, and SVM algorithms, which classify a test sample by considering its proximity to the labeled training samples in features' space as described in equation (9). The dataset is represented as $X = \{x_1, x_2, \cdots, x_N\}$, where, x_i represents the features of a sample, such as the range-Doppler map. Each $y_i \in Y$, where Y contains UAV types or operational modes. yi ∈ {DJI Matrice 600, DJI Matrice 300, Phantom 4}

1) Data preparation and feature extraction: To train the classifiers for identifying UAV types and their operational states, the raw radar signal (range-Doppler maps) is first preprocessed. The range-Doppler map, which represents the response of the radar to a moving object in terms of range and velocity, is flattened into a one-dimensional vector. Mathematically, let the range-Doppler map for a UAV U and velocity V be denoted as $RD_{U,V}(r, f_D)$, where r represents range and f_D represents Doppler frequency. To simplify this for machine learning, each map $RD_{U,V}$ is reshaped into a feature vector $X_{u,v} \in \mathbb{R}^n$, where n is the total number of points in the

range-Doppler map. Thus, the feature matrix X for all UAVs and states becomes Eq. (9):

$$X = \begin{bmatrix} X_{1,1} & X_{1,2} & \cdots & X_{1,V} \\ X_{2,1} & X_{2,2} & \cdots & X_{2,V} \\ \vdots & \vdots & \ddots & \vdots \\ X_{U,1} & X_{U,2} & \cdots & X_{U,V} \end{bmatrix} \quad (9)$$

where U represents the number of UAV types and V represents the number of velocity states (including hovering). Each row in X corresponds to the real part of the radar signal response, ensuring compatibility with standard machine learning models as indicated in Eq. (10).

$$Y = \begin{bmatrix} UAV\ Type_1 & Operation_1 \\ UAV\ Type_2 & Operation_2 \\ \vdots & \vdots \\ UAV\ Type_N & Operation_N \end{bmatrix} \quad (10)$$

a) Dataset: The dataset consists of radar return signals from three different types of UAVs: DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4. Each UAV is simulated, and its features are captured across a range of distances from the radar, spanning between [1000; 1000; 1000] meters (1km) towards the radar and [-100; -1000; -1000] meters (1km) away from the radar, with measurements taken in 10m intervals inclusive. The features extracted from the UAVs are the reflected radar signals from the UAVs that capture unique characteristics, structural design, movement patterns, and operational parameters such as rotor speed, body dimensions, and altitude. These features, derived from the signal's amplitude, phase shifts, and Doppler effects, provide distinctive signatures that can be used for identifying and classifying each UAV at various distances and orientations relative to the radar system. These reflected signals can be used to train machine-learning models to recognize the specific identity of each UAV, enabling robust identity-based authentication and detection. The dataset is extensive, capturing radar return signals from multiple locations within a specified range. Each UAV covering all locations within the range of [-1000; -1000; -1000] to [1000; 1000; 1000] at intervals of 10 meters, the total number of samples is calculated as the following.

Total samples per UAV:

$$\text{UAV} = 201 \times 201 \times 201 = 8,120,601$$

Therefore, the total dataset samples of the three UAVs (DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4) is the total number of samples across the UAVs.

$$\text{Total Dataset Samples} = 8,120,601 \times 3 = 24,361,803 \text{ samples}$$

This results in a dataset containing 24,361,803 samples in total, providing unique radar profiles for each UAV at all specified distances. This comprehensive dataset enables efficient training of machine-learning models for UAV identification and classification based on their radar return signals.

The structure of the captured information is described as follows:

- Reflected Signal: This matrix captures the amplitude of the radar return signals reflected by the DJI Matrice 600 at [1000; 1000; 0]:

$$X = \begin{bmatrix} -1.15193589623129 & 2.79463633718335 & \cdots & 0.854456914633749 \\ -0.267289748658581 & -0.368824215433807 & \cdots & -0.671501576572502 \\ \vdots & \vdots & \ddots & \vdots \\ -0.382196398043339 & 0.0841435521978612 & \cdots & -1.14575173405667 \end{bmatrix}$$

- Drone Type: The UAV information captured is that of DJI Matrice 600.
- Drone Features: The details of the UAV captured include the number of rotors, rotor radius, rotor speed, and other relevant features [6 0.5 36.6666666666667 1.13 6].
- Location: Indicates the coordinates of the UAV towards the radar [1000; 1000; 0].

b) Feature extraction: The range-Doppler maps are generated from radar signals for each UAV, capturing significant features related to the movement and MD signatures of the drone. These maps encode essential information about the range and velocity of UAVs, making them a valuable feature set for classification tasks. The formula of Range-Doppler maps is defined in Eq. (11):

$$R_D(n,f) = FFT_t\{FFT_r\{S_r(n,t)\}\} \quad (11)$$

Therefore, the features extracted from the Range Doppler maps are Mean Range μ_r, Mean Doppler-Shift μ_d, Standard Deviation of Range σ_r, and Standard Deviation of Doppler Shift σ_d. These are described in Eq. (12), (13), (14), and (15) respectively. Others include Peak-to-Average-Ratio (PAR), Spectral Centroid (SC), Spectral Bandwidth (SB), Peak Amplitude (PA), Number of Peaks, Energy Ratio (ER), and Entropy. The PAR, SC, SB, PA, ER, and Entropy are represented in Eq. (16), (17), (18), (19), (20) and (21) respectively.

$$\mu_r = \frac{1}{N}\sum_{n=1}^{N} r(n) \quad (12)$$

$$\mu_d = \frac{1}{M}\sum_{f=1}^{M} d(f) \quad (13)$$

$$\sigma_r = \sqrt{\frac{1}{N-1}\sum_{n=1}^{N}(r(n)-\mu_r)^2} \quad (14)$$

$$\sigma_d = \sqrt{\frac{1}{M-1}\sum_{f=1}^{M}(d(f)-\mu_d)^2} \quad (15)$$

$$(PAR) = \frac{max_d}{\mu_d} \quad (16)$$

$$SC = \frac{\sum_f f \times R_D(n,f)}{\sum_f R_D(n,f)} \quad (17)$$

$$BD = \sqrt{\frac{\sum_f (f - SC)^2 \times R_D(n,f)}{\sum_f R_D(n,f)}} \quad (18)$$

$$PA = max_{n,f} \times R_D(n,f) \quad (19)$$

The number of peaks counts the significant peaks in the range-Doppler map, which is related to the number of rotating blades or moving parts.

$$ER = \frac{\sum_{(n,f)\in Region} R_D(n,f)}{\sum_{n,f} R_D(n,f)} \quad (20)$$

ER is a ratio of energy in specific regions of the range-Doppler map to the total energy, which indicates specific features related to the UAVs.

$$Entropy = -\sum_{n,f} \frac{R_D(n,f)}{E} \log\left(\frac{R_D(n,f)}{E}\right), \quad (21)$$

Where

$$E = \sum_{n,f} R_D(n,f)$$

Therefore,

$$Features\ Vector\ (F_i) = [\mu_r, \mu_d, \sigma_r, \sigma_d, PAR, SC, SB, PA, Number\ of\ Peaks, ER, Entropy\ ]$$

The features vector provides a comprehensive representation of the UAV's radar signature that can ensure classification accuracy.

2) Training the classifiers: The kNN, Random Forest, and SVM classifiers are trained using the feature matrix X and the corresponding label matrix Y. The goal is to classify two outputs: the type of UAV and its operation. Let $y_{UAV\ Type}$ be the vector containing the UAV type labels, and $y_{Operation}$ be the vector containing the operational states (hovering or moving). The kNN classifier identifies the k nearest training points for each test point based on a chosen distance metric. In contrast, the Random Forest model uses an ensemble of decision trees to make predictions by averaging the outputs of multiple trees, while the SVM model finds the optimal hyperplane that maximizes the margin between classes for classification. Given a new test point $X_{Test} \in \mathbb{R}^n$, the classifier computes the distances to all training points $X_i \in \mathbb{R}^n\ in\ X$ as in Eq. (22).

$$\mathrm{d}(X_{Test}, X_i) = \sqrt{\sum_{\mathrm{j}=1}^{\mathrm{n}} \left(X_{Test}(j) - X_i(j)\right)^2} \quad (22)$$

The kNN, Random Forest, and SVM classifiers are each used to classify both UAV type and operational state. The kNN classifier identifies the k nearest points and uses majority voting to assign the test point X_{Test} to a class for both the UAV type and the operation. While Random Forest aggregates predictions from decision trees, and SVM identifies the optimal hyperplane to separate classes. In this case, two separate classifiers are trained: one for UAV-type prediction and one for operational state prediction.

3) Classification: The kNN, Random Forest, SVM models are trained to classify new radar signal data from unknown UAVs. For each radar signal, represented by its corresponding range-Doppler map X_{Test}, the models predicts both the UAV type and its operation. The UAV type classifier, $f_{UAV\ Type}$, assigns a predicted class label based on the features of the test data:

$$\hat{y}_{\mathrm{UAV\ Type}} = \mathrm{f}_{\mathrm{UAV\ Type}}(\mathrm{X}_{\mathrm{Test}}) \quad (23)$$

Similarly, the operation classifier, $f_{Operation}$, predicts the UAV's operational state by analyzing the same test signal.

$$\hat{y}_{Operation} = f_{Operation}(X_{Test}) \quad (24)$$

Both classifiers work in tandem to identify the UAV type and its operational state from the radar signal data, making predictions based on the nearest neighbors in the training set.

E. Visualization of the Signals

The visualization of radar signals from various UAVs is critical for understanding their operational characteristics and enhancing classification tasks. The research used the generated raw data to visualize the UAVs' extracted features through maps. These maps include time/frequency spectrograms, mean spectrograms, and range-Doppler maps of the captured signals to facilitate detailed analysis of UAV's behaviors under different conditions.

1) Time/Frequency-Spectrograms: The time/frequency spectrograms provide a dynamic view of how the frequency content of the radar signals varies over time. The spectrograms get frequency on the vertical axis and time on the horizontal axis to demonstrate how the UAV's motion influences the received radar signals. Fig. 2 depicts rapid changes in frequency, indicating a UAV accelerating or maneuvering, while stable frequency patterns suggest hovering or cruising at a constant speed. This visualization is particularly useful for identifying unique operational signatures associated with different UAV types.

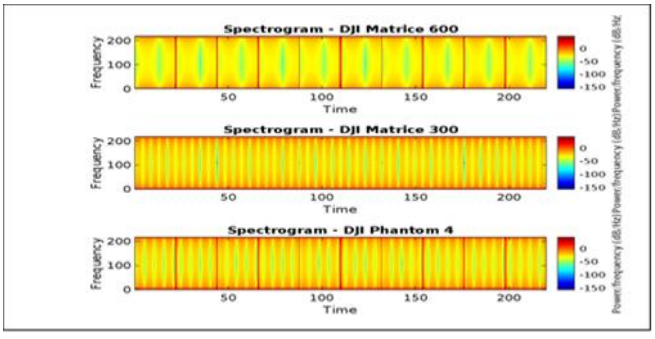

Fig. 2. UAV spectrograms.

2) Time/Frequency-mean spectrograms: The mean spectrograms is generated by averaging on multiple time/frequency spectrograms to emphasize the consistent features inherent to each UAV type. The smoothing out the

variability in individual recordings, mean spectrograms highlight the dominant frequencies and patterns associated with specific UAVs as indicated in Fig. 3. This helps in distinguishing between UAVs, as each type tends to exhibit distinct frequency profiles that can be utilized for classification.

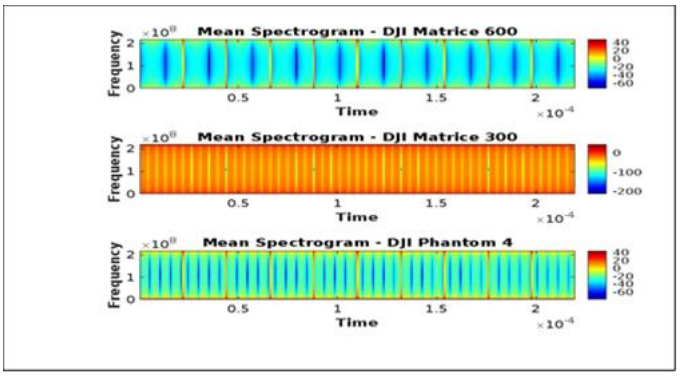

Fig. 3. UAV mean spectrograms

3) Doppler frequency/Range-Range-Doppler map: The Range-Doppler maps are pivotal in integrating both range and Doppler information into a single representation as indicated in Fig. 4. These maps reveal the detected UAVs' characteristics in a comprehensive manner. The intensity of the colors within the maps indicates the strength of the received radar signals, highlighting features specific to different UAV types. The variations in intensity help to differentiate between larger UAVs, which may have a stronger radar return, and smaller ones, which produce weaker signals.

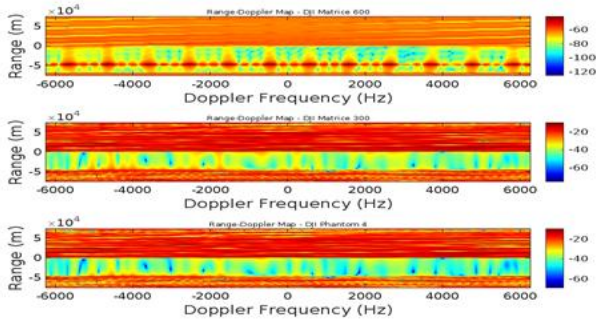

Fig. 4. UAV Range-Doppler Map

4) Doppler frequency/Range-Mean Range-Doppler maps: The mean range-Doppler maps are generated by averaging the range-Doppler data over multiple samples. This process reduces noise and highlights the typical signatures of each UAV type as described in Fig. 5. The mean range-Doppler maps assist in the classification process, making it easier to identify the unique characteristics associated with each UAV.

5) Doppler intensity plots: The Doppler intensity plots focus on specific points within the Doppler domain, illustrating the intensity of the received signals at various frequencies as presented in Fig. 6. These plots are beneficial for examining how signal intensity varies with Doppler frequency, offering insights into the operational states of the UAVs. The frequencies exhibit higher intensity levels during specific operations, such as takeoff or landing, enabling observers to infer the UAV's activity at a given time.

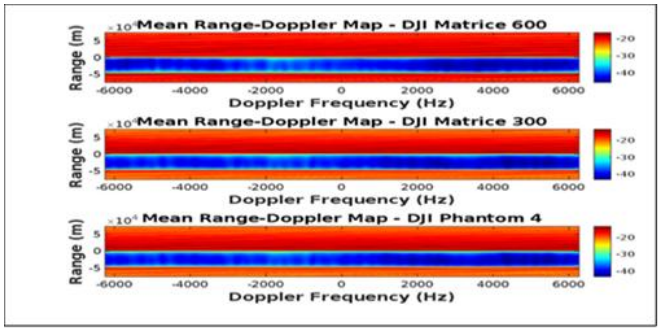

Fig. 5. UAV mean range-doppler map.

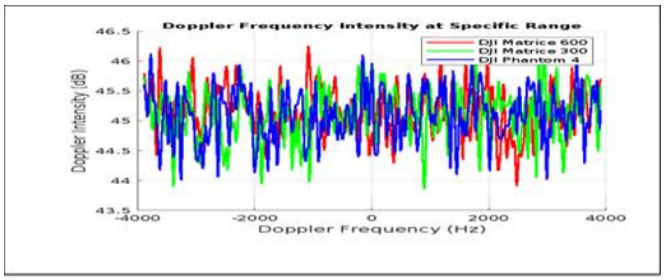

Fig. 6. UAV doppler frequency intensity.

IV. Evaluation and Testing

The captured radar signals information is deployed to kNN, Random Forest, and SVM to enable real-time classification of unknown UAVs based on their range-Doppler signatures. The relevant features are extracted from the radar signal and input into the classifiers to predict both the UAV type and its operational state (e.g., hovering or moving). The performances of the models are evaluated by comparing the predictions with the known ground truth. The performance metrics include classification accuracy, the F1 score, true positive confidence, and the false alarm rate. Additionally, the classification time delay is assessed to determine how fast the system can make predictions to ensure the model's viability for real-time UAV detection and authentication. These metrics provide an inclusive assessment of the classifier's effectiveness in accurately identifying UAV types and operational states from radar data.

1) Accuracy: This measures the proportion of correct predictions out of the total predictions made by the classifier.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{25}$$

where TP is True Positive, TN is True Negative, FP is False Positive, and FN is False Negative.

2) F1 Score: It provides a balance between precision and recall, especially useful for imbalanced classes. It is the harmonic mean of precision and recall.

$$F1\ Score = 2 \times \frac{Precision\ \times\ Recall}{Precission + Recall} \tag{26}$$

Where

$$Precision = \frac{TP}{TP+FP}, \text{ and } Recall = \frac{TP}{TP+FN}$$

3) True positive confidence: This reveals the confidence level of the classifier in its correct predictions, expressed in a percentage form. It is the average confidence score assigned to true positive predictions.

$$TPC = \frac{\Sigma_{1=1}^{n} Confidence\ (TP_i)}{n} \quad (27)$$

where TP_i is the confidence of each true positive prediction and n is the number of classes.

4) False Alarm Rate (FAR): This indicates the number of times the classifier incorrectly predicts the presence of a UAV when there is none (false positive rate).

$$FAR = \frac{FP}{FP + TN} \quad (28)$$

5) Classification time delay: It measures the time taken for the classifier to process the radar signal and make a prediction. This is critical for real-time systems and can be represented as:

$$CTD = t_{end} - t_{start} \quad (29)$$

Where CTD is the classification delay time.

V. Result and Discussion

The results of classification performance of the three models (kNN, Random Forest, and SVM) have been evaluated across three UAV classes (DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4). The results, as presented in confusion matrices shown Fig. 7, Fig. 8, and Fig. 9, and summarized in Table II, Table III, and Table IV, provide overview of how each model performs. The performances are in terms of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN), offering insights into their strengths and weaknesses.

	1	2	3	Percentage %	
1	36	4	4	89.40%	10.60%
2	4	18	22	62.90%	37.10%
3	2	19	23	62.90%	37.10%

Fig. 7. kNN's classification confusion matrix.

TABLE II. kNN's Classification Summary

Class	*TP*	*TN*	*FP*	*FN*
1 (DJI Matrice 600)	36	82	6	8
2 (DJI Matrice 300)	18	65	23	26
3 (DJI Phantom 4)	23	60	26	23
Total	**77**	**207**	**55**	**57**

The kNN exhibits varying levels of performance in the classification of UAV types. Class 1 (DJI Matrice 600): The classifier performs well and achieved 36 (TPs) with minimal FP (6) and FN (8). It shows the highest accuracy (89.4%) in this class, indicating that it can effectively distinguish the DJI Matrice 600 from the other UAVs. However, the classifier struggles with Class 2 (DJI Matrice 300), where it only correctly identifies 18 samples as Matrice 300, while misclassifying 23 samples from other classes as Matrice 300. In addition, it misses 26 actual Matrice 300 samples, leading to a moderate performance in the class. While, in Class 3 (DJI Phantom 4), kNN performs moderately well but faces challenges in balancing FPs and FNs, correctly classifying 23 samples as Phantom 4, while misclassifying 26 samples from other classes and failing to classify 23 actual Phantom 4 samples.

	1	2	3	Perc. %
1	44			100%
2		44		100%
3			44	100%

Fig. 8. Random forest's classification confusion matrice.

TABLE III. Random Forest's Classification Summary

Class	*TP*	*TN*	*FP*	*FN*
1 (DJI Matrice 600)	44	88	0	0
2 (DJI Matrice 300)	44	88	0	0
3 (DJI Phantom 4)	44	88	0	0
Total	**132**	**264**	**0**	**0**

In contrast, the Random Forest demonstrates outstanding performance in classifying all the UAV classes, and achieved 100% classification with no FPs or FNs, as indicated in Table III. Each class (DJI Matrice 600, DJI Matrice 300, and DJI Phantom 4) samples are correctly classified, and no misclassifications occur. It recorded 132 (TPs) and 264 (TNs) across all classes, and achieved an accuracy of 100%, showcasing its robustness and ability to effectively separate UAV classes. This perfect performance shows the utility of Random Forest for UAV detection and classification tasks, indicating that it can reliably distinguish between different UAV types without ambiguity.

Meanwhile, the SVM model performs well, with strong results across all three classes. Class 1 (DJI Matrice 600), the SVM achieves perfect classification, with 100% precision and 100% recall, correctly identifying all instances of this class. This suggests that the SVM model excels at detecting the DJI Matrice 600 UAV. While, in Class 2 (DJI Matrice 300), the model achieves a precision of 79.1% and a recall of 86.4%, with a

resulting F1-score of 0.826. While some FPs are present, the model correctly identifies the majority of DJI Matrice 300 instances, but occasional confusion with other UAV types lowers its performance slightly. Also, in Class 3 (DJI Phantom 4), the SVM model achieves 85% precision and 77.3% recall, with an F1-score of 0.81. While the model correctly identifies most Phantom 4 samples, some instances are misclassified as other UAV types.

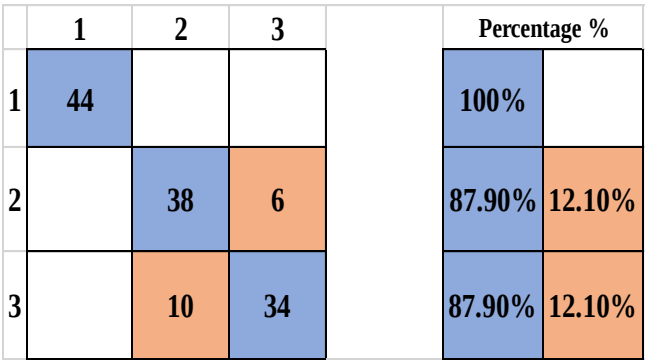

Fig. 9. SVM's classification confusion matrice.

TABLE IV. SVM'S CLASSIFICATION SUMMARY

Class	*TP*	*TN*	*FP*	*FN*
1 (DJI Matrice 600)	44	88	0	0
2 (DJI Matrice 300)	38	78	10	6
3 (DJI Phantom 4)	34	82	6	10
Total	**114**	**248**	**16**	**16**

TABLE V. SUMMARY OF PERFORMANCE OF THE THREE MODELS

Class	*Accuracy*	*F1 Score*	*TPC*	*FAR*
kNN	71.73%	58.14%	58%	0.21
Random Forest	100%	100%	100%	0.00
SVM	93.27%	88%	87%	0.06

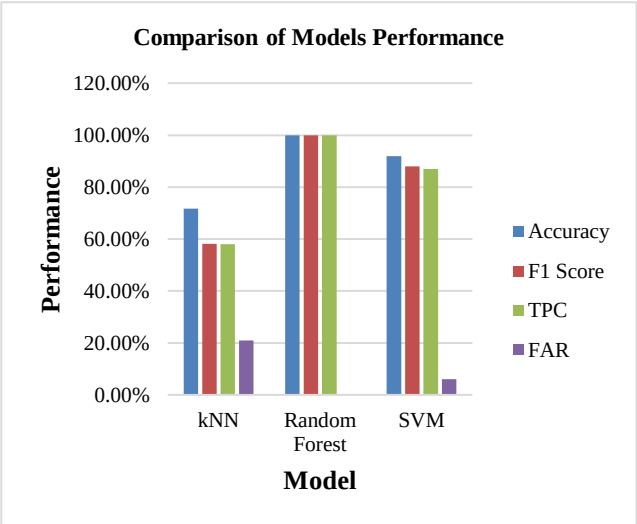

Fig.10. Models performances.

The Random Forest emerged as the best-performing model due to its perfect classification accuracy (100%) and zero false alarms as shown in Fig. 10 and Table V. This makes it well-suited for real-time UAV monitoring, where minimizing errors is paramount. Although kNN and SVM achieved high accuracy for some UAV types, their issues with misclassifying between DJI Matrice 300 and Phantom 4 suggest that further tuning or additional feature engineering is needed to improve their performance in distinguishing these specific UAV types.

VI. CONCLUSION AND FUTURE DIRECTION

This research presents significant strides in the detection and authentication of UAVs through the creation of a unique radar dataset comprising three distinct UAV models (DJI Matrice 600, DJI Matrice 300, and Phantom 4). The research has laid the groundwork for enhanced UAV detection and classification. The utilization of MD radar signals allows for detailed analysis of UAV characteristics, facilitating accurate identification and robust authentication processes. Among the three machine learning models tested, Random Forest demonstrated exceptional performance, achieving 100% classification accuracy with zero false alarms, making it highly suitable for real-time UAV monitoring where precision is critical. While kNN and SVM models also showed strong results, they encountered misclassification issues attributed to the similarities in the radar signatures of the DJI Matrice 300 and DJI Phantom 4 UAVs. These UAVs share the same number of rotors and propellers, as well as other design features. Their structural similarities result in overlapping micro-Doppler effects and radar reflections, making it difficult for the models to distinguish between the two UAV classes, suggesting a need for further refinement.

However, future work will focus on developing a system that leverages the Remote ID (RID) policy, and the radar datasets generated in this study to improve the detection, identification, and authentication of UAVs. The system will utilize the kNN, Random Forest, and SVM models, with particular attention to improving the performance of kNN and SVM to reduce misclassifications and enhance accuracy. These enhancements, combined with the broader application of RID data, will enable a more robust scalable solution that will detect and identify unknown UAVs and ensure monitoring and security in various operational environments.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Etienne Innovation Sdn. Bhd. for their invaluable support and contribution to this research. Additionally, the authors extend their heartfelt thanks to Universiti Tun Hussein Onn Malaysia (UTHM) for providing essential resources, facilities, and support throughout the research process. Their encouragement and commitment have been instrumental in the successful completion of this study.

Application of Residual Graph Attention Networks Algorithm in Credit Evaluation for Financial Enterprises

Wenxing Zeng*
Southwest Petroleum University, Chengdu, China

***Abstract*—In the context of digital transformation of enterprises, credit evaluation of financial enterprises faces new challenges and opportunities. Digital transformation introduces a large amount of data and advanced analytical tools, providing richer information and methods for credit evaluation. In this paper, we propose a credit evaluation model based on improved quantum genetic algorithm and residual graph attention network (DRQGA-ResGAT), which aims to utilize the complex correlation data and multi-dimensional information among enterprises for enterprise credit evaluation. The credit evaluation model based on DRQGA-ResGAT performs well in dealing with large-scale and high-dimensional data and can significantly improve the accuracy of credit evaluation. The experimental results show that the ResGAT model combined with the improved quantum genetic algorithm performs even better, and the proposed model has a high precision rate in the credit evaluation of financial enterprises, which has a greater application value. Compared with the traditional ResGAT model, the model improves about 17.06% in precision rate.**

***Keywords*—Quantum genetic algorithm; residual networks; attention mechanisms; graph neural networks; credit evaluation**

I. INTRODUCTION

In the context of enterprise digital transformation, financial enterprise credit evaluation faces new challenges and opportunities. Digital transformation not only changes the operation mode of enterprises, but also introduces a large amount of data and advanced analytical tools, providing richer information and methods for credit evaluation [1]. With the development of big data and artificial intelligence technology, deep learning algorithms are more and more widely used in the financial field. In particular, Residual Graph Attention Network (ResGAT), which is based on graph neural network, is excellent in processing graph-structured data and has been widely used in credit evaluation of financial enterprises [2].

Digital transformation refers to the optimization of business processes and the enhancement of operational efficiency and service capabilities by enterprises through the application of information technology [3-5]. In the financial industry, digital transformation not only includes the automation of traditional business, but also involves the in-depth integration of emerging technologies such as big data, cloud computing, and artificial intelligence [6]. The application of these technologies enables financial firms to process huge data sets more efficiently, thus realizing more accurate credit evaluation [7]. Deep learning, as an important branch of artificial intelligence, is able to automatically extract and learn complex features in data by simulating the neural network structure of the human brain. In financial enterprise credit evaluation, deep learning algorithms can effectively handle heterogeneous data, such as financial statements, transaction records, social media data, etc., so as to improve the precision and reliability of credit evaluation [8].

Shi et al. formulated a hybrid kNN-GNN model, investigated the integration of multiple graphs and the introduction of edge weights, and verified the feasibility and validity of the integrated model [9]. Zhang used a convolutional neural network (CNN) and a long short-term memory (LSTM) network to build a model that utilizes soft attention, and the gradient is propagated back to the rest of the model through the Attention Mechanism module [10]. The problem of recurrent neural network (RNN), which suffers from severe gradient vanishing under long sequence training, was solved. Gao et al. proposed a credit scoring model based on contrast-enhanced and tree-enhanced embedding mechanisms, which automatically constructs interpretable cross-features by using a tree-based model to learn decision rules from the data [11]. Currently, multiple improvement methods of graph neural networks shine in the aspect of credit risk evaluation for enterprises, especially after verifying the excellent effect of the attention mechanism, the practical effect of the graph attention model becomes more and more significant. Zhang et al. used a multimodal learning strategy to fuse two different data sources, and the cascade vectors derived from the data fusion were used as inputs to the feed-forward neural network to predict the credit risk of SMEs [12]. Sang et al. developed a graph attention network called DialogueGAT for predicting financial risk by simultaneously modeling the speakers and their words in a conversation during a teleconference [13].

However, GAT usually falls into overfitting or model degradation occurs when training a large amount of data, so residual networks were incorporated into GAT. Huang et al. proposed a residual-based graph attention network (ResGAT), which solves the over smoothing problem of the traditional graph convolutional networks (GCNs) when dealing with graph data by introducing the residual connectivity and attention mechanism, making it able to capture important features in the data and complex relationships between nodes [14]. Zhang et al. proposed two graph-based algorithms, E-ResSAGE and E-ResGAT algorithms, which build on the established GraphSAGE and GAT algorithms, respectively, to integrate residual learning into GNNs using available graph

information [15]. Adding residual ties as a strategy to cope with high class imbalances aims to preserve the original information and improve the performance of a few classes. Fan et al. proposed a multi-headed residual graphical attention network model using graph neural networks to extract interaction features from compiled graphical data, and designed the SDAE-GPC model for assembly condition classification to derive graphical data inputs for the ResGAT regression model [16].

In credit evaluation, ResGAT can utilize the complex correlation data and multidimensional information among enterprises to predict their future credit risk. It is shown that the credit evaluation model based on ResGAT performs well when dealing with large-scale and high-dimensional data, and can significantly improve the precision of credit scoring. Zhou et al. proposed a credit default risk prediction model based on graphic attention network, which considers the potential relationship between users by constructing a multi-view graph [17]. The experimental results on a real dataset verified the model's validity. Song et al. proposed a multi-structured cascading graph neural network framework for ECR evaluation, which enhances the learning of enterprise representations based on enterprise graph structures with different granularities [18]. These studies show that deep learning algorithms such as ResGAT have significant advantages and potentials in dealing with complex data in financial enterprise credit evaluation.

However, the hyperparameters of the network in deep learning are usually difficult to set to the optimal combinations and often require repeated human experiments, so optimization algorithms were developed to be combined with deep learning models to accomplish hyperparameter tuning of the algorithms through automatic optimization search. Nebojsa et al. proposed an improved version of the population intelligence and monarch butterfly optimization algorithms for training feed-forward artificial neural networks to enhance the exploration capabilities and the intensification-diversification balance [19]. Stefan et al. proposed a new hybrid meta-heuristic approach to optimize network neuron parameters by using the hybrid bat algorithm for feed-forward neural network training [20]. Nebojsa et al. explored the application of population intelligence techniques for tuning hyper-parameters in convolutional neural networks by proposing an augmented meta-heuristic algorithm through the implementation of the automated method for hyperparameter optimization and structural design [21].

In summary, enterprise digital transformation provides new data sources and technical means for financial enterprise credit evaluation [22]. Deep learning algorithms, especially ResGAT, significantly improve the precision and reliability of credit evaluation by effectively processing graph-structured data. The development and application of these technologies not only promote the digitalization process of financial enterprises, but also provide strong support for enterprise risk management. By combining the research results of several literatures, it can be seen that the application of ResGAT in the credit evaluation of financial enterprises has a broad prospect and is worthy of further in-depth research and practice.

This article is organized as follows. Section II presents related research work. Section III presents the details of the credit evaluation model, including the problem description and the evaluation indicators used in the analysis. Section IV introduces the Quantum Genetic Algorithm (QGA) and its application in optimizing the ResGAT network. Section V presents the integration of QGA with ResGAT for financial enterprise credit evaluation and discusses the proposed enhancements. Finally, Section VI shows the experimental results, including dataset preparation, performance metrics, and a comparison of the DRQGA-ResGAT model with other optimization algorithms, discussion is given in Section VII followed by conclusions and future work in Section VIII.

II. Related Work

A. Graph Neural Networks in Credit Risk Prediction

Recent advancements in credit risk assessment (CRA) have shifted from traditional methods, which primarily rely on individual borrower or loan-level predictors, to more complex models that incorporate relational and network-based data. One significant approach combines graph-based models with machine learning techniques to better capture the interactions between different entities, such as borrowers and financial institutions. For example, the use of Relational Graph Convolutional Networks (RGCN) has proven effective in assessing the creditworthiness of Micro, Small, and Medium-sized Enterprises (MSMEs). By leveraging the topological structures of business relationships, RGCN helps identify key factors that influence credit risk, significantly improving the accuracy of predictions compared to conventional credit scoring models. This approach is further enhanced by integrating Random Forest (RF) classifiers, which categorize enterprises based on the embeddings generated by the graph model, achieving a balanced accuracy of 92% in the case of MSMEs in India [23]. Additionally, the dynamic nature of borrower relationships has been recognized as a crucial factor in predicting default risk. Recent work has incorporated Graph Neural Networks (GNNs) and Recurrent Neural Networks (RNNs) to model these evolving connections. By constructing a multilayer network where each layer reflects different sources of connection—such as geographical location or mortgage provider—these models offer a more nuanced understanding of how defaults propagate through networks over time. The use of custom attention mechanisms further refines these models, enabling them to weigh the importance of different time snapshots, which enhances their predictive power in behavioral credit scoring tasks [24]. Moreover, combining Graph Attention Networks (GAT) with Long Short-Term Memory (LSTM) networks has shown promise in capturing both the spatial and temporal dynamics of borrower interactions. Empirical results have demonstrated that such hybrid models not only outperform traditional methods in predicting default probabilities but also provide novel insights into the critical role of borrower relationships and time-sensitive data in credit risk assessment [25].

B. Graph Attention Networks and Residual Networks

Recent advances in deep learning have led to the development of residual graph attention networks (ResGAT) for a wide range of applications, showcasing the model's

versatility across different domains. In molecular property prediction, ResGAT has been applied to quantitative structure-activity relationship (QSAR) modeling, significantly improving the prediction of molecular properties by utilizing graph-structured data. The model effectively extracts key features from molecular graphs, addressing both regression and classification tasks. When tested on benchmark datasets, ResGAT demonstrated competitive performance and stability, outperforming state-of-the-art methods in terms of accuracy and generalizability [26]. In the field of software vulnerability detection, ResGAT has been integrated with a custom local feature extraction module and a dynamic loss function to handle imbalanced data, enabling the model to learn more effective node features from control flow graphs and achieve state-of-the-art results in detecting vulnerabilities [27]. In hyperspectral image (HSI) classification, a spectral-spatial variant of ResGAT (S²RGANet) has been proposed to address the limitations of conventional convolutional networks by combining spectral residual modules with graph attention for adaptive aggregation of spatial information. This method significantly improves classification accuracy, especially when the number of training samples is limited [28]. Lastly, in visual grounding tasks, ResGAT has been employed to model complex relationships between objects in images and their corresponding textual descriptions. A language-guided residual graph attention network (LRGAT-VG) is introduced to better handle long and complex expressions, incorporating language-guided data augmentation (LGDA) to enhance training data diversity. The model has achieved competitive performance on multiple visual grounding benchmarks, demonstrating its effectiveness in handling complex cross-modal tasks [29].

C. Hyperparameter Optimization

Hyperparameter optimization is a critical yet challenging task in machine learning, especially when models involve a large number of hyperparameters. Recent studies have proposed various methods to address this challenge. One approach focuses on modifying gradient-based methods to optimize multiple hyperparameters simultaneously, using two model selection criteria—cross-validation and evidence lower bound. The results show that models optimized using the evidence lower bound exhibit greater stability, particularly in noisy data scenarios, though they may yield slightly higher error rates than those selected via cross-validation. This method is particularly useful when dealing with overfitting or when cross-validation is computationally expensive [30]. Another study proposes a genetic algorithm-based approach, named HESGA (Hierarchical Evaluation Strategy Genetic Algorithm), to optimize hyperparameters of Graph Neural Networks (GNNs). By combining a full evaluation with a fast evaluation strategy, HESGA reduces the computational cost while maintaining the quality of the model. The method demonstrated its effectiveness in optimizing GNNs, showing superior performance over traditional Bayesian hyperparameter optimization methods on benchmark datasets [31]. A third approach, HyperBRKGA, introduces a population-based method for hyperparameter optimization that combines the Biased Random Key Genetic Algorithm (BRKGA) with an exploitation method. HyperBRKGA improves search efficiency by incorporating strategies like Random Walk and Bayesian Walk for better hyperparameter space exploration. The method outperformed traditional optimization algorithms, such as Grid Search and Random Search, on multiple datasets, demonstrating significant improvements in predictive performance [32].

III. Credit Evaluation Model

A. Description of the Problem

The application of enterprise digital transformation in credit evaluation of financial enterprises is one of the key topics in the current financial industry. With the rapid development of information technology, financial enterprises are constantly exploring and adopting new technological tools to enhance the precision and efficiency of their credit evaluation. The digital transformation of enterprises has provided financial institutions with rich data sources and advanced analytical tools, enabling them to assess the credit risk of borrowers or customers more comprehensively. This transformation is not limited to traditional financial data analysis, but also includes the integration and analysis of unstructured data (e.g., social media behaviors, spending habits, etc.) to more accurately portray a customer's credit profile. By applying algorithms like DRQGA-ResGAT, financial institutions are able to handle complex data patterns more efficiently and improve the predictive power and precision of credit evaluations within the framework of digital transformation, thereby optimizing lending decisions and risk management strategies.

B. Evaluation Indicators

In accordance with the basic principles of combining qualitative and quantitative indicators and combining potential and actual capabilities, the following enterprise credit rating indicator system structure was established. In addition, we divided the enterprise credit evaluation model into 9 first-level indicators and 25 second-level indicators, and each second-level indicator corresponds to a measurement content, as shown in Table I.

C. Model Data Normalization

The data depicted in Table I are discretely distributed and each level 1 indicator is independent of each other, so normalization can speed up the learning of the data. Define a set of input data $X = [x_1, x_1, \cdots, x_n]$ for the second-level indicators, and the maximum value of this set of data is $max(X)$ and the minimum value is $min(X)$. The normalized data is shown in Eq. (1).

$$x_i' = \frac{x_i - min(X)}{max(X) - min(X)}, i = 1,2,\cdots,n \quad (1)$$

TABLE I. EVALUATION INDEX SYSTEM

Level 1 Indicators	Level 2 indicators	Measuring Content
The quality of the enterprise itself	Information Disclosure Assessment Results for Listed Companies	character
Solvency indicators	Long-term debt-to-equity ratio	capacity
	Long-term borrowings to total assets	capacity
	Gearing	capacity
	Current ratio	capacity
	Long-term debt to working capital ratio	capacity
	Total EBITDA/Liability	capacity
	Equity multiplier	capacity
Indicators of operational capacity	Current asset turnover ratio	capacity
	Total asset turnover	capacity
Profitability indicators	Return on net assets	capacity
	Return on investment (ROI)	capacity
	Net profit margin on current assets	capacity
	R&D expense ratio	capacity
	Non-recurring gains and losses	capacity
	Cash to total profit ratio	capacity
Cash flow indicators	Net cash flow per share	capacity
Capacity development indicators	Growth rate of selling expenses	capacity
	Total asset growth rate	capacity
	Revenue growth rate	capacity
	Rate of capital accumulation	capacity
Shareholder profitability	Earnings per share	capital
	Net asset per share	capital
Long term assets	Net fixed assets of enterprises	collateral
Supply Chain Status	Supply chain concentration	condition

IV. QUANTUM GENETIC ALGORITHM BASED ON DYNAMIC REVOLVING DOORS

Quantum Genetic Algorithm (QGA) is an optimization algorithm that combines quantum computing and traditional genetic algorithms. It takes advantage of the superposition of quantum bits and the parallel computing property of quantum gates to make the search space wider and thus improve the optimization performance. Individuals in QGA are usually represented in the form of quantum bits, and their states are described by probability magnitude, and population evolution is carried out through quantum gate operations. QGA can effectively search for the global optimal solution, and it performs well in dealing with the complex optimization problems of multi-peak functions.

A. Quantum Encoding

According to the principle of quantum superposition states, in two mutually independent quantum states $|0\rangle$ and $|1\rangle$, their arbitrary linear superposition forms a quantum state:

$$|\varphi\rangle = \alpha|0\rangle + \beta|1\rangle \tag{2}$$

where the squares of α and β denote the probability that the system is at $|0\rangle$ and $|1\rangle$, respectively, and $\alpha^2 + \beta^2 = 1$. The mathematical model of (2) can also be referred to as the probability amplitude, which is denoted as:

$$|\varphi\rangle = \alpha\begin{bmatrix}0\\1\end{bmatrix} + \beta\begin{bmatrix}1\\0\end{bmatrix} = \begin{bmatrix}\alpha\\\beta\end{bmatrix} \tag{3}$$

B. Quantum Chromosomes

Traditional genetic algorithms usually use the problem parameter variable itself as an individual for optimization calculations and are computed through binary coding to form chromosomes that serve as information carriers so that they can convert the solution space into a search space that can be processed, thus completing the construction of the genetic structure of the individual.

While the quantum chromosome does not contain the problem solution directly, it constructs the quantum chromosome through the encoding method of quantum bits and expresses the state information through the form of probability amplitude shown in Eq. (3). According to Eq. (3), the Bth

quantum chromosome of generation t with m quantum bits and m observation angles i is:

$$X_i^t = \begin{bmatrix} \alpha_{i1}^t, \alpha_{i2}^t, \cdots, \alpha_{im}^t \\ \beta_{i1}^t, \beta_{i2}^t, \cdots, \beta_{im}^t \end{bmatrix} \quad (4)$$

C. Dynamic Quantum Revolving Door

In quantum theory, transitions between individual quantum states are realized using quantum gates. The quantum gate rotates the probability amplitude angle of the quantum bits, taking into account the most individual information, which always makes the population converge to the optimal solution. The expression for a quantum rotating gate is:

$$U(\Delta\theta) = \begin{bmatrix} cos(\Delta\theta), -sin(\Delta\theta) \\ sin(\Delta\theta), cos(\Delta\theta) \end{bmatrix} \quad (5)$$

where $\Delta\theta$ denotes the rotation angle of the individual. The quantum rotating gate does not change the mode length of the quantum bit, but only changes the phase of the quantum bit, which is shown schematically in Fig. 1.

When the rotation angle is too large, the QGA is easy to fall into the local optimal solution, and the angle is too small will lead to too slow convergence and consume a lot of computational resources. Numerous improved versions of QGA use a fixed rotation angle as shown in Eq. (5), in order to minimize the impact of the rotation angle on the final computational precision, this paper proposes a dynamic rotation strategy, which is calculated as follows:

$$\Delta\theta_i^t = \frac{\Delta\theta_i^{t+c} - \Delta\theta_i^{t-c}}{2c} + \theta_{max} - \frac{t}{T}(\theta_{max} - \theta_{min}) \quad (6)$$

where c denotes the sequence scale from the current state, t is the current iteration number, T is the maximum iteration number, θ_{max} is the maximum rotation angle, and θ_{min} is the minimum rotation angle.

According to Eq. (6), it can be seen that the size of the rotation angle is determined by the number of iterations and the amount of accumulated angle change. From the first half of (6), it can be seen that the rotation angle is related to the difference of the previous rotation angle, which enables the rotation angle to be associated with the past and future states, and a larger rotation angle is used in the pre-evolutionary stage to expand the search range, and a smaller rotation angle is used in the later stage of the evolution for accurate search. DRQGA is able to change the angle dynamically according to the characteristics of the problem and the performance of the individual constantly, correlating the previous step and future state information, thus adjusting the current angle. The dynamic rotation angles for 2D coding are shown in Table II. The flowchart of the DRQGA algorithm is shown in Fig. 2.

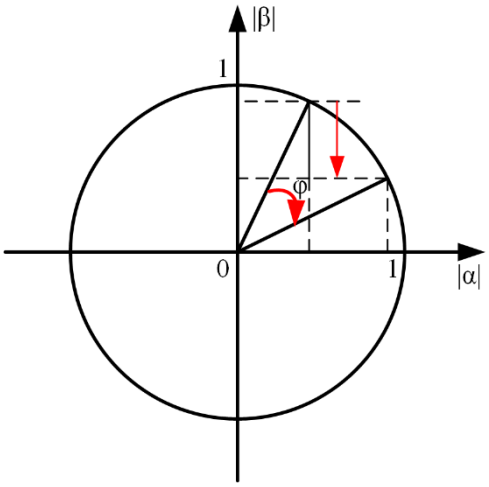

Fig. 1. Schematic diagram of a quantum revolving door.

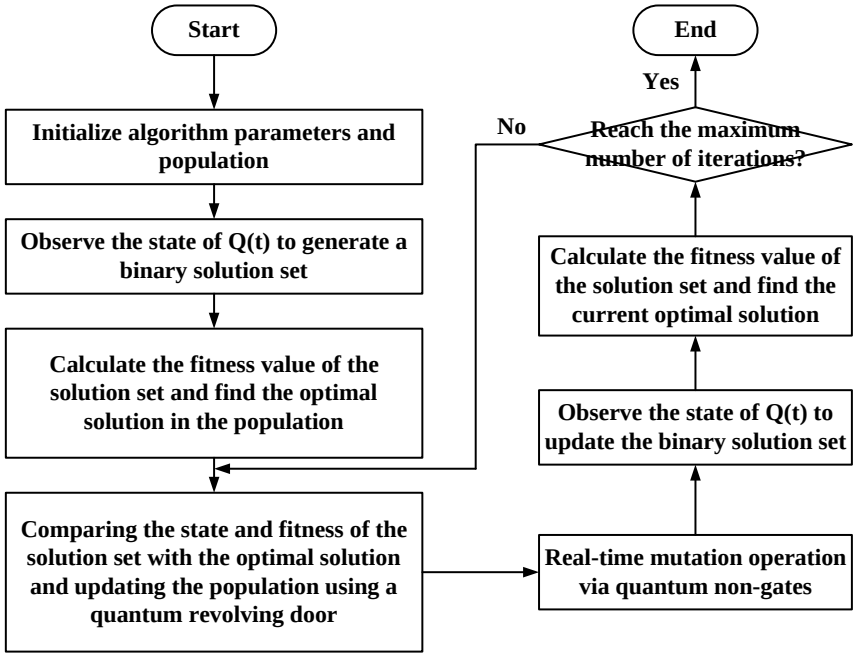

Fig. 2. Flowchart of DRQGA algorithm.

TABLE II. DYNAMIC ROTATION ANGLE LOOKUP TABLE FOR 2D CODING

x_i	x_i^{best}	$f(X) \geq f(X^{best})$	$\Delta\theta_i$	Rotary Angle Symbol

V. CORPORATE CREDIT EVALUATION MODEL BASED ON DRQGA-RESGAT

A. Financial Enterprise Credit Evaluation Mapping Data

In the process of credit evaluation of financial companies, we observe a significant effect of the financial leverage ratio on the overall credit score due to interactions between different credit evaluation indicators. The strength of these interactions varies with the particular combination of indicators, as determined by ANOVA. Considering these variables and their potential confounders in the modeling process, we propose to utilize the correlation information between the indicators as inputs to the model. To this end, we introduce a new data structure to accurately capture the effects of indicator interactions and improve predictive performance. We adopt the graph data structure approach proposed by Kipf and Welling [33], which proves to be very beneficial in analyzing the credit evaluation process. The graph data structure is able to efficiently encode information in a structured and meaningful way, representing both the attributes of each metric and the relationships between them. Fig. 3 illustrates an attribute-relationship graph describing the interrelationships of some of the credit evaluation metrics, where changes in the metric interactions can be interpreted as changes in the relationships between the nodes in the graph, utilizing $x_i, i = 1,2,\cdots,25$ to denote the second-level metrics we have defined and e_{ij} to denote the edges that are related, where $i, j = 1,2,\cdots,25, i \neq j$.

B. ResGAT Evaluation Model

In the process of credit evaluation of financial enterprises, GAT (Graph Attention Network) processes graph data, extracts attributes and relational features of nodes through a hidden masked self-attention layer, and uses an attention mechanism to process input variables, focusing on the most relevant parts. Credit evaluation metrics graph data can be processed through the graph attention network architecture to obtain higher-level feature representations. To cope with the overfitting problem under small sample conditions, we introduce a residual network architecture in the computation of the attention coefficients and the forward propagation of the model, which enhances the attention mechanism by introducing jump connections. As shown in Fig. 4, the ResGAT network consists of a residual feature extraction module and a graph attention module. The basic attribute features of credit evaluation metrics are represented by layers with residual connections, while the attention module provides learning focus based on the interaction information between metrics so that nodes can pay attention to the features in their neighborhood.

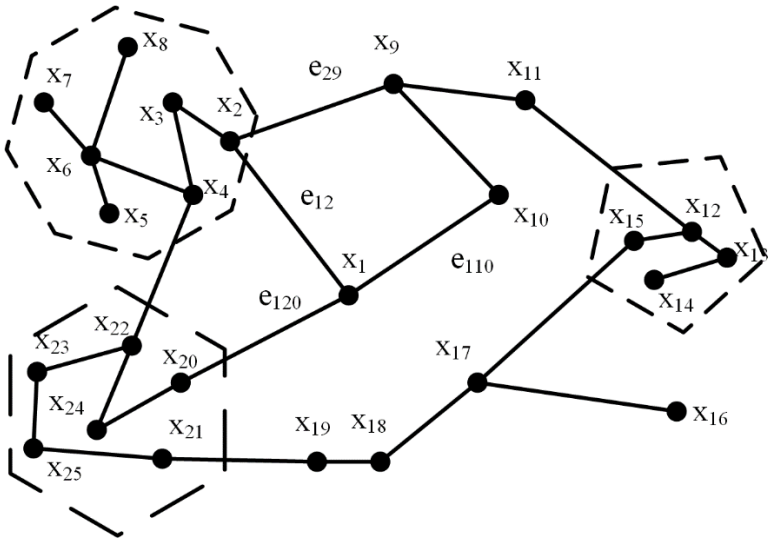

Fig. 3. Schematic diagram of indicator mapping.

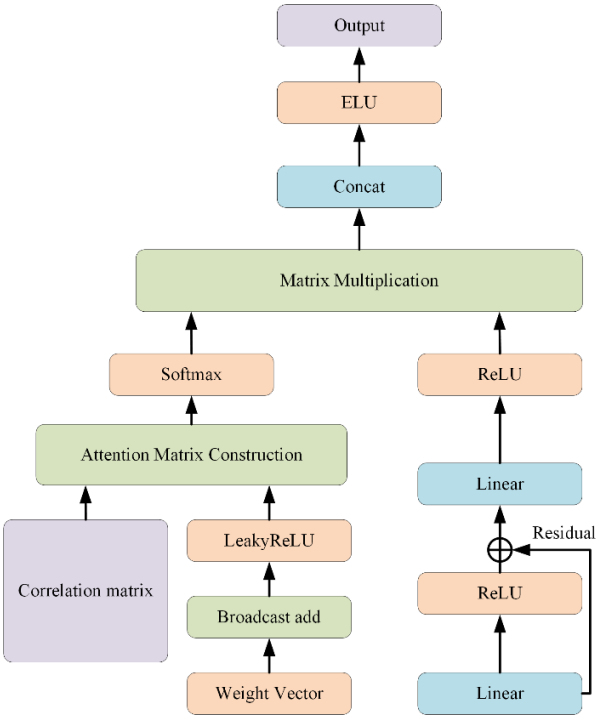

Fig. 4. Structure of the ResGAT network.

The input of the model is the evaluation index data after our normalization, and in the attention module, the attention coefficient e is calculated using the set of parameters to control the weight of the model, as shown in Eq. (7).

$$e = LeakyReLU((x \times a) + (x \times a)^T) \tag{7}$$

where x is the indicator parameter input, a is the trainable attention weights, and $LeakyReLU$ is the activation function as shown in Eq. (8). The plus sign in $(x \times a) + (x \times a)^T$ denotes the broadcast addition of the matrix.

$$y = max(0, x) + leak \cdot min(0, x) \tag{8}$$

Further, we use the adjacency matrix to represent the interaction between the parameters. Element A_{ij} indicates the existence of a significant interaction. When $A_{ij} = 1$, the interaction of indicator parameters X_i and X_j has a greater effect on the counterweight. An attention matrix Att is constructed using the attention coefficients e and 0 as shown in Eq. (10) and Eq. (11).

$$\hat{A} = \begin{bmatrix} 1 & A_{12} & A_{13} & \cdots & A_{1n} \\ A_{21} & 1 & A_{23} & \cdots & A_{2n} \\ A_{31} & A_{32} & 1 & \cdots & A_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & A_{n3} & \cdots & 1 \end{bmatrix} \tag{9}$$

$$\varepsilon_{ij} = \begin{cases} e, a_{ij} = 1 \\ 0, a_{ij} = 0 \end{cases} \tag{10}$$

$$Att_{ij} = Softmax(\varepsilon_{ij}) = \frac{exp(\varepsilon_{ij})}{\sum_{k \in N_i} exp(e_{ik})} \tag{11}$$

where ε_{ij} is an element of the adjacency matrix A, Att_{ij} is an element of the attention matrix Att, and N_i is the neighborhood quantity of node i in the graph. In order to avoid falling into degradation during the training of the network model, a residual connection is introduced in the propagation part of the right side, where the attention matrix of the left branch is multiplied with the result of the right branch after a nonlinear change, and w_1 and w_2 are assigned as weights thus obtaining the final result.

$$h = Att \times ReLU(x + ReLU(x \times w_1)) \times w_2 \tag{12}$$

C. DRQGA-ResGAT

In the credit evaluation process of financial enterprises, quantum genetic algorithm can significantly improve and enhance the performance of ResGAT network. The global optimization of ResGAT network using quantum genetic algorithm is as follows: the initial weights and attention coefficients of ResGAT network are optimized using quantum genetic algorithm. Then, the gradient descent algorithm is applied to adjust the parameters of the ResGAT network according to the negative gradient direction to train the network. The overall algorithm structure is schematically shown in Fig. 5.

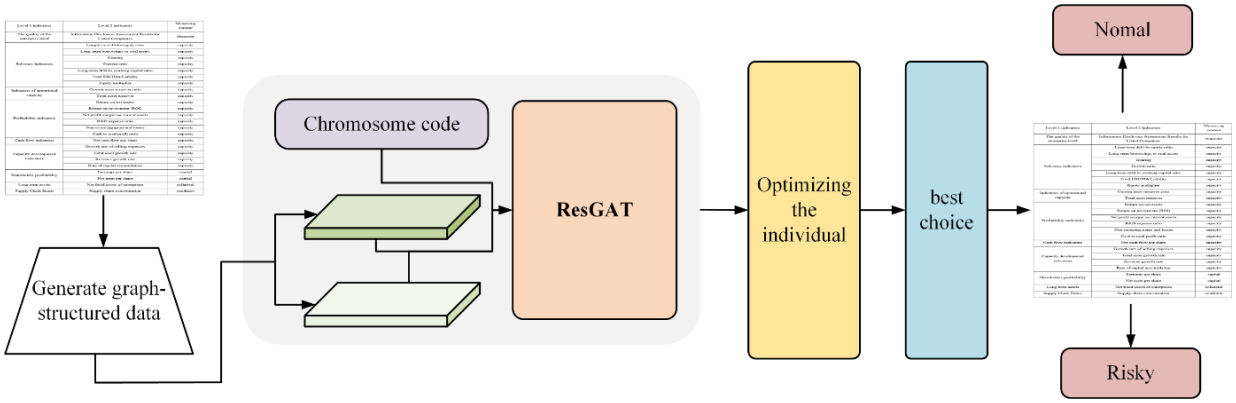

Fig. 5. The overall structure of the algorithm at a glance.

The main reasons for adopting this method to improve and enhance the ResGAT network are as follows:

- The quantum genetic algorithm utilizes quantum superposition and quantum gate operations to make the search space more extensive, effectively avoiding the shortcoming of the search range falling into a local minimum.
- The quantum genetic algorithm can converge quickly, thus reducing the number of training times of the weights and the attention coefficients.
- The parallel computing characteristics of the quantum genetic algorithm can significantly accelerate the convergence speed of the model.

The operation of the ResGAT network optimized by quantum genetic algorithm is divided into the following two steps:

1) Initialize the network parameters using quantum genetic algorithm: This step takes advantage of the superposition of quantum bits and the quantum revolving door operation to generate a variety of possible initial solutions, and obtain the optimal solution through quantum measurements, thus providing a better starting point for the network. Specifically, quantum genetic algorithms are used to determine the initial attention coefficients and weights of the ResGAT network, giving it a better performance from the start [34].

2) Chromosome coding: Since the quantum bit and quantum gate operations of the quantum genetic algorithm are able to represent continuous parameters, and the coding method of quantum states is characterized by continuous parameter optimization, the traditional steps of coding and decoding are omitted. To a certain extent, the computing speed and the precision of feasible solutions of quantum genetic algorithm are improved. Therefore, in this paper, the quantum state coding method is chosen to encode the chromosome. The quantum states are cascaded to the hidden layer nodes according to the input layer nodes and then cascaded from the hidden layer nodes to the output layer nodes. It should be noted that the chromosomes in the population are represented as a cascaded output array of quantum states.

3) Fitness function: The value of the fitness function determines the result of the quantum genetic algorithm's evaluation of the chromosome's survivability. The larger the value of the fitness function of a chromosome, the more likely it is to be selected for genetic manipulation and the smaller the sum of squares of the errors between the actual output value and the desired output value of the ResGAT network. The results show that the optimized ResGAT network has higher precision. In this paper, the logarithmic loss function is chosen as the adaptation evaluation function as shown in Eq. (13) to measure the performance of ResGAT network.

$$Loss = -\frac{1}{N}\sum_{i=1}^{N}[y_i log(p_i) + (1-y_i) log(1-p_i)] \quad (13)$$

VI. Model Experiment

A. Dataset

Dataset In this paper, 253 SMEs were selected from the CSMAR database in 2020 for the empirical study, and after the data preprocessing ticks, except for the enterprises with serious missing information, the missing information of the remaining enterprises was replaced by the mean value. Finally, 210 SMEs were selected. Among them, there are 137 normal enterprises and 73 risky enterprises.

B. Results

In this paper, precision rate and recall rate are selected as the key evaluation indexes, and six hyperparameters such as learning rate, batch size, number of hidden layers, number of hidden units per layer, weight initialization method, Dropout rate are optimized, and the precision rate is used as the objective function of the quantum genetic algorithm, and the GPU used in the training is the NVIDIA GeForce RTX 2080 Ti. The number of iterations of the quantum genetic algorithm $T=100$, the population size $Pop=100$, the number of quantum bits $nq=10$, and the mutation probability $mr=0.01$. The quantum genetic algorithm is compared with the classical simulated annealing algorithm, genetic algorithm, particle swarm algorithm, and whale optimization algorithm, and the algorithm comparison results obtained are shown in Fig. 6. A comparison of the results of DRQGA-ResGAT with other algorithms is shown in Table III.

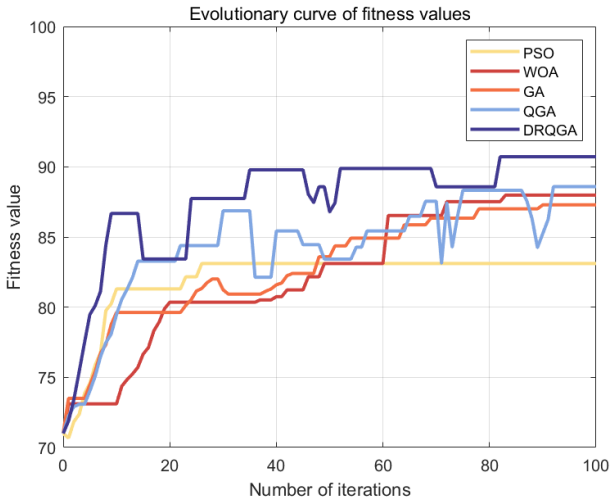

Fig. 6. Comparison of results of the optimization algorithm.

TABLE III. Performance of ResGAT Network Under Different Optimization Algorithms

Model	Precision	F1 score	AUC
PSO-ResGAT	0.8311	0.7939	0.9121
WOA-ResGAT	0.8798	0.8305	0.9476
GA-ResGAT	0.8728	0.7877	0.9298
QGA-ResGAT	0.8858	0.8439	0.9213
DRQGA-ResGAT	0.9071	0.8602	0.9647

The precision iteration curve of DRQGA-ResGAT under optimal hyperparameters is shown in Fig. 7. The training loss iteration curve is shown in Fig. 8. The validation loss iteration curve is shown in Fig. 9.

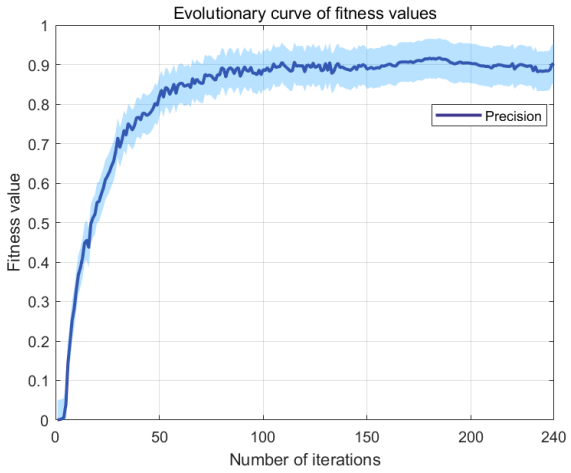

Fig. 7. Evolutionary curve of fitness values.

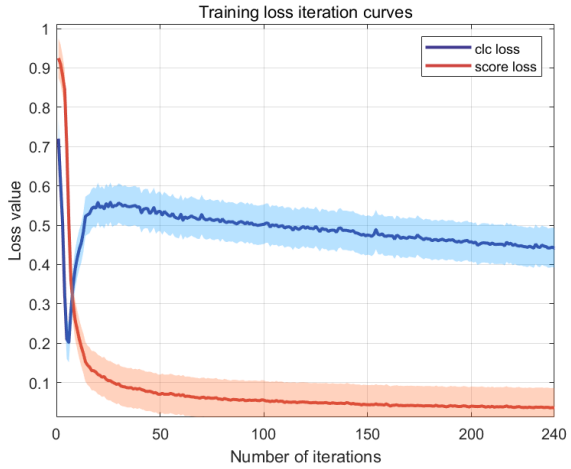

Fig. 8. Iteration curve of loss function for training set.

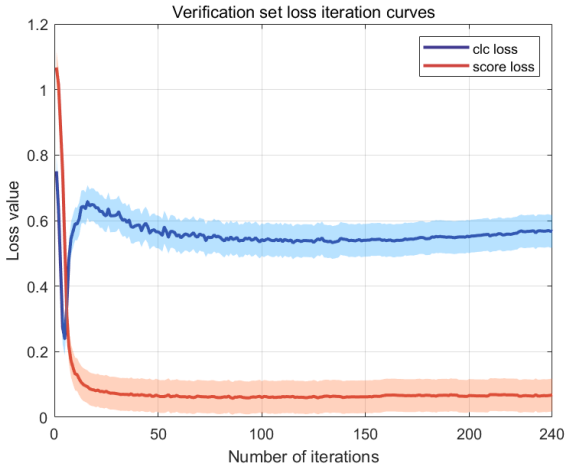

Fig. 9. Verification set loss function iteration curve.

TABLE IV. RESULTS OF ABLATION EXPERIMENTS

Model	Precision	F1 score	AUC
GAT	0.7310	0.7386	0.8431
ResGAT	0.7749	0.7795	0.8758
QGA-GAT	0.7705	0.7695	0.8812
QGA-ResGAT	0.8728	0.7877	0.9421
DRQGA-GAT	0.8001	0.7619	0.9257
DRQGA-ResGAT	0.9071	0.8602	0.9647

In order to explore the contribution of each improvement component, we conducted ablation experiments and the comparison results of the six different algorithms obtained are as follows. As can be seen in Table IV, DRQGA-ResGAT improves the precision by 24.09% compared to the most basic GAT, and the F1 score improves from 0.7386 to 0.8602. Compared to ResGAT, it improves by 17.06%. 3.92% compared to QGA-ResGAT and 13.37% compared to DRQGA-GAT. It can be seen that the precision of the models optimized with hyperparameters using DRQGA for GAT or ResGAT is significantly improved. Meanwhile, based on the GAT model, the ResGAT model with the introduction of the residual mechanism is able to achieve higher precision and more performance improvement with DRQGA optimization.

VII. DISCUSSION

Compared with the classical ResGAT model, DRQGA-ResGAT improves the evaluation precision by 17.06%, which is 3.92% higher compared with QGA-ResGAT. Compared with the classical optimization algorithm, the dynamic revolving door-based quantum genetic algorithm is able to explore the global optimal solution on a larger scale [35], and its ability to cope with mutant data makes the algorithm less susceptible to be interfered by special data. interference, thus ensuring the overall individual quality [36]. In future research, we will consider introducing the optimization strategy of the population intelligence optimization algorithm into the dynamic internal adjustment of the network model [37], and further exploring the combination of the optimization algorithm and deep learning network on the basis of hyperparameter tuning. In addition, on top of the existing datasets, larger datasets should be considered to enhance the scope of enterprises into the risk evaluation of enterprises in various industries.

VIII. CONCLUSION

Under the digital transformation of enterprises, in order to be able to evaluate the credit of financial enterprises more comprehensively and objectively, this paper adopts a quantum genetic algorithm based on dynamic revolving door for hyper-parameter tuning of residual map attention network. On this basis, a financial enterprise credit evaluation model is established. Specifically, the introduction of quantum genetic algorithm effectively enhances the optimization ability of the model and makes it perform well in the hyperparameter optimization search process. In addition, the excellent performance of the residual graph attention network in dealing with graph-structured data enables the model to better capture the complex associations among enterprises, thus enhancing

the precision of credit evaluation. The experimental results show that the DRQGA-ResGAT algorithm outperforms other algorithms in key metrics such as precision rate, F1 value and AUC value. Especially when compared with the classical simulated annealing algorithm, genetic algorithm, particle swarm algorithm and whale optimization algorithm, DRQGA-ResGAT shows obvious advantages, which verifies its potential for application in the credit evaluation of financial enterprises.

A Conceptual Framework for Agricultural Water Management Through Smart Irrigation

Abdelouahed Tricha, Laila Moussaid, Najat Abdeljebbar
National High School for Electricity and Mechanics (ENSEM), Hassan II University of Casablanca, Casablanca, Morocco

***Abstract*—The demand for freshwater resources has risen significantly due to population growth and increasing drought conditions in agricultural regions worldwide. Irrigated agriculture consumes a substantial amount of water, often leading to wastage due to inefficient irrigation practices. Recent breakthroughs in emerging technologies, including machine learning, the Internet of Things, wireless communication, and advanced monitoring systems, have facilitated the development of smart irrigation solutions that optimize water usage, enhance efficiency, and reduce operational costs. This paper explores the critical parameters and monitoring strategies for smart irrigation systems, emphasizing soil and water management. It also presents a conceptual framework for implementing sustainable irrigation practices aimed at optimizing water use, improving crop productivity, and ensuring cost-effective management across different agricultural settings.**

***Keywords*—Agriculture; irrigation system; water management; Internet of Things; sustainability**

I. Introduction

The growing global population demands a continuous supply of high-quality food, placing increasing pressure on agriculture to boost productivity [1]. Achieving this goal requires effective water management, as irrigation plays a critical role in crop yield. However, managing complex agricultural ecosystems demands constant monitoring and control of multiple factors, such as soil moisture, weather conditions, and crop health. To address these challenges, information and communication technologies (ICT) offer valuable solutions by enabling the efficient collection, transmission, and analysis of diverse datasets. ICT facilitates decision-making and policy development for agricultural planning and improves water management through remote monitoring and control of irrigation systems. With real-time feedback, farmers can optimize irrigation schedules, reducing water waste and enhancing crop performance. Additionally, ICT promotes the integration and interoperability of different irrigation technologies, including soil moisture sensors, water balance models, plant signals, remote sensing tools, and GPS mapping, leading to more sustainable and efficient farming practices.

Irrigation is one of the most vital services in the agricultural industry, particularly in regions with low rainfall. Meeting the water demands of crops is crucial for crop quality and production. However, inadequate irrigation can lead to a decrease in crop quality and production [1], [2]. Diverse methods and technologies are used to effectively manage water resources to address this issue. These include water balance, plant signals, or soil moisture sensors, which can be technically backed by cloud computing and the Internet of Things (IoT). IoT uses low-power network connectivity to link physical items to the internet. One application of IoT for irrigation scheduling includes wireless sensor networks (WSN), which connect soil moisture sensors to the web [3], [4], [5], [6], [7]. This allows farmers to remotely monitor and control their irrigation systems, leading to more efficient water usage and potentially higher crop yields. Additionally, the data collected from these sensors can be analyzed to provide insights into soil health and crop growth patterns, aiding in decision-making for future planting seasons.

This paper contributes to the field of smart irrigation by addressing critical gaps in the literature and proposing a systematic approach to enhance water management and sustainability in agriculture. By focusing on both the technical and practical challenges, the paper offers an integrated framework for developing more efficient irrigation systems. The paper is structured as follows: Section I introduces the importance of irrigation and water management in agriculture, while Section II presents a comprehensive survey of the literature on current smart irrigation technologies. In Section III, we explore critical parameters for smart irrigation systems, including soil and water management. Section IV reviews monitoring strategies, focusing on soil-based and weather-based approaches. In Section V, we propose a conceptual framework for implementing a smart irrigation system, including system architecture and workflow. Finally, Section VI concludes the paper by summarizing the key insights and potential directions for future research.

II. Related Works

In recent years, diverse technologies such as the IoT, machine learning (ML), and big data have significantly impacted irrigation practices. This section delves into various studies and works that involve the application of these emerging technologies in irrigation system management and control. The focus is on the primary technologies and methods used in smart irrigation systems: IoT, data-driven approaches, and advanced technologies. Each subsection summarizes key findings, advantages, and drawbacks of existing studies, while identifying research gaps and opportunities for future work.

A. Internet of Things

The IoT is a network of physical objects connected to the internet, capable of communication, data collection, and data exchange. IoT has been widely applied in irrigation, enabling remote monitoring and control of systems, and the collection

and analysis of diverse datasets related to soil, weather, and crop conditions.

Several studies have explored IoT-based irrigation systems for precision agriculture using various techniques and platforms. One such system developed an IoT-based irrigation system via the ARETHOU5A platform, incorporating wireless sensor nodes powered by a rectenna, which recovers radio frequency energy to power the nodes [8]. Another notable work proposed a highly accurate irrigation system utilizing IoT, fuzzy logic, and GSM [9]. This system employs a fuzzy logic controller to compute input variables such as humidity, temperature, and soil moisture to generate motor status, and includes an automatic shut-off mechanism during precipitation to conserve resources. Additionally, an intelligent multi-agent IoT precision irrigation strategy has been presented, leveraging technologies like the MQTT protocol and IoT for real-time monitoring and analysis of crop water requirements [10].

While these studies highlight the potential of IoT to enhance smart irrigation systems, they also underscore several challenges. Data quality and security of IoT devices and networks are major concerns. IoT devices, often exposed to harsh environmental conditions, can face reliability and accuracy issues. Furthermore, these devices and networks are vulnerable to cyberattacks, potentially compromising the integrity and availability of irrigation systems. Ensuring the robustness and resilience of IoT devices and implementing stringent data quality and security measures is crucial. Another challenge is the scalability and interoperability of IoT-based systems. Integrating and coordinating a growing number and diversity of IoT devices and platforms can be difficult, necessitating the development and adoption of common standards, protocols, and architectures to ensure seamless integration.

B. Data-Driven Approaches

Data-driven approaches utilize data to generate insights, predictions, or decisions, playing a significant role in optimizing irrigation systems by analyzing water usage based on various data sources and techniques. For instance, integrating Geographic Information System (GIS) technology with irrigation systems has improved water use efficiency [11]. A system leveraging cloud-based near real-time data storage and processing enables the adaptation of the Penman-Monteith evapotranspiration coefficient to local weather conditions, incorporating data collection and soil moisture measurement capabilities. Another study focused on optimizing water usage in an IoT system by moving data computation to the edge, allowing for real-time data processing and quick decision-making despite limited internet connectivity [12]. This system estimates water requirements by calculating evapotranspiration potential and employs AI algorithms for detecting plant diseases and pests. Furthermore, a non-contact vision system using a standard video camera and a neural network has been proposed to predict the irrigation needs of loamy soils based on soil color differences [13].

These studies illustrate the benefits of data-driven approaches in optimizing water usage and improving crop yield. However, challenges such as data availability and accessibility persist. Large and diverse data sets are essential for accurate results, but data may be scarce due to a lack of sources, collection devices, or sharing platforms. Incomplete, inconsistent, or noisy data can further affect result quality. Ensuring data availability, accessibility, and implementing proper data cleaning, preprocessing, and validation techniques is vital. Additionally, the complexity and interpretability of data-driven methods can pose difficulties, especially for non-experts. Simplifying and explaining these methods and results, along with providing user-friendly interfaces and feedback mechanisms, is crucial.

C. Advanced Technologies

Advanced technologies offer innovative solutions for enhancing smart irrigation systems, providing automation, intelligence, and security. An automatic irrigation system measuring soil humidity and temperature with sensors was designed to prevent irrigation when humidity is high, conserving water resources, and to permit irrigation when humidity is low [14]. This system employs the Decision Tree algorithm to predict and analyze data. Additionally, WSN have been leveraged to build comprehensive irrigation systems, covering different farm regions with various sensor modules transmitting data to a shared server [15]. ML algorithms support crop and weather-based irrigation model predictions. Addressing security concerns, lightweight cryptography techniques in IoT, such as the Expeditious Cipher (X-cipher) for secure channels in the MQTT protocol, have been proposed to protect data integrity and confidentiality [16].

While these studies highlight the benefits of advanced technologies in irrigation, challenges such as cost, maintenance, compatibility, and integration remain. Advanced technologies can be expensive and complex to acquire, install, and operate, especially for small-scale farmers. Frequent maintenance and updates increase operational costs. Ensuring the affordability, simplicity, and providing adequate training and support for users is essential. Additionally, integrating advanced technologies with existing systems and practices can be difficult, necessitating efforts to ensure compatibility and seamless integration.

III. Critical Parameters for Smart Irrigation

Several parameters are used to assess the efficacy of the smart irrigation system. Both soil and water management are incorporated into an intelligent irrigation system. Soil management incorporates numerous parameters, including soil moisture, temperature, conditions, salinity, and so on. Water management parameters consist of dewpoint temperature, evapotranspiration, air temperature, atmospheric temperature, and relative humidity. In addition to these variables, the smart irrigation system must take forecast accuracy, data transmission rate, and actual usage into account [17].

A. Soil Management

Historically, soil supervision was once among the most difficult agricultural tasks for both businesses and cultivators. Several environmental issues that affect agricultural performance are revealed by soil analysis. If these types of obstacles are precisely characterized, agricultural models and methods can be easily understood. Soil management involves

various parameters, such as soil moisture, soil temperature, soil conditions, soil salinity, and so on.

Soil moisture is one of the most important parameters for irrigation scheduling, as it indicates the water content and availability in the soil. Soil temperature is another parameter that affects the crop growth and development, as it influences the germination, root growth, nutrient uptake, and microbial activity. Soil conditions refer to the physical, chemical, and biological properties of the soil, such as texture, structure, pH, organic matter, nutrients, and microorganisms. They affect the water retention, infiltration, drainage, and availability in the soil, as well as the crop health and quality. Soil salinity is the concentration of soluble salts in the soil, which can affect the osmotic potential, water uptake, and nutrient availability for the crops. Soil salinity can be caused by natural factors, such as weathering, evaporation, or seawater intrusion, or by human factors, such as irrigation, fertilization, or drainage. Moisture sensors can measure these parameters using different methods, such as capacitance, resistance, or gravimetric for the moisture, thermistors or thermocouples for the temperature, electrodes or spectrometers for soil conditions, and conductivity, reflectance, or fluorescence for soil salinity. These sensors can be integrated with IoT systems to transmit the soil parameters data to a cloud server, where it can be processed and analyzed to determine the optimal irrigation status, to support fertilization and irrigation decisions, and to prevent the effects of soil salinity on the crops. The results of a soil analysis survey are used to enhance crop production and provide producers with fertilization options [18]. Overfertilization and crop degradation can be avoided when using IoT techniques for identifying dirty soil.

Soil management preserves and improves productivity. It boosts agricultural productivity and quality, lowers input costs, and reduces pollution. For the crop to grow quickly and efficiently, the topsoil must be in good condition before planting. Even if each farm and crop have its own soil requirements, organic fertilization, soil testing, right tillage, chemical soil protection, etc. can encourage healthy soil biology [19].

B. Water Management

Determining the proper amount of water needed in greenhouses is a challenging task. Several IoT strategies are used to place and control smart sensors to prevent water waste. Greenhouses achieve water storage by using an automated drip irrigation system that is controlled by a soil moisture threshold. Utilizing various types of sensors, IoT technology can aid in water management by preventing water loss. The quantity of water in the tank is monitored by sensors, and the data is stored in the cloud via a mobile app, so farmers can track the water level with their smartphones. Using this method, the engine will run autonomously. The engine will automatically start if the water level declines below a predetermined level, and if the water level rises above a predetermined level, the engine will automatically shut off. IoT-powered intelligent irrigation systems can help farmers conserve water and improve crop quality by watering crops at the optimal time. Intelligent irrigation systems deploy temperature and soil sensors on farms, and these sensors transmit field data to producers via a gateway. Controllers for weather-based precision agriculture monitor and adjust irrigation schedules based on local weather data [19], [20], [21].

In addition to IoT, numerous other technologies can be used to manage irrigation water and to estimate the quantity of irrigation water required by adjusting the evapotranspiration coefficient calculated using the Penman-Monteith method [22].

IV. Irrigation Monitoring Strategies

Constructing an effective irrigation management system that increases food production while minimizing water loss necessitates a dependable monitoring system for the various variables influencing plant growth and development. To collect data that precisely reflects the current soil, plant, and weather conditions of plant irrigation zones, the IoT and WSN technologies are both used for monitoring in the field of precision irrigation [23], [24].

When developing a real-time monitoring system, sensors must be integrated with the IoT Framework or a wireless sensor communication network. Because of their capabilities for sensing, processing, and transmission, wireless networks are vital for real-time monitoring in smart irrigation. Geography or climate may affect monitoring in intelligent irrigation.

A. Soil-Based Monitoring

One of the most important factors in the growth of plants is soil moisture. Comprehensive geographical and temporal monitoring of the soil moisture content is required to ensure effective irrigation scheduling. Additionally, it is crucial to monitor soil moisture in the plant roots because it sheds light on moisture dynamics and the relationship between irrigation water volume and plant water uptake. There are various indirect techniques for determining soil moisture levels, including electromagnetism, thermal conductivity, neutron counting, water potential, electrical resistance, and direct measurements of soil moisture (gravimetric sample) [25].

Real-time soil moisture monitoring using sensors is a practical and accurate method for measuring moisture fluxes [26]. This approach involves accurately correlating the volumetric water content of the soil with the capacity of the inserted sensor probes. A highly accurate method for soil moisture measurement uses time-domain reflectometry (TDR) sensors [27] , which consist of two parallel rods inserted into the soil at a depth corresponding to the target moisture level. In another example, the IoT soil moisture surveillance solution proposed by [28] leveraged wireless networks, specifically GSM and infrared communication, to provide automatic irrigation and conserve water. The system used a capacitance-based soil moisture sensor with two electrodes to measure soil resistance, which was then processed by a PIC 16F877A microcontroller. Based on the detected soil moisture level, the microcontroller activated or deactivated the water pump through a relay driver.

B. Weather-Based Monitoring

Real-time estimation of baseline evapotranspiration using observed meteorological variables as an indicator of water loss from the plant and soil environment is becoming increasingly popular in weather-based monitoring. Solar radiation, ambient temperature, and wind velocity are the primary determinants of

the rate of water loss. These parameters can be determined using a weather station [23].

The FAO Penman-Monteith equation [29], provides a robust method for estimating daily or hourly evapotranspiration values from standard meteorological data, including atmospheric temperature, solar radiation, relative humidity, and wind speed. This method is widely recognized as a reliable approach for calculating reference evapotranspiration (ET_0), which serves as the baseline for determining the water needs of crops. The equation is expressed as in Eq. (1):

$$ET_0 = \frac{0{,}408\Delta(R_N - G) + \gamma\frac{900}{T+273}\mu_2(u_s - u_a)}{\Delta + \gamma(1 + 0{,}34\mu_2)} \quad (1)$$

Where ET_0 is the reference evapotranspiration (mm/day), R_N is the net radiation at the crop surface (MJ/m²/day), G is the soil heat flux density (MJ/m²/day), T is the mean daily air temperature (°C), μ_2 is the wind speed at 2 meters (m/s), u_s is the saturation vapor pressure deficit (kPa), u_a is the actual vapor pressure (kPa), Δ is the slope of the vapor pressure curve (kPa/°C), γ is the psychrometric constant (kPa/°C).

The daily crop evapotranspiration (ETc) is then calculated using Eq. (2):

$$ET_C = k_C * ET_0 \quad (2)$$

Hence: ET_C is the evapotranspiration of plants (mm / Day). K_C is the crop coefficient and ET_0 is the evapotranspiration reference (mm / Day).

This method allows for the precise calculation of water requirements tailored to specific crops, ensuring that irrigation is applied in accordance with actual crop water demand. Weather-based monitoring systems often rely on WSN to monitor environmental conditions accurately. These systems have been widely implemented as an efficient method for interconnecting numerous sensors over large agricultural areas. Closed-loop, real-time monitoring, and analysis of sensor data activate control devices based on a predetermined threshold value [30], [31].

These strategies are visually summarized in Fig. 1, highlighting the key parameters for both soil-based and weather-based monitoring approaches.

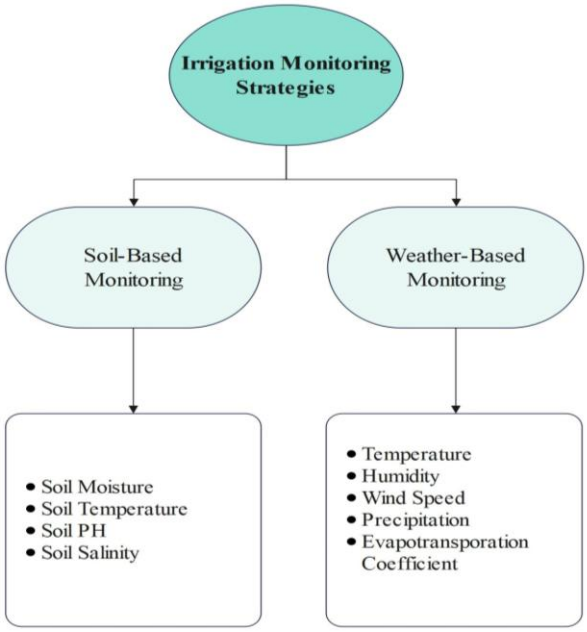

Fig. 1. Irrigation monitoring strategies adopted from study [25].

V. Proposed Framework for a Comprehensive Smart Irrigation System

A. System Overview

The proposed smart irrigation system is a sophisticated framework engineered to optimize water resource management in agricultural settings. It integrates advanced sensing technologies, data analytics, and automated control mechanisms to ensure precise, efficient, and sustainable irrigation practices. The system's core functionalities include real-time data acquisition, processing, analysis, and intelligent decision-making that leads to highly accurate control of irrigation processes.

As illustrated in Fig. 2, the system's architecture comprises multiple interconnected components, each playing a pivotal role in the overall management process. The system operates hierarchically, with data flowing from field-level sensors to the cloud, where comprehensive analysis and remote monitoring are conducted.

B. Fundamental Layers of the System

The proposed smart irrigation system is structured into distinct components that work collaboratively to ensure efficient and precise water management. These components are organized into layers, each with a specific function, enhancing the system's scalability, reliability, and ease of operation. Fig. 3 provides an overview of these layers.

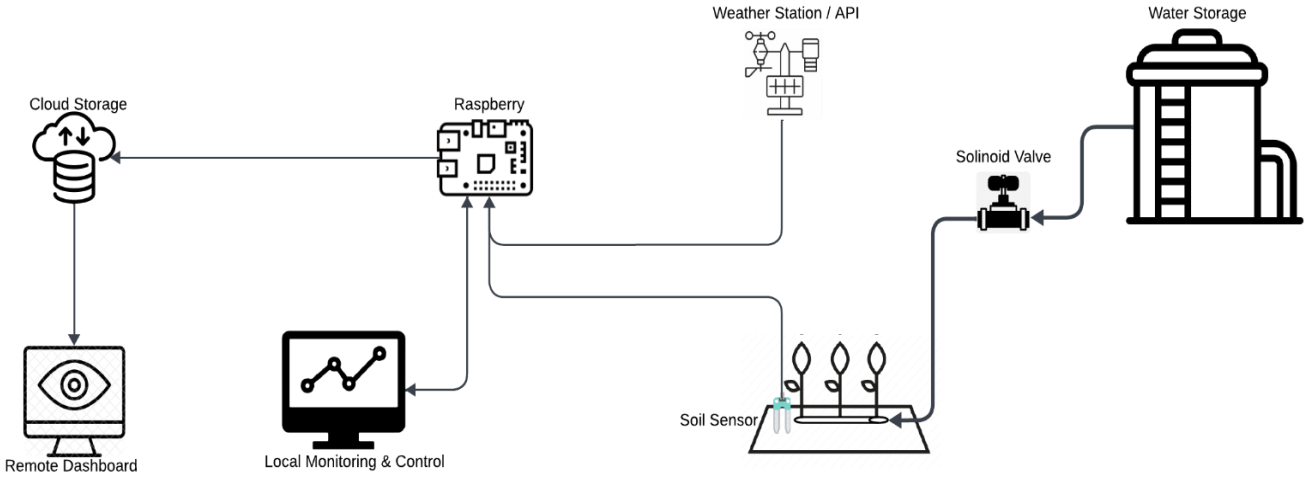

Fig. 2. Proposed system architecture.

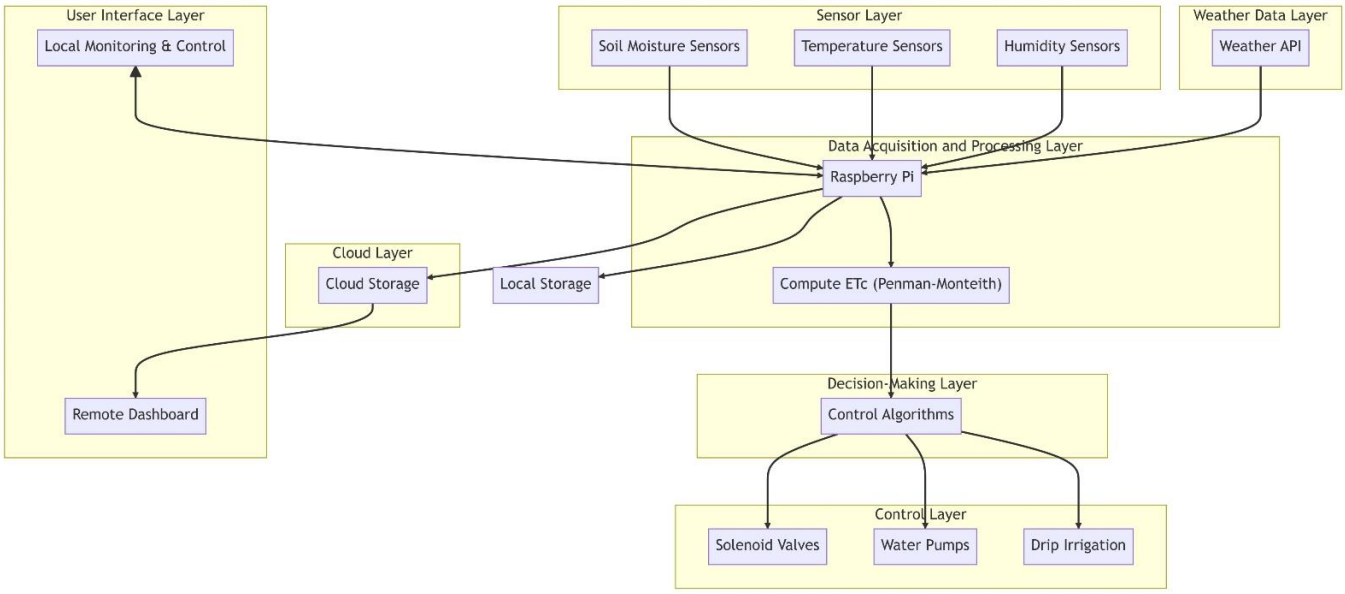

Fig. 3. Layers of the proposed system.

1) Sensor layer: The sensor layer forms the foundational tier of the system, designed to capture essential agroclimatic data from the field. This layer includes soil moisture sensors placed at various depths, allowing for accurate real-time monitoring of soil water content. These sensors provide critical insights into the hydration status of the soil, which directly informs irrigation decisions.

In addition to soil moisture sensors, the system integrates weather data either through meteorological stations or APIs, collecting parameters like temperature, humidity, solar radiation, wind speed, and precipitation. By combining soil and environmental data, the system accurately assesses water stress in crops, enabling precise irrigation scheduling. This data also plays a significant role in calculating the ET_0 using the Penman-Monteith Eq. (1), crucial for determining the crops' water needs.

2) Data acquisition and processing layer: This layer is responsible for collecting, transmitting, and preparing the data for further analysis. Sensor readings are transmitted to the control unit via efficient wireless communication protocols like LoRaWAN or Zigbee, ensuring low power consumption and minimal data loss. Once received, raw data undergoes preprocessing (cleaning, calibration, and normalization) to ensure accuracy and comparability. This process transforms the data into actionable insights, such as identifying soil moisture trends and temperature fluctuations.

Processed data is stored locally for real-time decision-making and periodically synchronized with the cloud for long-term analysis and backup. This dual-storage approach ensures the system operates efficiently while enabling remote access to historical data for improved decision-making.

3) Decision making layer: The decision-making layer is essential to the smart irrigation system, responsible for analyzing data from various sensors to generate precise irrigation schedules. It extracts insights on soil moisture, weather conditions, and crop development, enabling informed water management decisions based on real-time environmental factors. A critical function is calculating ET_C based on ET_0 (1) and applying crop coefficients K_C (2).

This layer generates irrigation schedules that optimize water usage by considering soil moisture, weather forecasts, and irrigation efficiency. Optimization algorithms or rule-based approaches ensure efficient irrigation timing. Additionally, ML models enhance decision-making by learning from historical data, improving predictions of crop water requirements and refining irrigation strategies over time, akin to methods used in precipitation prediction in Casablanca, Morocco [32].

4) Control layer: The control layer manages the execution of irrigation commands. It coordinates devices such as valves, pumps, and sprinklers, ensuring that water is delivered according to the schedules generated by the decision-making layer. The system continuously monitors environmental conditions and adjusts irrigation in real time. For instance, in case of unexpected rainfall, the control layer can halt irrigation to prevent overwatering.

Furthermore, this layer handles error detection and power management, optimizing energy use by aligning irrigation activities with off-peak hours, which reduces operational costs. By efficiently managing water and energy resources, the control layer supports sustainable irrigation practices.

5) Cloud layer: The cloud layer in the proposed smart irrigation system is primarily used for data storage and remote visualization through a centralized dashboard. It stores processed data, including sensor readings and irrigation schedules, ensuring secure, long-term access for analysis and system optimization. This approach is particularly suited for regions with poor or intermittent internet connectivity, as the system can function locally and synchronize data with the cloud when the connection is available, maintaining continuous operation without relying on constant internet access.

In addition to storage, the cloud layer provides real-time data visualization via a web-based dashboard. This allows farmers and administrators to remotely monitor critical metrics such as soil moisture levels, irrigation schedules, and overall system performance, even in areas where reliable connectivity is limited.

6) User interface layer: The user interface layer facilitates human-computer interaction for system monitoring, control, and data visualization. It comprises two primary components:

- Local User Interface: A user-friendly interface accessible through a local device (e.g., tablet, computer) allows farmers to monitor real-time sensor data, control irrigation schedules, and make necessary adjustments directly within the system. This local interface provides full control over the irrigation process, enabling immediate responses to changing conditions in the field.
- Cloud-Based User Interface: A web-based interface provides remote access for data visualization and performance monitoring. Through this interface, farmers and system administrators can visualize real-time and historical data, review system performance metrics, and analyze trends.

C. System Functionality and Workflow

The proposed smart irrigation system operates through a sequential process involving data acquisition, processing, analysis, decision-making, control, and user interaction. Fig. 4 illustrates the flowchart of this process.

- Data Acquisition: The system gathers environmental data, including soil moisture, temperature, humidity, and solar radiation, from sensors strategically placed throughout the agricultural field and weather station. This data is essential for understanding field conditions and informing irrigation decisions.
- Data Transmission: Collected data is transmitted to the central control unit via wireless communication protocols, ensuring reliable and efficient data transfer.
- Data Preprocessing: Raw sensor data undergoes cleaning, normalization, and feature extraction to prepare it for analysis and decision-making. Data cleaning identifies and removes outliers, missing values, or inconsistencies. Normalization scales data to a common range, facilitating comparison and analysis.
- ETc Calculation: Crop water requirements are estimated using the Penman-Monteith method as shown in Eq. (1) and Eq. (2).
- Irrigation Scheduling: Optimal irrigation schedules are generated based on ETc, soil moisture data, and weather conditions. Optimization algorithms or rule-based approaches are employed to determine the most efficient irrigation strategies.
- Irrigation Control: Irrigation devices are activated and deactivated according to the generated schedules. Real-time adjustments can be made based on sensor data and weather conditions.
- Data Analysis and Monitoring: Collected data and system performance metrics are analyzed to evaluate irrigation efficiency, crop water use, and equipment status. Regular monitoring and analysis enable continuous improvement and optimization of the system.
- User Interaction: Farmers and system administrators can interact with the system through local and cloud-based interfaces to monitor performance, adjust parameters, and access historical data.

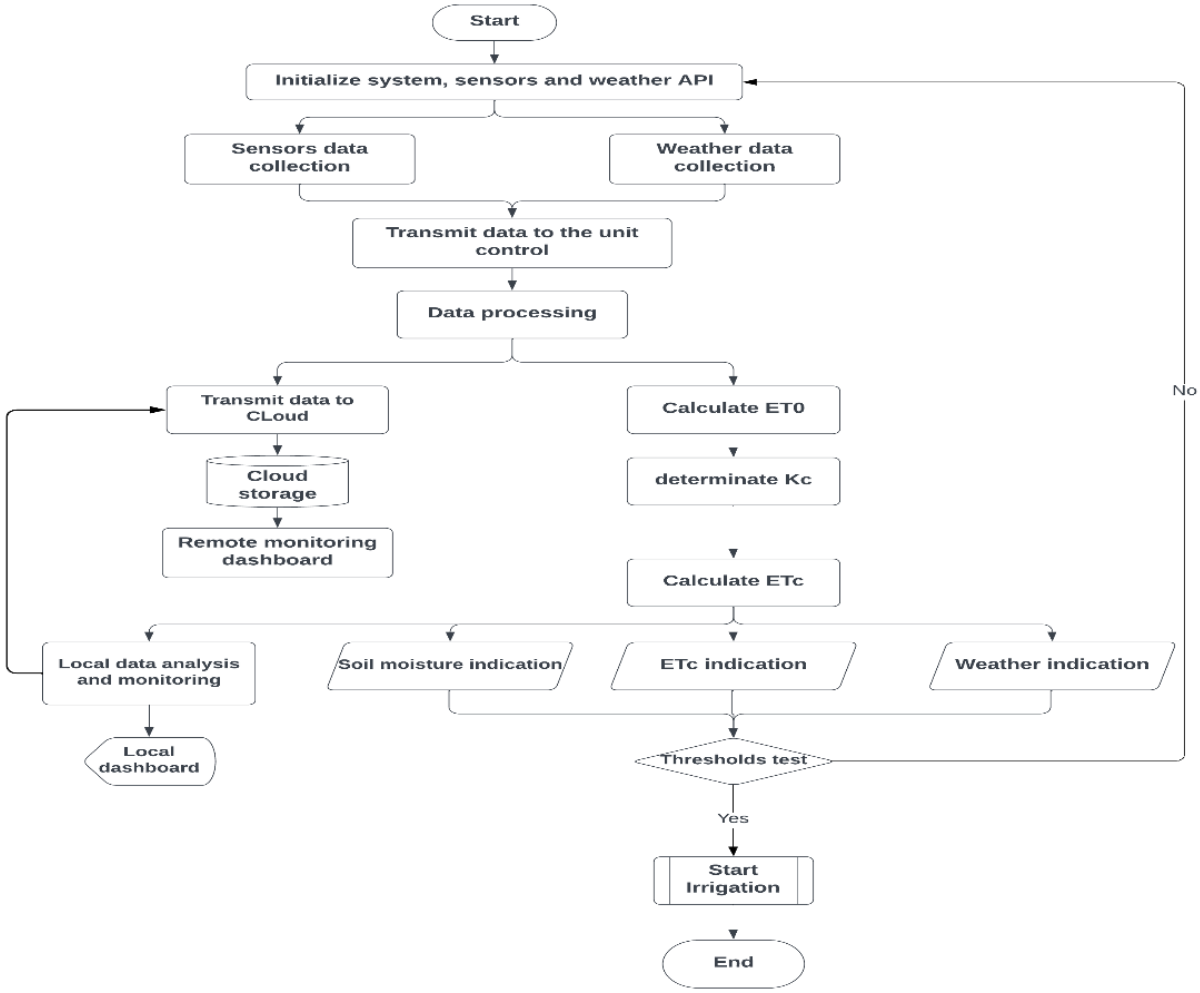

Fig. 4. Workflow of the proposed approach.

VI. Conclusion

The integration of advanced technologies into irrigation systems plays a pivotal role in delivering efficient and sustainable solutions for modern agriculture. Our proposed smart irrigation system, leveraging IoT technology, sensor networks, and intelligent algorithms, addresses the pressing challenges of water conservation while enhancing crop productivity. At its foundation, the sensor layer provides crucial real-time data on soil moisture and environmental conditions, feeding into advanced data processing and decision-making layers. By correlating soil moisture levels with meteorological data and calculating reference evapotranspiration, the system achieves a nuanced understanding of crop water requirements, enabling precise irrigation management that minimizes water waste while maximizing yield and crop quality.

While our approach shows great promise, further research and field testing are necessary to validate its effectiveness across various crop types and climatic conditions. Future work should focus on refining the system's predictive capabilities, incorporating ML algorithms, and exploring the integration of additional data sources. As we continue to refine and expand this system, we move closer to realizing the vision of precision agriculture, where resource use is optimized, environmental impact is minimized, and crop yields are maximized. Our proposed smart irrigation system represents a significant step forward in the pursuit of sustainable and efficient agricultural water management, offering a practical solution to the global challenge of water scarcity in agriculture.

An Efficient Diabetic Retinopathy Detection and Classification System Using LRKSA-CNN and KM-ANFIS

Rachna Kumari[1], Sanjeev Kumar[2] , Sunila Godara[3]
Research Scholar, Department of Computer Science & Engineering, Guru Jambheshwar University of Science & Technology, Hisar, India[1]
Professor, Department of Computer Science & Engineering, Guru Jambheshwar University of Science & Technology, Hisar, India[2, 3]

***Abstract*—If Diabetic Retinopathy (DR) is not diagnosed in the early stages, it leads to impaired vision and often causes blindness. So, diagnosis of DR is essential. For detecting DR and its diverse stages, various approaches were developed. However, they are limited in considering microstructural changes of visual pathways associated with the visual impairment of DR. Thus, this work proposes an effective Linearly Regressed Kernel and Scaled Activation-based Convolution Neural Network (LRKSA-CNN) to diagnose DR utilizing multimodal images. Primarily, the input Optical Coherence Tomography (OCT) image is preprocessed for contrast enhancement utilizing Contrast-Limited Adaptive Histogram Equalization (CLAHE) and resolution enhancement utilizing the Gaussian Mixture Model (GMM). Likewise, the Magnetic Resonance Imaging (MRI) image's contrast is also improved, and edge sharpening is performed utilizing Unsharp Mask Filter (USF). Then, preprocessed images are segmented utilizing the Intervening Contour Similarity Weights-based Watershed Segmentation (ICSW-WS) algorithm. Significant features are extracted from the segmented regions. Next, important features are chosen utilizing the Min-max normalization-based Green Anaconda Optimization (MM-GAO) algorithm. By utilizing the LRKSA-CNN technique, the selected features were classified into DR and Non-Diabetic Retinopathy (NDR). Hence, utilizing the Krusinka Membership-based Adaptive Neuro Fuzzy Interference System (KM-ANFIS), various stages of DR were classified based on the presence of intermediate features. Lastly, the proposed system achieves superior outcomes than the baseline systems.**

***Keywords*—Intervening contour similarity weights based watershed segmentation (ICSW-WS); min-max normalization based green anaconda optimization (MM-GAO); krusinka membership based adaptive neuro fuzzy interference system (KM-ANFIS); linearly regressed kernel and scaled activation based convolution neural network (LRKSA-CNN); and deep learning**

I. Introduction

The well-known reason for visual deficiency is DR, which is also known as diabetic eye disease. DR has turned into a global pandemic with 365 million individuals expected to be impacted by 2025 [1]. People who have diabetes for a long duration are more likely to develop DR, and it impressively causes vision loss by the gradual destruction of the retina's blood vessels over a while [2]. Lesions like Neovascularization (NV), exudates, hemorrhages, and microaneurysms may develop in DR patients. For proper intervention, these lesions need to be detected early. Thus, to manage DR and prevent progression, early detection and treatment are the most efficient ways [3] [4].

Various tasks associated with automatic DR diagnosis have been performed in the past decades. The automatic classification of DR from retinal images is increasingly studied owing to the huge number of diabetic patients and the need for more accurate and automatic diagnosis [5]. Artificial Intelligence (AI) can help in solving this problem. For analyzing raw medical images from beginning to end and predicting a goal result, Deep Learning (DL), particularly, Deep Convolutional Neural Networks (DCNN) and Deep Neural Networks (DNNs) can be utilized [6] [7].These systems have been trained on tens of thousands of medical images and demonstrated screening performance similar to that of retinal specialists [8]. Various screening tools are available to receive those kinds of medical images, such as the visual acuity test, OCT, colour fundus camera, eye angiography, and so on [9] [10]. The conventional screening of fundus images to diagnose DR lesions takes time, thus delaying therapy and minimizing the chance of success [11]. But, severe bleeding symptoms cover NV outside the macula in fundus photography, which leads to misdiagnosis [12]. However, evaluating the intensity of retinopathy in people with diabetes is mostly dependent on human assessment of retinal fundus pictures, which is complicated to perform [13] [14]. These problems can be alleviated via the use of OCT, which together provide micrometer-scale resolution structural, 3-dimensional (3D), depth-resolved, and vascular images of the retina [15]. But, recent studies showed that visual deficiency for DR is also associated with the pathophysiological changes of different parts of the visual pathway. To maintain visual function, the evaluation of the progressive visual pathway along with the visual field is considered to be a vital process.

A. Problem Statement

Most of the prevailing models developed for DR diagnosis were limited in solving the following challenges:

- Limited research was performed for exposing the invisible pathophysiological mechanism i.e.,

pathophysiological changes and related damages to the different retinal layers along with the cerebral visual pathway to diagnose diabetic retinopathy.

- Improper segmentation of small regions was caused by the loss of apparent activity in tiny objects or else regions due to the imaging systems' limited resolution that is, blurring of intensities near their edges.
- Owing to the poor image resolutions and the inability of such images to exhibit more pixel information, the segmentation techniques were ineffective on OCT images and ignored detailed information.
- Prevailing techniques utilized limited features and the model often predicted near the same value due to the exclusion of some key features, which influenced the outcome of the prediction system.
- Prevailing techniques utilized limited features, and the exclusion of some key features caused the model to often predict near the same value, which might influence the outcome of the prediction system.

Thus, for solving the aforementioned problems, this paper proposes an effective LRKSA-CNN-based DL technique for DR diagnosis. The proposed system includes the subsequent contributions:

- A multimodal imaging strategy is used to explore microstructural changes in the visual pathway and invisible pathologies inside the retina structure.
- To recover blurred intensities of edges, remove imperfections in the images, and make edges easier to the visible edge, sharpening is performed to avoid improper segmentation of small regions.
- The finer details of images were accurately revealed via the resolution enhancement of OCT images utilizing the PIR technique to improve the segmentation accuracy.
- Along with the intermediate features, the global and local features were also extracted, which enhances the model efficiency to better explore the progression of eye disease.

This paper's remaining portion is aligned as: Section II reviews the associated works, Section III describes the proposed technique, Section IV propounds the experimental outcomes and discussion, and Section V concludes the paper.

II. Related Literature Survey

M. Sakthisreedevi *et al.* [16] detected DR by identifying its features in OCT images. Utilizing the graph-cut technique, 7 retinal layers were segmented from the OCT images. Next, the features of retinal layers were extracted for differentiating normal and DR subjects. Experimental outcomes showed that for diagnosing DR, the extracted features were effective. But, the system was limited in specifying the classification process. Mahmoud Elgafi *et al.* [17] propounded a three-step model for DR detection using OCT images. The retinal layers were segmented and the 3D features were extracted from every single layer. Utilizing Backpropagation Neural Networks (BPNN), the features were classified. Experimental outcomes displayed the recommended technique's potential for DR detection using OCT images. But, the system accuracy was poor owing to the usage of limited data. Brahami Menaouer *et al.* [18] established a hybrid DL technique for DR detection. DCNN and Visual Geometric Group (VGG) network models-centric classification were followed in this model. The classification as per the visual risk was related to the retinal ischemia's severity. According to the experimental outcomes, the hybrid technique diagnosed DR accurately with more speed. The model's major limitation was the increased training time to train its parameters. Sambit S. Mondal *et al.* [19] presented an automated ensemble DL system for DR detection. The images were pre-processed and augmented utilizing a General Adversarial Network (GAN).For DR detection, the modified DenseNet101 and ResNet DL systems were the ensemble. The comparison exhibited that for DR classification, this technique had high accuracy. But, the system accuracy was low for five classes rather than two classes. M. Murugappan *et al.* [20] implemented the Few Shot Learning (FSL) classification networks to grade and detect DR centered on the attention mechanism. The model utilized an episodic learning strategy and attention mechanism for the few-shot classification task. As per the analysis of performance metrics, the model effectively detected DR. However, to prove the efficiency of the developed system, the comparison made in the paper was limited. Muhammad Mohsin Butt *et al.* [21] recommended a hybrid technique for DR detection as well as classification in fundus images. Utilizing transfer learning-based CNN, the features were extracted. The features were merged into a hybrid feature vector and utilized for the DR classification. Experimental outcomes revealed that significant performance improvement was provided by the model. But, the supremacy of model performance was degraded by the poor quality of input images. Abdüssamed Erciyas & NecaattinBarışçı [22] propounded a DL-centric framework for DR lesions' detection and classification. The DR lesions were detected from the DR data and marked utilizing Regional CNN (FRCNN).By utilizing the transfer learning and attention mechanism, the images from FRCNN were categorized. The result comparison showed that the developed system acquired more successful outcomes. Still, the system utilized larger computational resources. Mohamed Elsharkawy *et al.* [23] established an OCT-centric diagnosis technique for detecting DR. By utilizing prior shape knowledge, the model segmented the retinal layers. For global subject diagnosis, the classification was performed utilizing an Artificial Neural Network (ANN). The comparison outcomes indicated the ability of the system for diagnosing DR. However, the model attained poor classification accuracy owing to the limited number of features. Wejdan L. Alyoubi *et al.* [24] executed DR images' classification under various stages and localization of affected lesions. Two DL models, namely CNN-512 for classification and the YOLOv3 system for localizing DR lesions were utilized. The DR images were classified into five DR stages. The YOLOv3 model cannot detect smaller DR lesions owing to its anchor box design even though the acquired accuracy exceeded baseline outcomes. Mohammed Ghazal *et al.* [25]

concentrated on detecting Non-Proliferative DR (NPDR) utilizing CNN. Initially, the retina patches were extracted. Transfer learning centered on 2 pre-trained CNNs was utilized, where one was independently fed by nasal retina patches and the other one by temporal retina patches. The outcomes showed that the system attained a promising accuracy. But, the improper alignment of patches led to lower accuracy of the model. S. K. Sahu *et al.* [26] implemented different AI-based transfer learning models for diabetic retinopathy at early stages. The accuracy transfer learning models ranges from 74% to 81. S. Goswami [27] proposed an iterative attentional feature fusion (iAFF) method for DR detection. Model used InceptionV3 and Xception feature extraction. IDRiD data set was used for training and testing purpose. N. Z. Abidin and A. Ritahani Ismail [28] propose a federated deep learning model eliminate the need of pooling data in a single location. This model allowed deep learning algorithms to train from diverse sets of data from different sources. O. F. Gurcan *et al.* [29] proposed a metaheuristic algorithm based on deep learning for DR detection. In Model InceptionV3 was used to extract feature. The transfer learning method is applied in the extraction process. Particle Swarm optimization and Artificial Bee Colony were used for feature selection. Which were further classified eXtreme Gradient Boosting (XGBoost). M. Jahiruzzaman [30] proposed a k-means color compression technique to detect hemorrhages and exudates in color fumdus images. The different region of fundus images were segmented out and classified using fuzzy inference system. M. Ghazal [31] proposed a computer aided diagnostic (CAD) system using CNNs for non-proliferative DR (NPDR) detection at early stage. A two pre-trained CNNs, one is independent fed of nasal retina patches and the other is by temporal retina patches was used to optimize the performance of model which was accuracy of 94%. H. Mustafa *et al.* [32] proposed a multi-stream ensemble deep network to categorize DR severity at different stages. Model utilizes benefits of the deep networks and principal component analysis (PCA) to train inter-class and intra-class variations from image features. Pre-trained deep learning architecture DenseNet-121 was used to extract main feature and Ensemble machine learning classifiers PCA was applied to classify images. Further AdaBoost and random forest algorithms were applied to improve classification accuracy. K. Aurangzeb *et al.* [33] implemented a ColonSegNet model for retinal vessel segmentation. This method efficiently locate vessels and applied data augmentation to resolve fewer graded images issues using intelligent evolution algorithms optimal values for the contrast enhancement were identified. DRIVE, CHASE_DB, and STARE datasets were used for training and testing purpose. M. Nur-A-Alam [34] proposed an automatic and intelligent system to classify DR images. First retinal images were pre-processed, then histograms of oriented gradient (HOG), Shearlet transform, and Region-Based Convolutional Neural Network (RCNN) were used to extract discriminating features and merged features as one fused feature vector. By using the fused features, a faster RCNN classifier was used to DR severe stages. R. Pires et al. [35] presented the bag-of-visual-words (BoVW) based algorithm for lesion detection in retinal images. The input of the metaclassifier work as output 9BoVW) of several lesion detectors. This algorithm create a high-level feature representation for the retinal images to lesion detection. M. T. Islam *et al.* [36] proposed a multi-stage convolutional neural network (CNN)-based model DiaNet to DR. study of this paper revealed that fundus images restrain sufficient information to differentiate the Qatari diabetes cohort from the control group. D. Maji [37] proposed a novel deep learning approach for retinal blood vessel and DR. The EfficientNet model was used with pre-trained weights facilitating transfer learning and optimize convergence speed. X. Wang *et al.* [38] proposed a supervised deep learning framework for macula-related disease classification with uncertainty estimation. In their model a convolutional neural network based instance-level classifier was refined by through uncertainty-driven deep learning method. Second, a recurrent neural network extract features and generated bag-level. M. M. Farag *et al.* [39] proposed a noval deep-learning-based method for DR detection using a single Color Fundus photograph. Authors employed DenseNet169's encoder to assemble a visual embedding. Then, Convolutional Block Attention Module (CBAM) was utilized to reinforce its discriminative power. At last, the model was trained on (APTOS) dataset using cross-entropy loss. T. Liu *et al.* [40] proposed a novel deep symmetric convolutional neural network to detect the microaneurysms (MAs) and hard exudates (HEs) of DR. Furthermore, different convolution pooling structures were practiced to obtain feature filtering in feature extraction phase. They concluded that microaneurysms detection was improved by using ave-pooling layer. G. T. Reddy *et al.* [41] implemented Linear Discriminant Analysis (LDA) and Principal Component Analysis (PCA) dimensionality reduction techniques, on Random Forest Classifier, Decision Tree Induction, Naive Bayes Classifier and Support Vector Machine (SVM), using Cardiotocography (CTG) dataset. From their paper it is concluded that performance of the classifiers, Random Forest, Decision Tree is not much affected by PCA and LDA. E. O. Rodrigues *et al.* [42] proposed a new ELEMENT (vEsseL sEgmentation using Machine lEarning and coNnecTivity) framework for vessel segmentation. Features were extracted based on vessel connectivity and grey level properties. This model speeds up the segmentation throughput and minimize. S. Wang *et al.* [43] proposed an integrated machine learning approach for microaneurysms detection. In this method first Candidate objects were located through a dark object filtering process. Then correlation coefficient between each processed profile and MA profile was determined. Furthermore, K-nearest neighbor classifier was applied to extract set of statistical features. K. Shankar *et al.* [44] proposed an automated Hyperparameter Tuning Inception-v4 (HPTI-v4) model for DR detection. At the preprocessing stage, contrast limited adaptive histogram equalization (CLAHE) was used to improve the contrast level of images. Furthermore, the HPTI-v4 model was employed to extract the essential features from the segmented image and then multilayer perceptron (MLP) was used for classification. B. Yang *et al.* [45] implemented a global channel attention mechanism (GCA) framework to detect DR at early stages. In this module, a one-dimensional convolution kernel size algorithm was used and GCA-EfficientNet (GENet) was employed to classify images. Experimental outcomes

conclude that GENet are more effective to extract lesion features and classify DR stages. I. Usman and K. A. Almejalli [46] implemented a new machine learning technique based on Genetic Programming for MAs detection in retinal images. The optimal expression was evolved generation by generation using the binary fitness scores and a stepwise enhancement process. The best expression obtained was then used as a classifier MA. B. Abdillah *et al.* [47] implemented texture feature model based on Local Binary Pattern for DR detection. k-Nearest Neighbor (k-NN) and Support Vector Machines (SVM) was used for classification of images. M. J. J. P. van Grinsven et al. [48] proposed a CNN based method for detection of hemorrhages in retinal images. Based on current status of CNN, Training samples were heuristically misclassified negative samples and weights are assigned in the next CNN training iteration. A. Krestanova *et al.* [49] reviewed all segmentation techniques for retinal blood vessel extraction. Their review included analysis of segmentation techniques based on degree of curvature of retinal blood vessels and objectification parameters. They reviewed all calculations and metrics to obtain the degree of tortuosity of retinal blood vessels. K. Wisaeng and W. Sa-Ngiamvibool [50] proposed a mathematical morphology algorithm to localize OD. Firstly, a coarse segmentation method was utilized to obtain exudates and non-exudates candidates. Finally, mathematical morphology algorithm was applied to classify exudates pixels. X. Li *et al.* [51] proposed a self-supervised learning model for DR detection. They used a rotation-oriented collaborative method to extract rotation-related and rotation-invariant features. Model was evaluated on two public datasets. G. Gupta [52] proposed a supervised learning framework based on micro-pattern of local variations using texture based analysis to localize patches colored fundus images. Rule-based criteria was used to determine the presence or absence of PDR. R. Kommaraju and M. S. Anbarasi [53] developed a machine learning framework to detect DR at early stages of color fundus images. Their model employed a swin transformer to detect the type of DR and Contrast Limited Adaptive Histogram Equalization (CLAHE) technique was used for image enhancement and flip for data augmentation. R. Gambhir [54] proposed a Shufflenetv2 method to detect DR at severity levels. Smooth L2 loss had been used to improve performance of model.

III. Proposed Diabetic Retinopathy Detection System

The proposed model is a type for analyzing both the invisible pathologies on different retinal layers and pathophysiological changes on various parts of the visual pathway. For attaining this, the proposed LRKSA-CNN model is trained on multimodal medical images like OCT and fMRI. Fig. 1 displays the proposed system's detailed workflow.

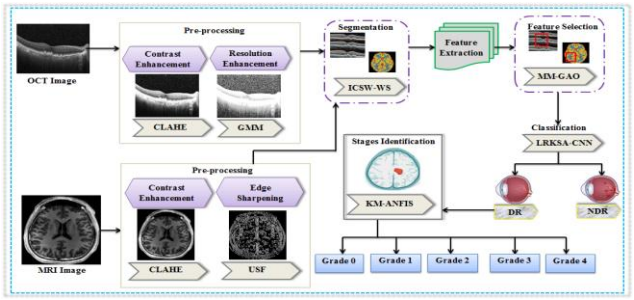

Fig. 1. Block diagram of the proposed methodology.

A. Preprocessing

The proposed technique's initial phase is preprocessing in which input OCT and MRI images are preprocessed for contrast enhancement. Since these images were obtained under various lighting conditions, they have lower contrast and require to be preprocessed before the execution model training. Thus, by utilizing the CLAHE technique, the input images' contrast was improved. Let $\left(R = \left\{R_{O(n)}, R_{M(n)}\right\}_{n=1}^{N}\right)$ be the set of input images, including two types of images, namely OCT $\left(R_{O(n)}\right)$ and MRI $\left(R_{M(n)}\right)$. These images are divided into smaller blocks $\left(R_m\right)$ by CLAHE, which computes the histogram $\left(\wp i(R_m) = \frac{\aleph_j}{\aleph_{avg}}\right)$ individually for each block. In the computation of the histogram, the average number of pixels per region is calculated as,

$$\aleph_{avg} = \frac{\aleph_h \times \aleph_v}{\aleph_{gr}}, \qquad \aleph \in R \tag{1}$$

Here, $\aleph_{avg}$ is the average number of pixels, $\aleph_{gr}$ is the number of grey levels, and $\aleph_h$ and $\aleph_v$ are the number of pixels in the horizontal and vertical dimensions. Subsequently, the clip limit to clip the histogram $\left(\wp i(R_m)\right)$ is defined and employed for the histogram as,

$$\aleph_\ell = \aleph_{avg} \times \aleph_{n\ell} \tag{2}$$

$$\wp i(R_m) = \begin{cases} \aleph_\ell & if\left(\aleph_j \geq \aleph_\ell\right) \\ \aleph_j & Otherwise \end{cases} \tag{3}$$

Here, $\aleph_j$ specifies the pixels with intensity (j), $\aleph_{n\ell}$ indicates the normalized level of contrast enhancement, and $\aleph_\ell$ depicts the clip limit. Next, the clipped pixel values are computed for evenly redistributing the clipped pixel values below the histogram.

$$\aleph_p = (\aleph_h \times \aleph_v) - \sum_{i=1 to K-1} \wp i(R_m) \quad (4)$$

Here, $\aleph_p$ depicts the number of clipped pixels, and K symbolizes the total number of grey levels. Next, the clipped histogram is normalized as,

$$\wp i(R_m) = \begin{cases} \aleph_\ell & if\left(\aleph_j + \frac{\aleph_p}{K} \geq \aleph_\ell\right) \\ \aleph_j + \frac{\aleph_p}{K} & Otherwise \end{cases} \quad (5)$$

Till all the pixels are redistributed, these steps are continued, and the cumulative histogram of every single region is calculated for grey-level mapping. Lastly, the histogram of each region is matched for computing the weighted sum of $(m_{1,2,3,4})$ neighboring regions, and the enhanced output is acquired by the interpolation of neighboring regions. The output image is acquired as,

$$R_{ce} = (1-h)(1-v) \times R_{m1} + h \times R_{m2} + v \times (1-h) \times R_{m3} + h \times R_{m4} \quad (6)$$

Here, $\left(R_{ce} = \{R_{eO(n)}, R_{eM(n)}\}_{n=1}^{N}\right)$ are the output-enhanced images, and (h) and (v) are the horizontal and vertical distances corresponding to the region.

From the preprocessed images, OCT images' spatial resolution is enhanced, and edge sharping for MRI images is performed.

1) Resolution enhancement of OCT: Here, the quality of $(R_{eO(n)})$ as OCT images' lower spatial resolution affects the segmentation outcome. Enhancing the resolution of OCT images gives vital information held in each pixel suitable for decision-making at the regional level. Thus, the patch-centric resolution enhancement utilizing GMM is given below:

The resolution enhancement technique executes the task of reconstructing the enhanced image $(R_{seO(n)})$ of *the input image* $(R_{eO(n)})$ centered on the low-resolution observation $(R_{lrO(n)})$ utilizing GMM. The enhanced image $(R_{seO(n)})$ is reconstructed by solving the following objective function as,

$$\arg\min_{R_{seO(n)}} \left\| \partial R_{eO(n)} - R_{lrO(n)} \right\|^2 - \sum_{i \in R} \log \hat{\lambda}\left(R_{eO(n)}, i\right) \quad (7)$$

Here, ∂ signifies the unknown operator for generating low-resolution observation $(R_{lrO(n)})$, $R_{lrO(n)}$ indicates the observed low-resolution image, $\hat{\lambda}$ symbolizes the probability density function, and $(R_{eO(n)}, i)$ are the patches in the input image.

To reconstruct the high-resolution image, the reference images $\{R'_{lrO(n)}, R'_{hrO(n)}\}$ are considered. From them, the low-resolution $\{R'_{lrO(n)}, i\}$ and high-resolution $\{R'_{hrO(n)}, i\}$ patches are extracted and concatenated $R' = \begin{pmatrix} R'_{lrO(n)} \\ R'_{hrO(n)} \end{pmatrix}$ for obtaining the parameters of GMM $(\alpha, \beta, \gamma, \lambda)$. The $\{R_{hrO(n)}, i\}$ from $(R_{eO(n)})$ is computed by choosing the best component of GMM as,

$$\chi = \arg\max_{\chi} \alpha \, p\left(R_{lrO(n)} \mid \alpha, \beta, \gamma, \lambda\right) \quad (8)$$

Here, the likelihood (p) of $\{R_{lrO(n)}, i\}$ to the χ component is maximal. Using the parameters, the high-resolution patch $\{R_{hrO(n)}, i\}$ is computed as,

$$R_{hrO(n)} = \alpha_{hr,\chi} + \sum_{hr,lr,\chi} \sum\nolimits_{lr,\chi}^{-1} \left(R_{lrO(n)} - \alpha_{lr,\chi}\right) \quad (9)$$

Here, the high-resolution patches $(R_{hrO(n)})$ are centered on the parameters of the generalized Gaussian mixture $\alpha_{hr,\chi}$. From all the estimated high-resolution patches, the high-resolution image $(R_{seO(n)})$ is reconstructed and utilized as input for the segmentation. This phase ignores the MRI images since they have better contrast resolution properties to extract images' finer details.

2) *Edge sharpening*: Here, the preprocessed MRI image $(R_{eM(n)})$ is utilized to recover edges that have been blurred owing to the partial volume effect. By doing so, the ideal boundary between two structures is restored for quantitatively distinguishingvarious types of tissues in the segmentation process. When performing edge sharpening for the OCT images, the noise in the image is also enhanced; thus, it becomes less natural and the level of information in flat and smooth areas is lost. Thus, the OCT images were not considered here. The USF is utilized for edge sharpening.

The main purpose of a USF is to subtract an unsharp mask from the input image. For this, the unsharp mask, that is, the original image's even more blurred version is yielded by spatially filtering the input image utilizing a Gaussian low-pass filter. The Gaussian function is derived as,

$$\eta(a,b) = \frac{1}{\varpi\sqrt{2\pi}} \exp\left(\frac{-a^2 - b^2}{2\varpi^2}\right) \quad (10)$$

Here, $\eta(a,b)$ indicates the Gaussian function, ϖ signifies the standard deviation value, and π specifies the weight mixing coefficient. The original image's Gaussian blurred version is acquired as,

$$R_{mM(n)} = \eta(a,b) * R_{eM(n)} \quad (11)$$

Next, the unsharp mask $\left(R_{mM(n)}\right)$ acquired is subtracted from the input image for getting edges as,

$$R_{sM}(n) = \frac{e}{2e-1} R_{mM}(a,b) - \frac{1-e}{2e-1} R_{eM}(n) \quad (12)$$

Here, $R_{sM}(n)$ symbolizes the output image, e is the constant to control the weightings of images, and $R_{mM}(a,b)$ indicates the brightness values of pixels at coordinates (a,b) in the unsharpmask R_{mM} .

B. Segmentation

After the success of resolution enhancement and edge sharpening, the resultant images $\left(R_{enh} = \{R_{seO(n)}, R_{sM(n)}\}\right)$ are subjected to the ICSW-WS algorithm for segmentation. The Watershed Segmentation (WS) algorithm is utilized as it can handle images with a considerable amount of irregular shapes and noise. But, the WS has the over-segmentation issue while a large number of small regions arise. For solving this problem, the conventional watershed algorithm calculates the intervening contour similarity weights. Hence, the segmentation is described below: Primarily, the input images are converted into greyscale, and local minima in the image are found. For this, by computing the intervening similarity weights, the watershed line between the two regions is created. The over-segmentation issue occurs as the segmentation process contains the segmentation of smaller regions. For solving this, the intervening similarity measure is computed as,

$$R_{wr} = \sqrt{\sum_{i=1ton} \left\| R_{enh(r1,i)} - R_{ref(r1,j)} \right\|_2} \quad (13)$$

Here, R_{wr} is the output image with weighted regions, and $R_{enh(r1,i)}, R_{ref(r1,j)}$ are the regions with different pixel values (i, j) in the reference image and input image. The similarity measure has the benefit of informing the intervention of another region, thus forming the outer contour of the region. Like this, the relation between the data samples was measured; for providing different regions of the image, the border information is jointly integrated.

After marking the regions, the algorithm floods the image with various colors and the color spreads for creating catchment basins by reaching the region boundary. The basins are formed utilizing the watershed function as,

$$R_{seg} = \varphi_{wsf}(d, R_{wt}) \quad (14)$$

Here, d signifies the point in the domain of the watershed function, R_{wt} indicates the regions assigned with the intervening weights, and φ_{wsf} specifies the watershed function.

In the proposed system, segmentation is performed in two different ways. The significant retinal layers are segmented from the OCT images for evaluating invisible changes in the retina. For segmenting the visual networks, namely posterior cingulate, calcarine, inferior parietal lobule, precuneus, lingual gyrus, cerebellum, and cuneus, the MRI images were utilized for analyzing the pathophysiological changes in the visual pathway. Thus, the segmented images are indicated as $\left(R_{seg} = \{R_{segO(n)}, R_{segM(n)}\}\right)$.

C. Feature Extraction

After segmentation, the significant features are extracted from $\left(R_{seg} = \{R_{segO(n)}, R_{segM(n)}\}\right)$. The proposed system extracted regional homogeneity, degree centrality, and Amplitude of Low-Frequency Fluctuations (ALFF) features from the visual network regions $\left(R_{segO(n)}\right)$, and reflectivity, curvature, volume, and thickness features from the segmented retinal layers $\left(R_{segM(n)}\right)$. Moreover, the global and local features to find interest points, contour, shape, texture, and visual information useful for class discrimination are extracted. Thus, the extracted features are given as,

$$\nabla_{fea(n)\in R_{seg}} = \{\nabla_{fea\in R_{segO(n)}}, \nabla_{fea\in R_{segM(n)}}, \nabla_{lfea\in R_{seg}}, \nabla_{gfea\in R_{seg}}\} \quad (15)$$

Here, the set of total features is signified as $\nabla_{fea(n)\in R_{seg}}$, the features extracted from the retinal layers and visual network areas are indicated as $\nabla_{fea\in R_{segO(n)}}, \nabla_{fea\in R_{segM(n)}}$, and the global and local features are symbolized as $\nabla_{lfea\in R_{seg}}, \nabla_{gfea\in R_{seg}}$.

D. Feature Selection

Here, the subset of the most relevant features is chosen from $\left(\nabla_{fea(n)\in R_{seg}}\right)$ for enhancing the system's performance. The MM-GAO algorithm is used for feature selection. The Green Anaconda Optimization algorithm is utilized for its ability to tackle a wider range of prey. However, the probability function of pheromone concentration in this algorithm only concentrates on maximum values, which leads to high risk of competition for captured food as it can't handle the minimum objective function. Thus, for solving this problem, the min-max normalization approach is

utilized in the prevailing green anaconda optimization algorithm for evaluating the probability of pheromone concentration.

In the MM-GAO algorithm, the positions of its population members are considered as the number of features extracted $\left(\nabla_{fea(n)\in R_{seg}}\right)$ from which the optimal solutions are chosen. The position of each green anaconda is randomly generated, and the objective function of problem space is calculated. It can be exposed as,

$$\nabla_{fea(n)} = \begin{bmatrix} \nabla_{fea(1,1)} & \cdots & \nabla_{fea(1,1)} \\ \vdots & \cdots & \vdots \\ \nabla_{fea(n,1)} & \cdots & \nabla_{fea(n,m)} \end{bmatrix} \quad (16)$$

$$\vartheta\left(\nabla_{fea(n)}\right) = \arg\min_{\nabla_{sf(n)}} \left|\xi_{tar(DR,NDR)} - \xi_{act(DR,NDR)}\right| \quad (17)$$

Here, m indicates the number of decision variables, $\vartheta(\bullet)$ signifies the objective function, and $|\bullet|$ depicts the distance between the actual output $\left(\xi_{act(DR,NDR)}\right)$ and the target $\left(\xi_{tar(DR,NDR)}\right)$ of the classifier output.

In the search process, the best value as per the objective function is chosen via two phases, namely exploration and exploitation.

Exploration: Here, the mating season of male and female anacondas is done. For updating the position of the green anaconda, the species strategy of the male is used. Utilizing this strategy, the male anaconda senses the pheromones, indicating the presence of the female anaconda, and moves towards it.

The set of female species is determined as,

$$\nabla_{FL(n)} = \left\{\nabla_{fea(k_n)} : \vartheta\left(\nabla_{fea(k_n)}\right)\right\}, \quad k_n \neq n \quad (18)$$

Here, $\nabla_{FL(n)}$ signifies the set of female species for each green anaconda in the first row of the population matrix k_n. Next, the probability of pheromone concentration for each population member utilizing the min-max approach is computed as,

$$\Phi_{(n,q)} = \sum_{l} \frac{\vartheta_l\left(\nabla_{fea(k_n)}\right) - \vartheta_{\min}\left(\nabla_{fea(k_n)}\right)}{\vartheta_{\max}\left(\nabla_{fea(k_n)}\right) - \vartheta_{\min}\left(\nabla_{fea(k_n)}\right)} \quad (19)$$

Here, $\Phi_{(n,q)}$ depicts the probability pheromone concentration of the q^{th} female for the n^{th} green anaconda, $\vartheta_l\left(\nabla_{fea(k_n)}\right)$ signifies the set of objective values of the candidate female, and $\vartheta_{\min}\left(\nabla_{fea(k_n)}\right)$, $\vartheta_{\max}\left(\nabla_{fea(k_n)}\right)$ are the minimum and maximum values.

The min-max approach assures the green anaconda's maxmin value to limit its search between minimum and maximum values, thus evaluating the minimum or maximum probability value that limits them in capturing food. Thus, the min-max approach finds the optimal move for the search agent via the complete assessment of search spaces and accelerates the decision-making process for quick convergence.

During exploration, the green anaconda randomly chooses a female species and moves towards it. Therefore, the green anaconda's position is updated as,

$$\nabla_{sFL(n)} = \nabla_{FL} : \Phi_{FL(n-1,q)} < \nabla_{sFL(n)} < \Phi_{FL(n,q)} \quad (20)$$

$$\Phi_{FL(n,q)} = \Phi_{(n,q)} + \Phi_{FL(n-1,q)} \quad (21)$$

$$^{d}\nabla_{fea(n,i)} = \nabla_{fea(n,i-1)} + \nabla_{fea(n,i-1)}\left(\nabla_{sFL(n,i-1)} - \tau.\nabla_{fea(n,i-1)}\right) \quad (22)$$

Here, $\nabla_{sFL(n)}$ signifies the selected female species, $\Phi_{FL(n,q)}$ depicts the cumulative probability function, $\nabla_{sFL(n)}$ symbolizes the random number, $^{d}\nabla_{fea(n,i)}$ is the newly updated position of the green anaconda in d dimensional search space, and $\nabla_{fea(n,i-1)}$ specifies the position updated in the prior iteration. Next, the objective function is assessed for updating the best solution.

Exploitation: Here, the hunting strategy of the green anaconda is followed in which it waits for the prey underwater, and when the prey passes, the anaconda surrounds and attacks the prey. Here, to obtain possible better solutions in local search, the position of group members is updated. The position is updated as,

$$\nabla_{fea(n,i)} = \nabla_{fea(n,i-1)} + (1-\tau)\frac{U-L}{i} \quad (23)$$

Here, U, V are the d-th search space's upper and lower bounds, and i indicates the number of iterations. Till the algorithm's last iteration, the updating process continues. The feature selection strategy utilizing the MM-GAO algorithm is displayed in Algorithm 1.

Algorithm 1: Feature Selection using MM-GAO

Input: Extracted feature $\left(\nabla_{fea(n)\in R_{seg}}\right)$

Output: Selected features $\nabla_{sf(n)}$

Begin

Initialize input data $\left(\nabla_{fea(n)\in R_{seg}}\right)$, parameters τ , Φ and ϑ , number of iterations i

Compute fitness of each individual (ϑ)

Select best solution

While $(i < i_{\max})$

Identify female species $\left(\nabla_{FL(n)}\right)$ //Exploration

Compute probability of pheromone concentration $\left(\Phi_{(n,q)}\right)$

Determine selected females $\nabla_{sFL(n)}$

Update new position ${}^{d}\nabla_{fea(n,i)}$

For each updated position **do**

If $\vartheta\left(\nabla_{fea(n,i)}\right) < \vartheta\left(\nabla_{fea(n,i-1)}\right)$

Update $\nabla_{fea(n,i)}$ as best-fit position

Else

Keep previous solution $\nabla_{fea(n,i-1)}$

End if

Ed for

Update new position using hunting strategy $\nabla_{fea(n,i)}$ //exploitation

Update best solutions

Set $i = i + 1$

End while

Return selected features $\nabla_{sf(n)}$

End

The best solutions were filtered in each iteration by using the exploration and exploitation phases after updating the position of all green anacondas. In this way, the optimal features are selected by utilizing the MM-GAO algorithm, and the selected features are given as,

$$\nabla_{sf(n)} = \begin{cases} \nabla_{fea(n,i)} & \vartheta\left(\nabla_{fea(n,i)}\right) < \vartheta\left(\nabla_{fea(n,i-1)}\right) \\ \nabla_{fea(n,i-1)} & Otherwise \end{cases} \quad (24)$$

Here, the total number of selected features is signified as $\nabla_{sf(n)}$.

E. Classification

For classification using anLRKSA-CNN, the selected features from the above phase $\left(\nabla_{sf(n)}\right)$ are utilized. CNN is selected as it is really efficient for image classification since the dimensionality reduction concept suits the huge number of parameters in an image. But, fixed kernel size utilization causes the loss of significant information hidden in unexplored regions, and the learning process is slowed down by the activation function utilized in the convolution layer owing to the biased shift effect. For overcoming this, the traditional CNN includes Linear Regression-based modeling of kernel size and Scaled Lineartanh (SLT) activation function for the convolution layer. Fig. 2 displays LRKSA-CNN's architecture.

Initially, the extracted features were inputted to the convolution layer. The convolution layer seeks to learn feature representations utilizing numerous convolution kernels and deploying the activation function.

The kernel size in the proposed system is determined utilizing the linear regression model. The LR approach provides the combination of kernels for the input points utilizing scalar-valued estimator as,

$$\delta_{lr(k)} = \psi\left(\sum_{k} \delta_k\left(\nabla_{sf(n)}, \nabla_{sf}\right)\gamma_k\right) \quad (25)$$

Here, the linear combination of kernels produced utilizing the scalar-valued function (ψ) is signified as $\delta_{lr(k)}$, δ_k depicts the scaled kernel at given input points $(\nabla_{sf(n)}, \nabla_{sf})$, and γ_k is the scaling factor.

The feature value obtained from the convolution layer is signified as,

$$\nabla_{con(n,k)} = \nabla_{sf(n)} * \theta_{\delta_{lr(k)}} + \varepsilon_k \quad (26)$$

Where, the convolution layer's output is signified as $\nabla_{con(n,k)}$, the weight vector of the k^{th} kernel is depicted as $\theta_{\delta_{lr(k)}}$, and ε_k signifies the bias term. Next, the activation function detects non-linear features by adding non-linearities to the output. It can be given as,

$$\nabla_{non-lin(n,k)} = \begin{cases} g.\left(\nabla_{con(n,k)}\right)^g & if\left(\nabla_{con(n,k)} < 0\right) \\ g * \exp\left(\nabla_{con(n,k)} - 1\right) & if\left(\nabla_{con(n,k)} > 0\right) \end{cases} \quad (27)$$

Here, $\nabla_{non-lin(n,k)}$ are the detected non-linear features, and g is the learnable parameter. Kernel size variation and SLT activation mechanisms have some advantages, such as reducing the model's complexity to explore each data point and making the network experience a faster learning process utilizing the activation function's calculations.

Next, the input's dimensionality is reduced by the pooling layer with the help of the max pooling technique. The pooling layer's feature maps are obtained as,

$$\nabla_{poo(n,k)} = \nu_{\max}\left(0, \nabla_{non-lin(n,k)}\right) \quad (28)$$

Here, the pooling layer's output is signified as $\nabla_{poo(n,k)}$, and the max pooling operation is depicted as $\nu_{\max}$.The final feature maps are flattened and fed to the fully connected layer after some executions of convolution and pooling operations to produce class scores from the activations for classification.

To produce the total number of output nodes, the softmax function is utilized in the output layer. The softmax function is derived as,

$$\xi_{(DR,NDR)} = \frac{\exp\left(\nabla_{flt(n)}\right)}{\sum_n \exp\left(\nabla_{flt(n)}\right)} \quad (29)$$

Here, $\nabla_{flt(n)}$ indicates the flattened one-dimensional feature vector, $\xi_{(DR,NDR)}$ signifies the softmax output that classifies the input images into two categories, namely patents with DR $\xi_{(DR)}$ and without DR $\xi_{(DR)}$. The classification process utilizing LRKSA-CNN is explained in Algorithm 2.

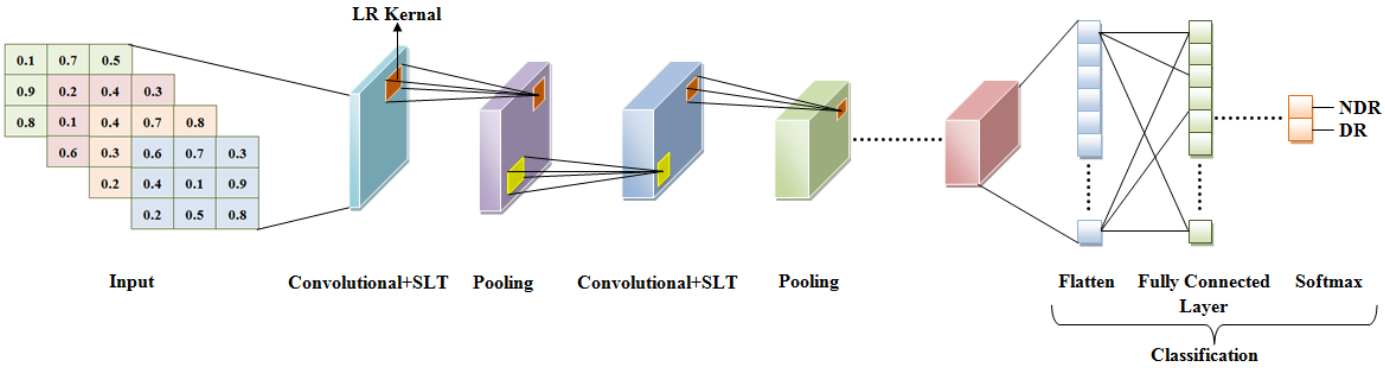

Fig. 2. Architecture of proposed LRKSA-CNN.

Algorithm .2. Classification using LRKSA-CNN

Input: Selected features $\nabla_{sf(n)}$

Output: Classified results $\xi_{(DR,NDR)}$

Begin

Initialize input $\nabla_{sf(n)}$, number of layers, model parameters $\theta_{\delta lr(k)}$, ε_k

For each layer **do**

Generate linear combination of kernels $\theta_{\delta lr(k)}$

For each kernel size **do** // convolution layer

Compute feature maps $\left(\nabla_{con(n,k)}\right)$

Detect non-linearities $\left(\nabla_{non-lin(n,k)}\right)$

If $\left(\nabla_{con(n,k)} < 0\right)$

$$\nabla_{non-lin(n,k)} = g.\left(\nabla_{con(n,k)}\right)^g$$

Else

$$\nabla_{non-lin(n,k)} = g * \exp\left(\nabla_{con(n,k)} - 1\right)$$

End if

End for

Compute pooled feature map $\nabla_{poo(n,k)}$

End for

Generate one dimensional feature vector $\nabla_{flt(n)}$

Return classified results $\xi_{(DR,NDR)}$

End

F. Stages Identification

From the classified results, the images with DR $\left(\xi_{(DR)}\right)$ are utilized for the formulation of grading to differentiate its severity into 5 stages, including severe NPDR, moderate NPDR, Mild NPDR, proliferative DR, and referable DR. Here, the KM-ANFIS is utilized for stages' identification. The ANFIS is selected since it has the advantage of having both numerical and linguistic knowledge. However, the membership function utilized in the traditional ANFIS causes the loss of interpretability in larger inputs. Thus, the Krusinka membership function is used here.

The features extracted from the retinal layers and visual network areas of DR-diagnosed images $\xi_{(DR)}$ were merged and used by the KM-ANFIS technique for stage identification. The KM-ANFIS structural design utilizes these features to form fuzzy if-then rules for grading.

Primarily, each node in the initial layer passes the input $\phi_{inp} = \left\{\xi_{(DR)}, \nabla_{fea \in R_{segO(n)}}, \nabla_{fea \in R_{segM(n)}}\right\}$ to the subsequent layers. For generating membership grades to the input, the nodes in layer 2 have a membership function. The Krusinka Membership function utilized in the proposed system is calculated as,

$$KMF\left(\phi_{inp}\right) = \frac{1}{2} + \frac{1}{\pi} arc\tan\left(\frac{\phi_{inp} - u}{v}\right) \quad (30)$$

Here, $KMF\left(\phi_{inp}\right)$ is the membership function, and (u, v) are the parameters set to change the membership function's shape. The KM membership function better interprets all the inputs in a fuzzy set by its ability to capture the interaction between variables and provide a reasonably smooth transition.

In Layer 3**,** each rule's firing strength $\left(fs_{(i)}\right)$ is computed utilizing fixed nodes through multiplication. Every single node output signifies the rule's firing strength; thus, the fuzzy AND operation is performed by the nodes.

$$fs_{(i)} = KMF.\nabla_{fea \in R_{segO(n)}} \times KMF.\nabla_{fea \in R_{segM(n)}} \quad (31)$$

Rule 1:If $\nabla_{fea \in R_{segO(n)}}$ is ς_p and $\nabla_{fea \in R_{segM(n)}}$ is ξ_a, then

$$\Delta_i = h_i \nabla_{fea \in R_{segO(n)}} + f_i \nabla_{fea \in R_{segM(n)}} + \sigma_i \quad (32)$$

Rule 2:If $\nabla_{fea \in R_{segO(n)}}$ is ς_a and $\nabla_{fea \in R_{segM(n)}}$ is ξ_p, then

$$\Delta_{i+1} = h_{i+1} \nabla_{fea \in R_{segO(n)}} + f_{i+1} \nabla_{fea \in R_{segM(n)}} + \sigma_{i+1} \quad (33)$$

Here, ς_p, ξ_a, ς_a and ξ_p indicate the fuzzy sets, h_i, f_i, σ_i, h_{i+1}, f_{i+1} and σ_{i+1} values are the parameter set, and Δ is a first-order polynomial and signifies the fuzzy inference system's outputs.

Layer 4 computes the ratio of each rule's firing strength to the sum of all rules' firing strengths. It can be given as,

$$\overline{fs_i} = \frac{fs_i}{fs_1 + fs_2}, \quad i = 1, 2 \quad (34)$$

There is only one node in the final output layer, which computes the sum of every output from the nodes of layer 5 for producing the overall KM-ANFIS output.

$$O_{0to4} = \frac{\sum_{i=1}^{n} \overline{fs_i} \, \Delta_i}{\sum_{i=1}^{n} fs_i} \quad (35)$$

Where, O_{0to4} is the overall output of the KM-ANFIS. By utilizing this, KM-ANFIS grades the DR severity into five stages. This grading scheme provides a more precise interpretation of disease stages for accurately evaluating the DR's effects in advance.

IV. Results and Discussion

Here, the proposed DR detection approach's effectiveness is assessed by analogizing its results with prevailing techniques. In the working platform of PYTHON, the proposed technique is deployed and trained by utilizing the OCT and fMRI images gathered from publicly available sources. Fig. 3 and Fig. 4 display the sample outcomes obtained for the input images.

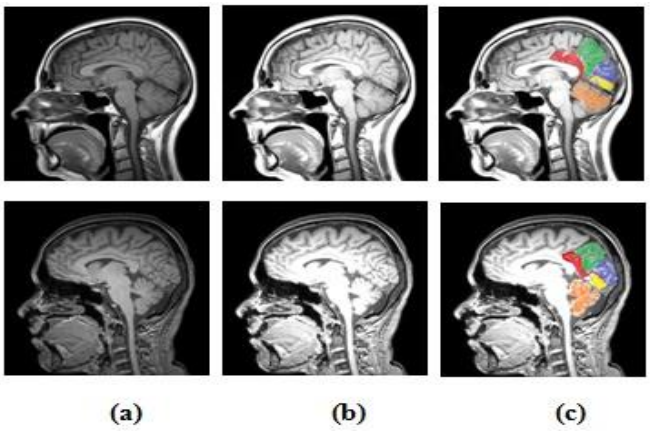

Fig. 3. (a) Input OCT images, (b) contrast-enhanced images using CLAHE, and (c) segmented regions using the ICSW-WS.

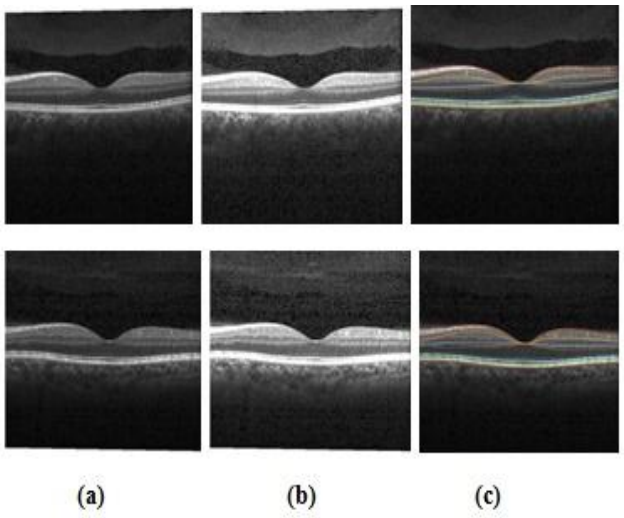

Fig. 4. (a) Input MRI images, (b) contrast-enhanced images using CLAHE, and (c) segmented regions using the ICSW-WS.

A. Performance Analysis

This section concentrates on analyzing the outcomes of different phases, namely KM-ANFIS-based stages identification, LRKSA-CNN-based classification, ICSW-based segmentation, and MM-GAO-based feature selection for quantitatively evaluating the proposed system. The performance of LRKSA-CNN is analyzed below:

TABLE I. Performance Measure of Classification Accuracy

Methods	Accuracy (%)
Proposed LRKSA-CNN	97.99
CNN	92.34
DNN	93.26
ANN	90.84
RNN	88.03

The classification accuracy of the proposed LRKSA-CNN and traditional CNN, DNN, ANN, and Recurrent Neural Network (RNN) techniques is displayed in Table I. This table reveals that the proposed technique's classification accuracy enhanced by 4.65% than the prevailing CNN. Thus, the use of LR-based kernels *includes large information with different dimensions and* efficiently increases the classification accuracy.

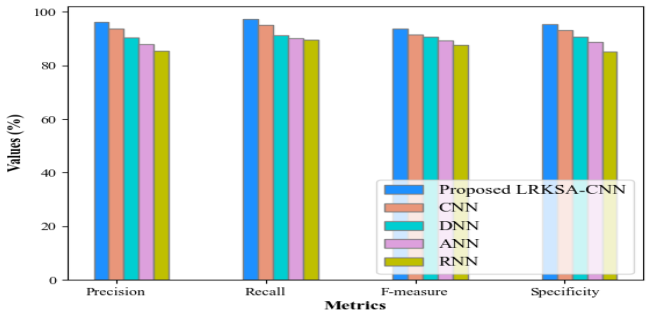

Fig. 5. Performance Analysis of LRKSA-CNN.

The proposed and conventional classification techniques' performance regardingprecision, F-measure, recall, and specificity is displayed in Fig. 5. The comparison shows that the proposed system outperforms the prevailing approaches in all metrics like precision (96.15%), recall (97.28%), F-measure (93.81%), and specificity (95.27%). This analysis reveals that by capturing larger patterns and accelerating its learning rate, the performance of the proposed model for DR classification was greatly improved with the inclusion of an LR-centric kernel and SA function.

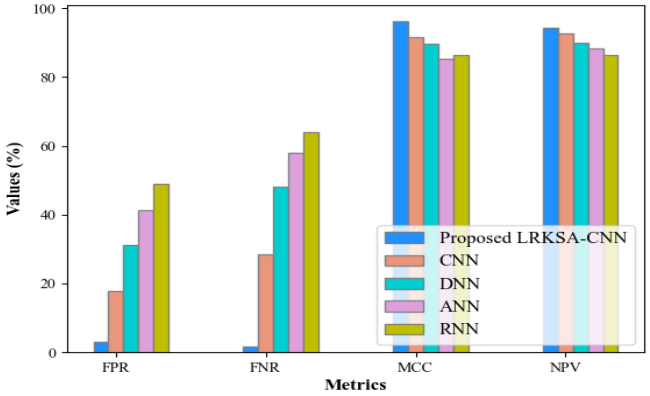

Fig. 6. Comparision of the proposed system with other classification methods.

The proposed LR-KSA technique's performance is analogized with the prevailing techniques regarding False Negative Rate (FNR), False Positive Rate (FPR), Negative Predictive Value (NPV), and Mathews Correlation Coefficient (MCC) in Fig. 6. Attaining lower values for FNR and FPR and higher values for MCC and NPV signifies better performance of the model. By the way, the proposed technique proffers superior performance regarding FNR (3.01%), FPR (1.63%), MCC (96.17%), and NPV (94.36%) analogized to the prevailingtechniques with the use of the LRKSA technique.

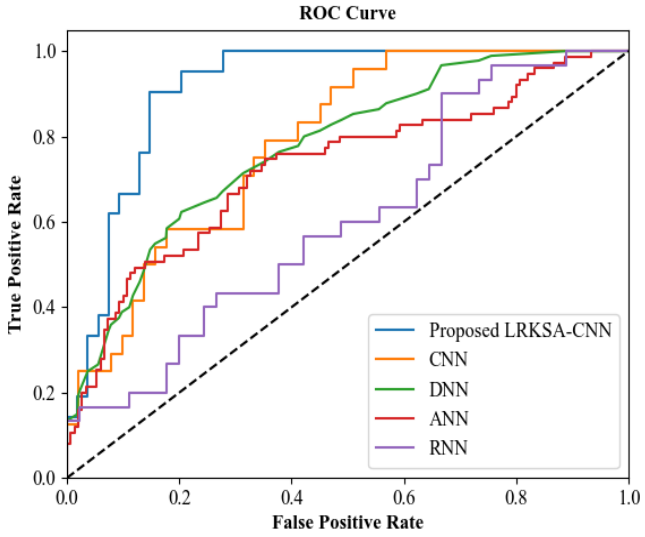

Fig. 7. ROC curve analysis.

The Receive Operative Characteristics (ROC) curve for the proposed and conventional techniques is displayed in Fig. 7. The ROC curve is for providing unbiased outcomes plotted between the true positive rate and the true negative rate. The ROC curve in Fig. 7 displays that when compared to prevailing techniques, the proposed system more accurately differentiated all classes with higher accuracy values.

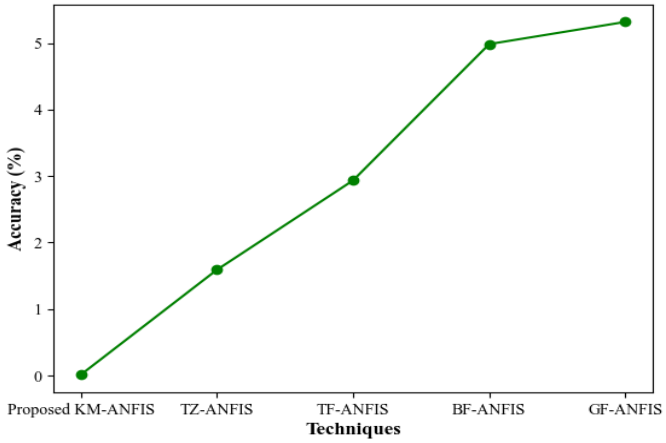

Fig. 8. Accuracy of stages identification.

The accuracy achieved by the proposed KM-ANFIS and prevailing Trapezoidal-based ANFIS (TZ-ANFIS), Triangular Function-based ANFIS (TF-ANFIS), Gaussian Function-based ANFIS (GF-ANFIS), and Bell-shaped Function-based ANFIS (BF-ANFIS) techniques are exhibited in Fig. 8. Here, the proposed technique provides higher accuracy than the prevailing techniques. The proposed system's accuracy is improved by 2.61% than the existing methods. Hence, the analysis concludes that the KM function has the efficiency to better interpret all the inputs and precisely differentiate DR stages.

TABLE II. PERFORMANCE COMPARISON OF SEGMENTATION RESULTS BASED ON VOI

Methods	VOI
Proposed ICSW-WS	0.0135
WS	0.0185
RG	0.0214
AC	0.0255
RSM	0.0264

The Variation Of Index (VOI) attained by the proposed ICSW-WS and prevailing WS, Region Growing (RG), Active Contour (AC), and Region Split and Merge (RSM) techniques are analogized in Table II. It displays that the proposed technique's VOI is much lesser by 0.005, 0.079, 0.012, and 0.013 than the prevailing WS, RG, AC, and RSm techniques. Hence, the analysis clearly defines that ICSW-centric marker identification resulted in the accurate segmentation of meaningful regions.

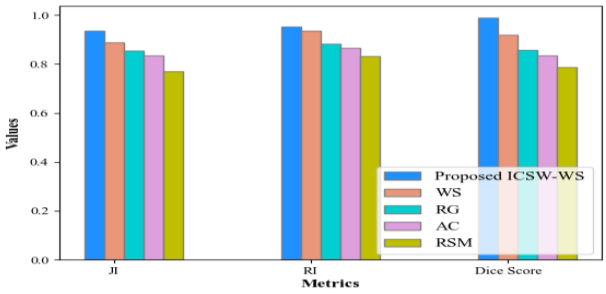

Fig. 9. Comparision of segmentation methods.

The proposed and prevailing segmentation techniques' Jaccard Index (JI), Rand Index (RI), and Dice Score (DS) are examined in Fig. 9. While comparing with prevailing techniques, the proposed technique's JI, RI, and DS are enhanced by 1.69%, 4.57%, and 6.83% than the prevailing WS technique.This indicates that the proposed ICSW-WS technique's performance was greatly influenced by the computation of ICSW weights forsegmenting small unique regions more accurately than the prevailing techniques.

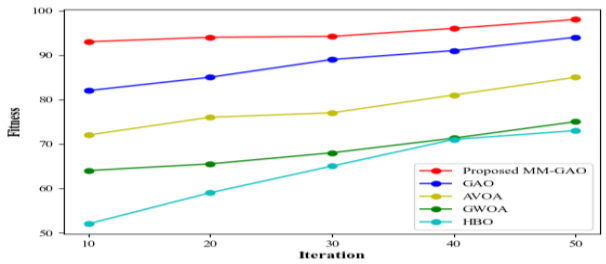

Fig. 10. Fitness vs. iteration.

The fitness values of MM-GAO and prevailing GAO, African Vultures Optimization Algorithm (AVOA), Gray Wolf Optimization Algorithm (GWOA), and Honey Badger Optimization Algorithm (HBO) techniques for 10,20,30,40, and 50 iterations are exhibited in Fig. 10. For a maximum of 50 iterations, the fitness attained by the proposed system is 98, while the prevailing techniques attained less than the proposed technique. Thus, the proposed technique is made to attain superior fitness in the given time than the prevailing techniques by the MM-centric probability calculation.

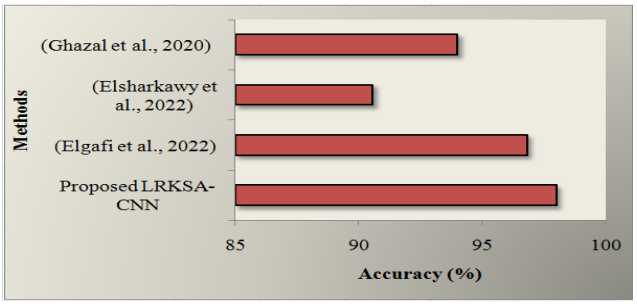

Fig. 11. Comparative analysis.

Fig. 11 analogizes the proposed LRKSA-CNN technique with the prevailing systems recommended by [17], [23], and [25] in Section II. Analyzing Fig. 11 shows that the proposed technique achieves superior performance than the prevailing techniques. Even though the prevailing techniques attained superior accuracy, they didn't concentrate on detecting DR centered on the pathophysiological changes of visual network areas.This displays the proposed system's superiority over the baseline works.

V. CONCLUSION

An effective DR detection model based on LRKSA-CNN using multimodal images is proposed in this work. The proposed system's major goal is early DR diagnosis by examining both invisible pathologies inside the retina and microstructural changes in the visual pathway. In addition, the proposed system concentrates on classifying various phases of DR. The proposed LRKSA-CNN system is trained and evaluated utilizing MRI and OCT images. The performance analysis analogizes the proposed LRKSA-CNN and KM-ANFIS techniques with the prevailing techniques. The outcomes exhibited that the detection accuracy of LRKSA-CNN enhanced to 97.99% and KM-ANFIS to 97.46%.The overall analysis of outcomes exposed that for detecting DR and classifying all stages of DR, the proposed technique performs superior compared to the prevailing techniques. The proposed model's potential will be analyzed in the future by merging other imaging modalities. Moreover, for improving the early DR diagnosis, the blood flow changes of retinal blood vessels will be considered.

Mining High Utility Itemset with Hybrid Ant Colony Optimization Algorithm

Keerthi Mohan[1], Anitha J[2]
Research Scholar[1], Professor[2],
Department of Computer Science and Engineering, RV Institute of Technology and Management, Bangalore, India

***Abstract*—A significant area of study within data mining is high-utility itemset mining (HUIM). The exponential problem of broad search space usually comes up while using traditional HUIM algorithms when the database size or the number of unique objects is huge. Evolutionary computation (EC) -based algorithms have been presented as an alternate and efficient method to address HUIM problems since they can quickly produce a set of approximately optimum solutions. In transactional databases, finding entire high-utility itemset (HUIs) still need a lot of time using EC-based methods. In order to deal with this issue, we propose a hybrid Ant colony optimization-based HUIM algorithm. Genetic operators' crossover is applied to the generated solution by the ant in the Ant Colony optimization algorithm. In this study, a single-point crossover is employed wherein, the crossover point is selected randomly and a mutation operator is applied by changing one or many random bits in a string. This technique requires less time to mine the same number of HUIs than state-of-the-art EC-based HUIM algorithms.**

Keywords*—Utility mining; high utility itemset; ant colony optimization; genetic algorithm; evolutionary computation

I. Introduction

The purpose of data mining is to uncover valuable insights or cognition from data which can aid in decision-making, prediction, and revealing hidden patterns or relationships within the data. Frequent itemset mining (FIM) is a crucial data mining approach aimed at identifying groups of items or elements that commonly occur together in large datasets. It is often applied in association rule learning, where the objective is to uncover relationships or patterns among items in transactional data, such as in market basket analysis. Although FIM mines itemsets based on the count of occurrence, the item's utility (profit) is not taken into consideration. To address this shortcoming, the concept of High Utility Itemset (HUI) was introduced. While traditional frequent itemset mining identifies itemsets based on their frequency of occurrence, HUIM takes into account the actual value or utility of items, which can include factors like profit, revenue, or user preference. An itemset is deemed high utility if its utility exceeds the user specified threshold. Here, a minimum utility value will be set, either manually or through a probabilistic function. Traditional HUIM algorithms encounter and have to deal with the exponential search space problem with increasing number of transactions and database items. Evolutionary algorithms such as genetic algorithms (GA), Ant Colony Optimization (ACO) algorithm, Particle swarm Optimization (PSO), and Artificial bee colony (ABC) algorithm are some efficient algorithms that solve the exponential search space problem. In order to find near-optimal solutions based on fitness functions, evolutionary algorithms effectively search enormous problem spaces. For mining HUIs beyond a minimum utility threshold, evolutionary-based HUIM algorithms are quicker than conventional precise approaches, although they still require a lot of time. Enhancing the diversity of the generated population is one way of reducing the time. Hybrid approach balances exploration and exploitation, handles sizably voluminous and unevenly distributed datasets preponderant, and acclimates well to dynamic environments. It outperforms standalone PSO, GA, or ACO in terms of haste, scalability, and solution quality. The Hybrid Ant Colony Optimization (GA-ACO) algorithm ameliorates HUI mining by cumulating the iterative refinement of ACO with the expeditious ecumenical search of GA, which expedites convergence and truncates the early-stage impuissance's of ACO.

II. Related Work

Agrawal and Srikant [1] explored association rules in large sales transaction databases. Agrawal, Imielinski, and Swami [2] used novel estimation and pruning techniques for efficient and fast mining of association rules. Tseng et al. [3] developed algorithms for mining high utility itemsets from a transactional database. They presented two algorithms, Utility-Pattern-Growth (UP-Growth) and also UP-Growth+, to carry out the mining of high utility itemset with a collection of effective approaches for pruning potential itemsets. They stored information associated with high utility itemsets into a tree-based data structure called "utility pattern tree" in such a way that candidate itemsets could be developed with only two scans of the database and obtained significant improvement in extracting high utility itemsets. Chan, Yang, and Shen [4] proposed a technique that targets mining the top-K high utility closed patterns directly aligned with a specific business objective. Their experimental results demonstrate that the algorithm does not require a user-defined minimum utility, making it practical and effective in real-world applications.

Yao, Hamilton, and Butz [5] examined the utility relationships among itemsets and identified two key properties: the utility bound property and the support bound property. They also developed a mathematical model for utility mining based on these principles. Ahmed et al. [6] introduced tree structures to efficiently conduct incremental and interactive high-utility pattern (HUP) mining. Their first tree structure, the Incremental HUP Lexicographic Tree (IHUPL-Tree), is organized by an item's lexicographic order, capturing incremental data without requiring any restructuring. The second tree structure, the IHUP Transaction FrequencyTree (IHUPTF-Tree), optimizes size by arranging items in descending order of transaction frequency. To

reduce mining time, the third structure, the IHUP Transaction-Weighted Utilization Tree (IHUPTWU-Tree), is based on the descending TWU (Transaction-Weighted Utilization) values of items. The authors demonstrated that these tree structures are highly efficient and scalable for incremental and interactive HUP mining.

In study [7], Liu and Qu introduced a data structure called the "utility-list" and introduced an algorithm named HUIMiner for mining high utility itemsets. The HUI-Miner algorithm introduces utility-lists to store utility and pruning information, enabling it to mine high utility itemsets without engendering candidate itemsets. This eliminates the computational overhead of traditional algorithms that process sizably voluminous numbers of low-utility candidates. By directly fixating on high utility itemsets, HUI-Miner evades the costly processes of itemset generation and utility computation. Performance comparisons with other state-of-the-art algorithms across multiple databases show that HUI-Miner offers better improvment in both runtime and memory utilization, making it a more efficient approach for mining high utility itemsets.

Fournier-Viger et al. [8] presented a new algorithm called FHM- Fast High-Utility Miner which improved the performance of HUI-Miner algorithm. FHM's key innovation lies in its strategic analysis of item cooccurrences, which substantially decreases the number of necessary join operations during the mining process. Testing on real-world datasets demonstrated FHM's efficiency, reducing join operations by as much as 95% and operating up to six times faster than its predecessor, HUI-Miner.

Zida et al. [9] introduced EFIM, a new algorithm for mining high-utility itemsets. EFIM's effectiveness arises from two main components: newly developed upper-bounds called the sub-tree utility and the local utility, and a streamlined array-based method named Fast Utility Counting. Their approach allows for linear time and space complexity when calculating these upper-bounds. To further enhance efficiency, EFIM incorporates techniques for database projection and transaction merging, also achieving linear time and space complexity. These methods significantly reduce the computational cost associated with database scans. Comprehensive experiments across diverse datasets demonstrated EFIM's superior performance.

Peng, Koh, and Riddle [10] introduced mHUIMiner, which leverages a tree-based framework to steer the process of itemset growth. This approach efficiently eliminates the need to examine non-existent database itemsets. mHUIMiner emerges as different from other methods by avoiding complex and computationally intensive pruning mechanisms.

One of the earliest works on mining high utility itemsets using evolutionary algorithms from transaction databases is using Genetic Algorithm (GA) proposed by Kannumuthu and Premalatha [11]. They proposed two approaches to mine high utility itemsets from transaction databases with or without specifying minimum utility threshold by using genetic algorithm. Results from experiments showed that authors' GA approaches accomplished better performance in terms of scalability and efficiency.

Lin et al. [12] proposed using discrete Particle Swarm Optimization (PSO) to represent particles as binary variables. They introduced HUIM-BPSO, an efficient PSO-based algorithm designed to discover High-Utility Itemsets (HUIs) effectively. Their algorithm employs the transaction-weighted utility (TWU) model to identify high-transaction-weighted utilization 1-itemsets (1-HTWUIs). They established that their method mitigated the combinatorial complexity typically encountered during the evolutionary process.

Lan, Hong, and Tseng [13] introduced a novel pattern category called high transaction-weighted utility itemsets. Three key factors are taken into consideration in this approach: individual item profits, item quantities within transactions, and the overall contribution of each transaction to the database. To uncover these high transaction-weighted utility itemsets, the authors developed a two-stage mining algorithm. They demonstrated their methods through experiments conducted on synthetic datasets, which revealed promising performance results.

A 2-phase algorithm was introduced by Liu, Liao, and Choudhary [15] which aimed at streamlining the high-utility itemset mining process. Their approach effectively minimized the candidate set while ensuring the comprehensive discovery of all high-utility itemsets. Their algorithm exhibited efficiency in both time and memory consumption across various database types - synthetic and real-world. Their method successfully handles large-scale databases that typically pose significant challenges for existing methods.

A new algorithm called HUIM-ACS for high-utility itemset (HUI) mining was introduced by Wu, Zhan, and Lin [16]. Their algorithm is an enhanced version of the standard ant colony optimization (ACO) technique called ant colony system (ACS). HUIM-ACS provides several benefits compared to existing methods like genetic algorithms and particle swarm optimization. It constructs solutions in a way that avoids impractical outcomes, maps the entire solution space to ensure comprehensive coverage, and uses pruning processes to improve efficiency. The algorithm also prevents redundant evaluations of solutions, saving computational resources. Experimentation on real-life datasets showed that HUIM-ACS outperforms other heuristic HUI mining algorithms in both the number of HUIs discovered and convergence speed. While most evolutionary algorithms can't guarantee finding the global optimum, HUIM-ACS's comprehensive exploration of the solution space could potentially address this limitation in high utility itemset mining.

Song and Huang [17] introduced Bio-HUI, a framework that adapts bio-inspired algorithms for high-utility itemset mining. Unlike traditional approaches, Bio-HUI selects discovered HUIs as targets for the next generation, enhancing population diversity. The proposed framework was implemented using genetic algorithms, particle swarm optimization and bat algorithms. Extensive testing on public datasets demonstrates that these Bio-HUI-based methods outperform current state-of-the-art algorithms in efficiency, result quality, and convergence speed. The authors established that their method shows significant promise in advancing the field of high-utility itemset mining by leveraging the strengths of bio-inspired computational techniques.

Nawaz et al. [18] proposed two new algorithms for high-utility itemset mining (HUIM): HUIM-HC based on Hill Climbing and HUIM-SA based on Simulated Annealing. These algorithms aim to focus on the limitations of existing evolutionary and heuristic methods, which are typically affected by long runtimes and may miss many high-utility itemsets (HUIs). Their techniques used efficient utility computation and search space pruning through bitmap transformation of the input database. Their algorithms also improved population diversity by using discovered HUIs as targets for subsequent generations, rather than simply maintaining current optimal values. Their experimentation using real-life datasets demonstrated that HUIM-HC and HUIM-SA outperform state-of-the-art heuristic and evolutionary HUIM algorithms in terms of speed. Their techniques represent a significant step forward in addressing the challenges of high-utility itemset mining, offering improved efficiency and effectiveness over existing methods.

Song and Nan [19] introduced a new high-utility itemset mining algorithm called HUIM-ACO, based on ant colony optimization. HUIM-ACO uses a constructive approach to produce candidate itemsets, represented as search paths. Pheromone values are stored in a matrix to guide the search process, and an efficient enumeration technique is used to discover more itemsets. Their experimentation showed that HUIM-ACO outperforms existing algorithms in terms of speed and the count of high-utility itemsets discovered.

Li et al. [20] also proposed a high-utility itemset mining algorithm called HUIM-ACO, based on ant colony optimization. HUIM-ACO uses a constructive approach to generate candidate itemsets, represented as search paths. Pheromone values are stored in a matrix to guide the search process, and an efficient enumeration technique is used to discover more itemsets. Experimental results demonstrated that HUIM-ACO outperforms existing algorithms in terms of both speed and the count of high-utility itemsets discovered.

Han et al. [22] introduced a new high-utility itemset mining algorithm that incorporates two key strategies: positional evolution based on the female elephant factor to reduce the search space and improve efficiency, and two-phase population diversity maintenance to prevent premature convergence. Their experimentation showed that this algorithm outperforms existing heuristic methods in terms of both speed and effectiveness.

In order to obtain a near-optimal solution based on fitness functions under a number of constraints, evolutionary algorithms can search through enormous problem spaces. Even though the current evolutionary-based HUIM algorithms can mine all HUIs that meet the minimum utility threshold faster than classic exact methods, they can still be quite time-consuming. This is mostly because search and evolutionary algorithms, which perform well in problems with fewer optimal solutions, keep the best values from one population to direct the next. However, because it overemphasizes previously discovered optimal values within a small number of iterations, this strategy runs the risk of missing some itemsets in High Utility Itemset Mining (HUIM), when results are many and unevenly distributed. Enhancing the diversity of the generated population, as suggested by Song and Huang [17], is one way to solve this issue. Rather than selecting HUIs with high utility values from the current population, this method applied roulette wheel selection to all of the identified HUIs in order to probabilistically choose the initial target of the next population.

To enrich the efficiency, this work suggests a hybrid approach that coalesces Ant Colony Optimization (ACO) and Genetic Algorithms (GA). Despite achieving expeditious global convergence, GAs have trouble with feedback and may carry out dispensable iterations, which can truncate precision. The lack of pheromone trails causes ACO to perform poorly at first, but it excels at updating information for optimal convergence. To get beyond these restrictions, the suggested genetic ant colony algorithm makes utilization of the advantages of both approaches. We modeled the HUIM problem from the perspective of the hybrid genetic algorithm, using the work done in study [17] as a starting point.

III. Problem Statement

The problem of HUIM is: Given a transaction database (*TD*), its profit table (*ptable*) and a user specified minimum utility threshold, the problem of HUIM is to identify all itemsets that have utility values equal to or greater than *min _util*. Let us say that Table I represents the Transaction Database of items procured and Table II represents the external profit value of each item.

TABLE I. Transaction Database

TD	Transactions	TU
*T*0	(a, 3) (c, 12) (e, 3)	54
*T*1	(b, 4) (d, 2) (e, 1) (f, 5)	47
*T*2	(a, 3) (c, 2) (e, 1)	16
*T*3	(a, 2) (d, 2) (f, 1)	15
*T*4	(a, 1) (c, 5) (d, 7)	52
*T*5	(b, 1) (d, 4) (f, 2)	29

TABLE II. Profit Table

Item	a	b	c	d	e	f
profit	2	7	3	5	4	1

From the transaction database in Table I and profit table from Table II, the utility value of an item *e* in the transaction T_0 is represented as $u(e,T_0) = 3 \times 4 = 12$. The utility of itemset {a, c} in transaction T_0 is $u(\{a,c\},T_0) = u(a,T_0) + u(c,T_0) = 3 \times 2 + 12 \times 3 = 42$. Along similar lines, the utility value of an itemset {a, c} in the transaction database TD will be $u(\{a,c\},T_0) + u(\{a,c\},T_2) + u(\{a,c\},T_4) = 42+12+17 = 71$. The transaction utility (TU) of an entire transaction T_0 is represented as $TU(T_0) = u(\{a,c,e\},T_0) = 54$. If the threshold utility *min util* = 80 then the itemset {a, c} is not considered an HUI as the itemset utility value $u(\{a,c\}) <$ *min util*. However, as the itemset {a, c} is part of three transactions T_0, T_2 and T_4 the TWU (Transaction Weighted-Utilization) is computed as $TWU(\{a,c\}) = TU(T_0) + TU(T_2) + TU(T_4)$. The value of this expression is 122. Since

TWU of the itemset $\{a,c\} > min\ util$ this itemset is considered an HTWUI (high transaction-weighted utilization itemset).

A. Terminologies

In this section, we define the terminologies related to the problem statement. Let $I = \{i_0,i_1,...,i_m\}$ represent a finite set of m itemsets in the transaction database $TD = \{T_0,T_1,...,T_d\}$. Each transaction T_k in TD is a subset of I which has a unique identifier $k(1 \le k \le n)$ and is called TID. Also, the set $X \subseteq I$ is called an *itemset* and an itemset which consists of k items is called a k-itemset. An itemset X is contained inside a transaction T_k if $X \subseteq T_k$. Every item i_j in T_k has a positive number $q(i_j,T_k)$ which is called it's *internal utility* and indicates the quantity (or occurrence) of i_j in T_k. The external utility$p(i_j)$, represents the unit profit value of the item i_j. The profit table $ptable = \{p_1,p_2,...,p_m\}$ depicts the profit value p_j of each item i_j in I.

The overall utility value of an item i_j in a transaction T_k is defined by the following equation as:

$$u(i_j,T_k) = p(i_j) \times q(i_j,T_k) \quad (1)$$

In any given transaction T_k, the utility if the itemset X is represented as $u(X,T_k)$ and characterizes the amount of money from the sale of X in that transaction [14]. Also, the overall utility value of an itemset X in TD denoted by $u(X)$ represents the total amount of money that the itemset yields for all transactions where X is purchased in the database. These two ideas are formally defined as:

$$u(X,T_k) = \sum_{i_j \in X \wedge X \subseteq T_k} u(i_j,T_k) \quad (2)$$

$$u(X) = \sum_{X \subseteq T_k \wedge T_k \in TD} u(X,T_k) \quad (3)$$

The user set minimum utility threshold (δ) is the percentage of total sum of all TU values in the input database. The minimum-utility value is defined as:

$$min\_util = \delta \times \sum_{T_k \in TD} TU(T_k) \quad (4)$$

An itemset X is considered an HUI if $u(X) \ge min\_util$. Search space reduction is often carried out in HUIM by defining another term called transaction weighted-utilization (TWU) which is an upper bound on the utility value of an itemset and its supersets.The TWU of an itemset X is the total sum of transaction utility values of all the transactions that contain X and is defined as:

$$TWU(X) = \sum_{X \subseteq T_k \wedge T_k \in TD} TU(T_k) \quad (5)$$

An itemset X is considered a high transaction weightedutilization itemset (HTWUI) if $TWU(X) \ge min\ util$; otherwise X is considered a low transaction weighted-utilization itemset (LTWUI).

IV. Proposed Methodology

This study addresses the challenge of high-utility itemset mining by proposing a hybrid algorithm approach which combines Genetic Algorithms (GA) and Ant Colony Optimization (ACO). Both GA and ACO are iterative optimization techniques, which forms the basis for their integration. GAs excel at rapid global convergence but struggle with feedback information. Once a solution reaches a certain range, GAs tend to perform redundant iterations, potentially reducing the accuracy of the final result. In contrast, ACO continuously gathers and updates information so that it converges to the optimal solution, leveraging its global search capabilities and parallel processing. However, ACO's initial performance is hindered by the lack of early pheromone trails. To address this limitation, we propose a genetic ant colony algorithm which capitalizes on the complementary strengths of both methods. The ACO algorithm is applied to itemsets, utilizing its ability to gather and update information continuously. Subsequently, GA is employed on the discovered High Utility Itemsets (HUI) to streamline the algorithm. In each iteration, mutation generates an HUI where crossover can be applied. GAs, inspired by natural selection and genetics, model the evolution of potential solutions through selection, crossover, and mutation. They are versatile and applicable to various optimization and search problems. ACO, on the other hand, mimics the foraging behavior of ants, simulating how they find paths by depositing and following pheromone trails. ACO excels in exploring complex solution spaces, adapting to changing conditions, and finding near-optimal solutions mainly for problems which have large search spaces. The hybrid approach aims to mitigate the premature convergence problem often encountered in genetic algorithms. By combining GA and ACO, the algorithm strikes a balance between exploitation and exploration. The ACO/GA hybrid typically reduces the number of offspring produced by constructing solutions gradually. This results in fewer new solutions needing to be stored in memory compared to a standard GA, leading to a larger pool of offspring for selection and significantly reduced memory usage.

A. Encoding and Pruning

An efficient representation method for mining HUIs is transformation of initial transaction database into a bitmap [16]. Here, the transaction is encoded using binary notation; an entry of '0' denotes the absence of an item, whereas an entry of '1' denotes its presence. The bitmap cover of an itemset X is computed as $Bit(X)$ = bitwise-AND $_{i \in X}(Bit(i))$. This indicates that X is a bit vector that is produced by applying a bitwise-AND operation to the bitmap covers of each and every item in X. For two itemsets X and Y, $Bit(X \cup Y)$ can be evaluated as $Bit(X) \cap Bit(Y)$, the bitwise-AND of $Bit(X)$ and $Bit(Y)$.

TABLE III. Bitmap Representation

T_k	a	b	c	d	e	f
$T0$	0	1	1	0	1	0
$T1$	1	0	1	0	1	1
$T2$	1	0	1	0	1	0
$T3$	0	1	0	1	0	1
$T4$	1	0	1	1	0	0
$T5$	1	0	0	1	0	1

Table III illustrates the bitmap of Table I's database, for reference. The column vectors $B(a)$ = 011011 and $B(c)$ = 111010, respectively, represent the bitmap covers of items a and c. The bitmap cover of itemset $\{a,c\}$ is the column vector obtained by performing the bitwise-AND of $B(a)$ and $B(c)$, that is $B(\{a,c\})$ = 011010. The study in [17] proposed a promising encoding vector for speeding up the process of mining HUI and is employed in this proposed work too.

Let's say that V represents an encoding vector that contains $0s$ and/or $1s$ and corresponds to a solution. If $Bit(X)$ only contains $0s$ then V is called an unpromising encoding vector ($UPEV$), otherwise V is called a promising encoding vector (PEV). Since an empty encoding vector indicates that the itemset does not contain any *HTWUI*, it is simple to understand that each itemset (solution) X that is represented by a *UPEV* cannot be an HUI.

This type of solution can significantly cut down on runtime because it does not require the fitness value to be computed. This technique is called PEV-Check (PEVC) pruning approach [17]. Every newly generated solution goes through this strategy to make sure that the solution actually exists in the database. The pseudocode of this strategy is given as follows:

Algorithm 1: Encoding and Pruning

Step 1	Determine which of the elements in the encoding vector (EV) are represented by $1s$ and stores it in VN after looking for $1s$ in the vector.
Step 2	Initialize a variable XV with bitmap cover of the first item in EV.
Step 3	Start a loop, for each item i_k, perform bitwise AND operation on XV with bitmap cover of i_k.
Step 4	If the resulting bit vector is a UPV, then the item is not kept in XV and the bits of i_k in EV is changed from 0 to 1.
Step 5	Repeat Steps 3 to 4 till VN is empty

B. Population Initialization

The initial population for hybrid ACO/GA is generated randomly. Algorithm 2 initially searches the database for all 1-HTWUIs, and as 1LTWUIs cannot be a part of any HUI, they are subsequently removed. After that, a bitmap is created from the database. After that, a for loop creates the first individuals one at a time, assigning a random number of 1s to each person in the i^{th} bit vector, where n is an integer between 1 and |1 - HTWUIs |. A bit vector with 1s in it is formed. The following formula indicates the likelihood that the bit corresponding to i_j will be set to 1 is as follows:

$$P_j = \frac{TWU(i_j)}{\sum_{k=1}^{|1-HTWUIs|} TWU(i_k)} \quad (6)$$

Algorithm 2: Population Initialization

```
Step 1   Perform a single scan on D to remove 1-LTWUIs
         and identify all 1-HTWUIs
Step 2   Transform the database D to a bitmap
         representation of D;
Step 3  Start a for loop from i = 1 to P
        3.1Generate a random number n_i,an integer
           between 1 and |1-HTWUIs |;
        3.2Generate V_i with n_i bits set to 1using the Eq 6
        3.3   if n_i > 1 then
                V_i = PEV C(V_i);
              endif
           endfor
end
```

C. Hybrid ACO Algorithm

The primary objective of ACO algorithm is to take full advantage of the features of ACO and GA for mining itemsets with high utility. Both ACO and GA gives best result for mining HUI. In the proposed technique, population is initialized by following Algorithm 2. The entire number of transactions in the database is represented by the number of ants' SN. Pheromones are initialized with the utility values, iff TWU(X,Tc) ≥ min util. Genetic operators crossover is applied on the generated solution by the ant. In this study, a single-point crossover is utilized. The crossover point is selected randomly. Now mutation operator is applied by changing one or more random bits in a string when Pm ≥ randomly generated value.

Algorithm 3: Hybrid ACO algorithm

```
Step 1   Population initialization
Step 2   Pheromone initialization with utility value
Step 3   iter = 1
Step 4   while (iter ≤ max iter)
Step 5   for each transaction in D
           Start each ant to visit each vertex
         endfor
Step 6   Apply genetic operators crossover
         on the selected population
Step 7    Perform mutation on the population of
          individuals with mutation probability pm.
          7.1   Verify the fitness value of individuals,
          7.2    If fv ≥ min util go to Step 6
          7.3    Else go to Step 8
Step 8    Pheromone update
Step 9    End of while
Step 10   Output all HUIs
```

V. Result and Discussion

This part includes a discussion of the findings and experimental assessment of the suggested algorithms. Experiments were performed on a computer equipped with an 8-core 3.6 GHz CPU and 8 GB RAM running Windows 10. The program was developed in Java.

A. Dataset

Four standard benchmark datasets- Chess, Mushroom, Connect, and Accident - are utilized to assess the performance and effectiveness of the suggested algorithm. The algorithm performance is also evaluated against a real dataset downloaded from the UCI repository. The benchmark datasets were sourced from SPMF data mining library [23].

A widely used dataset from the UCI Machine Learning Repository, the Mushroom dataset is often employed in association rule mining and High-Utility Itemset (HUI) mining applications. There are 8,124 different species of mushrooms in it, and each one is characterized by 22 different categories, including gill spacing, color, cap shape, and odour. Every instance has a label designating it as deadly or edible. The dataset can be modified in the context of HUI mining by giving utility values (such as profit or significance) to particular features in order to discover desirable itemsets based on utility thresholds as opposed to just frequency. When it comes to HUI mining, the Mushroom Dataset presents a problem because it requires categorical data to be transformed into a format that makes utility-based itemset mining feasible. In order to match with the utility mining paradigm, this frequently entails defining the utility of goods (attributes) and transactions (mushroom instances) in novel ways.

The chess dataset is widely used in High-Utility Itemset (HUI) mining as a benchmark for assessment of the performance of various algorithms. This dataset represents chess games transactionally, with each transaction denoting a series of moves or itemsets. Finding itemsets (e.g., common move sequences) with high utility, like winning strategies, is the goal. In this case, the utility values could stand for the significance or regularity of moves within the dataset. As the chess dataset is structured, repetitious, and dynamic [21], it's a great resource for researching utility-based itemset mining. Every transaction in HUI mining can be compared to a position in a chess game. Each item can stand for a particular move or the location of a chess piece.

Based on actual accident data, the Accident _10% dataset is a 10% sampling of the entire dataset. The dataset comprises transactions that typically contain attributes related to an accident, such as conditions, location, and involved entities. The utility values assigned to each attribute indicate its significance or influence. When mining for interesting patterns, this dataset aids researchers in assessing the accuracy, scalability and execution time of HUI algorithms.

High-utility itemset (HUI) mining research frequently uses the Connect dataset as a benchmark. It is derived from a Connect-4 game and is sourced from the UCI Machine Learning Repository. With 43 categorical attributes, the dataset consists of 67,557 instances, each of which represents a unique board configuration in the game. Each configuration can be looked at as a transaction in the context of HUI mining, where the objective is to mine itemsets (board configurations) that offer high utility or significance, frequently based on different utility values ascribed to different configurations. The Connect dataset is a valuable resource for examining recurring and noteworthy patterns in gaming, since its utility may be linked to winning plays or strategies in the Connect-4 game.

The proposed algorithm is also tested against a real dataset - the online retail dataset downloaded from UCI Repository. The dataset has 541909 instances with six features. A UKbased online retailer's sales transactions are included in this dataset from a period of December 2010 to December 2011. The dataset includes 8 attributes with approximately 4000 distinct items. Cancelled orders, returns (negative quantities), and possibly outliers are included in the dataset. In order to handle returned items or eliminate invalid transactions, preprocessing is frequently necessary. The dataset exhibits a high degree of transaction data skewness because it includes both huge bulk transactions and numerous low-quantity sales. The identification of high-utility itemsets is impacted by this skewness. Since utility values were not included in the dataset, they had to be manually determined using the following technique so that they could be used in HUI mining where *Utility = quantity × unit price*. Table IV shows characteristics of datasets and Table V shows sample online retail dataset.

TABLE IV. Characteristics of Datasets

Dataset	Trans. Len	No. of items	No. of Trans	Type
Mushroom	23	119	8,416	Dense
Chess	37	75	3,196	Dense
Connect	43	129	67,557	Dense
Accident 10%	34	468	34,018	Dense

TABLE V. Sample Online Retail Dataset

Invoice No	Stock Code	Description	Quantity	Invoice Date	Unit Price	CustomerID	Country
536365	71053	Jam making set	5	12/1/2010	2.25	13047	United Kingdom
536366	85123A	Jam making set	1	12/1/2010	2.25	12583	France
536367	71057	White Hanging Heart	6	12/1/2010	3.39	17850	United Kingdom
536367	22993	White Hanging Heart	6	12/1/2010	4.25	12678	France

B. Runtime efficiency

Experiments are conducted to assess the efficiency of the proposed algorithm with regards to runtime. The efficiency is tested by varying the minimum utility value.

Table VI summarizes the minimum utility value set for the dataset.

TABLE VI. MINIMUM UTILITY VALUES

Dataset	Minimum Utility Threshold				
Chess	28.5	29	29.5	30	30.5
Mushroom	14	14.5	15	15.5	16
Connect	31.8	32	32.2	32.4	32.6
Accident 10%	12.6	12.8	13	13.2	13.4

Fig. 1, 2, 3, and 4 show the execution time of our algorithm presented in this work. The runtime efficiency of our proposed algorithm is compared with HUIM-GA. Hybrid ACO/GA produces better runtime efficiency because it focuses on promising areas early on, reducing unnecessary evaluations of low utility items. The incremental building of solutions impacts the efficiency of our proposed algorithm. Also, the adaptive mechanisms such as pheromone evaporation leads to an efficient search, thus reducing runtime.

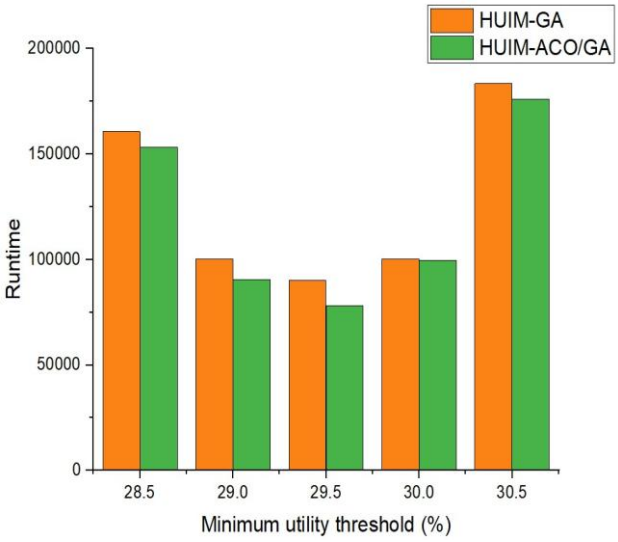

Fig. 1. Chess dataset (based on runtime).

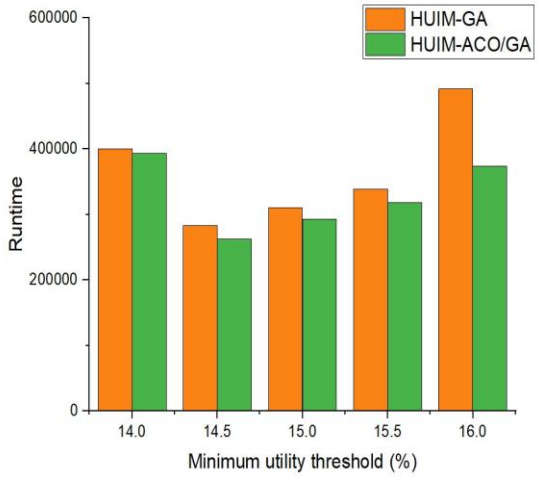

Fig. 2. Mushroom dataset (based on runtime).

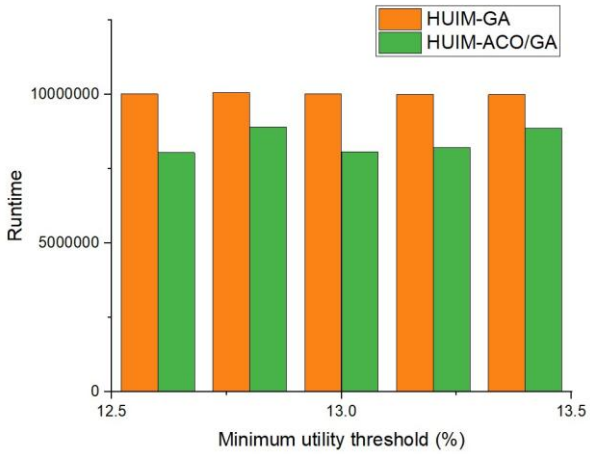

Fig. 3. Accident_10% dataset (based on runtime).

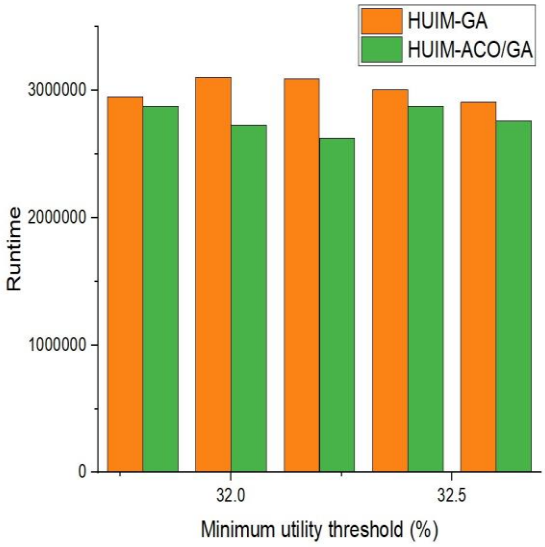

Fig. 4. Connect dataset (based on runtime).

A real-time retail dataset is also used to evaluate the recommended algorithm's runtime efficiency. Here at minimum utility threshold of 10%, maximum number of HUI's were identified. Fig. 5 demonstrates the result.

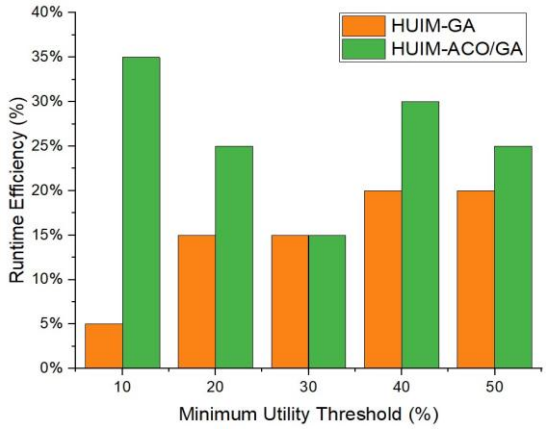

Fig. 5. Retail dataset (based on runtime).

C. Discovered number of High utility items(HUI)

This section analyzes the performance of the hybrid ACO/GA approach by evaluating the number of HUIs identified at various threshold levels. The proposed algorithm discovers the maximum number of HUIs. Fig. 6 to 10 demonstrate the graphical representation of the experimental results. It may be noticed that hybrid ACO/GA discovers more number of HUIs in most cases. However, for the real time retail dataset, the number of HUIs identified by hybrid ACO/GA algorithm were comparable to that of HUIM-GA algorithm as may be seen in Fig. 10.

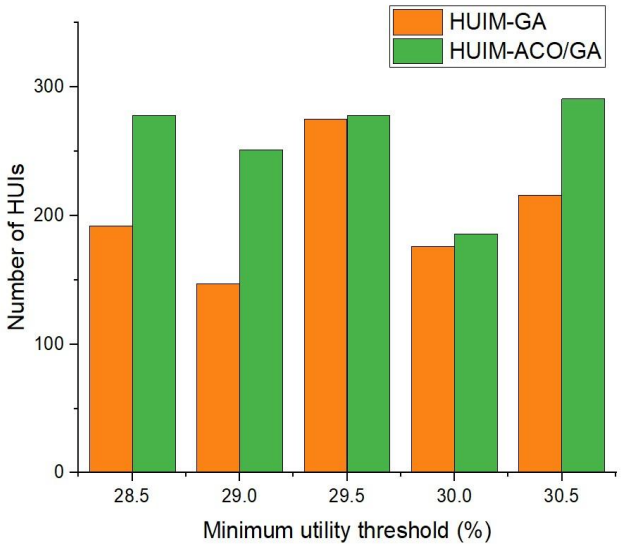

Fig. 6. Chess dataset.

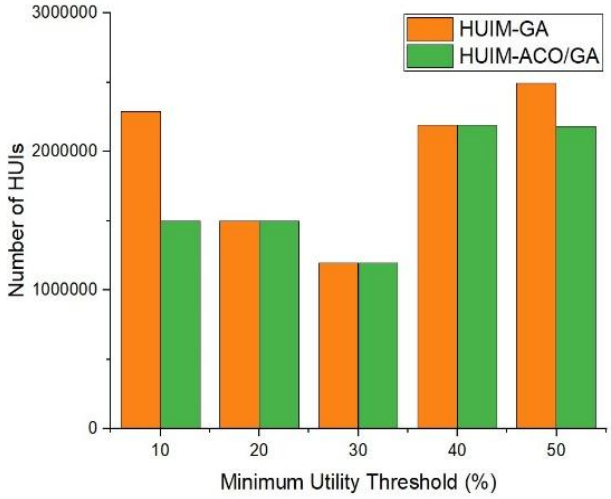

Fig. 7. Mushroom dataset (based on number of HUIs).

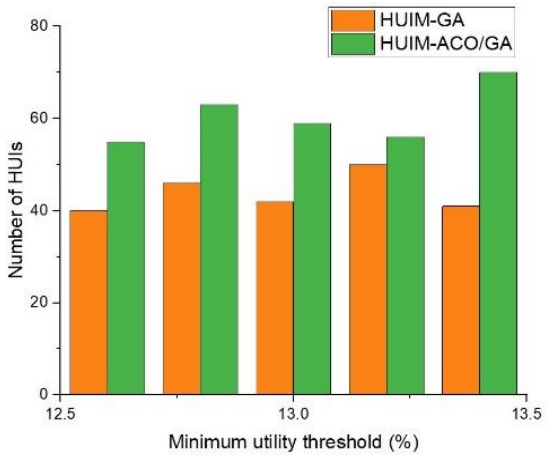

Fig. 8. Accident_10%dataset (based on number of HUIs).

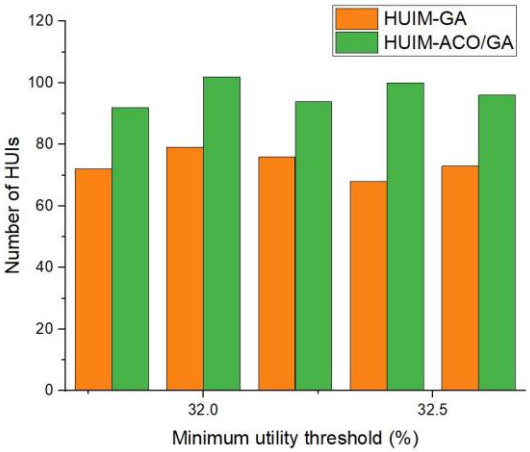

Fig. 9. Connect dataset (based on number of HUIs)..

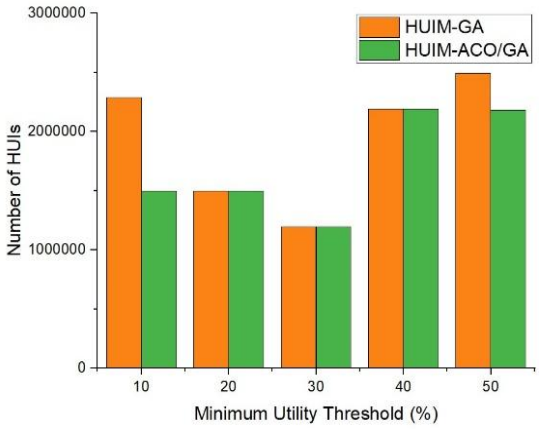

Fig. 10. Retail dataset (based on number of HUIs)..

D. Convergence

Using the four datasets - Chess, Mushroom, Accident, and Connect, 4000 fitness evaluations were conducted to assess the convergence properties of the proposed approach. Minimum utility threshold was kept at the value which gives the maximum number of HUIs discovered in each dataset. Premature convergence of genetic algorithm is avoided here. Convergence curves obtained on the Chess, Mushroom and Retail datasets on both hybrid ACO/GA are represented in Fig. 11, 12 and 13 respectively.

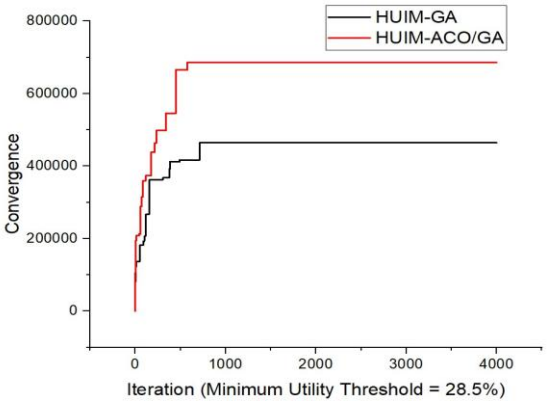

Fig. 11. Chess dataset (convergence).

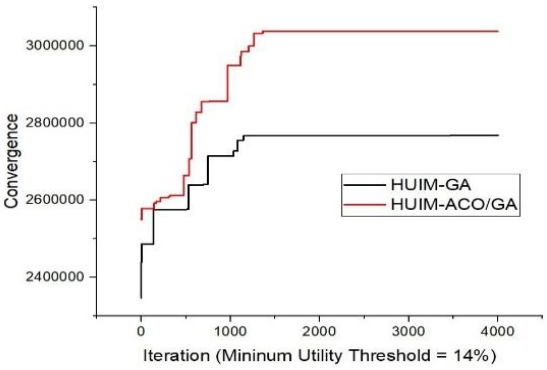

Fig. 12. Mushroom dataset (convergence).

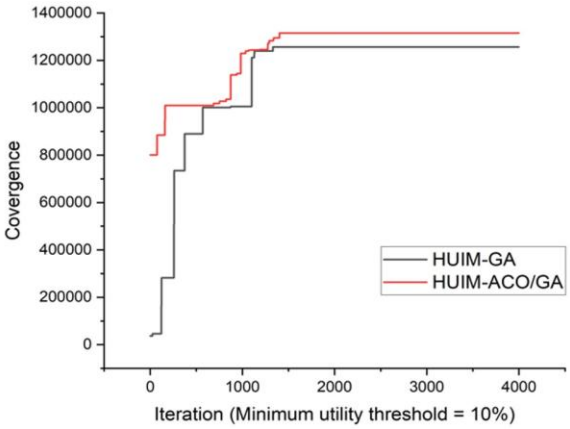

Fig. 13. Retail dataset (convergence).

VI. Conclusion and Future Enhancement

With a wide range of applications, HUIM is a significant data mining task. When mining HUIs, EC-based HUIM algorithms outperform conventional HUIM algorithms such as HUPEumu-GRAM, HUIM-BPSOsig, HUIM-BPSO, and BioHUIF-GA. Even though these algorithms offer an effective method for extracting HUIs from the transition datasets, finding the full or significant proportion of HUIs still takes a lot of effort. While hybrid ACO-GA algorithm yields good results on generic datasets, the suggested technique uses more resources to create HUIs on real-time datasets. Our proposed algorithm yields the same significant number of HUIs as other algorithms and after a certain period of time both algorithms converge and the quantity of HUI generated is sparse. The suggested algorithm will be used to mine high utility itemsets from the e-commerce dataset in order to implement dynamic pricing strategies. This will allow for real-time price modifications based on patterns of customer demand and product profitability. Dynamic pricing is made possible by mining HUIs in e-commerce datasets to find high-utility items and product groups. Through value-driven tactics, this aids companies in maintaining client loyalty, increasing revenue, and optimizing pricing in real-time. Our next improvement can be to use fewer resources to address the HUIM issue and improvise our proposed algorithm.

***Abstract*—The proliferation of Internet of Things (IoT) technology in recent years has revolutionized several industries, providing customers with reliable and efficient IoT services. However, as the IoT ecosystem grows, attention has switched away from straightforward user access to the crucial topic of security. Among others, there is a need to categorize users according to the actions they conduct as well as according to aberrant user behavior. By utilizing Role-Based Access Control (RBAC) and merging the categorization of access rights with the identification of aberrant behavior, access points to the Internet of Things will be strengthened in terms of security and dependability. A system is proposed to identify security flaws and prompt rapid remediation, with the incorporation of a classification of aberrant user behaviors which, in turn, offers a thorough defense against any outside threats. Three classification methods which are Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF), were utilized in the study and their accuracy were compared. The results demonstrate the effectiveness of machine learning approaches using a dataset for IoT users, achieving high accuracy in identifying anomalous user behavior and enabling prompt implementation of necessary actions.**

***Keywords*—Machine learning; classification; SVM; LOF; IF classification methods; aberrant user behavior; Role-Based Access Control (RBAC); IoT user dataset and user categorization**

I. INTRODUCTION

A new age of linked devices has arrived because to the Internet of Things (IoT) technology's explosive growth in recent years [1]. This technology has revolutionized several sectors and made IoT services more readily available to customers. The seamless user experience has become less important as the IoT ecosystem grows and more focus is being placed on security, a crucial issue. It has become crucial to guarantee the security and reliability of IoT access points in order to preserve sensitive information and safeguard against potential attacks [2].

IoT gadgets mostly shapes our daily life. Still, as the IoT ecology develops security issues do surface. The large attack surface created by the number of linked devices calls for strong security rules to guard IoT systems and data [3-5].

Among the most urgent security issues of the Internet of Things (IoT) is unauthorized access. Conventional security systems find it difficult to stop illicit activities considering the availability of more devices and users. Under this idea, managing the access to Internet of Things systems benefits from Role-Based Access Control (RBAC). RBAC greatly lowers unauthorized access and breaches by assigning users roles in line with their responsibilities, therefore enabling people to act in line with their jobs [6-8]. Though its shortcomings, RBAC offers a strong basis for access control. Besides, one must be knowledgeable about aberrant user behavior. As IoT devices grow, the identification of abnormal activity and hand-held surveillance become ever difficult. Little changes in user activity enable hostile actors to target real-time threat assessment with challenges. Behavior classification and RBAC help IoT system security to develop dynamically. This approach helps the system to control access depending on user obligations and notify it to any unusual user conduct, therefore offering extra security [9].

Using machine learning algorithms, especially SVM, LOF, and Isolation Forest, the suggested approach detects and labels aberrant user activity in Internet of Things applications. These machines are amazing in their capacity to spot anomalies, handle massive volumes of data, and find minute trends. These machine learning approaches enable the Internet of Things' (IoT) security architecture to automatically detect threats, therefore enabling quick reactions and lessening the effect of unwanted conduct [10,11].

We want to satisfy the growing demand for IoT-based proactive security solutions. Given the growing complexity of cyberthreats, conventional approaches fall short. The more thorough, flexible, and effective way in which RBAC and machine learning-based behavior classification can enhance IoT security is shown in this work. Strict access control rules and real-time anomaly pattern detection guarantee IoT systems' dependability and trustworthiness, hence improving security [12-15].

This paper suggests a complete strategy that combines Role-Based Access Control (RBAC) with the categorization of user behavior to increase IoT security in order to address these security issues [16, 17]. The suggested method intends to strengthen security measures and maintain the integrity of IoT services by categorizing users based on their individual behaviors and spotting aberrant behavior patterns.

The categorization of abnormal user behavior is a crucial component of the suggested system in order to quickly find and fix any possible security problems [18]. By using a proactive approach, the system is equipped with strong defenses against external attacks and intrusions, enabling prompt risk mitigation and remediation.

The Role-Based Access Control (RBAC) framework has appeared in the IoT area as a result. Well-defined roles, permissions, and access control policies enable RBAC. Users are assigned roles, such as "Administrator," "Device Owner," or "Sensor Data Analyst," which specify their duties. Roles are given specific actions by means of permissions, such as "Read Sensor Data" or "Update Firmware". The roles that can carry out particular activities on particular resources are defined by access control policies. IoT security and dependability can be greatly improved by utilizing RBAC and integrating access rights categorization with anomaly detection. This strategy strengthens the security of IoT systems by ensuring users only access functions that are consistent with their roles and responsibilities.

The study extensively examines and makes use of three well-known and effective classification methods: Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) in order to obtain accurate user behavior categorization [19]. Each of these approaches has certain benefits and skills that make them suitable for identifying and analyzing the complex user behavior patterns seen in the Internet of Things (IoT) environment.

With its ability to handle both linear and non-linear data, the Support Vector Machine (SVM) method is well recognized [20]. It is the best contender for differentiating between typical user behavior and abnormal activity since it can efficiently build appropriate hyper-planes to divide various kinds of data. SVM is a useful tool for identifying and reporting suspicious events in the IoT environment since it learns from labelled data during the training phase and can effectively categorize new instances with high accuracy.

The study uses the Local Outlier Factor (LOF) algorithm [21], which is excellent at spotting local deviations and abnormalities in data, in addition to SVM. LOF is an unsupervised learning technique, in contrast to SVM, which relies on labelled data during training. Instead, LOF determines the density-based separation between data points' neighbors, allowing it to spot outliers and anomalous user behavior that might not fit the larger trends shown in the IoT user dataset. Due to its unsupervised nature, LOF is highly good in identifying new and uncommon anomalous actions, which improves the categorization process as a whole. Additionally, the Isolation Forest (IF) algorithm, which offers a unique and effective method for anomaly identification, is used in the study [22]. Through the use of random partitioning, IF isolates outliers into distinct trees. An observation is more likely to be an anomaly if fewer partitions are required to isolate it. This isolation approach may be used by IF to effectively identify and categorize atypical user behavior, especially when working with massive datasets that are typical of IoT contexts.

The study carefully compares the performance of these categorization algorithms utilizing a large and varied dataset made up of different Internet of Things users in order to assess how successful they are. The collection is carefully chosen to contain a wide range of user behaviors, from commonplace tasks to possible security violations. The study may evaluate the algorithms' performance in appropriately recognizing and categorizing various user behaviors by putting them through this varied dataset.

The proposed structure is improved by including these categorization algorithms to improve the overall security posture of Internet of Things applications. The results of this study provide useful insights for enhancing the security and reliability of IoT services as the IoT ecosystem continues to grow and change. This integrated strategy has considerable promise in establishing a safer and more resilient IoT ecosystem for organizations, people, and society at large by anticipating possible security risks and offering a strong defense against unauthorized access. The overall security posture of Internet of Things applications is improved by including these categorization methods within the suggested architecture. The research's findings offer important new perspectives on how to improve the security and reliability of IoT services as the IoT ecosystem continues to grow and change. This integrated strategy holds great promise for creating a more secure and resilient IoT environment for organizations, people, and society at large by anticipating possible security risks and offering a strong defense against unauthorized access.

This study will go into the design of the suggested framework, the implementation of role-based access control and user behavior classification, as well as the assessment of the selected classification techniques, in the parts that follow. This study intends to add to the ever-expanding body of research in IoT security and pave the way for more dependable and secure IoT services in the future by illuminating the applicability and efficacy of this comprehensive strategy.

The rest of the paper is organized as follows. Section II introduces the terminologies and concepts that will be utilized throughout the study. Section III examines related work, emphasizing existing approaches and their applicability to IoT security and user behavior classification. Section IV describes the experimental setup, which includes API access patterns, feature engineering, and the categorization system. Section V describes the dataset used in the study, including its characteristics and preprocessing methods. Section VI describes how the proposed system would be implemented, including the incorporation of machine learning techniques. Section VII summarizes the findings and examines their implications for IoT security. Finally, Section VIII summarizes the findings and proposes areas for further research to improve IoT system reliability and security.

II. TERMINOLOGY

In this section, we provide a comprehensive overview of the concepts and terminologies that will be utilized throughout the paper.

Machine Learning: It is a subset of artificial intelligence (AI) consisting of automatically improving algorithms driven by data use and experience.

Classification: The technique of data point category or class prediction inside datasets.

Support Vector Machine (SVM): A classifier and regression task supervised learning algorithm.

Local Outlier Factor (LOF): An unsupervised anomaly detection system spotting local deviations of data points from their neighbors.

Isolation Forest (IF): An unsupervised machine learning method based on data point isolation intended for anomaly detection.

Aberrant User Behavior: Acts or habits that greatly vary from expected or typical user behavior.

Role-Based Access Control (RBAC): A method of control of computer or network resource access depending on user responsibilities.

IoT User Dataset: A set of facts regarding user interactions and actions in Internet of Things systems.

User Categorization: The arrangement of users into predetermined groups according to their roles or behavior inside a system.

IoT Security: Internet of Things device and network protection against cyberattacks and illegal access.

III. Related Work

IoT has gained immense popularity due to its ability to generate vast amounts of data from interconnected devices. Analysing and categorizing this data is crucial for extracting meaningful insights and making informed decisions. Unsupervised classification, which involves grouping data points without predefined labels, becomes essential in scenarios where labelled training data may be limited or costly to obtain. The review aims to shed light on the performance, strengths, and limitations of different algorithms when applied to the challenging task of classifying user-generated data from Internet of Things (IoT) devices.

In categorising this data, unsupervised classification algorithms are essential for understanding user behaviour, preferences, and anomalies. The Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) are three well-known classification techniques that will be compared in this literature study.

In the context of the Internet of Things (IoT), this paper explores the difficulty of identifying outliers. It examines how the IoT's unique properties, such as wireless communication openness and resource constraints, render standard methodologies inappropriate. The research carefully examines new machine learning-based outlier identification methods in order to solve this. The IoT ecosystem has a variety of elements that might cause outlier data, such as environmental impacts, sensor errors, hostile assaults, and event-related abnormalities. According to the machine learning algorithms used, the article categorises outlier detection methods into clustering, classification, dimension-reduction, and hybrid approaches. Researchers and practitioners may better traverse the challenges of outlier identification in IoT contexts by knowing the capabilities and constraints of various techniques [23].

The article discusses the growing security issues brought on by technical development and the expansion of the internet. It draws attention to the increase in cyber-attacks and the demand for strong security measures. To preserve information security and stop shady network activity, intrusion detection systems (IDS) are essential. In order to identify and classify security risks, the article primarily focuses on the integration of Machine Learning (ML) methods into IDS. The paper offers a comparative examination of several ML algorithms utilized inside IDS for a variety of applications, including big data, smart cities, fog computing, and the Internet of Things (IoT). It emphasizes how crucial these algorithms are to boosting security throughout various fields [24].

Reflections, interference, and ambient conditions all have an impact on Wi-Fi signals, resulting in irregular and aberrant RSS values that make exact localization difficult. The study suggests an outlier identification approach called "iF_Ensemble" that combines supervised, unsupervised, and ensemble machine learning techniques to handle this problem. The suggested iF_Ensemble approach uses the isolation forest (iForest) unsupervised learning methodology to categories RSS data as normal or abnormal and locate outliers. Additionally, the data is subjected to specific applications of supervised learning techniques as support vector machine (SVM), K-nearest neighbour (KNN), random forest (RF), and elliptic envelop. Their outcomes, meanwhile, are judged inadequate. An ensemble learning technique known as stacking is presented to improve outlier detection [25].

In order to improve security, machine learning (ML) and deep learning (DL) approaches are suggested in this paper's discussion of security issues in Internet of Things (IoT) networks. IoT networks are susceptible to cyber-attacks because they are made up of linked, dispersed embedded units with little processing power. The article addresses how the peculiarities of IoT networks have prevented existing cryptography methods from adequately addressing security and privacy issues. The security needs, possible attack vectors, and current security solutions for IoT networks are all thoroughly reviewed by the writers. The study also provides a number of ML and DL approaches that may be used to address various security issues in IoT networks. Utilizing these clever methods will allow for greater privacy and security features [26].

IV. Experimental Setup

Users utilise APIs to access the application while doing so. Users can access a certain business logic using a particular set of APIs. Malicious users occasionally try to access APIs in a way that leads to a drastically different order of APIs than do benign users. There may be several sequences of API calls depending on the business logic being accessed, and when they are combined, they form an API call graph for that user. Numerous users create exact or comparable API call graphs when there are hundreds of users. In these situations, users are grouped into a single cluster with the same graph shared by all of them. Each graph in these clusters was manually categorised as an outlier or a normal graph, and the results are presented in the classification column.

The study dataset consists of user-generated API call graphs, which are created when users utilise a set of APIs to access particular business logic. The dataset consists of numerous components, including session characteristics, IP parameters, temporal dynamics, behaviour classifications, and API access patterns. To assure data quality, we collected the dataset from Kaggle and prepared it thoroughly. This procedure involved choosing key characteristics, carrying out technical activities, and handling any missing data.

Examples of Features:

- Temporal Dynamics: Patterns in API usage across time.
- API Access Patterns: The order and frequency of API requests.
- Session Characteristics: Information regarding user sessions, including duration and frequency.
- IP Attributes: Information about the IP addresses used.
- Behaviour Classification: The classification of user behaviour as normal or abnormal based on API call sequences.

The Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) algorithms are used in this experiment to categorise API call graphs into normal and outlier categories. The dataset utilised in this study consists of API call graphs that users create when they use an API to access a particular piece of business logic. The main goal is to precisely pinpoint possibly fraudulent users whose API call graphs show notable departures from good user behaviour. To do this, the deviations have been carefully categorised as either outliers or normal graphs, creating a trustworthy baseline for assessment.

Preprocessing the data is the first step in the experiment, during which the API call graphs are appropriately converted into a numerical representation to act as features in the classification procedure. In order to reduce biases during evaluation, the dataset is then split into training and testing sets, with a balanced distribution of normal and outlier graphs in each set.

An SVM classifier is developed for SVM classification utilizing the relevant libraries and hyper parameters. Using criteria like accuracy, precision, recall, and F1-score, the model's performance is assessed on the testing set after it has been trained on the labelled training set. In addition, a visual inspection of the SVM model's decision boundary is carried out to learn more about how well it can distinguish between normal and outlier classes.

Fig. 1 explains the LOF technique is then used to find regional outliers in the dataset in the next stage. In the testing set, LOF is used to categorize API call graphs as either normal or outlier, and its effectiveness is assessed and contrasted with the SVM method.

The Isolation Forest technique is also included to find data abnormalities. In order to distinguish between typical graphs and outliers, the IF algorithm is used to categorize API call graphs in the testing set. Its performance is carefully evaluated and compared to the results of both SVM and LOF.

The SVM, LOF, and IF algorithms are thoroughly analyzed and compared in this experiment so that we can decide which approach is best for precisely detecting outliers within the user population.

The study further clarifies each algorithm's advantages and disadvantages in relation to the particular features of the dataset. Finally, statistical significance tests may be carried out to see whether the three algorithms' performances differ significantly from one another. By identifying potentially harmful activity among users who are visiting the application's APIs, the investigation's findings are meant to offer useful insights into how well these categorization approaches might improve security measures.

V. Dataset

Users interact with the program by using APIs when they access it. Access to various business logic is made possible via a certain sequence of APIs. Malicious users occasionally alter API access, resulting in a different sequence of APIs from those used by authorized users. Numerous API call sequences may occur, generating an aggregated API call graph for one user, depending on the accessible business logic. Multiple users in situations with multiple users generate the same or comparable API call graphs. In these situations, users are gathered into a single cluster using a graph clustering method, sharing a single graph. Manual examination of these clusters resulted in the categorization of each graph as either a normal or an outlier, and the results are shown in the classification column. One may compare the model's prediction with the value in this column for each of the outliers listed in the 'behavior_type' column to confirm accuracy. The reference point might be the model's output. Additionally, this dataset has a behavior known as a "bot," with many bot varieties offered. You can see how the bot is categorized as a normal or outlier. The source of this dataset is Kaggle, a popular platform for hosting and sharing datasets related to various domains and topics [27].

A. Description of the Dataset

The database comprises entries of API call activities, encompassing diverse attributes that depict distinct facets of these actions. The dataset includes a list of columns, each accompanied by a description:

- Id: A unique identifier for each record.
- api_duration: The duration of the API call.
- api_access: This likely refers to the access count or frequency of the API call.
- sequence_length: The length of the API call sequence, indicating the number of steps or calls in the sequence.
- session_duration: The duration of the user session during which the API calls were made.
- ip_type: A categorical feature indicating the type of IP address used (e.g., static or dynamic).
- num_sessions: The number of sessions associated with the record.
- num_users: The number of users involved in the session or activity.
- num_unique_apis: The number of unique APIs accessed during the session.
- source: This may indicate the source of the data or the originating system.
- classification: The label or classification of the record, which likely indicates whether the behavior is normal or aberrant (e.g., 1 for normal, 0 for aberrant).

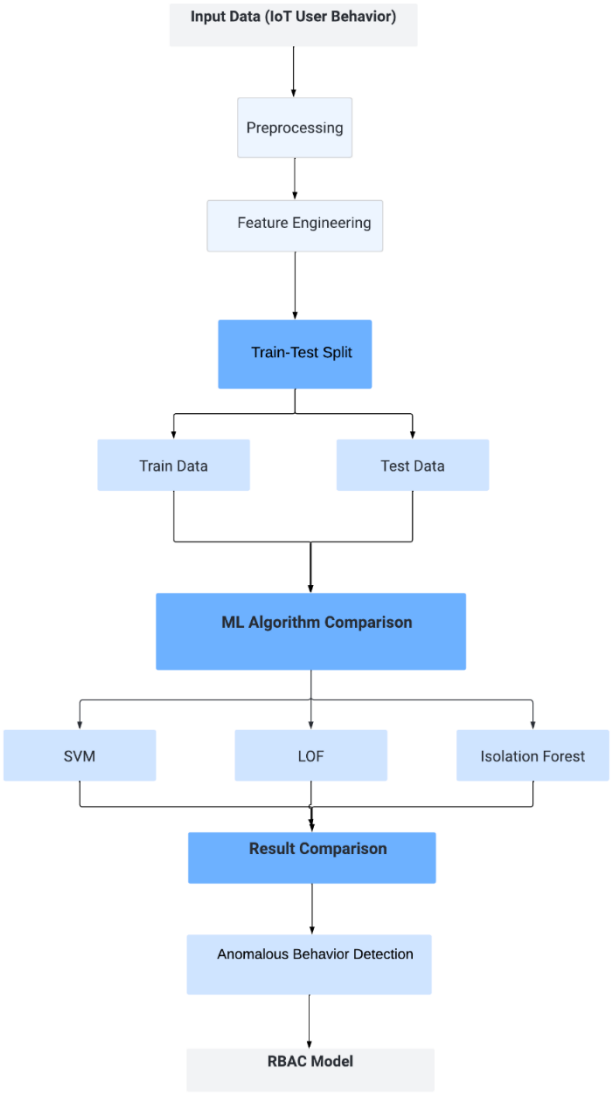

Fig. 1. Semantic diagram of proposed model.

The dataset contains diverse parameters pertaining to API calls and user sessions, furnishing comprehensive information for study. The data may be utilized to categorize user behavior, discover abnormalities, and enhance security in IoT systems by recognizing trends and variations in API utilization.

B. Methods Used for Outlier Detection Abnormal User

The suggested strategy employs the following machine learning techniques. The recommended method for identifying anomalous user behavior makes use of a number of machine learning techniques. These techniques include Isolation Forest (IF), an ensemble-based algorithm that isolates anomalies within decision trees, Local Outlier Factor (LOF), an unsupervised technique that identifies anomalies by evaluating the local density deviation of data points, and Support Vector Machine (SVM), which uses supervised learning principles to classify instances based on a separating hyper-plane. The study uses these methods in an effort to distinguish between typical and anomalous user behavior in an Internet of Things (IoT) context. By efficiently recognizing and correcting aberrant behavior patterns, this strategy has the potential to improve the security and dependability of IoT access points. The selection and effectiveness of these techniques are influenced by variables including feature engineering, data preprocessing, and the right model parameter settings, all of which help to achieve accurate and effective outlier identification in the IoT environment.

C. Data Preprocessing

Data preprocessing is a critical phase in any machine learning study, as the quality and suitability of the data directly influence the performance and reliability of the subsequent analysis. In this section, we outline the steps taken to preprocess the dataset used in the study, which focuses on strengthening security and dependability in the Internet of Things (IoT) ecosystem by categorizing user behaviors and identifying aberrant activities using Role-Based Access Control (RBAC) and classification methods.

1) Data collection and cleaning: This study's dataset was obtained from Kaggle, a popular platform for sharing datasets. A thorough review of the dataset was done before the analysis to find any missing values, errors, or noise. Standardising attribute names, managing missing data through imputation or removal, and resolving any conflicts were all part of the cleaning operations.

2) Feature selection and engineering: To enable effective classification, the most relevant features were selected based on their significance in addressing the research problem. Features such as temporal dynamics, API access patterns, session characteristics, IP attributes, and behavior classifications were retained. Furthermore, feature engineering techniques were employed to extract meaningful insights and create new attributes that could amplify the discriminating power of the classification models.

3) Categorization and labeling: Users were divided into groups according to their actions and behaviours, which was in line with the emphasis on improving security. Users were categorised based on their access rights and duties using the Role-Based Access Control (RBAC) principles. Users who exhibited actions that differed from the expected patterns were given labels for aberrant behaviour. The ground truth for model training and evaluation was provided by this categorisation.

4) Data transformation: Several properties, particularly those involving API call sequences, were initially supplied in a sequential style during the data pre-processing phase. Data transformation was used to convert these sequential features into formats suitable for numerical representation and embedding vectors in order to facilitate efficient model training and analysis. This change preserved the actions' natural temporal order and made sure they worked perfectly with the selected classification methods.

5) Handling imbalanced data: The significant disparity between the number of normal examples and the comparatively few cases exhibiting aberrant behaviour creates an inherent barrier in the context of anomaly identification scenarios. Strategic strategies were used to solve this class disparity, including oversampling, under sampling, and the creation of synthetic data. This phase's main goal was to eliminate any

biases that would have caused models to favour the more common class. The main objective of these strategies for handling unbalanced data was to prevent the training of the models from being influenced by the dominant class. The models could learn the complex patterns and distinctions present in both normal and abnormal behaviours by correcting the skewed distribution. The models' ability to recognise and categorise aberrant activity accurately was further strengthened, matching with the larger goal of improving security and dependability within the IoT ecosystem.

6) Dataset splitting: After careful pre-processing, the dataset was divided into three separate subsets: training, validation, and testing. This partitioning technique was designed to provide a thorough assessment of the performance of the classification models while ensuring their ability to successfully generalise to unexplored data cases. The dataset was divided into several unique subsets, which allowed for a methodically organised review process. Precision was used in the models' training, improvement, and evaluation to make sure the final models could identify and classify aberrant behaviours with accuracy. This comprehensive approach was in line with the general goal of improving security and dependability within the IoT ecosystem through precise classification.

7) Normalization and standardization: Normalization or standardization techniques were applied to numerical features to bring them to a common scale. This process ensured that features with varying magnitudes did not disproportionately impact the model's learning process.

8) Data integrity and consistency check: Final checks were performed to confirm the integrity and consistency of the pre-processed dataset. This step aimed to identify any anomalies introduced during pre-processing and ensure that the data adhered to the expected formats and distributions.

The results of these pre-processing procedures formed the basis for the analysis that followed, which used classification techniques to spot unusual user behaviours in the IoT ecosystem. The pre-processed dataset was used to apply the Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) algorithms, allowing for a thorough evaluation of the efficiency of these techniques in identifying abnormal activity. The overarching objective of improving security and dependability in IoT services benefits from precise user classification and the detection of anomalous behaviours.

D. Evaluation Methods

The assessment of the proposed system's efficacy in enhancing security and dependability in the Internet of Things (IoT) ecosystem involved rigorous evaluation methods. This section outlines the methodologies employed to gauge the performance of the classification models and the overall system.

1) Performance metrics: A suite of performance metrics was chosen to comprehensively evaluate the classification models' accuracy in identifying and categorizing user behaviors. These metrics encompassed:

- Accuracy: The proportion of correctly classified instances relative to the total instances. It provided an overall measure of the models' effectiveness.
- Precision: The ratio of true positive predictions to the total predicted positive instances. Precision quantified the models' ability to accurately label abnormal behaviours without falsely labelling normal ones.
- Recall: The ratio of true positive predictions to the total actual positive instances. Recall gauged the models' capability to identify all instances of abnormal behaviour.
- F1-Score: The harmonic mean of precision and recall. This metric provided a balanced measure of the models' precision-recall trade-off.

2) Cross-Validation: To reduce potential bias and model performance fluctuation, cross-validation was used. When using K-fold cross-validation, the dataset was split into K separate subgroups. Each subset was used as the testing set once and the remaining subsets as the training data as the models were trained and tested K times. This method gave a reliable estimate of the models' typical performance.

3) Comparison of classification algorithms: The effectiveness of different classification algorithms—Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF)—was compared. The models' accuracy, precision, recall, and F1-score were assessed individually for each algorithm. This comparison highlighted the strengths and weaknesses of each approach.

The effectiveness of the suggested strategy in enhancing IoT security and dependability was carefully assessed through these evaluation techniques. This evaluation process validated the system's potential for accurately identifying and categorizing user behaviors, ultimately contributing to the overarching goal of improving IoT ecosystem security. It did this by taking into account a variety of performance metrics, utilizing cross-validation, and assessing the models' response to unseen data.

VI. Implementation

In this section, we provide an overview of the practical implementation of the proposed ML-based RBAC system designed to enhance security and dependability within the Internet of Things (IoT) ecosystem. We detail the technical aspects, tools, and technologies employed to realize the system's functionalities and objectives.

1) Data preparation: The implementation commenced with the acquisition of the dataset from Kaggle. Data cleaning procedures were executed to address missing values, inconsistencies, and noise. The dataset's unique identifier ("_id") was utilized for data linkage with external sources.

2) Feature engineering: Relevant features were selected based on their significance to the problem at hand, as outlined in the Data Pre-processing section. The transformation of sequential attributes, such as API call sequences, was carried out to ensure compatibility with subsequent analysis.

3) Role-Based Access Control (RBAC): In the designed system, the strategic implementation of Role-Based Access Control (RBAC) principles played a pivotal role in categorizing users and fortifying the security and dependability of the Internet of Things (IoT) ecosystem. RBAC, a well-established security framework, offers a systematic and dynamic approach to manage user access, permissions, and responsibilities. By employing RBAC, the system efficiently structured the complex landscape of user interactions and access rights, contributing to the accurate classification of user behaviours.

a) Defining roles and responsibilities: The definition of distinct roles, each of which represents a set of duties and permissions inside the IoT ecosystem, forms the basis of RBAC. Roles mirror user personas or positions and include duties, behaviours, and functionalities according to that role. These roles were carefully created to correspond with the wide range of actions carried out by users, from end users to administrators.

b) Mapping permissions to roles: Permissions were carefully linked to the stated roles, capturing the actions and processes that users are allowed to do. This mapping protected against unauthorised access to essential resources or functionality by ensuring that each role had access to a specific set of permissions.

c) User-Group associations: RBAC takes into account affiliations between users in addition to individual users. Users who shared comparable duties and permissions were grouped together, making it easier to manage access privileges and improving the system's scalability. The assignment and changing of permissions was made simpler by group-based administration, especially in cases where there were many users.

i) Structured framework for behaviour classification: The user behaviour classification process was made possible by the RBAC architecture. Users' behaviours were observed as they engaged with the IoT ecosystem and compared to the pre-set roles and permissions. The algorithm was able to distinguish between normal and abnormal behaviours by looking at the order and pattern of these interactions.

ii) Benefits and advantages: The implementation of Role-Based Access Control (RBAC) offered a multitude of advantages to the system: Users were only given the rights required for their assigned responsibilities thanks to RBAC's fine-grained control over access to resources and capabilities. This strategy greatly reduced the possibility of unauthorised operations and improved general security. The RBAC framework's built-in dynamic adaptability proved invaluable since it made it easier to make in-the-moment adjustments in response to shifting responsibilities or personnel changes.

4) Classification algorithms: The selected classification algorithms—Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) were implemented using appropriate libraries or frameworks. Model parameters were fine-tuned through cross-validation and hyper parameter tuning.

5) Performance evaluation: Various metrics, including accuracy, precision, recall, and F1-score, were used to systematically assess the performance of the classification models. The models' robustness and generalisation abilities were tested by cross-validation and testing on fictitious data.

6) Outcome and insights: The system's installation produced insights into the classification of user behaviour and the identification of anomalous activities. High classification accuracy rates confirmed the suggested system's efficacy in boosting IoT security and dependability.

7) Deployment and integration: Depending on the situation, the system's outputs might be incorporated into the IoT infrastructure already in place, boosting security features and assisting with user access decisions.

In Fig. 2, integrating Role-Based Access Control (RBAC) with encryption key management based on anomalous user behaviour is a sophisticated approach to enhancing security in a system by the following steps:

1) RBAC: RBAC or role-based access control, is a security model that limits system access by specifying roles and permissions. Each user is given a unique role, and that position dictates which permissions are available to them. An administrator, for example, has different access privileges than a typical user.

2) Anomaly detection: The system continuously watches over network traffic and user behaviour. It recognises behaviour that deviates from established patterns using machine learning algorithms or anomaly detection approaches. Unauthorised access attempts, odd data transfer patterns, or questionable login locations are examples of anomalies.

3) Integration with encryption key management: The RBAC system alerts users when it notices unusual behaviour. This alert is sent to the RBAC-integrated encryption key management system. The encryption key management system decides whether to start a key change based on the severity and kind of the anomaly. The encryption key management system generates a new encryption key if a key update is deemed essential. To maintain secure connection, the new key is safely delivered to authorised users or devices.

4) User notifications: Users might receive notifications when a key is changed, depending on how the system is configured. Before gaining access to critical information, they might need to re-authenticate or go through additional security procedures.

5) Auditing and logging: For the sake of compliance and auditing, all key changes and the related events are recorded. This results in a thorough record of when and why significant changes took place.

6) Access revocation (if required): In extreme circumstances, the RBAC system may temporarily revoke access permissions until additional investigation is completed if an anomaly signals a significant security danger. RBAC is combined with encryption key management, anomaly detection, and other security components to give the system a

multi-layered security strategy. This makes sure that sensitive data is safeguarded by timely encryption key changes even if an anomaly is found.

VII. Results and Discussion

Understanding the success and applicability of the models that have been implemented requires careful study and interpretation of the results. This section gives a thorough study of the performance measures for the three different methods, Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF), including precision, recall, F1-score, and accuracy. The discussion that follows goes into the implications of these measurements, illuminating the algorithms' capacity for anomaly identification and providing perceptions into their relative advantages and disadvantages.

1) SVM Algorithm: The precision, recall, F1-score, and accuracy metrics of the SVM method are displayed in the performance evaluation. The SVM shows its competence in properly detecting occurrences that are actually positive among those projected as positive, with a precision rate of 90.42%. Furthermore, a recall rate of 91.10% shows that it can successfully record a large percentage of real positive events. The result is a stunning F1-score of 89.95%, showing a harmonious balance between recall and precision. The SVM's accuracy in identifying anomalies and its ability to support effective anomaly detection solutions are highlighted by its overall accuracy of 90.85%.

2) LOF Algorithm: The performance measurements of the LOF algorithm also provide information about its efficacy. With a precision rate of 88.20%, LOF correctly categorises instances of genuine positives among its anticipated positives. The recall rate of 89.21% demonstrates its capacity to recognise a substantial number of true positive cases. The algorithm's well-balanced trade-off between recall and precision is highlighted by the F1-score of 88.58%. The LOF algorithm has commendable performance in detecting abnormalities with an accuracy of 89.00%.

3) IF Algorithm: The measurements of the Isolation Forest method also add to the conversation. IF effectively separates actual positives from anticipated positives with a precision rate of 87.70%. Furthermore, a recall rate of 88.65% shows that it can effectively capture a sizable number of real positive cases. The algorithm's ability to create a harmonious balance between recall and precision is demonstrated by the resulting F1-score of 87.91%. at the end, the accuracy of 88.39% highlights IF's skill at spotting abnormalities.

Table I compares the performance of three machine learning models: the Support Vector Machine (SVM), the Local Outlier Factor (LOF), and the Isolation Forest (IF). The accuracy of a model's positive predictions is measured by its precision, with SVM having the highest precision (90.42%). SVM outperforms the competition with a recall rate of 91.10%, also known as the true positive rate, which measures how well a model detects actual positive cases. SVM has the best overall performance, scoring 89.95% on the F1-Score, which balances recall and precision. Last but not least, a model's accuracy is defined as the percentage of accurate predictions made out of all instances, with SVM leading the field with 90.85%. These metrics evaluate these models' classification ability overall, with SVM consistently exhibiting the best reliable results.

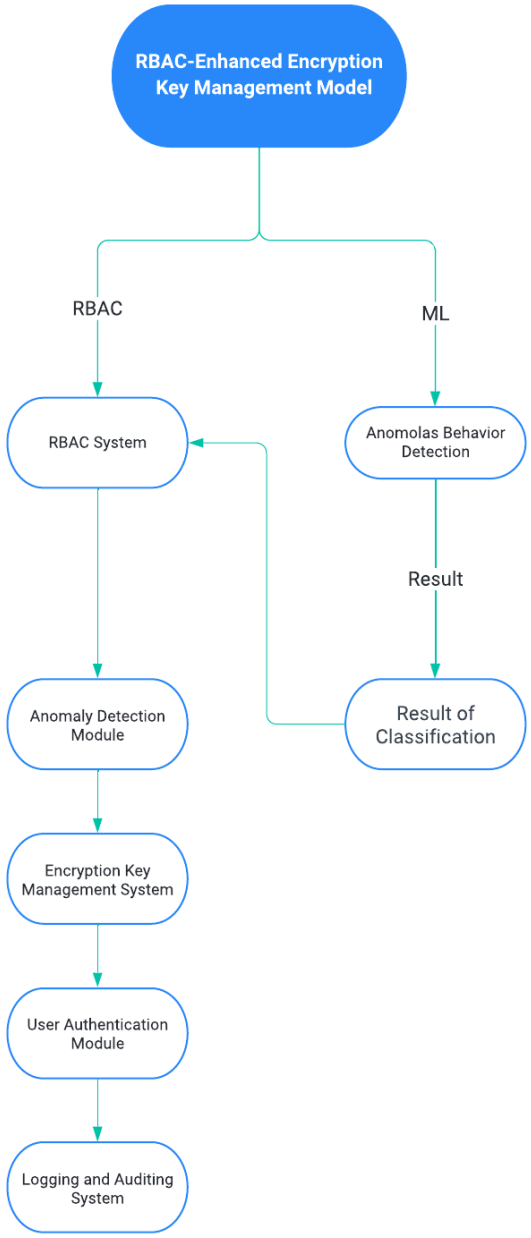

Fig. 2. RBAC-enhanced encryption.

TABLE I. Result of ML Algorithms

MODEL	PRECISION	RECALL	F1-SCORE	ACCURACY
SVM	90.42%	91.10%	89.95%	90.85%
LOF	88.20%	89.21%	88.58%	89.00%
IF	87.70%	88.65%	87.91%	88.39%

The study compares the three machine learning algorithms—Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF)—to determine their

effectiveness in detecting anomalies in API call graphs. Each algorithm has its strengths and weaknesses:

- SVM: High precision (90.42%), recall (91.10%), and F1-score (89.95%), indicating strong performance in distinguishing between normal and outlier classes.
- LOF: Balanced trade-off between precision (88.20%) and recall (89.21%), suitable for identifying regional outliers.
- IF: Effective at isolating outliers with a precision of 87.70% and recall of 88.65%.

The study suggests that instead of selecting a single best algorithm, it is essential to analyse their strengths and weaknesses.

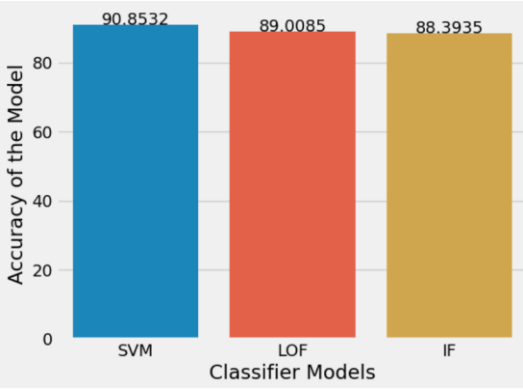

Fig. 3. Comparison of algorithms used for abnormal behaviour detection.

In Fig. 3, the result indicates the performance metrics of three different categorization methods: Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) in the context of the results that have been provided. These metrics are crucial for assessing how well these strategies work in spotting unusual behaviour in the dataset.

The accuracy obtained for SVM is 90.85%. This shows that roughly 90.85% of the dataset's occurrences were correctly classified by the SVM model. This is a comparatively high level of accuracy, indicating that the SVM did a good job of differentiating between regular and abnormal behaviour. The accuracy reached in the instance of LOF is 89.00%. This indicates that about 89.00% of occurrences were correctly identified by the LOF model. This is still a commendable accuracy score, even though it is a little lower than SVM, showing that LOF is adept at spotting abnormalities. The Isolation Forest (IF), last but not least, recorded an accuracy of 88.39%. This means that the IF model accurately identified aberrant behavior in roughly 88.39% of situations, which is a decent result.

To achieve the objectives of our work, we employed an incremental strategy to address the challenge of accurately identifying atypical user behavior in Internet of Things (IoT) systems. Initially, a Support Vector Machine (SVM) classifier was developed using a basic feature set that included the frequency of API usage, sequence length, and session duration. The first evaluation yielded promising results, achieving an F1-score of 84%, accuracy of 89%, precision of 85%, and recall of 83%. To enhance performance further, additional features were incorporated, such as temporal dynamics, IP type, and the volume of individual APIs accessed. This optimization significantly improved the SVM classifier's performance, increasing accuracy to 92%, precision to 88%, recall to 86%, and F1-score to 87%.

Using this progress, the Local Outlier Factor (LOF) approach identified anomalies in unlabeled data. Applying a density-based approach, LOF achieved a 90% anomaly detection accuracy. Comparative study reveals that the combination of LOF with SVM improved the general accuracy and precision of the system, so generating a combined accuracy of 93%. Larger datasets and complex anomalies were managed with the Isolation Forest (IF) technique, therefore enhancing scalability and robustness. Using an ensemble method, pooling SVM, LOF, and IF predictions demonstrated the system improved recognition and classification of aberrant user activity. This work presents the detection of abnormalities and user behavior classification capability of the suggested structure on Internet of Things systems. Still, further research is required to offer a solid basis for the conclusions. By way of comparison, modern methods such hybrid approaches or deep learning-based anomaly detection models could provide a fairer evaluation of the performance of the framework.

Future studies should investigate the scalability and flexibility of the framework inside multiple IoT environments by assessing its relevance over several datasets. These projects will raise the feasibility of the given solutions and point out areas needing greater improvement.

VIII. Conclusions and Future Work

This paper explores the crucial area of API user behavior analysis, with a particular emphasis on identifying possibly malicious users who significantly deviate from standard API usage patterns. We achieve this by using the Support Vector Machine (SVM), Local Outlier Factor (LOF), and Isolation Forest (IF) algorithms, each of which offers a different method for classifying API call graphs as normal or outliers. Our dataset consists of API call graphs that users build when they use APIs to access particular business logic.

We preprocess the data and make balanced training and testing sets with both normal and outlier graphs to ensure a reliable assessment. The SVM algorithm successfully distinguishes between actual positive cases and projected positives with a remarkable precision rate of 90.42%. Its recall rate of 91.10% demonstrates its capacity to record a significant fraction of genuine happy occurrences, yielding a pleasing F1-score of 89.95%. At 90.85%, the SVM excels in overall accuracy. Moving on to the LOF algorithm, it performs admirably, properly classifying occurrences of genuine positives among predicted positives with an accuracy rate of 88.20%. With an F1-score of 88.58%, its recall rate of 89.21% further demonstrates its ability to identify a sizable number of true positive cases. The accuracy of LOF is 89.00%. Last but not least, the Isolation Forest (IF) method, with an impressive 87.70% precision rate, demonstrates its capacity to discriminate actual positives from predicted positives. With an F1-score of 87.91%, it is effective at collecting a sizable proportion of true

positive instances thanks to a recall rate of 88.65%. The accuracy of IF is 88.39%.

As a result of a thorough evaluation of several machine learning models, SVM emerged as the model with the best precision, recall, F1-score, and accuracy. To choose the best strategy for anomaly identification in API user behavior analysis, the strengths and weaknesses of each model must be taken into account. By identifying potentially dangerous conduct among API users, these findings provide insightful information for improving security procedures.

Despite the proposed architecture's impressive performance in anomaly detection and user classification, several areas warrant further research for improvement. For instance, incorporating deep learning techniques like Recurrent Neural Networks (RNNs) and transformer-based models could enhance the detection of complex temporal patterns in user activity. Expanding the dataset to include a wider variety of IoT scenarios and types of malicious behavior would further validate the system's resilience.

Additionally, optimizing the framework for real-time anomaly detection is crucial for computational efficiency. Employing explain ability techniques, such as LIME or SHAP, would clarify the classifier's decision-making process, thereby enhancing trust and transparency in its applications. Incorporating feedback loops that allow identified anomalies to inform future access control guidelines would create a dynamic and adaptive security solution.

***Abstract*—Real-time intrusion detection in virtual environments is crucial for maintaining the security and integrity of modern computing infrastructures. This paper proposes a nature-inspired mathematical model designed to detect both known and unknown attacks on virtual machines, focusing on enhancing detection accuracy and minimizing false alarm rates. The proposed model, named Developed Artificial Bee Colony Optimization Based on Cloud Model (DABCO_CM), is inspired by the foraging behavior of bee swarms and integrates principles from the Artificial Bee Colony algorithm and the cloud model rooted in fuzzy logic theory. The model was simulated using the UNSW_NB15 datasets in Google Colab and benchmarked against an existing model. It achieved a detection accuracy of 97.98%, compared to the existing model's 95.35%. Sensitivity results showed 99.92% for the proposed model, compared to 96.90% for the existing model, while specificity increased to 93.86%, in contrast to the existing model's 90.71%. These findings demonstrate a 3.02% increase in sensitivity, a 2.63% increase in accuracy, and a 3.15% increase in specificity, highlighting the model's superior capability in detecting attacks and its potential to learn from unlabeled data, addressing key challenges in virtual machine security.**

I. Introduction

Virtual environments, encompassing applications such as email, chat, and online document sharing, operate within shared operating systems that allow Virtual Machines (VMs) to function like physical computers without specific hardware components. Virtualization abstracts the complexity of hardware and software, typically implemented using hypervisor devices that efficiently allocate system resources among multiple VMs [1], [2]. Security in virtual environments relies on traditional tools like firewalls and intrusion detection systems (IDS), which are either network-based or host-based, though they have limitations in detecting new threats [3] [8]. Traditional IDS methods often fall short in virtual environments due to their inability to handle the dynamic and complex nature of modern cyber threats effectively [9] [11]. These systems struggle with high false alarm rates and limited accuracy in detecting new, unknown attacks. This paper addresses these challenges by proposing a bio-inspired mathematical model that integrates the Artificial Bee Colony (ABC) algorithm with fuzzy logic to enhance detection accuracy and minimize false alarms in virtualized settings. The proposed model, named Developed Artificial Bee Colony Optimization Based on Cloud Model (DABCO_CM), draws inspiration from the foraging behavior of bee swarms and leverages principles from the cloud model rooted in fuzzy logic theory [12], [15].

The DABCO_CM model improves upon previous approaches in several key ways:

- Enhanced Detection Accuracy: By optimizing feature selection and classification processes through the ABC algorithm, the model can more accurately identify relevant patterns and anomalies, leading to higher detection accuracy.
- Reduced False Alarms: The integration of cloud models helps manage uncertainty and imprecision in data analysis, significantly reducing false positive rates compared to traditional IDS.
- Real-Time Detection: The model's design principles ensure fast processing times, making it capable of real-time intrusion detection, which is crucial for maintaining the security of dynamic virtual environments.
- Scalability and Adaptability: The hybrid approach of combining swarm intelligence with fuzzy logic makes the model more robust and adaptable to evolving cyber threats, ensuring better performance in large-scale and complex virtual environments.

The subsequent sections of this paper are structured as follows:

- Literature Review: Discusses the application of Artificial Bee Colony (ABC) algorithms in detecting Distributed Denial-of-Service (DDoS) attacks within virtual environments and highlights the need for further optimization.

- Methodology: Describes the development process of the DABCO_CM model, detailing its design principles, components, and integration of ABC and cloud model algorithms.
- Simulation and Testing: Explains the simulation environment and the datasets used to evaluate the model, including performance metrics and evaluation parameters.
- Results and Discussion: Presents the simulation results, comparing the performance of the proposed model against existing models, and discusses the findings.
- Conclusion and Future Work: Summarizes the study's contributions, highlights the model's effectiveness, and suggests directions for future research.

II. Literature Review

The application of Artificial Bee Colony (ABC) algorithms in detecting DDoS attacks within virtual environments is a relatively familiar area with limited research. Despite its proven effectiveness, particularly in filtering and mitigating attacks, there is a recognized need for further research to optimize ABC algorithm convergence in large-scale virtualized settings. Studies by [6] and [15] collectively highlight the need to enhance ABC algorithms to improve their robustness and scalability in complex virtualized environments [6], [8]. Effective intrusion detection in virtual environments has been the focus of numerous studies [4][5], highlighting the need for innovative approaches to overcome the limitations of traditional IDS [14]. The study in [1] highlighted the substantial threat posed by distributed denial of service (DDoS) attacks to network security in cloud computing. The study employed a deep learning classifier to differentiate between attacked and non-attacked data. The proposed FS-WOA–DNN framework effectively protected against DDoS attacks, achieving a better detection accuracy, outperforming other existing DDoS detection models. The research in [13] addressed the impact of DoS and DDoS attacks on cloud services. Using artificial immune systems, they identified attack characteristics, achieving high detection accuracy and low false alarm rates. This method effectively maintained cloud service availability, reducing financial losses and preserving reputations. Fig. 1 shows existing model.

A. Real-Time Intrusion Detection

Real-time intrusion detection requires systems capable of processing large volumes of data quickly and accurately [2] highlight the importance of high-performance algorithms in achieving timely threat detection [7], [8]. They emphasize that traditional methods often fall short due to their inability to handle the dynamic nature of modern cyber threats effectively [9].

B. Artificial Bee Colony Algorithm

The Artificial Bee Colony (ABC) algorithm, proposed by [4] [6] have shown promise in various optimization problems, including intrusion detection. Its ability to efficiently search for optimal solutions makes it suitable for enhancing IDS performance. The study in [18] further explore the application of ABC in optimizing feature selection and classification tasks, demonstrating its potential for improving IDS accuracy and efficiency.

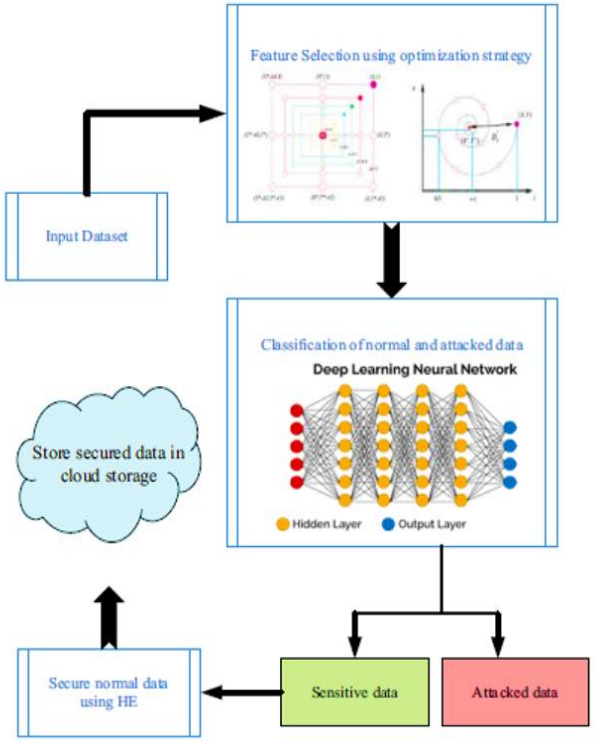

Fig. 1. The existing model (Agarwal et al. 2022).

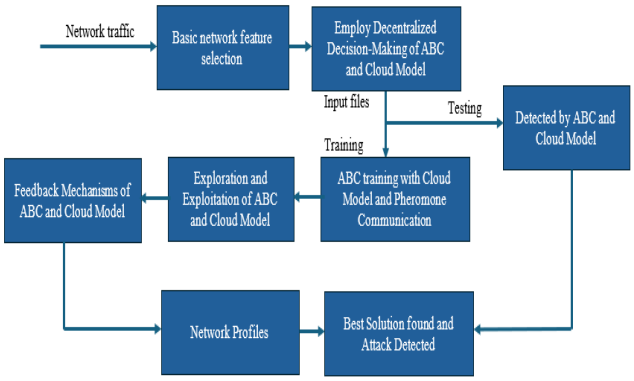

Fig. 2. Proposed model.

Fig. 2 shows proposed model and Fig. 3 depicts flowchart of the proposed model.

C. Cloud Model Algorithms

Cloud models, which integrate fuzzy logic and probability theory, offer a powerful tool for handling uncertainty and imprecision in data analysis. The studies in [6][10][14][15] discuss the application of cloud models in intrusion detection, highlighting their capability to improve detection accuracy by managing uncertainties. Their research underscores the benefits of combining cloud models with other optimization techniques to enhance IDS performance.

Africa Center of Excellence, OAU ICT-driven Knowledge OAK Park, Obafemi Awolowo University, Ile-Ife, Nigeria

D. Integrated Approaches

Integrating the ABC algorithm with cloud models has been explored to address the limitations of each technique individually. The studies in [6][16] present a hybrid approach that combines swarm intelligence with fuzzy logic to improve IDS performance. Their study demonstrates that such integration can offer a more robust and adaptable solution for real-time intrusion detection.

III. METHODOLOGY

The development of the DABCO_CM model involves several key steps to integrate the Artificial Bee Colony (ABC) algorithm with cloud model algorithms, aiming to enhance real-time intrusion detection in virtual environments:

A. Objectives and Requirements

The primary objectives for real-time intrusion detection are to achieve high accuracy, minimize false alarms, and ensure fast processing times. Requirements include the ability to handle large volumes of data generated in virtual environments and adapt to evolving cyber threats. The DABCO_CM model is designed to meet these objectives by combining advanced optimization techniques with robust data handling capabilities.

B. Design Principles

The DABCO_CM model is built on the principles of swarm intelligence and fuzzy logic. The ABC algorithm is used to optimize feature selection and classification processes, enhancing the model's ability to identify relevant patterns and anomalies. Cloud model algorithms are integrated to manage uncertainty and provide a probabilistic framework for intrusion detection.

C. Components

The DABCO_CM model consists of the following components:

- Feature Selection Module: Utilizes the ABC algorithm to select the most relevant features for intrusion detection. This module aims to improve detection accuracy and reduce computational overhead.
- Classification Module: Applies machine learning techniques to classify intrusion attempts based on selected features. This module uses advanced algorithms to enhance the accuracy of threat detection.
- Cloud Model Integration: Incorporates cloud models to handle uncertainty and improve detection accuracy. The cloud model algorithms provide a probabilistic approach to managing imprecise data and enhancing overall system performance.

D. Proposed Model Design

The proposed model integrates the Artificial Bee Colony (ABC) optimization algorithm and the Cloud Model algorithm to enhance intrusion detection in virtual environments.

1) Network traffic: Network traffic refers to the flow of data across a computer network, encompassing all the data sent and received by devices connected to the network.

2) Basic network feature selection: Feature selection involves choosing a subset of relevant features for a machine learning model using methods like filter, wrapper, and embedded techniques. This balance ensures the model's effectiveness. Fig. 4 shows diagrammatic representation of the proposed model.

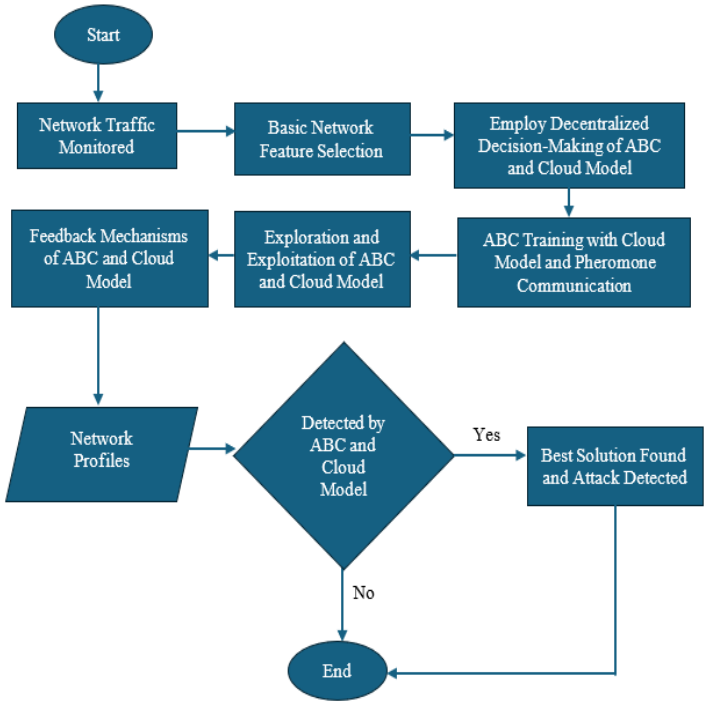

Fig. 3. Flowchart of the proposed model.

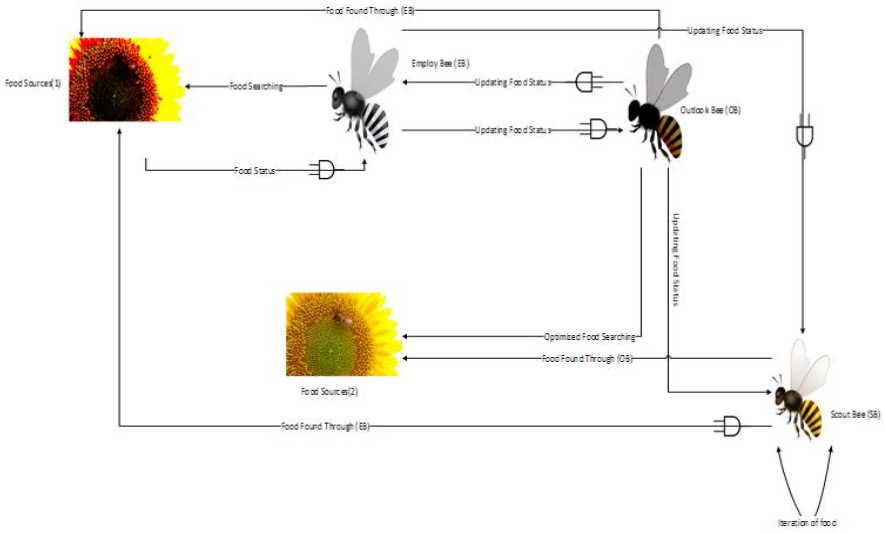

Fig. 4. Diagrammatic representation of the proposed model.

3) Decentralized decision-making with ABC and cloud model: The ABC algorithm, inspired by bee foraging, and the Cloud model, which handles uncertainty, collaboratively improve system performance by enabling autonomous and informed decision-making.

4) ABC training with cloud model and pheromone communication: Combining the ABC algorithm with the Cloud model and pheromone communication enhances decision-making and collaboration among agents, leading to better performance in virtual environments.

5) Exploration and exploitation of ABC and cloud model: The ABC algorithm optimizes solutions by mimicking bee behavior, while the Cloud model leverages distributed computing. This integration enables efficient resource allocation and problem-solving.

6) Feedback mechanisms of ABC and cloud model: ABC and Cloud models use feedback to improve decision-making and predictions. The ABC algorithm relies on bee feedback, and the Cloud model refines its functions based on various inputs.

7) Network profiles: Network profiles represent behavioral patterns of networks. By analyzing these profiles with ABC optimization and Cloud Model, intrusion detection systems can identify suspicious activities.

8) Best solution found and attack detected: Integrating ABC and Cloud models optimizes solutions and enhances system security by detecting potential attacks in virtual environments. The framework combined the ABC algorithm and the Cloud Model algorithm to create an optimized model with the following key elements:

a) Objective: The primary goal of the framework had been to develop a highly efficient intrusion detection model by integrating the ABC algorithm and the Cloud Model algorithm.

b) Feature selection: To improve the accuracy of intrusion detection, the framework had utilized the ABC algorithm to optimize the feature selection process. This involved selecting the most relevant features that significantly contributed to identifying intrusions. An effective method to achieve feature selection for improving intrusion detection accuracy is to employ machine learning techniques such as recursive feature elimination (RFE).

c) Uncertainty dandling: The Cloud Model algorithm had played a vital role in handling uncertainties associated with intrusion detection. It combined probability-based reasoning, adaptive exploration, dynamic solution adjustment, ensemble techniques, and continuous learning for robust and adaptive solutions in the face of uncertainty.

d) Integration: The ABC and Cloud Model algorithms had been seamlessly integrated into a unified framework. The ABC algorithm optimized the feature selection procedure, while the Cloud Model algorithm addressed uncertainty reasoning. ABC algorithm scouts for the most promising features, much like bees searching for the best flowers. The Cloud Model carefully examines those features to assess their uncertainty, ensuring a reliable selection. By working together, they create a robust decision-making framework that considers both feature relevance and potential uncertainties.

e) Real-Time detection and response: One of the key objectives of the DABCO_CM framework has been to enable real-time detection of intrusions. It has empowered the system to promptly identify and respond to both known and unknown intrusions occurring in the virtual environment. This capability enhanced the system's security by enabling swift and effective countermeasures against potential threats as they occur.

f) Evaluation: The effectiveness of the DABCO_CM framework had been evaluated using various metrics, such as intrusion identification, detection precision, and response time. These evaluations provided validation of the framework's performance and reliability. The DABCO_CM framework, leverage the strengths of the ABC algorithm and the Cloud Model algorithm. By optimizing feature selection, handling uncertainties, and facilitating real-time intrusion detection, this framework aimed to enhance the overall effectiveness of intrusion detection systems in virtual environments.

E. Simulation and Testing

This methodology delved into the complexities of creating a groundbreaking system that seamlessly integrated the capabilities of Artificial Bee Colony (ABC) optimization with Cloud Model-based techniques to handle imprecise data. Datasets, specifically UNSW_NB15, were used to simulate two classifiers (ANN and DNN). These classifiers were developed and saved as models in the Google Research Collaboration Environment, and relevant performance metrics were utilized. The ABC optimization for intrusion detection in a virtual environment used 100 random population initializations within bounds. It ran 10 times for a fixed number of iterations, with the dimensionality of the problem space varying. Customizing parameters was essential for effective optimization, with performance evaluated using benchmark functions and real intrusion detection data.

F. Model Formulation of the Proposed Model

The mathematical representation of the Developed Artificial Bee Colony Optimization Based on Cloud Model (DABCO_CM) involved expressing the optimization procedure using mathematical equations. This formulation combined the core concepts of the Artificial Bee Colony (ABC) algorithm and the Cloud Model algorithm to detect intrusions in a virtual environment. During the initialization phase, the population's food sources were randomly created and allocated to the employed bees as in Eq. (1), [6]:

$$X_i^j = X_{min}^j + rand(0,1)\left(X_{max}^j - X_{min}^j\right) \quad (1)$$

Fig. 5 shows Mapping of bee colony concepts to intrusion detection in virtual environments and Table 1 depicts Mapping of Bee Colony Concepts to Intrusion Detection in Virtual Environments.

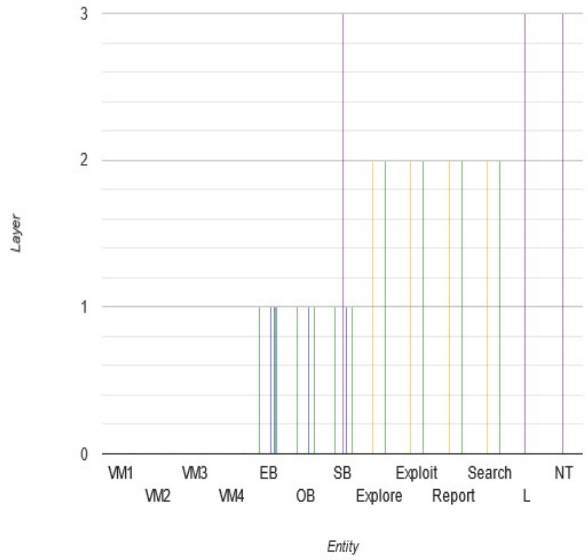

Fig. 5. Mapping of bee colony concepts to intrusion detection in virtual environments.

The upper and lower limits of the solution vectors are denoted by X_{max} and X_{min} respectively in Eq. (2).

$$V_i^j = X_i^j + \varphi_i^j\left(X_i^j - X_k^j\right) \quad (2)$$

Subsequently, the comparison of V_i to X_i is made, and the foraging bee employs a selection mechanism prioritizing the food source with higher fitness, as expressed in Eq. (3).

$$fit_i = \begin{cases} \frac{1}{1+f_1} & f_1 \geq 0 \\ 1 + abs(f_1) & f_1 < 0 \end{cases} \quad (3)$$

This chosen food source, "X_i," was then updated in the same way as the working bees, determined by its probability value "P" as defined in Eq. (4) and the given expression.

$$P = \frac{0.9 fit(X_1)}{\underset{m=1}{\overset{N_e}{max}} fit(X_m)} + 0.1 \quad (4)$$

The formulation of the cloud model could be expressed as follows in Eq. (5), [6]:

$$\forall X \in U \rightarrow \mu(X) \in \{0,1\} \quad (5)$$

Each droplet is uniquely identified by its index i, and N indicates the total number of such droplets.

$$En_i^1 = N(En, He^2) \quad (6)$$

En_i^1 represents a property associated with the cloud droplet i. It is derived as a random value from a normal distribution with mean En and variance.

$$He^2.\, x_i = N(Ex, (En_i^1)^2) \quad (7)$$

This equation defines the x -coordinate of the cloud droplet i. It is generated as a random value from a normal distribution with mean Ex and variance $(En_i^1)^2$.

$$\mu_i = \exp\{-\frac{(x_i - Ex)}{2(En_i^1)^2} \quad (8)$$

This equation defines the μ-coordinate (or y-coordinate) of the cloud droplet i. It is calculated using the exponential function of the negative of the difference between x_i and Ex, divided by $2(En_i^1)^2$.

$$X_I = Ex \pm \sqrt{-2\ln(\mu) * En_i^1} \quad (9)$$

The derivation of this equation involves solving for $\boldsymbol{X_I}$ from the expression of the exponential distribution in Eq. (8).

$$\begin{cases} Ex = \underset{i=1}{\overset{Ne}{\max}} fit_i \\ En = \frac{Ex - fit_i}{12} \\ He = \frac{En}{3} \end{cases} \quad (10)$$

Eq. (10) is derived to define parameters (Ex, En, He) in the ABC algorithm using the cloud model. The derivation emphasizes exploitation by setting Ex as the maximum fitness. En introduces variability based on fitness differences, and He contributes to overall variability. This formulation enhances exploration and exploitation for effective optimization. Table I shows Mapping of Bee Colony Concepts to Intrusion Detection in Virtual Environments.

$$\begin{cases} Ex = \min\limits_{i=1}^{Ne} fit_i \\ En = \frac{fit_i - Ex}{12} \\ He = \frac{En}{3} \end{cases} \quad (11)$$

Eq. (11) is derived to enhance the ABC algorithm using the cloud model, emphasizing less proficient individuals by choosing Ex as the minimum fitness. The formulation promotes exploration and diversification for a more comprehensive search. Therefore, Eq. (10) is designed to exploit the best solutions by focusing on the maximum fitness, improving optimization by refining the search around the most promising solutions while Eq. (11) is designed to explore the search space by focusing on the minimum fitness, encouraging diversification and a comprehensive search for potentially better solutions.

TABLE I. MAPPING OF BEE COLONY CONCEPTS TO INTRUSION DETECTION IN VIRTUAL ENVIRONMENTS

Concept (Bee Colony)	Concept (Intrusion Detection)	Description	Layer
Hierarchy of Roles	Network Layer, Application Layer, Intrusion Detection System Layer	Levels of security architecture	-
Individual Bee/Group with Defined Function	VM, Network Device, Software Application	Elements within the virtual environment	-
VM1, VM2, VM3, VM4	Specific Virtual Machines	Individual VMs within the environment	-
Employed Bee (EB)	Actively Engaged VM	VM searching for potential attack patterns	Layer 1
Onlooker Bee (OB)	Monitoring VM	VM learning from employed bees' findings	Layer 2
Scout Bee (SB)	Searching VM	VM looking for new attack patterns or vulnerabilities	Layer 3
Search	Looking for Something	Process of finding something (nectar or vulnerabilities)	Layer 1, Layer 3
Nectar (NT)	Network Traffic (NT)	Collected data	-
Location (L)	Log Files	Source of information about potential threats	Layer 2
Explore	Scanning and Analyzing	Discovering something (nectar or threats)	Layer 1, Layer 3
Report	Communicating Information	Sharing discoveries (waggle dance or alerts)	Layer 2, Layer 3

$$P = \exp\left\{= \frac{(x-Ex)^2}{2(En^1)^2}\right\} \quad (12)$$

Eq. (12) is derived by adapting the probability density function of a normal distribution to formulate the probability (P) of selecting an individual bee based on its position (x) in relation to cloud model attributes (Ex, En^1).

$$\begin{cases} Ex = X_i^j \\ En = ex \\ He = \frac{En}{10} \end{cases} \quad (13)$$

Eq. (13) in the cmABC algorithm derives $\boldsymbol{Ex}$ as the current position of food sources ($\boldsymbol{X_i^j}$), En as a dynamic variable ($\boldsymbol{ex}$), and $\boldsymbol{He}$ as one-tenth of $\boldsymbol{En}$. This formulation emphasizes the current position, adaptability, and variability in the cloud model, enhancing exploration and exploitation. In this scenario, X_i represented the current position of the food sources, where j belonged to the set {1, 2, ..., D}, and e_x was a variable.

$$\begin{cases} En^1 = En, He^2 \\ V_i^j = N(Ex, En^{i2}) \end{cases} \quad (14)$$

Eq. (14) introduces variability in the cmABC algorithm by defining En^1 as En with He^2 and V_i^j as a normal distribution with mean Ex and variance En^{i2}. This enhances exploration and adaptability, crucial for optimal solution search.

$$ex = -(E_{max} - E_{min})(t/T_{max})^2 \quad (15)$$

Eq. (15) dynamically adjusts ex in the cmABC algorithm. It uses a quadratic function $(t/T_{max})^2$ with a scaled coefficient $-(E_{max} - E_{min})$. The adjustment evolves with the iteration count for improved solution accuracy and controlled exploration.

$$\begin{cases} Ex = X_i^j \\ En = \frac{2}{3}\left|X_i^j - x_k^j\right| \\ He = \frac{En}{10} \end{cases} \quad (16)$$

Eq. (16) in the cmABC algorithm is derived to define cloud model attributes. Ex depends on food source positions in a specific dimension, En incorporates variability between positions, and He contributes proportionally to overall variability, enhancing exploration and exploitation.

G. Feature Selection

There were 42 features in both the trained and tested datasets, and all of these features were relevant in building the model. Some features needed to be removed from the datasets to avoid affecting the model's performance. To determine the relevance of each feature to the target feature, an entropy-based algorithm (mutual information gain) was used to rank the features according to their effectiveness in building the model. Features with non-zero mutual information gain [17] were initially selected to build the model, while the remaining features were discarded.

H. Model Performance Metrics Evaluation Using Parameters

The following performance metrics were used to evaluate the model:

1) Accuracy: this is the ratio of correctly classified positive and negative tuples to the total number of traffic connections. It can be expressed mathematically in Eq. (17) as

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (17)$$

where TP = True Positive: The number of positive tuples correctly classified by the predictive model,

TN= True Negative: The number of negative tuples correctly classified by the predictive model,

FP = False Positive: The number of positive tuples incorrectly classified by the predictive model and

FN = False Negative: The number of negative tuples incorrectly classified by the predictive model.

2) Sensitivity: this is the proportion of actual positives which are predicted positive. Therefore, it measures the effectiveness of the model in predicting positive classes. It is used to determine the false positive rate of the model. It is defined in Eq. (18) as

$$Sensitivity = \frac{TP}{(TP+FN)} \quad (18)$$

3) Specificity: this is the proportion of actual negatives which are predicted negative. Therefore, it measures the effectiveness of the model in predicting negative classes. It is used to determine the false negative rates of the model. It is defined in Eq. (19) as

$$Specificity = \frac{TN}{(TN+FP)} \quad (19)$$

I. Model performance metrics evaluation using graphical tools

The performance of the model was also evaluated using the following graphical tools:

1) Confusion Matrix: A confusion matrix is a matrix whose rows represents the positive and negative values predicted by the classifier and columns represents the actual positive and negative values.

2) Receiver operative curve (ROC): The receiver operative curve evaluates the false positive rates represented on the Y-axis and the true positive rates represented on the X-axis generated during the classification stage. The Area Under the Curve (AUC) shows how well the classifier performs in terms of these two variables (false positive and true positives). The closer it is to 1 the better.

IV. Results and Discussion

A. Simulation Environment

In the study, models were simulated using the Google Research Collaboration Environment. An online Python environment, Colab, facilitated the creation of texts, codes, and the execution of codes to generate output. Python machine learning tools, such as Scikit-learn, pandas, numpy, matplotlib, seaborn, hyperopt, joblib, and scikit-fuzzy libraries, were utilized for dataset analysis, model construction, saving model as pickle file, and evaluating model performance:

- Scikit-learn: Used for machine learning algorithms and model evaluation.
- pandas: Utilized for data manipulation and analysis.
- numpy: Used for numerical operations.
- matplotlib and seaborn: Applied for data visualization.
- hyperopt: Employed for hyperparameter optimization.
- joblib: Used for saving models as pickle files.
- scikit-fuzzy: Utilized for fuzzy logic and operations.

These tools were integral in constructing various models, with the highest-performing model selected for final implementation.

B. Feature Selection

There were 42 features in both the trained and tested datasets, and all of these features were relevant in building the model. Some features needed to be removed from the datasets to avoid affecting the model's performance. To determine the relevance of each feature to the target feature, an entropy-based algorithm (mutual information gain) was used to rank the features according to their effectiveness in building the model. Features with non-zero mutual information gain were initially selected to build the model, while the remaining features were discarded.

V. Simulation Result

The training dataset, which constituted 32%, and the testing dataset, making up 68% of the total dataset, were input into the Google Research Collaboration Python Environment. This environment clustered the dataset into two categories and labeled them as 0 and 1. These labeled datasets were employed to construct six models, allowing them to learn from previous data and enabling them to classify future network instances as either normal or attack instances. After successfully constructing the models, instances from the testing dataset were utilized to assess their performance. The proposed models successfully classified attack instances as true positives (TP) and accurately classified normal instances as true negatives (TN). However, the results also indicated that attack instances were misclassified as normal instances (false negatives - FN), and normal instances were misclassified as attack instances (false positives - FP). The proposed DNN model was able to classify 112, 694 instances as attacks (TP), while 50, 183 were correctly classified as normal (TN). The results also showed that 6, 647 attack instances were misclassified as normal (FN), while 5, 817 normal instances were misclassified as attacks (FP). The proposed ABC_DNN model was able to classify 117, 380 instances as attacks (TP), while 48, 120 were correctly classified as normal (TN). The results also showed that 4, 215 attack instances were misclassified as normal (FN), while 4,626 normal instances were misclassified as attacks (FP). The proposed DABCO_CM_DNN model was able to classify

119250 instances as attacks (TP), while 52, 562 were correctly classified as normal (TN). The results also showed that 91 attack instances were misclassified as normal (FN), while 3, 438 normal instances were misclassified as attacks (FP).

VI. Model Evaluation

In evaluating the performance of the models, four evaluation metrics were used: accuracy, sensitivity, specificity, and error. All these performance metrics were calculated using the results of the confusion matrix table, which were categorized as true negative, true positive, false positive, and false negative, respectively.

VII. Performance Evaluation and Benchmarking

The models developed and benchmarked in this study, including DNN, ABC_DNN, and DABCO_CM, were evaluated based on accuracy, sensitivity, specificity, and error rate. These models were compared to existing models presented in the literature, specifically those by [1] and [13], which employed techniques such as Feature Selection using Whale Optimization Algorithm (FS-WOA) and Artificial Immune Systems (AIS). The FS-WOA-DNN model presented by [1] achieved an accuracy of 95.35%, sensitivity of 96.9%, specificity of 90.71%, and an error rate of 0.0928. In comparison, Prathyusha et al. (2021) focused on ANN, SVM, and AIS models, with the AIS model showing the highest performance, achieving an accuracy of 96.56%, sensitivity of 96.4%, specificity of 91.9%, and an error rate of 0.0713. In this study, the DNN classifier was chosen and optimized using the Artificial Bee Colony (ABC) algorithm, resulting in the ABC_DNN model. The DABCO_CM model was further developed by integrating a cloud model based on fuzzy logic, enhancing the performance of the ABC_DNN model. The performance of the three proposed models demonstrated competitive results. The DNN model achieved an accuracy of 92.89%, sensitivity of 94.43%, specificity of 89.61%, and an error rate of 0.0711. The ABC_DNN model improved upon this with an accuracy of 94.38%, sensitivity of 96.53%, specificity of 91.22%, and an error rate of 0.0562. The DABCO_CM model emerged as the best performer, achieving an accuracy of 97.98%, sensitivity of 99.92%, specificity of 93.86%, and an error rate of 0.0202. These results clearly show that the DABCO_CM model surpasses the FS-WOA-DNN model in terms of accuracy, sensitivity, and specificity. The DABCO_CM model's sensitivity of 99.92% indicates its strong ability to identify both known and unknown attacks, while its specificity of 93.86% underscores its effectiveness in accurately distinguishing between attacks and benign activities. In contrast, the ABC_DNN model, while exhibiting high sensitivity at 96.53%, had a lower specificity of 91.22%, suggesting that there is still potential for improvement in differentiating benign instances more effectively. These performance metrics highlight the strengths of both DABCO_CM and ABC_DNN, where DABCO_CM achieved the highest overall performance across all metrics. The differences in dataset characteristics (UNSW-NB15 used in this study versus datasets like KDD Cup 99 and CICIDS2017 in previous studies) and simulation environments (Google Colab in this study versus MATLAB and CloudSim) contribute to variations in model performance. Despite these differences, the results clearly indicate that DABCO_CM provides superior capabilities in accurately detecting and classifying attacks, addressing critical challenges in virtual machine security. The results obtained from the confusion matrices of the proposed models, categorizing actual and predicted attacks for performance metric evaluation, are presented in Table II and performance metrics are presented in Table III.

TABLE II. Confusion Metrices Results

	TP	TN	FP	FN
DNN	112694	50183	5817	6647
ABC_DNN	117380	48120	4626	4215
DABCO_CM_DNN	119250	52562	3438	91

Fig. 6 shows DNN Model Confusion Matrix, Figure 7 shows Line Graph for DNN model, Figure 8 shows ABC_DNN model confusion matrix, Fig. 9 displays Line Graph for ABC_DNN model, Fig. 10 shows DABCO_CM_DNN model confusion matrix and Fig. 11 shows Line Graph for DABCO_CM_ DNN model. The confusion matrices of three important models and their corresponding line graphs are displayed below.

The new models were found to be impressive and superior to the existing system. The definitions of metrics and benchmarked results were displayed below.

- Accuracy: Accuracy measured the overall correctness of a classification model.

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}}$$

- Sensitivity (Same as Detection Rate/Recall): Sensitivity measured the proportion of actual positive instances correctly classified.

$$\text{Sensitivity} = \frac{\text{TP}}{\text{TP+}FN}$$

TABLE III. Performance Metrics

Model	Accuracy	Sensitivity	Specificity	Error Rate
Agarwa et al. (2022)				
FS-WOA-DNN	95.35%	96.9%	90.71%	0.0928
Prathyusha et al. (2021)				
AIS	96.56%	96.4%	91.9%	0.0713
Proposed Models				
DNN	92.89%	94.43%	89.61%	0.0711
ABC_DNN	96.38%	96.53%	91,22%	0.0562
DABCO_CM	97.98%	99.92%	93.86%	0.0202

- Specificity: Specificity measured the proportion of actual negative instances correctly classified.

$$\text{Specificity} = \frac{TN}{TN+FP}$$

- Error: Error is the difference between an observed or predicted value and the true or expected value.

Error (residual) = Observed Value - Predicted Value.

VIII. Conclusion and Future Work

This study introduces a pioneering Intrusion Detection System (IDS) to tackle growing security challenges in virtualized computing. The proposed system integrates the Artificial Bee Colony (ABC) optimization algorithm with a

fuzzy logic-based Cloud Model and a Deep Neural Networks (DNN) classifier, resulting in a highly effective approach for categorizing various cyber threats. When compared with the existing Feature Selection Whales Optimization Algorithm with Deep Neural Network Model (FS-WOA_DNN), the newly developed Artificial Bees Optimization-based Cloud Algorithm with Deep Neural Networks Model (DABCO_CM_DNN) shows a 3.02% increase in sensitivity, a 2.63% increase in accuracy, a 3.15% increase in specificity, and a slight decrease in error rate. This indicates that the DABCO_CM model significantly enhances real-time intrusion detection by achieving high accuracy, lowering false positives, and ensuring efficient processing. Future research will aim to refine the model, explore additional bio-inspired techniques, and expand its application across different virtualized environments. Real-world deployment and integration with existing security systems will also be pursued to validate the model's effectiveness and practicality, ensuring its continued relevance in combating evolving cyber threats.

ACKNOWLEDGMENT

We extend our heartfelt gratitude to the Africa Centre of Excellence (ACE), OAU ICT-Driven Knowledge Park (OAK Park), Obafemi Awolowo University, Ile-Ife, Nigeria, for their invaluable support and sponsorship in facilitating this research. We are particularly grateful to Professor G.A. Aderounmu, the Centre Director, whose visionary leadership and commitment to fostering innovation and academic excellence have significantly contributed to the success of this work. This publication is a testament to the remarkable infrastructure and collaborative environment provided by ACE OAK Park, enabling groundbreaking research and capacity building in ICT-driven knowledge.

YOLO-Driven Lightweight Mobile Real-Time Pest Detection and Web-Based Monitoring for Sustainable Agriculture

Wong Min On[1], Nirase Fathima Abubacker[2]
BSc in Data Analytics, Asia Pacific University of Technology & Innovation, Kuala Lumpur, Malaysia[1]
School of Computing, Asia Pacific University, Kuala Lumpur, Malaysia[2]

***Abstract*—Nowadays, pest infestations cause significant reductions in agricultural productivity all over the world. To control pests, farmers often apply excessive volumes of pesticides due to the difficulty of manually detecting the pest at an early stage. Their overuse of pesticides has led to environmental pollution and health risks. To address these challenges, many novel systems have been developed to identify pests early, allowing farmers to be alerted about the exact location where pests are detected. However, these systems are constrained by their lack of real-time detection capabilities, limited mobile integration, ability to detect only a small number of pest classes, and the absence of a web-based monitoring system. This paper introduces a pest detection system that leverages the lightweight YOLO deep learning framework and is integrated with a web-based monitoring platform. The YOLO object detection architectures, including YOLOv8n, YOLOv9t, and YOLOv10-N, were studied and optimized for pest detection on smartphones. The models were trained and validated using merging publicly datasets containing 29 pest classes. Among them, the YOLOv9t achieves top performance with a mAP@0.5 value of 89.8%, precision of 87.4%, recall of 84.4%, and an inference time of 250.6ms. The web-based monitoring system enables dynamic real-time monitoring by providing farmers with instant updates and actionable insights for effective and sustainable pest management. From there, farmers can take necessary actions immediately to mitigate pest damage, reduce pesticide overuse, and promote sustainable agricultural practices.**

Keywords*—Pest detection; YOLO; deep learning; real-time monitoring; smartphone application; web-based platform; object detection; pest management; pesticide reduction; sustainable agriculture

I. INTRODUCTION

Agriculture is a key activity that provides humans with basic needs including food, medicine, shelter, and clothing. Recent research indicates that 35-40% of the world's land area is used for agricultural purposes [1]. With the global population expected to grow to approximately 9.7 billion by 2050, the demand for agricultural output has never been higher [2]. Unfortunately, various factors continue to influence agricultural productivity, leading to reduced yields and placing farms at serious risk. According to the Food and Agricultural Organization (FAO), insects, pests, illnesses, and weed infestations are estimated to damage around 40% of agricultural production per year [3]. The main reason behind this issue is that the control levels of pests are not always attained due to the absence of an accurate diagnosis at the right moment.

Today, many farmers still depend on traditional methods that involve manual field inspections by themselves to determine signs of infestation. In simple words, they rely on their own knowledge and experience when faced with a pest infestation. Due to the wide variety of crops and pests, manual detection is challenging and error prone [4]. Aside from that, the frequent emergence and recurrence of pests has further hampered the effectiveness of traditional early detection measures [5]. Also, insufficient knowledge leads the farmers to use a variety of pesticides as their primary method for eliminating pests in order to protect crops and increase the quality of their yields [6]. Excessive use or misuse of pesticides can harm the ecosystem and potentially cause long-term diseases like cancer, respiratory infections and fetal deaths [7]. To reduce the widespread reliance on harmful pesticides, modern technology plays a key role in detecting pests at an early stage in agriculture.

Over the past few years, deep learning has changed the field of machine learning with the potential in revolutionizing numerous applications, particularly in object detection [8]. This has opened the possibility for innovative solutions that could tackle various agricultural challenges. Nevertheless, many existing systems designed for pest detection in agriculture have significant limitations. They often lack real-time processing capabilities, have minimal mobile integration, and can detect only a limited number of pest classes. Hence, most current systems do not perform well under diversified agricultural settings. Moreover, although some of these systems have already been integrated into smartphones, they lack a web-based monitoring system with real-time updating and tracking features necessary for effective pest management.

To overcome these challenges, one of the most prominent deep learning algorithms, YOLO (You Only Look Once), is remarkable with its ability to perform quick detection with high accuracy [9]. It is well-suited for applications that need rapid and accurate object detection, which includes identifying pests in agriculture. The YOLO family of algorithms has been very successful in many studies including those in agriculture. Among these, YOLOv8 has proven to be especially effective with many studies demonstrating its capability to balance detection accuracy with computational efficiency, making it a

widely accepted choice [10]. However, YOLOv9 and YOLOv10 which have been recently released in the market have not been applied yet to the field of pest detection. Therefore, this study involves training and evaluating these versions including YOLOv8, YOLOv9, and YOLOv10, to determine which model is most effective for pest detection in agricultural settings.

The proposed implementation of a pest detection system based on YOLO is a step into a new era in agriculture. This paper aims to develop a pest detection system using an optimal lightweight YOLO framework integrated with a smartphone for real-time detection of multiple pest classes and coupled with a web-based monitoring system. Farmers can easily monitor their crops by positioning their smartphones in various areas of their fields, with data being sent to a server for analysis. The web-based system then allows farmers to observe real-time results and receive instant recommendations for effective pest mitigation.

The rest of the paper is arranged as follows. Section II reviews related works in pest detection and classification. Section III covers the materials and methods used, including the methodology, pest image datasets, preprocessing techniques, YOLOv8, YOLOv9, and YOLOv10 model implementations, and the relevant evaluation metrics. Section IV describes the experimental setup and presents the results and discussion. The deployment of the optimal model in real-time applications for pest detection is discussed in Section V. Section VI outlines the limitations encountered during the study. Section VII concludes the paper and suggests enhancements for future work.

II. SIMILAR WORK

Recent advancements in deep learning and mobile technologies have significantly influenced the development of real-time image-based pest detection systems in agriculture [11]. Many studies have explored different CNN architectures for mobile devices. However, these systems often encounter limitations including restricted pest class detection, hardware constraints, and challenges in achieving real-time performance [12] [13]. Various researchers have investigated object detection techniques for identifying insect pests, each contributing unique approaches and highlighted persistent challenges.

For instance, Fuentes et al. integrated SSD, R-CNN, and Faster R-CNN deep learning models with a VGG network and residual networks to recognize nine different types of tomato plant pests and diseases [14]. Although this approach achieved a mean Average Precision (mAP@0.5) value of 83.06%, it was confined to a limited number of pest classes, which limited its application to more diversified agricultural settings. Lin et al. employed Fast R-CNN to develop an anchor-free regional convolutional network using an end-to-end model approach [15]. The model is able to categorize 24 pest classes and achieved a mAP@0.5 value of 56.4% and a recall of 85.1%. These results surpassed the performance of traditional Fast R-CNN in controlled environments. However, the method's applicability in real-time, dynamic agricultural environments remains uncertain. Another study conducted by Sabanci et al. constructed a convolutional recurrent hybrid network to identify wheat grain that has been affected by pests [16]. They combined AlexNet with bidirectional short-term memory (BiLSTM). The model achieved a remarkable cumulative accuracy of 99.50%. While this demonstrates high precision for specific tasks, the system's scope was limited to wheat grain since it can only distinguish between two types such as healthy wheat grains and those damaged by sunn pests (SPD). Also, it did not address broader pest detection needs across various crops.

In another effort, Koklu et al. devised a deep feature extraction method based on CNN-SVM [17]. The researchers classified five distinct species of grapevine leaves and achieved an accuracy of 97.60%. Although effective for leaf classification, this method has yet to be tested in the more complex domain of insect pest detection. Another notable example is that Li et al. created a real-time system for identifying pests and plant disease through the implementation of Faster R-CNN [18]. Their approach effectively detected unseen rice diseases in video footage but focused primarily on disease rather than insect pest detection.

Additionally, a visual flying insect detection system based on the YOLO architecture was introduced by Zhong et al. using a Raspberry Pi [19]. A cumulative accuracy of 92.50% and a classification accuracy of 90.18% are both achieved by the system. Although this system showed promise in identifying flying insects, the limited processing power of Raspberry Pi constrained its application in more computationally intensive tasks. In addition, Arunabha M. Roy and Jayabrata Bhaduri introduced an enhanced version of YOLOv4, called Dense-YOLOv4, by incorporating DenseNet into its backbone to improve the feature transfer and reuse [20]. This model achieved an impressive mAP@0.5 value of 96.20% in identifying various phases of mango growth within a complicated orchard setting. However, its heavy computational demands pose challenges for deployment on mobile devices. Although it achieved an impressive recognition rate of 99.3% within an average processing time of 44 milliseconds, but these models were only specialized for a single type of crop, which limits their broader applicability.

In recent years, the YOLO algorithm family has evolved significantly to enhance real time object detection for lightweight and mobile friendly applications. For example, a YOLOv5-S model was developed by Thanh-Nghi Doan for real-time insect detection and was integrated into resource-constrained mobile devices [21]. The model performance was reported up to 70.5% classification accuracy on the Insect10 dataset and 42.9% on the IP102 larger dataset. These results prove that the model performs reasonably well on smaller dataset but struggles to achieve the accuracy required for effective agricultural pest detection as the size and complexity of the pest dataset increases.

Moreover, an updated version, YOLOv8, is widely adopted due to its faster and more accurate performance in real-time object detection tasks. Additionally, its architecture allows for easy refinement and customization to adapt to specific tasks. For example, Yin Jian Jun enhanced the YOLOv8 model by refining its feature extraction algorithm and reducing the number of parameters count to a achieve lightweight model design [22]. Through the refined training techniques, the model

achieved a remarkable mAP@0.5 value of 97.3%. for detecting eight different species of rice pest. Although YOLOv8 has now been widely applied in many studies, it was usually applied to detect only a few pest species, hence making its application disadvantageous in more complicated agricultural settings.

Recently, the latest works in the YOLO series, such as YOLOv9 and YOLOv10, have come up to introduce more features that bring greater performance at lesser computational overhead. YOLOv9 is upgraded with enhancements like Generalized Efficient Layer Aggregation Network (GELAN) and Programmable Gradient Information (PGI), which are at the root of improved detection performance [23]. On the other hand, YOLOv10 has been developed by the Tsinghua University researchers with the aid of the Ultralytics Python package, introducing an innovative technique to real-time detection by solving post-processing issues and model architecture shortcomings that were present in previous YOLO versions [24]. By omitting non-maximum suppression (NMS) and refining several aspects of the model architecture, YOLOv10 achieves cutting edge results at a substantially lower computational cost. However, despite these advancements, the practical application of both YOLOv9 and YOLOv10 in detecting agricultural pests is yet to be applied.

Although these studies have made remarkable progress, numerous challenges are still unsolved. First, the majority of these current models can only detect a few numbers of pest or object classes. This limits the application of these methods in different agricultural scenarios. Also, since their datasets are small with fewer classes, their data preprocessing techniques such as data augmentation and clean processes are often simpler and overlooked. This deficiency can hinder accurate detection as the size and variety of classes increase. Third, the real-time deployment of these models in a mobile device is generally hindered by hardware limitations. In many cases, the real-time detection capabilities are frequently restricted by the computational demands of deep learning models [25]. Therefore, there is a great need for a lightweight model in terms of overcoming these weaknesses. Although some have been developed and integrated with smartphones, such systems are not capable of providing real-time updates and comprehensive pest detection across multiple classes. Additionally, they also lack a web-based platform responsible for pest data monitoring and analysis.

To address the limitations identified in existing studies, this paper aims to develop a pest detection system using a lightweight and optimized YOLO deep learning framework, integrated into mobile devices and complemented with a web-based monitoring system.

The main contributions of this paper are as outlined below:

- Employing advanced data augmentation techniques, including hue adjustment, horizontal flipping, and scaling, to significantly increase dataset diversity and enhance the model's ability to classify pests in complex agricultural conditions.
- Introducing a lightweight YOLO-based deep learning model that is optimized to detect a broader range of pest classes compared to previous studies, balancing accuracy and efficiency for real-time smartphone applications in diverse agricultural settings.
- Integrating the optimized model with smartphone technology for real time detection of multiple pest classes, making advanced pest detection tools more accessible and user-friendly.
- Creating an interactive web-based monitoring platform that offers dynamic real-time updates of pest detection and provides sustainable recommendations for effective pest management strategies.

III. Materials and Methods

A. Methodology

The proposed methodology follows a structured approach to develop an effective pest detection model for agricultural applications as shown in Fig. 1. At the beginning, the researchers collected multiple pest image datasets and merged them to form a unified dataset through several preprocessing processes such as data standardization. Data standardization is a technique to ensure that datasets are in a consistent and standardized format for configuring the YOLO format. Secondly, the researchers preprocessed the dataset by employing data augmentation techniques including hue adjustments, image translation, horizontal flipping and scaling to expand the training dataset for enhancing its variability. This step aims to prepare a dataset that can be used to train a robust detection model capable of generalizing across diverse agricultural scenarios. Following this, the images were annotated with bounding boxes to label pest instances accurately. After that, the researchers split the dataset by allocating 80% of the dataset for the model training and 20% for the model validation. Researchers then proceeded to train various YOLO object detection models with the pest training dataset. The trained models were fine-tuned to optimize their performance across different YOLO versions. Then, researchers validated and evaluated the performance of each base and fine-tuned model by using the shared validation dataset. During validation, new pest images that were not previously used for training or fine-tuning were introduced to assess the models' effectiveness with unseen data. The researchers also integrated each model into the smartphone application for measuring their real-time performance to assess its capabilities in a practical setting. By comparing the results, the optimal model was identified for practical field adaptation. This model was then deployed within a smartphone application to enable real-time pest detection in agricultural environments. Finally, a web-based monitoring system was developed to provide dynamic and real-time updates on pest detection. This allows users like farmers to monitor captured pest data and receive actionable insights for effective pest management.

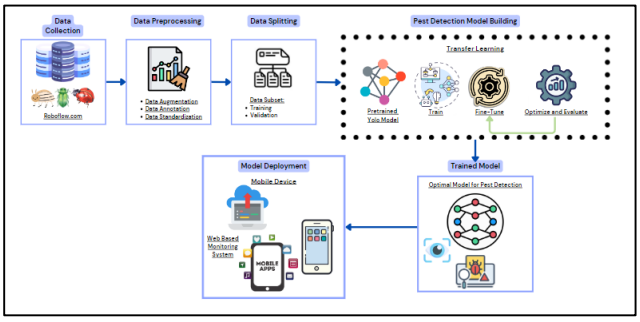

Fig. 1. Proposed methodology to develop the pest detection system.

B. Data Collection

To train and evaluate the pest detection model, the researchers utilized two publicly available datasets from Roboflow platform as a source in the experimental study: YOLOIP1 dataset and Pest_Dataset_3 [26] [27]. Since both datasets are different in terms of the structures and class distribution, the datasets were subjected to a data standardization process to ensure uniformity. Both datasets were reorganized to have consistent directory structures, file naming conventions, and annotation formats. After standardization, the researchers removed the redundant classes to avoid confusion due to the similar morphological features. For example, classes like "white margined moth" and "margined moth" which differed only slightly in color were removed. The researchers then merged the datasets manually by selecting the most relevant pest classes that are frequently encountered in agricultural scenarios for accurate detection. The final merged dataset comprised 29 pest classes. Each class contains a significant number of images as detailed in Table I. However, the merged dataset contained fewer images than the expected threshold of a total of 10k images. Therefore, data augmentation techniques were employed in the next step to expand the dataset's size.

TABLE I. FINAL CLASS DISTRIBUTION OF THE MERGED DATASET

Index	Pest Class	Total Count
0	Alfafa plant bug	99
1	Ampelophaga	126
2	Aphids	886
3	Beet spot flies	79
4	Flea beetle	414
5	Grain spreader thrips	118
6	Grub worm	522
7	Icerya-purchasi-Maskell	73
8	Limacodidae	95
9	Lycorma delicatula	111
10	Lygus	318
11	Mole cricket	888
12	Oides decempunctata	77
13	Paddy stem maggot	94
14	Peach moth	223
15	Pieries canidia	147
16	Plant hopper	856
17	Protaetia	180
18	Red spider	245
19	Rice gall midge	244
20	Rice leaf caterpillar	235
21	Rice leaf roller	233
22	Rice leafhopper	242
23	Rice shell pest	115
24	Rice stemfly	108
25	Weevil	650
26	Wireworm	464
27	Xylotrechus	68
28	Yellow rice borer	591
Total number of images		8,501

C. Data Augmentation

To improve the generalization capabilities of models, several data augmentation techniques were applied to the dataset. Firstly, the researchers adjusted the hue, saturation and value (HSV) of images to randomly alter the color intensity and brightness in a manner to mimic different environmental conditions. Secondly, the researchers shifted the images along the x and y axes through image translation. This step is to provide different angles of the same image. They also applied horizontal flipping to mirror the images for creating variations in how objects are oriented. Finally, they resized images while keeping their aspect ratios through image scaling process to ensure the model remains robust and can handle differences in object size effectively. Fig. 2 illustrates examples of the augmented images.

After completing the data augmentation process, the final dataset was prepared with sufficient images and met the expected requirements to have at least 10,000 images for training the robust model. The details of the dataset after augmentation are presented in Table II.

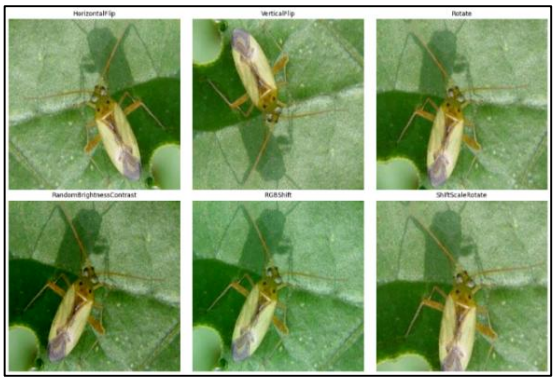

Fig. 2. Samples of augmented pest images.

TABLE II. DETAILS OF DATASET

Dataset Aspect	Number
Number of classes	29
Number of images	14,147
Number of instances (objects labeled within the images)	17,856

D. Data Annotation

After data augmentation, the researchers carefully reviewed the images to ensure that each one was annotated and assigned with a pest class ID correctly. A deep learning model such as YOLO model learn features from the labeled images [28]. Therefore, the correctness of feature labeling will greatly influence the performance of training model especially considering the similarities between many pest species. If any discrepancies were found such as incorrect class labels or annotations, the researchers made corrections to those particular images using the Roboflow platform. The annotation process involved normalizing the coordinates between 0 and 1 to accommodate varying image sizes. After this process, the annotations across the entire dataset were consistent and accurate. Each annotation was recorded in a text file containing the following details for each bounding box as shown in Eq. (1). A sample of a pest image with the correct annotation bounding box is shown in Fig. 3.

$$(id_{class}, x_{centre}, y_{centre}, width, height) \quad (1)$$

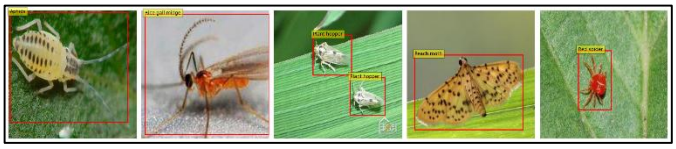

Fig. 3. Visualization of labeled images.

E. Data Splitting

Before training the YOLO model, the researchers split the dataset into training and validation sets with an 8:2 ratio. This step is to ensure that the model is trained on a diverse and representative set of images while also being evaluated on a separate validation set. The summary of final dataset aspects is shown in Table III. It is well prepared for the next stages of model training and evaluation.

TABLE III. SUMMARY OF FINAL DATASET ASPECTS

Dataset Aspect	Details
Number of classes	29
Image Size	640x640 pixels
Training Images and Label Files	10,097
Validation Images and Label Files	4,050
Total Instances in Training	12,658
Total Instances in Validation	5,198

F. Overview of YOLO Model

The YOLO algorithm, which stands for "You Only Look Once" was first introduced by Joesph Redmon et al. in 2015 [29]. It is renowned for its efficiency in object detection since it can identify objects and their positions by examining the entire image only once. As seen in Fig. 4 below, the YOLO algorithm divides the image into N grids, each of which contains an equal-sized S × S region. Each grid is responsible for detecting and locating the object within it.

Unlike the conventional methods that employ two-stage object detectors, YOLO treats object detection as a regression problem [30]. It predicts bounding boxes around the objects and their corresponding class probabilities straight from the feature maps in a single pass. This means that YOLO can recognize objects in an image faster than the two-stage detector. Therefore, the YOLO algorithm is considered as a one-stage detector that prioritizes speed and is thus ideal for real-time object detection.

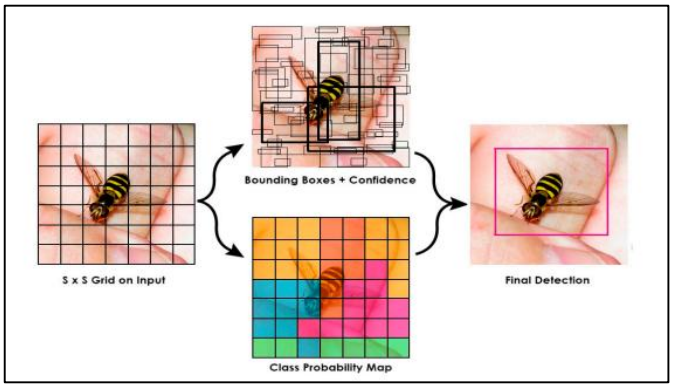

Fig. 4. Illustration of the YOLO framework for object detection [31].

1) YOLOv8: YOLOv8 is the most popular and widely used model in the whole You Only Look Once (YOLO) series. It signifies a notable development in the domain of object detection with its remarkable enhancements in both speed and accuracy through extensive architectural optimization and innovation. The architecture of YOLOv8 is depicted in Fig. 5. The YOLOv8 model considers the multi-scale attributes of objects by using three detection layers at different scales to handle objects that come in different sizes [32]. This method allows the model to efficiently manage objects of varying sizes and proportions.

In its architectural design, there are three main components including Backbone, Neck and Head [33]. The Backbone is used for extracting multi-scale features to ensure the model can perceive inputs across different scales. It includes modules such as Conv, C2f, and SPPF (Spatial Pyramid Pooling-Fast). In the Neck section, YOLOv8 combines features without enforcing standardized channel dimensions by integrating a path aggregation network and a feature pyramid network [34] [35]. This method reduces both the number of parameters and the overall tensor size. To simplify anchor box operations and prevent displacement issues, YOLOv8 adopts a decoupled head method to separate the detection and classification head [36]. The Head component is responsible for tasks such as bounding box regression, target classification and confidence assessment in the prediction layers. It ultimately delivers precise detection results through the use of non-maximum suppression.

To support diverse computational requirements, YOLOv8 is available in five versions as detailed in Table IV [37]. Each model comes with different parameter counts and resource consumption due to differences in width and depth parameters. The higher the scale of the model is, the higher the detection performance is as the parameter count and resource consumption rise. The MS COCO dataset is frequently used for benchmarking object detection models. By comparing the performance between models on the MS COCO dataset, the researchers selected YOLOv8n as their baseline model for this study because of its relatively low parameter count and resource efficiency. FLOPs (Floating Point Operations per Second) are listed in Table IV to indicate the computational complexity of each model.

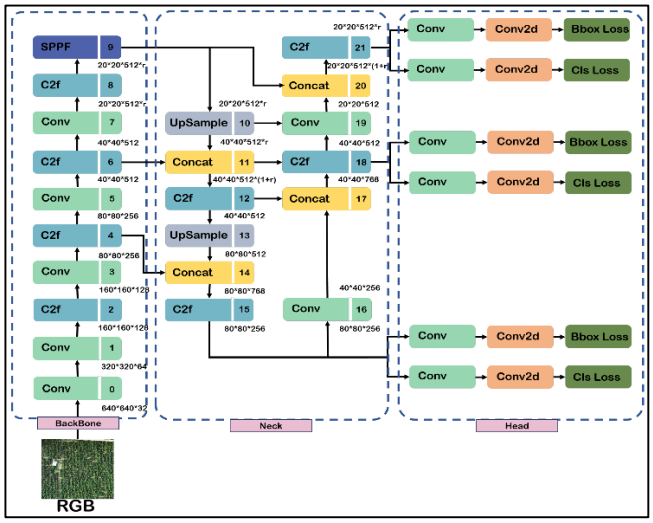

Fig. 5. Model architecture of YOLOv8 [38].

TABLE IV. YOLOv8 VARIANT COMPARISON

Model	Params (M)	FLOPs (B)
YOLOv8n	3.2	8.7
YOLOv8s	11.2	28.6
YOLOv8m	25.9	78.9
YOLOv8l	43.7	165.2
YOLOv8x	68.2	257.8

2) YOLOv9: YOLOv9 is the most recent addition to the YOLO versions in 2024. It introduces two major innovations such as the Programmable Gradient Information (PGI) and the Generalized Efficient Layer Aggregation Network (GELAN). The PGI framework tackles the challenges of information bottlenecks in deep neural networks and makes supervision mechanisms compatible with lightweight architecture [39]. By leveraging PGI, substantial accuracy improvements can be achieved in both complex and lightweight architectures. This is due to the fact that PGI mandates reliable gradient information during training, which in turn enhances the architecture's ability to learn and make predictions.

The GELAN architecture was designed with a purpose of improving the performance of objection detection tasks by lightweight and high efficiency footprint [40]. Because of its strong performance across different depth configurations and computational blocks, it is well-suited for deployment on various inference devices including devices that are resource constrained. In simple words, PGI and GELAN solved the issues related to computational efficiency and information loss. By integrating both GELAN and PGI frameworks, YOLOv9 represents a substantial advancement in lightweight object detection.

Table V presents five YOLOv9 variants along with their parameter count and FLOPs as assessed on the MS COCO Dataset [41]. YOLOv9t was chosen as another baseline model for this study due to its lowest parameter count and computational demand.

TABLE V. YOLOv9 VARIANT COMPARISON

Model	Params (M)	FLOPs (B)
YOLOv9t	2.0	7.7
YOLOv9s	7.2	26.7
YOLOv9m	20.1	76.8
YOLOv9c	25.5	102.8
YOLOv9e	58.1	192.5

3) YOLOv10: In 2024, another groundbreaking development emerged with the introduction of YOLOv10. This version further expands the boundaries of real-time object detection by resolving its inherent difficulties. It sets a new benchmark by completely eliminating non-maximum suppression (NMS) during post-processing, thereby enhancing inference speed [42]. The model introduces a novel dual-label assignment system to maintain an optimal balance between accuracy and speed. By integrating one-to-one and one-to-many label assignments, YOLOv10 benefits from rich supervisory signals during its training, ensuring computational efficiency while acquiring important detection features without any post-preprocessing NMS [43].

Furthermore, the enhancements in YOLOv10's architecture involve the implementation of spatial-channel decoupled down sampling, lightweight classification heads, and rank-guided block design [42]. Each of these additions lowers the computational requirements and the number of parameters. These enhancements enhance both the efficiency and scalability of the model over a wide range of devices from powerful servers to edge devices with limited processing power and storage capacity. The performance of both the lightweight and heavyweight versions of YOLOv10 model on the COCO dataset is compared in Table VI [44]. YOLOv10-N with the least parameters and computational resource is selected for this study as the baseline model for YOLOv10.

TABLE VI. YOLOv10 VARIANT COMPARISON

Model	Params (M)	FLOPs (G)
YOLOv10-N	2.3	6.7
YOLOv10-S	7.2	21.6
YOLOv10-M	15.4	59.1
YOLOv10-B	19.1	92.0
YOLOv10-L	24.4	120.3
YOLOv10-X	29.5	160.4

G. Evaluation Metrics

In object recognition methods, the detection result and classifier performance are the two key indices used to evaluate models [45]. Mean Average Precision (mAP) is a widely used metric for evaluating the overall performance of object detection systems [46]. The mAP score is derived by comparing the predicted bounding boxes with the ground truth boxes. Higher mAP score indicates more accurate model detections. This metric is calculated using several sub-metrics: Precision, Recall, Intersection over Union (IoU), and data from the Confusion Matrix.

To evaluate the detection result, Intersection over Union (IoU) metric is employed. IoU measures the ratio of the intersection to the union of predicted and ground truth bounding boxes [47]. It indicates how closely the predicted bounding box matches the ground truth. When the IoU value exceeds a threshold of 0.5, the detection is regarded as a True Positive (TP). Conversely, if the IoU value falls below 0.5, the detection is considered a False Positive (FP). A False Negative (FN) occurs when the model fails to detect an object that exists in the ground truth. A True Negative (TN) refers to the model correctly identifying that no object exists in a region where there is indeed no object. The concept of IoU is illustrated in Fig. 6, where the rectangles R1 and R2 serve as bounding frames for the object's ground truth and prediction.

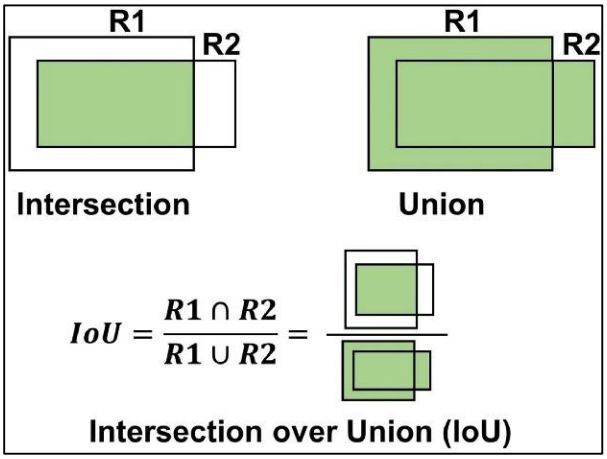

Fig. 6. Concept of Intersection over Union (IoU).

For accessing the performance of the classifier, a Confusion Matrix is used. It categorizes the model's predictions into four attributes [48]:

- True Positives (TP): The model correctly identifies and matches a label with the ground truth data.
- True Negatives (TN): The model correctly identifies that a label is absent when it is indeed not present in the ground truth data.
- False Positives (FP): The model incorrectly predicts a label that is not actually present in the ground truth data.
- False Negatives (FN): The model fails to detect a label that is present in the ground truth data.

Using the IoU value along with the Confusion Matrix outputs (TP, TN, FP, and FN), key performance metrics such as Precision, Recall, and mAP are calculated. All these metrics are used to assess the overall performance of object detection models by calculating them using Formulas (1) to (3).

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$mAP = \frac{1}{n}\sum_{k=1}^{k=n} AP_k \quad (3)$$

AP_k = the average precision of class k, and n = number of classes

IV. RESULT AND DISCUSSIONS

A. Experimental Setup and Training

In this study, the training and evaluation of the selected YOLO models like YOLOv8n, YOLOv9t and YOLOv10-N were conducted on Google Colab using Nvidia L4 GPU with 24 GB of RAM. The dataset which had already been preprocessed and split into 80:20 ration in previous phase was used to ensure consistent and high-quality input for model training. Each YOLO model was trained on the training set which consists of 10,097 pest images while their performances were evaluated on the validation set containing 4,050 images.

To ensure a fair comparison, all YOLO models were trained using the same hyperparameters. The model was created using Pytorch and runs for 150 epochs to train with a batch size of 16, learning rates of 0.001 and default dropout rates provided by the YOLO framework. Adam optimizer which is known as "Adaptive Moment Estimation" was used as the optimization algorithm. After training the model, a fine-tuning process was conducted using a grid search method to optimize each model. Grid search method tuned the model by testing out all combinations of critical parameters [49]. This fine-tuning process ran for 10 additional epochs to refine the models' performance.

During training, the YOLO models will automatically perform in-training evaluations at the end of each epoch using the validation set. The metrics reflect the ongoing learning process and may result in slightly higher performance or overfitting due to continuous weight adjustments [50]. Once training is completed, the reseachers conducted a post-training evaluation to access the model's generalization ability by using the same validation set in a static environment with fixed weights.

The experimental configuration for training and testing these models is detailed in Table VII.

TABLE VII. EXPERIMENTAL CONFIGURATION

Configuration	Params (M)
Platform	Google Colab
CPU	2.0 Intel Xeon (R) CPU @ 2.20GHz × 12
GPU	Nvidia L4 (24 GB RAM)
Accelerated Environment	Nvidia L4 CUDA 12.2
Operating System	Ubuntu 22.04.3 LTS
CUDA Version	12.2
PyTorch GPU Availability	True
PyTorch CUDA Version	12.4

B. Experimental Results

1) Training loss: Training loss is the first focus of this analysis. It encompasses multiple components including classification loss (cls_loss), distribution focal loss (dfl_loss) and bounding box loss (box_loss). Each component of the training loss tracks the degree of error in the model's outputs. It provides insights into how well the models fit the data and aids in determining the best weights [51]. As shown in Fig. 7 to Fig. 9, all training loss curves demonstrate a clear downward trend throughout the training process. This means that the proposed models excel at learning early and detecting pests during the training time. As the networks undergo further epochs, the classification loss declines slowly. The models converged after 140 epochs. This enabled researchers to conclude that 150 epochs was a good parameter for building the model.

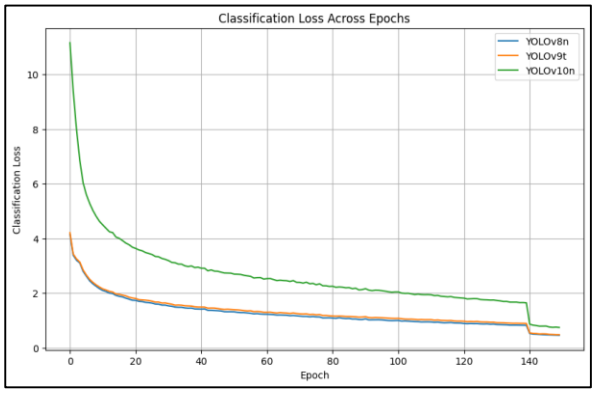

Fig. 7. Classification loss graph.

As can be seen in Fig. 7 to Fig. 9, YOLOv8n and YOLOv9t architecture have achieved similar and lower training losses when compared to the YOLOv10-N. This observation could be attributed to the increased complexity of YOLOv10-N architecture. YOLOv10-N learns more intricate patterns from the data to handle the object detection tasks. However, this statement does not imply that other models are inadequate. Further analysis is required to determine a balanced approach where the model performs well on both training data and real-world data.

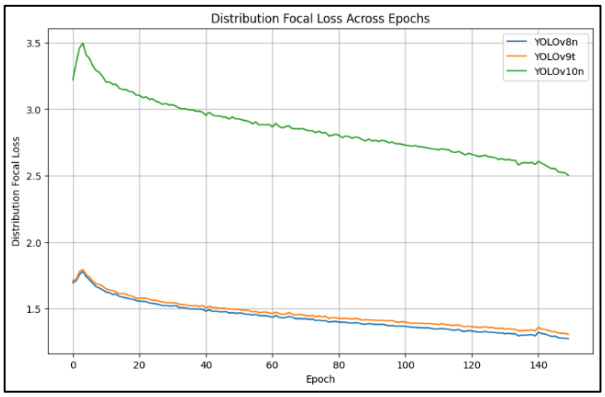

Fig. 8. Distribution focal loss graph.

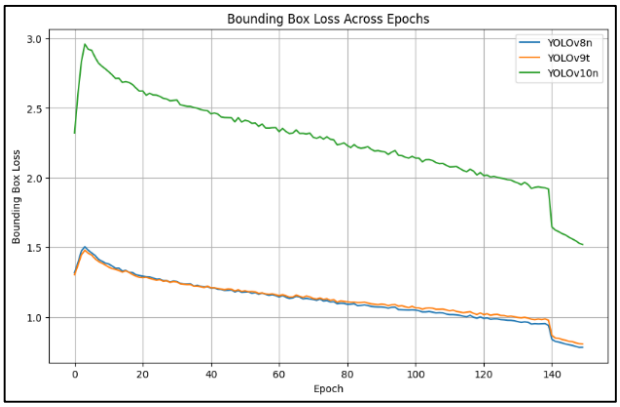

Fig. 9. Bounding box loss graph.

2) Performance evaluation: To further evaluate the models' performance, the researchers compared the baseline and fine-tuned versions of YOLOv8n, YOLOv9t, and YOLOv10-N using the statistical indicators which includes precision, recall, mAP@ 0.5 and mAP@ 0.5:0.95. The results of models are presented in Table VIII and illustrated in Fig. 10. All fine-tuned models demonstrate improvements across all the key metrics. As depicted by the graph below, the YOLOv8n model does not top in any of these metrics but shows improvement over its baseline. In fact, it has actually achieved quite good results when not compared with other versions. Moving to the YOLOv9t model, the fine-tuned version attained the highest precision of 94.2% and the best value for recall of 91.4%. This points to a high effectiveness of the YOLOv9t model in doing accurate pest identifications. Meanwhile, the fined-tuned version of YOLOv10-N model achieved the highest mAP@0.5 at 96.7% and mAP@0.5:0.95 at 77.1%. This means that the YOLOv10-N model performs exceptionally well in detecting pests across various IoU thresholds. It is particularly robust for handling complex detection tasks. From this point onward, all references to the YOLO models will pertain to their fine-tuned versions.

TABLE VIII. RESULTS OF YOLOV8N, YOLOV9T AND YOLOV10-N ON VALIDATION DATASET DURING TRAINING

Models	Precision	Recall	mAP^{val}@0.5	mAP^{val}@0.5:0.95
YOLOv8n Baseline	0.853	0.847	0.881	0.629
YOLOv9t Baseline	0.85	0.823	0.874	0.637
YOLOv10-N Baseline	0.884	0.829	0.884	0.643
YOLOv8n Fine-tuned	0.932	0.891	0.951	0.733
YOLOv9t Fine-tuned	0.942	0.914	0.962	0.751
YOLOv10-N Fine-tuned	0.94	0.93	0.967	0.771

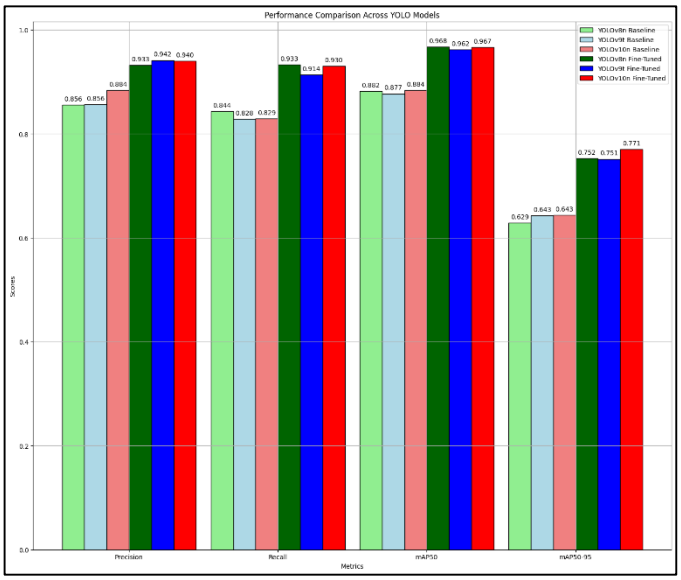

Fig. 10. Comparison of YOLOv8n, YOLOv9t, and YOLOv10-N on validation data during training.

3) *Confusion matrix analysis:* To better demonstrate the results, confusion metrices were employed to evaluate and visualize the performance of the trained YOLO models. A confusion matrix describes the actual and predicted object classification of a classification system [52]. The significance of the prediction results is indicated by the diagonal line in the central of the confusion matrix. The horizontal line shows false negatives, whereas the vertical line shows false positives. The darker the blue in the matrix, the higher the count of correct classifications. Based on the confusion matrices presented in Fig. 11 to Fig. 13, all YOLO models have done quite well with high accuracy values among their predictions.

4) Post-Training evaluation: The previous validation results were all generated automatically by YOLO itself during training. These in-training metrics tend to be higher due to the dynamic adjustments the models make during the learning process such as ongoing weights and gradient updates. Therefore, the researchers reassessed the models using the same validation set containing 4050 images in a post-training static environment where the weights and parameters of each model were fixed. The results are presented in Table IX. It reveals that the YOLOv9t model emerged as the top performer with the highest scores in Precision at 87.4%, Recall at 84.4%, mAP@0.5 at 89.8%, and mAP@0.5:0.95 at 66.7%. It was followed closely by the YOLOv10-N and YOLOv8n model. These findings indicate that although models perform excellent during training and validation, but their performance changes when they are exposed to new data. The causes for this change in performance might be due to slight overfitting during training or the complexities of the real-world image environments. Sample predictions made by each model on test data are presented in Fig. 14, Fig. 15, and Fig. 16.

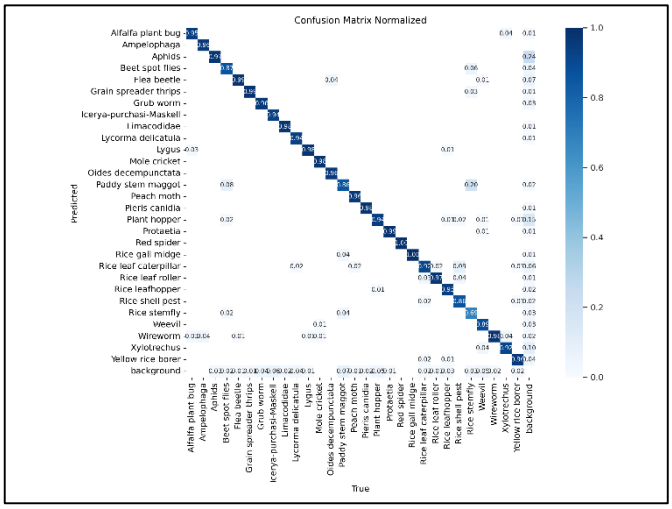

Fig. 11. Confusion matrix of YOLOv8n.

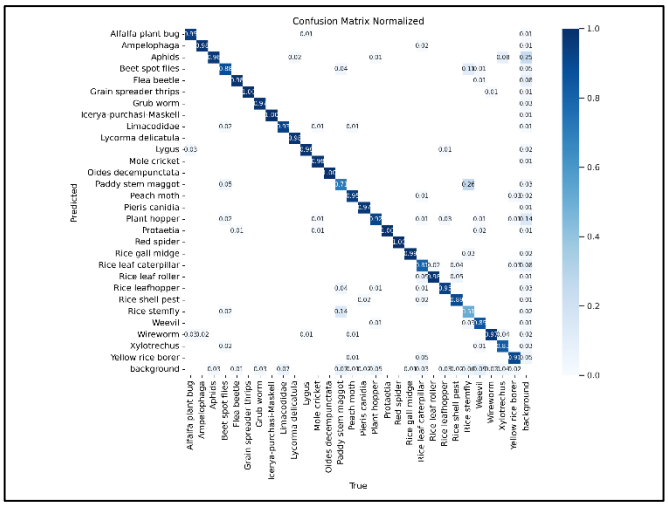

Fig. 12. Confusion matrix of YOLOv9t.

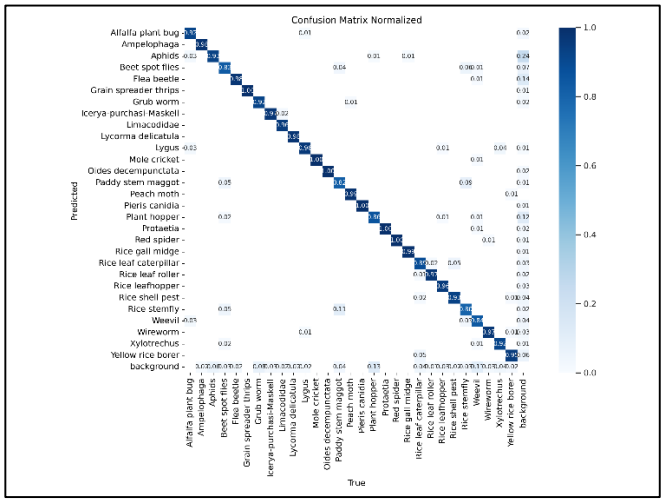

Fig. 13. Confusion matrix of YOLOv10-N.

TABLE IX. RESULTS OF YOLOV8N, YOLOV9T AND YOLOV10-N ON VALIDATION DATASET IN POST-TRAINING PHASE

Models	Precision	Recall	mAP^{val}@0.5	mAP^{val}@0.5:0.95
YOLOv8n	0.859	0.827	0.871	0.618
YOLOv9t	0.874	0.844	0.898	0.667
YOLOv10-N	0.873	0.837	0.883	0.639

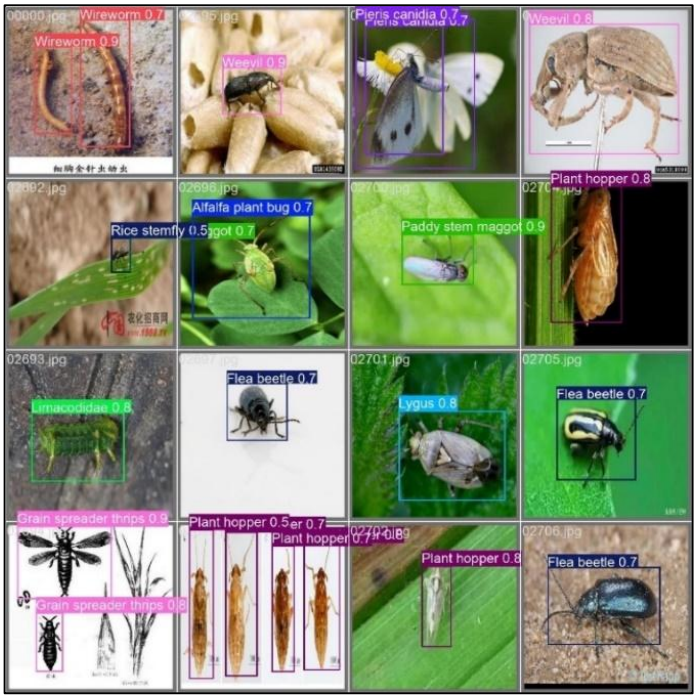

Fig. 14. Sample predictions made byYOLOv8n.

5) *Real-world application testing:* Strong performance of model during training and validation does not always guarantee equal success in real-world situations [53]. To further evaluate the YOLO models, they were converted to TensorFlow Lite format and integrated into a smartphone application. The testing was performed on a smartphone configured as detailed in Table X. This setup was used to evaluate the average inference time of each model by running them 10 times on a set of printed pest photos placed in a plant environment. The purpose of this test was to assess the models' practicality for real-time pest detection in agricultural fields.

Fig. 15. Sample predictions made byYOLOv9t.

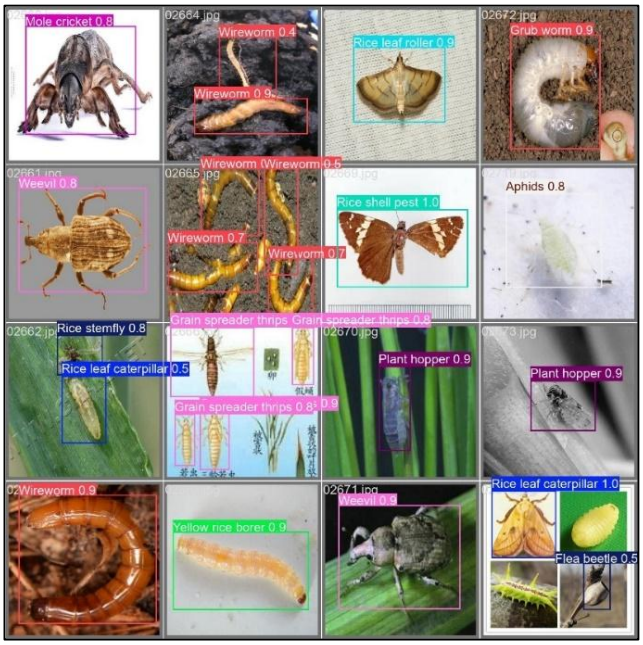

Fig. 16. Sample predictions made byYOLOv10-N.

As shown in the Table XI, lighter models like YOLOv9t recorded the fastest average inference time at 250.6ms, followed by YOLOv8n at 320.5ms and YOLOv10-N at

550.7ms. These results provide strong evidence that YOLOv9t is the optimal model to deploy on resource-constrained devices for achieving real-time detection in complex scenes.

TABLE X. ANDROID DEVICE SPECIFICATIONS

Component	Specification
Operating System	Android
Model	Xiaomi 11T Pro
RAM	16GB
Internal Memory	129GB
Chipset	Snapdragon 888 5G (5 nm)
CPU	Octa-core (1x2.84 GHz Cortex-X1 & 3x2.42 GHz Cortex-A78 & 4x1.80 GHz Cortex-A55)
GPU	Adreno 660

TABLE XI. AVERAGE INFERENCE TIME FOR EACH MODEL PERFORMED IN ANDROID APP (CALCULATED OVER 10 RUNS)

Model	Average Inference Time (ms)
YOLOv8n	320.5
YOLOv9t	250.6
YOLOv10-N	550.7

C. Discussion

A summary of the overall results can be seen in Table XII. The YOLOv9t model outperformed the other proposed models by achieving the highest values in key metrics such as accuracy and speed. Among the models tested, YOLOv9t provided the best balance between accuracy and speed. Therefore, it can accurately detect various tiny pests in real-time within challenging agricultural environments.

When compared the outcome of this study with recent studies as shown in Table XIII, it is evident that those models classified fewer object classes which ranged from 1 to 24 classes. While several studies achieved over 90% accuracy, their focus was often limited to specific object categories such as detecting leaves or identifying the presence of certain pests. Although the proposed model does not achieve the highest accuracy, it still obtains a remarkable result with 89% accuracy. It is closely comparable to the best-performing models while handling a larger and more diverse range of pest species.

The comparison also highlights the advantages of YOLOv9t over previous methods. For instance, Fuentes et al. and Lin et al. used SSD and Fast R-CNN, but these models struggled to detect a wide variety of pest classes. As a result, they achieved lower mAP scores and were less effective in diverse agricultural environments. Similarly, Sabanci et al.'s model demonstrated impressive precision. However, it was limited to binary classification for specific crops. This limitation restricted its overall versatility. Koklu et al. and Zhong et al. also made progress in tasks like leaf classification and insect recognition, but their models faced challenges due to a smaller number of pest classes and hardware limitations.

In contrast, the proposed YOLOv9t model stands out by successfully detecting 29 different pest classes with an accuracy of 89.8% and an inference time of just 250.6ms. Its lightweight architecture and scalability make it well-suited for real-time applications across a range of agricultural settings. Furthermore, the conversion of the YOLOv9t model to TensorFlow Lite (TFLite) and its integration into a mobile application significantly enhance its deployment capabilities on resource-constrained devices. The TFLite model allows for faster and more efficient inference, enabling real-time pest detection directly on smartphones. This integration ensures that pest management can be carried out in the field, improving efficiency for farmers and agricultural workers. This model's ability to overcome the limitations of earlier approaches highlights its practical advantages for pest management in real-world agricultural environment.

TABLE XII. OVERALL PERFORMANCE COMPARISON OF YOLOV8N, YOLOV9T AND YOLOV10-N USED IN THE EXPERIMENTAL STUDY

Models	Precision	Recall	mAP^{val}@0.5	mAP^{val}@0.5:0.95	Average Inference Time (ms)
YOLOv8n	0.859	0.827	0.871	0.618	320.5
YOLOv9t	0.874	0.844	0.898	0.667	250.6
YOLOv10-N	0.873	0.837	0.883	0.639	550.7

TABLE XIII. COMPARISON OF PEST DETECTION MODEL WITH PREVIOUS STUDIES

Author & Reference	Model	Pest Classes	Accuracy (%)	Key Insights
Fuentes et al. [14]	SSD, R-CNN, Faster R-CNN	9	83.06	Limited pest classes; lacks real-time performance.
Lin et al. [15]	Fast R-CNN	24	56.4	High recall but poor mAP, unsuitable for real-time dynamic environments.
Sabanci et al. [16]	AlexNet + BiLSTM	2	99.5	Extremely high precision but limited to specific crops and pests.
Koklu et al. [17]	CNN-SVM	5	97.6	Effective for leaf classification; untested for insect pest detection or broader applications.
Zhong et al. [19]	YOLO + Raspberry Pi	1	90.18	High accuracy but lacks scalability for detecting diverse pest classes.
Thanh-Nghi Doan [21]	YOLOv5-S	10; 102	70.5; 42.9	Performs well on small datasets; struggles with complex datasets due to limited scalability.

Author & Reference	Model	Pest Classes	Accuracy (%)	Key Insights
Yin Jian Jun [22]	YOLOv8	8	97.3	High accuracy but lacks scalability for detecting diverse pest classes.
Proposed YOLOv8n	YOLOv8n	29	87.1	Provides balance between computational efficiency and detection performance; lower accuracy than YOLOv9t.
Proposed YOLOv9t	YOLOv9t	29	89.8	Achieves high accuracy and scalability; balances speed and accuracy effectively.
Proposed YOLOv10-N	YOLOv10-N	29	88.3	Higher computational complexity; excels in detecting complex patterns but slower inference speed.

V. APPLICATION

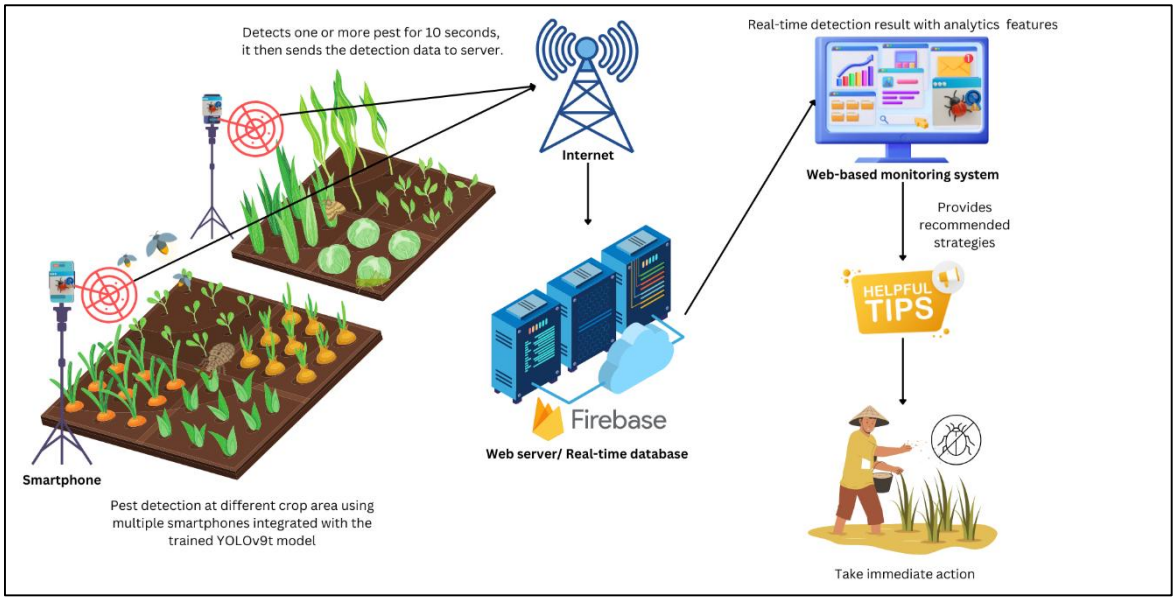

Fig. 17. Overview of the proposed lightweight mobile pest detection system with real-time monitoring.

A. Deployment

The YOLOv9t model was selected for deployment in the smartphone pest detection application due to its strong performance compared to other versions. The application detects pests in real-time but is programmed with a 10-second delay before sending the data to Firebase. This delay ensures that the pest remains on the plant and is not just passing by. Users can specify the crop area where the monitoring is taking place. Once the application detects one or more pests for 10 seconds, it sends the detection result to the Firebase server where it integrates a web-based monitoring system. This setup allows the user to track which particular area of the crop is getting infected. By providing this information, users can evaluate the situation and take immediate action if necessary. An overview of the pest detection system is shown in Fig. 17.

B. Example of Successful Pest Detection by YOLOv9t

Fig. 18 below shows the predictions made by the YOLOv9t model integrated into a smartphone application for detecting pests in real-time. It performs well in correctly identifying various pests in a simulated plant environment.

Fig. 18. Correct real-time predictions of pests using the YOLOv9t model integrated into a smartphone application in a simulated plant environment.

By using the app, users can also upload pest images for detection. They can retrieve detailed information about that uploaded pest, including a description and recommendations for managing the pest. If the pest is not detectable by the model, user can even upload the image to Firebase for experts to further refine the capabilities of model in detecting new pests in future. The web-based monitoring system complements the app by providing real-time detection logs, pest summary details, analytics dashboard, and access to detailed pest information for recommended strategies. Fig. 19 to Fig. 24 illustrate these additional features of the pest detection system.

VI. Limitations and Potential Improvements

In this study, several limitations were identified that affect the detection performance of the integrated model within the application. One notable issue is when the pests overlap or move rapidly in the real-world condition. This makes the model difficult to detect pests and differentiate between them. As shown in Fig. 25, the integrated model successfully detects the aphids but fails to identify the mole cricket underneath. This results in false negative detection. Another challenge is that the model mistakes a leaf for aphids due to their similar color and shape. This misidentification affects the accuracy of the

detection especially when the environment closely resembles the pests. These limitations underscore the need for further refinement of models to improve detection accuracy in complex environments in future study.

To address these issues, incorporating object tracking and motion filtering techniques could be beneficial. By using these methods, the model could track and identify pests even when they overlap or move rapidly. Expanding the dataset to include more diverse pest images and backgrounds could also help the model generalize better to handle a broader range of real-world conditions.

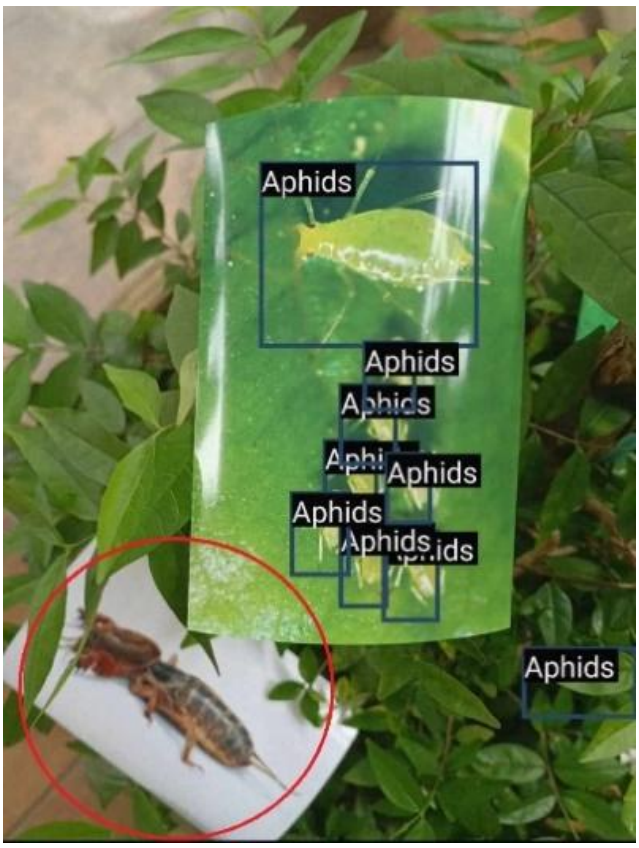

Fig. 25. The integrated YOLOv9t model detecting aphids but missing the mole cricket and misidentifying a leaf as aphids.

VII. CONCLUSION

This paper presented the development of a YOLO-based pest detection system integrated with a smartphone for real-time detection of multiple pest classes along with a dynamic web-based monitoring system for sustainable agriculture. The proposed system employs the YOLOv9t model due to its ability to strike a balance between computational resources, detection accuracy and speed. It has been shown to outperform similar systems by detecting a wider range of pests with fewer computational resources while achieving similar high detection accuracy.

The improved results can be attributed to the lightweight architecture of the proposed YOLOv9t model. It ensures faster inference times for detecting different kinds of pests on mobile devices without compromising accuracy. The numerical results show that the proposed YOLOv9t model achieved a remarkable accuracy with an mAP@0.5 of 89.8%, an mAP@0.5:0.95 of 66.7%, a Precision of 87.4%, a Recall of 84.4%, and an inference time of 250.6 ms. Also, the system enables farmers to monitor their crops by receiving instant updates through the web-based platform in real time. This combination allows for better pest management by providing detailed insights into pest activity across different fields. This approach offers notable advantages in terms of features, computational efficiency, practical implementation, and real-time detection speed.

While some detection inaccuracies might still occur when pests are overlapping or when there are similar backgrounds, shapes, and colors, future improvements will focus on addressing these challenges. The researchers plan to expand the dataset by including a wider variety of pest images taken from more diverse and complex environments. This will help the model better generalize to different real-world scenarios especially those with varying lighting conditions, backgrounds, and angles. Additionally, the researchers also plan to incorporate object tracking and motion filtering techniques to enable the model for tracking the pests more accurately even in situations where they overlap or move rapidly. These enhancements will improve the performance of the pest detection model in complex agricultural environments by ensuring higher detection accuracy and robustness in diverse pest management applications.

Improved Decision Tree, Random Forest, and XGBoost Algorithms for Predicting Client Churn in the Telecommunications Industry

Mohamed Ezzeldin Saleh, Nadia Abd-Alsabour
Cairo University, Egypt

***Abstract*—Traditional machine learning models, especially decision trees, face great challenges when applied to high-dimensional and imbalanced telecommunication datasets. The research presented in this paper aims to enhance the performance of traditional Decision Tree (DT), Decision Tree with grid search (DT+), random forest (RF), and XGBoost (XGB) models. This is accomplished by augmenting them with robust preprocessing techniques, as well as optimizing them through grid search. We then evaluated how well the enhanced models can accurately predict customer churn and compared their performance metrics in detail. We utilized a dataset derived from the benchmark Cell2Cell dataset by applying combined preprocessing methods including KNN imputation, normalization, and resampling with SMOTE Tomek to address class imbalance. The findings reveal that XGBoost outperformed all other models with an accuracy of 0.82, demonstrating strong precision, recall, and F1 scores. RF also delivered robust results, achieving an accuracy of 0.82, benefiting from its ensemble nature to improve generalization and reduce overfitting.**

***Keywords*—Churn prediction; decision trees; grid search; random forest; XGBoost**

I. INTRODUCTION

The rapid evolution of the telecommunications industry has been marked by significant technological advancements and massive competition, leading to a saturated market where customer retention has become a critical challenge. As new telecom providers emerge, often offering specialized services at competitive prices, established firms must adopt more sophisticated strategies to maintain their market share. Customer churn has emerged as a significant concern in this highly competitive environment. Retaining existing customers is more cost-effective than acquiring new ones, but it is also crucial for maintaining steady revenue streams and long-term business growth [1]-[2].

Machine Learning (ML) has transformed the telecom industry by providing advanced tools for analyzing large datasets and predicting customer behavior. ML algorithms, particularly those focused on customer churn prediction (CCP), enable telecom companies to implement proactive retention strategies by accurately identifying at-risk customers [3]-[4]. However, the high dimensionality and imbalance inherent in telecom datasets pose significant challenges to traditional ML models like Decision Trees (DT). While these models are popular due to their simplicity and interpretability, they often suffer from overfitting and biased predictions when applied to complex, high-dimensional data [5]. The need for robust preprocessing techniques, such as imputation, normalization, and resampling, is essential to address these limitations and improve the predictive performance of ML models [6]-[7].

Despite advances in ML, gaps remain in optimizing churn prediction models for real-world applications. Current methodologies often struggle with imbalanced datasets, leading to skewed predictions that fail to capture minority class churners effectively. Ensemble models such as Random Forest (RF) and XGBoost (XGB) offer improved generalization and accuracy but require careful tuning of hyperparameters to maximize their effectiveness. Moreover, the lack of standardized preprocessing pipelines and scalable solutions limits the broader adoption of these methods in the telecom industry.

This study addresses these challenges by proposing a systematic approach to enhance the performance of DT, RF, and XGB models. The research emphasizes integrating advanced preprocessing techniques such as KNN imputation, normalization, and SMOTE Tomek resampling—with hyperparameter optimization using grid search. This approach seeks to mitigate the impact of imbalanced datasets and improve the robustness of predictive models for CCP.

The key objectives of this work are to:

- Develop a DT+ model optimized through grid search to address the limitations of traditional DT models.
- Compare the outcomes of DT+, RF, and XGB models in predicting customer churn, focusing on precision, accuracy, F1-score, and recall.
- Investigate the impact of preprocessing techniques, including imputation, normalization, and resampling, on the performance of these models.

By addressing these objectives, this research aims to contribute to the development of scalable, reliable, and interpretable models for customer churn prediction, offering actionable insights for the telecommunications industry to retain customers and reduce churn rates effectively.

The literature review is depicted in the following section. Section III introduces the proposed work with enhanced algorithms and its pseudocode. Hyperparameter optimization is presented in Section IV, the performance metrics are

addressed in Section V. Results and discussion are in Section VI. Section VII gives detail about the CCP performance. The closing section addresses the real-world significance in Section VIII, with limitations, conclusion, and the future scope of research of this research in Section IX.

II. Literature Review

CCP has become an important area of concern in the telecommunications industry, prompting extensive research on the effectiveness of various ML models. Among the most studied algorithms are DT, RF, and XGB, each offers unique strengths in enhancing predictive accuracy and model stability.

The study by [8] introduced a smart hybrid scheme that combined clustering and classification algorithms. Their results demonstrated that a stacking-based ensemble model combining k-medoids, Gradient Boosted Tree (GBT), DT, RF, and Deep Learning (DL) achieved the highest accuracy of 96%, highlighting the potential of hybrid models.

The study in [9] explored the use of advanced machine learning methods, particularly focusing on RF optimized by Grid Search and a low-ratio undersampling strategy. Their findings showed that the RF-GS-LR model achieved near-perfect accuracy on the applied datasets, underscoring the importance of hyperparameter optimization and sampling techniques in improving churn prediction models.

The study in [10] provided a comprehensive analysis of integrated algorithms, including enhanced Random Forest and XGBoost models.

Studies by [11] and [12] emphasized the role of big data platforms, ensemble methods, and attribute selection in enhancing the accuracy and stability of churn prediction models. Using techniques such as SMOTE and Edited Nearest Neighbor (ENN) for data balancing and ensemble procedures like bagging and boosting has significantly improved model performance.

DT methodologies are highly regarded for their straightforwardness and interpretability. The research in [13] demonstrated that the DT models can achieve 3% higher accuracy than more complex models, such as random forests, under certain conditions. However, DT models are susceptible to overfitting and need to be enhanced through hyperparameter tuning methods such as grid search. The study in [9] illustrated how grid search optimization could significantly improve DT's accuracy and stability, especially when combined with controlled undersampling strategies.

RF is an ensemble method built on multiple DTs and is recognized for its robustness and ability to handle large datasets. The study in [14] highlighted RF's high accuracy of 95% when feature engineering techniques were applied, underscoring the importance of preprocessing steps [14]. In spite of its preferences, RF's complexity can be a restriction. However, studies have shown that when RF is regularized or combined with techniques like up-sampling and Edited Nearest Neighbor (ENN), it can achieve exceptionally high accuracies, reaching up to 99.09% [11], [15].

XGB, a gradient-boosting technique, has received widespread popularity for its outstanding usefulness in classification activities, particularly in churn prediction. Studies have revealed that XGB outperformed other ensemble algorithms, including Adaboost and CatBoost, especially when coupled with grid search cross-validation for hyperparameter tuning. XGB's capacity to handle sparse data and mitigate overfitting makes it highly effective for complex datasets [16]-[17]. The study in [18] further validated XGB's efficacy, achieving a 97% accuracy rate on the Cell2Cell dataset.

Integrating decision trees, random forests, and XGBoost algorithms alongside advanced optimization techniques like Grid search provides a comprehensive and robust approach to churn prediction. Studies by [19] emphasized the advancements in predictive power achieved through the combination of feature engineering, ensemble methods, and hyperparameter optimization, which significantly improved the accuracy, stability, and generalization across diverse telecom datasets.

Despite the advancements in CCP models, there are still several gaps that need to be addressed. Traditional decision tree models, while effective, are prone to overfitting and require optimization techniques like grid search to achieve optimal performance. Existing literature has shown improvements through these techniques, but further exploration is needed to address limitations in model interpretability and scalability [9], [13]. Random forest models, though robust, present challenges in terms of complexity and computational cost [11], [14]. The reliance on feature engineering to achieve high accuracy suggests the need for more efficient methods to handle raw data effectively. Additionally, although XGBoost shows superior performance, its susceptibility to overfitting and the need for extensive hyperparameter tuning suggest opportunities for further research on more generalized models. Furthermore, while recognized as crucial, hyperparameter optimization and sampling techniques require deeper investigation to develop standardized methodologies that can be applied to different datasets and industries [16]-[17].

III. Proposed Work

This section depicts the study details, pre-processing, and methodologies employed.

The study used the comprehensive dataset Cell2Cell, which contains client behavior attributes such as personal information, utilization patterns, client interactions, demographic details, billing data, and value-added services. These properties provide a solid foundation for developing and validating machine learning models [8], [20].

The research process, illustrated in Fig. 1, is structured into distinct phases, beginning with data preprocessing, which is crucial to ensuring the accuracy and reliability of the models. KNN Imputation (Mean/Median) addresses lost values within the dataset. This is followed by normalization utilizing MMADN Min-Max Scaling, and class imbalance is managed with SMOTE Tomek [20].

The preprocessed dataset is then split into training and testing parts in an 80-20 ratio, facilitating a robust evaluation of the models' performance. The DT and DT+ models serve as the baseline, with DT+ incorporating enhancements such as optimized hyperparameters identified through grid search techniques. RF, known for its ensemble approach, is also applied to improve the prediction accuracy and generalization further. Finally, XGBoost, renowned for its efficiency and scalability, is utilized, leveraging grid search for hyperparameter tuning.

The models were implemented on Google Colab, leveraging its computing resources for efficient processing. The analysis underscores the importance of systematic preprocessing and model enhancement in achieving high accuracy in churn prediction. By comparing the performance metrics of the DT, DT+, RF, and XGB models, this study provides empirical evidence for the effectiveness of advanced classification algorithms in CCP.

The preprocessing phase is essential to ensuring accurate predictions for customer churn models. Missing data is addressed using KNN imputation and median/Mean imputation techniques, preserving the dataset integrity and reducing bias [20]-[21]. Normalization follows, employing a combination of MMADN and Min-Max Scaling, which standardizes features while managing outliers effectively [22], [23], [24], [25]. To address the class imbalance, the SMOTE Tomek was utilized [18], [20], [25]. These preprocessing steps ensure that the data is optimally prepared for applying the DT, DT+, RF, and XGB models, leading to improved prediction accuracy and model robustness.

The proposed approach involves analyzing customer churn using the following four different algorithms:

- Traditional Decision Tree (DT)
- Decision Tree with Grid Search (DT+)
- Random Forest (RF)
- XGBoost (XGB)

A. Traditional Decision Tree (DT)

The Traditional Decision Tree model is valued for its effortlessness and intuitive interpretability. It works by recursively partitioning the dataset based on feature values, creating a tree-like structure where nodes represent decision rules and leaves denote class labels. This model excels at handling non-linear relationships, making it a popular choice for classification tasks. Nevertheless, DTs are inclined to overfit, particularly with complex or noisy data, necessitating careful tuning of parameters like max_depth, min_samples_split, and min_samples_leaf to enhance generalization.

B. Decision Tree with Grid Search (DT+)

The Decision Tree with grid search model refines the traditional Decision Tree by incorporating advanced techniques to mitigate overfitting and improve predictive accuracy. DT+ is designed to balance model complexity and interpretability, making it particularly suitable for applications where both robust performance and transparency in decision-making are crucial. By optimizing hyperparameters, DT+ effectively captures meaningful patterns from data, addressing the limitations of the traditional DT model.

DT+ leverages a few essential parameters to boost performance:

- Max_depth: Restricts the tree's depth, averting the model from getting too complicated and prone to overfitting
- Min_samples_split: Defines the minimum number of samples required to split a node, reducing the risk of creating insignificant splits.
- Criterion: The choice of Gini impurity or entropy when splitting a node directly affects the quality of the formed decision boundary.
- Pruning Techniques: These are applied post-training to remove branches that do not provide significant power in classifying the target variable, further reducing overfitting.

The implementation of DT+ begins with training an initial Decision Tree model using default parameters to establish a baseline. This model is then evaluated using accuracy metrics, a classification report, and a confusion matrix. To enhance the traditional DT model, grid search performs hyperparameter tuning to identify the best parameter settings from a predefined distribution. The tuned model is then evaluated on the test set, with pruning techniques applied to ensure that the model is not only accurate but also generalizable. This systematic approach ensures that the DT+ model outperforms the standard DT by avoiding overfitting and improving decision-making transparency.

Despite its enhancements, DT+ faces several challenges:

- Overfitting: Although it can be mitigated via pruning and parameter tuning, the risk of overfitting still exists, especially when the tree becomes too complex.
- Sensitivity to Data Variability: Like the traditional DT, DT+ can be sensitive to small changes in the dataset, which might lead to significant variations in the tree structure.
- Computational Complexity: Including advanced techniques such as hyperparameter tuning and pruning increases the computational burden, particularly with large datasets and extensive parameter grids.

The Pseudocode for the DT+ model development is:

- Initial Model Training with Default Parameters
- Hyperparameter Tuning using Grid search

- Comparison of Parameters and Accuracy
- Visualization Based on Performance Metrics

C. Random Forest (RF)

The Random Forest algorithm addresses single Decision Trees' limitations, particularly their susceptibility to overfitting. It is an ensemble learning strategy that boosts classification performance by consolidating the predictions of a number of Decision Trees, each trained on distinct portions of the data and attributes. This ensemble approach improves generalization, stability, and accuracy, making RF a powerful tool for complex classification tasks such as CCP. RF's ability to handle large datasets with high dimensionality and provide feature importance estimation further strengthens its applicability in various domains.

RF relies on several key parameters to optimize its performance:

- n_estimators: Determine the no. of decision trees in the ensemble. Increasing this number generally improves accuracy but increases computational costs.
- max_attribute: Determine the maximum no. of attributes considered for partitioning at every node, which provides randomness & diversity amongst the trees, boosting the model's robustness.
- Tree-Specific Parameters: These include parameters like max_depth, min_samples_split, and criterion, similar to those in Decision Trees but applied collectively across all trees in the ensemble.

The development of RF starts with creating an ensemble of decision trees. Every tree is trained on a bootstrap example of the data, with a random portion of attributes chosen for every partition. The last prediction is obtained by aggregating the predictions from all trees, regularly by means of majority voting. Hyperparameters such as the no. of trees (n_estimators), maximum features (max_features), and tree-specific parameters are fine-tuned to optimize the model's performance. Grid search allows for efficient hyperparameter tuning, ensuring that the model generalizes well to unseen data.

RF offers several advantages over single-decision trees. One of its main merits is enhanced generalization. By averaging the predictions of numerous trees, RF diminishes the risk of overfitting, which typically enhances execution on novel data. In addition, the strength of RF comes from the diversity amongst its constituent trees, making it less sensitive to noise & variability in the data. Another advantage is its ability to provide estimates of feature importance, which can be valuable for interpreting the model's decisions.

However, RF also has its drawbacks. The ensemble nature of RF demands significantly more computational resources than single Decision Trees, thus increasing the computational complexity. Moreover, while RF's accuracy is superior, its predictions are less interpretable due to the complexity involved in aggregating the outputs of multiple trees. Reduced comprehensibility hinders comprehension of how the model arrived at its conclusions.

D. XGBoost (XGB)

XGBoost (Extreme Gradient Boosting) is employed in CCP to leverage its superior performance in handling complex data interactions and minimizing errors through iterative refinement. Differentiated from conventional ensemble strategies, XGBoost develops trees sequentially, with each novel tree rectifying the errors caused by the past ones [10], [16]. This iterative strategy, integrated with gradient descent optimization, permits XGBoost to accomplish large accuracy & strength in classification issues. Its ability to incorporate regularization techniques makes it particularly effective in preventing overfitting [17], [19].

XGBoost's performance is susceptible to its hyperparameters, and tuning these parameters is crucial to prevent overfitting and ensure robust performance. Grid search efficiently explores a wide range of hyperparameter combinations, allowing for a thorough yet computationally feasible optimization process [16]-[17].

XGBoost's performance is highly dependent on several key parameters:

- Learning Ratio: Controls the commitment of each tree to the last model. A lower learning rate requires more boosting rounds but can lead to a better generalization.
- Greatest Depth (max_depth): Constrains the depth of each tree, adjusting model complexity with overfitting risk.
- No. of Boosting Rounds (n_estimators): Determines the no. of trees to be included successively. More trees can capture more patterns, but this may increase the risk of overfitting.

Implementing XGBoost begins with importing the necessary libraries. The data is split into training and testing parts, similar to the process used for RF. A parameter grid is set, and Grid search is utilized to seek the ideal hyperparameters efficiently. This approach ensures that the model achieves the best possible performance while avoiding overfitting. The best model identified through Grid search is then trained on the full training set and evaluated on the test set to validate its accuracy and generalization capabilities.

While XGBoost offers several advantages, including superior accuracy and the ability to handle missing data, it also presents challenges:

- Computational Complexity: XGBoost's iterative approach and need for extensive hyperparameter tuning can increase computational costs.
- Overfitting: Despite its regularization techniques, XGBoost can still overfit, particularly on small or noisy datasets, if not properly tuned.
- Interpretability: The complexity of the model can make it challenging to interpret, especially when compared to simpler models like decision trees.

The detailed Pseudocode for the XGB model development has been described below.

Input: dataset.csv, Output: Model evaluation metrics, plots

IV. Hyperparameter Optimization

Hyperparameter tuning was conducted using grid search to optimize the performance of the predictive models. This process systematically evaluated a range of hyperparameter combinations to identify the best configuration for each model. The optimal hyperparameters for the DT+, RF, and XGBoost models are summarized below.

A. Improved Decision Tree (DT+)

The DT+ model, an optimized version of the traditional Decision Tree, was tuned to improve its performance by leveraging grid search. The best-performing hyperparameter combination for DT+ included:

- class_weight: {0: 1, 1: 5}
- criterion: entropy
- max_depth: 70
- max_features: None
- min_samples_leaf: 1
- min_samples_split: 2
- splitter: random

This configuration balanced the dataset effectively, reducing overfitting and improving decision-making across deep trees.

B. Random Forest (RF)

The Random Forest model, an ensemble technique, was optimized to maximize generalization and reduce variance. The best hyperparameter combination for RF was:

- bootstrap: False
- class_weight: {0: 1, 1: 2}
- criterion: gini
- max_depth: None
- max_features: log2
- min_samples_leaf: 1
- min_samples_split: 2
- n_estimators: 120

This configuration emphasized utilizing a larger number of estimators while balancing the dataset using class_weight, enhancing the model's robustness.

C. XGBoost (XGB)

The XGBoost model demonstrated its strength in handling high-dimensional and imbalanced datasets with the following optimized hyperparameters:

- learning_rate: 0.05
- max_depth: 50
- n_estimators: 100
- subsample: 0.8

This combination provided a balance between the learning rate and the depth of the trees, enabling the model to refine predictions iteratively while avoiding overfitting.

D. Impact of Hyperparameter Optimization

The tuning process significantly contributed to the improved performance of the models, as demonstrated in the results:

- DT+: Showed notable consistency in metrics, particularly recall, due to balanced class weights and randomized splitting criteria.
- RF: Achieved strong generalization with an accuracy of 0.82 and a ROC-AUC of 0.87, leveraging its optimal tree-based ensemble design.
- XGB: Delivered the best overall performance with an ROC-AUC of 0.88, benefiting from gradient boosting and iterative error correction.

These hyperparameter combinations underscore the importance of systematic optimization in achieving reliable and accurate predictions for CCP.

V. Performance Metrics

To evaluate the predictive accuracy of our models in churn prediction, we utilize key metrics from the confusion matrix, which categorizes predictions into four essential types: true positives, true negatives, wrong positives, and wrong negatives. These metrics are critical for assessing the effectiveness of our classification algorithms [22], [23], [24], [25].

- F-measure: Balances precision and recall by calculating their harmonic mean, offering a single metric to evaluate overall model performance.
- Precision: Valuates the accuracy of figuring out the extent of true positives with regard to all discovered churners.
- Recall: Measures the model's ability to correctly identify actual churners by calculating the proportion of true positives out of all actual churners.
- Accuracy: Reflects the overall correctness of the model by measuring the ratio of correct predictions to total predictions.

VI. Results and Discussion

This section compares the DT, DT+, RF, and XGB models to assess their effectiveness in predicting customer churn in the telecommunications industry. The performance of each model is evaluated based on accuracy, precision, recall, F1-score, and ROC-AUC to provide a clear understanding of their relative strengths.

The effectiveness of the classification models was assessed using the prepared Cell2Cell dataset. Preprocessing steps included imputation, normalization, and resampling techniques, ensuring the dataset was adequately prepared for model evaluation. As shown in Table I, ensemble methods (RF and XGB) significantly outperformed single-tree models (DT and DT+).

TABLE I. The Performance of Utilized Models

Models	Accuracy	Precision	Recall	F1-Score	ROC
DT	0.77	0.78	0.77	0.77	0.74
DT+	0.77	0.77	0.77	0.77	0.73
RF	0.82	0.83	0.82	0.81	0.87
XGB	0.82	0.82	0.82	0.81	0.88

- DT Model: The DT model reported moderate performance with an accuracy of 0.77, precision of 0.78, recall and F1-score of 0.77, and ROC-AUC of 0.74. These metrics highlight the baseline capability of a traditional decision tree structure.
- DT+ Model: With grid search hyperparameter optimization, the DT+ model achieved similar results, with accuracy, precision, and recall, an F1-score of 0.77 each, and a ROC-AUC of 0.73. The enhancements ensured consistent performance but did not significantly outperform the traditional DT.
- RF Model: The RF model demonstrated substantial improvement across all metrics. It achieved an accuracy of 0.82, precision of 0.83, recall of 0.82, and F1-score of 0.81. Its ensemble approach effectively leveraged imputed data and the SMOTE Tomek resampling method, resulting in a high ROC-AUC value of 0.87.
- XGBoost Model: XGBoost delivered the highest overall performance, achieving an accuracy of 0.82, precision, recall, and F1-score of 0.82 each, and a ROC-AUC of 0.88. The advanced optimization of gradient boosting and integration of regularization features contributed significantly to this outcome.

Fig. 2 to 7 provide classification reports and confusion matrices for the DT+, RF, and XGBoost models, illustrating their predictive performance.

The results highlight the advantages of ensemble methods like RF and XGBoost over single-tree models in churn prediction. The XGBoost model's superior performance can be attributed to its gradient-boosting framework, which iteratively refines predictions, effectively capturing complex patterns in the data. This aligns with findings from prior studies that emphasize the efficacy of gradient-boosting techniques for high-dimensional datasets. The RF model's robust results further underscore the value of ensemble techniques in enhancing generalization and reducing overfitting. The use of SMOTE Tomek in preprocessing was critical in addressing the class imbalance, as evident in the improved recall and precision scores for both RF and XGBoost. However, the limited impact of this technique on DT and DT+ indicates that more sophisticated models are better equipped to exploit balanced datasets.

While the DT and DT+ models offered a balanced trade-off between recall and precision, their performance was constrained by inherent algorithmic limitations, such as susceptibility to overfitting. Grid search optimization for DT+ improved consistency but did not elevate its metrics significantly above those of the traditional DT model. The imputation and normalization steps proved vital, as they contributed to the balanced recall values across all models, ensuring accurate identification of churners. However, the reliance on advanced optimization techniques, such as those employed in XGBoost, demonstrates the need for robust preprocessing and model design to maximize predictive accuracy. Future work could explore alternative preprocessing strategies or combine these methods with deep learning models to achieve further improvements.

VII. CCP Performance Comparison with Existing CCP Methods Using The CELL2CELL Dataset

The Cell2Cell dataset has been extensively used in the telecommunications sector to develop and evaluate customer churn prediction (CCP) models. Various studies have explored various approaches, from traditional machine learning techniques to advanced deep learning frameworks, achieving diverse outcomes based on the methodologies and preprocessing techniques employed. The study in [26] applied a Deep-BP-ANN model combined with Lasso Regression and Variance Thresholding, achieving an accuracy of 79.38%. Their results outperformed traditional XGBoost and Logistic Regression models, demonstrating the potential of deep learning for churn prediction in imbalanced datasets. The study in [8] developed a hybrid ensemble approach combining clustering and classification algorithms, including k-medoids, Gradient-Boosted Trees (GBT), Decision Trees (DT), and Deep Learning (DL). This method achieved an accuracy of 93.6%, highlighting the effectiveness of integrating clustering techniques to manage class imbalance. The study in [19] explored decision forest models enhanced with weighted soft voting. Their approach achieved an accuracy of 96.57%, showcasing the advantages of ensemble methods in improving prediction accuracy and robustness by effectively identifying churn patterns.

Table II summarizes the performance metrics reported in these studies, providing a benchmark for assessing the efficacy of different CCP methodologies.

TABLE II. Performance Metrics Comparison from Existing Studies

Method	Accuracy	Precision	Recall	F1-Score	AUC
Deep-BP-ANN [26]	79.38	74.50	89.32	81.24	79.38
Hybrid.Ensemble [8]	93.6	79.10	67.45	72.81	93.6
Decision Forest [19]	96.57	96.57	85.45	83.72	96.57

Our study, which uses the Cell2Cell dataset with advanced preprocessing techniques, aligns with findings from these prior works while offering unique contributions. Preprocessing steps like KNN imputation, normalization, and SMOTE Tomek resampling effectively addressed class imbalance, enhancing model performance. Ensemble models such as RF and XGBoost achieved high accuracy (0.82), as highlighted in Table I, which compares the metrics of the models used in this study and key observations are as follows:

- Performance Context: Our study's ensemble approaches (RF and XGBoost) achieved competitive accuracy scores compared to more straightforward machine learning frameworks like DT and DT+. While slightly below the performance of Decision Forest reported by [19], the balance between interpretability and accuracy makes these models practical for real-world use.

- Preprocessing Impact: SMOTE Tomek and normalization proved essential in balancing class distribution, improving recall and precision across models. This approach parallels the findings of Liu et al. [8], who leveraged clustering techniques for similar benefits.
- Scalability and Practicality: Unlike computationally intensive deep learning models, XGBoost and RF offer a cost-effective solution for telecom companies. Their high accuracy and efficient preprocessing make them suitable for deployment in dynamic environments where real-time churn prediction is critical.

VIII. Real World Significance

The findings of this study have critical implications for addressing real-world challenges in the telecommunications industry, where customer churn remains a significant concern. By leveraging predictive models like XGBoost, telecom companies can transition from reactive to proactive churn management strategies, leading to tangible business benefits.

Customer churn directly impacts revenue and operational efficiency in saturated markets where acquiring new customers is significantly costlier than retaining existing ones. The predictive models evaluated in this study, particularly XGBoost and RF, provide robust tools for identifying high-risk customers. These insights empower telecom companies to design targeted retention strategies, such as personalized offers, improved customer service, or loyalty programs, mitigating churn effectively.

The predictive algorithms demonstrated in this study can be seamlessly integrated into Customer Relationship Management (CRM) systems. For instance, by embedding XGBoost into customer analytics platforms, companies can automate churn predictions and deliver actionable insights in real-time. The models' ability to handle high-dimensional data and imbalanced classes also ensures scalability, making them suitable for large, complex telecom datasets.

Proactive churn management driven by these models could result in measurable outcomes, including:

- Cost Savings: Reducing churn by even a small percentage can save millions in customer acquisition costs.
- Revenue Enhancement: Retaining high-value customers boosts recurring revenue and long-term profitability.
- Operational Efficiency: Automating churn prediction reduces manual analysis, freeing resources for strategic initiatives.

The study also addresses broader industry challenges, such as fostering customer loyalty in a competitive landscape. Predictive models not only assist in retaining existing customers but also enhance customer experience by anticipating needs and preferences. These advancements align with the strategic goals of telecom firms to sustain growth and remain competitive. The practical relevance of this research extends beyond theoretical improvements, offering telecom companies a pathway to adopt data-driven strategies for churn management. By implementing these models, businesses can achieve financial benefits and strengthen customer relationships, driving sustainable growth in a dynamic market environment.

IX. Conclusion and Future Work

This study comprehensively analyzed customer churn prediction (CCP) using a Decision Tree (DT). The Decision Tree improved with grid search (DT+), Random Forest (RF), and XGBoost (XGB) algorithms applied to the preprocessed Cell2Cell dataset. Among these models, XGBoost emerged as the most effective, achieving strong precision, recall, and F1 scores with an accuracy of 0.82. Its advanced optimization techniques, such as gradient boosting and error correction, maximized the benefits of preprocessing methods, demonstrating its superiority in handling complex and high-dimensional datasets. The RF model also delivered robust performance, achieving an accuracy of 0.82 while effectively balancing precision and recall. Its ensemble nature successfully mitigated overfitting and enhanced generalization. In contrast, the DT+ model, despite its improvements through grid search, faced limitations in reaching comparable performance, underscoring the inherent constraints of decision tree-based models.

This research contributes to the field by integrating robust preprocessing techniques, such as KNN imputation, normalization, and SMOTE Tomek resampling, with grid search optimization. These methodologies collectively address critical challenges posed by imbalanced and high-dimensional telecom datasets, providing a scalable and systematic framework for CCP. By evaluating the comparative performance of DT, RF, and XGBoost models, the study underscores the value of ensemble methods and advanced hyperparameter tuning in achieving accurate and reliable predictions. Furthermore, the findings validate the significance of preprocessing as a cornerstone for effective churn prediction, offering insights into how these techniques enhance model robustness.

While this study provides valuable insights, certain limitations should be acknowledged. The analysis is constrained to the Cell2Cell dataset, which, while comprehensive, may not fully represent the diversity of customer behaviors in other industries or regions. Additionally, the models used in this study rely heavily on preprocessing and hyperparameter tuning, which may increase computational costs for large-scale datasets. Although effective, the interpretability of ensemble methods like XGBoost can be challenging, potentially limiting their application in contexts requiring high transparency.

Future research could explore incorporating deep learning models like neural networks that integrate different classifiers for enhanced predictive power. Investigating advanced feature engineering techniques, such as automated feature selection and interaction effects, could further improve model performance. Additionally, extending this research to other industries, such as finance or retail, with diverse customer behaviors would help validate the generalizability of the proposed methods. Exploring real-time churn prediction systems and using external data sources, such as social media

or customer feedback, could also offer new avenues for development.

The study's findings hold significant practical implications for the telecommunications industry. By providing actionable insights into the design and optimization of predictive models, this research supports proactive customer retention strategies, enabling telecom companies to reduce churn rates and enhance profitability. Moreover, the methodologies presented in this work contribute to advancing the knowledge base in CCP, offering scalable and interpretable solutions for addressing the challenges of imbalanced and high-dimensional datasets.

***Abstract*—The rapid development of cloud computing demands an effective cybersecurity framework for protecting the sensitive information of the infrastructure. Currently, many organizations depend on cloud services for their operation, increasing the risk of cybersecurity. Hence, an intelligent risk assessment mechanism is significant for detecting and mitigating the cybersecurity threats associated with cloud environments. Although various risk assessment methods were developed in the past, they lack the efficiency to handle the dynamic and evolving nature of threats. In this study, we proposed an innovative framework for cybersecurity risk assessment in cloud customers and service providers. Initially, the historical cloud customer and service provider database was collected and fed into the system. The collected dataset contains historical security risks, network traffic, system behavior, etc., and the accumulated dataset was pre-processed to improve the quality of the dataset. The data pre-processing steps not only ensure quality but also transform the dataset into appropriate format for subsequent analysis. Further, a risk assessment module was created using the combination of deep recurrent neural network with krill herd optimization (DRNN-KHO) algorithm. In this module, the DRNN was trained using the pre-processed database to learn the pattern and interconnection between normal and abnormal network traffic. Subsequently, the KHO refines the DRNN parameters in its training phase, increasing the efficiency of risk assessment. This integrated module ensures adaptability to the system, leading to accurate prediction of evolving security threats. Then, a secure data exchange protocol was created for secure transmission between cloud customer and service provider. This protocol is designed by integrating artificial bee colony optimization with the elliptic curve cryptography (ABC-ECC). Thus, this collaborative framework ensures security in the cloud customer and service providers.**

Keywords*—Deep recurrent neural network; krill herd optimization; artificial bee colony optimization; elliptic curve cryptography

I. Introduction

In recent years, the significance of cloud computing (CC) has been rising, and it has received a growing interest in both business and scientific organizations [1]. The report from the National Institute of Standards and Technology (NIST) stated that the CC model offers configurable resources such as storage, networks, servers, applications, etc., in the most convenient and on-demand manner [2]. The CC delivers these resources with various kinds of service provider interaction by following a simple Pay-As-You-Go (PAYG) model. In the PAYG model, the cloud service consumers (CSC) demand the computing services for their business demands [3]. Consequently, the cloud service provider (CSP) delivers the demanded computing services to the CSC. In the CC model, the CSC has to pay only for the services they have utilized, reducing the cost and making the process more convenient [4]. In addition to this, the CC model has several advantages such as greater scalability, high availability, enhanced flexibility, well-documented, excellent reliability, etc., [5]. These advantages bring more benefits to the business organizations. In accordance with the report by Forbes, the CC has imposed a greater growth, and the CC market reached $411 Billion in 2020 [6]. Furthermore, the survey made by the LogicMonitor in 2020 illustrated that the cloud services landscape has gained 83% interest of the enterprises [7].

Although the CC brings more benefits to the organizations, it offers several issues. One among the issues is the cybersecurity threats, which degrades confidence and feasibility of the CC model [8]. From the perspective of CSC, the primary reason for confidence issues on CC is because of its multitenancy nature, sensitive data transformation, critical infrastructure and applications [9]. On the other hand, security is the primary issue from the perspective of CSP, which is mainly because of the cloud model's complexity. This complexity arises from the management of diverse security controls and measures [10]. Also, the security threats arise while transferring the data in the CC. These security threats induce distrust and fears in the business organizations, making them to redefine their decisions in adapting the CC model [11]. Despite how strongly the CC is secured, the business units suffer from trust issues on cloud models and remain uncertain about its economic feasibility [12].

While it's unrealistic to guarantee a zero-risk service, implementing an efficient security risk management algorithm can significantly enhance organizations' confidence in the CC model [13]. This risk management technique empowers organizations to make informed decisions about adopting this emerging technology [14]. The conventional risk management algorithms do not fit into the CC model because of the inherent assumptions made by them [15]. In recent decades, artificial intelligence (AI) techniques are widely used in different research fields because of its capacity to decide like humans [16]. The AI evolution paved a way for handling the security risks in the CC model. The utilization of AI techniques such as deep learning (DL) and machine learning (ML) techniques

provides an effective way of identifying the potential security risks in CC [17]. Although they offer better security compared to the conventional models, they face certain challenges like overfitting, large computational time, huge computational resource demand, lack of scalability, less adaptability, lower reliability, etc., [18]. Moreover, they cannot provide security to the sensitive data during transmission in the CC model [19]. This demands an optimal and reliable security risk management algorithm, which must potentially identify the cybersecurity risks, and provide greater protection to data in the cloud model [20]. By evaluating risks across different dimensions such as data sensitivity, regulatory compliance, access controls, and service-level agreements (SLAs), the framework enables both customers and providers to identify weak points and implement appropriate mitigation strategies. To resolve the above issues, we proposed a collaborative security risk assessment framework combining deep learning, meta-heuristic optimizations, and cryptographic algorithms. The main contributions of the work are described as follows.

- This study proposes a collaborative security risk assessment framework by integrating the efficiencies of deep learning, meta-heuristic optimizations, and cryptographic algorithms for effectively identifying the cybersecurity threats and securely transmitting the data in the cloud model.
- The developed framework creates a cybersecurity threat detection module named DRNN-KHO by integrating Krill Herd optimization and Deep Recurrent Neural Network, which is trained using the cloud security database to identify the normal and malicious activities in the cloud model.
- The study also developed a hybrid ABC-ECC model, which is designed by incorporating artificial bee colony optimization into the elliptic curve cryptographic algorithm for securely transmitting the sensitive data in the cloud model.
- The presented collaborative mechanism was implemented in the Python language, and the results are assessed and validated using metrics like attack detection accuracy, data confidential rate, computational time, encryption time, decryption time, etc.

The enduring sections of the article are organized as follows: Section II illustrates the literature survey, Section III depicts the system model and problem statement, Section IV explains the proposed algorithm, Section V analyzes the study results, and Section VI provides the study conclusion.

II. Related Works

A. Few Recent Studies Related to the Developed Framework are Described Below:

Lav Gupta et al. [21] presented a deep hierarchical stacked neural system for precise prediction of anomaly activities in the cloud environment. This study aims to resolve the security problems associated with the healthcare applications, as the malicious agents threaten the patient's life and health by changing their medical data flow into the healthcare networks. The experimental results depict that this DL model minimized the training time by 26.2%, and achieved better convergence. Moreover, this algorithm predicts the malicious agents with an average accuracy ranging from 93% to 95%. However, this framework offers limited generalization and is vulnerable to adversarial attacks.

Reem Al Saleh et al. [22] proposed a reputation-based trust evaluation algorithm by integrating Net Brand Reputation (NBR) with the deep learning approach for the cloud market. The DL algorithm used in this approach is CBiLSTM, which is the combination of Convolutional Neural Networks (CNN), and Bidirectional Long Short-Term Memory (BiLSTM). The implementation outcomes manifest that this algorithm obtained performances of 96.7% accuracy, 97% f-measure, 96.5% recall and 97.4% recall. In addition to this, this model consumed a minimum training time of 519ms. Although this approach offered improved performances, it is less scalable and interpretable.

R. Denis and P. Madhubala [23] developed a hybrid encryption algorithm for ensuring confidentiality in the cloud computing environment. This hybrid strategy combines Advanced Encryption Standard (AES) and Rivest-Shamir-Adleman for secure data transmission. Also, an adaptive genetic algorithm was applied in the proposed work to ensure adaptability to the changing CC environment. This adaptiveness enables the system to respond to the emerging threats in the CC model. Finally, the simulation outcomes validate that this framework obtained data confidential rate of 0.95, and minimum running time of 5.4s. However, it faces complexity in managing keys, resulting in increased computational overhead.

Fursan Thabit et al. [24] developed an innovative lightweight cryptographic algorithm for improving the data security in the CC model. This approach is designed based on feistal and substitution permutation architectural approaches to enhance the encryption complexity. In addition, this approach obtained Shannon's theory of diffusion and confusion by including logical functions like XOR, shifting, XNOR, and swapping. The experimental outcomes suggest that this algorithm achieved a strong security level and less execution time compared to the existing cryptographic techniques. However, it is less adaptable for emerging threats.

P. Chinnasamy et al. [25] developed an efficient data security algorithm using hybrid cryptographic techniques for the CC model. This hybrid algorithm combines Elliptic curve cryptography (ECC) and Blowfish to provide a high level of data transfer and storage security. The main objective of this algorithm is to address the security challenges like confidentiality, availability, and integrity. This work was validated in the medical cloud environment, and the experimental data depicts that it achieved higher security and confidentiality than the symmetric and asymmetric algorithms.

Shaopeng Guan et al. [26] designed a distinct framework named Hadoop-assisted big data storage scheme for the CC environment. The primary concern of this work is to resolve the issues associated with the single encryption algorithm like low encryption efficiency, and unreliable data storage. The study utilizes the ECC encryption to encrypt the original data, which

ensures protection against security threats during transmission. Then, a homomorphic encryption was employed to ensure data integrity in the system. The experimental outcomes manifest that this algorithm improves the storage efficiency by 27.6%. Moreover, it offers greater protection to the sensitive information against cyberthreats. However, this framework cannot handle large volumes of data. Table I presents the literature survey.

TABLE I. LITERATURE SURVEY

Authors	Technique	Results	Merits	Demerits
Lav Gupta et al. [21]	Deep hierarchical stacked neural system	Reduced training time by 26.2%, obtained an average accuracy between 93% to 95%	High convergence, less training time, and greater detection accuracy	Limited generalization and vulnerable to adversarial attacks
Reem Al Saleh et al. [22]	NBR with CBiLSTM	Accuracy-96.7%, f-measure-97%, recall-96.5%, and recall-97.4%	High malicious data detection performances, and minimum training time	Less scalable and interpretable
R. Denis and P. Madhubala [23]	Hybrid encryption scheme (AES-RSA)	Data confidential rate-0.95. running time-5.4s	Provides greater protection to data during transmission	Key management complexity, and increased computational overhead
Fursan Thabit et al. [24]	Lightweight cryptographic algorithm	Execution time-6.4s	Strong security level and less execution time	Less adaptable for emerging threats
P. Chinnasamy et al. [25]	Hybrid cryptographic algorithm combining ECC and Blowfish	Data confidentiality-96%, security level-97%	Higher security and confidentiality	Highly complex, and resource intensive
Shaopeng Guan et al. [26]	Hadoop-assisted big data storage scheme	Improves cloud storage efficiency by 27.6%	Protects the sensitive data from cyberthreats	Cannot handle large volumes of data

III. SYSTEM MODEL WITH PROBLEM STATEMENT

Cloud computing is the process of delivering computing services such as databases, storage, servers, networking, analytics, software, and intelligence over the internet for offering flexibility and reliability, and fostering faster innovation. Although the CC model offers various benefits to the business institutions, it is prone to security challenges. This demands an effective security risk assessment framework to ensure confidentiality, integrity, and availability of the CC model [27]. A system security risk assessment model includes data collection module, preprocessing component, and risk assessment module (quantitative, statistical, DL or ML models). Fig. 1 presents the system model. The data acquisition component contains various data like network traffic, logs, system behavior, historical security risks, etc. In the preprocessing component, the collected database undergoes preprocessing steps to improve its quality for subsequent analysis. After preprocessing, a risk assessment module was created using either DL or ML models. These models are trained using the database to differentiate the patterns between the normal and malicious behavior. After the training process, it is validated for unseen data or real-time scenarios for risk evaluation.

Although these risk assessment models provide automatic prediction of malicious behavior, they often rely on threshold settings to differentiate normal and anomalies behavior. This may lead to incorrect predictions. Moreover, the conventional models require more computational resources for intensive training, making the system costly and complex. Also, they face challenges in providing scalability to handle large-scale cloud environments. In addition to this, the traditional security risk analysis algorithms can adapt to the emerging and evolving cyber threats, making it less reliable and effective for real-world scenarios. Moreover, only few studies concentrated on implementing the security measures on the CC model to ensure protection to the sensitive data during transmission and storage. To address the issues with the conventional security risk assessment techniques, and to bridge the research gap, we developed a collaborative framework, which uses deep learning and meta-heuristic optimization algorithms to precisely identify the security threats, and implements an optimized cryptographic algorithm for secure transmission of information in the cloud.

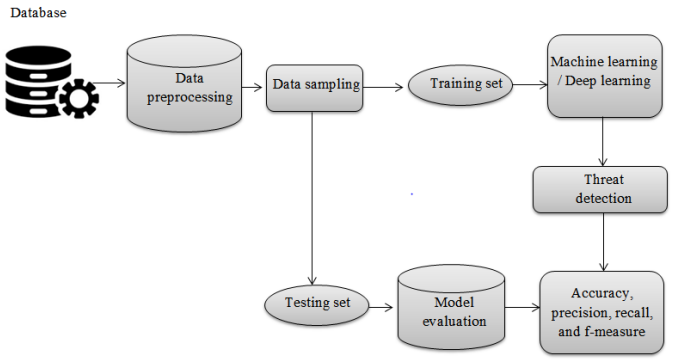

Fig. 1. System model.

IV. PROPOSED FRAMEWORK FOR SECURITY RISK ASSESSMENT

A novel collaborative security framework was proposed in this article by combining the benefits of deep learning, meta-heuristic optimizations, and cryptographic algorithms. The novelty of the study lies in the seamless and effective integration of these algorithms for ensuring security to the CC

model. The primary objective of the model is to identify the security threats/risks associated with the CC model, and to ensure secure data communication in the cloud. Firstly, a database containing network traffic, historical security risks, etc., was collected and imported into the system. Secondly, the accumulated database was preprocessed to handle the missing values, outliers, errors, etc. This process enhances the quality of the database, and makes it suitable for subsequent analysis. Then, an attack prediction module was created by integrating deep recurrent neural network and krill herd optimization.

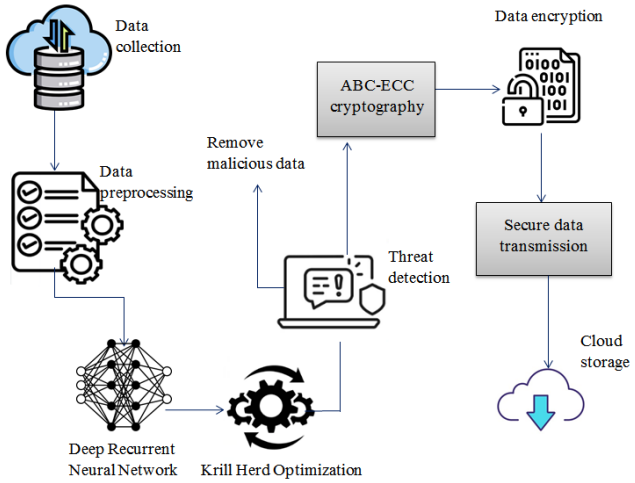

Fig. 2. Architecture of the proposed framework.

In this module, the DRNN was trained using the collected database to distinguish the patterns between the normal and malicious behavior, consequently we applied krill herd optimization for hyperparameter tuning and optimization. This combination enables the system to continuously learn the patterns and correlations between the normal and malicious traffic, ensuring adaptability to the emerging threats. After threat detection, the detected threats are eliminated from the system to offer a higher security level. Further, an optimized cryptographic algorithm was proposed to ensure security against the cyberthreats during the transmission process. The developed algorithm incorporates the efficiency of ABC into the ECC algorithm for optimally selecting the parameters for key generation, and distribution. This algorithm encrypts the data before transmission, making it unreadable for third parties. After encryption, the encrypted data is transferred to the cloud for storage, where the decryption step can be performed by the authenticated authorities and decode the data. Fig. 2 presents the architecture of the proposed strategy.

A. Data Collection

The proposed study commences with the collection of dataset relevant to cloud computing. The collected database may contain information like network traffic, logs, system characteristics, historical security risks, etc. The presented study utilized the publicly available security database named "DDoS SDN", and it is accessible at https://www.kaggle.com/datasets/aikenkazin/ddos-sdn-dataset. This database contains 104,345 instances and 23 features, and it is developed for categorizing network traffic as either traffic or malicious within a cloud environment. The dataset is structured with a target variable named "label," containing binary values (0 or 1). Here 1 indicates malicious, and 0 defines benign. Out of the 23 features, 3 are categorical features, and 20 are numerical features, providing a wide range of information relevant to network traffic investigation. The size of the dataset is 12.56MB and it is available in csv format.

B. Preprocessing

Data preprocessing is an important step, which plays a significant role in improving the quality of the dataset. It includes steps like cleaning, transforming, scaling, etc., to make the database ready and reliable for further analysis. In the proposed work, we applied steps like handling missing values, feature scaling, and handling class imbalance to the raw database for making it effective for subsequent processes. Handling missing values indicates the process of detecting the null values in the database and replacing them with values determined using an imputation algorithm. In imputation, the missing value was replaced with the mean of the non-missing values of the dataset. The imputation process is mathematically represented in Eq. (1).

$$M_n = \frac{\sum_{i=1}^{m} D_i}{m} \tag{1}$$

Where M_n indicates the mean, m indicates the number of samples, and D indicates non-missing value. Then, feature scaling was performed to ensure that all the features in the dataset contribute equally to the analysis. This step prevents the dominance of a single feature in threat detection. Here, we applied a min-max scaling algorithm to rescale all features to a fixed range (0 and 1), and it is expressed in Eq. (2).

$$S_D = \frac{D - D_{mn}}{D_{mx} - D_{mn}} \tag{2}$$

Where S_D indicates the scaled value of the feature, D_{mn} denotes the maximum value of the feature, and D_{mx} represents the minimum value of the feature. Then, the database was checked for class imbalance. If there is imbalance in the class, then oversampling was done to address that. Finally, the database was split into training and testing to evaluate the performance of the proposed threat detection algorithm. The introduction of these steps not only enhances the dataset quality but also increases the speed of subsequent analysis, leading to enhanced and timely assessment of cybersecurity threats. This preprocessed dataset was fed into the DRNN-KHO for cybersecurity risk assessment.

C. DRNN-KHO for Threat Detection

Threat detection defines the process of classifying the normal and malicious network traffic. In the developed work, we proposed an innovative threat detection model by combining the efficiency of deep recurrent neural network, and krill herd optimization algorithm. Here, the DRNN acts as a classification module categorizing normal and malicious data,

while the KHO intends to refine its parameters to improve the overall threat detection process. The DRNN is an artificial neural network, which is mainly used in sequential data processing. The architecture of DRNN is similar to the conventional RNN structure with an additional dense layer. Generally, there are two different RNN architectures namely: Long Short-Term Memory (LSTM), and Gated Recurrent Unit (GRU) [28]. In the proposed work, we used a LSTM model for predicting the cybersecurity threats. The proposed DRNN contains input layer, recurrent layer (LSTM), dense layer, and output layer. The input layer of the system accepts the preprocessed database as input. This layer converts into a suitable format for further analysis, and forwards into the recurrent layer, where the model intends to learn the patterns and long-range dependencies within the data for identifying the normal and malicious data. The LSTM layer includes input gate, forget gate, candidate cell state, hidden state, cell state, and output gate. These cells and gates process the input sequence and capture the complex intricate patterns and correlations within the data, and they are expressed in Eq. (3), (4), (5), (6) and (7).

$$f_t = \sigma\left(W_f .\left[H_{t-1}.D_t\right] + B_f\right) \tag{3}$$

$$i_t = \sigma\left(W_i .\left[H_{t-1}.D_t\right] + B_i\right) \tag{4}$$

$$o_t = \sigma\left(W_o .\left[H_{t-1}.D_t\right] + B_o\right) \tag{5}$$

$$c_t' = \tanh\left(W_c .\left[H_{t-1}.D_t\right] + B_c\right) \tag{6}$$

$$H_t = H_t * \tanh\left(c_t\right) \tag{7}$$

Where f_t defines the forget gate, i_t denotes the input gate, c_t' indicates the candidate cell state, c_t represents cell state, o_t refers to the output gate, σ represents the sigmoid activation function, $\tanh$ denotes the hyperbolic tangent activation function. Further, W defines the weight matrices, and B represents the bias vectors. D_t indicates the input sequence at time step t, and H_{t-1} represents the hidden state at the previous time step. These gates perform certain functions to capture the long-term dependencies and intricate patterns within the sequential data for detecting the threats. The outcome of this layer is forwarded into the dense layer, which is typically a fully connected layer. In this layer, each neuron is interconnected with every neuron in the recurrent and output layer, making the system understand the difference between normal and malicious data. The dense layer is presented in Eq. (8).

$$ds_t = \sigma\left(W_{dh} .H_t + B_d\right) \tag{8}$$

Where W_{dh} defines the weight interconnecting the LSTM layer and dense layer, B_d denotes the bias vector, and σ represents the activation function. These learned patterns and extracted features are fed into the output layer, which produces the probability of being normal or malicious data. The resultant of the output layer is represented in Eq. (9).

$$y_t = \left(W_{ot} .ds_t + B_{ot}\right) \tag{9}$$

Where y_t defines the output at time step t, which indicates the probability of the input being normal or malicious. If the output value is 0, the system indicates it as “normal,” and “malicious.” defines the bias vector and indicates the activation function, which converts the learned features into probability values. At each iteration, this system learns to understand the difference between the normal and malicious data. The loss incurred by the model is presented in Eq. (10).

$$L_{oss} = -\frac{1}{m}\sum_{t=1}^{m}\left[a_t \log\left(y_t\right) + \left(1-a_t\right)\log\left(1-y_t\right)\right] \tag{10}$$

Where L_{oss} indicates the loss, m defines the number of training samples, and a_t represents the actual outcome. This loss function was minimized by adjusting its parameters like weight and bias. In the proposed work, the training loss incurred by the DRNN is optimized using the KHO algorithm by continuously iteratively adjusting its hyperparameters. The KHO is a nature-inspired algorithm developed based on the herding behavior of krills to solve the optimization problems. Here, the objective function of KHO is to maximize the prediction accuracy of DRNN by refining and fine-tuning its hyperparameters to its optimal range. This optimization algorithm was developed based on three main actions: (1) movement induced by other krill individuals, (2) foraging characteristics, and (3) random diffusion. The optimization process begins with the random initialization of the krill population in the search space [29]. Each krill individual in the population defines the hyperparameter values. After initialization, the fitness value of each individual was determined based on the defined objective function, which is represented in Eq. (11).

$$O_{bj} = \max\left(Ac\right) \tag{11}$$

Where O_{bj} indicates the objective function, and Ac denotes the threat detection accuracy of the DRNN model. The fitness of the parameter set will be high if the DRNN model achieved high threat detection accuracy and vice versa. After fitness evaluation, the parameter values are updated following the three actions mentioned above. These steps enable the system to explore the population space and find the optimal value. The parameter updation is mathematically expressed in Eq. (12).

$$p_v\left(t+1\right) = p_v\left(t\right) + \Delta t \frac{dp_v}{dt} \tag{12}$$

Where $p_v\left(t\right)$ indicates the parameter value at time t, $p_v\left(t+1\right)$ defines the updated parameters, and $\Delta t \frac{dp_v}{dt}$

represents the scale factor. Then, the fitness solution was determined for updated parameter sets. Finally, the updated fitness and old fitness was compared. If the updated fitness is greater than the old fitness, the updated parameter values are used for training. This process continues until reaching the maximum iteration count. Thus, the hybrid mechanism detects and classifies the normal and malicious data by learning the patterns within the data effectively. After threat detection, the malicious data is removed from the network for ensuring security and privacy to the data.

D. ABC-ECC for Secure Data Storage

After threat detection, we developed a hybrid cryptographic algorithm combining the efficiency of artificial bee colony optimization with the elliptic curve cryptography (ABC-ECC) for secure data transmission and storage in the cloud. Here, before transmitting the data to the cloud, we encrypt the data using the proposed ABC-ECC model, which prevents the intrusion of third parties during transmission. Elliptic curve cryptography is a public-key cryptographic algorithm developed based on the concept of elliptic curves over finite fields [30]. The elliptic curve is mathematically defined in Eq. (13).

$$y^2 + xy = x^3 + ux + v \tag{13}$$

Where x and y defines the coordinates of the curve, u indicates the curve slope, and v represents the constant term indicating the curve displacement. The important property of this curve is that we can define a rule for adding two points U and V on the curve to determine a third point W, which is also on the curve. This defined rule agrees with the normal addition properties. This forms the basis for operations like scalar multiplication, which are at the heart of ECC's security and efficiency. Consider a case where Alice and Bob want to share the information. Firstly, Alice selects a random integer A_r as its private key, and it is denoted as. Consequently, Bob also selects a random secret integer B_r as his private key, which is defined as. Before key generation and transmission, both Bob and Alice agree upon a non-secret (elliptic curve) and fixed curve point F_p (non-secret). Then, both Alice and Bob calculate their public key, which is represented in Eq. (14), and (15).

$$A_p = F_p A_r \tag{14}$$

$$B_p = F_p B_r \tag{15}$$

Where A_p and B_p define the public keys of Alice and Bob. They compute the public keys by multiplying their private keys with the fixed curve point. These keys are used for performing the encryption operations. If Alice wants to send the data to Bob, it computes a shared secret using her private key and Bob's public key. Subsequently, Bob also computes a shared secret using its private key and Alice's public key. After generating a shared secret, it is used to establish a secure communication channel between Alice and Bob, where both parties use their shared secret as the key for encrypting and decrypting messages exchanged between them. Although the ECC approach is more reliable and effective than conventional cryptographic techniques like Rivest-Shamir-Adleman, its efficiency and security relies on the selection of fixed curve points. Hence, we applied the Artificial Bee Colony algorithm for selecting the fixed curve point from the defined elliptic curve for improving the efficiency and security of the conventional ECC approach. The ABC is a meta-heuristic optimization algorithm developed based on the intelligent foraging characteristics of honey bee swarms. The ABC model contains three bee groups namely: onlookers, employed, and scouts. In the proposed work, we employed the employed bee phase for finding the optimal fixed curve point [31]. The initialization of the ABC population was expressed in Eq. (16).

$$F_{pi} = l_b + rand(0,1) * (u_b - l_b) \tag{16}$$

Where l_b and u_b defines the lower and upper bound of the parameter, respectively. After initialization, the employed bees search for new food sources. Here, the food sources represent the optimal fixed curve point. First they find the neighboring food source and determine its profitability (fitness solution). In case of fixed curve point selection, the fitness indicates its ability to improve the efficiency and security of ECC, which is mathematically represented in Eq. (17).

$$F'_{pi} = F_{pi} + \phi_{pi}(F_{pi} - r_{pi}) \tag{17}$$

Where r_{pi} indicates the randomly selected fixed curve point. Further, the bees explore the population to find the best solution. Further, the fitness solution was again evaluated to select the optimal solution. This process is an iterative process, and at each iteration, the ABC optimization finds the optimal fixed curve point; thereby improving the efficiency and security in data encryption. The encrypted data is then transferred into the cloud for storage and further analysis. Thus, the proposed collaborative framework detects the threats and offers security within the cloud network. The working of the proposed algorithm is described in pseudocode format in Algorithm 1.

Algorithm 1
Start {
Initialize the DDoS database;
Data preprocessing:
1. Handling missing values//*Apply imputation*
2. Feature scaling; //*Apply min-max scaling*
3. Handling class imbalance;// *Perform oversampling*
Data splitting;
Threat detection:
Define DRNN layers;
Initialize epoch count, weights;
Model training:
For each training epoch:
Extract the features;
Learn the patterns and correlations;
Determine output probability;

if (y_t =0) **Normal**;
else **Malicious**;
End for;
Eliminate threats;
Determine loss function;
Optimization:
Initialize KHO parameters (population size, maximum iteration);
Initialize the population;
Define objective function;
For each iteration:
Determine fitness solution;
Update parameter set;
Evaluate fitness for updated parameter sets;
if (new fitness> old fitness) **return updated parameters;**
else **return old parameters;**
End for;
Secure data transmission:
Initialize ECC parameters;
Select fixed curve point;
Select random integers;
Generate public keys;
Perform data encryption;
ABC optimization:
Initialize ABC population, maximum iteration;
Define objective;
For each iteration:
Determine fitness;
Exploration;
End for;
Return optimal fixed curve point;
Model evaluation;
}Stop

V. Results and Discussion

A collaborative security framework was proposed for assessing the cybersecurity risks within the cloud network. The proposed framework was modeled in the Pycharm tool, running in Windows 10 Operating system. The proposed framework was trained and validated using the DDoS dataset, and the results are determined in terms of accuracy, recall, f1-score, mean absolute error (MAE), mean square error (MSE), etc.

A. Training and Testing Performances

In this module, we discuss the training and testing performances of the proposed algorithm. Firstly, the database was split for training and testing purposes, and the performances are assessed as accuracy and loss for different learning rates (70% and 80%). The accuracy metric measures how quickly the proposed algorithm learns the patterns of normal and malicious traffic. The loss metric measures the deviation between the actual and predicted outcomes. Fig. 3 presents the training and testing performance of the developed algorithm for 70% learning rate. The training accuracy indicates how effectively the designed model fits into the training sequence and learns the patterns and correlations for distinguishing the normal and malicious traffic. The developed algorithm achieved greater training accuracy of 0.96, and 0.99 for 70% and 80% learning rates. This validates that the designed approach fastly learns and understands the pattern difference between the normal and threats.

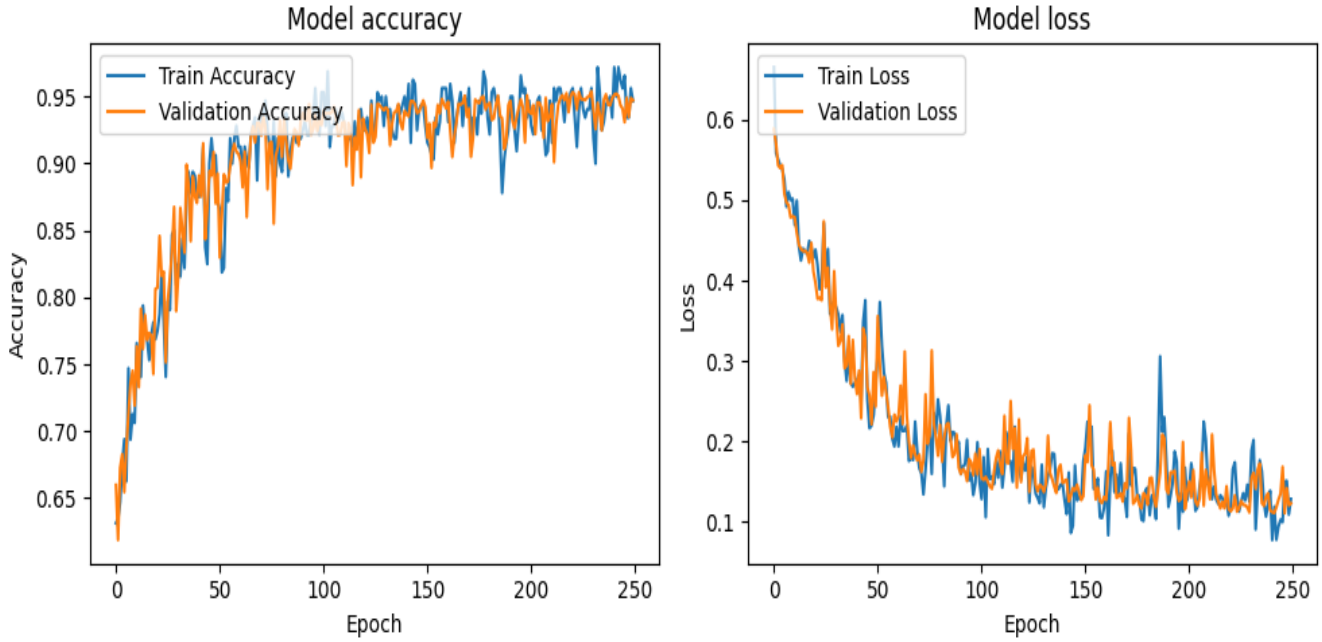

Fig. 3. Training and Testing performance of the proposed model for 70% learning rate.

Consequently, the testing accuracy was evaluated for 70% and 80% learning rates. The testing accuracy defines how effectively the developed model performs predictions on unseen data. The proposed algorithm achieved greater testing accuracy of 0.95, and 0.98 for 70% and 80% learning rates. These improved testing accuracy highlights that the proposed algorithm generalizes well on the new data, making it effective and reliable for real-time threat detection. Also, it is observed that the designed model obtained greater accuracy for 80% learning rate, which manifests that the model's performance increases with higher learning rate.

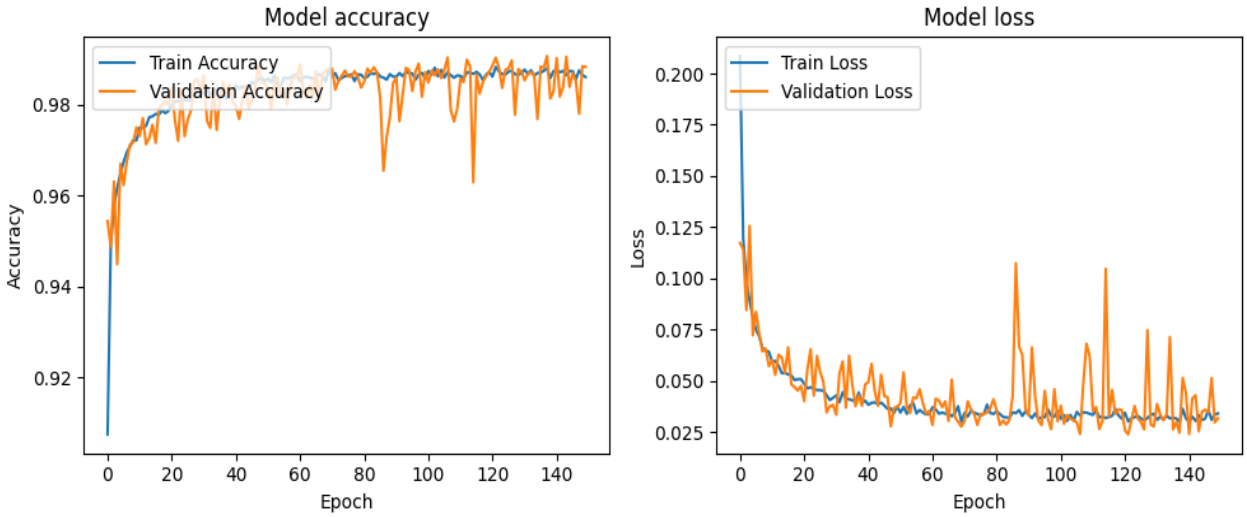

Fig. 4. Training and testing performance of the proposed model for 80% learning rate.

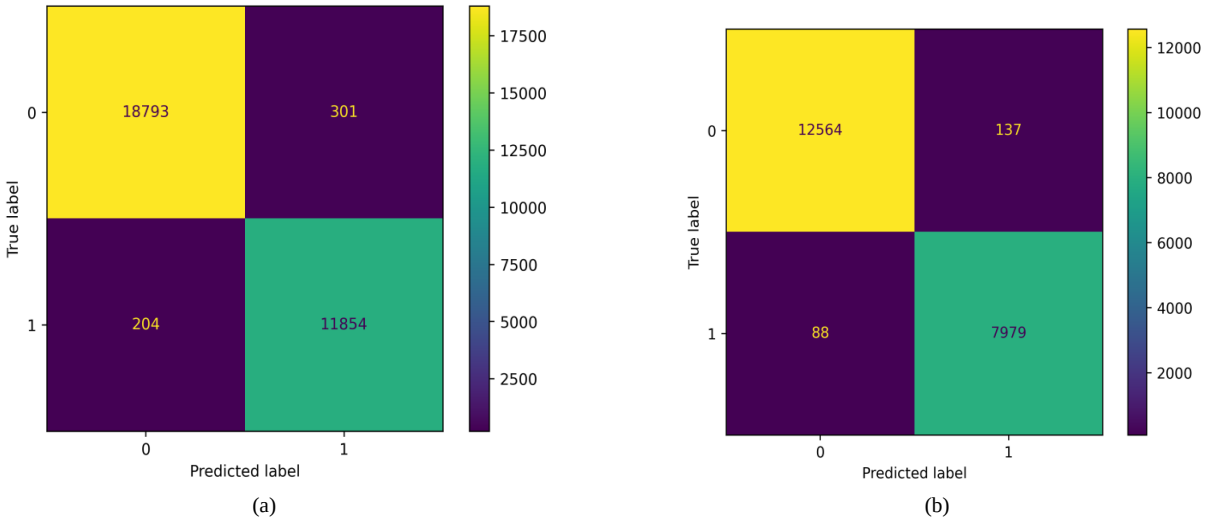
The training loss quantifies the misclassification made by the proposed algorithm within the training sequence. It measures the deviation between the actual and the predicted results in the training sequence. The developed model obtained lower training loss of 0.1, and 0.03 for 70% and 80% learning rates. On the other hand, the testing loss was determined for 70% and 80% learning rates. The testing accuracy measures the model's generalization to unseen data by quantifying the difference between the actual and the predicted outcomes. The designed approach attained minimum loss of 0.11, and 0.4 for 70% and 80% learning rates. Fig. 4 presents the training and testing performance incurred by the developed algorithm for 80% learning. From this intensive model evaluation, it is clear that the proposed algorithm achieved better performances for increased learning rate. Also, it achieved greater accuracy and minimum loss in both train and test phases, highlighting its generalization ability and capacity to prevent the overfitting problem. This illustrates that the proposed technique effectively learns the patterns within the database, and predicts the normal and malicious data accurately.



(a) (b)

Fig. 5. Confusion matrix: (a) 70% learning rate, (b) 80% learning rate.

The confusion matrix is a performance evaluation tool deployed in deep learning to determine its efficiency in classification tasks. It is a table, which visualizes the classification performance of the model by summarizing the counts of correct and incorrect classifications made by the system on the sequence of data for which the actual values are known. Fig. 5 (a, b) presents the confusion matrix obtained for 70% and 80% learning rates. The cell in the matrix indicates the count of instances where the predicted class correlates with the actual class. This matrix is divided into four sections namely, true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN). TP indicates the instances where the malicious traffic is correctly predicted, while TN represents the instances where the normal traffic is correctly predicted. On the other hand, FP defines the scenario when the normal traffic is incorrectly predicted as malicious, while FN denotes the scenario when the malicious traffic is incorrectly predicted as normal. By examining the confusion matrix, we determine the efficiency of the proposed model in threat detection and classification.

1) Cryptographic algorithm performances: In this module, the performance incurred by the proposed cryptographic algorithm (ABC-ECC) was examined in terms of encryption time, decryption time, success rate, and turnaround time. These performances are assessed by increasing the data size from 1 to 100000. Fig. 6 presents the assessment of cryptographic algorithm performances. Fig. 6 (a) presents the encryption time analysis. The encryption time measures the time taken by the proposed system for performing the encryption operation. The proposed algorithm obtained an average encryption time of 0.055, which illustrates that it consumes less time for encoding the dataset. Consequently, the decryption time of the system was determined and it is depicted in Fig. 6 (b). The proposed technique obtained an average decryption time of 0.03, which highlights that the system consumes minimum time for performing the decryption task.

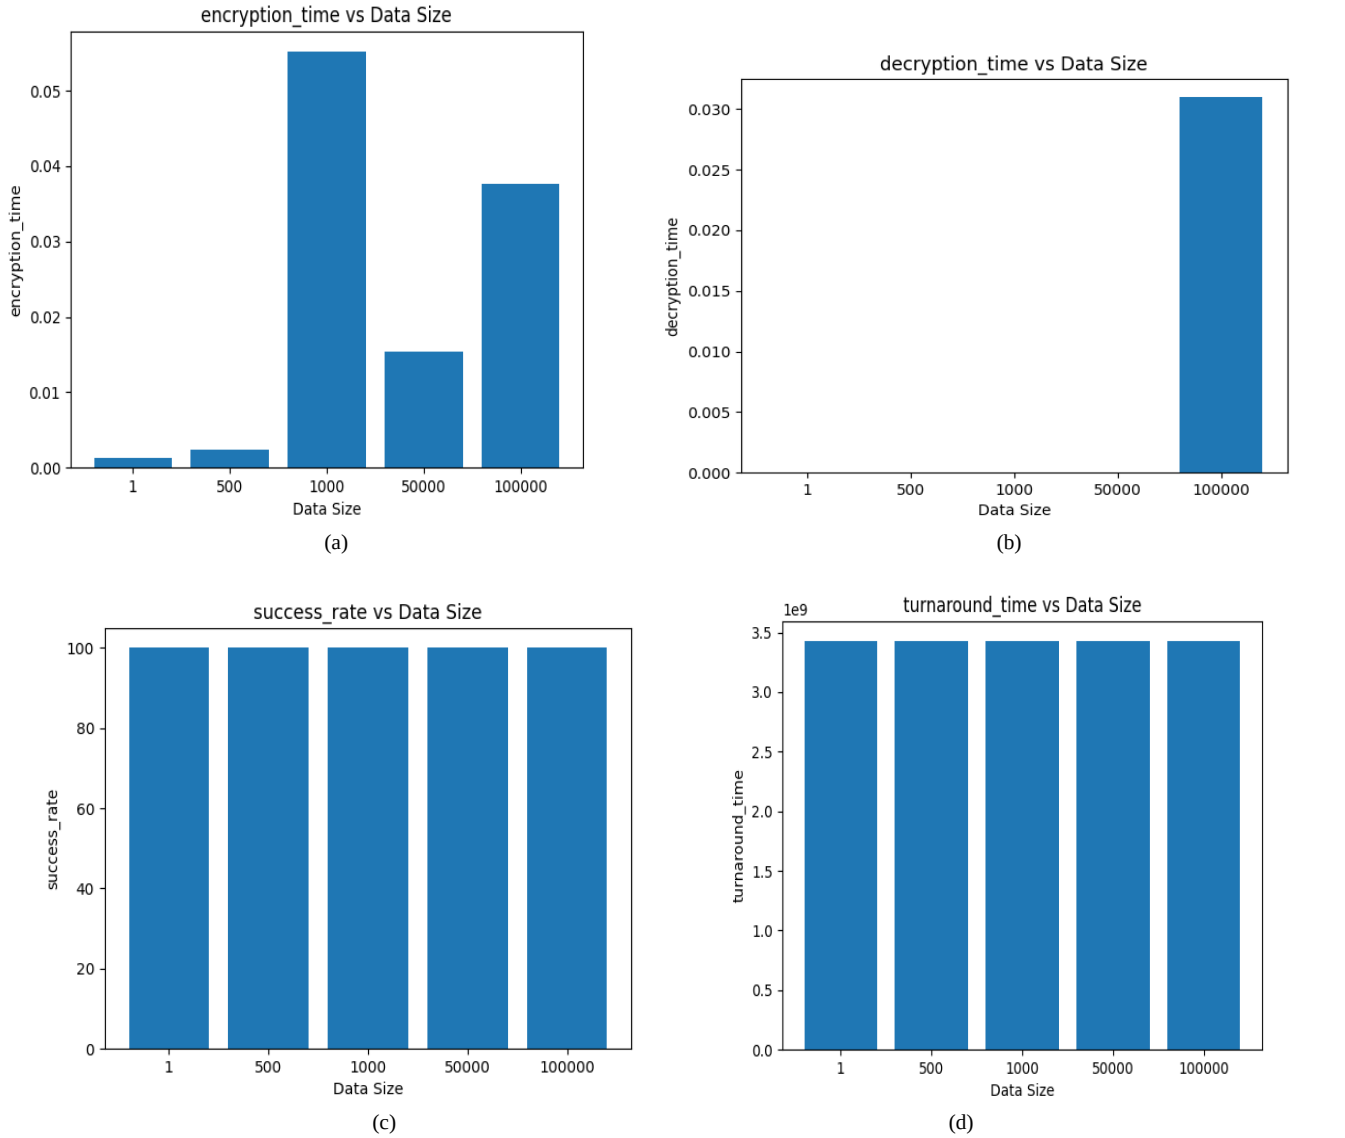


Fig. 6. Performance analysis: (a) encryption time, (b) decryption time, (c) success rate, and (d) turnaround time.

Further, the success rate was determined to evaluate how the proposed system prevents the cyber security threats during transmission. Fig. 6 (c) presents the analysis of success rate over increasing data size. The proposed technique achieved a maximum success rate of 100%, highlighting that it effectively resists the attacks and protects the data. Finally, the turnaround time was assessed over increasing data sizes. The turnaround time indicates total time required to complete a cryptographic operation, including both encryption and decryption processes, in association with other tasks like key generation, initialization, and data processing. The developed model obtained a minimum turnaround time of 3.43E+09, demonstrating its computational efficiency and data processing speed.

B. Evaluation Metrics

In this module, we discuss the parameters used for examining the performance of the proposed algorithm. The parameters include accuracy, recall, f1-score, MSE, MAE, Normalized Mean Square Error (NMSE), success rate, encryption time, decryption time, and turnaround time. The definition for the parameters are described below.

a) Accuracy: Accuracy measures how effectively the developed model predicts the threats in the cloud model. It quantifies the correctly predicted positive and negative instances to the total instances, and it is formulated in Eq. (18).

$$Accuracy = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \tag{18}$$

Where T_p T_n F_p, and F_n defines TP, TN, FP, and FN, respectively.

b) Recall: Recall measures the proportion of true positives that were correctly identified by the developed model. It is calculated using Eq. (19).

$$\text{Re}call = \frac{T_p}{T_p + F_n} \tag{19}$$

c) F1-score: F1-score: F1-score is the harmonic mean of precision and recall, providing a balanced measure between them. It is mathematically expressed in Eq. (20).

$$F - measure = \frac{2 * T_p}{\left(2 * T_p + F_p + F_n\right)} \tag{20}$$

d) Mean squared error: MSE measures the average squared difference between the predicted values and the actual values, and it is formulated in Eq. (21).

$$MSE = \frac{1}{m}\sum_{i=1}^{m}\left(y_i - y\right)^2 \tag{21}$$

Where y defines the actual value, and y_i indicates the predicted value.

e) Mean absolute error: MAE measures the average absolute difference between the predicted values and the actual values. It is expressed in Eq. (22).

$$MAE = \frac{1}{m}\sum_{i=1}^{m}\left|y_i - y\right| \tag{22}$$

f) Normalized mean square error: NMSE measures the relative mean squared error between the predicted values and the actual values, normalized by the variance of the actual values, and it is formulated in Eq. (23).

$$NMSE = 10\log_{10}\left[\frac{\sum_{i=1}^{m}\left|y_i - y\right|^2}{\sum_{i=1}^{m}\left|y_i\right|^2}\right] \tag{23}$$

g) Success rate: Success rate refers to the effectiveness of a cryptographic algorithm in resisting attacks. It measures how effectively the developed model prevents cyber security threats.

h) Encryption time: Encryption time measures the time taken by a cryptographic algorithm to encode the entire data.

i) Decryption time: Decryption time measures the time taken by a cryptographic algorithm to decode the original message from the encrypted data.

j) Turnaround time: Turnaround time indicates the total time required to complete a cryptographic operation, including both encryption and decryption processes.

These parameters provide comprehensive insights into different aspects of the performance of the proposed algorithm, encompassing accuracy, efficiency, security, and reliability.

C. Comparative Analysis

In this section, the performances incurred by the proposed model were compared and validated with the existing techniques such as Convolutional Neural Network (CNN) [32], Deep Neural Network (DNN) [33], Recurrent Neural Network (RNN) [34], and Support Vector Machine (SVM) [35].

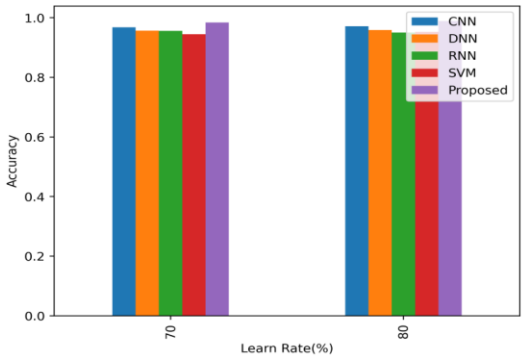
1) Comparison of threat detection performance: In this subsection, we compare the threat detection performance of the developed model with the conventional techniques such as CNN, DNN, RNN, and SVM. The performances are evaluated in terms of metrics like accuracy, f1-score, recall, MAE, MSE, and NMSE at 70% and 80% learning rates. Fig. 7 presents the comparative assessment. Fig. 7 (a) presents the accuracy comparison. The above-stated existing techniques and the proposed DRNN-KHO algorithm obtained an approximate accuracy of 0.96, 0.95, 0.955, 0.94, and 0.983, respectively at 70% learning rate, while the above techniques achieved an approximate accuracy of 0.97, 0.958, 0.95, 0.952, and 0.989, respectively at 80% learning rate. From this analysis, it is clear that the proposed algorithm achieved improved accuracy than the existing techniques. The improvement of accuracy signifies its efficiency in detecting and classifying the normal and

malicious traffic within the network. Consequently, we evaluated the MSE with the above-stated existing techniques. The above-mentioned existing algorithms and the developed approach obtained MSE of 0.03, 0.04, 0.044, 0.05, and 0.01, respectively at 70% accuracy. On the other hand, these approaches earned a MSE of 0.02, 0.041, 0.049, 0.047, and 0.01, respectively at 80% learning rate. The significant reduction of MSE by the designed model highlights that it accurately classifies normal and malicious traffic. Fig. 7 (b) presents the comparison of MSE.

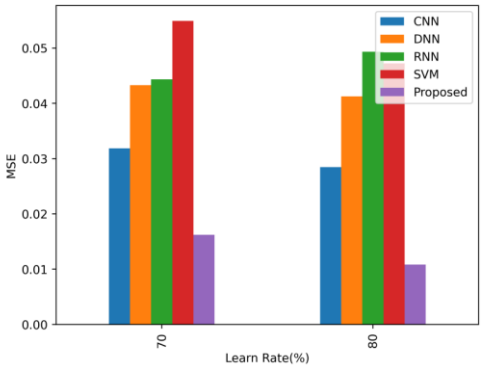
TABLE II. PERFORMANCE COMPARISON AT 70% LEARNING RATE

Metrics	CNN	DNN	RNN	SVM	PROPOSED
MSE	0.031876	0.043304	0.044331	0.054924	0.016211
MAE	0.031876	0.043304	0.044331	0.054924	0.016211
NMSE	0.015315	0.020805	0.021299	0.026389	0.007789
Recall	0.968206	0.956729	0.956029	0.945172	0.983659

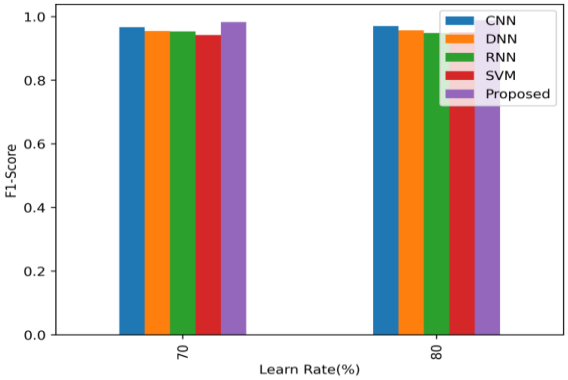
On the other hand, the f1-score was compared with the existing techniques. The f1-score determines the balanced classification performance considering both positives and negatives. These conventional models and the algorithm obtained f1-score of 0.96, 0.954, 0.953, 0.942, and 0.982, respectively at 70% learning rate, while these algorithms obtained f1-score of 0.966, 0.954, 0.953, 0.942, and 0.982, respectively, at 80% learning rate. The significant improvement made by the developed model highlights its efficiency in balanced classification performance than the conventional techniques. Fig. 7(c) depicts the comparison of f1-score. Subsequently, the recall was also evaluated and compared with the existing techniques. The above-stated existing algorithms and the proposed approach earned recall rate of 0.968, 0.956, 0.956, 0.945, and 0.983, respectively at 70% learning rate, while these models obtained recall of 0.970, 0.956, 0.948, 0.950, and 0.988, respectively at 80% learning rate. The enhancement of the recall made by the developed algorithm highlights its efficiency in classifying the network traffic. Fig. 7(d) presents recall comparison. Table II presents the comparative analysis of classification performance at 70% learning rate.



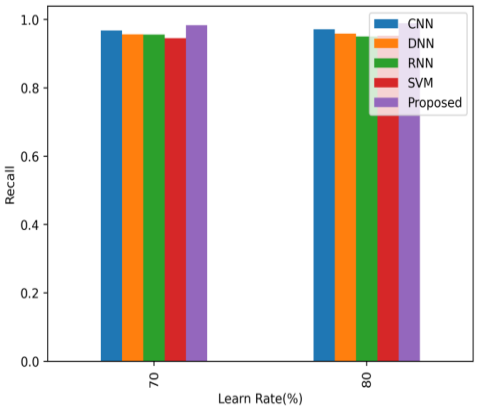
(a)



(b)



(c)



(d)

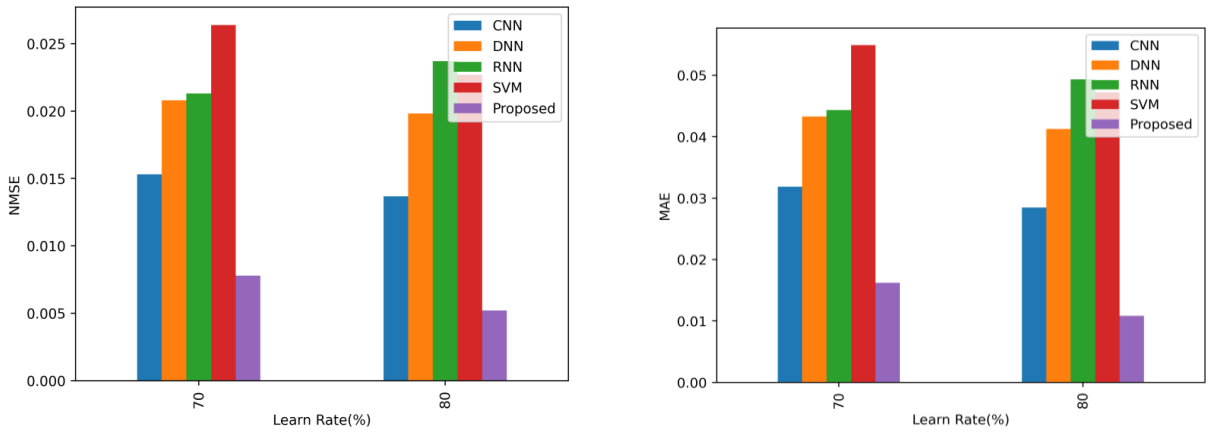


Fig. 7. Comparative analysis: (a) accuracy, (b) MSE, (c) F1-score, (d) recall, (e) NMSE, and (f) MAE.

TABLE III. PERFORMANCE COMPARISON AT 80% LEARNING RATE

Metrics	CNN	DNN	RNN	SVM	PROPOSED
MSE	0.028473	0.041281	0.049339	0.04722	0.010834
MAE	0.028473	0.041281	0.049339	0.04722	0.010834
NMSE	0.01368	0.019834	0.023705	0.022687	0.005205
Accuracy	0.971527	0.958719	0.950661	0.95278	0.989166
F1-Score	0.970089	0.9567	0.948259	0.950446	0.988611
Recall	0.971578	0.958868	0.950477	0.952343	0.989152

Furthermore, the MAE, and NMSE performances of the developed algorithm were compared and evaluated with the conventional techniques. Fig. 7 (e, f) presents the comparison of MAE and NMSE. These metrics measure the error in classification. The existing techniques and the developed approach obtained MAE of 0.03, 0.04, 0.044, 0.05, and 0.01, respectively at 70% learning rate, while these techniques earned NMSE of 0.01, 0.02, 0.021, 0.026, and 0.007, respectively at 70% learning rate. On the other hand, these models obtained MSE of 0.03, 0.04, 0.044, 0.05, and 0.01, respectively, and these algorithms achieved NMSE of 0.01, 0.02, 0.021, 0.026, and 0.007, respectively at 80% learning rate. From this analysis, it is clear that the developed algorithm achieved minimum MAE and NMSE compared to the existing techniques. This highlights the model's efficiency of accurately classifying the threats. In addition, it manifests that the designed model provides minimum error, and lower false positives and negatives. Table III presents the comparison of classification performance of different models at 80% learning rate. From this comprehensive comparative evaluation, it is clear that the designed model achieved better performances compared to the existing techniques, highlighting its efficiency of accurately classifying normal and malicious network traffic.

2) Comparison of cryptographic algorithm performance: In this section, we compare and evaluate the performance of the cryptographic algorithms with the existing algorithms like RSA [36], Advanced Standard Encryption (ASE) [37], ECC [38], and Diffie Hellman Key Exchange (DHKE) [39]. The performances are evaluated in terms of success rate, encryption time and decryption time, and they are evaluated for increasing data size from 1 to 100000.

The encryption time measures the time taken by the proposed algorithm for encoding the entire dataset. The existing techniques such as RSA, ASE, ECC, and DHKE obtained an average encryption time of 0.30, 0.41, 0.23, and 0.15, while the proposed algorithm achieved a minimum encryption time of 0.055. This illustrates that the designed algorithm quickly encrypts the dataset. Fig. 8 (a) presents the comparison of decryption time. Consequently, the decryption of above-stated existing techniques and the proposed are evaluated, and it is displayed in Fig. 8 (b). The decryption time defines the time taken by the developed algorithm for decoding the original message from the encrypted data. These models obtained decryption time of 0.30, 0.89, 0.35, 0.25, and 0.0309, respectively. From this analysis, it is clear that the proposed approach obtained less decryption time than others, highlighting its efficiency and speed in decrypting the data.

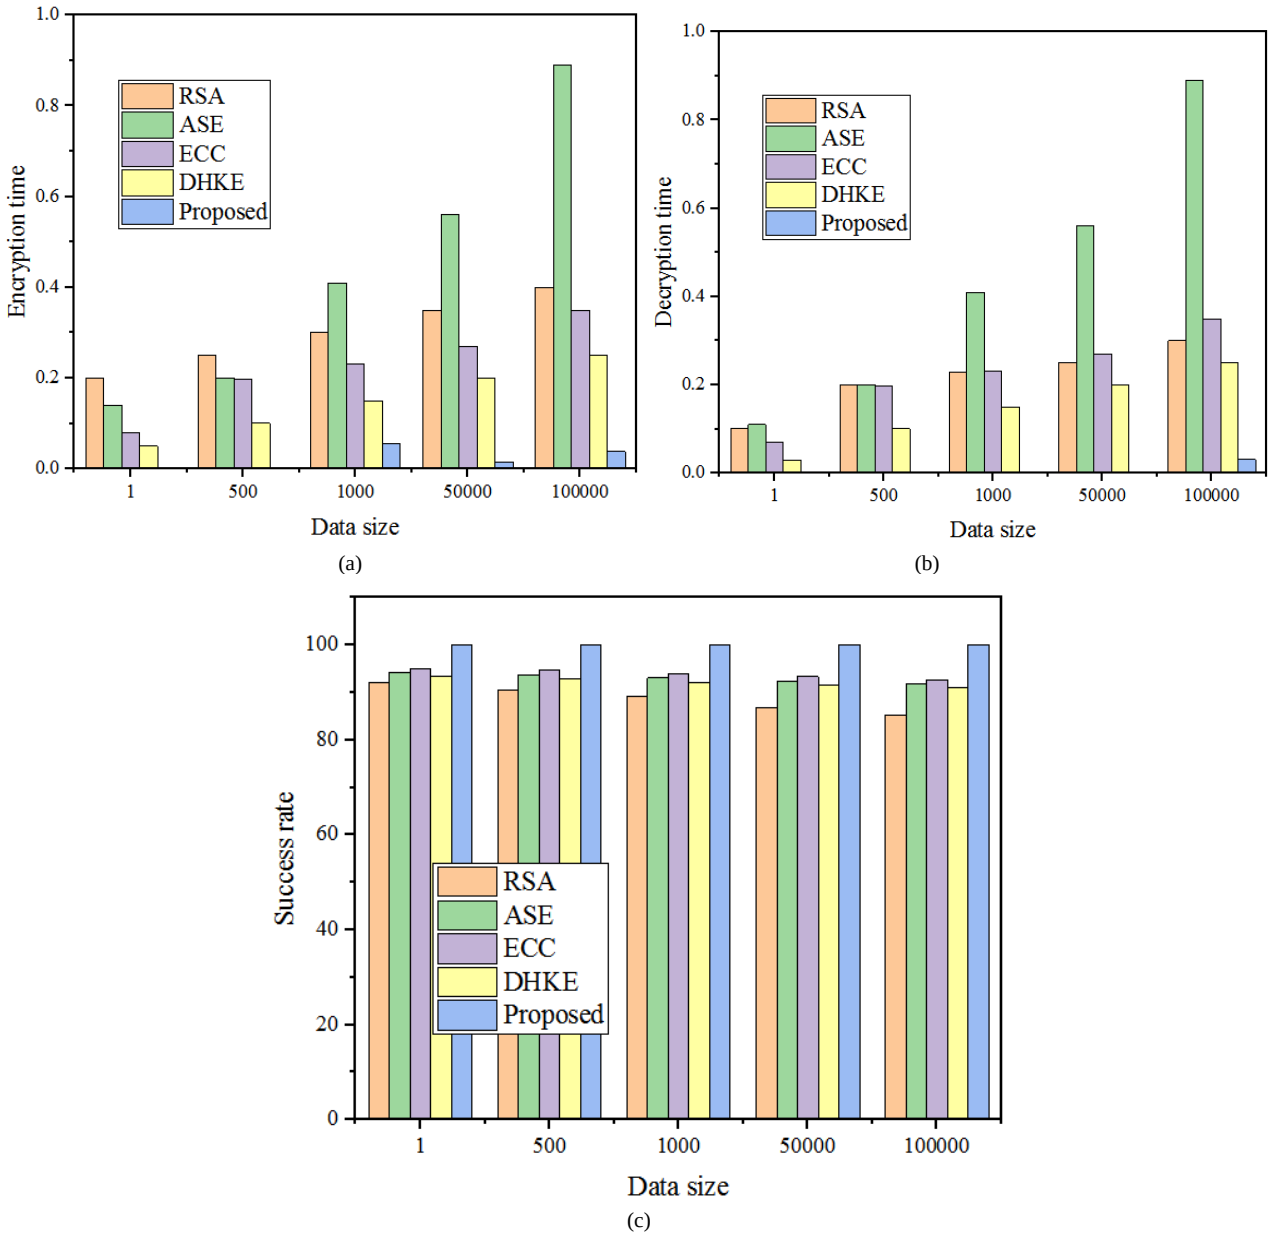

Fig. 8. Comparative analysis: (a) encryption time, (b) decryption time, and (c) success rate.

Finally, the success rate was also determined and compared with the existing techniques. The above-mentioned existing techniques and the proposed algorithm obtained an average success rate of 92.11, 94.21, 95.05, 93.52, and 100, respectively. The significant improvement of the success rate by the proposed algorithm manifests its effectiveness in preventing the intrusion during data transmission. Fig. 8 (c) presents the comparison of success rate. This intensive analysis of system performances suggest that the developed algorithm resists the security attacks and provides greater level of security to the data during transmission.

VI. Conclusion

In this study, we proposed a collaborative framework for ensuring security in the cloud environment. The objective of the work is to assess the cyber threats and provide secure data transmission within the cloud network. The developed model was validated using the publicly available DDoS database, which is preprocessed and trained into the DRNN-KHO module for cyber attack detection. Consequently, we developed a hybrid cryptographic algorithm by integrating ABC into the ECC algorithm for securely transmitting the information into the cloud. The developed framework was modeled and implemented in the Pycharm tool, and the performances are assessed as accuracy, recall, f1-score, MSE, MAE, NMSE, success rate, etc. The experimental results highlight that the developed approach obtained greater accuracy of 0.989, higher recall of 0.989, improved f1-score of 0.988, reduced MSE of 0.010, lower MAE of 0.0108, and minimum NMSE of 0.005, respectively in threat detection. Consequently, the implementation of ABC-ECC algorithm suggests that it achieved 100% success rate, 0.037s encryption time, 0.0309s

decryption time, and 3.43E+09 turnaround time. Finally, we made a comparative assessment with the existing techniques, and it validated that the proposed algorithm achieved better performances than others.

***Abstract*—Cervical cancer remains a significant global health issue, particularly in developing countries where it is a leading cause of mortality among women. The development of machine learning-based approaches has become essential for early detection and diagnosis of cervical cancer. This research explores the optimization of classification algorithms through Correlation-Based Feature Selection (CFS) for early cervical cancer detection. A dataset consisting of 198 samples and 22 attributes from medical records was processed to reduce dimensionality. CFS was used to select the most relevant features, which were then applied to three classification algorithms: Naïve Bayes, Decision Tree, and k-Nearest Neighbor (k-NN). The results showed that CFS significantly improved classification accuracy, with Decision Tree achieving the highest accuracy of 85.89%, followed by Naïve Bayes with 83.34%, and k-NN with 82.32%. These findings demonstrate the importance of feature selection in enhancing classification performance and its potential application in the development of cervical cancer detection tools.**

***Keywords*—Cervical cancer; feature selection; machine learning**

I. Introduction

Cervical cancer is a major global health concern and a leading cause of women's death; the situation is even worse in developing regions due to a lack of health facilities and people's knowledge regarding this deadly disease. People have various assumptions regarding this disease; on the contrary, their knowledge often misleads them on how to prevent the deadly disease or to heal it [1].

For example, a common misconception about cervical cancer is that it only affects women who are sexually active or those with a history of multiple sexual partners. While human papillomavirus (HPV) infection, a key risk factor for cervical cancer, is often transmitted through sexual contact, it is crucial to note that the disease can also develop in women with a limited sexual history with only one partner in conservative marriage or even those who have never been sexually active since HPV can be spread through various ways.

HPV (Human Papillomavirus) is most commonly associated with sexual transmission, but there is a strong possibility that HPV will be transmitted through non-sexual means. One possible way is through direct skin-to-skin contact. HPV can be transmitted when the skin comes into contact with an infected area, even without sexual intercourse. This means that activities such as touching or rubbing areas where the virus is present—like the genital, anal, or oral regions—can lead to transmission. The virus can enter the body through tiny cuts, abrasions, or micro-tears in the skin or mucous membranes, making it possible for someone to contract HPV without having penetrative sex. Since the youth has been experiencing pre-sexual activity, there are strong possibilities that such a viral transmission through this case will eventually occur due to the frequency and possibility that happened after pre-sexual activities.

Another potential, although less common, route of HPV transmission is through indirect contact with contaminated objects. This can happen if personal items such as towels, razors, or undergarments, which an infected person has used, come into contact with broken skin or mucous membranes. While the likelihood of contracting HPV in this manner is lower, it is still a possible mode of transmission. Thus, sharing personal items should be avoided to reduce the risk of spreading the virus.

HPV can also be transmitted from mother to child during childbirth, a process known as vertical transmission. In these cases, the newborn may come into contact with the virus in the birth canal, which can lead to conditions such as recurrent respiratory papillomatosis—a rare disorder where warts grow in the respiratory tract. While such occurrences are uncommon, they highlight the need for awareness that HPV transmission is not solely linked to sexual behavior.

Since HPV is highly infectious, this misconception can lead to a dangerous delay in screening or seeking medical advice, as many women might mistakenly believe they are not at risk since the women do not have enough exposure to information that viral infection can be caused by non-penetrative activities and the virus can remain dormant for years before slowly transforming cellular changes in the cervix.

Furthermore, other factors such as genetics, smoking, and a weakened immune system also play a role in the development of cervical cancer. Raising awareness about the true risk factors and promoting regular screening, such as Pap smears and HPV tests, are crucial in early detection and prevention, regardless of one's sexual history.

Not only the risk of infection that urgently needs to be addressed but simultaneously, we should discuss the fatality of this disease. Naturally, cervical cancer originates in a woman's

cervix, a part of the female reproductive system that is particularly vulnerable to infections and abnormal cellular changes. This vulnerability is due to its location and exposure to the external environment, making it susceptible to open wounds, abrasions, and subsequent infections by viruses or bacteria. HPV infection, in particular, poses a significant risk because it can cause cellular mutations in the cervix that may eventually lead to cancer. Unfortunately, cervical cancer can be deceptively slow in its development, with precancerous changes taking years or even decades to progress into invasive cancer. This gradual progression often results in many women being unaware of the presence of the disease until it reaches an advanced stage, by which time treatment becomes more complex, and outcomes are less favorable.

What makes cervical cancer particularly dangerous is that the symptoms often do not appear until the cancer has progressed significantly. Symptoms like unusual vaginal bleeding, pelvic pain, or discomfort during intercourse may not manifest until the cancer is already advanced, making early detection crucial. Regular screenings, such as Pap smears and HPV tests, are therefore vital for catching any abnormalities at the earliest possible stage. Despite these challenges, advancements in cancer detection technology are continually improving. For instance, the development of the HPV vaccine and the ability to test specifically for high-risk HPV strains have greatly enhanced the ability to prevent and diagnose this type of cancer early on. By identifying the presence of high-risk HPV strains before they lead to cellular changes, healthcare providers can intervene with treatment or increased monitoring to prevent the progression of cervical cancer.

Regular, yearly examinations are strongly recommended for all women, particularly those between the ages of 21 and 65, to detect early HPV infections or precancerous changes. Early diagnosis significantly reduces the risk of cervical cancer progressing to a life-threatening stage and provides the opportunity for effective treatment and management. Education and awareness about the non-sexual transmission of HPV and the importance of regular screenings can help dispel misconceptions and encourage more women to take preventive action against this potentially devastating disease.

What makes cervical cancer particularly dangerous is that the symptoms often do not appear until the cancer has progressed significantly. Symptoms like unusual vaginal bleeding, pelvic pain, or discomfort during intercourse may not manifest until the cancer is already advanced, making early detection crucial. Regular screenings, such as Pap smears and HPV tests, are therefore vital for catching any abnormalities at the earliest possible stage. Despite these challenges, advancements in cancer detection technology are continually improving. For instance, the development of the HPV vaccine and the ability to test specifically for high-risk HPV strains have greatly enhanced the ability to prevent and diagnose this type of cancer early on. By identifying the presence of high-risk HPV strains before they lead to cellular changes, healthcare providers can intervene with treatment or increased monitoring to prevent the progression of cervical cancer.

Regular, yearly examinations are strongly recommended for all women, particularly those between the ages of 21 and 65, to detect early HPV infections or precancerous changes. Early diagnosis significantly reduces the risk of cervical cancer progressing to a life-threatening stage and provides the opportunity for effective treatment and management. Education and awareness about the non-sexual transmission of HPV and the importance of regular screenings can help dispel misconceptions and encourage more women to take preventive action against this potentially devastating disease.

Based on the nature of this virus, several prevention systems should be established. if the sexual educational system is designed systematically and the anti-HPV campaign can reach youth efficiently, the spread of HPV can be contained further. Thus, in reality, the youth does not have enough strong relationships and bonds with stakeholders, and an adequate prevention system for protecting women from HPV has not been established firmly.

Consequently, according to the World Health Organization (WHO), in 2018, there were over 570,000 new cases of cervical cancer, leading to more than 311,000 deaths linked to the disease [2]. This statistic highlights that, despite advances in medical technology, the failure of the cervical cancer prevention system has not successfully yet halted cervical cancer as a remaining significant threat to women's health globally.

From the early situation, the urgency of the significance of early detection of cervical cancer is a top priority for saving women widely in different social and economic classes. By detecting cervical cancer as early as possible, women’s lives would be saved, and they can maintain a proper and standardized quality for women as expected based on the conception of human rights. This statement is strengthened by further research that measures the standardization of human life quality and the development of early-stage detection of HPV and cervical cancer. By detecting cervical cancer earlier, the treatment will work significantly, and the impact on women’s lives is undeniably positive. Undoubtedly, when cervical cancer is identified in its early stages, the chances of successful treatment significantly increase. For example, preventive measures such as Pap smear tests and HPV vaccinations have been successfully efficient in controlling the more profound impacts of cervical cancer in terms of health and social welfare.

Nonetheless, while these strategies have successfully reduced incidence and mortality rates in some developed countries, access to early detection methods in developing nations remains severely limited. The challenges include a lack of medical resources, high diagnostic costs, and insufficient public awareness regarding the importance of early detection [3].

With the advancement of technology and data processing, information technology-based methods—such as machine learning and data mining—are increasingly being utilized in the analysis of medical records to assist in diagnosing and early detection of diseases, including cervical cancer. Classification is one of the most frequently employed techniques in data mining, wherein models are created to predict whether a patient is at high risk of a specific disease, including cervical cancer, based on historical or existing medical data [4]. The application of classification algorithms allows researchers to uncover patterns

within datasets and produce accurate predictions based on the available attributes.

Nevertheless, one of the most significant challenges in medical classification processes, particularly for the early detection of cervical cancer, is the high dimensionality of the data. Medical datasets often contain numerous attributes or features, many of which may be irrelevant for predictions or could introduce noise into the model. This situation is referred to as the high dimensionality problem, which can lead to reduced model performance and an increased risk of overfitting, where the model becomes overly focused on the training data and fails to generalize well to new data [5]. In the context of early cervical cancer detection, attributes within the dataset might include various patient information such as age, pregnancy history, age at first menstruation, and symptoms like fatigue, abnormal bleeding, and abdominal lumps. While some attributes may hold greater significance than others, the sheer number of attributes complicates the classification process and makes it challenging to interpret.

To address the high dimensionality issue, feature selection is employed. Feature selection involves selecting the most relevant and informative subset of features from the dataset while discarding irrelevant or redundant ones. The aim of this process is to simplify the model, enhance interpretability, and, most importantly, improve predictive performance. By utilizing feature selection methods, it is anticipated that classification algorithms can operate more efficiently and accurately [6]. One popular feature selection method used in various classification applications is Correlation-Based Feature Selection (CFS).

High dimensionality in medical datasets presents various challenges, particularly in computation and interpretation. As the number of features increases, the potential combinations in data analysis also rise exponentially. This implies that classification algorithms require more time and computational resources to process datasets with a larger number of features, increasing the likelihood of overfitting. Overfitting occurs when the model is too complex and fits the training data closely, yet fails to generalize to new test data, resulting in poor predictive performance when applied to real-world data [7].

For instance, in a medical dataset aimed at the early detection of cervical cancer, certain attributes may be highly relevant for predicting outcomes, such as the patient's age or pregnancy history. Conversely, there may be attributes that are irrelevant or have a low correlation with the target variable, such as unrelated family health history regarding cervical cancer risk. These extraneous features complicate the model without significantly contributing to predictive accuracy. Thus, implementing feature selection methods to identify the most important attributes for the classification process is essential [8].

Correlation-Based Feature Selection (CFS) is a technique that identifies an optimal subset of features based on the correlation between features in the dataset and the target variable. The fundamental concept behind CFS is that a good subset of features should consist of those that have a strong correlation with the target variable while maintaining a low correlation with one another. In other words, CFS selects features that have a robust relationship with the target variable (i.e., whether a patient is diagnosed with cervical cancer) while avoiding redundant features that provide overlapping information [9].

CFS operates by calculating the Pearson correlation between each feature and the target variable, as well as between the features themselves. The Pearson correlation measures the strength and direction of the linear relationship between two variables. Features with strong positive or negative correlations with the target variable are retained, while those with weak or insignificant correlations are discarded. Additionally, CFS considers the correlation among features to prevent redundancy. Features that are highly correlated with one another are deemed to provide similar information, allowing for one of them to be removed without diminishing model performance [10].

The primary advantage of CFS lies in its ability to reduce data dimensionality without compromising predictive accuracy. By eliminating irrelevant or redundant features, CFS helps classification models become simpler, faster, and more interpretable. This aspect is particularly crucial in medical applications, where the interpretability of the model is a key factor in providing trustworthy diagnoses [11].

In this study, after applying feature selection using CFS, the reduced dataset will be used to train classification models. The three classification algorithms employed are Decision Tree [12], Naïve Bayes [13], and k-nearest Neighbor (k-NN) [14]. These algorithms were selected for their differing approaches to classification problems and their unique strengths in medical data analysis. Each algorithm has its own advantages and limitations, and the findings of this study will assess the performance of each algorithm following feature selection using CFS.

Previous research on early detection of cervical cancer utilizing data mining techniques has yielded positive results. For instance, a study by Ali [4] employed the Random Forest method to analyze medical datasets, achieving a high level of accuracy in predicting cervical cancer. Another study by Rahmi [15] implemented the SMOTE algorithm and Naïve Bayes to address imbalanced data issues in the early detection of cervical cancer in Indonesia. Both studies acknowledged the importance of feature selection as a critical factor in enhancing the performance of classification models.

However, challenges remain unresolved in prior research, particularly concerning high dimensionality and model interpretability. This study aims to address these challenges by applying the Correlation-Based Feature Selection (CFS) method to reduce data dimensionality and by comparing the performance of various classification algorithms to identify the most effective approach for detecting cervical cancer.

II. Literature Review

The optimization of cervical cancer diagnosis has seen significant advancements with the integration of correlation-based feature selection and machine learning models. Recent research [16] emphasized the critical role of selecting key clinical and behavioral criteria in risk assessment. Their methodology combined fuzzy Multi-Criteria Decision Making (MCDM) with machine learning to improve the reliability of diagnostic outcomes, highlighting the importance of reducing data complexity while preserving essential diagnostic features.

Addressing the challenges of high-dimensional datasets, Nithya and Ilango [17] introduced a fused feature selection framework that combines filter and wrapper methods to optimize cervical cancer classification. Their approach effectively mitigates issues such as redundant attributes, irrelevant features, and class imbalance, resulting in improved classification accuracy. This demonstrates the importance of integrated feature selection strategies in handling complex medical datasets.

Deep learning has further enhanced cervical cancer diagnostics, particularly in image-based classification tasks. Tawalbeh [18] conducted a comparative study of six feature fusion techniques applied to deep learning models. By leveraging canonical correlation analysis, they achieved a classification accuracy of 99.7%, underscoring the power of optimized feature fusion in improving performance across multiple cancer classes.

Hasan [8] explored machine learning explainability in cervical cancer classification, employing the Boruta algorithm for feature selection and tools like SHAP for model interpretability. Using Random Forest as a classifier, they achieved an accuracy of 99.85%, demonstrating the value of combining explainable AI techniques with advanced feature selection to enhance diagnostic reliability.

The use of wrapper-based feature selection techniques has also proven effective in cervical cancer diagnostics. Setiawan [19] employed Grey Wolf Optimization (GWO) with classifiers like Naive Bayes and Support Vector Machines. Their findings revealed that NB-GWO outperformed other configurations, achieving an accuracy of 96.30%, highlighting the effectiveness of metaheuristic algorithms in selecting optimal features.

Machine learning has been pivotal in developing self-risk assessment tools for cervical cancer. Ramzan [20] utilized AdaBoost and feature selection algorithms to create personalized risk assessment models. Their technique enabled women to estimate their cervical cancer risk with high accuracy, leveraging demographic and medical history data.

Feature selection techniques, such as mutual information and genetic algorithms, have been extensively studied for their ability to remove irrelevant attributes and enhance model performance. Combining these methods with machine learning has proven particularly effective in addressing issues of overfitting and improving the generalization ability of models.

The application of explainable AI in medical diagnostics has received considerable attention, as demonstrated by Hasan [8]. Their integration of feature importance with interpretable models not only improved diagnostic accuracy but also provided clinicians with insights into the key predictors of cervical cancer, bridging the gap between AI and clinical practice.

Comparative analyses of feature selection methods have highlighted the need for tailored strategies to address the unique challenges of medical datasets. Studies like those of Tawalbeh [18] and Setiawan [19] illustrate the benefits of combining advanced feature engineering with machine learning, fostering the development of robust diagnostic tools.

Together, these studies underscore the transformative potential of correlation-based feature selection and machine learning in cervical cancer diagnosis. By integrating these techniques, researchers have achieved higher accuracy, better interpretability, and improved reliability in diagnostic models, paving the way for early detection and personalized healthcare solutions.

III. Methodology

The methods section of this research includes a series of steps starting with data collection, then moving to data preprocessing, feature selection using the Correlation-Based Feature Selection (CFS) technique, the application of classification algorithms, and finally, the assessment of the classification model's performance [21] (Fig. 1).

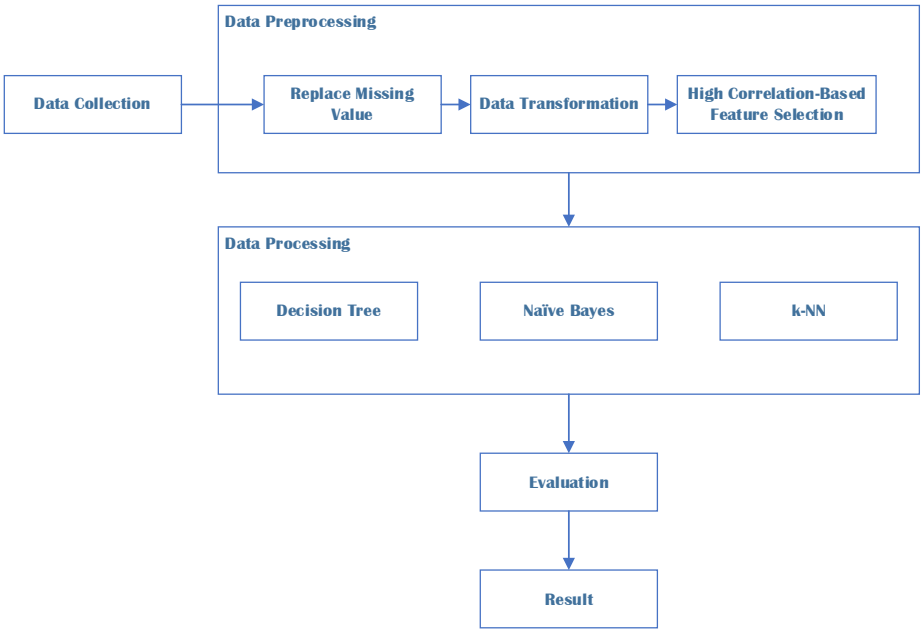

Fig. 1. The flow of research.

A. Data Collection

The data utilized in this research was collected from a hospital located in the area where the researcher resides, comprising a dataset of 198 patient samples who have undergone medical assessments related to cervical cancer. This dataset contains 22 attributes or features that represent various factors that may impact the diagnosis of cervical cancer. These attributes include demographic factors such as age and pregnancy history, as well as clinical symptoms like pelvic pain, abnormal discharge, and bleeding that occurs outside the menstrual cycle. The target variable for this study is the classification of cervical cancer stages, which includes in-situ, early, and advanced stages [22]. Table I shows attributes and variables of cervical cancer.

TABLE I. ATTRIBUTES AND VARIABLES OF CERVICAL CANCER

Variables	Attributes	Description
X1	Age	Age of the patient in years
X2	Marriages	Patient's history of number of marriages
X3	Miscarriages	Patient's history of number of miscarriages
X4	Childbirths	Patient's history of number of deliveries
X5	Age at first marriage	Patient's age at first marriage
X6	Age at first menstruation	Patient's age at first menstruation
X7	Difficulty defecating	0 = no, 1 = yes
X8	Difficulty urinating	0 = no, 1 = yes
X9	Decreased appetite	0 = no, 1 = yes
X10	Pelvic pain	0 = no, 1 = yes
X11	Lower abdominal pain	0 = no, 1 = yes
X12	Weight loss	0 = no, 1 = yes
X13	Nausea	0 = no, 1 = yes
X14	Vomiting	0 = no, 1 = yes
X15	Fatigue	0 = no, 1 = yes
X16	Foul-smelling discharge	0 = no, 1 = yes
X17	Discharge color	milky white, yellowish, greenish
X18	Bleeding outside of cycle	light, heavy
X19	Duration of bleeding	0-7 days, 7-14 days, more than 14 days
X20	Post-coital bleeding	0 = no, 1 = yes
X21	Abdominal lump	0 = no, 1 = yes
X22	Shortness of breath	0 = no, 1 = yes
Y	Cancer stage classification	in-situ, early stage, advanced stage

B. Data Preprocessing

Data pre-processing is an essential phase in preparing datasets to ensure they are suitable for analysis and classification. In this research, the pre-processing stage consists of three primary steps: addressing missing values, transforming the data, and selecting features using the Correlation-Based Feature Selection (CFS) method [23]. A detailed explanation of each step is provided below:

1) Replace missing values: In medical datasets, the occurrence of missing values is common due to incomplete data collection or inconsistencies in patient record documentation. It is essential to address these missing values to ensure the dataset's integrity, allowing the classification model to perform effectively. This study employs two prevalent methods for handling missing values:

a) Row deletion: When a row contains a significant proportion of missing data (for instance, more than 50%), it is removed from the dataset. This approach is taken because a high volume of missing data can compromise subsequent analyses.

b) Imputation: For attributes with only a small number of missing values, imputation techniques are utilized. This method replaces missing values using the information available within the dataset. The imputation process can be done through:

- Mean imputation: for numerical attributes, missing values are substituted with the average value of that attribute.
- Mode imputation: for categorical attributes, missing values are filled with the mode (the most frequently occurring value) of that attribute.

For instance, if there are some missing values in the age attribute, these values are replaced with the average age of the available patients. These techniques help maintain the distribution of the data without introducing significant bias.

2) Data transformation: Once the missing values have been addressed, the subsequent step involves transforming the data to ensure that all attributes are on an appropriate scale and in a format suitable for the classification algorithms being utilized. The data transformation process consists of:

a) Normalization of data: Normalization is essential to ensure that all numerical attributes are consistent in scale, particularly because algorithms such as k-Nearest Neighbor (k-NN) are very sensitive to variations in scale among the attributes. In this research, the Min-Max Scaling method is employed, which adjusts each attribute value to fall within a range of 0 to 1. The formula for normalization is:

$$x' = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

where x is the original value of the attribute, $x_{\min}$ is the minimum value of that attribute, and $x_{\max}$ is the maximum value. Normalization helps prevent attributes with larger scales from dominating those with smaller scales [24].

b) Data standardization: In addition to normalization, standardization is applied to certain attributes that exhibit distributions significantly different from a normal distribution. Standardization is performed by subtracting the mean of each attribute from its value and then dividing by the standard

deviation of that attribute, as illustrated in the following equation:

$$z = \frac{x-\mu}{\sigma} \quad (2)$$

where z is the standardized value, x is the original value, μ is the mean, and σ is the standard deviation. Standardization ensures that the attributes have a distribution with a mean of 0 and a standard deviation of 1.

3) Correlation-based feature selection (CFS): After the data transformation process, the final step in pre-processing is feature selection using the Correlation-Based Feature Selection (CFS) method. CFS is a feature selection technique that automatically identifies the most relevant attributes in relation to the target variable while minimizing redundancy among the attributes. CFS operates by calculating the correlation between attributes and the target variable, as well as the correlation among the attributes themselves.

The steps in CFS are as follows:

a) Feature correlation with the target variable: CFS computes the Pearson correlation between each feature and the target variable (cervical cancer classes: in situ, early, advanced). Attributes with a high correlation to the target variable are retained, while those with low correlation are discarded.

b) Elimination of redundancy among features: In addition to retaining features that are highly correlated with the target variable, CFS also considers the correlation among the features themselves. Attributes that exhibit high correlation with one another are deemed redundant, and one of them is removed. The goal is to minimize multicollinearity within the dataset.

CFS calculates the "goodness value" (Merit) for each subset of features using the following formula:

$$Merit_S = \frac{k\,.\overline{r_{cf}}}{\sqrt{k+k\,(k-1).\overline{r_{ff}}}} \quad (3)$$

where:

- k is the number of selected features,
- $\overline{r_{cf}}$ is the average correlation between the features and the target variable,
- $\overline{r_{ff}}$ is the average correlation among the features.

The result of the CFS method is a reduction in the number of features from 22 to the 10 most relevant attributes for classification. This feature reduction not only enhances computational efficiency but also helps mitigate the risk of overfitting caused by the inclusion of irrelevant attributes.

C. Classification Algorithms

This study utilizes three popular classification algorithms to develop predictive models: Decision Tree, Naïve Bayes, and k-Nearest Neighbor (k-NN). Below is a detailed explanation of each algorithm:

1) Decision tree: The Decision Tree algorithm constructs a decision tree where each internal node represents an attribute or feature, each branch represents a decision based on the attribute's value, and each leaf node represents a classification outcome. Decisions are made by recursively partitioning the dataset into smaller subsets based on feature values that provide the most information. To select the most informative features, the concept of Information Gain based on Shannon entropy is employed. The formula for calculating entropy is as follows:

$$H(D) = -\sum_{i=1}^{C} p(i) log_2 p(i) \quad (4)$$

where p_i is the probability of class i in the dataset, and C is the total number of classes. The feature with the highest Information Gain is used to split the dataset at each node.

2) Naïve bayes: Naïve Bayes is a probability-based algorithm grounded in Bayes' Theorem. This algorithm assumes that all features are independent of one another, which is often unrealistic in real-world applications. However, in practice, Naïve Bayes continues to yield favorable results, particularly in text classification and large datasets. The basic equation of Naïve Bayes is:

$$P(C_k|X) = \frac{P(X|C_k)\,.P(C_k)}{P(X)} \quad (5)$$

where:

- $P(C_k|X)$ is the probability that sample X belongs to class C_k,
- $P(X|C_k)$ is the probability of observing X given class C_k,
- $P(C_k)$ is the prior probability of class C_k,
- $P(X)$ is the overall probability of the data X.

3) k-Nearest neighbor (k-NN): k-NN is an instance-based algorithm that classifies samples based on their distance to the nearest samples in the dataset. The algorithm works by calculating the Euclidean distance between the unknown sample and all existing samples in the dataset, then selecting the k closest neighbors and determining the majority class among them. The formula for Euclidean distance used in k-NN is:

$$d(p,q) = \sqrt{\sum_{i=1}^{n}(p_i - q_i)^2} \quad (6)$$

where p and q are two samples in the data space, and n is the number of features.

D. Evaluation

To evaluate the performance of the classification model, this study uses metrics derived from the Confusion Matrix, which includes calculations for accuracy, sensitivity, specificity, and precision [25]. Below are the explanations and formulas used to compute these metrics:

1) Accuracy: Accuracy measures the proportion of correct predictions against the total samples and is calculated using the following formula [26]:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

where:

- *TP* (True Positive) is the number of positive samples correctly classified,
- *TN* (True Negative) is the number of negative samples correctly classified,
- *FP* (False Positive) is the number of negative samples incorrectly classified as positive,
- *FN* (False Negative) is the number of positive samples incorrectly classified as negative.

2) Sensitivity (Recall): Sensitivity measures the model's ability to correctly identify positive samples and is calculated using the following formula:

$$Sensitivity = \frac{TP}{TP+FN} \quad (8)$$

A high sensitivity indicates that the model is effective in detecting positive conditions.

3) Specificity: Specificity measures the model's ability to accurately identify negative samples and is calculated using the following formula:

$$Specificity = \frac{TN}{TN+FP} \quad (9)$$

High specificity means that the model can identify negative samples with a high degree of accuracy.

4) Precision: Precision measures the accuracy of positive predictions, indicating how many of the positive predictions were correct, and is calculated using the following formula:

$$Precision = \frac{TP}{TP+FP} \quad (10)$$

A high precision indicates that the model rarely produces false positive results.

After evaluating all the metrics, a comparative analysis is conducted to determine which algorithm performs best in detecting cervical cancer based on the processed dataset.

IV. Results and Discussions

This study aims to enhance classification performance in the early detection of cervical cancer using the Correlation-Based Feature Selection (CFS) method alongside three classification algorithms: Decision Tree, Naïve Bayes, and k-Nearest Neighbor (k-NN). Following the pre-processing and feature selection processes, the results of this research provide valuable insights into the impact of CFS on the performance of the employed classification algorithms. Below is a discussion of the results from each stage of the model performance evaluation.

A. Results of using Correlation-based Feature Selection (CFS)

The feature selection phase utilizing the CFS method revealed that only 10 out of 22 attributes in the dataset had significant relevance to the target variable (in-situ, early, advanced). The features selected through CFS include those directly related to clinical symptoms and risk factors known to contribute to the development of cervical cancer. Some important selected attributes include:

1) Abdominal lumps
2) Duration of bleeding
3) Bleeding outside the menstrual cycle
4) Color of discharge
5) Fatigue
6) Weight loss
7) Lower abdominal pain
8) Pelvic pain
9) Difficulty urinating
10) Difficulty defecating (specifically for the Decision Tree and k-NN algorithms)

The feature selection using CFS significantly reduced the number of irrelevant or less important attributes, ultimately enhancing the classification model's performance. Before feature selection, the dataset contained 22 attributes, but after selection, this number was reduced to 10. This reduction contributes to decreased computational complexity and minimizes the risk of overfitting commonly associated with high-dimensional datasets.

B. Evaluation of Classification Algorithm Performance

After the dataset was refined through feature selection using CFS, all three classification algorithms were implemented to predict the classification outcomes for cervical cancer. The performance of each algorithm was evaluated using several metrics, including accuracy, sensitivity, specificity, and precision.

1) Decision Tree: The Decision Tree algorithm is highly interpretable, and the results from this study indicate that it provides the highest accuracy compared to the other two algorithms. The maximum accuracy achieved by Decision Tree was 85.89% with all 10 selected attributes. This model also demonstrated a balanced performance in terms of sensitivity (79.3%) and specificity (83.1%), indicating its ability to accurately detect both positive and negative cases.

One of the main strengths of the Decision Tree is its capability to visualize the decision-making process in tree form, facilitating easier interpretation for medical practitioners. By examining the nodes and branches of the tree, doctors can discern which factors most influence the model’s decisions. In this case, attributes such as "abdominal lumps," "bleeding outside the cycle," and "color of discharge" emerged as key features underlying the decision of whether a patient is at risk for cervical cancer. This aligns with previous medical research indicating these symptoms are early warning signs of cervical cancer.

Another advantage of the Decision Tree is its ability to handle diverse data types, whether numerical or categorical, which is common in medical datasets. Furthermore, the process of partitioning the dataset into smaller subsets enables the Decision Tree to effectively manage high-dimensional issues after feature selection is applied.

1) Naïve bayes: Naïve Bayes is an efficient algorithm for handling large datasets and provides rapid predictions. In this dataset, following feature selection, the Naïve Bayes algorithm achieved the highest accuracy of 83.34% with 8 selected attributes. Despite the underlying assumption of independence among features often not being met in real-world applications, this algorithm still managed to deliver good predictive results. However, its sensitivity (72.5%) was somewhat lower compared to other algorithms, indicating that this model occasionally fails to detect some positive cases of cervical cancer.

The low sensitivity suggests that Naïve Bayes tends to have a higher rate of false negatives, which can be dangerous in medical cases like cervical cancer, where patients requiring treatment may go undetected. Nevertheless, the specificity attained (85.9%) is quite high, indicating that this algorithm is proficient in identifying negative cases and avoiding false positives, which is crucial for reducing unnecessary anxiety among patients deemed at low risk.

2) k-Nearest Neighbor (k-NN): The k-Nearest Neighbor (k-NN) algorithm showed significant performance improvement following feature selection using CFS. Before feature selection, k-NN only achieved an accuracy of 46.82%, demonstrating that this algorithm was highly affected by the high dimensionality of the data. However, after feature selection, accuracy increased to 82.32% with 8 selected attributes.

This substantial improvement indicates that k-NN relies heavily on a smaller number of relevant attributes. The k-NN algorithm functions by calculating the distance between new samples and existing samples in the dataset, classifying the new sample based on its nearest neighbors. When too many irrelevant features are included, the distance calculations become less accurate, leading to inaccurate classification results. Therefore, feature selection with CFS allows k-NN to concentrate on the most relevant features, yielding more accurate predictions.

Despite the notable accuracy improvement, k-NN still has a weakness in sensitivity (69.5%), suggesting that it tends to overlook some positive cases of cervical cancer. Additionally, this algorithm is sensitive to data scaling, necessitating proper normalization to ensure all attributes contribute equally to the distance calculations.

C. Comparative Analysis of Classification Algorithms

To provide a clearer picture of the performance of the three tested algorithms in this study, the following table compares the results for accuracy, sensitivity, specificity, and precision:

TABLE II. COMPARISON OF CLASSIFICATION ALGORITHM RESULTS

Algorithm	Accuracy	Sensitivity	Specificity	Precision
Decision Tree	85.89%	79.3%	83.1%	80.5%
Naïve Bayes	83.34%	72.5%	85.9%	74.1%
k-Nearest Neighbor	82.32%	69.5%	84.4%	71.8%

From the Table II, it is evident that the Decision Tree algorithm delivers the best overall performance, with the highest accuracy and relatively good sensitivity, followed by Naïve Bayes and k-NN. Meanwhile, Naïve Bayes excels in specificity, indicating that this algorithm is more accurate in identifying patients who are not at risk of cervical cancer. However, the drawback of Naïve Bayes lies in its sensitivity, which implies a higher risk of missing cases of cervical cancer.

The strength of k-NN lies in its simplicity and effectiveness in classification following feature selection. However, its lower sensitivity suggests that this algorithm tends to miss more positive cases of cervical cancer compared to the others.

D. Implementation in Early Detection of Cervical Cancer

The findings from this study indicate that correlation-based feature selection (CFS) is highly effective in enhancing the performance of classification algorithms in detecting cervical cancer. By reducing the number of irrelevant attributes and focusing solely on the most significant features, classification algorithms can produce more accurate and efficient predictions. This is crucial in medical applications, where diagnostic accuracy is a key factor in determining further actions.

Additionally, the Decision Tree stands out as the most ideal algorithm for use in the early detection of cervical cancer, as it not only provides the highest accuracy but also allows for easy interpretation of the decision-making process. This makes the Decision Tree a valuable tool for medical practitioners to understand the factors contributing to a cervical cancer diagnosis. One of the main benefits of the Decision Tree is its ability to visually represent the classification process, breaking down complex decision-making into a clear and straightforward flowchart. This visual representation helps healthcare professionals trace the sequence of factors leading to a diagnosis, making it easier to explain results to patients and colleagues in an understandable manner.

Another significant advantage of implementing the Decision Tree algorithm is its robustness in handling both categorical and numerical data, which is often the case in medical datasets. This flexibility allows for the integration of a diverse range of patient information, such as demographic factors, test results, and clinical history, into a single cohesive model without requiring extensive data preprocessing. Additionally, Decision Trees are not as sensitive to outliers or missing values as other algorithms, making them highly resilient in real-world medical applications where data quality can vary.

Moreover, Decision Trees facilitate effective feature selection by prioritizing the most important attributes early in

the model, which can lead to more efficient and faster computations. This is particularly beneficial in large-scale healthcare systems or when developing real-time diagnostic applications, as it reduces the processing time and computational resources needed to generate accurate predictions. The interpretability and efficiency of Decision Trees make them ideal for use in telemedicine and remote diagnostic tools, providing a means for timely and accurate assessments even in resource-constrained environments.

Lastly, the transparency of the Decision Tree's decision-making process supports better compliance with healthcare regulations and ethical standards. Because each step of the diagnosis can be easily traced and justified, Decision Tree models can enhance trust between medical professionals and patients and ensure accountability in the diagnostic process. These benefits position Decision Trees as a highly effective and practical solution for implementing early detection systems for cervical cancer, ultimately contributing to improved patient outcomes and more accessible healthcare.

With the results obtained, this research can serve as a foundation for developing information technology-based applications that assist individuals in conducting early screenings for cervical cancer independently. By leveraging proven classification algorithms and effective feature selection methods, such applications can deliver accurate results and help raise public awareness about the importance of early detection of cervical cancer.

V. Conclusion and Future Works

This study demonstrates that the Correlation-Based Feature Selection (CFS) method can significantly enhance classification performance on cervical cancer datasets. The Decision Tree, Naïve Bayes, and k-Nearest Neighbor (k-NN) algorithms all showed substantial improvements in accuracy following feature selection. Among the three algorithms, the Decision Tree achieved the highest accuracy, while k-NN experienced the most significant improvement after feature selection. These results indicate that employing appropriate feature selection techniques can optimize the predictive capabilities of machine learning models, leading to better diagnostic outcomes.

Furthermore, this research highlights the crucial role of feature selection in reducing data dimensionality and eliminating irrelevant or redundant features. By focusing on the most relevant attributes, the CFS method improves the computational efficiency of the models, resulting in faster and more accurate predictions. This optimization is particularly beneficial when dealing with complex datasets, such as those involving medical records or diagnostic tests, where irrelevant data can hinder model performance and lead to misleading results.

Widely, the implementation of these findings has practical applications beyond the academic context, especially in the development of technology-based tools to support the early detection and diagnosis of cervical cancer. By integrating machine learning algorithms enhanced with feature selection methods into digital healthcare platforms, it becomes possible to build robust and reliable diagnostic systems that can be used by healthcare professionals and patients alike. Such systems are particularly valuable in regions with limited access to specialized medical care, where timely diagnosis and treatment can be challenging.

Nonetheless, the use of these advanced diagnostic tools can significantly improve early detection rates, enabling healthcare providers to identify potential cases of cervical cancer at an earlier stage when treatment is more effective and the chances of recovery are higher. Early detection systems can also alleviate the burden on healthcare infrastructure by allowing patients to be triaged more effectively, prioritizing those who need immediate medical attention. Ultimately, this study underscores the potential of machine learning and feature selection techniques to revolutionize cervical cancer screening and contribute to better health outcomes for women worldwide.

***Abstract*—Accurate segmentation of chest X-rays is essential for effective medical image analysis, but challenges arise due to inherent stability issues caused by factors such as poor image quality, anatomical variations, and disease-related abnormalities. While Generative Adversarial Networks (GANs) offer automated segmentation, their stability remains a significant limitation. In this paper, we introduce a novel approach to address segmentation stability by integrating GANs with wavelet transforms. Our proposed model features a two-network architecture (generator and discriminator). The discriminator differentiates between the original mask and the mask generated after the generator is trained to produce a mask from a given image. The model was implemented and evaluated on two X-ray datasets, utilizing both original images and perturbed images, the latter generated by adding noise via the Gaussian noise method. A comparative analysis with traditional GANs reveals that our proposed model, which combines GANs with wavelet transforms, outperforms in terms of stability, accuracy, and efficiency. The results highlight the efficacy of our model in overcoming stability limitations in chest X-ray segmentation, potentially advancing subsequent tasks in medical image analysis. This approach provides a valuable tool for clinicians and researchers in the field of medical image analysis.**

Keywords*—Deep learning; X-rays; segmentation; medical imaging; Generative Adversarial Networks; wavelet transforms

I. Introduction

In recent years, the application of deep learning (DL) has seen significant strides in the field of medical imaging, revolutionizing the automation and enhancement of tasks such as detection, classification, and segmentation of medical images. At the forefront of these advancements are neural networks, sophisticated machine learning algorithms designed with layers of interconnected neurons. This architectural mimicry of the human brain enables neural networks to interpret incoming data, extracting intricate patterns and features with a level of sophistication that traditional algorithms struggle to achieve [1, 2].

Neural networks are trained on annotated medical images to detect anatomical structures and abnormalities [1]. Neural networks can be used to automate disease detection, such as identifying lung nodules on chest X-rays or brain tumors on MRI images. It's an effective tool to improve the quality of medical images, with backpropagation function which removes the noise and enhance image resolution. Neural networks can detect specific anatomical structures in images, for example, to isolate a tumor in an MRI image or to measure the dimensions of an organ in an ultrasound image [1, 2]. Deep learning is widely used in medical image analysis to analyze images from a variety of modalities, such as Computed Tomography (CT), X-ray, Positron Emission Tomography (PET), Ultrasound, Magnetic Resonance Imaging (MRI), Optical Coherence Tomography (OCT) [3, 6, 7]. The X-rays are considered as a type of medical imaging that uses ionizing radiation to produce images of bones and other dense body structures. X-rays are commonly used for diagnosis and treatment planning for conditions such as fractures, joint problems, dental issues and chest [3]. They are fast, widely available, and inexpensive compared to other medical imaging modalities.

In this article, we used in our experiments the chest X-rays (CXRs) [3], a type of medical imaging that employs X-rays to create images of the chest, including the heart, lungs, and blood arteries. They are frequently employed to identify and keep track of illnesses like pneumonia, lung cancer, tuberculosis, heart issues, and fluid retention in the lungs. Compared to other imaging techniques used in medicine, CXRs are quick, accessible, and affordable [4]. The detection of COVID-19 has also been tried in this manner [4]. Chest X-rays (CXRs) are used more frequently for early triage of ARDS patients who are already exhibiting COVID-19 symptoms and acquiring accurate because they are simpler to obtain than computed tomography (CT) [5].

Segmentation of a Chest X-ray is the process of separating the foreground (such as the lung and heart) from the background (such as the chest wall) in a chest X-ray image. This can be done using various techniques such as thresholding, morphological operations, and machine learning algorithms [6]. The purpose of chest X-ray segmentation is to accurately identify and isolate specific structures in the image,

which can be used for diagnosis, treatment planning, and measurement of structures such as lung volume. Segmenting chest X-rays is a challenging task due to the diverse range of anatomy, disorders, and appearances that can be present. However, it is a crucial step for enhancing the accuracy and efficiency of medical image analysis [8]. On the other hand, the stability of images segmentation is very important to improve the data security against attackers on medical images field. Images contain sensitive and confidential patient information, and their unauthorized access or manipulation can have serious consequences [9]. Segmentation of medical images, such as chest X-rays, can help improve their security against attackers by reducing the amount of data that needs to be protected. By isolating relevant structures and removing unnecessary information, the risk of unauthorized access or manipulation of sensitive and confidential patient information can be reduced. To further protect the segmented images, encryption can be used to scramble the data using secure algorithms. This makes it difficult for unauthorized users to access or view the confidential information contained in the images. Access to segmented images can also be controlled through authentication and authorization procedures, such as role-based access control or password protection. This helps ensure that only authorized users have access to the data, further reducing the risk of data breaches.

It's important to note that while these techniques can provide some level of security against attackers, no single method can provide complete security. A combination of these techniques, along with robust security protocols throughout the life cycle of medical X-ray images, is recommended for the best results [10]. Deep learning algorithms have shown promising results in both segmentation tasks and security against potential attackers, particularly for chest X-rays.There are several deep learning algorithms used for medical image segmentation, including Convolutional Neural Networks (CNNs). [10] CNNs are a type of neural network specifically designed for image analysis tasks. They can be trained to perform image segmentation by learning the relationships between image pixels and object boundaries. CNNs have achieved notable success in semantic segmentation in [11], Long et al. Semantic segmentation was suggested in early work on integer convolutional networks (FCNs). Where the authors have tested the label map using deconvolutional layers to acquire classification results for each pixel, they have substituted the conventional fully connected CNN layers with convolutional layers to generate a coarse label map. However, CNNs have some drawbacks, they present good results with clear and well-defined images and poor performance on security applications, typical low-resolution, noisy, or occluded images [11]. The U-Net algorithm [12], a well-known CNN architecture created expressly for medical image segmentation, is the alternative segmentation algorithm. In order to record both high-level and low-level characteristics in the image, it employs an encoder-decoder architecture.

II. Related Work

The section provides an overview of existing research, methodologies, and advancements relevant to this study. By examining prior contributions, this section highlights the current state of knowledge, identifies gaps in the literature, and demonstrates how this work builds upon or diverges from earlier studies. The review also contextualizes this research within the broader academic discourse, ensuring clarity in its contributions and alignment with ongoing developments in the field. In recent years, medical image segmentation has become a critical area of research in medical imaging and computer vision. Numerous studies have proposed innovative methods to improve the accuracy and reliability of segmentation models, especially for challenging tasks involving small, unclear, or complex anatomical structures. The U-Net architecture for medical image segmentation is extended in the work for auteur [12], introducing an attention mechanism to enhance performance on challenging objects like the pancreas. In order to enable the network to recognize key features for the target item, the proposed Attention U-Net employs a gating mechanism to dynamically weight feature mappings in the network's encoding and decoding sections. For a dataset of CT scans used for pancreatic segmentation, the Attention U-Net performed better than the regular U-Net and a number of cutting-edge segmentation techniques. Auteur [12] presents, a deep learning framework for U-Net architecture-based segmentation of chest X-ray images. To more effectively handle the present small and hazy structures, the authors suggested changes to the basic U-Net architecture. For improving the accuracy and realism of the segmentation results, they used adversarial segmentation, it's a type of image segmentation technique that uses adversarial training. Adversarial training is a machine learning technique that trains a model using adversarial examples, which are inputs designed to mislead the model. In the context of image segmentation, adversarial training is used to guide the segmentation model towards producing accurate and visually plausible segmentation masks. The model is trained using a combination of a segmentation loss and an adversarial loss, which measures the realism of the generated segmentation masks. Authors of [13], explore the application of SegAN for medical image segmentation and suggest using adversarial training to increase the segmentation accuracy and realism of the segmentation masks created. Two parts make up SegAN: a generator and a discriminator. The segmentation masks are created by the generator, and the discriminator assesses how realistic they are. In order to increase the segmentation accuracy, the authors also suggest a multi-scale loss function that takes into consideration background data from several scales. In order to train the SegAN, the multi-scale loss function is combined with the adversarial loss. For numerous medical imaging datasets, experimental results demonstrate that SegAN is superior to other cutting-edge approaches. Additionally, the authors demonstrate how SegAN can deal with small and hazy structures. The authors of [14] demonstrate how SegAN can be used for unsupervised adversarial training on medical image segmentation. Using a number of medical imaging datasets, they assess the performance of the unsupervised SegAN and demonstrate that it can produce results that are on par with or even superior to those of the conventional supervised SegAN.

The paper in [15], presents an interesting extension of SegAN by incorporating unsupervised adversarial training, which can help address the limitations of supervised adversarial training, such as the need for large amounts of annotated data. However, more research is needed to fully

understand the benefits and limitations of unsupervised adversarial training for medical image segmentation. While the unsupervised adversarial training approach has advantages, it comes with limitations. In this method, the generator is trained without using ground truth masks, potentially resulting in suboptimal performance. This differs from supervised adversarial training, where ground truth masks are employed. Generative Adversarial Networks (GANs) pose challenges in training and can experience stability issues, such as mode collapse, leading to suboptimal performance. The authors evaluated the performance of unsupervised SegAN on various medical imaging datasets. However, it's important to note that these datasets may not fully represent all medical imaging modalities and applications. This version maintains the key points while presenting them in shorter, more digestible sentences. Authors in study [16], present a new approach to medical image segmentation that leverages the advantages of both multimodal imaging and adversarial learning. The authors propose a multi-modal GAN called SegAN, which is trained using both modalities and adversarial learning. The network is trained to segment the target structures in both modalities while maintaining the multi-modal information in the generated results. However, the limitations of the proposed approach include the need for large amounts of annotated data for training, the stability issues associated with GANs, and the lack of interpretability of the model's predictions. In study [17], to improve the performance of adversarial networks for medical image segmentation tasks, the authors propose to use self-supervised learning, where the model can learn from the input data without requiring manual annotations, The SS-GAN is trained using a combination of adversarial loss and self-supervised loss, which helps the network to generate accurate and plausible segmentation mask. The experimental results demonstrate that the proposed SS-GAN's more effective than other state-of-the-art methods for medical image segmentation. The limitations are not specified in the article [18]. However, some common limitations of self-supervised learning and adversarial networks can be the model's performance might be affected by the presence of outliers or data with different distributions, the model may not perform well on unseen data and generalize poorly to new medical imaging modalities, the stability issues associated with GANs, and the lack of interpretability of the model's predictions.

A new paradigm for medical image segmentation employing an adversarial attention network is proposed by S. Kim et al. in [19] (AAN). The AAN enhances segmentation performance by combining adversarial learning with an attention mechanism. Within the network, both a generator and a discriminator coexist. The generator divides the image into segments, while the discriminator assesses the segmentation output. The generator is given access to the attention mechanism to aid with segmentation accuracy and focus on the target regions. The technique was put to the test on several medical image datasets, and the results indicated enhanced performance when compared to other segmentation techniques already in use. X. Song et al. [20], proposes a multiple adversarial network (MAN) architecture for medical image segmentation. The MAN architecture is made up of a number of adversarial sub-networks, each of which is trained to provide various aspects of the input medical image. These features are then combined to give the segmentation result. The results of the experiments the authors undertake on two medical image segmentation datasets show that the MAN architecture is superior to other cutting-edge techniques. The paper [21], does not provide any constraints. However, some typical drawbacks of self-supervised learning and adversarial networks include the instability of GANs, the unintelligibility of the model's predictions, and the model's performance being impacted by the existence of outliers or data with different distributions. In study [22], authors presents a decision support system based on a GAN model for brain tumor segmentation. The authors aim to improve the accuracy and efficiency of brain tumor segmentation using GANs. The proposed system is tested and evaluated using a dataset of brain MRI scans, and the results demonstrate its effectiveness and superiority compared to traditional methods. Some common limitations of the proposed system include stability issues associated with adding noise to the images. The model may not perform well when incorporating such noise.

Through our review of several studies focusing on the segmentation by GAN's algorithms, we discovered that the biggest limitations was the stability constraints related to the GAN's network. In this paper, we proposed a new approach to chest X-ray segmentation based on the GAN with wavelet transforms. The GAN consists of two neural networks: the generator and the discriminator. The generator is responsible for generating a mask for a given original chest X-ray image, while the discriminator distinguishes between the original mask and the generated mask. To evaluate the proposed approach, we implemented their model on two datasets of chest X-ray images. One dataset consisted of original images, while the other dataset consisted of perturbed images with added noise using the Gaussian noise method [38]. The performance of the proposed approach was compared to that of the traditional GAN algorithm. The results showed that the proposed approach based on the GAN algorithm with wavelet transforms outperformed the traditional GAN algorithm in terms of stability, accuracy, efficiency, and it can help to improve the accuracy of subsequent medical image analysis tasks. The proposed approach has the potential to be a valuable tool for clinicians and researchers in the field of medical image analysis. It can help improve the accuracy and efficiency of medical image analysis tasks, which can ultimately lead to better diagnosis and treatment outcomes for patients. The rest of this paper is organized as follows: In Section III, we show methods. The proposed approach of our work in Section IV. The experimental results are discussed in Section V. Finally, a conclusion are presented in Section VI.

III. Methodology

This section, provides an overview of the GAN architecture. Subsequently, we will introduce two models for GAN-based segmentation, with the first model being our initial approach and the second model being a novel technique to overcome stability limitations of GAN.

A. Generative Adversarial Networks (GAN)

Goodfellow et al. [23] were the ones who first proposed the traditional GAN architecture. When creating new synthetic data that is similar to a training set, GANs combine two

separate types of neural networks generator G and a discriminator D. The role of the D is to learn how to distinguish between genuine and fake samples, whereas the G is responsible for generating artificial samples. The min-max game involves two networks competing against each other, where one network aims to maximize the value function 1 while the other seeks to minimize it. In a game-theoretic framework, the two networks are trained concurrently while the generator strives to generate samples that deceive the discriminator, and the discriminator tries to properly identify the generated samples. The discriminator gets better at spotting fraudulent samples, and the generator gets better over time at producing synthetic samples that are close to the training set.

Below, Formula 1 present an illustration of how network G and network D can be understood mathematically with value function V (G, D):

$$\min_G \max_D V(D,G) = \mathbb{E}_{x\sim p_{data}(x)}[\log D(x)] + \mathbb{E}_{Z\sim p_Z(Z)}[\log(1-D(G(Z)))] \quad (1)$$

where:

- $\mathbb{E}_{x\sim p_{data}(x)}[\log D(x)]$: log probability of D predicting that real-world data is real.
- $\mathbb{E}_{Z\sim p_Z(Z)}[\log(1-D(G(Z)))]$: log probability of D predicting that G's generated data is not real.
- x: with real images drawn from $p_{data}(x)$ real data images distribution.
- Z: the prior input noise from $p_Z(Z)$.

GANs can be used for a variety of tasks, like image synthesis by use type of GAN called conditional-GAN (cGAN) [24], text to image generation [24], Data augmentation [25], classification, and segmentation [39].

B. GAN for Image Segmentation

The discriminator network is trained to differentiate between real and fake (mask segmented) masks, while the generator network is trained to create realistically segmented images known as mask segmented. The two networks play a game in which the generator tries to produce masks that the discriminator cannot distinguish from real ones, and the discriminator tries to correctly identify the generated masks. Over time, the generator improves, producing more and more realistic masks, while the discriminator becomes better at identifying generated masks. In this way, GANs can be used for image segmentation by training the generator to produce accurate segmentations of input images. The general structure of the GAN for segmentation is shown in Fig. 1.

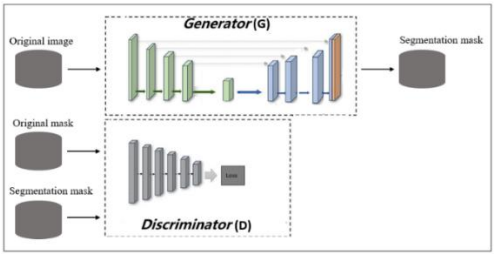

Fig. 1. Architecture GAN.

a) Generator: Our goal is to enhance the preliminary: segmented output of the segmentation component by leveraging the generative component, which is known for its advanced optimization capabilities. To achieve this, we employed the U-Net neural network as the generator, given its exceptional performance in previous works [23]. A U-Net generator for segmentation is a type of deep learning neural network architecture designed for image segmentation tasks. The U-Net architecture is based on a fully convolutional network, with a "U" shaped structure that merges feature from lower-level to higher-level layers in the network [12]. In the U-Net architecture, the contracting path, represented by the left half of the "U" shape called encoder, is used to extract features and reduce the spatial resolution of the input image, and the expanding path, represented by the right half of the "U" shape called decoder, is used to upsample and recover the spatial resolution, while also combining features from the contracting path to make segmentation predictions [12]. The U-Net generator is commonly used in medical imaging to segment organs, tumors, or other structures of interest. However, it can also be applied to other types of image data, such as satellite imagery or aerial photographs, for tasks such as object detection and semantic segmentation. The general structure of the generator in our model is shown in Fig. 2.

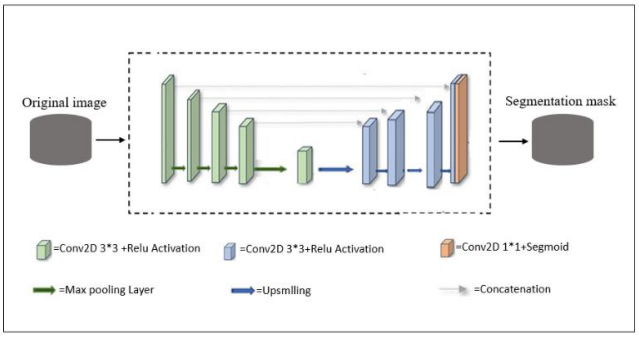

Fig. 2. Structure of the generator.

The network is composed of five layers for the encoder and decoder: first one is the input layer, next three layers of the Relu convolutional batch normalization model are hidden, and the last one is the final output layer. The architecture is comprised of a total of 10 layers, with the encoder and decoder each containing five layers. The encoder consists of five layers, with each layer being composed in the following manner: The first layer contains an input size of $512 * 512$, Conv2D is a 2D convolution layer with a $3 * 3 * 32$ filter size for identifying spatial patterns in an image, such as edges and activation the max pooling layer of size $2 * 2$ is used to minimize representation size and speed up computations in Relu, a piecewise linear function that outputs the input directly if it is positive. With a multiplication filter $*2$, the remaining layers share the same structure. The decoder constitutes the latter half of the architecture, comprising of five layers. Each compound layer is structured in the following manner: Transposition-based deconvolution is an upsampling technique used to increase the size of an image. To achieve this, the transposed convolution is applied, and the resulting image is concatenated with the corresponding image from the contracted path. This

process creates an image of the same size as the input. In the Conv2D class, the padding parameter can have one of two values: "valid" or "same". When set to "valid", convolution can be applied to reduce the spatial dimensions of the input volume, assuming that it is not empty. When set to "same", convolution can be applied to reduce the spatial dimensions, and the input volume is assumed not to be empty. Including prior information in the process increases the accuracy of the output. In our work, we utilized "same" padding, and the final layer consists of a convolutional layer with a filter size of 1 × 1. The output of the sigmoid activation function is specified on real numbers and ranges between 0 and 1. It can be interpreted as a probability value [26].

b) Discriminator: Within our work, the discriminator: is implemented as a deep convolutional neural network that takes in two images one that is original and another that is generated by the generator. The objective of the discriminator is to categorize each image as either "real" or "fake". Fig. 3 provides a visual representation of the overall structure of the discriminator that was employed in our work.

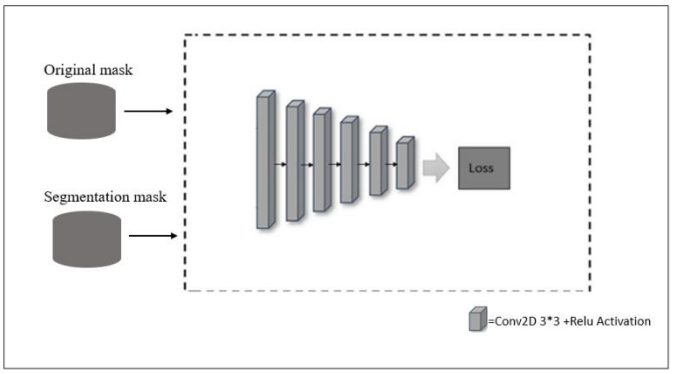

Fig. 3. Structure of the discriminator.

In our work, the discriminator examines two sequences to determine whether they are real or fake by using two images: a original mask and a mask produced by the generator. For the discriminator in our model, we used a total of five layers, starting with the input layer, followed by four Conv2D layers each with a size of 3 × 3. Hidden and dropout layers were incorporated, implementing the Relu activation function and batch normalization. The fifth layer was another Conv2D layer, this time with a size of 3 × 3, utilizing the Relu activation function, and employing max pooling layers. The 2-dimensional arrays resulting from the pooled feature maps are then flattened in the final layer before being passed on as a continuous linear vector to the fully connected layer, which generates the final output [27, 28].

C. Wavelet Transforms

A subfield of mathematics known as the wavelet transform (WT) started to develop gradually in the 1980s [40]. The wavelet transform is another outstanding example of the ideal fusion of pure and applied mathematics, following the fourier transform. It shares the mathematical microscope renown. The wavelet transform has significantly advanced approaches in nonlinear science, engineering technology, signal processing, image processing, and computer applications in recent years. It is one of the most effective and popular time frequency analysis techniques, and it has been utilized extensively in signal and image processing [31, 32]. WT is classified into two types: continuous WT (CWT) and discrete WT (DWT). In general, DWT is more useful than CWT for resolving practical issues. We used the Discrete Wavelet Transform (DWT) to implement our new approach. The DWT can be used to decompose signals into different frequency components and provide a multiresolution representation of the signal [32]. This can be useful in image processing and computer vision applications, where the goal is to extract important features and remove noise from the signals [29, 32]. The data is split into high and low pass bands by the DWT algorithm, with or without information loss. It is built on high and low pass filters that are sub-sampled. Functions over a finite range are defined as DWT. The goal of DWT is to convert data from the time-space domain to the time-frequency domain in order to improve compression efficiency. We have simplified the DWT by describing how it works as follows in Fig. 4:

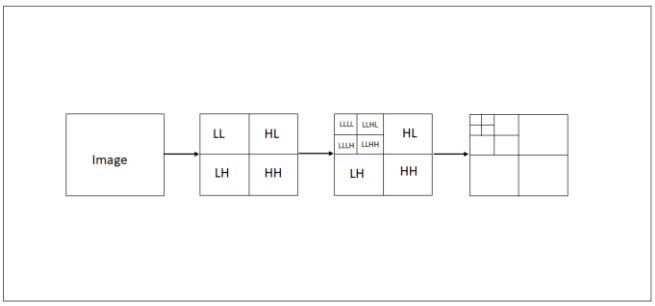

Fig. 4. Block diagram of 3-level wavelet transform.

Low-Low (LL), Low-High (LH), High-Low (HL), and High-High are the names of the four bands that are created (HH). As the LL band still contains information that resembles an image, it is possible to use the same set of wavelet filters that were used on the original image. The image can be divided into sub bands for as many levels as needed (up to the image resolution), however for image compression, only 4 or 5 levels are often used [33]. An image is a two-dimensional (2-D) signal with rows and columns. The wavelet decomposition of an image (rows and columns) can be represented by decomposing one-dimensional signals. The low-frequency components in horizontal and vertical directions (LL), low-frequency components in horizontal and vertical directions (LH), high-frequency components in horizontal and vertical directions (HL), and high-frequency components in horizontal and vertical directions (HH) are obtained following a one-layer wavelet decomposition of an image [33]. The DWT performs two steps of calculation on pairs of data items from the signal after it has been processed, as presented on following Formula 2.

$$\begin{cases} L_i = \frac{1}{\sqrt{2}}(X_{2i} + X_{2i+1}) \\ H_i = \frac{1}{\sqrt{2}}(X_{2i} - X_{2i+1}) \end{cases} \quad (2)$$

An approximation (average) of the two data items is what comes out of the first step, and an approximation (difference) of the two data items is what comes out of the second step.

Where :

- i=0...N/2
- X=the signal data of length N.
- L=the low subband of length N.
- H=the high subband of length N.

The inverse Wavelet transform (IDWT), in contrast, fuses four sub-images to the original image by up-sampling while utilizing the same filters. As shown on Formula 3.

$$\begin{cases} X_{2i} = \frac{1}{\sqrt{2}}(L_i + H_i) \\ X_{2i+1} = \frac{1}{\sqrt{2}}(L_i - H_i) \end{cases} \quad (3)$$

a) Wavelet transforms for generative adversrial network: The GAN-based image segmentation model: that incorporates wavelet transforms is a deep learning architecture that combines two powerful techniques to achieve accurate segmentation results. In this approach, the wavelet coefficients of the input image are used as features to train a GAN model, which generates a segmented image output. The generator network is designed to optimize the segmentation performance by minimizing the difference between the generated output and the ground truth segmentation mask, while the discriminator network objective is to distinguish between the generated segmentation mask and the ground truth. By iteratively training the generator and discriminator, the GAN model can learn to accurately segment complex images [30]. A GAN based on Wavelet coefficients can help improve the stability of image segmentation by using the wavelet coefficients as inputs to the network. The wavelet transform allows the decomposition of an image into different frequency components, which can provide a more robust representation of the image compared to using raw pixel values. By training the GAN on these wavelet coefficients, it can learn to produce stable segmentations even with variations in the input image. This approach can help improve the robustness and generalization ability of the image segmentation model, it's that's what we actually got by implementing our new approach based on a GAN with a wavelet and comparing it to a simple GAN.

IV. Proposed Approach

Using DWT and IDWT in our approach, we were able to develop a reliable segmentation model that could handle variations in input images. Our results indicate that our approach enhanced the robustness and generalizability of the original image segmentation model. Unlike the original generator that used convolutions to transform its 3 channel input image, Fig. 2. We used convolutions to convert the original images into 12-channel and 16-channel data within the generator, along with DWT and IDWT. We then employed convolutions iteratively, replacing max pooling and upsampling with DWT and IDWT, respectively. By adopting DWT, we could retrieve multiscale edge characteristics while reducing the data by a fourth and multiplying the number of channels by four. We adjusted the convolution stride to reduce the data size, unlike the original method with max pooling, which discards partial original data and loses minor edge features. We also substituted DWT for the sampling operations max pooling to enhance the segmentation capabilities of our discriminator. Fig. 5 illustrates the general structure of our generator using the wavelet transform.

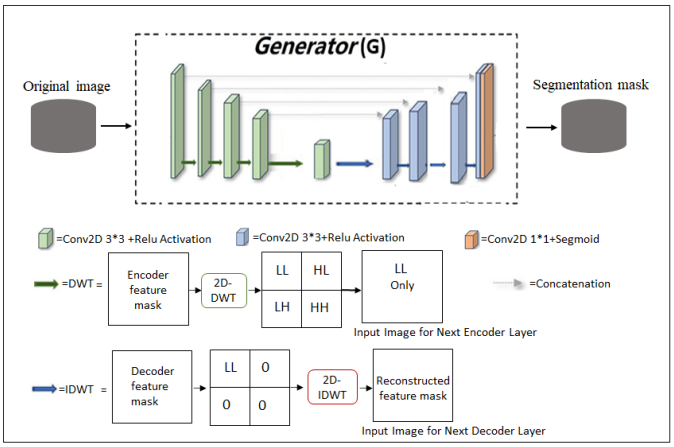

Fig. 5. Generator with wavelet transforms structure.

In our study, we employed two approaches. Firstly, we compared the effectiveness and advanced nature of two models: GAN and GAN with DWT. This evaluation aimed to assess the performance and capabilities of the proposed approach. Secondly, we introduced noise to the testing data and compared the performance of the two models to address stability limitations. This comparison was conducted to analyze the models' ability to handle and mitigate the effects of noise.

A. Evaluation Metrics

In our work, we used three metrics below to assess the effectiveness of our approach.

1) Accuracy [34]: is the ratio of correct predictions to the total number of predictions made by the classifier and can be found using Eq. (4).

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (4)$$

Where:

- TP (True positive): The model predicts an already present object.
- FP (False positive): The model predicts an object that is not actually present.
- FN (False negative): The model is unable to predict an already present object.
- TN (True Negative): The model correctly predicts the negative class.

2) IoU (Intersection over union) [35]: The intersection over union also known as Jaccard is the area of overlap between the predicted mask and the original mask divided by the area of union between the two sets and can be found using Eq. (5).

$$\text{IoU} = \frac{\text{TP}}{\text{TP+FP+FN}} = \frac{Areaof Overlap}{Areaof Union} \quad (5)$$

3) DSC (Dice Score Coefficient) [34]: The Dice Score Coefficient or what is said as the F1-Score is the arithmetic mean of precision and recall and can be used to better assess the segmentation effect and can be found using Eq. (6).

$$\text{DSC} = \frac{2\times\text{P}\times\text{R}}{\text{P+R}} \quad (6)$$

Where:

P is the proportion of samples among the correctly categorized samples that are classed as positive samples.

$$P = \frac{\text{TP}}{TP+FP} \quad (7)$$

R is a measure of how many correctly identified positive samples there are compared to all positive samples.

$$R = \frac{TP}{TP+FN} \quad (8)$$

Simply put, the Dice Coefficient is 2 ∗ the Area of Overlap between the predicted mask and the original mask divided by the total number of pixels in both images.

$$\text{DSC} = \frac{2\times\text{AreaofOverlap}}{\text{Totalnumberofpixels}} \quad (9)$$

B. Datasets

For our experiments, we used two datasets for training and testing:

- The first is the Shenzhen Hospital (SH) dataset [36],

which consists of 662 images, 336 of which are from abnormal individuals displaying various tuberculosis signs, and 326 from healthy individuals. Hospitals in Shenzhen, Guangdong province, China, collected the JPEG formatted X-ray images used in this data set. These segmentation masks for the Shenzhen Hospital X-ray Set were manually created by in structors and students from the National Technological University of Ukraine's Computer Engineering Department of the Faculty of Informatics and Computer Engineering.

- The second, COVID-19 Chest X-ray images and

Lung masks Database [37]. It contains chest X-ray images for COVID-19 positive cases along with Normal and Viral Pneumonia images in cooperation with medical professionals, created by a group of researchers from Qatar University, Doha, Qatar, and the University of Dhaka, Bangladesh, as well as collaborators from Pakistan and Malaysia. The collection includes 2905 chest X-ray (CXR) images with the segmentation mask, 219 of which are from abnormal patients showing COVID-19 positive, 1341 normal, and 1345 images with viral pneumonia.

We scale the images in the training and test sets to 512*512 for training and testing. We use 20% for testing, 10% for validation, and 70% for training. A train-test split was used to divide the data as shown in Table I.

TABLE I. DATASETS

Datasets	Total images	Format	Original Dimension	Training	Testing	Validation
SH	662	JPEG	(512,512,3)	70%	20%	10%
COVID-19	2905	PNG	(512,512,3)			

C. Experimental Setup and Training Parameters

After data enhancement, we trained two GAN models (Traditional GAN and GAN with DWT) for 200 epochs. Experiments were conducted on a server equipped with a GPU P100. The two models we provided for our dataset were trained on 200 epochs with a batch size of 3, and one model's training might take up to 6 hours. The implementation of our work is based on the Keras and Tensorflow libraries. We used the Adam algorithm to optimise the network with a learning rate of 0.0003 and a decay rate of 0.5.

V. Results and Discussion

A. Training Results

We used the two architectures on both the SH dataset and the COVID-19 dataset, and we compared them to evaluate the effectiveness and advanced nature of the proposed approach. The following Fig. 6 and Fig. 7 present the results of the training and validate the Dice score coefficient of our models.

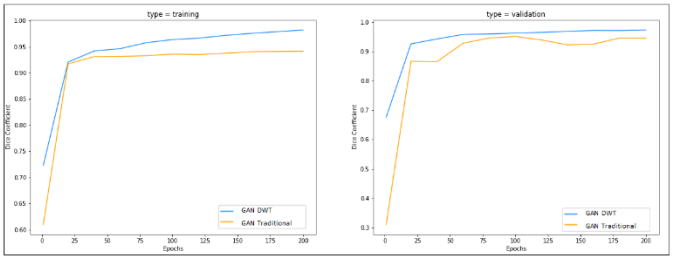

Fig. 6. Training results in the SH dataset.

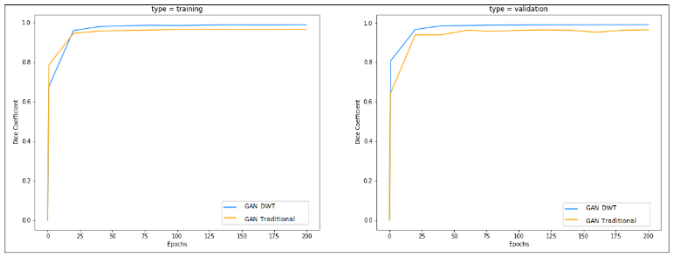

Fig. 7. Training results in the COVID-19 dataset.

It can be seen from the above results. It shows that our algorithm GAN with DWT has better robustness and stability and has given the best performance for the training in two datasets. So, it can be said through our comparison between the two training models in these datasets, a GAN based on Wavelet coefficients can help improve the performance for the training of image segmentation.

B. Stability Results

To see if GAN with DWT prevents the stability limit of a GAN Traditional. We have added multiple ε levels of noise density to the original images in the testing phase. The Table II flow shows the results of testing the dice score coefficient of our models in two datasets at every ε level of noise. To add ε noise into the testing data, we utilized the Gaussian noise method. This approach entailed introducing random values sampled from a Gaussian distribution and adding them to the original data. By employing the Gaussian noise method, we were able to simulate realworld noise sources and introduce random variations characterized by a normal distribution. To apply Gaussian noise to an image, we use the following equation:

$$\mathbf{noisy_{image}} = \mathbf{original_{image}} + \boldsymbol{\varepsilon} \times \mathbf{N(0, sigma^2)} \quad (10)$$

- $\text{noisy}_{\text{image}}$:represents the resulting image after adding Gaussian noise.
- $\text{original}_{\text{image}}$: is the original input image.
- ε : is a scaling factor that controls the intensity of the noise.
- $N(0, \text{sigma}^2)$: represents a random variable drawn from a Gaussian distribution with.

TABLE II. STABILITY ON TESTING PHASE

	SH Dataset		COVID-19 dataset	
ε	GAN DWT	GAN Traditional	GAN DWT	GAN Traditional
0	0.9685	0.9384	0.9906	0.9744
0.10	0.9685	0.0071	0.9904	0.0012
0.20	0.9635	0.0068	0.9904	0.0012
0.30	0.9636	0.0067	0.9900	0.0011

We used the two architectures on both the SH dataset and the COVID-19 dataset, and we compared them to evaluate the effectiveness and advanced nature of the proposed approach. The following Fig. 8 present the results of Stability on testing phase our models.

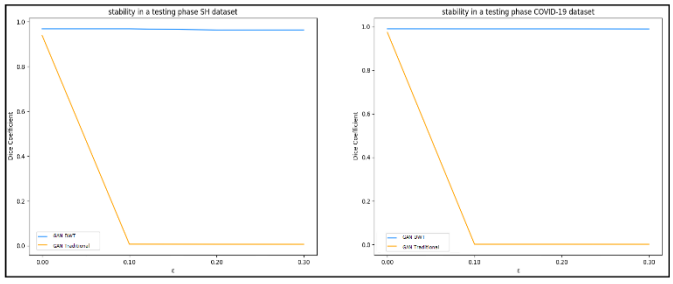

Fig. 8. Stability on testing phase.

According to the results, when adding ε=0.10, 0.20, and 0.30 levels of noise density to the original images in the testing phase. The performance in the dice score coefficient of algorithm GAN with DWT remained stable compared to GAN Traditional. So, it can be said through our comparison between the two models in these datasets, a GAN based on Wavelet coefficients can help to prevent stability limitation in image segmentation of the GAN Traditional. The prediction segmentation results of the two models for datasets SH and COVID-19 for ε levels of noise density added are shown in the Fig. 9 to 16 are as follows:

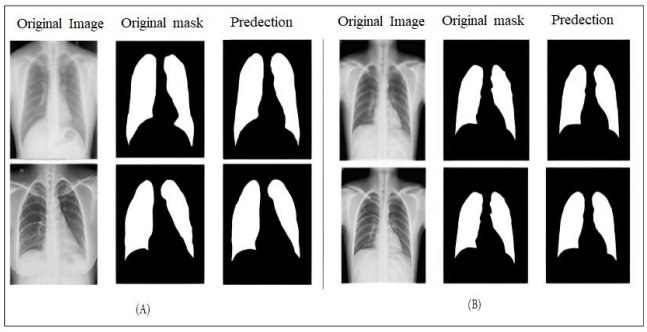

Fig. 9. Results of SH dataset with 0 noise added: (A) GAN with DWT; (B) GAN traditional.

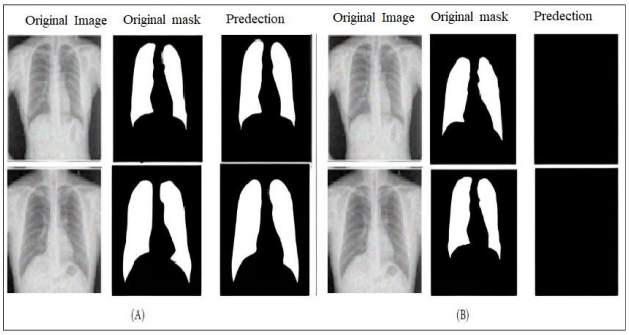

Fig. 10. Results of SH dataset with 0.10 noise added: (A) GAN with DWT; (B) GAN traditional.

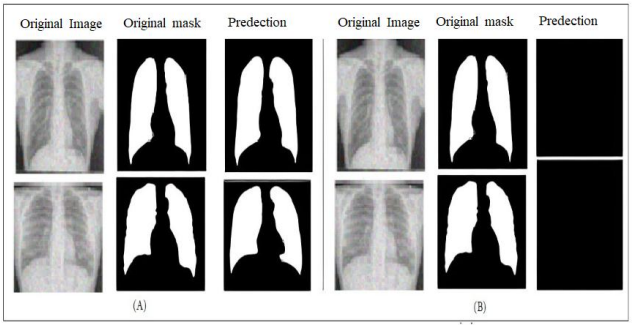

Fig. 11. Results of SH dataset of 0.20 noise added : (A) GAN with DWT; (B) GAN traditional.

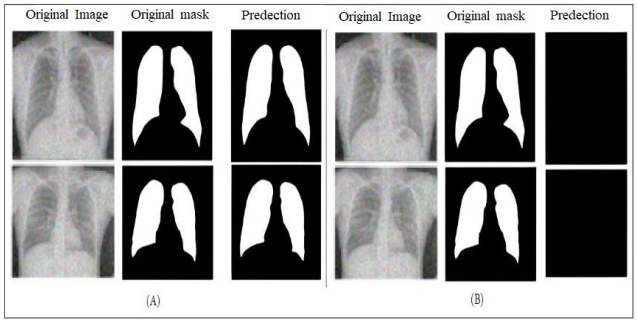

Fig. 12. Results of SH dataset of 0.30 noise added: (A) GAN with DWT; (B) GAN traditional.

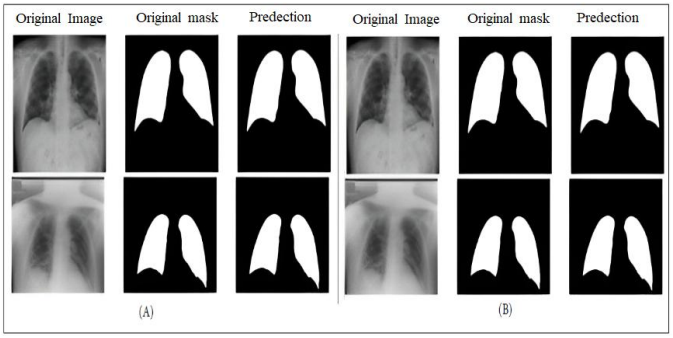

Fig. 13. Results of COVID-19 dataset with 0 noise added: (A) GAN with DWT; (B) GAN traditional.

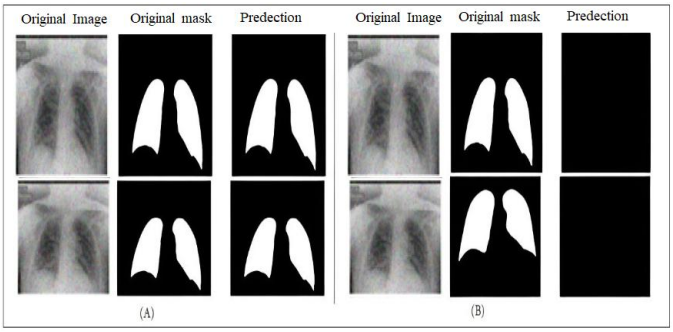

Fig. 14. Results of COVID-19 dataset of 0.10 noise added. (A) GAN with DWT; (B) GAN traditional.

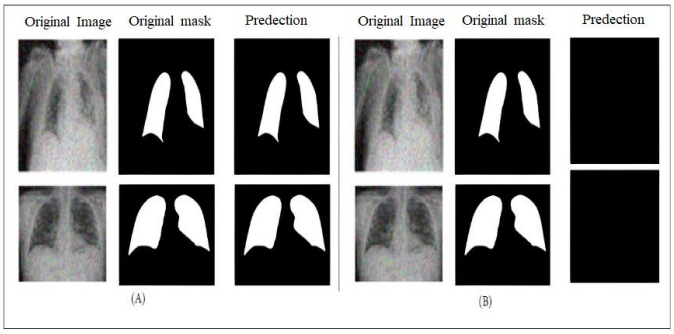

Fig. 15. Results of COVID-19 dataset with 0.20 noise added: (A) GAN with DWT; (B) GAN traditional.

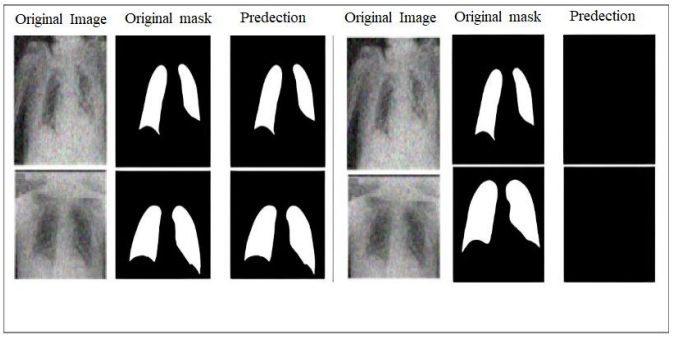

Fig. 16. Results of COVID-19 dataset with 0.30 noise added: (A) GAN with DWT; (B) GAN traditional.

VI. Conclusion

This paper present an innovative segmentation approach that leverages the power of GAN combined with wavelet transforms. The objective was to tackle stability issues commonly encountered in the image segmentation process when using GAN Traditional. By incorporating wavelet transforms into the approach, we aimed to enhance the robustness and reliability of the segmentation results. The wavelet transforms played a crucial role in effectively capturing multi-scale features and spatial details within the images, enabling more accurate segmentation outcomes. Additionally, we recognized that image segmentation with traditional GAN can introduce instability, resulting in artifacts and inaccurate boundaries. To overcome this challenge, our proposed approach offered an alternative approach to pooling that mitigated stability issues, thereby improving the overall quality and consistency of the segmentation results. Our approach results demonstrate the effectiveness of our approach to achieve high segmentation performance compared to existing methods. The integration of GANs, wavelet transforms, and the alternative pooling technique showcased the potential for significant advancements in image segmentation accuracy and stability. The proposed approach not only provided a robust solution to stability challenges but also opened up new avenues for exploring the synergistic benefits of combining GANs, wavelet transforms, and alternative pooling strategies in the image segmentation field.

***Abstract*—The efficacy of Closed-Circuit Television systems (CCTV) in residential areas is often linked to the lack of real-time alerts and rapid response mechanisms. Enabling immediate notifications upon the identification of irregularities or aggressive conduct can greatly enhance the possibility of averting serious incidents, or at the very least, significantly mitigate their impact. The integration of an automated system for anomaly detection and monitoring, augmented by a real-time alert mechanism, is now a critical necessity. The proposed work presents an advanced methodology for real-time detection of accidents and violent activities, incorporating a sophisticated alarm system that not only triggers instant alerts but also captures and stores video frames for detailed post-event analysis. MobileNetV2 is utilized for spatial analysis due to its computational efficiency compared to other Convolutional Neural Networks (CNN) architectures, while Visual Geometry Group 16 (VGG16) enhances model accuracy, especially on large-scale datasets. The integration of Bi-directional Long Short-Term Memory (BiLSTM) strengthens temporal continuity, significantly reducing false alarms. The proposed system aims to improve both safety and security by enabling authorities to intervene timely to incidents. Combining rapid computation with high detection accuracy, the proposed model is ideally suited for real-time deployment across both urban and residential settings.**

Keywords*—Rapid response; anomaly detection; MobileNetV2; VGG16; BiLSTM

I. Introduction

The growth in crime and the need for protection especially in the residential compounds has led to the installation of CCTV systems in the compound; the need to enhance safety and control of incidents has also boosted the usage of CCTV systems in residential areas. One typical use of these devices is for real-time monitoring and recording of events, which enable the authorities to respond to any emergent incidents such as violent criminal incidents or accidents occurring in premises [1]. The major drawback with the conventional method of monitoring is that several instances go unnoticed even with the increasing use of the CCTV in commercial and residential areas [2, 3]. Manual monitoring system is vulnerable to human mistakes, weariness, and slow response times. Besides this, there is feedback delay and lost opportunities for timely intervention and prompt action required in case of occurrence of incidents. The necessity for automatic real-time anomaly detection is highlighted by the growing number of CCTV systems installed in homes and in residential societies [4, 5]. Delays in emergency response often stem from the late detection or lack of reporting of violent incidents and traffic accidents in residential premises. This underscores the need for a lightweight, scalable system designed to rapidly detect abnormal events and automatically raise notifications to designated authorities. Implementing such a system would enhance civilian safety and significantly improve traffic management efficiency.

Traditional methods of monitoring, which rely on human operators, are time-consuming and often inefficient, as operators may not be able to keep up with multiple camera feeds or notice critical details in the video. As human fatigue sets in, the effectiveness of these systems further diminishes. Given the vast volume of data generated by modern CCTV networks, manual monitoring is no longer feasible. As a result, automated tools for tasks such as object recognition, classification, and anomaly detection have been developed using deep learning models like Residual Networks (ResNet) and Densely Connected Networks (DenseNet). While these models offer high accuracy, they face challenges in real-time applications due to their computational demands. It has been noted that both ResNet and DenseNet have high accuracy, though, the computing complexity of these two models are massively different. Due to the tensed structure and millions of parameters ResNet cannot be used effectively in real-time scenario and requires a huge amount of RAM and computation power. While DenseNet employs few parameters, it calls for several convolutions per layer and thus, has high processing intensity. These aspects make such models unsuitable for real-time applications since in real-life one has to decide based on the available information, which in turn is valuable in cases where the amount of resources is limited, but the decision has to be made as soon as possible. Earlier automated techniques frequently failed to give real-time alerts and relied on computationally heavy and expensive frameworks. Furthermore, earlier automated systems such as ResNet and DenseNet are not suited for real-time use because of their high processing cost [6]. One of them is ResNet, which helps in achieving high accuracy, but makes the model computationally

expensive. ResNet layers utilize typical convolutions, which demand many multiplications and adds [7]. The deep architecture with many layers translates to many parameters. For instance, ResNet-50 has approximately 25 million parameters. The extensive depth and numerous operations in ResNet contribute to high latency time and computation complexity when employed for anomaly detection [8, 9]. DenseNet connects each layer to every other layer in a feed-forward manner, ensuring maximum information flow between layers [10]. The dense connectivity increases the complexity of the network. Despite the efficient parameter consumption achieved through feature reuse, DenseNet still requires a substantial number of convolutions. The necessity to retain and process feature maps from all previous layers raises memory and computing requirements [11].

The proposed methodology addresses these challenges by providing a scalable and efficient solution for real-time violence detection in residential areas. This system uses MobileNetV2, a convolutional neural network for spatial feature extraction, considerably minimizes the computational overhead while maintaining the accuracy compared to previous models [12]. It uses depth wise separable convolutions, which decompose a standard convolution into two simpler operations: depth wise convolution and pointwise convolution. Furthermore, the model uses BiLSTM networks for temporal sequence analysis for violence detection. This enables the model to better comprehend the context and course of events, minimizing false predictions thus increasing the accuracy of violence detection. By focusing on temporal coherence, it is ensured that the model not only accurately recognizes violent acts but also distinguishes them from nonviolent activity [13].

Despite advances in anomaly detection, most existing research focuses solely on detecting accidents or unusual events, often overlooking the crucial step of raising alerts for timely intervention in violent incidents. Many studies primarily enhance the performance of models like CNNs for anomaly detection, but they neglect the integration of alert systems for quick response. For example, Trilles et al. [14] discuss the use of AIoT for anomaly detection but focus on detection rather than alerting. Similarly, Chandrakar et al. [15] improve moving object detection and tracking for traffic surveillance, but their work does not address automated response mechanisms. Ullah et al. [16] combine CNNs and BiLSTM networks for real-time anomaly detection, but their focus is on feature extraction and classification, not alerting systems. Kamble et al. [17] propose a smart surveillance system for anomaly detection but exclude alert mechanisms. Wang et al. [18] utilize DenseNet for anomaly detection, but their work also lacks a real-time alerting system. While these studies focus on detection accuracy, they fail to address the critical need for real-time alerts, a limitation that impedes their practical application in real-world security settings.

The prime objective of the proposed work is to design a lightweight model for detecting similar anomalies in residential areas. Besides an alert mechanism is also incorporated, within the model to raise alert to inform concerned authorities for prompt action and also to mitigate the effect of incidents occurring in residential premises. Hence, to meet the needs that require real-time monitoring, automated systems that can promptly generate the alert to enable authorities respond to occurrences are needed.

This paper aims to compare various models and techniques to determine which offers the best performance for anomaly detection in the form of accidents or violence occurring in residential areas. The rest of this paper is structured as follows: the literature review in Section II, the methodology is detailed in Section III, results findings are shown in Section IV, followed by model comparison and analysis discussion in Section V, and the final conclusion with future research directions are provided in Section VI.

II. Literature Review

The domain of video surveillance and security has seen significant advancements with the use of various AI related Machine Learning or Deep learning methodologies. These technologies have enabled the development of sophisticated systems capable of real-time behavior analysis, object detection, anomaly detection, and activity recognition.

Khan et al. [3] proposed a method combining Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) for behavior analysis, achieving 92% accuracy on the UCF101 dataset. While effective for real-time human action recognition, this approach is constrained by the dataset's limited variety and struggles with complex backgrounds. Similarly, Lindemann et al. [19] utilized Long Short-Term Memory (LSTM) networks for activity recognition, achieving 90% accuracy with the KTH dataset. Although LSTMs excel at distinguishing activities, they face challenges with overlapping actions and require large training datasets.

For anomaly detection, Reddy [10] applied VGG16-based neural networks on the Avenue Dataset, achieving a high Area Under the Curve (AUC) of 88%. However, this method struggles with anomaly diversity and distinguishing between minor and major anomalies. Raiyn and Toledo [13] leveraged Generative Adversarial Networks (GANs) for pattern recognition, effectively augmenting training data using the CIFAR-10 dataset. Despite its efficacy, GANs demand extensive training and may produce unrealistic samples.

In facial recognition, Wang et al. [18] employed self-supervised learning models, achieving 95% accuracy on the LFW dataset. These models perform well without labeled data but are sensitive to occlusions and lighting variations. For image classification, Huang et al. [20] introduced DenseNet-based models that demonstrated 96% accuracy on the ImageNet dataset, showcasing high performance. However, they require substantial computational resources and are prone to overfitting on smaller datasets.

In object detection, Piekarski et al. [21] utilized YOLO (You Only Look Once), achieving 83% mean Average Precision (mAP) on the COCO dataset. While efficient for real-time detection, YOLO struggles with small or overlapping objects and shares the computational demands of more complex models. Hassan et al. [22] explored Faster R-CNN for object detection, achieving 84% mAP on the Pascal VOC dataset. This method offers high precision but requires significant computational power and exhibits slower inference times compared to single-shot detectors.

While these methodologies achieve remarkable results, their limitations highlight the need for improved algorithms to handle complex scenarios, reduce computational overhead, and enhance generalizability. Table I summarizes the methodologies, domains, datasets, performances, and limitations discussed in this section.

TABLE I. WORK DONE ON ANOMALY DETECTION

Ref. No.	Methodology Used	Domain	Data Set Used	Performance	Outcome/Limitations
[3]	Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN)	Behavior Analysis	UCF101	92% Accuracy	Real-time human action recognition; limited by dataset variety; performance may degrade with complex backgrounds
[10]	Autoencoders	Anomaly Detection	Avenue Dataset	88% AUC	High accuracy in anomaly detection; limited by anomaly diversity and type; difficulty in distinguishing between minor and major anomalies.
[13]	Generative Adversarial Networks (GANs)	Pattern Recognition	CIFAR-10	Improved data generation	Effective for training data augmentation; requires extensive training; potential for generating unrealistic samples
[18]	Self-Supervised Learning Models	Facial Recognition	LFW	95% accuracy	High accuracy without labeled data; sensitive to occlusions and variations in lighting conditions
[19]	Faster Region-based Convolutional Neural Network (R-CNN)	Object Detection	Pascal VOC	84% mAP	High accuracy for object detection; slower inference time compared to single-shot detectors; requires significant computational resources
[20]	Long Short-Term Memory (LSTM)	Activity Recognition	KTH Dataset	90% accuracy	Accurate activity recognition; struggles with overlapping activities and requires large training dataset
[21]	YOLO (You Only Look Once)	Object Detection	COCO	83% mAP	Enhanced real-time object detection; struggles with small or overlapping objects; requires significant computational resources.
[22]	Residual Network (ResNet)	Image Classification	ImageNet	96% accuracy	Highly accurate image classification; requires large computational resources and training data; potential overfitting on small datasets

III. METHODOLOGY

Using CCTV video data, the suggested traffic anomaly detection system effectively detects and classifies traffic incidents in real-time by utilizing deep learning models. The proposed model for anomaly detection in residential areas aims to detect dual anomalies occurring in residential areas, one is violence detection, and another is accidents occurring in residential areas. The system uses a step-by-step methodology that includes object detection, geographical and temporal feature extraction, and data preprocessing.

To overcome the challenges of computational complexity and real-time anomaly detection the suggested method employs MobileNetV2, a lightweight CNN architecture designed specifically for deep learning on resource constraint devices. Fig. 1 outlines the methodology steps for both whereas Fig. 2 and Fig. 3 depict violence and accident detection model respectively.

For violence detection, an ensemble model of BiLSTM for temporal feature extraction and MobileNetV2 for Spatial feature extraction is used. For accident detection the ensemble model employed is a combination of VGG16 and MobileNetV2. Further for violence detection 800 samples of violence and nonviolence in the form of video are taken for training and testing ensemble model proposed for detection. On the other hand, accident detection dataset consists of 990 files in the form of frames as images taken from public available dataset for accidents occurring in residential areas. To overcome the challenges of computational complexity and real-time anomaly detection the suggested method employs MobileNetV2, a lightweight CNN architecture designed specifically for deep learning on resource constraint devices. Hence, MobileNetV2 as a model has lesser computational complexity than typical CNNs and therefore ideal for anomaly detection workloads involving real time processing. Due to all of this breakdown, MobileNetV2 emerges as a perfect real-time CCTV footage processing option since it cuts all parameters and computation needs greatly. Another advantage of MobileNetV2 architecture is that it is capable of utilizing pre-trained weights which are trained on large datasets such as ImageNet.

As mentioned earlier, anomaly detection of proposed model includes violence detection and accident detection in residential areas. The first type of anomaly being detected is accidents occurring in residential societies specifically in parking areas. The proposed model can obtain the high-level spatial features from the CCTV feed employing these pre-trained weights and the technique will then be able to effectively identify the outliers such as the violent crime or the traffic accident. Furthermore, the lightweight structure of the model also gives it flexibility in its operational environment and enables its deployment in scenarios that have hardware limitations such as in embedded systems and edge computing systems. The system further improves the MobileNetV2 by adding extra convolutional layers that helps in the feature extraction process. After characteristics of space have been extracted, the model is able to group identified patterns into pre-defined categories. For In traffic monitoring the categories could be “Accident” “No Accident” where the two main categories which will be flagged will be “Violence” and “Non-Violence” for residential areas surveillance. This allows the system to monitor CCTV footage by itself and generate real-time alerts when an anomaly is

detected thus ensuring that the authorities act promptly to prevent further damage from happening. Fig. 2 shows the Methodology involve in violence detection for anomaly detection in residential areas.

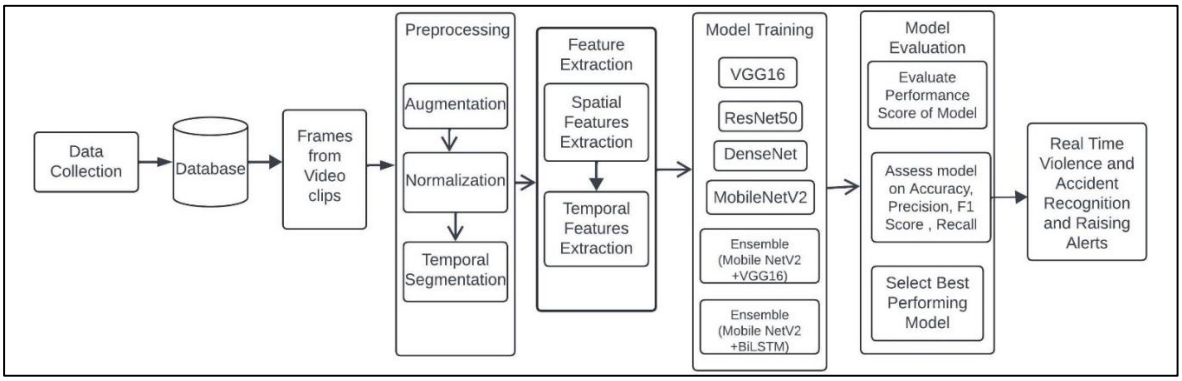

Fig. 1. Methodology of proposed anomaly detection in residential areas.

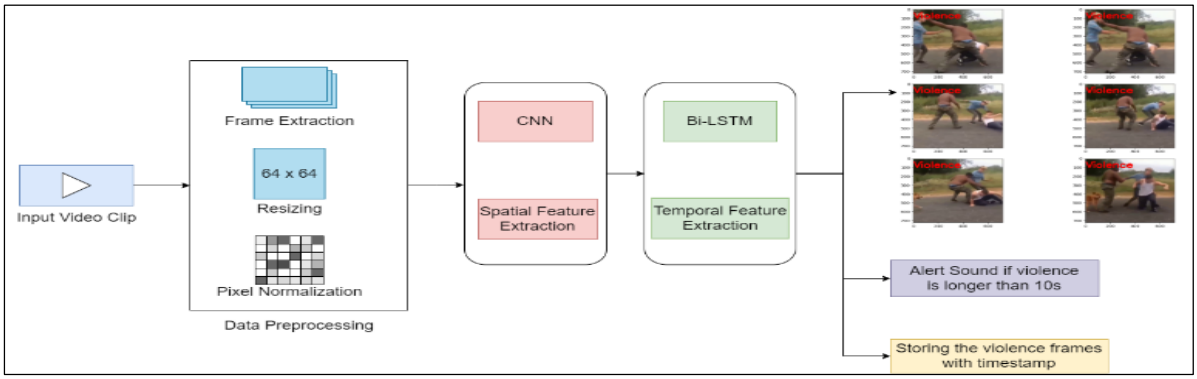

Fig. 2. Architecture of violence detection.

To have a comprehensive analysis the proposed model which focuses on anomaly detection and raising alerts considered dataset in the form of video clips for Violence detection and in the form of Frames from video for Accident detection. This ensures that system will be able to raise alerts on detection of anomaly, irrespective if the input is in the form of image or video. Further for violence detection the system proposes an ensemble model of MobileNetV2 and BiLSTM for spatial and temporal features extraction [23]. However for accident detection the proposed model utilizes ensemble model of MobileNetV2 and VGG16 for features extraction [19]. The architecture for accident detection models is given in the images Fig. 3:

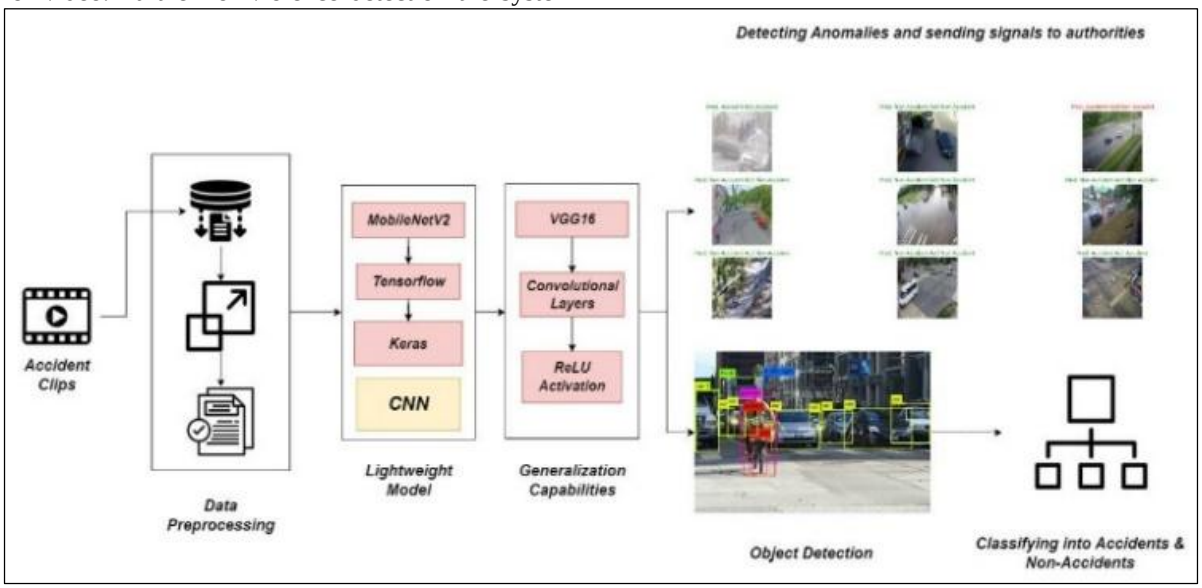

Fig. 3. Architecture of accident detection.

A. Data Preprocessing

The "Real Life Violence Situations Dataset" from Kaggle was used, which contained 800 MP4 files of both violent and non-violent clips with maximum length of 5 seconds. Violent clips were typically real street fight situations with people fighting bare-handed or with items such as sticks and rods. While the Non-Violent clips were various human activities like sports, eating, walking and other ordinary activities. This diversified dataset allowed the model to generalize more reliably and distinguish between violent and nonviolent scenarios. Preprocessing is considered as a critical step in preparing the video data for both model training and testing. By extracting frames at regular intervals, it was ensured that the frames are uniformly distributed across the video. The proposed model extracted 16 frames per video, ensuring it efficiently captures the temporal properties of video content, allowing the model to comprehend the development of activities across time without being overloaded by redundant information.

The first step to process videos into one scene is to extricate frames from the video stream. This is going to be necessary for the later steps of temporal analysis. The first step in the pre-processing of an input image is swapping the color channels, i.e., RGB channel rearranging to make the image compatible with Keras. The next step is the resizing of the input image to a fixed size, i.e., 224 × 224, without taking the aspect ratio of the image into consideration. In the last step in the pre-processing of an image, mean subtraction is applied to the image, where the mean is calculated for all pixel values in the image and the mean is subtracted from the pixel values. The reason behind this step is to make a standardization to which the other parameters such as weights and biases can refer to. The pre-processing of an image makes the image ready to be provided to a CNN model. In the testing phase of this research, the same set of techniques was applied. The testing of the CNN model was performed on videos, so while testing, the frames of the videos were looped, and all the frames were subjected to the same pre-processing as the training images.

Another technique used in the pre-processing phase of training is data augmentation. This technique is very popular while working with images, as it helps create more data, which helps the computation models to be able to generalize better. In this research, multiple data augmentation techniques were used, i.e., shift, rotation, shear, Flip, etc. Data augmentation was not applicable in the testing phase, as there was no need to multiply data and generate more. Raw frames from the video have various shapes each sample provides a set of raw frames with varying size, so before feeding those frames to deep learning models, the frames are resized to have the fixed, standard shape. The pixel values for the frames which have been retrieved are then scaled to fit into an agent ratio which is mostly a range from 0 to 1. This in turn means that consistencies of the intensity values are preserved, enhancing the performance of subsequent CNN based models.

B. Lightweight Model

MobileNetV2 model is used to get spatial features for the frames that were normalized from the frames extracted from the videos. MobileNetV2 is a light CNN model with high accuracy so it used in real-time applications such as traffic anomaly detection and violence recognition in residential areas. MobileNetV2's architecture is the depth wise separable convolution that reduces the amount of computation required while maintaining the extraction of features accurate. It captures immobile objects in a scene such as cars, traffic flow and other elements of the scene.

Then there is Batch Normalization followed by ReLU as the activation functions after the convolutional layers. This guarantees the model's non-linearities and promotes quicker training convergence: This guarantees the model's non-linearities and promotes quicker training convergence:

$$z = ReLU\ (BN\ Wconv * X)$$

Where Wconv are convolution weights, X is input, and BN refers to Batch Normalization.

C. Generalization using (VGG16)

To measure the temporal features; the features that are spatial are first extracted using mobile NetV2; then the VGG16 is used. They work to provide a perspective of the deeper convolutional layers of the VGG16, to identify how objects within frames of a video move. Dependencies between Space and Time: The weights provided by the VGG16 architecture help in model's ability to detect intricate temporal patterns, which are crucial for detecting such anomalies as mishaps or erratic movements.

$$ht = \sigma\ (WhhHt\text{-}1 + WxhXt)$$

Where Whh are weights for temporal connections, and Wxh captures spatial-temporal dependencies as shown in Fig. 4.

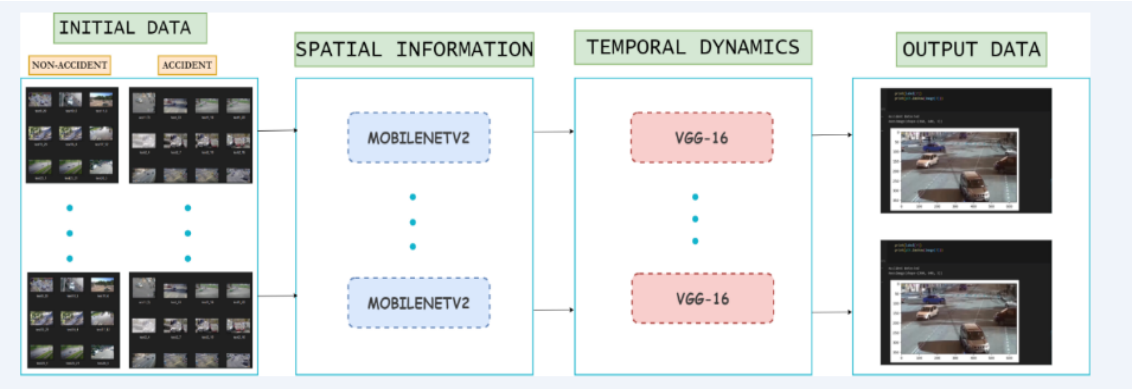

Fig. 4. Extracting temporal and spatial features for anomaly detection.

D. Object Identification

A variety of CNN based object detection algorithms detect objects in each video frame such as vehicles, pedestrians, and others traffic elements. The objects detected have a rectangular frame placed around and the movement of these objects is recorded over time. For this purpose, movement of the observed objects is compared between frames to identify any odd, unexpected behavior which could consist of crash occurrences, traffic congestions, or irregular driving patterns.

1) Accidents Classification and Anomaly Detection: Based on the space and time information gathered all the events depicted in the video as either accidents or non-accidents. In this case, the CNN and the Bi-LSTM models are very important in the identification of traffic pattern such as sudden halts, collisions or erratic movements indicating an accident [20]. The system monitors the occurrence of any irregularities in the flow and activity of the traffic on the road. For this, the technology identifies features that are likely to be abnormal such as times when the car suddenly stops, unpredictably veers or has a crash. Once an irregularity or accident has occurred, a real time alert is made to facilitate the correction of the problem. This may lead to an alert to the right authorities to ensure the situation does not happen again hence ensuring that it act as a stop gap measure.

2) Violence Detection and Time-Based Alerts: For events like violence or aggressive behavior (as depicted in the violence detection figure), if such events last longer than 10 seconds, the system triggers an alert sound to draw attention. The violence frames, along with timestamps, are stored for further analysis or evidence, which could be used in legal or administrative actions.

3) Anomaly Detection in violence cases Temporal features: While extraction of spatial characteristics is helpful in extracting any inconsistencies in a certain frame of a CCTV film, the temporal characteristics of the frames are as important as the former in order to detect anomalies. That is; it might take several frames to gather adequate information in traffic accident detection to help determine that an accident had occurred. As similarly with this, in distinguishing between an aggressiveness and mere touching or coming contact within violent activity detection, the events over time is important.

This difficulty can be addressed by the suggested system Bi-directional Long Short-Term Memory (BiLSTM) networks that are made especially to deal with sequential data. With the help of BiLSTM networks, the model is able to look at temporal sequences in forward as well as in the backward direction thereby adding to the understanding of context and flow of such sequences [19].

IV. Results

A comprehensive evaluation strategy was used to validate the effectiveness of the proposed model for detecting violent activities in residential areas. This involved training and testing the model on the "Real Life Violence Situations Dataset" from Kaggle. An 80-20 ratio was used to divide the dataset into training and testing sets. The testing set was used to assess the model's performance after it had been trained using the training set. The confusion matrix which can be seen in Fig. 5 was used to validate the model's efficiency with a primary focus on accuracy and recall in the Table II.

TABLE II. Model Evaluation Metrics for Violence Detection

Classes	Precision	Recall	F1 Score
Non Violent	0.98	0.89	0.94
Violent	0.94	0.99	0.91

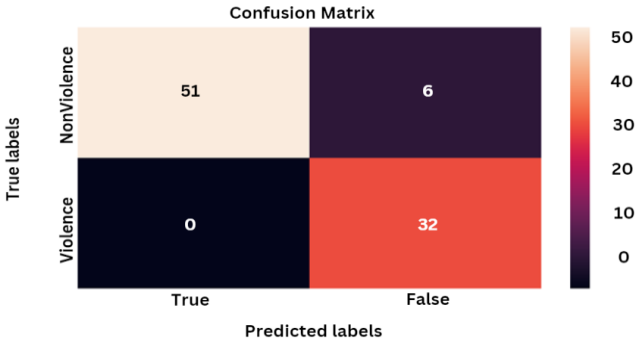

Fig. 5. Confusion matrix for violence classification.

Performance Parameters obtained from ensemble model of MobileNetV2 and VGG16 for accident classification is shown in Table III and the confusion matrix for calculation of performance for the same is shown in Fig. 6.

TABLE III. Model Evaluation Metrics for Accident Detection

Classes	Accuracy	Precision	Recall	F1Score
Non-Accident	0.96	0.96	0.84	0.93
Accident	0.96	0.95	0.91	0.89

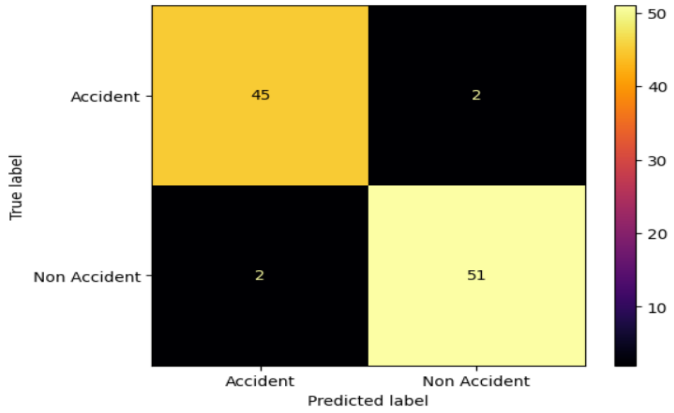

Fig. 6. Confusion matrix for accident classification.

The accuracy depicts the overall accuracy of the model in classifying the video clips correctly. A plot of Loss and Accuracy of the ensemble model for anomaly detection is shown in Table IV. The model's accuracy improved consistently throughout epochs, and the loss consistently decreased with the number of epochs.

TABLE IV. ACCURACY AND LOSS OF THE PROPOSED MODEL OVER EPOCHS

Epoch	Loss	Accuracy	Validation Accuracy
1	0.62	0.55	0.50
3	0.50	0.70	0.62
5	0.40	0.82	0.69
7	0.32	0.89	0.75
9	0.25	0.92	0.80
11	0.15	0.96	0.82
13	0.10	0.96	0.85
15	0.06	0.98	0.86
17	0.04	0.98	0.88
19	0.02	0.99	0.89

For real-time validation, the model was combined with OpenCV and evaluated on live video feeds to imitate real-world settings. The cv2 library was implemented to analyze the video frames. The model demonstrated high accuracy and low loss values for violent/non-violent action recognition, making it suitable for real-time applications.

V. DISCUSSION

The proposed model demonstrates exceptional performance in identifying violent and non-violent activities, achieving an overall test accuracy of 93.25%. Its Recall score of 0.99 for the violent class underscores its effectiveness in identifying nearly all instances of violence, a critical feature for anomaly detection systems in safety-critical environments. This aligns with prior research emphasizing the importance of high recall for detecting relevant instances of violence [22,23].

The model was further validated in real-time using OpenCV, where the cv2 library facilitated frame-by-frame video analysis to simulate real-world scenarios. This integration tested the model's ability to detect violent behavior in live settings, ensuring the classification process remained accurate and prompt. The high accuracy, low loss values, and strong classification metrics achieved in real-time settings validate its practical applicability and reliability for violence/non-violence recognition, as supported by prior findings in similar validation studies [24].

Fig. 7 compares the ROC curves of three models: BiLSTM, MobileNetV2, and the ensemble approach. The BiLSTM model, with an AUC of 0.88, effectively captures temporal features but falls short in spatial feature representation, limiting its ability to distinguish classes [25]. In contrast, MobileNetV2, which specializes in spatial feature extraction, achieves a superior AUC of 0.95. The ensemble model leverages the strengths of both, achieving a near-optimal AUC of 0.98. This performance reflects the ensemble model's ability to comprehensively extract temporal and spatial features, ensuring high classification accuracy across diverse scenarios[26].

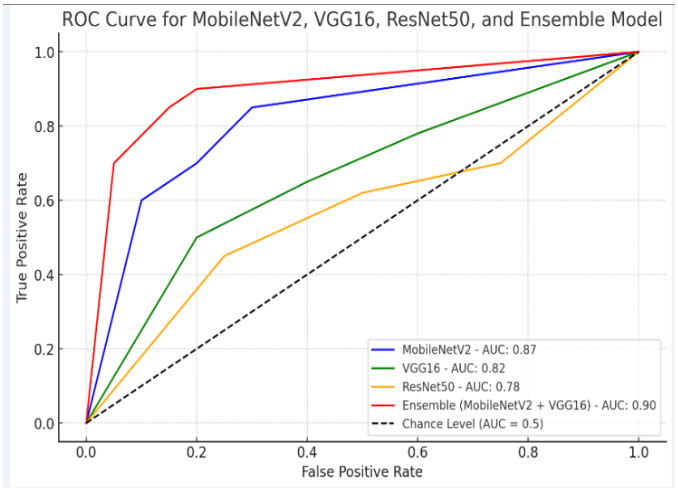

Fig. 7. ROC Curve for comparison of different models.

The comparative analysis in Table V highlights the superiority of the proposed model over existing solutions. Competing models, such as Faster R-CNN with RegNet+, EfficientNetB3 with Cascaded Convolution, and CNN-BiLSTM autoencoder, exhibit limitations, including reliance on low-quality datasets, inability to handle edge cases, and lack of real-time alert mechanisms. The proposed model surpasses these challenges by achieving 96% accuracy and raising alerts within 10 seconds of anomaly detection. Furthermore, its reliance on publicly available datasets enhances its adaptability, addressing limitations seen in prior research.

The dataset was stratified into an 80% training set and a 20% test set to ensure robust model training and unbiased performance evaluation. The confusion matrix reveals an accuracy of 96% and a recall score of 0.90 for accident detection, underscoring the model's efficiency in identifying activities associated with accidents. By raising alerts post-detection, the model further enhances its utility for real-time safety applications.

Thus, the proposed ensemble model effectively combines temporal and spatial feature extraction capabilities, achieving state-of-the-art performance in violence and accident detection. Its high recall and accuracy metrics, superior ROC performance Fig. 7, and unique real-time alert mechanism position it as a robust solution for enhancing community safety. Comparative insights from Table V affirm its versatility, addressing the shortcomings of existing systems and establishing it as a critical tool for anomaly detection in real-world settings. These findings align with prior research, validating its potential as a scalable and reliable anomaly detection system.

TABLE VI. COMPARATIVE ANALYSIS OF PROPOSED MODEL WITH OTHERS

Ref No.	*Dataset Used*	*Model Used*	*Data Balancing*	*Alerts Raised*	*Accuracy (In %)*	*Limitation*
[27]	Animated Customized dataset for Violence detection	Faster RCNN, RegNet+	Yes- Adam Optimzer	No	80.8	Dataset quality can be improved as it consists of animation videos. Also inference time can be further reduced
[28]	MVTec-AD, Railway Track Foreign Object Detection (TFOD)	Cascaded Convolution Self Attention Efficient NetB3	NA	No	99	Anomaly detected on Railway tracks but the model do not work well on edge points.
[29]	unique RGB+D dataset for Bank ATM anomaly detection	CNN-BiLSTM autoencoder framework	No	No	91	Used for Anomaly detection of ATM without raising alerts.
Proposed Model	Violence Recognition from Videos- Kaggle and Accident detection from CCTV footage Dataset .	Ensemble lightweight model for Violence and accident detection	Yes- SMOTE	Raise alerts after 10 sec of anomaly detection	96	Besides detection of anomaly as accidents or violence activity in residential areas, post detection alerts are also raised. Moreover, datasets used are those available in public domain so effective in varied situations.

VI. CONCLUSION

The use of AI-driven machine learning and deep learning techniques has significantly advanced the field of video surveillance and security. These technologies enable near real-time behavior analysis, object recognition, anomaly detection, and activity recognition, enhancing overall system efficiency. The proposed methodology focuses on detecting accidents and violent activities, generating and storing frames for post-event analysis, and raising real-time alerts for timely intervention. This dual functionality—anomaly detection and alert generation—addresses the critical need for proactive safety measures, particularly in residential areas where CCTV systems are primarily installed to detect and respond to emergencies. Unlike many existing anomaly detection models, which are computationally expensive, lack real-time responsiveness, and fail to trigger alerts, the proposed system is lightweight, efficient, and practical for real-world applications. By integrating an alert mechanism, the model ensures that authorities are notified promptly, reducing the impact of undesirable activities and improving community safety.

Future work will focus on improving the system to handle more complex situations, like detecting early signs of violence or predicting accidents before they happen. The model will also be improved to work better in different environments, such as low lighting or when objects are blocking the view. Additionally, using more types of data, like combining video with sound or sensor information, could make the system better at detecting unusual activities. Lastly, the system will be optimized for use on smaller devices, ensuring it can run quickly and efficiently without needing too much computing power.

***Abstract*—To achieve automatic recognition and understanding of image sentiment analysis, the study proposes an image sentiment prediction network based on multi-excitation fusion. This network simultaneously handles multiple excitations, such as color, object, and face, and is designed to predict the sentiment associated with an image. A visual emotion inference network based on scene-object association is proposed using the association reasoning method to describe the emotional associations between different objects. The multi-excitation fusion image sentiment prediction network achieved the highest accuracy of 75.6% when the loss weight was 1.0. The network had the highest accuracy of 76.5% when the object frame data was 10. The average accuracy of the visual sentiment inference network based on scene-object association was 91.8%, which was an improvement of about 3.7% compared to the image sentiment association analysis model. The outcomes revealed that the multi-stimulus fusion method performed better in the image emotion prediction task. The visual emotion inference network based on scene-object association can recognize objects and scenes in images more accurately, and both the scene-based attention mechanism and the masking operation can improve the network performance. This research provides a more effective approach to the field of image sentiment analysis and helps to improve the computer's ability to recognize and understand emotional expressions.**

***Keywords*—Sentiment analysis; multi-excitation fusion; image emotion prediction; associative reasoning; attention mechanism**

I. Introduction

Due to the quick advancement of computer technology, the Internet is now a necessary component of daily life. People can watch videos, browse pictures online, and even communicate with friends thousands of miles away in real time [1]. However, with the popularization of the Internet, many problems have emerged. Online images play an important role in human life, but they also have some negative impacts, such as the pornification of online images, violence and false information [2-3]. In order to solve these problems, sentiment analysis of web images is needed, i.e., computer algorithms are used to determine the emotional attributes of web images. Sentiment representation is a key concept in image sentiment analysis, which refers to the use of a certain way to represent and describe the emotions or feelings expressed in an image, so that computers can understand and process the emotional information of the image. Common sentiment representation methods include extracting sentiment words from textual descriptions of images (such as titles, descriptions, labels, etc.) and calculating the sentiment polarity of the words using sentiment dictionaries (such as SentiWordNet). Encode emotional information using low-level visual features of images, such as local areas, colors, textures, etc., and learn a vectorized emotional representation by integrating visual and textual features of the image with conceptual features in the emotional ontology [4]. However, traditional sentiment analysis methods often rely on hand-designed feature extraction, such as color, shape, and texture, etc., which often fail to comprehensively reflect the emotional attributes of web images. The topic of web image emotion (IE) analysis has witnessed significant advancements in machine learning (ML) methods in recent times. ML-based sentiment analysis uses a large amount of text data with labeled sentiment to train models to automatically analyze the sentiment tendencies in the text, thus helping people to better understand and process large-scale sentiment information [5].

Halim et al. proposed a framework for recognizing sentiment in short texts using email text, employing an ML approach and six sentiment classifications. Experimental results indicated that the framework had better performance in sentiment recognition with an average accuracy of 83% [6]. Britzolakis' group presented a tool for sentiment analysis based on lexicon and ML algorithms and explored alternative implementations and open topics for political sentiment analysis on Twitter. The results demonstrated that the methodology could help readers to understand the field and identify the best options to conduct related work and research [7]. Alasmari et al. utilized ML methods for sentiment analysis of Arabic tweets from Saudi Arabian tourism industry using decision trees, random forests, logistic regression, and Naïve Bayes for three categories of classification. The results showed that logistic regression and Naive Bayes performed the best when dealing with Arabic morphology, achieving 86% accuracy [8]. Chirgaiya et al. used natural language processing techniques to train a classifier model for sentiment classification of movie reviews through feature extraction and ranking. The method's 97.68% accuracy in sentiment classification, as demonstrated by the testing data, was a supplement to the web's current movie rating systems [9]. Using a dataset of Facebook user book reviews and taking demographic data into account, Kumar's group investigated the effects of age and gender on sentiment analysis. Utilizing ML techniques for sentiment analysis, the study produced fresh findings about the effects of sentiment analysis on age and gender [10].

Associative inference refers to finding relationships and correlations between various variables in data, and feature

extraction is the selection and transformation of important features from raw data for subsequent analysis. Liewlom's group proposed a new inference framework for determining association rules without defining values for measure, minimum support, and minimum confidence. The study validated the feasibility and effectiveness of the approach through a tree of association rules found from a cancer dataset that reflected the sequential relationships of 15 items associated with the dataset [11]. Li et al. suggested a pedestrian recognition framework based on attribute mining and inference, which improved the performance of pedestrian re-recognition by designing a spatial channel attention module and utilizing the semantic inference and message passing functions of graph convolutional networks. Experimental results indicated that the method achieved 87.03% accuracy on the Market-1501 dataset [12]. The wear monitoring system that Lin' et al. proposed a rapid Fourier transform to extract features from vibration and auditory signals by using a variety of sensors and feature fusion techniques. Through the use of cross-validation, the system developed with a hierarchical neural network structure and sensor feature fusion demonstrated its efficacy and performance under various tightening torque values and spindle speeds [13]. To achieve automatic clustering processing of grid intrusion features, Zhang et al. proposed a fuzzy c-mean clustering based method for extracting intrusion features. This was combined with a fuzzy association rule scheduling method to reconstruct the structure of intrusion statistical feature sequences, and a global optimization method to achieve automatic clustering processing. The approach could enhance the power grid's resistance to attacks and enable autonomous clustering of intrusion feature extraction, according to the results [14]. Guo et al. suggested a new method to extract feature points based on topological information, which achieves feature point detection of point neighborhood topology by introducing an improved local binary pattern to process the original point cloud. Experiments demonstrated that the method performed robustly in extracting point cloud shape features [15].

In summary, many researchers have conducted various designs and studies for sentiment analysis and associative feature extraction. However, these methods and models still have limitations. For example, emotional representation methods are relatively single and rely on manually designed feature extraction, making it difficult to fully reflect the emotional attributes of images. There are many applications in sentiment analysis, and some algorithms need to improve their accuracy when dealing with complex emotions and cross-cultural scenarios. In addition, sentiment analysis research in different fields and languages is relatively scattered, lacking universality and comparability. To improve the effectiveness of sentiment analysis techniques, the study proposes an approach to Web IE analysis that combines ML and associative reasoning concepts.

The study is divided into five sections, with Section II proposing sentiment analysis methods. Section III is the validation and application analysis of the method. Section III is a discussion of research methods, application analysis, etc. Finally, Section V concludes the paper.

II. Methods and Materials

A. IEPN-MIF-Based Method

The Internet is growing quickly, and as a result, a lot of photos and videos with rich emotional content are shared online. Aiming at the problem of image sentiment analysis, the study proposes an IE prediction network based on multi-excitation perception (IEPN-MIF), as shown in Fig. 1. The network consists of three stages, including incentive selection, feature extraction, and emotion prediction. In the incentive selection stage, using object detection and face detection methods in deep learning, specific emotional incentives are accurately selected, which cover aspects such as color I_g, objects I_s, and faces I_e. Then, the feature extraction stage is entered, which synchronously extracts different emotional features from different stimuli. Finally, in the emotion prediction stage, the hierarchical cross-entropy (CE) loss function is used to optimize the emotion prediction results, while fully combining the inherent hierarchical structure of emotions to distinguish between simple negative samples and difficult negative samples. The research also innovatively proposes a new hierarchical CE loss function to further optimize the performance of the whole network and achieve more accurate and efficient IE prediction based on multi-stimulus perception [16].

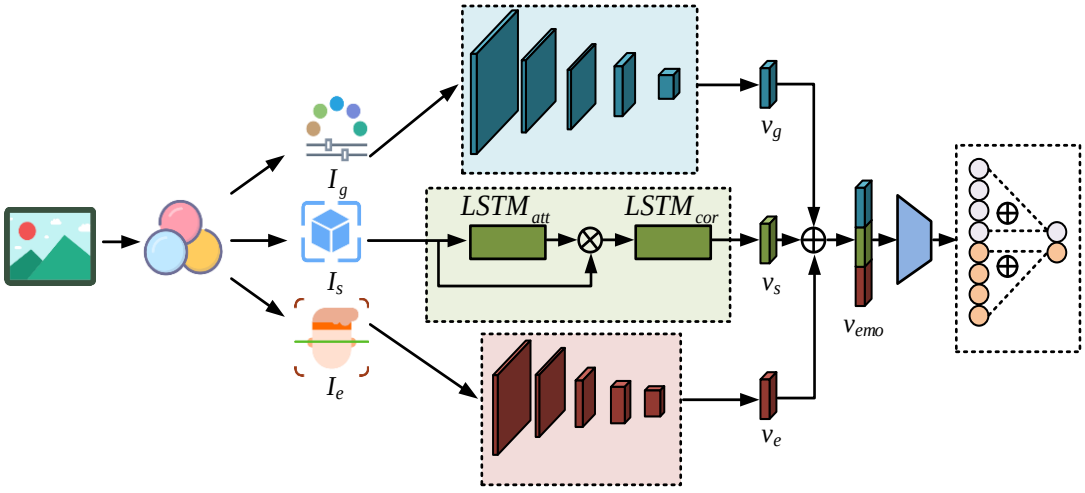

Fig. 1. Image emotion prediction network based on multi-incentive fusion.

In emotion feature extraction, the study extracts color features and other global features in images by constructing a global network. To balance computational efficiency and accuracy, the global network makes use of the ResNet-50 network, which has five convolutional layers and a global average pooling layer [17]. The features output from the last convolutional layer are shown in Eq. (1).

$$F_g = FCN_{res}(I_g) \tag{1}$$

In Eq. (1), the final convolutional layer outputs features as F_g and the full convolutional network as FCN_{res}. The final extracted global features are shown in Eq. (2).

$$G_g = G_{avg}(F_g) \tag{2}$$

In Eq. (2), the global feature is G_g and the fully convolved global average pooling layer is G_{avg}. To better mine the correlation between different objects, the object features are considered as a sequence data and a long short-term memory (LSTM) has been used to carve out this dependency [18]. The study also designed an emotion-specific semantic network for mining semantic associations between different objects and thus inferring IEs. The network consists of two LSTM layers, i.e., attention and association LSTM. The computational procedure of Attention LSTM is shown in Eq. (3).

$$h_t^{att} = LSTM_{att}(x_t^{att}, h_{t-1}^{att}) \tag{3}$$

In Eq. (3), the output of the attention LSTM is h_t^{att} and the input vector is x_t^{att}. The output of the attention LSTM at time t is calculated by the attention LSTM module based on the input vector at time t and the output of the previous time (t-1). The attention output at the current time depends on the current input and the attention state of the previous time. The weight $a_{i,t}$ of the attention module is calculated as shown in Eq. (4).

$$a_{i,t} = w_a \tanh(W_i f_i + W_h h_t^{att}) \tag{4}$$

In Eq. (4), the module learnable parameters are w_a, W_i, and W_h, respectively, and the object features are f_i. The weighted object features are calculated as shown in Eq. (5).

$$f_{att} = \sum_{i=1}^{N} a_{i,t} f_i \tag{5}$$

The weighted object feature f_{att} in Eq. (5) is sent to the associative LSTM. The output vector h_t^{cor} in the associative LSTM is computed as shown in Eq. (6).

$$h_t^{cor} = LSTM_{cor}(x_t^{cor}, h_{t-1}^{cor}) \tag{6}$$

In Eq. (6), the association LSTM input vector is x_t^{cor}, and the output vector of the previous moment is h_{t-1}^{cor}. By feeding object excitations into the attention LSTM and association LSTM separately, the possible redundancy of information between multiple objects can be reduced and the semantic correlations between different objects can be mined [19]. Therefore, the output of the semantic network can be regarded as the higher-level semantic features of the object excitations, as shown in Eq. (7).

$$G_s = h_T^{cor} \tag{7}$$

In Eq. (7), the last moment of LSTM is T, and the semantic features extracted from the object excitation are G_s. In order to extract the face expression features, the study adopts ResNet-18 as the base network to construct the expression network, and the expression features are calculated G_e if shown in Eq. (8).

$$G_e = \begin{cases} G_{avg1}(FCN_{res1}(I_e)), \exists I_e \\ 0, \quad others \end{cases} \tag{8}$$

In Eq. (8), the fully connected layer (FCL) of the expression network is FCN_{res1}, and the average pooling layer is G_{avg1}. Under the given expression category, the expression features are calculated by the ResNet-18 network layer, while in other cases the feature values are 0. The study analyzes three typical emotion incentives (color, object, and face), and designs a dedicated network to extract their emotion features (global features, semantic features, and expression features). These features are independent and complementary to each other, and together determine the final emotion classification result. In order to perform sentiment prediction, these several sentiment features will be spliced, and the final generated sentiment features are shown in Eq. (9).

$$G_{emo} = Concate[G_g, G_s, G_e] \tag{9}$$

In Eq. (9), the splicing operation is $Concate$. The final generated sentiment feature G_{emo} will be input into the subsequent sentiment classifier. In traditional categorization tasks, CE loss is widely used and has made breakthroughs in several tasks. However, sentiment categories are not completely independent from each other, but there is an inherent hierarchical relationship. An eight-category psychological model—which comprises the emotion categories of enthusiasm, amazement, contentment, anger, disgust, sadness, and fear—will serve as the foundation for the dataset that the study will construct. Positive and negative emotions are the emotional polarities of the emotion categories. In the eight-category emotion model, the first four emotions are positive emotions and the last four belong to negative emotions. The eight-category emotion model is shown in Fig. 2.

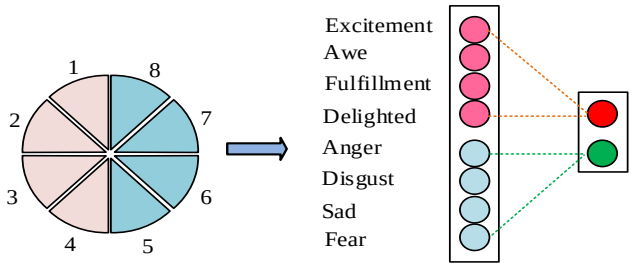

Fig. 2. Eight classification of the emotion model.

After cascading the sentiment features, they are sent to the classifier and activation function respectively to perform operations to obtain the sentiment vector as shown in Eq. (10).

$$p_{emo}(i|G_{emo},W)=\frac{\exp(w_i G_{emo})}{\sum_{i=1}^{C}\exp(w_i G_{emo})} \quad (10)$$

In Eq. (10), the sentiment vector is p_{emo}, and the sentiment type is C. The learnable parameter in the sentiment classifier is W, and its constituent elements are w_i. The traditional CE loss cannot distinguish between positive samples and negative samples, so this study proposes the auxiliary polarity loss and the hierarchical CE loss to solve this problem. Among them, the auxiliary polarity loss is used to distinguish between simple negative samples and difficult negative samples, while the stratified CE loss combines sentiment loss and polarity loss to obtain more accurate sentiment prediction. The final obtained stratified CE loss L_{CE} is shown in Eq. (11).

$$L_{CE}=L_{emo}+\lambda L_{pol} \quad (11)$$

In Eq. (11), the affective loss is L_{emo}, the polarity loss is L_{pol}, and the equilibrium setting hyperparameter is λ.

B. *Image Emotion Classification Based on Associative Reasoning*

When studying IE, one must focus on the scenes and objects it contains and use reasoning to understand IE in the context of how the two interact. The study suggests a scene object-interrupted visual emotion reasoning network (SOLVER) based on this, as seen in Fig. 3.

In the operating mechanism of the SOLVER network, it first uses a faster region convolutional neural network (Faster R-CNN) object detector to extract semantic concepts and visual features of various objects, and then filters and transforms these extracted features. On this basis, sentiment maps are constructed based on object features to represent emotional associations between different objects. Then, a graph neural network (GNN) is used for inference, connecting different object nodes by sentiment edges to generate object features enriched with emotions [20]. In addition, the study also designed a scene-object fusion module, which utilizes the attention mechanism (AM) to fuse object features based on scene features, while constructing the mutual relationship between the scene and objects. In the specific operation, the Faster R-CNN object detector is used to select a set of target candidate regions, pre-trained on the dataset, and finally output attribute categories. Through these steps, the SOLVER network is able to complete its complex operations and feature extraction process. As illustrated in Fig. 4, the sentiment graph is constructed by outputting the ten objects with the highest confidence ranking as its nodes. Each sentiment image is represented by a sequence of object semantic concepts, corresponding confidence scores, and VFs following Faster R-CNN.

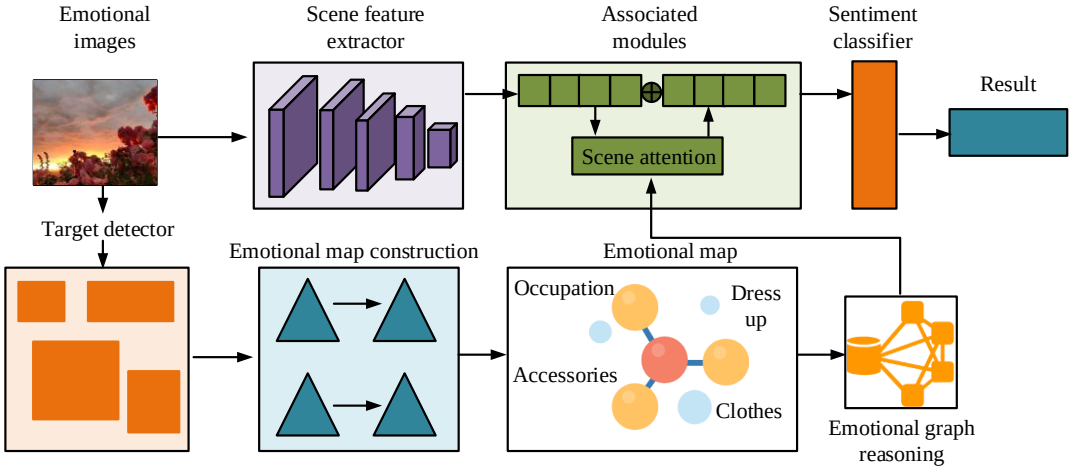

Fig. 3. SOLVER network.

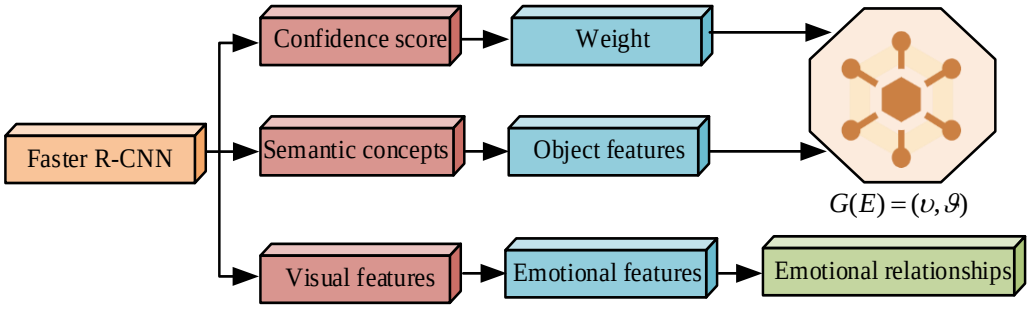

Fig. 4. The construction of emotion map.

The edges of the emotion graph are constructed by VFs and the nodes of the emotion graph are constructed by semantic features, and the emotion VF vector v_i^e is constructed as shown in Eq. (12).

$$v_i^e = \ell_1(W_e v_i + b_e) \tag{12}$$

In Eq. (12), the learnable embedding matrix is W_e, the embedding bias is b_e, the nonlinear regular function is ℓ_1, and the object VFs are v_i. The emotional relationship between different objects is shown in Eq. (13).

$$r_{i,j}^e = \phi(v_i^e)^T \cdot \varphi(v_j^e) \tag{13}$$

In Eq. (13), the sentiment relation of two objects in the same picture is $r_{i,j}^e$, and the two sets of embedding functions are ϕ and φ, respectively. The composition of the sentiment map vector is shown in Eq. (14).

$$G(E) = (\upsilon, \vartheta) \tag{14}$$

In Eq. (14), the emotion graph is $G(E)$, the objects containing different semantic features are υ, and the emotion relationship between different objects is ϑ and is described by an affinity matrix. Then, nodes with a confidence level lower than 0.3 are filtered out by setting a threshold for the confidence level, and the edges connected to the redundant nodes are subjected to a masking operation to reduce the information redundancy of the nodes. Finally, the masked affinity matrix is obtained by weighting the masked matrix to the affinity matrix to describe the sentiment relationship between different objects. Subsequently, the GCN will reason about the sentiment graph to exchange and disseminate information through the structured graph structure. In the design of GCN, residual structures are incorporated to better maintain the original node characteristics. Object features are propagated over the whole sentiment graph based on sentiment relationships in multilayer GCN, where each node is updated based on itself and its neighbors [21]. The multilayer GCN structure iterates the object features based on the sentiment relations to realize the inference of the sentiment graph. The result of emotion graph inference is shown in Eq. (15).

$$O'^{(l)} = f(O'^{(l-1)}, R^{e'}) \tag{15}$$

In Eq. (15), the relationship function between different nodes is f, the output of the last GCN layer is $O'^{(l)}$ and the input edge features are $R^{e'}$. The emotion-enhanced object features are formed by modeling different emotional relationships between objects. Scene is regarded as an additional motivator in the emotional arousal process, which greatly affects the image's emotional tone. When doing an IE analysis, scene features shouldn't be overlooked [22]. Consequently, as illustrated in Fig. 5, the study suggests a scene-based AM. Using ResNet-50 as a base network to build a scene network, this technique mines the emotional connections between objects and scenes, taking an emotional image as input and producing the scene attributes of that image.

Based on scene features and emotion-enhanced object features, AM first projects scene features onto the same embedding space to reduce the difference between scene features and object features. Then the attention weight of each object feature is computed by emotion association to fuse the scene features and object features to establish deep emotional relationships. The attentional weights are calculated as shown in Eq. (16).

$$a_i = \sigma(F_s(f_{sce}) \cdot F_o(o_i')) \tag{16}$$

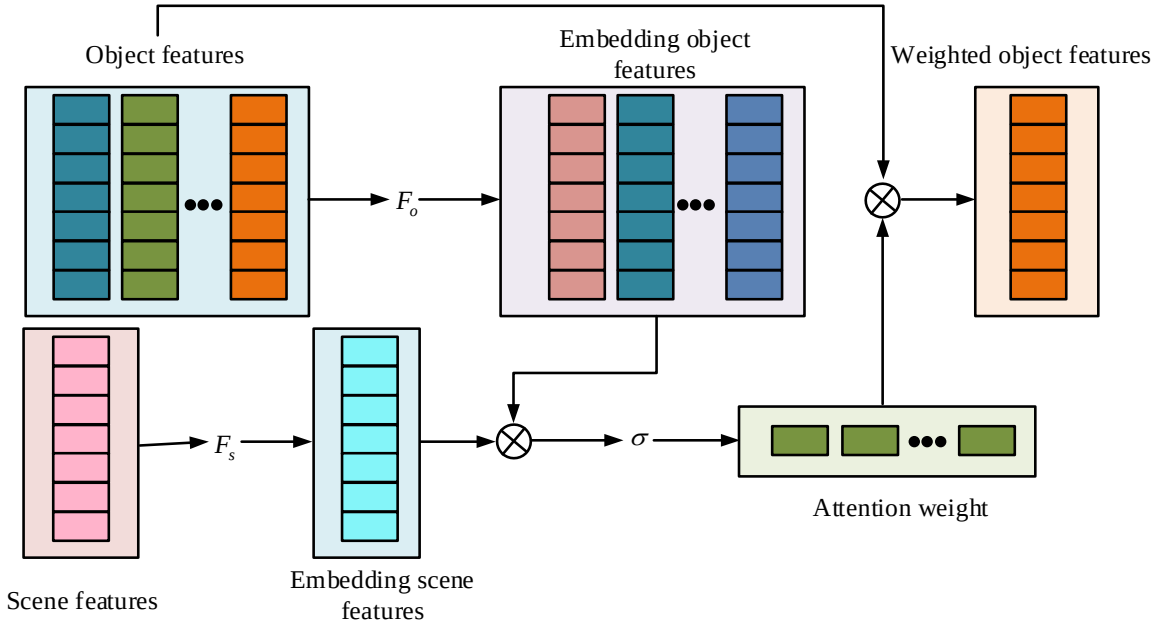

Fig. 5. Scenario-based attention mechanism.

In Eq. (16), the attention weight is a_i, and the activation function is σ. The embedded scene feature input is F_s, and the scene feature is f_{sce}. The embedded object feature is $o_i^{'}$, and the emotionally augmented object feature is F_o. The weighted object feature calculation is shown in Eq. (17).

$$f_{obj} = \sum_{i=1}^{M} a_i o_i^{'} \tag{17}$$

In Eq. (17), the weighted object feature is f_{obj} and the number of objects is M. The emotion feature after cascading the scene and the weighted object feature is shown in Eq. (18).

$$f_{emo} = Concate(f_{sce}, f_{obj}) \tag{18}$$

In Eq. (18), the cascaded sentiment feature is f_{emo}. The study interacts and fuses the scene and object features via AM to obtain weighted object features. Next, the scene and object features are cascaded to obtain the emotion features, which are used for subsequent emotion prediction along with a learnable weight matrix. The results of the sentiment prediction are compared with the sentiment class labels in the dataset and the network is optimized by CE loss.

III. Results

A. IEPN-MIF based Application Analysis

The experiments are performed on a computer based on the Pytorch framework with an Intel(R) Xeon (R) CPU E5-2640 2.40 GHz and an NVIDA GeForce GTX TITAN GPU (12G RAM) with Linux as the operating system. The experimental environment provides powerful computational capabilities to support the analysis and processing of large-scale datasets, which provides a good foundation for the training and testing of deep learning models. Three datasets are used for the experiments, namely, the FI dataset, the IAPS dataset and the ArtPhoto dataset. Table I displays the breakdown of the dataset. 2000 photos are chosen at random as the training set and 1000 images as the test set from the IAPS dataset. 2000 photographs are chosen at random as the test set and 6000 images as the training set from the Artphoto dataset. 15,000 photos are chosen at random as the training set and 7,000 images as the test set from the F1 dataset.

The experiments compare CNN-LSTM, LSTM, convolutional neural network (CNN), and the semantic emotion model proposed in 2023, and the various methods are applied in the small-scale dataset in order to validate the efficacy of the research proposed image emotion prediction network with multi-incentive fusion (IEPN-M). The accuracy and recall in IAPS are shown in Fig. 6.

Fig. 6 (a) shows the accuracy comparison in the dataset IAPS, the average accuracy of the study proposed IEPN-MIF is 80.3%, which improves about 18.6%, 29.5%, 25.6%, and 15.3% compared to the CNN-LSTM, LSTM, CNN models, and semantic sentiment models, respectively. Fig. 6 (b) shows the recall comparison in the dataset IAPS, and the average recall of the proposed IEPN-MIF is 83.2%, which is improved by about 10.3%, 14.3% 15.6%, and 9.8% compared to CNN-LSTM, LSTM, CNN model and semantic sentiment model, respectively. The results show that the multi-stimulus fusion methods have better performance in IE prediction tasks. The accuracy comparison of different methods on Artphoto and F1 datasets is shown in Fig. 7.

TABLE I. Dataset Division

Data set	Training set	Test set	Total number
IAPS	20000	1000	3000
Artphoto	6000	2000	8000
FI	15000	7000	23000

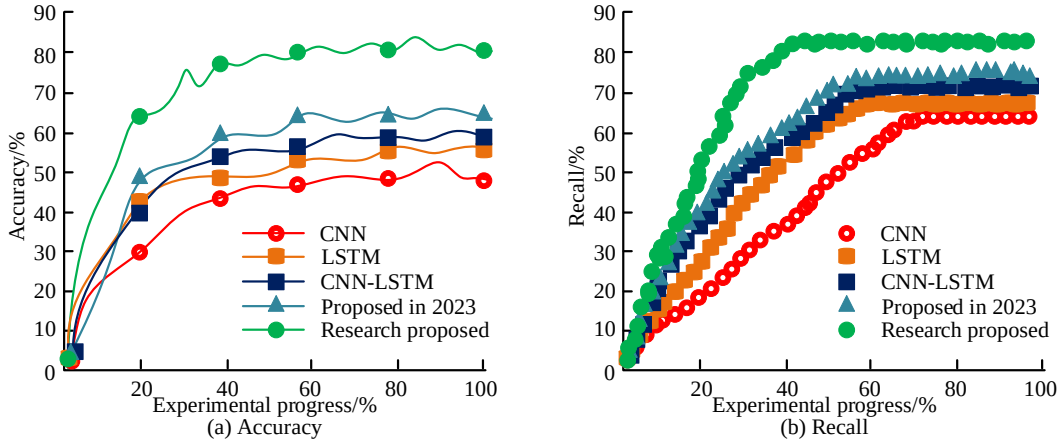

Fig. 6. Accuracy and recall in the dataset IAPS.

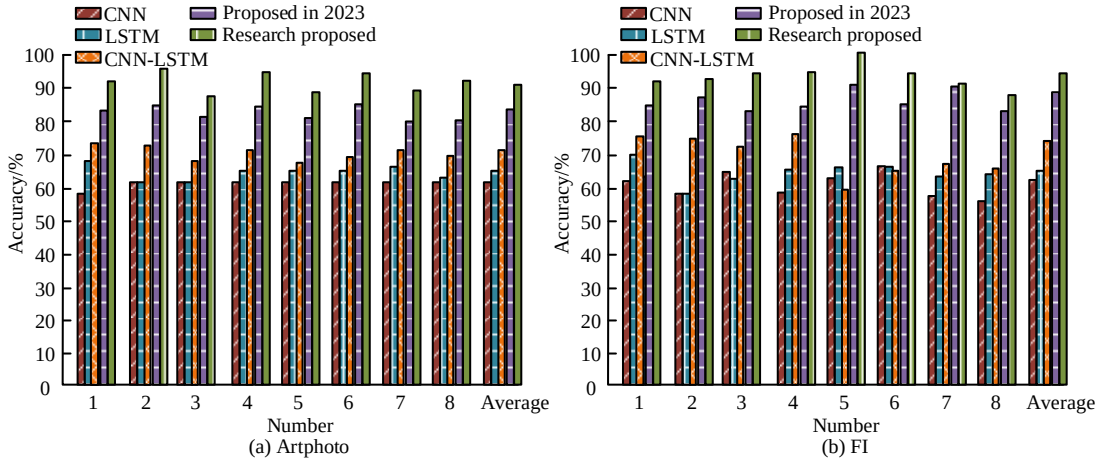

Fig. 7. Accuracy in the Artphoto and FI datasets.

TABLE II. RESULTS OF IMAGE EMOTION PREDICTION NETWORK ABLATION EXPERIMENTS FOR MULTI-EXCITATION FUSION

Global network		Semantic network		Expression network	Accuracy
RGB	Y	LSTM	FCL		
×	√	×	×	×	59.3%
√	×	×	×	×	67.2%
√	×	√	×	×	71.6%
√	×	×	√	×	62.7%
√	×	√	×	√	91.3%

In Fig. 7, 1-8 denote eight emotions, respectively. Fig. 7 (a) shows the accuracy comparison in the Artphoto dataset, and the average accuracy of IEPN-MIF is 91.3%, which improves about 19.6%, 23.8%, 27.8%, and 5.7% compared to CNN-LSTM, LSTM, CNN model and semantic sentiment model, respectively. Fig. 7(b) shows the accuracy comparison in the FI dataset, and the average accuracy of the IE prediction method with multi-incentive fusion is 93.6%, which improves about 20.7%, 30.1%, 27.5%, and 4.7% compared to CNN-LSTM, LSTM, CNN model, and semantic sentiment model, respectively. The outcomes demonstrate the increased accuracy and greater potential of the multi-excitation fusion IE prediction approach in the emotion identification domain. Table II displays the outcomes of the IEPN-MIF ablation trials.

In Table II, the global, semantic, and expression networks each contribute to sentiment prediction to varying degrees. When the three sub-networks act alone, the global network has the highest accuracy of 67.2%, indicating the strong representational power of global features. In the absence of color features, the three-branch network outperforms the two-branch network only to a lesser extent, while the three-branch network considering color features performs superiorly. The results show that by setting up the LSTM layer and the FCL for comparison, the LSTM layer structure can better mine the semantic information between different objects, and thus predict emotions more accurately. The addition of the expression network further improves the accuracy of the network, with a final accuracy of 91.3%. The results of the impact of hyperparameters on the network performance are shown in Fig. 8.

Fig. 8 (a) shows the effect of loss weights on network performance, and the accuracy of IEPN-MIF first increases and then decreases as the loss weights increase. The highest accuracy of 75.6% is achieved when the loss weight is 1.0. Fig. 8 (b) displays the effect of the object frames on the object performance, with the increase of the number of object frames, the accuracy of IEPN-MIF gradually increases and then decreases and stabilizes. When the object frame data is 10, the network has the highest accuracy rate of 76.5%. In conclusion, the model performs best when the IEPN-MIF loss weight and object frame count are set to 1.0 and 10, respectively.

B. Application Analysis of Image Emotion Classification based on Associative Reasoning

To validate the performance of the SOLVER network proposed in the study, the experiments use Faster R-CNN, GCN and the IE correlation analysis model based on hierarchical graph convolutional network proposed in 2023 as comparisons. The comparison of the accuracy of the different methods on the IAPS and Artphoto datasets is shown in Fig. 9.

Fig. 9 (a) shows the accuracy comparison in the IAPS dataset, where the average accuracy of SOLVER network is 92.1%, which is an improvement of about 29.8%, 25.3, and 7.4% compared to the Faster R-CNN, GCN, and IE correlation analysis models, respectively. Fig. 9 (b) shows the accuracy comparison in Artphoto dataset, the average accuracy of SOLVER network is 91.8%, which improves about 32.6%, 31.7, and 3.7% compared to Faster R-CNN, GCN and IE correlation analysis model, respectively. This indicates that the SOLVER network is able to recognize objects and scenes in images more accurately because of the more optimized inference method used in the SOLVER network. The results of the ablation experiments and hyperparametric analysis of the SOLVER network are shown in Fig. 10.

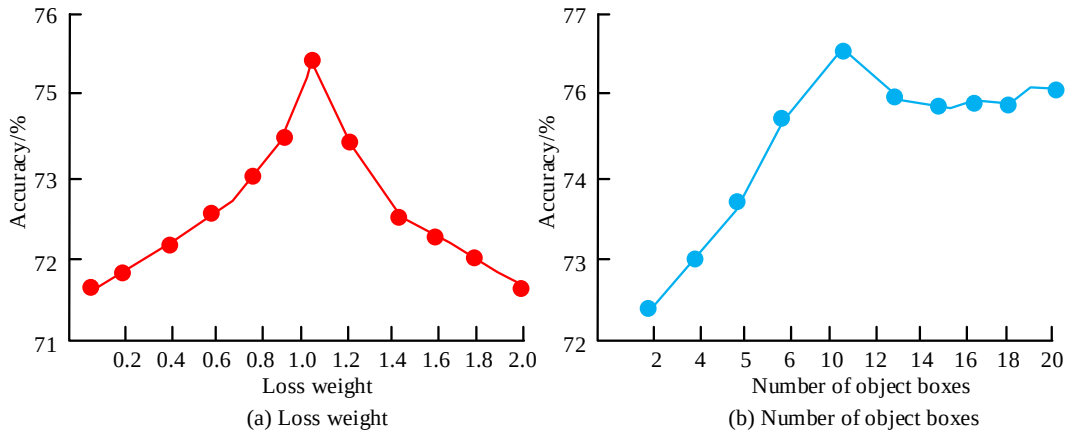

Fig. 8. Results of the influence of hyperparameters on network performance.

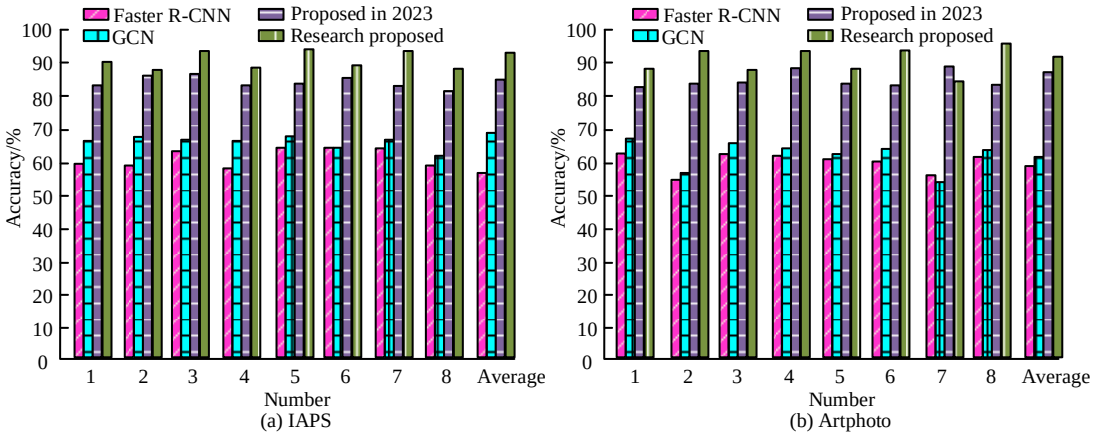

Fig. 9. Comparison of accuracy in the IAPS and Artphoto datasets.

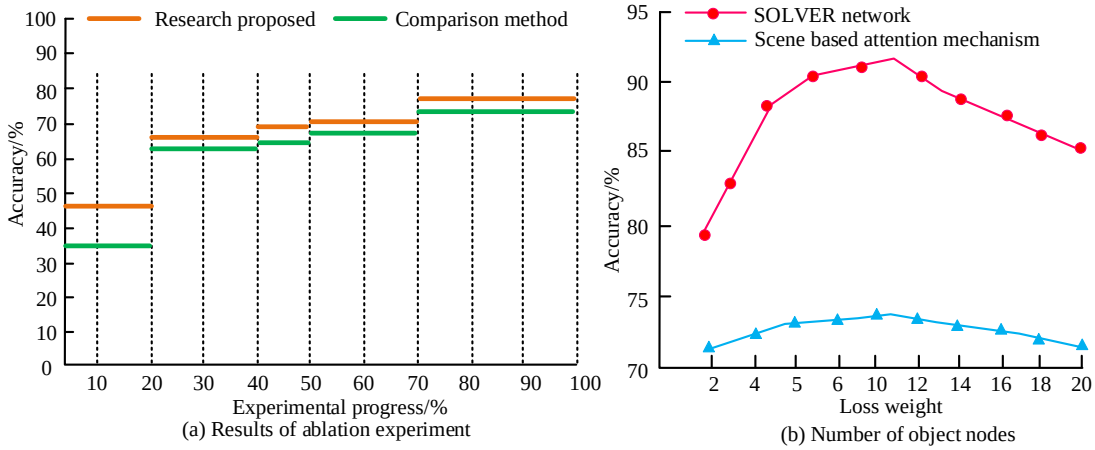

Fig. 10. Results of the ablation experiments and the hyperparameter analysis of the SOLVER network.

The results of the ablation tests are displayed in Fig. 10(a). In the 0%–10% phase, several objects result in a greater performance improvement than a single item. Two separate parameter embedding functions perform better than one embedding function in the 10%–40% stage. The mask operation can enhance performance even more in the 40%–50% range. Scene branching and scene-based AM both significantly contribute to emotion classification. In the 50%-70% stage, scene features direct the fusion process of object features. The results of the hyperparameter analysis are displayed in Fig. 10(b), where the accuracy of the scene-based AM and SOLVER network steadily rises as the number of object nodes increases until stabilizing. The scene-based AM and SOLVER networks get the maximum accuracy rates of 73.6% and 91.9%, respectively, when there are eleven object nodes. Therefore, the number of object nodes should be set to 11 to ensure network performance.

IV. Discussion

The proposed network image sentiment analysis method demonstrates high performance. This method fully utilized the advantages of ML in automatically recognizing image features, and deeply analyzed emotional expression through the idea of associative reasoning, achieving significant results in the field of sentiment analysis. In different emotional scenarios, this method could accurately identify various emotions such as joy, anger, sadness, and happiness, and achieve efficient emotional judgment in complex backgrounds. This was due to the fact that ML algorithms can effectively extract image features and improve the accuracy of emotion recognition. Meanwhile, the introduction of associative reasoning enabled this method to combine contextual information for more detailed analysis and judgment of emotional expression, thereby demonstrating high performance in different emotional scenarios. However, this fusion method also had certain limitations. Firstly, due to the ambiguity and diversity of emotional expression in network images, ML models might find it difficult to fully capture all key features during training, resulting in uncertainty in sentiment analysis results. Second, some environmental factors present in the associative reasoning process might affect the accuracy of sentiment analysis, resulting in results that are somewhat limited by human cognition. In addition, with the continuous changes in the expression of emotions in network images, ML and associative reasoning models needed to be constantly updated and optimized to adapt to new emotional trends.

These results are not limited to the dataset used, and the principles and methods behind them are applicable to other image and video datasets with rich emotional information. For example, in areas such as social media analysis, movie sentiment scoring, and advertising effectiveness evaluation, IEPN-MIF networks can accurately predict the emotional content of images by extracting emotional features from multiple sources, such as colors, objects, and faces. The SOLVER network can be applied to intelligent surveillance systems to support safety warnings and behavior understanding by analyzing the emotional relationship between scenes and objects. In the future, these networks are expected to be widely used in practical applications such as emotional interactive robots and personalized recommendation systems, thereby enhancing user experience and system intelligence.

V. Conclusion

To achieve accurate recognition and classification of IE, the study proposed an IEPN-MIF based network which was capable of utilizing different emotional incentives, including color, object, and face. It can achieve accurate prediction of emotions through deep learning techniques. Secondly, the study proposed SOLVER network to classify the emotion of images by fusing scene features and object features. The outcomes indicated that the average accuracy of the proposed IEPN-MIF in the dataset IAPS was 80.3%, which was improved by about 18.6%, 29.5%, 25.6%, and 15.3% compared to the CNN-LSTM, LSTM, CNN models and the semantic sentiment model, respectively. As the loss weight increased, the accuracy of IEPN-MIF first increased and then decreased. The highest accuracy of 75.6% was achieved when the loss weight was 1.0. The average accuracy of the SOLVER network in the IAPS dataset was 92.1%, which improved about 29.8%, 25.3, and 7.4% compared to the Faster R-CNN, GCN and IE correlation analysis models, respectively. Scene-based AM can effectively fuse scene and object features and classify emotions. Finally, the results of ablation experiments and hyperparameter analysis indicated that the number of object nodes should be set to 11 to ensure network performance. This method had great potential in practical applications, such as in the fields of intelligent interaction, psychology, and advertising marketing, where more accurate emotion recognition and classification could be achieved by analyzing IEs. Meanwhile, the scene based AM could effectively integrate scene and object features, and classify emotions, which provided the possibility for further improving the accuracy of IE recognition. The shortcoming of this research was that only datasets were used for the experiments. Therefore, the results only reflected the performance on these datasets. Future research directions can revolve around the following aspects. First, explore more advanced neural network architectures. Although CNN and LSTM networks have achieved good results in image sentiment analysis, the latest architectures such as Transformer AMs may provide better performance. Second, more effective loss functions should be developed, such as contrast loss or cosine similarity loss. Future research should test the methods on more diverse datasets to ensure their generalizability. Finally, consider multimodal sentiment analysis. Image sentiment analysis typically focuses only on visual content, and combining modal information, such as text associated with images or background audio, can improve analysis accuracy. With this dependency, future research can further expand the field of image sentiment analysis, develop more accurate and robust methods for understanding the emotional content of online images, and make greater contributions to the development of artificial intelligence technology.

***Abstract*—Coronary artery stenosis (CAS) is a critical cardiovascular condition that demands accurate localization for effective treatment and improved patient outcomes. This study addresses the challenge of enhancing CAS localization through a comparative analysis of deep learning techniques applied to electrocardiogram (ECG), photoplethysmograph (PPG), and their combined signals. The primary research question centers on whether the fusion of ECG and PPG signals, analyzed through advanced deep learning architectures, can surpass the accuracy of individual modalities in localizing stenosis in the left anterior descending (LAD), left circumflex (LCX), and right coronary arteries (RCA). Using a dataset of 7,165 recordings from CAS patients, three models—CNN, CNN-LSTM, and CNN-LSTM-ATTN—were evaluated. The CNN-LSTM-ATTN model achieved the highest localization accuracy (98.12%) and perfect AUC scores (1.00) across all arteries, demonstrating the efficacy of multimodal signal integration and attention mechanisms. This research highlights the potential of combining ECG and PPG signals for non-invasive CAS diagnostics, offering a significant advancement in real-time clinical applications. However, limitations include the relatively small dataset size and the focus on single-lead ECG and PPG signals, which may affect the generalizability to broader populations. Future studies should explore larger datasets and multi-lead signal integration to further validate the findings.**

***Keywords*—Coronary artery stenosis; deep learning; ECG; PPG; ECG-PPG fusion; CNN; LSTM; attention mechanism**

I. INTRODUCTION

Coronary artery stenosis, and other cardiovascular diseases, remain a major cause of death globally, and thus present a major public health concern [1]. Accurate and timely diagnosis of these conditions, as well as continuous monitoring, are crucial for effective treatment and management, ultimately improving patient outcomes [2]. Coronary artery stenosis, a common and serious manifestation of cardiovascular disease, has been the subject of extensive research, with a focus on developing accurate, non-invasive, and accessible detection methods that can enable early intervention and better disease management strategies [3], [4]. This research emphasis underscores the importance of advancing the field of cardiovascular disease diagnosis and monitoring to address this pressing global health concern.

ECG have long been used in the diagnosis and monitoring of cardiac conditions, and recent advancements in machine learning have shown promising results in ECG-based detection and classification of various cardiovascular diseases. For example, changes in the ECG waveform, such as ST-segment depression or T-wave inversion, can be indicative of myocardial ischemia caused by coronary artery stenosis [5]. A study by [6] explores cardiovascular disease (CVD) prediction using machine learning techniques on ECG and physiological data, finding that an artificial neural network (ANN) model achieves the highest predictive accuracy (90%) by utilizing significant parameters such as the R-R interval, RMSSD, blood pressure, and cholesterol levels, highlighting its potential as a non-invasive diagnostic tool for early CVD detection. Deep learning models trained on ECG data have demonstrated the ability to detect and localize specific patterns associated with different regions of coronary artery disease, such as LAD artery, LCX artery, or RCA obstructions [7].

In contrast, photoplethysmographic is an opto-electrical technique that uses light to quantify hemodynamic changes that is an important aspect of cardiovascular analysis. PPG signals can capture blood volume changes in the peripheral vasculature, which can be indicative of changes in the cardiovascular system, such as those associated with coronary artery disease [8], [9]. For example, [10] investigates photoplethysmography (PPG) as a non-invasive alternative to assess coronary artery disease (CAD) severity, finding that a Discriminant Analysis classifier achieved 88.46% accuracy in detecting severe stenosis, thus highlighting PPG's potential for CAD pre-diagnosis in resource-limited or pandemic-impacted environments. In addition, the analysis of PPG waveforms has shown potential in detecting and monitoring conditions like coronary artery stenosis, as it can provide insights into the vascular dynamics and hemodynamic changes related to this cardiovascular disorder [11].

Deep learning, a powerful subset of machine learning, has emerged as a promising approach for the analysis of various biomedical signals, including electrocardiograms and photoplethysmography [12]. These techniques have the ability to extract complex patterns and features from the data, enabling accurate classification and localization of cardiovascular conditions, such as coronary artery stenosis [13]. Among the deep learning methods, Convolutional Neural Networks have demonstrated good efficiency for identification of both ECG and PPG signals for diagnostics of coronary artery disease location [14]. By leveraging the hierarchical feature extraction capabilities of CNNs, researchers have been able to develop robust models for identifying characteristic patterns in cardiac data that are indicative of coronary artery stenosis [15].

LSTM networks, have also shown promise in the analysis of ECG and PPG signals for the detection and monitoring of coronary artery disease [16]. LSTM models overcome the limitation of capturing long range of temporal dependencies and hence suitable for processing these continuous physiological signals [17]. Some recent works have proved that LSTM networks can capture ECG and PPG patterns related to coronary artery stenosis, indicating that deep learning structures might contribute for the localization and diagnosis of this cardiovascular disease [18].

Moreover, it is also understood that the application of attention-based mechanisms in deep learning systems can potentially improve the assessment and visualization of coronary artery disease based on these multiple modal signals [19]. Attention-based architectures, such as Transformer models, have shown promising results in healthcare applications by allowing the models to focus on the most relevant features and patterns in the data, which can be crucial for the precise localization of coronary artery stenosis [20].

The combination of ECG and PPG data may provide a more comprehensive understanding of the cardiovascular system, potentially leading to improved accuracy in the localization of coronary artery stenosis. This study aims to conduct a comparative analysis of deep learning approaches using ECG, PPG, and the combined ECG-PPG modalities to enable accurate and non-invasive localization of coronary artery stenosis, which could enhance early diagnosis and management of this critical cardiovascular condition.

In the following sections, this paper details the methodology for signal acquisition, dataset preparation, and preprocessing, followed by the development and evaluation of three deep learning architectures: CNN, CNN-LSTM, and CNN-LSTM-ATTN. A comprehensive comparative analysis of these models using ECG, PPG, and combined ECG-PPG signals is presented, highlighting the advantages of multimodal signal fusion and attention mechanisms. Finally, the results are discussed in relation to prior studies, and conclusion was made with insights into the clinical implications of our findings and potential directions for future research. This structure aims to provide readers with a clear roadmap of the study, fostering deeper engagement with the content.

II. Related Works

Tao et al. [21] developed an automatic ischemic heart disease (IHD) detection and localization system using magnetocardiography (MCG) signals and machine learning methods. They used 164 features derived from the MCG recordings and divide into three groups, which are time domain feature, frequency domain feature, information theory feature, and compared the performance of many classifiers. Their ensemble model of SVM and XGBoost achieved high performance in IHD detection, with an accuracy of 94.03%, precision of 86.56%, recall of 94.78%, and an AUC of 0.98. For stenosis localization in the LAD, LCX, and RCA, they employed 18 time-domain features with XGBoost, achieving accuracies of 74%, 68%, and 65%, respectively. The study demonstrated that features related to T-wave repolarization synchronicity and magnetic field patterns were critical in both detection and localization, providing a non-invasive, fast, and accurate tool for clinical use.

In their work, Huang et al. [22] propose the creation of an AI-based ECG algorithm that will help predict and indicate the location of angiography-verified CAD. The study employs a CNN model to examine 12-lead ECG data of patients with CAD who have been verified through ICA. The dataset consists of clinical data from 2303 CAD patients and ECG data of 1053 healthy patients as well as 12,954 ECG records. The CNN model provided an AUC of 0.869 to identify CAD, and specific AUC of 0.885, 0.816, 0.776 to detect stenosis in LAD, LCX, RCA respectively. The AUC of the model reached 0.973 in the case when ECGs demonstrated features of myocardial ischemia. The study proves that the AI-based algorithm on the ECG signal as the primary diagnostic tool can be effective and non-invasive for identifying severe CAD and localized stenosis.

Roopa and Harish [23] proposed an automated system for localizing thrombus in coronary arteries using 12-lead ECG signals and an Information Fuzzy Network (IFN). Their method utilizes ECG feature extraction techniques, including the Stockwell Transform and Nearest-Neighbor Interpolation, to identify key features like ST-segment deviations, time intervals, and peak amplitudes in the ECG waveform. An initial rule-based system is then used to separate ischemic and non-ischemic signals and to determine the culprit artery, which might be LAD, RCA, LCX or another artery. This experimental study showed that the proposed system has an accuracy of 92.30%; sensitivity of 87.50%; and specificity of 100%; thus, it could be a valuable noninvasive solution for diagnosing coronary artery blocks and supporting clinical decision making.

Previous studies on CAD localization have primarily focused on using single physiological signals, including MCG and ECG, alongside traditional machine learning models like XGBoost and CNNs. However, the integration of multimodal signals, particularly ECG and PPG, remains underexplored. Furthermore, while advanced deep learning techniques, such as LSTM networks and attention mechanisms, are increasingly recognized for their ability to capture both spatial and temporal dependencies, their application in CAD localization is limited.

The existing literature often lacks the incorporation of attention-based models that can dynamically focus on the most relevant signal features, potentially enhancing diagnostic accuracy. Additionally, few comparative analyses have been conducted to evaluate the relative effectiveness of ECG, PPG, and their combined modalities for CAD localization. Moreover, most studies have focused on offline models, with limited exploration of real-time clinical applications. This study addresses these gaps by employing deep learning models that integrate CNNs, LSTMs, and attention mechanisms to analyze multimodal signals, offering a comprehensive and more accurate approach to CAD localization with potential for real-time clinical implementation.

III. Materials and Methods

A. Study Population

This research involved a cohort of patients diagnosed with significant coronary artery disease, as confirmed through angiography. Participants, aged 20 to 65 years, were selected based on the presence of severe stenosis, which was quantitatively assessed using coronary angiography. Only individuals with no prior history of CAD were included. The study received ethical clearance from the Research Ethics Committee of Universiti Kebangsaan Malaysia (UKMPPI/111/8/JEP-2020-806), and all participants provided written informed consent.

B. Data Collection

The study followed a protocol for recording both ECG and PPG signals concurrently from participants, as illustrated in Fig. 1. A total of 60 patients with confirmed significant coronary artery disease through angiography were included, resulting in a dataset containing 7,156 simultaneous single-lead ECG and PPG recordings. The patients were categorized into three groups based on their angiography findings: All those patients who had stenosis in LAD, LCX, and RCA arteries were included in this study.

In the LAD group, 27 patients provided 3,884 concurrent single-beat ECG and PPG recordings. The LCX group consisted of 16 patients, contributing 1,565 recordings, while the RCA group included 17 patients, resulting in 1,707 recordings. Fig. 2 displays sample single-beat ECG and PPG signals for each artery group (LAD, LCX, and RCA).

The dataset was derived from the MAX86150EVS ECG/PPG module, which recorded standard single-lead ECG and PPG signals at a 400 Hz sampling rate for 10 minutes per patient. Signal processing techniques, such as baseline wander removal, smoothing, and segmentation, were applied to isolate individual cardiac cycles and enhance the quality of single-beat signals. This resulted in a final dataset of 7,165 simultaneous single-beat ECG and PPG waveforms, each consisting of 187 data points per sample. This dataset is used in the next sections to develop and evaluate various deep learning models.

C. Dataset Preparation and Preprocessing

Prior to proceeding with the deep learning models, the collected data is partitioned into three distinct datasets: the ECG dataset, the PPG dataset, and the combined ECG and PPG dataset. These datasets share the same number of samples and targets. The purpose of this division is to enable the training and evaluation of deep learning models on the individual modalities as well as the combined modality. For the combined ECG and PPG dataset, each sample comprises a concatenation of both the ECG and PPG signals into a single feature vector. This integration aims to leverage the complementary information present in the ECG and PPG signals to potentially enhance the overall performance of the CAD stenosis localization task. Fig. 3 shows examples of the concatenated ECG and PPG signals belonging to the classes, namely LAD, LCX, and RCA.

In the experiment, the datasets are split into subsets with the training, validation, and test data that should not overlap, 70% of the dataset for training, 10% for validation and the remaining 20% for testing. It is noteworthy to mention that the training and test sets are completely disjoint in terms of patient-wise separation, adhering to best practices for evaluating deep learning models. All three groups of datasets are subjected to the same train-validation-test split ratios.

The three datasets seem to be unbalanced, with the LAD group containing a significantly larger number of samples compared to the LCX and RCA groups. Such distribution skew could result into biased deep learning models and performance of the models when trained and tested on the datasets [22]. As a result, to address this problem, we resorted to applying down sampling where we sampled a proportionate sample of the majority class to create a new smaller set of samples that was equivalent in size to the other two classes. Fig. 4 shows bar chart representations of the distribution of samples before and after the down-sampling process for each group.

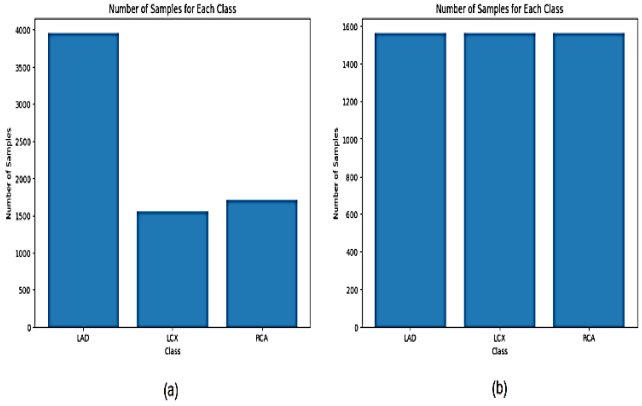

Fig. 4. (a) Dataset showing class imbalance prior to the balancing process, and (b) Dataset with balanced classes after the data balancing procedure.

D. Model Build-up

In this study, a series of deep learning models were developed to classify CAD stenosis location using ECG, PPG the combination of both signals. These models were developed using Google Colaboratory (Colab), a cloud-based platform that provides access to powerful GPU resources and comprehensive deep learning libraries, such as TensorFlow and PyTorch. To effectively process the complex time-series data, three models were explored: a CNN-based model, a hybrid CNN-LSTM model, and an advanced CNN-LSTM-ATTN model. Each architecture was designed to leverage different aspects of deep learning, namely spatial feature extraction, temporal dependency modeling, and attention-based focus mechanisms, to improve classification accuracy.

The initial model utilizes a CNN, designed to automatically extract features from raw ECG and PPG signals. This is a simple sequence model starting with one-dimensional convolutional layer (Conv1D) with 32 filters and 3×1 kernel, that is then passed through a max-pooling (MaxPooling1D) to minimize the dimensionality of the formed feature maps. The convolutional layers identify local features in the input signals; max-pooling reduces dimensionality and masks significant characteristics. Further, subsequent feature maps are subjected to flatten layer and then fed to the fully connected layer containing 128 units with ReLU activation followed by softmax output layer for classification into three diagnostic categories. This CNN model efficiently captures spatial patterns in the signals, establishing a strong baseline for coronary artery disease classification.

The second model enhances the CNN by incorporating LSTM layers to capture temporal dependencies in the sequential ECG and PPG data. Following the convolutional and max-pooling layers, two LSTM layers, each with 50 units, are added. The first LSTM layer is set to return sequences, enabling the second LSTM layer to process both short- and long-term dependencies within the signal data. This combination of CNN and LSTM layers allows the model to extract spatial features while also understanding their temporal progression, thereby boosting its ability to classify coronary artery disease based on dynamic signal changes. A final dense layer with softmax activation generates a probability distribution across the three diagnostic categories.

The third and most advanced architecture incorporates an attention mechanism to further enhance the model's ability to focus on the most relevant portions of the input signals. The model begins with a convolutional layer with 32 filters and a max-pooling layer, followed by an LSTM layer with 50 units and return_sequences=True. After the LSTM layer, an attention mechanism is applied to dynamically weigh the importance of each time step in the signal, allowing the model to focus on the most significant information. This attention mechanism improves the interpretability of the model by highlighting the critical sections of the ECG and PPG signals that contribute to the classification. The attention-weighted features are then flattened and passed to a softmax output layer for final classification. The architectural representation of the model is represented in Fig. 5 after performing data balancing process and the overall flow of the study is represented in Fig. 6.

By combining CNNs for spatial feature extraction, LSTMs for temporal modeling, and attention mechanisms for focused learning, these architectures present a robust approach to CAD classification. The CNN-based model provides a solid baseline by capturing local signal patterns, while the CNN-LSTM hybrid improves the model's ability to learn temporal dependencies. The CNN-LSTM-ATTN model further enhances performance by focusing on the most relevant parts of the signals, making it the most comprehensive and accurate architecture for the task of CAD diagnosis based on ECG and PPG signals.

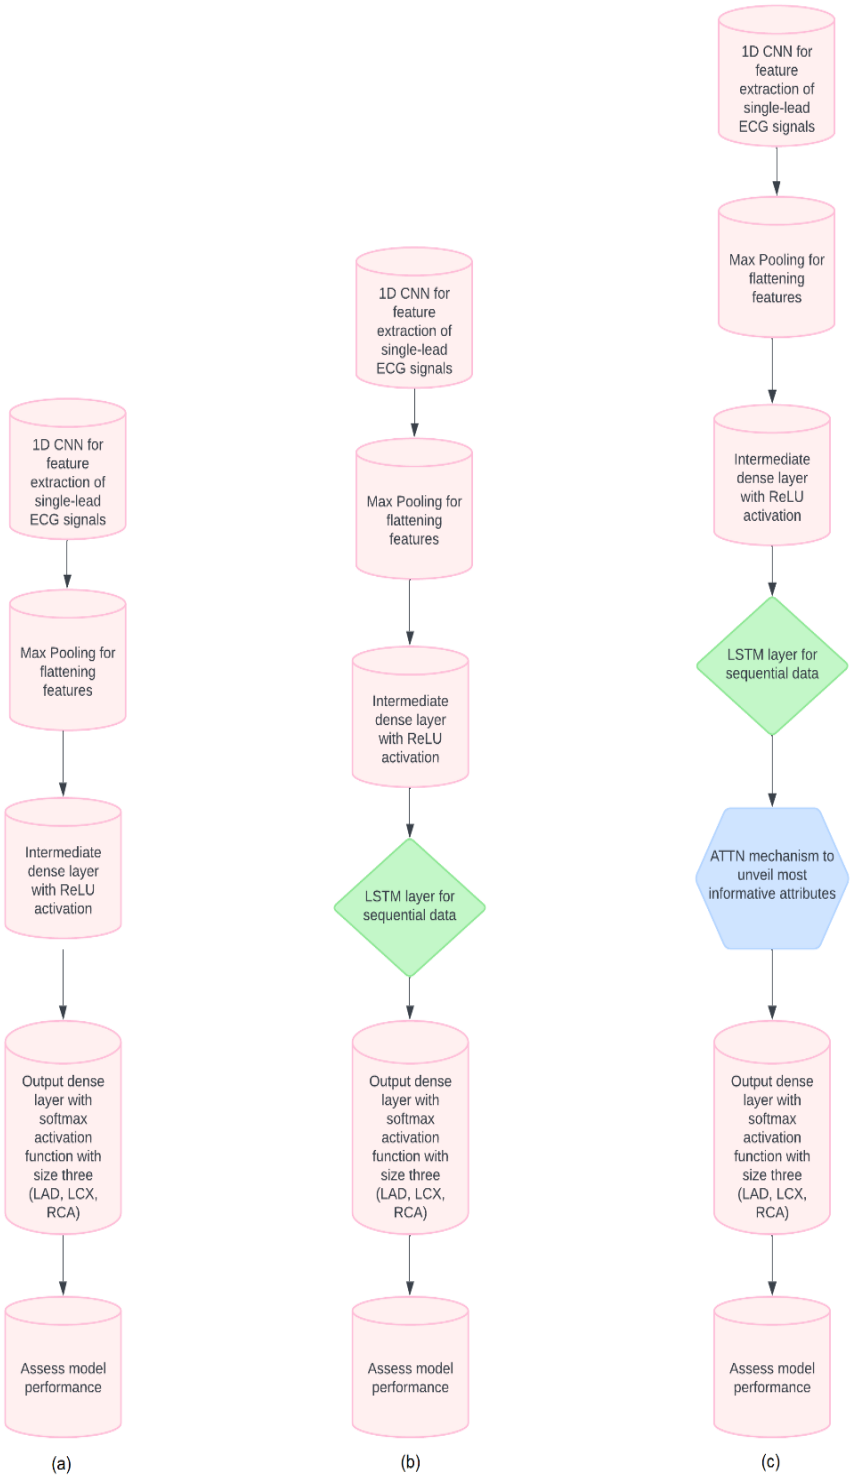

Fig. 5. Architecture for coronary artery blockage localization prediction model for (a) CNN, (b) CNN+LSTM, (c) CNN+LSTM+ATTN.

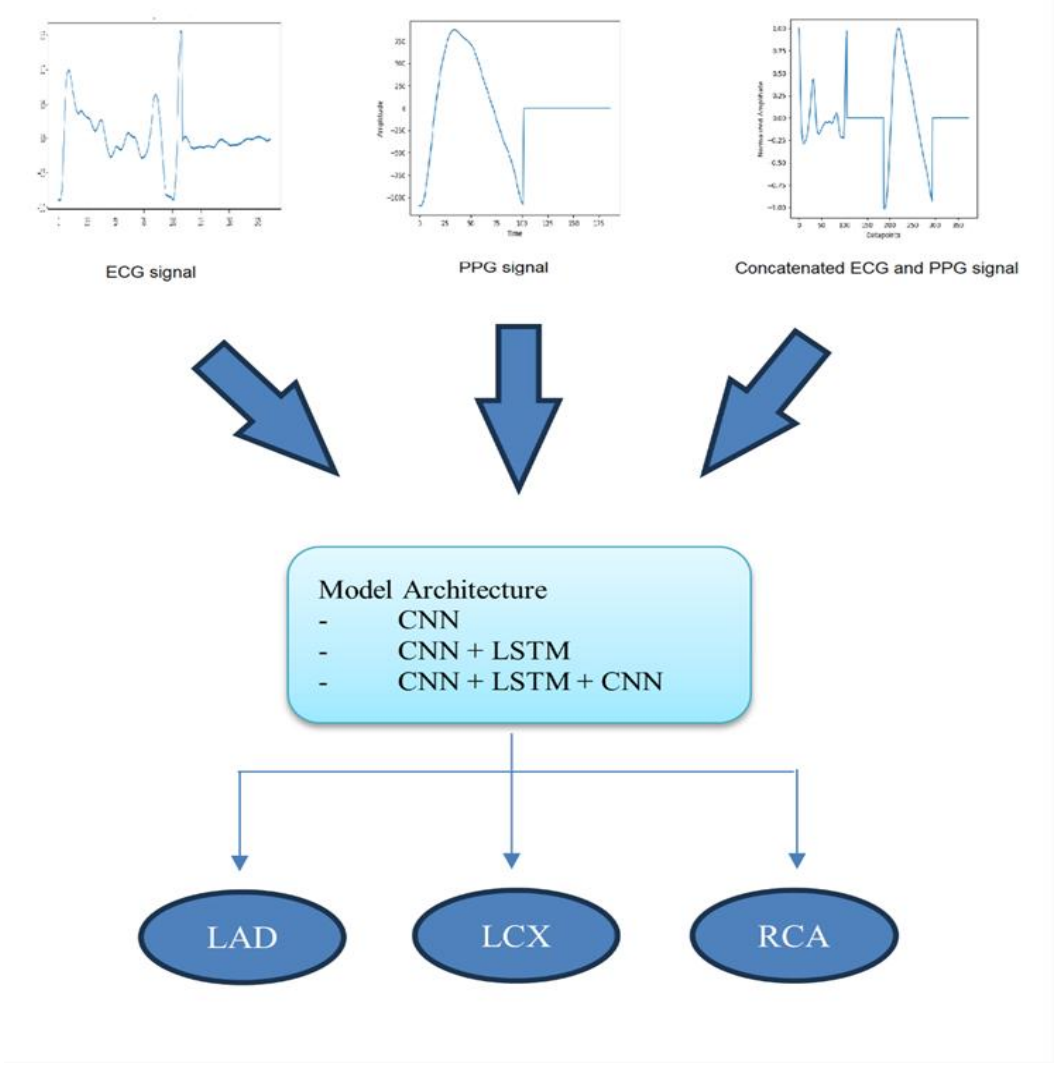

Fig. 6. Model architecture for predicting the localization of coronary artery blockages.

E. Training Process

The training process for each model involves the use of the Adam optimizer with a learning rate of 0.001 and a batch size of 32. The categorical cross-entropy loss function is applied to optimize the models during training. To reduce the risk of overfitting, a dropout layer with a 0.2 rate is introduced after the first fully connected layer in all models. Moreover, the practice of early stopping is used to terminate the learning process when there is a failure to get any improvements in the validation error. The models are trained for up to 100 epochs, with the best-performing model, based on validation accuracy, saved for final evaluation on the test set.

F. Evaluation Metrics

The study aimed to evaluate an AI-enhanced ECG as a means of identifying the location of coronary artery stenosis from single-lead standard ECG recordings, together with comparison based on full lead set. The testing and the performance of the proposed deep learning models was assessed in terms of accuracy metric, area under the receiver operating characteristic curve (AUC-ROC) and the confusion matrix.

The measurement of accuracy is the extent to which samples have been classified correctly; it is the number of correctly predicted over the total samples. This is the ratio of true positive calculated by dividing it by all the positive cases that have been identified as positive by the application. Precision and recall are measurement indicators used in this study. Precision deals with the number of actually positive cases found to be positive by the application, calculated by dividing the true positive value by the actual positive samples. The true positive rate depicts the ratio of the actual positive samples to the total numbers of positive samples that were classified as such the false positive rate depicts the ratio of the negative samples that were classified as positive. Also, the true negative rate expresses the share of real negative patterns that correctly classified and the false negative rate describes the percentage of actual positive patterns that misleading classified as negative.

The area that the curve corresponding to the ROC forms, in short AUC-ROC serves as a rich measure that encapsulates the ability of a classification model in terms of its ability of class separation. Also known as Receiver Operating Characteristic,

this metric measures the true positives along the true negatives across the range of classification thresholds that gives a balanced measure of a model's discriminative abilities.

The confusion matrix is used to display accuracy of the model in terms of the three diagnostics types. It gives an account of the right and wrong classifications made by the model, which aids in determination of its efficiency for each class. This characteristic of the confusion matrix helps to analyze the advantages and disadvantages of the model in terms of identifying the various conditions of coronary artery disease.

IV. Results And Discussion

To enhance the model's performance, we carried out several experiments to assess the effectiveness of various deep learning architectures in classifying CAD stenosis locations using ECG, PPG and combination of ECG and PPG signals. The architectures examined in this study comprised a baseline CNN network, a hybrid CNN-LSTM model, and a CNN-LSTM-ATTN model. Table I provides a summary of the performance metrics, including classification accuracy and AUC, for each of these models on the test set. Additionally, the corresponding ROC curve and confusion matrix based on the best model obtained are illustrated in Fig. 7.

In Table I, the results highlight the comparative performance of three deep learning models for CAD stenosis localization using ECG, PPG, and their combined signals. These models include a CNN, a hybrid CNN-LSTM model, and an advanced CNN-LSTM-ATTN.

TABLE I. Performance Metrics of the Three Models Utilized in this Study

Signal	Model	Accuracy	AUC		
			LAD	***LCX***	***RCA***
ECG	CNN	94.25%	0.99	0.98	0.99
	CNN + LSTM	95.53%	0.99	0.99	0.99
	CNN + LSTM + ATTN	97.61%	0.99	0.98	0.99
PPG	CNN	86.10%	0.95	0.96	0.96
	CNN + LSTM	91.97%	0.97	0.99	0.98
	CNN + LSTM + ATTN	92.25%	0.97	0.98	0.98
Combined ECG & PPG	CNN	94.69%	0.96	0.97	0.97
	CNN + LSTM	92.47%	0.98	0.99	0.98
	CNN + LSTM + ATTN	98.12%	1.00	1.00	1.00

For ECG-based detection, the CNN model achieved an accuracy of 94.25%, AUC scores ranging from 0.98 to 0.99 across the three coronary arteries: LAD, LCX, and RCA. Integrating the LSTM layer improved accuracy to 95.53%, indicating the added value of temporal feature extraction, while AUC scores remained consistently high.

The introduction of the attention mechanism (CNN-LSTM-ATTN) led to a significant performance boost, achieving 97.61% accuracy and maintaining near-perfect AUC values for all three arteries, underscoring the ability of the attention mechanism to focus on the most relevant features in the data.

For PPG signals, the CNN model started with a lower accuracy of 86.10%, yet the inclusion of LSTM and attention mechanisms progressively improved the results. The CNN-LSTM model raised accuracy to 91.97%, and the CNN-LSTM-ATTN model further increased it to 93.32%, while AUC scores improved, especially for the LCX and RCA arteries.

When the ECG and PPG signals were combined, the results demonstrated the most substantial improvement. The CNN model reached 94.69% accuracy, and while the CNN-LSTM model saw a slight dip in accuracy to 92.47%, the addition of the attention mechanism significantly enhanced performance, resulting in 98.12% accuracy and perfect AUC scores of 1.00 for all three coronary arteries. This illustrates the clear advantage of combining both signal modalities, which, coupled with advanced deep learning techniques, maximized diagnostic accuracy and precision.

Overall, the results indicate that while individual signals (ECG or PPG) provide valuable diagnostic insights, combining both signals with sophisticated deep learning architectures, especially with attention mechanisms, offers superior performance in localizing coronary artery stenosis. The CNN-LSTM-ATTN model demonstrates exceptional potential for clinical application, offering a non-invasive, highly accurate method for detecting blockages in major coronary arteries.

Table II presents a comparative analysis between the best model obtained from the study and three previous studies—Tao et al. [21], Huang et al. [22], and Roopa and Harish [23]—in terms of accuracy and Area Under the Curve (AUC) for coronary artery stenosis (CAS) localization. The proposed model, which employs a CNN-LSTM-ATTN architecture integrating both ECG and PPG signals, achieves an impressive overall accuracy of 98.12%, substantially outperforming earlier models. In terms of AUC, the model demonstrates exceptional performance, achieving perfect scores of 1.00 for detecting stenosis in LAD, LCX, and RCA. However, Tao et al.'s XGBoost based model, which employed magnetocardiography, yielded lower AUC of 0.74, 0.68, and 0.65 for these arteries, respectively. Huang et al.'s CNN model, only with ECG signals, achieved the AUCs of 0.89, 0.82, and 0.78 for LAD, LCX, and RCA respectively. At the same time, Roopa and Harish proposed an ECG-based model that yielded an accuracy of 92.3%, but AUC values were not disclosed. The exceptional performance of the proposed model achieved because the proposed model relies on the fusion of the ECG and PPG signals; the two methods improve both the feature extraction and temporal models. Moreover, attention mechanisms help to pay more attention to useful signal characteristics, which in turn contributes to better definition of the location of blockages in coronary arteries.

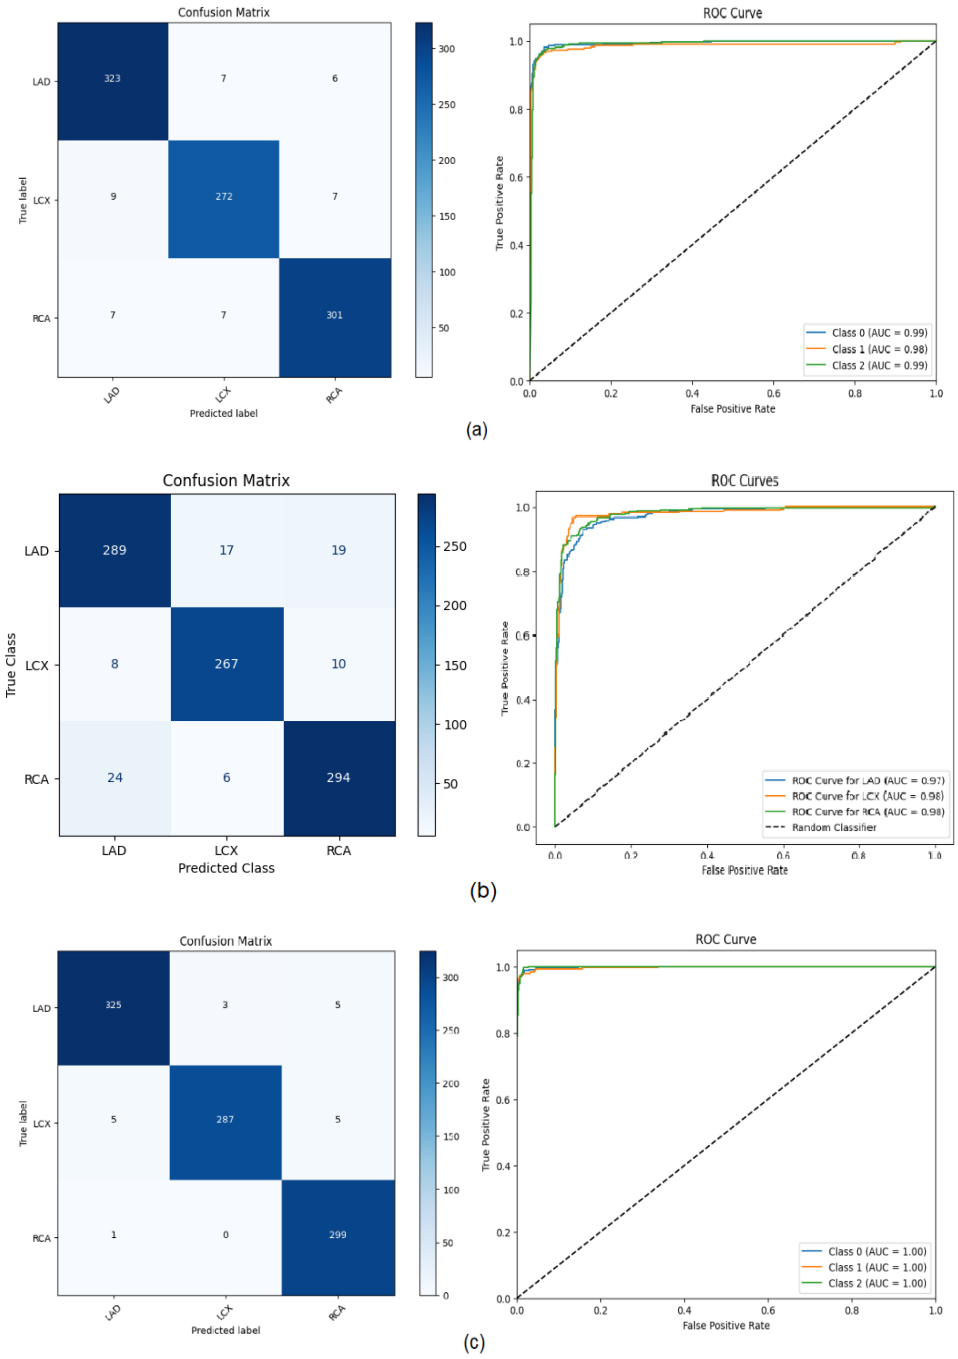

Fig. 7. Confusion matrices and ROC curves of the best models obtained (CNN+LSTM+ATTN) for (a) ECG, (b) PPG, and (c) combination of ECG and PPG signals.

TABLE II. COMPARISON OF PERFORMANCE WITH PRIOR STUDIES

Author, Year	Data	AI Model	Acc.(%)	AUC		
				LAD	*LCX*	*RCA*
Tao et al., 2018 [21]	MCG	XGBoost	NA	0.74	0.68	0.65
Huang et al., 2022 [22]	12 lead ECG	InceptionV3		0.89	0.82	0.78
Roopa and Harish, 2019 [23]	12 lead ECG	IFN	92.3	NA		
Proposed work	Combined simultaneous single lead ECG and PPG	CNN + LSTM + ATTN	98.12	1.00	1.00	1.00

V. CONCLUSION

This paper proposes a method to diagnose and examine coronary artery stenosis (CAS) using ECG and PPG signals, further aided by deep learning algorithms. The comparison between three models—CNN, CNN-LSTM, and CNN-LSTM-ATTN—verifies that the effects of applying progressive AI structures upon CAS localization are prominent. The results demonstrate that both ECG and PPG signals are informative individually; however, when combined and processed through the CNN-LSTM-ATTN model, the highest classification accuracy of 98.12% and AUC scores of 1.00 were achieved for stenosis in LAD, LCX, and RCA.

These findings underscore the necessity of fusing multiple physiological signals to enhance CAS localization predictability and highlight the effectiveness of the CNN-LSTM-ATTN model in capturing spatial and temporal characteristics of multiple physiological signals while selectively attending to essential features. This approach shows great potential for non-invasive diagnosis of coronary artery diseases and the localization of obstructive lesions, which current clinical imaging techniques may inadequately address.

However, the study is not without limitations. The dataset used was relatively small, with data collected from a single hospital, which may limit the generalizability of the findings. Additionally, the study focused solely on single-lead ECG and PPG signals, excluding the potential benefits of multi-lead configurations or other physiological signals. Future research should explore larger, more diverse datasets and investigate the integration of additional modalities to further validate and enhance the proposed method. Moreover, real-time clinical implementation remains a challenge that warrants further development to ensure the practicality and reliability of the approach in routine healthcare settings.

In conclusion, while the proposed method demonstrates promising results for non-invasive CAS diagnostics, addressing these limitations will be crucial for broader adoption and impact in clinical practice.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial support provided by the Ministry of Higher Education Malaysia through the Trans-disciplinary Research Grant Scheme (TRGS/1/2019/UKM/01/4/3).

Unlocking the Potential of Cloud Computing in Healthcare: A Comprehensive SWOT Analysis of Stakeholder Readiness and Implementation Challenges

Alaa Abas Mohamed
Information System Department, Al-Neelain University, Khartoum, Sudan

***Abstract*—The adoption of cloud computing in healthcare holds the potential to revolutionize healthcare delivery, particularly in developing regions. Despite its promise of scalability, cost-effectiveness, and improved data management, challenges such as digital literacy gaps, infrastructure deficiencies, and security concerns hinder its implementation. This study evaluates the readiness for adopting cloud computing in Sudan's healthcare sector through a comprehensive SWOT analysis. Findings reveal that 93.75% of patients are willing to learn electronic health systems (EHS), yet 53.12% prefer paper records, indicating trust issues. Among medical staff, 34.38% report poor digital literacy, and 46.88% cite limited access to technology as a barrier. Ministry of Health employees highlight poor infrastructure (33.33%) and limited resources (30%) as significant obstacles. By identifying strengths, weaknesses, opportunities, and threats, this research provides actionable recommendations for overcoming these barriers. The findings contribute to the ongoing discourse on digital health transformation, offering insights into fostering trust in cloud technologies for enhanced healthcare outcomes.**

***Keywords*—Cloud computing; SWOT; strength; weakness; opportunities; threat**

I. Introduction

The healthcare sector is undergoing significant digital transformation, with cloud computing emerging as a cornerstone of these advancements. Cloud-based solutions offer scalable, flexible, and cost-effective systems that improve patient care, enhance data management, and facilitate collaboration among healthcare providers (Rimal, Choi, & Lumb, 2017) [1]. Recent studies highlight that cloud computing is pivotal in facilitating the exchange of critical health information, such as in dialysis management, enabling better patient outcomes and streamlined care delivery (Ehteshami et al., 2024) [9]. This potential is particularly critical in developing regions like Sudan, where healthcare systems face persistent challenges, including resource constraints, inadequate infrastructure, and limited access to advanced technologies (Alotaibi, 2020; Liu, Wu, & Sun, 2019) [4], [3]. Furthermore, the COVID-19 pandemic underscored the need for resilient and technology-driven healthcare systems to effectively respond to emerging challenges (Jalali & Kaiser, 2018) [2]. Despite its promise, adopting cloud computing in healthcare is hindered by significant barriers. Key issues include limited digital literacy among healthcare professionals, insufficient infrastructure, and concerns regarding the security and privacy of sensitive patient data (Griebel et al., 2015) [7]. These challenges hinder the implementation of electronic health systems (EHS), which are critical to leveraging cloud computing's full potential. Additionally, the integration of the Internet of Medical Things (IoMT) with cloud systems offers transformative potential by enabling real-time monitoring and enhancing connectivity across healthcare systems, but this requires overcoming technical and infrastructural challenges (Sarıkaya & Dicle, 2024) [10]. Addressing these barriers is vital to creating a robust, secure, and efficient healthcare ecosystem that meets the needs of patients and providers alike. This study evaluates the readiness and feasibility of adopting cloud computing in Sudan's healthcare sector through a comprehensive SWOT analysis. By analyzing the perspectives of patients, medical staff, and Ministry of Health employees, the research identifies the strengths, weaknesses, opportunities, and threats associated with cloud adoption. The findings contribute to the literature by offering actionable recommendations tailored to Sudan's unique challenges and opportunities. The remainder of this paper is structured as follows. Section II outlines the methodology, detailing the data collection process and SWOT framework used. Section III reviews previous studies on cloud computing in healthcare to contextualize the findings. Comparative analysis is given in Section V. Section IV presents the results of the SWOT analysis, while Section VI discusses the implications and offers recommendations. Finally, Section VII concludes with key insights and suggestions for future research. By focusing on readiness and barriers to adopting cloud computing, this study addresses a critical gap in the literature and provides actionable insights for healthcare policymakers aiming to enhance digital transformation efforts.

II. Methodology

Cloud computing in healthcare presents multifaceted challenges that require a structured and comprehensive approach to understanding and addressing them effectively. This study employs a SWOT (Strengths, Weaknesses, Opportunities, Threats) analysis framework, which is a strategic planning tool widely used to assess both internal and external factors influencing a system or organization. The SWOT framework is particularly suitable for evaluating the

readiness and feasibility of cloud computing adoption, as it allows for a holistic examination of enablers and barriers from multiple stakeholder perspectives. Recognizing the critical importance of data security in cloud adoption, Alshar'e et al. (2024) [11] highlight blockchain technology as an effective solution for enhancing data security and mitigating privacy risks, which underscores the necessity of addressing security concerns in this study. The following steps outline the systematic approach used to conduct the research:

1) Defining the scope and objectives: The primary objective of this study is to evaluate the readiness for adopting cloud computing in Sudan's healthcare sector. This involves identifying key strengths, weaknesses, opportunities, and threats from three stakeholder groups: patients, medical staff, and Ministry of Health employees.

2) Survey design and data collection: Surveys were designed to capture both qualitative and quantitative data. Each stakeholder group was asked specific questions regarding:

a) Technological readiness such as comfort with using electronic systems).

b) Perceived challenges such as digital literacy and infrastructure.

c) Willingness to adopt electronic health systems.

A structured questionnaire was used to ensure consistency across responses. The data was collected over a predefined period to ensure accuracy and reliability.

3) SWOT Analysis framework: Responses were categorized into the four SWOT dimensions:

a) Strengths: Positive attributes that support cloud computing adoption.

b) Weaknesses: Internal limitations that could hinder adoption.

c) Opportunities: External conditions that could facilitate adoption.

d) Threats: External risks that could undermine success.

The categorization was performed using a systematic coding process based on predefined criteria.

4) Comparative analysis across stakeholder groups: ata from patients, medical staff, and Ministry of Health employees were compared to identify common themes and divergent perspectives. This comparative analysis helped highlight stakeholder-specific needs and challenges.

5) Synthesis of findings and recommendations: Based on the SWOT analysis, actionable recommendations were developed to address key barriers and leverage existing opportunities.

III. Previous Studies

Cloud computing has been extensively studied for its potential to improve healthcare systems globally. A study by Rimal et al. (2017) [1] found that cloud computing offers improved efficiency, flexibility, and cost-effectiveness in managing patient records and delivering telemedicine services. Similarly, Jalali and Kaiser (2018) [2] identified that cloud-based health systems enable faster data retrieval and collaboration between healthcare providers.

However, barriers such as security concerns and limited infrastructure have been highlighted by Liu et al. (2019) [3], who argued that trust in cloud systems must be built through rigorous data protection measures and staff training. Alotaibi (2020) [4] explored the challenges of adopting cloud solutions in healthcare, finding that staff resistance to change and lack of technical expertise were common obstacles in low-resource settings.

These studies provide valuable insights into the general benefits and challenges of cloud computing in healthcare and form the basis for analysing the specific conditions in Sudan.

IV. SWOT Analysis

A. Patients

1) Strengths:

a) Comfort with technology: 50% of patients are "very comfortable" using technology, while 93.75% are willing to learn how to use electronic health systems if it improves their healthcare experience.

b) Implication: This demonstrates a high level of technological readiness among patients, which can facilitate the adoption of cloud computing systems.

2) Weaknesses:

a) Preference for paper records: 53.12% of patients prefer paper records, reflecting distrust in digital systems.

b) Implication: Trust-building initiatives will be needed to overcome this preference, especially regarding concerns about data security and reliability.

3) Opportunities:

a) Need for additional support: 87.5% of patients believe they need more support to use electronic health systems effectively.

b) Implication: Providing educational resources and support can bridge the gap between readiness and effective adoption.

4) Threats:

a) Resistance to digital records: The preference for paper records (53.12%) poses a threat to the full implementation of EHS, as it suggests potential resistance to change.

5) Gender divide: There may be differences in comfort with technology between genders, indicating a need for tailored training.

B. Medical Staff

1) Strengths:

a) Adaptability to technology: 37.5% of medical staff adapt "Somewhat well," and 25% adapt "Well" to new technologies.

b) Implication: Medical staff are generally open to adopting electronic systems, which is crucial for the success of cloud computing initiatives.

2) Weaknesses:

a) Low digital literacy: 34.38% of medical staff rated their digital literacy as "Poor," while 28.13% rated it as "Fair."

b) Implication: Training programs are necessary to enhance the digital competency of staff to effectively use EHS.

3) Opportunities:

a) Demand for additional training: 93.75% believe that additional training is necessary for EHS to succeed.

b) Implication: This presents a clear opportunity for healthcare institutions to implement targeted training programs.

4) Threats:

a) Limited access to technology: 46.88% of staff reported that limited access to technology is a significant barrier to adopting EHS.

b) Implication: Without addressing this issue, the successful adoption of cloud computing could be limited to certain facilities with better infrastructure.

C. Ministry of Health Employees

1) Strengths:

a) Strong support from MOH: 36.67% of Ministry employees rated the Ministry's support for EHS as "High."

b) Implication: Institutional support is a key enabler for the transition to cloud computing in healthcare.

c) Stakeholder engagement: 96.67% believe that stakeholder engagement is crucial for the success of EHS.

d) Implication: The recognition of the importance of collaboration across different sectors can accelerate the digital transformation process.

2) Weaknesses:

a) Technological infrastructure: 33.33% rated the technological infrastructure as "Poor," indicating a significant gap that must be addressed to ensure the success of EHS.

b) Implication: Investment in modern infrastructure is essential to support cloud-based systems.

3) Opportunities:

a) Providing more training: 36.67% believe that additional training is needed to support the transition to EHS.

b) Implication: Investment in capacity-building initiatives is crucial for the success of digital transformation in healthcare.

4) Threats:

a) Limited financial resources: 30% identified limited financial resources as a key challenge to implementing EHS.

b) Implication: Securing adequate funding is essential to support the infrastructure and training needs required for cloud adoption.

V. Comparative Analysis

A comparison of the perspectives from patients, medical staff, and Ministry of Health employees reveals common themes of willingness to adopt EHS but highlights the need for support and infrastructure improvements. Table I provides a detailed breakdown of responses across stakeholder groups, highlighting key metrics such as comfort with technology, willingness to learn, main weaknesses, opportunities, and threats. Fig. 1 illustrates these metrics visually, showing that while 93.75% of patients and medical staff are willing to learn electronic health systems (EHS), comfort with technology varies significantly, with only 50% of patients feeling very comfortable compared to 37.5% of medical staff and 36.67% of MOH employees. Weaknesses, such as 53.12% of patients preferring paper records and 34.38% of medical staff reporting poor digital literacy, are notable barriers to adoption. Opportunities are evident, as shown in Fig. 2, with all three groups identifying a need for resources and support. 87.5% of patients, 93.75% of medical staff, and 96.67% of MOH employees emphasize the importance of additional resources to enable successful implementation. However, threats such as resistance to digital records (affecting 53.12% of patients) and limited financial resources (affecting 30% of MOH employees) underscore the challenges ahead. Fig. 3 further compares survey responses across the groups, presenting a comprehensive view of the disparities and commonalities in stakeholder perspectives. This highlights the critical areas that need to be addressed, including investment in digital literacy programs, improved access to technology, and sustained stakeholder engagement.

TABLE I. A Comparison of the Perspectives from Patients, Medical Staff, and Ministry of Health Employees

Category	Patients	Medical Staff	MOH Employees
Comfort with Technology	50% are "Very comfortable."	37.5% adapt "Somewhat well," 25% "Well."	36.67% rate support as "High."
Willingness to Learn	93.75% willing to learn EHS.	93.75% agree continuous engagement is key.	96.67% agree on stakeholder engagement.
Main Weakness	53.12% prefer paper records.	34.38% rated digital literacy as "Poor."	33.33% rated infrastructure as "Poor."
Opportunities	87.5% need support to use EHS.	93.75% demand additional support/resources.	96.67% believe more resources are needed.
Main Threat	Resistance to digital records (53.12%).	Limited access to technology (46.88%).	Limited financial resources (30%).

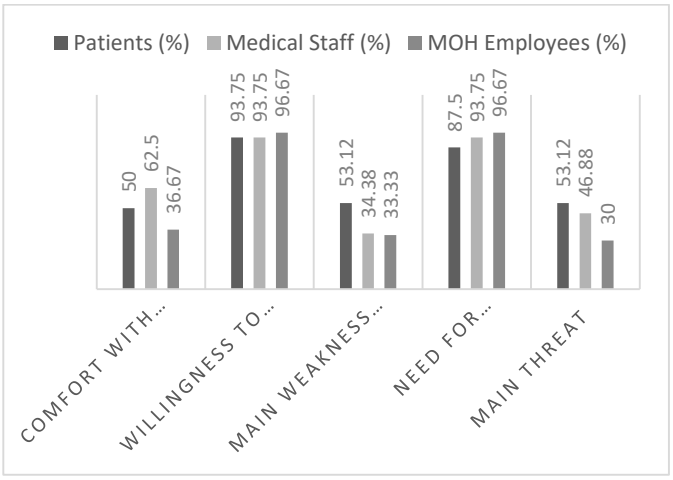

Fig. 1. A comparison of the perspectives from patients, medical staff, and Ministry of Health employees.

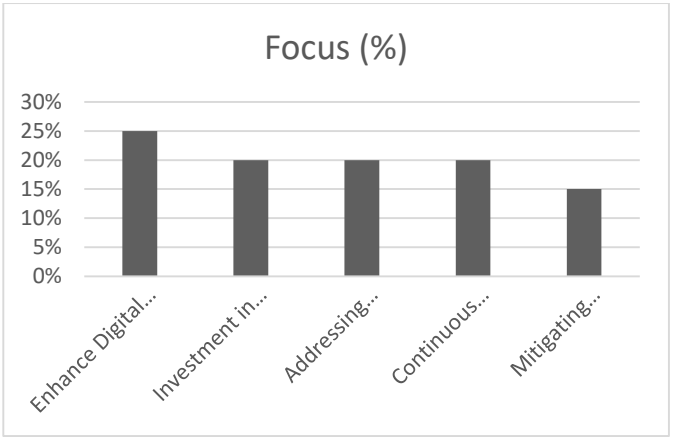

Fig. 2. The focus areas in the recommendations.

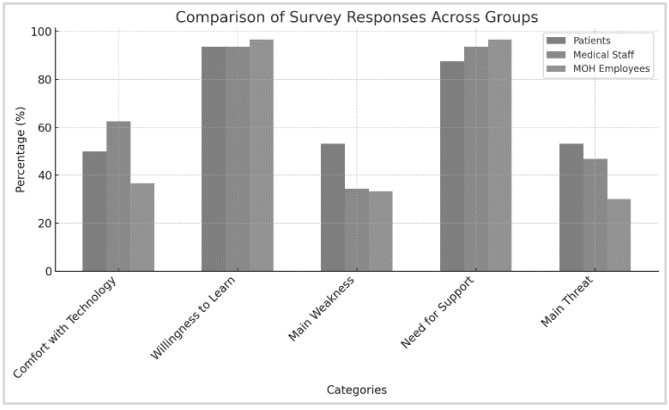

Fig. 3. Comparison of survey response across groups.

VI. Recommendations

1) Digital literacy training: Given the low digital literacy among medical staff (34.38% rated as "Poor"), it is critical to implement targeted training programs. These programs should be designed to improve competency in using electronic health systems (EHS) and address the specific technological needs of both healthcare professionals and patients. Tailored workshops, online modules, and continuous support could enhance digital readiness.

2) Investment in technological infrastructure: 33.33% of Ministry of Health employees reported poor technological infrastructure in healthcare facilities. Investing in modern, reliable infrastructure is essential to support cloud-based systems. This includes upgrading hardware, ensuring stable internet connections, and implementing secure cloud platforms to handle sensitive patient data. Adequate infrastructure is a foundational element for cloud computing in healthcare.

3) Addressing resistance to digital records: 53.12% of patients prefer paper records, indicating a significant trust issue with digital systems. To overcome this resistance, awareness campaigns should be launched to educate patients and staff about the benefits of electronic records, including security, accessibility, and efficiency. Building trust in digital systems is critical to ensuring successful adoption. Highlighting the security features and showing real-world examples of the improved outcomes of using cloud systems could help ease concerns.

4) Continuous support and stakeholder engagement: 96.67% of Ministry of Health employees and 93.75% of medical staff agree that continuous engagement and support are essential for the success of EHS. To ensure a smooth transition to cloud computing, healthcare institutions must provide ongoing technical assistance, regular feedback sessions, and open communication channels between healthcare providers, patients, and stakeholders. Stakeholder engagement ensures that concerns are addressed in real time, and that users feel supported throughout the process. This could include dedicated technical support teams, helplines, and regular system updates based on user feedback to improve system functionality and user satisfaction.

VII. Conclusion

The adoption of cloud computing in healthcare presents a transformative opportunity to modernize healthcare systems, improve patient outcomes, and enhance operational efficiency. This study evaluated the readiness and feasibility of adopting cloud computing in Sudan's healthcare sector through a comprehensive SWOT analysis, capturing the perspectives of patients, medical staff, and Ministry of Health employees. The findings highlight significant strengths, such as the willingness of 93.75% of patients to learn electronic health systems and the adaptability of medical staff. However, challenges, including low digital literacy among healthcare professionals (34.38% rated as poor), limited technological infrastructure, and concerns about data security, remain significant barriers. Actionable recommendations have been proposed to address these issues, such as targeted training programs, investment in infrastructure, and trust-building initiatives. Despite the contributions of this study, several limitations should be acknowledged. First, the reliance on survey-based data collection may introduce self-reporting biases, as respondents' perceptions may not fully represent their actual capabilities or behaviors. Second, the study's focus on Sudan's healthcare system limits the generalizability of the findings to other

regions or contexts with differing levels of technological readiness and resources. Third, the SWOT analysis, while effective in providing a comprehensive overview, does not explore the causal relationships between the identified factors or quantify their relative impact. Finally, the study primarily assesses the readiness for cloud adoption and does not investigate the long-term outcomes or sustainability of such initiatives. Acknowledging these limitations provides a balanced perspective on the study's findings. Nevertheless, the insights presented offer valuable guidance for policymakers and healthcare institutions seeking to adopt cloud computing. Future research should aim to address these limitations by exploring longitudinal studies, employing mixed-method approaches, and extending the analysis to diverse healthcare contexts to further validate and enhance the understanding of cloud adoption.

***Abstract*—This study presents a novel approach to predicting the helpfulness of online reviews using Artificial Neural Networks (ANNs) focused on information relevance. As online reviews significantly influence consumer decision-making, it is critical to understand and identify reviews that provide the most value. This research identifies four key textual features namely content novelty, content specificity, content readability, and content reliability, that contribute to perceived helpfulness and incorporates them as primary inputs for the ANN model. Datasets of Amazon reviews are analyzed, and various preprocessing steps are employed to ensure data quality. Reviews are classified as helpful or unhelpful based on helpful vote thresholds, with experiments conducted across multiple helpful vote thresholds to determine the optimal threshold value. Performance was evaluated using accuracy, precision, recall, and F1 scores, with the best-performing classifier achieving 74.34% accuracy at a helpful vote threshold of 12 votes. These results highlight the potential of information relevance-based criteria to enhance the accuracy of online review helpfulness prediction models.**

***Keywords*—Review helpfulness; online reviews; information relevance; review novelty; review readability; review specificity; Artificial Neural Networks**

I. INTRODUCTION

The emergence of internet has revolutionized life, bringing significant changes essential to people's daily life. In the past, tasks such as making purchases had to be done face-to-face. In this traditional market settings, consumers acquire new information via advertisements, brochures and word-of-mouth (WOM) about various products and services before making purchases. In the context of online reviews, consumer often reads multiple reviews before making purchasing decision. Online reviews have impacted not only consumers but also business, platforms and reviewers. Reviews can help consumers reduce uncertainty [1] regarding the quality of a product or service by offering firsthand insights and experiences from other users. For businesses, positive reviews can lead to increased sales as they build trust and credibility [2]. Platforms benefit from the continuous creation of online reviews and building consumer trust, which attracts more consumers. In turn, reviewers gain recognition from their peers and receive gifts and special promotion on platforms. Such incentives encourage them to continue providing useful reviews [3].

As the number of reviews rapidly increasing, platforms face the challenge of managing this large amount of information to ensure that consumers can easily access to the most relevant and helpful review. To address the issue, platforms have introduced feedback mechanisms that allow consumers to vote for posted reviews that they considered helpful. Readers are more likely to trust the statements if it has been marked as helpful by other consumers [4]. However, helpful vote is a manual process and could result in helpful reviews being ignored. Moreover, it is unclear to potential customers whether previous customers marked a review as "helpful" before using a product or service or after having used it. The criteria for what constitute a "helpful" review is not strictly defined and thus can be difficult to assess.

Many studies have utilized various theories such as Elaboration Likelihood Model (ELM) and Information Adoption Model (IAM) to capture numerous factors that affect review helpfulness [5-9]. In the context of IAM, it suggests that information helpfulness is influenced by argument quality and source credibility. Recent research has revealed inconsistencies on how to properly judge the quality of arguments in reviews. Some experts believe that certain parts of a review are difficult to measure objectively and can be changed depending on the situation [10]. Also, many traditional ways of measuring argument quality might not work well for evaluating personal, subjective aspects of the review content [11]. As a result, relevance has been suggested as an important factor, with its importance depending on the specific decision a reader is trying to make [12]. Information relevance is recognized as a key determinant of information diagnostic for gaining a better understanding of consumers' opinions and their relevance to electronic WOM communications [13]. Online reviews are perceived as relevant when businesses provide information that aligns with consumers' expectations [14].

Previous studies have typically examined factors that contribute to review helpfulness including, text sentiment [15, 16], review depth [17, 18], readability [19-21], novelty [22], credibility [2, 23], specificity [24], reliability [19] and reading enjoyment [25]. However, the research on this topic is quite scattered and inconsistent. Different studies focus on various parts of quality text or use different methods, which makes it hard to get a clear and complete picture. As a result, there is no definitive list of key factors related to information relevance, leading to an incomplete and fragmented understanding of the subject.

Drawing from this observation, this study introduces four key textual features based on information relevance perspective of content novelty, content specificity, content readability and content reliability that potentially contribute to the helpfulness of reviews. These factors represent essential dimensions of information relevance, to enhance quality of online review. Novelty introduces previously unmentioned perspectives, while specificity provides detailed information tailored to the reader's needs. Readability ensures that the information is easily understood, and reliability supports the trustworthiness and accuracy of the content. Therefore, the proposed features can help to better understand how the subjective qualities of reviews impact their helpfulness and influence customer purchasing decisions.

Next, this study adopts a 'threshold' approach to identify helpful reviews by categorizing them based on the number of helpful votes received. The concept of helpful votes threshold provides an innovative way to filter reviews, ensuring that reviews deemed helpful by a larger number of users are given prominence. By setting these thresholds, platforms can prioritize reviews that have resonated with consumers, thereby helping potential buyers make informed decisions more quickly. For instance, reviews exceeding a certain number of helpful votes can be classified as "helpful," allowing the system to highlight feedback that users have found insightful and trustworthy.

Although results did not show a dramatic improvement in classification accuracy, the threshold approach offers practical benefits. It enables a structured and automated system for identifying helpful content, reducing the reliance on manual helpfulness voting and minimizing the risk of helpful reviews being overlooked. The threshold system also aids in understanding how different levels of helpful votes correlate with review helpfulness, providing insights that could guide future improvements in review filtering algorithms. Furthermore, this threshold-based method could serve as a foundation for iterative refinements, where feedback from user interactions helps to adjust the threshold levels dynamically, enhancing the platform's ability to deliver relevant and valuable reviews to consumers.

The rest of this paper is organized as follows. The detail literature reviews of various factors or indicators that contribute to review helpfulness and helpful votes threshold impact on model performance is presented in Section II. Section III introduces methodology that integrates four review text characteristics. Section IV presented results and discussion. Lastly, Section V provides the conclusion of this work.

II. Literature Review

Previous works on review helpfulness have demonstrated association between various review characteristics and review helpfulness and serve as primary source of information over other aspects such as reviewer's identity, metadata and product [26-28]. Research indicates that the content quality, clarity, and emotional tone of the text significantly affect its perceived helpfulness as they enhance the review's credibility and relatability to readers [29]. In addition, text-related features such as length and structure can impact engagement levels, making them more critical than metadata or reviewer-related characteristics, which may not consistently correlate with helpfulness [30, 31]. Therefore, emphasizing text-related characteristics allows for a more direct assessment of review helpfulness.

Previous studies on novelty detection have explored various techniques to identify new and unique information within data. These studies aim to identify new information within a document by employing various approaches tailored to different objectives. Various widely used measurement metrics for novelty detection are utilized across document such as Simple New Word Count, Set Difference, TF-IDF scoring, and Cosine Distance [32, 33]. These methods apply a bag-of-words approach, utilizing word counts within a document. Some novelty measures are derived from probabilistic document models [33-35]. The Simple New Word Count measure, which examines the occurrence of novel words in sentences, has been shown to be as effective as probabilistic document models and other bag-of-words-based methods [33]. Recently, Deep Learning methods such as BERT (Bidirectional Encoder Representations from Transformers) have gained popularity for tasks involving semantic textual similarity [36]. One such method, Sentence-BERT [37], utilizes a pre-trained BERT model to generate context-aware text embeddings, which can be employed to assess the similarity between documents. Sentence-BERT was adapted to calculate the novelty measure in the main analysis, and the analyses were replicated using new word pairs and a revised version of the Simple New Word Count measure [22]. The work also demonstrated review novelty impacts on consumers and businesses.

The discussion on specificity primarily focuses on the sentence level. A common definition of specificity, as used by [38-40], refers to the amount of detail within a sentence. Research on specificity utilizes a broad array of features to indicate sentence specificity. While some studies employ a large collection of features, others may rely on just one. Given the significant variation in feature sets, it is logical to analyze the importance of each feature. Based on current knowledge, the simplest prediction method relies on just one feature which is normalized inverse word frequency (IDF). The sum, average, minimum, and maximum IDF values for all words within a sentence were evaluated, with the maximum IDF value found to be the best indicator of specificity [41]. However, relying on a single feature has its limitations, as the predictor may lose effectiveness in tasks involving multiple topics, due to the significant variation in word distribution across different topics. Speciteller [42] is a popular tool for predicting sentence specificity. It generates 17 features, including sentence characteristics and word representations. Typically, researchers combine Speciteller features with their own custom features to build specificity estimators. For instance, the study by [43] combined Speciteller features with online dialogue features, resulting in a model that outperforms Speciteller in predicting specificity in classroom discussions. In contrast, the work by [24] used a model developed by [38] to assess the specificity of sentences in product reviews. They introduced three new metrics: the percentage of specific sentences in a review, the overall specificity of the review, and the balance between specific and general sentences. This study represents the first attempt to approach the helpfulness prediction problem from sentence specificity perspective.

Review readability, which refers to the ease with which a text can be understood, significantly affects the perceived helpfulness of reviews. Consumers are more likely to find a review helpful if they can easily interpret it. Therefore, higher readability generally facilitates better understanding. Like novelty and specificity, numerous features are used to predict readability. The features commonly employed in readability prediction studies are generally consistent. These features were categorized into semantic and syntactic groups, with an analysis of both the words and sentence structures [44]. Syntactic features include sentence length, average number of characters per word, average number of syllables per word and the percentage of various part-of-speech tags. Semantic features involve the frequency of various 1-, 2-, and 3-word sentences in a review. Many studies have utilized various readability indices, including the Simple Measure of Gobbledygook (SMOG), Automated Readability Index (ARI), Gunning Fog Index (GFI), Flesch–Kincaid Grade Level (FKGL), Coleman–Liau Index (CLI), and Flesch–Kincaid Reading Ease (FKRE) to predict review helpfulness [21, 28, 45] found that a hybrid set of features based on linguistic categories, review metadata, readability, and subjectivity offered the best review predictive performance. Review content features, such as readability, were identified as the most effective predictors of helpfulness [28]. Readability, along with linguistic and psychological features, was utilized to predict the helpfulness of movie reviews [45].

The reliability of online reviews has attracted significant attention in recent years. Various studies have explored the factors that influence the reliability of online reviews, and the methods used to assess and enhance this reliability. The Linguistic Inquiry and Word Count (LIWC) program was used to analyze the proportion of positive and negative words in reviews [46, 47]. It has been discovered that the sentiment of a review, whether positive or negative, along with advice for decision-making and claims of expertise, significantly influences the perceived helpfulness of the review [46]. Additionally, previous studies have highlighted that both sentiment orientation (positive or negative) and the writing style of the review (subjective or objective) are key factors in determining its believability [46, 48]. Consequently, research conducted by [19] leveraged these elements as reliability indicators to assess review helpfulness. The detection of spam reviews is also critical in evaluating online review reliability. Early research focused on identifying spam reviews by detecting copied content [49-51]. Various reliability features, such as Kullback-Leibler divergence, syntactic text characteristics, and review semantics, have been employed to distinguish fake reviews from genuine ones. Additionally, several algorithms have been developed to filter out unreliable reviews [52-53].

The concept of helpful votes threshold in the context of online reviews, is a crucial parameter in binary classification systems. It directly impacts the performance of algorithms that distinguish between helpful and unhelpful reviews by setting a boundary that defines what qualifies as "helpful." An inappropriate threshold can lead to the misclassification of reviews, where helpful reviews are categorized as unhelpful or vice versa, ultimately weakening the model's performance and skewing results.

The choice of classification threshold is essential to improve classification precision. Studies, such as those by Ghose and Ipeirotis [64], have found that a threshold where the ratio of helpful votes to total votes equals 0.6 can significantly enhance classification accuracy for review helpfulness on platforms like Amazon. This threshold value, also adopted by researchers such as Krishnamoorthy [21] and Malik and Hussain [69], minimizes the chances of misclassifying helpful reviews as unhelpful and vice versa, improving the reliability of the helpfulness measure.

III. METHODOLOGY

The section introduces methodology for predicting the helpfulness of online reviews, including the collection of product reviews, review characteristics and the helpfulness of a review as shown in Fig. 1.

A. Data Collection

Many e-commerce platforms provide product or service reviews and relevant data. This study is focused on products available in Amazon.com. The data collected included review rating, review title and text, identification number of a product, user identification number, the time a review is posted, number of helpful votes received by a review and verified purchase of a product. Reviews from the year 2022 until the year 2023 were downloaded for this study [54].

B. Data Preparation

This study utilized a dataset consisting of 9,369 helpful reviews and 9,369 unhelpful reviews sourced from the Beauty, Health, and Personal Care categories on Amazon.com. The dataset is consistent across all helpful votes thresholds employed in this experiment. As many e-commerce platforms provide valuable insights through product and service reviews, this research specifically focuses on products available on Amazon.com.

The collected data included various attributes such as review ratings, review titles, review text, product identification numbers, user identification numbers, timestamps of when the reviews were posted, the number of helpful votes each review received, and whether the purchase was verified. The reviews analyzed were collected from the years 2022 to 2023 [54]. To refine the data before feature extraction, non-English text is filtered out from the dataset. Since text containing URLs and HTML tags might point to a promotional site, or competitors, rows of data with these elements are also removed. In addition, text with emojis and emoticons are also eliminated. Then, the rows of data where the text column is empty or contains fewer than 5 words are excluded, as these offer limited information for potential customers [55]. Besides, data with duplicated text are also omitted. Review duplication can potentially occur in three difference situations [56]:

- Duplicate reviews of the same product with a different user identification number.
- Duplicate reviews from the same user ID but on different products.
- Duplicate reviews from different user IDs on different products.

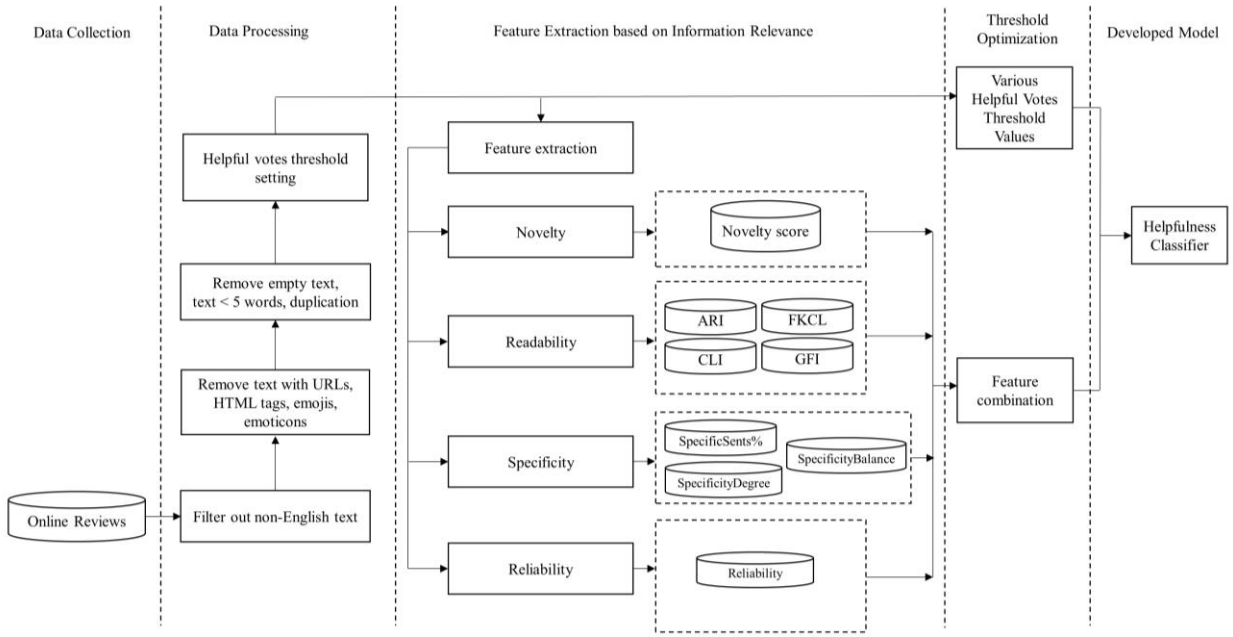

Fig. 1. Research process of this work

In terms of helpful indicator, the study by [57] suggest that highly adopted review helpfulness ratio (number of helpful votes/total number of votes) could lead to highly bias results. Hence, this study utilized the various helpful votes threshold values that is transformed into binary representation.

C. Feature Extraction

1) Content novelty: Some previous studies have described novel information as information that is different from what readers already know or expect [58]. However, most consumers cannot rely solely on their prior knowledge to guide them when making decision in an online environment, especially when purchasing experienced goods [59]. New information and perspective in online reviews may influence consumers to purchase products as it increases consumer's awareness about a product or a service. Consumers highly value knowledge gained from firsthand experience, often spending substantial time and effort searching for and reading reviews to find new information and insights. Therefore, novel information in reviews can be perceived as helpful by consumers.

Empirical evidence indicates that most consumers do not look beyond the first page of search results [60, 61]. Additionally, a consumer survey reveals that most consumers read no more than ten reviews before making a purchase [62]. Hence, content novelty can be defined as the amount of novel information in current review compared with the 10 most recent reviews on a single page. Novelty score for each review is used to determine the amount of novel information in reviews. The method of measuring the amount of novel information in each review is based on method proposed by [22]. First, let r_i represent the focal review and let $C_i = \{r_{i1}, r_{i2}, r_{i3}, \ldots, r_{ij}\}$ represent the comparison set for r_i, where j is the number of reviews in the comparison set (up to 10).

The novelty score for r_i given the comparison set C_i can be expressed as:

$$N(\rho_\iota, X_\iota) = \min_{\rho_{\iota\kappa} \square X_\iota} \left(1 - \chi o \sigma \left(\varepsilon \mu \beta(\rho_\iota), \varepsilon \mu \beta(\rho_{\iota\kappa})\right)\right) \quad (1)$$

Where

- emb(r) represent the embedding of review r using the context-aware representation method.
- $\cos(\text{emb}(r_i), \text{emb}(r_{ik}))$ is the cosine similarity between the embeddings of the focal review r_i and a review r_{ik} in the comparison set C_i.

The final novelty score for the review r_i, considering all possible comparison sets $C_1, C_2, C_3, \ldots, C_n$ is the average of the minimum novelty score across all comparison sets:

$$\Phi \iota \nu \alpha \lambda \ No \varpi \varepsilon \lambda \tau \psi \ \Sigma \chi o \rho \varepsilon \ (\rho_\iota) = \frac{1}{\nu} \sum_{\mu=1}^{\nu} N(\rho_\iota, X_\mu) \quad (2)$$

Where n is the number of different comparison sets considered for r_i and m is the index of the comparison set.

2) Content readability: The readability of a review is another crucial factor that can influence its perceived helpfulness. A review that is highly readable is more likely to be read and voted on by a larger number of users. Readability refers to the ease with which a reader can understand and process a piece of textual information [63]. The readability feature also determines the complexity of any review for the user [45]. Previous research by [64] shows that readability and subjectivity features outperform the lexical features employed by [65]. The work by study [21] shows that the combination of features derived from linguistic categories, readability, review metadata, and subjectivity provide the most accurate predictive performance.

To assess review readability, four grade level readability metrics can be utilized namely (1) Automated Readability Index (ARI), (2) Flesch–Kincaid Grade Level (FKGL), (3) Gunning Fog Index (GFI), and (4) Coleman–Liau Index (CLI) [21].

ARI was selected in this study because it is one of the primary measures used to assess text readability and is less prone to error than other readability measures [66]. The ARI can be calculated using its standard formula:

$$\text{API } \Sigma\chi\text{o}\rho\varepsilon\text{=4.71 } \left(\frac{\nu\upsilon\mu\beta\varepsilon\rho \text{ o}\phi \chi\eta\alpha\rho\alpha\chi\tau\varepsilon\rho\sigma}{\nu\upsilon\mu\beta\varepsilon\rho \text{ o}\phi \omega\text{o}\rho\delta\sigma}\right) +0.5 \left(\frac{\nu\upsilon\mu\beta\varepsilon\rho \text{ o}\phi \omega\text{o}\rho\delta\sigma}{\nu\upsilon\mu\beta\varepsilon\rho \text{ o}\phi \sigma\varepsilon\nu\tau\varepsilon\nu\chi\varepsilon\sigma}\right) - 21.43 \quad (3)$$

By analyzing sentence length, word difficulty, and text cohesion, the FKGL formula measures how challenging readers may find a text. The formula is as follows:

$$\text{K}\Gamma\Lambda\ \Sigma\chi\text{o}\rho\varepsilon = 0.39 \left(\frac{\omega\text{o}\rho\delta\sigma}{\sigma\varepsilon\nu\tau\varepsilon\nu\chi\varepsilon\sigma}\right) - 11.8 \left(\frac{\sigma\psi\lambda\lambda\alpha\beta\lambda\varepsilon\sigma}{\omega\text{o}\rho\delta\sigma}\right) - 15.59 \quad (4)$$

The Gunning Fog Index formula is based on the idea that shorter sentences written in clear, straightforward language receive a better score than longer, more complex sentences. Online reviews that score well on the Gunning Fog Index are likely to be more accessible and comprehensible to a broader audience, enhancing user engagement and improving the overall quality of the review content. The formula is given by

$$\Gamma\Phi\text{I=0.4} \left[\left(\frac{\omega\text{o}\rho\delta\sigma}{\sigma\varepsilon\nu\tau\varepsilon\nu\chi\varepsilon\sigma}\right) + 100 \left(\frac{\chi\text{o}\mu\pi\lambda\varepsilon\xi \ \omega\text{o}\rho\delta\sigma}{\omega\text{o}\rho\delta\sigma}\right)\right] \quad (5)$$

Meanwhile, CLI scores indicate the complexity of a text and are determined using the formula:

$$\text{X}\Lambda\text{I } \Sigma\chi\text{o}\rho\varepsilon\text{=0.0588} \left(\frac{\lambda\varepsilon\tau\tau\varepsilon\rho\sigma}{100 \ \omega\text{o}\rho\delta\sigma}\right) - 0.296 \left(\frac{\sigma\varepsilon\nu\tau\varepsilon\nu\chi\varepsilon\sigma}{100 \ \omega\text{o}\rho\delta\sigma}\right) - 15 \quad (6)$$

3) Content specificity: To assess content specificity in reviews, we adopted a two-step approach that involves calculating a specificity score based on the Normalized Inverse Document Frequency (NIDF) method and then deriving three specific features as outlined in prior research.

Inverse Document Frequency (IDF) is a widely recognized metric that measures the discriminative ability of a term within a document collection. It is defined as the logarithmic ratio of the total number of documents in the collection (n_d) to the number of documents containing the term (known as the term's document frequency, $df(t_i)$), as shown as follow:

$$IDF(t_i) = \log\left(\frac{n_d}{df(t_i)}\right) \quad (7)$$

In this study, we employed the Normalized Inverse Document Frequency (NIDF)The NIDF, defined in equation 8, normalizes with respect to the number of documents not containing the term ($n_d - df(t_i)$) and adds a constant 0.5 to both the numerator and the denominator to moderate extreme values:

$$NIDF(t_i) = \log\left(\frac{n_d - df(t_i) + 0.5}{df(t_i) + 0.5}\right) \quad (8)$$

Commonly used words, such as "the", "and", and "it" are likely to appear in nearly every document and are therefore not particularly discriminative. This lack of discriminative capability is reflected in their low NIDF values. Conversely, terms that occur in only a small number of documents are more useful for distinguishing between documents, resulting in higher NIDF values.

Our assumption is that documents dominated by terms with low NIDF values are less specific than those containing more discriminative terms. Consequently, we define a document specificity score, S_1, as follows:

$$S_1(d) = \frac{1}{l_d} \sum_{t_i \in d} tf(t_i) \cdot \log\left(\frac{n_d - df(t_i) + 0.5}{df(t_i) + 0.5}\right) \quad (9)$$

In this equation, $tf(t_i)$ represents the term frequency of t_i in document d, and l_d denotes the length of document d. The inclusion of l_d in the denominator reduces the impact of varying document lengths on the specificity score.

Following this calculation of the specificity score for each review, we further derived three specific features that have been proposed in previous study [24]. These features aim to assess different aspects of specificity within the context of helpfulness in online reviews.

- SpecificSents% represents the percentage of specific sentences within a review. A sentence is classified as "specific" if its specificity score is 0.5 or higher. This feature is designed to assess whether the number of specific or general sentences in a review affects its perceived helpfulness.
- SpecificityDegree represents the overall specificity of a review. Given the set *P* all sentences in a review and $\sigma(p)$ as the specificity score of a sentence $p \in P$, the specificity degree of the review is defined as:

$$\Sigma\pi\varepsilon\chi\iota\phi\iota\varpi\iota\tau\psi\Delta\varepsilon\gamma\rho\varepsilon\varepsilon = \frac{\sum_{\pi}^{\Pi} \int(\pi)}{|\Pi|} \quad (10)$$

Where |P| is the total number of sentences in the review.

- SpecificityBalance measures the balance between specific and general sentences in a review. Let S be the set of specific sentences (with a specificity degree ≥ 0.5) and G the set of general sentences (with a specificity degree < 0.5) in a review. The specificity balance of a review is calculated as:

$$\Sigma\pi\varepsilon\chi\iota\phi\iota\chi\iota\tau\psi\text{B}\alpha\lambda\alpha\nu\chi\varepsilon = \frac{||\Sigma| - |\Gamma||}{|\Sigma| + |\Gamma|} \quad (11)$$

Where |S| is the number of specific sentences, |G| is the number of general sentences and $||S|-|G||$ represents the absolute difference between these quantities. A value of 0 indicates a perfect balance between specific and general sentences, whereas a value of 1 means the review consists entirely of either specific or general sentences. According to a study by [67], general sentences are vital for high-quality journalism summaries, suggesting that this balance might influence the perception of helpfulness in product reviews as well.

4) Content reliability: Content reliability plays a critical role in determining the trustworthiness of online reviews. For this feature, a binary indicator is used to represent the reliability

of the review, specifically through the presence of a verified purchase. Reviews from verified customers are considered more genuine because they come from individuals who have actually bought and used the product. This authenticity boosts the perceived reliability of the review, as users are more likely to trust feedback from verified buyers, viewing it as a truthful and accurate reflection of the product [68]. By using a binary indicator - where 1 represents a review from a verified purchase and 0 represents a non-verified review—this feature effectively captures the connection between the genuineness of the review and its perceived reliability. Incorporating this binary indicator allows for a more structured evaluation of content reliability, enhancing the accuracy of any model that seeks to assess the trustworthiness and overall value of online reviews.

D. Neural Network Architecture for Helpfulness Prediction

To predict review helpfulness, we developed an Artificial Neural Network (ANN) using a Multi-Layer Perceptron (MLP) classifier. The MLP architecture was carefully tuned to achieve optimal predictive performance by experimenting with the number of hidden neurons and analyzing the network's response to input features.

1) Model architecture: The MLP model receives each review as an input vector of features that capture key aspects related to content quality, readability, novelty, and specificity, which are hypothesized to influence helpfulness. The input layer of the MLP is designed to process these 9 input features (illustrated in Fig. 2), each representing a distinct attribute of the review. This input layer serves as the foundation for the subsequent layers, encoding the feature values as the model begins to learn from the data.

The final MLP model configuration is as follows:

- Input Layer: Accepts a vector of 9 features per review, providing the model with a rich, multi-dimensional view of each review.
- Hidden Layer Size: A single hidden layer with 140 neurons, which was selected as the optimal configuration after experimenting with values of 20, 40, 60, 80, 100, and 140 neurons. This configuration effectively balances complexity and generalization ability.
- Activation Function: The Rectified Linear Unit (ReLU) activation function was used for the hidden layer, providing computational efficiency and mitigating the vanishing gradient problem.
- Solver: The Adam optimizer was employed to train the network. Adam combines the benefits of Adaptive Gradient Algorithm (AdaGrad) and Root Mean Square Propagation (RMSProp), ensuring efficient convergence.
- Learning Rate: An initial learning rate of 0.001, which allows the model to learn gradually and converge steadily.
- Epochs: Training was set to a maximum of 2000 iterations, with early stopping to prevent overfitting.
- Random State: A random state of 42 ensures reproducibility across different runs.
- Output Layer: The output layer consists of a single neuron with a sigmoid activation function, which produces a binary output of either 0 or 1 for each review. Here, an output of 1 indicates that the model predicts the review as "helpful" while an output of 0 indicates a prediction of "not helpful".

The optimal configuration of 140 hidden neurons, based on its predictive accuracy, provided the best balance between model complexity and performance. By systematically testing different neuron counts, we identified this structure as the most suitable for the task of review helpfulness prediction.

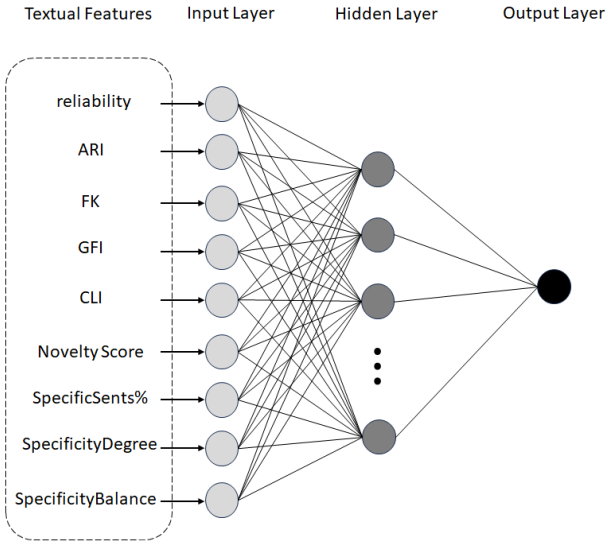

Fig. 2. Layout of MLP model.

2) Performance metrics: To evaluate the effectiveness of our model in classifying online reviews as helpful or unhelpful, we utilized several performance metrics: accuracy, precision, recall, and F1 score. Each of these metrics provides insight into different aspects of model performance, particularly in the context of user-generated content where the classification of reviews can significantly impact consumer decision-making.

Accuracy measures the overall correctness of the model's predictions. It is defined as the ratio of the number of correct predictions to the total number of predictions made. In the context of online reviews, it can be expressed mathematically as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (12)$$

Where

- TP is True Positives (number of helpful reviews correctly classified as helpful).
- TN is True Negatives (number of unhelpful reviews correctly classified as unhelpful).
- FP is False Positives (number of unhelpful reviews incorrectly classified as helpful).

- FN is False Negatives (number of helpful reviews incorrectly classified as unhelpful).

Precision quantifies the accuracy of the positive predictions made by the model, focusing specifically on how many of the predicted helpful reviews are actually helpful. This metric is particularly important in online reviews, where consumers benefit from identifying truly helpful feedback. Precision is calculated as follows:

$$Precision = \frac{TP}{TP+FP} \quad (13)$$

Recall, also known as sensitivity, measures the model's ability to identify all relevant instances of helpful reviews. It assesses how many of the actual helpful reviews were correctly identified by the model. Recall is computed using the formula:

$$Precision = \frac{TP}{TP+FN} \quad (14)$$

The F1 score provides a balance between precision and recall, offering a single metric that captures both aspects of the model's performance. It is especially useful in scenarios where there is an uneven class distribution, such as when the number of helpful reviews significantly differs from unhelpful reviews. The F1 score is calculated as:

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (15)$$

In the context of online reviews, these metrics allow us to assess how well our model performs in distinguishing between helpful and unhelpful reviews. A high accuracy indicates that the model correctly identifies most reviews, while high precision ensures that consumers can trust the reviews labeled as helpful. Additionally, high recall signifies that the model successfully captures most helpful reviews, which is crucial for users seeking reliable information. The F1 score serves as a comprehensive measure, ensuring a balanced consideration of both precision and recall, which is vital in enhancing the overall consumer experience in online platforms.

E. Optimization of Helpful Votes Threshold Values

The use of Amazon.com's publicly available dataset, which contains only helpful votes, provides a reliable measure of review quality based on user interaction. Given the time constraints of this study, this dataset allowed for an efficient and effective investigation into the impact of helpfulness thresholds. Future research could expand this investigation by incorporating datasets that include total votes for comparison.

In this study, we examine various thresholds for helpful votes, ranging from more than 2 to more than 12, using intervals of 2 votes. Reviews with helpful votes exceeding the specified threshold are classified as helpful, while those with votes below the threshold are deemed unhelpful. Table I summarizes these thresholds.

The experiment stops at the helpful votes threshold of more than 14 because the data available for that threshold is not consistent with the data used for the previous thresholds (more than 2, 4, 6, 8, 10, and 12). For accurate model performance comparisons, it is crucial that the number of data points remains the same across all thresholds. This consistency ensures that any observed differences in model performance can be attributed to the thresholds themselves rather than variations in data quantity.

TABLE I. HELPFUL AND UNHELPFUL REVIEWS BY HELPFUL VOTES THRESHOLD

Helpful Votes Threshold	Helpful Reviews	Unhelpful Reviews
More than 2	> 2	≤ 2
More than 4	> 4	≤ 4
More than 6	> 6	≤ 6
More than 8	> 8	≤ 8
More than 10	> 10	≤ 10
More than 12	> 12	≤ 12

IV. RESULTS AND DISCUSSION

Fig. 2 illustrates the relationship between test accuracy and the number of hidden neurons in a neural network across different helpful vote thresholds. The x-axis represents the number of hidden neurons, ranging from 20 to 140, while the y-axis displays test accuracy as a percentage. Each line corresponds to a different threshold for the number of helpful votes, ranging from "> 2" to "> 12," offering insights into how the model performs with varying thresholds.

A general trend shows that test accuracy improves slightly with an increasing number of hidden neurons, though the gains are more pronounced for certain thresholds. The performance tends to stabilize around 100–140 hidden neurons for most thresholds, but the overall accuracy is highly dependent on the threshold used.

The helpful vote thresholds have a significant impact on performance. Lower thresholds, particularly "> 2" and "> 4", exhibit the lowest performance, with test accuracies ranging from 66% to 68%. This indicates that when the model includes reviews with very few helpful votes, it struggles to make accurate predictions. In contrast, moderate thresholds such as "> 6" and "> 8" show improved accuracies, ranging between 70% and 72%, but still do not reach the highest performance levels.

The highest test accuracies, around 73–74%, are achieved with higher thresholds such as "> 10" and "> 12". These thresholds indicate that when the model focuses on reviews with a greater number of helpful votes, it is able to generalize more effectively and perform better. Notably, the highest overall accuracy, approximately 74%, occurs at a threshold of "> 12" with 80 hidden neurons. This suggests that reviews with many helpful votes provide the model with more reliable data for classification, possibly due to clearer distinctions between helpful and unhelpful reviews in these subsets.

In summary, higher thresholds for helpful votes (such as "> 10" and "> 12") combined with around 80–100 hidden neurons offer the best classification performance, while lower thresholds lead to poorer model accuracy. The moderate thresholds (Fig. 3) provide a middle ground, but ultimately, the model benefits most from training on reviews with a larger number of helpful votes, which may contain clearer patterns for the network to learn from.

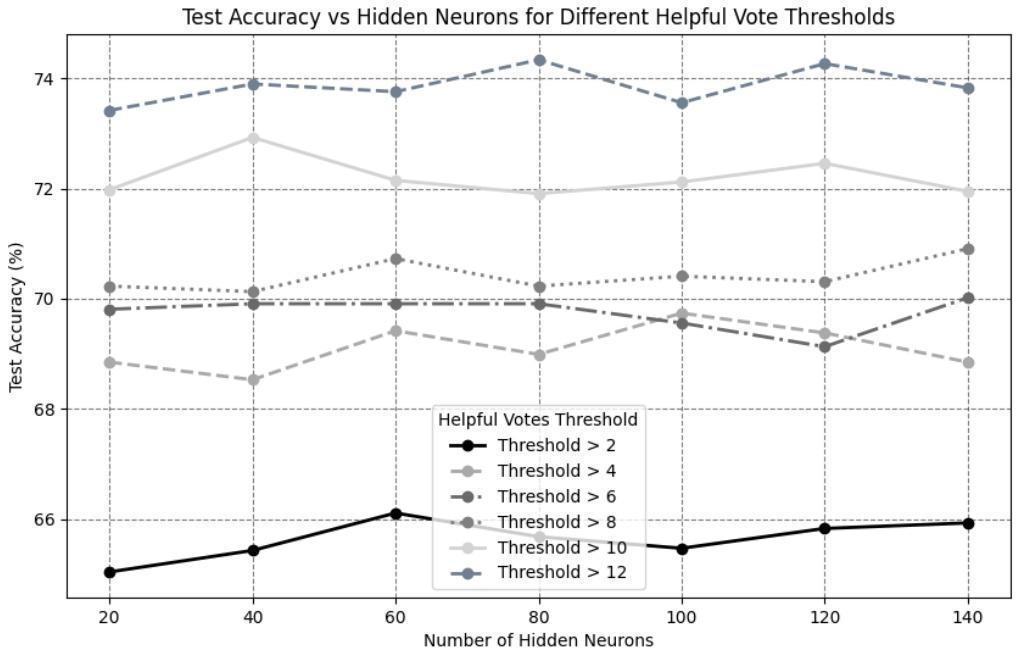

Fig. 3. Results of test accuracy with various helpful votes threshold and number of hidden neurons.

Table II presents model performance across various helpful vote thresholds and hidden neuron configurations, with metrics such as accuracy, precision, recall, and F1 score. These metrics provide a comprehensive evaluation of how well the model classifies reviews as helpful or unhelpful.

TABLE II. THE TEST ACCURACY, PRECISION, RECALL, AND FI SCORE FOR VARIOUS HELPFUL VOTES THRESHOLD AND NUMBER OF HIDDEN NEURONS

Helpful Votes Threshold	Hidden Neuron	Accuracy (%)	Precision	Recall	F1 Score
> 2	60	66.11	0.65	0.70	0.67
> 4	60	69.42	0.68	0.72	0.70
> 6	140	70.02	0.69	0.72	0.71
> 8	140	70.91	0.72	0.69	0.70
> 10	40	72.93	0.72	0.74	0.73
> 12	80	74.34	0.75	0.73	0.74

The model's accuracy improves steadily as the threshold for helpful votes increases. For the lowest thresholds, "> 2" and "> 4", the model achieves accuracy scores of 66.11% and 69.42%, respectively. As the threshold increases to "> 6" and "> 8", accuracy rises to 70.02% and 70.91%. The highest accuracy, 74.34%, is achieved with the "> 12" threshold and 80 hidden neurons. This suggests that reviews with a higher number of helpful votes are easier for the model to classify, possibly due to clearer patterns of helpfulness in more highly voted reviews.

Precision generally improves as the threshold increases, indicating the model's growing ability to correctly identify helpful reviews as the threshold rises. For the "> 2" and "> 4" thresholds, precision starts at 0.65 and 0.68, respectively. It peaks at 0.75 for the "> 12" threshold, demonstrating that the model is better at reducing false positives (i.e., labeling unhelpful reviews as helpful) when working with reviews that have garnered more helpful votes.

The recall metric, which measures the model's ability to correctly identify all helpful reviews, is relatively stable across different thresholds, ranging from 0.69 to 0.74. Interestingly, the highest recall value of 0.74 is achieved at the "> 10" threshold, slightly higher than the recall at the "> 12" threshold (0.73). This suggests that the model is not significantly more likely to miss helpful reviews as the threshold increases.

The F1 score, which balances precision and recall, follows a similar trend to accuracy. It starts at 0.67 for the "> 2" threshold and gradually increases to 0.74 for the "> 12" threshold. This indicates that as the threshold rises, the model becomes better at balancing false positives and false negatives. The highest F1 score (0.74) at the "> 12" threshold demonstrates the model's overall strongest performance with this higher threshold.

The model's performance improves consistently as the threshold for helpful votes increases. Higher thresholds, such as "> 10" and "> 12," yield the best results in terms of accuracy, precision, and F1 score, showing that reviews with more helpful votes provide better training data for classifying helpfulness. In particular, the threshold "> 12" paired with 80 hidden neurons achieves the highest overall accuracy (74.34%) and F1 score (0.74), making it the optimal configuration in this context. However, recall remains relatively stable across thresholds, indicating that the model consistently identifies a high proportion of helpful reviews regardless of the threshold. This analysis suggests that setting a higher helpful votes threshold allows the model to focus on more reliable data, leading to better classification performance. Overall, the findings indicate a robust performance in the model's classification capabilities, highlighting its potential for assisting users in identifying helpful content amidst a large volume of reviews.

The model's performance may be impacted by the presence of both search and experience products within the beauty, health, and personal care category. Search and experience products have distinct characteristics that influence how consumers evaluate reviews. For search products, features like skin type compatibility, ingredients, and fragrance are objective and easy to compare [70], [71], [18], leading consumers to generally agree on these qualities. Consequently, reviews for search products often need a higher number of helpful votes to meet consumer expectations for helpfulness, as they offer limited new insights [72].

On the other hand, experience products involve more subjective aspects, with consumers forming varied opinions based on personal experience [71]. Reviews for these products tend to provide unique, valuable perspectives [73] that consumers find helpful even if they receive fewer helpful votes. This difference means that a dataset containing both types of products may create diversity in review patterns that affect the model's ability to generalize and accurately predict helpfulness. As a result, the model might struggle to perform optimally compared to models trained exclusively on either search or experience product data.

V. Conclusion

This study presents a research process aimed at enhancing the classification of helpful reviews on online platforms, ultimately improving the experience for consumers navigating through vast amounts of user-generated content. The findings demonstrate that the performance of our model significantly improves as the threshold for helpful votes increases, particularly when combined with an optimal number of hidden neurons. The highest test accuracy and F1 score were achieved with thresholds of "> 10" and "> 12," suggesting that reviews receiving greater helpful votes provide clearer patterns for the model to learn from.

While the model achieved balanced F1 scores and demonstrated robustness in distinguishing between helpful and unhelpful reviews, certain limitations emerged, particularly in handling both search and experience products within the beauty, health, and personal care domains. The varied characteristics between these product types - where search products offer more objective qualities, and experience products depend heavily on subjective assessments - introduced challenges in model generalization. This differentiation emphasizes the need for adaptive models that can account for the unique features of each product type, potentially by utilizing additional domain-specific content indicators.

Overall, the findings underscore the value of content-based features in predicting review helpfulness and provide a foundation for future advancements in online review classification systems. By identifying and prioritizing content that is likely to aid consumer decision-making, e-commerce platforms can enhance the user experience, foster trust, and promote customer engagement. This work contributes to the ongoing effort to make consumer review systems more effective and efficient in delivering relevant, trustworthy information to users. Furthermore, this research flow can be integrated into existing e-commerce platforms by enhancing the review sorting mechanisms to prioritize helpful reviews based on consumer preferences. For example, platforms could implement an algorithm that displays reviews with high helpfulness scores at the top of product pages, facilitating quicker decision-making for consumers. Additionally, the framework could offer visual indicators for reviews deemed most helpful, improving user engagement with content that meets their specific needs. By integrating our framework, e-commerce platforms could not only improve the quality of information presented to consumers but also foster greater trust and satisfaction, ultimately leading to enhanced purchasing decisions.

While this study has demonstrated significant advancements in predicting the helpfulness of online reviews using information relevance theory and Artificial Neural Networks (ANN), certain limitations must be acknowledged. Firstly, the dataset utilized focuses exclusively on reviews from a single platform (Amazon) within specific product categories, which may limit the generalizability of the findings to other e-commerce platforms or product types. Additionally, the binary classification approach based on helpful votes thresholds may not fully capture the nuanced perceptions of review helpfulness among diverse consumer groups. Another limitation is the potential bias introduced by the predominance of English-language reviews, which excludes multilingual perspectives and insights. Lastly, the variability in consumer behavior across search and experience products introduces challenges in model generalization, underscoring the need for adaptive or hybrid approaches that consider product-specific factors for improved predictive accuracy. Future research should address these limitations to enhance the robustness and applicability of the proposed model.

VI. Future Work

Future research could explore several directions. First, it would be valuable to explore whether the conclusions drawn from this study apply to data from other online marketplaces beyond Amazon.com, which could broaden the relevance of our findings. Second, expanding the dataset reviews spanning a broader range of years to assess the framework's robustness over time and capture evolving trends in review helpfulness. Third, integrating other advanced natural language processing techniques, such as sentiment analysis and topic modeling, could enhance the model's ability to capture intricate aspects of helpfulness that vary across review types. Additionally, employing adaptive thresholding, which dynamically adjusts based on product type or user interaction data, might yield a more tailored approach to identifying helpful reviews. Finally, investigating the potential of hybrid models that combine content features with reviewer and product metadata could offer a more comprehensive framework for evaluating review helpfulness across various platforms and consumer needs.

An Advanced Semantic Feature-Based Cross-Domain PII Detection, De-Identification, and Re-Identification Model Using Ensemble Learning

Poornima Kulkarni[1], Cauvery N K[2], Hemavathy R[3]
Department of ISE, RV College of Engineering, Bengaluru, India[1, 2]
Department of CSE, RV College of Engineering, Bengaluru, India[3]

Abstract*—The digital data being core to any system requires communication across peers and human machine interfaces; however, ensuring (data) security and privacy remains a challenge for the industries, especially under the threat of man-in-the-middle attacks, intruders and even ill-intended unauthorized access at warehouses. Almost all digital communication practices embody personally identifiable information (PII) like an individual's address, contact details, identification credentials etc. The unauthorized or ill-intended access to these PII attributes can cause major losses to the individual and therefore it is inevitable to identify and de-identify aforesaid PII elements across digital platforms to preserve privacy. Unfortunately, the diversity of PII attributes across disciplines makes it challenging for state-of-arts to perform PII detection by using a predefined dictionary. The model developed for a specific PII type can't be universally viable for other disciplines. Moreover, applying multiple dictionaries for the different disciplines can make a solution more exhaustive. To alleviate these challenges, in this paper a robust ensemble of ensemble learning assisted semantic feature driven cross-discipline PII detection and de-identification model (EESD-PII) is proposed. To achieve it, a large set of text queries encompassing diverse PII attributes including personal credentials, healthcare data, finance attributes etc. were considered for training based PII detection and classification. The input texts were processed for the different preprocessing tasks including stopping-word removal, punctuation removal, website-link removal, lower case conversion, lemmatization and tokenization. The tokenized text was processed for Word2Vec driven continuous bag-of-word (CBOW) embedding that not only provided latent feature space for analytics but also enabled de-identification to preserve security aspects. To address class-imbalance problems, synthetic minority over-sampling techniques like SMOTE, SMOTE-BL, SMOTE-ENN were applied. Subsequently, the resampled features were processed for the feature selection by using Wilcoxon Rank Sum Test (WRST) method that in sync with 95% confidence interval retained the most significant features. The selected features were processed for Min-Max Normalization to alleviate over-fitting and convergence problems, while the normalized feature vector was classified by using ensemble of ensemble learning model encompassing Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier as base classifier. The proposed model performed a consensus-based majority voting ensemble to annotate each text-query as PII or Non-PII data. The positively annotated query can later be processed for dictionary-based PII attribute masking to achieve de-identification. Though, the use of semantic embedding serves the purpose towards NLP-based PII detection, de identification and re-identification tasks. The simulation results reveal that the proposed EESD-PII model achieves PII annotation accuracy of 99.77%, precision 99.81%, recall 99.63% and F-Measure of 99.71%.

Keywords*—PII Detection; machine learning; natural language processing; artificial intelligence; de-identification

I. INTRODUCTION

The last few years have witnessed significantly high-pace rise in digital data and allied communication. Increasing internet uses has broadened the horizon for digital data communication to serve socialization, business communication, networking etc. [1]. In fact, the modern world with exponentially rising population can't be hypothesized to exist without digital data. The digital data obtained by means of Email, Blogs, reviews, diagnosis details, business communication etc. can have personally identifiable elements including phone number, email ID, bank account details, social security numbers, diagnosis or ailments, insurance details, vehicle number, passport number etc. [1], [2]. The unauthorized and ill-intended intentional or unintentional use of these personally identifiable elements can cause both privacy breaches as well as losses [3-7]. For instance, an intruder can misuse insurance number and diagnosis details to cause cyber frauds and financial losses. Similarly, the unauthorized access to the bank account number, user identity number can give passage to the cyber criminals to cause digital crimes. Even the disclosure of house number to an unexpected intruder might broaden the horizon for stalking etc. [3], [4], [7]. To alleviate these issues, ensuring abstraction or masking of aforesaid personally identifiable elements can be of great significance. Though, the organizations claim to use personally identifiable information (PII) for constructive decisions including market-segmentation, profiling, marketing, business communication [8], [9]; however, the likelihood of PII misuse within organization or outside the mainstream mechanism can't be ruled out [10-13]. The unauthorized users or intruders might exploit one's online digital behaviour including texts, reviews, Email, personal chats etc. to misuse foresaid PII elements. To ensure privacy preserved communication identifying aforesaid PII is really a challenging task [5-7]. It becomes even more difficult to detect PII elements from unstructured and heterogenous data, which is unavoidable in modern digital world [6], [7].

Though, the classical approaches apply dictionary-based methods to detect and identify PII elements in text; however, preparing a large set of dictionaries for each discipline is near

infeasible or highly exhaustive. Moreover, the PII elements vary across the disciplines. For example, the PII elements pertaining to the user's personal identify might differ from the one from healthcare domain. In this case, generalizing the dictionary from one discipline is infeasible for the other and hence a model trained over one type of dictionary can't be used for other [14]. It limits efficacy of these solution towards real-time PII identification tasks. On the other hand, it is really difficult to prepare dictionary for each discipline distinctly. To alleviate these challenges, though a few machine-learning (ML) based solutions are proposed in the past [14]; however, almost all state-of-arts have been prepared for single domain and hence their scalability towards other discipline remains suspicious. To alleviate it, recently, the organization named European Unions suggested General Data Protection Regulation (GDPR) define PII attributes over broader spectrum to enable PII named identify representation (NER) for the different domains or disciplines [7]. However, ensuring both PII element heterogeneity, contextual details and optimal computing remained challenge for industry to ensure PII detection, de-identification and re-identification optimal. It can limit the performance of solution over large heterogenous data environment [15-17]. The lack of contextual details over large heterogenous and unstructured data makes PII detection challenging [15][16][18][19] and complex [20]. Though, to reduce computational exhaustion fast search space method was proposed [20] where expression matching was done over text content to perform PII detection. Ontology methods too can lack contextual dependencies to perform PII detection [17]. Though, the natural language programming (NLP) methods possess greater significance with the ML classifiers; however, ensuring feature optimality is inevitable to achieve better performance [21]. Despite efforts the diversity of PII elements amongst the different discipline such as healthcare [18][19], legal text documents [22], user browsing data and email [23] and academic or non-academic publication [24], make major state-of-arts confined and generalizing a solution over other discipline texts can yield low accuracy. This is because almost all ML-driven solutions perform PII detection for a specific data type or discipline [24], [25]. It clearly indicates that a model designed to perform PII detection in financial data can't be applicable in EHR-related dataset [75]. It motivates researchers to design a cross-domain learning environment, where one can take the inputs text data from the different domains (i.e., healthcare, business communication, financial data etc.) and train a model to have broader knowledge ability for PII detection and classification. Ironically, none of the state-of-art could address this problem so far. Though, the use of NLP with better feature engineering, contextual learning and robust classification can enable a cross-domain PII detection and classification. However, it requires training a robust learning model with maximum possible features encompassing samples from the different domains. Despite numerous studies in the past, none of the solutions could address class-imbalance problem while using ML or NLP methods for PII detection and classification. On the contrary, it is inevitable that the real-time systems might have text queries relatively higher for non-PII than the PII containing queries or sentences. Such skewed data and allied learning might force model(s) yielding false positive or false negative. Therefore, an NLP driven PII detection and classification model requires addressing class-imbalance problem to improve learning and classification results. Additionally, processing a training model over most representative PII text samples with embedded latent or semantic details can make learning more efficient and accurate. These key inferences can be considered as the predominant motivation behind this study.

Considering aforesaid motivations and allied scopes, in this paper a novel and robust ensemble of ensemble learning assisted semantic feature driven cross-discipline PII detection and de-identification model (EESD-PII) is proposed. To achieve it, a large set of text queries encompassing diverse PII attributes including personal credentials, healthcare data, finance attributes etc. were considered for training based PII detection and classification. The input texts were processed for the different pre-processing tasks including stopping-word removal, punctuation removal, website-link removal, lower case conversion, lemmatization and tokenization. The tokenized text was processed for Word2Vec-CBOW embedding that not only provided latent feature space for analytics but also enabled de-identification to preserve security aspects. To address class-imbalance problem, synthetic minority over-sampling techniques like SMOTE, SMOTE-BL, SMOTE-ENN were applied. Subsequently, the resampled features were processed for the feature selection by using WRST algorithm that in sync with 95% confidence interval retained the most significant features. The selected features were processed for Min-Max Normalization to alleviate over-fitting and convergence problems, while the normalized feature vector was classified by using ensemble of ensemble learning model encompassing Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier as base classifier. The proposed ensemble learning model performed consensus-based majority voting ensemble to annotate each text-query as PII or Non-PII data. The positively annotated query was later processed for a dictionary-based PII attribute detection and masking to achieve de-identification. The simulation results reveal that the proposed EESD-PII model achieves PII annotation accuracy of 99.77%, precision 99.81%, recall 99.63% and F-Measure of 99.71%.

The remaining sections in this paper are divided as follows. Section II discusses the related work, while the problem formulation and questions are given in Section III and Section IV, respectively. The overall proposed model is discussed in Section V, while the proposed model is given in Section VI. Conclusion and allied inferences are given in Section VII, while Section VIII discusses the future scope. The references used are given at the end of the manuscript.

II. Related Work

The authors in study [26] applied conditional random field (CRF) and SVM to learn the pre-annotated PII lexical and embedding features to classify PII query. On the other hand, the authors [27] infused the phrase embedding concept to yield semantic details, which was later trained over machine learning to perform named entity detection and classification. On the other hand, the allied challenges in named entity recognition were discussed in study [28], where the authors concluded that the use of text-specific semantic details trained over better learning environment can perform more accurate PII identification. However, the authors failed to indicate their

suitability over the different sets of text inputs. The authors [29] used long and short-term memory (LSTM) deep network to extract and learn contextual features from the input queries to perform PII detection. The recurrent neural networks (RNNs) were applied in [30], [31] as well where the authors used pre-trained transformer-based language models for PII prediction. These approaches couldn't address large PII heterogeneity amongst queries from the different disciplines. Moreover, merely applying cross-validation learning can't generalize the solution for cross-discipline PII detection and classification [32]. In study [33], PrivacyBot was designed, especially to perform privacy sensitive PII detection over unstructured text input. The authors applied machine learning models to train over the text content for classification. Yet, their generalizability over large unstructured muti-source inputs remains suspicious [34]. In [35] deep learning was applied to classify annotated text corpus for PII classification. The authors in study [36] made use of the convolutional neural network to perform named entity recognition in unstructured text data. However, it was completely depending on the local hierarchical features, while a non-lineal environment demands a model to have contextual learning capabilities to yield accurate prediction results. In study [37], the conceptual relationship amongst the unstructured text was applied to perform PII detection from input texts. More specifically, an association extraction approach was applied on Twitter data to assess the relatedness of each word with PII attributes by using pointwise mutual information statistical association rule. The authors in study [38] exploited privacy information across privacy-related topics, including plan for the vacations, alcohol and healthcare conditions to perform PII detection and classification. Despite ML classifier, guaranteeing scalability of solution over large heterogenous inputs makes it suspicious. In [39], a semi-supervised ML [17] was applied for PII detection in healthcare text. The authors in study [17] fused topic modelling, privacy ontology and sentiment score, which was later processed by Naïve Bayes (NB) classifier to detect PII attribute in Twitter data. In study [40], PII dictionary was applied to annotate text elements as PII or non-PII. In study [41], the authors used ontologies with rule-based method to perform PII detection in text. The authors in study [42] designed a text feature learning driven PII detection interface for software-defined networks (SDN) that classifies each query as PII or non-PII. Though, it failed addressing numerous issues including feature optimality, class-imbalance and low accuracy problem. In [43], the authors used dictionary and intra-query structural details to perform PII detection and classification. RenCon [44] was proposed to detect PII in mobile network traffic, where supervised ML was used to annotate each query as PII or Non-PII. A similar work was done in study [5] where the authors applied ML algorithm to learn PII attributes personal identification (ID), phone number, social graph, email, location and biometric ID detail for PII detection. In [45] as well ML was applied where the Person of interest (PoI) and PII attributes were detected from the email dataset. The authors suggested that unlike standalone classifier, the use of ensemble learning method by using decision tree, SVM, neural network and random forest can yield better accuracy. PII detection over healthcare data was done in study [46], yet, despite BigData problem the authors failed in addressing the problem of class-imbalance [47]. The authors in study [48] used random forest algorithm with Simpson index that measured the diversity amongst the PII elements to annotate them as PII or non-PII element. Ontology method was applied in [49], [50] to detect PII and its masking. In [50], ML was applied to solve PII detection as an NLP problem.

In study [70], the authors focused on developing a new Korean dialogic dataset, especially designed for the PII de-identification. For PII detection, the authors used text anonymization benchmark and network intrusion detection dataset, based on which a new de-identification dataset was prepared. Unfortunately, there are very less efforts made towards text data de-identification; though there exists certain works related to the face de-identification in video or image dataset. For instance, in study [71] the authors developed a disentangled representation learning for multiple attributes preserving face de-identification. More specifically, they proposed replacing and restoring variational autoencoders (R 2 VAEs) that disentangle the identity-related factors and the identity-independent factors so that the identity-related information can be obfuscated, while they do not change the identity-independent attribute information. In [72], UU-Net was developed for the reversible face de-identification in visual surveillance video data. Here, the proposed UU-Net model learns jointly by optimizing a public module that receives the raw data and generates the de-identified stream, along with a private module, especially designed for security authorities. The second module receives the public stream and regenerate the original data by exploiting semantic and contextual details, disclosing the actual IDs of the subjects in a scene. This method made use of the conditional generative adversarial network to achieve synthetic faces by preserving pose, lighting, background information and even facial expressions. In study [73], the authors developed de-identification method by applying both human perceptions derived as semantic information and the face recognition models. This method explored the tradeoff between a user misidentifying the original identity with a well-known celebrity and a facial recognition model that tries to identify the original identity. It generated caricature faces of the de-identified faces to ensure that the manipulated faces can be distinguished effortlessly. In study [74], an attribute-preserving face de-identification framework called Enhanced Embedded Auto Encoders was developed. The proposed model embodied three components, privacy removal network (PRN), feature selection network and privacy evaluation network. Here, PRN made the model capable to discard information involving identity privacy and retaining desired face attributes for certain prediction applications. The other modules focused on exploiting global or contextual features to improve learning-based classification accuracy. Despite efforts, ensuring de-identification in text data, especially carrying critical details like electronic healthcare records (EHR) remains a challenge [75]. It broadens the horizon for the researchers to develop a scalable and robust PII detection, classification and deidentification and re-identification [75] model.

III. PROBLEM FORMULATION

This research hypothesizes that the inclusion of PII texts from the different disciplines for improved NLP analytics can enable cross-discipline PII detection and classification. This hypothesis considers optimization on both data as well as

computational front, where initially it embodies PII queries from the different domains which are processed for the different pre-processing tasks including stopping-word removal, punctuation removal, website-link removal, lower case conversion, lemmatization and tokenization. This approach can strengthen the proposed PII detection model to address data heterogeneity and unstructured-ness and hence can make it suitable for the real-world applications. In addition, it can make the proposed model suitable for cross-discipline PII detection and classification. Moreover, unlike syntactical term matching based solutions, to retain sufficiently large contextual details Word2Vec CBOW method is proposed that can provide large latent information to make cross-domain PII detection. It also helps in achieving de-identification by transforming input texts into equivalent embedding matrix, which can later be used to perform de-identification and re-identification. Realizing the at hand computational challenges like local minima and convergence, redundant computation, in addition to the aforesaid data optimization the proposed work focuses on computational aspects as well, where at first WRST significant predictor test is applied over the embedded metrics which retains a sufficiently large set of samples with high representativeness. It can reduce computational cost decisively while ensuring that the performance remains high. The selected samples have been processed for resampling by using SMOTE resampling methods including SMOTE, SMOTE-BL and SMOTEENN methods. Noticeably, these resampling methods intend to alleviate any probable class-imbalance problem and skewed data problem without undergoing iterative hotspot creation as witnessed with random sampling and up-sampling methods. The resampled data has been later processed for Wilcoxon Rank Sum Test (WRST) method that in sync with 95% confidence interval retained the most significant features. Subsequently, Min-Max normalization is performed that maps each input data in the range of 0 to 1, and thus alleviates the problem of over-fitting problem. Finally, the normalized feature vector was classified by using ensemble of ensemble learning model encompassing Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier as base classifier. The proposed ensemble learning model performed consensus-based majority voting ensemble to annotate each text-query as PII or Non-PII data. In this manner, it performs two-class classification which classifies each query as PII or Non-PII. Once annotating query as PII, the predefined dictionaries can be applied to perform search-based method to detect and mask PII element. Though, the proposed model applied word-embedding method that transformed original input text into equivalent embedding metrics and hence preserved privacy and/or de-identification to the data while retaining data-sanity for analytics.

IV. RESEARCH QUESTIONS

In reference to the aforesaid formulations, this research defines certain questions, whose justifiable answers can put foundation for a robust PII detection and classification system. These research questions (RQ) are:

RQ1: Can the use of multi-disciplinary PII text with multi-aspects pre-processing tasks like stopping-word removal, punctuation removal, website-link removal, lower case conversion, lemmatization and tokenization enable NLP to achieve cross-discipline PII detection and classification?

RQ2: Can the use of Word2Vec CBOW embedding, WRST significant predictor test, SMOTE resampling, and Min-Max normalization provide semantically rich feature vector for PII detection and classification?

RQ3: Can the use of ensemble-of-ensemble learning environment encompassing Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier as base classifier to perform PII detection and classification?

RQ4: Can the strategic amalgamation of the solutions RQ1-RQ4 provide a robust cross-discipline PII detection and classification system?

As indicated in RQ1, the use of the text data and allied PII variables (say, artefacts) can enable an AI tool to learn more effectively. Here, training any machine learning or deep model over heterogenous PII elements belonging to the different categories of text inputs can improve learning ability and knowledge. Undeniably, it can improve learning; however, the data heterogeneity over the different input sources, data nature, diversity of presentation etc. can impact overall learning. To address this problem, there is the need of transforming input raw data into corresponding processed structured data for further feature extraction and learning. In this reference, this research defines research question (RQ1) which assesses whether the pre-processing tasks like stopping-word removal, punctuation removal, website-link removal, lower case conversion, lemmatization and tokenization enable NLP to achieve cross-discipline PII detection and classification. In the same manner, to improve scalability even with the reduced computational costs, this research intends to use contextual or latent semantic information, which can enhance learning and classification accuracy. To achieve it, this research makes use of the semantic embedding technologies like Word2Vec embedding. This method intends to transform input (pre-processed text data) into corresponding latent embedding matrix (low-dimensional matrix). To further improve computational efficacy and reliability over non-linear, imbalanced data environment, it performs SMOTE resampling (to alleviate class-imbalance problem), and WRST significant predictor test-based feature selection. These methods altogether can improve feature environment and hence can alleviate any likelihood of class-imbalance, premature convergence, local minima etc. In this reference, this research defines research question RQ2, whether aforesaid methods can improve overall performance towards a run-time PII detection and classification solution. Unlike traditional machine learning methods like decision tree (DT), support vector machine (SVM), naïve bayes (NB), etc. the ensemble learning methods like random forest (RF), AdaBoost, extra tree classifier, XGBoost etc. have performed better for the different data and image classification problems. Being consensus driven prediction solutions, it yields higher accuracy and reliability towards PII detection and classification. Considering it as motivation, this research intends to use only ensemble learning methods, such as the Bagging, Boosting, RF, ETC, XGBoost to perform maximum voting ensemble-based learning and classification. In this method, a total of five base classifiers (here, ensemble classifiers) are considered. This is because, out of five base classifiers, if three of the base classifiers classifies an input as PII and annotates it as 1, it would

be classified as PII. On the other hand, if three base classifiers annotate an input as 0, the final prediction is made as non-PII. Being consensus driven approach or maximum voting-based approach, it can be more reliable towards run-time significances. These aspects are defined in terms of the research question RQ3. Since, the at hand problem is a challenge of text classification, this work considers standard classification related performance parameters such as the accuracy, prediction, recall and F-Measure as performance variable. In this reference, this work defines research question RQ4. Thus, the overall research intends to achieve justifiable answer for these questions (RQ1-RQ4).

V. System Model

This section discusses the overall proposed method and allied implementation. The overall research method encompasses the following key steps:

a) Data Acquisition,
b) Pre-processing,
c) Word2Vec CBOW Embedding,
d) Significant Predictor Test,
e) Resampling,
f) Normalization, and
g) Ensemble(E2E) MVE Classification.

A snippet of the overall proposed model is given in Fig. 1.

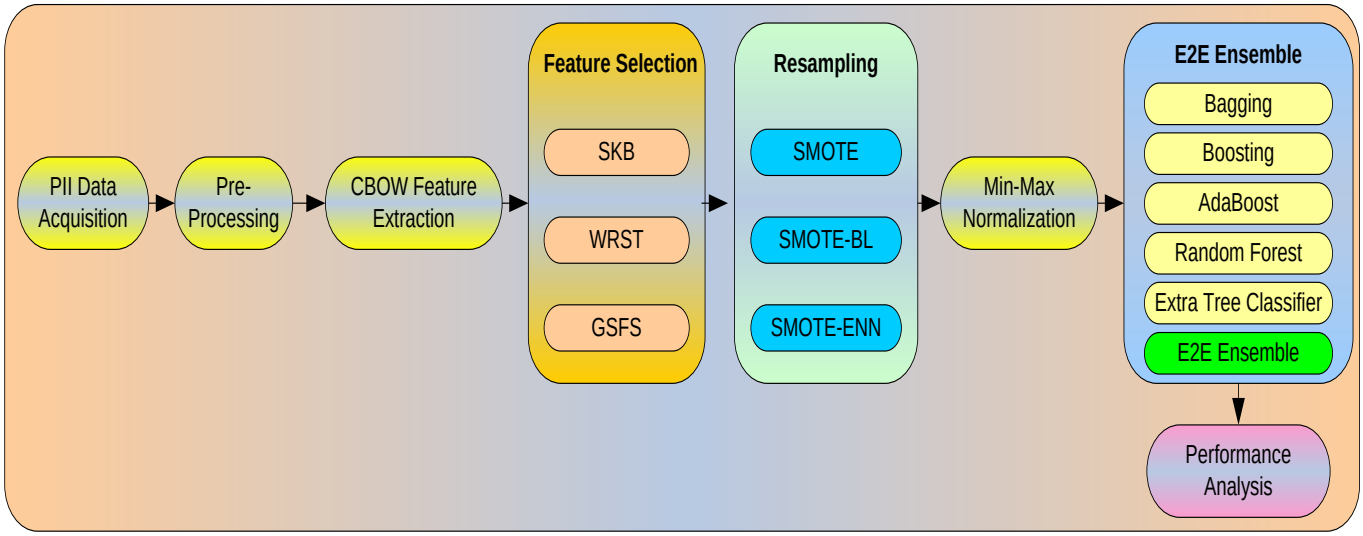

Fig. 1. Proposed EESD-PII model.

The detailed discussion of the overall proposed work is given as follows:

A. Data Acquisition

Considering real-world heterogenous and unstructured text data available across digital communication platforms such as Email, Blogs, social media, data warehouses etc., in this research primary data was synthesized. Moreover, since there exists very limited data available towards cross-discipline PII detection problem, we synthesized own primary data encompassing sufficiently large text queries possessing PII elements from the different domains, including personal credentials, healthcare data, financial data etc. In sync with targeted PII detection and classification problem, Python Faker tool was taken into consideration where a total of 12000 text (reviews) queries were synthesized. Realizing the diversity of PII attributes across different disciplines, a set of PII elements were prepared for each discipline. A snippet of the different PII attributes used for the different discipline is given in Table I.

As depicted in Table I, text queries from three different domains including personal credentials, healthcare credentials and financial credentials were prepared. Here, personal credentials encompassed the key PII attributes as “Name”, “Address”, “Email”, “Aadhar Number”, “PAN”, “SSN”, “Vehicle Number”, and “Phone Number”. Similarly, three different PII credentials including “Health Insurance Number”, “Diagnosis Details”, and “Life Insurance Number” were considered. The other attributes like “bank Account Number”, “Loan Account”, “Balance Details”, “OTP”, “Access PIN” and “Credit Card Number”, were prepared towards financial credentials. We synthesized 4000 queries from each discipline and thus a total of 12000 queries were obtained. To synthesize these reviews Python’s Faker package was applied that embodies different callable functions to generate a large number of unstructured texts. The aforesaid text reviews were generated arbitrarily in such way that it embodies aforesaid PII credentials (Table I) in the different texts and allied disciplines. In other words, each of the queries generated possessed the different PII elements pertaining to the personal credentials, healthcare and finance. Thus, the queries generated provided data heterogeneity while ensuring data privacy and integrity. This approach also serves the purpose of PII privacy preserving and anonymized data preparation. Recalling the fact that the faker generates queries with the aforesaid credentials randomly and hence guaranteeing uniform proportion of each PII attribute remains difficult. In this manner, the data can be hypothesized to be unbalanced and hence can give rise to the skewed learning. It eventually can give rise to the false positive or false negative performance. To alleviate this problem, applying resampling can

be of great significance. The resampling can improve data distribution uniform throughout and hence training a model over such balanced sample can improve learning and classification accuracy.

TABLE I. PII ATTRIBUTES

Discipline	PII Attributes	No. of Samples
Personal Credentials	Name Address Email Aadhar Number Permanent Account Number Social Security Number Vehicle Number Phone Number	4000
Healthcare Credentials	Health Insurance Number Diagnosis Details Life Insurance Number	4000
Financial Credentials	Bank Account Number Loan Account Balance Details One Time Password Access PIN Credit Card Number	4000

B. Pre-processing

In reference to the real-world data scenarios where the likelihood of data-heterogeneity and unstructured-ness can't be ruled out, strengthening data with the different pre-processing tool can be of great significance. Additionally, since the proposed method intends to exploit semantic word-embedding metrics (feature) improving data with certain set of pre-processing tasks can be of great significance. With this motive, we performed the different pre-processing tasks including the removal of stopping words, punctuation marks, Emoji, lower case conversion, lemmatization etc. We apply the following pre-processing tasks to ensure optimal data presentation and input towards targeted PII detection, de-identification and identification tasks.

a) Missing value removal
b) Unicode normalization
c) Emoji removal
d) Website link removal
e) Punctuations and Stopping word removal
f) Converting to the lower case
g) Removing stop-words
h) Lemmatization
i) Tokenization.

A snippet of these pre-processing tasks is given as follows:

1) Missing Value Removal: In real-world data environment, the text queries or reviews, especially collected from email, online Blogs, reviews, social media etc. can have certain broken sentences or incomplete words. There can be the set of words or strings with incomplete sentence representing the missing data element. Any NLP and allied AI-based solution, especially the text-analysis methods might yield inaccurate prediction results with aforesaid missing elements. In fact, the lack of contextual relatedness amongst aforesaid incomplete words or missing elements can impact overall performance. Learning over their allied features can impact learning and classification results. To address this problem, removing broken words and sentences from the input text corpuses can be vital. To achieve it, we applied standard NLTK Python library to remove the incomplete sentences. The overall process of missing value removal ensured that the proposed method examines and retains associations amongst the PII attributes and incomplete sentence(s).

2) Unicode Normalization: Realizing diversity amongst the reviews where the different users can have written the reviews with the different word-constitution, formats, (personalized) writing method, skills and texting designs, the proposed method performed Unicode normalization on each input query or sentence. The aforesaid data heterogeneity (amongst the word constituents and writing style) might impact NLP solution and hence transforming raw input text into a uniform structure is must. To achieve it, we performed Unicode normalization that transferred the input text into the single norm data output for further semantic feature extraction and corresponding de-identification tasks.

3) Emoji Removal: Though, the considered Faker tool didn't introduce any emoji element; however, in real-world data systems the likelihood of emoji (Ex. 😊, 😵) can't be ruled out, especially the modern mobile based text communications. Though, there exists no concrete literature which could prove their efficacy or significance towards NLP problems; however, their presence in raw data can impact learning adversely. In fact, readability of such elements can be difficult and can introduce data ambiguity that eventually can impact overall performance. Considering these facts, we performed emoji removal by using NLTK libraries and rule-based functions. This ability can make the proposed model robust in real-time applications where the targeted PII detection tool can be applied as an interface to detect, de-identify and re-identify PII attributes.

4) Hashtag and URL Removal: In present day digital world, where social media, web-media etc. have been playing decisive role in digital data promotions and allied marketing (say, communication). The users often try to mention the different URLs or web-links pertaining to certain subject matter. In addition, there can be user defined or organization driven hashtag information (i.e., #). The aforesaid URLs and #Hashtag helps the individual or organization gaining broader market space or audiences. Despite such significances, such web-URLs, links and/or #Hashtag don't have any significance towards PII detection and classification. The presence of such elements in texts can impact NLP learning and prediction (accuracy or) efficiency. It makes it inevitable to remove such elements before executing feature extraction and learning. In this paper, we applied rule-based methods to remove different hashtag and web-URLs. The rule-based method helped in identifying the URL components including www, https:// etc.,

that eventually helped in removing aforesaid contents or attributes. We applied Python URL removal function to remove hashtag and URL elements from each input query.

5) Punctuation and Stopping Words Removal: In text data the presence of the non-word symbols or the punctuation (i.e., ",", "?", "!",";", ":", etc.) can't be ruled out. Though, such elements have decisive significance towards contextual role or presentation; however, are not much related to the PII probability. Though, their presence in vicinity of a PII element, for instance, "AA0123456" can't be ruled out. Noticeably, though AA0123456 can be certain PII element; however, "" seems to be not related to the PII and just represents a highlighting element and/or remark. Therefore, removing such elements can be vital, especially when exploiting NLP for PII detection and classification. We applied NLTK library to remove punctuation marks from each text query or sentence. The deployed method applied standard expression and the rule-based approach to detect and remove punctuations from the input texts.

In general, the stop-words represent the terms that add no value to the sentence. In at hand NLP problem, the presence of these words can impact feature purity and its significance towards contextual (or semantic) learnability. Considering this fact, we dropped aforesaid stop-words from the input text corpus without making any change to the original intend behind the text phrase.

6) Lower Case Conversion: The ML algorithms can be case-sensitive and therefore the diversity amongst the case might impact learning efficiency. To cope up with the NLP solution, the relatedness and significance amongst the terms like SMART and smart can be differ and hence can cause contextual ambiguities in the extracted features. To alleviate this problem, the input texts were processed for lower case conversion, where each word or term was converted into lower case. We used Python's inbuilt lower-case conversion function to perform lower-case conversion.

7) Lemmatization: Once converting text data into equivalent lower-case sequence, each query was processed for lemmatization. In this method, the extended word was transformed into the respective root form. It assessed the expected component of the text without losing the original sense behind the word. Noticeably, stemming and lemmatization performs similar task; however, differs the way it (i.e., lemmatization) assesses the context first, which is then followed by the transformation of the extended word to the root word. On the contrary, in stemming the extended characters like "s", "es" etc. at the end of the word are removed that loses the actual intend of the word. The following illustrations depicts the process of stemming and lemmatization methods.

Studies → Lemmatization→ Study,

Studies → Stemming→ Studi.

As depicted above, to retain original intend or originality, lemmatization was performed where each word was transformed into respective original form.

8) Tokenization: Once performing lemmatization of the input text or queries, tokenization was performed that transformed each query into certain set of tokens. In this work, the tokenization method at first transformed input query or sentence into corresponding set of tokens, which were later processed for semantic feature extraction and learning to perform feature learning and classification.

C. Semantic Feature Extraction

Though, in the past a few ML and NLP-based efforts have been made towards PII detection and classification; however, most of the state-of-arts fail in address or exploit contextual feature to perform learning and classification. Additionally, unlike term-matching based approaches the use of latent information or semantic features can improve efficacy, especially in NLP-based solutions including at hand PII detection and classification. Unlike traditional PII detection models, in this work the focus was made on exploiting depth or semantically enriched features or latent features from the input queries is hypothesized. In addition, to presence data sanity, originality with privacy preserving (say, de-identification), word-embedding can be of great significance. More specifically, the use of Word2Vec based Continuous Bag of Words (CBOW) model can yield low-dimensional semantic feature to perform learning and classification for PII detection and classification. Unlike other approaches such as TF-IDF or N-skip gram with $n = 1$, CBOW yields low-dimensional features to perform learning and classification towards PII-detection. The use of Word2Vec CBOW model can be even effective over the data encompassing PII attributes from the different disciplines, including personal credentials, healthcare and finance. With such data diversity, the proposed Word2Vec CBOW model can be vital. Moreover, in the considered dataset there can be limited text elements amongst the non-PII attributes and therefore retaining allied contextual details can provide more insight towards NLP-based PII detection and classification. Training a ML solution with aforesaid contextual and semantic (or latent) information can make PII detection more efficient and accurate over unannotated or minimally annotated inputs. Though, the literatures suggest different semantic extraction methods including TF-IDF, Skip-Gram, Glove, etc.; however, CBOW provides more intrinsic feature with easier implementation over large inputs. Additionally, it yields relatively low-dimensional features with intact feature vector or contextual significance, which can provide suitable feature environment for ML to predict PII in input sentence or query. In reference to these inferences, we applied Word2Vec CBOW method to perform word-embedding over the tokenized inputs for each query. In this method, for each query it generates set of embedding metrics, which is subsequently used for optimization and learning to perform PII detection. A brief of the CBOW method used in this work is given as follows:

In Word2Vec CBOW, we performed word-embedding on the input tokenized inputs (say, text sequences per query). More specifically, Gensim Word2Vec method was applied that transformed the set of tokens into corresponding low-

dimensional semantic embeddings (say, embedding vector). To achieve it, we designed Word2Vec with dual-layer neural network having two hidden layers. It helped achieving more contextually rich but sparser features so as to improve computational aspects. In CBOW method, let, W_{i-1}, W_{i-2}, W_{i+1}, W_{i+2} be the context words retrieved from the sentence or review text. Then, CBOW predicts W_i which is related with the other tokens available in that specific query. The predicted embedding outputs are always related to the target token W_i. The detailed discussion of CBOW embedding is given as follows:

In general, the CBOW method contains two sets of word-embedding vectors, say, "Source-side" and "Target-side" vectors, signifying $v_w, v'_w \in \mathbb{R}^d$ for each sentence or query's tokens. Noticeably, in our proposed method, we obtained $w \in V$ as the tokenized vocabulary once performing tokenization for each text input or sentence. Being Gensim-based embedding, a text window within the input review or sentence contains central token w_0 which generates respective context embedded vector $w_1, \dots, w_C$. For the above stated conditions, (say, text-window), the CBOW loss is measured as in Eq. (1).

$$v_c = \frac{1}{C}\sum_{j=1}^{C} v_{w_j} \tag{1}$$

$$\mathcal{L} = -\,log\,\sigma\left(v'_{w0}\,T_{v_c}\right) - \sum_{i=1}^{k} log\,\sigma\left(-v'_{n_i}\,T_{v_c}\right) \tag{2}$$

In (2) $n_1, \dots, n_k \in V$ be the negative examples obtained from the noise distribution P_n over the input vector V. In Eq. (2), the parameter $\mathcal{L}$ gradient is estimated with respect to the target value v'_{w0}, negative target value v'_{n_i} and average context source (v_c).

$$\frac{\partial \mathcal{L}}{\partial v'_{w0}} = \left(\sigma\left(v'_{w0}\;T_{v_c}\right) - 1\right)v_c \tag{3}$$

$$\frac{\partial \mathcal{L}}{\partial v'_{n_i}} = \left(\sigma\left(v'_{n_i}\;T_{v_c}\right) - 1\right)v_c \tag{4}$$

$$\frac{\partial \mathcal{L}}{\partial v_c} = \left(\sigma\left(v'_{w0}\;T_{v_c}\right) - 1\right)v'_{w0} + \sum_{i=1}^{k}\left(\sigma\left(v'_{n_i}\;T_{v_c}\right) - 1\right)v'_{n_i} \tag{5}$$

Now, deploying Chain-rule method over the source context embedding, the gradient of the predicted word vector, also called the context vector is obtained as per Eq. (6).

$$\frac{\partial \mathcal{L}}{\partial v_{w_j}} = \frac{1}{C}\left[\left(\sigma\left(v'_{w0}\;T_{v_c}\right) - 1\right)v'_{w0} + \sum_{i=1}^{k}\left(\sigma\left(v'_{n_i}\;T_{v_c}\right) - 1\right)v'_{n_i}\right] \tag{6}$$

To address the problem of inaccurate context vector update, in this work context word normalization was performed. To achieve it, we sampled the context window's width arbitrarily in the predefined range of 1 to C_{max} for each target word. Thus, applying this method the embedded metrics for each query was obtained for further processing or eventual analytics task(s). Noticeably, this method not only provided the embedded metrics as semantic feature for learning and classification; but also transformed the original text including PII elements or attributes into equivalent pseudonymized data and hence fulfils the goal of deidentification, without losing data intend and originality towards further analytics. Unlike data masking, our proposed model can provide a suitable reversible data form with certain rule-based approaches. Though, in the proposed work, such tasks are not required as the PII element itself has been transformed into anonymized embedding vector or numeric value.

D. Ensemble Feature Selection

This is the matter of fact that in real-time applications, the volume of data inputs (here, text reviews) can be gigantic and hence training a ML method over such humongous data might give rise to the local minima and convergence and hence can yield inaccurate prediction result. Additionally, it can make overall processing exhaustive. The severity of such problems can be high in NLP domain, especially over the large text inputs. To alleviate these problems, retaining the set of most-significant samples having decisive impact on the (PII) prediction results can be vital. Though, there exists a number of state-of-art feature selection methods; however, in this work we examined applied three different methods, named Select K-Best, Wilcoxon Rank Sum Test and Gini-Score based significant predictor test to retain the optimal set of features, which were horizontally concatenated to yield an ensemble feature vector for further learning and classification. A brief of these methods is given as follows:

1) Select k-Best Feature Selection: The Select k-Best (SKB) method identifies the top-k most significant samples or allied features. We applied Chi-Squared method to perform Select K-Best based most significant feature selection. The applied Chi-Squared feature selection approach measures the level of significance of each feature to retain the top-K features. It is mainly achieved by estimating the value of χ^2statistics in reference to the target class. In this mechanism, each feature is examined separately to assess the relationship between the feature and target class. It acts as a non-parametric test method which compares the different variables for an arbitrarily chosen data. As an independence-test approach, it identified the difference and independence amongst the different arbitrarily selected variables. Thus, it measured a value on the basis of the association between the feature instance and the class it must belong to. For output 0, it states that there exists no association between the feature element and the class. The greater association refers stronger relationship between the feature (say, sample) and the probable class. The use of Chi-Squared method was done by using scikit-learn library which helped retaining the set of most significant samples. In the developed approach, the Chi-square method performed in reference to the information-theoretic feature selection paradigm, where it measured the intuition that the best terms $t_k$for a class c_i are the one distributed amongst the set of positive and negative examples of the class c_i. Chi-square's test can be derived as per Eq. (7).

$$Chi - Square(t_k, c_i) = \frac{N(AD-CB)^2}{(A+C)(B+D)(C+D)} \tag{7}$$

In Eq. (7), N represents the total samples or features available in the input feature vector (for the considered text corpus), and A be the elements in class c_i with t_k. The feature elements carrying t_k in other classes is defined as B. The number of features in class c_i that don't possess any term of t_k

is given by $C.D$ on the other hand, represents the number of feature elements with no term t_k in other classes. Thus, by using above Eq. (7), the proposed method assigned a score value for each feature towards a class (i.e., PII or Non-PII). Eventually, the scores are amalgamated to yield a final score, given as Eq. (8).

$$max\big(Chi - Square(t_k, c_i)\big) \tag{8}$$

Thus, with the obtained score as shown in Eq. (8), it retained the top-K features (or samples) to perform further processing.

2) Wilcoxon Rank Sum Test: It is also called as the significant predictor test which belongs to a type of non-parametric test with independent samples. Functionally, it measures the level of significance of each embedding metrics value and allied probability towards PII or Non-PII query. Here, WRST compares the location of the two samples by using two matched samples. More specifically, Signed Rank Sum test approach was applied to measure the level of significance. Consider, the paired data contains the samples $(X_1, Y_1), \dots, (X_n, Y_n)$, where each sample signifies a pair of measurements. These measurements are converted to the real-numbers, while the paired sample test is converted to the one-sample test by replacing each pair of numbers (X_i, Y_i) by respective difference $X_1 - Y_1$. This method enables ranking of the difference in between the pairs. However, it needs that the data remains on an ordered metric scale. Consider the data for one-sample test be $X_1, \dots, X_n$, then assuming that the samples carry different absolute values, and no sample is equal to zero, then it applies the following steps to examine the level of significance of each data in the sample.

- ✓ Estimate the value $|X_1|, \dots, |X_n|$
- ✓ Sort $|X_1|, \dots, |X_n|$ and use the sorted-list to assign ranks $R_1, \dots, R_n$, where the rank of the smallest measurement remains unit value (i.e., 1). And the rank of the subsequent smallest becomes two and so on.
- ✓ Consider sgn be the sign-function stating $sgn(x) = 1$, if $x > 0$ and $sgn(x) = -1$ if $x < 0$. It provides signed rank sum value T by using following formulation [see Eq. (9)].

$$T = \sum_{i=1}^{N} sgn\,(X_i) R_i \tag{9}$$

- ✓ Retrieve a $p - value$ by estimating T to its distribution under the null-hypothesis.

Here, the ranks can be assigned in such manner that the value R_i remains the number of j for which $|X_j| \leq |X_i|$. Additionally, for $\sigma: \{1, \dots, n\} \rightarrow |X_{\sigma(1)}| \leq |X_{\sigma(n)}|$, then $R_{\sigma(1)} = i$ for all element i. With the obtained $p - value$ for each sample, the level of significance is measured and each sample was annotated as significant or insignificant. Thus, applying this approach, the significant feature elements were retained for further computation.

3) Gini Score based significant feature selection (GSFS): Gini Score measures the level of impurity in a data by applying a function as shown in Eq. (10).

$$m(s) = \sum_{i \neq j} \widehat{P_{si}}\, \widehat{P_{sj}} = 1 - \sum_j \widehat{P_{sj}} \tag{10}$$

This method generalizes the variance impurity, signifying the variance of a distribution belonging to the two class labels i and j. GSFS is also referred as the expected error rate when the class label is selected randomly from the input feature distribution (here, CBOW embedding metrics). The impurity criterion applied to be highly peaked at the same likelihood in comparison to the entropy-based approaches that makes Ginni Index based feature selection suitable for our targeted PII detection and classification problem. In this work, the Eq. (11) was applied to measure the likelihood of a feature (or sample) to be retained for further computation.

$$GSFR(S) = 1 - \sum_{i=1,\dots,m} P_i^2 \tag{11}$$

In Eq. (11), P_i states the likelihood that a tuple in feature set S belongs to the class C_i. Here, we obtained the value of P_i as per $|C_i, S|/|S|$.

Once performing aforesaid feature selection methods over the input embedding metrics, the retained features were horizontally concatenated to yield a composite or fused (say, ensemble) feature vector for further learning and (PII) prediction.

E. Resampling

As discussed in the previous section, in real-world scenario or dataset, the frequency of PII attributes over a large text input can be smaller. In other words, the number of non-PII elements can be higher than the PII elements, signifying class-imbalance problem. The similar problem can be unavoidable in at hand PII classification problem as well. Since, in this work, the total samples comprised a massive 12000 queries, containing 4000 samples from each discipline (i.e., personal credential, health credential and financial credential). However, the number of queries or sentences (say, review) containing PII element were almost 1100, which is smaller than even 10% of the original data size, which is 12000. Though, the data combination is prepared intentionally, emulating or representing the real-time data condition where the PII elements can be of minority class than the non-PII elements (signifying majority class). This data imbalance problem can skew the learning process and hence can yield inaccurate performance. To alleviate this problem, resampling method can be applied which can make effort to retain sufficient balance between the samples belonging to the PII data as well as non-PII queries. Though, in the past, different classical approaches like up-sampling, random sampling methods have been applied; however, such approaches might often result iterative hot-spot problem (i.e., iterative class-imbalance). Noticeably, the classical up-sampling method intends to increase the minority samples to leverage the imbalance, while in down-sampling the majority class samples are reduced. On the other hand, in random sampling technique, the additional samples are appended by selecting samples from the original feature space (i.e., original minority samples). An inappropriate selection of samples might give rise to the aforesaid hot-spot or imbalance data conditions, iteratively. To address this problem, in this work three different improved resampling methods are applied. More specifically, we have applied three different variants of the synthetic minority over-sampling method (SMOTE), named SMOTE, SMOTE-

Boundary line (SMOTE-BL), and SMOTE with Edited Nearest Neighbor (SMOTE-ENN). Unlike traditional resampling techniques, SMOTE method generates synthetic samples depicting most correlated features, without impacting original sample distribution or allied (sample) ratio. Though, in exceedingly high non-linear data or feature space, SMOTE can yield better performance than the classical random sampling or up-sampling methods; however, it undergoes a scenario where there can be the multiple data instances belonging to both minority as well as majority class (it can happen due to feature relatedness or ambiguity). The classical SMOTE doesn't address this problem. Though, it has been solved by using SMOTE-BL. Considering the efficacy of SMOTE-BL method over classical SMOTE, we applied Python Imbalance Data library's SMOTE-BL method to resample the selected features (by using, Select K-Best, WRST and GSFS, distinctly).

In addition to the above discussed SMOTE and SMOTE-BL resampling method, we applied SMOTE-ENN as well that used minority samples as input to generate the synthetic samples. The generated samples were subsequently processed with k-Nearest Neighbor (k-NN) classifier, where Euclidean distance-based k-NN algorithm was taken into consideration. This approach formed a vector between the current samples and the one from obtained k-neighbors. The estimated vector was multiplied with a random number existing in between 0 to 1, which was appended to the original sample to obtain the final synthetic sample as output. Unlike classical SMOTE resampling method where defining class-boundaries can be challenging as there can be certain synthetic minority samples undergoing cross-over or overlap with the majority class. The severity of such events can be more frequent over the large non-linear features. This problem can mis-label the synthetic samples inappropriately, while training over such data might impact overall classification results or can yield false positive or false negative results. To address this problem, we applied an improved SMOTE algorithm called SMOTE-ENN. It possesses an additional computing ability in conjunction with the Edited Nearest Neighbor (ENN) classifier in which the label of each synthetic sample is compared in reference to the vote of its k-NNs neighbors. If it finds any inconsistency between the input sample and corresponding k-NNs, it drops that sample from the synthetic sample set, else it retains the same. Here, the higher $k - value$ enables stringent cleaning and therefore appends original data with the optimal set of synthetic samples to alleviate class-imbalance problem. It also provided consistent set of input features for further learning and classification.

F. Min-Max Normalization

In sync with huge non-linear features, to alleviate any probable over-fitting and convergence problem, we performed feature normalization by using Min-Max Normalization method. The proposed Min-Max normalization method mapped input features in the range of [0 1]. Noticeably, Min-Max normalization was done over each feature set retained after feature selection. Mathematically, we applied equation (12) to perform Min-Max normalization over the input features. As depicted in (12), the variable x_i be the feature element, where $x_i \in N$, which is mapped to the corresponding normalized value signifying x_i'. Here, x_i' is obtained in the range of 0 to 1. In (12), the parameters $min(X)$ and $max(X)$ states the minimum and the maximum values of X, respectively.

$$Norm(x_i) = x_i' = \frac{x_i - min(X)}{max(X) - min(X)} \quad (12)$$

G. Ensemble of Ensemble Classification

Unlike traditional ML-based solutions where the authors have applied merely single or standalone ML algorithm to perform learning and classification, we have designed a robust ensemble of ensemble (E2E) learning method that applies five different ensemble learning methods including Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier algorithms. In the developed E2E model, each classifier performs learning over the normalized features, and provides label for each sentence as 1 and 0, for PII and Non-PII element respectively. Finally, applying the concept of the maximum voting ensemble (MVE), it labels each input query as PII or Non-PII. Noticeably, unlike traditional machine learning methods like decision tree (DT), support vector machine (SVM), naïve bayes (NB), etc. the ensemble learning methods like random forest (RF), AdaBoost, extra tree classifier, XGBoost etc. have performed better for the different data and image classification problems. Being consensus driven prediction solutions, it yields higher accuracy and reliability towards PII detection and classification. Considering it as motivation, this research intends to use only ensemble learning methods, such as the Bagging, Boosting, RF, ETC, XGBoost to perform maximum voting ensemble-based learning and classification. In this method, a total of five base classifiers (here, ensemble classifiers) are considered. This is because, out of five base classifiers, if three of the base classifiers classifies an input as PII and annotates it as 1, it would be classified as PII. On the other hand, if three base classifiers annotate an input as 0, the final prediction is made as non-PII. Being consensus driven approach or maximum voting-based approach, it can be more reliable towards run-time significances. A brief of the different ensemble base classifiers used to design E2E ensemble is given as follows:

1) AdaBoost: It represents a kind of adaptive boosting ensemble learning method that possesses superior instance-wise analysis ability. In this work, to implement AdaBoost method, the allied prerequisite tests were doled-out to the equivalent weight that enables generation or forming certain weak learners. For each cycle of computation, it measures the error rate for the aforesaid weak classifier and eventually the weight for the accurately classified sample is improved, while the weights for the inaccurately classified samples are reduced. Finally, the weak learner becomes the strong learner and classifies each sentence as PII or PII-Free and labels them as "1" and "0", respectively. The gradient boosting method is an improved Boosting ensemble in which the weights for the accurately classified samples are varied gradually, rather with a fixed update. It solves convergence problem.

2) Bagging: In this work, we applied bagging ensemble learning method with two different kernels. More specifically, we applied k-NN algorithm and MNB classifier as the two base classifiers to design Bagging ensemble learning algorithms.

3) Random Forest (RF): It is one of the most efficient ensemble-learning methods that embodies multiple tree-based classifiers. Being a tree-based learning model, each tree generates its own predicted output or vote for the most probable class (for each sentence or allied embedding feature vector). Consider that the input training samples be N, then a sample possessing N cases are selected arbitrarily from the input data (say, input feature vector). The selected samples are subsequently used as training set to constitute a new tree. Let, there be the M input variables, then the best split is applied over m to split the node. Noticeably, in this work the value of m was fixed as constant while performing forest development. Thus, the proposed method develops each tree to the possible largest level or size. Noticeably, unlike other machine learning algorithms, RF requires relatively smaller number of parameters to be calculated during learning and classification and hence serves a lightweight and computationally efficient classifier (solution). In sync with above discussed forest growth process, the RF algorithm can be defined as the amalgamation of the different tree-structures, given as Eq. (13).

$$\{h(x, \theta_k), k = 1,2, \dots i \dots\} \quad (13)$$

In Eq. (13), h represents the classifier function, while the arbitrary vector generated unformal across tress is given by $\{\theta_k\}$. Here, each tree embodies a unit vote for its most probable class towards a unit query or sentence (say, input x). To be noted, the ability to employ multiple DTs where each DT performs respective classification makes proposed RF method more suitable for learning and classification. We applied a bootstrapped subset of training samples to train each tree across the formed forest that uses 70% of the training data, while the remaining data elements are labeled as the out-of-bag samples, which are subsequently applied for inner cross-validation to predict output. Thus, applying this method, we classified each input query or sentence (say, corresponding embedded feature vector) as PII or PII-Free, which were subsequently labelled as "1" or "0", correspondingly.

4) Extra Tree Classifier (ETC): This algorithm forms a cluster of unpruned DTs as per the conventional top-down paradigm. Unlike RF method, ETC algorithm comprises randomization of attribute and cut-point selection when performing node-split. It is also able to form overall randomized trees containing structures which are independent of the outputs of the training sample. In fact, it distinguishes itself from the other tree-based ensemble algorithms because of the two key factors. The first is that it splits nodes by choosing cut-points arbitrarily and the second it applies the complete training sample to for forest (say, tree growth). The predicted output from the encompassing trees is amalgamated to yield final PII prediction result by using MVE method. The key approach behind the ETC method is that the complete randomization of the cut-point and attribute altogether with ensemble averaging that minimizes the variance in more efficient way than the weaker randomization methods applied in other machine learning approaches. Additionally, the use of the original training samples minimizes the probability of bias and therefore accomplishes higher accuracy for classification. Applying this ensemble approach each sentence was classified as PII and PII-Free, which was labelled as "1" and "0", respectively.

Once obtaining labelled output from each base (ensemble) classifier, for each query or sentence, the proposed MVE method estimated the consensus, signifying the maximum vote for each sentence (i.e., PII or Non-PII). As the proposed model applied five different ensemble ML classifier as base classifier, a query with minimum three 1 was classified as PII and the one with three 0 was annotated as the non-PII query. In this manner, the proposed model applied consensus (say, Maximum Voting) score to predict each query as PII or non-PII.

The use of this approach can help identifying a set of those queries having PII elements, which can not only enable further PII element detection and identification, but can also make computation fast due to reduced search space (or queries). Once identifying a query as PII, dictionary-based technique(s) can be applied to perform specific PII attribute detection from each sentence or query. Though, this research considers it a scope for future efforts, and hence is beyond the research scope. Simulation results and allied inferences are given in the subsequent section.

VI. Results and Discussion

In this work, the key emphasis is made on developing a robust cross-discipline PII detection and classification system for privacy preserved digital data transmission and storage. In this work, the PII detection and classification task is solved as an NLP problem, where it exploits semantic features from the input queries to learn and predict PII elements in each query. The overall proposed model emphasizes on addressing almost major challenges in at hand PII detection problem. In other words, we made effort to address both data challenges (feature engineering) as well as classification so as to ensure a reliable and optimized solution. In this reference, this work contributed a robust ensemble of ensemble learning assisted semantic feature driven cross-discipline PII detection and de-identification model (EESD-PII). Being a machine learning driven NLP solution, we have tried to exploit PII attributes from the different disciplines, which provide sufficiently large feature space to learn and hence predict PII queries in real-world application. Moreover, realizing class-imbalance, convergence, local minim and over-fitting problems, different computational optimization measures were taken into consideration that ensured optimal data (or feature) as well as computational component to achieve a robust cross-discipline PII detection and classification solution. In sync with the real-world data conditions where the likelihood of data heterogeneity, unstructured-ness ss etc. can' be ruled out, we at first performed pre-processing over the input cross-discipline datasets. Noticeably, we synthesized a total of 12000 text queries containing PII attributes from three different categories including personal credentials ("Name", "Address", "Email", "Aadhar Number", "PAN", "SSN", "Vehicle Number", and "Phone Number"), healthcare credentials ("Health Insurance Number", "Diagnosis Details", and "Life Insurance Number") and financial credentials ("Bank Account Number", "Loan Account", "Balance Details", "OTP", "Access PIN" and "Credit

Card Number"). Here, the key motive was to strengthen the proposed PII detection model to detect and classify each input text query irrespective of its subject matter or allied discipline. To address aforesaid problem of data heterogeneity and unstructured-ness different pre-processing tasks were performed including missing value removal, Unicode normalization, removal or emoji, website link, punctuations, stop-words, and lower-case conversion. Additionally, lemmatization and tokenization were performed, where the earlier one helped in retaining the root-intends or contextual information, while the use of tokenization helped tokenizing each query to exploit corresponding semantic features for learning and prediction. The tokenized outputs were passed to the CBOW feature extraction that obtained semantically enriched feature vector to perform learning and prediction. Noticeably, we applied CBOW as Word2Vec embedding method to retain maximum possible contextual feature even in low-dimensional feature which helped retaining sufficiently large contextual feature vector even with the low computational cost. Subsequently, CBOW feature was processed for feature selection, where the different algorithms including Chi-Square based Select K-Best (SKB) method, WRST algorithm and Ginni Score based feature selection (GSFS) methods. Unlike traditional feature selection methods, we designed an ensemble feature model by concatenating the selected features from the SKB, WRST and GSFS methods. Thus, the combined feature vector was later applied for feature resampling. In this work, we applied three different resampling methods including SMOTE, SMOTE-BL and SMOTE-ENN. Noticeably, in the proposed model, we executed these three resampling methods individually over the selected features. It helped addressing class-imbalance problem. Subsequently, the resampled features were then processed for Min-Max normalization that mapped each input in the range of 0 to 1 and thus alleviated any likelihood of convergence and over-fitting problem. The normalized outputs were passed to the E2E classifier which was designed by using five different ensemble learning methods named Bagging, Boosting, AdaBoost, Random Forest, and Extra Tree Classifier. We applied consensus oriented MVE method to perform learning and classification.

The proposed model was developed using Python Notebook, and the simulation was done on Google Co-laboratory platform, which helped reducing implementation complexity and cost. The simulation was done on a central processing unit configured with Microsoft Window operating system operating with 8 GB RAM and Intel i5 processor. To quantify the performance of the proposed PII detection and classification system, we retrieved confusion metrics in terms of true positive (TP), true negative (TN), false positive (FP) and false negative (FN). These parameters were used to measure performance in terms of accuracy, precision, recall and F-Measure, which were obtained by using following equations (Table II).

TABLE II. PERFORMANCE PARAMETERS

Parameter	Mathematical Expression
Accuracy	$\frac{(TN+TP)}{(TN+FN+FP+TP)}$
Precision	$\frac{TP}{(TP+FP)}$
Recall	$\frac{TP}{(TP+FN)}$
F-measure	$2.\frac{Recall.Precision}{Recall+Precision}$

Observing the implementation schematic (Fig. 1), it can be found that the overall proposed model encompasses the different feature selection, resampling and classification models; though, the proposed model defines the term "proposed" with the CBOW feature extraction, ensemble feature selection, resampling, Min-Max normalization and E2E MVE-based classification. It signifies that the proposed model encompasses sub-algorithms for the different phases, including feature selection, resampling and classification. Considering this fact, we at first examined the performance with the different feature selection model, feature resampling and classifiers. Subsequently, with the best performing model the comparison was done with the existing state-of-arts. In this reference, the overall performance characterization is done in terms of intra-model characterization and inter-model characterization. The detailed discussion of the results and allied inferences is given in the subsequent sections.

A. Intra-Model Characterization

In this section, the performance comparison with the different feature selection methods, feature resampling and classifiers is given. Noticeably, in this work we applied single Word2Vec CBOW feature extraction method, which is subsequently processed for the different feature selection, feature resampling, and ensemble classifiers. In this reference, this research performs relative performance with the different algorithms. The key purpose of this assessment is to identify the best performing set of algorithms towards targeted PII attribute detection and classification solution. The detailed discussion of the results obtained and allied inferences is given as follows:

In the proposed model, the CBOW features are fed as input to the three different feature selection methods, including SKB, WRST and GSFS method. Table III presents the simulated performance outcomes with the different feature selection methods. The outputs obtained reveal that with the CBOW input feature, SKB feature selection model exhibits the accuracy of 94.91%, while WRST and GSFS method yielded PII prediction accuracy of 95.03% and 94.89%, respectively. Similarly, the F-Measure outputs were measured as 94.93%, 95.08% and 95.10%, for SKB, WRST and GSFS feature selection methods, correspondingly. The simulation results signify that the intrinsic features driven approaches whether WRST and GSFS methods yield better performance towards PII prediction. The precision performance by SKB, WRST and GSFS methods were obtained as 94.86%, 94.97% and 95.21%. It clearly indicates that the WRST method or GSFS can be suitable towards at hand text-review driven PII prediction solution. Noticeably, these results (Table III to Table V) have been obtained by using proposed E2E MVE ensemble learning classifier.

TABLE III. PERFORMANCE WITH THE DIFFERENT FEATURE SELECTION METHODS

Feature	Feature Selection	Performance (%)			
		Accuracy	Precision	Recall	F-Measure
CBOW	SKB	94.91	94.86	95.01	94.93
	WRST	95.03	94.97	94.82	95.08
	GSFS	94.89	95.21	95.00	95.10

Table IV presents the efficiency with the different resampling methods. More specifically, three different resampling methods were applied towards targeted PII detection and prediction model. The simulation results reveals that the CBOW features with SMOTE, SMOTE-BL and SMOTE-ENN methods exhibited the accuracy of 97.77%, 97.93% and 99.35%, respectively. The simulation results also reveal that the SMOTE, SMOTE-BL and SMOTE-ENN methods achieves precision of 99.63%, 99.81% and 99.88%, respectively. These algorithms exhibit the recall of 99.37%, 99.63% and 99.94%, correspondingly. The depth assessment also exhibits that the F-Measure performance by SMOTE, SMOTE-BL and SMOTE-ENN resampling method exhibited the F-Measure of 99.49%, 99.71% and 99.90%, respectively. The simulation clearly depicts that the proposed SMOTE-ENN method exhibits the superior performance than the other approaches. Recalling the theoretical aspects where SMOTE-ENN methods possess superior efficacy than the classical random sampling, up-sampling and even classical SMOTE variants. The results obtained confirm efficacy of the proposed SMOTE-ENN model towards at hand PII detection and prediction model.

TABLE IV. PERFORMANCE WITH THE DIFFERENT FEATURE RESAMPLING METHODS

Feature	Feature Resampling	Performance (%)			
		Accuracy	Precision	Recall	F-Measure
CBOW	SMOTE	97.77	99.63	99.37	99.49
	SMOTE-BL	97.93	99.81	99.63	99.71
	SMOTE-ENN	99.35	99.88	99.94	99.90

The simulation results with the different ensemble learning classifiers including the proposed E2E MVE ensemble model are given in Table V. Here, the key motive is to assess relative efficacy of the different base classifiers and assess whether the proposed E2E ensemble with MVE concept can yield superior performance or not. In this reference, the accuracy, precision, recall and F-Measure performance obtained are given in Table V. As depicted in Table V, Bagging ensemble method exhibits the accuracy of 97.89%, while Boosting, AdaBoost, Random Forest and Extra Tree Classifier algorithms exhibit the accuracy of 96.68%, 96.72%, 98.67% and 98.81%, respectively. On the contrary, the proposed E2E MVE ensemble method which applied aforesaid ensemble learning methods as base classifier achieved the PII prediction of 99.77%. The precision performance by Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier algorithms was measured as 94.37%, 96.61%, 94.99%, 94.99% and 96.01%, respectively. The precision performance by the proposed E2E MVE method exhibited the recall of 99.63%, which is higher than other standalone ensemble learning classifiers. The F-Measure performance by Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier algorithms were obtained as 95.45%, 96.69%, 95.88%, and 96.065, respectively. The proposed E2E MVE method exhibited the F-Measure of 99.71%, which is superior than any other approaches.

TABLE V. PERFORMANCE WITH THE DIFFERENT CLASSIFIERS

Feature	Feature Resampling	Performance (%)			
		Accuracy	Precision	Recall	F-Measure
CBOW	Bagging	97.89	94.37	96.57	95.45
	Boosting	96.68	96.61	96.69	96.69
	AdaBoost	96.72	94.99	96.80	95.88
	Random Forest	98.67	94.99	96.80	95.88
	Extra Tree Classifier	98.81	96.01	96.13	96.06
	Proposed E2E	**99.77**	**99.81**	**99.63**	**99.71**

Taking into consideration of the overall results and allied inferences, it can be quantified that the proposed model encompassing CBOW semantic features, WRST feature selection, SMOTE-ENN resampling, and E2E MVE ensemble method exhibits the accuracy of 99.77%, precision 99.81%, recall 99.63% and F-Measure of 99.71%. Here onwards we call this method as the proposed model and thus with this specific performance, we have performed the relative performance comparison with other state of arts, which is given in the subsequent sections.

B. Inter-Model Characterization

In sync with the results obtained and allied inferences, we define proposed model as the PII detection solution encompassing CBOW feature extraction, WRST feature selection, SMOTE-ENN resampling, Min-Max normalization and E2E MVE ensemble classifier. Here onwards, we define accuracy, precision, recall and F-Measure performance of the proposed model as 99.77%, 99.81%, 99.63% and 99.71%, respectively. This section discusses the relative performance with the other state-of-arts, as given in Table VI.

This is the matter of fact that in the very few efforts have been made for PII detection, where the different algorithms have been applied for feature extraction, and classification (say, learning). A few approaches have used deep learning as well to learn over the local deep features pertaining to each PII related query to perform (PII) detection and classification. However, their inability to address class-imbalance problems, convergence and local minima etc. make then inferior towards a robust and optimal PII detection and classification solution. Moreover, the different existing approaches have applied the different datasets

and hence generalizing solutions for the same data becomes difficult, especially when the data availability is a challenge. Despite this we have compared the efficacy of our proposed model with other state of arts. Noticeably, in sync with the above discussions (i.e., Inter-Model Assessment), we have identified CBOW feature extraction followed by CCRA feature selection, SMOTE-ENN resampling, Min-Max normalization and ETC classifier as the optimal solution towards the targeted PII detection and classification system. And therefore, respective performance (say, accuracy 99.77%, precision 99.81%, recall 99.63% and F-Measure of 99.71%) is considered as the proposed method towards targeted PII detection and classification system. In this reference, a comparison between the proposed method and other state-of-arts is given in Table II. Noticeably, in the past the different state-of-arts have applied the different performance variables for efficacy analysis, we considered a common performance variable F-Measure to assess relative efficiency. Furthermore, the considered state-of-arts represent the different approaches towards NER (Named Entity Recognition) analysis that possess similar intends as that of PII detection.

TABLE VI. INTER-MODEL PERFORMANCE COMPARISON

Reference	Method	F-Measure (%)
[51]	Bi-LSTM-CRF +CNN	93.5
[52]	Bi-LSTM-CRF+ELM (Extreme Learning Machine) + BERT+ Flair	93.38
[53]	Bi-LSTM + Flair embeddings	93.09
[54]	BERT+ BI-LSTM	92.80
	BERT Base	92.4
[55]	Bi-LSTM + multi-task	92.61
[56]	Bi-LSTM + BERT + ANN-LM	92.22
[57]	Word-Embedding + ANN-LM	91.93
[58]	Bi-LSTM + CRF +Auto-encoders+ Lexical Features	91.89
[59]	Bi-LSTM + CRF + Lexical Features	91.73
[60]	LM- LSTM +CRF	91.71
[61]	Bi-LSTM+ CRF	91.62
[62]	Hybrid Semi-Markov +CRF	91.38
[63]	IXA-Pipes	91.36
[64]	CCNN+ WLSTM+ CRF	91.35
[65]	CRF +GRU	91.26
[66]	BI-LSTM +CRF	90.94
[67]	Glove	88.30
[68]	CBOW	88.20
[69]	Bi-LSTM + Glove + Flair	85.51
Proposed	**CBOW + WRST + SMOTE-ENN + Min-Max Normalization + E2E MVE**	**99.71**

In sync with the results obtained (Table VI), it can be found that the major at hand efforts towards NER or applied PII detection methods have exploited deep learning methods with the different feature embedding techniques such as CBOW [68], Glove [67], Flair [69]. Though, the major state-of-arts have directly applied varied deep learning methods such as LSTM, Bi-LSTM, CNN etc., to perform two-class classification by using Softmax classifier. However, most of these methods fail in addressing contextual details within the input text corpus. Moreover, none of these approaches could address inherent challenges of NLP including unstructured data, class-imbalance, local minima and convergence. Such limitations might make any solution suspicious, especially when the solution is supposed to be applied over real-world BigData. Unlike aforesaid approaches, in this work, we emphasized on addressing above stated issues so as to contribute a generalizable optimal PII detection and classification system. Moreover, a few approaches like [56][57] tried to extract local features from the sequential text embeddings for further learning and classification by using machine learning methods (i.e., ANN-LM); however, the highest F-Measure observed was 92.2%, which is almost 7% lower than the proposed method. Here, the impact of feature engineering such as class-imbalance (SMOTE-ENN), feature selection (WRST) and normalization can't be ruled out. Noticeably, these feature improvement methods helped our proposed model to achieve features with minimum redundant data or non-redundant feature elements. It helped in alleviating pre-mature convergence. SMOTE-ENN helped in addressing class-imbalance problem, while the use of Min-Max normalization resolved over-fitting problem. Thus, the improvement in data or allied feature enabled our proposed method to exhibit superior over other state-of-arts. The overall results confirm superiority of the proposed method over other state-of-arts available in PII detection domain. The depth assessment affirms positive response or answers for the research questions (RQ1-RQ4), as discussed in Section IV.

VII. CONCLUSION

Unlike existing PII detection approaches where the authors have either applied predefined dictionaries to detect and classify (PII) text for a specific dataset or discipline, in this work a robust multi-disciplinary PII detection method was developed. To achieve it, the PII detection, de-identification and re-identification tasks were solved as an NLP problem. In this reference, unlike predefined dictionary or syntactical learning-based solutions, the texts encompassing PII and normal queries related to the different disciplines including personal credential, healthcare, business communication details etc. were processed for NLP processing that eventually enabled a cross-discipline PII detection system. Additionally, this research made effort to alleviate at hand computational limitations including class-imbalance, local minima and convergence and over-fitting. More specifically, novel and robust ensemble of ensemble learning assisted semantic feature driven cross-discipline PII detection and de-identification model (EESD-PII) was developed in this work. In sync with cross-discipline PII detection and classification task, a large set of text queries

possessing PII elements belonging to the personal credentials, healthcare data, financial texts and queries etc. were used for training. The collected cross-discipline texts were processed for pre-processing tasks like the removal of stopping-words, punctuations, URL-link, lower case conversion, lemmatization and tokenization. The tokenized text-sequences were processed for continuous bag-of-word (CBOW) word-embedding that provided semantic feature space for further learning. The use of CBOW embedding provided contextually-rich feature vector to ensure better learning and PII detection (and/or classification). Realizing real-world scenarios where the frequency of PII terms is very small in comparison to the non-PII elements (signifying severe class-imbalance problem), SMOTE resampling methods including SMOTE, SMOTE-BL and SMOTE-ENN were applied. This approach helped in alleviating the class-imbalance problem and hence curse of dimensionality, thus helping the model to achieve higher learning accuracy. Subsequently, Wilcoxon Rank Sum Test (WRST) method was applied to retain the most representative samples in reference to the 95% confidence interval. The retained features were processed for Min-Max Normalization which helped alleviating any over-fitting and convergence problems. Finally, a robust ensemble of ensemble (E2E) learning classifiers was designed by using five different ML algorithms encompassing Bagging, Boosting, AdaBoost, Random Forest and Extra Tree Classifier as base classifier. This approach not only helped in achieving more reliable outcome but also alleviated performance diversity problem. Noticeably, the use of tokenization and word-embedding helped achieving de-identification goals as well, without losing data essence for further learning and classification. The proposed E2E model performed majority voting ensemble to annotate each text-query as PII or Non-PII data. The simulation results reveal that the proposed EESD-PII model achieves PII annotation accuracy of 99.77%, precision 99.81%, recall 99.63% and F-Measure of 99.71%. In future, the authors can design AI driven multi-disciplinary dictionary with PII-sensitive masking approach to improve de-identification; though, the proposed model retains aspects of de-identification and re-identification to serve real-time decisions.

VIII. Future Scope

This is the matter of fact that the proposed method has yielded superior and generalizable performance towards PII detection and classification; however, it was mainly based on exploiting semantic features trained over ensemble machine learning classifiers. The use of deep features can also be explored. The recent development in advanced deep structures, especially designed to address long-term dependency problems like multi-attention-based Bi-LSTM, Bi-GRU, residual networks etc. can be applied as ensemble feature structure. It can help to exploit more contextual details with no probability of any gradient vanishing or gradient explode over large deep structure running over non-linear data space. In this reference, the researchers can focus on applying deep (hybrid) feature models for feature extraction and learning to achieve better outputs. The use of GAN can also be considered in future to improve de-identification and word-restructuring.

***Abstract*—This paper briefly introduces the analytic hierarchy process (AHP) method and uses the fuzzy decision-making and trial evaluation laboratory (DEMATEL) method to adjust the index weight in it. The geological exploration project of Qingdao undersea tunnel project in Shandong Province was selected as the subject of case study. Firstly, the fuzzy-DEMATEL method was used to analyze the degree of influence between different risk factors in the project and the types of risk factors. Then, the AHP method divided the risk factors and calculated their weight. Finally, the influence parameters calculated by the fuzzy-DEMATEL method was employed to adjust the weight of the indicators in the AHP method. The fuzzy-DEMATEL analysis obtained the driving, conclusion, and transitional risk factors. It was found from the analytic results of the AHP method that the construction supervision unit's qualification risk, management mechanism, and awareness risk had the greatest impact on the risk of the project, and the overall risk level of the project was 2.1 points.**

Keywords*—Geological exploration project; analytic hierarchy process; DEMATEL; fuzzy theory; risk assessment

I. Introduction

With the extensive development of geological exploration projects around the world, its risk management has become the key to ensure the smooth progress and successful implementation of projects [1]. Geological exploration projects are faced with a variety of risk factors due to their technical complexity, long cycle, large investment, and changing environment [2]. Geological exploration projects have a wide range of risk sources, including but not limited to technical risk, market risk, environmental risk, management risk, financial risk, etc. Therefore, in the risk management assessment of geological exploration projects, it is necessary to first identify the source of risk and then set corresponding indicators for investigation and analysis [3]. In order to solve the complexity and uncertainty problems in the risk assessment of geological exploration projects, this paper introduced the fuzzy decision-making and trial evaluation laboratory (DEMATEL) method [4]. The DEMATEL method is a structural modeling method used to visualize the structure of complex causal relationships and can calculate the influence degree of each element in the system on other elements. The fuzzy DEMATEL method introduces the fuzzy mathematics theory and is used to deal with the problems of complex systems with fuzziness and uncertainty [5]. The advantage of the fuzzy DEMATEL method in the risk assessment of geological exploration projects lies in that this method can reveal the mutual influence and causal relationship among various risk factors, which is helpful to identify the key risk factors and potential risk chains. Secondly, by calculating indicators such as the influence degree, influenced degree, centrality, and cause degree of each risk factor, the fuzzy DEMATEL method can provide a quantitative basis for risk assessment, enabling decision-makers to understand the distribution and severity of risks more intuitively [6]. Finally, based on the assessment results, it can also provide targeted risk management suggestions for the project team and help formulate effective risk response strategies. Liu et al. [7] proposed a risk assessment method that combined fuzzy weighted average and fuzzy decision-making trial with evaluation laboratory to sort the failure risks in system failure mode and effects analysis. Mentes et al. [8] proposed an integrated approach to identify and evaluate the driving factors, including the geographical location at the time of the accident and the failure mode leading to the death on the cargo ship. Sangaiah et al. [9] used a hybrid fuzzy multi-criteria decision-making method to effectively identify and rank significant software project risks. The evaluation results showed that compared with the existing software project risk evaluation methods, the fuzzy comprehensive evaluation method was effective and accurate. The above-mentioned related studies have all conducted relevant analyses on how to evaluate risks. Some adopted the method of fuzzy weights to evaluate risks, while others focused on the identification of related factors affecting risks. This paper used the analytic hierarchy process (AHP) to assess the risks of geological exploration projects and utilizes the Fuzzy DEMATEL method to adjust the hierarchical weights in the AHP method, thereby improving the accuracy of risk assessment. This paper briefly introduces the AHP method and uses the fuzzy DEMATEL method to adjust the indicator weights in the AHP method. A case study was performed on the geological exploration project of an undersea tunnel project in Qingdao, Shandong Province. The structure of this article is: abstract - introduction - introduction of AHP and fuzzy DEMATEL method - case analysis - discussion - conclusion.

II. AHP Method and Fuzzy-DEMATEL Method

With the rapid development of economy, in order to adapt to the rapid growth of population, a variety of basic livelihood projects continue to be established. The specifications of these livelihood projects are large or small, but they require a certain area of land, so before the implementation of livelihood projects, it is necessary to carry out geological exploration of the construction area, in order to improve safety [10]. The main

purpose of geological exploration projects is to understand the geological conditions of the construction area. The geological conditions are unknown during the implementation of geological exploration projects [11], which means that there are risks in projects. In addition, geological exploration projects will be affected by various risk factors such as market, management mode, and finance during operation. Therefore, geological exploration projects also need to carry out risk management assessment, so as to reduce the risks of projects.

The AHP method is one of the many methods that can analyze the risk of geological exploration projects. As a multi-criteria decision-making technology [12], the AHP method can divide the problem into small problems at multiple levels and then carry out qualitative and quantitative analyses on the small problems. The steps of the AHP method are as follows. (1) The risk sources of geological exploration projects are divided into different hierarchies, and the risk indicators of each hierarchy are obtained. ② Starting from the lowest risk indicator, the pairwise judgment matrix is constructed for the different indicators of each hierarchy. ③ The indicator weight is calculated according to the pairwise judgment matrix [13], and the consistency check is used to adjust the weight. After the weight of the risk indicators is obtained, the score of each risk indicator can be collected by questionnaire, and the risk level is calculated based on it.

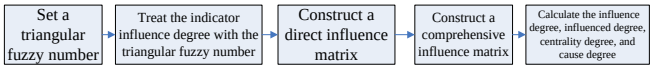

Fig. 1. The flow of the fuzzy-DEMATEL method.

When the AHP method is used, the key is to build a suitable pairwise judgment matrix to calculate the weight of indicators. In this process, the AHP method usually regards each indicator as an independent indicator, but in actual geological exploration projects, there are more or less mutual influences among risk indicators, which will affect the result of risk assessment [14]. Therefore, DEMATEL is adopted in this paper to revise the weights of the AHP method. The function of DEMATEL is to evaluate the influence degree of one indicator on other indicators and then to correct the weights in the AHP method. However, DEMATEL also needs to build an indicator influence matrix when calculating the influence degree of indicators, and the element values in the matrix are also obtained by manual evaluation. Therefore, a triangular fuzzy number [15] is introduced to process the element values in the matrix, thereby minimizing the subjective influence. The steps are shown in Fig. 1.

1) A triangular fuzzy number is set [16], and the expression of triangular fuzzy number A is: $A=(l,m,r)$, where l is the minimum value, m is the most likely value, and r is the maximum value. This paper adopts the form of manual scoring to evaluate the influence degree of a risk indicator on other indicators and sets an A for each influence degree level. The greater the influence degree, the closer A is to 1; otherwise, the closer A is to 0. For example, the A of the evaluation level of "no influence" is set as $(0,0.1,0.3)$.

2) The evaluation level of the influence degree of the indicator given by the manual score is converted into a triangular fuzzy number according to the setting.

3) Direct influence matrix B is constructed, and the matrix is expressed as:

$$B=\begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1j} \\ b_{21} & b_{22} & \cdots & b_{2j} \\ \vdots & \vdots & \vdots & \vdots \\ b_{i1} & b_{i2} & \cdots & b_{ij} \end{bmatrix}, \quad (1)$$

where b_{ij} represents the value of the influence of risk indicator i on risk indicator j after fuzzy processing. Its calculation formula is:

$$\begin{cases} b_{ij}=\dfrac{\sum_{k=1}^{k} b_{ij}^{k}}{k} \\ b_{ij}^{k}=\min l_{ij}^{k}+x_{ij}^{k}\Delta_{\min}^{\max} \\ \Delta_{\min}^{\max}=\max r_{ij}^{k}-\min l_{ij}^{k} \\ x_{ij}^{k}=\dfrac{x_{lsij}^{k}(1-x_{lsij}^{k})+x_{rsij}^{k}x_{rsij}^{k}}{1-x_{lsij}^{k}+x_{rsij}^{k}} \\ x_{lsij}^{k}=\dfrac{x_{mij}^{k}}{1+x_{mij}^{k}-x_{lij}^{k}} \\ x_{rsij}^{k}=\dfrac{x_{rij}^{k}}{1+x_{rij}^{k}-x_{mij}^{k}} \end{cases}, \quad (2)$$

where x_{lij}^{k}, x_{mij}^{k}, and x_{rij}^{k} are triangular fuzzy numbers of the influence degree between risk indicators i and j given by rater k after standardization, x_{lsij}^{k} and x_{rsij}^{k} are the left and right standard values of the triangular fuzzy number of the influence between indicators i and j given by rater k, x_{ij}^{k} is the total standard value of the triangular fuzzy number of the influence between indicators i and j given by rater k [17], $\Delta_{\min}^{\max}$ is the difference between the largest maximum value and the smallest minimum value among the triangular fuzzy numbers given by all raters, and b_{ij}^{k} is the clear value between indicators i and j given by rater k [18].

4) The formula of the comprehensive influence matrix is:

$$\begin{cases} C=\dfrac{B}{\max_{1\le i\le n}\sum_{j=1}^{n} b_{ij}} \\ D=C\cdot(E-C)^{-1} \end{cases}, \quad (3)$$

where C is the direct influence matrix after normalization, D is the comprehensive influence matrix, and E is the identity matrix [19].

5) The comprehensive influence parameter of the risk indicators is calculated according to D:

$$\begin{cases} d_i = \sum_{j=1}^{n} d_{ij} \\ e_i = \sum_{j=1}^{n} d_{ji} \\ f_i = d_i + e_i \\ g_i = d_i - e_i \end{cases}, \quad (4)$$

where d_i is the influence degree of risk indicator i, e_i is the influenced degree, f_i is the degree of centrality, and g_i is the degree of cause [20].

After obtaining the comprehensive influence parameter of risk indicators through the above steps, the degree of centrality can be used to adjust the weight of indicators calculated in the AHP method. The adjustment formula is:

$$W_i = \frac{\omega_i f_i}{\sum_{i=1}^{n} \omega_i f_i}, \quad (5)$$

where ω_i is the weight of risk indicator i in the AHP method and W_i is the weight of risk indicator adjusted by the fuzzy-DEMATEL method.

III. Case Analysis

A. Case Overview

This paper took the geological exploration project of an undersea tunnel project in Qingdao, Shandong province as a case analysis. The project is located at Jiaozhou Bay in Qingdao. The main purpose of the undersea tunnel project is to directly connect the economic zones on both sides of Jiaozhou Bay, so as to improve the efficiency of freight and passenger transport and further promote economic development.

In the geological exploration project, the method of drilling was used to survey the seabed geology of Jiaozhou Bay, and a total of 16 drilling points were set up. The ship-borne drilling platform was used at the drilling point. In the process of drilling, the ship-borne drilling platform was fixed to the drilling point by using multiple ship anchors. Then, the drilling casing was driven vertically into the sea bed by traction until the casing reached the stable layer.

B. Methods for Risk Analysis of the Geological Exploration Project

Firstly, 20 experts from the related field were invited to identify and summarize the risk sources of the geological exploration project. The risk hierarchical structure of the geological exploration project was constructed, as shown in Fig. 2.

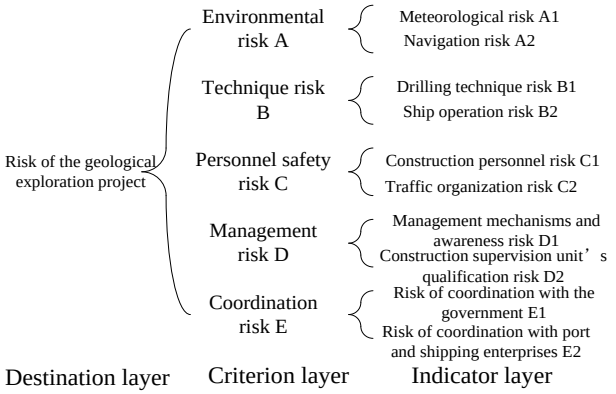

Fig. 2. Hierarchical structure.

After that, 20 experts were distributed the criterion-level rating table and the indicator level rating table. They marked the importance degree of the risk factors in the criterion level and the indicator level through the rating tables. Taking the criterion level score table as an example, as shown in Table I, the five risk factors in the criterion level were compared pairwise, and "1, 2, 3... 8, 9" was used to evaluate the relative importance between two factors. "1" indicates that the two factors are equally important; the larger the value, the more important the former factor is than the latter factor. When the former and latter factors are exchanged during comparison, the reciprocal of the value is used. The same is true for the indicator level score table, but the difference is that the risk indicators of the indicator level for pairwise comparison needs to belong to the same criterion level indicator. According to the rating tables, the judgment matrix of the criterion layer and indicator layer was constructed successively, and the weight of risk factors of the criterion layer and indicator layer was calculated based on it. At the same time, consistency check was used to determine whether the weight is reasonable. If not, the score in the judgment matrix was re-adjusted, and the weight was calculated until passing the consistency check.

TABLE I. Indicator of Importance Rating Table

Risk factor	Factor A	Factor B	Factor C	Factor D	Factor E
Factor A	1				
Factor B		1			
Factor C			1		
Factor D				1	
Factor E					1

After calculating the weight of the risk factors through the above steps, the fuzzy-DEMATEL method was used to calculate the degree of influence between the risks. First of all, the 20 experts were given the risk factor influence degree score table, which compared all risk factors in the indicator layer pairwise. The evaluation of the influence degree from weak to strong was divided into five levels, and a triangular fuzzy number was set for each level. After that, equation (2) was used to deblur the rating table, and the average score of the influence degree was calculated. A direct influence matrix was constructed according to the average score of the influence degree in the score table, and then the centrality degree of each risk factor was calculated following the steps mentioned above.

The weight of the risk factor obtained by the AHP method was adjusted accordingly.

Finally, a questionnaire was designed according to the indicator layer in the hierarchical structure given by the AHP method, and the score of each indicator was set from 0 to 10 according to the risk degree from low to high. Then, the 20 experts scored the risk factor indicators in the questionnaire.

IV. Analysis of Results

This paper used the fuzzy-DEMATEL method to analyze the degree of mutual influence of risk factors in the geological exploration project. After a series of calculations, comprehensive influence matrix D of risk factors in the geological exploration project is shown in Table II. The causal relationship diagram of risk factors drawn according to Table III is shown in Fig. 3. Matrix D reflects the comprehensive influence of a risk factor on other risk factors. A scatter plot of the distribution of risk factors in a plane was obtained by using the centrality degree as the x-axis and cause degree as the y-axis. After introducing the average centrality degree of risk factors, the plane was divided into four quadrants. It can be seen that meteorological risk A1, management mechanism and awareness risk D1, and construction supervision unit's qualification risk D2 were in the second quadrant, belonging to driving risk factors. Drilling technique risk B1, risk of coordination with the government E1, and risk of coordination with port and shipping enterprises were in the third quadrant, belonging to conclusion risk factors. Navigation risk A2, ship operation risk B2, construction personnel risk C1, and traffic organization risk C2 were in the fourth quadrant, belonging to transitional risk factors.

TABLE II. Comprehensive Influence Matrix D of Risk Factors in the Geological Exploration Project

E2	2.117	2.967	5.084	0.850	7

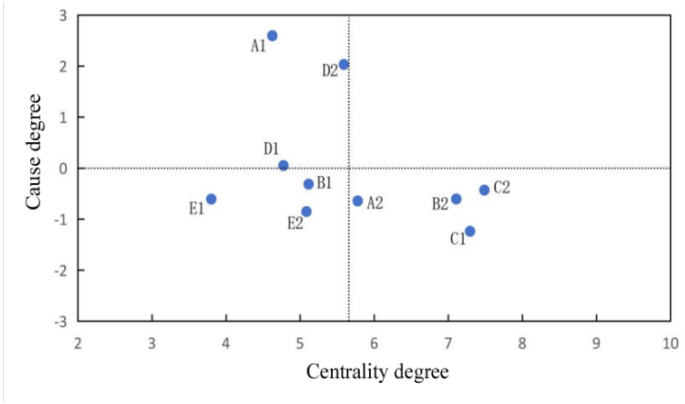

Fig. 3. Causal relationship diagram of risk factors in the geological exploration project.

Then, the AHP method was used to carry out hierarchical analysis on the risk of the geological exploration project, and the weight of risk indicators was calculated and adjusted using the centrality degree. The results and the scores of each risk indicator collected by questionnaire are shown in Table IV. After the adjustment, the weight distribution of risk indicators changed, among which construction supervision unit's qualification risk D2 had the highest weight, management mechanism and awareness risk D1 had the second-highest weight, and risk of coordination with the government E1 had the lowest weight. After combining the adjusted weight with the average score of the corresponding risk indicators, the overall risk score of the geological exploration project risk was 2.1, indicating that the overall risk of the geological exploration project was low.

TABLE IV. THE HIERARCHICAL ANALYSIS STRUCTURE OF THE RISK OF THE GEOLOGICAL EXPLORATION PROJECT AND THE WEIGHT DISTRIBUTION AND AVERAGE SCORES OF INDICATORS BEFORE AND AFTER ADJUSTMENT

Destination layer	Criterion layer	Indicator layer	Initial weight	Centrality degree	Weight after adjustment	Average score
The risk of the geological exploration project	A	A1	0.180	4.624	0.154	1.2
		A2	0.120	5.776	0.128	1.3
	B	B1	0.040	5.114	0.038	1.2

	E	E1	0.045	3.800	0.032	1.1
		E2	0.055	5.084	0.052	1.0

V. DISCUSSION

During the construction of infrastructure, it is common to conduct a geological survey of areas where the facility will be constructed in order to ensure the safety of the building facility as well as the construction personnel [21]. Geological survey projects often face many risk factors due to complicated technology, long period, large investment, and changing environment [22]. In order to ensure the safe implementation of geological exploration projects, it is necessary to evaluate and analyze the risk factors involved in these projects. Some studies related to risk assessment are reviewed. Lin et al. [23] analyzed the risk of heavy metal pollution in the Beibu Gulf. The results of the analysis using principal component analysis, positive matrix factor model, and mercury isotope method showed that heavy metal pollution mainly came from industrial pollution sources, including petrochemical, coal combustion, metal and metalloid processing, leather tanning, and human activities, among which anthropogenic pollution sources accounted for approximately 70% of all pollution. Pan [24] established a wind power output power model based on the output characteristics of wind power and established probability models of generating units, lines, and loads considering the uncertainty of other system components to evaluate system operation risks. Based on the "source-sink" landscape theory, Zhao et al. [25] established the location-weighted landscape contrast index and non-point source pollution risk index, in order to study the pollution risk of Baihua Lake in Guiyang City. The evaluation results were compared with the measured water quality data and field investigation results to verify the reliability of this method. This paper used the AHP method to perform qualitative and quantitative analysis of the risk factors in geological exploration projects. Firstly, through the analysis of the risk sources of projects, the hierarchical structure of the risk of projects was constructed, experts were invited to score the importance between two indicators in the hierarchy, and the weight of these indicators was calculated. In addition, in order to reduce the subjectivity brought by the expert score, this paper used the fuzzy-DEMATEL method to calculate the degree of mutual influence between the risk factors and adjusted the weight of the risk factor indicators in the AHP method. Then, a case study was conducted using the geological exploration project of an undersea tunnel project in Qingdao, Shandong province as the subject. The fuzzy-DEMATEL method analyzed the influence degree between the risk factors and the types of risk factors in the project, and then the AHP method divided the risk factors and calculated their weight. Finally, the influence parameters calculated by the fuzzy-DEMATEL method were used to adjust the weight of the indicators in the AHP method, and moreover, the risk level of the project was scored.

Case analysis results showed that meteorological risk A1, management mechanism and awareness risk D1, and construction supervision unit's qualification risk D2 belonged to the driving risk factors, of which A1 and D2 had high cause degree but low centrality degree. Meteorological risk and construction supervision unit's qualification risk were external risks, and D1 could affect the factors in the project, but the influence was small. Drilling technique risk B1, risk of coordination with the government E1, and risk of coordination with port and shipping enterprises E2 belonged to the conclusion risk factors, which had low cause and centrality degrees. These risk factors were the internal risks of the project, which were easy to be affected by other factors, but not easy to influence other factors. Navigation risk A2, ship operation risk B2, construction personnel risk C1, and traffic organization risk C2 belonged to transitional risk factors. These risk factors had low cause degree but high centrality degree, indicating that these internal factors of the project were susceptible to the influence of other factors and not easy to impact other factors.

In the analysis results of the AHP method, the construction supervision unit' qualification risk D2 had the highest weight, followed by management mechanism and awareness risk D1, and risk of coordination with the government had the lowest weight, indicating that the risk caused by the construction supervision unit' qualification, management mechanism and awareness had the greatest impact on the risk of the entire project. Moreover, the risk score of the project was calculated by combining the score given by the experts for the risk indicators with the corresponding weight, and the result was 2.1, suggesting that this project was at a relatively low risk level.

VI. CONCLUSION

This paper briefly introduces the AHP method and uses the fuzzy-DEMATEL method to adjust the indicator weight in the AHP method. A case study was performed using the geological exploration project of an undersea tunnel project in Qingdao, Shandong Province. Firstly, the fuzzy-DEMATEL method was employed to analyze the influence degree between different risk factors and the types of risk factors in the project. Then, the AHP method divided the risk factors and calculated their weight. Eventually, the indicator weight in the AHP method was regulated using the influence parameters calculated by the fuzzy-DEMATEL method. Meteorological risk A1, management mechanism and awareness risk D1, and construction supervision unit's qualification risk D2 belonged to the driving risk factors, drilling technique risk B1, risk of

coordination with the government E1, and risk of coordination with port and shipping enterprises E2 belonged to the conclusion risk factors. Navigation risk A2, ship operation risk B2, construction personnel risk C1, and traffic organization risk C2 belonged to the transitional risk factors. In the analysis results of the AHP method, the construction supervision unit's qualification risk (D2) had the highest weight, the management mechanism and awareness risk (D1) was the second, and the risk of coordination with the government (E1) had the lowest weight. The score of the overall risk level of the project was 2.1.

Blockchain-Based Financial Control System

Tedan Lu
School of Business, Jiangxi Modern Polytechnic College, Nanchang 330095, China

***Abstract*—In order to solve the problems of data security and low efficiency of information transmission in traditional financial control systems, this paper discusses in depth the application of blockchain technology in financial control systems. In order to optimize the performance of the traditional financial control system, this paper introduces blockchain technology into it and analyzes the structure and function of the financial control system. By constructing a blockchain-based financial data collection, information exchange and security consensus mechanism, a more efficient financial control system is designed, which can significantly improve the cost efficiency, shorten the audit cycle and enhance the data security. In the model, resource allocation within the financial control system is optimized, information exchange is more efficient, and a consensus mechanism is established. The experimental results prove that the model simplifies data entry and storage, reduces the workload of financial staff and improves transparency. The study bridges the gap between blockchain and traditional financial frameworks and advances the development of modern financial control systems.**

***Keywords*—Blockchain technology; financial control system; resource allocation; information exchange; consensus mechanism**

I. Introduction

With the development of information technology, internet technology has been widely applied in various industries. As one of the important contents of internal management control in enterprises, financial data has a large number of human factors that affect the recording forms of accounting vouchers, books, and other records in traditional financial data entry methods [1-3]. Encrypting the original accounting vouchers is a necessary prerequisite to ensure the authenticity and completeness of accounting information [4]. As the size and complexity of enterprise financial data grows, traditional financial control systems are exposed to many limitations. It faces serious challenges in data recording accuracy, processing efficiency and security, and is difficult to adapt to the rapidly changing business environment. With the rise of blockchain technology, its decentralization, transparency, and tamperability have brought a new dawn to the field of financial control. However, blockchain still has many problems in integrating with existing financial infrastructure and meeting regulatory compliance. Therefore, this study aims to deeply analyze the shortcomings of the traditional financial control system, explore the optimization path of blockchain technology integration with it, and construct a new financial control model. This article provides a deep understanding of the decentralized structure and analyzes the development and application of blockchain technology based on existing literature, in order to establish a long-term development strategy for optimizing and improving the performance of traditional financial control systems.

*Corresponding Author

Blockchain technology has obvious advantages in optimizing transmission architecture and improving system characteristics. Analyzing the application and development of blockchain technology in various fields is an important basis for studying its feasibility. The research on traditional blockchain has not been investigated from a technical and application perspective. Javaid conducted a comprehensive investigation into blockchain technology to fill this gap [5]. Xie explored the application theory of blockchain in the financial field, and designed a financial management control platform based on blockchain technology to better summarize the development direction of blockchain technology, providing a case study for analyzing the role of blockchain technology in the supply management process [6]. Zhang conducted research on financial control systems in the financial industry from three perspectives: data, rules, and applications, and provided constructive suggestions for promoting the development of blockchain technology in the field of financial control [7]. With the outdated performance of existing financial control systems and increasingly fierce market competition, Markos Zachariadis explored the process of building a distributed billing structure using blockchain technology and provided insights from a critical perspective [8]. Francesca Antonucci took advantage of the transparency and relatively low transaction costs of blockchain technology to construct control systems in an encrypted and distributed form to achieve new optimization solutions [9]. The above plan analyzes the feasibility of blockchain technology application in various fields, opening up new directions for the optimization and development of control systems.

The quality of financial control systems is influenced by many factors. In order to determine the reasons for the insufficient performance of traditional financial control systems and the effective improvement of advanced information technology in financial control systems, it is necessary to explore them. Ratmi Dewi studied the impact of the use of internal financial control systems on the quality of financial statements and reflected on the application of advanced information technology in financial control systems [10]. With the advancement of information technology stimulating the relevant advantages of financial systems in the financial industry, Ulrich Bindseil reviewed the impact of effective control of financial systems on the financial system, and compared and discussed the development direction and optimization trend of financial control systems [11]. Javad Oradi summarized the internal weaknesses of financial control systems, providing a research case for reducing audit costs and improving accounting efficiency [12]. In the process of examining the internal control strength of financial control systems, SAPUTRA Komang Adi Kurniawan found that organizational culture and human resource capabilities are one

of the key factors affecting the performance of financial control systems [13]. In the process of traditional access to financial control systems, a large amount of private data is generated. Due to the inability of traditional access control methods to ensure the security of financial data transmission, the current system optimization trend has made prospects for the development and application of blockchain technology in financial systems [14-16]. The above research only provides a brief analysis of the factors that affect financial control systems and the direction in which information technology can improve financial systems, and further research is needed.

In order to improve the performance of financial control systems and enhance the confidentiality and convenience of financial information data transmission, this article studied the architecture and workflow of traditional financial control systems, and analyzed the factors that affect the operational mode of financial control systems. In response to the shortcomings and shortcomings of traditional financial control systems, improvement suggestions were proposed. Based on blockchain technology, an anonymous financial control credit mechanism was constructed, and a decentralized financial control system was established by combining consensus algorithms. In this optimized financial control system, point-to-point information exchange can greatly improve system efficiency, and distributed data storage can reduce information acquisition costs while also improving the security and objectivity of financial data.

Compared with other existing solutions, the financial control system constructed based on blockchain technology in this paper shows significant advantages in many aspects. It solves the problems of the traditional financial control system, such as difficult to distinguish the subject, easy to tamper with information, and limited resource allocation, etc. By optimizing the structure and functions, such as establishing an anonymous crediting mechanism, adopting distributed storage and encryption technology, it achieves a significant increase in cost efficiency, which can significantly reduce the cost of cross-border transactions; significantly shortens the auditing cycle and reduces the risk of accounting fraud; and enhances the security of data and effectively prevents the tampering of data.

Main Contributions:

The main contributions of this paper can be summarized as follows:

1) Significant improvement in cost efficiency: The blockchain-based financial control model constructed in this paper has made a breakthrough in cost efficiency. Through experimental verification, the model can significantly reduce cross-border transaction costs and save a lot of money for enterprises.

2) Significant reduction in audit cycle: By optimizing the audit process, the model in this paper significantly reduces the audit cycle of transactions, improves the efficiency of financial data processing, and reduces the risk of accounting fraud.

3) Enhanced data security: Using the distributed storage and encryption technology of blockchain, the model in this paper enhances the security of financial data. Through comparative experiments, its excellent performance in preventing data tampering and improving data storage security is verified.

4) Combination of theory and practice: This paper not only theoretically analyzes the application of blockchain technology in the field of financial control, but also verifies the effectiveness of the model through actual cases and experiments, providing practical guidance for the application of blockchain technology in financial control systems.

II. Defects in Traditional Financial Control Systems

The financial control system is an important control component in the business process of an enterprise, which is a program that adjusts and constrains the financial activities of the enterprise to achieve commercial value. Traditional financial control systems have key functions such as financial prediction, financial decision-making, financial analysis, and financial evaluation to process and manage financial data, and have smooth and systematic operation. If the financial control system of an enterprise falls into chaos and cannot effectively control and manage financial data, it would reduce the management efficiency of the enterprise and leave the entire business in a disorderly state [17-19]. In short, financial control systems play a crucial role in curbing fraudulent economic activities and ensuring the safety and integrity of economic assets. Analyzing and summarizing the shortcomings of traditional financial control systems is the foundation for building a scientific and efficient financial control system.

A. Main Body of Financial Control System

In the application process of traditional financial control systems, reasonable control is based on the financial flow information, goods transaction information, and raw material procurement information generated in enterprise economic activities. Financial decisions in economic activities are comprehensively determined by various stakeholders, regulating the relationships between various operating entities in the economic plan, and forming a complete functional network. However, this makes it difficult to distinguish the controlling entities of the financial system [20]. In order to strengthen the information management of the financial control system, this article analyzes the control subjects of the financial system, hoping to make a unified plan for the control subjects of the financial system, and arrange and process financial information and economic processes.

The control subject of traditional financial systems should have the functions of financial departments and work arrangements, and should be in a central position in the governance structure of enterprises, with absolute discourse power in decision-making on financial conditions and economic activities. Faced with complex sources of financial information, the information management capabilities of traditional financial control systems are limited. Therefore, the subject of financial control should exist in the system as a multi-level state, in order to manage and process financial data with higher efficiency in modern enterprise economic activities.

B. Financial Control System Structure

With the rapid development of technology, the form of capital flow in the enterprise economy is also undergoing a huge transformation, and the transformation process from the real economy to the digital economy is breathtaking. Electronic vouchers are more convenient and easier to manage compared to paper vouchers. However, the digital form of currency has led to an explosive growth of information in financial control systems. Compared to traditional forms of currency, data in financial information management is prone to tampering, and data storage and transmission processes are no longer reliable [21-23]. In the new situation of modern capital flow, the establishment of a comprehensive financial control system cannot only be limited to plans and considerations.

With the changes and development of capital flow forms, the management philosophy of the financial control system should be updated, and ultimately implemented in the structural transformation of the financial control system [24-25]. Due to the inability of traditional financial control systems to ensure the confidentiality and objectivity of financial information storage and transmission processes, this article tentatively utilizes blockchain technology to optimize its structure, such as constructing a reasonable anonymous credit mechanism and decentralized system structure, and efficiently handling problems throughout the entire production and operation process with a sounder financial control system structure. The structure of the financial control system constructed in this paper is shown in Fig. 1:

C. Resource Allocation of Financial Control System

From the perspective of system resource allocation, the financial control system should solve problems encountered in financial information processing difficulties, risk response, and business models with more economical and reasonable resource allocation plans [26]. The resource allocation plan for the financial control system must include all levels of participation in enterprise economic activities to achieve the initial goal of integrating resources and covering the entire company. Under the influence of a comprehensive financial control system resource allocation plan, the means of financial control are no longer limited to a single audit and inspection in traditional financial control systems.

With the advancement of modern economic construction, financial control systems have put forward higher performance requirements. A financial control system with principles, competitiveness, and objectivity is conducive to the healthy development of the economic market and the integration of the financial field and control system. Analyzing the workflow and structural characteristics of traditional financial control systems can effectively identify the application deficiencies of traditional financial control systems in modern economic activities. This article summarizes the shortcomings of traditional financial control systems and proposes effective solutions to address these shortcomings. This innovation and development have been made to achieve efficient management of financial information in financial control systems and promote the progress of modern financial information management work.

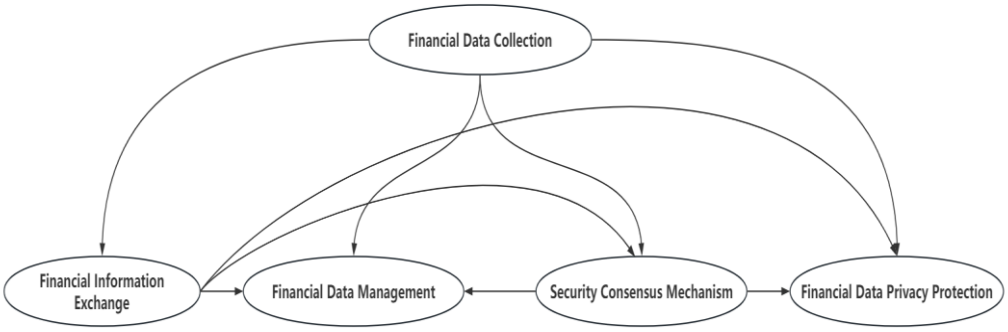

Fig. 1. System structure diagram.

III. Basic Scheme of Financial Control System

In order to achieve the goal of optimizing traditional financial control systems, this article tentatively combines blockchain technology to analyze the structure and functions of financial control systems. The financial control system not only has accounting and bookkeeping functions, but also assists leaders in decision-making and management. It can also analyze financial data through financial information processing software to generate financial statements that reflect the operation of enterprise economic activities. A more reasonable and scientific financial control system structure can better collect, analyze, and predict financial information.

A. Financial Data Collection

The collection of financial data by the financial control system is a prerequisite for its operation. Good data collection capabilities can provide raw data support to the financial control system and ensure its normal operation. This article is based on blockchain technology to encrypt and save financial data, enabling timely generation of corresponding timestamps and authentication signatures during the process of uploading and downloading financial data in the system. Before extracting financial data, proof of work must be provided for the financial data in the blockchain. The financial data collection function based on blockchain makes the operation of the financial control system more transparent and secure. Each system operator can be recorded in real-time while performing any operation on financial data, including various commercial transaction data and daily operational flow information, as well as transaction records of enterprises, distributors, and even individuals, which can be stored in encrypted form in the blockchain, providing necessary technical support for the normal operation of the financial control system.

B. Financial Information Exchange

In the financial control system, the main purpose of constructing an interaction layer is to process various financial information generated in enterprise economic activities. While funds flow, the financial control system based on blockchain technology abandons the traditional form of paper currency transactions and instead uses encrypted digital currencies similar to Bitcoin for transactions on the blockchain. Every process of financial information interaction reflects a real enterprise economic transaction, and the initiation and end of each transaction are recorded in encrypted form in the blockchain. This ensures the security of financial information while also ensuring the objectivity of financial information, and records various details and processes of the transaction in detail.

C. Financial Data Management

In the enterprise's economic activities, the management is responsible for the interactive operation of recording the capital flow and financial data in the form of cryptocurrency, and assisting the financial information interaction layer to process and manage the relevant financial data while recording the main economic transaction records. In an optimized financial control system based on blockchain technology, management can apply corresponding types of cryptocurrency systems to different types of transactions, enabling enterprises to record and manage all processes related to economic activities from the beginning to the end. Due to the fact that all fund transfer records in the financial control system are stored on the blockchain, it ensures that the financial data during the transaction process and fund flow conversion cannot be tampered with by third parties, ensuring the reliability of encrypted financial data storage and greatly enhancing the company's ability to control financial data. The working interface of the financial control system is shown in Fig. 2.

D. Security Consensus Mechanism

Based on the application of blockchain technology, a security consensus mechanism is established in the financial control system. Due to the susceptibility to network latency during peer-to-peer network access, it is common for nodes in the blockchain to receive financial data at different times. Therefore, this article applies a randomly parallel blockchain security consensus algorithm to establish a security consensus mechanism, which unifies the receiving time of each node in the blockchain during transactions. The member who first completes the transaction using the consensus algorithm records the transaction time, thereby obtaining the identity of the bookkeeper and receiving accounting rewards.

E. Financial Data Privacy Protection

In order to improve the privacy of financial data, the optimized financial control system in this paper tentatively refers to blockchain homomorphic encryption technology to optimize it. In the practical application of optimizing financial control systems, each node in the blockchain has the same copy of financial data, thus achieving a balanced treatment of the objectivity and privacy of the transaction process in the entire enterprise's economic activities. In the process of point to point transactions, it is not necessary to fully read financial data to ensure the objectivity and privacy of the transaction, while also preventing illegal hackers from invading and stealing.

In the face of increasingly complex economic transaction activities, this article analyzes the workflow and infrastructure of the financial control system in order to build a more reliable financial control system and achieve more efficient control of financial data for companies. The working structure diagram of the optimized financial control system is shown in Fig. 3. The above section introduces the basic scheme and functions of a financial control system designed based on blockchain technology in this article. However, further experiments are needed to verify the working performance and application effectiveness of the optimized financial control system.

Fig. 2. Financial control system work interface.

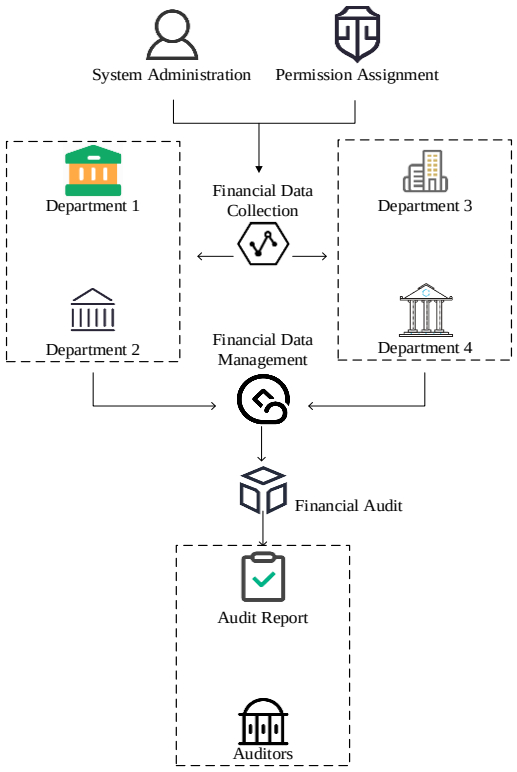

Fig. 3. Optimizing the work structure of financial control system.

IV. Performance Comparison Experiment of Financial Control System

A. Cross Border Transaction Cost Comparison

The coordination of financial information is an important function of financial control systems, and improving the information coordination performance of financial control systems is the key to enhancing the competitiveness of enterprises. Cost control in cross-border transactions is an important indicator of a company's strength. Low cost capital operation often provides enormous convenience for enterprises. How to open up a broader economic market with more efficient cost control is a serious challenge to the information coordination ability of financial control systems. The indicators for cost calculation by the control center are shown in Table I.

To explore the impact of blockchain technology on financial control systems and verify that optimizing financial control systems can reduce the cost of cross-border transactions by coordinating financial information, this article conducted an application experiment on a financial control system in a certain e-commerce enterprise. 60 e-commerce transaction orders in the same batch were randomly sampled as experimental data and divided into two groups, with 20 transaction orders for children's toys, mother and baby products, and women's and men's clothing. The experiments that applied traditional financial control systems and optimized financial control systems were divided into a control group and an experimental group, and the average transaction costs of 60 transaction orders in the two groups of experiments were compared. Fig. 4(a) and Fig. 4(b) are comparative analyses of transaction costs between traditional and optimized system applications.

Enterprises often face high capital operating costs when facing overseas markets, and the operational processes in economic transactions are complex and have high transaction fees. Efficient and cleverly structured financial control systems can help simplify the complex process of economic transactions, making transactions that originally required multiple stages simpler. This article is based on the blockchain network to optimize the financial control system. In practical applications, it crosses the clearing process of import and export banks and intermediate third parties, and directly conducts point-to-point transactions in the blockchain network. Fund transfer is carried out in the form of encrypted digital currency, reducing the complexity of transactions and improving the operational efficiency of funds. As shown in Fig. 4(a), the average cost of transaction orders for children's toys, mother and baby products, and women's and men's clothing in the control group with traditional financial control systems was 60000, 70000, and 70000 yuan, respectively. As shown in Fig. 4(b), the average cost of transaction orders for children's toys, mother and baby products, and women's and men's clothing in the experimental group with the application of the optimized financial control system was 50000 yuan, 50000 yuan, and 40000 yuan, respectively. Compared to the transaction orders with the application of traditional financial control systems, the transaction orders with the optimized financial control system had significantly reduced costs.

TABLE I. Indicators Involved in Cost Coordination Responsibility Report

Projects	Indicators			Projects	Indicators		
Material Costs	Budget	Actual	Differences	Uncontrollable costs	Budget	Actual	Differences
Labor Costs	Budget	Actual	Differences	Depreciation of equipment	Budget	Actual	Differences
Variable Costs	Budget	Actual	Differences	Other	Budget	Actual	Differences

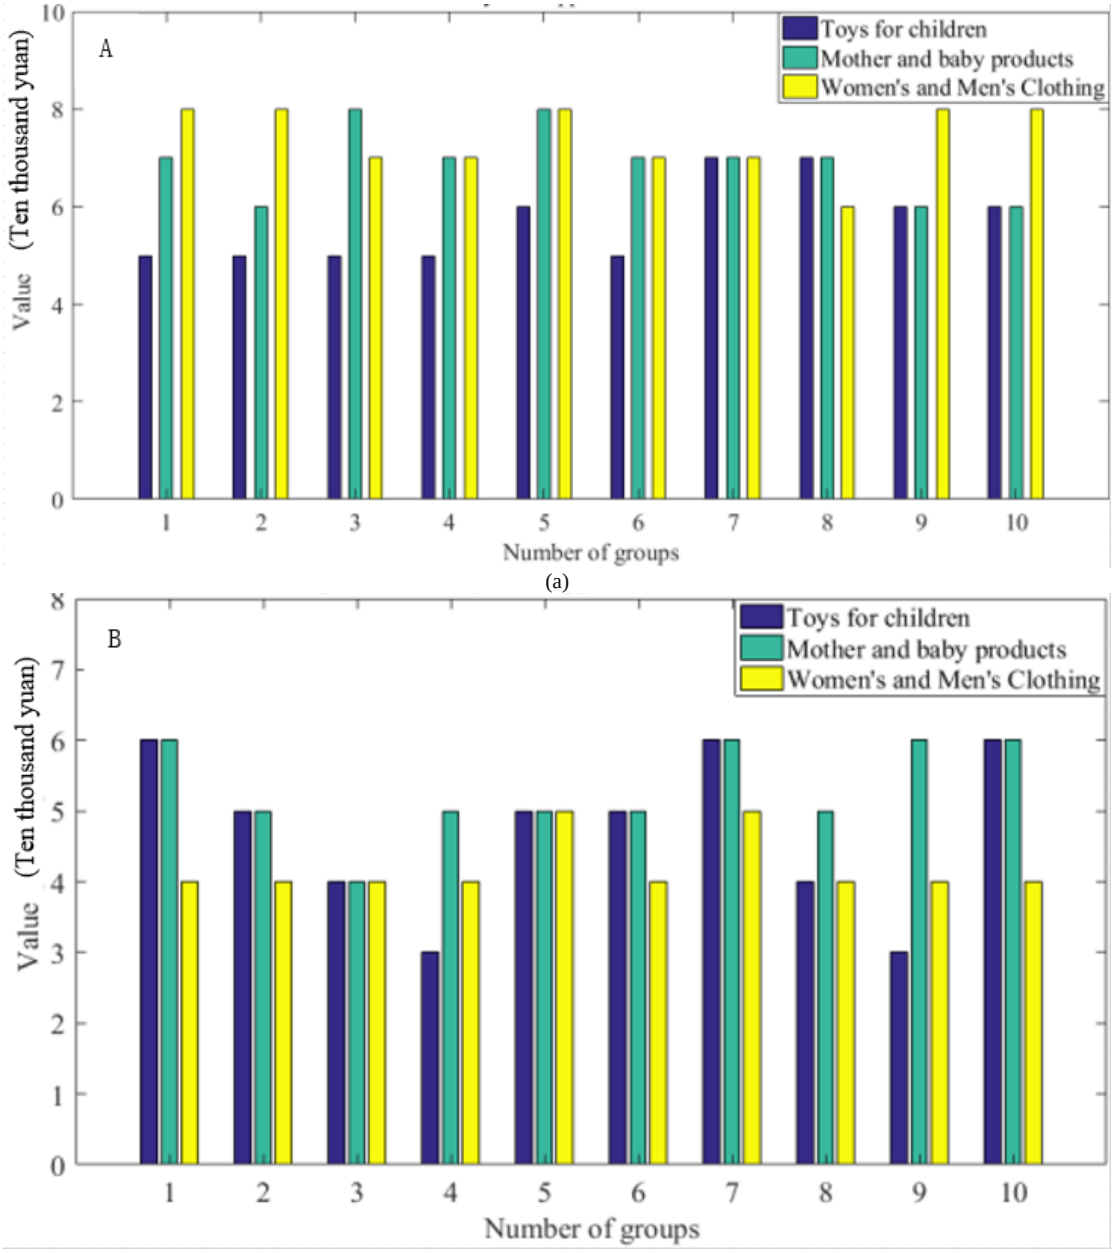

Fig. 4. (a) Traditional transaction cost diagram, (b) Optimized system transaction cost diagram.

B. *Comparison of Audit Process Cycles*

Traditional financial control systems have complex transaction processes for enterprise economic activities, such as counterparty confirmation, financial data analysis, information registration, system auditing, etc. The efficiency of decision-making plans for economic activities is not high, and the audit process of accounting bookkeeping, confirmation, and final generation of accounting reports after transactions are completed increases the risk of accounting fraud. To verify the positive role of optimizing financial control systems in the audit process cycle, this article conducted a comparative experiment. 80 transactions were divided into control and experimental groups, with 40 orders for children's toys and 40 orders for mother and baby products. The experiment using traditional financial control systems was set as the control group, while the experiment using optimized financial control systems was set as the experimental group. The audit cycles of transactions in two sets of experiments were recorded and compared. As shown in Fig. 5, a comparative analysis of audit cycles between traditional and optimized systems is presented.

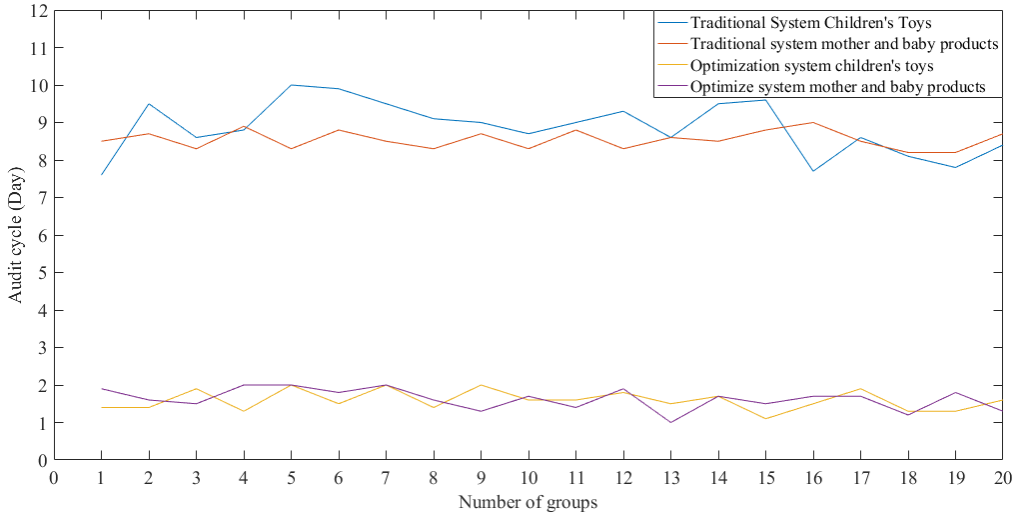

Fig. 5. Comparison of audit cycles between traditional and optimized systems.

As can be seen from the image in Fig. 5, in the traditional financial control systems, transactions of economic activities of enterprises must be reviewed and approved by central institutions. Without the allocation and supervision of control centers, transaction chaos can easily occur in complex audit processes. Due to the overly complex audit process of traditional financial control systems, errors in financial information exchange often occur, such as duplicate payments, which can cause varying degrees of confusion in the transaction records of both parties. The optimized financial control system based on blockchain technology architecture in this article can record transaction information in real-time, and the arrangement of blocks in the blockchain network can be sequentially recorded. Only then can the initial audit information be recognized by other nodes in the network, and there is no risk of confusion in the process of auditing financial information. As shown in Fig. 4, in the control group with the application of traditional financial control systems, the average audit period for children's toy type transaction orders was 8.9 days, and the average audit period for mother and baby product type transaction orders was 8.6 days. In the experimental group that applied the optimized financial control system, the average audit period for children's toy type transaction orders and mother and baby product type transaction orders was 1.6 days. From the comparison of data in Fig. 4, it can be seen that the optimized financial control system based on blockchain technology has greatly improved the audit process compared to traditional financial control systems, greatly refining important links in the audit process, skipping or even removing the process of relative shortcomings, greatly increasing the efficiency of the financial data audit process.

C. Comparison of Financial Data Security

As a financial control system, ensuring the security of financial data storage is crucial. The process of managing and controlling financial data in traditional financial control systems is uniformly planned by the control center, and the top management formulates a rough process to process and store financial data in a top-down structure. In the complex financial data processing process, the security of financial data cannot be fully guaranteed. The security protection of financial data is not comprehensive, leading to difficulties in perfect handover between various departments in the enterprise during accounting and auditing, and even causing huge commercial loopholes and economic losses. The optimized financial control system based on blockchain technology in this article adopts a distributed encrypted storage method for financial data, greatly improving the security of financial data. In order to verify the positive effect of blockchain technology on financial data storage security performance, security comparison experiments were conducted. This article simulated hackers invading and tampering with the financial data storage modules of traditional and optimized financial control systems, in order to verify the security level of financial control system storage of financial data. Establishing a logically rigorous security evaluation standard is the prerequisite and foundation for verifying the security of financial control systems. In each intrusion experiment, the security of the financial control system was evaluated, with an upper limit of 12, 1-3 being poor, 4-6 being average, 7-9 being good, and 10-12 being excellent. The results of each intrusion were recorded as the evaluation basis. The recorded results of 15 intrusion experiments are shown in Table II.

The blockchain network adopts decentralized auditing and accounting, with each node in the network participating together and copying financial data separately. Each node only determines the ownership of accounting rights based on whether the transaction was completed first and recorded, which is recognized by all nodes. The optimized financial control system based on blockchain network is different from the traditional classified accounting structure of financial control systems, but adopts a distributed accounting structure. Each node in the fully running blockchain network can access transaction data that has been confirmed to exist, and can independently check and verify the integrity of the branch chain. Due to the immutability and persistence of the optimized financial control system based on blockchain technology, the financial data stored in the optimized financial control system is also more secure. As shown in Table 2, after 15 simulated intrusion experiments, in the control group experiment that applied the traditional financial control system, the intrusion was successful twice with an average evaluation index of 7. In the experimental group experiment that applied the optimized financial control system, all simulated intrusions

failed with an average evaluation index of 11. According to data comparison, the optimized financial control system based on blockchain technology architecture has an improved security performance evaluation index of four compared to traditional financial control systems in terms of financial data storage.

TABLE II. RECORD ANALYSIS OF INTRUSION EXPERIMENTS

	Traditional Financial Control System		Optimize financial control systems	
Number of experiments	Evaluation Index	Intrusion results	Evaluation Index	Intrusion results
1 time	7	Failed	12	Failed
2 time	5	Succeed	9	Failed
3 time	7	Failed	12	Failed
4 time	8	Failed	11	Failed
5 time	8	Failed	12	Failed
6 time	9	Failed	10	Failed
7 time	7	Failed	11	Failed
8 time	8	Failed	10	Failed
9 time	5	Succeed	12	Failed
10 time	7	Failed	9	Failed
11 time	8	Failed	12	Failed
12 time	7	Failed	12	Failed
13 time	6	Failed	11	Failed
14 time	9	Failed	10	Failed
15 time	8	Failed	11	Failed

V. RESULT AND DISCUSSION

Compared with traditional systems, the blockchain based financial control system proposed in this article has achieved significant improvements in all aspects. Through experimental verification, the model can effectively reduce cross-border transaction costs. In the e-commerce enterprise experiment, after applying the optimized system, the average cost of different product transaction orders significantly decreased. In terms of audit cycle, the optimization system based on blockchain technology greatly shortens the audit process. The traditional system has a relatively long review cycle for different types of transactions, while the optimized system greatly shortens the review cycle and improves the efficiency of financial data processing. In terms of data security, optimizing the distributed encrypted storage method of the system makes financial data more secure. After multiple intrusion experiments, traditional systems have a certain success rate of intrusion with a low average evaluation index, while optimized systems can effectively resist all simulated intrusions with a high average evaluation index. These results demonstrate the effectiveness and superiority of the proposed model.

With the vigorous development of the digital economy, blockchain technology has gradually entered the social perspective and played an important role in multiple fields, especially in the economic field, where there is an urgent need for strong support from advanced technology. The management system and classified accounting structure of traditional financial control systems are difficult to enable rapid interaction and transmission of financial information between relevant departments, and traditional system solutions are prone to hacker intrusion and tampering, leading to frequent examples of major economic accidents. Due to the advantages of distributed data storage structure and immutability, blockchain technology can achieve secure and efficient processing of financial data, ensure the authenticity of financial data and the transparency of economic transaction processes, and promote the work efficiency and management level of financial control systems.

This article analyzed the workflow and structural architecture of traditional financial control systems, tentatively applied blockchain technology to optimize the financial control system, and designed a more excellent financial control system. The performance and application effectiveness of the optimized financial control system were verified through comparative experiments. The results showed that the optimized financial control system in this article had more precise cost control and a safer financial data storage structure, ensuring the normal progress of enterprise economic activities while saving a lot of time and costs. In the future, this paper will conduct in-depth research on the compatibility issues that the current system may face with existing financial infrastructure, explore effective integration strategies, and ensure that the system can smoothly integrate into the current financial ecosystem. Thus promoting the application and popularization of blockchain financial control systems in a wider range of fields, providing more efficient, secure, and intelligent solutions for enterprise financial control.

***Abstract*—This research aims to show the user interface design of the SEVIMA EdLink platform to facilitate *Tri Kaya Parisudha*-based asynchronous learning in the nuances of independent learning. This research used the Research and Development method with the Borg & Gall development model, which focused on several stages, including research and field data collection, planning, design development, initial trial, and revision of the initial trial results. The number of respondents involved in the initial trial of the user interface design was two education experts, two informatics experts, 40 teachers of Tourism Vocational Schools in Bali, and 60 students of Tourism Vocational Schools in Bali. The data collection tool for the initial trial of the user interface design was a questionnaire consisting of ten questions. The analysis was conducted by comparing the effectiveness percentage of the user interface design with the effectiveness categorization standard referring to the five scales. The results showed that the user interface design of the SEVIMA EdLink platform was effective in facilitating *Tri Kaya Parisudha*-based asynchronous learning. The impact of this research on stakeholders in the field of education is the existence of new information related to the existence of an online learning platform called SEVIMA EdLink, which is integrated with an asynchronous learning strategy, independent learning policy, and Balinese local wisdom.**

***Keywords*—Design user interface; SEVIMA EdLink; asynchronous; Tri Kaya Parisudha; independent learning**

I. Introduction

One of the efforts made by Tourism Vocational School to improve the quality of learning and the character of its students in the frame of implementing the independent learning policy is to determine the right learning strategy. One of the learning strategies used to make this happen is asynchronous learning. However, an asynchronous learning strategy has still not been effectively implemented. This is because the teacher does not directly meet the students like in-class learning. In addition [1], in asynchronous learning, teachers are also constrained to assess each student's character and quality of learning objectively. Teachers can easily assess the character and quality of student learning if they can interact with students directly in the classroom. An innovation is needed to solve the problems associated with such asynchronous learning. One of the innovations is adapting the SEVIMA EdLink platform into asynchronous learning based on the concept of Tri Kaya Parisudha. SEVIMA EdLink [2] is a learning platform that can be freely obtained from the internet. This platform provides facilities to make the learning process asynchronous, which refers to the cognitive, affective, and psychomotor domains [3]. The concept of Tri Kaya Parisudha consists of three parts [4], namely Manacika (thinking well), Wacika (saying well), and Kayika (doing well). Manacika [5] can be used as a foundation in asynchronous learning to determine the quality of student learning, especially in the cognitive domain. Wacika [5] determines student character (affective domain). Kayika [5] is used as a basis for determining the quality of student learning, especially in the psychomotor domain. The innovation will run well if followed by implementation. The initial effort made to implement the innovation was to design the user interface design of the SEVIMA EdLink platform based on Tri Kaya Parisudha. Based on this, the research question is: How is the user interface design of the SEVIMA EdLink platform to facilitate asynchronous learning based on Tri Kaya Parisudha in the nuances of independent learning?

II. Literature Review

Some of the research behind this study includes research by Utomo & Ahsanah [6], which shows that online learning using the Edmodo application is very effective. This is based on the results obtained from the field trial: giving a pretest and posttest and seeing the quantity of student communication in the forum and chat through the Edmodo application. The obstacle of Utomo & Ahsanah's research is that it has not shown the visualization of online learning in terms of material content and test questions used in measuring the quality of students' abilities and characters. Research by Soesanto et al. [7] showed the aspects of measuring the effectiveness of the blended learning model based on user activities in accessing content. The constraint of Soesanto et al.'s research has not shown the completeness of blended learning regarding test questions used in measuring the user's ability and character. Research by Sela et al. [8] shows that the blended learning model assisted by Google Classroom is very effective based on the percentage of learning implementation results. The limitation of Sela et al. research is that it has not shown the completeness of blended learning regarding material content

*Corresponding Author

and test questions used in measuring the quality of students' abilities and characters. The research of Anggraeni et al. [9] showed the measurement of the level of effectiveness of the blended learning model based on independent and collaborative asynchronous activities. The research constraint of Anggraeni et al. is that it has not shown the completeness of blended learning in terms of material content and test questions used in measuring the quality of students' abilities and characters.

Papadakis' research [10] states that people can access educational content for free through platforms that provide online learning content. The limitation of Papadakis' research is that it does not specifically explain the platforms that can be used for the online learning he means. Papadakis et al.'s research [11] shows the combined power of cloud technology and augmented reality in supporting the educational process. The limitation of Papadakis et al.'s research is that it has not shown in detail the process of combining cloud technology and augmented reality that can support the educational process, especially in measuring the quality of student's character.

III. Method

A. Research Approach

The approach of this research was development. This research used the Research and Development method, with a research development model, namely Borg & Gall, which consists of 10 stages of development [12], [13], [14], [15], including (1) research & field data collection; (2) planning; (3) design development; (4) initial trial; (5) revision of initial trial results; (6) field trial; (7) revision of field trial results; (8) usage trial; (9) final product revision; (10) desimination and implementation of the final product. Specifically for this 2024 year research, several stages were carried out, including (1) research and field data collection, (2) planning, (3) design development, (4) initial trial, and (5) revision of the initial trial results.

B. Research Subjects

The subjects in this study were determined using the Purposive Sampling technique. This technique was conducted by selecting research subjects initially determined based on the subject's direct relationship with the SEVIMA Edlink platform to facilitate Tri Kaya Parisudha-based asynchronous learning. The subjects involved in this 2024 year research were two education experts, two informatics experts, 40 Tourism Vocational School teachers in Bali, and 60 Tourism Vocational School students in Bali who will be involved in conducting the initial trial. All subjects involved have obtained official and valid consent from each individual without any coercion or conflict of interest.

C. Object and Location of Research

The object of research was the main topic that must be studied and researched in depth. The object of this study was the design of the SEVIMA Edlink platform to facilitate asynchronous learning based on Tri Kaya Parisudha in the nuances of independent learning. This research is implemented in several Tourism Vocational Schools spread across six regencies in Bali Province. The six regencies are Gianyar, Tabanan, Buleleng, Klungkung, Badung, and Denpasar.

D. Research Data Collection Instruments

The instruments used in collecting data in this research are questionnaires. The questionnaires were used to obtain primary data in the form of quantitative data from respondents as a basis for making decisions about the percentage level of effectiveness of the design of the SEVIMA Edlink platform used in asynchronous learning based on Tri Kaya Parisudha in the nuance of independent learning at some Tourism Vocational School in Bali.

E. Data Analysis Techniques

The technique used to analyze the collected data was quantitative descriptive technique through descriptive percentage calculation. The results of the descriptive percentage calculation were used as the basis for interpreting the results of the research on the design of the SEVIMA Edlink platform used in the asynchronous learning based on Tri Kaya Parisudha in the nuanced of independent learning to improve the learning outcomes of Tourism Vocational School students in Bali in the cognitive domain, affective, and psychomotor domains. The formula for calculating the descriptive percentage is as follows [16], [17], [18], [19], [20], [21].

$$P = \frac{f}{N} \times 100\% \quad (1)$$

Notes:

P = Effectiveness percentage

f = Total acquisition value

N = Maximum total value

The percentage results obtained from that formula are then converted into the following Table I [22], [23], [24], [25], [26].

TABLE I. Categorization Standards Referring to Five's Scale

Category of Effectiveness	Percentage of Effectiveness (%)	Follow-up
Poor	0-54	Revision
Less	55-64	Revision
Moderate	65-79	Revision
Good	80-89	No Revision
Excellence	90-100	No Revision

IV. Results and Discussion

A. Results

Some of the research results in 2024 were focused on five stages that refer to the Borg and Gall model. The five stages include 1) research and field data collection stage, 2) planning, 3) design development, 4) initial trial, and 5) revision of the initial trial results. The research results based on these five stages can be shown as follows.

1) The results of the research and field data collection stage: At this stage, data related to several things supporting asynchronous learning for entrepreneurship subjects in the Tourism Vocational School was obtained. The data intended includes 1) the content of entrepreneurship material given to students, 2) examples of test questions based on the concept of Tri Kaya Parisudha, and 3) the features needed in the SEVIMA EdLink platform to support learning asynchronous

in the nuances of independent learning. The data related to entrepreneurship material content can be seen in Table II. Examples of test questions based on the Tri Kaya Parisudha concept can be seen in Table III. The features provided in the SEVIMA EdLink platform to support the occurrence of asynchronous learning based on Tri Kaya Parisudha in the nuances of independent learning can be seen in Table IV.

TABLE II. CONTENT OF ENTREPRENEURSHIP MATERIALS PROVIDED TO STUDENTS OF TOURISM VOCATIONAL SCHOOL IN BALI

No	Content Material
1	Identify entrepreneurial attitudes and behaviors
2	Prestigious work attitudes and behaviors
3	Problem solution formulation
4	Development of spirit entrepreneurship
5	Build commitment to self and others
6	Business risks
7	Decision making

TABLE III. EXAMPLES OF ENTREPRENEURSHIP TEST QUESTIONS BASED ON THE CONCEPT OF TRI KAYA PARISUDHA

No	Content Material	Test Questions	
1	Identify entrepreneurial attitudes and behaviors	*Manacika*	Explain the difference between entrepreneurship, self-employment, and entrepreneurship!
		Wacika	Make a sound recording that shows an entrepreneur who can appreciate the work and experience of others as input for his/her development!
		Kayika	Make a video recording that shows the attitude of an honest and realistic entrepreneur!
2	Prestigious work attitudes and behaviors	*Manacika*	Explain the meaning, purpose, and benefits of presentative work behavior!
		Wacika	Make a voice recording that shows an entrepreneur's ability to maintain their emotional self while realizing presentative work behavior!
		Kayika	Make a video recording that shows the attitude of an entrepreneur who always works to get ahead!
3	Problem solution formulation	*Manacika*	Explain the meaning and difference between problems and non-problems!
		Wacika	Make a voice recording that shows an entrepreneur negotiating well when solving a problem!
		Kayika	Make a video recording that shows the attitude of an entrepreneur who always has how to determine alternative solutions to problems!
4	Development of spirit entrepreneurship	*Manacika*	Explain factors that influence entrepreneurial morale!
		Wacika	Make a voice recording that shows the attitude of an entrepreneur who can influence work morale!
		Kayika	Make a video recording that shows an entrepreneur being able to inspire the spirit of entrepreneurship!
5	Build commitment to self and others	*Manacika*	Explain the factors that show a person is highly committed to their entrepreneurial activities!
		Wacika	Make a voice recording that shows the attitude of an entrepreneur who can maintain a high commitment to self-control!
		Kayika	Create a video recording that shows an entrepreneur who is punctual in his work environment and daily life!
6	Business Risks	*Manacika*	Describe the types of risk in a business!
		Wacika	Make a voice recording that shows the attitude of an entrepreneur in avoiding/minimizing risk in business!
		Kayika	Make a video recording that shows the attitude of an entrepreneur when handling risks in business !
7	Decision making	*Manacika*	Explain the steps of decision-making in an enterprise!
		Wacika	Make a voice recording that shows the attitude of an entrepreneur when giving instructions to subordinates!
		Kayika	Make a video recording that shows the attitude of an entrepreneur in making a decision fairly!

TABLE IV. FEATURES PROVIDED IN THE SEVIMA EDLINK PLATFORM TO SUPPORT ASYNCHRONOUS LEARNING BASED ON TRI KAYA PARISUDHA IN INDEPENDENT LEARNING

No	Features
1	Class
2	Material
3	Task
4	Info
5	Quiz
6	Event
7	Survey
8	Comments

2) The result of planning stage: Data about the number of people involved, personal job descriptions, and the time needed to complete this research was obtained at this stage. The total time prepared for data collection and the revision of the trial results of the user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning in nuances of independent learning was 30 days. The complete data related to this research planning can be seen in Table V.

TABLE V. DETAILS OF THE NUMBER OF PERSONAL JOB DESCRIPTIONS AND COMPLETION TIME USER INTERFACE DESIGNS OF SEVIMA EDLINK PLATFORM TO FACILITATE TRI KAYA PARISUDHA-BASED ASYNCHRONOUS IN THE NUANCES OF INDEPENDENT LEARNING

No	Total Personal	Personal Job Description	Time (Day)
1	6	Field data collection	6
2	3	Designing user interface of SEVIMA EdLink Platform to facilitate *Tri Kaya Parisudha*-based asynchronous learning	8
3	104	Initial testing of user interface design	12
4	3	Revision of initial trial results	4
Total	**116**		**30**

3) The result of the design development stage: Referring to some of the features provided in the SEVIMA EdLink platform to support the occurrence of asynchronous learning based on Tri Kaya Parisudha in the nuances of independent learning in some Tourism Vocational Schools in Bali, and the research planning that has been shown in Table V, then the initial design of the user interface of the SEVIMA Edlink platform used in asynchronous learning based on *Tri Kaya Parisudha* in the nuances of independent learning at several

Tourism Vocational School in Bali can be done. The user interface design of this platform was taken directly from the SEVIMA EdLink platform. The results of the initial design of the SEVIMA Edlink platform used in asynchronous learning based on *Tri Kaya Parisudha* in the nuances of independent learning can be seen in Fig. 1 to Fig. 8.

Respondent-103	5	4	4	4	4	4	4	4	5	5	43	86.00
Respondent-104	5	4	4	4	5	5	5	4	4	4	44	88.00
Average												**87.38**

Respondents made several suggestions during the initial trial of the user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning. These suggestions, which can be seen in Table VII, were used to improve the user interface design.

5) Revision stage of the initial trial results: Referring to the respondents' suggestions in Table VII, it was necessary to revise the user interface design of the SEVIMA EdLink Platform to facilitate Tri Kaya Parisudha-based asynchronous learning. Three research teams made revisions. The revised user interface design can be seen in Fig. 9 to Fig. 14.

TABLE VII. SUGGESTIONS FROM RESPONDENTS WHO WERE GIVEN ON THE INITIAL PILOT TEST

No	Respondents	Suggestions
1	Respondent-10	Show the facility to create *Manacika*-based test questions in detail
2	Respondent-16	Demonstrate the feature to set question weight and the minimum passing score for *Manacika*-based test
3	Respondent-24	Show the facility to create *Wacika*-based tasks in detail
4	Respondent-42	Indicate the existence of a feature to randomize test questions based on *Manacika.*
5	Respondent-50	Show the facility to create *Kayika*-based tasks in detail
6	Respondent-63	Show the feature to set a time limit for *Manacika*-based test questions
7	Respondent-84	Demonstrate the feature of setting question weights on tests to measure students' cognitive abilities
8	Respondent-95	Show the feature to randomize cognitive test questions

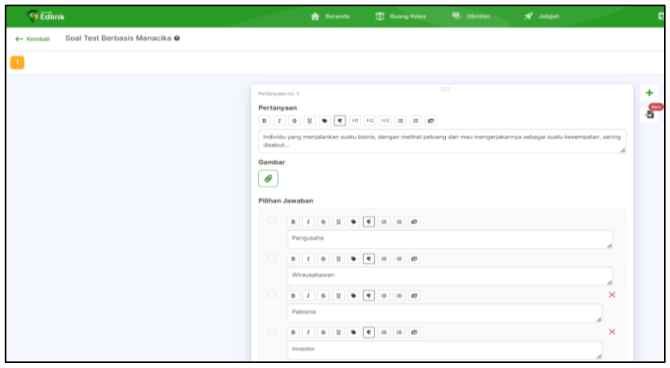

Fig. 9. Design showing the facilities for creating manacika-based test questions in detail (in bahasa format).

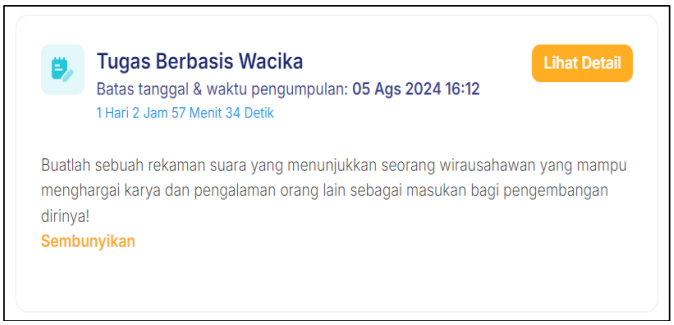

Fig. 10. Design showing the facilities for creating wacika-based tasks in detail (in bahasa format).

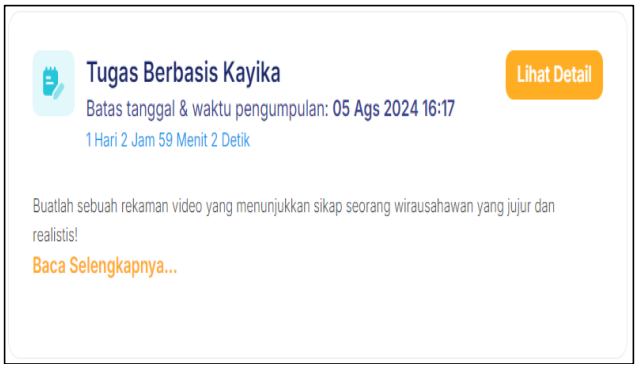

Fig. 11. Design showing the facilities for creating kayika-based tasks in detail (in bahasa format).

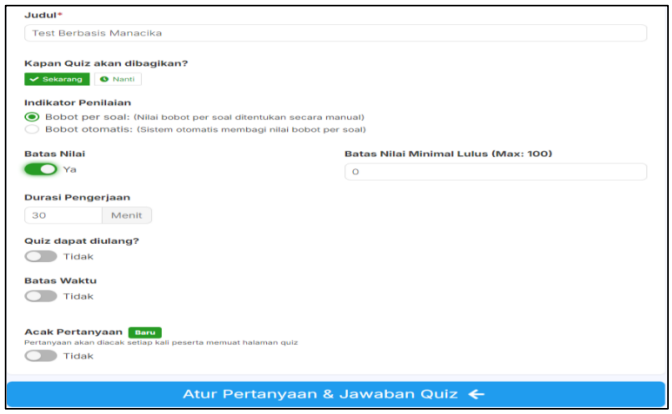

Fig. 12. Design showing features for setting question weights and minimum passing limits for manacika-based tests (in bahasa format).

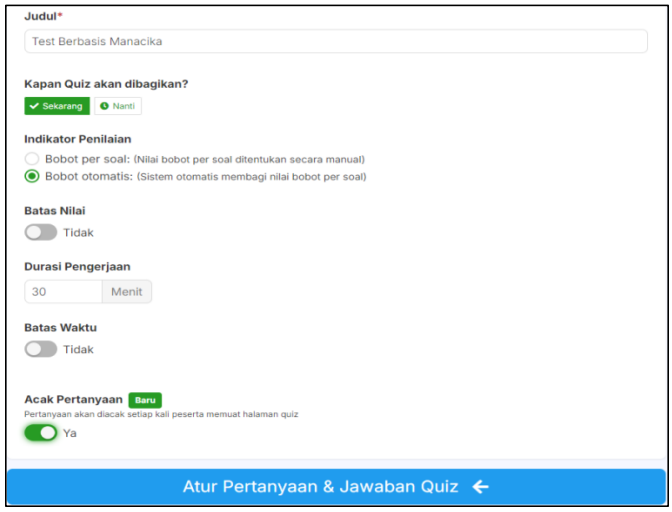

Fig. 13. Design showing the existence of a feature to randomize manacika-based test questions (in bahasa format).

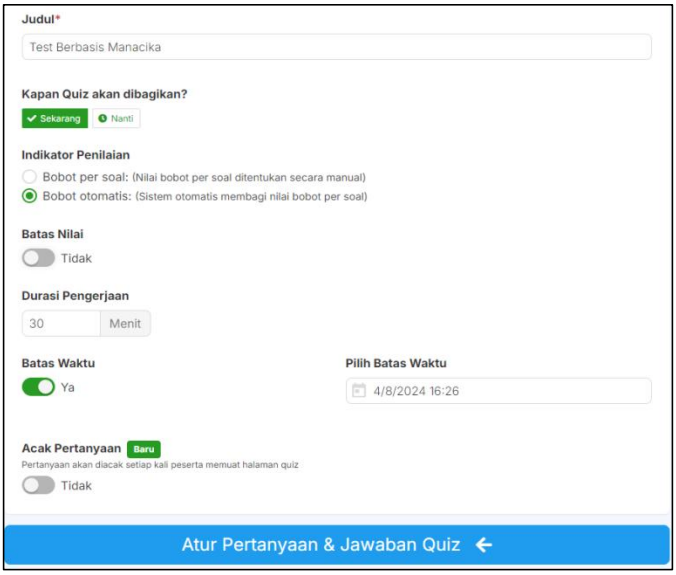

Fig. 14. Design showing features to set time limits for completing test questions based on manacika (in bahasa format).

B. Discussion

The effectiveness of the SEVIMA EdLink platform user interface design to facilitate Tri Kaya Parisudha-based asynchronous learning was included in the category of good effectiveness level. This was because the average percentage of effectiveness was 87.38%. When referring to the effectiveness categorization standard, which refers to a five-scale in Table I, it was evident that the average percentage of effectiveness was included in the good category. The underlying reason for testing the effectiveness of the SEVIMA EdLink platform user interface design is to show developers and users on a wider scale that the design has been tested and is ready to be developed into the application product creation stage.

There were ten questions used in the initial trial of the user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning. Item-1 is related to the suitability of the design form that shows the

facility to create a class. Item-2 is related to the suitability of the design form which indicates the presence of facilities for entering the subject matter. Item-3 is related to the suitability of the design form that shows the facilities for entering Wacika and Kayika concept-based tasks. Item-4 is related to the suitability of the design form that shows the presence of facilities for entering learning information/news. Item-5 is related to the suitability of the design form that shows the facility to create Manacika concept-based test questions. Item-6 is related to the suitability of the design form that shows the facility to enter events/programs related to learning. Item-7 is related to the suitability of the design form that shows the facility to enter survey question items. Item-8 is related to the suitability of the design that showed the facility to enter comments. Item-9 is related to the ease of use of the SEVIMA EdLink platform in realizing Tri Kaya Parisudha-based asynchronous learning in the nuances of independent learning. Item-10 is related to data storage security in the SEVIMA EdLink platform to realize Tri Kaya Parisudha-based asynchronous learning in the nuances of independent learning.

The entire user interface of the SEVIMA EdLink platform, which facilitates Tri Kaya Parisudha-based asynchronous learning, uses the Indonesian language format. This is because the SEVIMA EdLink platform is an online learning platform developed by one of the limited liability company in Indonesia, namely PT. Sentra Vidya Utama (SEVIMA). This platform is intended to support the online learning process in Indonesia.

Fig. 9 is the revised user interface design of the SEVIMA EdLink Platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestion from respondent 10. Fig. 9 shows the facility to create Manacika-based test questions in detail. Figure 10 is the revised user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestions from respondent 24. Fig. 10 shows the facility to create Wacika-based tasks in detail. Fig. 11 is the revised user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestions from respondent 50. Fig. 11 shows the facility to create Kayika-based tasks in detail. Fig. 12 is the revised user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestions from respondent-16 and respondent-84. Fig. 12 shows the ability to set question weights and minimum passing scores for Manacika-based tests to measure students' cognitive abilities. Fig. 13 is the revised user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestions from respondent-42 and respondent-95. Fig. 13 shows the existence of a feature to randomize test questions based on Manacika in order to measure students' cognitive abilities. Fig. 14 is the revised user interface design of the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning to follow up on the suggestion from respondent-63. Fig. 14 shows the presence of a feature to set a time limit for tests based on Manacika.

This research has been able to answer the limitations of Utomo & Ahsanah' research [6], research by Soesanto et al. [7], research by Sela et al. [8], and Anggraeni et al.'s research. [9], by showing the user interface design of an online learning platform called SEVIMA EdLink, which is integrated with asynchronous learning strategies, independent learning policies, and Balinese local wisdom. This platform is appropriate for use as an asynchronous learning facility to improve student learning outcomes in the cognitive, affective, and psychomotor domains. This research in principle has the same characteristics, objectives, and concepts as research by Arvianti & Wahyuni [27], research by Fajri & Saputri [28], research by Hikmawati et al. [29], research by Ramdhani et al. [30], research by Supiatman et al. [31], and research by Yulianto et al. [32], which internalized the concept of local wisdom into the online learning process.

The novelty of this research is in the form of an innovative learning platform user interface design that combines the SEVIMA EdLink platform, asynchronous learning strategy, independent learning policy, and Balinese local wisdom, namely Tri Kaya Parisudha. This user interface design shows the SEVIMA EdLink platform used in facilitating asynchronous learning based on Tri Kaya Parisudha in the nuances of independent learning. Therefore, the presence of this platform can provide practical impacts that support the improvement of learning outcomes of Tourism Vocational School students in Bali in the cognitive (knowledge), affective (character), and psychomotor (skills) domains in the nuances of independent learning.

Although this research has novelty, but in reality this research also has limitations. The limitation of this research is that it has not been shown in detail how to operate the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning. This is because the research is focused only on the design of the user interface.

V. Conclusion

In general, the results of this research have produced a user interface design for the SEVIMA EdLink platform used in facilitating asynchronous learning based on Tri Kaya Parisudha in nuances independent learning with good quality. This user interface design shows the visualization form of Sevima EdLink learning platform, asynchronous learning strategy, independent learning policy, and Balinese local wisdom, namely Tri Kaya Parisudha, to give birth to a unique and distinctive form of learning platform in order to improve the learning outcomes of Tourism Vocational School students in Bali in the cognitive, affective, and psychomotor domains. The future work that needs to be done to overcome the obstacles of this research is to show how to operate the SEVIMA EdLink platform to facilitate Tri Kaya Parisudha-based asynchronous learning at the Tourism Vocational School in Bali. The impact of this research on stakeholders in the field of education is the existence of new information related to the existence of an online learning platform called SEVIMA EdLink, which is integrated with an asynchronous learning strategy, independent learning policy, and Balinese local wisdom. Educational stakeholders can use this online learning platform to present an asynchronous learning process based on Balinese local culture to improve the learning outcomes of Tourism Vocational

School students in Bali in the cognitive, affective, and psychomotor domains.

ACKNOWLEDGMENT

The authors express their sincere gratitude to the Directorate General of Research and Development, Ministry of Education, Culture, Research and Technology of the Republic of Indonesia, who had to provide this research funding. This research was funded and completed on time based on research grant with main contract number: 081/E5/PG.02.00.PL/2024 and derivative contract number: 343/UN48.16/LT/2024.
